Conclusions: Immunotherapy appears to have activity in patients with SOT, HIV and Hep B and Hep C. It can be given to renal transplant pts without rejection, however this is not universal . PD1 does not appear to adversely affect the viral control in HIV and Hep B and Hep C pts.

Background: CV9104 is a novel prostate cancer immunotherapy based on sequence-optimized, free and protamine-complexed mRNA encoding the antigens PSA, PSMA, PSCA, STEAP1, PAP and MUC1. Safety and immune responses to the predecessor therapy CV9103 encoding 4 of the antigens have been described previously. We assessed whether immunotherapy with CV9104 on top of standard of care (SOC) results in longer overall survival than placebo plus standard of care in patients with mCRPC.

Methods: After completion of a safety lead-in phase I, men with chemo-naïve, oligosymptomatic/asymptomatic mCRPC without visceral metastases were randomized 2:1 to intradermal CV9104 or placebo (P). Double-blinded treatment was continued beyond initial progression until progression under first subsequent SOC therapy or toxicity. The primary endpoint (EP) was overall survival (OS). Key secondary EPs included radiographic progression-free survival (rPFS1/rSPFS from randomization until initial progression/second progression on SOC therapy and rPFS2 from start of SOC therapy to second progression), time to symptom progression and cellular and humoral immune responses.

Results: 197 patients (pt) were randomized 2:1 to either CV9104 ($n = 134$) or P ($n = 63$). Pt characteristics, median number of administrations and first subsequent SOC therapies were well balanced between the arms. No significant difference in OS was found, median (m) OS was 35.5 months (mo) [28.-NE] in the CV9104 arm vs. 33.7 mo [28.7-NE] in the P arm (hazard ratio [HR] 1.1, 95% CI 0.70-1.76; one-sided $p = 0.33$). There were also no significant differences in the rPFS endpoints and time to symptom progression. Incidence of Grade $\geq$3 AEs (51.1% vs. 59.7%) and serious AEs (44.5% vs. 43.5%) was similar in both arms, injection site reactions and flu like symptoms were more frequent in the CV9104 arm.

Conclusions: CV9104 did not improve OS compared to placebo. Additional clinical outcomes and analyses of cellular and humoral immune responses will be presented and impact on further development will be discussed.

1150P Phase II clinical trial of peptide vaccination for advanced head and neck cancer patients induced immune responses and prolonged OS

Y. Yoshitake[1], D. Fukuma[2], M. Hirayama[2], H. Nakayama[2], H. Ogi[2], M. Shinohara[2]

[1]Department of Oral & Maxillofacial Surgery, Graduate School of Medical Sciences, Kumamoto University, Kumamoto City, Japan, [2]Department of Oral & Maxillofacial Surgery, Kumamoto University, Kumamoto, Japan

Background: The peptides derived from ideal cancer-testis antigens, including LY6K, CDCA1 and IMP3 (identified using genome-wide cDNA microarray analyses), were utilized in immunotherapy for head and neck squamous cell cancer (HNSCC). In this trial, we analyzed the immune response to and safety and efficacy of vaccine therapy.

Methods: A total of 40 patients with advanced HNSCC were enrolled in this trial of peptide vaccine therapy, and the OS, PFS and immunological response were evaluated using enzyme-linked ImmunoSpot (ELISPOT) and pentamer assays. The peptides were subcutaneously administered weekly with IFA. The primary endpoints were evaluated based on differences between HLA-A*2402-positive (A24(+)) patients treated with peptide vaccine therapy and –negative (A24(-)) patients treated without peptide vaccine therapy among those with advanced HNSCC.

Results: Our cancer vaccine therapy was well tolerated. The OS of the A24(+)v accinated group ($n = 40$) was statistically significantly longer than that of the A24(-) group ($n = 18$) (MST 4.9 vs. 3.5 month, respectively, $p < 0.05$). One of the patients exhibited a complete response. In the A24(+) vaccinated group, the ELISPOT assay identified LY6K-, CDCA1- and IMP3-specific CTL responses in 85.7%, 64.3% and 42.9% of the patients, respectively. The patients showing LY6K- and CDCA1-specific CTL responses demonstrated a longer OS than those without CTL induction. Moreover, the patients exhibiting CTL induction for multiple peptides demonstrated better clinical responses.

Conclusions: The immune response induced by this peptides vaccine may improve the prognosis of patients with advanced HNSCC.

1151P Phase I study of glypican-3-derived peptide vaccine therapy for patients with refractory pediatric solid tumors

A. Hosono[1], T. Yoshikawa[2], N. Tsuchiya[3], N. Fujinami[3], K. Saito[3], S. Mizuno[3], T. Nakatsura[3]

[1]Division of Pediatric Oncology, National Cancer Center Hospital East, Kashiwa, Japan, [2]Division of Cancer Immunotherapy, Exploratory Oncology Research and Clinical Trial Center, National Cancer Center, Chiba, Japan, [3]Cancer Immunotherapy, Exploratory Oncology Research & Clinical Trial Center, National Cancer Center, Chiba, Japan

Background: The carcinoembryonic antigen glypican-3 (GPC3) is a good target of anticancer immunotherapy against pediatric solid tumors expressing GPC3. In this non-randomized, open-label, phase I clinical trial, we analyzed the safety and efficacy of GPC3-peptide vaccination in patients with pediatric solid tumors.

Methods: We conducted a phase I study of pediatric patients with solid tumors. GPC3 is a target of anticancer immunotherapy against some pediatric solid tumor especially hepatoblastoma. Vaccinations were carried out biweekly from the first until disease progression with the primary endpoint being the safety of GPC3-peptide vaccination and the secondary endpoints being immune response, as measured by interferon (IFN)-γ enzyme-linked immunospot assay and Dextramer staining, and the clinical outcomes of tumor response, progression free survival (PFS), and overall survival (OS).

Results: A total of 18 patients (7 hepatoblastoma, 4 rhabdomyosarcoma, 3 brain tumor, 1 MRT, 1 pancreatoblastoma,1 Wilms tumor, 1 germ cell tumor) were enrolled from 5 hospitals, all cases showed no dose-limiting toxicity (DLT), which was the primary endpoint of this trial. No grade 3-4 hematological and non-hematological toxicity due to GPC3 vaccine therapy occurred. Clinical benefit ratio was 66.7% with six long SD (SD during more than 24 weeks; 5 hepatoblastoma,1 MRT) The GPC3-peptide vaccine induced a GPC3-specific CTL response in seven patients, with PFS and OS significantly longer in patients with high GPC3-specific CTL frequencies than in those with low frequencies. Furthermore, we established GPC3-peptide-specific CTL clones from a resected-recurrent tumor from one patient, with these cells exhibiting GPC3-peptide-specific cytokine secretion.

Conclusions: GPC3 peptide vaccine therapy is well tolerated in heavily pretreated pediatric patients with refractory solid tumors especially hepatoblastoma with acceptable toxicities in outpatient setting and keep good QOL.

Background: The HSP105 protein has been identified in pancreatic cancer by the SEREX method, and this protein has also been reported to play a role in controlling

apoptosis in cancer cells. HSP105 is highly expressed in various human cancers, including colorectal cancer, esophageal cancer, pharyngeal cancer, pancreatic cancer, breast cancer, and melanoma. We have therefore identified the respective HSP105-derived peptides that bind to HLA-A24 and HLA-A2(EP1536006, JP5112615, JP5291641, US9,404,925). We investigated the safety and efficacy of HSP105-derived peptide vaccine for patients ((pts)) with advanced esophageal cancer/colo-rectal cancer.

Methods: We conducted a multicenter phase 1 study of HSP105-derived peptide vaccine for pts with advanced esophageal cancer/colo- rectal cancer. The recommended dose is determined based on the incidence of dose-limiting toxicity (DLT) during phase 1a (P1a). Pts will then be added in phase 1b (P1b) to investigate the safety and efficacy of the vaccine. The vaccine was injected intradermally every 7 days. The primary objective of this study was to evaluate DLT (P1a), response rate (P1b). Progression-free survival, treatment failure rate, and toxicity were also evaluated as secondary objectives. As exploratory endpoint, immunological effect was investigated.

Results: A total 30 pts (HLA-24 group 15pts, HLA-02 group 15 pts) were enrolled and grouped into level 1 which received intradermally administration of peptide vaccine (emulsifying agent: Montanide ISA 51 VG) 3 mg/body. No DLT occurred and no major safety problems were reported throughout the trial. Although pts with objective clinical efficacy was not apparent, 7 pts showed stable disease 2 months after initiation of treatment. The HSP105-derived peptide vaccine induced HSP105-specific CTL response in 15 pts (50%) of 30 pts. Additionally, we established several HSP105 peptide-specific CTL clones from PBMCs and tumor of pts vaccinated with HSP105 peptide by single cell sorting using Dextramer or anti-CD107a antibody.

Conclusions: Although objective clinical efficacy was not apparent, HSP105-derived peptide vaccine appears safe and well tolerated with minimal local toxicity.

1153P An observational clinical study with RAS peptide vaccine TG01 evaluating immune response, safety and overall survival in patients with non-resectable pancreatic cancer

J.A. Eriksen[1], I.P. Gladhaug[2], A. Rosseland[3], K. Risberg Handeland[4], T. Buanes[2]

[1]Technology Innovation, Targovax ASA, Oslo, Norway, [2]Department of Hepato-Pancreato-Biliary Surgery, Oslo University Hospital, Oslo, Norway, [3]Surgical Department, Central Hopital of Akershus, Lillestrøm, Norway, [4]Clinical Department, Targovax ASA, Oslo, Norway

Background: The study evaluated the immune response, safety and survival of the TG01/GM-CSF vaccine, an antigen-specific cancer immunotherapy consisting of 7 RAS peptides targeted to KRAS mutated pancreatic adenocarcinoma, in treatment naive non-resectable pancreatic cancer patients (pts). TG01/GM-CSF was recently reported to elicit immune response and increased survival in resectable pancreatic pts (ASCO 2017).

Methods: 25 treatment naive non-resectable pancreatic cancer pts were immunised with TG01/GM-CSF at week 1, 2, 3, 4, 6, 10 (immunisation period) followed, after a 3 months pause, by a booster period of four weekly administrations. Pts were followed up for up to 12 months from 1st dose of TG01/GM-CSF. Immune response was evaluated by Delayed Type Hypersensitivity (DTH) skin reaction test, (S)AEs recorded throughout the study and survival data calculated using Kaplan-Meier.

Results: 14/25 pts (56%) had a positive DTH by week 10. The TG01/GM-CSF treatment was well tolerated with no reports of allergic or other adverse hypersensitivity reactions. 13 pts experienced 19 SAEs; 5 were due to disease progression, 13 were deaths due to disease progression, and one was treatment related (hypoglycaemia). Median survival (MS) from first administration of TG01/GM-CSF was for all treated pts (n = 25) 4.5 months, for DTH responders (n = 14) 5.1 months and for DTH non-responders (n = 11) 3.6 months. For the DTH responders the result compares favorably with untreated patients (MS ≈ 3.7 months)[1]. At 1 year, 4 pts of whom three DTH responders were alive. 1. Palmer KR *et al.*, Br J Surg: 81, 882-885 (1994).

Conclusions: In pts treated with TG01/GM-CSF monotherapy, immune response was recorded in 56% of the pts, results that correspond with data from a Phase I/II trial with a similar RAS peptide vaccine in non-resectable pancreatic pts[2]. Even though not statistically significant, the results indicate increased survival for the immune responders. In the otherwise incurable disease, the non-resectable pancreatic pts may therefore benefit from immunisation with TG01/GM-CSF RAS peptide vaccine with few side effects. 2. Gjertsen M *et al.*, Int J Can: 92, 441-450 (2001).

1154P Telomerase peptide vaccine combined with ipilimumab in metastatic melanoma: Reports from a phase I trial

E. Aamdal[1], G. Gaudernack[2], E.M. Inderberg[1], W. Rasch[2], J. Bjørheim[2], S. Aamdal[1], T.K. Guren[1]

[1]Oncology, Oslo University Hospital, Oslo, Norway, [2]Scientific, Ultimovacs AS, Oslo, Norway

Background: The checkpoint inhibitor ipilimumab has improved survival for a proportion of patients with metastatic melanoma. However, most patients do not benefit from single agent immunotherapy. Patients lacking a spontaneous immune response may benefit from combining checkpoint blockade with a tumor-specific vaccine. UV1 is a therapeutic cancer vaccine consisting of three long synthetic peptides of the enzyme telomerase (hTERT). The UV1 peptides comprise epitopes recognized by T cells from cancer patients experiencing long-term survival following vaccination with a first-generation hTERT vaccine. The aim of this trial was to investigate the safety and efficacy of combining UV1 and ipilimumab in the treatment of patients with metastatic melanoma.

Methods: In a phase I, single center trial [EudraCT No. 2013-005582-39], patients with metastatic melanoma received treatment with UV1 (300 µg) + GM-CSF (75 µg) as adjuvant, combined with ipilimumab (3 mg/kg). Safety was assessed according to CTCAE v. 4.0, and tumor responses according to RECIST v.1.1. Immune responses against UV1 peptides were monitored in peripheral mononuclear blood cells by using 3H-thymidine proliferation and IFN-γ ELISPOT assays.

Results: 12 patients were recruited from Jan to Oct 2015. Treatment was generally well tolerated. Adverse events mainly included injection site reactions and diarrhea. Eleven serious adverse events (SAEs) were reported; nine treatment-related and two not related. Ten out of twelve patients showed an immune response (one negative, one not evaluable). Three patients obtained a partial response. Overall survival at 18 months was 75%. A comparison to a reference population from a phase IV ipilimumab trial in our center will be made.

Conclusions: Combining UV1 and ipilimumab is safe and induces clinical responses. The high proportion of immune responders and early induction of detectable immune responses suggest a synergistic effect due to *de novo* tumor-specific immune responses, likely due to blockage of CTLA-4, allowing expansion of hTERT-specific T-cell clones.

Background: CV9104 is a multivalent mRNA-based active cancer immunotherapy containing sequence-optimized free and protamine complexed mRNA coding for six prostate cancer associated antigens (PSA, PSMA, PSCA, STEAP1, PAP and MUC1). CV9104 has been investigated in a placebo controlled Phase IIb study in pts with metastatic castrate-resistant PC. Administration of mRNA based immunotherapy by needle free jet devices has been shown to improve antigen expression and immunogenicity vs needle injection in preclinical models. The purpose of this study was to evaluate immune responses and safety of CV9104 administered by conventional intradermal (cID) injection or with a needle-free ID (nfID) injection device in pts with intermediate/high-risk localized PC.

Methods: 48 pts with intermediate or high risk localized PC and an indication to undergo RPE were randomized in a 1:1:1 ratio to receive presurgical CV9104 by nfID injection (960 µg mRNA per administration) (A), or cID injection (1920 µg mRNA per

administration) (B), or no treatment (C). CV9104 was administered in weeks 1, 2, 3 and 5 before RPE was performed in week 6-7. Postoperative CV9104 was offered to all pts with high-risk PC. Cellular (against all antigens) and humoral immune responders (against PSA, STEAP1, PAP, MUC1) were determined in blood at week 6-7 before RPE and 8 weeks after surgery. Further samples (prostatectomy, exprimate urine, serum) were collected for exploratory biomarker analyses.

Results: 48 pts were randomized (A: 15; B: 17; C: 16); Treatment with CV9104 was well tolerated using either nflD or clD injection. Most frequent adverse events (AEs) in Arms A and B were Grade 1-2 injection side reactions, transient flu-like symptoms (FLS) and AEs related to RPE. There were no CV9104 related Grade $\geq$3 AEs or SAEs. FLS were most frequent in Arm B (76.5%) vs Arm A (37.5%) and Arm C (6.3%).

Conclusions: CV9104 was well tolerated using either nflD or clD injection, with a safety profile similar to other previous mRNA-based cancer immunotherapies. Cellular and humoral immune responses including responses per antigen and additional biomarker results will be presented.

Background: Nivolumab monotherapy has shown survival benefit in patients (pts) with different tumors, including melanoma, lung cancer, renal cell carcinoma and head and neck cancer. The experience of pts and physicians in routine clinical practice is often different from that in a controlled clinical trial setting. Here, we report efficacy and safety of nivolumab monotherapy in pts with non-squamous non-small cell lung cancer (NSCLC) treated in the nivolumab Expanded Access Programme in Italy.

Methods: Nivolumab was available upon physician request for pts aged $\geq$18 years who had relapsed after a minimum of one prior systemic treatment for stage IIIB/stage IV non-Squamous NSCLC. Nivolumab 3 mg/kg was administered intravenously every 2 weeks to a maximum of 24 months. Pts included in the analysis had received at least 1 dose of nivolumab and were monitored for adverse events (AE) using Common Terminology Criteria for Adverse Events.

Results: In total, 1588 Italian pts participated in the EAP across 168 centers. Baseline characteristics of pts were representative of the population with non-squamous NSCLC, in the advanced disease setting. With a median follow-up of 7.8 months (1-21.9) and a median of 7 doses, the overall response rate (ORR) was 18%, including 10 pts (<1%) with complete response and 280 pts (17%) with partial response. Stable disease has been defined for 414 pts (26%) and totally 279 patients were treated beyond progression. As of March 2017, median overall survival (OS) was 11 months (range: 10.0-12.0). Response rates and survival were comparable among pts regardless age (< and $\geq$ 75 years), presence of brain metastasis and number of prior therapies. Overall, among 1588 pts, 1254 discontinued treatment for any reason, with only 80 pts (5%) who discontinued treatment due to related adverse events.

Conclusions: To date, this is the largest clinical experience with nivolumab in a real-world setting. These preliminary EAP data confirm that nivolumab seems to be an effective and safe therapy for pre-treated patients with non-squamous NCSLC, supporting its use in current clinical practice.

1157P Correlation and differences in Effect sizes between Progression Free Survival (PFS) and Overall Survival (OS) among PD-1 inhibitors

B. Gyawali, T. Shimokata, Y. Ando

Clinical Oncology and Chemotherapy, Nagoya University, Graduate School of Medicine, Nagoya, Japan

Background: Programmed death 1 (PD-1) inhibitors, such as nivolumab and pembrolizumab, have now been approved for various cancers based on results from pivotal randomized controlled trials (RCTs). These drugs are known for unconventional response patterns with varying effects on PFS and OS. We aimed to compare the correlation between PFS and OS and evaluate the differences in treatment size between PFS and OS for PD-1 inhibitors.

Methods: We carried out a systematic search on PubMed and conference abstracts for RCTs of nivolumab and pembrolizumab versus non-immunotherapy control and obtained data on median PFS, median OS for both arms and hazard ratio (HR) and confidence intervals (CIs) for PFS and OS. We evaluated the correlation between PFS and OS as well as between Delta (PFS) and Delta (OS). We also evaluated the ratio of HR of PFS to HR of OS for each trial (rHR) and obtained a summary rHR by random-effects meta-analysis across trials.

Results: Of 52 studies identified, a total of 11 phase 3 RCTs met the eligibility criteria. However, 2 trials didn't have data on OS. So our analysis includes 9 RCTs that had data on both PFS and OS (6 Nivolumab, 3 Pembrolizumab). There was no significant correlation between PFS and OS ($r = 0.676$, $R^2 = 0.457$, $P = 0.095$) or between Delta (PFS) and Delta (OS) ($r = 0.474$, $R^2 = 0.225$, $P = 0.282$). Using random-effects meta-analysis, treatment effects were in general 19% higher for OS than PFS (rHR 1.19, 95% CI 1.07 to 1.32, $p = 0.001$). There was no statistical evidence for lack of homogeneity ($I^2 = 0.0\%$, $p = 0.850$) and thus, subgroup analysis were not conducted. PFS and OS were discordant for 5 RCTs (3 Nivolumab, 2 Pembrolizumab) and in all these 5 RCTs, OS was significant but PFS was not. All RCTs ($n = 3$) showing benefit for PFS also showed benefit for OS. Only one RCT was negative for OS.

Conclusions: Unlike targeted therapies where benefit in PFS mayn't translate to OS, treatment effect sizes in RCTs of PD-1 inhibitors were greater for OS than PFS. The benefit in OS was poorly captured by PFS. There was no correlation between PFS and OS. OS should remain the standard endpoint for PD-1 inhibitor RCTs unless better surrogate endpoints such as immune-criteria based PFS are introduced and validated.

1158P Is objective response rate (ORR) a valid primary endpoint in phase 2 trials (Ph2t) of immune checkpoint inhibitors (ICI) for advanced solid cancers?

G. Ritchie[1], H. Gasper[2], J. Man[3], S. Lord[4], M. Friedlander[1], C. Lee[4], I. Marschner[4]

[1]Medicine, University of New South Wales, Sydney, Australia, [2]Medical Oncology, Coffs Harbour Hospital, Sydney, Australia, [3]Medical Oncology, Westmead Hospital, Sydney, Australia, [4]University of Sydney, NHMRC Clinical Trials Centre, Sydney, Australia

Background: ORR is commonly used as the primary endpoint in Ph2t. ICI have different mechanisms of action to chemotherapy or molecular targeted agents (MTA). The validity of ORR as a surrogate for progression-free survival (PFS) and overall survival (OS) with ICI is uncertain and may differ by tumor type. We performed a meta-analysis of randomized controlled trials (RCTs) in advanced solid cancers that compared ICI to chemotherapy, MTA or placebo to address this question.

Methods: We performed a literature search to determine the current Ph2t designs used in ICI trials. Efficacy data from single-arm trials and RCTs were extracted. Amongst the RCTs, correlations between ORR odds ratio (OR) with PFS hazard ratio (HR) and OS HR were examined for between randomized arms comparisons. Correlations within ICI treatment arms of the RCTs between ORR with PFS and OS rates were also studied. Using data from the RCTs, multivariable models that examined the relationships

between ORR, 6-month PFS and 12-month OS rates were developed and their predictive performances validated in the single-arm trials.

Results: Of 87 Ph2ts identified, most were single arm design (68%), and only 10% were RCTs with concurrent standard of care arms. ORR was the most common (60%) primary endpoint and PFS was uncommon (8%). A total of 20 RCTs (4 Ph2t and 16 phase 3 trials) with mature data were examined. There were 25 treatment comparisons in 8 different tumors (non-small cell lung cancer 44%, melanoma 24%). For RCTs in all tumors, the correlations (*r*) between ORR OR with PFS HR, ORR OR with OS HR, and PFS HR with OS HR were 0.63, 0.57 and 0.42 respectively. Within the ICI arms, *r* between ORR with 6-month PFS, ORR with 12-month OS, and 6-month PFS with 12-month OS were 0.37, 0.08 and 0.74 respectively. In the single-arm trials dataset, we were able to accurately predict 12-month OS using the actual 6-month PFS with the multivariate model developed from our RCTs dataset. Conversely, when ORR was used to predict 6-month PFS or 12-month OS, there was poor agreement between actual and predicted results.

Conclusions: These data do not support the use of ORR as a surrogate for OS in ICI trials. In future ICI Ph2t, 6-month PFS should be the primary endpoint rather than ORR.

1159P Long term survival in patients responding to an Anti-PD-1/PD-L1 therapy and disease outcome upon treatment discontinuation

M-L. Gauci[1], E. Lanoy[2], S. Champiat[3], J-M. Michot[1], A. Varga[1], R. Bahleda[1], E. Angevin[1], A. Gazzah[1], L. Verlingue[1], F. Bigot[1], S. Aspeslagh[1], E. Castanon[1], C. Baldini[1], S. Postel-Vinay[1], C. Massard[1], A. Hollebecque[1], J-C. Soria[1], A. Marabelle[1]

[1]Drug Development Department (DITEP), Gustave Roussy, Villejuif, France, [2]Biostatistiques et Epidémiologie, Institut Gustave Roussy, Villejuif, France, [3]INSERM U981, Gustave Roussy, Villejuif, France

Background: The long-term outcome of cancer patients responding to an anti-PD-1/PD-L1 immunotherapy (IT) remains unknown. This study aimed to describe the long-term survival of patients responding to anti-PD-1/PD-L1 monotherapy across multiple cancer types.

Methods: 306 patients treated with an anti-PD-1 or PD-L1 monotherapy in a phase 1 trial at Gustave Roussy were retrospectively analyzed over a period of 5 years. Major inclusion criteria were: at least 18 years-old, performance status 0-1, at least 1 infusion, evaluation by RECIST 1:1 and/or irRC. Multiple myeloma patients were excluded as they do not respond to anti-PD-1 monotherapy. All other cancer types (n = 19) were included.

Results: The overall objective response rate within this cohort of 262 patients was 29% (n = 76; 77% being evaluated by irRC). The median PFS of responders was 22 months and the median OS was not reached. The OS of patients responding to IT at 3 years was 76% and at 5 years was 63%. Long responders (patients with enough follow up to have tumor responses lasting more than 2 years) represented 11.8% of the cohort (31 patients). No death occurred in the 21 complete responders over this long term follow up. The median duration of response was not reached. Out of the 33 patients who disontinued immunotherapy, 9 patients showed a disease relapse (median response duration after treatment discontinuation: 6 months). Clinical and biological factors associated with response, long term survival, and secondary refractory disease will be reported at the ESMO meeting.

Conclusions: This study shows that, across cancer types, patients with objective tumor responses under anti-PD-1/PD-L1 immunotherapy have a high level of overall survival. Best survivals are seen with complete responses (no deaths in our cohort). Complete response rate might be a good short term surrogate marker for overall survival benefits. Clinical trials aiming at putting patients with partial responses under immunotherapy into complete responses should be assessed in a near future.

1160P Meta-Analysis of Anti-PD-1/PD-L1 Therapy Related Adverse Events in Clinical Trials

Y. Wang[1], X. Wang[2], F. Yang[2], X. Guan[2], N. Duma[1], J. Vera Aguilera[1], G.S. Nowakowski[3], A.V. Chintakuntlawar[1], K.A. Price[1], J.R. Molina[1], T.R. Halfdanarson[1], A. Grothey[1], S.N. Markovic[1]

[1]Medical Oncology, Mayo Clinic, Rochester, NY, USA, [2]Medical Oncology, Medical School of Nanjing University, Nanjing, China, [3]Hematology, Mayo Clinic, Rochester, NY, USA

Background: Anti-PD-1/PD-L1 immunotherapy is a major breakthrough in cancer treatment. With increasing use, its adverse event (AE) profile continues to be defined. We performed a meta-analysis to summarize AEs of anti-PD-1/PD-L1 therapy in clinical trials.

Methods: Clinical trials involving monotherapy with PD-1 or PD-L1 antibody in cancer patients published before April 1, 2017 were reviewed, and treatment related AE data were extracted. Meta-analysis of AE rates was done by Comprehensive Meta-Analysis (v2) using a random effects model. Average AE rate (Total AE No./Total Patient No.) was calculated in Microsoft Excel.

Results: 63 studies involving 10592 patients were included: 27 on nivolumab, 23 on pembrolizumab, 8 on atezolizumab, 4 on avelumab, and 1 on BMS-936559. Treatment related AE rates were summarized in the Table. In meta-analysis, all grade AE (AEx) rate was 71.5%, and grade 3-4 AE (AE3) rate was 14.9%. Common AEx included fatigue (>20%), pruritus, rash, diarrhea, nausea (10-20%), decreased appetite, arthralgia, vitiligo, pyrexia, hypothyroidism, and asthenia (5-10%). Most common AE3 included hyponatremia, lymphopenia, and fatigue (>1%). Average immune-mediated AEx/AE3 rates (%) were uveitis 0.9/0.0, pneumonitis 2.9/0.8, colitis 1.4/0.9, ALT increase 3.7/0.9, AST increase 4.0/0.8, pancreatitis 1.7/0.4, vitiligo 8.2/0.1, alopecia 1.0/0.0, asthenia 7.3/0.4, paresthesia 1.0/0.0, dysgeusia 2.2/0.0, peripheral neuropathy 1.5/0.0, hypothyroidism 7.0/0.1, hyperthyroidism 3.0/0.1, hypophysitis 0.5/0.4, and adrenal insufficiency 1.2/0.5. 31 (0.3%) treatment related deaths were reported. Pulmonary causes were most common, including 11 pneumonitis, 3 pneumonia and 1 respiratory failure.

Conclusions: Common AEs of anti-PD-1/PD-L1 therapy were primarily constitutional and gastrointestinal. Most grade 3-4 AE rates were < 1%. Rates of immune-related AE were low. Treatment related death was rare, and pneumonitis was the most common cause.

Background: SCHOLAR-1 (Crump, ASCO 2016) is a large, pooled analysis of rNHL and demonstrated poor outcomes: objective response rate (ORR)= 26%; complete response (CR)=8%. ZUMA-1 is the first, multicenter trial of anti-CD19 CAR T cells (axi-cel) in rNHL and reported positive results: ORR= 82%; CR = 54%. This is a comparative analysis of outcomes from ZUMA-1 and SCHOLAR-1 after adjusting for imbalances in key covariates of patients enrolled.

Methods: Eligible pts for both studies had rNHL (stable disease ≤6 mos with ≥4 cycles frontline or ≥ 2 cycles later-line therapy, progressive disease as best response, or relapse ≤12 mos post autologous stem cell transplant). Standardized analyses were performed to account for other baseline covariates that were imbalanced between the studies despite similar inclusion criteria. These analyses equally weighted the proportions of patients with select prognostic covariates between the two studies. The pre-specified covariates selected for weighting were refractory subgroup and occurrence of SCT after refractory status. Sensitivity analyses included additional covariates.

Results: 101 ZUMA-1 pts received axi-cel; SCHOLAR-1 included data from 508 pts. Baseline characteristics for each study are listed in the Table. ZUMA-1 median follow-up was 8.7 mos. Using the standardized analysis, the estimated ORR and CR rates in SCHOLAR-1 were 20% and 6%, respectively. Standardized 6-mo survival rate for SCHOLAR-1 was 35%. Risk of death in ZUMA-1 was reduced by 77% relative to SCHOLAR-1 (P < .0001).

Table: 1161P

	ZUMA-1 mITT N = 101	SCHOLAR-1 Response N = 508
Age, ≥65 y, n (%)	24 (24)	74 (15)
Refractory subgroup, n (%)		
Primary refractory	2 (2)	101 (20)
Refractory to ≥ 2L	78 (77)	316 (62)
Relapse <12 mo post-ASCT	21 (21)	91 (18)
Received stem cell transplant*, n (%)	11 (11)	161 (32)
Prior lines of chemotherapy & ASCT	**n = 101**	**n = 417**
Median prior lines, n	3	2
ECOG performance score	**n = 101**	**n = 288**
0-1, n (%)	101 (100)	230 (80)
IPI Score	**n = 101**	**n = 215**
≥2, n (%)	74 (73)	142 (66)

*Autologous or allogeneic SCT at any time after determination of refractory status. ASCT, autologous stem cell transplant; ECOG, Eastern Cooperative Oncology Group; IPI, International Prognostic Index; mITT, modified intent-to-treat.

Conclusions: Despite the imbalances between the ZUMA-1 and SCHOLAR-1 studies, axi-cel appears to represent a significantly improved treatment option for pts with rNHL compared with currently available therapies as used in the SCHOLAR-1 study.

1162P Predictive factors for poor progression-free survival in patients with non-small-cell lung cancer treated with nivolumab

Y. Taniguchi[1], A. Tamiya[1], S-I. Isa[2], K. Nakahama[1], K. Okishio[2], T. Shiroyama[3], H. Suzuki[3], T. Inoue[4], M. Tamiya[4], K. Nishino[4], T. Kumagai[4], T. Hirashima[3], F. Imamura[4], S. Atagi[2]

[1]Internal Medicine, Kinki-chuo Chest Medical Center, Sakai, Japan, [2]Clinical Research Center, Kinki-chuo Chest Medical Center, Sakai, Japan, [3]Thoracic Malignancy, Osaka Prefectural Habikino Hospital, Habikino, Japan, [4]Thoracic Oncology, Osaka International Cancer Institute, Osaka, Japan

Background: Nivolumab (Nivo) has shown promising effects in patients with non-small-cell lung cancer (NSCLC) as a second- or later-line treatment. However, owing to the inclusion of random patients, the observed progression-free survival (PFS) in a clinical setting may be shorter than that in a clinical trial. For treatment effectiveness, it is important to clarify which patients may not experience any benefit from Nivo treatment. Therefore, in this multicenter retrospective study, we aimed to identify which patients would not be eligible for Nivo treatment.

Methods: In this study, data for 201 patients treated with Nivo during 17 December 2015 to 31 July 2016 at three respiratory medical centers in Japan were retrospectively reviewed. We collected clinical data including age, sex, smoking history, performance status (PS) score, body mass index (BMI), histological types, epidermal growth factor receptor (EGFR) mutation status, number of previous treatment, steroid use and laboratory data (Lactate Dehydrogenase (LDH) and C-reactive protein) at the time of Nivo treatment commencement. We investigated relationship between PFS and patient characteristics. Patients were followed-up for disease status until September 2016.

Results: The median age at the time of administration Nivo was 68 years, 135 patients were male, 157 patients had smoking history, 153 patients had a PS score of 0–1, and 23 patients received steroids. For all participants, median PFS was 2.9 months, over all response rate was 15.9% and disease control rate was 51.7%. In the univariate analysis, PS score ≥2, steroid use at baseline, and LDH level >240 IU/L was significantly associated with poor PFS. Furthermore, in the multivariate analysis, PS score ≥2 (hazard ratio [HR]: 1.57; 95% confidence interval (CI): 1.06–2.29; p = 0.027), steroid use at baseline (HR: 2.37; 95% CI: 1.44–3.74; p = 0.001) and LDH level >240 IU/L (HR: 1.63; 95% CI: 1.15–2.31; p = 0.007) were significantly associated with poor PFS.

Conclusions: PS score ≥2, steroid use at baseline, and high LDH levels were predictive of poor PFS in patients with NSCLC treated with Nivo. Careful monitoring is recommended for treating such patients with Nivo.

1163P Immunotherapy phase I trials in patients over 70 years with advanced solid tumours: The Gustave Roussy experience

H. Herin[1], E. Castanon[1], V. Dyevre[2], S. Aspeslagh[1], A. Marabelle[1], S. Postel-Vinay[1], A. Varga[1], A. Gazzah[1], V. Ribrag[1], R. Bahleda[1], J-M. Michot[1], O. Mir[1], C. Massard[1], A. Hollebecque[1], J-C. Soria[1], C. Baldini[1]

[1]Drug Development Department (DITEP), Gustave Roussy Cancer Campus, Villejuif, France, [2]Biostatistics and Epidemiology, Institut Gustave Roussy, Villejuif, France

Background: More than half of new cases of cancer are diagnosed in patients over 65 years. However only few elderly patients have so far been included into trials, despite general awareness of the need. The revolution of immune checkpoint blocker development brings new hope in older patients because of clinical efficacy and low toxicity. Clinical indications are rising steadily but very few data are available in this population where co-morbidities, reduced functional reserve and immunosenescence may affect efficacy and tolerance.

Methods: All cases of patients enrolled in immunotherapy phase I trial between January 2012 and December 2016 in the Drug Development Department (DITEP) at Gustave Roussy were retrospectively reviewed. Case-control analysis was performed in a group of patients ≥ 70 years (elderly patients EP) matched to a group of patients < 70 years (younger patients YP) by trial and treatment dose. We compared cumulative incidence, grade and type of adverse events (AEs) and survival outcomes. Cumulative incidence was calculated according to Fine and Gray method and survivals using Kaplan-Meier method.

Results: Median age of EP and YP were respectively 75 (70 - 88) and 55 (22 - 70). Among the 46 EP and the 174 YP enrolled in 13 protocols, 10 (22%) and 23 (13%) patients experienced grade 3-4 AEs. Cumulative incidence of grade 1-2 AEs was significantly higher in EP versus YP (p < 0.05). For grade 1 AEs, median time of occurrence was 0.67 for EP *versus* 2.67 months for YP. For grade 2 AEs, median was not reached. No difference was observed between the two groups for grade 3-4 AEs (p = 0.50). Older age was not associated with lower dose intensity of treatment (p = 0.14). The response rate was respectively 14% for EP and 18.5% YP (p = 0.52). Median overall survival and median progression free survival were similar between the two groups (10.1 months, HR 0.93 [0.58-1.48] p = 0.77; 6.2 months, HR 1.41 [0.94-2.11] p = 0.09 for EP and YP, respectively).

Conclusions: Immune checkpoint blockade appears to be a practicable option of treatment for elderly patients. The toxicity and efficacy profiles appear similar to the ones in younger patients. Dedicated studies in this population are warranted.

1164P Patterns of progression under antiPD1/PDL1 in advanced NSCLC patients allow discriminating pseudo-progression from real progression

C. Caramella[1], M. Tazdait[1], L. Mezquita[2], J. Lahmar[2], R. Ferrara[2], A. Marabelle[3], C. Balleyguier[1], D. Planchard[2], A. Gazzah[4], J-C. Soria[5], B. Besse[2]

[1]Imaging, Gustave Roussy, Villejuif, France, [2]Medical Oncology, Institut Gustave Roussy, Villejuif, France, [3]Département d'Innovation Thérapeutique et d'Essais Précoces, Gustave Roussy, Université Paris-Saclay, Villejuif, France, [4]Départemement d'Innovation Thérapeutique et des Essais Précoces (DITEP), Institut Gustave Roussy, Villejuif, France, [5]Drug Development Department (DITEP), Institut Gustave Roussy, Villejuif, France

Background: Immunotherapy (IT) is now a standard of care in advanced NSCLC patients. However, patients may present with various patterns of response, including initial progression followed by long stabilization or response, making it difficult to decide whether or not we should continue the treatment at the occurrence of progression. Our aim was to explore the patterns of responses based on CT-scans in order to differentiate real progression (PD) from pseudoprogression (PsPD).

Methods: We conducted a retrospective analysis of all NSCLC patients treated with IT in our Institution. All CT-scans were reviewed and the responses were assessed by RECIST 1.1 and iRECIST criteria. Seven different patterns of PD were considered based on the combination of target (T) and/or non-target (NT) and/or new lesions (NL). A confirmatory CT scan was performed at 4 weeks to discriminate real progression from PsPD. PsPD was defined as any decrease or stable disease for at least 6 months following an initial progression. Dissociated responses (DR) were defined as concomitant progressing and responding lesions for patients treated at least 6 months. Patterns of PD were correlated with overall survival (OS).

Results: Out of 202 patients treated by IT, 39 patients (19%) were excluded due to the absence of confirmatory CT. 87 patients (53%) had an initial PD, confirmed by a subsequent CT, or by death related to tumor progression. 14 patients (9%) experienced PsPD or DR. PsPD or DR patients had higher OS than PD patients ($p = <.05$). The pattern which was the most likely to confer PsPD or DR was the appearance of NL in the thoracic area (lung, pleura) or lymph nodes. The concomitant increase of T, NT and appearance of NL was only observed in real PD. New extra-thoracic visceral lesions (especially liver and brain) were very unlikely related to PsPD. New liver lesions occurring during IO were detrimental on OS ($p = <.05$).

Conclusions: On the first occurrence of progression upon IT, a concomitant increase of T, NT and appearance of NL or appearance of extra-thoracic visceral lesions were strongly suggestive of real PD. IT should be stopped in these patients, and a confirmatory CT scan should be avoided.

Background: MITF translocation renal cell carcinoma (tRCC) is a rare RCC subtype harbouring TFE3/TFEB translocations with poor prognosis and no standard of care in metastatic setting. Program death ligand-1 (PDL-1) expression was reported in 90% of cases prompting us to analysed the benefit of immune checkpoint inhibitors (ICI) in this population.

Methods: A multicenter retrospective study was conducted to identify patients with MITF family tRCC who had received ICI in referral centres in France and USA. In the majority of cases, the diagnosis was confirmed by FISH. Overall response rate (ORR) according to RECIST criteria, progression-free survival (PFS) and overall survival (OS) were analyzed.

Results: Overall, 23 patients (4 males and 19 females) with metastatic disease were identified in 12 institutions (median age 33.5 years), all receiving ICIs as 2nd or later line. For first-line treatment, 19 (82.6%) patients received vascular endothelial growth factor receptor (VEGFR) inhibitors with a median PFS on therapy of 3 months (range, 1-22 months) and 2 (10.5%) responders. Regarding ICI, 19 patients received Nivolumab, 3 patients Ipilimumab and 4 patients combinations of ICIs +/- VEGFR inhibitors. Median PFS for patients under first ICI administered was 2.45 months (range, 1-40 months); among those, 4 patients experienced partial responses (17.4%) and 2 patients (9.5%) a stable disease with a median PFS of those responders under ICI of 9 months (range 8,3-30), similar to the first line PFS with VEGFR inhibitors [9 months, (range 1-22)]. One patient with partial response to Ipilimumab lasting for 9 months showed hyperprogressive disease following treatment by Nivolumab. With a median follow-up of 19 months, median OS was 23.5 months.

Conclusions: MITF family tRCC is an aggressive disease with occasional responses to ICI. Valid targets and clinical trials remain warranted in this disease.

1166P Tumor flare reaction (TFR) in cancer treatments: a systematic review

A. Taleb

Oncology, Groupe Hospitalier Sud Ile de France, Melun, France

Background: In the last decade, TFR was described as a side-effect associated with immunomodulatory agents IMiDs (thalidomide and lenalidomide), and as a specific condition to chronic lymphocytic leukemia (CLL). However, this phenomenon is seen with the use of new immunotherapy (checkpoints inhibitors) in solid tumors, in addition, cases of TFR were reported in advanced gynecologic, prostate cancer and lymphoid malignancies. TFR is defined as an increase of lesion size related to treatment which simulates disease progression. This phenomenon that occurs after initiating cancer therapy is poorly understood and incidence is under-estimated, since not captured by Recist. It has been suggested that TFR may be the results of immune system activation and may precede tumor shrinkage. TFR is associated with morbidity, severe cases were reported, some of them life-threatening or leading to death. So, early recognition and initial management of patients presenting with TFR, is critical.

Methods: From 1985 to 2016, a search was performed in the Pubmed, ASCO and ASH abstracts to identify publications reporting TFR or pseudoprogression.

Results: The incidence of all grades of TFR in CLL, ranged from 28% in a study to 58% in another trial. In CLL, painful lymph nodes and/or spleen enlargement were reported with a sudden onset after the first dose. Following initial progression (TFR), tumor response in patients treated beyond progression, was reported in melanoma trials: 9.7% with ipilimumab, 10% with nivolumab, 6.7% and 12% with pembrolizumab, and in renal cell carcinoma 69% with nivolumab. Even if rare cases of life-threatening or fatal TFR were reported, symptoms are usually mild. While correct diagnosis and adequate management are critical, it is important to better recognize TFR, and avoid an effective treatment discontinuation. Some studies showed that treating patients beyond progression yielded tumor responses, considering TFR as predictive of response.

Conclusions: Treatment with immunomodulatory agents is associated with TFR. This is likely to be misinterpreted as progression, hence the need to identify appropriate clinical benefit criteria and the use of immune-related RECIST (irRC) in prospective trials for a better understanding.

1167P Melanoma brain metastases patients treated with stereotactic radiosurgery and ipilimumab versus stereotactic radiosurgery alone: a systematic review with meta-analysis

S.M. Nguyen[1], A. Castrellon[2], O. Vaidis[3], A. Johnson[4]

[1]College of Medicine, University of Central Florida, Orlando, FL, USA, [2]Breast Cancer Center, Memorial Cancer Institute, Hollywood, FL, USA, [3]Department of Mathematics & Statistics, University of South Florida, Tampa, FL, USA, [4]Department of Computer Science, University of Houston, Houston, TX, USA

Background: The synergistic effects of radiotherapy and novel immunotherapy agents have shown renewed interest in cancer management. We examined survival outcomes in melanoma brain metastases (MBM) patients treated with stereotactic radiosurgery (SRS) and ipilimumab immunotherapy. We compared these outcomes with those of MBM patients receiving SRS without added immunotherapy.

Methods: We conducted the first systematic review with meta-analysis of studies comparing combined SRS and ipilimumab with SRS only in MBM. The protocol was published in the PROSPERO register for systematic reviews. MEDLINE and CENTRAL databases were searched using PRISMA method by three separate reviewers. Studies that examined SRS and ipilimumab compared to SRS without ipilimumab in MBM were included. Newcastle-Ottawa Scale Risk of Bias Assessment and the GRADE evidence quality rating method were used for qualitative appraisal. Statistical analysis was performed using Review Manager.

Results: We found 37 publications in our search and identified 4 retrospective studies to further assess; 3 studies were chosen for pooled-analysis. Evidence for survival benefits with combined treatment was rated "low", per GRADE method. Meta-analysis of 222 patients confirmed significant survival advantage for SRS and ipilimumab (pooled median survival: 16.8 vs. 6.2 months; HR 0.38, 95% CI: [0.28 – 0.52]; $p < 0.01$). One study's cohorts ($n = 58$) demonstrated non-significant trend for improved local and distant brain control. Otherwise, we found no differences in local control, distant brain control, radiation necrosis, or intracranial bleeding in our analysis.

Conclusions: Combining stereotactic radiosurgery and ipilimumab in melanoma brain metastases can dramatically improve survival rate compared to stereotactic radiosurgery without immunotherapy. There is no increased risk of radiation necrosis and/or intracranial bleeding with combining radiation and immunotherapy in this setting.

1168P Estimation of benefice to anti-PD-(L)1 for metastatic patients by real-time quantitative and functional estimation of immune infiltrate with RNAseq

L. Verlingue[1], L. Mahjoubi[1], D. Brandao[2], S. Michiels[3], S. Champiat[4], S. Aspeslagh[5], Y. Loriot[6], Y. El Dakdouki[7], S. Postel-Vinay[1], C. Nicotra[1], H. Zouhri[1], G. Chartier[1], E. Solary[8], O. Bernard[9], D. Gautheret[2], E. Angevin[1], A. Hollebecque[1], A. Marabelle[1], F. André[10], J-C. Soria[1]

[1]Drug Development Department (DITEP), Gustave Roussy, Villejuif, France, [2]Bioinformatic platform, Gustave Roussy, Villejuif, France, [3]Biostatistics, Institut Gustave Roussy, Villejuif, France, [4]INSERM U981, Gustave Roussy, Villejuif, France, [5]Drug Development Department (DITEP), Gustave Roussy Cancer Campus, Villejuif, France, [6]Oncology, Institut Gustave Roussy, Villejuif, France, [7]DUERTEC, Institut Gustave Roussy, Villejuif, France, [8]UMR 1170, Institut Gustave Roussy, Villejuif, France, [9]UMR, Gustave Roussy, Villejuif, France, [10]Breast Cancer Unit, Department of Medical Oncology, Gustave Roussy Institut de Cancérologie, Villejuif, France

Background: There is a current need to broadly evaluate the ability of RNA sequencing (RNAseq) to identify patients that will respond or not to PD-1 or PDL-1 immune checkpoint blockers (ICB) across metastatic tumor types.

Methods: RNA sequencing analysis were prospectively performed by a unique platform on patients' fresh frozen biopsies collected in the MOSCATO (NCT01566019) and MATCH-R (NCT02517892) prospective trials, ongoing at Gustave Roussy. We have analyzed more than 100 signatures related to immune cell types or immune mechanisms with several methods, and have evaluated their relation to PFS and OS under ICB, up to January 2017.

Results: RNAseq performed on a frozen tumor biopsy before receiving an ICB were available for 67 patients. The median time between the biopsy and start of the ICB was 41 days. The results of RNAseq analysis were available within a median of 42 days. The majority of patients were affected by either head-and-neck carcinomas ($N = 12$), bladder carcinomas ($N = 11$) or lung adenocarcinomas ($N = 11$). The majority of patients were treated with PD-1 ($N = 41$) or PD-L1 ($N = 28$) inhibitors either in monotherapy or in combination. The immune infiltrate was heterogeneous across patients and neither related to the histology nor to the location of the biopsy. The top RNAseq pipeline of analysis related to PFS were GSVA enrichment method and the combination of GSEA on Z transformed log TPM pipeline. Taken individually, 60% of the tested signatures had a significant relation to PFS under ICB whatever the pipeline used (logrank FDR<0.05). Using the best pipeline of analysis, the signatures with a significant continuous relation with PFS and OS were represented by 7 different T cells signatures, antigen processing and presentation, and PD-1 signaling (min-max ranges for PFS; HR 0.19-0.39, FDR = 0.0008-0.02 and for OS; HR = 0.17-0.32, FDR = 0.04 for all). An independent cohort is under constitution to validate these findings.

Conclusions: The use of RNAseq to orient patients to ICB is feasible. Estimation of immune infiltrate and function from RNAseq may be associated with treatment benefice either in term of PFS or in term of OS.

Clinical trial identification: MOSCATO (NCT01566019) and MATCH-R (NCT02517892)

1169P Topography of Tumor Mutational Burden (TMB) and Immune-related Genomic Alterations (GA) Across Gastrointestinal Malignancies (GIm): A Study of 22,570 Cases

S.J. Klempner[1], G.M. Frampton[2], J. Chao[3], M. Bailey[4], P. Stephens[5], J.S. Ross[6], V.A. Miller[7], S.M. Ali[8], A.B. Schrock[9]

[1]Medical Oncology, The Angeles Clinic and Research Institute, Los Angeles, CA, USA, [2]Oncology, Foundation Medicine, Cambridge, MA, USA, [3]Medical Oncology, City of Hope, Duarte, CA, USA, [4]Oncology, Foundation Medicine, Cambridge, MA, USA, [5]R & D, Foundation Medicine, Cambridge, MA, USA, [6]Pathology, Albany Medical Center, Albany, NY, USA, [7]Medical Affairs, Foundation Medicine, Cambridge, MA, USA, [8]Clinical Development, Foundation Medicine, Cambridge, MA, USA, [9]R & D, Foundation Medicine, Cambridge, MA, USA

Background: Response to immune checkpoint inhibitors (ICPIs) is mediated in part by tumor neoantigens. TMB has emerged as a predictive biomarker, but data is lacking in GIm. We examined TMB and concurrent GA across GIm to identify patient subsets for further study.

Methods: Comprehensive genomic profiling was used to determine TMB, microsatellite instability (MSI), and additional GA using previously described methods. GA were compared among anatomically defined tumor types and stratified by TMB status (mutations/DNA megabase), and those associated with response or resistance to ICPIs were compared to identify patient subsets.

Results: Median TMB was higher for tubular vs. non-tubular GIm ($p = 0.032$). Among the entire cohort, 3.5% and 7.4% of samples had a TMB >20 and >10, respectively. The proportion of tumors with TMB ≥10 was greatest within tubular foregut structures (esophagus, stomach, duodenum; 11.2%). MSI was observed across all anatomic subtypes (range: 0.2-6%). Overall 1.2% of cases harbored receptor tyrosine kinase (RTK) fusions; colon and biliary tumors with RTK fusions had high (11) and low (2.5) median TMB, respectively. Validated immunoresponsive GA including PD-L1 amplification and POLE mutations were mutually exclusive and enriched in tubular GI structures [esophagus (0.5%), stomach (0.8%), colon (0.9%), duodenum (1.3%) and rectum (0.9%)]. POLE mutation, but not PD-L1 amplification, correlated with high TMB (median 100 and 5.4, respectively). PIK3CA catalytic (H1047R) vs. helical (E545K) domain GA were strongly associated with high TMB ($p < 0.0001$), and similar findings were observed within MSI vs. MSS samples ($p < 0.0001$). Pre-existing GA that may decrease ICPI responsiveness including or JAK1 inactivating GA were rare (4.7% and 0.3% of cases, respectively). Representative clinical cases will be presented.

Conclusions: GAs associated with increased sensitivity and/or resistance to ICPIs are observed across GI cancers. Baseline genomic profling may inform rational patient selection for immunotherapy treatment. The observation that high TMB and MSI are strongly enriched for PIK3CA H1047R, and whereas low TMB and MSS are enriched for E545K, warrants further study.

1170P Analysis of POLE mutation and tumor mutational burden (TMB) across 80,853 tumors: Implications for immune checkpoint inhibitors (ICPIs)

A.B. Schrock[1], D. Fabrizio[2], Y. He[3], J. Chung[1], M. Resnick[4], P.J. Stephens[5], J.S. Ross[6], V.A. Miller[7], S. Ramkissoon[8], J.A. Elvin[8], S.M. Ali[1], M. Fakih[9], S.J. Klempner[10]

[1]Clinical Development, Foundation Medicine, Cambridge, MA, USA, [2]Cancer Immunotherapy, Foundation Medicine Inc., Cambridge, MA, USA, [3]Cancer Genomics, Foundation Medicine, Cambridge, MA, USA, [4]Pathology, Brown University, Providence, RI, USA, [5]R & D, Foundation Medicine, Cambridge, MA, USA, [6]Pathology, Albany Medical Center, Albany, NY, USA, [7]Medical Affairs, Foundation Medicine, Cambridge, MA, USA, [8]Pathology, Foundation Medicine Inc., Cambridge, MA, USA, [9]Oncology, City of Hope, Duarte, CA, USA, [10]Oncology, The Angeles Clinic, Los Angeles, CA, USA

Background: Mutations of the DNA polymerase epsilon (POLE) can lead to a hypermutated tumor phenotype, in the absence of microsatellite instability (MSI).

Exceptional responses to ICPIs in POLE-mutated endometrial adenocarcinoma (EA), colorectal (CRC), and glioblastoma (GBM) are described, but detailed pan-tumor POLE analyses are lacking.

Methods: We prospectively analyzed 80,853 primarily advanced solid tumors using hybrid-capture based comprehensive genomic profiling. TMB (mutations/Mb) was calculated from 1.11 Mb of sequenced DNA (PMID: 28420421). Known genomic alterations (kGA) were defined as those reported as somatic in the COSMIC database or with published evidence indicating loss of function.

Results: POLE GA were identified in 5.0% of cases: melanoma (10%), duodenal adeno (DA, 7.8%), uterus carcinosarcoma (CS, 6.9%), EA (6.4%), unknown primary carcinoma (CUP, 6.3%), NSCLC (6.1%), CRC (5.1%), prostate adeno (5.0%), and GBM (4.6%). Most POLE GA were variants of unknown significance (VUS). POLE kGA were found in only 259 (0.3%) total cases, including ovary or uterus CS (2.2%), DA (1.3%), EA (1.2%), CRC (0.7%), GBM (0.6%), and CUP (0.6%). Patients with POLE kGA had a median age of 58 yrs (range 7-95); 53% were male. Median TMB in cases with POLE kGA, VUS and wild-type was 31, 9 and 3.6, respectively (each $p < 0.0001$). Of cases with POLE kGA, 54% had high TMB (>20), while 28% had low TMB (<5). The most common POLE kGA were R446Q (n = 77), P286R (n = 41), V411L (n = 29) and L424X (n = 17). R446Q, which is uncharacterized, was associated with low TMB ($p < 0.0001$) and predominantly germline, while P286R and V411L were associated with high TMB (each $p < 0.0001$), predominantly somatic, and enriched in CRC and EA. Inactivating GA in mismatch repair genes co-occurred with POLE kGA in 28% of cases; these cases had low MSI (7% vs. 5% for all kGA POLE cases), but very high TMB (median 230). PD-L1 IHC and outcomes will be presented for a subset of cases.

Conclusions: POLE GA are found across tumor types, but functionally significant GA may be less frequent than previously reported, particularly in advanced tumors. Identification of specific POLE GA associated with a hypermutated phenotype may be important to identify likely responders to ICPIs.

Background: Microsatellite unstable (MSI) tumors have showed high response rates to checkpoint inhibitors. Nonetheless, patterns of response and characteristics of responders remain poorly understood. We hereby report preliminary results of response to immunotherapy in a cohort of patients (pts) with metastatic MSI tumors.

Methods: We included all pts with metastatic MSI tumors of various histologic types treated at our institute with checkpoint inhibitors as monotherapy or combinations. Somatic MSI status has been identified by immunohistochemistry with PCR at diagnosis and/or whole-exome sequencing in molecular screening trials at metastatic stage. Pts not previously known to have Lynch syndrome (LS) have been tested for inherited germline defect.

Results: From November 2014 through April 2017, 43 pts were enrolled. Main pts characteristics were as follow [median (range)]: age at treatment was 56.4 years (26-78) and number of previous treatment lines was 2 (1-5). The most frequently treated histologic types were gastro-intestinal (22/43: 15 colorectal (CRC), 2 small bowel, 2 biliary, 2 pancreatic, 1 duodenal) and gynecologic (11/43: 8 endometrial, 3 ovarian) tumors. Diagnosis of hereditary LS has been confirmed in 12 pts (28%) and screening results are awaited in 6 pts. After a median follow-up of 5.6 months and treatment with a median of 7 cycles (Range 1-47), median overall survival was not reached (NR) and median progression-free survival (PFS) was 11.1 months (95% CI 2.8-19.5). In the 38 evaluable pts who received more than 2 cycles, overall objective response (ORR) and stable disease rates were 31.6% (12/38; 4 complete responses (CR), 8 partial responses (PR)) and 18.4% (7/38) respectively. ORR was 33.3% (5/15; 4 CR, 1 PR) in CRC and 30.4% (7 PR/23) in non-CRC. PFS was significantly better in confirmed LS than sporadic tumors (NR and 5 months, respectively, $p = 0.028$) and in CRC than non-CRC (NR and 5.6 months, respectively, $p = 0.025$) in univariate analysis.

Conclusions: We reported high response rates and survival benefit with checkpoint inhibitors in pts with MSI tumors remarkably in CRC and LS. A comprehensive analysis of immune microenvironment would be of clinical interest to characterize responders and non-responders.

1172P Single nucleotide polymorphisms in PD-L1 and outcome in nivolumab-treated advanced non-small-cell lung cancer patients

T. Nomizo, T. Funazo, H. Ozasa, T. Tsuji, Y. Yasuda, H. Yoshida, Y. Sakamori, H. Nagai, T. Hirai, Y.H. Kim

Respiratory Medicine, Kyoto University-Graduate School of Medicine, Kyoto, Japan

Background: Nivolumab is an established agent in the management of non-small-cell lung cancer (NSCLC); however, while some patients with lung cancer have marked responses to nivolumab, others do not respond. To determine the efficacy of nivolumab, we retrospectively evaluated treatment response with respect to PD-1/PD-L1 SNPs among patients with NSCLC.

Methods: Between December 2015 and October 2016, a total of 68 patients with histologically or cytologically confirmed NSCLC were treated with nivolumab. Among these 68 patients, all of whom were registered at Kyoto University Hospital. Genomic DNA was extracted from peripheral blood and genotyping was performed using real-time PCR method. We investigated the possible correlation of PD-1/PD-L1 SNPs with PFS (progression-free survival) using Kaplan-Meier method.

Results: A total of 68 patients were evaluated for clinical response. The G allele of PD-L1 rs2282055 was significantly associated with better clinical response. The median PFS time was 4.2 months (95% confidence interval [CI], 1.7 months to 3.9 months) for the G/G and G/T genotypes of rs2282055 and 2.0 months (95% confidence interval [CI], 0.9 months to 2.2 months) for the T/T genotype ($P = 0.0388$). Moreover, the T/T and C/T genotypes of PD-L1 rs1411262 were significantly associated with better PFS in NSCLC patients treated with nivolumab.

Conclusions: The G/G and G/T genotypes of PD-L1 rs2282055 were significantly associated with better ORR and PFS in NSCLC patients treated with nivolumab. These results suggest that PD-L1 SNPs may be a biomarker for the efficacy of nivolumab.

1173P Efficient identification of neoantigens for personalized cancer immunotherapy in advanced refractory epithelial cancer patients

F. Chen, Z. Zou, J. Du, J. Wei, J. Shao, F. Meng, N. ding, B. Liu*The Comprehensive Cancer Centre of Drum Tower Hospital, Medical School of Nanjing University & Clinical Cancer Institute of Nanjing University, Nanjing 210008, China, Nanjing, China*

Background: Recent genomic and bioinformatic technological advances have made it possible to dissect the immune response to personalized neoantigens encoded by tumor-specific mutations. However, rapid and efficient identification of neoantigens is still fraught with difficulty, and a systematic evaluation of personalized neoantigens based immunotherapy in advanced refractory epithelial tumors is lacking.

Methods: Tumor and ctDNA samples from 16 advanced epithelial cancer patients were underwent mutational profiling by cancer-associated genes panel. Neoantigens identification were performed by two strategies:(1) As classic mode, somatic mutations were subjected to in silico analysis to predict potential high-affinity epitopes and mutated peptides were denovo synthesized; (2) Hotspot mutations were matched to our customized driver mutation-derived neoantigens peptide library. Candidate neoepitopes were identified. Approximately 10^8 neoantigen loaded DC vaccine and 10^{10} bulk T cells composed of 10^9 neoantigen reactive CD8+T cells were generated for personlized immunotherapy.

Results: Among the sequenced patients, 1∼2 neoantigens recognized by autologous T cells have been successfully identified in 3 of 4 patients who utilized the classic mode and 6 of 12 patients who performed customized neoantigens library, respectively. Subsequently, a total number of 6 patients received immunotherapy targeting personalized neoantigen following immunomodulatory chemotherapy or radiotherapy. One patient with metastatic thymoma is achieving a complete and durable response beyond 12 months. In addition, immune related partial response was observed in another advanced pancreatic cancer patient. The remaining 4 patients achieved prolonged stabilization of disease with median PFS of 8.6 months.

Conclusions: Our costomized neoantigens library can provide a novel approach for neoantigens screening in advanced epithelial cancer patients. Besides, targeted sequencing is sufficient for somatic variant and neoantigen identification. The combination of two strategies can accelerate the neoantigen-based translational immunotherapy research into the paradigm of precision medicine.

1174P KRAS mutations (KRAS-mut) and antiPD1/PDL1 therapy in a cohort of non-small cell lung cancer (NSCLC) patients (p): Experience from a single institution

C. Erasun Lecuona[1], M.T. Moran Bueno[1], L. Vila[1], I. Teruel[2], L. Angelats[2], A. Ferrando[2], A. Plaja[2], P. Torres[3], E. Lopez[3], R. Muriel[3], A.M. Muñoz-Marmol[4], J.L. Mate[4], J.M. Velarde[5], E. Carcereny Costa[1]

[1]Medical Oncology, Catalan Institute of Oncology Badalona, Hospital Universitari Germans Trias i Pujol, Badalona, Spain, [2]Medical Oncology, Catalan Institute of Oncology Badalona, Hospital Universitary Germans Trias i Pujol, Badalona, Spain, [3]Medical Oncology and Hematology, Catalan Institute of Oncology Badalona, Hospital Universitary Germans Trias i Pujol, Badalona, Spain, [4]Pathology, Hospital Universitari Germans Trias i Pujol, Badalona, Spain, [5]Biostatistics, Hospital Universitari Germans Trias i Pujol, Fundació Institut d' Investigacions en Ciencies de la Salut Germans Trias i Pujol, Catalan Institute of Oncology Badalona, Badalona, Spain

Background: AntiPD1/antiPDL1-based immunotherapy has changed dramatically the prognosis of NSCLC p with a substantial improvement of overall survival (OS) and even presenting long lasting responses in a subset of p. Several factors have been associated with the likelihood of better survival, which include the smoking exposure and the presence of KRAS-mut according to data from randomized clinical trials that compared chemotherapy to these immunotherapeutic agents.

Methods: By reviewing the clinical records of all stage IV NSCLC p treated with antiPD1/antiPDL1 agents, we identified p with KRAS-mut and evaluated their clinical outocomes.

Results: 129 p with advanced NSCLC were treated with nivolumab, pembrolizumab or atezolizumab (65.1%, 17.1% and 17.8%, respectively) from November 2013 to April 2017. 14 p were identified as adenocarcinomas with KRAS-mut (20.3%) of all non-squamous NSCLC (60p) once squamous cell carcinoma (39 p), p with Kras status unknown (15p), or due to other reasons (6p) were excluded. Kras-mut subgroup included 28.5% of female, with median age of 62.3 years, 92.8% of ever smokers, and PS0 and 1 in 21.4 and 78.6%, respectively. The immunotherapy consisted of nivolumab (71.4%) and pembrolizumab and atezolizumab (14.3% each) and was administered as 1st, 2nd and $\geq$3rd therapy in 7.1, 78.6 and 14.3% of p, respectively. 71.4% of p responded to therapy (64.3% were evaluated as partial response) and in 42.8% of p this response lasted $\geq$12 months (range 12-32). For this cohort of p median progression-free survival was 7.65 months and median OS was 58 months. At the time of analysis 57.1% were still receiving treatment.

Conclusions: Although the number of p is small, KRAS-mut p represent a subgroup of p that seem to substantially benefit from antiPD1/PDL1 agents in terms of both response and survival.

1175P Comparability of programmed death-ligand 1 (PD-L1) expression on tumor-infiltrating immune cells (IC) and tumor cells (TC) in advanced urothelial bladder cancer (UBC) using clinically relevant immunohistochemistry (IHC) assays

K. Schwamborn[1], R. Knüchel[2], A. Hartmann[3], G. Baretton[4], F. Lasitschka[5], P. Schirmacher[6], T. Braunschweig[2], R. Tauber[7], F. Erlmeier[1], S. Hieke-Schulz[8], J. Ammann[9], W. Weichert[1]

[1]Institut für Pathologie, Technische Universität München, Munich, Germany, [2]Instituts für Pathologie, Uniklinik RWTH Aachen, Aachen, Germany, [3]Pathologie, Universität Erlangen-Nürnberg, Nürnberg, Germany, [4]Institut für Pathologie, Universitätsklinikum Carl-Gustav Carus Dresden, Dresden, Germany, [5]Pathologisches Institut, Universitätsklinikum Heidelberg, Heidelberg, Germany, [6]Pathologisches Intitut, Universitätsklinikum Heidelberg, Heidelberg, Germany, [7]Klinik und Poliklinik für Urologie, Technische Universität München, Munich, Germany, [8]Biostatistics, Roche Pharma AG, Grenzach-Wyhlen, Germany, [9]Medical Affairs, Roche Pharma AG, Grenzach-Wyhlen, Germany

Background: PD-L1/PD-1 checkpoint inhibitors have shown clinical activity in UBC. It has been shown that PD-L1 expression on TC and/or IC correlates with clinical efficacy. In this study (ML39708) we examined technical comparability and inter-reader agreement of 4 clinically relevant assays for PD-L1 expression on IC and TC in locally advanced UBC.

Methods: Archived formalin-fixed paraffin-embedded sections from 30 patients with locally advanced UBC (70% cystectomies, 30% transurothelial resections) were selected from 150 cases based on PD-L1 status per VENTANA SP142 IC < 1%, 1–5% or > 5% (10 cases each). The study cohort was stained for PD-L1 using SP142, SP263 (VENTANA), 22C3, and 28-8 (DAKO) assays at two sites according to manufacturer protocols. Stainings were blinded and scored at 5 sites for the PD-L1 expression on IC (% per tumor area) and TC (%). All readers were trained on scoring IC with SP142.

Results: Percentage of IC cells staining for PD-L1 varied from 6.54 to 8.18%, and TC from 5.46 to 15.85%, depending on the assay used (Table). For each assay, IC staining varied slightly to moderately between readers, with small non-significant differences between assays. Results for TC were comparable except for significantly lower staining with SP142. Pairwise comparison revealed –0.3 to 1.6% differences in adjusted means between assays for IC, and for TC, –10.5 to –7.8% (SP142 vs other assays) and –1.9 to 2.7% (other comparisons). Retrospective allocation to binary cut-offs (1%, 5% and 10%) for IC or TC only predominantly showed substantial or high Kappa agreement scores (0.6–0.8) for IC and TC between assays for each reader.

Table: 1175P

Assay	PD-L1 on IC % (95% CI)*	Reader ICC†	PD-L1 on TC % (95% CI)*	Reader ICC†
VENTANA SP142	8.18 (7.32–9.03)	0.699	5.46 (2.85–8.07)	0.609
VENTANA SP263	7.08 (6.22–7.94)	0.729	15.85 (13.24–18.47)	0.805
DAKO 22C3	6.54 (5.68–7.39)	0.532	13.19 (10.57–15.80)	0.883
DAKO 28-8	6.88 (6.02–7.74)	0.573	15.15 (12.54–17.77)	0.845

*Adjusted means for each assay;
†Intra-class correlation per test between 5 readers

Conclusions: This is the first multicenter study for analytical comparison of PD-L1 IHC staining on IC and TC in UBC. High concordance rates across all assays were achieved between trained readers for scoring PD-L1 on IC and TC.

1176P IDO-1 and PD-L1 predict response to immunotherapy in advanced non small cell lung cancer: An NGS and multiplex IHC analysis

L. Leroy[1], J. Massé[2], J. Adam[3], V. Brouste[4], N. Signolle[3], I. Soubeyran[1], V. Velasco[2], E. Khalifa[1], B. Lortal[5], A. Italiano[6], B. Besse[7], S. Le Moulec[2]

[1]Département de Biopathologie, Institut Bergonie, Bordeaux, France, [2]Pathology, Bergonié, Bordeaux, France, [3]Pathology, Institut Gustave Roussy, Villejuif, France, [4]Medical Oncology, Bergonié, Bordeaux, France, [5]Pharmacological, Bergonié, Bordeaux, France, [6]Medical Oncology, Institute Bergonié, Bordeaux, France, [7]Oncologie Médical, Gustave Roussy, Villejuif, France

Background: PD1/PD-L1 inhibitors (IO) can be prescribed as first line treatment in high PD-L1 positive NSCLC pts. There is an important need for additional predictive factors to identify pts with PDL1 weak or negative NSCLC that could benefit from these.

Methods: In this retrospective study, pts with stage III/IV NSCLC eligible for an IO were selected. All pts consented for tissue analysis. Pt characteristics and outcome were collected. A NGS panel on 52 genes was performed with an immunochemistry analysis (PDL-1 with the SP-263 clone, CD8, PTEN, beta-catenine, MSI, FOXP3, IDO-1 and CD163). We used image analysis with density results. PD-L1 was classified as negative/weak/positive if 0/1-9%/10%+ of tumor cells were stained.

Results: Sixty-seven pts were enrolled. Median age was 64 years, 8 pts were never smokers, 90% had PS 0-1, 11.3%/58.1%/30.6% received an IO as 1st/2nd/3rd line or more, 69% had a non-squamous carcinoma. 38.7% of the tumors were PD-L1 positive, and 15% weak. Median progression-free survival (PFS) was 3.5 months (IC95%, 1.9-7.6), 12 months overall survival rate was 63.3% (IC 95% 46.6-76.1). The objective response rate (ORR) was 50.8%. In univariate analysis PS, line of IO, positivity for PD-L1 (cut

off 10%), CD8 (H-SCORE ≥ 284,4), FOXP3 (H-SCORE ≥ 155,4) and IDO-1 (H-SCORE ≥ 0,4) were significantly correlated with ORR and PFS. ORR was 77% in IDO-1 positive (n = 26), 32% in IDO-1 negative (n = 25) NSCLC pts. KRAS mutation, smoking status, histological type, response to platinum-based chemotherapy were not correlated with PFS and ORR. In multivariate analysis, positive PD-L1 and IDO-1 were the only factors correlated with ORR. ORR was 87.5% if both positive (n = 16), 60% if one of them was positive, 22.7% if both negative. Only IDO-1 was correlated with PFS.

Conclusions: Along with PD-L1, IDO-1 appears as a promising predictive factor for IO. A prospective validation is ongoing.

1177P Undiscovered immune heterogeneity in pancreatic adenocarcinoma (PDAC)

C. Ragulan[1], P. Poudel[1], K. Young[1], G. Nyamundanda[1], R.T. Lawlor[2], A. Scarpa[2], A. Sadanandam[1]

[1]Molecular Pathology, The Institute of Cancer Research/Royal Marsden Hospital, Sutton, UK, [2]ARC-Net Centre for Applied Research on Cancer, University and Hospital Trust of Verona, Verona, Italy

Background: Our group previously identified three subtypes of human PDAC based on gene expression (PDAassigner, classical, quasi-mesenchymal (QM) and exocrine-like subtypes). Recently Bailey *et al.* published four subtypes that were concordant with our three subtypes except that their immunogenic subtype (enriched for immune genes) is a sub-subtype of the classical subtype. Here we applied our published prognostic/predictive colorectal cancer gene expression subtype classifier (CRCassigner) to PDAC patient samples to establish if these subtypes existed in PDAC and if they could be used to further refine our original PDAC subtypes.

Methods: CRCassigner signatures were used to classify 123 PDAC patient samples. Comparisons between different subtype classifications were performed using hypergeometric test. Patient survival analysis were performed using Kaplan-Meier plots and log-rank test. Pathway enrichment analysis was performed using gene set enrichment analysis (GSEA) on RNAseq expression profiles.

Results: We confirmed the existence of the five CRCassigner subtypes – enterocyte, goblet-like, inflammatory, stem-like and transit-amplifying (TA) - in PDAC. These subtypes were found to be sub-groups of original three PDAssigner subtypes. By combining our subtype classification with Bailey et al.'s we classified PDAC into six sub-subgroups of three published subtypes – classical (pancreatic progenitors and immunogenic); QM/squamous (stem-like and inflammatory) and exocrine-like/ADEX (TA and enterocyte). Interestingly, we observed differences in the distribution of immune cells between Bailey's immunogenic and our inflammatory subtypes. We noted a significant increase in the expression of most of the immune regulatory genes in the inflammatory (n = 7) subtype compared to the immunogenic subtype (n = 13).

Conclusions: This study further refines our published PDAC subtypes. The data reveals a new subgroups with a different immune and stromal profiles associated with different overall survival in this small data set. Further validation of these results is warranted to determine if subtype classifier can stratify patient samples for treatment with immunotherapy or immunotherapy combinations in PDAC.

Background: Pembrolizumab (pembro) is approved for treatment of PD-L1–expressing NSCLC in both treatment-naive patients with a PD-L1 expression tumor proportion score (TPS) ≥50% and previously treated patients with a PD-L1 TPS ≥1%. Testing for PD-L1 expression is mostly carried out using the PD-L1 IHC 22C3 pharmDx companion diagnostic test on the Dako Autostainer Link 48 (ASL48) platform. We developed optimized protocols for laboratory-developed tests (LDTs) that use the 22C3 antibody (Ab) concentrate on more widely available IHC autostainers for tumor tissue. We are also developing LDT protocols for cytology specimens.

Methods: PD-L1 expression was evaluated using the 22C3 Ab concentrate on 3 commercially available autostainers: ASL48, Ventana BenchMark ULTRA, and Leica BOND-III. Staining results were compared with the PD-L1 IHC 22C3 pharmDx kit on the ASL48 platform. PD-L1 expression was evaluated in tonsil specimens and a training set of 3 NSCLC specimens. Optimized protocols were validated in 120 NSCLC tumor tissue specimens. Cytology staining is being evaluated in 70 cell blocks from bronchial washes and pleural effusions with >100 tumor cells using the 22C3 Ab concentrate and optimized protocols.

Results: Protocols for LDTs were established on both BenchMark ULTRA and ASL48; the BOND-III autostainer protocol could not be optimized without a prohibitively high concentration of 22C3 Ab. Intraclass correlation coefficients, which measure the correlation of TPS score as a continuous variable, were 98.7% to 99.9% for the 22C3 Ab concentrate on the ASL48 and ULTRA platforms relative to the PD-L1 IHC 22C3 pharmDx kit on the ASL48. Interpathologist agreement was high for both LDTs and for the PD-L1 IHC 22C3 pharmDx kit. Optimized protocols for evaluation of PD-L1 expression in cytology specimens will also be presented.

Conclusions: Optimized protocols to determine PD-L1 expression in tumor tissue and cytology specimens using the 22C3 Ab concentrate on multiple autostainer platforms will expand the ability of laboratories to assess eligibility of patients with NSCLC for treatment with pembro in a reliable and reproducible manner.

1179P Tumor-infiltrating lymphocytes expression in stage IIIc/IV of high-grade serous ovarian cancer: Variation with neoadjuvant chemotherapy and prognostic value

C. Bárcena[1], K. Rojas[2], L. Lema[2], L. Manso Sánchez[2], J. Rios[3], R. García-Martín[1], A. Maroto[1], J.L. Rodríguez-Peralto[1], E.M. Ciruelos Gil[2], D.C. Mendiola[2], L. Paz-Ares[2]

[1]Pathology, University Hospital 12 de Octubre, Madrid, Spain, [2]Medical Oncology, University Hospital 12 de Octubre, Madrid, Spain, [3]Medical Statistics, Hospital Clinic Barcelona, Madrid, Spain

Background: Ovarian cancer is a malignancy with a complex immune suppressive microenvironment mediated by the recruitment or induction of CD4+ regulatory T cell. The purpose of this study was to assess the effect of neoadjuvant chemotherapy (NACT) on immune activation in stage IIIc/IV of high-grade serous ovarian carcinoma (HGSOC), and its relationship to treatment response.

Methods: We retrospectively identified 33 patients diagnosed with HGSOC and treated with neoadjuvant platinum-paclitaxel from 2005-2014. Pre and post-neoadjuvant treatment tissue samples were submitted to *immunohistochemical* analyses with anti-CD3, CD4 and CD8 antibodies for the identification of tumor-infiltrating lymphocytes (TILs). Pathological response classification to NACT was made according to Steffen Bohm (JCO 2015). Response score system (CRS) was explicitly defined (CRS-1; No or minimal tumor response, CRS-2; Appreciable tumor response amid viable tumor that is readily identifiable, CRS-3; Complete or near-complete response).

Results: The average age of patients was 63.44 years (46.53-84.14). BRCA-mutation status was negative in 78.8% of patients (26/33); BRCA-mutation was positive in 6.1% (2/33); and variant of uncertain significance was found in 15.1% (5/33). The majority of patients (78.8%) were stage IIIc. The area under the ROC curve of post-surgery TILs for complete pathological response were: CD4 (epithelial): [0.73 (0.5; 0.97), p: 0.084]; CD4 (stromal): [0.74 (0.51; 0.97), p: 0.077] and CD8 (epithelial): [0.81 (0.63; 1.0), p: 0.02]. The expression of epithelial CD4 TILs in pre-surgery samples (≤ 0.5 [OR: 0.7(0.01; 0.86), p: 0.038]) and epithelial CD8 TILs in post-surgery samples (≤ 5.4 [OR: 0.1(0.01; 1.19, p: 0.06]) proved to be a marker of good prognosis for pathological response. Survival analysis demonstrated that the expression of epithelial CD3 ≤ 4.3 in pre-surgery samples is a marker of poor prognosis.

Conclusions: The high number of tumor-infiltrating lymphocytes in post-surgery samples was significantly associated with higher rates of complete pathological response and better prognosis. It is convenient to carry out further and multicentric studies to validate these results.

1180P Development of OAT-1746, a novel arginase 1 and 2 inhibitor for cancer immunotherapy

P.S. Stanczak[1], M.M. Grzybowski[1], P. Wolska[1], A.M. Zdziarska[1], M. Mazurkiewicz[1], R. Blaszczyk[2], J. Nowicka[2], A. Sosnowska[3], K. Ramji[3], D. Nowis[4], J. Golab[3], A. Golebiowski[2], P. Dobrzanski[1], K. Dzwonek[1]

[1]Department of Biology, OncoArendi Therapeutics SA, Warsaw, Poland, [2]Department of Chemistry, OncoArendi Therapeutics SA, Warsaw, Poland, [3]Department of Immunology, Medical University of Warsaw, Warsaw, Poland, [4]Genomic Medicine, Medical University of Warsaw, Warsaw; Laboratory of Experimental Medicine, Centre of New Technologies, University of Warsaw, Warsaw, Poland

Background: Clinical success of PD-1/PD-L1 and CTLA-4 checkpoint inhibitors demonstrated that reactivation of anti-tumor immunity provides strong clinical benefits including curative responses. However, only a fraction of patients demonstrate long-lasting therapeutic effects prompting efforts to target additional pathways regulating antitumor immune response. Depletion of arginine inhibits proliferation and activation of T cells and is an important mechanism of immunosuppression. High plasma and tumor arginase (ARG) activity has been found in patients with a wide spectrum of cancers correlating with a poor prognosis. Therefore, we developed ARG inhibitors and report the immunoregulatory and antitumor activity of the lead compound (OAT-1746) alone or in combination.

Methods: The IC_{50} of the compounds was determined against the recombinant ARG1/2. M2-polarized, bone marrow derived murine macrophages and CHO cells transfected with human ARG1 were used to assess the cellular activity. Murine and human CD4+/CD8+ T cells were negatively isolated and incubated with anti-CD3/CD28 beads to trigger proliferation, CD3ζ levels were measured. The in vivo antitumor efficacy was evaluated in syngeneic mouse models after oral administration at 50 mg/kg bid.

Results: We have developed potent, selective, orally active inhibitors of ARG1 and 2. Our lead compound, OAT-1746, has a low nanomolar activity against ARG1/2 and < 50 nM cellular activity. It reversed the ARG1-inhibited proliferation of human and murine T cells and restored CD3ζ expression in ex vivo assays. In vivo, OAT-1746 showed good pharmacological properties with significant antitumor efficacy in multiple tumor models as a monotherapy and in combinations with checkpoint inhibitors and gemcitabine. The efficacy correlated with sustained PD effects: suppression of tumor arginase activity and 3-6 fold increase in plasma and tumor arginine concentrations that exceeded those required for the maximal stimulation of T cell proliferation. Induction of inflammatory markers in tumors confirmed reversal of immunosuppression. No toxicity was observed after multiple oral dosing in mono- or combinatorial therapies.

Conclusions: These results support the clinical development of OAT-1746 for cancer therapy.

Hoffmann-La Roche AG - Switzerland, Schlieren, Switzerland, [8]Roche Innovation Center New York, F. Hoffmann-La Roche AG - Switzerland, New York, NY, USA, [9]Roche Innovation Center Basel, F. Hoffmann-La Roche AG - Switzerland, Basel, Switzerland, [10]Roche Innoavtion Center Munich, F. Hoffmann-La Roche AG - Switzerland, Penzberg, Germany

Background: CA is a CEA-specific antibody fused to IL2v with abolished CD25 binding. Compared to wildtype (wt) IL-2, CA was designed to preferentially expand natural killer (NK) and CD8 T cells but not T regulatory cells (Tregs), to be retained within CEA+ tumors, and for improved PK.

Methods: In this FIH phase I study, PK/PD analyses were performed using samples from solid tumor patients treated weekly (QW) or biweekly (Q2W) with 6 – 40 mg CA monotherapy IV. Methods: PK - population modeling; PD analysis of baseline (BL) and on-treatment (OT) samples; flow cytometry of peripheral blood monocytes (PBMCs); immunohistochemistry (IHC) on tumor biopsies; PD-L1 expression using SP142 assay; measurement of plasma cytokines and sCD25.

Results: During cycle 1, CA exhibited prolonged exposure (8-fold) vs. wt IL2. Following multiple cycles, serum exposure showed typical target-mediated drug disposition kinetics, likely due to clearance by IL-2 receptor-expressing cells. In PBMCs from patients treated QW x 4, a significant increase in the absolute number of NK cells and CD8 T cells was seen (median of 13- and 2.3-fold, respectively). By contrast, moderate or no increase was seen in the absolute number of CD4 T or Tregs (median of 1.5- and 1.2-fold). Similar but less prominent changes were observed in patients treated Q2W. Treatment was accompanied by upregulation of the activation marker CD314 (NKG2D), which was undetectable on more than 20% of NK cells in 9 of 39 patients at BL, suggesting increased functional activity of NK cells in the affected patients. A transient increase in the level of various cytokines was seen, peaking 24 hours after administration. Changes in the level of sCD25 correlated with drug exposure. OT biopsies showed an increase in the number of infiltrating Ki67+ CD8 T cells and PD-L1+ immune cells (median of 3.5- and 3-fold, $n = 11$).

Conclusions: PK data confirmed that CA has longer exposure than wt IL2. PD data demonstrated preferential expansion and reinvigoration of NK and CD8+ T cells in both PBMCs and tumors. This data suggest that CA can be a potent combination partner for cancer immunotherapies targeting CEA+ solid tumors.

1182P A first-in-human study of a novel monoclonal antibody INCSHR01210 directed against programmed cell death protein 1 (PD-1) in patients with advanced or metastatic cancer

J. Lickliter[1], H. Gan[2], B. Gao[3], P. Grimison[4], J. Zou[5], H. Kallender[6], K. Sun[6], X. Chen[6], A. Behren[2], P. Fernandez-Penas[7], A. Nagrial[3], M. Voskoboynik[1], K. Woods[8], M. Millward[9], T. Meniawy[9]

[1]Oncology, Nucleus Network, Melbourne, Australia, [2]Oncology, Austin Hospital/Olivia Newton-John Cancer Research Institute, Heidelberg, Australia, [3]Oncology, Blacktown Hospital, Blacktown, Australia, [4]Oncology, Chris O'Brien Life House, Camperdown, Australia, [5]Oncology, Jiangsu Hengrui Medicine Co., Ltd., Shanghai, China, [6]Oncology, Incyte Corporation, Wilmington, DE, USA, [7]Oncology, The University of Sydney, Camperdown, Australia, [8]Cancer Immunobiology, Austin Hospital/Olivia Newton-John Cancer Research Institute, Heidelberg, Australia, [9]Oncology, Linear Clinical Research Limited, Nedlands, Australia

Background: INCSHR01210 is a novel PD-1 inhibitor with a safety and activity profile that may be different from that of other PD-1 inhibitors.

Methods: This is an ongoing, open-label, Phase1, dose-escalation/tumor-expansion study to evaluate the safety of INCSHR01210 in patients (pts) with relapsed/refractory solid tumors (NCT02492789). In Part 1, INCSHR01210 was administered IV at 1, 3, 6, or 10 mg/kg, initially on Day 1 of a 28-day cycle (for safety, PK and PD) and then Q2W, in a standard 3 + 3 dose-escalation design. Based on Part 1 data, Part 2 consisted of different tumor expansion cohorts, in which fixed doses of INCSHR01210 (600 mg and 200 mg Q4W) were evaluated.

Results: As of data cutoff (3Feb2017), 23 pts were treated in Part 1 (median age, 62 y [range, 32–73]; 74% women). Treatment-related AEs in $\geq$ 20% of pts (all Gr; Gr3/4) were skin capillary hemangioma (61%; 0%) and diarrhea (26%; 4%). Skin capillary hemangiomas were scattered and typically: <1 cm in diameter; on the face and upper chest; considered Gr1/2; regressed after stopping INCSHR01210. Immune-related AEs were consistent with other PD-1 inhibitors and observed in 3 (13%) pts. Treatment discontinuation due to AEs was reported in 1 pt (10 mg/kg; Gr1 skin hemangioma [resolved after stopping treatment]). The PK profile showed a dose-dependent increase in half-life from 3 days at 1 mg/kg to 7 days at 10 mg/kg. The receptor occupancy (RO) assessment at 10 mg/kg showed a target PD-1 inhibition of ~80% for up to 28 days. Of 21 efficacy evaluable pts, 5 (24%) had PR (median DOR, 163 days [range, 36–316]) and 4 (19%) had SD. Pts with PR included 1 pt each with SCC of the parotid gland (1 mg/kg), breast cancer (1 mg/kg), RCC (6 mg/kg), bladder cancer (10 mg/kg) and ovarian cancer (10 mg/kg). Based on the safety (including tolerability of hemangioma), PK and RO data from Part 1 and from Part 2 at 600 mg Q4W flat dosing, the remainder of Part 2 patients were treated at the 200 mg Q4W flat dose; Part 2 data will be presented.

Conclusions: INCSHR01210 demonstrated manageable toxicity, but with Gr1/2 hemangioma not seen with prior PD-1 inhibitors. The recommended Phase 2 dose/schedule is 200 mg Q4W.

1183P Safety, efficacy, pharmacokinetics (PK) and pharmacodynamics (PD) of PF 06801591, an anti-PD1 antibody administered intravenously (IV) or subcutaneously (SC)

S. Hu-Lieskovan[1], M. Johnson[2], F.S. Braiteh[3], J. Grilley-Olson[4], J. Chou[5], J. Davda[6], B. Jin[7], A. Forgie[5], D. Rassam[6], S. Youssef[5]

[1]School of Medicine, UCLA, Los Angeles, CA, USA, [2]Oncology, Sarah Cannon Research Institute, Nashville, TN, USA, [3]Medical Oncology, Comprehensive Cancer Centers of Nevada, Las Vegas, NV, USA, [4]Hematology/Oncology, University of North Carolina, Chapel Hill, NC, USA, [5]Research and Development, Pfizer, South San Francisco, CA, USA, [6]Research and Development, Pfizer, La Jolla, CA, USA, [7]Biostatistics, Pfizer, Cambridge, MA, USA

Background: PF-06801591, a humanized IgG4 monoclonal antibody, blocks the Programmed Cell Death (PD-1) pathway by binding with high affinity to PD-1 and preventing its interaction with its ligands. A phase 1 study to assess the safety and tolerability of PF-06801591 after IV or SC administration is ongoing in patients (pts) with locally advanced or metastatic solid tumors.

Methods: PF-06801591 was administered at 0.5, 1, 3, or 10 mg/kg IV once every 3 weeks (q3w), or 300 mg SC once every 4 weeks (q4w). Dose escalation occurred after the first 2-4 pts at each dose cohort, with additional pts then enrolled to each cohort for further PD assessment. Safety, tolerability, PK, and PD were assessed for all pts.

Results: As of January 31, 2017, 26 pts (ovarian cancer, n = 12; sarcoma, n = 6; head and neck cancer [SCCHN]; n = 5; melanoma, n = 1; small cell lung cancer, n = 1; and malignant peritoneal neoplasm, n = 1) were treated in the dose-escalation phase: 0.5 (n = 2), 1 (n = 8), 3 (n = 7), 10 (n = 5) mg/kg IV, and 300 mg (n = 4) SC. Maximum tolerated dose was not reached. No drug-related SAEs or dose-limiting toxicities were observed. All drug-related AEs were Grade 1 or 2, and the most frequently reported in > 15% of pts include nausea (15.4%) and fatigue (15.4%). No dose-dependency of AEs was observed during IV dose escalation nor serious skin toxicity with SC administration. Four pts had partial response at 0.5, 1, and 10 mg/kg IV (ovarian pts) and 300 mg SC (SCCHN pt) and 3 pts had stable disease lasting >24 wks. There was a dose-dependent increase in the maximum concentration (C_{max}) and area under the concentration-time curve (AUC) after IV administration. Following SC administration, PF-06801591 was slowly absorbed, with a median time to C_{max} of 182 hours. The mean average concentration (C_{av}) after the first SC dose at 300 mg q4w was approximately 50% of the mean C_{av} following IV administration at 3 mg/kg q3w. Full receptor occupancy of PD-1 was seen in all dose cohorts.

Conclusions: Preliminary results demonstrate that PF-06801591 is well-tolerated with objective responses observed across the dose levels tested in both IV and SC forms. PK data confirmed the appropriateness of the dosing frequency.

1185P Safety, pharmacodynamic, and pharmacokinetic profile of TSR-042, an anti–PD–1 monoclonal antibody, in patients (pts) with advanced solid tumors

J.C. Sachdev[1], A. Patnaik[2], J. Waypa[3], J. Pelusi[1], M. Beeram[2], E. Im[4], D. Jenkins[5], K. McEachern[6], S. Lu[6], W. Guo[7], R. Tran[8], V. Reichert[9], D. Bobilev[4], V. Kansra[6], G.J. Weiss[10]

[1]Oncology, HonorHealth Research Institute, Scottsdale, AZ, USA, [2]Medical Oncology, South Texas Accelerated Research Therapeutics, San Antonio, TX, USA, [3]Oncology, Western Regional Medical Center, Cancer Treatment Centers of America, Goodyear, AZ, USA, [4]Clinical Science, TESARO, Inc., Waltham, MA, USA, [5]Research Pharmacology, TESARO, Inc., Waltham, MA, USA, [6]Clinical Pharmacology, TESARO, Inc., Waltham, MA, USA, [7]Biostatistics, TESARO, Inc., Waltham, MA, USA, [8]Clinical Trial Management, TESARO, Inc., Waltham, MA, USA, [9]Clinical Research, TESARO, Inc., Waltham, MA, USA, [10]Clinical Research, Western Regional Medical Center, Cancer Treatment Centers of America, Goodyear, AZ, USA

Background: TSR-042, an immunoglobulin G4k humanized monoclonal antibody targeting programmed death (PD)–1, is being evaluated in a phase 1 study (NCT02715284) in pts with advanced solid tumors. We present preliminary safety, efficacy, receptor occupancy (RO), and pharmacokinetic (PK) data.

Methods: Pts were ≥18 years old with recurrent and advanced solid tumors, and adequate organ function. In part 1, pts received intravenous (IV) weight based doses of TSR-042 (1, 3, or 10 mg/kg every 2 weeks [Q2W]). Additionally, based on a PK predictive model from part 1, pts received 500 mg Q3W or 1000 mg Q6W TSR-042 IV in part 2A. Serum was collected for PK and RO analyses.

Results: 33 pts received TSR-042 in parts 1 (N = 21) and 2A (N = 12). No DLTs were observed. In part 1, all pts had ≥1 treatment-emergent adverse event (TEAE) with grade ≥3 TEAEs in 9/21 pts; most common TEAEs were fatigue (9 pts), nausea (7 pts), decreased appetite (6 pts), and dehydration (6 pts); 17/21 pts had treatment related TEAEs (TRTEAEs); 7/21 pts had serious TEAEs; 1 case of grade 3 TEAE (AST/ALT elevation) was deemed treatment related. In part 2A, 10/12 pts had ≥1 TEAE with grade ≥3 TEAEs in 1/12 pts; most common TEAEs were abdominal pain, fatigue, nausea, tachycardia and influenza like illness (each in 2 pts); 6/12 pts had TRTEAEs; no serious TEAE occurred. In part 1, 2 pts had a partial response (ovarian cancer [OC], small cell lung cancer) and 5 had stable disease (parotid gland, fallopian tube, anal canal, OC [2 pts]). Pts in part 2A have not yet been evaluated for clinical activity. TSR-042 PK was dose proportional for all dose groups in both parts. The mean trough serum concentrations were 40 (500 mg Q3W) and 50 mg/mL (1000 mg Q6W) after a single dose, which exceeds the 2.4 μg/mL required for ∼100% receptor occupancy in part 1.

Conclusions: TSR-042 is safe and well tolerated, with a safety profile expected for an agent targeting the PD-1 pathway, with evidence of linear PK and sustained target engagement at administration intervals up to 6 weeks. TSR-042 showed clinical benefit in heavily pretreated pts in the initial phase 1 study and will be further evaluated in defined tumor types in part 2B. Updated results will be presented.

1186P Phase Ia study of a humanized anti-PD-1 monoclonal antibody (JS001) in Chinese patients with refractory solid tumors

F-H. Wang[1], C. Ren[1], Y. Zhang[2], S. Yao[3], H. Feng[3], H. Wu[3], H-F. Song[3], R. Zhang[4], X-L. Wei[1], X-J. Xia[5], Q. Zhao[5], J-P. Yun[6], B-Y. Zou[1], M. Qiu[1], Z-Q. Wang[1], Y-H. Li[1], R. Xu[1]

[1]Medical Oncology, Cancer Centre Sun Yat-Sen University, Guangzhou, China, [2]GCP, Cancer Centre Sun Yat-Sen University, Guangzhou, China, [3]Clinical trial research, Shanghai Junshi Bioscience Co., Ltd, Shanghai, China, [4]Imaging, Sun Yat-sen University Cancer Center, Guangzhou, China, [5]Experiment, Cancer Centre Sun Yat-Sen University, Guangzhou, China, [6]Pathology, Cancer Centre Sun Yat-Sen University, Guangzhou, China

Background: JS001, a recombinant humanized IgG4 antibody, selectively blocks the interactions of PD-1 with its ligands PD-L1 and PD-L2, and promotes host immune response against Cancer.

Methods: A Phase I open-label study is designed to evaluate the safety and tolerability of JS001 in solid tumor patients who are refractory to standard therapy. The study has a traditional 3 + 3 dose escalation design with planned cohorts at 0.3, 1.0, 3.0, 10 mg/kg Q2W and a fixed-dose 240 mg Q2W followed by a dose expansion.

Results: Enrollment was completed by October 2016 with 25 patients enrolled including 6 esophageal, 5 gastric, 6 nasopharyngeal, 2 pancreatic, 2 head and neck, and 1 Cholangio carcinoma and 3 melanomas. No dose limit toxicity was observed and no maximum tolerated dose was identified. Adverse events (AEs) occurred in 21/25 patients (84%), which were mostly grade 1/2, including fatigue (72%), elevation of liver enzymes (52%), proteinuria (40%), anemia (40%), rash (32%), fever (24%), hyponatremia (24%), hyper- or hypo-thyroidism (20%), and hypokalemia (20%). The emergence of AEs appeared unrelated to dose levels. JS001 PK analysis shows linear dose-dependent exposure with the elimination half-life of 6 to 15 days. Among 13 patients who had underwent at least one scheduled radiographic evaluation, 1 has confirmed complete response (melanoma), 2 have confirmed partial response (1 Head and neck and 1 esophageal), and 2 achieved stable disease. PD-L1 expression by IHC on pretreatment biopsy samples was correlated with the clinical response. Patients with positive PD-L1 staining (> 1%) observed a 30% response rate (n = 10, 1 CR and 2 PR) and a 50% DCR. Whole exon sequencing was performed on selected biopsy samples. Mutations on p53, MDM2, TAP2 et al, might contribute to the favorable response to immunotherapy. Interestingly, a divergent spectrum of mutations from mixed

response patients were observed on tumor cells from different metastases, which at the time of biopsy had drastically different clinical response to the treatment.

Conclusions: JS001 demonstrated an acceptable safety profile in solid tumor patients. Additional phase II studies to evaluate the safety and clinical activity of JS001 in selected tumor types are ongoing.

1187P A Phase 1/2 trial of intratumoral (i.t.) IMO-2125 (IMO) in combination with checkpoint inhibitors (CPI) in PD-(L)1-refractory melanoma

A. Diab[1], C. Haymaker[2], M. Uemura[2], R. Murthy[3], M. James[4], J. Geib[5], M. Cornfeld[5], S. Swann[5], C. Yee[4], J. Wargo[4], R. Amaria[4], S. Patel[4], H. Tawbi[4], I. Glitza[4], S. Woodman[4], W-J. Hwu[4], M.A. Davies[4], W. Overwijk[4], C. Bernatchez[2], P. Hwu[6]

[1]Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA, [2]Melanoma Medical Oncology - Research, MD Anderson Cancer Center, Houston, TX, USA, [3]Interventional Radiology Department, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [4]Department of Melanoma Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA, [5]Clinical Science, Idera Pharmaceuticals, Exton, PA, USA, [6]Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA

Background: CPI have transformed melanoma treatment, however many patients remain refractory and subsequent treatment options are limited. IMO, a Toll-like receptor 9 agonist, may improve response to CPI by activating innate and adaptive immune responses to overcome immune escape. Initial clinical experience with IMO + ipi is promising (Uemera, ASCO-SITC 2017). Dose-finding is now complete and is the basis for this updated report.

Methods: Adults with unresectable or metastatic melanoma refractory to a PD-(L)1 inhibitor are eligible if they have tumor accessible to biopsy. IMO is administered i.t. to a single tumor at escalating doses during weeks 1,2,3,5,8, and 11 along with ipi or pem per the product label. The primary endpoint of Phase 1 is safety and for Phase 2 is overall response rate using a 2-stage design. Serial biopsies are obtained from both the injected and a non-injected lesion for immune analysis.

Results: A total of 22 subjects have been treated with either IMO-ipi (N = 18) or IMO-pem (N = 4) and dose-escalation is now complete for the IMO-ipi arm. Dose-limiting toxicities have not been reported. Immune-related AE were observed in 4 IMO-ipi subjects [hypophysitis (N = 2), hepatitis (1), colitis (1)]. These responded well to standard measures. Of 9 patients treated at the RP2D of 8mg, 6 have experienced clinical benefit (1CR, 1PR, 1uPR, 3 SD). Biopsies show maturation of the mDC1 subset ($CD1c^+CD303^-$), upregulation of PD-L1 by malignant cells, and an IFNα response gene signature. Biopsies of uninjected tumors show expression of $CD56^+$ and $Ki67^+$ effector $CD8^+$T cells in responding patients, indicative of an abscopal effect. Phase 2 accrual using the 8 mg IMO dose is ongoing.

Conclusions: IMO + ipi is a viable strategy to revive the immune response in CPI-resistant tumors and shows preliminary clinical activity worthy of further development.

[1]ImmunOncology Clinical Reserach, Centro de Investigacion de Cancer en Sonora campus Seattle (CICS USA), Seattle, WA, USA, [2]ImmunoOncopathology, Centro de Investigacion de Cancer en Sonora campus Ciudad Obregon, Sonora, Mexico, Ciudad Obregon, Mexico, [3]ImmunoOncology Clinical Reserach, Centro de Investigacion de Cancer en Sonora campus Seattle (CICS USA), Seattle, WA, USA, [4]Clinical Oncology and ImmunoOncology, Centro de Investigacion de Cancer en Sonora campus Ciudad Obregon, Sonora, Mexico, Ciudad Obregon, Mexico

Background: Several patients progressed with their cancer disease despite treatment and eventually they become refractory. We selected patients from several malignancies with PD despite standard of care treatment (n = 30) and performed a pilot clinical study to evaluate the effect of two intravenously, two oral and one subcutaneously agent. With this in mind and with a systematic review and immunomodulatory, anti-angiogenic and anti-tumoral validation of each drug was studied. We tested the preexisting CD8 and Th1 antigen specific immune response against several clinically relevant peptides from bad prognosis proteins.

Methods: 30 subjects were included after the CICS ethics committee approved the protocol. The inclusion criteria include ECOG=0, complete CT scan from neck, thorax, abdomen and pelvis, laboratory tests such as CBC, phase acute proteins, etc. The patients were accepted after initial IFN-gamma and Elispot assays were done to make sure we have only patients with Th1 and CD8 immune response, as we know that ipilimumab unleashes every T cell. The tumors included were PDAC (n = 5), HGSOC (n = 12), TNBC (n = 10) and MM (3). The patients received the oral and the IV treatment biweekly for 4 months.

Results: We had 60% of CR and 40% of PR. The tumor with more significant response was ovarian (90%). There was an immunological correlation of CD8 immune response between in both CR ($p = 0.001$) and PR ($p = 0.05$). The combination was well tolerated and after 16 months of stopping the treatment some patients have persistent CD8 antigen specific immune response.

Conclusions: The combination is clinically feasible, looks promising and we now understand the importance of preserving the immune response and the use of biomarkers to improve the rational and generate new combinations with this approach to improve clinical outcomes.

1189P 4SC-202 plus anti-PD1: Breaking PD1-refractoriness to increase efficacy of checkpoint inhibition in patients with advanced melanoma

F. Hermann

Clinical Development, 4SC AG, Planegg-Martinsried, Germany

Background: Despite successes in the treatment of melanoma patients with checkpoint inhibitors (CI), majority of patients do not respond to CI alone and a high unmet medical need remains for these patients. One promising approach is to enhance the immunogenicity and alter the tumor microenvironment from an immune-deserted to an inflamed phenotype with combination therapy. Epigenetic modulation has been reported as one key determining factor in shaping the immune microenvironment and compounds altering these processes (e.g. histone deacetylases (HDAC) inhibitors) are particularly promising.

Methods: Tumor bearing animals (CT26 & C38 syngenic models) were treated with 4SC-202, an oral clinical stage combined HDAC class I/LSD1 inhibitor, or CIs PD-(L)-1 alone and in combination. Tumor growth was assessed continuously and after approx. 2 weeks of treatment tumors were excised and analyzed by flow cytometry and gene expression profiling. Additionally, animals not intended for these analyses were further monitored and tumor growth/survival was monitored.

Results: 4SC-202 treatment led to an increase of MHC molecules and enhanced expression of inflammatory markers like IFN-γ and various chemokines in tumors. Detailed analysis of the tumors revealed that 4SC-202 strongly altered the immune cell composition; particularly the number of cytotoxic T cells (CTL) was markedly increased. Importantly, subsequent combination treatment of 4SC-202 with CIs in syngenic animal models showed a strong synergistic effect resulting in significant longer survival in both models leading to 55% of tumor free animals (C38 model).

Conclusions: In an upcoming study, patients with advanced melanoma who are refractory/non-responding to anti-PD-1 antibodies will be treated with 4SC-202 plus anti-PD1. These patients do not only represent a population with a high unmet medical need but melanoma also represents a model tumor for immunotherapy in general and CI in particular. We hypothesize that addition of 4SC-202 to anti-PD-1 antibody treatment may lead to increased immunogenicity of the tumor, an inflamed tumor microenvironment and ultimately to clinical benefit in anti-PD-1 refractory/non-responding advanced-stage melanoma patients.

1192P Cytomegalovirus reactivation in patients with refractory checkpoint inhibitor-induced colitis

C. Franklin[1], I. Rooms[1], M. Fiedler[2], H. Reis[3], L. Milsch[1], S. Herz[1], E. Livingstone[1], L. Zimmer[1], K.W. Schmid[3], U. Dittmer[2], D. Schadendorf[1], B. Schilling[1]

[1]Department of Dermatology, Venerology and Allergology, University Hospital Essen, West German Cancer Centre, Essen, Germany, [2]Institute for Virology, University Hospital Essen, West German Cancer Centre, Essen, Germany, [3]Department of Pathology, University Hospital Essen, West German Cancer Centre, Essen, Germany

Background: Objectives: Immune checkpoint inhibitors have become a standard treatment in patients with metastatic malignant melanoma. Showing significant anti-tumor effects by unleashing the immune-system, checkpoint inhibitors can also cause high-grade immune-related adverse events, with immune-related diarrhea and colitis

(irColitis) being amongst the most frequent ones. While the majority of patients with irColitis respond well when treated according to standard treatment algorithms with corticosteroids +/- other immunomodulatory drugs such as infliximab, some patients do not show resolution of diarrhea and colitis. In the present study, we analyzed the frequency of therapy-refractory irColitis, the underlying cause and useful diagnostic measures.

Methods: In this retrospective, monocenter study we collected data of 370 patients with metastatic malignant melanoma. All patients had been treated with checkpoint inhibitors at the skin cancer unit of the Department of Dermatology at the University Hospital Essen from 2006-2016. Demographic and clinical data of all patients were collected. Digital patient records of all 370 patients were searched for the terms "diarrhea" and "colitis".

Results: We identified 41 patients with irColitis, the majority occurring during treatment with ipilimumab. Amongst these patients, 5 (12.2%) were refractory to standard immunomodulatory treatment with corticosteroids and infliximab. Therapy-refractory cases tended to show more severe inflammation in colonic biopsies performed during colonoscopy ($p = 0.04$). CMV-DNA in colonic biopsies and in plasma was significantly more often detectable in therapy-refractory cases (80% vs. 6.75% in non-refractory cases in biopsies, 80% vs. 0% in plasma). Presence of serum CMV IgM as well as positive immunohistochemical stainings of colon biopsies for CMV were also strongly associated with refractory colitis (40% in refractory vs. 0% in non-refractory cases), but not reliable markers in the majority of refractory patients.

Conclusions: This report on CMV reactivation during management of checkpoint inhibitor induced colitis emphasizes the need for repetitive diagnostic measures in treatment-refractory irColitis.

1193P Pooled data analysis of the safety and tolerability of intravenous pelareorep in combination with chemotherapy in 500 + cancer patients

A.A. Gutierrez, C. Reid, M. Crawford, K. Cheetham, A. Dzugalo, M. Parsi, A. Penman, N. Noronha, D. Galindez, R. O'Flynn, M. Coffey

Clinical Development, Oncolytics Biotech Inc, Calgary, Canada

Background: Oncolytic viruses are promising cancer immunotherapies but questions have been raised regarding their safety. Pelareorep (REOLYSIN, R), an unmodified Reovirus Dearing strain, selectively replicates and lyses cancer cells and induces anti-tumor immunity. To date, 900+ patients (pts) have been treated with intravenous (IV) pelareorep. In a phase 2 trial, its combination with paclitaxel improved overall survival (17.4m) vs paclitaxel (10.4m) in metastatic breast cancer (MBC) pts (HR 0.65, 80% CI 0.46-0.91, $p = 0.1$; Berstein et.al. AACR2017). A pooled analysis was thus conducted to better characterize pelareorep's safety profile in combinations with paclitaxel.

Methods: 1417 pts have been enrolled in 36 trials: 934 pts received IV pelareorep and 359 were in control arms. Data from 8 trials with paclitaxel (P), paclitaxel + pelareorep (PR), carboplatin + paclitaxel (CP) or carboplatin + paclitaxel + pelareorep (CPR) were pooled. Standard doses of P (weekly) and CP were administered. Pelareorep IV dose was 3x1010 TCID50 (5-6 doses q21-28 d). Various advanced solid tumors were evaluated, including the 81 pts with MBC.

Results: A total of 563 pts were included in P (86), PR (95), CP (118) or CPR (264) groups. Median age (59-62 y) and ECOG 0-1 status (90-96%) were similar across the groups. All pts in P or PR had received prior chemo but only 26% in CP and 38% in CPR. Fatigue was the most common grade $\geq$3 treatment related adverse event (TRAE) in PR (9.5%) and CPR (8.3%) vs P (8.1%) and CP (2.5%). Grade $\geq$3 neutrophil count decreased and/or WBC decreased were more frequent in PR (15.8%/17.9%) than in P (5.8%/3.5%), but addition of pelareorep did not increase the frequency or severity of other grade $\geq$3 TRAEs with P or CP. Serious TRAEs (%) of interest in P vs PR and CP vs. CPR, included: fever (0 vs 3.2 & 0 vs 3.8), febrile neutropenia (0 vs 1.1 & 3.4 vs 3.4), sepsis (1.2 vs 0 & 0 vs 1.5) and flu-like syndrome (0 vs 1.1 & 0 vs 0.8).

Conclusions: This is the largest database reported to date examining the safety of an IV viral agent. Pelareorep's administration, in combination with paclitaxel or carboplatin-paclitaxel, is safe and well tolerated. Continued evaluation in a registration trial is planned.

1194P Impact of prior immune checkpoint inhibitors on haematological toxicity in phase I patients receiving chemotherapy

A.H. Ingles Garces[1], J.E. Ang[1], M. Ameratunga[1], M. Chenard-Poirier[1], D. Dolling[2], R. Sundar[1], S. Kaye[1], J. de Bono[1], U. Banerji[1], J. Lopez[1]

[1]Drug Development Unit, The Royal Marsden NHS Foundation Trust, London, UK, [2]Oncology, Institute of Cancer Research Royal Marsden Hospital, Sutton, UK

Background: Immune checkpoint inhibitors (ICI) are used increasingly and earlier to treat multiple cancers. Although rates of on-treatment myelotoxicity are low, there are no published data on the long-term effects of ICI. This is a pilot study to evaluate the impact of prior ICI exposure on chemotherapy-related myelotoxicity in patients in the Phase I setting.

Methods: We conducted a retrospective chart review of patients treated between 2012 and 2016 in the Drug Development Unit, The Royal Marsden Hospital. Multivariate logistic regression (including number of previous treatment lines and type of chemotherapy) was used to assess possible relationships between G3/4 neutropenia or thrombocytopenia and previous treatment with immunotherapy in patients receiving combination chemotherapy and targeted agents.

Results: We identified 99 patients (median age 62 years [range 34-79]; chemotherapy partners: cisplatin, carboplatin and paclitaxel). Fourteen patients (14%) received prior immunotherapy (PI) and 85 (86%) had no prior immunotherapy (NPI). Patient characteristics, including baseline full blood count, previous pelvic radiotherapy, sites of metastasis and serum albumin, were comparable between the 2 groups, apart from number of previous treatment lines, which was lower in the PI patients (median 1.5 vs 2, $p = 0.003$). The odds of G4 neutropenia were higher in the PI group (OR = 7.1, 95% CI = 1.7-29.6, $p = 0.007$). PI was associated with significantly increased odds of G3/4 thrombocytopenia (OR = 14.4, 95% CI = 2.7-77.4, $p = 0.002$) on chemotherapy. In multivariate analysis, incorporating lines of prior chemotherapy (OR 1.3, 95% CI = 1.0-1.5, $p = 0.037$) and type of chemotherapy (carboplatin vs others: OR 2.3, 95% CI = 0.9-6.2, $p = 0.094$), the odds of developing G3/4 myelotoxicity were significantly higher in PI patients (OR 4.3, 95% CI: 1.3-14.4, $p = 0.02$).

Conclusions: In our small cohort, previous treatment with immunotherapy was associated with the development of G3/4 myelotoxicity, especially thrombocytopenia, on subsequent chemotherapy. These preliminary data require further prospective validation but may impact on decision making regarding optimal sequencing of systemic therapy.

1195P Compromised efficacy of PD-L1 blockade therapy in axenic (germ-free) mice with syngeneic tumors

A. Mansfield[1], X. Liu[2], S. Cao[3], W. Bindeman[4], P. Yin[5], L. Till[6], S. Harrington[7], H. Dong[8]

[1]Division of Medical Oncology, Mayo Clinic, Rochester, MN, USA, [2]Urology and Immunology Research, Mayo Clinic, Rochester, MN, USA, [3]Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN, USA, [4]Research Services, Mayo Clinic, Rochester, MN, USA, [5]Medical School, Campbell University School of Osteopathic Medicine, Lillington, USA, [6]Research, Mayo Clinic, Rochester, MN, USA, [7]Immunology Research, Mayo Clinic, Rochester, MN, USA, [8]Immunology, Mayo Clinic, Rochester, MN, USA

Background: The microbiome can have profound effects on the innate immune system. Since the innate immune system regulates the adaptive immune response to antigens, we hypothesized that the microbiome may influence anti-tumor responses to immune checkpoint inhibitors. Accordingly, we sought to characterize the anti-tumor

effects of PD-L1 blockade therapy between mice with syngeneic tumors in conventional (specific pathogen-free, SPF) and germ-free (GF) environments.

Methods: B16-OVA or Lewis Lung Cancer (LLC) cell lines were injected subcutaneously into the flanks of 10-12 week-old C57BL/6 mice in both SPF and germ-free (axenic) environments. Mice with B16-OVA tumors in SPF (n = 6) and GF (n = 12, 6 females and 6 males) environments, and mice with LLC tumors in GF (n = 6) environments were randomized to receive the murine PD-L1 blocking antibody 10B5 or an isotype control. Tumor growth was evaluated every 2-3 days until days 35-40 when all mice were euthanized. Tumor size was compared between treatment groups in each environment at day 24 with the Mann Whitney U test. This project was approved by Mayo Clinic's Institutional Review Board and Institutional Animal Care and Use Committee. Funding was provided by the NIH (K12 CA90628) and Mayo Clinic's Center for Individualizing Medicine's Microbiome Project.

Results: Whereas injection of the anti-PD-L1 antibody (clone 10B5) controlled tumor growth compared to treatment with an isotype control in SPF female mice with B16-OVA ($p = 0.05$), PD-L1 blockade had no effect on tumor growth in female axenic mice with B16-OVA ($p = 0.20$) or male axenic mice with B16-OVA ($p = 0.34$) or axenic mice with LLC ($p = 0.56$).

Conclusions: PD-L1 blockade therapy loses its anti-tumor efficacy in axenic mice. The microbiome may influence the efficacy of PD-L1 blockade through of its effects on both innate and adaptive immune responses to tumors.

1197P iRGD enhances T cells infiltration and augments response to PD-1 gene knockout immunotherapy in gastric cancer

N. Ding, S. Su, F. Meng, H. Sha, F. Chen, J. Wei, S. du, B. Liu

The Comprehensive Cancer Centre of Drum Tower Hospital, Medical School of Nanjing University & Clinical Cancer Institute of Nanjing University, Nanjing, China

Background: Poor infiltration of activated lymphocytes into tumors can be a fundamental factor limiting their efficacy and impeding the therapeutic effect of the checkpoint blockade immunotherapy. A tumor-penetrating peptide, iRGD, has a well-defined role in delivering drugs into extravascular tumor tissues in both the combination regimen and conjugated pattern, Here, we explored for the first time whether this cycled peptide could facilitate the infiltration of lymphocytes into tumor and furtherly overcome resistance to PD1 gene knockout immunotherapy.

Methods: We used polyethylene glycol-conjugated phospholipid (PEG-lipid) derivatives, a time-efficient and versatile platform, to immobilize iRGD on T cell membrane. The ability of iRGD modified or co-applied lymphocytes infiltration was detected in both the 3D tumor spheroids in vitro and subcutaneous tumor model and peritoneal tumor model of gastric cancer in vivo. Furthermore, the synergistic effect of iRGD modification and PD-1 gene knockout in adoptive T cell transfer immunotherapy was examined in a xenograft model of EBV-associated gastric cancer.

Results: In this study, we showed that T cells could be modified by the synthetic iRGD-PEG-lipid without compromising their vitality, expansion, phenotype and effector function. In vitro, co-administration of iRGD could promote the infiltration of T cells while iRGD modification made T cells spread more extensively throughout the multicellular spheroids. Near infrared results showed that iRGD modification made a tenfold improvement infiltration of T cells into tumors without a parallel increase in normal tissues. Most importantly, we demonstrated that iRGD modified T cells had superior antitumor efficiency owing to sufficiently increased T cells infiltration, and exhibited robust synergistic effect with PD-1 gene knockout immunotherapy.

Conclusions: Our study indicates that modification of T cell membrane with iRGD might be a potent strategy to increase T cells infiltration, thereby overcome the bottleneck of solid tumor immunotherapy.

1198P Immunomodulation by regorafenib alone and in combination with anti PD1 antibody on murine models of colorectal cancer

S. Hoff[1], S. Grünewald[2], L. Röse[1], D. Zopf[2]

[1]Oncology III, Bayer AG, Berlin, Germany, [2]Oncology II, Bayer AG, Berlin, Germany

Background: Regorafenib is a small molecule inhibitor of multiple kinases involved in normal cellular functions and in pathologic processes such as oncogenesis, angiogenesis, and tumor immunity. Regorafenib is approved for the treatment of advanced colorectal cancer (CRC) and gastrointestinal stromal tumors. In addition, an overall survival benefit has recently been shown in patients with hepatocellular carcinoma who had previously progressed on sorafenib (RESORCE trial). Immuno-oncology treatment strategies have recently expanded the arsenal of highly effective cancer therapies. In addition to their activity in monotherapy, they are being tested in combination with other therapies, including those inhibiting angiogenesis, to further improve their antitumor activity. We investigated the immunomodulatory effect of regorafenib alone and in combination with a mouse-reactive anti PD1 antibody in mouse models of CRC.

Methods: CT26 or MC38 syngeneic tumors were treated with regorafenib alone and in combination with anti PD1. We monitored tumor growth and analyzed the immune status of tumors *ex vivo* at the end of the study. Immune infiltrates were characterized by flow cytometry, intratumoral cytokines by multiplex ELISA, and expression of immunologically relevant genes by qPCR.

Results: Both regorafenib and anti PD1 inhibited the growth of MC38 tumors vs control, and this effect was significantly enhanced by concomitant treatment or when regorafenib was given after anti PD1. Regorafenib treatment most consistently reduced tumor-infiltrating macrophages in both MC38 and CT26 tumors in a dose-dependent manner. Additionally, signs of M1-type macrophage conversion were detected by elevated inducible NO synthase and reduced arginase expression. This may be due to a regorafenib-mediated inhibition of the CSF1 receptor, as shown *in vitro* in the murine macrophage cell line RAW264.7. Anti PD1 treatment was associated with elevated interferon-g levels, indicative of enhanced T cell activation.

Conclusions: These results warrant further exploration of a combination of regorafenib and PD1 for the treatment of colorectal cancer.

Magrassi e A. Lanzara", Università degli Studi della Campania "Luigi Vanvitelli", Naples, Italy, [5]Oncologia Medica, Dipartimento di Internistica Clinica e Sperimentale "F. Magrassi", Università degli Studi della Campania Luigi Vanvitelli, Naples, Italy

Background: Understanding of cancer-immune system interaction led to development of immunotherapy; anti-programmed cell death protein-1 (PD-1)/programmed cell death ligand-1 (PD-L1) antibodies are now used in non small cell lung cancer (NSCLC) treatment. MAPK cascade is a key intracellular network for tumor proliferation and recent data suggest that it is implicated in interplay of tumor and T-CD8+ cytotoxic lymphocytes (CTL).

Methods: We evaluated PD-L1 mRNA level by Real Time qPCR (RT-qPCR) and its protein production, togheter with MAPK proteins, by western blot (WB), in NSCLC cell lines. Then, we studied the changes in PD-L1 and major histocompatibility complex class-I (MHC-I) expression and cytokines' production, after MAPK-inhibition or -stimulation, by MEK-inhibitor, cobimetinib, or phorbol 12-myristate 13-acetate (PMA), respectively. In addition, we explored the effect of cobimetinib on cytokines' genes by RT-qPCR on cDNA, obtained from retro-transcription of RNA extracted from T-lymphocytes, derived from Peripheral blood mononuclear cells (PBMC) of healthy volunteers, by density gradient separation, and activated with anti-CD3/anti-CD28 coated beads.

Results: WB and RT-qPCR for PD-L1 in NSCLC cells revealed a consistent correlation between mRNA and protein levels, togheter with activated MAPK and MEK1/2 signals, and suggested that ectopic PD-L1 mainly depends on trascriptional regulation. PDL-1 levels were significantly decreased by cobimetinib and increased by PMA, suggesting that MAPK can regulate PD-L1. Moreover, MEK-inhibition resulted on cancer cells in increased synthesis of MHC-I, IFN-gamma, IL-6, IL-1B, and TNFalpha, involved in CTL activation, and on activated human pheripheral T-lymphocytes in increment of mRNA levels of IL-12, TNFalpha and IFNgamma, that are pro-inflammatory cytokines typical of CTL subset, that seems more involved in immune response against cancer.

Conclusions: These results demonstrate that MEK-inhibion induces the establishment of a pro-inflammatory microenvironment and may represent a potential mechanism to convert otherwise resistant cancers through treatment combination strategies of MEK-inhibitors and anti-PD-L1/PD-1 antibodies in NSCLC.

1200P Exploring personalized immunotherapy opportunities in colorectal cancer

B. Navarro Rodrigo[1], S. Bobisse[1], S. Viganò[1], P. Baumgartner[1], T. Nguyen-Ngoc[1], P. Gannon[1], R. Genolet[1], B. Stevenson[2], C. Sempoux[3], M-O. Sauvain[4], M. Hubner[4], D. Hahnloser[4], N. Demartines[4], M. Montemurro[1], L. Kandalaft[1], S. Rusakiewicz[1], A. Harari[1], G. Coukos[1]

[1]Department of Oncology, Ludwig Institute for Cancer Research, Lausanne, Switzerland, [2]Vital-IT, SIB Swiss Institute of Bioinformatics, Lausanne, Switzerland, [3]Institute of Pathology, CHUV/UNIL, Lausanne, Switzerland, [4]Department of Visceral Surgery, CHUV/UNIL, Lausanne, Switzerland

Background: Adoptive T cell therapy (ACT) with tumor-infiltrating lymphocytes (TIL) can induce prolonged clinical responses in selected patients with gastrointestinal tumors while a significant fraction of patients do not respond. The association between immune profiles and antigenic specificity of TIL and clinical responses remains unclear. We addressed these issues, including the recognition of neoantigens, in order to explore the potential of personalized cell-based and vaccine therapy in colorectal cancer (CRC).

Methods: Tumor specimens of primary (n = 11) and metastatic (n = 12) colon adenocarcinoma were dissected in fragments and cultured with IL-2 (6000U/ml) for 17-28 days. TIL were analyzed by multiparametric flow cytometric analyses and interrogated with private sets of predicted neoepitopes derived from non-synonymous mutations. T-cell responses against neoepitopes were detected by IFNγ ELISpot and validated with peptide-MHC multimers.

Results: TIL (i.e.>$50x10^6$ cells, mean±SEM 239±$52x10^6$) were obtained from 7 and 8 patients with primary and metastatic colon adenocarcinoma, respectively. In primary tumors, the highest potential for TIL expansion was observed for microsatellite-instable tumors as opposed to microsatellite-stable (MSS) tumors (mean±SEM 435±$194x10^6$ vs. 84±$34x10^6$ cells; p = 0.05, Mann-U). TIL yield was similar in primary and metastatic tumors, however in metastatic tumors the CD4/CD8 T cells ratio was higher (median 11 vs. 1; p = 0.002, Mann-U) and inversely correlated with TIL expansion (r_s -0.8; p = 0.005). Most (>90%) T cells had a phenotype of effector-memory ($CCR7^-CD45RA^-$) activated ($HLADR^+PD1^+TIM3^+$) cells. Mutational load (ranging from 23 to 2760) and potential neoepitopes (from 25 to 2373) were determined and, of interest, initial screening experiments identified 2% of neoantigen specific-TIL (mutMALT1; V380A) in a representative MSS metastatic tumor harboring only 47 missense mutations.

Conclusions: We demonstrate the spectrum of TIL expansion across CRC subtypes and stages, including the validation of neoepitopes in a non-hypermutated advanced tumor. These observations stress the potential of CRC patients for different strategies of personalized immunotherapy.

1203P Functional screening of B7H6-based chimeric antigen receptor (CAR) designs

B. Demoulin, L. Springuel, D. Daro, J. Bolsée, J. Houssa, F. Huberty, C. Jacques-Hespel, C. Marchand, J. Marijsse, T.L.T. Nguyen, N. Ramelot, B. Violle, C. Lonez, D.E. Gilham, V. Steenwinckel

Research & Development, Celyad SA, Mont Saint Guibert, Belgium

Background: B7H6, a stress-induced ligand for the NK-activating receptor Nkp30, is widely expressed at the surface of transformed cells yet absent in healthy tissues. This makes B7H6 an attractive target for a CAR T-cell therapy with broad clinical applicability, including colon cancer and neuroblastoma. CARs are artificial receptors comprising an extracellular antigen-binding region (often a single chain variable fragment (scFv)) fused to an intracellular T-cell activation tail (usually CD3ζ in tandem with one or two costimulatory domain(s)). Here, we report the *in vitro* screening of various B7H6-based CAR designs differing by either the origin of their targeting moiety (murine versus humanized scFv), the costimulatory signaling module (either CD28 or 4-1BB as a 2nd generation CAR) or a combination of CD28 and 4-1BB in a 3rd generation CAR context.

Methods: Primary human T-cell populations expressing the diverse B7H6-specific CAR constructs were compared for viability and fold expansion at the end of manufacturing as well as *in vitro* functionality (IFNg secretion and cytolytic activity when challenged with B7H6 expressing cell lines).

Results: All B7H6-based CAR T-cells yielded comparable fold expansion with high viability suggesting that the CAR design has no impact on process parameters. CARs with targeting moiety of murine scFv origin were functionally superior to humanized versions in terms of killing and IFNg release potentially due to a difference in target affinity between the scFv. Second generation CARs containing CD28 endowed CAR T-cells possessed superior *in vitro* anti-tumor activity compared to all other constructs. Cryopreservation of these 2nd generation CAR T-cells did not significantly reduce viability and potency post-thawing.

Conclusions: In these studies, a B7H6-based CAR comprised of murine scFv fused to CD28-CD3ζ signaling tail represented the best choice candidate after *in vitro* testing warranting further investigation. Subsequent studies will include *in vivo* xenograft models of colon cancer and neuroblastoma as well as target profiling through immunohistochemistry assessing B7H6 expression in a wide panel of tumor and normal tissues. This work focuses upon developing a package to support the clinical testing of B7H6 targeted CAR T-cell therapy.

1204P Concurrent immuno-radiotherapy in lung and renal cancer- a new treatment paradigm

J. Ansari[1], M. Ali[1], A. Alomair[2], A. Mohammed Ali[1], E. Murshid[1], A. Shaukat[1], E. Batubara[3], F. Bashir[1], A. Farrag[1], K. Hussein[1], A. Alhamad[1]

[1]Department of Oncology, Prince Sultan Military Medical City, Riyadh, Saudi Arabia, [2]Radiation Oncology, King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia, [3]Department of Pulmonology, Prince Sultan Military Medical City, Riyadh, Saudi Arabia

Background: Concurrent administration of checkpoint inhibitors and radiotherapy (Immuno-RT) remains investigational and is the subject of multiple clinical trials. Nivolumab is an anti-programmed death-1 receptor monoclonal antibody that exhibits checkpoint-mediated immune response against tumor cells. Nivolumab has received regulatory approval for the second-line management of metastatic non-small cell lung cancer (NSCLC) & renal cell carcinoma (RCC). Ionising radiation could increase the diversity & quantity of tumoral antigen presentation, thereby augmenting anti-tumour immune response achieved with checkpoint inhibitors. The aim of this study was to assess the efficacy & toxicity of concurrent administration of nivolumab and radiotherapy.

Methods: We identified 6 patients that received concurrent nivolumab and radiotherapy to 19 lesions; metastatic NSCLC (n = 4), metastatic RCC (n = 2). Treatment-related toxicities were identified by retrospective review of patient notes. Measurable lesions were assessed by RECIST 1.1 criteria. Pain score was used to assess symptomatic responses.

Results: Stereotactic and conformal radiotherapy were delivered to 9 and 10 lesions, respectively. Treatment sites (number of lesions): lung (n = 8), hip (n = 3), brain (n = 4), shoulder, scalp, ethmoid and adrenal. The gap between radiotherapy & nivolumab did not exceed 2 weeks for all patients. No grade 3-4 toxicities were observed. Two of the lung cancer patients developed grade 1 pneumonitis. Fractionation schedules included 48Gy/4 fractions (#), 40Gy/4#, 34Gy/4#, 22Gy/1#, 30Gy/10#, 25Gy/5#, 20Gy/4# and 20Gy/5#. Of the 14 measurable lesions, 86% had excellent response including complete response of 3 lesions. Symptomatic benefit was observed in 4 out of 6 treatment sites (66%).

Conclusions: The of role of concurrent nivolumab & radiotherapy in patients with metastatic NSCLC and RCC has never been reported previously. In our study, concurrent administration of nivolumab and radiotherapy appears to be well tolerated with excellent radiological and symptomatic responses. Ongoing clinical trials may help determine the future role of Immuno-RT in the rapidly evolving treatment paradigm of metastatic NSCLC and RCC management.

1205P Optimum fractionation of radiation dose to combine anti-PD-1 mAb in MC38 mice model

F. Teng, X. Wang, J. Yu, L. Kong

Radiation Oncology, Shandong Cancer Hospital, Jinan, China

Background: The irradiated tumor cell death can enhance antitumor immunity by inducing antigen expression on tumor cells and activating lymphocytes. Radiotherapy (RT) combined with immunotherapy has revealed promising outcomes in various animal models. However, the optimum fractionation of radiation for priming immune response is controversial. This study aimed to explore the fractionation of radiation to maximize immunity in combinatorial treatment.

Methods: Mice bearing MC38 murine colon cancer were treated with up to 24Gy radiation given in various sized fractions as 24Gy x 1f, 8Gy x 3f, 8Gy x 1f followed by 2Gy x 8f and 2Gy x 12f, and tumor growth followed. The immune response in the tumor, drainage lymph node(dLN) and spleen at 48h after radiation were assessed. 8Gy x 3f was chosen to combine anti-PD-1 immunotherapy. The abscopal effects and immune response were assessed by flow cytometry and immunohistochemistry(IHC).

Results: Single dose of 24Gy and 8Gy x 3f brought best tumor control. No abscopal effects was observed after radiotherapy alone. Fractionation of 8Gy x 3f increased the irradiated tumor infiltrating lymphocytes(TILs). However, conventional 2Gy doses decreased $CD4^+$TILs and $CD8^+$TILs and increased myeloid myeloid-derived suppressor cell (MDSC) in spleen significantly. As the optimal fractionation to maximize immunity, 8Gy x 3f was chosen to combine anti-PD-1 mAb. Compared to radiotherapy or anti-PD-1 mAb alone, 8Gy x 3f combining with anti-PD-1 mAb brought obvious abscopal effect. $CD8^+$T cells in the dLNs of the irradiated tumors were increased significantly in the combining group. Also, the combining treatment regimen increased $CD4^+$T cells and $CD8^+$T cells and decreased MDSC in the spleen. No serious toxicity of heart, liver, spleen, lung and kidney in each group was observed by using IHC.

Conclusions: Hypofractionation of 8Gy x 3f was the fractionation of radiation dose to maximize immunity, compared to single dose of 24Gy and conventional 2Gy doses. Radiation with 8Gy x 3f combining with anti-PD-1 mAb had synergistic antitumor effect.

1206P Efficacy of tumor treating fields (TTFields) and anti-PD-1 in non-small-cell lung cancer (NSCLC) preclinical models

M. Giladi[1], T. Voloshin[1], O. Talyitzhaki[2], U. Weinberg[3], E.D. Kirson[2]

[1]Preclinical, Novocure, Haifa, Israel, [2]Research and Development, Novocure, Haifa, Israel, [3]Clincal Development, Novocure, Luzern, Switzerland

Background: Tumor Treating Fields (TTFields) are an effective anti-neoplastic treatment modality delivered via non-invasive application of low intensity, intermediate frequency, alternating electric fields. TTFields is approved for the treatment of both newly diagnosed and recurrent glioblastoma. TTFields interrupt mitosis in cancer cells by disrupting microtubules and septin filaments, which play key roles in mitosis. The mitotic effects of TTFields include abnormal chromosome segregation that trigger different forms of cell death. We evaluated TTFields' effect on immunogenic cell death and its efficacy when combined with an immune checkpoint inhibitor (αPD1) in NSCLC.

Methods: Murine Lewis lung carcinoma (LLC) cells were treated with TTFields using the inovitro™ system. Levels of cell surface calreticulin (CRT) and intracellular ATP levels were evaluated using flow cytometry. High mobility group box 1 (HMGB1) secretion was measured using an ELISA assay. Mice inoculated with LLC cells were treated with isotype control, TTFields, αPD-1, or TTFields + αPD-1. Tumor volume monitoring and intra-tumor immune cell profiling were performed.

Results: TTFields induced elevated cell surface expression of CRT, decreased ATP levels, and promoted HMGB1 secretion. In vivo, the combined treatment of TTFields + α-PD-1 led to a significant decrease in lung tumor volume compared to all three other groups ($P < 0.001$). Significant increase in CD45+ tumor infiltrating cells was observed in the TTFields + αPD-1-treated mice. Infiltrating cells demonstrated a significant upregulation of surface PD-L1 expression. Both F4/80+CD11b+ cells and CD11c+ cells exhibited higher tumor infiltration and elevated PD-L1 expression, as compared to the control group. These findings indicate enhanced inflammatory antitumor environment conferred by the combination of TTFields + αPD-1.

Conclusions: Our results demonstrate that TTFields treatment potentiates immunogenic cell death in NSCLC cancer cells. Combining TTFields with specific immunotherapies such as anti-PD-1 may enhance antitumor immunity and result in increased tumor control. A phase III clinical study on TTFields in combination with either PD-1 inhibitors or docetaxel in NSCLC is underway.

1207TiP An open-label, Phase IB study of NEO-PV-01 + Adjuvant with Nivolumab in Patients with Melanoma, Non-Small Cell Lung Carcinoma, or Transitional Cell Carcinoma of the Bladder

P.A. Ott[1], A. Naing[2], G. Ramaswamy[3], K. Margolin[4], M. Moles[5], R. Gaynor[5], M.J. Goldstein[5], S. Hu-Lieskovan[6]

[1]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, USA, [2]Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA, [3]Medical Oncology, Washington University School of Medicine, St. Louis, MS, USA, [4]Medical Oncology, City of Hope, Duarte, CA, USA, [5]R&D, Neon Therapeutics, Boston, MA, USA, [6]Medical Oncology, UCLA - School of Medicine, Los Angeles, CA, USA

Background: Cancer cells harbor DNA mutations that encode altered amino acid sequences known as neoantigens. Absent from normal tissues and highly specific for tumors, neoantigens bypass central tolerance and have been established as critical targets for tumor directed T cell responses. Tumor mutational burden and neoantigen load have been associated with anti-tumor activity of immune checkpoint inhibitors. Vaccines targeting neoantigens have the potential to induce de novo and expand existing tumor directed T cell responses. NEO-PV-01 is a personalized neoantigen long peptide vaccine designed specifically for the molecular profile of an individual patient's tumor.

Trial design: NT-001 is a single-arm, phase IB study evaluating the safety of administering NEO-PV-01 + adjuvant (Poly-ICLC) with the PD-1 directed antibody, nivolumab, in patients with advanced melanoma, smoking-associated non-small cell lung carcinoma, or transitional cell carcinoma of the bladder who have received no more than one prior systemic treatment. NEO-PV-01 is custom designed and generated for each patient by DNA and RNA sequencing of a recently biopsied tumor, HLA typing, selection of neoantigen epitopes, and synthesis of up to 20 peptides (14-35 amino acids in length). Patients receive treatment with nivolumab at a dose of 240 mg IV q2 weeks while their vaccine is produced. These peptides are formulated into four distinct pools, mixed with Poly-ICLC, and administered subcutaneously into up to 4 non-rotating anatomical sites. Beginning at Week 12, patients receive five priming immunizations over a three-week period followed by booster vaccinations at Weeks 19 and 23 while continuing nivolumab. The primary endpoint is safety. Secondary endpoints are ORR, CBR, PFS, and assessment of response conversion between Week 12 and Week 24. Exploratory endpoints include extensive immune monitoring. The study is open as of October 2016 with estimated enrollment of 90 patients.

Background: Although acquired immunodeficiency syndrome-related mortality is decreasing with the introduction of effective antiretroviral therapy, it has been reported a significant increase in the proportion of non-acquired immunodeficiency syndrome defining malignancies in HIV infected patients, often associated with premature immunosenescence and exhaustion. It has been shown in murine models and humans that programmed cell death ligand 1 (PD-L1) and its receptor, programmed cell death 1 (PD-1) play an active and reversible role mediating T-cell exhaustion both in cancer and in chronic infections. Binding PD-1 to its ligand PD-L1negatively regulates T-cell response, leading to an exhausted phenotype on CD8+ T cells. Therefore, there is a potential of immunotherapeutic intervention targeting PD-1/PD-L1 in order to enhance anti tumoral immune responses as well as to facilitate viral eradication. Durvalumab (MEDI4736) is a human monoclonal antibody (MAb) of the immunoglobulin G1 kappa (IgG1κ) subclass that inhibits binding of programmed cell death ligand 1 (PD-L1) to programmed cell death 1 (PD-1; CD279) and CD80 (B7-1). Durvalumab has demonstrated in cancer patients a favorable safety profile with encouraging antitumor activity, but there are no data about tolerance or anti retroviral activity in HIV patients.

Trial design: This is an ongoing multicenter, open-label, phase 2 study (EUDRACT: 2016-004524-38) whose primary objective is to assess the feasibility of durvalumab at the recommended dose of 1500 mg every 4 weeks in HIV-infected patients with solid tumors for which no additional oncologic standard treatment is available. As secondary objectives the response rate (RECIST 1.1 and irRECIST), duration of response, PFS and OS will be measured. Exploratory objectives include the assessment of antiviral activity by measuring the changes in the HIV viral reservoir, the residual viral replication and the composition and function of circulating T lymphocytes and the study of molecular predictive factors of antitumoral activity on pretreatment tumor samples.

1209TiP A first-in-human, open-label, multicenter phase 1/2a study to evaluate the safety and efficacy of increased repeated doses of the first in class RORγ agonist LYC-55716 in treating locally advanced or metastatic solid tumors

H.J. Wilkins[1], E.P. Hamilton[2], D. Mahalingam[3]

[1]Clinical Development, Lycera Corp., Plymouth Meeting, PA, USA, [2]Breast Cancer and Gynecologic Cancer Research Program, Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN, USA, [3]Medical Oncology, University of Texas Health Science Center San Antonio, San Antonio, TX, USA

Background: LYC-55716, a first-in-class oral, small-molecule agonist of nuclear receptor retinoic acid–related orphan receptor γ (RORγ), has been shown in preclinical models to modulate gene expression to reprogram immune cell antitumor effector function and decrease immunosuppressive mechanisms, resulting in immune-mediated tumor growth control and enhanced survival. Data suggest that LYC-55716 acts via well-known antitumor mechanisms by increasing immune cell trafficking and recruitment to tumors, enhancing T cell effector function and memory development, and promoting T cell survival. LYC-55716 may enhance immune-mediated antitumor responses via its effects on T effector/Treg cell ratios, PD-1 expression, and sensitivity to PD-L1 inhibition of T cell proliferation. A first-in-human, single-arm, open-label multicenter Phase 1/2a study is ongoing to evaluate the safety and tolerability of LYC-55716 and determine the maximum tolerated dose and objective response rate. All adult subjects enrolled will have relapsed or refractory metastatic cancer and have failed to responded to standard therapies.

Trial design: The Phase 1 portion of the study will follow a dose-escalation design to evaluate the occurrence of dose-limiting toxicities (DLTs) and determine the maximum tolerated dose and recommended Phase 2 dose of LYC-55716. Following a screening period, adults with locally advanced or metastatic solid tumors will receive 28-day treatment cycles of LYC-55716 BID (n = 4–6/cohort). Dosing escalation considers dose and dosing regimen and is determined by PK profile and safety. Primary endpoints include safety (monitoring of adverse events, physical examination, and lab results) and incidence of DLTs (Grade 3 or 4 toxicities) during the first 28-day treatment cycle. Secondary endpoints include objective tumor response rate as assessed via response evaluation criteria in solid tumors (RECIST) v1.1 assessed at scans performed every 8 weeks, pharmacokinetics, and pharmacodynamics. Results for the first three cohorts of the Phase 1 portion of the study will be available at the time of presentation.

Clinical trial identification: NCT02929862

Background: Because of its increasingly demonstrative successes, CAR-T therapy has been well recognized as one of the most promising therapies for cancer. We have developed a novel autologous CAR-T, NKR-2, incorporating the full-length human natural killer receptor NKG2D fused with the human CD3 zeta signaling domain. When expressed in T-cells, the naturally-expressed DAP10 provides the co-stimulatory signals to NKR-2 to be fully activated. NKR-2 selectively target tumor cells upon recognition of up to eight different NKG2D ligands expressed in many distinct cancer indications. In preclinical studies, NKR-2 demonstrated long-term anti-tumor activity towards multiple solid and hematologic tumors deploying multiple mechanisms of action targeting tumor cells and cells from the neo-vasculature and tumor suppressive immune environment, resulting in an adaptive response. In our recently completed Phase 1 study in hematologic cancers, a single administration of autologous NKR-2 was safe with initial signs of clinical benefit. Likewise, to overcome the operational challenges, our trial design incorporates strategies to harmonize multiple clinical and manufacturing processes while also enhancing patient safety and clinical outcomes.

Trial design: THINK trial (THerapeutic Immunotherapy with NKR-2) is a EU/US open-label Phase I study to assess the safety and clinical activity of NKR-2 therapy administered in three infusions, two weeks apart in five solid tumor indications (CRC, urothelial, TNBC, pancreatic, ovarian) and two hematologic indications (AML/MDS and MM). No lymphodepleting conditioning is required in this study. The study contains two consecutive segments. The dose escalation segment will enroll 18 patients in two separate hematologic and solid malignancy arms, and evaluate 3 dose levels of NKR-2 ($3x10^8$, $1x10^9$ and $3x10^9$ cells per injection) following a 3 + 3 design. The expansion segment will then enroll 96 additional patients in 7 separate cohorts for each indication with 3 steps of statistical analysis (overall futility, futility within each cohort and final evaluation). At time of submission, the trial has completed enrollment in its first cohort among solid indications.

1211TiP FAK-PD1: a phase I/IIa trial of FAK (defactinib) & PD-1 (pembrolizumab) inhibition

S. Symeonides[1], T.R.J. Evans[2], V. Coyle[3], A. Serrels[4], F. Thomson[5], D. Currie[6], S. Dillon[6], J. Paul[6], D.A. Fennell[7], C. Ottensmeier[8]

[1]Experimental Cancer Medicine Centre, University of Edinburgh, Edinburgh, UK, [2]Beatson West of Scotland Cancer Centre, University of Glasgow, Glasgow, UK, [3]Medical Oncology, Northern Ireland Cancer Centre, Belfast City Hospital, Belfast, UK, [4]MRC Centre for Inflammation Research, University of Edinburgh, Edinburgh, UK, [5]Translational Pharmacology Laboratory, Institute of Cancer Sciences, University of Glasgow, Glasgow, UK, [6]Cancer Research UK Clinical Trials Unit, University of Glasgow, Glasgow, UK, [7]Department of Cancer Studies, University Hospitals of Leicester NHS Trust Leicester Royal Infirmary, Leicester, UK, [8]Cancer Research UK Centre, Southampton General Hospital, Southampton University Hospitals NHS Trust, Southampton, UK

Background: Focal Adhesion Kinase (FAK) is a pivotal intracellular mediator of extracellular contact interactions. It is over-expressed in cancer, with a long-established role in migration, invasion & survival, and is associated with poor prognosis. Recently FAK has been found to have a similar activity in recruitment of immunosuppressive cells to the tumour. We have shown that FAK inhibition can re-model the tumour immune microenvironment *in vivo*, shifting the balance from inhibitory Tregs, macrophages, fibroblasts and myeloid progenitors, to one which supports an active CD8+ adaptive immune response, resulting in tumour clearance and lasting immunity. FAK inhibition synergises with Programmed cell death receptor 1 (PD-1) blockade in more resistant models. Defactinib (VS-6063, Verastem) is a small molecule FAK inhibitor in Phase II development with an encouraging safety profile and biological activity. Pembrolizumab (MK-3475, MSD) is a humanized IgG4/kappa monoclonal antibody to PD-1, licensed for the treatment of an increasing number of tumour types. This recently open trial will assess the safety, tolerability and preliminary activity of defactinib plus pembrolizumab in patients with advanced solid malignancies.

Trial design: FAK-PD1 is an open label, phase I/IIa clinical trial, combining 200 mg pembrolizumab as a 3-weekly IV infusion, with defactinib given orally twice daily at either 200 mg or 400 mg, before leading into three tumour-specific expansions (non-small cell lung cancer, mesothelioma and pancreatic cancer) at the selected dose. Up to 60 patients, PS 0-1, with adequate blood parameters, measurable disease, baseline tissue, and without contraindications to either agent, will be treated for up to 2 years until clear clinical progression, unacceptable toxicity, or withdrawal. Primary endpoint is safety (NCI-CTCAE v4.03); secondary endpoints include objective response rate (irRECIST), progression-free survival, FAK Y397 phosphorylation and immune cell infiltrate effects. Exploratory endpoints include comprehensive cellular and molecular characterisation of baseline and on-treatment tumour samples, and serial blood immune cell and cytokine profiling. Positive data will support further development of the combination.

Clinical trial identification: FAK-PD1 EudraCT number: 2015-003928-31

Background: Abundance and functional quality of tumor infiltrating lymphocytes are positively linked with tumor response and improved survival with checkpoint inhibitors. NKTR-214 is a CD122-biased agonist that targets the IL2 pathway and is designed to provide sustained signaling through the heterodimeric IL2 receptor pathway (IL2Rβɤ) to preferentially activate and expand NK and effector CD8+ T cells over CD4+ T regulatory cells within the tumor microenvironment. NKTR-214 has been administered to 28 patients with advanced cancers. NKTR-214 as a single agent demonstrated a substantial increase in both CD8+ T and NK cells within the tumor microenvironment in patients with prior immune checkpoint therapy (Bernatchez et al 2016). Given the favorable safety profile and strong biomarker data, a trial combining NKTR-214 and nivolumab was initiated.

Trial design: PIVOT-02 is a phase 1/2 open-label trial in patients (pts) with locally advanced or metastatic melanoma (mM), non-small cell lung cancer (NSCLC), renal cell carcinoma (RCC), urothelial carcinoma, or triple-negative breast cancer (TNBC). The primary objectives are to evaluate safety and tolerability, determine the recommended phase 2 dose (RP2D), and assess tumor response by RECIST 1.1. In an outpatient setting, NKTR-214 is administered at dose levels of 0.003, 0.006 and 0.009 mg/kg in combination with nivolumab at two flat dose schedules of either 240 mg @ q2w or 360 mg @ q3w. As of May 8, 17 pts (7 mM, 8 RCC, and 2 NSCLC) have been enrolled into 4 cohorts in the dose-escalation phase. In the dose-expansion phase, approximately 250 pts will be enrolled in five tumor types and eight indications; immunotherapy naïve patients and patients who are relapsed/refractory to checkpoint therapy are being studied separately. Extensive blood and tumor tissue samples are being collected to measure immune activation using immunophenotyping including flow cytometry, immunohistochemistry (IHC), T cell clonality and gene expression analyses. Enrollment is ongoing.

Background: In clinical studies, 10-15% of patients (pts) treated with anti-PD-1 monotherapies achieved durable CRs. Combination treatment with NIVO+IPI resulted in higher response rates, longer progression-free survival (PFS), and improved overall survival (OS) vs IPI alone, but with an increased frequency of adverse events (AEs). Here, we characterized CRs among pts who received combination therapy vs NIVO or IPI alone.

Methods: In this post hoc analysis, efficacy and safety data were pooled for NIVO+IPI (N = 409), NIVO (N = 526), and IPI (N = 362) from the phase 2 CheckMate 069, phase 3 CheckMate 066, and phase 3 CheckMate 067 studies in pts with MEL. Across studies, the minimum duration of follow-up was 24 months (median ~31 months).

Results: In the pooled analysis, the CR rate was 18% for NIVO+IPI, 16% for NIVO, and 4% for IPI, with partial responses (PRs) in 41%, 28%, and 14% of pts, respectively (Table). Among the 75 CR pts in the NIVO+IPI cohort, the majority (77%) are off treatment and 8% received a subsequent systemic therapy; 15% had elevated LDH levels and 32% had M1c disease. Median duration of CR has not been reached, with 63/75 pts (84%) remaining in response. After an additional follow-up of 12 months (from the 1-year initial follow-up), 24/166 pts (14%) with a PR converted to a CR. For the 75 CR pts in the NIVO+IPI cohort, 2-year PFS and OS rates were 86% and 92%, respectively. Treatment-related AEs of grade 3-4 occurred in 60% of NIVO+IPI-treated pts with a CR, 65% with a PR, and in 60% with stable disease; 31%, 36%, and 35%, respectively, led to discontinuation. There were no treatment-related deaths.

Table: 1213O

	NIVO+IPI (N = 409)	NIVO (N = 526)	IPI (N = 362)
Objective response rate (%)	58.9	43.9	18.0
CR, n (%)	75 (18)	83 (16)	14 (4)
PR, n (%)	166 (41)	148 (28)	51 (14)
Pts remaining in response (CR)	63/75 (84%)	75/83 (90%)	11/14 (79%)
CR pts continuing on treatment	17/75 (23%)	41/83 (49%)	4/14 (29%)
CR pts not continuing on treatment	58/75 (77%)	42/83 (51%)	10/14 (71%)

Conclusions: MEL pts treated with NIVO+IPI had a high rate of durable CRs, with the majority remaining in response and often not requiring additional treatment at a median follow-up of ~31 months. Some pts with a PR convert to a CR over time. Updated analyses based on 3-year data will be presented.

Clinical trial identification: NCT01844505 (067) NCT01721772 (066) NCT01927419 (069)

1214O Epacadostat plus pembrolizumab in patients with advanced melanoma: Phase 1 and 2 efficacy and safety results from ECHO-202/KEYNOTE-037

O. Hamid[1], T.F. Gajewski[2], A.E. Frankel[3], T.M. Bauer[4], A.J. Olszanski[5], J.J. Luke[6], A.S. Balmanoukian[1], E.V. Schmidt[7], B. Sharkey[8], J. Maleski[8], M.J. Jones[8], T.C. Gangadhar[9]

[1]Research, The Angeles Clinic and Research Institute, Los Angeles, CA, USA, [2]Department of Pathology and Department of Medicine, Section of Hematology/Oncology, University of Chicago, Chicago, IL, USA, [3]Internal Medicine, University of Texas Southwestern Medical Center, Dallas, TX, USA, [4]Drug Development Unit, Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN, USA, [5]Department of Medical Hematology/Oncology, Fox Chase Cancer Center, Philadelphia, PA, USA, [6]Hematology/Oncology, University of Chicago, Chicago, IL, USA, [7]Oncology Clinical Research, Merck & Co., Inc., Kenilworth, NJ, USA, [8]Drug Development, Incyte Corporation, Wilmington, DE, USA, [9]Medicine, Hematology/Oncology Division, Abramson Cancer Center of the University of Pennsylvania, Philadelphia, PA, USA

Background: Tumors can evade immunosurveillance through upregulation of indoleamine 2,3-dioxygenase 1 (IDO1). Epacadostat (E) is a potent, selective inhibitor of the IDO1 enzyme. The combination of E + the PD-1 inhibitor pembrolizumab (P) is being evaluated in an open-label, phase 1/2 study in multiple tumor types (ECHO-202/KEYNOTE-037). We report phase 1 and 2 efficacy and safety data for patients (pts) with advanced melanoma (27Feb2017 data cutoff).

Methods: Pts previously treated with checkpoint inhibitors were excluded. Pts received E (25, 50, 100, or 300 mg PO BID) + P (2 mg/kg or 200 mg IV Q3W) during phase 1.

MTD was not exceeded. E (100 mg BID) + P (200 mg Q3W) was selected for phase 2. Responses were assessed in RECIST 1.1 evaluable pts.

Results: 64 pts enrolled (phase 1, n = 22; phase 2, n = 42). Median age, 65; male, 70%; BRAF+, 30%; M1c disease, 52%. Median duration of follow-up was 253+ days (range, 5 to 904+ days). Among 54 efficacy evaluable pts, ORR was 56% (30/54; 8 CR, 22 PR) and DCR (CR+PR+SD) was 78% (42/54). In treatment-naïve pts (n = 45), ORR was 56% (25/45; 6 CR, 19 PR) and DCR was 78% (35/45). Among treatment-naïve pts receiving E 100 mg BID (n = 30), ORR was 60% (18/30; 2 CR, 16 PR). Responses were observed regardless of PD-L1 and BRAF mutation status. At data cutoff, 28/30 responses in the melanoma cohort were ongoing (median duration of response = 287.5+ days, range 1+ to 763+ days). Median PFS was 12.4 mo; PFS rates at 6, 12, and 18 mo were 70%, 54%, and 50%, respectively. In treatment-naïve pts, median PFS has not been reached; PFS rates at 6, 12, and 18 mo were 68%, 52%, and 52%. The most common (>15%) all-grade treatment-related AEs (TRAEs) were fatigue (39.1%), rash (32.8%), pruritus (26.6%), and arthralgia (15.6%). Grade ≥3 TRAEs were observed in 17.2% of pts (most common: lipase increased, n = 4; rash, n = 3; and amylase increased, n = 2). 3 pts discontinued for TRAEs (lipase increased, n = 1; arthralgia, n = 2). No treatment-related deaths occurred. Biomarker evaluation is ongoing.

Conclusions: Consistent with the phase 1 results, E + P continues to be well tolerated and showed promising clinical activity. A phase 3 study in pts who are treatment-naive for advanced melanoma is ongoing (NCT02752074).

Background: The addition of a MEK inhibitor (MEKi) to a BRAF inhibitor (BRAFi) in *BRAF* V600-mutant metastatic melanoma improves efficacy, including progression-free survival (PFS) and objective response rate (ORR), and attenuates some BRAFi–associated toxicities. Part 1 of the COLUMBUS study met its primary endpoint. The BRAFi ENCO 450 mg once daily (QD) + the MEKi BINI 45 mg twice daily (BID; COMBO450) improved PFS vs vemurafenib (VEM) alone and ENCO 300 mg QD (ENCO300) alone in patients (pts) with advanced *BRAF* V600-mutant melanoma. The tolerability of COMBO450 was favorable compared with VEM or ENCO300. In Part 2, the contribution of BINI to the combination was further evaluated by maintaining the same dose of ENCO in the combination (ENCO 300 mg QD + BINI 45 mg BID; COMBO300) and comparator arms (ENCO300 alone; ClinicalTrials.gov, NCT01909453; EudraCT, 2013-001176-38).

Methods: Pts were randomized 3:1 to COMBO300 or ENCO300. Data from ENCO300 arms in Parts 1 + 2 were combined for the primary efficacy comparison of PFS by independent blinded central review (BCR). Other analyses included PFS for COMBO300 vs ENCO300 (Part 2 only), ORR, complete response (CR) and partial response (PR) by BCR and local review, and safety.

Results: Pt characteristics are presented in the Table. Median PFS (95% CI) for COMBO300 was 12.9 mo (10.1–14.0) vs 9.2 mo (7.4–11.0) for ENCO300 (Parts 1 + 2) and 7.4 mo (5.6–9.2) for ENCO300 (Part 2). The hazard ratio (HR) for COMBO300 was 0.77 (0.61–0.97; P = 0.029, 2-sided) vs ENCO300 (Parts 1 + 2) and 0.57 (0.41–0.78; $P<0.001$, 2-sided) vs ENCO300 (Part 2). ORR, CR, and PR by BCR/local review (%) were 66/72, 8/11, and 58/62 for COMBO300, 50/56, 5/8, and 45/49 for ENCO300 (Parts 1 + 2), and 50/53, 3/3, and 47/50 for ENCO300 (Part 2). Safety profiles were consistent with Part 1 (Table).

Table: 1215O COLUMBUS Part 2: Baseline Characteristics, Duration of Exposure, and Safety

	COMBO300	ENCO300 (Parts 1 + 2)	ENCO300 (Part 2 only)
	n = 258	n = 280	n = 86
Patient characteristics			
Baseline ECOG PS1, %	26	28	28
Baseline LDH high, %	31	28	37
Stage M1c disease at study entry, %	67	64	67
Tolerability			
Median duration of exposure, wk	52	32	32
AEs leading to discontinuation, %	12	13	10
AEs requiring dose modification, %	45	69	63
AEs requiring additional therapy, %	82	94	92
AEs (all-grade; ≥20% in any group), %			
Diarrhea	28	12	7
Nausea	27	36	29
Arthralgia	22	43	42
Fatigue	22	26	30
Increased creatine phosphokinase	20	1	0
Vomiting	15	25	19
Myalgia	14	27	23
Alopecia	13	49	33
Headache	12	26	23
Pain in extremity	11	20	14
Grade 3/4 AEs (≥5% in any group), %			
Increased alanine aminotransferase	5	<1	0
Increased creatine phosphokinase	5	0	0
Increased gamma-glutamyltransferase	5	4	2
Palmar-plantar erythrodysesthesia syndrome	<1	11	5
Arthralgia	1	8	5
Myalgia	<1	8	5

Conclusions: COMBO300 meaningfully improved PFS, ORR, and tolerability vs ENCO300, confirming the contribution of BINI to both efficacy and safety.

Clinical trial identification: Trial protocol number, CMEK162B2301 (release date, July 13, 2015)

Background: Combination of anti–PD-1 agents with BRAF/MEK inhibitors (i) may provide synergistic antitumor effects in *BRAF*-mutant melanoma. The ph 1/2 KEYNOTE-022 study (NCT02130466) is assessing safety and antitumor activity of recommended doses of pembro + BRAFi D + MEKi T; updated and additional ph 1 results are reported.

Methods: Treatment-naive pts with $BRAF^{V600E/K}$-mutant stage III/IV melanoma received pembro 2 mg/kg Q3W + D 150 mg BID + T 2 mg QD. Primary end point was safety; AEs were graded per CTCAE v4.0. Efficacy end points were ORR, PFS, and OS. Data cutoff: Mar 1, 2017.

Results: Of the 15 pts enrolled, 10 (66.7%) had PD-L1+ tumors (≥1% staining), 13 (86.7%)/2 (13.3%) had ECOG PS 0/1, and 1 (6.7%) had stable brain metastases. Median follow-up was 19.7 mo (range, 15.9-31.1). 3/15 (20.0%) pts had DLTs (pt 1 had gr 4 neutropenia; pt 2 had gr 4 ALT increase; and pt 3 had gr 4 ALT, gr 3 AST, and gr 3 GGT increase); all resolved. Thus, this dose was the MTD and recommended ph 2 regimen. 11 (73%) pts had gr 3-4 TRAEs; ALT increase, AST increase, and pyrexia occurred in ≥ 20% of pts. 7 (46.7%) pts had immune-mediated AEs, most commonly hyperthyroidism in 3 pts (2 gr 1 and 1 gr 2) and hypothyroidism in 4 pts (all gr 1). Treatment was discontinued (d/c) for 2 events (1 gr 2 pneumonitis and 1 gr 3 autoimmune hepatitis) and was interrupted for 3 events (1 gr 1 hyperthyroidism, 1 gr 2 anterior uveitis, and 1 gr 3 erythematous rash); all resolved. ORR (RECIST v.1.1, investigator; confirmed + unconfirmed) was 67%; 1 pt had CR, 9 had PR; an additional 2 pts had SD and 3 had PD. ORR (RECIST v.1.1, investigator; confirmed only) was 53%; 8 pts had PR; an additional 3 pts had SD and 4 had PD. Median time to response was 2.8 mo (range, 2.2-3.0); median DOR was not reached (range, 2.8-26.5 mo). Among the 8 pts with confirmed ORR, 6 had ongoing responses and 2 had progression at data cutoff. 2 pts remained on triplet therapy, 2 d/c D + T, and 4 d/c pembro + D + T as of last follow-up.

Conclusions: Updated results show that approved doses of pembro + D + T continue to demonstrate promising antitumor activity for *BRAF*-mutant melanoma. A randomized ph 2 study is currently evaluating this triplet regimen as first-line therapy for *BRAF*-mutant melanoma.

1217PD Comprehensive genomic profiling (CGP) and tumor mutational burden (TMB) assessment in subtypes of metastatic melanoma

J.S. Ross[1], J.A. Carlson[1], J.A. Elvin[2], J-A. Vergilio[2], J. Suh[2], S. Ramkissoon[2], E. Severson[2], S. Daniel[2], S.M. Ali[2], A.B. Schrock[3], D. Fabrizio[2], G.M. Frampton[2], V.A. Miller[2], P.J. Stephens[2], L.M. Gay[4], D.B. Johnson[5]

[1]Pathology, Albany Medical Center, Albany, NY, USA, [2]R & D, Foundation Medicine, Cambridge, MA, USA, [3]Clinical Development, Foundation Medicine, Cambridge, MA, USA, [4]Pathology, Foundation Medicine, Cambridge, MA, USA, [5]Medical Oncology, Vanderbilt Ingram Cancer Center, Nashville, TN, USA

Background: Metastatic melanoma (MM) is widely treated with both kinase inhibitors and immunotherapies, providing meaningful survival benefit. Contrasting CGP and TMB results across MM subtypes provides a blueprint for rational decision making in light of increasing effective therapeutic options.

Methods: CGP for 2,225 MM evaluated up to 315 genes plus introns of 28 genes commonly rearranged in cancer using hybrid-capture, adaptor ligation-based libraries (mean coverage >620X). TMB was calculated from ~1.1 Mb of sequenced DNA. Base substitutions, insertions and deletions (short variants; SV); rearrangements; and copy number changes were assessed.

Results: We evaluated 9 MM subtypes: routine cutaneous (CT), desmoplastic (DM), acral lentiginous (AL), Spitzoid (SP), gynecologic mucosal (GMC), head and neck mucosal (HN), anorectal (ARM) and ocular (OC). Each group harbored characteristic genomic alterations (GA) (Table). *BRAF* was mutated in 38% of CT (92% SV; 8% amplifications, fusions or cases with >1 *BRAF* GA). Patients with TMB ≥20 mut/Mb were common in CT and DM, but 5% or less in all other subtypes. The frequency of *BRAF* GA was lower in AL, GMC, HN, ARM and OC. SP commonly harbored fusions in *BRAF* (60%) and other kinases. *KIT* GA were prominent in GMC and AL. Key findings include novel drivers of BRAF inhibitor resistance including *BRAF* rearrangements, kinase duplications and MEK GA.

Conclusions: In the largest cohort of MM with CGP to date, genomic profiles and TMB differ across MM subtypes. Highly prevalent BRAF GA in CT and high TMB in CT and DM permit effective use of targeted and immunotherapies, although novel BRAF inhibitor resistance mechanisms were observed. In addition, a variety of non-BRAF kinase targets are apparent in some MM subtypes.

1218PD Precision medicine for the treatment of metastatic uveal melanoma: A pilot study

S. Leyvraz[1], M. Schuette[2], D.T. Rieke[1], T. Kessler[2], S. Ochsenreither[1], V. Amstislavskiy[3], T. Risch[3], C. Wierling[2], K. Joehrens[4], C.A. Peuker[5], M. Lamping[1], S. Burock[1], G. Poch[6], F. Kiecker[6], R. Schaefer[1], B. Lange[2], H. Lehrach[3], A. Joussen[7], U. Keilholz[1], M-L. Yaspo[8]

[1]Charite Comprehensive Cancer Center, Charité University Hospital, Berlin, Germany, [2]Alacris Theranostics GmbH, Alacris Theranostics GmbH, Berlin, Germany, [3]Otto Warburg Laboratory Gene Regulation and Systems Biology of cancer, Max Planck Institute for Molecular Genetics, Berlin, Germany, [4]Institut of Pathologie, Charité University Hospital, Berlin, Germany, [5]Department of Hematology and Medical Oncology, Charite, Campus Benjamin Franklin, Berlin, Germany, [6]Clinic of Dermatology, Charité University Hospital, Berlin, Germany, [7]Department of Ophtalmology, Charité University Hospital, Berlin, Germany, [8]Department of Vertebrate Genomics, Max Planck Institute for Molecular Genetics, Berlin, Germany

Background: There is no standard active treatment for metastatic uveal melanoma. Precision medicine with high-throughput genomics could improve the outcome of patients suffering of "hard-to-treat" cancer.

Methods: Metastatic uveal melanoma included in the prospective TREAT20Plus study had fresh tumor biopsies that were subjected to a complete genomic analysis program (WGS, whole exome seq, RNAseq, Methylome, Proteome and cell culture). Integrative data analysis was performed and generated a comprehensive molecular tumor analysis (CMTA). An interdisciplinary molecular tumour board interpreted the data and provided treatment recommendations.

Results: Thirteen patients (6 F, 7 M) were biopsied. Age: 68 (33-81). Site of biopsy: soft tissue: 5, liver: 4, lung: 2, pleura: 1, lymph node: 1. Pre-treatment number: 2 (0-4) and type: iv chemotherapy: 10, checkpoint Inh:6, intra-hepatic: 8. Genomic results were available in the first 10 patients within 34 days (31-40). The number of mutations was low: median 25 (16-44.). Mutations were found in *GNAQ*: 11, *GNA11*: 6, *BAP1*; 3, *SF3B1*: 4. We detected one gene-fusion: *ZNF704-PKIA*. The most frequent gene overexpression affected the following genes: *MYC*: 7, *MET*: 5, *BCL2*: 4, *CCND2*: 1, *ERBB3*: 1. There was a loss of expression of: *CDKN2A*: 2, *PTEN*: 1, *EFS*: 1. A slightly up-regulated expression of *ALK* was detected in one patient and confirmed as an oncogenic ALK^{ATI} isoform that originates from an alternative internal transcription start site in intron 19. At time of recurrence a second biopsy showed a complete loss of *CDKN2A* expression through a bi-allelic loss of chromosome 9. Treatment recommendations were the following: inhibitor of MEK: 10, of MET: 5, of CDK4/6: 3, of ALK: 1, of PI3K: 1. Treatment was initiated in 7 patients: 5 received Trametinib, one patient each received Palbociclib, Crizotinib or Cabozantinib, respectively. Among the 6 currently evaluable patients one showed minor response (15%), one a stable disease, one progressive disease, and 3 patients cannot yet be evaluated.

Conclusions: Genomic integrative analysis showed a net advantage over exome-only or panel sequencing. This strategy is clinically feasible and led to individualized treatment recommendations. Treatment outcome will be presented for the whole cohort.

1219PD Combined radiofrequency ablation and ipilimumab in uveal melanoma: Results from the SECIRA-UM trial

E.A. Rozeman[1], W. Prevoo[2], M.A.J. Meier[2], K. Sikorska[3], B.A. van de Wiel[4], A. Broeks[5], H. van Tinteren[3], E. Kapiteijn[6], J.V. Thienen[1], J.B. Haanen[1], C.U. Blank[1]

[1]Medical Oncology Department, Het Nederlands Kanker Instituut Antoni van Leeuwenhoek (NKI-AVL), Amsterdam, Netherlands, [2]Department of Radiology, Het Nederlands Kanker Instituut Antoni van Leeuwenhoek (NKI-AVL), Amsterdam, Netherlands, [3]Department of Biometrics, Het Nederlands Kanker Instituut Antoni van Leeuwenhoek (NKI-AVL), Amsterdam, Netherlands, [4]Department of Pathology, Het Nederlands Kanker Instituut Antoni van Leeuwenhoek (NKI-AVL), Amsterdam, Netherlands, [5]Core Facility Molecular Pathology & Biobanking, Het Nederlands Kanker Instituut Antoni van Leeuwenhoek (NKI-AVL), Amsterdam, Netherlands, [6]Department of Clinical Oncology, LUMC, Leiden, Netherlands

Background: After enucleation or radiotherapy of the primary lesion, 50% of uveal melanoma (UM) patients develop distant metastases. In contrast to cutaneous melanoma, targeted therapies and checkpoint inhibitors failed to improve overall survival (OS) in UM. Chemoembolization or intrahepatic artery perfusion improved local control, but failed to show OS benefit. The anti-CTLA-4 antibody ipilimumab (IPI), showed limited clinical activity in UM, thus combination therapies may be required. Preclinical experiments in a murine melanoma model indicated that additional radiofrequency ablation(RFA) enhanced antigen presentation and induced durable responses.

Methods: We therefore have set-up a phase 1b/2 study to assess safety and efficacy of the combination of RFA and IPI in UM patients with at least 2 unresectable liver lesions. In the phase 1b part patients underwent RFA of one liver lesion and received 4 courses IPI 0,3mg/kg, 3mg/kg or 10mg/kg q3wk in a 3 + 3 design. Primary endpoint of the phase 1b part was safety in terms of dose limiting toxicities per cohort to define the recommended phase 2 dose(RP2D). Primary endpoints of the phase 2 part were confirmed objective response rate (ORR) and disease control rate (DCR) according to RECIST 1.1 (only non-RFA lesions), secondary endpoints were progression free survival (PFS) and OS.

Results: IPI 10mg/kg + RFA was defined as the RP2D. After 19 patients had been treated, the study was amended to adjust the RP2D to IPI 3mg/kg + RFA, because 9 patients (47%) had developed grade 3 colitis. In the 3mg/kg IPI + RFA cohort also 19 patients have been treated, and baseline characteristics were balanced between the cohorts. Treatment related grade ≥3 AEs were seen in 53% of patients in the 10mg/kg cohort versus 32% in the 3mg/kg cohort. No confirmed objective responses were observed; the confirmed DCR was 21% in the 10mg/kg cohort and 11% in the 3mg/kg cohort. Median PFS was 2.8 months and was comparable for both groups, median OS was 13.6 months for the 10mg/kg cohort versus 9.5 months for the 3mg/kg cohort ($p = 0.23$).

Conclusions: The combination of IPI 3mg/kg +RFA was safe but showed limited clinical activity in UM. However, overall survival seems to be longer compared to other study cohorts of UM patients, especially in the IPI 10mg/kg cohort.

1220PD Phase 2 study of neoadjuvant dabrafenib + trametinib (D+T) for resectable stage IIIB/C BRAF V600 mutant melanoma

A.M. Menzies[1], M. Gonzalez[1], A. Guminski[1], O. Nieweg[2], K. Shannon[2], J.F. Thompson[2], R. Kefford[3], S. Ch'Ng[2], J. Stretch[1], A.J. Spillane[2], J. Lee[4], H. Lee[5], R. Kapoor[6], L. Emmett[7], H. Rizos[8], R.P. Saw[2], R.A. Scolyer[9], G.V. Long[1]

[1]Medical Oncology, Melanoma Institute Australia, University of Sydney, North Sydney, Australia, [2]Surgical Oncology, Melanoma Institute Australia, Sydney, Australia, [3]Medical Oncology, Macquarie University, Macquarie Park, Australia, [4]Medical Oncology, Macquarie University, Sydney, Australia, [5]Pathology, Melanoma Institute Australia, Sydney, Australia, [6]Radiology, Royal Prince Alfred Hospital, Sydney, Australia, [7]Nuclear Medicine, St Vincent's Hospital, Sydney, Australia, [8]Biology, Macquarie University, Sydney, Australia, [9]Pathology, Royal Prince Alfred Hospital, Camperdown, Australia

Background: Combination D+T improves the overall survival (OS) of patients (pts) with BRAF V600 mutant advanced melanoma, and an adjuvant trial is in progress (NCT01682083). We sought to explore neoadjuvant D+T for pts with bulky but resectable stage III melanoma.

Methods: In this phase 2 study, 35 pts received standard dose D+T for 12 wks prior to complete resection of the pre-therapy tumour bed (RES), then 40 wks of further D+T. Eligible pts had ECOG PS ≤ 1 with histologically confirmed resectable bulky AJCC v7 stage IIIB/C BRAF V600 mutant melanoma. CT and PET scans were performed at baseline and 12 wks just prior to RES for RECIST and metabolic complete response (rCR and mCR respectively). CT monitoring was continued 12 wkly thereafter to 2 yrs then 6 monthly to 3 yrs. Biopsies were taken at baseline and wk 1. The primary endpoints were the complete pathological response (pCR) and RECIST response rate (rRR) at wk 12. Secondary endpoints were surgical morbidity, mCR, relapse free survival (RFS), OS, toxicity and translational endpoints.

Results: At data cut 18th April 2017, 35 had commenced D+T. 33 had reached RES (27 stage IIIC [8 in-transit only], 6 IIIB; 32 V600E, 1 V600K; 12 LDH >ULN). At RES, 17/33 (52%) had pCR, 16 (48%) had rCR (rRR 88%), and 16 (48%) had mCR. The pathologic response was discordant with RECIST response in 7 (21%) pts and metabolic response in 9 (27%) pts; only 11 (65%) pts with pCR had rCR and mCR. No pt discontinued D+T and no pt progressed during the neoadjuvant period, D+T did not make surgery more difficult in any pt, and in 16 (48%) surgery was deemed easier. Median F/U post RES was 12.1 mo (95% CI 8.8-14.8). 12 (36%) pts had recurred (median 12.9 mo), 4 while on D+T, 6 with prior pCR, 8 at distant sites, and 1 pt had died. 26 (79%) pts developed drug fever. 18 (55%) had ≥ 1 surgical complication post RES; 11 had a wound infection requiring antibiotics, 5 had a seroma, 2 bled. Updated data will be presented including tumour biopsy and and ctDNA biomarker data.

Conclusions: Neoadjuvant D+T has a high response rate and high pCR rate in resectable stage III melanoma. Surgical complication rates were consistent with historic controls and stage of disease.

1221PD (Neo-)adjuvant ipilimumab + nivolumab (IPI+NIVO) in palpable stage 3 melanoma – updated relapse free survival (RFS) data from the OpACIN trial and first biomarker analyses

E.A. Rozeman[1], L. Fanchi[2], A.C.J. van Akkooi[3], P. Kvistborg[2], J.V. Thienen[1], B. Stegenga[4], B. Lamon[5], J.B. Haanen[1], T.N.M. Schumacher[2], C.U. Blank[1]

[1]Medical Oncology Department, Het Nederlands Kanker Instituut Antoni van Leeuwenhoek (NKI-AVL), Amsterdam, Netherlands, [2]Department of molecular oncology and immunology, Het Nederlands Kanker Instituut Antoni van Leeuwenhoek (NKI-AVL), Amsterdam, Netherlands, [3]Surigical Oncology Department, Het Nederlands Kanker Instituut Antoni van Leeuwenhoek (NKI-AVL), Amsterdam, Netherlands, [4]Immuno-oncology, Bristol-Meyers Squibb, Utrecht, Netherlands, [5]Immuno-oncology, Bristol-Myers Squibb, Princeton, NJ, USA

Background: The combination of IPI+NIVO induces high response rates and improved overall survival in late stage melanoma. T cell checkpoint inhibition is of greatest value at the moment of TCR triggering and therefore dependent on the amount of antigen present, indicating that adjuvant immunotherapy will work most efficiently, when initiated prior to surgery.

Methods: Two-arm Phase 1b feasibility trial consisting of 20 high risk AJCC stage 3B/C melanoma patients with palpable nodal disease receiving the combination of IPI 3mg/kg and NIVO 1mg/kg, either adjuvant four courses after surgery, or split neo-adjuvant and adjuvant.

Results: In this update 20 patients are evaluable. Neo-adjuvant application of IPI+NIVO was feasible and no surgery-associated adverse events were attributed to (neo-) adjuvant therapy. 18/20 patients had to stop earlier due to grade 3/4 toxicities. Neo-adjuvant IPI+NIVO reduced tumor load in 8/10 patients (3 pCR, 4 near pCRs [minimal remaining micro metastases], 1 pPR [<50% vital tumor cells], 1 pSD and 1 pPD). So far, none of the responders in the neo-adjuvant arm has relapsed. Relapse was observed for the 2 non-responders within the neo-adjuvant arm and for 3 patients within the adjuvant arm. We will present at ESMO 2017 the 18 months RFS update and in detail the biomarker analyses. Latter comprises RNA sequencing and Nanostring™ microscope spatial profiling to identify biomarkers for response, and TCR sequencing, with the aim to distinguish T cell responses between both, the two treatment arms and between patients relapsing or remaining free of disease.

Conclusions: The combination of IPI+NIVO in the (neo-)adjuvant treatment setting for high risk stage 3 melanoma patients is promising and currently tested in an international phase 2 randomized trial comparing different combination schemes (OpACIN-neo trial, NCT02977052) with the aim of preserving efficacy, but reducing toxicity. Biomarkers identifying patients responding upon neo-adjuvant IPI+NIVO and remaining relapse-free for a long time, will help to select the patients that need to be exposed to IPI+NIVO associated toxicity.

1222PD Regional differences in overall survival (OS) in patients with advanced melanoma (MEL) who received nivolumab (NIVO) combined with ipilimumab (IPI) or NIVO alone in a phase 3 trial (CheckMate 067)

J-J. Grob[1], D. Schadendorf[2], J. Wagstaff[3], I. Márquez-Rodas[4], C. Lebbé[5], P.A. Ascierto[6], F.S. Hodi[7], K. Grossmann[8], J.C. Hassel[9], D. Walker[10], R. Bhore[10], J. Larkin[11], J.D. Wolchok[12]

[1]Dermatology, Hospital de la Timone, Marseille, France, [2]Department of Dermatology, University of Essen, Essen, Germany, [3]Medical Oncology, South West Wales Cancer Institute, Singleton Hospital, Swansea, UK, [4]Servicio de Oncología Médica, Hospital General Universitario Gregorio Marañón, Madrid, Spain, [5]APHP Dermatology and CIC Departments, Hôpital Saint-Louis, INSERM U976, Université Paris Diderot, Paris, France, [6]Department of Medical Oncology, Istituto Nazionale Tumori Fondazione Pascale, Naples, Italy, [7]Medical Oncology, Dana–Farber Cancer Institute, Boston, MA, USA, [8]Oncology, Huntsman Cancer Institute, Salt Lake City, UT, USA, [9]Department of Dermatology and NCT, University Hospital Heidelberg and National Center for Tumor Diseases, Heidelberg, Germany, [10]Oncology, Bristol-Myers Squibb, Princeton, NJ, USA, [11]Department of Medical Oncology, Royal Marsden Hospital, London, UK, [12]Oncology, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY, USA

Background: NIVO+IPI and NIVO significantly improved PFS and OS vs. IPI alone in the CheckMate 067 study. Descriptively, NIVO+IPI showed longer OS than NIVO (hazard ratio: 0.88), with 2-year OS rates of 64% and 59%, respectively. Post-hoc analyses by region were performed to evaluate potential differences between patients (pts) treated in the EU and those treated in the USA.

Methods: Baseline patient characteristics, safety and efficacy were evaluated in the two highest enrolling regions (EU, 55% and USA, 22%) using data from the CheckMate 067 study. Minimum follow-up of the pts was 28 months.

Results: EU pts were more likely to have M1c disease than USA pts (60% vs 53%), and more likely to have *BRAF* wild-type (WT) tumors (69% vs 59%). In a multivariate analysis, which adjusted for baseline factors, the only significant interaction between NIVO+IPI and NIVO was by region. Adjusted hazard ratios (HRs) for OS in the NIVO+IPI vs NIVO groups were 0.90 (0.66–1.23) for the EU and 0.53 (0.29–0.98) for the USA. Across all arms, 2-year OS rates were lower in the EU vs USA pts, particularly for pts with *BRAF* WT tumors (Table). In pts with *BRAF* mutant tumors, similar OS outcomes were observed between regions. Treatment exposure, safety, management of adverse events, and use of subsequent therapies did not differ substantially between the two regions. Objective response rates and progression-free survival were also similar between the two regions.

Conclusions: Differences in OS between the EU and the USA appear to be largely due to poorer survival outcomes in EU pts with BRAF WT tumors, which likely impacted OS differences between NIVO+IPI and NIVO in the overall population. Additional analyses by region, the first report of 3-year OS, as well as analyses by tumor mutational burden will be presented. Acknowledgement: J. Larkin and J.D. Wolchok contributed equally to this study.

1223PD Quality-adjusted survival of combined nivolumab plus ipilimumab (NIVO+IPI) or NIVO alone vs IPI among treatment-naïve patients (pts) with advanced melanoma (MEL): a quality-adjusted time without symptoms or toxicity (Q-TWiST) analysis

M. Botteman[1], R. Shah[1], K. Gupte-Singh[2], L. Luo[1], J. Sabater[2], S. Rao[2], D.F. McDermott[3], M.B. Atkins[4], M. Regan[5]

[1]*Global Health Economics and Outcomes Research, Pharmerit International, Inc, Bethesda, MD, USA,* [2]*Health Economics Outcomes Research, Bristol-Myers Squibb, Princeton, NJ, USA,* [3]*Oncology, Beth Israel Deaconess Medical Center, Boston, MA, USA,* [4]*Oncology, Lombardi Cancer Center Georgetown University, Washington, DC, USA,* [5]*Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, USA*

Background: We compared quality-adjusted survival (OS) of combined NIVO+IPI or NIVO alone vs IPI among treatment-naïve pts with advanced MEL enrolled in the CheckMate 067 trial.

Methods: The Q-TWiST approach was used to partition OS into 3 health states: time without disease progression or symptoms of toxicity (TWiST), time with grade ≥3 treatment-related AE toxicity after randomization but before progression (TOX), and time after progression (REL). Q-TWiST was calculated by multiplying mean time spent in each state at 36 months (mos) by their utility (TWiST=1.0, TOX=0.5, and REL=0.5). Q-TWiST differences were assessed at various times ranging from 3 to 36 mos. A ≥ 15% relative Q-TWiST gain (vs mean IPI OS) was considered clearly clinically important.

Results: Compared with IPI, NIVO+IPI pts had longer (difference in mean mos, 95% CI) TWiST (9.6, 7.4 to 11.7) and TOX (0.3, 0.1 to 0.4) but shorter REL time (-5.2, -7.1 to -3.2). Compared with IPI, NIVO pts had a longer TWiST (7.3, 5.0 to 9.6), shorter REL time (-3.4, -5.5 to -1.3), and shorter TOX (-0.1, -0.2 to 0.1). Q-TWiST was highest for NIVO+IPI, followed by NIVO, and IPI (Table). Relative Q-TWiST gains were also favorable for NIVO+IPI (+34.0% v IPI) and NIVO (+26.4% v IPI) and increased as follow-up increased from 3 to 36 months for all comparisons.

Conclusions: At 36 months, NIVO and NIVO+IPI pts had a clinically important improvement in Q-TWiST vs IPI. As these benefits continue to accrue over time, future analyses with longer follow-up are planned.

Table: 1223PD

Mean (95% CI) time, mos

	NIVO+IPI (n = 314)	NIVO (n = 316)	IPI (n = 315)
TOX	0.6 (0.4 to 0.7)	0.2 (0.1 to 0.3)	0.3 (0.2 to 0.4)
TWiST	19.1 (17.4 to 20.8)	16.8 (15.1 to 18.5)	9.5 (8.1, 10.9)
REL	6.1 (4.7 to 7.6)	7.9 (6.5 to 9.3)	11.3 (9.8 to 12.8)
Q-TWiST	22.4 (21.0 to 23.9)	20.9 (19.4 to 22.3)	15.3 (14.1 to 16.5)

Background: Treatment with checkpoint inhibitors can result in durable responses and deepening of responses over time with conversion of SD to PR or CR, and PR to CR. In the randomized KEYNOTE-002 study (NCT01704287), pembro 2 mg/kg or 10 mg/kg improved PFS (HR 0.57 and 0.50; $P<0.0001$ for both) vs chemo in pts with ipi-refractory melanoma. In this post hoc analysis, we assessed evolution of response and survival for 361 pembro-treated pts.

Methods: Pts were treated until disease progression (PD), unacceptable toxicity or investigator/pt decision. Response (RECIST v1.1; investigator review) was assessed at wk 12, every 6 wk until wk 48, then every 12 wk, and confirmed by subsequent scan. Survival was assessed every 12 wk during follow-up. Pembro arms were combined given no difference in efficacy of doses.

Results: As of 3 Feb 2017, median follow-up duration was 42.7 mo. In pembro-treated pts, median PFS was 4.2 mo (95% CI 3.3-5.6), and 36-mo PFS rate was 16%. Median OS was 14.0 mo (11.8-16.2), and 36-mo OS rate was 30%. 99 of 361 pts had CR (n = 29) or PR (n = 70) for ORR of 27.4% (95% CI 22.9-32.3); 88 pts had SD. Median time to response was 2.9 mo. Of 29 pts with CR, 5 converted from SD, 21 from PR. Of 70 pts with PR, 28 converted from SD. Median time from SD to PR was 2.7 mo (range 0.9-25.2), from SD to CR was 6.9 mo (3.9-21.9), and from PR to CR was 8.0 mo (1.4-25.2). Median DOR was not reached in pts with CR or PR (Table). Median duration of SD was 6.9 mo (range 0.8+ to 38.8+). 9 (31%) pts with CR, 28 (40%) with PR and 63 (72%) with SD had subsequent PD; in these pts, median duration of CR was 17.1 mo (5.5-36.1), PR 7.7 mo (2.0-31.8), and SD 5.8 mo (2.7-25.3). Median PFS and OS were longer in pts with CR or PR (Table).

Conclusions: Responses to pembro are durable and associated with prolonged OS in ipi-refractory melanoma. Even in these heavily pretreated pts best response can evolve over time, with late conversions from SD to PR/CR and PR to CR observed.

Background: Imaging with FDG-PET allows early recognition of metabolic response to targeted agents. We evaluated the timing of complete metabolic response (CMR) on PET as a predictor of clinical outcome in BRAF V600 mutant melanoma patients treated with vemurafenib and cobimetinb, as part of the BRIM-7 trial.

Methods: BRAF inhibitor naïve patients from BRIM-7 were included if they had evaluable PET scans at baseline, in cycle 1 (C1) (D10-15) and in C2 (D35-49). Metabolic response was evaluated by percentage injected dose (%ID). 52 of 63 BRAF-naïve patients were eligible for analysis (3 excluded - no C1 scan; 6 no C2 scan; 2 unevaluable scans due to excessive physiological muscle uptake). The primary aim was to evaluate the prognostic significance of an early CMR to combination vemurafenib and cobimetinib therapy. We divided patients into 3 groups, based on timing of CMR attainment.

Results: 13 patients achieved CMR in cycle 1 (CMR1), 15 patients achieved CMR in cycle 2 (CMR2) and 24 patients did not achieve CMR within the first 2 cycles of treatment (noCMR). The median, 2 year and 3 year progression free survival (PFS) and overall survival (OS) of the 3 above groups are summarized in Table.

Table: 1224PD

Outcomes	CR (n = 29)	PR (n = 70)	SD (n = 88)	All-treated (N = 361)
Median time to response*, mo (range)	2.9 (2.4-24.9)	2.9 (1.9-27.9)	–	2.9 (1.9-27.9)
Median DOR, mo (range)	NR (5.5-41.6+)	NR (1.9+ to 43.5+)	6.9 (0.8+ to 38.8+)†	NR (1.9+ to 43.5+)
Median PFS, mo (95% CI)	41.0 (38.9-NR)	35.8 (27.9-NR)	7.0 (5.8-9.7)	4.2 (3.3-5.6)
12/24/36-mo PFS rate‡	97%/75%/72%	76%/66%/49%	24%/6%/1%	29%/21%/16%
Median OS, mo (95% CI)	NR (NR-NR)	NR (NR-NR)	16.5 (13.8-20.5)	14.0 (11.8-16.2)
12/24/36-mo OS rate‡	100%/93%/89%	96%/86%/71%	71%/31%/24%	55%/37%/30%

*Best overall response with confirmation;
†Duration of SD;
‡Kaplan-Meier method for censored data; CI, confidence interval; NR, not reached

Table: 1225PD

	CMR1	CMR2	No CMR
Median PFS (yrs)	Not reached	1.1	1.0
2 yr PFS (%, 95% CI)	83.9 (65.7-100)	13.3 (3.7-48.4)	37.5 (22.4-62.9)
3 yr PFS (%, 95% CI)	71.9 (48.8-100)	13.3 (3.7-48.4)	18.8 (7.9-44.5)
Median OS (yrs)	Not reached	2.4	2.5
2 yr OS (%, 95% CI)	84.6 (67.1-100)	63.0 (41.5-95.8)	58.3 (41.6-81.8)
3 yr OS (%, 95% CI)	74.0 (52.2-100)	21.0 (6.3-70.2)	30.9 (16.5-57.9)

Patients achieving CMR1 had significantly better outcome than patients achieving CMR2 in terms of PFS (HR 0.18, 95% CI 0.05-0.62) and OS (HR 0.23, 95% CI 0.06-0.85). Similar results were observed comparing CMR1 over no CMR in PFS (HR 0.19, 95% CI 0.06-0.64) and in OS (HR 0.25, 95% CI 0.07-0.87). There was no difference between the CMR2 and noCMR groups in terms of PFS or OS.

Conclusions: Attainment of CMR on an early D10-14 PET was highly predictive of long-term survival with BRAF and MEK inhibition. However, attainment of CMR at a later time point at D35-49 did not appear predictive of a survival benefit. In fact, no difference in PFS or OS could be observed in patients who achieved CMR at D35-49, compared to those patients who did not attain CMR. Correlative science analysis to investigate the mechanism of these observations are underway.

N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation, [8]Department of Dermatology, Elbeklinikum Buxtehude, Buxtehude, Germany, [9]Department of Dermatology and NCT, University Hospital Heidelberg and National Center for Tumor Diseases, Heidelberg, Germany, [10]Department of Soft Tissue/Bone Sarcoma and Melanoma, The Maria Sklodowska-Curie Memorial Institute and Oncology Centre, Warsaw, Poland, [11]Department of Dermatology, University Hospital Zürich-Dermatology, Zurich, Switzerland, [12]Dermatooncology, German Cancer Research Center, Heidelberg, Germany, [13]Clinic of Dermatology, Charité University Hospital, Berlin, Germany, [14]Skin Unit, Royal Marsden Hospital, London, UK, [15]Global Oncology, Novartis Pharmaceuticals Corporation, East Hanover, New Jersey, NJ, USA, [16]Department of Medicine, Gustave Roussy and INSERM Unité 981, Villejuif–Paris Sud, France

Background: BRAF mutations are found in 50% of patients (pts) with advanced melanoma. Previously, the METRIC trial (NCT01245062) demonstrated that the MEK inhibitor trametinib (T) increased PFS in this population of patients with a clinical benefit that could last ≥ 2 yrs in some pts. We report findings from the 5-year follow-up analysis

Methods: METRIC is an open-label, randomized Ph3 study of pts who received ≤ 1 prior regimen of chemotherapy (C) for histologically confirmed unresectable stage IIIC or IV cutaneous BRAF V600E/K–mutant metastatic melanoma (MM). Pts were randomized (2:1) to T (2 mg/day) or intravenous C (dacarbazine [1000 mg/m^2] or paclitaxel [175 mg/m^2] every 3 wks). Pts were stratified according to baseline lactate dehydrogenase level and previous C for advanced disease. Pts who progressed on C were allowed to crossover and receive T. The primary endpoint was progression-free survival (PFS); secondary endpoints included overall survival (OS), duration of response and safety.

Results: 322 pts (V600E: 281, 600K: 40, V600E/K mutation: 1) were enrolled (T: 214; C: 108). At data cutoff (Dec 16, 2016), median follow-up was 12.3 months (mo). The median OS for the T arm was 15.6 mo vs 11.3 mo for the C arm (HR = 0.84 [95% CI, 0.63–1.11], P = 0.19). Landmark OS for the T arm vs the C arm at 1, 2, 3, and 5 yrs were 60.9% vs 49.6%; 32.0% vs 29.4%; 20.6% vs 22.6%; and 13.3% vs 17.0%, respectively. Most pts (n = 70, 65%) in the C arm crossed over and received T. Median time to crossover was 3.1 (1–20) mo; median duration of follow-up after crossover was 8.8 (0–67) mo. Among pts who received post-tx anti-cancer therapy (n = 208), most received targeted therapy (n = 118), immunotherapy (n = 90), or C (n = 84). No new safety signals were observed.

Conclusions: This is the longest reported follow up for T monotherapy in pts with BRAF V600E/K–mutant MM and demonstrates that some of these pts experience long-term benefit with targeted therapy. Pts with extended follow-up after initiation of T, contributed to long-term survival for those randomized to the C arm.

Lee Moffitt Cancer Center and Research Institute, Inc, Tampa, FL, USA, [3]Department of Dermatology and NCT, Universitaetsklinikum Heidelberg, Heidelberg, Germany, [4]APHP Dermatology and CIC Departments, Hôpital Saint-Louis, INSERM U976, Université Paris Diderot, Paris, France, [5]Department of Medicine, Hematology/Oncology, University of California Los Angeles, Jonsson Comprehensive Cancer Center, Los Angeles, CA, USA, [6]Head and Neck Cancer, Dana Farber Cancer Institute, Boston, MA, USA, [7]Department of Dermatology, University of Lübeck, Lübeck, Germany, [8]Dermatology, National Cancer Institute, Bethesda, MD, USA, [9]Biostatistics, Merck KGaA, Darmstadt, Germany, [10]ImmunoOncology, Global Clinical Development, Merck Serono SIA, Riga, Latvia, [11]Global Clinical Development, Immuno-Oncology, EMD Serono Research Center, Billerica, MA, USA, [12]Surgical Oncology, Rutgers Cancer Institute of New Jersey Rutgers, The State University of New Jersey, New Brunswick, NJ, USA

Background: MCC is a rare, aggressive skin cancer. In a phase 2 study of patients with mMCC progressed on or after chemotherapy (JAVELIN Merkel 200; NCT02155647), avelumab (a human anti–PD-L1 antibody) showed durable responses and a manageable safety profile, including an objective response rate (ORR) of 33.0%, proportion of responses with ≥1-year duration of 74% (Kaplan-Meier estimate), and estimated 1-year overall survival (OS) rate of 52%. Based on these results, avelumab was approved by the US FDA in March 2017 and is the only approved treatment for patients with mMCC. Here, we report early interim results from patients with mMCC receiving first-line avelumab.

Methods: Eligible patients with mMCC and no prior systemic treatment for metastatic disease received avelumab 10 mg/kg Q2W. Tumors were assessed every 6 weeks (RECIST v1.1) by independent review committee (IRC). Adverse events (AEs) were assessed by NCI CTCAE v4.0.

Results: At data cutoff on Dec 30, 2016, 29 of 112 planned patients had been enrolled. Median follow-up was 3.1 months (range 0.3–8.5) and median duration of treatment was 8.1 weeks (range 2.0–37.9). Of 16 patients with ≥13 weeks of follow-up, confirmed ORR by IRC was 62.5% (95% CI 35.4–84.8) with response ongoing in all 10 patients, including in all 5 patients with ≥6 months of follow-up. Of 25 patients with ≥6 weeks

of follow-up, unconfirmed ORR by IRC was 68.0% (95% CI 46.5–85.1); responses were ongoing at last follow-up in 16 of 17 responders (94.1%; 1 censored due to other therapy). 23 of 29 patients (79.3%) had a treatment-related AE (TRAE), including 5 (17.2%) with a grade 3 or 4 TRAE. There was 1 immune-mediated TRAE (grade 1 rash). 5 patients (17.2%) discontinued avelumab due to a TRAE. There were no treatment-related deaths. Updated analyses of 39 patients will be presented (n = 29 and n = 14 with ≥13 weeks and ≥6 months of follow-up, respectively; data cutoff Mar 24, 2017), including PFS and OS analyses.

Conclusions: First-line avelumab treatment resulted in early responses and a high ORR in distant mMCC, substantiating prior findings with second-line or later avelumab treatment. Most responses were ongoing, including all responders with ≥6 months of follow-up. Enrollment is ongoing.

1228P Long-term effects of sonidegib on tumor burden: 30-month results from the phase 2 randomized bolt trial

R. Dummer[1], M. Migden[2]

[1]*Dermatology, University of Zurich Hospital, Zurich, Switzerland,* [2]*Medical Affairs, MD Anderson Cancer Center, Houston, TX, USA*

Background: Sonidegib, a hedgehog pathway inhibitor (HPI), is approved in the United States and European Union for locally advanced basal cell carcinoma (laBCC) based on primary results from the BOLT trial (Migden, *Lancet*, 2015). Updated data from 30-months analysis demonstrated continued efficacy and manageable safety (Dummer ASCO 2016). Here we present 30-month tumor burden results, which have not previously been presented or published.

Methods: Eligible HPI-treatment-naïve patients with laBCC not amenable to curative surgery/radiotherapy or patients with metastatic BCC (mBCC) were randomized 1:2 to receive sonedegib 200 or 800 mg QD. For all patients, tumor burden was assessed as decrease of best percentage change from baseline by central review. For patients with laBCC, tumor lesions were assessed by photography and modified RECIST criteria; for patients with mBCC, photography or MRI/computed tomography (CT) and RECIST 1.1 were used.

Results: Evaluable patients at 30 months were from the primary efficacy analysis set (pEAS) for laBCC patients (200 mg, n = 32; 800 mg, n = 74) and mBCC patients (200 mg, n = 12; 800 mg, n = 19). Consistent with the primary, 12- and 18-month analyses, 96.9% (n = 31) and 94.6% (n = 70) of patients with laBCC experienced a substantial reduction in tumor size with sonidegib 200 and 800 mg, respectively. Reduction in target lesions for patients with mBCC receiving 200 mg was 91.7% (n = 11) across all time points; for the 800 mg group, 84.2% (n = 16) of patients experienced reduction in tumor lesions in the primary, 12-, 18-month analyses and 89.5% (n = 17) at 30 months. Sonidegib 200 mg had a more favorable safety profile compared to 800 mg, with lower rates of grade 3/4 adverse events (AEs; 43.0% vs 64.0%) and AESs events leading to discontinuation (30.4% vs 40.0%).

Conclusions: Sonedegib 200 and 800 mg in patients with laBCC and mBCC demonstrated substantial target tumor lesion reduction across 30 months. Safety/tolerability was manageable and similar across 30 months with no new side effects emerging following the primary analysis.

1230P Modulation of Risk and Prognosis of Cutaneous Melanoma Patients by Genetic Polymorphisms on PDCD1 Gene

G.V.B. Gomez[1], J.A. Rinck-Junior[1], D.H.L. Da Silva[2], R.L. Mamoni[2], G.J. Lourenço[1], A.M. Moraes[1], C.S.P. Lima[1]

[1]*Department of Internal Medicine, University of Campinas, Campinas, Brazil,* [2]*Department of Clinical Pathology, University of Campinas, Campinas, Campinas, Brazil*

Background: This study aimed to evaluate whether PD1.1 (c.-606G>A), PD1 (c.627 + 252C>T), PD1.5 (c.804C>T) and PD1.9 (c.644C>T) single nucleotide polymorphisms (SNPs) on *PDCD1* gene influence risk, clinicopathological aspects and survival of patients with cutaneous melanoma (CM).

Methods: We evaluated 250 CM patients diagnosed at the University of Campinas and 250 blood donors (controls). DNA was analyzed by real-time polymerase chain reaction (PCR) for genotyping. *PDCD1* gene expression and PD1 protein expression were assessed by quantitative PCR and flow cytometry, respectively. The statistical significance of differences between groups was calculated using the Fisher's exact or chi-square test. Bonferroni method was used in multiple comparisons. *PDCD1* expression and PD1 expression on T lymphocytes were calculated, using Kruskal-Wallis and Mann-Whitney test, respectively. The prognostic impact of SNPs on recurrence-free survival (RFS) and overall survival (OS) of CM patients were examined using the Kaplan Meier and Cox analyses.

Results: Individuals with PD1 CC genotype isolated and associated with PD1.5 CC genotype were under 2.20 (95% CI: 1.00-4.82, $P = 0.04$) and 2.51 (95% CI: 1.04-6.03, $P = 0.03$) times greater risks of developing CM, respectively. Individuals with phototype I or II and PD1 CC genotype or PD1 CC plus PD1.5 CC genotype had 5.89 and 6.71 more chances of presenting CM than others, respectively. PD1.5 TT genotype was associated with increased expression of *PDCD1* gene when compared with CT or CC genotype ($P = 0.03$). PD1.5 CT or TT genotypes and T allele increased expression of PD1 protein in $CD4^+$ lymphocytes ($P = 0.01$, $P = 0.006$; respectively). At 60 months of follow-up, shorter RFS was observed in patients with PD1.1 AA genotype (33.3% *vs* 72.5%, $P = 0.02$). Patients with PD1.1 AA genotype had 4.39 more chances of presenting tumor progression or relapse in univariate Cox analysis ($P = 0.04$) and patients with PD1.5 CC genotype had 2.38-fold increased risk of evolving to death in multivariate Cox analysis ($P = 0.02$).

Conclusions: The data suggest, for the first time, preliminary evidence that inherited abnormalities in regulation of T lymphocyte activities, related to PD1.1, PD1 and PD1.5 SNPs, alter CM risk and prognosis.

1231P Role of an intronic polymorphism in the CREB1 gene, involved in melanogenesis, with the risk and the aggressiveness of cutaneous melanoma

J.K. Silva[1], C. Oliveira[1], B. Sá Carvalho[2], C. Torricelli[1], G.V.B. Gomez[1], W.D.L. Oliveira[1], J.A. Rinck-Junior[3], A.M. Moraes[3], M.M. Ortega[4], C.S.P. Lima[3], G.J. Lourenço[1]

[1]*Laboratory of Cancer Genetics, Faculty of Medical Sciences, Universidade Estadual de Campinas-UNICAMP, Campinas, Brazil,* [2]*Department of Statistics, Institute of Mathematics, Statistic and Computer Science, Universidade Estadual de Campinas-UNICAMP, Campinas, Brazil,* [3]*Department of Internal Medicine, Faculty of Medical Sciences, Universidade Estadual de Campinas-UNICAMP, Campinas, Brazil,* [4]*Laboratory of Cell and Molecular Tumor Biology and Bioactive Compounds, São Francisco University, Bragança Paulista, Brazil*

Background: Recently, we observed 12,882 new single nucleotide polymorphisms (SNPs) associated with cutaneous melanoma (CM) risk in 103 patients and 103 controls, using large-scale genotyping with microarrays. CREB1 c.303 + 373G>A, involved in melanogenesis and located in regulatory sequence of mRNA processing (splicing), was selected for further analyses. An in silico analysis showed that referred SNP may alters the binding sites of splicing regulatory proteins, such as SF1 and hnRNP A1. However, the role of this SNP in the risk, aggressiveness and prognosis of CM is unknown. Verify whether the distinct genotypes of CREB1 c.303 + 373G>A influence the CM risk and prognosis, clinicopathological aspects, and CREB1, SF1 and HNRNPA1 mRNA levels.

Methods: Genomic DNA of 262 patients and 280 controls was analyzed by RT-PCR. Patients were treated with conventional procedures. Gene expressions were determined

by qPCR using total RNA of 56 controls. Chi-square, logistic regression model, Mann-Whitney and Student's t tests analyzed the differences between groups. Progression-free survival (PFS) and overall survival (OS) times were calculated using Kaplan-Meier and Cox regression analyses.

Results: CREB1 GA or AA genotypes were more frequent in CM patients than in controls (72.0% vs. 61.1%, P = 0.02). Carriers of the genotypes were under 1.61-fold increased risk of CM (95% CI: 1.07-2.41) than others. An excess of CREB1 AA variant genotype was seen in patients with Breslow's thickness higher than 1.5mm (28.2% vs. 18.5%, P = 0.04) and high Clark's level (26.2% vs. 13.3%, P = 0.02). The median of follow-up of CM patients was 76 months; no association of referred SNP and patients' PFS and OS was observed in this study. Individuals with CREB1 GA or AA genotypes presented higher mRNA expression of CREB1 (0.94 vs. 0.60 arbitrary units (UAs), P = 0.007), SF1 (1.33 vs. 1.05 UAs, P = 0.03) and HNRNPA1 (0.77 vs. 0.57 UAs, P = 0.02) than those with GG wild-type genotype.

Conclusions: Our data suggest, for the first time, that CREB1 c.303 + 373G>A SNP is an important hereditary factor for the risk and aggressiveness of CM, possibly due to variation of the splicing factors.

1232P Investigation of AMBRA1 as a melanoma susceptibility gene

V. Hoeiom[1], M. Yang[1], K. Nosrati[1], A. Azimi[2], S. Egyhazi Brage[1], R. Tuominen[1]

[1]Oncology and Pathology, Karolinska Institutet, Stockholm, Sweden, [2]Oncology-Pathology, Karolinska Institutet, Stockholm, Sweden

Background: Melanoma is the most lethal form of skin cancer, which shows a rapid increase in incidence in many countries including Sweden. To date, the annual increase is over 5% and there is an urgent need to improve possibilities for prevention and early diagnoses when the prognosis is far favorable compared to disseminated disease. Melanoma is caused by an interplay of environmental and genetic factors and is one of the cancer forms showing highest heritability. Still a substantial extent of the genes underlying melanoma susceptibility is unknown.

Methods: We have executed whole-exome sequencing of melanoma-prone families to identify novel melanoma predisposing genes. Further genetic and functional studies of strong candidate genes using patient samples and melanoma cell lines has been performed. Various in vitro assays have been used to determine the role of these genes in for example autophagy and cell proliferation.

Results: One gene discovered was the autophagy/beclin-1 regulator 1 (AMBRA1), where a putative splice variant was co-segregating with the melanoma phenotype in a 4-case family. This mutation was not found among over 6000 Swedish population-based controls nor in any additional melanoma patients. AMBRA1 is essential in the regulation of autophagy and apoptosis and has been suggested to function as a tumor suppressor. By gene expression analysis we identified several transcripts of AMBRA1, with differential expression in melanoma tumors and in various melanoma cell lines. In tumor material from the splice variant carrier AMBRA1 showed low levels of expression. In melanoma cell lines, AMBRA1 was up-regulated when adding an autophagy activating reagent while down-regulated when treating the cells with Chloroquine, a drug inhibiting autophagy. AMBRA1 was also significantly up regulated when treating the cells with Crizotinib, a drug that targets the tyrosine kinase receptor c-MET and may induce autophagy, whereas no effect was seen when using the BRAF-inhibitor Vemurafenib. Thus, AMBRA1 may be involved in the Crizotinib-induced autophagy pathway.

Conclusions: Preliminary data suggest AMBRA1 as a candidate melanoma susceptibility gene with a role during autophagy in melanoma cells. Further studies are needed to elucidate the specific role of this gene in melanoma development.

1233P Influence of an intronic polymorphism in the MITF gene, of melanogenic pathway, in the risk and the prognosis of cutaneous melanoma

C. Torricelli[1], C. Oliveira[1], B. Sá Carvalho[2], J.K. Silva[1], G.V.B. Gomez[1], W.D.L. Oliveira[1], J.A. Rinck-Junior[3], A.M. Moraes[3], M.M. Ortega[4], C.S.P. Lima[3], G.J. Lourenço[1]

[1]Laboratory of Cancer Genetics, Faculty of Medical Sciences, University of Campinas, Campinas, Brazil, [2]Department of Statistics - Institute of Mathematics, Statistics and Computer Science, University of Campinas, Campinas, Brazil, [3]Department of Internal Medicine, University of Campinas, Campinas, Brazil, [4]Laboratory of Cell and Molecular Tumor Biology and Bioactive Compounds, São Francisco University, Bragança Paulista, Brazil

Background: We identified more than 12,000 new single nucleotide polymorphisms (SNPs) associated with cutaneous melanoma (CM) risk in 103 patients and 103 controls, using large-scale genotyping with DNA microarrays. A bioinformatics analysis showed that MITF c.938-325G>A SNP, involved in melanogenesis and located in regulatory sequence of mRNA processing (splicing), may alter the binding sites of splicing proteins, such as SF1 and hnRNP A1. However, the role of this SNP in the risk and prognosis of CM patients is still unknown. We aim to evaluate the influence of this SNP on the risk and prognosis of CM, clinical and tumor characteristics, and MITF, SF1 and HNRNPA1 levels.

Methods: MITF genotypes of 262 CM patients and 280 controls were identified in DNA by RT-PCR. Patients were treated with conventional protocols. Gene expressions were evaluated by qPCR using RNA of 73 controls. The differences between groups were assessed by chi-square, logistic regression, t test and ANOVA. Progression-free (PFS) and overall survival (OS) times were estimated by Kaplan-Meier and Cox methods.

Results: The frequency of the AA variant genotype was higher in patients than in controls (26.8% vs. 21.1%, P = 0.03). Individuals with referred genotype were under 1.60-fold increased risk of CM (95% CI: 1.02-2.52) than others. The frequency of GA or AA genotypes was more common in patients with lower phototype (I-III) (90.8% vs. 80.9%, P = 0.04) and with vertical tumors (83.7% vs. 67.5%, P = 0.04). The median of follow-up was 76 months. At 60 months, PFS (53.4% vs. 71.6%, P = 0.005, Cox: HR: 1.84, P = 0.006) and OS (76.2% vs. 82.4%, P = 0.02, Cox: HR: 1.79, P = 0.03) were shorter in patients with AA genotype than others. We observed similar frequencies of MITF (1.2 vs. 1.1 vs. 1.0 arbitrary units (AUs), P = 0.30), SF1 (1.1 vs. 1.2 vs. 1.0 AUs, P = 0.94) and HNRNPA1 (1.1 vs. 1.3 vs. 1.3 AUs, P = 0.61) mRNA levels in individuals with distinct genotypes.

Conclusions: Our results suggest, for the first time, that MITF c.938-325G> SNP is an important inherited factor for the risk and prognosis of CM. Our findings, once validated in additional studies, will contribute to personalize the therapy of CM patients.

1234P Hybrid-capture based genomic profiling identifies BRAF V600 and non-V600 alterations in melanoma samples negative by prior testing

L. Boussemart[1], A. Wang[2], M.K.K. Wong[3], J.S. Ross[4], P.J. Stephens[5], S.M. Ali[6], J. Sosman[7], J.M. Mehnert[8], G. Daniels[9], K. Kendra[10], A.B. Schrock[6], V.A. Miller[11]

[1]Department of Dermatology, Pontchaillou Hospital, CHU de Rennes, Rennes, France, [2]Clinical Development, Foundation Medicine, Inc., Cambridge, MA, USA, [3]Department of Melanoma Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA, [4]Pathology, Albany Medical Center, Albany, NY, USA, [5]R & D, Foundation Medicine, Cambridge, MA, USA, [6]Clinical Development, Foundation Medicine, Cambridge, MA, USA, [7]Oncology, Northwestern University, Chicago, IL, USA, [8]Division of Medical Oncology, The Cancer Institute of New Jersey, New Brunswick, NJ, USA, [9]Medicine, University of California San Diego, La Jolla, CA, USA, [10]Oncology, The Ohio State University, Columbus, OH, USA, [11]Medical Affairs, Foundation Medicine, Cambridge, MA, USA

Background: BRAF and MEK inhibitors are approved for V600-mutated melanoma, and response rates of up to 70% are seen for patients with V600 mutations. Responses to targeted therapies have also been observed for a variety of non-V600 BRAF alterations. Thus, sensitive, accurate, and broad detection of BRAF alterations is critical to match patients with available targeted therapies.

Methods: Pathology reports were reviewed for 385 consecutive melanoma cases (Mar 2016 - Mar 2017) with BRAF mutations or rearrangements identified using a hybrid-capture based next generation sequencing (NGS) assay during the course of clinical care.

Results: Records of prior BRAF molecular testing were available for 79 (21%) cases, utilizing PCR (n = 30), Sanger sequencing (n = 13), IHC (n = 10), non-hybrid capture based NGS (n = 9), or other or unspecified methodology (n = 17). Of cases with BRAF V600 mutations 11/57 (19%) with available data were negative by prior BRAF testing, including 2/11 (18%) with confirmation that the same biopsy was tested. In cases with BRAF V600 mutations, there was no significant difference in mutant allele frequencies (median 35% vs. 40%, p = 0.25) or percentage of tumor nuclei (median 50% for both, p = 0.97) between samples with prior negative and prior positive results. Prior negative results were also identified in 16/20 (80%) cases with non-V600 mutations, two of which harbored multiple BRAF alterations [K601E (4), D594A/G/N (4), S467L (2), L584F (2), G464V, G466V, G469V, E586K, N581I, L597Q, A589_T599insT]. Two of 2 (100%) cases with activating BRAF fusions also had prior negative BRAF results. Clinical outcomes for a subset of patients will be presented.

Conclusions: Despite approved companion diagnostics, significant variability exists in methods for BRAF testing in the clinical setting. Hybrid-capture based NGS identifies diverse activating mutations and fusions, including BRAF V600E, in a significant fraction of cases for which prior BRAF testing returned negative results. Given the proven clinical benefit in patients with BRAF alterations treated with match targeted therapies, hybrid-capture based NGS should be considered for patients with metastatic melanoma, particularly if other testing is negative.

1235P Post-transcriptional regulation of immune checkpoint genes by mir-16 in melanoma

R. Leibowitz-Amit[1], A. Layani[2], J. Roszik[3], Y. Sidi[2], D. Avni[2], E. Grimm[4]

[1]Oncology, Chaim Sheba Medical Center, Ramat Gan, Israel, [2]Cancer research center, Chaim Sheba Medical Center, Ramat Gan, Israel, [3]Genomic medicine, MD Anderson Cancer center, Houston, TX, USA, [4]Melanoma medical oncology, MD Anderson Cancer center, Houston, TX, USA

Background: The complex interface between T lymphocytes and cancer ('the immunological synapse') comprises of both co-stimulatory and co-inhibitory proteins that modulate lymphocytes towards activation or anergy. 'Checkpoint inhibitors' have impressive activity in melanoma, but not all patients respond and drug resistance often develops. MiRNAs are master regulators of gene expression. Our aim is to study the regulation of the immunological synapse by miRNAs in melanoma.

Methods: Bioinformatic analyses of mRNAs and miRNA expression in 451 samples from the melanoma TCGA database was performed. Spearman rho correlation coefficients were calculated and survival analysis was performed using the Kaplan-Meier method. Direct mRNA targets of miRNAs were found using luciferase reporter assays, and mRNA/miRNA expression was assessed by qRT-PCR following either ectopic expression or depletion of specific miRNAs.

Results: Of 15 checkpoint mRNAs and 8 miRNAs examined, nine checkpoint mRNAs showed a highly statistically significant positive correlation to each other and, to a lesser extent, to mir-16. These results were fully corroborated in vitro. Mir-16 may potentially target the 3'UTR of 3 of these mRNAs. CD80 (B7.1) was found to a direct target of mir16 in vitro. Overexpression of mir-16 in melanoma cell lines led to downregulation of CD80, CD274 (PD-L1) and CD40, while downregulation of mir-16 increased the expression of these genes. Survival data from 163 stage III melanoma patients show that high levels of mir-16 and low levels of any of six checkpoint mRNAs (among them CD80) is significantly associated with poor prognosis.

Conclusions: Our results suggest that mir-16 and many checkpoint mRNAs are generally under a strict joint transcriptional regulation. The ability of mir-16 to decrease CD80 expression suggests that it serves as a key regulator of the immunological sample. We hypothesize that in vivo, an aberrantly high expression of mir-16 decreases the expression of the co-stimulatory checkpoint CD80 in melanoma and other checkpoint mRNAs, leading to immune evasion and compromised outcome. Further elucidation of both the transcriptional and post-transcriptional regulation of the immunological synapse may help point to novel targets and means for immune modulation.

1236P Does melanoma or other skin cancers belong to the BRCA2 phenotype?

R. Vitorino[1], F. Vaz[2], A.L. Carvalho[3], S. Bento[2], A. Luís[2], A. Opinião[3], A. Clara[2], J. Dupont[4], S. Santos[5], P. Machado[6], S. Fragoso[5], P. Rodrigues[4], J. Parreira[4], C. Moura[4]

[1]Medical Oncology, Instituto Português de Oncologia de Lisboa Francisco Gentil, E.P.E. (IPOLFG EPE), Lisbon, Portugal, [2]Familiar Cancer Risk Clinic, Instituto Português de Oncologia de Lisboa Francisco Gentil, E.P.E. (IPOLFG EPE), Lisbon, Portugal, [3]Medical Oncology, Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisbon, Portugal, [4]Familiar Cancer Risk Clinic, Instituto Português de Oncologia de Lisboa Francisco Gentil, E.P.E. (IPOLFG EPE), Lisbon, Portugal, [5]Molecular Pathobiology Research Department, Instituto Português de Oncologia de Lisboa Francisco Gentil, E.P.E. (IPOLFG EPE), Lisbon, Portugal, [6]Molecular Pathobiology Investigation Unit, Instituto Português de Oncologia de Lisboa Francisco Gentil, E.P.E. (IPOLFG EPE), Lisbon, Portugal

Background: The *BRCA2* phenotype includes breast (BC) and ovarian cancer (OC) as well as, less frequently, prostate (PC), gastric (GC) and pancreatic cancer. The association with melanoma remains unclear, because previous studies were retrospective and included non- confirmed carriers. With this study we intend to determine the rate of melanoma and nonmelanoma skin cancers diagnoses in a consecutive prospective cohort of confirmed BRCA2 carriers.

Methods: Review of all skin cancer diagnoses in BRCA2 carriers under prospective surveillance.

Results: Four hundred and eighty six BRCA2 carriers (376 female, 110 male) belonging to 216 families were identified. The median age for genetic diagnosis was 48,3yrs with the BRCA2 c.156_157inAlu being the mutation most frequently observed (43,6%). Most carriers (359/486) had yearly full skin examinations. Although a majority of women (226/376) were cancer survivors (209 BC, 29 OC and 12 with breast/ovarian cancer), only 30/110 men had a previous cancer diagnosis (20 BC, 8 PC and 2 GCs). For a median follow up of 4 yrs, melanoma diagnoses were 3 in 2 female with bilateral BC. The patient with 2 melanomas had the first melanoma at 28yrs before BC diagnoses. Other skin cancers: 14 squamous cell carcinoma (SCC) (8 invasive, 6 in situ SCC) and 14 pts with basal cell carcinoma (BCC), 6 of which with multiple BCC. Four pts were diagnosed with actinic keratosis (AK). The rate for melanoma is 0,4% and for nonmelanoma skin cancers 5%. The rate for skin cancer in BRCA2 carriers with a previous cancer diagnosis is 2%. No statistical significance was found either for the association of skin cancer ($p = 0{,}221$) or melanoma ($p = 0{,}9$) with specific BRCA2 mutations.

Conclusions: The low rates of melanoma diagnosis in our prospective confirmed BRCA2 cohort, raises questions about the previously described association of melanoma and BRCA2 mutations. Also, no association was found between the Portuguese founder mutation and melanoma or other skin cancers. Although more follow up may be needed, there is insufficient evidence to warrant increased skin surveillance of BRCA2 carriers in the absence of standard skin cancer risk factors.

1237P Resected malignant melanoma at high risk of recurrence in SEER-Medicare

N. Sadetsky[1], J. Yi[2], A. Hernandez[1], D. Colburn[1], G. Goodman[1]

[1]Product Development, Genentech, Inc., South San Francisco, CA, USA, [2]Epidemiology/Analysis, Genesis Research Group, Hoboken, NJ, USA

Background: While surgery remains a mainstay in the management of high-risk resectable malignant melanoma (MM), there is a high chance of recurrence. Utilization of approved adjuvant therapies (e.g. interferon α and ipilimumab) are limited by the common occurrence of debilitating side effects. The objective of our study was to describe characteristics of patients (pts) with resected MM at high risk of recurrence in the older US population.

Methods: A retrospective cohort study was undertaken using the Surveillance, Epidemiology, and End Results (SEER)-Medicare population-based linked database. The study population included pts with Stage IIC-IIIC surgically resected MM diagnosed between 2004 and 2011. Demographic and clinical characteristics, adjuvant therapies, including radiation (XRT) and/or systemic therapy (eg, interferon α, interleukin, pegylated interferon), and overall survival (OS) were evaluated.

Results: We identified 1016 pts; the mean age was 75.2 years (interquartile range [IQR], 72–82) and 66.2% were males. The majority of pts had Stage IIC-IIIB disease at diagnosis (Cohort 1; $n = 877$ [86.3%]); the remainder had stage IIIC disease (Cohort 2; $n = 139$ [13.7%]). Adjuvant therapy was utilized in 27.3% ($n = 239$) and 43.2% ($n = 60$) of pts in Cohorts 1 and 2, respectively, and consisted of XRT in 74% and 78% of pts, systemic therapy in 16% and 10% of pts (with interferon α representing 98.6% of systemic therapies), and a combination of XRT and systemic therapy in 10% and 12% of pts. OS differed between cohorts, with a median of 32.3 months (IQR, 17.9–53.3) for Cohort 1 and 19.8 months (IQR, 11.5–36.2) for Cohort 2. Landmark OS at 5 years was 20.8% for Cohort 1 and 12.2% for Cohort 2.

Conclusions: Among pts with resected MM at high risk of recurrence in the older US population, utilization of adjuvant therapy and OS varied based on disease stage at diagnosis. Pts with Stage IIIC disease were exposed to more medical interventions; however, use of highly toxic systemic therapy available during the study period was limited in both cohorts. As more therapies for the adjuvant setting are being developed, the evaluation of clinical and demographic characteristics may help tailor treatment regimens.

1238P Independent prognostic impact of lympho-vascular invasion in cutaneous melanoma patients with sentinel lymph node biopsy

R. Luca, M. Rizzo, P. Mando, C. Perez de La Puente, A. Blanco, S. Rivero, G. Lutter, F. Cappuccio, M. Amat, J. Kaplan, R. Chacon, M. Chacon

Medical Oncology, Instituto Alexander Fleming, Caba, Argentina

Background: Incidence of cutaneous melanoma (CM) is increasing worldwide. The primary treatment of CM is surgery. Prognosis is determined by characteristics of the lesion such as depth of invasion, ulceration and sentinel lymph node (SLN) status. The aim of this study was to analyze the prognostic impact of lympho-vascular invasion (LVI) in CM patients (pts) undergoing SLN biopsy since LVI has not been established as a clear prognostic factor in the current AJCC 8th ed. cancer staging system.

Methods: Retrospective, descriptive and observational analytical study. We used the institutional database of pts with diagnosis of CM, submitted to SLN biopsy between November 1994 and August 2016. The association between pathological characteristics and SLN were analyzed using Chi2 and logistic regression model. Kaplan Meier and Log rank were used for disease free survival (DFS) analysis.

Results: 385 pts with a diagnosis of CM were analyzed. Median follow-up 45.2 months (IQR: 15.66-91.77). Median age: 52 years (IQR 42-65). SLN+: 47/384 (12.2%). Evaluated prognostic factors: Breslow (Br) 1.5 mm md (IQR 1-2.67), ulceration + 94/385 (24.4%), LVI + 32/144 (22.2%). Relapse 86/367 (23.4%). In the univariate analysis we found association between relapse and the following factors: LVI + (OR: 2.97, $p = 0.0125$), SLN + (OR: 3.97, $p < 0.01$), Br ≥ 1mm (OR: 4.13, $p = 0.01$) and ulceration + (OR: 2.08, $p < 0.01$). There was no association with age and sex. In the multivariate analysis LVI + (OR: 2.47, $p = 0.049$) and SLN + (OR: 3.91, $p = 0.048$)

were associated with relapse, whereas neither Br ≥ 1 mm, sex nor ulceration were associated with relapses. 5-year-DFS was higher in SLN - (79.3% vs 56.1%, p < 0.01), LVI - (80.7% vs 57.9%, p 0.019), Br < 1 mm (89.5% vs 71%, p < 0.01) and ulceration - (80.4% vs 59.7%, p < 0.01).

Conclusions: In our retrospective series, after a long period of follow-up, the presence of LVI as an independent factor was associated with relapse and DFS. Within CM pts the best candidate for adjuvant therapy is yet to be defined, LVI + as a prognostic factor should be validated in prospective trials in this scenario.

1239P Validating prognostic models in metastatic uveal melanoma (MUM), an international rare cancers initiative

L. Khoja[1], E. Atenafu[2], A.M. Joshua[3], I.R.C.I. Ocular Melanoma Group[4]

[1]Clinical Development Unit, AstraZeneca plc, Melbourn, UK, [2]Biostatisticis, University of Toronto, Toronto, ON, Canada, [3]Medical Oncology, Kinghorn Cancer Centre, Sydney, Australia, [4]Cancer Research UK, International Rare Cancers Initiative, London, UK

Background: We validated 2 models (the 7thAmerican joint committee on cancer (AJCC) and the Helsinki university central hospital (HUCH) staging) and 1 nomogram; the Padova-Mayo (PMN), for progression free (PFS) and overall survival (OS) using patient (pt) level data from the PUMMA meta-analysis.

Methods: 29 prospective trials' (1988-2015) pt data was analysed. Models were validated with cox regression analysis for survival in months (m). Concordance index (CCI) was used to test predictive value.

Results: Comparable data was available for 463 pt; see table for variables used in each system. Models were prognostic differentiating into M1a, M1b and M1c groups. Median PFS for AJCC was 4m for M1a, 3 for M1b and 2 for M1c. Median PFS for HUCH was 3.5m for M1a, 2.5 for M1b and 1 for M1c. CCI for PFS using AJCC was 0.69 (SE 0.02, 95%CI 0.65-0.73), for HUCH it was 0.79 (SE 0.02, 95%CI 0.74-0.83). Median OS for AJCC was 15m for M1a, 9 for M1b and 5 for M1c. Median OS for HUCH was 13m for M1a, 6 for M1b and 2 for M1c. CCI for OS for AJCC was 0.69 (SE 0.02, 95%CI 0.65-0.73). For HUCH it was 0.79 (SE 0.02, 95%CI 0.74-0.83). Using ECOG and LDH (available variables used in PMN) median PFS was 4m (95% CI 4-5) for normal LDH and ECOG 0, 7 (3-9) for normal LDH and ECOG > 0, 2.6 (2-3) for elevated LDH and ECOG 0 and 2.5 (2-3) for elevated LDH and ECOG > 0. Corresponding median OS was 17m (95%CI 15-18), 12.7 (95%CI 10-19), 7.4 (95%CI 6.3-8.9) and 5.3 (95%CI 3.8-6.1). CCI were PFS 0.72 (SE 0.02, 95% CI 0.69-0.75), OS 0.73 (SE 0.02, 95% CI 0.7-0.76).

Conclusions: Prognostic models in MUM remain imprecise in an externally validated dataset. Further validation is needed to find clinical utility

1240P Impact of an active surveillance programme on outcome of patients (pts) with uveal melanoma (UM) after primary curative therapy (PTx): results of a single-institution experience

C.L. Lee[1], G. Gullo[1], N. Horgan[2], C. Baily[2], R. Abdul Rahman[1], D. Smith[1], C. Buckley[1], J. Crown[1]

[1]Medical Oncology, St Vincents University Hospital, Dublin, Ireland, [2]Opthalmology, Royal Victoria Eye and Ear Hospital, Dublin, Ireland

Background: About 30% of pts with UM develop metastatic disease (MUM) despite PTx. Liver is by far the commonest site of metastases. MUM has poor prognosis and no systemic treatment (STx) has been proven to improve overall survival (OS). However, the role of active surveillance for metastatic disease is still controversial.

Methods: We performed an outcome analysis of all UM pts prospectively registered onto our active surveillance programme after PTx. All pts had systemic staging at initial diagnosis of UM and then 6-monthly liver imaging (CT triple-phase or ultrasound) and clinical review for the first 5 years and 12-monthly afterwards. Progression-free survival (PFS) was calculated from time of first systemic relapse to first disease progression, OS from time of first systemic relapse to death or latest FU.

Results: Out of 166 pts registered between April 2009 and April 2017, 36 (22%) developed MUM: 14 pts relapsed <2 yrs, 17 between 2 and 5 yrs, 5 >5 yrs from PTx. MUM pts characteristics: males 19 (53%); median age 58 (range 34-85); median tumour thickness at diagnosis 9mm (2-22); sites of metastases: liver only 13 (36%), liver + other sites 21 (58%), extra-hepatic only 2 (6%). Relapses were asymptomatic and detected on surveillance imaging in 29 (80%) pts. Nine pts (7 detected from surveillance) underwent primary hepatic metastasectomy (HM), 27 (75%) pts were non-resectable (NR) and underwent STx (n = 18), locoregional Tx (n = 4), best supportive care (n = 5). Overall, 29/36 MUM pts received immunotherapy with either ipilimumab or nivolumab/pembrolizumab. At a median FU of 36.5 mos (1-103), 27 pts have died and the median OS is 16.6 mos (95%CI: 7.8-25.3). Both PFS and OS were statistically significantly longer for HM pts compared to NR pts (PFS: 10.8 vs 4.4mos, $p = 0.01$/OS: 24.9 vs 13.4mos, $p = 0.04$). Eight out of 9 pts developed further disease relapse after HM.

Conclusions: Our data indicate that active surveillance after PTx of UM can allow detection of asymptomatic potentially resectable liver metastases, especially in pts with

1241P Impact of duration of response (DOR) on overall survival (OS) in patients with metastatic melanoma treated with dacarbazine (DTIC), vemurafenib (V), or cobimetinib plus vemurafenib (C+V): a pooled analysis

K. Lewis[1], J. Larkin[2], A. Ribas[3], K.T. Flaherty[4], G.A. McArthur[5], P.A. Ascierto[6], B. Dréno[7], E. McKenna[8], Q. Zhu[9], Y. Mun[8], A. Hauschild[10]

Background: Evaluation of treatment efficacy in oncology using OS is confounded by survival benefit from post-progression treatment. We pooled data from the BRIM-2, -3, -7, and coBRIM studies (BRAF inhibitor–naive patients with $BRAF^{V600}$-mutated metastatic melanoma) to evaluate whether DOR could be a surrogate for OS.

Methods: Time-dependent Cox proportional hazards regression was used to model the association of DOR (interval from date of first RECIST response to progressive disease [PD] or death) with OS. The risk of death for DORs of 1–10 months (in 1-month increments) was evaluated. Patients with best response of stable disease or PD [nonresponders (NR)] were assigned a DOR of zero. Models were adjusted for time-fixed baseline covariates (ECOG status, demographics, disease covariates, and first-line treatment), and time-dependent covariates (DOR and post-progression treatment [immunotherapy, targeted therapy, or other]).

Results: This analysis included 1365 patients (DTIC = 338; V = 717; C+V = 310). Objective response was 47.5% for the overall population and 11.5%, 53.6%, and 72.9% for the DTIC, V, and C+V cohorts, respectively. Median DOR was 9.3 months in the overall population and 6.4, 7.6, and 14.6 months in the DTIC, V, and C + V cohorts, respectively. Cox proportional hazards adjusted for time-dependent covariates showed a significant and progressive reduction in the risk of death with increasing DOR vs NR. The absolute risk of death decreased by a mean of ≈6.3–7.7% per month increase in DOR in the overall population and across treatment cohorts (Table). Sensitivity analyses in responders only showed similar results.

Conclusions: These exploratory analyses suggest that DOR is independently associated with OS outcomes regardless of treatment and merits further exploration as a surrogate endpoint to assess long-term treatment benefit.

1242P Neutrophil to Lymphocyte Ratio (NLR) as an independent prognostic measure in patients receiving targeted therapy or immunotherapy for stage IV melanoma

E. Blackley[1], L.E. Lim[1], M. Moore[1], M. Voskoboynik[1], C. McLean[2], A. Haydon[1]

[1]*Medical Oncology, Alfred Health, Melbourne, Australia,* [2]*Department of Pathology, Alfred Health, Melbourne, Australia*

Background: Treatment of metastatic melanoma has rapidly evolved with the introduction of targeted and immunotherapies in recent years. An elevated NLR (neutrophil-lymphocyte ratio) has been shown to be an independent marker of poor prognosis in malignancies including melanoma. Here we present an updated survival analysis demonstrating the utility of NLR as a marker of prognosis in patients with metastatic melanoma receiving targeted and immunotherapy.

Methods: We identified patients with stage 4 melanoma who received systemic therapy with targeted therapy (BRAF +/- MEK inhibitor) or immunotherapy (Anti-CTLA-4 or Anti-PD-1) at our institution. Patients not receiving any systemic therapy were excluded. We retrospectively reviewed all medical records collecting data on baseline demographics, prognostic factors (stage, LDH, CNS and Liver metastases), treatments received, pre-treatment NLR and outcomes. Overall survival (OS) and Progression-free survival (PFS) were measured from date of first dose received.

Results: 174 patients were treated between August 2010 to November 2016, 74 received targeting therapy and 100 receiving immunotherapy. Median follow up was 10 months. At time of interim analysis median OS for patients with NLR < 5 was 11.7 months compared to 4.8 months in NLR >5 (HR 0.45, 95% C.I. 0.31-0.67, p = 0.00007), this was seen in patients treated with both targeted therapies (HR 0.48, p = 0.012) and immunotherapies (HR 0.40, p = 0.0009). Median PFS was also longer in patients with NLR <5 4.8 vs. 3.6 months (HR 0.65, p = 0.02). Multivariate analysis including age, sex, M stage, baseline LDH and CNS/Liver metastases, demonstrated NLR was the strongest predictor of OS (HR 0.39 95% C.I. 0.25-0.60, p = 0.00002).

Conclusions: NLR >5 is a strong independent predictor of poor outcome in patients with metastatic melanoma regardless of targeted or immunotherapy. We hypothesis that at final data lock in July 2017 this association will remain strong given it was a clear predictor of outcome at the time of interim analysis. NLR may assist selection of initial therapy, for example, a favourable ratio may indicate suitability for single agent rather than doublet immunotherapy with its greater toxicity profile.

1243P The prognostic significance of distant metastasis free interval (DMFI) in BRAF mutant advanced melanoma patients treated with first line targeted therapy

D. Bafaloukos[1], H. Linardou[1], P. Diamantopoulos[2], T. Sergentanis[3], A. Laskarakis[1], K-M. Giati[1], A. Tarampikou[1], A. Anastasopoulou[2], H. Gogas[2]

[1]A' Oncology Dept, Metropolitan Hospital, Athens, Greece, [2]1st Dept of Medicine, Laikon Hospital, Medical School, National and Kapodestrian University of Athens, Athens, Greece, [3]Dept of Hygiene, Epidemiology and Medical Statistics, Medical School, National and Kapodestrian University of Athens, Athens, Greece

Background: Prognostic models are investigated for advanced melanoma patients treated with targeted therapy. This study aims to identify the relationship between DMFI and outcome of 1st line targeted therapy in BRAF mutant (BRAFmut) patients.

Methods: BRAFmut patients identified from 2 referral centres were assigned to 3 prognostic groups: A (PS 0, Metastatic sites $\leq$3, LDH normal, CNS not involved), B (PS 1, Metastatic sites $\leq$3, LDH >1-2ULN, CNS not involved), C (PS 2, Metastatic sites >3, LDH $\geq$2ULN, CNS involved or not). Factors analysed: Distant Metastasis Free Interval (DMFI from primary melanoma to 1st distant metastasis), Post Relapse Progression Free Survival (PRPFS post relapse to BRAFi), Post Relapse Survival (PRS), number of metastatic sites, LDH, CNS involvement, PS. Univariate and multivariate Cox regression analysis was used adjusted with the 3 prognostic groups. Statistical analysis with STATA/SE V13.0.

Results: From 380 advanced melanoma patients, 161 BRAFmut patients received 1st line BRAFi only (101) or BRAFi+MEKi (60). Patients relapsed from primary at a median DMFI 12 months (range 0-185) and were included in the 3 prognostic groups (Group A 27, Group B 72, Group C 56). To study DMFI significance, we defined 2 patient groups according to DMFI: DMFI <24 months Group 1, DMFI $\geq$24 months Group 2. Median PRPFS was 5 months for Group 1 and 8 months for Group 2 with statistically significant difference (HR = 1.45, 95%CI 1.01-2.09, p = 0.046). In multivariate analysis, DMFI also emerged as independent prognostic factor (HR 1.44, 95% CI 0.99-2.10, p = 0.059). Prognostic Group (C vs A), number of metastatic sites ($\geq$3 vs < 3), PS (0 vs 1-2), and LDH (>2ULN vs normal) were confirmed as independent prognostic factors for PRPFS and PRS. ROC analysis on progression showed best DMFI cut-off at 26 months (9 vs 5), HR 1.6 (95%CI 1.10-2.33), p = 0.014 [sen 46.2%, spec 69.6%]. No difference in median PRS between the 2 groups (14 vs 16 months, p = 0.517), possibly reflecting effect of therapies after BRAFi.

Conclusions: Patients with BRAFmut advanced melanoma and DMFI <2 years have significantly worse post relapse PFS after 1st line targeted therapy. Our results indicate DMFI as an independent prognostic factor for BRAFmut patients.

Background: Part 1 of the COLUMBUS study demonstrated that the BRAF inhibitor ENCO 450 mg once daily (QD) + the MEK inhibitor BINI 45 mg twice daily (BID; COMBO450) improved progression-free survival vs VEM 960 mg BID alone and ENCO 300 mg QD (ENCO300) alone in patients (pts) with advanced *BRAF* V600–mutant melanoma. Tolerability of COMBO450 was favorable compared with VEM or ENCO300. Here we evaluate resource utilization based on hospitalization data (ClinicalTrials.gov, NCT01909453; EudraCT, 2013-001176-38).

Methods: Pts were randomized 1:1:1 to receive COMBO450, VEM, or ENCO300. Efficacy endpoints, including the number of pts hospitalized and number of hospitalizations, were described. Time to first occurrence of hospitalization was assessed by the Kaplan-Meier method. Hospitalization endpoints were adjusted per 100 pt-months (pt-mo) of exposure to study drug.

Results: Among 577 pts, 192 were randomized to COMBO450, 191 were randomized to VEM, and 194 were randomized ENCO300. Exposure-adjusted hospitalization rates (per 100 pt-mo) were 3.5% in the COMBO450 arm compared with 4.3% and 6.2% in the ENCO300 and VEM arms, respectively. Exposure-adjusted mean duration of hospitalization per 100 pt-mo was 32.5, 38.2, and 53.7 days in the COMBO450, ENCO300, and VEM arms, respectively. Median (95% CI) time to first hospitalization for pts with $\geq$1 event was 5.1 (2.6–6.1) mo in the COMBO450 arm compared with 2.8 (0.8–4.2) and 2.8 (2.0–3.8) mo in the ENCO300 and VEM arms, respectively.

Conclusions: Resource utilization, as determined by hospitalization data in COLUMBUS Part 1, was lower with COMBO450 compared with VEM or ENCO300 monotherapy.

Background: In COLUMBUS Part 1, the BRAF inhibitor ENCO 450 mg once daily (QD) + the mitogen-activated protein kinase kinase (MEK) inhibitor BINI 45 mg twice daily (BID; COMBO450) improved progression-free survival vs VEM 960 mg BID alone and ENCO 300 mg QD (ENCO300) alone in patients (pts) with advanced *BRAF* V600-mutant melanoma. Tolerability of COMBO450 was favorable compared with VEM or ENCO300. Here we compare patient-reported health-related QoL between the treatment arms.

Methods: Pts were randomized 1:1:1 to receive COMBO450, VEM, or ENCO300. Patient-reported health-related QoL was assessed by 2 validated instruments, the Functional Assessment of Cancer Therapy–Melanoma (FACT-M) questionnaire and the European Organization for Research and Treatment of Cancer's Quality of Life Questionnaire–Core 30 (EORTC QLQ-C30). Higher scores represent better QoL on both instruments. A mixed-effect model for repeated measures was used to compare the change from baseline (BL) in the domain scores over time.

Results: Among 577 pts, 192 were randomized to COMBO450, 191 were randomized to VEM, and 194 were randomized ENCO300. Compliance of pts completing the FACT-M and EORTC QLQ-C30 questionnaires was equivalent; approximately 80%–90% of pts still at risk completed the assessment from BL through cycle 25. Mean BL FACT-M scores were similar between arms (52.39, 52.01, and 52.84 in the COMBO450, VEM, and ENCO300 arms, respectively). FACT-M subscale change over time indicated that COMB450 was associated with an estimated 2.98 point higher post-BL score vs VEM (95% confidence interval [CI] 1.34–4.63) and a 4.01 pt higher post-BL score vs ENCO300 (95% CI 2.47–5.54). Mean EORTC QLQ-C30 scores at BL were 66.72, 64.74, and 66.10 with COMBO450, VEM, and ENCO300, respectively. Evaluation of change over time found that COMBO450 was associated with an estimated 5.25 point higher post-BL score vs VEM (95% CI 1.21–9.29) and an 8.32 higher post-BL score vs ENCO300 (95% CI 4.54–12.11).

Conclusions: Patient-reported health-related QoL was rated consistently and significantly better with COMBO450 vs VEM or ENCO monotherapy.

Clinical trial identification: Trial protocol number, CMEK162B2301 (release date, July 13, 2015)

1246P Loss of USP28 drives resistance to BRAF targeted therapy in melanoma

A. Saei[1], M. Palafox[2], T. Benoukraf[3], N. Kumari[3], P.W. Jaynes[3], P.V. Iyengar[3], J.L. Charles Richard[3], Z.F. Isa[3], B. Pang[3], M. Guzman[2], H. Yang[3], W.L. Tam[1], V. Serra[2], P.J.A. Eichhorn[3]

*[1]Genome Institute of Singapore, A*STAR, Cancer Science Institute, NUS, Singapore, [2]Vall d'Hebron Institute of Oncology (VHIO), Vall d'Hebron University Hospital, Barcelona, Spain, [3]Cancer Science Institute, National University of Singapore, Singapore*

Background: Metastatic melanoma is a lethal malignancy leading to an estimated 65,000 deaths annually worldwide. The serine threonine kinase BRAF is mutated in 40-60% of all melanoma patients frequently at a single hotspot BRAF V600E, which results in hyperactivation of MAPK pathway. RAF kinase inhibitors are clinically active in patients with BRAF (V600E) mutant melanoma. However, rarely do tumours regress completely with the majority of responses being partial and short-lived. Several mechanisms of resistance to RAF inhibitors have been suggested in melanoma. In addition to somatic genomic alterations recent studies have revealed the importance of ubiquitination in the role of MAPK signaling. Yet very little is known about the deubiquitinating enzymes that counteract ubiquitination mediated functions. Our study identified loss of deubiquitinating enzyme, USP28 as a novel mechanism of resistance to vemurafenib in BRAF mutant melanoma.

Methods: A genome wide shRNA screen targeting all known deubiquitinating enzymes was performed and level of phosphorylated ERK as the representative of MAPK pathway was assessed by western blotting. Significant hits of the screen were validated and mechanism of action in regulation of MAPK pathway and resistance to MAPK inhibitors in melanoma has been investigated.

Results: Using a functional RNAi screen targeting all known human deubiquitinating enzymes, we identified USP28 as a critical regulator of MAPK pathway. It is known that USP28 binds to and stabilizes the E3 ligase substrate recognition subunit, FBW7 to regulate stability of various proteins. We showed that the USP28/FBW7 complex directly ubiquitinates BRAF and targets BRAF for ubiquitin mediated degradation. Importantly, TCGA datasets indicates that USP28 is deleted in 9% of melanoma patients. Using Kaplan-Meier analysis, we showed that loss of USP28 confers poorer overall survival in melanoma patients. We showed that loss of USP28 enhances MAPK activity through the stabilization of BRAF. Our results revealed the Loss of USP28 drives resistance to RAF inhibitor therapy in BRAF(V600E) tumors both *in vitro* and *in vivo*.

Conclusions: Taken together we showed loss of USP28 as a potential biomarker for MAPK activation and vemurafenib resistance in BRAF 600E mutant melanoma.

1247P Patterns of progression in metastatic melanoma patients treated with Braf and Mek inhibitors: an Italian Melanoma Intergroup (IMI) study

R. Marconcini[1], E. Marra[2], F. De Rosa[3], L.S. Stucci[4], L. Orgiano[5], S. Ribero[2], F. Bloise[1], A. Antonuzzo[1], A. Falcone[1]

[1]Oncology Department, Azienda Ospedaliera Universitaria S.Chiara, Pisa, Italy, [2]Department of Medical Sciences, Dermatologic Clinic, University of Turin, Turin, Italy, [3]Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori, IRST IRCCS, Meldola, Italy, [4]Medical Oncology Unit, University of Bari, Bari, Italy, [5]Oncology Department, Azienda Ospedaliero Universitaria di Cagliari, Monserrato, Italy

Background: Patterns of progression after BRAF+MEK inhibitors (I) could help clinicians in understanding the best treatment strategy among the multiple available

options in the BRAFv600 melanoma setting. We analysed outcomes in patients (pts) treated with BRAF+MEK I to characterize pts with rapid progression.

Methods: In this multicenter retrospective analisis, 164 consecutive pts affected by BRAFv600 metastatic melanoma and treated with BRAF+MEK I from February 2012 to April 2017 were included.

Results: Overall, 164 patients were enrolled. Baseline LDH was elevated in 68 (41%) pts, baseline number of metastatic organs were 1, 2, 3 and more in 52 (32%), 52 (32%), 29 (18%), and 32 (19%) pts. BRAF+MEK I administered were dabrafenib+trametinib in 151 pts and vemurafenib+cobimetinib in 13 pts, and they were administered in first line in 129 (79%) pts. Best response was CR, PR, SD and PD in 27 (16%), 87 (53%), 17 (10%) and 27 (16%) pts. On cutoff date, progression was observed in 104 (63%) pts; 60 (37%) pts still on treatment. mPFS was 9,83 (1-54,7+) months: significant difference in PFS was showed in pts with normal baseline LDH or high LDH (13.2 vs 6.3 months, $p < 0.0001$), and in pts with number of metastatic organs lower or higher then 2 (13,4 vs 7 months, $p < 0.0001$). mOS was 18.3(1-62,5+) months: significant difference in OS was showed in pts with normal baseline LDH or high LDH had (24,7 vs 10 months, $p < 0.0006$), and in pts with number of metastatic organs lower or higher then 2 (25.9 vs 10 months, $p < 0.0003$). Among 104 progressed pts, 72 (69%) pts died, mOS after progression was 2,5 months (0,5-42+ months); Subsequent treatments were administered in 44 (42%) pts. Duration of response (DR) was defined as time from BRAF+MEK I best response to progression of disease. Significant difference in OS after BRAF+MEK I progression was observed in pts with DR < 6 months(77 pts -74%) or > 6 months (27 pts - 26%) (2 vs 8,3 months, $p < 0.0023$) and in pts with number of metastatic organs after progression lower or higher then 3 (4,5 vs 2 months, $p < 0.022$).

Conclusions: DR and extension of progression during BRAF+MEK I are factors that can be useful to identify pts with lower OS after progression, in addiction to known parameters like LDH and baseline number of metastatic organs.

1248P Tumor-stroma interactions as a determinant of drug resistance in BRAF-mut melanoma

I. Falcone[1], R. Loria[2], U. Cesta Incani[1], L. Ciuffreda[1], C. Bazzichetto[1], F. Conciatori[1], B. Bellei[3], D. Kovacs[3], M. Picardo[3], R. Falcioni[2], M. Milella[1]

[1]Medical Oncology 1, Regina Elena National Cancer Institute, Rome, Italy, [2]Department of Research Advanced Diagnostic and Technological Innovation, Regina Elena National Cancer Institute, Rome, Italy, [3]Of Cutaneous Physiopathology and Integrated Center of Metabolomics Research, San Gallicano Dermatologic Institute, Rome, Italy

Background: In BRAF-mut melanoma combined BRAF/MEK inhibition increases survival; however, pharmacological effects on the genetically "normal" tumor microenvironment (i.e. paradox MAPK activation) may set the stage for the development of drug resistance.

Methods: GFP-labeled cutaneous fibroblasts (HFF) were co-cultured with melanoma cells, in the presence or absence of direct cell-cell contact, and response to Dabrafenib (D) and Trametinib (T), alone or combined, was monitored over time. SEMA6A and AXL were preliminarily evaluated as potential mediators of such interactions.

Results: HFF significantly protected (60-100% protection at the lowest two drug concentrations) BRAF-mut M14 melanoma cells from the growth inhibitory activity of D and T, alone or combined; however, combined D+T at the highest concentrations overcame stroma-mediated protection and eliminated both cell populations. Thus, combined BRAF/MEK inhibition resulted in strongly synergistic interactions, as compared to single agent treatments, only under co-culture conditions (CI 0.6 and 0.2 for M14 and HFF cells, respectively). Protective melanoma/stroma interactions were mediated by direct cell-cell contact, as co-cultures in trans-well Boyden chambers or isolated cultures using conditioned medium (HFF-conditioned medium for M14; M14-conditioned medium for HFF), did not affect pharmacological response. As SEMA6A expression is tightly controlled by MAPK and AXL mediates resistance to MAPK inhibition in melanoma, we assessed their potential as mediators of stroma-mediated melanoma protection: interestingly, SEMA6A and AXL expression in a panel of melanoma cell lines were inversely correlated; moreover, in cell lines derived by primary and cutaneous metastases of the same patient, AXL expression was upregulated at the mRNA and protein level in cells derived from metastatic lesions.

Conclusions: Tumor-stroma interactions protect BRAF-mut melanoma from MAPK inhibition; such functional protection is mediated by cell-cell contact. SEMA6A and AXL are possible mediators of this interaction and their reciprocal relationships are being studied in melanoma cell line models and clinical series.

1249P Extended survival analysis of ipilimumab for the treatment of advanced malignant melanoma in pretreated patients: Five-year long-term follow-up of the South African expanded access program

B. Rapoport[1], D. Vorobiof[2], L. Dreosti[3], A. Nosworthy[4], G. Mcadam[5], A. Jordaan[6], M. De Necker[7], J. De Beer[8], H. Duvenhage[9]

[1]Medical Oncology, The Medical Oncology Centre of Rosebank, Sandton, South Africa, [2]Oncology, Sandton Oncology Centre, Sandton, South Africa, [3]Oncology, Pretoria Academic Hospital, Pretoria, South Africa, [4]Oncology, University of Witwatersrand Medical School, Johannesburg, South Africa, [5]Oncology, GVI Oncology, Cape Town, South Africa, [6]Oncology, Westridge Medical Centre, Durban, South Africa, [7]Data Services, TCD Outcomes Research, Pretoria, South Africa, [8]Data Services, TCD Outcomes Research, Centurion, South Africa, [9]Head of Medical, Bristol-Myers Squib, Woodmead, South Africa

Background: Ipilimumab is a human monoclonal IgG1 antibody against CTLA-4 that has been shown to prolong the overall survival of patients with advanced pretreated melanoma. In 2015, a retrospective, multi-centre, non-interventional analysis was performed on data collected from the ipilimumab expanded access programme in South Africa, with last follow-up date (or death) in December 2014. The current study extends this analysis by follow-up on the long-term survival of pre-treated metastatic patients up to September 2016.

Methods: Follow-up questions were sent to participating investigators, who had patients who were still alive (29) or for whom it was not known whether they were still alive (11) following the last ipilimumab infusion. Investigators had to confirm whether patients were still alive, the date of death or last contact, clinical response at last contact, and whether the patient was still responding to ipilimumab.

Results: Of the 108 patients, 84 (78%) had cutaneous melanoma and 24 patients (22%) had non-cutaneous melanoma, including uveal, mucosal, and melanoma of unknown primary. Twenty patients previously received two or more lines of treatment for metastatic melanoma. The median age was 59 years (range 27 – 86) and there were 73 (68%) males and 35 (32%) females. Baseline ECOG PS was 0 in 33%, PS 1 in 58% and PS 2 in 6% of patients. The longest follow-up time available was 5.4 years. The median OS was 9.36 months (95% CI 7.48 – 11.84). One-year survival was 39% (95% CI 29% - 48%), 2-year survival was 22% (95% CI 15% - 30%), 3-year survival was 19% (95% CI 12% - 27%), 4- and 5-year survival was 15% (95% CI 8% - 21%). In the group of cutaneous melanoma patients, the 4- and 5-year survival was 17% (95% CI 9% - 25%) while in the non-cutaneous group the 4- and 5-year survival was 6% (95% CI 0% - 16%).

Conclusions: Ipilimumab at a dose of 3mg/kg is an effective treatment for patients with pre-treated advanced (unresectable or metastatic) melanoma and is associated with durable remissions and long-term survival.

Clinical trial identification: Protocol number: CA184-515 Ethics approval extended on protocol REC 2/21/05/14

1250P Real-world use of ipilimumab and nivolumab monotherapy or in combination in patients with advanced melanoma: results from a retrospective chart review

A. Tarhini[1], C. Macahilig[2], C. Atzinger[3], K. Gupte-Singh[4], C. Solem[3], S. Rao[4]

[1]Division of Hematology-Oncology, University of Pittsburgh Medical Center, Pittsburgh, PA, USA, [2]Research Operations, Medical Data Analytics, Parsippany, NJ, USA, [3]Global Health Economics and Outcomes Research, Pharmerit International, Bethesda, MD, USA, [4]Health Economics Outcomes Research, Bristol-Myers Squibb, Princeton, NJ, USA

Background: The advanced melanoma treatment landscape has significantly changed with approval of ipilimumab (IPI) and nivolumab (NIVO). This analysis aimed to describe real-world characteristics and treatment patterns of patients (pts) prescribed IPI, NIVO, or NIVO+IPI.

Methods: This interim analysis of an observational, retrospective, multisite study collected data for US pts diagnosed with unresectable or metastatic melanoma who received IPI, NIVO, or NIVO+IPI (index) between January 2015 and May 2016. Demographics and treatment patterns were abstracted from medical records through most recent visit (≥6 months). Data were descriptively reported.

Results: Of 115 pts from 20 sites in the USA, 43 received IPI (mean±SD age 61.5±11.3 years, 51.2% female, 86.0% ECOG PS ≤ 1), 41 NIVO (age 65.9±13.7 years, 48.8% female, 90.3% ECOG PS ≤ 1), and 31 NIVO+IPI (age 57.1±11.3 years, 48.4% female, 100% ECOG PS ≤ 1). Tests for BRAF and PD-L1 were conducted in 98.3% and 39.1% of pts, respectively; 14.3%, 6.7%, and 12.2% of tested IPI, NIVO, and NIVO+IPI patients had a BRAF mutation, and 60%, 50%, and 79.0% of IPI, NIVO, and NIVO+IPI patients had a positive PD-L1 status. The index treatment was first line for 98.3% of pts; mean±SD days from advanced diagnosis to treatment initiation was 21.5±16.1 days for IPI, 55.1±68.6 for NIVO, and 41.5±68.6 for NIVO+IPI. The most common rationales for treatment initiation across treatments were improved efficacy (73.9%) and documented survival benefit (44.4%). Dose delays occurred in 9.3% of IPI pts (mean delay 12.7 days) and 6.5% of NIVO pts (mean delay 45 days); no NIVO+IPI pts had dose delays. At 6 months, 16% of pts remained on IPI, 85% remained on NIVO,

and 71% remained on the NIVO portion of the NIVO+IPI regimen. Permanent discontinuation of treatment prior to completing planned courses of therapy was relatively infrequent (IPI: 16%, NIVO: 26%, NIVO+IPI: 19%), possibly reflecting improved experience in toxicity assessment and management.

Conclusions: Within this real-world cohort, a minority of pts discontinued NIVO or NIVO+IPI by 6 months. This research sheds light on current treatment patterns for IPI, NIVO, and their combination.

1251P Baseline neutrophil-to-lymphocyte ratio and its values monitored over time is associated with outcome of metastatic melanoma patients treated with immunotherapy

I. Lugowska[1], B. Cybulska-Stopa[2], P. Jagodzinska-Mucha[1], P. Teterycz[1], H. Koseła-Paterczyk[1], K. Kozak[1], K. Szamotulska[3], K. Roman[2], T. Switaj[1], M. Ziobro[2], P. Rutkowski[1]

[1]*Soft Tissue/Bone Sarcoma and Melanoma, The Maria Sklodowska-Curie Memorial Institute and Oncology Centre, Warsaw, Poland,* [2]*Systemic Neoplasm, The Maria Sklodowska-Curie Memorial Institute and Oncology Centre, Krakow, Poland,* [3]*Biostatistics, Institute of Mother and Child, Warszawa, Poland*

Background: Neutrophil-to-lymphocyte ratio (N/L) was shown to be prognostic in several solid malignancies. There are limited data about changes of N/L ratios during immunotherapy. The aim of the study was to asses a clinical value of this ratio and its association with tumour response in patients with advanced melanoma.

Methods: Between June 2011 and March 2017, 308 patients with metastatic/unresectable melanoma were included to the analysis. Patients age was 58.4±17.3 years (mean), 43 cases had brain metastases. *BRAF* mutation was present in 107 cases, and 98 patients with positive mutation received targeted therapies with BRAF+/- MEK followed by ipilumumab and/or anti-PD1 therapy. Patients with *BRAF* negative mutation received immunotherapy (pembrolizumab or nivolumab with/without ipilimumab). In all patients the N/L ratio was assessed at the baseline and monitored during treatment until disease progression or last observation. The cut off for ratio N/L was set at 3. Logistic GEE and Kaplan-Meier survival probability estimation were used for analysis.

Results: N/L ratio $\geq$3 at baseline was significantly associated with poorer overall survival (OS) ($p < 0.001$ in log-rank test). Median overall survival time was 25.8 months (95%CI 20.4-31.2) for N/L ratio <3 vs. 14.0 months (95%CI 10.7-17.3) for N/L ratio $\geq$3. In repeated measurements analysis, increased N/L ratio was significantly associated the confirmed disease progression, both in univariate random effect model ($p < 0.001$) and multivariate model adjusted for age, gender, presence of *BRAF* mutation and LDH>URL ($p < 0.001$). N/L ratio in all 6 patient who had pseudo-progression on immunotherapy was not elevated over time.

Conclusions: Our results confirm the usefulness of N/L ratio as a prognostic and predictive marker in patients with metastatic melanoma, and monitoring of the N/L ratio over immunotherapy may be helpful for assessment of the disease progression, response, as well as pseudoprogression, thus likely contributes to an optimization of treatment and resource allocation in patients with metastatic melanoma.

Background: T-VEC is the first FDA-approved oncolytic immunotherapy designed to activate antitumor immune responses. Pembro is a mAb against human programmed death receptor-1 that can stimulate inactivated anticancer T cells and is approved for the treatment (tx) of SCCHN. This combination of agents may further enhance antitumor immune response. This phase 1b/3 study will evaluate the safety and efficacy of T-VEC and pembro in patients (pts) with R/M SCCHN progressing after platinum (NCT02626000).

Methods: The primary objective for phase 1b is to assess dose-limiting toxicities (DLTs). Key secondary objectives include objective response rate, best overall response, and safety. Key eligibility criteria include histologically confirmed R/M SCCHN unsuitable for resection/radiotherapy, progressing after platinum tx, and injectable lesions. T-VEC was given by intralesional injection $\leq$ 8 mL of 10^6 PFU/mL on day 1, then after 3 w, $\leq$ 8 mL of 10^8 PFU/mL Q3W; pembro was given IV at 200 mg Q3W. Approximately 18 pts in the safety cohort and an additional 22 pts for long-term safety and efficacy will be enrolled into phase 1b.

Results: 28 pts have been enrolled; 16 are DLT evaluable: 12 (75%) male, median age 57.5 y (range: 35, 77), ECOG 1 (75%). There was a DLT in 1 pt after 2 doses of both drugs: fatal arterial hemorrhage (AH). Grade 3/4 AEs were seen in 6 (38%) of pts - none led to tx discontinuation. There were 2 grade 5 AEs: AH (DLT) and disease progression. Incidence of SAEs possibly related to T-VEC was 5 (31.3%: chills, pyrexia, stridor, odynophagia, AH) and to pembro was 2 (12.5%: eczema, pyrexia) - none led to tx discontinuation.

Table: 1252P

	All DLT Evaluable* (N = 16)	Non-DLT Evaluable (N = 12)	All Pts (N = 28)
All tx-emergent AEs	15 (93.8)	11 (91.7)	26 (92.9)
Grade 3	5 (31.2)	2 (16.7)	7 (25)
Grade 4	1 (6.3)	1 (8.3)	2 (7.1)
Grade 5	2 (12.5)	7 (58.3)	9 (32.1)
AEs related to T-VEC	11 (68.8)	2 (16.7)	13 (46.4)
Grade 3	4 (25)	1 (8.3)	5 (17.9)
Grade 4	0 (0)	0 (0)	0 (0)
AEs related to pembro	9 (56.3)	1 (8.3)	10 (35.7)
Grade 3	1 (6.3)	1 (8.3)	2 (7.1)
Grade 4	0 (0)	0 (0)	0 (0)

*To be DLT evaluable, pt must have had $\geq$ 6 w of follow up from the initial dosing and have received $\geq$ 2 doses of T-VEC and pembro in combination, or have a DLT during the DLT evaluation period after at least 1 dose of T-VEC and pembro.

Conclusions: There was 1 DLT of 16 evaluable pts. The combination regimen was deemed safe to continue into the phase 1b efficacy portion. The protocol was amended to exclude pts who have received reirradiation to the neck and are at high risk for AH.

1253P Characteristics of metastatic melanoma (MM) patients with leptomeningeal disease (LMD) and survival of > 1 year

I.C. Glitza[1], J. Ma[2], S.D. Ferguson[3], R. Bassett Jr[2], L. Haydu[4], M.A. Davies[1]

[1]Melanoma Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA, [2]Department of Biostatistics, MD Anderson Cancer Center, Houston, TX, USA, [3]Department of Neurosurgery, MD Anderson Cancer Center, Houston, TX, USA, [4]Surgical Oncology, MD Anderson Cancer Center, Houston, TX, USA

Background: Several studies have demonstrated that the presence of LMD correlates with very short overall survival (OS) in metastatic melanoma patients (pts). However, a subset of pts have OS > 12 months (mts). We reviewed the outcomes of a large cohort of patients with LMD to identity predictors of improved outcomes.

Methods: The clinical features, treatments, and OS of MM pts diagnosed with LMD by CSF cytology and/or radiographic findings from 2000 to 2015 were reviewed. Landmark Cox proportional hazard regression models were used to identify factors significantly associated with OS > 12 mts.

Results: 178 pts with LMD were identified. For these, median age at diagnosis (dx) was 51.2 years, 62% were male, 75% pts had a performance status of ECOG 0-1, 39% had elevated LDH, extracranial disease present in 75% and concurrent brain metastasis in 77%. 56% of pts were tested for BRAF mutation, and 37% (of those tested?) were positive. 61% of pts had CSF analysis done, but 49% of these had positive cytology. Neurological deficits were reported in 49%. Median OS from LMD diagnosis was 4.27 mts (95%CI: 3.12-5.55), and 12-, 36-, and 60-mts cumulative OS was 0.22 (95%CI: 0.163-0.290), 0.11 (95%CI: 0.069-0.169), and 0.09 (95% CI: 0.054-0.151), respectively. Compared to those who died within 3 mts, pts who lived longer than 12 mts (n = 36) were more likely to have: ECOG of 0 (57.1% versus 15.3%), previous surgery (55.6% versus 25.3%), systemic disease controlled (41.7% versus 33.3), intrathecal therapy (69.4% versus 21.6%), systemic therapy with targeted therapy (55.6% versus 18.9%) or chemotherapy (61.1% versus 37.8%); and were less likely to have neurological deficits (27.8% versus 62.7%), previous systemic therapy (63.9% versus 88.0%), and LDH above normal (19.4% versus 45.9%). Positive CSF cytology (HR = 3.06, 95% CI 1.02-9.17) and concomitant systemic disease (HR = 2.65, 95%CI 1.03-6.82) were associated with significantly shorter OS.

Conclusions: Long term survival in MM pts with LMD is rare, but possible. Features significantly associated with OS may help strengthen the design and interpretation of future trials for pts with LMD.

1254P Tolerance and outcomes of stereotactic radiosurgery combined with anti-PD1 (pembrolizumab) for melanoma brain metastases

C. Nardin[1], C. Mateus[1], M. Texier[2], E. Lanoy[2], S. Hibat-Allah[3], S. Ammari[3], C. Robert[1], F. Dhermain[4]

[1]Dermatologie, Institut Gustave Roussy, Villejuif, France, [2]Biostatistiques et Epidémiologie, Institut Gustave Roussy, Villejuif, France, [3]Radiologie, Institut Gustave Roussy, Villejuif, France, [4]Radiothérapie, Institut Gustave Roussy, Villejuif, France

Background: Anti-PD1 antibodies are currently the first-line treatment for patients with metastatic BRAF wild-type melanoma, alone or combined with the anti-CTLA4 mAb, ipilimumab. To date, data on safety and the outcomes of patients treated with the anti-PD1 mAbs, pembrolizumab (PB) or nivolumab, combined with stereotactic radiosurgery (SRS) for melanoma brain metastases (MBM) are lacking.

Methods: Patients with MBM treated with PB combined with SRS between 2012 and 2015 were retrospectively reviewed. The primary endpoint was neurotoxicity. The secondary endpoints were local control, distant intracranial control and overall survival (OS).

Results: Among 74 patients with MBM treated with SRS, 25 patients with a total of 58 MBM treated with PB combined with SRS within 6 months were included. Radionecrosis, occurring within a median time of 6.5 months, was observed in four metastases (6.8%) in four different patients. No significant other SRS-related adverse event had been reported. After a median follow-up of 8.4 months, local control had been achieved in 46 metastases (80%). The median time to local progression was 2 months. Perilesional oedema and intratumour haemorrhage appearing or increasing after SRS were mostly associated with local progression ($P < 0.001$). Median OS was 15.3 months (95% CI 4.6-26). The timing between SRS and PB administration did not seem to influence radionecrosis, intracranial control or OS.

Conclusions: SRS combined with PB was well tolerated and achieved high local control as recently described with SRS and nivolumab. Prolonged OS were achieved compared to that currently yielded with recommended treatments. Prospective studies are required to confirm these results and define the best timing between SRS and PB for the management of MBM.

[1]Dermatology, AP-HP Saint-Louis hospital, Paris, France, [2]Dermatology, CHRU Montpellier, Montpellier, France, [3]Dermatology, CHU Dijon, Dijon, France, [4]Dermatology, Hopital Claude Huriez, Lille, France, [5]Dermatology, CHU Bordeaux Hopital St. André, Bordeaux, France, [6]Dermatology, CHU Grenoble - Hopital Michallon, La Tronche, France, [7]Dermatology, Hôpital Archet 1, Nice, France, [8]Dermatology, Centre Hospitalier Lyon Sud, Pierre Bénite, France, [9]Dermatology, Hopital Ambroise Pare, Boulogne-Billancourt, France, [10]Dermatology, CHU Bordeaux Haut-Leveque, Pessac, France, [11]Dermatology, CHU Amiens Picardie Hôpital Nord, Amiens, France, [12]Dermatology, CH Annecy Genevois, Metz-Tessy, France, [13]Dermatology, CHRU Jean Minjoz, Besançon, France, [14]Oncology, Centre Eugene - Marquis, Rennes, France, [15]Dermatology, CHU de Nantes, Nantes, France, [16]Centre d'épidémiologie clinique, AP-HP Hotel-Dieu hospital, Paris, France

Background: Combining BRAF and MEK inhibitors is a standard of care in BRAF-mutated advanced melanoma patients. Dabrafenib (D) and Trametinib (T) have led to a 3-year overall survival (OS) rate around 44% in patients without active brain metastases (BMs) at enrollment. Recently, T received French Health Authority approval but little information is available in D+T combination use in real life, especially with active BMs patients. We report the first results of efficacy and tolerance in real life patients treated with D+T, including BMs, within national French MelBase cohort.

Methods: MelBase is a French multicentric clinical biobank dedicated to the prospective follow-up (FU) of adults with unresectable stage III or stage IV melanoma. Since March 2013, 1168 patients were included (26 centers). Available data were collected (April 2017) and analyzed (demography, OS, progression-free survival (PFS), response rate, safety).

Results: 2 groups are presented: all patients treated with D+T (g1) and patients with BMs treated with D+T (g2). The characteristics at baseline are: - g1 (n = 135): mean age 57 years, PS 0-1 87%, elevated LDH 33%, BRAF V600E mutated 78%, brain metastases 29%, treated in first line 79%. After median FU 11.2 months, median OS and PFS were respectively 17.8 months (95%CI: 15.5-Not Reached (NR)) and 8.1 months (95%CI: 6.2-11.2). Best overall response (BORR) was 63% and disease control rate (DCR) 79%. - g2 (n = 39): mean age 55 years, PS 0-1 87%, elevated LDH 46%, BRAF V600E mutated 72%, treated in first line 73%. After median FU 10.3 months, median OS and PFS were respectively 15.5 months (95%CI: 13.3-NR) and 5.9 months (95%CI: 4.3-10.7). BORR was 56% and DCR 72%.

Conclusions: We report the first real life D+T data in France. Even though our results still need to mature with a longer FU, BORR is similar to COMBI-d updated data (63% g1 *versus* 69%). In addition, our results point out for the first time D+T efficacy in patients with active BMs. Indeed the combination appears more efficient in patients with BMs compared to D alone in already published clinical data (BREAK-MB).

Background: BRAF targeted and CTLA-4/PD-1 immunotherapies have high response rates and improve survival for patients (pts) with metastatic melanoma, however, most still die of this disease. It is hypothesised the activated cytotoxic T cell infiltrate that occurs early during treatment with BRAF/MEK inhibitors is potentiated by adding checkpoint inhibitors, resulting in improved response and survival. While trials combining BRAF/MEK inhibitors and anti-PD-1/L1 antibodies are underway in the metastatic setting, the neoadjuvant setting provides an opportunity to test different treatment schedules in small cohorts of pts. Tissue and blood biomarkers can be drawn at several timepoints and correlated to clinical and pathological endpoints to explore mechanisms of response, biomarkers of efficacy, and to select the best schedules to take forward to larger-scale trials.

Trial design: Eligible pts with BRAF V600 mutant, stage IIIB/C/D, resectable and measurable (RECIST 1.1) metastatic melanoma are evenly assigned to 3 cohorts (n = 60). All pts undergo complete macroscopic resection (RES) at week 12 and receive neoadjuvant therapy for 12 weeks preceding RES, followed by 40 weeks of adjuvant therapy. Cohort 1 receive sequential therapy with D+T for 2 weeks, followed by 4 pembrolizumab (pembro) doses until week 12, and 3 weekly pembro after RES. Cohort 2 receive concurrent D+T and 3 weekly pembro before and after RES. Cohort 3 receive 3 weekly pembro for the entire treatment course. Pembro is given at a flat dose of 200mg. Ultrasound surveillance of known disease areas is undertaken during the neoadjuvant period. Serial CT and FDG PET/CT are used to measure response and exclude progression in the neoadjuvant phase, and to monitor for recurrence during adjuvant and post treatment phases. Blood and tumour samples are collected at baseline, week 1, 4 and 12. The primary endpoint is the complete pathological response rate at RES following 12 weeks of therapy. Secondary endpoints include RECIST response, metabolic response, OS, RFS, safety/tolerability, surgical outcomes, quality of life, as well as biomarker analysis.

Background: Standard-dose pembro (2 mg/kg Q3W) + reduced-dose ipi (1 mg/kg Q3W × 4 doses) showed preliminary efficacy in patients (pts) with melanoma in part 1B of the phase 1/2 KEYNOTE-029 study (NCT02089685), but 42% of pts had treatment-related AEs (TRAEs). In part 1C, 2 more dosing regimens of this combination will be evaluated to further assess efficacy and aim to reduce the toxicity seen in part 1B.

Trial design: Pts aged ≥18 y with histologically confirmed unresectable stage III/IV melanoma not amenable to local therapy; no prior treatment ([neo]adjuvant treatment, excluding PD-1/PD-L1 or BRAF/MEK inhibitors, was allowed if pts did not discontinue for TRAEs, all TRAEs returned to baseline/stabilized, and relapse did not occur within 6 mo of discontinuation for anti–CTLA-4 therapy); measurable disease per RECIST v1.1; ECOG PS 0/1; tumor sample for determination of PD-L1 status; no active brain metastases (baseline brain MRI required) were eligible. ~100 pts will be randomized 1:1 to pembro 200 mg Q3W + ipi 50 mg Q6W (arm 1) or 100 mg Q12W (arm 2). Combination therapy will continue for ≤24 wk in arm 1 and ≤48 wk in arm 2, followed by pembro monotherapy for ≤24 mo or until PD, intolerable toxicity, or patient/physician decision. Tumor imaging will occur every 6 wk until wk 24, and every 12 wk thereafter. Response will be assessed per RECIST v1.1 by independent central review (for efficacy) and modified RECIST v1.1 by investigator review (for treatment decisions). Survival follow-up will occur every 12 wk. AEs will be graded per CTCAE v4.0. Pts with investigator-determined, confirmed CR who received ≥24 wk pembro and ≥2 doses after initial CR may discontinue pembro; pts with investigator-determined, confirmed CR or very good PR (percentage change from baseline in tumor size >60%) who received ≥1 ipi dose may discontinue ipi. Pts with SD or better who subsequently have PD may be eligible for a second course of pembro + ipi or pembro monotherapy (maximum 17 doses pembro and 4 doses ipi). Eligible pts with PD may remain on treatment until a confirmatory scan ≥4 wk later. Primary end points are safety and ORR; secondary end points include PFS, OS, and DOR. Enrollment is ongoing in the US, Australia, and New Zealand.

1258TiP Phase 2 Study Comparing Pembrolizumab with Intermittent/short-term dual MAPK pathway inhibition plus Pembrolizumab(PEM) in patients harboring the BRAFV600 mutation (IMPemBra Trial)

E.A. Rozeman[1], M.A. Deken[2], J. Gadiot[3], M.H. Geukes Foppen[1], L. Pronk[4], J.V. Thienen[1], J.B. Haanen[1], C.U. Blank[1]

[1]Medical Oncology Department, Het Nederlands Kanker Instituut Antoni van Leeuwenhoek (NKI-AVL), Amsterdam, Netherlands, [2]Molecular Oncology and Immunology, Het Nederlands Kanker Instituut Antoni van Leeuwenhoek (NKI-AVL), Amsterdam, Netherlands, [3]Immunology, Het Nederlands Kanker Instituut Antoni van Leeuwenhoek (NKI-AVL), Amsterdam, Netherlands, [4]Department of Biometrics, Het Nederlands Kanker Instituut Antoni van Leeuwenhoek (NKI-AVL), Amsterdam, Netherlands

Background: Continuous combinations of targeted therapy (TT), e.g. BRAF+MEK inhibitors(BRAFi+MEKi), with immunotherapy (IT), e.g. CTLA-4 or PD-1 blockade are currently tested in several phase1/2 trials with the aim to improve response rate and response duration in melanoma patients with a BRAFV600 mutation. However, high toxicity rates have been observed, revealing PD-1 blockade currently being the only possible combination partner for TT. Recently we have published preclinical data, showing that short-time TT induces strong T cell infiltration and is synergistic with PD-1 blockade. Analysis of biopsies of patients during TT indicate that long-term TT might be counterproductive, as T cell infiltration decreases in some patients already beyond 2 weeks. This raises the question which time period of MAPK pathway inhibition is optimal for combination with anti-PD-1. The IMPemBra trial will address this question, comparing PEM monotherapy with combination schemes of intermittent/short-term BRAFi + MEKi plus PEM. The primary objective is to explore safety, feasibility and the immune-activating capacity of the different regimens.

Trial design: Stage IV BRAFV600E/K mutation positive melanoma patients, naïve for IT and TT, will start treatment with PEM 200mg q3wk. After 6 wks the patients will be randomized (stratified according their LDH level) to continue PEM for up to 2 years (cohort 1), or to one of the experimental cohorts receiving either dabrafenib 150mg BID + trametinib 2mg QD two times intermittent for 1 wk (cohort 2), two times intermittent for 2 wks (cohort 3), or continuous for 6 wks (cohort 4). All cohorts continue afterwards with PEM for up to 2 years. Each cohort will consist of 8 patients. Primary endpoints are SUSARs and adherence to the study timeline, the intra-patient alteration in intratumoral CD8+ T cells and the percentage PD1+ CD8+ T cells in the peripheral blood. Tumor biopsies and blood samples including PBMCs are taken at baseline, wk 6, 9, 12, 18 and in case of progression. Secondary endpoints are objective response rate and progression free survival. Enrollment started in May 2016, 11 patients have been included so far.

Background: Checkpoint inhibitor and targeted therapies are both important tools in the management of *BRAF* V600–mutated unresectable or metastatic melanoma. Although these therapies have improved responses and overall survival, many patients still progress and die from this disease. Thus, additional treatment strategies are needed to improve durability of responses and related long-term outcomes in these patients. Based on preclinical and preliminary clinical data, BRAF and MEK inhibitors can reverse the oncogenic BRAF-induced immune-suppressive phenotype through enhanced melanoma antigen expression and enhanced tumor antigen-specific T-lymphocyte recognition in vivo. These data suggest that there is potential clinical benefit in combining dabrafenib and trametinib with checkpoint inhibitor therapy.

Trial design: The 3-part COMBI-i phase 3 study (NCT02967692) will evaluate the safety and efficacy of PDR001, an investigational anti–programmed death 1 antibody, in combination with dabrafenib and trametinib in previously untreated patients with *BRAF* V600–mutated unresectable or metastatic melanoma. In part 1, a safety run-in will establish the recommended phase 3 regimen (RP3R) for use in part 3 using an adaptive Bayesian logistic regression model. In part 2, tissue and blood samples from the biomarker cohort will be used to characterize baseline immune markers and explore potential immune marker modulation by the triplet therapy. Part 3 is the randomized, double-blind, placebo-controlled portion that will open once the RP3R has been determined. Approximately 500 patients will be randomized 1:1 to receive either PDR001 in combination with dabrafenib and trametinib or placebo in combination with dabrafenib and trametinib, with randomization stratified based on Eastern Cooperative Oncology Group performance status and lactate dehydrogenase level. The primary endpoint will be progression-free survival per investigator's assessment according to RECIST v1.1. Overall survival will be a key secondary endpoint.

Clinical trial identification: NCT02967692 First received: November 16, 2016

Background: After the introduction of ipilimumab, an anti-CTLA-4 monoclonal antibody, durable, long term survival has become a possibility for a subgroup of advanced melanoma patients. Since ipilimumab is a relatively novel drug there are limited data on the long-term physical, psychological, and social functioning of these patients. This study will evaluate the long-term physical and psychosocial performances and the information needs of advanced melanoma survivors who have been treated with ipilimumab.

Trial design: This is a prospectively enrolling, multicentre cohort study. **Objectives:** To assess health-related quality of life (HRQoL), anxiety, depression, fatigue, fear of cancer recurrence, sexual health and generic health status in patients with advanced melanoma who have survived at least 2 years after ipilimumab treatment (without subsequent other systemic therapies) as compared with healthy controls, and to describe the melanoma-specific HRQoL, impact of cancer, social functioning and information needs in patients with advanced melanoma who have survived at least 2 years after ipilimumab treatment. **Patients and healthy control population:** Patients with advanced (stage IV or unresectable stage III) melanoma who survived at least 2 years and were treated with ipilimumab between 2011 and 2015 in 14 hospitals in the Netherlands are included. The patient population consists of 3 treatment groups based on time since ipilimumab treatment: 24 to $<$ 36 months, $\geq$ 36 to $<$ 48 months and $\geq$ 48 months post-ipilimumab treatment. The healthy control population will be selected from 'Patient Reported Outcomes Following Initial treatment and Long term Evaluation of Survivorship (PROFILES)'. PROFILES contains a reference cohort of more than 2000 healthy individuals and is designed to be representative of the Dutch-speaking population in the Netherlands. **Measurements:** The primary and secondary study outcomes will be measured by questionnaires, at 3 time-points in patients 24 to $<$ 36 months and at 1 time-point in patients $\geq$ 36 months post-ipilimumab treatment. The primary outcome, HRQoL will be assessed with the European Organisation for Research and Treatment of Cancer quality of life questionnaire-C30 (EORTC QLQ-C30).

NEW DIAGNOSTIC TOOLS

1261P mRNA capture sequencing enabled liquid biopsy screening

J. Vandesompele

Research and Development, Biogazelle, Zwijnaarde, Belgium

Background: In contrast to general belief, a substantial part of the human protein coding transcriptome is abundantly present in the blood as extracellular mRNA, ready to exploited. It is well known that cancer cells actively and passively release RNA cargo into circulation and their detection may inform on the patient disease status.

Methods: We developed and applied a probe based RNA capture sequencing method as a sensitive RNA sequencing workflow to study thousands of transcripts in cell-free RNA from cancer patients' plasma. The method is based on exome-style enrichment of a randomly primed cDNA library with preservation of strandedness information. More than one million capture probes target 21,000 human messenger RNA and 60,000 human long non-coding RNA genes. Apart from RNA abundance profiling, this type of data can also be used to detect structural RNA variants, such as somatic mutations, fusion genes, and RNA editing events, all known to play an important role in cancer.

Results: On average, between 6000-10,000 RNA genes are reproducibly detected in 0.2 ml of plasma. Detection and coverage sensitivity is greatly increased by using larger plasma volume and improved adaptor ligation strategies. We also observed a positive correlation between number of platelets in plasma and detected genes and variants, in line with their tumor-educated nature. Our benchmarked RNA variant pipeline identifies thousands of germline and somatic variants in circulating mRNA. A dedicated titration experiment in which plasma from cancer and healthy individuals were mixed in known ratios demonstrates excellent quantitative performance. Pronounced RNA abundance differences and enriched pathways are observed between cancer types and during treatment. The RNA capture sequencing also works on other body fluids, such as urine and serum, and simultaneous targeting of mRNA and lncRNA provides substantial enrichment of otherwise low-abundant lncRNAs.

Conclusions: RNA capture sequencing of liquid biopsies is a promising new application to support precision oncology and is expected to enhance therapy stratification, treatment response monitoring and early detection of relapse.

1262P Use of droplet digital PCR for quantitative and automatic analysis of the HER2 status in breast cancer patients

K. Otsuji[1], T. Sasaki[2], A. Tanaka[2], A. Kunita[2], M. Ikemura[2], K. Matsusaka[3], K. Tada[1], M. Fukayama[2], Y. Seto[4]

[1]Department of Breast and Endocrine Surgery, Faculty of Medicine, The University of Tokyo, Tokyo, Japan, [2]Department of Pathology, Faculty of Medicine, The University of Tokyo, Tokyo, Japan, [3]Department of Molecular Oncology, Graduate School of Medicine, Chiba University, Chiba, Japan, [4]Department of Stomach and Esophageal Surgery, Faculty of Medicine, The University of Tokyo, Tokyo, Japan

Background: Digital polymerase chain reaction (dPCR) has been used to yield an absolute measure of nucleic acid concentrations. Recently, a new method referred to as droplet digital PCR (ddPCR) has gained attention as a more precise and less subjective assay to quantify DNA amplification. We demonstrated the usefulness of ddPCR to determine HER2 gene amplification of breast cancer.

Methods: In this study, we used ddPCR to measure the HER2 gene copy number in clinical formalin-fixed paraffin-embedded samples of 41 primary breast cancer patients. To improve the accuracy of ddPCR analysis, we also estimated the tumour content ratio (TCR), the ratio of tumour cell count per section, for each sample.

Results: Our determination method for HER2 gene amplification using the ddPCR ratio (ERBB2:ch17cent copy number ratio) combined with the TCR showed high consistency with the conventionally defined HER2 gene status according to ASCO-CAP (American Society of Clinical Oncology/College of American Pathologists) guidelines ($P < 0.0001$, Fisher's exact test). The equivocal area was established by adopting 99% confidence intervals obtained by cell line assays, which made it possible to identify all conventionally HER2-positive cases with our method. In addition, we succeeded in automating a major part of the process from DNA extraction to determination of HER2 gene status.

Conclusions: The introduction of ddPCR to determine the HER2 gene status in breast cancer is feasible for use in clinical practice and might complement or even replace conventional methods of examination in the future.

1263P BRCA1 large gene rearrangements (LGRs) in Russian breast cancer patients: the development of the droplet digital PCR assay for LGR detection and the identification of recurrent exon 8 deletions

E. Imyanitov[1], E. Preobrazhenskaya[1], I. Bizin[2], E. Kuligina[1], E. Anisimova[3], S. Laptiyev[4], E. Suspitsin[1], S. Aleksakhina[1], A. Togo[1], A. Sokolenko[1]

[1]Department of Tumor Biology, N.N. Petrov Institute of Oncology, St.-Petersburg, Russian Federation, [2]Laboratory of Bioinformatics, Polytechnical University, St.-Petersburg, Russian Federation, [3]Outpatient Clinic, Leningrad Regional Oncology Dispensary, Saint Petersburg, Russian Federation, [4]Department of Medical Biology and Genetics, I.P. Pavlov Medical University, St.-Petersburg, Russian Federation

Background: Some pathogenic BRCA1 mutations are represented by large gene rearrangements (LGRs). LGRs cannot be detected by conventional Sanger sequencing. Multiplex ligation-dependent probe amplification (MLPA) is a leading method for LGR detection, however it is entirely based on the use of commercial kits, includes relatively lengthy hybridization step and is poorly suitable for the large-scale screening for recurrent deletions.

Methods: We developed and validated the droplet digital PCR (ddPCR) assay, which covers the entire coding region of BRCA1 gene and is capable to precisely quantitate the copy number for each exon.

Results: 141 breast cancer (BC) patients, who demonstrated evident clinical features of hereditary BC but turned out to be BRCA1/2 mutation-negative upon Sanger sequencing, were subjected to the LGR analysis. 4 patients with LGR were identified, with 3 cases of exon 8 deletion and 1 women carrying the deletion of exons 3-7. Excellent concordance with MLPA was observed. Exon 8 copy number was tested in additional 720 high-risk BC, and another 3 cases with the deletion were revealed; MLPA re-analysis demonstrated that exon 8 loss was a part of a larger genetic alteration in 2 cases, while the remaining patient had isolated defect of exon 8. Long-range PCR and next generation sequencing revealed, that 3 out of 4 samples with isolated exon 8 deletion had an identical rearrangement.

Conclusions: Droplet digital PCR is a reliable tool for detection of large gene rearrangements. BRCA1 LGRs are rare in Russian hereditary BC patients, with exon 8 deletion being a recurrent allele in this population.

1264P Clinical evaluation of low density array based EGFR mutation detecting kit using tissue samples and liquid biopsies

J. Hernández-Losa[1], Y. Ruano[2], R. Somoza[1], A. Muro[2], S. RamónY Cajal[1], J.L. Rodríguez-Peralto[2]

[1]Anatomical Pathology, Vall d'Hebron University Hospital, Barcelona, Spain, [2]Department of Pathology, 12 de Octubre University Hospital, Madrid, Spain

Background: The information on EGFR mutations status improves the benefit of targeted therapies for the non-small-cell lung cancer patients. These determinations are already part of standard protocols for cancer treatment. The study of the mutations in EGFR in liquid biopsy also permits a follow-up throughout the treatment and detection of acquired resistance.

Methods: CLART® CMA EGFR kit (GENOMICA, Spain) detects the 40 high-prevalence mutations associated with sensitivity or resistance to the treatment. These mutations are located in the exons 18, 19, 20 and 21. The kit is based on the multiplex ARMS-PCR followed by detection on a low-density microarray platform: CLART® (Clinical Arrays Technology). The samples were processed in a bench-top semi-automated system, Autoclart. A new version of the kit, CLART® CMA EGFR LB, allows using liquid biopsy as a sample with only an additional pre-PCR step.

Results: A 107 tissue biopsies from metastatic NSCLC patients were obtained and analyzed in two University Hospitals in Spain: Vall d'Hebron (Barcelona) and 12 de Octubre (Madrid). The EGFR mutations were detected with CLART® CMA EGFR kit with 96.3% concordance with the routine methods used in the hospital practice (Cobas/Therascreen/Sanger sequencing). The discrepant results were analyzed by Sanger sequencing. The sensitivity of the CLART® CMA EGFR kit is 100% and specificity is 96.5%. The same CLART platform, only with the addition of one pre-PCR amplification step was used for processing the plasma samples (liquid biopsy) from the NSCLC metastatic patients. A total of 8 samples were tested. In six samples the results obtained from tissue samples and liquid biopsies were concordant. In the two discordant samples the exon 19 deletions detected in tissue were not detected in plasma samples. The wt results obtained for these two liquid biopsies were confirmed by Next Generation Sequencing.

Conclusions: Given the high specificity and sensitivity and excellent concordance with the other platforms in hospital practice, CLART® CMA EGFR kit is valid for the use in

the clinical routine. Furthermore, using the same semi-automated platform for tissue samples and liquid biopsy facilitates laboratory work and reduces turnover time per sample.

1265P Correlation of somatic genomic alterations between tissue genomics and circulating tumor DNA (ctDNA) employing next generation sequencing (NGS) analysis in lung and gastrointestinal cancers

M.M. Toor[1], W. bahaj[1], Z. Ahmed[1], L. Kujtan[1], T.J. Pluard[2], M.E. McNally[3], L.S. Cummings[3], E. Island[3], J. Forster[3], K.F. Kennedy[4], J. Subramanian[2], A. Masood[2]

[1]Department of Medicine, UMKC(University of Missouri Kansas City), Kansas City, MO, USA, [2]Department of Medical Oncology, Saint Luke's Cancer Institute, Kansas City, MO, USA, [3]Department of Surgery, UMKC(University of Missouri Kansas City), Kansas City, MO, USA, [4]Department of Cardiovascular Research, Saint Luke's Health System, Kansas City, MO, USA

Background: Peripheral blood circulating tumor DNA (ctDNA) and tumor tissue next-generation sequencing (NGS) is routinely performed to guide therapy in cancer patients. However, little is known about the concordance or discordance between commercially available tissue genomics testing panels and ctDNA. The aim of our study was to assess concordance between matched cancer tissue genomics and blood based ctDNA in lung and gastrointestinal (GI) cancers.

Methods: Tissue genomic analysis was performed with Paradigm® (n = 17)/Caris® (n = 11) and ctDNA was analyzed with Guardant360® (n = 28). Samples included, non-small cell lung cancer (n = 10), small cell lung cancer (n = 4), colorectal cancer (n = 5), hepatocellular carcinoma (n = 2), intrahepatic cholangiocarcinoma (n = 1), pancreatobiliary adenocarcinoma (n = 3), esophageal adenocarcinoma (n = 2) and gastric adenocarcinoma (n = 1).

Results: We identified 6 (21%) patients with at least one gene mutation that was detected by both tissue genomic and ctDNA analysis. Total number of gene mutations identified in 28 patients were 106, but only 8 (7.5%) were detected by both tissue and ctDNA panels. When this testing was done within 90 days the concordance increased to 10.20%. Table.

Table: 1265P

Patients with at least one mutation detected by both platforms	21% (n = 6/28)
Mutations detectable by both platforms	7.54% (n = 8/106)
Mutations detectable by both platforms if interval between tissue and blood collection <90 days.	10.20% (n = 5/49)

Conclusions: We identified significant discordance between tissue and ctDNA mutational profiles in lung and GI cancers. Therefore, the results from NGS platforms should be interpreted with extreme caution. Our analysis reveals that these platforms should not be used interchangeably. The discordance rate may be due to tissue heterogeneity and/or spatial and temporal clonal evolution. Standardization of the sequencing techniques and education of practicing oncologists about the limitations of liquid biopsies needs to be highlighted.

1266P Analytical and clinical validation of a next-generation sequencing-based circulating tumor DNA (ctDNA) assay assures its clinical application

W. Liu[1], S. Mu[1], J. Yao[2], H. Chen[3], Z. Hu[4], J. Hu[5], G. Chirn[3], H. Kang[4], K. Wang[2], M. Yao[5]

[1]Department of computational oncology, Origimed, Shanghai, China, [2]Department of bioinformatics, Origimed, Shanghai, China, [3]Department of Bioinformatics, OrigiMed, Shanghai, China, [4]Department of Genome Center, Origimed, Shanghai, China, [5]Department of Clinical Analysis, OrigiMed, Shanghai, China

Background: To date, ctDNA has been exhibiting its unprecedented translational potential in cancer care. However, accurate identification of comprehensive genomic alternations is rigorously needed for its clinical utility.

Methods: Three biologically relevant reference materials with allele frequencies expected at 0.1%, 1% and 5% were used to analytically evaluate the accuracy and reproducibility. Clinically, 43 ctDNA samples from lung, liver, colorectal, breast and gastric cancers were genomically profiled and compared to the known alternations in their matched solid tumors, in terms of single base substitution, insertions/deletions, copy number variations and rearrangement.

Results: The analytical validation demonstrated unprecedented accuracy: near 100% specificity (99.6%, 99.9% and 100%) and 95.8%, 100% and 100% sensitivity for 3 reference materials, respectively. The actual detection limit was as low as 0.05%. The reproducibility was assessed as 0.998 (jaccard index) by sequencing 2 replicates of each reference. In clinical validation, compared to matched FFPE results, this ctDNA assay showed overall 99.9% specificity and 89% sensitivity, with > 90% sensitivity when only drug-gable hotspots were concerned. Eight events of gene rearrangements involving known targeted genes of ALK (n = 4), ROS1 (n = 3) and MET (n = 1) were detected from seven patients with 100% sensitivity and 100% specificity, confirmed either by IHC or panel sequencing (depth > 1,000X) over their matched FFPE biopsies. Due to its typically low abundance, CNV from ctDNA was detectable only for those highly amplified genes (> =8 copies) with > =4 exons, demonstrating 72.2% sensitivity and 99.5% specificity.

Conclusions: Stringent criteria for both analytical and clinical validations are required for clinical utility of ctDNA. Our ctDNA assay has demonstrated high accuracy and reliability in comprehensively genomic profiling of ctDNA, especially in regard to drug-gable targets, which assures its translational utility in optimizing and monitoring targeted therapies in cancer management.

1267P Combination of solid and liquid biopsy genomic profiling for tumor heterogeneity characterization

J. Garcia Foncillas[1], L. Álvarez[2], A. Rodrigo[2], A. Terrádez[2]

[1]Cancer Institute, University Hospital "Fundacion Jimenez Diaz", Madrid, Spain, [2]Translational Oncology Division, Oncohealth Institute, IIS-Fundacion Jimenez Diaz-UAM, Madrid, Spain, Madrid, Spain

Background: Characterization of inter- and intra-tumoral heterogeneity has become a central issue in the implantation of personalized medicine. In this sense, although, the liquid biopsy has been recognized as a promising tool for prognostic, molecular profiling and monitoring of cancer disease, we are still at the beginning of its incorporation alone into the routine oncology practice. In the present study, we evaluate the usefulness of an integrated approach that combines the analysis of both solid (FFPE block) and liquid (blood sample) biopsy, into the clinical routine.

Methods: We analyzed 163 samples of metastatic patients, with different cancers types, using the OncoSTRAT&GO® solution (Biosequence SL, Valencia, Spain through OncoDNA SA, Gosselies, Belgium); that allows i) sequencing of more than 200 genes, identification of 350 genes fusion and evaluation of the expression level of tens of proteins in solid biopsy and ii) sequencing of hotspot mutations of a 27-gene panel in liquid biopsy.

Results: We focus the analysis on those actionable variants that could be detected in both solid and liquid biopsies. A complete concordance of 62.6% was observed between both types of biopsies variants. The minimum variant allele frequencies (VAFs) was found to be 0.1% and 1% in liquid and solid biopsy, respectively. The concordant and discordant VAFs were compare showing similar distributions, no significant statistical differences were found: mean values of 14.5/8.9% (P = 0.79; Mann-Whitney test) and 39.4/29.9% (P= .08; Mann-Whitney test) in liquid and solid biopsy, respectively.

Conclusions: Our findings indicate that the combination of solid and liquid biopsies analysis in clinical practice provides additional information in 37.4% of the cases. Discordant variants cannot be put down to the sensibility of the analysis and consequently should be associated to tumor heterogeneity, low tumor burden and/or treatment response. Our results show the usefulness of an integrated approach, resulting in a broad characterization of the tumor for a better disease management.

1268P Retrospective analysis of a SHIVA01 trial cohort using functional mutational analysis successfully predicted treatment outcome

G. Tarcic[1], C. Le Tourneau[2], M. Kamal[2], O. Edelheit[1], Z. Barbash[1], M. Vidne[1], S. Dureau[2], B. Miron[1], C. Callens[3], N. Servant[2], I. Bieche[4]

[1]R&D, NovellusDx, Jerusalem, Israel, [2]Dept of Medical Oncology, Institut Curie, Paris, France, [3]Pharmacogenomic Unit, Genetics Laboratory, Institut Curie, Paris, France, [4]Genetics, Curie, Paris, France

Background: The SHIVA01 trial was a randomized proof-of-concept phase II trial, testing the hypothesis of treating patients (pts) based on molecular profiles with molecularly targeted agents (MTA) in a histology agnostic manner. The trial results

showed no statistically significant difference in PFS between MTA and control arm. The addition of functional information on identified mutations and their response to MTA's may improve treatment outcomes.

Methods: The molecular profile of 20 pts treated with a MTA in the trial was analyzed in the NovellusDx Functional Annotation for Cancer Treatment (FACT), a functional mutational analysis platform, to reveal activated signaling pathways and measure the activity of these mutations in the presence of the MTA's administered in the trial. The results of FACT were used to stratify the pts into responders and non-responders.

Results: We uncovered the functional landscape in 12 of the 20 pts in the analyzed group. In the remaining 8 pts, no relevant mutational alterations were identified. This analysis provided experimental evidence to the oncogenic activity of the mutations and of the combination of mutations identified in the pts. Furthermore, the response of these pts' mutations to the MTA's used was measured in-vitro, blinded to the actual clinical results. Each patient was then assigned as either a responsive or non-responsive. When the results were used to stratify the pts' PFS data, positive patients had a median PFS of 5.8 months vs. 1.7 months in the negative group ($P = 0.03$ in a non-parametric test).

Conclusions: This analysis shows the predictive power of a new and innovative method for characterization of pts molecular profiles and their in-vitro response to MTA's. The abundance of mutations classified as VUS and multiple mutations in different genes reveals the complexity in assigning the optimal MTA and the necessity of a functional assay. The FACT analysis accurately provided prognostic predictions of the pts treated into responsive and pts with no molecular basis for a benefit in MTA treatment. Importantly, the hypothesis driving the SHIVA01 trial proved positive by the addition of the functional interpretation of the mutational data.

1269P Integrative multi-platform meta-analysis of gene expression profiles in pancreatic ductal adenocarcinoma patients for identifying novel diagnostic biomarkers

O. Caba[1], A.L. Irigoyen[2], C. Jimenez-Luna[3], M. Benavides[4], F.M. Ortuño[5], C. Guillen-Ponce[6], I. Rojas[5], E. Aranda Aguilar[7], J.C. Prados[3]

[1]Health Sciences Department, University of Jaén, Jaen, Spain, [2]Medical Oncology, Hospital Virgen de la Salud, Toledo, Spain, [3]Human Anatomy and Embriology, University of Granada, Granada, Spain, [4]Medical Oncology, Hospital Universitario Regional y Virgen de la Victoria, Malaga, Spain, [5]Computer Architecture and Computer Technology, University of Granada, Granada, Spain, [6]Medical Oncology, Hospital Universitario Ramon y Cajal, Madrid, Spain, [7]Medical Oncology, University Hospital Reina Sofia. CIBERONC Instituto de Salud Carlos III, Cordoba, Spain

Background: Applying differentially expressed genes (DEGs) to identify feasible biomarkers in diseases can be a hard task when working with heterogeneous datasets. Expression data are strongly influenced by technology, sample preparation processes, and/or labeling methods. The proliferation of different microarray platforms for measuring gene expression increases the need to develop models able to compare their results, especially when different technologies can lead to signal values that vary greatly. Integrative meta-analysis can significantly improve the reliability and robustness of DEG detection. The objective of this work was to develop an integrative approach for identifying potential cancer biomarkers by integrating gene expression data from two different platforms. Pancreatic ductal adenocarcinoma (PDAC), where there is an urgent need to find new biomarkers due its late diagnosis, is an ideal candidate for testing this technology.

Methods: Expression data from two different datasets, namely Affymetrix and Illumina (18 and 36 PDAC patients, respectively), as well as from 18 healthy controls, was used for this study. A meta-analysis based on an empirical Bayesian methodology (ComBat) was then proposed to integrate these datasets. DEGs were finally identified from the integrated data by using the statistical programming language R.

Results: After our integrative meta-analysis, 5 genes were commonly identified within the individual analyses of the independent datasets. Also, 28 novel genes that were not reported by the individual analyses ('gained' genes) were also discovered. Several of these gained genes have been already related to other gastroenterological tumors.

Conclusions: The proposed integrative meta-analysis has revealed novel DEGs that may play an important role in PDAC and could be potential biomarkers for diagnosing the disease.

1270P 3D Cultured Tumour from Patients to Predict Treatment Response

W. Vader[1], L. Price[2], B. Herpers[2], S. Basten[2]

[1]R&D, VitroScan B.V., Leiden, Netherlands, [2]CRO, OcellO B.V, Leiden, Netherlands

Background: Treatment selection for cancer patients is still a challenge. Average response rates for standard chemotherapy are low due to a lack of predictive markers. Genetic approaches to improve treatment efficacy have not yet delivered solutions for the day-to-day clinic. Functional testing of 3D cultures of patient tumour biopsies has the potential to identify tumours that are sensitive to standard drugs, search for alterative drugs when treatment options appear exhausted, and prevent overtreatment. Our technology based on image analysis of 3D tumour cultures accommodates accurate evaluation of drug sensitivity with small amounts of heterogeneous tumour material. We aim to validate our methods, and develop diagnostics to predict drug response for cancer patients.

Methods: 3D cultures embedded in a protein-rich hydrogel are generated from tumour biopsies, and exposed to standard-of-care therapies, targeted therapies and drug combinations. An automated high content screening platform measures cell and tissue morphology, and reports responses such as tumour cell killing, growth arrest and local invasion. Per tumour type and drug, morphological features are selected as standard read-outs for the response. Proof of Concept (PoC) trials have been initiated to compare drug sensitivity of tumour cultures with treatment response in the clinic.

Results: We present results of PoC experiments showing drug sensitivity in 3D cultures of fresh and cryopreserved tumour material of gastric, endometrial, cervical, and ovarian cancer patients. Standard-of-care therapies were tested and results were compared per drug (combination). Differentiated drug responses are identified for treatment schedules including platinum-based drugs, taxanes, anthracyclines, 5-FU. In addition, responses to drugs that are not (yet) considered standard of care (PARP inhibitors) were measured.

Conclusions: Our technology enables drug sensitivity testing in 3D cultures of tumour tissues. This allows patient-specific treatment responses to developmental and standard-of-care drugs to be determined. Ongoing PoC trials will reveal the correlation of our in vitro test with treatment responses in the clinic.

1271P 5-ALA administration for photodynamic diagnosis of peritoneal metastases due to advanced gastric cancer: A randomised, double-blind, multicentre phase I/II study

T. Takahashi[1], K. Fujitani[2], T. Omori[3], K. Nishikawa[4], T. Hayashi[5], T. Namikawa[6], E. Otsuji[7], S. Takiguchi[8], Y. Doki[1]

[1]Department of Gatroenterological Surgery, Osaka University Hospoital, Suita, Japan, [2]Department of Surgery, Osaka General Medical Center, Osaka, Japan, [3]Department of Surgery, Osaka International Cancer Institute, Osaka, Japan, [4]Surgery, National Hospital Organization Osaka National Hospital, Osaka, Japan, [5]Surgery, Saito Yukoukai Hospital, Ibaraki, Japan, [6]Surgery, Kochi University Hospital, Nankoku, Japan, [7]Surgery, Kyoto Prefectural University Hospital, Kyoto, Japan, [8]Surgery, Nagoya City University Hospital, Nagoya, Japan

Background: For advanced gastric cancer, diagnosis of peritoneal dissemination is mandatory prior to the decision of therapy; therefore, staging laparoscopy (SL) has gained wider clinical acceptance. We have reported the efficacy of SL with photodynamic diagnosis (PDD) using 5-aminolevulinic acid (5-ALA). In this study, the safety and effectiveness of oral administration of 5-ALA PDD compared with that of conventional white-light laparoscopic diagnosis is assessed in a phase I/II study. This research also used a randomised double-blind comparison to explore the optimum dose of 5-ALA to be followed by a confirmatory study.

Methods: Subjects were patients with type 3 or 4 gastric cancer. A total of 20 or 40 mg/kg 5-ALA was administered orally 180–300 minutes before SL. The primary endpoint was safety; the secondary endpoints were sensitivity, specificity, positive predictive value, negative predictive value, and the proportion of patients with peritoneal dissemination.

Results: Thirty-one patients, comprising 19 men and 12 women, were enrolled. Fourteen patients were allocated to the 20 mg/kg group and 17 to the 40 mg/kg group. The median age was 70 years. The proportions of adverse events were 53.8% and 41.2% in the 20 and 40 mg/kg groups, respectively. Hypotension was noted as serious adverse event in 1 patient. The sensitivities of PDD in the 20 and 40 mg/kg groups were higher (95.7% and 100%, respectively) than those of conventional diagnosis (73.9% and 67.8%) ($p = 0.0625$ and $p = 0.0313$). In terms of precision, the evaluation values of diagnosis through conventional imaging compared with PDD were as follows: sensitivity, 83.5% vs. 98.6%; specificity, 75.5% vs. 38.8%; positive predictive value, 82.2% vs. 69.6%; and negative predictive value, 75.5% vs. 95.0%, respectively. In addition, one more patient was found positive for dissemination via PDD.

Conclusions: This investigator-initiated clinical trial confirmed the safety and effectiveness of 5-ALA administration in PDD for peritoneal metastases in gastric cancer. Results indicated that both doses of 5-ALA may be clinically applicable. Thus, we are now conducting a confirmatory study to apply for pharmaceutical approval of 5-ALA.

1272P Diagnostic performance of dedicated breast PET scanner with a ring detector

R. Hashimoto[1], S. Akashi-Tanaka[1], C. Watanabe[1], H. Masuda[1], K. Taruno[1], T. Takamaru[1], Y. Ide[1], T. Kuwayama[1], Y. Hirota[2], Y. Kobayashi[3], T. Sawada[1], M. Hirose[4], S. Nakamura[1]

[1]Breast Surgical Oncology, Showa University Hospital, Tokyo, Japan, [2]Pathology, Showa University Hospital, Tokyo, Japan, [3]Radiology, Midtown Clinic Tokyo bay, Tokyo, Japan, [4]Radiology, Showa University Hospital, Tokyo, Japan

Background: Dedicated breast positron emission tomography scanners (dbPET) have been developed to make possible higher spatial resolution and sensitivity. The purpose of this study was to investigate the diagnostic performance of a dbPET scanner with an O-shaped detector in patients with known breast cancer.

Methods: A total of 82 female patients diagnosed with breast cancer consented to participate in this study (84 lesions: 10 ductal carcinomas in situ (DCIS), 74 invasive cancers). All patients underwent a WB-PET/MRI using Biograph mMR® (Siemens Healthcare) approximately 80 minutes after fluorine-18 fluorodeoxyglucose ((18)F-FDG;3.0MBq/kg) injection, followed by dbPET using Dedicated Breast PET System Elmammo®(Shimadzu, Kyoto, Japan) which required 5 minutes per breast.

Results: The overall imaging sensitivities of dbPET and WB-PET/MRI were 89% (75/84) and 87% (74/84) respectively. The sensitivities excluding 5 lesions which were outside the field of view of dbPET, were 95% (75/79) and 87% (69/79) respectively. The standardized uptake values (SUV) of dbPET (SUVmax mean13, range 1.64-41.6) and WB-PET/MRI (SUVmax mean 5.71, range 1.15-13.3) showed correlation with nuclear grade (NG) (Spearman's rank-correlation coefficient $r = 0.507, 0.455, p < 0.001$), Ki67 ($r = 0.56, 0.62, p < 0.001$) and estrogen receptor ($r=-0.524, -0.475, p < 0.001$). The sensitivities for DCIS were 90% (9/10), 60% (6/10) respectively. The sensitivities for DCIS and invasive cancers with 1cm or less maximal diameter were 86% (18/21) and 57% (12/21) respectively. We observed six lesions (three high grade DICS (1.7 cm - 5cm), three high grade invasive cancers with 0.3-0.9cm) that were only detected by dbPET. On the contrary, four lesions could not be detected by either modality (low grade DCIS, invasive lobular carcinoma;2cm, low grade invasive ductal carcinoma with 0.6cm).

Conclusions: Both dbPET and WB-PET/MRI showed high imaging sensitivity, but dbPET had significantly higher sensitivity to high grade DCIS and invasive lesions up to 1cm. This level of diagnostic performance could help to detect early stage cancers as part of breast screening.

Background: Several guidelines recommend a follow-up based on clinic visits and chest CT-scans for completely resected NSCLC. However, evidence to support these recommendations is poor, in the absence of randomized data. The IFCT-0302 trial is a randomized multicenter trial which compared 2 follow-up programs for completely resected stage pI, II, IIIA and T4 (pulmonary nodules in the same lobe) N0-2 NSCLC (TNM 6th edition).

Methods: In the control arm (arm 1), follow-up consisted of clinical examination and Chest X-ray (CXR). In the experimental arm (arm 2), patients underwent clinical examination, CXR, thoraco-abdominal CT-scan (CT) plus bronchoscopy (optional for adenocarcinomas). In both arms, procedures were repeated every 6 months after randomization during the first 2 years, and yearly until 5 years. Supplementary procedures were allowed in case of symptoms. The primary endpoint was overall survival (OS).

Results: Between January 2005 and November 2012, 1775 patients were randomized (arm 1: 888; arm 2: 887). Patient characteristics were well-balanced between the two arms: males 76.3%, median age 63 years (range: 34-88), squamous and large cell carcinomas 39.5%, stage I 68.1%, stage II 13.7%, stage III 18.3%, lobectomy or bilobectomy 86.6%, pre- and/or post-operative radiotherapy 8.7%, and pre- and/or post-operative chemotherapy 45%. Median follow-up was 8.7 yrs (95% CI: 8.5-9). OS was not significantly different between arms ($HR = 0.92$, 95% CI: 0.8-1.07; $p = 0.27$). Median OS was 8.2 yrs (95% CI: 7.4-9.6) and 10.3 yrs (95% CI: 8.5-not reached) in arms 1 and 2, respectively. Three-year disease-free survival rates were 63.3% (95%CI: 60.2%-66.5%), and 60.2% (95% CI: 57.0%-63.4%), respectively. Eight-year OS rates were 51.1% (95% CI: 47.2%-55.1%) and 55.6% (95% CI: 51.7%-59.4%) respectively.

Conclusions: The IFCT-0302 trial is the first randomized study of follow-up in resected NSCLC. The primary endpoint was not met. A longer follow-up is necessary not to miss a potential long-term OS benefit of CT-scan-based surveillance.

Background: The study of the tumour microenvironment is leading to a better understanding of the evasion of immune surveillance and the development of new therapies. This research focuses on the analysis of immunoregulatory genes as potential prognostic biomarkers in resectable non-small cell lung cancer (NSCLC).

Methods: The expression of 8 genes involved in immune-regulation (*PD-L1, PD-L2, IDO-1, IDO-2, ICOS-LG, CD5, CD6 and CD200*) was analysed by RTqPCR in 257 paired fresh frozen tumour and normal tissue samples of resected NSCLC. Relative expression was calculated by Pfaffl formulae using *ACTB, CDKN1B* and *GUSB* as endogenous controls. Non-parametric tests were used for correlations between clinicopathological and analytical variables and survival was assessed by Kaplan-Meier curves (long rank-test), considering significant $p < 0.05$.

Results: Patients median age was 64 years, 82% were males, 88% were former or current smokers, 47% were adenocarcinomas (ADC). Patients with higher expression of *CD5* and *IDO2* had a significant increase in overall survival (OS, 53.3 vs NR months, $p = 0.032$; 51.9 vs NR months, $p = 0.049$, respectively). A signature combining the expression of *CD5* and *IDO2* was able to better prognosticate survival (40.4 vs NR months, $p = 0.028$). The multivariate analysis (including clinico-pathological and analytical variables) showed that this signature has independent prognostic information OS (HR = 0.553 [0.344-0.887], $p = 0.016$). Moreover, in the subgroup of ADC increased expression of *CD5* and *IDO2* was associated with longer OS as well as increased relapse-free survival (RFS, 19.1 vs NR months, $p = 0.045$; 18.8 and 67.0 months, $p = 0.029$, respectively). The multivariate analysis established this gene signature as an independent prognostic biomarker for OS (HR = 0.380 [0.166-0.872]; $p = 0.026$) and RFS (HR = 0.288 [0.139-0.597]; $p = 0.002$).

Conclusions: The analyses revealed the prognostic value of *CD5* and *IDO2*, being their combination an independent prognostic marker in resectable NSCLC. Supported by grants from FEDER and PI12-02838 and PI15-00753 from ISCIII.

Background: Treatment resistance and relapse have been associated to cancer stem cells (CSCs), a highly tumorigenic subpopulation of cells with self-renewal properties and the ability to grow forming tumorspheres in non-adherent conditions. The aim of this study was to isolate and characterize CSCs from lung cancer cell lines and tumor-tissue from resectable non-small cell lung cancer (NSCLC).

Methods: The study was performed on tumour cells from 8 resected NSCLC patients and 12 NSCLC cell lines grown in monolayer and as spheroids. The expression of 60 genes, including CSC-markers, pluripotency inducers, cell cycle regulators, invasion promoters and components of Notch, Wnt and Hedgehog pathways was analysed by RTqPCR. In addition, protein levels of CSC-markers (ALDH1A1, CD133, CD166, CD44 and EpCAM), pluripotency inducers (Nanog, Oct-4 and Sox2), Wnt components (Wnt3 and β-catenin) and Notch1 were assessed by western blot and immunofluorescence.

Results: Lung tumorspheres had significantly higher expression levels of CSC-related genes EPCAM1, CD44, ALDH1A1, CDKN1A, CCND1, and KLF4 compared to their paired-adherent cells. Similarly, epithelial to mesenquimal transition (EMT) inducer SNAI1 and integrins ITGA2, ITGA6 and ITGB1 were overexpressed in lungspheres. Notch pathway ligands, JAG1 and DLL4, receptors, NOTCH1, NOTCH2 and NOTCH3, and the effector factor HES1 showed increased expression in spheroids. In Wnt, higher expression levels of WNT3, CTNNB1 and GSK3B were found in tumorspheres. No significant differences were found for the rest of genes analyzed. Western blot and immunofluorescence analyses revealed that CD44, CD133, Sox2 and β-catenin were highly expressed in spheroids from cell lines and patients' samples. The expression of the rest of proteins evaluated differed among specimens.

Conclusions: Our results suggest four molecules which could act as markers for CSCs in NSCLC. Genes related to Notch and Wnt signaling pathways were more expressed in spheroids compared to the cells grown in adherence, suggesting that both pathways could be interesting targets against lung CSCs. Supported by grants RD12/0036/0025 from RTICC-FEDER, and PI12-02838 and PI15-00753 from ISCIII.

Legal entity responsible for the study: Fundación de Investigación Hospital General Universitario de Valencia.

1277PD A phase II randomized trial of adjuvant chemotherapy for the patients completely resected pathological stage IB (T > 5cm), II, IIIA non-small cell lung cancer comparing S-1 versus S-1 with cisplatin

T. Okamoto[1], T. Yano[2], M. Shimokawa[3], S. Takeo[4], K. Yamazaki[4], K. Sugio[5], M. Takenoyama[6], A. Nagashima[7], T. Tagawa[1], Y. Emi[8], Y. Maehara[1]

[1]Department of Surgery and Science, Kyushu University, Graduate School of Medical Sciences, Fukuoka, Japan, [2]Department of Thoracic Surgery, National Hospital Organization Beppu Medical Center, Beppu, Japan, [3]Clinical Research Institute, National Kyushu Cancer Center, Fukuoka, Japan, [4]Department of Thoracic Surgery and Clinical Research Institute, National Kyushu Medical Center Hospital, Fukuoka, Japan, [5]Department of Thoracic and Breast Surgery, Oita University, Faculty of Medicine, Yufu, Japan, [6]Department of Thoracic Oncology, National Kyushu Cancer Center, Fukuoka, Japan, [7]Department of Thoracic Surgery and Clinical Research Institute, Kitakyushu Municipal Medical Center, Kitakyushu, Japan, [8]Department of Surgery, Saiseikai Fukuoka General Hospital, Fukuoka, Japan

Background: Platinum-based combination chemotherapy is a standard postoperative adjuvant treatment for pathological stage II/III non-small cell lung cancer (NSCLC).

Oral S-1 therapy has been demonstrated to have a good efficacy with less toxicity for advanced NSCLC treatment. S-1 might be also useful in the adjuvant setting for surgical NSCLC.

Methods: We performed a phase II randomized open label multi-institutional study in surgical patients with pathological stage IB (T > 5 cm), II or III NSCLC (7th TNM classification), who underwent complete resection from 2009 to 2013. One hundred and thirty-nine patients were randomly assigned to two arms: S-1 80mg/m2 oral, day1 to 14, q3w, 1year (arm A, n = 70) or S-1 80mg/m2 oral day1 to 21, q5w + cisplatin 60mg/m2 day8, q5w, 4 courses, followed by S-1 80mg/m2 oral day1 to 14, q3w, total 1year (arm B, n = 69). The primary endpoint was the disease free survival (DFS) rate at 2 years and was evaluated using Bayesian method. Either treatment arm would deserve further study if the Bayesian posterior probability that the 2-year DFS rate would exceed a value of 40% were more than 0.85. The secondary endpoints were overall survival (OS), safety, and feasibility.

Results: The clinical characteristics of the patients were well balanced in terms of age, sex and pathological stage between the two arms. The DFS rate at 2 years was 51.4% (95% confidence interval [CI], 0.399–0.628) in arm A and 59.4% (95% CI, 0.476 – 0.702) in arm B. Both treatment arms met the primary endpoint: the probability of a DFS rate $\geq$ 40% at 2 years was over 0.97 in Arm and 1 in arm B. Neither DFS nor OS were significantly different (log-rank test; p = 0.1695 and p = 0.8684, respectively). No treatment-related deaths were observed in either treatment. The main G3/4 adverse events were appetite loss (arm A vs. arm B, 4.3% vs. 11.6%) and anemia (0% vs. 5.8%), which were not statistically different between the two arms. Treatment completion rate did not differ between the two arms (arm A vs. arm B: 45.7% [95% CI, 41.9–66.3%] vs. 43.5% [95% CI, 44.0–68.4%]).

Conclusions: Oral S-1 based adjuvant chemotherapy was feasible and promising for patients with completely resected NSCLC.

1278PD Major pathological response after preoperative chemotherapy as a surrogate marker of survival in early-stage non-small cell lung cancer: cohort of NATCH phase III trial

J. Remon[1], A. Martinez-Marti[1], E. Carcereny Costa[2], J. Zeron-Medina Cuairan[1], I. Sansano[3], J.L. Mate[4], N. Pardo[5], S. Cedres[1], A. Navarro[6], A.M. Martinez de castro[5], T. Moran[7], E. Felip Font[8]

[1]Medical Oncology, Vall d'Hebron University Hospital, Barcelona, Spain, [2]Medical Oncology, Catalan Institute of Oncology (ICO Badalona), Hospital Germans Trias i Pujol, Badalona, Spain, [3]Pathology, Vall d'Hebron University Hospital, Barcelona, Spain, [4]Pathology, Hospital Universitari Germans Trias i Pujol, Badalona, Spain, [5]Medical Oncology, Vall d'Hebron University Hospital/Vall d'Hebron Institute Oncology, Barcelona, Spain, [6]Deparment of Oncology, University Hospital Vall d'Hebron, Barcelona, Spain, [7]Medical Oncology, Hospital Universitari Germans Trias i Pujol, Badalona, Spain, [8]Medical Oncology Service (Lung Cancer Unit), Vall d'Hebron University Hospital, Barcelona, Spain

Background: Randomized phase III NATCH trial in early-stage non-small cell lung cancer (NSCLC) patients (p) reported no statistically differences in disease-free survival (DFS) or overall survival (OS) with the addition of preoperative or adjuvant chemotherapy to surgery. In pre-operative arm, those p who achieved a complete response obtained a benefit in 5-year DFS rate (59% vs. 38%). Recently, major pathological response (MPR) to preoperative chemotherapy (10% or less of residual viable tumor after preoperative therapy) has reported as surrogate marker of OS. The aim of this study is to validate MPR as prognostic factor in a cohort of patients included the NATCH trial.

Methods: MPR was analysed in a whole cohort of 57 early-stage NSCLC p treated in the preoperative arm into NATCH trial from 2 institutions. OS according to MPR was analysed (long-rank test) in the whole population and by histologic subtype.

Results: In this cohort, median age was 67 years (47-78), 48 p (84%) were males, 26 p (46%) squamous subtype. By stage according to 6th TNM: 9 p (16%) stage IA, 35 p (61%) stage IB, 12 p (21%) stage IIB and 1 p (2%) stage IIIA. 95% p completed 3 cycles of preoperative treatment. Surgical procedures: 81% lobectomies, 14% pneumonectomies, 5% no surgery. 13 out of 57 p (22.8%) had MPR. In the whole population, there was an increase in 5-year OS among those patients with MPR compare to p without MPR (84.6% vs. 58.5%, p = 0.106). According to histological subtype, 5-year OS in squamous NSCLC p with MPR was significantly longer than in p without MPR (100% *vs.* 47.1%, p = 0.026), but not differences in OS in non-squamous were detected (66.7% *vs.* 66.7%, p = 0.586).

Conclusions: MPR is a prognostic value in squamous NSCLC p who receive preoperative chemotherapy. Validation in extended cohort merits further evaluation.

1279P Factors predicting worse outcomes in patients with N0 lung adenocarcinoma of 3cm or smaller

J-J. Hung, W-H. Hsu

Department of Surgery, Taipei Veterans General Hospital, Taipei, Taiwan

Background: The role of adjuvant chemotherapy for patients with stage I non-small cell lung cancer remains unknown. The prognostic value of histological subtypes in resected node-negative small-sized lung adenocarcinoma has not been widely investigated. This study investigated the prognostic factors in patients with node-negative lung adenocarcinoma of 3cm or smaller to find potential candidates for adjuvant chemotherapy.

Methods: A total of 746 patients with completely resected node-negative lung adenocarcinoma of 3cm or smaller were included in the study. Prognostic factors for overall survival or probability of freedom from recurrence (FFR) were investigated.

Results: The 5-year overall survival and recurrence-free rates were 86.8% and 84.8%, respectively. During follow-up, 59 (7.9%) patients developed recurrence. Univariate analysis showed that micropapillary/solid predominant group had significantly lower probability of FFR ($P = 0.001$) in node-negative lung adenocarcinoma of 3cm or smaller. Older age ($P = 0.007$), greater tumor size ($P = 0.006$), and micropapillary/solid predominant group ($P = 0.031$) had significantly lower probability of FFR in multivariate analysis.

Conclusions: The new adenocarcinoma classification has significant impact on recurrence in node-negative lung adenocarcinoma of 3cm or smaller. Patients with micropapillary/solid predominant pattern have significant higher risk for recurrence.

1280P Regulatory variants in cancer-related pathway genes predict survival of patients with surgically resected non-small cell lung cancer

M.J. Hong[1], K.M. Shin[2], S.Y. Lee[3], J.H. Lee[4], J.Y. Park[3]

[1]Cell and Matrix Research Institute, Kyungpook National University School of Medicine, Daegu, Republic of Korea, [2]Department of Radiology, Kyungpook National University, Daegu, Republic of Korea, [3]Department of Internal Medicine, Kyungpook National University, Daegu, Republic of Korea, [4]Biochemistry and Cell Biology, Kyungpook National University School of Medicine, Daegu, Republic of Korea

Background: We conducted this study to identify genetic variants in cancer-related pathway genes which can predict prognosis of NSCLC patients after surgery, using a comprehensive list of regulatory single nucleotide polymorphisms (SNPs) prioritized by RegulomeDB.

Methods: A total of 509 potentially functional SNPs in cancer-related pathway genes selected from RegulomeDB were evaluated. These SNPs were analyzed in a discovery set (n = 354), and a replication study was performed in an independent set (n = 772). The association of the SNPs with overall survival (OS) and disease-free survival (DFS) were analyzed.

Results: In the discovery set, 76 SNPs were significantly associated with OS or DFS. Among the 76 SNPs, the association was consistently observed for 5 SNPs (*ERCC1* rs2298881C>A, *BRCA2* rs3092989G>A, *NELFE* rs440454C>T, *PPP2R4* rs2541164G>A, and *LTBP4* rs3786527G>A) in the validation set. In combined analysis, *ERCC1* rs2298881C>A, *BRCA2* rs3092989, *NELFE* rs440454C>T, and *PPP2R4* rs2541164G>A were significantly associated with OS and DFS (adjusted HR aHR for OS = 1.46, 0.62, 078, and 0.76, respectively; $P = 0.003$, 0.002, 0.007, and 0.003 respectively; and aHR for DFS = 1.27, 0.69, 0.86, and 0.82, respectively; $P = 0.02$, 0.002, 0.03, and 0.008, respectively). The *LTBP4* rs3786527G>A was significantly associated with better OS (aHR = 0.75; $P = 0.003$).

Conclusions: Our results suggest that five SNPs in the cancer-related pathway genes may be useful for the prediction of the prognosis in patients with surgically resected NSCLC.

1281P Relevance between PD-L1 and radiological invasiveness in pathological stage I lung adenocarcinoma

G. Toyokawa, K. Takada, T. Okamoto, Y. Kozuma, T. Matsubara, S. Takamori, T. Akamine, M. Katsura, F. Shoji, Y. Maehara

Department of Surgery and Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan

Background: Programmed death-ligand 1 (PD-L1) was reported to predict the response of immunotherapy; however, the association between PD-L1 expression and radiological/pathological features has yet to be elucidated.

Methods: A total of 292 patients with resected pathological stage I adenocarcinoma were analyzed for PD-L1 expression by immunohistochemistry and evaluated to determine the association between PD-L1 expression and the radiological/pathological invasiveness. Specifically, the radiological invasiveness and noninvasiveness were determined based on the consolidation/tumor (C/T) ratio, with a cut-off value of 0.25 by thin-section computed tomography.

Results: Among 292 patients, 47 (16.1%) were positive for PD-L1 expression; the remaining 245 patients (83.9%) were negative for PD-L1 expression. Fisher's exact test demonstrated that PD-L1 expression was significantly associated with a higher C/T ratio (P=0.029) and higher maximum standardized uptake value (SUVmax; P=0.004). The mean values of C/T ratio and SUVmax in patients with and without PD-L1 expression were 0.845±0.052 and 7.241±0.795, and 0.607±0.023 and 3.60±0.364, respectively (P<0.001 and P<0.001, respectively). Among 47 adenocarcinomas harboring PD-L1 expression, the frequencies of PD-L1 expression for C/T ratios of 0, 0.1-0.25, 0.26-0.5 and ≥0.51 were 6.4%, 2.1%, 4.3% and 87.2%, respectively (P=0.007). Pathologically, PD-L1 was identified exclusively only in more invasive subtypes, not in less invasive ones, such as atypical adenomatous hyperplasia, adenocarcinoma in situ, minimally invasive adenocarcinoma, and lepidic predominant ones (P<0.001).

Conclusions: PD-L1 expression was significantly associated with radiological/pathological invasive adenocarcinomas. This study provides the first evidence of the radiological/pathological invasiveness in resected pathological stage I adenocarcinoma with PD-L1 expression.

Background: Lung cancer stem cells (CSCs) are a small subpopulation of cells with self-renewal, tumorigenic properties and the ability to grow forming tumourspheres in non-adherent conditions. CSCs in non-small cell lung cancer (NSCLC) are targets poorly recognized by the immune surveillance system given that they favour an immunosuppressive microenvironment. The aim of this work was to compare the release of cytokine between monolayer cells and tumourspheres.

Methods: The study was performed on medium supernatant of cells from two NSCLC tumour patients (patient 1 and patient 2) samples and ten cell lines (A549, H1650, H460, H23, H358, H2228, HCC827, PC9, H1993, and SW900) grown in monolayer and tumourspheres at 3 different densities (10^4, $5{\cdot}10^5$ and 10^5 cells/ml). We analysed four soluble factors with immunosuppressive (IL-4, IL-10), and immunoregulatory (IL-6, IL-8) capacity through sensitivity bead-based multiplex assay using the Millipore kit and the Luminex 100/200.

Results: All human tumour cell lines and primary cells secreted detectable levels of IL-6 and IL-8. In contrast, IL-10 and IL-4 levels were below detectable range (<1.83 and <1.46 pg/ml, respectively) for most of these cell lines and NSCLC tumour samples. We have observed differences between levels of IL-6 and IL-8 secreted by adherent cells and tumourspheres and differences between samples (Table).

Conclusions: Our preliminary results suggest that cells grown in adherence show increased levels of IL-6 compared to lung-tumourspheres. The next step is the expansion of the cohort to obtain significant results.

1283P Non-invasive detection of lung cancer by identifying copy number aberrations in circulating cell-free DNA with next generation sequencing to aid early detection

F. Taylor[1], J. Bradford[2], P. Woll[1], D. Teare[3], A. Cox[4]

[1]Academic Unit of Oncology, University of Sheffield Medical School, Sheffield, UK, [2]Academic Unit of Molecular Oncology, University of Sheffield, Sheffield, UK, [3]School of Health and Related Research, University of Sheffield, Sheffield, UK, [4]Academic Unit of Molecular Oncology, University of Sheffield, Sheffield, UK

Background: Population stratification with molecular biomarkers could improve the cost-benefit of lung cancer screening programmes and reduce false positives. We aim to establish that somatic copy number aberrations (SCNA) are detected in circulating cell-free DNA (cfDNA) of lung cancer cases. We hypothesise that the number and magnitude of SCNA might also serve as a discriminative test to aid early lung cancer detection.

Methods: Standard protocols were followed to process matched cfDNA and lymphocyte DNA for 51 untreated lung cancer cases, 30 high risk controls and 10 low risk controls. Low coverage DNA sequencing was carried out on the Illumina Hiseq 2500 and read copy number profiles were established with the software CNAnorm. A genomic instability score was evaluated by defining the area under the receiver operating characteristic curve (AUROC).

Results: The median coverage of the genome for cfDNA was 0.49X (range 0.2X-0.63X). There was no significant difference between the median whole genome copy number aberration (CNA) score for early stage lung cancer and high risk controls, 398 (117-15373) vs 252 (149-7122) p = 0.25. The AUROC was 0.60 (95% CI 0.47-0.78) for early stage cancer (N = 21) and high risk controls compared to an AUROC of 0.74 (95% CI

Table: 1282P Differences in the secretion of IL-6 and IL-8 in adherent cells and tumourspheres by multiplex analysis. Detection range of IL-6 (0.17-1750.12 pg/ml). Detection range of IL-8(0.28-2273.3 pg/ml)

Samples	pg/ml x 10^5 cells IL-6		pg/ml x $\cdot 10^5$ cells IL-8	
	Adherent cells	Tumourspheres	Adherent cells	Tumourspheres
A549	<0.17	1.3	130.1	158.2
H2228	1750,11	>1750.12	>2273.3	172.80
HCC827	348.2	>1750.12	2177.4	>2273.3
H358	10.9	27.8	1774.8	>2273.3
H1993	34.4	2.2	658.2	479.3
PC9	144.4	5.4	597.2	321.9
SW900	121.7	5.4	1006	225.2
H460	359.8	227.8	1298.8	2201.3
H23	3.7	2.8	407.8	1290.8
H1650	995.9	352.2	30.2	50.3
Patient 1	17.4	0.6	>2273.3	30.0
Patient 2	>1750.12	>1750.12	>2273.3	>2273.3

0.63-0.85) for all lung cancer cases. The CNA score was a significant prognostic factor in univariable (HR 1.22 (95% CI 1.05-1.42 p = 0.008) but not multivariable analyses (HR 0.91 (95% CI 0.73-1.15 p = 0.45).

Conclusions: Our preliminary results demonstrate non-invasive detection of tumour derived copy number alterations with low coverage whole genome sequencing. The CNA score is not recommended as a stand-alone test to aid early lung cancer detection.

1284P HOXA-related long non-coding RNAs impact prognosis in early stage NSCLC patients

A. Navarro[1], S. Santasusagna[1], N. Vinolas Segarra[2], J.J. Castellano[1], J. Moises[3], S. Morales[1], J. Canals[1], C. Muñoz[1], J. Ramírez[4], R.M. Marrades[3], L. Molins[5], M. Monzo[1]

[1]Molecular Oncology and Embryology Laboratory, Human Anatomy Unit, University of Barcelona, Barcelona, Spain, [2]Medical Oncology, Hospital Clinic y Provincial de Barcelona, Barcelona, Spain, [3]Pneumology, Hospital Clinic y Provincial de Barcelona, Barcelona, Spain, [4]Pathology, Hospital Clinic y Provincial de Barcelona, Barcelona, Spain, [5]Thoracic Surgery, Hospital Clinic y Provincial de Barcelona, Barcelona, Spain

Background: HOX genes, grouped in four clusters in humans (HOXA-D), encode for transcription factors that are master regulators of embryonic development and oncogenesis. HOXA cluster, located in chromosome 7, play a critical role in the patterning of tissues with mesodermal components such as lungs. Long non-coding RNAs (lncRNAs) are especially abundant in the HOXA cluster (HOXA10-AS, HOXAS2, HOXAS3, HOXA11-AS, HOTAIRM1 and HOTTIP). We aimed to evaluate the prognostic role of HOXA-related lncRNAs in early stage non-small cell lung cancer (NSCLC).

Methods: 100 early stage NSCLC patients resected in our center from June 2007 to November 2013 were studied. Patient characteristics: median age, 65 (32-84); 78% males; 74% stage I; 56% ADK; 23% received adjuvant treatment. With a mean follow-up of 28.7 months, 31% relapsed. As validation data set 200 NSCLC patients from TCGA Research Network were used (RNAseq data). Only stage I-II TCGA samples without prior malignancy or synchronous cancer that not received neoadjuvant treatment were included. Statistical analysis was performed using R and TANRIC.

Results: HOTTIP and HOXA11AS impacted prognosis in our cohort of patients. HOTTIP was expressed in all samples and patients with high levels of HOTTIP had shorter TTR (78.3 vs 58 months; p = 0.048) and shorter OS (81.2 vs 61 months; p = 0.023). HOTTIP was overexpressed in SCC (p = 0.007) and in smokers (p = 0.018). HOXA11AS was expressed only in 9% of patients but the patients expressing HOXA11AS had shorter TTR (73.5 vs 32 months; p = 0.002). In the multivariate analysis HOXA11AS emerged as an independent prognostic marker for TTR (OR: 3.13, 95%CI: 1.3-7.3; p = 0.009), while HOTTIP (OR: 2.357, 95%CI: 1.1-5.2; p = 0.036) and age>65 (p = 0.022) for OS. In the validation data set HOXA11AS was validated as prognostic marker (p = 0.019). HOXA11AS expression correlated positively with development genes HOXA11, HOXA13, HOXA10, HOXA9, HOXA3, FOXD1, ZIC5 and miR-196b (HOXA cluster miRNA) and negatively with surfactant metabolism genes SFTPB and NAPSA or let-7a(p < 0.001). Interestingly, the high expression was associated to patients harboring RTN1 mutations (p < 0.0001).

Conclusions: HOXA11AS expression in early stage NSCLC patients is a high-risk relapse marker.

1285P Association between polymorphisms in microRNA target sites and survival in early-stage non-small cell lung cancer

J.H. Lee[1], S.S. Yoo[2], M.J. Hong[3], J.E. Choi[3], S.Y. Lee[2], J.Y. Park[2]

[1]Biochemistry and Cell Biology, Kyungpook National University School of Medicine, Daegu, Republic of Korea, [2]Departments of Internal Medicine, Kyungpook National University, Daegu, Republic of Korea, [3]Cell and Matrix Research Institute, Kyungpook National University School of Medicine, Daegu, Republic of Korea

Background: MicroRNAs (miRNAs) are small non-coding RNAs that function in regulation of gene expression. Recent studies have also suggested that single nucleotide polymorphisms (SNPs) located in miRNA target sites can influence the prognosis of diverse human cancers, including lung cancer. This study was conducted to evaluate the associations between single nucleotide polymorphisms (SNPs) in miRNA target sites using CLASH data and the survival outcomes of early-stage non-small cell lung cancer (NSCLC) patients.

Methods: 100 potentially functional polymorphisms were selected based on cancer-related miRNA target site in PolymiRTS database 3.0(http://compbio.uthsc.edu/miRSNP), CLASH data, and CancerGenes database (http://cbio.mskcc.org/cancergenes). All polymorphisms were genotyped using SEQUENOM's MassARRAY® iPLEX assay according to instructions of the manufacturer. The genotype association with overall survival (OS) and disease-free survival (DFS) in 782 patients with NSCLC who underwent curative surgical resection were analyzed.

Results: Among the 100 SNPs studied, two SNPs showed significant association with survival outcomes. Patients carrying the *POLR2A* rs2071504TT or CT genotypes showed significantly lower overall survival and disease-free survival than those with the *POLR2A* rs2071504CC genotype (HR = 1.42, 95% CI = 1.08–1.88, *P* = 0.01 and HR = 1.34, 95% CI = 1.08–1.67, P = 0.01, respectively). The *NR2F6* rs2288539C>T variant was found to be significantly associated with higher overall survival under the recessive model (HR = 0.13, 95% CI = 0.02–0.90, *P* = 0.04).

Conclusions: Our findings suggest that the *POLR2A* rs2071504C>T and *NR2F6* rs2288539C>T can influence the prognosis of early-stage NSCLC patients.

Background: Lung cancer is the primary cause of cancer mortality in western countries. The cure is unlikely in patients with NSCLC and locally advanced stage who are not surgical candidates, with a 3-year survival rate of 27% in those patients receiving chemotherapy and concomitant radiotherapy. On the contrary, in localized stages (stage I, II, IIIA) with surgical resection and cytostatic therapy, a survival of 5 years of 51% is achieved. Currently, there is no consensus on the best standard treatment: the surgical management of stage IIIA NSCLC remains highly controversial and most patients with stage IIIB disease are generally considered inoperable. Since distant metastases remain the major site of failure, it is likely that more effective cytotoxic or other anti-tumor agents will be required. Chemotherapy stimulates an immune response against tumors, which may facilitate immunotherapy anticancer activity. Evidence of synergy between chemotherapy and immunotherapy was shown in several studies.

Trial design: Phase II, single-arm, open-label multicenter study that assesses feasibility, safety and efficacy of combined neoadjuvant therapy with Nivolumab 360 mg + Paclitaxel 200mg/m2 + Carboplatin AUC 6 Q3W, three cycles, in resectable stage IIIA NSCLC patients followed by adjuvant treatment for 1 year with Nivolumab 240 mg Q2W for 4 months and Nivolumab 480mg Q4W for 8 months. The primary endpoint will be Progression Free Survival at 24 months from diagnosis and to assess the efficacy of the combination. The secondary endpoints will be time to progression and overall survival at 3 years, response rate, toxicity profile of the combination, the down-staging rate and complete resection rate. Also, surgical outcome and complications will be assessed. Perform correlatives studies with the objectives of exploring the expression of other biomarkers, such as PD-L1, in tumor tissue, free DNA and circulating tumor cells in liquid biopsy. Describe whether PD-L1 expression is a predictive biomarker for ORR, describe PFS in PD-L1 + (≥1%) population and report imaging response versus pathological response rate.

Background: Stage IIIB NSCLC treatment is definitive chemo-radiotherapy (CRT). In our SAKK 16/01 trial, neoadjuvant chemotherapy (CT) followed by neoadjuvant accelerated radiotherapy (RT) and surgery showed a median survival of 28.7 months (mos) in selected stage IIIB patients (pts). These promising results are the rationale for the current trimodality concept, introducing concomitant cetuximab (CET) to neoadjuvant CRT.

Methods: Pts with pathologically proven resectable stage IIIB (T4N0-3M0 or T1-4N3M0, 6th TNM) NSCLC, PS 0-1, and adequate organ function were treated with 3 cycles of neoadjuvant CT (cisplatin 100 mg/m^2 and docetaxel 85 mg/m^2 d1, q3w) followed by accelerated concomitant boost RT (44 Gy in 22 fractions in 3 weeks), both with concomitant weekly CET (250mg/m^2) and subsequent surgery. The primary endpoint was progression-free survival (PFS) at 1 year (yr).

Results: 69 pts were treated in 11 Swiss centers. 2/3 were men, median age was 60 yrs. Histology was squamous in 41% and adenocarcinoma in 49%, with T4 disease in 61%, N3 in 46% and both in 7%. A median relative total dose intensity of 99% of CT and 91% of CET was delivered. Per protocol RT was delivered to 95% of pts. 57 (83%) pts underwent surgery, with complete resection (R0) in 74% and a postoperative 30d mortality of 4%. Response rate after CT-immunotherapy was 57% and 64% after CRT-immunotherapy (CRT-I). Major pathologic response was found in 36% of the resected pts. 1-yr PFS based on Kaplan-Meier estimation was 50% (95% CI: 37%-62%). Median PFS was 12 mos (95% CI: 9-16), median OS was 21 mos (95% CI: 14-25), with a 2 and 3-yr survival of 41% and 30%, respectively.

Conclusions: This is one of the largest prospective phase II trials to evaluate the role of induction CRT-I and surgery in resectable stage IIIB disease, and the first to associate concurrent CET to the neoadjuvant strategy. Trial treatment is feasible with excellent adherence to the protocol and promising clinical and pathological response rates, PFS and OS, supporting an aggressive approach including surgery in selected IIIB pts. As compared to our previous SAKK 16/01 experience, the addition of CET does not improve the outcome of this group of locally advanced NSCLC pts.

Clinical trial identification: SAKK 16/08, NCT01059188, original version dated: 24.08.2009, including amendments: 04.07.2013.

1288PD Randomized phase ii trial comparing chemoradiotherapy with chemotherapy for completely resected unsuspected N2-positive non-small cell lung cancer

J-M. Sun[1], M-J. Ahn[1], J.S. Ahn[1], H.K. Kim[2], Y.C. Ahn[3], J.I. Zo[2], Y.M. Shim[2], K. Park[1]

[1]Medicine, Samsung Medical Center Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [2]Thoracic and Cardiovascular Surgery, Samsung Medical Center Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [3]Radiation Oncology, Samsung Medical Center Sungkyunkwan University School of Medicine, Seoul, Republic of Korea

Background: We investigated whether concurrent chemoradiotherapy (CCRT) would increase survival in patients with completely resected unsuspected N2-positive non-small cell lung cancer (NSCLC), compared with adjuvant chemotherapy alone.

Methods: Eligible patients were randomly assigned (1:1 ratio) to either the CCRT arm or the chemotherapy arm. In the CCRT arm, patients received concurrent thoracic radiotherapy (50 Gy in 25 fractions) with five cycles of weekly paclitaxel (50 mg/m^2) and cisplatin (25 mg/m^2), followed by two additional cycles of paclitaxel (175 mg/m^2) plus cisplatin (80 mg/m^2) at three-week intervals. In the chemotherapy arm, patients received four cycles of adjuvant paclitaxel (175 mg/m^2) and carboplatin (AUC 5.5) every three weeks. The primary endpoint was disease-free survival.

Results: We enrolled and analyzed 101 patients. The median disease-free survival of the CCRT arm was 24.7 months, which was not significantly different from that of the chemotherapy arm (21.9 months; hazard ratio [HR] 0.94, 95% CI: 0.58–1.52, P = 0.40). There was no difference in overall survival (CCRT: 74.3 months, chemotherapy: 83.5 months, HR: 1.33, 95% CI: 0.71–2.49). Subgroup analysis showed chemotherapy alone increased overall survival in never-smokers and multi-station N2-positive patients. The pattern of disease recurrence was similar between the two arms.

Conclusions: There was no survival benefit from adjuvant CCRT compared with platinum-based chemotherapy alone for completely resected unsuspected N2-positive NSCLC. However, the role of sequential radiotherapy administered after adjuvant chemotherapy is being evaluated, and further study is needed to evaluate the optimal radiotherapy approach for completely resected N2-positive NSCLC.

1289PD Clinical course in patients with stage III non-small cell lung cancer and interstitial lung disease treated with chemoradiotherapy: a retrospective analysis in a single institute

H. Kobayashi[1], T. Naito[1], K. Omae[2], S. Omori[1], K. Nakashima[1], K. Wakuda[1], A. Ono[1], H. Kenmotsu[1], H. Murakami[1], M. Endo[3], H. Harada[4], T. Takahashi[1]

[1]Thoracic Oncology, Shizuoka Cancer Center, Shizuoka, Japan, [2]Clinical Research Promotion Unit, Clinical Research Center, Shizuoka Cancer Center, Sunto-gun, Japan, [3]Diagnostic Radiology, Shizuoka Cancer Center, Shizuoka, Japan, [4]Radiation Oncology, Shizuoka Cancer Center, Shizuoka, Japan

Background: Patients with non-small cell lung cancer (NSCLC) and interstitial lung disease (ILD) are often excluded from clinical trials because they are considered to be at high risk for acute exacerbation (AE) of ILD triggered by radiotherapy. Therefore, data on the clinical course in these patients are limited. We examined the relationship between chemoradiotherapy (CRT) and occurrence of AE of ILD as well as the clinical course in these patients at our institution.

Methods: A retrospective analysis was performed on 37 patients with stage III NSCLC and ILD treated with first-line CRT in a clinical setting between January 2009 and December 2014 at our institution.

Results: Patient characteristics are shown in Table 1. Patients treated with CRT had milder ILD than those treated with chemotherapy alone. Eighteen patients treated with CRT received corticosteroids for the treatment of AE of ILD. Univariate analysis revealed that the risk factors for AE of ILD were ILD classification, smoking history, and V20. In multivariate logistic regression analysis, the independent risk factor for AE of ILD was ILD classification. AE of ILD occurred in nine (82%) patients with usual interstitial pneumonia (UIP) pattern and in nine (35%) with non-UIP pattern. Median overall survival (mOS) was 34.6 months. Univariate analysis and multivariate logistic regression analysis revealed that the prognostic factor for patients with stage III NSCLC and ILD treated with CRT was ILD classification. mOS was 10.9 and 43.0 months in UIP and non-UIP patterns, respectively.

Conclusions: In conclusion, this retrospective analysis suggests that ILD classification (UIP or non-UIP) is associated with the occurrence of AE of ILD and prognosis in patients treated with first-line CRT.

Table: 1289PD

First-line treatment Variable	Chemoradiotherapy (N = 37)	Radiotherapy (N = 17)	Chemotherapy (N = 25)
Age, median (range)	73 (52–85)	80 (59–89)	69 (58–81)
Sex, male/female	32/5	15/2	21/4
PS, 0/1/2	15/22/0	6/7/4	10/15/0
Clinical staging (TNM classification, 7th edition), IIIA/IIIB	20/17	8/9	10/15
Smoking history, yes/no	33/4	16/1	24/1
Histology, squamous/non-squamous	19/18	7/10	13/12
ILD classification, UIP/non-UIP	11/26	6/11	16/9
%VC, median (range)	96 (59–129)	86 (62–112)	85 (64–121)
V20, median (range)	27 (12–35)	26 (14–36)	
Lung volume loss or honeycombing	4	4	13

1290P DNA repair gene expression in bronchial washing fluid as new molecular tool for clinical outcome decision

D. Schveigert[1], R. Askinis[2], J. Fadejeva[1], V. Sapoka[3], A. Krasauskas[2], S. Cicenas[2]

[1]Laboratory of Molecular Oncology, National Cancer Institute, Vilnius, Lithuania, [2]Department of Thoracic Surgery and Oncology, National Cancer Institute, Vilnius, Lithuania, [3]Clinics of Internal Diseases, Vilnius University hospital Santariskiu Klinikos, Vilnius, Lithuania

Background: Platinum-based drugs (cisplatin, etc.) are used as a first-line therapy for NSCLC patients. However, such treatment is not effective for all patients. Biomarkers that could predict efficiency of the platinum-based treatment should be identified. Aim: To evaluate whether the response to treatment of NSCLC patients is based on *ERCC1* and *RRM1* gene expression in bronchial washing fluid.

Methods: 70 patients with a first-time diagnosed NSCLC receiving Cisplatin+Etoposid were involved in the study. RNA was extracted from bronchial washing fluid using "RNeasy Plus Mini Kit" (*QIAGEN*, Germany). The analysis of *ERCC1* and *RRM1* expression was done by qRT-PCR method. A χ^2 test was used to analyze gene expression in relation to clinicopathological parameters. The survival rates were calculated by the Kaplan-Meier method. The prognostic significance was assessed by the Cox proportional hazards regression model.

Results: Statistically significant differences were found between *ERCC1* expression and tumour differentiation grade, *RRM1* expression and disease stage and lymph node status. *ERCC1* expression was associated with NSCLC patient progression-free survival (PFS) rate depending on gender, disease stage, response to treatment. Patients from high *ERCC1* expression group had 7.6 months longer survival than patients from low expression group. *RRM1* expression was associated with NSCLC patients PFS rates depending on gender, age, tumour histology and differentiation grade. Patients from low *RRM1* expression group had 7.9 months longer survival than those from high expression group. Multivariate analysis of factors influencing PFS rate showed that disease stage ($p = 0.01$), tumor differentiation grade ($p = 0.009$), response to treatment ($p = 0.02$) and RRM1 expression ($p = 0.001$) were independent prognostic factors of NSCLC patients PFS.

Conclusions: *ERCC1* and *RRM1* genes may influence platinum-based chemotherapy treatment of NSCLC patients. In order to improve the effectiveness of treatment it is appropriate to identify *RRM1* expression changes in the bronchial washing fluid. Therefore, NSCLC patients with high *RRM1* expression should be actively followed-up because of quicker disease progression.

1291P Diagnosis and monitoring of non-small cell ung cancer patients by next generation sequencing and droplet digital PCR on circulating tumor DNA

P. Vannuffel, C. De Rop

Molecular Biology, Institut de Pathologie et de Génétique, Gosselies, Belgium

Background: About 80% to 85% of lung cancers are non-small cell lung cancer (NSCLC). EGFR tyrosine kinase inhibitors as well as several other targeting molecules have been demonstrated to be effective in treating patients with activating mutations. We investigated the use of circulating tumor DNA (ctDNA) and high sensitive detection techniques for mutational profiling to improve the diagnosis and monitoring of NSCLC patients.

Methods: ctDNA was extracted from plasma using the QIAamp Circulating Nucleic Acid kit (Qiagen). A custom panel was designed to cover EGFR, KRAS, NRAS, BRAF, PIK3CA, DDR2, AKT1, PTEN, MEK1 and ERBB2 hotspot mutations. Libraries, constructed according to the AmpliSeq protocol, were sequenced on the semiconductor Ion Torrent S5XL platform. The presence of the EGFR T790M mutation was also assessed by a digital PCR assay.

Results: A total of 120 patients from 30 Belgian institutions were enrolled in this prospective study. The majority of patients presented with stage IV adenocarcinoma and progression. Forty-six (46) patients had a mutation detected on a former biopsy: EGFR exon 19 (26), EGFR exon 21 (8), KRAS (10), PIK3CA (1) and ERBB2 (1). Among those patients, 28 (61%) harbored the same mutation when their ctDNA was sequenced with our NGS panel: EGFR exon 19 (15), EGFR exon 21 (6), KRAS (5), PIK3CA (1) and ERBB2 (1). For 7 patients, for which no mutation had not been previously detected, 4 EGFR, 2 KRAS and 1 NRAS mutations were found after ctDNA analysis. As far as the ddPCR detection of EGFR T790M was concerned, the mutation was detected on 7 (21%) of the 34 patients presenting EGFR mutations in their prior biopsy (5 in exon 19 and 2 in exon 21). Patients with acquired T790M mutation were previously treated by Afatinib (3), Erlotinib (2) or Gefitinib (1).

Conclusions: Our results indicate that ctDNA can be an alternative and noninvasive source of tumor DNA, a surrogate to classical biopsies, particularly when access to tumor tissue is limited. NGS and ddPCR assays are sensitive enough to promote a clinical translation of ctDNA analysis into disease management and therapeutic decision. Supported by a grant from Boehringer Ingelheim.

1292P Safety data from randomized phase II study of cisplatin (CDDP)+S-1 versus CDDP+pemetrexed (PEM) combined with thoracic radiotherapy (TRT) for locally advanced non-squamous (non-sq) non-small cell lung cancer (NSCLC): SPECTRA study

S. Niho[1], T. Yoshida[2], T. Akimoto[3], K. Sakamaki[4], T. Takahashi[5], T. Seto[6], M. Nishio[7], N. Yamamoto[8], T. Hida[9], H. Okamoto[10], T. Kurata[11], M. Satouchi[12], K. Goto[1], T. Yamanaka[4], Y. Ohe[8]

[1]Department of Thoracic Oncology, National Cancer Center Hospital East, Kashiwa, Japan, [2]Department of Thoracic Oncology, Aichi Cancer Center Hospital, Aichi, Japan, [3]Department of Radiation Oncology, National Cancer Center Hospital East, Kashiwa, Japan, [4]Department of Biostatistics, Yokohama City University School of Medicine, Yokohama, Japan, [5]Division of Thoracic Oncology, Shizuoka Cancer Center, Shizuoka, Japan, [6]Department of Thoracic Oncology, National Kyushu Cancer Center, Fukuoka, Japan, [7]Department of Thoracic Medical Oncology, The Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, Japan, [8]Department of Thoracic Oncology, National Cancer Center Hospital, Tokyo, Japan, [9]Department of Thoracic Oncology, Aichi Cancer Center, Nagoya, Japan, [10]Department of Respiratory Medicine and Medical Oncology, Yokohama Municipal Citizen's Hospital, Yokohama, Japan, [11]First Department of Internal Medicine, Kansai Medical University, Hirakata, Japan, [12]Department of Thoracic Oncology, Hyogo Cancer Center, Akashi, Japan

Background: Both CDDP+S-1 and CDDP+PEM could be given at full systemic doses with TRT in locally advanced NSCLC, and CDDP+PEM is one of the standard chemotherapy regimens in patients with advanced non-sq NSCLC. This multicenter, randomized, open-label, phase II study (SPECTRA) compared the efficacy and safety of the two above-mentioned promising regimens combined with TRT in patients with unresectable locally advanced non-sq NSCLC.

Methods: Patients were randomly assigned to receive CDDP+S-1 (CDDP 60mg/m2, d1, and S-1 80mg/m2, d1-14, q4w, up to 4 cycles) or CDDP+PEM (CDDP 75mg/m2, d1, and PEM 500mg/m2, d1, q3w, up to 4 cycles) combined with TRT 60Gy in 30 fractions. The primary endpoint was 2-year progression-free survival (PFS) rate. The sample size was set at 100 patients.

Results: Between Jan 2013 and Oct 2016, 102 patients were enrolled in this study from 9 institutions in Japan. All 102 patients were eligible and assessable, of whom 52 were assigned to CDDP+S-1 and 50 to CDDP+PEM. Baseline characteristics were similar (CDDP+S-1/CDDP+PEM): median age (range) 64.5 (39-73)/63.5 (32-74) years; women, n = 17 (33%)/n=17 (34%); stage IIIB, n = 21 (40%)/n=20 (40%); ECOG PS of 1, n = 14 (27%)/n=14 (28%); never smoker, n = 12 (23%)/n=12 (24%); and adenocarcinoma, n = 47(90%)/n=45(90%). Completion rate of TRT (60Gy) and chemotherapy (4 cycles) was 92%/98% and 73%/86%, respectively. Response rate was 60%/64%. Grade 3 toxicities included febrile neutropenia (12%/2%), anorexia (8%/16%), diarrhea (8%/0%), esophagitis (6%/8%), pneumonia (4%/4%), neutropenia (35%/50%), anemia (8%/12%), thrombocytopenia (4%/6%), and hyponatremia (12%/12%). Grade 2 radiation pneumonitis was observed in 8 (15%)/2 (4%) patients. No treatment-related death was observed. The data on PFS and overall survival is immature.

Conclusions: Response rate was similar between two arms. Toxicities were tolerable and manageable in both arms; however febrile neutropenia was more frequently observed in the CDDP+S-1 arm. Survival data will be analyzed in late 2018.

Background: CT-RT is the standard treatment for unresectable LA-NSCLC. P plus vinorelbine is widely used. Metronomic CT is a frequent administration of low doses of CT. mOV has shown good efficacy and improved safety, and could improve the RT effect. Our goal is to evaluate the efficacy and safety of P-mOV with radical RT in patients (pts) with LA-NSCLC.

Methods: Pts aged 18-75 years with histologically proven untreated and unresectable LA-NSCLC, adequate bone marrow, hepatic & renal function, ECOG PS0-1, received P 80mg/m^2 D1 every 3 weeks combined with mOV 50mg/day on days D1, 3 & 5/weekly, 2 cycles (cy) as induction; patients without progression received 2 more cy of P at the same dose with mOV 30mg/day on D1, 3 & 5/weekly, concurrently with RT (66Gy in 6.5weeks). Primary endpoint was progression-free survival (PFS) by RECIST v1.1; secondary endpoints were: overall response rate, overall survival and safety profile. To guarantee an overall type-1 α error no greater than 0.05 and a type II (β) error 0.1 for PFS, a sample size of 67 pts was planned.

Results: Since May 2016, 58 pts have been recruited. Fifty-three pts have been included in the analysis. Pt characteristics: Male 72%; median age 63 (range 33-75); PS 0/1 62/48%; smokers 48%; adenocarcinoma/squamous 43.4/35.9%; stage IIIA/B 35.9/58.5%. Hematological G3-4 toxicities: neutropenia 18.9%; anemia 3.8%; febrile neutropenia 7.5%. Non-hematological G3-4 toxicities: esophagitis 1.9%; infection without neutropenia 1.9%; dyspnea 3.8%; thromboembolism 3.8%. No treatment-related deaths were reported.

Conclusions: mOV-P administered with RT has a manageable safety profile. Based on this, accrual is ongoing.

Clinical trial identification: EudraCT 2015-003312-21.

1294P Real world data of practice patterns and outcomes for pemetrexed plus platinum as neoadjuvant chemotherapy in adenocarcinomas of lung from a tertiary cancer center of India: Looking beyond the usual paradigm

A. Kapoor[1], S. Zanwar[1], A. Joshi[1], V. Noronha[1], V. Patil[1], A. Chougule[2], A. Mahajan[3], P. Bhargava[1], K. Prabhash[1]

[1]Medical Oncology, Tata Memorial Hospital, Mumbai, India, [2]Medical Oncology (Molecular Lab), Tata Memorial Hospital, Mumbai, India, [3]Radiodiagnosis, Tata Memorial Hospital, Mumbai, India

Background: Neoadjuvant chemotherapy (NACT) is the standard of care in non-small cell lung cancers (NSCLC) with locally advanced N2 disease. There is scarcity of data for pemetrexed-platinum regimen as NACT. Also, aside from N2 disease, role of NACT in locally advanced NSCLCs for tumor downstaging is unclear.

Methods: Nonmetastatic adenocarcinomas of lung treated with pemetrexed-platinum based NACT were analysed. The patients with locoregionally advanced N2 disease and those who were borderline candidates for upfront definitive treatment were planned for NACT after discussion in a multidisciplinary clinic. Total 4 cycles of 3-weekly pemetrexed and platinum were delivered in combined neoadjuvant and adjuvant setting. Response assessment was done using RECIST criteria. Progression free (PFS) and overall survival (OS) were calculated using Kaplan Meier method.

Results: Out of 114 evaluable patients, 99 patients received NACT with pemetrexed-platinum. Most common indication for NACT was N2 disease at baseline (46.4%). Objective response rate was 38.2% (95% CI: 23%-53%) including two complete and 34 partial responses. 12.7% patients had progressive disease on NACT. Median PFS was 15 months (95% CI 11.6-18.4) and median OS was 22 months (95% CI 15.6-28.3) at a median follow-up of 16 months. There was a significant improvement in the OS of patients undergoing definitive therapy versus no definitive therapy (median OS 25 months [95% CI 19.4-30.3] vs 12 months [95% CI 3.2-20.3] respectively; p = 0.047, HR 1.6). Amongst patients who could not undergo definitive CTRT upfront due to dosimetric constraints (n = 36), 26 (72.2%) patients finally underwent CTRT after NACT. Those patients who were not able to undergo definitive CTRT had median PFS of 5 months [95% CI 2.1-7.9] versus 10 months [95% CI 3.8-16.1] in those who were made amenable to definitive CTRT post NACT; p = 0.018.

Conclusions: Pemetrexed-platinum based NACT appears to be an effective option and many borderline cases where upfront definitive therapy is not feasible may become amenable to the same after incorporation of NACT.

Background: Atezo (anti–PD-L1) was FDA approved for 2L+ NSCLC based on results from the randomized OAK and POPLAR trials, with atezo showing superior efficacy vs docetaxel (doc). We previously showed that TMB in tissue correlates with atezo efficacy in 1L+ NSCLC. To address the significant challenge of consistently obtaining sufficient tumor tissue for molecular testing, we developed a novel blood-based assay to measure bTMB. Here we analyzed plasma samples from OAK and POPLAR with the bTMB assay to correlate bTMB with atezo clinical activity.

Methods: The biomarker evaluable population (BEP) included 211 pts in POPLAR (ITT=287) and 583 pts in OAK (excludes pts with known *EGFR*/*ALK* mutations; ITT=850), with blood samples available for targeted genomic sequencing. The bTMB assay interrogates single nucleotide variants (SNVs) in 394 genes from cell-free DNA in plasma and reports a score based on the number of high-confidence SNVs identified. The BEP was grouped by bTMB cut points based on the minimum number of SNVs present.

Results: In POPLAR, improved PFS and OS HRs with atezo vs doc were observed at a range of bTMB cut points compared with the ITT and BEP. In OAK, PFS benefit with atezo vs doc was observed at bTMB cut points $\geq$ 10 compared with BEP. (Table) Importantly, bTMB did not correlate with PD-L1 expression (SP142 or 22C3).

Conclusions: These exploratory analyses represent the first demonstration of a novel blood-based assay measuring bTMB that may predict atezo clinical efficacy in 2L+ NSCLC. Thus, the bTMB assay may provide a non-invasive biomarker to identify pts who may derive clinical benefit from single agent checkpoint inhibition. Prospective studies using bTMB are currently ongoing in pts with 1L NSCLC (B-F1RST/BFAST).

Table: 1295O Clinical efficacy of atezo vs doc in bTMB subgroups

	POPLAR study		
	ITT (N = 287)		**BEP (N = 211)**
OS HR (95% CI)	0.73 (0.53, 0.99)		0.68 (0.50, 0.93)
PFS HR (95% CI)	0.94 (0.72, 1.23)		0.90 (0.68, 1.20)
bTMB subgroup	**$\geq$ 10**	**$\geq$ 16**	**$\geq$ 20**
No. of patients	96	63	42
OS HR	0.59	0.56	0.51
PFS HR	0.68	0.57	0.58
	OAK study		
	ITT (N = 850)		**BEP (N = 583)**
OS HR (95% CI)	0.73 (0.62, 0.87)		0.64 (0.53, 0.77)
PFS HR (95% CI)	0.95 (0.82, 1.10)		0.87 (0.73, 1.04)
bTMB subgroup	**$\geq$ 10**	**$\geq$ 16**	**$\geq$ 20**
No. of patients	251	158	105
OS HR	0.69	0.64	0.65
PFS HR	0.73	0.65	0.61

BEP, biomarker-evaluable population; bTMB, tumor mutational burden in blood; ITT, intention to treat.

Background: In the Phase III OAK trial, patients (pts) with previously treated advanced NSCLC had improved median overall survival (OS) with atezo vs docetaxel (doc), regardless of PD-L1 expression (per VENTANA PD-L1 SP142 IHC assay). Although efficacy correlated with PD-L1 expression on tumor cells (TC) and tumor-infiltrating immune cells (IC), an OS benefit was also observed in pts with PD-L1–negative tumors (i.e., TC0 and IC0; HR, 0.75 [95% CI: 0.59, 0.96]). To determine whether these results were consistent across PD-L1 IHC assays, we assessed atezo efficacy in PD-L1 subgroups as defined by SP142 and Dako 22C3 pharmDx PD-L1 IHC assays.

Methods: PD-L1 expression was assessed prospectively with SP142 and retrospectively with 22C3. The SP142 assay measured PD-L1 expression on TC and IC, while the 22C3 assay gave a tumor proportion score (TPS) based on TC membrane staining.

Results: Among the primary population of 850 pts (ITT850), 400 had results from the 22C3 assay (biomarker-evaluable population [BEP]). Clinical outcomes in the BEP vs ITT850, and prevalence in PD-L1 subgroups are summarized (Table). Among pts with tumors negative by SP142 (TC0 and IC0), most (77%) were also negative by 22C3 (TPS $<$ 1%). Comparable OS benefit with atezo was seen in PD-L1–negative subgroups defined by both assays. Improved clinical benefit was observed in pts with the highest PD-L1 expression by either assay (TC3 or IC3 by SP142, or TPS $\geq$ 50% by 22C3; Table).

Conclusions: Prevalence of PD-L1 subgroups in the BEP was consistent with previous reports for both assays. Most tumors considered negative by SP142 were also negative by 22C3. An OS benefit (atezo vs doc) was observed in PD-L1–negative subgroups defined by either assay and was consistent with the overall population results from OAK. These data provide evidence of atezo OS benefit in pts with PD-L1–negative tumors irrespective of the PD-L1 IHC assay used.

Table: 1296O

Clinical efficacy in OAK ITT850 and BEP populations

	ITT850 (N = 850)	BEP (N = 400)
OS HR (atezo vs doc) (95% CI)	0.73 (0.62, 0.87)	0.56 (0.44, 0.71)
PFS HR (atezo vs doc) (95% CI)	0.95 (0.82, 1.10)	0.75 (0.61, 0.93)
Prevalence of PD-L1 subgroups in OAK BEP (n = 400)		
	SP142	**22C3**
PD-L1 negative TC0 and IC0, or TPS < 1%	38%	55%
PD-L1 positive TC1/2/3 or IC1/2/3, or TPS ≥ 1%	62%	46%
PD-L1 high TC3 or IC3, or TPS ≥ 50%	18%	25%
OS HR (atezo vs doc) in PD-L1 subgroups in OAK BEP (n = 400) (95% CI)		
	SP142	**22C3**
PD-L1 negative TC0 and IC0, or TPS < 1%	0.55 (0.37, 0.80)	0.61 (0.45, 0.84)
PD-L1 positive TC1/2/3 or IC1/2/3, or TPS ≥ 1%	0.58 (0.42, 0.78)	0.51 (0.36, 0.73)
PD-L1 high TC3 or IC3, or TPS ≥ 50%	0.37 (0.20, 0.66)	0.49 (0.29, 0.80)

Background: Nivolumab, the anti-programmed death (PD)-1 antibody, has demonstrated durable responses and survival benefit in pts with advanced NSCLC, with some pts continuing to derive benefit even after discontinuation of nivolumab (due to adverse events [AEs] or a stopping rule). This raises the question of whether continuous nivolumab treatment is necessary for long-term benefit. CheckMate 153 (NCT02066636), an ongoing phase IIIB/IV study conducted primarily in the community setting, is evaluating the clinical benefit of a fixed-duration (1 yr) of nivolumab treatment vs continuous treatment in pts with previously treated advanced NSCLC. Pts who remained on nivolumab treatment for 1 yr were randomized to either continue receiving treatment or to stop treatment.

Methods: Pts with stage IIIB/IV NSCLC and ≥1 prior systemic therapy were enrolled and treated with nivolumab 3 mg/kg IV Q2W. The primary objective of the study overall was the incidence of high-grade (grade 3–5) select treatment-related AEs. Pts still on treatment at 1 yr were randomized 1:1 either to continue nivolumab until progressive disease, unacceptable toxicity, or withdrawal of consent (continuous-treatment arm), or to discontinue treatment, with the possibility of resuming treatment upon disease progression (fixed-duration arm). Prespecified exploratory objectives included safety and efficacy in the 2 randomized arms.

Results: As of April 2016, 1375 pts were enrolled and treated; 218 pts were randomized after 1 yr of treatment to the continuous-treatment arm (n = 111) or the fixed-duration arm (n = 107). Of these 218 pts, 133 (61%) had received ≥2 prior therapies and 10 (5%) had baseline ECOG PS 2. Data from an upcoming database lock (at which time, the expected post-randomization follow-up ≥10.7 mo) will be presented for randomized pts and will include overall survival, progression-free survival, and safety. In addition, data from pts who were re-treated in the fixed-duration arm will be presented.

Conclusions: The results from CheckMate 153 represent the first insights from a randomized trial evaluating the impact of stopping treatment with a PD-1/PD-L1 inhibitor at 1 yr vs continuing treatment in pts with advanced, previously treated NSCLC.

1300PD Impact of co-occurring genomic alterations on overall survival of BRAF V600E and non-V600E mutated NSCLC patients: Results of the Network Genomic Medicine

A. Kron[1], R. Riedel[1], S. Michels[1], J. Fassunke[2], S. Merkelbach-Bruse[2], M. Scheffler[1], L. Nogova[1], R. Fischer[1], F. Ueckeroth[2], D. Abdulla[1], F. Kron[1], B. Pauli[1], B. Kaminsky[3], J. Braess[4], U. Graeven[5], C. Grohe[6], S. Krueger[7], R. Büttner[2], J. Wolf[1]

[1]Department I of Internal Medicine, Lung Cancer Group Cologne, University Hospital of Cologne, Cologne, Germany, [2]Institute of Pathology, University Hospital of Cologne, Cologne, Germany, [3]Department of Pneumology, Bethanien Hospital, Solingen, Germany, [4]Department of Oncology and Haematology, St. John of God's Hospital, Regensburg, Germany, [5]Department of Oncology and Haematology, Kliniken Maria Hilf GmbH, Mönchengladbach, Germany, [6]Department of Respiratory Diseases, Universitätsmedizin Charite, Berlin, Germany, [7]Department of Pneumology, Florence Nightingale-Krankenhaus, Düsseldorf, Germany

Background: Activating BRAF mutations are found in 1-3% of lung adenocarcinomas. Treatment with a combination of a BRAF- and a MEK-inhibitor is now the approved standard therapy for V600E mutated patients. The molecular co-alterations that drive the heterogeneity of BRAF mutated lung cancer patients (pts) are poorly characterized by the lack of multiplex diagnostics results. Frequently used single gene tests are unable to detect co-occurring mutations and their mutual impact on overall survival. The Network Genomic Medicine (NGM) performs high sensitive next generation

sequencing (NGS) based diagnostics on a central platform in Cologne for inoperable lung cancer pts in Germany.

Methods: The NGS panel used in NGM consists of 17 genes to cover potentially targetable aberrations and is run on Illumina (MySeq) platform. In 2016, we have started the retrospective evaluation of BRAF mutated pts with available clinical data and given consent who had received NGS-based molecular diagnostics. In particular, we have focused on BRAF V600E and non-V600E mutated lung cancer pts with and without co-occurring mutations: their frequency, significance and impact on overall survival.

Results: We have analyzed 174 pts (V600E=55 pts, non-V600E=119 pts) with eligible clinical data. Co-occurring mutations were detected in 121 BRAF mutated pts (70%). The most frequent co-alteration was found in TP53 for 89 pts (74%). Regardless of treatment regime, BRAF mutated lung cancer pts without co-alterations seem to have a better overall survival (OS) with 15 versus 13 month ($p = 0.463$), same data for the TP53 co-mutated pts ($p = 0.449$). Likewise, non-targeted treatment of V600E mutation seems to be a negative prognostic factor with OS = 15 month versus 22 month in non-V600E mutated pts ($p = 0.957$).

Conclusions: We report for the first time to our knowledge the heterogeneity of BRAF mutated lung cancer pts in the largest cohort. This work provides evidence that co-occurring genomic alterations influence the overall survival of these pts and stresses the relevance of the multiplex genotyping. Further data including therapies, co-alterations in V600E and other clinicopathologic parameters will be provided.

Background: Long-term data comparing outcomes with immune checkpoint inhibitors versus chemotherapy in NSCLC are limited. The phase 3 trials CheckMate 017 and 057 demonstrated improved overall survival (OS), objective response rates (ORR), and quality of life, as well as a favorable safety profile, with the anti-programmed death (PD)-1 antibody nivolumab versus docetaxel in patients with previously treated advanced squamous and non-squamous NSCLC, respectively. Updated results based on a minimum follow-up of 3 y are reported.

Methods: Patients were randomized 1:1 to receive nivolumab 3 mg/kg Q2W (with option to change to 480 mg Q4W after Sep 2016) or docetaxel 75 mg/m^2 Q3W until progression or discontinuation. After completion of the primary analyses, patients who ended treatment with docetaxel could cross over to receive nivolumab. The primary endpoint of each study was OS; other endpoints were ORR, progression-free survival, and efficacy by PD ligand 1 (PD-L1) expression.

Results: After a minimum follow-up of 36.6 mo in each study (Feb 2017 database locks), 6% of the 427 total patients randomized to the 2 nivolumab arms remained on treatment; no patients remained on docetaxel. Nivolumab continued to show an OS benefit versus docetaxel, with 3-y OS rates of 16% versus 6% in CheckMate 017 and 18% versus 9% in CheckMate 057. Similar to prior reports, an OS benefit was observed in squamous NSCLC regardless of PD-L1 expression, and in non-squamous NSCLC was enhanced at higher PD-L1 expression levels (Table). Of 427 patients in the combined nivolumab arms, 71 (17%) had OS $\geq$ 3 y. Additional 3-y data across trial endpoints will be presented.

Conclusions: With $\geq$3 y of follow-up from 2 randomized phase 3 studies, nivolumab continued to demonstrate an OS benefit versus docetaxel in patients with advanced squamous and non-squamous NSCLC. Overall, 3-y survival was achieved in 17% of nivolumab-treated patients.

Background: Nivolumab is a standard option for second-line treatment in pts with advanced NSCLC. Real-life data are lacking regarding the efficacy of nivolumab and post-nivolumab treatment.

Methods: This analysis included the first 600 consecutive pts with stage IIIB/IV NSCLC who received ≥1 dose of nivolumab 3mg/kg q2w through the French EAP from 01/2015 for Squamous (Sq) and 06/2015 for Non-Sq NSCLC, until 08/2015.

Results: Median age was 64 yo, there were 409 (68%) men, 521 (87%) smokers, 478 (80%) PS0/1 pts, 230 (38%) Sq and 370 (62%) Non-Sq NSCLC, 130 (22%) pts with brain metastases. Nivolumab was administered as $2^{nd}/3^{rd}/\geq 4^{th}$-line for 26%/33%/41% pts, respectively. Best response was PR/SD/PD for 17%/30%/37% of patients, respectively, with 16% not assessable. Toxicities occurred in 187 (31%) pts, including 10% grade ≥3 events. After a median follow-up of 22.1 (95% CI 21.6-22.6) months, median PFS and OS from the initiation of nivolumab were 2.1 (95%CI 1.9-2.3) and 9.5 (95%CI 8.4-10.8) months, respectively. Post-nivolumab treatment was administered to 262 (44%) pts, and mostly consisted of gemcitabine (19%), docetaxel (18%), paclitaxel (14%), erlotinib (12%), vinorelbine (9%), platin-based doublet (8%), or pemetrexed (8%). Access to post-nivolumab treatment was higher in PS0/1 vs. PS2 pts (48% vs. 23%, $p < 0.001$), but was not different according to histology or treatment line or disease control with nivolumab. Best response to post-nivolumab treatment was PR/SD/PD for 15%/42%/42% of pts, respectively. In the whole cohort, median post-nivolumab OS was 4.0 (95%CI 2.8-4.6) months, and was significantly higher in case of PR to nivolumab (HR = 0.38; 95%CI 0.23-0.64; $p < 0.001$), and if subsequent treatment was delivered (HR = 0.30; 95%CI 0.24-2.13; $p = 0.001$); median post-nivolumab OS in pts receiving post-nivolumab treatment was 7.5 (95%CI 6.8-8.7) months, and did not differ based on histology or treatment line.

Conclusions: Efficacy and safety of nivolumab was in line with available data. Post-nivolumab treatment may be delivered in many pts, and impact OS. Data on the whole cohort of 900 pts enrolled in the EAP will be presented.

Background: Nivolumab, a fully human PD-1 immune checkpoint inhibitor antibody, demonstrated a favorable efficacy and safety profile in previously treated SQ NSCLC in a phase 3 trial (CheckMate 017), with significantly longer OS (median 9.2 mo) and fewer treatment-related (TR) grade 3–4 AEs (7%) vs. docetaxel (median OS: 6.0 mo; grade 3–4 TRAEs: 55%). In a North American community-based study (CheckMate 153; SQ/non-SQ NSCLC), nivolumab showed comparable efficacy and safety to that observed in controlled clinical trials.

Methods: Patients aged ≥18 yr from 13 European countries with advanced SQ NSCLC, progressive disease after ≥1 systemic treatment, and ECOG performance status (PS) 0–2 were eligible to receive nivolumab. The primary objective of the study (NCT02409368) was to evaluate safety. OS and ORR were secondary objectives.

Results: 809 patients were enrolled: 79% male and 93% current/former smokers. Most patients had received 1 (42%) or 2 (40%) prior lines of therapy. Median duration of nivolumab therapy was 4.4 mo (range: 0.0, >14.7). 324 patients (40%) were continuing treatment at database lock. 403 patients (50%) had TRAEs. 95 (12%) had grade 3–4 TRAEs, most frequently asthenia (12 [2%]) and fatigue (10 [1%]). Of the 5 cases (1%) of TR grade 3–4 pneumonitis, 3 had a documented resolution, and in these patients, resolution occurred within 5 wk. TRAEs led to treatment discontinuation in 45 patients (6%), most commonly pneumonitis, asthenia, and fatigue (7, 5, and 5 patients each). 2 deaths were deemed TR. Median OS was 9.9 mo (95% CI: 8.7, 13.1). In the subgroup aged ≥70 yr (n = 279), 155 patients (56%) had TRAEs and 16 (6%) discontinued due to TRAEs. In the subgroup with ECOG PS 2 (n = 98), 45 patients (46%) had TRAEs and 5 (5%) discontinued due to TRAEs. Additional data including outcomes in the age ≥70 yr and ECOG PS 2 subgroups will be presented.

Conclusions: The safety of nivolumab in this study was consistent with prior studies of nivolumab in previously treated SQ NSCLC, with no new safety signals. Tolerability in patients aged ≥70 yr or with ECOG PS 2 was comparable to the overall population.

1304PD Correlation of radiation pneumonitis history before nivolumab and onset risk of interstitial lung disease or progression free survival of nivolumab in patients with non-small cell lung cancer

A. Tamiya[1], M. Tamiya[2], K. Nakahama[1], Y. Taniguchi[1], T. Shiroyama[3], S-I. Isa[4], T. Inoue[2], K. Nishino[2], T. Kumagai[2], H. Suzuki[3], T. Hirashima[5], F. Imamura[2], S. Atagi[4]

[1]Internal Medicine, Kinki-chuo Chest Medical Center, Sakai, Japan, [2]Thoracic Oncology, Osaka International Cancer Institute, Osaka, Japan, [3]Thoracic Malignancy, Osaka Prefectural Habikino Hospital, Habikino, Japan, [4]Clinical Research Center, Kinki-chuo Chest Medical Center, Sakai, Japan, [5]Thoracic Oncology, Osaka Prefectural Habikino Hospital, Habikino, Japan

Background: Nivolumab (Nivo) demonstrated the promising efficacy for patients (pts) with non-small cell lung cancer (NSCLC) as second or later line treatment. And, abscopal effect of the immune checkpoint inhibitor after the radiotherapy (RT) attracts attention. However, it has not clarified the correlation of radiation pneumonitis history (RPH) before Nivo and onset risk of interstitial lung disease (ILD) or progression free survival (PFS) of Nivo. So we retrospectively analyzed the correlation of RPH before Nivo and onset risk of ILD or PFS of Nivo treatments in patients with NSCLC.

Methods: 201 pts treated with Nivo from December 2015 to July 2016 were retrospectively reviewed. This study was multicenter study conducted by the three respiratory medical centers in Japan. We collected clinical data including age, sex, smoking history, histological types, performance status (PS), RPH, and history of RT to chest field, at the time of starting Nivo. And we evaluate the ILD and efficacy. We investigated relationship between RPH and ILD or PFS. The data cut off was on the end of November 2016.

Results: Median age was 68 years old, 135 pts were male, 157 pts had smoking history, 153 pts were PS 0 or 1, 34 pts experienced radiation pneumonitis before Nivo, and 50 pts received the RT to chest field (31 pts were curative RT). For all participants, median PFS was 2.8 months (M), overall ILD rate was 12.4%. In the incidence of ILD, no RPH vs RPH; 9.6% vs 26.5% (relative risk ratio (RRR): 2.76, 95% confidence interval (CI): 1.33-5.73), non-RT to chest field vs RT to chest field; 8.6% vs 22.0% (RRR: 2.37, 95% CI: 1.15-4.88). Furthermore, median PFS was no RPH vs RPH; 2.3 M vs 3.6 M, non-RT to chest field vs RT to chest field; 2.2 M vs 3.3 M, and in univariate analysis, RPH had a trend with PFS (hazard ratio (HR): 0.71, 95% CI: 0.44-1.10), however RT to chest field did not correlate with PFS (HR: 1.02, 95% CI: 0.69-1.47). In multivariate analysis, RPH significantly correlated with PFS (HR: 0.58, 95% CI: 0.35-0.93).

Conclusions: The RPH before Nivo not only gives onset risk of ILD but also contributes to the prolongation of PFS of Nivo.

1305PD Whole body PD-1 and PD-L1 PET in pts with NSCLC

A-L. Niemeijer[1], E. Smit[1], I. Bahce[1], O. Hoekstra[2], M. Huisman[2], G.A. van Dongen[2], B. Windhorst[2], N. Hendrikse[3], A.J. Poot[2], D. Vugts[2], D.K. Leung[4], W. Hayes[4], R.A. Smith[4], L.M. Wilson[4], E. Thunnissen[5], J. de Langen[1]

[1]Pulmonary Diseases, Vrije University Medical Centre (VUMC), Amsterdam, Netherlands, [2]Radiology and Nuclear Medicine, Vrije University Medical Centre (VUMC), Amsterdam, Netherlands, [3]Clinical Pharmacology & Pharmacy & Radiology and Nuclear Medicine, Vrije University Medical Centre (VUMC), Amsterdam, Netherlands, [4]Imaging, Bristol-Myers Squibb, Princeton, NJ, USA, [5]Pathology, Vrije University Medical Centre (VUMC), Amsterdam, Netherlands

Background: Tumor PD-L1 IHC relates moderately with treatment outcome following anti-PD1 therapy in pts with NSCLC and single biopsies do not account for tumor heterogeneity. Aim: 1. Assess safety of the PET procedures. 2. Quantify ^{89}Zirconium-labeled nivolumab (^{89}Zr-nivo) and ^{18}F-labeled BMS-986192 (^{18}F-PD-L1) uptake. 3. Assess tracer uptake heterogeneity. 4. Correlate tracer uptake with PD-1/PD-L1 IHC in tumor, stroma and with treatment outcome.

Methods: NSCLC pts eligible for treatment with nivolumab were included. Pts received whole body ^{18}F-PD-L1 and ^{89}Zr-nivo PET scans. Baseline tumor biopsy was required to assess PD-(L)1 IHC status (28.8 assay). SUV_{peak} was calculated for delineable lesions and correlated to PD-(L)1 IHC and response after 12 wks of nivolumab treatment.

Results: 10 pts (3 $\geq$50%, 5 $\geq$1%, 5 negative by PD-L1 IHC) were enrolled and 37 lesions analysed. No toxicity related to radiotracer was observed. Tumor uptake of both tracers was visualized in all pts, but not in all lesions. Tracer uptake varied among pts with mean ^{18}F-PD-L1 SUV_{peak} 4.6, range 0.5 - 14.4 and mean ^{89}Zr-nivo SUV_{peak} 5.0, range 1.6 – 11 ($p = 0.03$) and within pts with mean SUV_{peak} difference 3.6-fold ($\pm$2.1) and 2.4-fold ($\pm$0.77) between lesions for ^{18}F-PD-L1 and ^{89}Zr-nivo, respectively. For lesions with $\geq$50% PD-L1 IHC, mean ^{18}F-PD-L1 SUV_{peak} was 8.0 ($\pm$4.7) as compared to 3.5 ($\pm$1.6) for lesions with <50% PD-L1 IHC ($p = 0.03$). For tumors with high TIL/stromal PD-1 expression, mean ^{89}Zr-nivo SUV_{peak} was 8.6 ($\pm$2.4) as compared to 6.1 ($\pm$2.1) for lesions with low PD-1 expression ($p = 0.1$). Mean SUV_{peak} for ^{18}F-PD-L1 was 8.4 ($\pm$5.4) for pts with PR and 4.5 ($\pm$2.9) for pts with PD/SD ($p = 0.3$). Mean SUV_{peak} for ^{89}Zr-nivo was 7.8 ($\pm$1.8) for pts with PR and 5.4 ($\pm$2.2) for pts with PD/SD ($p = 0.2$).

Conclusions: 1. PET-imaging with both tracers is safe and feasible, with good tumor-to-normal tissue contrast. 2. Tumor uptake showed heterogeneity among pts and among tumors within pts. 3. Pts with $\geq$50% tumor PD-L1 expression showed higher ^{18}F-PD-L1 uptake. 4. Pts with high PD-1 expression showed higher ^{89}Zr-nivo uptake, and pts with PR demonstrated higher ^{18}F-PD-L1 and ^{89}Zr-nivo tracer uptake than pts with PD/SD, although these are without statistical significance which may be due to the small dataset.

Background: Using Tumor Growth Rate (TGR), we previously described HPD in 10% of 89 NSCLC pts treated with IO in a single institution. In this retrospective study, we explored HPD in a larger and multicenter cohort of advanced NSCLC pts treated with IO.

Methods: We performed a clinical and radiological retrospective analysis of consecutive NSCLC pts, treated with IO, in 5 different institutions, between November 2012 and March 2017. Eligibility criteria required, for each patient, 3 CT scans performed before IO, at baseline and during IO respectively, centrally reviewed by a senior radiologist and assessed according to RECIST 1.1 criteria. We calculated TGR at baseline of IO (baseline CT scan (n) vs (n-1) CT scan), TGR during IO (n + 1 CT scan vs baseline) and the variation per month of TGR between both (delta TGR). Pts were defined HPD if the absolute delta TGR increased by at least 50%. Median overall survival (mOS) and median progression free survival (mPFS) were estimated using the Kaplan-Meier method and compared between HPD and not HPD using the log-rank test.

Results: 242 pts were eligible. 64% were male, 50% $\geq$65 years, 51% smokers, 10% PS $\geq$ 2, 63% adenocarcinoma. 19% of NSCLC had KRAS mutation, 2% EGFR mutation, 2% ALK rearrangement, 35% had unknown molecular status. PD-L1 expression was positive in 12% of pts, negative in 11% and unknown in 77%, more than 90% of pts received single agent PD1-inhibitor in $\geq$ 2 line. Response rate (RR) to IO, mPFS and mOS were respectively 15%, 3.9 months (m) [3; 5], 13.4m [9; 42], median follow up was 10m [8; 12]. Compared to baseline, TGR decreased during IO (delta TGR $\leq$0) in 64% of pts, increased (delta TGR>0) in 36% (not regressing tumors). 40 pts (16%) had HPD. Only 3 pts (1,2%) had confirmed pseudoprogression, 2 of them were initially

qualified as HPD. Tumor burden baseline, clinical, molecular, pathological characteristics, PD-L1 status and RR to treatment before IO were not different between HPD and not-HPD pts. Compared to not-HPD population, HPD pts had significantly lower mPFS (1.4 vs 4.9m, $p < 0.001$) and mOS (3.4 vs 17m, $p < 0.001$).

Conclusions: HPD occurs in 16% of 242 advanced NSCLC pts treated with IO, leading to decreased survival. Further work is needed to better characterize this population.

1307PD Detection of driver and resistance mutations in leptomeningeal metastases of NSCLC by next-generation sequencing of cerebrospinal fluid circulating tumor cells

Y-S. Li[1], B-Y. Jiang[1], W-B. Guo[1], X-C. Zhang[1], J-J. Yang[1], Y. Shao[2], B. Huang[3], Y-H. Liu[4], Y-L. Wu[1]

[1]Guangdong General Hospital & Guangdong Academy of Medical Sciences, Guangdong Lung Cancer Institute, Guangzhou, China, [2]Geneseeq Biotechnology, Geneseeq, Nanjing, China, [3]Guangdong General Hospital & Guangdong Academy of Medical Sciences, Department of Radiology, Guangzhou, China, [4]Guangdong General Hospital & Guangdong Academy of Medical Sciences, Department of Pathology, Guangzhou, China

Background: Leptomeningeal metastases (LM) are more common in non-small cell lung cancer (NSCLC) with *EGFR* mutations. The diagnosis is difficult by traditional imaging only, and leads to poor understanding of resistance mechanisms of LM.

Methods: We compared the CellSearch Assay™, the Thinprep cytologic test (TCT), and brain magnetic resonance imaging (MRI) in 21 NSCLC patients with suspected LM. Next-Generation sequencing that included 416 cancer-associated genes was also performed on cerebrospinal fluid circulating tumor cells (CSFCTCs) of 19 patients.

Results: Twenty-one patients were diagnosed with LM, and CSFCTCs were captured by CellSearch in 20 patients (median, 969 CSFCTCs/7.5 mL; range, 27–14,888). CellSearch had a sensitivity of 95.2% for LM diagnosis, which was higher than that of TCT (12/21, 57.1%), MRI (10/21, 47.6%), and MRI plus TCT (19/21, 90.5%), respectively. CTCs were found only in 5 of 14 patients (median, 2 CTCs/7.5 mL; range, 2–4), which was a much lower ratio than CSFCTCs. Genetic profiles of CSFCTCs were highly concordant with molecular mutations identified in the primary tumor (17/19, 89.5%). The resistance gene *EGFR* T790M was detected in 7 of 9 patients with extracranial lesions, but was only detected in 1 of 14 CSFCTCs samples. Other potential resistant mutations such as *MET* amplification and *ERBB2* mutation were also identified in CSFCTCs.

Conclusions: CellSearch could be a more sensitive method for detecting tumor cells in CSF, and potentially provides earlier diagnosis of LM. More importantly, CSFCTCs could be an important and new way of "liquid biopsy" for genetic profiles of metastatic tumor cells in LM patients of NSCLC.

1308PD Preliminary efficacy and safety of lorlatinib in patients (Pts) with ROS1-positive non-small cell lung cancer (NSCLC)

B. Besse[1], A.T. Shaw[2], B.J. Solomon[3], T.M. Bauer[4], R. Chiari[5], C-C. Lin[6], M. Satouchi[7], J.S. Clancy[8], L.P. James[9], A. Abbattista[10], E. Felip Font[11]

Background: Most pts with ROS1-rearranged NSCLC achieve initial benefit with crizotinib but subsequently develop resistance, and further treatment options are limited. In Phase 1 of this study, lorlatinib, a potent and brain-penetrant TKI, was associated with a response rate of 50% in ROS1-positive NSCLC pts, most of whom had central nervous system (CNS) metastases (mets) and a majority of whom had received prior crizotinib. Antitumor activity and safety were explored at the recommended Phase 2 dose.

Methods: In this ongoing, Phase 2 study (NCT01970865), pts with ROS1+ NSCLC, ± asymptomatic untreated or treated CNS mets were enrolled with no restriction on the type or number of prior lines of therapy. Pts received lorlatinib 100 mg QD. The primary objective was overall and intracranial (IC) antitumor activity, measured as overall and IC response by independent central review.

Results: 23 pts with ROS1+ NSCLC were treated; 12 had CNS involvement, 16 had received prior crizotinib and 1 had received prior crizotinib and ceritinib. The overall response rate (ORR) by investigator assessment for this cohort was 8/23 (34.8%; 95%

Table: 1307PD

Patient No.	Primary gene profile	Targeted therapy before LM	Rebiopsy gene profile	CSFCTCs gene profile (NGS)

21	*EGFR* L858R (lung)	Gefitinib	UA	*EGFR* L858R

CI: 16.4, 57.3). The best overall response was SD in 11 pts (47.8%) and progressive disease (PD) in 2 pts (8.7%). The disease control rate at 12 weeks was 17/23 (73.9%; 95% CI: 51.6, 89.8). Of 8 pts with a confirmed response, 3 have progressed (after a range of 3.5–7.0 mos) and the remainder are in follow-up (range: 5.6–8.3 mos). The IC-ORR was 3/12 (25%) (95% CI: 5.5, 57.2). The most commonly reported treatment-related adverse events (TRAEs) were hypercholesterolemia (95.7%) and hypertriglyceridemia (69.6%) both managed with statins or other lipid lowering agents. Additional TRAEs included peripheral edema (34.8%) and cognitive effects (30.4%). Treatment-related dose interruptions and dose reductions occurred in 26.1% and 17.4% of pts, respectively; there were no treatment-related discontinuations or deaths. Most pts remain on treatment.

Conclusions: Lorlatinib has shown clinical activity in ROS1+ NSCLC pts, a majority of whom had CNS involvement and most of whom had received prior crizotinib. Overall, lorlatinib was well-tolerated with lipid elevations being the most common TRAEs.

1309P Efficacy and safety of necitumumab and pembrolizumab combination therapy in patients with stage IV non-small cell lung cancer (NSCLC)

B. Besse[1], P. Garrido Lopez[2], J. Puente[3], A. Cortot[4], M.E. Olmedo Garcia[5], M. Perol[6], M. Gil[7], G. Chao[8], J. Shahidi[9], J. Bennouna[10]

[1]Cancer Medicine, Institut de Cancérologie Gustave Roussy, Villejuif, France, [2]Medical Oncology, Hospital Universitario Ramón y Cajal, Madrid, Spain, [3]Medical Oncology, Hospital Clinico Universitario San Carlos, Madrid, Spain, [4]Pneumology-Oncology, Hospital Albert Calmette, Lille, France, [5]Medical Oncology, Hospital Universitario Ramon y Cajal, Madrid, Spain, [6]Oncologie, Centre Léon Bérard, Lyon, France, [7]Medical Oncology, Eli Lilly Poland, Warsaw, Poland, [8]Biometrics, Eli Lilly and Company, Bridgewater, NJ, USA, [9]Medical Oncology, Eli Lilly and Company, Bridgewater, NJ, USA, [10]Medical Oncology, CHU de Nantes, Nantes, France

Background: Studies of EGFR-directed monoclonal antibody (mAb) necitumumab (neci) and anti-PD1 pembrolizumab (pembro) demonstrate activity of each agent in NSCLC.

Methods: This phase 1b, multicenter, single arm study of neci and pembro examined the safety, efficacy, and tolerability in pretreated patients with Stage IV NSCLC (NCT02451930). PDL1 was centrally assessed retrospectively using IHC 22C3 pharmDx assay (negative, weak positive, strong positive if $< 1\%$, 1-49%, $\geq 50\%$ of tumor cells were stained, respectively). Escalating doses of neci 600 – 800 mg IV (days 1 and 8 every 3 weeks [Q3W]) were administered with pembro (200 mg IV) on Day 1 Q3W (Part A). Established dose from Part A was used in the expansion cohort (Part B). Study objectives were to determine the dose-limiting toxicity (DLT) and evaluate tolerability and overall response rate (ORR) by RECIST 1.1. Secondary objectives included progression-free survival (PFS) and overall survival (OS).

Results: for 64 patients are reported. Part A completed without DLTs (9 patients; 2 squamous, 7 nonsquamous). Overall, 3 patients received neci 600 mg and 61 patients received neci 800 mg; all patients received pembro 200 mg. ORR (95% CI) was 23.4% (13.8, 35.7). Median PFS (95% CI) was 4.1 m (2.4, 6.9). Six-month OS rate (95% CI) was 74.7% (61.5, 83.9). Treatment-emergent adverse events occurring in $\geq 20\%$ of all patients (n (%)) included dermatitis acneiform: 43 (67.2); asthenia: 24 (37.5); dry skin: 23 (35.9); hypomagnesemia: 21 (32.8); fatigue: 20 (31.3); decreased appetite and diarrhea (each): 17 (26.6); headache, pruritus, and stomatitis (each): 14 (21.9). Two neci 800 mg + pembro patients experienced grade 5 respiratory tract infection.

Conclusions: The results suggest modest activity of the combination in a NSCLC patient population with a relatively high proportion of PDL1 negative tumors (Table).

1310P Survival and safety of atezolizumab by best overall response (BOR) in the phase III NSCLC OAK study

F. de Marinis[1], F. Barlesi[2], A. Rittmeyer[3], J. von Pawel[4], J-Y. Han[5], M. Kozloff[6], A. Spira[7], L. Fehrenbacher[8], D.R. Gandara[9], W. Yu[10], P. He[11], C. Yun[12], M. Ballinger[13], M. Gandhi[12], S. Gadgeel[14]

[1]Thoracic Oncology, European Institute of Oncology, Milan, Italy, [2]Multidisciplinary Oncology & Therapeutic Innovations, Aix Marseille University, Marseille, France, [3]Thoracic Oncology, Lungenfachklinik Immenhausen, Immenhausen, Germany, [4]Thoracic Oncology, Asklepios-Fachkliniken München-Gauting, Gauting, Germany, [5]Center for Lung Cancer, National Cancer Center, Goyang, Republic of Korea, [6]Medicine, Ingalls Memorial Hospital, Harvey, USA, [7]Oncology, Virginia Cancer Specialists Research Institute, Fairfax, USA, [8]Oncology, Kaiser Permanente Medical Center, Vallejo, CA, USA, [9]Thoracic Oncology, UC Davis Comprehensive Cancer Center, Sacramento, CA, USA, [10]USMA Biometrics, Genentech, South San Francisco, CA, USA, [11]PD Biostatistics, Genentech, Inc., South San Francisco, CA, USA, [12]USMA, Genentech, South San Francisco, CA, USA, [13]Product Development Oncology, Genentech, South San Francisco, CA, USA, [14]Medical Oncology, University of Michigan, Ann Arbor, MI, USA

Background: Atezolizumab (atezo; anti–PD-L1) inhibits binding of PD-L1 to PD-1 and B7.1, thereby restoring tumor-specific T-cell immunity. OAK, the first randomized Ph III study of atezo vs docetaxel (doc) in 2L/3L NSCLC demonstrated a superior OS benefit of atezo (HR 0.73; 95% CI: 0.62, 0.87; $P = 0.0003$) in patients (pts) regardless of PD-L1 expression levels on tumor cells (TC) or tumor-infiltrating immune cells (IC). Here we present efficacy and safety analyses in the OAK primary population (n = 850) by BOR subgroups.

Methods: Previously treated pts were randomized 1:1 to atezo (1200 mg) or doc (75 mg/m^2) IV q3w. Co-primary endpoints were OS in ITT and PD-L1 expression subgroup (≥ 1% PD-L1 on TC or IC). Secondary endpoints included ORR and safety. BOR subgroups were defined based on RECIST v1.1 response determined by investigators. Time to response (TTR) was based on tumor assessment every 6 weeks. Data cut-off, July 7, 2016.

Results: Baseline demographics were generally similar across BOR subgroups except for PD-L1 expression status. TC1/2/3 or IC1/2/3 prevalence was 74% in CR/PR, 53% in SD and 55% in PD subgroups, respectively. The survival benefit of atezo vs doc was observed across BOR subgroups with greatest benefit occurring in the CR/PR subgroup (HR, 0.32; 95% CI 0.16, 0.63; see Table). Among pts in the CR/PR subgroup, the median TTR was comparable between atezo and doc arms (2.8 mo each). The median duration of response was longer in the atezo arm pts (16.3 mo, 95% CI: 10.0, NE) vs doc arm pts (6.2 mo, 95% CI: 4.9, 7.6). OS benefit with atezo was also observed in patients with SD and PD as BOR (see Table). No new safety findings were observed among BOR subgroups.

Conclusions: Atezo responses were durable. Atezo responders had more than two-thirds reduction in the risk of death compared with doc responders. In addition, the improved OS with atezo vs doc seen in pts with SD and PD suggests that clinical benefit also extended to patients who did not have a radiographic response.

Table: 1310P Efficacy of atezolizumab vs docetaxel by BOR subgroups

Patient Population	Atezolizumab		Docetaxel		HR (95% CI)[a]
	n	mOS (95% CI), mo	n	mOS, (95% CI) mo	
ITT (N = 850)	425	13.8 (11.8, 15.7)	425	9.6 (8.6, 11.2)	0.73 (0.62, 0.87)
BOR subgroups					
CR/PR	58	NE (NE, NE)	57	20.0 (15.9, NE)	0.32 (0.16, 0.63)
SD	150	17.6 (15.7, 20.2)	177	13.0 (11.5, 14.7)	0.70 (0.53, 0.92)
PD	187	7.3 (6.7, 9.4)	117	6.4 (5.6, 7.3)	0.72 (0.56, 0.93)

Background: We previously reported that *KRAS*-mutant lung adenocarcinomas (LUAC) with co-occurring genetic events in *STK11/LKB1* (KL) or *TP53* (KP) define subgroups with marked differences in immune contexture, including paucity of infiltrating CD8+ lymphocytes in KL LUACs. Here, we present updated data on the clinical efficacy of PD-1/PD-L1 inhibitors in co-mutation defined *KRAS*-mutant LUAC subsets using data assembled by members of the SU2C/ACS Lung Cancer Dream Team.

Methods: Patients (pts) with metastatic *KRAS*-mutant LUAC who received at least one cycle of PD-1/PD-L1 inhibitor therapy, were alive for ≥14 days thereafter, and had available molecular profiling were identified retrospectively. Efficacy assessment was based on RECIST v1.1. PD-L1 expression was tested using 22C3 pharmDx or E1L3N IHC assays. Isogenic derivatives of the LKR10 *Kras*$^{LA1/+}$ murine LUAC cell line with CRISPR/Cas9-mediated *Lkb1* knockout were used in preclinical experiments.

Results: 192 immunotherapy-treated (82% nivolumab, 12% pembrolizumab, 5% anti-PD1/PD-L1 plus anti-CTLA-4) pts with *KRAS*-mutant LUAC were included in the analysis. The ORR differed significantly between the KL (8.9%), KP (37.9%) and K-only sub-groups (25.8%) ($P = 0.00069$, Fisher's exact test) and was concordant for each genotype across patient cohorts [ORR for KL: 8.3% in the MDA cohort, 8.7% in the MSKCC cohort and 9.5% in the DFCI/MGH cohort). KL LUAC exhibited significantly shorter PFS (mPFS 1.8m vs 3m, HR = 0.47, 95% CI 0.32-0.7, $P = 0.0002$, log-rank test) and OS (mOS 6.8m vs 16.1m, HR 0.48, 95% CI 0.3 to 0.76, $P = 0.0018$, log rank test) compared to *KRAS*-mutant LUAC with wild-type *LKB1*. 11/14 KL tumors with available IHC data were negative for PD-L1 expression. Among 7 PD-L1-negative KP tumors, 3 PRs and 2SDs were recorded. In syngeneic murine models loss of Lkb1 promoted resistance to PD-1 inhibitor monotherapy, suggesting a causative role.

Conclusions: Inactivation of LKB1 represents a novel genomic predictor of *de novo* resistance to PD-1/PD-L1 blockade in *KRAS*-mutant LUAC. In addition to tumor PD-L1 status and tumor mutational burden precision immunotherapy approaches should take into consideration the *LKB1* status of individual tumors.

1312P Prediction of survival with durvalumab in locally advanced or metastatic NSCLC using early tumor assessments

X. Zhang[1], K. Park[2], N.A. Rizvi[3], P.A. Dennis[4], R. Narwal[5], Y. Huang[6], R. Arani[7], P. Mukhopadhyay[7]

[1]Immuno-Oncology GMD, AstraZeneca, Gaithersburg, MD, USA, [2]Division of Hematology/Oncology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [3]Department of Medicine, Columbia University Medical Center, New York, NY, USA, [4]Global Medicines Development, AstraZeneca USA, Gaithersburg, MD, USA, [5]Clinical Pharmacology, Pharmacometrics, & DMPK (CPD), MedImmune, Gaithersburg, MD, USA, [6]GMD Oncology B&I, AstraZeneca, Gaithersburg, MD, USA, [7]Biometrics & Information Sciences, AstraZeneca, Gaithersburg, MD, USA

Background: The analysis objective was to assess if limited tumor assessments can predict long-term overall survival (OS) in patients (pts) with locally advanced or metastatic (Stage IIIB-IV) non-small cell lung cancer (NSCLC) treated with durvalumab.

Methods: We used data from a Phase II, non-comparative, open-label multicenter study of durvalumab in NSCLC pts with ≥2 prior systemic treatment regimens,

Table: 1312P

	ATLANTIC (model building)		Study 1108 (validation)	
	Bad Group (n = 157)	**Good Group (n = 34)**	**Bad Group (n = 117)**	**Good Group (n = 58)**
Median OS (95% CI), days	340 (292, 403)	NE (557, NE)	265 (194, 315)	739 (616, NE)
6-month OS rate (95% CI)	0.742 (0.665, 0.804)	0.941 (0.785, 0.985)	0.605 (0.517, 0.682)	0.937 (0.855, 0.973)
1-year OS rate (95% CI)	0.478 (0.397, 0.554)	0.882 (0.716, 0.954)	0.371 (0.282, 0.460)	0.819 (0.708, 0.891)
HR [Good vs. Bad] (95% CI)	0.2059 (0.0569, 0.4437)		0.2637 (0.1661, 0.4187)	

NE, not estimable

including 1 platinum-based (ATLANTIC). Per exploratory analysis, the first 2 post-baseline assessments were used to develop the model. Using an elastic net statistical method, combined with cross validation, we identified important baseline variables, built a scoring system (defined as 0.28*sex + 0.188*histology group + 0.034*smoker group – 0.176*line of therapy – 0.041*tumor assessment) in which assessments are represented as a single variable (interpreted as a weighted average), and identified the optimal score thresholds to segment pts into 2 groups ('good' vs. 'bad') with significant differences in long-term OS.

Results: As of June 3, 2016, 444 pts had received treatment; 191 from cohort 2 (EGFR/ALK wild-type pts) with sufficient assessments (baseline and ≥1 follow-up) were used to develop the model. Median age was 64.0 years, 61.8% had WHO PS 1, 18.8% had squamous histology, mean number of prior anticancer regimens was 4.0, and 83.7% were current/ex-smokers; PD-L1 expression was high (≥25% of tumor cells stained) in 57.1%, low/negative in 35.6%, and unknown in 7.3%. OS results are summarized in the table. The model was validated using data from a Phase I/II open-label trial of durvalumab (1108).

Conclusions: We developed an algorithm based on baseline characteristics and tumor assessments to segment NSCLC pts treated with durvalumab into 2 groups with distinct OS. The scoring system was independently validated. However, the predictive versus prognostic value of this algorithm needs further evaluation using data from randomized trials.

Background: A superior survival benefit with atezolizumab (atezo; anti–PD-L1) vs docetaxel (doc; HR 0.73; 95% CI: 0.62, 0.87) has been demonstrated in OAK, the first randomized Ph III study of atezo in NSCLC patients (pts) who had failed prior platinum therapy. In the primary efficacy population (n = 850), atezo benefit was seen regardless of PD-L1 expression levels on tumor cells (TC) or tumor-infiltrating immune cells (IC). Here, we present the analyses of irAEs in the safety population (N = 1225) of OAK.

Methods: Pts were randomized 1:1 to atezo (1200 mg) or doc (75 mg/m^2) IV q3w. Co-primary endpoints were OS in ITT and in PD-L1 expression subgroups. Secondary endpoints included ORR and safety. irAEs were defined using MedDRA Preferred Terms that included both diagnosed immune conditions and signs and symptoms potentially representative of immune related events, regardless of investigator-assessed causality. Safety analyses conducted were incidence, nature and severity of irAEs, corticosteroid use and irAEs leading to atezo interruption/discontinuation. Data cutoff: July 7, 2016.

Results: In the atezo arm, 6.2% of pts had grade 3-4 irAEs and 25.0% of pts had grade 1-2 irAEs. No grade 5 irAEs were reported. Low rates of any-grade hypothyroidism (3.9%), pneumonitis (1.5%), hepatitis, (1.1%), and colitis (0.3%) were observed. Grade 3-4 irAEs included pneumonitis (0.7%) and hepatitis (0.7%); no pts developed Grade 3-4 colitis. 36 (5.9%) atezo arm pts experienced irAEs requiring corticosteroid treatment. Majority of irAEs in the atezo arm were manageable; 13 pts (2.1%) discontinued atezo. Meningoencephalitis (0.7%) and AST/ALT elevation (0.3%/0.2%) were the most frequently reported irAEs leading to atezo discontinuation. 26 pts (4.3%) had dose interruptions due to irAEs. AST/ALT elevation (0.8%/0.8%) and diarrhea (0.8%) were the most frequently reported irAEs leading to dose interruption.

Conclusions: The irAEs occurring in atezo-treated pts were mostly low grade and manageable, with few pts requiring dose interruption/discontinuation of atezo and corticosteroid treatment. Efficacy data based on irAE subgroups of OAK are presented separately.

1314P Association between immune-related adverse events (irAEs) and atezolizumab efficacy in advanced NSCLC: analyses from the phase III study OAK

J. von Pawel[1], K. Syrigos[2], J. Mazieres[3], D. Cortinovis[4], R. Dziadziuszko[5], D.R. Gandara[6], P. Conkling[7], J. Goldschmidt[8], C.A. Thomas[9], R. Bordoni[10], M. Kosty[11], F.S. Braiteh[12], S. Hu[13], M. Ballinger[14], H. Patel[15], M. Gandhi[16], L. Fehrenbacher[17]

[1]Medical Oncoloy, Asklepios-Fachklinikum, Gauting, Germany, [2]3rd Department of Medicine, Athens School of Medicine, Athens, Greece, [3]Thoracic Oncology, Toulouse University Hospital, Toulouse, France, [4]Medical Oncology Unit, AOU San Gerardo, Monza, Italy, [5]Department of Oncology and Radiotherapy, Medical University of Gdansk, Gdansk, Poland, [6]Thoracic Oncology, UC Davis Comprehensive Cancer Center, Sacramento, CA, USA, [7]Medical Oncoloy, Virginia Oncology Associates, Norfolk, VA, USA, [8]Clinical Research, Blue Ridge Cancer Care, Blacksburg, USA, [9]Medical Oncoloy, New England Cancer Specialists, Scarborough, ME, USA, [10]Medicine, Georgia Cancer Specialists; Northside Hospital Cancer Institute, Atlanta, GA, USA, [11]Division of Hematology/Oncology, Scripps Clinic, La Jolla, USA, [12]Medical Oncology, Comprehensive Cancer Centers of Nevada, Las Vegas, USA, [13]Biostatistics, Genentech, Inc., South San Francisco, CA, USA, [14]Product Development Oncology, Genentech, South San Francisco, CA, USA, [15]Product Development Safety Science, Genentech, South San Francisco, CA, USA, [16]USMA, Genentech, South San Francisco, CA, USA, [17]Oncology, Kaiser Permanente Medical Center, Vallejo, CA, USA

Background: OAK, the first randomized Ph III study of atezolizumab (atezo; anti–PD-L1), demonstrated a superior survival benefit with atezo vs docetaxel (doc) in NSCLC patients (pts) who had failed prior platinum therapy (HR 0.73; 95% CI: 0.62, 0.87). This analysis evaluates the benefit of atezo in pts with and without irAEs from the primary efficacy population (n = 850) of OAK. Safety data are reported separately.

Methods: Pts were randomized 1:1 to atezo (1200 mg) or doc (75 mg/m^2) IV q3w. irAEs were defined using MedDRA Preferred Terms that included both diagnosed immune conditions and signs and symptoms potentially representative of immune related events, regardless of investigator-assessed causality. For this analysis, efficacy was evaluated in pts with and without irAEs in the atezo and doc arms; efficacy endpoints were OS, PFS and ORR. To overcome the inherent survivor bias between irAE subgroups (pts surviving longer may be more likely to have irAEs), OS was evaluated using a time-dependent (TD) Cox model. Additional exploratory analyses included atezo efficacy in pts who did vs did not receive systemic steroids for irAEs. Data cutoff: July 7, 2016.

Results: The incidence of irAEs in the atezo arm was 31% (25.0% grade 1-2, 6.2% grade 3-4, no grade 5). Baseline characteristics including PD-L1 expression on tumor cells or tumor-infiltrating immune cells were generally similar between irAE subgroups. OS per TD Cox model was in favor of atezo arm pts with irAEs vs those without irAEs (HR 0.79; 95% CI: 0.60, 1.05). Median time to onset of first irAE was 1.6 mo; post irAE mOS was 17.3 mo (95% CI: 11.7, 21.2). 24 atezo arm pts (6%) required corticosteroid treatment. Median OS in pts who did vs did not receive corticosteroids was 16.0 mo (95% CI: 10.3, 23.5; n = 24) vs 21.9 mo (95% CI: 16.6, NE; n = 106), respectively. Median PFS was 5.9 mo (95% CI: 2.6, 14.5) vs 5.4 mo (95% CI: 4.2, 8.8) and ORR was 29% (95% CI: 13, 51) vs 21% (95% CI: 13, 30) in pts who did vs did not receive corticosteroids.

Conclusions: In this analysis, irAEs did not negatively impact the survival benefit of atezo. Further investigation on the impact of corticosteroids on atezo efficacy in randomized trials is needed.

Background: Brain metastases are a very common secondary localization of disease in patients (pts) with lung cancer. The prognosis of these pts is still poor and they are usually excluded from clinical trials. The EAP offered an opportunity to evaluate nivolumab treatment in these patients outside of a controlled clinical trial in Italy.

Methods: Nivolumab was available upon physician request for pts aged ≥18 years with a diagnosis of non-squamous non-small cell lung cancer (non-Sq-NSCLC) who had relapsed after a minimum of one prior systemic treatment for stage IIIB/stage IV non-Sq-NSCLC. Nivolumab 3 mg/kg was administered intravenously every 2 weeks to a maximum of 24 months. Pts included in the analysis had received ≥ 1 dose of nivolumab and were monitored for adverse events using Common Terminology Criteria for Adverse Events. Pts with brain metastasis were eligible if asymptomatic, neurologically stable and either off corticosteroids or on a stable dose or decreasing dose of ≤ 10 mg daily prednisone.

Results: Of 1588 patients with non-Sq-NSCLC participating in the EAP in Italy, 409 (26%) had asymptomatic and controlled brain metastases. With a median number of 7 doses (1-45) and a median follow-up of 6.1 months (0.1-21.9), the disease control rate was 40%, including 3 pts with a complete response, 65 patients with a partial response and 96 with stable disease. As of March 2017, median overall survival among patients with brain metastases was 8.1 (6.2-10.1) months. Among these pts, 117 were receiving steroid therapy at baseline and 74 received concomitant radiotherapy. Overall, safety profile and discontinuations for drug-related toxicity were consistent with what observed in the general population.

Conclusions: These preliminary data showed efficacy of nivolumab in patients with non-Sq-NSCLC with brain metastases, with safety results consistent to what already reported in controlled clinical trials, thus supporting the use of nivolumab in this population with poor prognosis.

1316P Efficacy and immune activation with PEGylated human IL-10 (AM0010) in combination with an anti-PD1 in advanced NSCLC: Update

D.J. Wong[1], J.G. Schneider[2], R. Aljumaily[3], M.W. Korn[4], K. Autio[5], J.R. Infante[6], M.R. Patel[7], K. Papadopoulos[8], A. Naing[9], N. Gabrail[10], P. Munster[11], J. Goldman[1], P. Van Vlasselaer[12], A. Hung[13], G. Brown[13], M. Oft[13], E.B. Garon[14]

[1]Department of Medicine, University of California, Los Angeles, CA, USA, [2]Oncology, Winthrop University Hospital, Mineola, USA, [3]Hematology/Oncology, Oklahoma University Medical Centre, Oklahoma City, OK, USA, [4]Cancer Center, UCSF, San Francisco, CA, USA, [5]Genitourinary Oncology, MSKCC, New York, NY, USA, [6]Medical Oncology, Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN, USA, [7]Oncology, Sarah Cannon Research Institute (Nashville, TN); Florida Cancer Specialists & Research Institute, Sarasota, FL, USA, [8]Oncology, South Texas Accelerated Research Therapeutics (START), San Antonio, TX, USA, [9]Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA, [10]Oncology, Gabrail Cancer Center, Ohio, USA, [11]Cancer Center, UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA, USA, [12]Corporate, ARMO BioSciences, Redwood City, USA, [13]Clinical Development, ARMO BioSciences, Redwood City, USA, [14]Oncology/Hematology, David Geffen School of Medicine at UCLA, Los Angeles, CA, USA

Background: At therapeutic concentrations, AM0010 stimulates the cytotoxicity, survival and proliferation of intratumoral antigen activated CD8+ T cells in pre-clinical cancer models and in patients. AM0010 activates antigen stimulated CD8 T cells while

PD-1 inhibits them, providing a rationale for combining AM0010 with PD-1 inhibitors.

Methods: 34 NSCLC pts. received AM0010 (10-20mg/kg QD, SC) with pembrolizumab (2mg/kg, q3wk IV; n = 5) or nivolumab (3mg/kg, q2wk IV; n = 29). Tumor responses were assessed by irRC. Immune responses were measured by analysis of serum cytokines (Luminex), activation of blood derived T cells (FACS) and peripheral T cell clonality (TCR sequencing).

Results: Pts had a median of 2 prior therapies. Median follow-up is 12.9 mo (range 3.7-26.9). AMO010 plus anti-PD-1 was well tolerated. All TrAEs were reversible. G3/4 TrAEs included thrombocytopenia (8), anemia (7), fatigue (6), rash (4), pyrexia (2), hypertriglyceridemia (3) and pneumonitis (1). As of May 5 2017, 26 pts had at least 1 tumor assessment, and partial responses (PRs) were observed in 10 pts (38.5%). 12 patients had stable disease (SD: 46.1%). mPFS and mOS were not reached. Updated efficacy data will be available by Aug. 31 2017.

Table: 1316P Preliminary response data stratified for PD-L1 (Study in progress)

NSCLC (n = 26)	PD-L1 (22C3 IHC) (n = 20)			IHC not available n = 6
	<1% (n = 11)	1-49% (n = 4)	≥50% (n = 5)	
PR, n (%)	3 (27%)	2 (50%)	4 (80%)	1 (17%)
SD, n (%)	7 (64%)	(25%)	1 (20%)	3 (50%)

AM0010 plus anti-PD1 increased Th1 and Th2 cytokines and FasL in the serum and led to a sustained increase in the number and proliferation of PD1+ Lag3+ activated CD8+ T cells, suggesting the invigoration of previously exhausted CD8+ T cells. In addition, previously undetectable T cell clones in the blood expanded to rank amongst the most abundant clones in the patient. The magnitude of novel T cell expansion and the number of invigorated CD8+ T cell correlated with objective tumor responses.

Conclusions: AM0010 in combination with anti-PD-1 is well-tolerated in advanced NSCLC pts. AM0010 improved on the expected response rates of nivolumab regardless of PD-L1 status. The observed CD8 T cell activation is promising and encourages the continued study of AM0010 in combination with an anti-PD-1.

Gorbacheva Memorial Institute of Children Hematology and Transplantation of Pavlov Saint-Petersburg State Medical University, Saint Petersburg, Russian Federation, [6]Department of Chemotherapy, Saint-Petersburg Clinical Research Center of Specialized Types of Medical Care (Oncological), Saint-Petersburg, Russian Federation, [7]Department of Chemotherapy, City Clinical Oncology Dispensary, Saint-Petersburg, Russian Federation, [8]Department of Oncology and Hematology, Multinational Center for Quality of Life Research, Saint-Petersburg, Russian Federation, [9]Department of Oncology, Saint-Petersburg State University, Saint-Petersburg, Russian Federation

Background: We aimed to evaluate clinical and patient-reported outcomes of Nivo as ≥ 2nd line treatment in NSCLC pts within the expanded access program. The interim data on response rates, survival and safety as well as base-line QoL and its changes are presented.

Methods: Adult pts with advanced refractory NSCLC received Nivo 3 mg/kg q2w. Tumor response was assessed using RECIST v. 1.1, adverse events (AEs) with NCI CTCAE v3.0; for QoL and symptom assessment RAND SF-36 and ESAS-R were used. Progression-free survival (PFS) and overall survival (OS) from the start of Nivo treatment were evaluated using Kaplan-Meier method. Group QoL comparisons were made using Mann-Whitney and Wilcoxon tests.

Results: At the cut-off 172 pts were enrolled in 7 centers in RF with median follow-up – 19 weeks (mean age – 60 (29 – 80); males – 65%; ECOG PS 0-1/2-3 – 81%/19%; former/current smokers – 71%; non-squamous NSCLC – 65%; ≥2 lines of previous systemic treatment – 51%). At baseline pts had dramatically compromised QoL as compared to healthy controls: Integral QoL Index (IQoLI) – 0.283 vs 0.505 ($p < 0.001$); the worst QoL was observed for *physical functioning* and *role functioning* ($p < 0.001$). The majority of pts (98%) had LC symptoms; the most common and severe were fatigue and shortness of breath. After 2 cycles QoL improvement was registered in 51% of pts (Mean IQoLI increased by 59%); fatigue decreased in 43% of pts; shortness of breath – in 32%. Efficacy was evaluated in 112 pts (median first evaluation – 9.4 weeks): PR – 7%, SD – 45%, PD – 48%. 13 pts died before first efficacy evaluation. 47 pts were not evaluated for response on cut-off. In the group of pts who completed Nivo treatment (n = 106) median PFS – 2.5 mos (95%CI 2.2–2.9), median OS – 8.4 mos (95%CI 6.0–10.8); median follow-up – 17.4 weeks. AEs were registered in 51 pts (median of Nivo treatment – 12.4 weeks); among them 12 had grades 3-4 AEs.

Conclusions: Early data from this study supports the acceptable efficacy and safety of Nivo (7% of pts with 3-4 grades AEs) in NSCLC pts. Nivo treatment is accompanied with noticeable QoL improvement in 51% pts.

Background: Nivolumab is the first checkpoint inhibitor approved for the treatment of non-Squamous non-small cell lung cancer (non-Sq-NSCLC). In previous studies, a greater clinical benefit was shown in current and former smokers than in never smokers and in EGFR mutated patients (pts). Nevertheless, no data are available from a real-world setting. Here we report the data from Italian expanded access program (EAP) in the never smoker pts and EGFR mutated pts.

Methods: Nivolumab was provided upon physicians' request for pts aged ≥18 years who had relapsed after a minimum of one prior systemic treatment for stage IIIB/stage IV non-Sq-NSCLC. Nivolumab 3 mg/kg was administered intravenously every 2 weeks for ≤24 months. Pts included in the analysis received ≥1 dose of nivolumab and were monitored for adverse events (AEs) using Common Terminology Criteria for Adverse Events.

Results: Of 1588 patients with non-Sq-NSCLC, 305 (19%) were never smokers and, among 1455 pts evaluable for EGFR mutation, 102 (7%) were positive. In the never smoker group, EGFR status was available for 287 pts, with 51 (19%) who harbored an activating EGFR mutation. Among never smokers, with a median follow-up (FU) of 7.0 months (0.1-20.3) and a median of 7 doses (1-38), the objective response rate (ORR), the disease control rate (DCR) and the median overall survival (OS) were 9%, 42% and 10.0 months (8.1-11.9), respectively. Among all EGFR positive pts, with a median FU of 5.5 months (0.1-20.9) and a median of 6 doses (1-40), the ORR, DCR and median OS were 9%, 30% and 8.3 months (2.2-14.4), respectively. In the never smoker group, EGFR positive pts had 2% ORR, 26% DCR and 5.6 months (3.4-7.8) of median

OS. However, it should be considered that these pts had poorer prognostic factors (ECOG performance status, brain metastasis) at baseline.

Conclusions: These preliminary results represent the first real-life data regarding the efficacy of nivolumab in special subpopulations, including never smokers and EGFR positive pts. Even if ORR and OS seem lower than in general population, due to lack of alternatives and good safety profile, nivolumab should be considered as a therapeutic option.

1319P Efficiency of nivolumab in the treatment of second-line advanced non-squamous non-small cell lung cancer (NSCLC) in Spain

P. González[1], N. Ortega-Joaquín[2], M. Provencio Pulla[3], C. Garrido[1], M. Echave[2]

[1]Medical Department, Bristol-Myers Squibb, Madrid, Spain, [2]Pharmacoeconomics, PORIB (Pharmacoeconomics and Outcomes Research Iberia), Pozuelo De Alarcón, Madrid, Spain, [3]Servicio de Oncología Médica, Hospital Universitario Puerta de Hierro, Majadahonda, Madrid, Spain

Background: The aim was to estimate the cost per life year gained (LYG) and quality-adjusted life year (QALY) of nivolumab compared to the standard of care, docetaxel, as second-line (2L) treatment in advanced non-squamous (NSQ) NSCLC patients in Spain.

Methods: An economic model with 3 health-states: progression free (PF), progressive disease (PD) and death was used to simulate, for a lifetime horizon, the total costs (€,2016) and clinical evolution of 1,000 NSQ NSCLC patients, treated with nivolumab or docetaxel. PF survival (PFS) and overall survival (OS) Kaplan-Meier curves, derived from CheckMate 057 trial, were used for monthly modelling of patient survival. Adverse event (AE) frequency and quality of life (utilities) were derived from CheckMate 057. PD implied the administration of one subsequent treatment (3L, defined by local oncologists). Costs relevant for the National Health System were included: acquisition drug costs (for 2L and subsequent treatments) using public list prices (confidential reimbursed price was used in an alternative analysis), administration, Grade 3-4 AE management, monitoring, and follow-up disease management at PF, PD and "end of life" care. Dosages for both therapies were derived from Summary of Products Characteristics. Costs and outcomes were discounted (3% annually). Unitary costs were obtained from a national costs database. Resources consumption for AE, disease management and pattern for 3L were defined by local oncologists. Sensitivity analyses (SA) were performed to verify the model robustness.

Results: Nivolumab was more effective than docetaxel, yielding 0.96 LYG and 0.81 additional QALY per patient. Total cost was higher with nivolumab (increment of €31,656), mainly driven by 2L drug and follow-up cost. Incremental ratios were €41,431/LYG and €45,738/QALY at public list prices (33,047€/QALY at reimbursed prices). In the probabilistic SA 92.5% of iterations resulted <€45,000/QALY gained at reimbursed prices.

Conclusions: Considering a willingness-to pay threshold of €30,000-€45,000/QALY gained, nivolumab versus docetaxel could be considered a cost-effective option for 2L treatment in Spanish patients with NSQ NSCLC.

Background: The efficacy and safety of nivolumab in patients with non-squamous non-small cell lung cancer (Non-Sq-NSCLC) have been demonstrated in several trials including the phase 3, randomized, controlled CheckMate 057 study which led to the approval of the product for this indication. However, data on the use of nivolumab in the real-BVLworld setting is still limited. The Italian nivolumab EAP for Non-Sq-NSCLC represents an important source of information. The current analysis describes results of the use of nivolumab in the group of EAP patients (pts) aged >70 and >75 years.

Methods: Nivolumab was available upon physician request for pts aged ≥18 years who had relapsed after a minimum of one prior systemic treatment for stage IIIB/IV Non-Sq-NSCLC. Nivolumab 3 mg/kg was administered intravenously every 2 weeks to a maximum of 24 months. Pts included in the analysis had received ≥ 1 dose of nivolumab and were monitored for adverse events (AEs) using Common Terminology Criteria for Adverse Events.

Results: Of 1588 Italian pts with advanced non-Sq-NSCLC participating in the EAP in Italy, 522 (33%) were ≥70 years and 232 (15%) were ≥75 years. The median follow up was 7.6 months (0.1-20.8) and 8.3 (0.1-20), respectively. For pts aged ≥70, median number of doses was 9 (1-44) and the disease control rate (DCR) was 48%, including 2 pts with a complete response (CR), 106pts with a partial response (PR) and 145 with stable disease (SD). For pts aged ≥75, median number of doses was 11 (1-39) and the DCR was 53%, including 58pts with a PR and 64 with SD. Among pts aged >70, 403 discontinued treatment for any reason, with only 25 (5%) discontinuation due to related AEs vs 177 discontinuation for any reason, with only 13 (6%) due to related AEs among pts aged >75. As of March 2017, median overall survival was 11.5 months (10.0-13.0) and 12.0 months (9.2-14.8) respectively in ptsaged ≥70 and ≥75. The efficacy, safety and drug-related discontinuation results are in line with what observed in the general population.

Conclusions: These results suggest that elderly population receive similar benefit from nivolumab treatment both in term of efficacy and safety than younger patients, supporting the use of nivolumab in this subpopulation.

Background: Nivolumab has been approved by different regulatory agencies worldwide for the treatment of nSq-NSCLC based on its superiority in Overall Survival (OS)

versus docetaxel in CheckMate 057 trial. In a pre-specified subgroup analysis of the same trial, this advantage was confirmed also in *KRAS*-mutation+ pts but the small number precluded any definitive conclusion. The Italian nivolumab EAP for non-sq-NSCLC might represent an important source of information in that respect. The current analysis describes results of the use of nivolumab in the group of EAP pts with *KRAS* mutations.

Methods: Nivolumab was provided upon physicians' request for pts aged ≥18 years who had relapsed after a minimum of one prior systemic treatment for stage IIIB/stage IV non-Sq-NSCLC. Nivolumab 3 mg/kg was administered intravenously every 2 weeks for ≤24 months. Pts included in the analysis received ≥1 dose of nivolumab and were monitored for adverse events (AEs) using Common Terminology Criteria for Adverse Events.

Results: In total, 1588 Italian pts with advanced nSq-NSCLC received at least one dose of nivolumab in the EAP across 168 sites. Among pts evaluated for *KRAS* mutation, 206 (39%) resulted positive. In this subgroup of pts, with a median follow-up of 7.7 months (0.1-21.2) and a median number of 8 doses (1-45), the best overall response rate (BORR) was 20%, including 2 pts with complete response and 39 pts with partial response, and the median OS was 10.7 months (8.6-12.8). These results were in line with those ones showed in the overall population (18% BORR and 11 months median OS, respectively).

Conclusions: This analysis confirms, in a real word setting and in a much larger number of pts, the efficacy of nivolumab in *KRAS*-positive pts in CheckMate 057. Nivolumab represents a potentially effective therapeutic option for *KRAS* mutation, a molecular alteration for which there is currently no direct targeted therapy.

1323P Baseline corticosteroids (CS) could be associated with absence of benefit to immune checkpoint inhibitors (ICI) in advanced non-small cell lung cancer (NSCLC) patients

G. Martínez Bernal[1], L. Mezquita[2], E. Auclin[3], R. Ferrara[2], D. Planchard[2], J. Remon Masip[2], J. Lahmar[2], M-E. Boucher[2], C. Caramella[4], J. Adam[5], A. Gazzah[6], J-C. Soria[6], B. Besse[2]

[1]*Medical Oncology, Hospital Universitario Virgen del Rocio, Seville, Spain,* [2]*Medical Oncology, Institut Gustave Roussy, Villejuif, France,* [3]*Medical and Gastrointestinal Oncology, Hopital European George Pompidou, Paris, France,* [4]*Radiology, Institut Gustave Roussy, Villejuif, France,* [5]*Pathology, Institut Gustave Roussy, Villejuif, France,* [6]*Drug Development Department (DITEP), Institut Gustave Roussy, Villejuif, France*

Background: Concomitant use of corticosteroids (CS) during immune checkpoint inhibitors (ICI) therapy are not recommended, but their real impact on ICI efficacy remains unknown. The aim of this study was to assess the impact of CS on ICI outcomes in NSCLC pts.

Methods: Baseline CS intake and dose, patient characteristics and outcome were retrospectively collected in patients treated with PD1/PDL1 inhibitors from Nov. 2012 to Mar. 2017 in our Institute. Primary endopoints were overall survival (OS) and disease control rate (DCR: complete response + partial response + stable disease) and secondary endpoint was progression free survival (PFS).

Results: We enrolled 244 pts. Median age was 63 years (30-85), 158 (65%) were males, 212 (87%) smokers, 196 (80%) PS 0-1; 155 (64%) had non-squamous cells carcinoma. The median of prior lines was 1 (0-11). KRASmut and EGFRmut was present in 62 (25%) and 14 (6%) of NSCLC, 3 (1%) were ALK+, 64 (26%) PDL1 + (cut-off 1% of tumor cells), 24 (10%) PD-L1- and 156 (64%) PD-L1 unknown. In the whole population, the overall response rate (ORR) was 20% and DCR 50%. Median OS and PFS were 9 months (m) [6-12] and 2m [2-3], respectively. The median follow-up was 10m [7-12]. Sixty-six patients (27%) received CS at baseline. Main reasons for taking CS were dyspnea (48%) and brain metastasis (15%). The median dose of daily prednisone was 16.25 mg [5;32.75] and >20mg in 19 (29%). CS dose >20mg was an independent factor for poor OS [HR 1,013, 95% CI 1,006; 1,02, p < 0,0001). For patients taking CS > 20mg, the median OS was 3m [2-12] vs. 10m [7-15] for <20mg (p = 0.005). The median PFS for >20mg was 1m [1-4] vs. 3m [2-4] for < 20mg (p = 0.002). CS > 20mg was also significantly associated with progressive disease (p = 0.011).

Conclusions: Baseline daily prednisone intake of at least 20mg is associated with poor outcomes in advanced NSCLC treated with ICI. Further prospective studies are awaited for validating the real impact of CS in ICI efficacy.

Background: Nivolumab, an immune checkpoint inhibitor, is now a standard treatment for previously treated advanced non-small cell lung cancer. We aimed to evaluate the real-world efficacy and safety of nivolumab in a non-selective population and identify clinical characteristics that influence efficacy.

Methods: One hundred and forty-two patients with previously treated advanced non-small cell lung cancer who were administered nivolumab at Keio University and affiliated hospitals (in Japan) between January and July 2016 were enrolled. Treatment responses and adverse events were retrospectively reviewed and clinical characteristics associated with nivolumab responses were evaluated using univariate and stratified analyses and the Cochran-Mantel-Haenszel test.

Results: The objective response rate was 17.0%, while the proportion of patients with adverse events of any grade was 45.0%. Clinical characteristics such as age, sex, Eastern Cooperative Oncology Group performance status, histological type, presence or absence of central nervous system metastases, smoking status, and the number of previous lines of treatment, were not related to efficacy. However, *EGFR*/*ALK* mutation status was inversely associated with treatment response ($P < 0.05$). Prior radiotherapy also exhibited a positive association with treatment response ($P = 0.012$). Although no significant difference was observed between current/ex-smokers and non-smokers ($P = > 0.05$), a subgroup analysis revealed smoking status in pack-years to be significantly higher in responders than non-responders ($P < 0.05$). Nivolumab is effective and safe regardless of age or the number of previous lines of treatment.

Conclusions: The objective response rate and adverse event profiles were comparable to those observed in previous clinical trials. An *EGFR*/*ALK* mutation-negative status and prior radiotherapy are key clinical characteristics that are statistically associated with a positive treatment response. Our findings may aid in the efficient immunotherapeutic management of advanced non-small cell lung cancer.

We will add other measurements of the treatment activity such as progression-free survival by the congress.

1325P Generalization and representativeness of phase III immune checkpoint inhibitor trials in NSCLC

S.H. Yoo, M. Kim, B. Keam, T.M. Kim, D-W. Kim, D.S. Heo

Internal Medicine, Seoul National University Hospital, Seoul, Republic of Korea

Background: Immune checkpoint inhibitors (ICBs) have become standard treatment in platinum-failed non-small cell lung cancer (NSCLC) based on several phase III studies. Recent randomized phase III trials have led to the approval of ICB. However, strict criteria for patient enrollment of phase III trials raise questions regarding generalization in the real world. The aim of this study was to evaluate whether pivotal phase III trials using ICB represent the real world NSCLC patients.

Methods: We reviewed the inclusion/exclusion criteria of 3 practice changing phase III trials (CheckMate057, CheckMate017, KEYNOTE-010). Availability of tumor tissue and other exclusion criteria for KEYNOTE-010 were additionally checked. We retrospectively analyzed the database of stage IIIB or IV NSCLC patients diagnosed from 2011 to 2013 at Seoul National University Hospital (cohort 1). We also analyzed the criteria in 53 NSCLC patients who have treated with nivolumab or pembrolizumab as a routine practice (cohort 2).

Results: Among the 715 NSCLC patients in cohort 1, 499 (69.9%) were ineligible for 3 trials. Reasons for ineligibility were as follows: no platinum doublet 23.6%, lack of tissue 22.7%, the Eastern Cooperative Oncology Group performance status > 1 14.1%, steroid use 18.2%, active central nervous system metastasis 8.3%, hepatitis B or C virus/human immunodeficiency virus 8.0% and no measurable lesion 7.3%. EGFR mutation was more common in ineligible group than eligible group (44.7% vs 19.7%, P < 0.001) In cohort 2 which comprise 53 patients who received ICB as a routine practice, 67.9% were classified as ineligible group. Treatment outcomes of ICB in cohort 2 seems to be inferior than those of 3 trials: response rate of 11.3%, disease control rate of 26.4%, and median progression-free survival of 1.67 months.

Conclusions: Only 30.2% of NSCLC patients were eligible for ICB phase III trial. Although ICB have approved for all platinum-failed NSCLC, the real world efficacy of 60% ineligible patients were still unknown. These findings suggest that a huge gap between the practice changing phase III trials and real world NSCLC patients.

1326P Long-term follow-up results of stage III-IV non-small-cell lung cancer (NSCLC) patients treated with an epitope derived from Indoleamine 2,3 Dioxygenase (IDO) in a phase I study

J.W. Kjeldsen[1], T.Z. Iversen[2], L.E. Noerregaard[2], A. Mellemgaard[2], M.H. Andersen[1], I-M. Svane[1]

[1]Department of Hematology and Department of Oncology, Herlev Hospital, University of Copenhagen, Center for Cancer Immune Therapy, Herlev Hospital, Herlev, Denmark, [2]Department of Oncology, Herlev and Gentofte Hospital, Herlev, Denmark

Background: A long-term follow up on an earlier published clinical trial of 15 stage III-IV NSCLC patients treated with and IDO peptide vaccine.[1]

Methods: 15 patients with stage III-IV NSCLC in disease stabilization after standard chemotherapy were treated with subcutaneous vaccinations (100 µg IDO5 peptide, seq ALLEIASCL, in 900 µl Montanide). Patients were enrolled from 2010 to 2012 and treated biweekly for 2.5 months and thereafter monthly until progression or up to 5 years. As published in Clin Cancer Res 2013, the vaccine was well tolerated and a long-lasting PR + SD (>8.5 months) was seen in 47% of the patients. A long-term follow-up has been made, investigating the long term clinical benefit and immunity.

Results: 3 of the 15 patients are still alive (May 2017) corresponding to a 5-year overall survival of 20%. One was excluded due to progression after 11 months; the other two have continued vaccination for 5 years and have both received 56 vaccines in total. One of the two patients developed a partial response of target lesions in the liver 15 months after the first vaccine and has been in stable disease ever since. The other patient had a solitary metastasis in a retroperitoneal gland at baseline and at the 1st evaluation scan the patient had no sign of malignancy and has been tumour free ever since. The vaccine was well tolerated for all 5 years. Analyses of PBMCs every 3rd to 6th month during treatment of the two long-term responders demonstrated a stable CD8+ T-cell population. The percentage of NK cells, MDSCs and Tregs were stable over time, demonstrating no sign of toxicity of the immune cells in the blood. Presence of IDO-specific $CD8^+$ T cells were demonstrated by IFN-γ Elispot and could be detected in both patients at several time points during vaccinations.

Conclusions: The vaccine was well tolerated with no severe toxicity for administration up to five years. Two of 15 patients are long-term survivors with ongoing clinical response five years after 1. vaccination. 1. Iversen, T. Z. *et al.* Long-lasting disease stabilization in the absence of toxicity in metastatic lung cancer patients vaccinated with an epitope derived from indoleamine 2,3 dioxygenase. *Clin. Cancer Res.* 20, 221–232 (2014).

Background: Derived NLR (neutrophils/(leucocytes-neutrophils) ratio) and lactate dehydrogenase (LDH) have been correlated to immune checkpoint inhibitors (ICI) benefit in melanoma. We tested whether baseline dNLR and LDH, as a score, could have the same role in advanced NSCLC patients.

Methods: Baseline dNLR and LDH were retrospectively collected in 466 patients treated with ICI from Nov. 2013 to Jan. 2017, in a training cohort (N = 161) and a validation cohort (N = 305) from 8 European centers. As a control, a cohort (N = 162) treated only with chemotherapy between Nov. 2012 and Jul. 2016 from 2 centers. The primary endpoint was overall survival (OS), and secondary endpoints were progression free survival (PFS) and disease control rate (DCR).

Results: In the immunotherapy cohort, 301 patients (65%) were males, 422 (90%) smokers and 401 (87%) with PS ≤ 1, with median age 63 years; 270 (58%) had adenocarcinoma and 159 (34%) squamous; 85 (18%) were KRASmut, 19 (4%) EGFRmut and 6 (1%) ALK positive. PDL1 was ≥ 1% by immunohistochemistry in 96 (74%), negative in 33 (26%) and unknown in 337 patients. The median of prior lines was 1 (0-11). In the training cohort, the median PFS and OS were 3 months (m) [2-4] and 10m [8-13]. dNLR>3 and LDH> Upper Limit of Normal (ULN) were independent factors for OS (HR 2.22, 95% CI 1.23-4.01; HR 2,51, 1.32-4.76, respectively). According to dNLR>3 and LDH>ULN, LIPI categorized 3 groups (good: 0 factor, intermediate: 1 factor, poor: 2 factors), which correlated with outcome in both cohorts. Median OS for good, intermediate, and poor was 34m, 10m and 3m, respectively (p = 0.0001). The PFS and DCR were also correlated (p = 0.001, p = 0.005). Same results were observed in the validation cohort for OS (p = 0.004), PFS and DCR (both p = 0.005), but not in the chemotherapy cohort for both factors analyzed.

Conclusions: Baseline LIPI, combining dNLR>3 and LDH>ULN, predicts the resistance to ICI acording to OS, PFS and DCR, but it is not correlated with the efficacy of chemotherapy, suggesting LIPI as a predictive score in ICI treatment.

1328P Association of single nucleotide polymorphisms with efficacy in nivolumab-treated NSCLC patients

E.A. Basak[1], S. Bins[1], S. El Bouazzaoui[2], S.L.W. Koolen[1], E. Oomen-De Hoop[1], C. van der Leest[3], A.A.M. van der Veldt[1], S. Sleijfer[1], R. Debets[1], R.H.N. van Schaik[2], R.H.J. Mathijssen[1], J.G.J.V. Aerts[4]

[1]Medical Oncology, Erasmus MC Cancer Institute, Rotterdam, Netherlands, [2]Clinical Chemistry, Erasmus University Medical Center, Rotterdam, Netherlands, [3]Pulmonology, Amphia Hospital, Breda, Netherlands, [4]Pulmonology, Erasmus University Medical Center, Rotterdam, Netherlands

Background: Proper patient selection for PD-1 checkpoint inhibitors is crucial given its limited efficacy in the majority of patients. We previously showed that a single nucleotide polymorphism (SNP) in the auto-immunity (AI) related *PTPN11* gene (rs2301756) is associated with increased toxicity on nivolumab (Bins et al, ESMO immuno-oncology symp, 2016). The objective of the current analysis was to assess whether SNPs in *PTPN11* and other genes associated with AI, which are putatively considered important in PD-1 influenced T-cell responses, are correlated with treatment efficacy of nivolumab in NSCLC patients.

Methods: The association between 5 SNPs and efficacy was evaluated in 161 (chemotherapy pretreated) advanced NSCLC patients. Efficacy measures included early progressive disease (PD; ≤ 90 days after start), tumor response according to RECISTv1.1, PFS and OS. The SNPs were located on 4 genes, being *PDCD1*, *PTPN11*, *ZAP70* and *IFNG*, respectively, encoding for the proteins PD-1, SHP-2 and ZAP70 and IFN-γ. The best model for every SNP, being either a dominant, recessive, multiplicative or additive model, was selected. SNPs were analyzed in multivariable logistic regression models if they showed a p-value <0.1 in univariable analysis, and were corrected for age and gender. PFS and OS analysis was done using the Kaplan-Meier method.

Results: Overall, 54 patients showed PR or CR according to RECIST. Patients with at least one variant allele in *PTPN11* had a higher response rate compared to wild-type (50% vs 30%; OR 2.4; 95% CI 1.0 – 5.5; p = 0.042). Other SNPs were not associated with response rate, and none of these SNPs were associated with early PD. Until the day of analysis, at which 128 patients had PD and 107 patients were dead, none of the SNPs was associated with PFS or OS.

Conclusions: Our results show that the SNP in *PTPN11* predisposes for a higher response rate to nivolumab therapy. Together with our earlier finding that this SNP is associated with grade ≥ 3 toxicity, this may indicate that SHP-2 activity influences treatment outcome of anti-PD-1 therapy in terms of both toxicity and anti-tumor effects. If confirmed, SNPs in *PTPN11* should be considered to be included as a biomarker in routine analysis of NSCLC patients to be treated with nivolumab.

1329P Systematic inflammation and histologic grade in non-small cell lung carcinoma

K. Tsapakidis[1], N. Tsoukalas[2], C. Giaginis[3], I. Gioulbasanis[2], M. Tolia[1], E. Aravantinou[4], M. Galanopoulos[3], M. Kiakou[3], I. Kostakis[3], I. Litos[1], M. Liontos[5], E. Sogka[1], V. Tzouda[6], K. Liaskonis[3], S. Theocharis[3]

[1]Medical Oncology, University Hospital of Larissa, Larissa, Greece, [2]Oncology, 417 NIMTS Veterans Hospital, Athens, Greece, [3]First Department of Pathology, Medical School, National and Kapodistrian University of Athens, Athens, Greece, [4]On behalf of the Hellenic Group of Young Oncologists (HeGYO), under the auspices of the Hellenic Society of Medical Oncology (HeSMO), Athens, Greece, [5]Clinical Therapeutics, General Hospital Alexandra, National and Kapodistrian University of Athens, Athens, Greece, [6]Medical Oncology, Agios Savvas Regional Cancer Hospital, Athens, Greece

Background: Tumor grade is an important factor of cancer outcome. Systematic inflammation has been associated with tumorigenesis and tumor aggressiveness and prognosis in several human malignancies. Cancer cells create an inflammatory peritumoral microenviroment by releasing a number of cytokines.

Methods: In total, 100 patients (88 males) with histologically proven NSCLC and no signs of active infection were evaluated. Tumor grade was examined and systematic inflammatory response was assessed by circulating levels of C-reactive protein (CRP), albumin, ferritin, transferring and the modified Glasgow Prognostic Score (mGPS). Patients were followed up and survival data were subsequently collected. Associations with clinicopathological, histological parameters and patients' survival were studied.

Results: Histological grade was associated with tumor size, the presence of pathological lymph nodes, organ metastases and advanced disease stage ($p = 0.010$, $p < 0.001$, $p < 0.001$ and $p < 0.001$, respectively). There was a trend of higher histological grade in adenocarcinomas compared to squamous carcinomas ($p = 0.263$). High tumor histological grade was also significantly associated with elevated serum CRP levels ($p < 0.001$), hypoalbuminemia ($p = 0.009$), elevated ferritin levels ($p = 0.049$), abnormal mGPS ($p = 0.006$) and a trend for reduced transferrin levels ($p = 0.101$). In multivariate analysis, histological grade, stage, ECOG performance status and mGPS were identified as independent prognostic factors for overall survival (Cox regression analysis, $p = 0.002$, $p = 0.001$, $p = 0.010$ and $p = 0.019$, respectively).

Conclusions: Our data support the association of tumour grade with the presence of systemic inflammation; two well described negative prognostic factors for NSCLC. To our knowledge this is the first time that these factors are associated with each other giving more information about the prognosis in patients with NSCLC.

1330P Impact of next generation TKI and co-occurring mutations in ALK-positive NSCLC patients: Results of the Network Genomic Medicine

R. Riedel[1], A. Kron[1], S. Michels[1], J. Fassunke[2], M. Scheffler[1], R. Fischer[1], L. Nogova[1], D. Abdulla[1], C. Heydt[2], F. Ueckeroth[2], B. Pauli[1], M. Serke[3], S. Krueger[4], C. Grohe[5], M. Sebastian[6], D. Koschel[7], K-O. Kambartel[8], T. Zander[1], R. Büttner[2], J. Wolf[1]

[1]Department I of Internal Medicine, Lung Cancer Group Cologne, University Hospital of Cologne, Cologne, Germany, [2]Institute of Pathology, University Hospital of Cologne, Cologne, Germany, [3]Department of Pneumology, Lungenklinik Hemer des Deutschen Gemeinschafts-Diakonieverbandes GmbH, Hemer, Germany, [4]Department of Pneumology, Florence Nightingale-Krankenhaus, Düsseldorf, Germany, [5]Department of Pneumology, Evangelische Lungenklinik ELK Berlin Chest Hospital, Berlin, Germany, [6]Department of Oncology and Haematology, Universitätsklinikum Frankfurt(Johannes-Wolfgang Goethe Institute), Frankfurt am Main, Germany, [7]Department of Pneumology, Fachkrankenhaus Coswig, Coswig, Germany, [8]Department of Pneumology, Bethanien Hospital Moers-Lungenzentrum, Moers, Germany

Background: Anaplastic lymphoma kinase (ALK) gene rearrangements define a molecular subtype of 3-4% of non-small-cell lung cancer (NSCLC), highly sensitive to therapy with ALK-directed tyrosine kinase inhibitors (TKI). Genetic heterogeneity of ALK-positive lung cancer patients (pts) is poorly characterized due to the lack of multiplex diagnostics results besides conventional FISH diagnostics. The Network Genomic Medicine (NGM) performs next generation sequencing (NGS) based diagnostics on a central platform in Cologne for advanced lung cancer pts in Germany.

Methods: The NGS panel used in NGM consists of 17 genes covering potentially targetable aberrations and is run on an Illumina (MySeq) platform. In 2016, we have started retrospective evaluation of ALK-positive NGM pts with available clinical data from the time period before and after NGS implementation. In particular, we have focused on ALK-positive NSCLC pts treated with chemotherapy, crizotinib and next generations TKI. Furthermore, we have analyzed the impact of co-occurring mutations: their frequency, significance and impact on overall survival.

Results: We have analyzed 289 ALK-positive pts with eligible clinical data. Co-occurring mutations were detected in 31% of these pts. The most frequent co-alteration was mutated TP53 in 23% of the ALK-positive patients. Regardless of the treatment regime, pts without co-occurring mutations seem to have a better overall survival (OS) with 37 versus (vs.) 15 month in pts with co-mutations ($p = 0.038$). TP53 co-mutated pts show an OS of 10 month ($p = 0.004$). Likewise, next generation TKI treatment exerts a highly positive impact on overall survival compared to chemotherapy and crizotinib treatment: 50 vs. 11 vs. 31 month ($p > 0.0001$).

Conclusions: While the first NGM evaluation in 2013 already showed a survival benefit of pts with activating genetic aberrations in EGFR and ALK, our current evaluation shows the heterogeneity of ALK-positive lung cancer pts and, for the first time to our knowledge, the impact of co-occurring mutations in these pts cohort. This work provides evidence for the efficacy of sequential ALK inhibitor treatment using next generation inhibitors and underlines the relevance of multiplex genotyping.

1331P Detection of EGFR T790M in Asia-Pacific patients (pts) with EGFR mutation-positive advanced non-small cell lung cancer (NSCLC): Circulating tumour (ct) DNA analysis across 3 platforms

C. Zhou[1], M. Wang[2], Y. Cheng[3], Y. Chen[4], X. Ye[5], Y. Sun[5], X. Huang[6], S. Patel[6], Y. Chen[5], Y-L. Wu[7]

[1]Shanghai Pulmonary Hospital, Tongji University, Shanghai, China, [2]Department of Respiratory Medicine, Peking Union Medical College Hospital, Beijing, China, [3]Department of Oncology, Jilin Cancer Hospital, Jilin, China, [4]Cancer Centre of Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China, [5]China Development Unit, AstraZeneca, Shanghai, China, [6]Biostatistics and Informatics, AstraZeneca, Cambridge, UK, [7]Guangdong Lung Cancer Institute, Guangdong General Hospital and Guangdong Academy of Medical Sciences, Guangzhou, China

Background: Osimertinib is an oral, potent, CNS active, irreversible EGFR-TKI approved to treat pts with T790M-positive NSCLC. Non-invasive methods to confirm presence of T790M are needed to identify pts who could benefit.

Methods: AURA17 (NCT02442349) is a Phase II, single arm study investigating the safety and efficacy of osimertinib 80 mg once daily in an Asia-Pacific pt population with T790M positive advanced NSCLC, who had disease progression following EGFR-TKI therapy. Tumour tissue T790M status was centrally confirmed by **cobas**® EGFR Mutation Test (Roche Molecular Systems). Where possible, matched plasma ctDNA samples collected at screening were analysed for EGFR mutations using 3 tests: **cobas**® EGFR Mutation Test v2.0 (cobas plasma), AmoyDx SuperARMS EGFR T790M Mutation Detection Kit (SuperARMS) and droplet digital PCR (ddPCR; in-house research assay).

Results: Table summarises concordance data.

Table: 1331P Sensitivity and specificity of plasma tests using cobas tissue test as the reference

% (95% CI)		cobas plasma (n = 240)	SuperARMS (n = 249)	ddPCR (n = 249)
T790M	PPA	42 (34, 50)	49 (41, 57)	56 (48, 64)
	NPA	83 (72, 91)	78 (67, 86)	73 (62, 83)
L858R	PPA	65 (54, 75)	NA*	62 (51, 72)
	NPA	100 (98, 100)	NA*	99 (96, 100)
Exon 19 deletions	PPA	86 (80, 92)	NA*	66 (58, 74)
	NPA	97 (91, 99)	NA*	98 (93, 100)

NPA, negative percent agreement (specificity); PPA, positive percent agreement (sensitivity); *SuperARMS used solely for detection of T790M Number of patients tested with cobas tissue test: 277 In the evaluable for response (EFR; 4 March 2016 data cut-off) set, pts with T790M-positive status by both tumour and plasma analysis had confirmed objective response rates (ORR) with osimertinib (RECIST 1.1 by blinded independent central review) of 56% (95% CI 43, 69; 36/64 pts) using cobas plasma, 64% (52, 74; 49/77 pts) using SuperARMS, and 56% (45, 67; 49/87 pts) using ddPCR. ORR in the overall EFR tumour T790M-positive population was 60% (52, 68; 100/166 pts).

Conclusions: Using cobas tissue test as the reference, sensitivity for plasma T790M detection slightly increased with superARMS and ddPCR compared to cobas plasma test. Conversely, specificity slightly decreased. In pts with tumour T790M positive status, ORR with osimertinib was consistent across plasma tests, and with the overall tumour T790M-positive population. Biopsy is recommended for pts with a plasma T790M-negative test result, where feasible.

1332P Influence of plasma T790M mutation on clinical decision after 1st generation EGFR-TKI resistance in a Real-world study

S. Zhang[1], L. Zhu[2], B. Xia[2], X. Chen[3], S. Ma[2]

[1]Hangzhou Translational Medicine Research Center, Hangzhou First People's Hospital, Nanjing medical university, Hangzhou, China, [2]Radiation Oncology, Hangzhou First People's Hospital, Nanjing Medical University, Hangzhou, China, [3]Medical Oncology, Hangzhou First People's Hospital, Nanjing Medical University, Hangzhou, China

Background: T790M mutation detection in circulating tumor DNA (ctDNA) has shown great potential in clinical application. However, few studies reported the influence of plasma T790M mutation on selection of clinical treatment and survival time after first generation TKI resistance.

Methods: 307 patients with advanced or recurrent NSCLC who had progressed during EGFR-TKIs treatment were enrolled prospectively (NCT02418234) from March 2015 to March 2016. Blood samples were drawn within two weeks from PD occurred. T790M mutations were evaluated by droplet digital PCR. We undertook follow-up every 3 months by phone till April 2017. The median follow-up time was 11 months (range, 2 to 22 months).

Results: Our results showed that the median survival time after TKI progression was 17.5 months (95%CI, 15-20 months) and six kinds of treatments were used in these patients, including continuation of TKI (27.0%), AZD9291 (27.7%), chemotherapy with or without radiotherapy (15.3%), TKI combined with chemo/RT (6.5%), switch to another TKI (2.6%) and best supportive care (11.4%). 88.6% of patients received subsequent treatment. T790M- patients were likely to receive continuation of original TKIs, which accords for 29.5% (52/176), the percentage of switch to another TKI is the lowest (2.8%, 5/176). In T790M+ patients, AZD9291 is the first choice as the subsequent treatment, which accords for 38.9% (51/131). Switch to another TKI (2.2%, 3/131) and TKI combined with chemo/RT (6.1%, 8/131) is the least selection. Although most T790M- patients received continuation of original TKIs, combination of TKI and chemotherapy/radiotherapy seems to be a better choice, which got the longest survival than other treatment. For T790M+ patients, patients who choose AZD9291 had the longest survival.

Conclusions: T790M status in ctDNA have the great influence on clinical decision of the subsequent treatment, AZD9291 is the most frequent choice for the plasma T790M+ patients, which contributed the longest survival after 1st generation EGFR-TKI resistance.

1333P Detectability of RET fusions by amplicon-based next generation sequencing in nationwide lung cancer genomic screening project: LC-SCRUM-Japan

Y. Usui[1], K. Kirita[1], S. Matsumoto[1], Y. Ohe[2], M. Nishio[3], T. Seto[4], M. Kodani[5], K. Taima[6], Y. Hattori[7], T. Kohno[8], K. Yoh[1], K. Goto[1]

[1]Thoracic Oncology, National Cancer Center Hospital East, Kashiwa, Japan, [2]Department of Thoracic Oncology, National Cancer Center Hospital, Tokyo, Japan, [3]Department of Thoracic Medical Oncology, The Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, Japan, [4]Department of Thoracic Oncology, National Kyushu Cancer Center, Fukuoka, Japan, [5]3rd Internal Medicine, Tottori University Hospital, Yonago, Japan, [6]Department of Respiratory Medicine, Hirosaki University, Hirosaki, Japan, [7]Department of Thoracic Oncology, Hyogo Cancer Center, Akashi, Japan, [8]Research Institute, National Cancer Center, Tokyo, Japan

Background: RET fusions have been identified as a therapeutic target in non-small cell lung cancer (NSCLC). The establishment of molecular diagnostics for RET fusions is required for the development of molecular-targeted therapies for fusion-positive patients. We have operated molecular testing for various actionable gene alterations, including RET fusions, in our nationwide lung cancer genomic screening project in Japan (LC-SCRUM-Japan).

Methods: Since 2013, RET fusions were analyzed by multiplex RT-PCR, and fusion-positive samples were confirmed by break-apart FISH. Since 2015, an amplicon-based next generation sequencing (NGS) system, Oncomine™ Comprehensive Assay was also applied in our genomic screening.

Results: As of February 2017, 244 institutions across Japan were participating, and a total of 4015 lung cancer patients including 3392 non-squamous (Non-Sq) NSCLCs were enrolled into the LC-SCRUM-Japan. Of the Non-Sq NSCLCs, available samples for multiplex RT-PCR and NGS were 94% (3186/3392) and 90% (1671/1852), respectively. RET fusions were detected in 89 samples (2.8%), including 54 detected by NGS. The types of variants found were KIF5B-RET (n = 50, 56%), CCDC6-RET (n = 20, 22%) and undetermined (n = 19, 21%). Of the 54 RET fusion-positive samples by NGS, the positivity was confirmed using break-apart FISH in 35 (92%) of 38 available samples. Among the 1335 samples available for both RT-PCR and NGS, the concordance rate between the two assays for the detection of RET fusions were 0.99. The detection sensitivity and specificity of the fusions in NGS assay were 0.98 and 0.99.

Conclusions: Our nation-wide screening results revealed that this amplicon-based NGS assay showed high sensitivity and specificity for the detection of RET fusions and is clinically applicable for diagnosis of RET fusions in lung cancer.

1334P A comparison of Bronchial Washing Fluid (BWF) and histologic samples in the analysis of EGFR mutation in NSCLC patients

X. Zhang[1], M. Ye[1], C. Li[1], Q. Hu[2], M. Du[2], X. Wang[2], Z. Gong[3], D. Zhang[3], Q. Hong[1], J. Hu[1], L. Mei[1], Y. Hou[2], X. Zhang[1]

[1]Department of Pulmonary Disease, Shanghai Zhongshan Hospital, Shanghai, China, [2]Department of Pathology, Shanghai Zhongshan Hospital, Shanghai, China, [3]Shanghai Yunying Medical Technology, Co. Ltd, Shanghai, China

Background: The aim of the current study was to examine the clinical application of BWF samples in detecting epidermal growth factor receptor (EGFR) mutations in a large sample set of NSCLC patients.

Methods: In diagnostic bronchoscopic examinations, before or after biopsy to target lesions, subsequent bronchial washing by saline was performed. Thereafter, EGFR mutation testing for both supernatant and sediment of BWF and histologic tissues was performed via amplification refractory mutation system real-time PCR (ARMS RT-PCR) assay.

Results: A total of 127 cases of histologic and corresponding BWF samples of patients underwent bronchoscopy for suspected lung malignant tumor lesions on chest radiography were successfully obtained. Of these, 72 cases were pathologically confirmed to be NSCLC based on forceps biopsy samples and EGFR mutations were identified in 26 cases. In 70 of 72 cases, the results of EGFR mutation status were concordant for BWF and histologic samples, and the concordance rate was 97%. In 13 cases that were not pathologically diagnosed with NSCLC with forceps biopsy samples but other samples, five cases (38.46%) with EGFR mutated-type were detected by BWF. The overall EGFR mutation concordance rate between supernatant and sediment specimens was 100%. The detection of EGFR mutations with supernatant/sediment of BWF samples showed a sensitivity of 86.5%, a specificity of 100%.

Conclusions: This study demonstrates a clear comparison of supernatant/sediment of BWF samples and histologic tissues for EGFR mutation testing with largest clinical samples to date. Both supernatant and sediment of BWF samples showed high credibility and concordance via highly sensitive PCR analysis. BWF is considered a simple, rapid and effective alternative for histologic samples in EGFR mutation testing.

1335P EGFR T790M detection in TKI-naïve NSCLCs carrying sensitive EGFR mutations

G. Pinotti[1], R. Cerutti[2], N. Sahnane[2], L. Lettig[2], C. Albeni[2], A. Tuzi[1], F. Franzi[2], A. Pastore[1], F. Ogliari[1], F. Sessa[2], D. Furlan[2]

[1]Oncology, Ospedale di Circolo Fondazione Macchi, Varese, Italy, [2]Dept of Medicine and Surgery, University of Insubria-Ospedale del Circolo, Varese, Italy

Background: To date, the frequency of EGFR T790M in TKI-naïve patients remains unclear, ranging from 2% to 80% depending on the sensitivity and specificity of the methods. In this study we aimed to identify the frequency of EGFR T790M in NSCLCs before TKI treatment, comparing the detection rate of three highly sensitive molecular methods.

Methods: Among 1100 NSCLCs (adenocarcinomas at stage IIIB or IV), we identified 130 NSCLCs with EGFR TKI-sensitive mutations, by MALDI-TOF mass spectrometry (MALDI-TOF MS) and Myriapod® Lung Status kit. The diagnostic performance in detecting de-novo EGFR T790M in these 130 tumors was evaluated comparing three methods, namely MALDI-TOF MS, Real Time AS-PCR (Easy®EGFR kit) and ddPCR™ (QX200 Droplet Digital PCR, PrimePCR™ Assays). Sensitivity and specificity of each method were defined by using a DNA reference standard set (Horizon). Limit of blank (LOB) of AS-PCR and ddPCR were determined by measuring replicates of 16 wild-type EGFR DNA samples obtained from peripheral blood lymphocytes and from formalin-fixed paraffin embedded (FFPE) normal lung tissues.

Results: Comparison of the three methods was possible for 91 of the 130 NSCLCs. Overall, we identified a total of 16 de-novo T790M in the analyzable tumors (18%). In detail, 4 cases were identified by MALDI-TOF MS and confirmed by AS-PCR and ddPCR. Two T790M-mutated cases were additionally detected by AS-PCR. ddPCR confirmed EGFR T790M in all these tumors and additionally identified 10 mutated cases. Most of mutated cases showed a mutant-allele frequency between 5% and 0.1%. Titration experiments using a DNA reference standard set demonstrated higher sensitivity of ddPCR (0.1%) than AS-PCR (1%) and MALDI-TOF MS (5%). Analysis of wild-type EGFR DNA from FFPE samples was crucial for the determination of LOB of ddPCR in order to maximize sensitivity, avoiding loss of specificity.

Conclusions: In this study, 18% of TKI-naïve NSCLCs show EGFR T790M mutation together with an EGFR activating mutation. Most of mutated cases showed a mutant-allele frequency between 5% and 0.1%. ddPCR is a robust method enabling the detection of mutant-allele frequencies as low as 0.1%. However, a careful preliminary evaluation of the specificity of this test is mandatory, especially when FFPE tissues are investigated.

1336P ALK fusion variants detection by targeted RNA-next generation sequencing and clinical responses to crizotinib in ALK-positive non-small cell lung cancer

A. Mc Leer[1], M. Duruisseaux[2], J. Pinsolle[2], S. Dubourg[1], J. Mondet[1], M. Phillips-Houlbracq[2], N. Magnat[1], J. Fauré[3], A. Chatagnon[3], F. de Fraipont[1], M. Giaj Levra[2], A.C. Toffart[2], G. Ferretti[4], E. Brambilla[5], P. Hainaut[1], D. Moro-Sibilot[2], S. Lantuéjoul[5]

[1]Cancer Molecular Genetics Platform, CHU Grenoble - Hopital Michallon, La Tronche, France, [2]Thoracic Oncology, CHU Grenoble - Hopital Michallon, La Tronche, France, [3]Molecular Biology Platform, CHU Grenoble - Hopital Michallon, La Tronche, France, [4]Radiology and Imaging Dept, CHU Grenoble - Hopital Michallon, La Tronche, France, [5]Pathology Department, CHU Grenoble - Hopital Michallon, La Tronche, France

Background: The aim of the present study was to assess the yields of an amplicon-based parallel sequencing (RNA-seq) assay for ALK fusion transcript variants detection in comparison with immunohistochemistry (IHC) and fluorescent in-situ hybridization (FISH) in a selected population of ALK-positive and ALK-negative non-small cell lung cancer (NSCLC) cases, and to evaluate the impact of the ALK variant on crizotinib efficacy.

Methods: Our population comprised fifty-three NSCLC cases positive for ALK by IHC and/or FISH and twenty-three ALK-negative samples. For the ALK-positive samples, a distinction was made between 'truly' IHC/FISH positive or 'truly' IHC/FISH negative samples, and the samples for which the IHC and/or FISH were equivocal (IHC) or borderline-positive (FISH).

Results: On the overall population, RNA-seq sensitivity and specificity were of 80% and 100%, respectively when IHC and FISH were combined and of 100% for both for 'truly' positive samples. Interestingly, this assay also appeared to be a promising rescue technique in equivocal and/or borderline-positive IHC/FISH cases. Moreover, when crizotinib efficacy was evaluated according to the type of ALK variant detected, better clinical outcomes were observed in crizotinib-treated patients with EML4-ALK v1/v2/ others variants compared to v3a/b variants. A lack of efficacy of crizotinib was noted in KLC1-ALK variants.

Conclusions: RNA-seq detects *ALK* rearrangements with a high sensitivity and specificity and may be particularly useful in equivocal/borderline-positive IHC/FISH cases. In addition, it offers a unique opportunity to identify *ALK* fusion variants and to evaluate their predictive value for ALK inhibitors efficacy.

1337P A meta-analysis on epidemiology of ROS1 rearrangement in Asian and non-Asian population

V. Gupta[1], N. Godre[1], M. Alam[2]

[1]Medical & Research Division, Pfizer Limited, Mumbai, India, [2]Oncology, Pfizer Limited, West Ryde, Australia

Background: ROS1 is now recognised as a definite molecular target in NSCLC.[1] Studies showed that ROS1 positive patients are significantly younger & more likely to be non-smokers.[2] Previous studies found epidermal growth factor receptor (EGFR) mutation in NSCLC was significantly higher in Asian population compared to non-Asian.[3] Objective of the study is to evaluate difference between epidemiological parameters of ROS1 rearrangements in Asian & non-Asian patients by performing meta-analysis.

Methods: We systematically searched databases like PubMed & e-journals since 2011. Statistical analysis for this study was done on 20 studies (11,665 patients) conducted globally & open source software R (version 3.3.2) was used for meta-analysis.

Results: Global prevalence of ROS1 rearrangement was 2% (95% CI: 0.016- 0.026) & it was higher in Asian [2.2% (95% CI: 0.016- 0.029)] than non-Asian [1.9% (95% CI: 0.012-0.027)] ($p = 0.92$). Mean age of Asian & non-Asian was 54.5 yrs & 59 yrs respectively. The prevalence rate in non-Asian females, was significantly higher [3.8% (95% CI: 0.011-0.078)] than non-Asian males [0.7% (0.003- 0.012)] ($p = 0.003$). Similarly, prevalence rate in Asian females [2.8% (95% CI: 0.019-0.038)] was higher than Asian males [2.1% (95% CI: 0.012-0.033)] ($p = 0.88$). Smokers in Asia were more likely to have ROS1 rearrangement [1.8% (95% CI: 0.005-0.037)] compared to non-smokers [0.6% (95% CI: 0.0004-0.0152)] ($p = 0.93$). Whereas, prevalence rate amongst non-smokers in non-Asia [7.1% (95% CI: 0.039-0.110)] was significantly higher than smokers [0.7% (95% CI: 0.002-0.007)] ($p = 0.008$). Clinical stage IV was more common in both population than other stages. In 5 out of 20 studies, ROS1 positivity was higher (3-12.5%) in enriched (EGFR-ve/ALK-ve) population [non-smokers 6.5% (95% CI: 0.046-0.083)] compared to overall population.

Conclusions: Our meta-analysis showed that ROS1 gene rearrangement was more prevalent in NSCLC, females, non-smokers & patients with clinical stage IV while there is no significant difference in Asians vs non-Asians. **References** 1] Bubendorf et al. 1338P EGFR mutation detection in plasma cell-free DNA correlates with clinical outcomes in non-small cell lung cancer

J. Shi[1], J. Mong[1], T.M. Chin[2], Y.H. Lim[1], W.L. Tan[3], C.K. Toh[3], H.S. Tan[3], S-W. Wong[4], A. Tee[5], D. Chan[6], K. Wong[6], S. Yeap[7], L. Ngo[8], Y-O. Tan[6], M-H. Tan[1]

[1]Biodevices and Diagnostics, Insitute of Bioengineering and Nanotechnology (IBN), Singapore, [2]National University Cancer Institute, National University Cancer Institute, Singapore, [3]Division of Medical Oncology, National Cancer Centre, Singapore, [4]The Cancer Centre, The Cancer Centre, Singapore, [5]Department of Respiratory & Critical Care Medicine, Changi General Hospital, Singapore, [6]Singapore Oncology Consultants, Singapore Oncology Consultants, Singapore, [7]Novena Cancer Centre, Novena Cancer Center-Mount Elizabeth Specialist Centre, Singapore, [8]Raffles Cancer Centre, Raffles Hospital, Singapore

Background: Cell-free DNA (cfDNA) testing of epidermal growth factor receptor mutations (*EGFR*mut) is being investigated as an adjunct for diagnosis and monitoring in non-small cell lung cancer (NSCLC) patients. The performance of various amplicon-based targeted next-generation sequencing (NGS) methods, both with and without error correction, is of high interest. Outcomes of error-corrected NGS in plasma EGFRmut testing have not been previously independently reported. We deployed an in-house amplification-refractory mutation system PCR (ARMS-PCR) assay in a prospective study, benchmarking its performance against two NGS platforms in a patient subset.

Methods: An ultrasensitive ARMS-PCR assay for hotspot *EGFR*mut was established, with detection limits between 0.02% and 0.1%. A total of 134 plasma samples were prospectively analysed from 68 patients with metastatic lung adenocarcinoma at diagnosis or progression, recruited between Jan 13-Apr 17 from 5 centres, with serial monitoring of plasma *EGFR*mut till radiologic progression in one centre. We further evaluated the performance of ARMS-qPCR assay, AmpliSeq Lung and Colon NGS assay and Oncomine Lung cfDNA NGS assay in 29 NSCLC and 20 healthy plasma controls.

Results: Concordance rate between cfDNA and tumor was 83.8%, with sensitivity 80.0%, specificity 94.4%, positive predictive value 97.6%, and negative predictive value 63.0%. Dynamic monitoring of plasma EGFRmut levels demonstrated rising levels a median of 2.1 months [0.9-3.9] before radiological progression. This detection also held true for tissue EGFRmut positive patients negative for plasma EGFRmut at study entry. 20 of 49 patients at progression were plasma T790M-positive, and clinical benefit rates were 91.0% for osimertinib-treated patients. Evaluation of ARMS-PCR and NGS platforms yielded an average concordance rate, sensitivity and specificity was 85.9%, 63.4%, 92.3% (ARMS-qPCR), 87.2%, 47.8%, 100% (Ampliseq) and 84.1%, 83.1%, 87.4% (Oncomine).

Conclusions: ARMS-PCR provides a useful diagnostic and monitoring adjunct for NSCLC EGFRmut patients. Amplicon-based targeted next-generation sequencing approaches with error correction is a promising approach requiring additional validation.

Background: HER2 is a potential driver oncogene. HER2-targeted precision therapy has been tested in NSCLC. However, the demographics of HER2-positive NSCLC have not been defined systematically.

Methods: Pts with advanced NSCLC were registered. HER2-IHC and FISH assays were performed with commercial kits. HER2 mutations were identified by the direct sequencing. The aim of this study was to clarify the frequency, characteristics and outcome of HER2-positive NSCLC.

Results: Of 1,126 tumors screened (Table A), 34 (3.0%) were IHC3+, and 34 (3.0%) were IHC2+/FISH+. Among the 724 EGFR wild-type tumors, 21 (2.9%) were HER2-mutant tumors, including A775_G776insYVMA (n = 15). Interestingly, the IHC3+ tumors and mutant tumors were entirely exclusive. Female pts had HER2 mutant tumors more frequently, while IHC/FISH+ tumors were detected more often in males (Table B). HER2-positive tumors had similar survival outcome to triple negative tumors, but significantly worse prognoses than EGFR-mutant and ALK-positive tumors ($p < 0.05$ each).

Conclusions: This is the first prospective study showing a small fraction of NSCLC possessed HER2 aberrations. HER2-positive tumors had relatively poor prognosis. NSCLCs with HER2 IHC3+ and mutation seemed to be distinct subsets.

Clinical trial identification: UMIN registration number 000017003

1340P Transcriptomic analysis of bronchoalveolar lavage cells from advanced non-small cell lung cancer identifies overexpressed immunoglobulin genes of immunosuppressive implication

C-H.S. Kuo[1], C-Y. Liu[1], Y-L. Lo[2], Y-W. Wang[1], T-H. Wang[3], C-T. Yang[1]

[1]Thoracic Medicine, Chang Gung Memorial Hospital-Taipei, Taipei, Taiwan, [2]Airway Disease, Chang Gung Memorial Hospital-Taipei, Taipei, Taiwan, [3]Genomic Medicine Research Core Laboratory, Chang Gung Memorial Hospital-Taipei, Taipei, Taiwan

Background: Diverse pattern of inflammatory cells infiltration in the microenvironment of non-small cell lung cancers (NSCLCs) has key implication for successful immunotherapeutic approaches (*Gajewski et al. Nat Immunol 2013*). However, study of these cells remains challenging particularly in advanced disease where tumor resection is never possible. We hypothesized that transcriptomic study of bronchoalveolar lavage (BAL) cells is useful in this setting to identify characteristic gene expression of immunological significance.

Methods: BAL cells were obtained from 13 patients of advanced NSCLC and 6 normal controls. In NSCLC group, lavage was performed from the lung segment where tumor was located. RNA was extracted and hybridized to Affymetrix HG-U133 plus2

Table: 1339P

A. The Genotype-Specific Subsets*

	HER2 (n = 88)	EGFR (n = 358)	ALK (n = 44)	Triple negative/ unknown (n = 664)	Total (n = 1,126)
Age, median Sex (male) Smoking habit Non-Sq Stage III/IV	69 61 (69%) 58 (66%) 78 (89%) 51 (58%)	69 142 (40%) 142 (40%) 351 (98%) 220 (61%)	62 21 (48%) 19 (43%) 44 (100%) 35 (80%)	69 516 (78%) 544 (82%) 503 (76%) 423 (64%)	69 726 (64%) 754 (67%) 951 (84%) 714 (63%)
MST (mo) 1-yr OS rate	17.5 59%	NR 85%	NR 79%	15.1 59%	19.8 67%

B. The Subsets of HER2 aberrations**

	IHC3 + (n = 34)	IHC2+/FISH + (n = 34)	Mutant (n = 21)

*including 22 pts with HER2-positive tumors with EGFR mutations, 2 with both HER2- and ALK-positive tumors, and 2 had ALK-positive tumors with EGFR-mutations.

**1 had an IHC2+/FISH+ tumor with mutation.

transcriptomic microarray. Raw intensity data was normalized by Robust Multi-Array Average and analyzed for differential expressed genes (DEGs) using Bioconductor R limma package.

Results: A total 129 DEGs were identified whose gene ontology enrichment analysis revealed the top over-represented pathways as circulating immune complex (GO: 0042571, $p=2.2x10^{-10}$), FCGR activation (REAC: 2029481, $p=5.4x10^{-11}$), and regulation of B cell activation (GO: 0050864, $p=2.4x10^{-5}$), in which a number of up-regulated genes encoding immunoglobulins, Src family kinases and interleukin (IL)-10 were noted. We integrated the immunoglobulin genes into a signature and calculated the enrichment score for each subject using Gene Set Variation Analysis (*Sonja et al. BMC Bioinformatics 2013*). Medium to high correlation of immunoglobulin signature with *IL-10* (Pearson's *r*: 0.64, $p=0.003$), with *FCGR2B* (Pearson's *r*: 0.43, $p=0.066$) and *FCGR2B* with *IL-10* (Pearson's *r*: 0.50, $p=0.029$) were determined. In addition, mild to medium correlation were identified between *IL-10* and Src family kinases *BLK* (Pearson's *r*: 0.48, $p=0.038$), *LCK* (Pearson's *r*: 0.40, $p=0.090$) and *YES1* (Pearson's *r*: 0.25, $p=0.300$).

Conclusions: Transcriptome of BAL cells around advanced NSCLCs showed characteristic expression of immunoglobulin signature that may implicate the immunosuppressive property in tumor milieu.

[1]Medicine (Medical Oncology), Yale University School of Medicine, New Haven, CT, USA, [2]Therapeutic Radiology, Yale University School of Medicine, New Haven, CT, USA, [3]Scientific Computing Core, Simon's Foundation, New York, NY, USA, [4]Genetics, Yale University School of Medicine, New Haven, CT, USA, [5]Biostatistics, Yale University School of Medicine, New Haven, CT, USA, [6]Thoracic Surgery, Yale University School of Medicine, New Haven, CT, USA, [7]Pathology, Yale University School of Medicine, New Haven, CT, USA

Background: Evaluation of response to immune checkpoint inhibitors by serial imaging can be complicated by the possibility of pseudo-progression or delayed response, sometimes resulting in discontinuation of an effective therapy or delay of alternate treatment. Monitoring tumor cell death by measuring changes in circulating tumor DNA (ctDNA) levels in blood may permit early assessment of immunotherapy efficacy.

Methods: We examined ctDNA levels in plasma samples from patients with metastatic non-small cell lung cancer (NSCLC) undergoing treatment with a PD-1 or PD-L1 inhibitor. CtDNA was quantified in plasma by determining the allele fraction of cancer-associated somatic mutations using a multi-gene next-generation sequencing assay. A ctDNA response was defined as more than 50% decrease in mutant allele fraction from baseline, with a second confirmatory measurement. Radiographic response assessment was performed using RECIST 1.1. Changes in ctDNA levels over time were correlated with imaging findings and with clinical outcomes.

Results: Twenty-eight patients with metastatic NSCLC had ctDNA quantified in serial blood samples collected before and during treatment with a PD-1 axis inhibitor. Strong agreement was observed between ctDNA response and radiographic response (Cohen's Kappa = 0.753, $P < 0.001$). The median time to response was 24.5 days by ctDNA versus 72.5 days by imaging. Patients who had a ctDNA response remained on immunotherapy for a median of 205.5 days compared to a median of 69 days for those who did not have a ctDNA response ($p < 0.001$). Progression-free survival (PFS) and overall survival (OS) were significantly better for patients with a ctDNA response versus those without (hazard ratio [HR] for PFS, 0.29; 95% confidence interval [CI], 0.09-0.89; P = 0.03 and HR for OS 0.17; 95% CI, 0.05-0.62; P = 0.007).

Conclusions: An early drop in ctDNA level enables assessment of response to immune checkpoint inhibitor therapies at a time when radiographic response may be uncertain for patients with metastatic NSCLC. Achievement of such a ctDNA response is predictive of a longer duration of therapeutic benefit as well as superior PFS and OS.

1342P Detection of epidermal growth factor receptor mutations in circulating cell-free DNA versus tumor biopsy

I-J. Oh[1], H-W. Seo[1], H-J. Cho[1], C-K. Park[1], J-H. Lim[1], Y-C. Kim[1], Y-D. Choi[2]

[1]Department of Internal Medicine, Chonnam National University Medical School & Chonnam National University Hwasun Hospital, Hwasun, Republic of Korea, [2]Department of Pathology, Chonnam National University Medical School, Hwasun, Republic of Korea

Background: Epidermal growth factor receptor (EGFR) mutations are predictive marker of EGFR-tyrosine kinase inhibitor (TKI) therapy. We compared the sensitivity of EGFR mutation detection techniques between matched tumor tissue and peripheral blood sample in patients with lung adenocarcinoma.

Methods: We collected the paired samples from plasma and paraffin-embedded tumor tissue in 295 patients before EGFR-TKIs therapy. DNA extraction was performed using the QIAamp MinElute virus spin kit and EGFR mutation analysis was done by two detection methods. One is the PNAClamp™ (Clamp) which is the PNA-based PCR clamping that selectively amplifies only the mutated target DNA sequence as minor portion in mixture with the major wild type DNA sequences. The other is the PANAMutyper™ EGFR kit (Mutyper), which use PNA clamping-assisted fluorescence melting curve analysis to perform mutation detection and genotyping.

Results: In tissue samples, the positive rates of EGFR sensitive mutation were not different between two methods (26.8% in Mutyper vs. 24.7% in Clamp). Plasma sensitivity was significantly higher in Mutyper than Clamp (70.9% vs. 30.1%, $p < 0.001$) with tissue as reference. The overall concordance and degree of agreement between two samples were better in Mutyper (91.2%, $k = 0.756$, $p < 0.001$) than Clamp (81.7%, $k = 0.369$, $p < 0.001$). The median progression-free survival (PFS) was significantly higher in EGFR sensitive group in tissue sample regardless of the two methods. In plasma sample, the median PFS of EGFR sensitive group was significantly longer than negative group only by Mutyper (11.8 vs. 3.7 months, $p = 0.020$), not by Clamp (9.8 vs. 11.0 months, $p = 0.968$).

Conclusions: The plasma sensitivity and concordance of Mutyper were better than Clamp test. And Mutyper could better predict the PFS of EGFR mutation in plasma. So this technique is expected to be useful to detect EGFR mutation in circulating cell-free DNA sample.

Background: Standard therapy for advanced anaplastic lymphoma kinase $(ALK)^+$ NSCLC consists of first-line crizotinib, followed by 2nd-generation ALK tyrosine kinase inhibitors (TKIs) such as ceritinib, alectinib, or brigatinib. While pts can achieve some clinical benefit from these agents, most will subsequently develop resistance. Lorlatinib, a brain-penetrant next-generation ALK TKI, is active against most known resistance mutations that can develop during treatment with 1st- and 2nd-generation TKIs. Here, we explore the antitumor activity and safety of lorlatinib in pts with ALK^+ NSCLC treated with ≥1 prior 2nd-generation TKI.

Methods: In this ongoing phase 2 study (NCT01970865), pts with ALK^+ or $ROS1^+$ NSCLC, ± asymptomatic untreated or treated central nervous system (CNS) metastases, were enrolled into 1 of 5 ALK^+ cohorts dependent on the number of prior TKIs received, and 1 $ROS1^+$ cohort with no restriction on the extent of previous therapy. Pts received lorlatinib 100 mg QD. The primary objective was overall and intracranial (IC) antitumor activity, measured as confirmed overall and IC response by independent central review (ICR).

Results: At the data cutoff (15 Aug 2016), 65 pts with ALK^+ NSCLC were treated with ≥1 prior 2nd-generation TKI (alectinib, ceritinib, brigatinib, or other). Of these pts, 41 had CNS metastases at baseline. The table shows the confirmed overall and IC responses (complete response + partial response) by ICR. The most common treatment-related adverse events (TRAEs) of any grade in pts who received prior ALK TKIs were hypercholesterolemia, hypertriglyceridemia, and peripheral neuropathy. Hyperlipidemia was successfully managed by appropriate medical treatment.

Table: 1343P

Type of 2nd-Generation TKI	Overall		Intracranial	
	N[a]	Confirmed Responses, n (%)	N[a]	Confirmed Responses, n (%)
Alectinib	33	9 (27)	16	8 (50)
Ceritinib	29	9 (31)	23	11 (48)
Brigatinib	6	1 (17)	3	0 (0)
Other	5[b]	2 (40)	4	2 (50)

[a]Patients in each group of prior TKI; a patient could have received more than one type of prior TKI.
[b]Other TKIs included entrectinib (n = 3) and ensartinib (n = 2).

Conclusions: Lorlatinib has shown clinical activity in pts with *ALK*$^+$ NSCLC who had received ≥1 prior 2nd-generation TKI.

Background: The next-generation ALK inhibitor BRG has shown activity in ALK+ NSCLC patients (pts) in clinical trials.

Methods: Pts with advanced malignancies (N = 137; including 79 pts with ALK+ NSCLC) received oral BRG (30–300 mg/d) in a phase 1/2, open-label, multicenter trial (NCT01449461). We report activity by RECIST v1.1 in ALK+ NSCLC pts and safety in all pts, with long-term follow-up (>31 months since last pt was enrolled).

Results: Among 79 ALK+ NSCLC pts, median age was 54 years; 90% (71/79) had received prior crizotinib (CRZ). As of 21 Feb 2017, 32% of ALK+ NSCLC pts (25/79) and 25% (7/28) of those receiving 180 mg qd with a 7-day lead-in at 90 mg (a regimen evaluated in the phase 2 portion of the trial) continued to receive BRG. Median treatment duration was 20.0 months (1 day to 56.1 months). Confirmed objective response rate (ORR) was 63% (45/71) in pts with prior CRZ and 100% (8/8) in CRZ-naive pts. Additional efficacy data are shown in the table. At 180 mg qd (with lead-in), confirmed ORR was 76% (95% CI, 55%–91%) and median progression-free survival (PFS) was 16.3 months (95% CI, 9.2–28.1) in pts with prior CRZ. Treatment-emergent adverse events (AEs) in ≥ 30% of all 137 pts, mostly grade 1/2, were nausea (55%), fatigue (45%), diarrhea (42%), headache (36%), and cough (34%). Grade ≥3 treatment-emergent AEs in ≥ 5% of pts were increased lipase (12%), pneumonia (7%), dyspnea (6%), and hypertension (6%). Eleven percent of pts (15/137) discontinued BRG due to an AE.

Conclusions: BRG shows major antitumor activity in ALK+ NSCLC pts with an acceptable safety profile in this long-term follow-up. PFS of > 16 months in pts receiving 180 mg qd with a 7-day lead-in at 90 mg is among the longest reported in CRZ-resistant ALK+ NSCLC. This dosing regimen is being investigated in a randomized phase 3 trial of BRG vs CRZ in ALK inhibitor–naive pts with advanced ALK+ NSCLC (ALTA-1L; currently recruiting pts).

Background: The CNS is often a site of first disease progression in CRZ-treated ALK+ NSCLC pts; we report BRG efficacy and safety in pts with CRZ-refractory advanced ALK+ NSCLC in the phase 2 ALTA trial who had baseline CNS metastases.

Methods: ALTA (NCT02094573) permitted baseline CNS disease (including pts with prior whole brain radiotherapy/stereotactic radiosurgery and asymptomatic untreated pts). 222 pts stratified by presence of brain metastases and best response to prior CRZ were randomized 1:1 to receive BRG 90 mg qd (arm A, n = 112) or 180 mg qd with a 7-day lead-in at 90 mg (arm B, n = 110). This analysis included an exploratory competing risks analysis to estimate cumulative incidence of CNS progression vs non-CNS progression vs death in pts with baseline brain metastases.

Results: 80 (71%)/73 (66%) pts in A/B had baseline brain metastases per independent review committee (median age, 49/55 years; 76%/74% had received chemotherapy). As of 21 Feb 2017, median follow-up for pts with brain metastases was 17.7 months; 34%/40% continued to receive BRG in A/B. Table shows intracranial efficacy. 5 pts with measurable baseline brain metastases in A had progression in the brain (≥20% growth in target lesions or new lesions) while receiving BRG 90 mg qd and escalated to 180 mg qd with ≥1 additional scan; all 5 had a reduction in measurable lesions after escalation (−14% to − 100%). While pts without baseline brain metastases did not have routine brain MRI scans, 3/32 and 1/36 pts without baseline brain metastases per investigators in A and B, respectively, had a new brain lesion identified by MRI.

Conclusions: In this update of ALTA, BRG continued to show robust intracranial efficacy in ALK+ NSCLC pts with baseline brain metastases, particularly at 180 mg (with lead-in), with a higher intracranial response rate and a numerically lower incidence of disease progression in the CNS and outside the CNS, compared to 90 mg.

Table: 1345P

Intracranial Efficacy of BRG in Pts With CRZ-Refractory ALK+ NSCLC and Baseline Brain Metastases (per IRC)	**Arm A 90 mg qd**	**Arm B 90 mg → 180 mg qd[a]**
Confirmed iORR (pts with measurable brain metastases), n/N (%)	13/26 (50)	12/18 (67)
Confirmed iORR (pts with measurable, active[b] brain metastases), n/N (%)	9/19 (47)	11/15 (73)
Median duration of intracranial response[c] (pts with measurable brain metastases), months (95% CI)	NR (3.7–NR) n = 13	16.6 (3.7–16.6) n = 12
Median iPFS[c] (pts with any baseline brain metastases), months (95% CI)	12.8 (9.0–18.3) n = 80	18.4 (12.6–NR) n = 73
Competing risks analysis	n = 80	n = 73
CIR of first disease progression in CNS, % (95% CI)		
By 6 months	20 (12–29)	15 (8–25)
By 12 months	33 (23–44)	27 (17–37)
By 18 months	41 (30–52)	34 (23–45)
CIR of first disease progression at non-CNS site, % (95% CI)		
By 6 months	14 (7–23)	11 (5–20)
By 12 months	21 (13–31)	20 (11–30)
By 18 months	23 (15–34)	21 (13–32)
CIR of death prior to all disease progression (in CNS or at non-CNS site), % (95% CI)		
By 6 months	5 (2–12)	3 (1–9)
By 12 months	9 (4–17)	6 (2–13)
By 18 months	9 (4–17)	7 (3–15)

Hoffmann-La Roche Ltd., Basel, Switzerland, [11]Center for Intergrated Oncology, University Hospital Cologne, Cologne, Germany

Background: Alectinib has shown central nervous system (CNS) activity in phase II trials of previously treated *ALK*+ NSCLC. We report CNS efficacy data from the phase III ALUR study (NCT02604342) of alectinib vs standard relapse chemotherapy (CT) in pts with *ALK*+ NSCLC who previously failed platinum-based doublet CT and crizotinib.

Methods: Pts aged ≥18 years with *ALK*+ NSCLC, previously treated with CT and crizotinib were randomised 2:1 to alectinib (600mg twice daily) or CT (pemetrexed 500mg/m^2 every three weeks [q3w] or docetaxel 75mg/m^2 q3w) until disease progression (PD), death or withdrawal. After PD, pts could crossover from CT to alectinib. Primary endpoint was progression-free survival (PFS) by investigator assessment in the intent-to-treat (ITT) population. A key secondary endpoint was CNS overall response rate (CORR) by Independent Review Committee (IRC) in pts with measurable CNS mets at baseline (BL) (mC-ITT). Other CNS outcomes were CORR in pts with measurable and non-measurable CNS mets (C-ITT); 6-month cumulative incidence rate in the ITT, and C-ITT; CNS duration of response (CDOR) and disease control rate (CDCR); and safety.

Results: In total, 107 pts were randomised (alectinib n = 72, CT n = 35; ITT) of whom 76 had BL CNS disease (alectinib n = 50, CT n = 26; C-ITT); 40 had measurable CNS mets (alectinib n = 24; CT n = 16; mC-ITT) and 36 had non-measurable CNS mets (alectinib n = 26, CT n = 10; nC-ITT). CNS efficacy endpoints are shown in the Table. The 6-month cumulative incidence rate of CNS PD was 11% (alectinib) vs 48% (CT) in the ITT, 15% vs 52% in the C-ITT and 0% vs 39% in pts without BL CNS disease. Safety and tolerability profile compared favourably for alectinib vs CT.

Conclusions: CNS-related outcomes were significantly improved with alectinib vs chemotherapy in previously treated *ALK*+ NSCLC. Alectinib reduces CNS PD and prevents the development of new CNS mets.

1347P Treatment beyond disease progression: ALK inhibitors in ALK-rearranged advanced NSCLC

N.B. Leighl[1], J. Kuo[1], A. Pavel[1], M. Prescilla[1], F.A. Shepherd[2], G. Liu[3], P. Bradbury[4], M. Moskovits[1]

[1]Department of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University of Toronto, Toronto, ON, Canada, [2]Department of Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada, [3]Department of Medical Oncology and Hematology, Princess Margaret Hospital, Toronto, ON, Canada, [4]Medical Oncology, Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: Treatment of patients with ALK-EML4 gene rearrangement with ALK inhibitors (ALK-I) yields high response rate (RR) and prolonged progression free survival (PFS). Defining progressive disease (PD) using RECIST has been challenging in the era of targeted and immunotherapy, as some patients are perceived to be deriving ongoing benefit despite PD by RECIST. We explore the impact of treatment beyond progression with ALK-I on patient symptoms and treatment duration.

Methods: Patients with advanced ALK-rearranged lung cancer treated at the Princess Margaret Cancer Centre between 2009 and 2017 were identified. Treatment duration was obtained from medical records, assessment of PFS by RECIST 1.1 from patient imaging, and patient self-reported symptoms and performance status (Edmonton Symptom Assessment Scale (ESAS), ECOG PS) were collected prospectively.

Results: 66 patients were identified with advanced ALK-rearranged lung cancer. The median age at diagnosis was 61 years, 49% were male, 78% presented with stage 4 disease, 47 received ALK-I therapy (median 2 lines, range 1-4). Over half (26/47, 55%) continued ALK-I treatment beyond RECIST PD. PD occurred most commonly in brain (15/47), lung and/or pleura (11/47); 17/47 received local therapy (predominantly radiation) and continued ALK-I. Data on time to RECIST PD and treatment failure are shown below. Only 34/47 patients had symptom data available at baseline, 22 with severe symptoms; 70% improved with initial ALK-I treatment. At the time of RECIST PD, most of those continuing ALK-I beyond progression had not experienced deterioration of symptoms.

Table: 1347P ALK-I Treatment Patterns

	Initial ALK-I (N = 47)	Second ALK-I (N = 26)
Median Time to RECIST PD	10.1 months (range 0.3-– NR)	4.8 months (range 0.5 – NR)
Pts continuing ALK-I beyond PD	17/47 (36%)	8/26 (30%)
Median duration of treatment beyond progression	5.0 (range 0.6 – NR)	3.9 (range 1.3-21.5)

NR- not reached.

Table: 1346P CNS efficacy endpoints

	C-ITT N = 76		mC-ITT N = 40	
	Alectinib N = 50	Chemotherapy N = 26	Alectinib N = 24	Chemotherapy N = 16
CORR, % (95% CI)	36	0	54.2	0
Difference (95% CI) P value	36% (13%–57%) p < 0.001		54% (23%–78%) p < 0.001	
CDOR, months (95% CI)	NE (6.2–NE)	0	NE (3.6–NE)	0
CDCR, %	80	26.9	79.2	31.3

NE, not evaluable

Conclusions: Treatment beyond disease progression for patients with advanced lung cancer harboring ALK rearrangement is common and is often associated with maintenance of symptom burden.

Background: Osimertinib is an oral, potent, CNS active, irreversible EGFR-TKI approved to treat pts with T790M-positive advanced NSCLC. Here we present updated data from a pre-planned pooled analysis of Phase II studies: AURA extension (NCT01802632), AURA2 (NCT02094261).

Methods: Pts with centrally confirmed T790M-positive (by cobas® EGFR Mutation Test) advanced NSCLC, who had progressed following EGFR-TKI treatment, received osimertinib 80 mg once daily. Other inclusion criteria were measurable disease, WHO performance status 0/1 and acceptable organ function. Pts with stable CNS metastases were eligible. The primary efficacy endpoint was objective response rate (ORR) by RECIST 1.1 per blinded independent central review (BICR). Secondary endpoints included duration of response (DoR), progression-free survival (PFS), OS and safety.

Results: As of the 1 Nov 2016 data cut-off (DCO) 411 pts had received osimertinib (129 pts as second-line and 282 pts as ≥third-line); median treatment exposure was 16.4 months (mo; range 0–29.7 mo). Pooled results (BICR) were: ORR (evaluable for response set; EFR), 66% (95% confidence interval [CI] 61, 70); median DoR (EFR), 12.3 mo (95% CI 11.1, 13.8); median PFS (full analysis set), 9.9 mo (95% CI 9.5, 12.3). At DCO, 188 pts (46%) had died, 191 pts (47%) remained in survival follow up, and 32 pts (8%) had discontinued before death. Pooled median OS was 26.8 mo (95% CI 24.2, not calculable [NC]); median OS in the second-line and ≥third-line cohorts (95% CI) was 25.8 mo (24.0, NC) and NC (22.1, NC), respectively. The 12 and 24 mo survival rates were 80% and 56%, respectively. The most common (investigator assessed) possibly causally-related adverse events (AEs) were rash (grouped term 42%, [grade ≥3, 1%]) and diarrhoea (39% [<1%]). Four pts died due to possibly causally related AEs (pneumonitis [n = 3], interstitial lung disease [n = 1]).

Conclusions: With a median treatment exposure of 16.4 mo, osimertinib resulted in a median OS of 26.8 mo. This pooled analysis represents the most mature clinical trial data for osimertinib in pts with pre-treated T790M positive advanced NSCLC, and further establishes osimertinib as standard of care in this setting.

Background: Acquired resistance after front-line treatment (tx) with 1st-/2nd-generation EGFR TKIs necessitates further therapies for pts with EGFRm+ NSCLC. We explored the outcome of subsequent therapies, including other EGFR TKIs and chemotherapy (CT) after 1st-line afatinib in the LL3, 6 and 7 randomised trials.

Methods: We retrospectively assessed subsequent therapy outcomes in pts with common EGFR mutations, who were randomised to 1st-line afatinib in the LL3/6/7 trials. Data had been prospectively collected as study follow-up information. Tx duration was assessed by descriptive medians or KM estimates. Biopsies at afatinib resistance were not required in LL3/6/7.

Results: Of the 553 pts with common EGFR mutations who received 1st-line afatinib and later discontinued it, 2nd-line therapy was given in 394 (71%) pts and consisted of platinum-based CT for 252 (46%), single agent CT for 39 (7%), 1st-generation EGFR TKI for 49 (9%) and other tx for 54 (10%) pts. Median time on 2nd-line tx was 2.9 months for platinum-based and 1.4 months for single-agent CT, with no relevant difference between Del19 and L858R mutation subgroups. Among 186 (34%) pts who received 1st-generation EGFR TKIs post-afatinib, median time on tx was 3.9 months. Of 212 pts randomised to 1st-line CT in LL3 and LL6, 117 (55%) received 1st-generation EGFR TKI monotherapy as 2nd-line tx, with a median time on tx of 11.2 months. Interestingly, 34 pts received osimertinib after 1st-line afatinib, the majority in ≥ 3rd line; median time on osimertinib tx was 31.5 months (95% CI 16.8–31.5 months). Median OS for osimertinib-treated pts is not yet evaluable.

Conclusions: The majority (71%) of pts who received 1st-line afatinib were fit enough to receive subsequent therapies and there was no relevant difference in 2nd-line tx duration by Del19/L858R EGFR mutation subgroup. Introduction of a different TKI was common, with good outcome. Time on tx with osimertinib after afatinib was unexpectedly long among 34 pts; this should be examined in a larger cohort. Overall, these findings suggest that pts treated with 1st-line afatinib are well suited for subsequent therapies, including CT, 1st-generation EGFR TKIs and osimertinib.

Background: TAS-121 is an orally available, potent, novel epidermal growth factor receptor (EGFR)-tyrosine kinase inhibitor (TKI) selectively targeting EGFR activating and T790M resistance mutations. This first-in-human phase I study evaluated the maximum tolerated dose (MTD), safety, tolerability, pharmacokinetics (PK), and antitumor activity of TAS-121.

Methods: The study was conducted in Japan and consisted of three phases: dose escalation phase (DEP), expansion phase first stage (EP1), and second stage (EP2). Patients were eligible for inclusion in the study if they had advanced EGFR mutation-positive non-small-cell lung cancer (NSCLC) and were previously treated with a first or second-generation EGFR-TKI, or both. The central confirmation of EGFR T790M mutation in plasma circulating cell-free DNA or tumor tissue or both was required for enrollment in the EP2 phase.

Results: As of January 31, 2017, 127 patients had received 4–16 mg TAS-121 dose once daily (QD) or 8–12 mg daily in two divided doses (BID). The most common adverse drug reactions (ADRs) were platelet count decreased (66.9%), pyrexia (44.9%), and rash (37.8%). Other notable ADRs were interstitial lung disease (ILD) (7.9%) and pulmonary embolism (7.1%). All ILD incidences were manageable, and no treatment-related deaths occurred during the study. Dose-limiting toxicities (DLTs) were observed in five and three patients treated QD (drug-induced liver injury, platelet count decreased, urticaria, and ILD) and BID (ILD, platelet count decreased, and left ventricular failure), respectively. The MTD was determined as 10 mg QD and 8 mg BID. PK analyses showed that the area under the curve (AUC) of TAS-121 even at the lowest dose was significantly higher than that of the effective dose in preclinical tumor xenografts model. Furthermore, in the EP2 group, confirmed objective responses according to the independent central review were observed in 25.0 and 44.4% of patients (4/16 and 8/18) administered 8 mg QD and BID, respectively.

Conclusions: TAS-121 was well tolerated up to the MTD and demonstrated antitumor activity in this preliminary phase I study in patients with EGFR T790M mutation-positive NSCLC.

1351P The addition of apatinib to gefitinib or icotinib for advanced non-small cell lung cancer with acquired resistance to first-generation epidermal growth factor receptor tyrosine kinase inhibitor: An assessment of effectiveness and safety

C. Ying, Y. Wu

Thoracic Department, 2nd Affiliated Hospital of Zhejiang University University School of Medicine, Hangzhou, China

Background: Epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs) have been proved as an effective treatment of advanced non-small-cell lung cancer patients with EGFR mutations. However, resistance to EGFR-TKIs develops in most patients and leads to eventual loss of efficacy. Nowadays combined therapy inhibiting EGFR and vascular endothelial growth factor (VEGF) pathways has become a promising therapy in the treatment of advanced non-small-cell lung cancer. This study aims to assess the efficacy and safety of the addition of low dose of apatinib, a kind of TKIs targeting vascular endothelial growth factor receptor 2 (VEGFR-2), to first-generation EGFR-TKIs for advanced non-small cell lung cancer with acquired resistance to first-generation EGFR-TKIs.

Methods: We retrospectively assessed the efficacy and safety of patients with non-small cell lung cancer who had gradual progression after experiencing effective targeted therapy with first-generation EGFR-TKIs. Patients received apatinib 250 mg once daily and gefitinib 250mg once daily or icotinib 125mg thrice daily until disease progression again or unacceptable toxicity occurs.

Results: The study group comprised 33 Chinese patients, among whom 15 (45.5%) were males and 20 (60.6%) were non-smokers. The median duration of combined therapy was 5.5 month. 17 patients (51.5%) had a partial response (PR) and 13 patients had stable disease (SD). The overall response rate was 51.5%. 21 cases of adverse events were observed in this study. The incidence of severe adverse events was only 3.0%. The incidence of adverse events in patients decreased in hypertension, rash, proteinuria, hand-foot syndrome, gastrointestinal reaction, mucosal inflammation, bleeding, alanine aminotransferase increased and hypoovarianism.

Conclusions: The addition of low dose of apatinib to gefitinib or icotinib can significantly inhibit tumor growth and improve the progression-free survival of patients received first-generation EGFR-TKIs. Potential advantage in safety were identified which warrant further validation.

1352P Leptomeningeal carcinomatosis from EGFR-mutated non-small cell lung cancer

T. Iuchi[1], M. Shingyoji[2], T. Setoguchi[1], Y. Yoshida[2], H. Ashinuma[2], Y. Hasegawa[1], T. Sakaida[1]

[1]Neurological Surgery, Chiba Cancer Center Hospital, Chiba, Japan, [2]Respirology, Chiba Cancer Center, Chiba, JapanBackground: Diagnosis of leptomeningeal carcinomatosis (LMC) is made based upon the findings on MRI (LMCi), and/or cytologically confirmed cancer cells in the cerebrospinal fluid (CSF) (LMCc). However, in EGFR-mutated (EGFRm) cases, brain metastasis (BM) has a tendency to arise close to CSF space, and discrepancies between imaging and cytological results makes it difficult to construct treatment strategy. Although the effect of tyrosine kinase inhibitors (TKIs) on LMC has been expected, a little is known regarding the effect and limitation of TKIsMethods: Overall survival (OS) after diagnosis of BM were compared between patients with and without LMC at diagnosis, and prognostic value of LMCi and LMCc were retrospectively compared to clarify the reliable diagnostic method of LMC. Survival differences of patients with LMC after treatment with and without TKIs were also compared to evaluate the efficacy of TKIs on LMC

Results: From Aug. 2006 to now, 215 BMs from *EGFR*m non-small cell cancers were treated. At diagnosis of BMs, LMCi was diagnosed in 140 cases. Among these cases, CSF cytology was evaluated in 113 cases, but malignant cells were detected only in 47 cases (41.6%). TKIs were administrated in 159 patients. Without TKIs, OS after BM with LMCi (9.5m) was shorter than that without LMCi (26.9m) (HR: 1.75, P=0.096), but this difference was reduced in patients treated with TKIs (18.1m vs. 20.9m, P=0.123).

On the other hand, without TKIs, OS after BM with LMCc (4.9m) was extremely worse than that without LMCc (16.6m) (HR:7.76, *P*=0.001), but this significant difference was lost by TKIs (HR:1.16, *P*=0.671). During the follow up, 152 deaths were observed, and 45 were owing to the progression of intracranial lesions (CNS death). Not LMCi but LMCc was a significant risk factor of CNS death (OR: 0.59 and 6.26, *P*=0.148 and 0.002, respectively). TKI had decreased the incidence of CNS death from 100% to 64% in LMCc cases, but LMCc was still a significant risk factor of CNS death even with TKIs (OR: 5.13, *P*=0.017), and disappearance of cancer cells in CSF by TKIs was observed only in 41.2% of patients.

Conclusions: MRI was insufficient to diagnose LMC. TKIs were strongly recommended for patients with LMCc, but its' effect was still inadequate in half of the patients.

1353P CNS response to osimertinib in Asian-Pacific patients (pts) with T790M-positive advanced NSCLC: data from an open-label Phase II trial (AURA17)

C. Zhou[1], Y. Cheng[2], Y. Lu[3], M. Shi[4], J-Y. Han[5], M. Wang[6], S-W. Kim[7], J. Wang[8], Y. Chen[8], Y-L. Wu[9]

[1]Medical Oncology, Shanghai Pulmonary Hospital, Tongji University, Shanghai, China, [2]Department of Thoracic Oncology, Jilin Provincial Cancer Hospital, Changchun, China, [3]Department of Thoracic Oncology, West China Hospital, Sichuan University, Chengdu, China, [4]Medical Oncology, Jiangsu Cancer Hospital, Nanjing, China, [5]Center for Lung Cancer, National Cancer Center, Goyang, Republic of Korea, [6]Department of Oncology, Peking Union Medical College Hospital, Beijing, China, [7]Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [8]China Development Unit, AstraZeneca, Shanghai, China, [9]Guangdong General Hospital & Guangdong Academy of Medical Sciences, Guangdong Lung Cancer Institute, Guangzhou, China

Background: Osimertinib has shown CNS efficacy in a pooled analysis of two Phase II trials (AURA extension: NCT01802632, AURA2: NCT02094261) in pts with T790M-positive advanced NSCLC. We report osimertinib efficacy in CNS metastases (mets) from a Phase II, open-label, single-arm trial (AURA17: NCT02442349) in Asia-Pacific pts with T790M-positive advanced NSCLC who had progressed on prior EGFR-TKI therapy, with or without additional anti-cancer regimens.

Methods: Pts with stable, asymptomatic, CNS mets were eligible for enrolment and received osimertinib 80 mg once daily. This prespecified subgroup analysis was conducted in pts with CNS mets present on baseline brain scan as assessed by blinded independent central neuroradiology review (BICR). Endpoints included CNS objective response rate (ORR), duration of response (DoR) and progression-free survival (PFS) by RECIST 1.1. The CNS full analysis set (cFAS) comprised pts with ≥1 measurable and/or non-measurable CNS lesion present on baseline brain scan by BICR; the CNS evaluable for response set (cEFR) comprised pts with ≥1 measurable CNS lesion.

Results: At the data cut-off of 4 November 2016, 59/171 pts (35%) were included in the cFAS. In the cFAS and cEFR (n = 23), 3 and 0 pts had brain radiotherapy ≤6 months prior to study entry, respectively. CNS ORR was 42% (25/59; 95% CI 30, 56) for the cFAS and 70% (16/23; 95% CI 47, 87) for the cEFR. Median CNS DoR was not reached (95% CI 9.2, not calculable [NC]) for the cFAS and 11.1 months (95% CI 8.2, NC) for the cEFR. CNS DCR was 85% (95% CI 73, 93) for the cFAS and 91% (95% CI 72, 99) for the cEFR. Median CNS PFS was not reached in both cFAS (95% CI 12.4, NC) and cEFR groups (95% CI 9.4, NC), with a median follow-up for CNS PFS of 7.1 and 8.2 months, respectively. At 12 months, 70% (95% CI 53, 82) of pts in the cFAS and 61% (95% CI 31, 81) of pts in the cEFR were estimated to remain on study, alive and CNS progression-free.

Conclusions: These data are consistent with previous reports of CNS response to osimertinib in pts with T790M-positive advanced NSCLC in global studies, and demonstrate clinically meaningful efficacy in Asian-Pacific pts with CNS mets.

Background: Osimertinib is an oral, potent, CNS active, irreversible EGFR-TKI selective for EGFR-TKI sensitising and T790M resistance mutations. AURA17 (NCT02442349) is a Phase II, open-label, single arm study investigating the safety and efficacy of osimertinib in Asia-Pacific pts with T790M-positive advanced NSCLC, who had progressed on prior EGFR-TKI therapy, with or without additional anti-cancer regimens.

Methods: Eligible pts had measureable disease, WHO performance status 0/1 and acceptable organ function; asymptomatic CNS metastases were allowed. T790M-positive status was confirmed by central testing of biopsy samples using the cobas® EGFR Mutation Test. Osimertinib 80 mg was administered orally once daily until disease progression. The primary endpoint was objective response rate (ORR) according to RECIST 1.1 by blinded independent central review. Secondary endpoints included duration of response (DoR), PFS, disease control rate (DCR), overall survival, safety and tolerability.

Results: As of 4 Nov 2016 data cut-off (DCO), 171 pts had received osimertinib (53 [31%] second-line; 118 [69%] ≥third-line), median treatment exposure was 12.3 (range 0.2–14.6) mo. Median age 60 (range 26–82) years; female 68%; Chinese ethnicity 87%; never smokers 78%; EGFR Exon 19 deletion 64%; EGFR L858R mutation 35%; CNS metastases at study entry 37%. Confirmed ORR in pts evaluable for response (n = 166) was 63% (95% confidence interval [CI] 55, 70) and DCR was 89% (95% CI 83, 93). Median DoR was 9.9 mo (95% CI 8.3, not calculable). Median PFS in the full analysis set (n = 171) was 9.7 mo (95% CI 7.0, 11.1); 94 pts (55%) had progression. At DCO, 39 pts had died (23%). All causality adverse events (AEs) of CTCAE Grade ≥3 were reported by 43 (25%) pts. Most common AEs were diarrhoea 35% (Grade ≥3 1%) and rash grouped term 27% (Grade ≥3 0%). There was one reported case of interstitial lung disease and pneumonitis, respectively.

Conclusions: The high ORR of 63% was supported by the durable response assessed by DoR (median 9.9 mo) and PFS (median 9.7 mo). The efficacy data were consistent with global clinical trials of osimertinib. No new safety signals were observed.

KG, Vienna, Austria, [12]Department of Internal Medicine, Taichung Veterans General Hospital, Taichung, Taiwan

Background: Approximately 1–4% of lung adenocarcinomas harbour a *HER2* mutation. No targeted treatment is approved yet for this NSCLC pt subgroup. Initial results for the treatment of *HER2*m+ NSCLC with the irreversible ErbB family blocker, afatinib, have been encouraging, with some pts showing notable responses or promising disease control. Pts with *HER2*m+ NSCLC were included in a global NPU program for afatinib, which was initiated in 2010, and their treatment outcomes are presented here.

Methods: A global NPU program included patients with advanced NSCLC who had progressed after clinical benefit on prior erlotinib/gefitinib, had an activating *EGFR* or *HER2* mutation, had exhausted all other treatment options; and were ineligible for afatinib trials. Pts received daily oral afatinib (starting dose: 40 or 50 mg). Collection of safety data was mandatory. Time to treatment failure (TTF) was defined as time from start of afatinib treatment to the date of treatment discontinuation.

Results: As of May 2017, data were available for 28 pts with *HER2*m+ NSCLC (male/female: 12/16 [43/57%]; median age: 55 yrs; starting dose 40/50 mg: 17/11 [61/39%]). Patients were heavily pretreated; 16 (57%) received afatinib as ≥ 4th-line treatment and 7 (25%) had received prior targeted anti-HER2 treatment. Median TTF for afatinib, calculated for all 28 patients was 2.9 months and, notably, 9 (32%) pts had TTF >1 yr. Response assessments were reported for 16 pts; disease control rate was 69% (11/16 pts) and objective response rate was 19% (3/16 pts). No new or unexpected safety findings were observed.

Conclusions: This analysis of a heavily pre-treated pt population with *HER2*m+ NSCLC from the afatinib NPU program showed a promising 32% of pts with TTF >1 yr, durable disease control and a manageable safety profile. With the limitation of retrospective analysis, and also considering that different *HER2* mutations can display different treatment sensitivities, these findings suggest that the evaluation of afatinib in earlier treatment lines in *HER2*m+ NSCLC pts may be warranted.

Background: Tyrosine kinase inhibitors (TKI) are the standard of treatment in first line for advanced EGFR-mutated NSCLC. Few data exist about their tolerance and efficacy in octogenarians particularly in Caucasian population. The purpose of this multicentric real world study was to assess tolerance and efficacy of EGFR-TKI in this population.

Methods: We retrospectively identified patients aged 80 years or older with EGFR-mutated NSCLC treated by EGFR-TKI between 01/01/2011 and 31/03/2015 whatever the line of treatment. Patients were described according to their clinical characteristics, management and outcomes (progression-free survival (PFS) and overall survival (OS).

Results: The 20 french participating centers included 114 patients: 77% were women, the median age was 83,9 ±3,9 years; 98,2% were caucasians and 84,6% were home life (45% had home help), 71% took more than 5 drugs/d. Respectively 64%,17.5% and 8,5% of patients had a performance status of 0-1/2/3 at diagnosis. 76% of them were non-smokers, 95,6% had adenocarcinomas; 80%/13%/7% had respectively stage IV/III/II–I at treatment initiation. EGFR mutations were identified on exon 19 (46,5%), exon 21 (40,3%), exon 20 (5,2%). A geriatric assessment was assessed in 35% of cases. Median time between first symptoms and diagnosis was 55 days. 97.3% of the patients were treated by TKI as first or second line. Median PFS was 11,9 months, 95% CI: 8,6-14,7. Response and disease control rates were 67% and 79% respectively. In 40% of the cases EGFR-TKI treatment was maintain beyond progression. After progression, 44,7% of the patients received another line of treatment (chemotherapy: 44,7%). Median OS was 20,9 months, 95% CI: 14,3-27,1. Main toxicities were cutaneous: 66% (grade 3/4:10%), diarrhea 56% (grade 3/4:15%, grade 5: 2%), others 25,6% (grade 3/4: 41%).

Conclusions: In this real-world analysis, compared to younger, octogenarians patients with EGFR-mutated NSCLC treated by EGFR TKI present comparable outcomes and toxicity profile. Geriatric assessment is still under-used in this population.

1357P Prospective evaluation of the relationship between erlotinib concentration and efficacy in patients with non-small cell lung cancer harboring EGFR-activating mutations

H. Kenmotsu[1], C.K. Imamura[2], T. Kawamura[1], T. Oyakawa[1], S. Omori[1], K. Nakashima[1], K. Wakuda[1], A. Ono[1], T. Taira[1], T. Naito[1], H. Murakami[1], N. Yamamoto[3], T. Takahashi[1], Y. Tanigawara[2]

[1]Division of Thoracic Oncology, Shizuoka Cancer Center, Shizuoka, Japan, [2]Department of Clinical Pharmacokinetics and Pharmacodynamics, Keio University School of Medicine, Tokyo, Japan, [3]Internal Medhicine, Wakayama Medical University, Wakayama, Japan

Background: Erlotinib is an epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI), which has shown improved clinical outcomes in the treatment of patients with non-small cell lung cancer (NSCLC) harboring EGFR exon 19 deletions and exon 21 L858R mutations. Previous reports regarding the relationship between erlotinib pharmacokinetics and pharmacodynamics evaluated toxicities but not efficacy. Therefore, to evaluate the relationship between erlotinib exposure and efficacy, we conducted this prospective study.

Methods: Erlotinib was orally administered at a dose of 150 mg/body once daily to patients with NSCLC, who were not previously treated with EGFR-TKIs. A series of blood samples were taken at predetermined times on day 1 to calculate the area under the concentration-time curve (AUC). Erlotinib trough concentrartions (C_{trough}) at each visit and the level of alpha1-acid glycoprotein (AAG), which is a binding protein of erlotinib in serum, were measured.

Results: Of 70 patients enrolled, 61 had activating EGFR mutations (30 patients with exon 19 deletions and 31 with exon 21 L858R mutations). The AUC was 37.0 μg·h/mL in median (range; 9.7-63.3). Objective response rate and median progression-free survival (PFS) were 72% and 12.4 months in the patients with EGFR-activating mutations. Response was not associated with AUC. There was also no significant difference in PFS between patients with AUC > 37.0 μg·h/mL and ≤ 37.0 μg·h/mL. C_{trough} was significantly correlated with the grade of skin rash ($p < 0.01$), but not with objective response. In multivariate analyses, pretreatment AAG level, which was 0.97 g/L in median (0.53-3.83), was found to be a significant factor in PFS for patients with EGFR-activating mutations (median PFS; AAG > 0.97 g/L, 7.9 months; AAG ≤ 0.97 g/L, 16.8 months, $p < 0.01$).

Conclusions: The lack of a relationship between erlotinib exposure and efficacy shows that the approved dose of erlotinib is sufficient to reach the therapeutic range in EGFR-activating mutant NSCLC, even with dose reduction due to toxicities. AAG level can be a prognostic factor for patients with NSCLC harboring EGFR-activating mutations treated with erlotinib.

1358P First-in-human phase I study of PF-06747775, a third-generation mutant selective EGFR tyrosine kinase inhibitor (TKI) in metastatic EGFR mutant NSCLC after progression on a first-line EGFR TKI

H. Husain[1], R.G. Martins[2], S.B. Goldberg[3], P. Senico[4], W. Ma[5], J. Masters[6], N. Pathan[6], D-W. Kim[7], M.A. Socinski[8], Z. Goldberg[5], B.C. Cho[9]

[1]Medicine, UC San Diego Moores Cancer Center, San Diego, CA, USA, [2]Oncology/Hematology, Seattle Cancer Care Alliance, Seattle, WA, USA, [3]Medical Oncology, Yale Cancer Center, New Haven, CT, USA, [4]Oncology, Pfizer, Collegeville, USA, [5]Oncology, Pfizer, New York, NY, USA, [6]Oncology, Pfizer, La Jolla, USA, [7]Oncology, Seoul National University Hospital, Seoul, Republic of Korea, [8]Oncology, University of Pittsburgh, Pittsburgh, USA, [9]Oncology, Yonsei Cancer Center, Yonsei, Republic of Korea

Background: PF-06747775 ("PF-7775") is a selective, 3rd generation Epidermal Growth Factor Receptor (EGFR) TKI effective against EGFR sensitizing and T790M mutations in preclinical models. Enrollment was completed in a phase I study of PF-7775 in EGFR mutant (EGFRm+) NSCLC patients (pts) who progressed after a prior EGFR TKI.

Methods: EGFRm+ NSCLC pts with resistance to first-line EGFR-TKIs enrolled in a multicenter trial in 6 dose escalation (25 mg–600 mg) and 2 dose expansion cohorts

(200 mg and 300 mg). Biopsy for EGFR T790M at clinical progression was not required for study entry. PF-7775 was given orally once daily. All pts were assessed for response, adverse events (AEs), and pharmacokinetics. Plasma T790M testing was conducted retrospectively.

Results: As of a 3 Feb17 data cutoff, 44 pts were enrolled (59% female, median age 63.5, Asian/Caucasian 73/25%).The most common all grade AEs in all enrolled patients ($\geq$ 25%) were: diarrhea (57%), rash (59%), paronychia (52%), dermatitis acneiform (34%), stomatitis (32%), pruritus (27%), dry skin (25%), and rhinorrhea (25%). Grade 3 events were consistent with known EGFR TKI toxicities (diarrhea and skin toxicity) and easily managed. No grade 4 treatment related AEs were noted in dose escalation or expansion. Nineteen pts (43%) had dose reductions due to treatment related AEs at the higher dose cohorts and the RP2D of 200 mg was selected based on the AE profile and tolerability of drug at this dose for longer term administration. The prevalence rate of T790M, L858R, and del 19 in plasma samples, along with data correlating ORR (CR and PR rate) and CBR (CR + PR + SD) is ongoing.

Conclusions: PF-7775 is well tolerated at 200 mg dose in EGFRm+ NSCLC pts with acquired resistance to first-line EGFR-TKIs. Data relating mutational status to response rate in plasma is ongoing.

1359P Impact on OS and PFS of 2nd and 3rd generation TKI in EGFR mt+ and ALK+ pts: Results of the NOWEL network

J. Roeper[1], A. Lueers[1], M. Netchaeva[1], M. Falk[2], C. Hallas[2], M. Tiemann[2], N. Neemann[3], L. Heukamp[3], C. Wesseler[4], G.H. Wiest[4], D. Ukena[5], S. Sackmann[5], F. Griesinger[1]

[1]Department of Internal Medicine-Oncology, Pius Hospital Oldenburg, University of Oldenburg, Oldenburg, Germany, [2]Department of Hematopathology, Hematopathology Hamburg, Hamburg, Germany, [3]Department of Pathology, NEO New Oncology, Cologne, Germany, [4]Department of Oncology, Asklepios Klinik Harburg, Hamburg, Germany, [5]Department of Oncology, Klinikum Bremen Ost, Bremen, Germany

Background: Clinical research data shows that early mutation testing for pts with NSCLC stage IV could lead to an effective choice of therapy for pts with proven mutations. Targeted therapies achieve a higher ORR, OS, PFS and a better quality of life than chemotherapy in mt+ pts. With the advent of 2nd and 3rd generation TKÍs effective in 1st generation TKI resistant tumors, we wanted to study the impact of these drugs on the outcome of pts in a real life setting.

Methods: 1381 pts from three cancer centers diagnosed with non-squamous cell NSCLC stage IV (UICC 7) were examined. Methods for the mutation testing was performed according to the German Oncopedia guidelines using either Sanger Sequencing or COBAS® or Next Generation Sequencing (hybrid capture NGS, New Oncology Cologne).

Results: 879/1381 (64%) consecutive pts with non-squamous cell NSCLC from three cancer centers were studied for the presence of tumor mutations, especially for EGFR and ALK mt+. The EGFR mt+ rate was 16.6% (141/847), and the ALK-translocation rate 3.8% (24/635). Median OS in EGFR mt+ pts was 28 (n = 79) vs. 28 (n = 38) vs. 16 (n = 14) months respectively (center 1 vs. center 2 vs. center 3). Median OS in ALK mt+ pts was 24 months (n = 17) in center 1 and 11 months (n = 5) in center 2 ($p < 0.033$). The ORR in the CR/PR group was 54.2% for pts treated with chemotherapy and 77% for pts treated with TKI on 1st line therapy. The chance to reach a CR/PR on 1st line therapy is 2.83 higher for pts on TKI than for pts on chemotherapy ($p < 0.02$). The use of 3rd generation TKI Osimertinib (n = 19) lead to a significantly higher OS (n = 19, median OS 67 months) than the use of only 1st and 2nd generation TKI (n = 111, median OS 23 months, $p < 0.000$). Pts treated with 3rd gen TKI had significantly longer PFS (11 months, n = 7) than patients treated without 3rd generation TKI (5 months, n = 45) ($p < 0.037$). Similarly, use of 2nd and 3rd generation ALKi impacted significantly on median OS: Crizotinib alone (n = 8), 17 months, Crizotinib followed by Ceritinib and/or Brigatinib (n = 10) median OS not reached and 3 months for other therapies (n = 6) ($p < 0.001$).

Conclusions: Small differences in OS were observed, depending on the treatment centers, but the use of multiple EGFR and ALK-I impacted highly significantly on the outcome of pts with EGFR and ALK mt+ in a real life setting.

1360P Phase II trial of AZD9291 in second line treatment after acquired resistance with T790M mutation detected from circulating tumor DNA (LiquidLung-O-Cohort 2)

Y-C. Kim, C.K. Park, I-J. Oh, J-H. Lim, Y-D. Choi, H. Cho, S-J. Ahn, S-Y. Song, J.S. Yun, K-J. Na

Lung Cancer Clinic, Chonnam National University Medical School & Chonnam National University Hwasun Hospital, Hwasun, Republic of Korea

Background: Administering the best treatment after acquiring resistance to epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs) requires the knowledge of the resistance status. In this trial, the treatment efficacy of osimertinib (AZD9291) was assessed in patients with non-small-cell lung carcinoma (NSCLC) harboring T790M resistance mutation, which was detected in the circulating tumor DNA (CtDNA) without re-biopsy of the tumor tissue.

Methods: To prove 60% response rate of osimertinib compared to 30% as null hypothesis, and considering 10% drop out rate, 19 subjects was recruited. To extract CtDNA, 15 mL of peripheral blood was withdrawn and centrifuged immediately before storage. Cobas® v2 RUO (Roche diagnostics) and PANA mutyper® (Pangene, Korea) were used to detect the EGFR mutations from CtDNA. Osimertinib was prescribed as an 80mg tablet once in a day irrespective of the food intake.

Results: Eighty patients with acquired resistance to prior EGFR TKIs were screened for T790M resistance mutation, and the CtDNA of 21 subjects (26.3%) showed T790M mutation. T790M mutation was detected by both PANA mutyper® and Cobas® in 13 cases, T790M was detected only by PANA mutyper® in 4 cases, and only by Cobas® in 4 cases. Nineteen subjects (age: 64.4 $\pm$ 11.6 years old, 14 women, 5 men) were enrolled in this prospective single arm trial from September 2016 to April 2017. Prior EGFR TKIs were afatinib (n = 3), erlotinib (n = 4), gefitinib (n = 10), erlotinib and afatinib (n = 1), and gefitinib and afatinib (n = 1). Twelve subjects had exon 19 deletion of EGFR gene, 4 had L858R point mutation, one showed exon 19 deletion and L858R, 1 had G719X, and 1 case showed no activating mutation.

Conclusions: By April 2017, the response to osimertinib was evaluated in 13 subjects; 4 subjects dropped out from this trial before response evaluation, and the responses in 2 subjects are still pending for evaluation. Among the 13 subjects whose responses were evaluated (efficacy analysis set), partial remission was observed in 8 cases (61.5%). In the final efficacy analysis, toxicity and survival analyses will be performed.

1362P Safety and clinical activity of DS-6051b, a ROS1/NTRK inhibitor, in Japanese patients with NSCLC harboring ROS1 fusion gene

M. Takeda[1], T. Seto[2], Y. Fujiwara[3], N. Yamamoto[3], K. Nosaki[2], R. Toyozawa[2], C. Abe[4], R. Shiga[4], K. Nakamaru[5], K. Nakagawa[1]

[1]Department of Medical Oncology, Kindai University Faculty of Medicine, Osaka, Japan, [2]Department of Thoracic Oncology, National Kyushu Cancer Center, Fukuoka, Japan, [3]Department of Experimental Therapeutics, National Cancer Center Hospital, Tokyo, Japan, [4]Oncology Clinical Development Department, Daiichi Sankyo Co., LTD, Tokyo, Japan, [5]Biomarker Department, Daiichi Sankyo Co., LTD, Tokyo, Japan

Background: ROS1 or NTRK genetic abnormality is a key oncogenic driver, especially in non-small cell lung cancer (NSCLC). DS-6051b is an orally available and potent selective small molecule inhibitor of ROS1 and NTRK. Preclinical pharmacology studies exhibited antitumor activity of DS-6051b against several types of tumor with ROS1 or NTRK fusion gene.

Methods: This is an ongoing phase 1 study in Japanese patients with advanced solid tumors harboring either a ROS1 or NTRK fusion gene. Patients receive continuous once daily (QD) dosing of DS-6051b. Pharmacokinetics (PK) samples are collected from Day1 to Day22. If patients consented, liquid biopsy samples for circulating tumor DNA (ctDNA) analysis are collected at screening and study discontinuation. The primary objective is to evaluate the safety profile and secondary objectives are to determine the maximum tolerated dose (MTD), the recommended phase 2 dose (RP2D) and to assess the PK profile. Exploratory objectives are to assess the tumor responses to DS-6051b by means of Investigator evaluation per RECIST v.1.1 and to explore biomarkers. ClinicalTrials.gov identifier: NCT02675491.

Results: As of Apr 10, 2017, 15 patients are enrolled. The median age is 51 (34-69) years, 46.7% are female, all 15 patients are ROS1 fusion positive NSCLC, and 4 had prior crizotinib (CRZ) treatment. Patients received DS-6051b at doses of 400mg QD (n = 6), 800mg QD (n = 3) and 600mg QD (n = 6). Common adverse events are AST increased, ALT increased, diarrhea and nausea. There are no DLTs in the 400mg and 600mg QD cohorts, and 2 out of 3 patients in the 800mg QD cohort experienced DLTs with grade 3 ALT increased. In 12 patients who had measurable target lesions, 7 demonstrated partial response (PR) and 5 demonstrated stable disease. In 9 CRZ-naïve patients, the overall response rate is 66.7% (6 PRs) and the disease control rate is 100%. Early clinical response was also shown in a subject with brain metastasis. The plasma drug concentration increased in a dose-dependent manner. Currently, ctDNA analyses obtained from pre/post DS-6051b treatment are ongoing.

Conclusions: DS-6051b is well tolerated in Japanese patients with NSCLC and effective especially in CRZ-naïve. The MTD/RP2D is identified as 600mg QD.

1363P Efficacy and safety of abemaciclib combined with either LY3023414 or pembrolizumab in stage IV NSCLC

P. Garrido Lopez[1], J. Goldman[2], K. Kelly[3], E.S. Kim[4], T.J. Beck[5], M. Alonso Garcia[6], Z. Yang[7], K-J. Ingram[8], L. Amstutz[8], W.J. John[8], M. Provencio Pulla[9]

[1]Medical Oncology, Hospital Universitario Ramón y Cajal, Madrid, Spain, [2]Hematology & Oncology, University of California-Los Angeles, Santa Monica, USA, [3]Medical Oncology, UC Davis Comprehensive Cancer Center, Sacramento, CA, USA, [4]Medical Oncology, Levine Cancer Institute, Charlotte, USA, [5]Medical Oncology, Highlands Oncology Group, Fayetteville, USA, [6]Medical Oncology, Hospital Universitario Virgen del Rocío, Seville, Spain, [7]Biometrics, Eli Lilly and Company, Indianapolis, USA, [8]Medical Affairs, Eli Lilly and Company, Indianapolis, USA, [9]Medical Oncology, Servicio de Oncología Médica Hospital Universitario Puerta de Hierro, Madrid, Spain

Background: Abemaciclib (abema), a cyclin D kinase 4 & 6 inhibitor, has single-agent activity and an acceptable safety profile when dosed continuously in patients with previously treated metastatic NSCLC (NCT01394016). In tumor models, CDK inhibition induces an escape pathway involving PI3kinase (PI3K) and abema induces synergistic immune activation with checkpoint inhibitors. We report on activity and safety of abema plus LY3023414 (LY), a PI3K/mTOR dual inhibitor, and abema plus pembrolizumab (pembro), an anti-PD-1 antibody, in an ongoing Phase 1b open-label, 3 + 3 multicenter trial of previously treated advanced NSCLC (NCT02079636).

Methods: For escalation, Abema [100, 150 mg, or 200 mg (cohort D only)] was given orally on a continuous schedule every 12 hours (q12h) with LY at 100, 150, or 200 mg q12h (cohort D) or with pembro at 200 mg I.V. infusion q3 weeks (cohort E). Confirmatory cohorts were given 150 mg abema with 150 mg LY or 200 mg pembro. Pts were treated until progression or other discontinuation criteria were met. Responses were evaluated with RECIST v1.1. Safety assessments followed the NCI-CTCAE v4.0.

Results: As of 01-Mar-2017, cohort D (n = 29) had 62.1% males, 37.9% ≥65 years of age, median # prior systemic therapies=3; 86.2% stage IV; 72.4% adenocarcinoma; 62.1% ECOG PS = 1. 9 pts (31%) had stable disease (SD), 3 pts had progressive disease (PD), and the status for the remaining 17 pts was unknown or under evaluation. There were 3 deaths unrelated to study drug (2 disease related and 1 stroke). 24/29 pts had a treatment emergent, related AE (TRAE), 10/24 had a Grade 3/4 TRAE. Any grade TRAEs (>30% pts) were nausea (51.7%), diarrhea (51.7%), vomiting (41.4%), and decreased appetite (31%). Cohort E had 19 pts entered (42.1% male, 42.1% ≥65 years of age, median # prior systemic therapies=2; 52.6% stage IV; 89.5% adenocarcinoma; 57.9% ECOG PS = 1). 8 pts (42.1%) had SD, 1 had PD, and the status for the remaining 10 pts was unknown or under evaluation. There were 3 disease related deaths. 15/19 pts had a TRAE, 5/15 had a G3/4 TRAE. Any grade TRAEs (>30% pts) were fatigue (n = 47.4%) and diarrhea (36.8%).

Conclusions: To date, stable disease as best response and acceptable safety have been observed using combinations of abema and either LY or pembro in advanced NSCLC.

Background: Exposed phosphatidylserine (PS) in the tumor microenvironment is highly immunosuppressive. Bavituximab targets PS and repolarizes M2 macrophages to M1 resulting in production of pro-inflammatory cytokines such as IFN-γ and IL-12, maturation of dendritic cells, and tumor specific cytotoxic T lymphocyte immunity. In a prior blinded Phase II trial in 2nd-line nonsquamous NSCLC, bavituximab + docetaxel was well-tolerated and demonstrated 60% improvement (11.7 vs 7.3 months) in median overall survival (mOS) (HR, 0.66; P = 0.11) compared to control.

Methods: 597 patients with Stage IIIb/IV nonsquamous NSCLC that progressed on platinum-doublet chemotherapy were randomized 1:1 to receive up to six 21-day cycles of docetaxel in combination with weekly 3 mg/kg bavituximab (B+D) or placebo (D) until progression or toxicity. The primary endpoint was OS. Secondary endpoints included progression-free survival (PFS), objective response rate (ORR) and safety.

Results: With 12 months follow-up from the last patient randomized and ~85% of the targeted OS events reached, mOS was 10.5 months (95% confidence interval [CI], 8.4-11.9) among 297 patients in B+D and 10.9 months (95% CI, 9.2-12.1) among 300 patients in D (HR, 1.06; P = 0.533). PFS was 4.2 months (95% CI, 3.9-4.6) in B+D and 4.1 months (95% CI, 3.2-4.8) in D (HR, 1.02; P = 0.876). The ORR was 15% in B+D vs. 11% in D (odds ratio, 0.7; P = 0.15). The safety profile was similar between groups. Grade 3 or higher adverse events occurred in 68% of patients in B+D and 60% in D. In an exploratory analysis of OS for patients who received subsequent immune checkpoint inhibitors (ICI), the mOS was not reached (95% CI, 15.2-NA) in B+D (n = 46) and 12.6 months (95% CI, 10.4-17.8) in D (n = 47) (HR, 0.46; P = 0.006).

Conclusions: The combination of B+D was well-tolerated though no OS difference was observed compared to D alone in the ITT population of previously treated nonsquamous NSCLC. An exploratory analysis of patients who received subsequent ICI found significantly longer OS in patients who received prior B+D than those who received D and support further clinical investigation of B+ICI in NSCLC.

Background: The effect on QOL of adding platinum to first line treatment of elderly patients (pts) with advanced NSCLC is unknown. In this setting, MILES-3 and MILES-4 trials prospectively showed that adding cisplatin (Cis) to single-agent gemcitabine (Gem) or pemetrexed (Pem) does not significantly prolong overall survival.

Methods: Advanced NSCLC pts, >70 years old, ECOG performance status 0-1, were eligible. In MILES-3, pts with any tumor histology were randomly assigned to CisGem or Gem. In MILES-4, pts with non-squamous histology were randomly assigned to CisGem, Gem, CisPem or Pem. The trials were joined together because of slow accrual. Overall survival was the primary endpoint. QOL (EORTC QLQ C30 and LC13) was a secondary endpoint. Five questionnaires were planned in MILES-3 and 7 in MILES-4; QOL was measured in both the trials at 3 time points (baseline, end cycle 1, end cycle 2) used for joint analysis. Intention-to-treat strategy was applied; analyses were adjusted for baseline QOL, stage, PS, gender, age, size of centre, trial, histotype and companion drug.

Results: Overall, 458/531 pts (86.3%) answered baseline questionnaire. Rate of missing questionnaires at end cycle 1 and 2 was slightly higher among pts receiving Cis. Mean change in fatigue after cycle 1 ($P = 0.01$) and in sore mouth after cycle 2 ($P = 0.02$) were worse with Cis. Using a 10% change from baseline as clinically relevant threshold to categorize response, alopecia was significantly worse with Cis ($P = 0.05$). In time to deterioration analysis with progression/death as competitive risk, sore mouth and alopecia deteriorated more with Cis (HR 1.72 95%CI 1.02-2.89 $P = 0.04$ and HR 1.84 95%CI 1.09-3.10, $P = 0.02$, respectively). Response analysis in MILES-3 confirmed findings of the joint analysis while time to deterioration analysis in MILES-4 did not find any significant difference. Cis did not significantly improve any QOL item, in any type of analysis.

Conclusions: The addition of Cisplatin did not improve QOL of elderly patients with advanced NSCLC. Partially supported by AIFA (grant FARM8KAJZK) and Eli Lilly.

Zangmeister Center, Columbus, USA, [4]Oncology/Hematology, Thoraxklinik Heidelberg, Heidelberg, Germany, [5]Oncology/Hematology, Asklepios-Fachklinikum, Gauting, Germany, [6]Oncology/Hematology, Hazard ARH Regional Medical Center Cancer Center, Hazard, USA, [7]Oncology, Florida Cancer Specialists, Leesburg, FL, USA, [8]Oncology, Stephenson Cancer Center OU, Oklahoma City, USA, [9]Oncology/Hematology, Harold Leever Regional Cancer Center, Waterbury, USA, [10]Oncology/Hematology, St. Antonius Hospital Klinik für Hämatologie/Onkologie, Eschweiler, Germany, [11]Oncology, Celgene Corporation, Summit, USA, [12]Medical Oncology, Sarah Cannon Research Institute/Tennessee Oncology, PLLC, Nashville, TN, USA

Background: Patients with advanced NSCLC experience a high symptom burden; therefore, identifying a treatment that maintains or improves QoL is important. QoL outcomes in patients with SCC NSCLC receiving nab-P/C in the induction part of the ABOUND.sqm study are reported.

Methods: Patients with stage IIIB/IV SCC NSCLC and no prior chemotherapy for metastatic disease received 4 cycles of induction therapy with nab-P 100 mg/m^2 days 1, 8, and 15 + C area under the curve 6 on day 1 (21-day cycles). Patients not progressing after induction received (2:1) maintenance nab-P 100 mg/m^2 days 1 and 8 (21-day cycles) + best supportive care (BSC) or BSC alone until progression/unacceptable toxicity. The primary endpoint is progression-free survival (randomization to maintenance). Patient-reported QoL (exploratory endpoint) was assessed on day 1 of each cycle using the Lung Cancer Symptom Scale (LCSS) and EuroQoL 5 Dimensions-5 Levels (EQ-5D-5L).

Results: In 343 patients receiving treatment in the induction phase were evaluated. Median age was 68 years; 90% were white, 68% male, and 67% had ECOG PS 1. Of 332 patients treated for $\geq$ 2 cycles, 298 (90%) completed baseline + $\geq$ 1 postbaseline QoL assessment. During induction, the mean change from baseline in LCSS symptom burden index and total score ranged from 5.5%-7.8% and 5.5%-7.7%, respectively. Clinically meaningful improvements ($\geq$ 10 mm [visual analog scale]) from baseline were observed in composite LCSS pulmonary symptom items of cough, shortness of breath, and hemoptysis in 44% of patients. Each individual dimension of the EQ-5D-5L was maintained/improved from baseline in the majority of patients (82%-91%), and $\geq$ 32% reported complete resolution at least once during treatment.

Conclusions: QoL was improved/maintained in patients with advanced SCC NSCLC treated with nab-P/C induction therapy. These results continue to support nab-P/C as a treatment option in patients with SCC NSCLC, as was initially demonstrated in a subset analysis of the phase III registration trial. NCT02027428.

Sammons Cancer Center, Dallas, TX, USA, [11]Oncology/Hematology, Celgene Corporation, Summit, NJ, USA, [12]Oncology/Hematology, UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC, USA

Background: Treatment of elderly pts with advanced NSCLC remains challenging, and the impact of therapies on QoL can be an important factor in clinical decisions. nab-P/C demonstrated efficacy in a subset of pts $\geq$ 70 yrs with NSCLC in a phase 3 trial.

ABOUND.70+ was designed to determine whether a 1-wk break can further improve tolerability of nab-P/C in these patients. QoL outcomes are reported here.

Methods: Pts ≥ 70 yrs with locally advanced/metastatic NSCLC were randomized 1:1 to first-line nab-P 100 mg/m^2 on d 1, 8, and 15 + C AUC 6 on d 1 of a 21-day cycle (Arm A) or the same regimen with a 1-week break between cycles (Arm B). Primary endpoint: percentage of pts with grade ≥ 2 peripheral neuropathy or grade ≥ 3 myelosuppression. Key secondary endpoints: PFS, ORR, OS for which statistical analyses do not control for type I error (P values unadjusted). QoL (exploratory endpoint) was assessed using Lung Cancer Symptom Scale (LCSS) and EuroQoL-5 Dimensions-5 Levels (EQ-5D-5L) at d 1 of each cycle.

Results: At interim evaluation, primary endpoint was similar across arms, resulting in early closure of enrollment. In Arms A and B, 78% and 79% completed a baseline and ≥ 1 postbaseline QoL assessment. LCSS item of cough improved with each cycle; at the end of cycle 6, mean change from baseline in Arms A and B was 25.4 and 13.8 mm (visual analog scale). For cough, median time to deterioration (TTD) was 4.4 and 4.7 mos (P = 0.7003). For the composite LCSS pulmonary symptom items of cough, shortness of breath, and hemoptysis, the median TTD was 4.4 and 6.0 mos (P = 0.3347). Mean maximum improvement (at any point during treatment) in EQ-5D-5L visual analog scale was 10.1 and 12.8 points. Table lists key safety, efficacy and QoL data.

Table: 1367P

	Arm A n = 71	Arm B n = 72
Safety		
Primary endpoint, n (%)	52/68 (76)	54/70 (77)
P value	0.9258	
Grade ≥ 2 peripheral neuropathy	25/68 (37)	25/70 (36)
Grade ≥ 3 myelosuppression	48/68 (71)	45/70 (64)
Neutropenia	39/68 (57)	39/70 (56)
Anemia	14/68 (21)	17/70 (24)
Thrombocytopenia	17/68 (25)	12/70 (17)
Efficacy		
Confirmed ORR, %	24	40
P value	0.0376	
PFS, median, months	3.6	7.0
P value	0.0019	
HR (95% CI)	0.48 (0.30 - 0.76)	
OS, median, months	15.2	16.2
P value	0.1966	
HR (95% CI)	0.72 (0.44 - 1.19)	
QoL		
Mean maximum improvement from baseline, mm		
LCSS Total score	5.8	11.7
LCSS Pulmonary symptom	9.2	14.9

Conclusions: These results support nab-P/C as a treatment option in elderly pts with NSCLC. Safety (primary endpoint) and OS were similar across the two arms, while there was a signal of improvement in ORR, PFS, and QoL with a 1-wk break. NCT02151149.

Background: Although nab-PTX plus carboplatin is one of the standard treatment for chemo-naive advanced non-small cell lung cancer (NSCLC), the efficacy, safety and optimal schedule of nab-PTX monotherapy as 2nd or 3rd line for NSCLC pts without any driver mutations remains unknown.

Methods: This was a single arm phase I/II study. Eligible pts are advanced NSCLC without EGFR mutation and ALK rearrangement that progressed after platinum-doublet chemotherapy. The pts were received 100 mg/m^2 of nab-PTX on day 1, 8, 15 and 22 (level 0) or on day 1, 8, and 15 (level -1) every 4-week in phase I. Dose limiting toxicities (DLT) were assessed and the recommended schedule was determined in the phase I. The primary endpoint was objective response rate (ORR), assuming that estimated ORR was 15% and threshold ORR was 5% with α error of 0.05 and β error of 0.2 in the phase II part. Total 55 pts were planned to be enrolled.

Results: The recommended schedule of nab-PTX was determined as the level -1, because the DLTs were found in 4 of 5 pts in level 0. Total 55 pts were enrolled in the phase II and the characteristics were as followings; median age, 66 years (range, 41–90 years), male/female = 40/15, PS 0/1/2 = 12/39/4, 2nd/3rd line = 34/21, adeno/squamous/large/others = 34/17/2/2. The median number of treatment cycles was three (range, 1–10). The ORR was 7.3% (95% [CI], 2.0 – 17.6%) (PR (n = 4), SD (n = 26), PD (n = 24), and NE (n = 1)). At the median follow-up time of 5.3 months (range, 1.9 – 26.0 months) for all pts, the median PFS was 3.4 months (95%[CI], 1.9 – 4.0 months). Treatment related grade 3 or 4 toxicities were neutropenia (36%), pulmonary infection (3.6%), and pneumonitis (5.4%). One patient (2%) was died due to treatment-related ARDS.

Conclusions: In phase I part, we confirmed that schedule level -1 was tolerable and the schedule had been recommended. In phase II part, this study failed to meet predefined primary endpoint although PFS was comparable and toxicity was acceptable for pts with advanced NSCLC without any driver mutations as 2nd or 3rd line treatment.

1369P nab-paclitaxel/carboplatin (nab-P/C) induction therapy in squamous (SCC) non-small cell lung cancer (NSCLC): Interim safety results from ABOUND.sqm

C. Gridelli[1], M. McCleod[2], D. Morgensztern[3], D.B. Daniel[4], R. Page[5], T. Wehler[6], O. Juan[7], B. Levy[8], A. Ardizzoni[9], T. Berry[10], T. Chen[10], N. Trunova[10], R. Jotte[11]

[1]Oncology, S.G. Moscati Hospital, Avellino, Italy, [2]Oncology, Florida Cancer Specialists, Cape Coral, USA, [3]Oncology, Washington University Schoo of Medicine, St Louis, MO, USA, [4]Oncology, Tennessee Oncology, Chattanooga, TN, USA, [5]Oncology, The Center for Cancer and Blood Disorders, Fort Worth, TX, USA, [6]Oncology, University Hospital Mainz, Mainz, Germany, [7]Medical Oncology, Hospital Universitari i Politècnic La Fe, Valencia, Spain, [8]Oncology, Beth Israel Medical Center, New York, NY, USA, [9]Oncology, Universitari iPolitécnicLa Fe, Valencia, Italy, [10]Oncology, Celgene Corporation, Summit, USA, [11]Oncology/Hematology, Rocky Mountain Cancer Center, Denver, CO, USA

Background: The ABOUND.sqm trial is currently investigating treatment outcomes of 4 cycles of nab-P/C followed by nab-P maintenance therapy in patients (pts) with SCC NSCLC. Given that tolerability is an important consideration for treatment decisions, this analysis evaluated the safety of nab-P/C during induction.

Methods: Chemotherapy-naive pts with stage IIIB/IV SCC NSCLC received 4 cycles of induction therapy with nab-P 100 mg/m^2 d1, 8, and 15 + C area under the curve 6 d 1 (21-d cycles). Pts not progressing after induction received (2:1) maintenance nab-P 100 mg/m^2 d1 and 8 (21-d cycles) + best supportive care (BSC) or BSC alone until progression/unacceptable toxicity. The primary endpoint is progression-free survival (randomization to maintenance). Secondary endpoints include safety analyzed as treatment-emergent adverse events (TEAEs), overall survival, overall response rate, and disease control rate.

Results: A total of 334 pts were included in this analysis. Median age was 68 yrs; 90% were white, 68% male, and 68% had ECOG PS 1. During induction, 145/334 pts (43%) discontinued treatment. Of these, 51/145 (35%) discontinued due to progressive disease, 39/145 (27%) due to adverse events, 16/145 (11%) each due to death and pt withdrawal, 13/145 (9%) due to symptomatic deterioration, 9/145 (6%) due to other, and 1/145 (< 1%) due to protocol violation. The median percentage of per-protocol dose of *nab*-P was 74%; median *nab*-P dose intensity and cumulative dose were 74.08 mg/m^2/week and 900 mg/m^2, respectively. *nab*-P dose modifications included ≥ 1 reduction, missed dose, or dose delay in 55%, 60%, and 60% of pts, respectively. Grade ≥ 3 TEAEs were mainly hematologic and included neutropenia (148/334 [44%]), anemia (92/334 [28%]), and thrombocytopenia (48/334 [14%]). Grade ≥ 3 peripheral neuropathy was observed in 14/334 pts (4%).

Conclusions: This interim analysis demonstrates the safety and tolerability of nab-P/C induction therapy in pts with SCC histology. The findings are consistent with those reported in subset analysis of the phase III study and provide additional support for the use of this regimen in this pt population. NCT02027428.

1370P Comparison of platinum agents cisplatin and carboplatin in routine treatment of advanced NSCLC: Results from prospective German TLK cohort study

N. Marschner[1], U. von Verschuer[2], R. Schnell[3], M-O. Zahn[4], J. Eggert[5], A. Binninger[6], L. Spring[6], M. Jänicke[6]

[1]Oncology and Hematology, Praxis für interdisziplinäre Onkologie & Hämatologie, Freiburg, Germany, [2]Oncology and Hematology, MVZ für Hämatologie und Onkologie Essen gGmbH, Essen, Germany, [3]Oncology and Hematology, Praxis Internistischer Onkologie und Hämatologie (PIOH), Frechen, Germany, [4]Oncology and hematology, Überörtliche Berufsausübungsgemeinschaft MVZ Onkologische Kooperation Harz, Goslar, Germany, [5]Oncology and hematology, Gemeinschaftspraxis für Innere Medizin, Moers, Germany, [6]Clinical Epidemiology and Health Economics, IOMEDICO AG, Freiburg, Germany

Background: Lung cancer is the leading cause of cancer-related mortality and the majority of patients (pts) are diagnosed with advanced or metastatic disease. Despite advances in targeted therapies for selected patient subgroups, the majority of pts (∼80%) are treated with platinum-based doublet chemotherapies (CT). The choice between the platinum agents cisplatin (CIS) or carboplatin (CAR) has been subject of a long debate. Here we present data on the treatment of advanced non-small cell lung cancer (aNSCLC) in routine practice. Such real-world data are of central importance to improve the standard of care.

Methods: 107 sites in Germany recruited 1,239 pts with aNSCLC at start of 1st-line therapy into the prospective clinical cohort study TLK (Tumour Registry Lung Cancer) between Feb 2010 and Dec 2013. Details on systemic treatment and outcome were collected until Jan 2016. A longitudinal health-related quality of life (HRQOL) analysis using the questionnaires EORTC QLQ-C30 and –LC13 was conducted every 2 months (mts) for a period of up to 10 months.

Results: 46% of the pts received CAR- and 35% CIS-based doublet CT in 1st-line treatment. Pts receiving CIS- were younger than pts receiving CAR-combinations (median age at start of treatment 62 vs. 69 years), more often had a good performance status (33% vs. 17% ECOG =0) and less comorbidities (34% vs. 56% Charlson Comorbidity Index ≥1). The main combination partner was pemetrexed for CIS (33%) and paclitaxel for CAR (24%). Median overall survival was 11.9 mts (95% CI 10.2-13.8) for CIS- and 12.2 mts (95% CI 10.0-13.3) for CAR-combinations. The median time to deterioration of the global health status was 6.8 mts for CIS- and 6.4 mts for CAR-combinations. Considerable deteriorations in the symptoms nausea, fatigue, dyspnoea and pain were reported after 4-6 mts, with no difference between CIS and CAR.

Conclusions: Numerous meta analyses have been dedicated to finding the optimal platinum agent for the 1st-line treatment of aNSCLC. With our data from the prospective, population-based cohort study TLK, we complement the results from clinical trials. We show that there is no considerable difference in outcome or HRQOL between CIS- and CAR-combinations in the treatment of aNSCLC.

Paolo, Milan, Italy, [4]EORTC, European Organisation for Research and Treatment of Cancer, Brussels, Belgium, [5]Oncology, Institute Jules Bordet, Brussels, Belgium, [6]Oncology, Institut Curie, Paris, France, [7]Oncology, U.Z.A. University Hospital Antwerp, Edegem, Belgium, [8]Pulmonology, Maastricht University Medical Center, Maastricht, Netherlands, [9]Radiotherapy, The Christie NHS Foundation Trust, Manchester, UK, [10]Pneumologie, Hôpital Louis Pradel-Hospices Civils de Lyon, Bron, France, [11]Pneumologie, Hopital St. Marguerite Assistance Publique Hopitaux de Marseille, Marseille, France, [12]Pathology department, CHU Grenoble - Hopital Michallon, La Tronche, France, [13]Oncology, Royal Marsden Hospital NHS Foundation Trust, London, UK, [14]Thoracic Oncology, Krankenhaus Grosshansdorf, Grosshansdorf, Germany, [15]General Medical Oncology, University Hospitals Leuven, Leuven, Belgium, [16]Oncology, University of Turin, Orbassano, Italy

Background: The EORTC Lung Cancer Group (LCG) and the Elderly Task Force (ETF) developed a pan-european survey that aims to provide an overview of the management and treatment strategies for elderly patients (pts) diagnosed with advanced NSCLC, as well as to identify potential needs and scientific pending questions that could be addressed in new trials.

Methods: An electronic 13-topic survey explaining the study purpose was developed and sent to all EORTC LCG and ETF members. The 25-items included multiple-choice and open-ended questions requesting the following information on general demographics (6 items), pts population (3 items) and diagnostic, treatment preferences and outcomes (4 items). Elderly pts were defined as those older than 70 years.

Results: Sixty-two individual sites, from 19 countries, completed the online questionnaire. In 42 centers (67.7%) there is no dedicated team for the management and treatment of elderly pts; on the other hand, only in 2 centers (3.2%) pts with suspected NSCLC are not discussed by a multidisciplinary board. Notably, oncogeriatric assessment is routinely performed in 17 (27.4%) centers; G8, CGA or both scales are the preferred evaluation tools (35.3%, 23.6% and 11.8% respectively). In fit pts, the preferred first-line chemotherapy regimens are Carboplatin (CBDCA)-Pemetrexed (PEM) 19 (31.7%), CBDCA-Paclitaxel (PAC) 15 (24.2%), Cisplatin (CDDP)-PEM 14 (22.6%), CBDCA-Gemcitabine (GEM) 10 (16%), other 3 (4.8%). In the second line setting the preferred treatments are Nivolumab 30 (45.5%), PEM 11 (16.7%), Docetaxel 9 (13.6%), PAC 8 (12.1%), GEM 4 (6.1%), Erlotinib 4 (6.1%); while PEM 15 (24.2%), Nivolumab 13 (20.1%), PAC 9 (14.5%), Docetaxel 6 (9.7%), GEM 6 (9.7%), other 11 (17.7%) represent a second level option.

Conclusions: The survey provides an overview of the clinical practice in the management of elderly patients with advanced NSCLC, summarizing relevant and updated background for the possible development of future collaborative trials. In this survey, different treatment regimens are used by different centers, and geriatric assessment is used heterogeneously, reflecting the lack of a "standardized" approach and the need for further research in this area.

1372P Diversity of brain metastasis (BM) management in non-small cell lung cancer (NSCLC) in Europe (EU): Results of the Young Investigators European Organisation for Research and Treatment of Cancer Lung Cancer Group (YI EORTC LCG) survey

L. Hendriks[1], C. Faivre-Finn[2], B. Hasan[3], E. de Maio[4], A. Berghoff[5], A-M. Dingemans[1], S. Novello[6], T. Berghmans[7], B. Besse[8], A. Levy[9]

[1]Pulmonary Diseases, Maastricht University Medical Center (MUMC), Maastricht, Netherlands, [2]Radiotherapy, The Christie NHS Foundation Trust, Manchester, UK, [3]Statistics, EORTC - European Organisation for Research and Treatment of Cancer, Brussels, Belgium, [4]Medical oncology, EORTC - European Organisation for Research and Treatment of Cancer, Brussels, Belgium, [5]Department of Medicine I, Medical University of Vienna, Vienna, Austria, [6]Department of Oncology, University of Turin, Turin, Italy, [7]Oncology, Institute Jules Bordet, Brussels, Belgium, [8]Cancer Medicine, Institut de Cancérologie Gustave Roussy, Villejuif, France, [9]Radiation oncology, Institut de Cancérologie Gustave Roussy, Villejuif, France

Background: BM are frequent in NSCLC patients (pts) but management can vary.

Methods: An online survey containing questions on NSCLC BM screening and treatment (tx) was widely distributed between 16/02/17 and 16/04/17 to all EORTC LCG members, and through several EU societies involved in lung cancer tx.

Results: 478 physicians (phys) (radiation oncologist: 51.9%, pulmonologist: 27%, medical oncologist: 15.3%, others: 5.8%; 73.2% with >5 years experience in NSCLC) responded. Italy [17.8%], Netherlands [14.2%], UK [13.0%], and France [11.5%] contributed most. 84.9% screened neurologically asymptomatic pts for BM at diagnosis (49% used MRI). Phys screened stage III (66.9%) and IV (40.8%) most often. 35.4%

used a prognostic (p) classification to guide initial tx decisions. In 48.1% lowest p-score threshold to actively treat pts did not differ between driver mutation (MUT+) and non-driver (MUT-) pts. 38.1% used less WBRT in poor prognosis pts based on QUARTZ trial (NCT3826061) results. 88.9% had access to stereotactic radiosurgery (SRS). After single BM surgery, 50.8% systematically prescribe adjuvant SRS or WBRT, and 44.2% only in case of incomplete resection. Preferred tx in neurologically asymptomatic tx-naive pts diagnosed with >5 BM was systemic tx (78.4%). 46.9% stated that WBRT could increase systemic tx efficacy. 44.8/49.8% stated that all tyrosine kinase inhibitors (TKI) and immune checkpoint blockers (IO) were discontinued (timing varied) during SRS/WBRT, respectively. Drugs that were most often continued during SRS-WBRT were erlotinib (44.5-40.1%), gefitinib (38.0-34.0%), afatinib (29.9-25.1%), crizotinib (32.2-26.7%) and IO (PD-(L)-1: 28.4-22.8%), CTLA4: 10-9.8%), because of no perceived safety issues (44.6%) or risk of systemic flare (37.9%). MUT+ pts with > 3 BM were more likely to receive SRS than MUT-. 76% of phys preferred local tx & TKI continuation over a switch to next-line tx in pts with only intracranial progression.

Conclusions: BM management differs: screening is not uniform, p-classifications are not often used, and MUT+ NSCLC pts generally receive more aggressive local tx.

1373P Clinical features of never smoker patients with lung squamous cell carcinoma: A retrospective multicenter study

S. Frega[1], M. Macerelli[2], A. Del Conte[3], L. Bonanno[1], M. Bartoletti[2], V. Polo[4], G. Zago[1], A. Follador[2], I. Attili[1], A. Pavan[1], L. Urso[4], S.M.M. Basso[5], G. Fasola[2], P.F. Conte[1], G. Pasello[1]

[1]Medical and Experimental Oncology Department, Medical Oncology, Istituto Oncologico Veneto IRCCS, Padua, Italy, [2]Medical Area Department, AOU Santa Maria della Misericordia, Udine, Italy, [3]Medical Oncology Department, Centro di Riferimento Oncologico Aviano, Aviano, Italy, [4]Surgical, Oncological and Gastroenterological Sciences Department, University of Padova, Padua, Italy, [5]General Surgery and Perioperative Medicine Department, Azienda Ospedaliera Sta Maria degli Angeli, Pordenone, Italy

Background: Squamous cell carcinoma of the lung (LSCC) is the second most common histological subtype of non-small cell lung cancer (NSCLC) having smoking habit as the major risk factor. LSCC in non-smokers is an exceptional finding possibly related to professional exposure and subsequent carcinogenesis even though clinical and biological landscape is largely unexplored.

Methods: This is a retrospective multicenter study investigating clinical features of never-smoker LSCC patients (pts) referred to three Italian Centers between 2010 and 2016. Relapse (RFS) or progression free (PFS) and overall (OS) survival curves were calculated by Kaplan-Meier method. Cox regression proportional hazards model was used to estimate the impact of covariates on OS.

Results: Among 791 LSCC pts, 37(4,6%) occurred in never-smokers; our case series included 19 males and 18 females with a median age of 63 years. ECOG PS was 0-1 in 30(81%) pts. Median Charlson Comorbidity Index (CCI) was 6. Two (5%) pts referred second-hand smoking history and 13(35%) occupational exposure. Additional tumor history was reported by 15(41%) patients: head and neck (N=4), basocellular skin (N=5), breast (N=2), lung (N=2), prostate (N=1) cancer and leukemia (N=1). Molecular characterization was performed in 12(32%)pts: EGFR and KRAS mutations were found in 2 and 1 pts respectively. Median time from symptoms appearance and diagnosis was 7 weeks. Twelve (32%) pts showed a limited stage, while the other 25(68%) showed advanced/metastatic disease at the diagnosis. Nineteen (52%) pts received a first-line palliative chemotherapy (pct), mostly platinum-based doublets plus gemcitabine (N=11) or taxane (N=3), achieving a response rate and disease control rate of 37% and 58% respectively. Median RFS in resected patients (N=9) was 21 months. Median PFS and OS after first-line pct were 5 months and 8.5 months respectively. No covariate significantly impacted on OS.

Conclusions: Never-smoker LSCC pts represent a rare subgroup characterized by more females, younger age and a not negligible CCI and second-tumor history compared with the known features of smoker LSCC. Treatment outcome of advanced disease is still dismal as for most LSCC pts.

1374P Characteristics and prognostic impact of advanced non-small-cell lung cancer patients who were ineligible for clinical trials

H. Kawachi[1], D. Fujimoto[1], T. Morimoto[2], M. Ito[1], S. Teraoka[1], Y. Sato[1], K. Nagata[1], A. Nakagawa[1], K. Otsuka[1], Y. Imai[3], K. Tomii[1]

[1]Respiratory Medicine, Kobe City Medical Center General Hospital, Kobe, Japan, [2]Clinical Epidemiology, Hyogo College of Medicine, Nishinomiya, Japan, [3]Clinical Pathology, Kobe City Medical Center General Hospital, Kobe, Japan

Background: The majority of non-small cell lung cancer (NSCLC) patients are ineligible for clinical trials. Nevertheless, very few studies report the profiles and treatment outcomes of such ineligible patients. Therefore, we investigated the characteristics, outcomes, and survival of advanced NSCLC patients who were ineligible for clinical trials.

Methods: We analyzed a retrospective cohort of 786 consecutive patients diagnosed with advanced NSCLC between January 2006 and December 2014. We reviewed the criteria in phase 3 clinical trials, and classified patients using the common first-line eligibility criteria for lung cancer.

Results: Of the 786 patients, 469 (60%) were ineligible for clinical trials. The main reasons for ineligibility were brain metastasis (41%), a poor performance status (PS) (25%), and respiratory disease (24%). In all patients, ineligibility was identified as an independent predictor of overall survival (OS) (adjusted hazard ratio [HR] 0.78, 95% confidence interval [CI], 0.65–0.93, P = 0.008), even in patients with a good PS who received chemotherapy (HR 0.80, 95% CI, 0.65–0.99, P = 0.037). In subgroup analyses of ineligible patients, the survival varied depending on the reasons for their ineligibility. In particular, prior cancer history was not associated with a poor outcome, though this was a common reason for ineligibility (14.5%).

Conclusions: Most patients were ineligible for clinical trials and had shorter survival. The survival of ineligible patients varied depending on the reasons for their ineligibility. We should consider these results when applying clinical trial outcomes to real-world patients. More studies for ineligible patients are needed to improve real-world treatment.

1375P Treatment paradigm shift in NSCLC: Patient data analysis from 2005 to 2016

L. Mitrofan[1], M. Sahni[2], D. Dhingra[2], H. Mistry[3], C. Anger[3]

[1]Global Oncology, RWI, QuintilesIMS, Paris, France, [2]Global Delivery Center, QuintilesIMS, Gurgaon, India, [3]Global Oncoloy, RWI, QuintilesIMS, London, UK

Background: In the last decade, chemotherapies were the SoC in advanced NSCLC treatment with limited benefit to long-term survival. Discovery of EGFR/ALK and PD1/PDL1 followed by of approval targeted therapies (TTs) and immunotherapies (IOs), respectively, marked two major treatments shifts. In addition, science advancement on drug resistance issued from TTs and new drug gable mutations continue to transform the treatment landscape and options for patients with advanced NSCLC.

Methods: This study used IMS Oncology Analyzer^{TM} a syndicated, retrospective, longitudinal cancer treatment database collecting anonymized patient-level oncology data in EU5, projected to national level. Data collected between 2005 and 2016 was used to identify changes in the treatment paradigm in advanced NSCLC. Three time period groups have been compared: period 1: from 2005 to 2008; period 2: from 2009 to 2014 and period 3: 2015 and 2016.

Results: Of the currently 1,602,026 (projected number) treated populations, there is an increase in protein kinase Inhibitors (TKIs) usage, mainly represented by anti EGFR and anti ALK, from 8% to 23% to 30% in period 1, 2 and period 3 respectively. Monoclonal antibodies (MAb) follows a similar trend increasing from 1% to 15% in the last years, respectively, while the platinum agents slightly decreases. IOs captures 52% in the last couple of years from the overall MAb group. Till recently, bevacizumab (BEVA) was leading this therapeutic class. Increased granularity in patient stratification, will allow identification of more spectacular treatment changes or identification of those who would have passed unnoticed. In 1L, mutant segment, paradigm switch occurred end 2008 when TKIs reached directly 84%. In 2L, IOs jump is much less noticeable, entering directly in the last analyzed period with 25% from MAb group. In WT segment, we can notice 2 switches: one in 1L, end 2014 when BEVA reached directly 13% and a second one in 2L, end 2016, when MAbs captured 28%, with IOs representing 90% from this therapeutic group.

Conclusions: Currently, the advent of IOs has completely overshadowed existing TTs. Emerging genetic markers (ROS-1, KRAS, RET), specific EGFR/ALK mutations due to resistance along with combinations of IOs and TTs will continue to add new treatment options.

1376TiP Phase III study of atezolizumab (atezo) vs chemotherapy (chemo) in patients (pts) with treatment-naive advanced, recurrent or metastatic NSCLC unsuitable for platinum (plat)-based chemo

S.M. Lee[1], C. Schulz[2], A. Cardona[3], P. Bartakova[4], S. Peters[5]

[1]Department of Oncology, UCLH/UCL Cancer Institute/Cancer Research UK Lung Cancer Centre of Excellence, London, UK, [2]Department of Internal Medicine II, University Hospital Regensburg, Regensburg, Germany, [3]PDMA Biometrics, F. Hoffmann-La Roche Ltd., Basel, Switzerland, [4]Global Product Development Medical Affairs (Oncology), F. Hoffmann-La Roche Ltd., Basel, Switzerland, [5]Oncology, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland

Background: Most pts with newly diagnosed NSCLC have locally advanced or metastatic disease, with 30%-40% having poor performance status (ECOG PS $\geq$ 2) due to

disease burden and comorbidities. These pts have poor prognosis vs pts with PS < 2 and higher toxicity with standard doublet chemo. Despite limited efficacy, single-agent chemo (vinorelbine [vin], gemcitabine [gem], docetaxel [doc]) is often used for pts who do not tolerate plat-based regimens, highlighting the need for new treatments. Atezo (anti–PD-L1) prevents PD-L1 from binding its receptors PD-1 and B7.1, restoring cancer-specific T-cell immunity. In OAK, a Phase III 2L+ NSCLC study, atezo monotherapy was well tolerated and showed significant OS improvement vs doc regardless of PD-L1 status. Thus, atezo could provide superior clinical benefit vs single-agent chemo and demonstrate a more favorable safety profile in these pts. The open-label, randomized, multicenter Phase III PS2 study will evaluate the efficacy and safety of atezo vs single-agent chemo (vin, gem) in pts with untreated advanced, recurrent or metastatic NSCLC unsuitable for plat-based chemo.

Trial design: Eligible pts have Stage IIIB/IV NSCLC; are considered unsuitable for plat-based chemo due to poor PS (ECOG PS 2-3); have substantial comorbidities or contraindications for plat-based doublet chemo; have measurable disease; have no *EGFR*/*ALK* mutations and have received no prior systemic therapy. Pts will be randomized 2:1 to receive atezo 1200 mg IV q3w or single-agent chemo (vin [PO/IV], gem [IV]) per local practice until PD. Pts on atezo may continue therapy until loss of clinical benefit. Stratification factors include histology subtype (squamous vs nonsquamous), PD-L1 status (by VENTANA SP142 IHC assay) and presence of brain metastases. Primary endpoint is OS. Secondary endpoints include OS at 6, 12, 18 and 24 mo; ORR; PFS; DOR and safety. Tumor biopsies and blood samples (pre-treatment all mandatory; at PD only blood mandatory) will be assessed for biomarkers associated with atezo responses and immune escape. Planned enrollment is ≈ 441 pts.

Background: Avelumab is a human anti–PD-L1 IgG1 antibody that has shown promising antitumor activity and manageable safety in several tumor types, including NSCLC, and is approved in the US for the treatment of metastatic Merkel cell carcinoma. Reports with anti–PD-(L)1 therapies suggest a role in 1L treatment of NSCLC using tumor PD-L1 expression selection criteria; however, optimal treatment for patients (pts) with different PD-L1 expression status is currently undefined. Preliminary exposure-response analysis from pts with NSCLC treated with avelumab 10 mg/kg Q2W in the JAVELIN Solid Tumor trial (NCT01772004) suggest enhanced antitumor activity with higher avelumab exposure. This phase 3 trial (NCT02576574) compares avelumab vs platinum doublet chemotherapy as 1L treatment for PD-L1+ NSCLC. Here, we describe the updated design, including an additional treatment arm to investigate the role of higher avelumab exposure in this setting.

Trial design: JAVELIN Lung 100 is an ongoing global, multicenter, randomized, open-label trial. The study protocol has been amended to demonstrate superiority of avelumab in prolonging PFS or OS as co-primary endpoints vs platinum doublet therapy, per RECIST v1.1 by blinded independent review. A hierarchical testing strategy will be applied to compare avelumab arms vs chemotherapy in terms of PFS and OS by PD-L1+ enriched populations (expression cutoff levels: high, moderate, and any, determined by the Dako 73-10 assay) at an overall significance level of 2.5% (one-sided). Eligibility criteria include: stage IV NSCLC, ECOG PS ≤ 1, no prior systemic treatment for advanced disease, and no EGFR mutation/ALK translocation. Approximately 1,095 pts will be randomized to 1 of 3 arms: arm A (avelumab 10 mg/kg 1-hour IV Q2W), arm B (investigator's choice of specified platinum-based chemotherapy), or arm C (avelumab 10 mg/kg every week for 12 weeks, then 10 mg/kg Q2W), stratified by NSCLC histology and baseline tumor PD-L1 expression level. Secondary endpoints include objective response, duration of response, safety, pt-reported outcomes, PK, and biomarker assessments.

1378TiP A phase 3 study of first-line durvalumab vs platinum-based chemotherapy in patients with advanced NSCLC and high PD-L1 expression: PEARL

Y-L. Wu[1], S. Lu[2], S. Clarke[3], K. Lactionov[4], P. Li[5], M. Kirkby[5], Y. Xie[6], P. Stockman[7]

[1]Guangdong Lung Cancer Institute, Guangdong General Hospital, Guangzhou, China, [2]Shanghai Lung Cancer Center, Shanghai Chest Hospital, Shanghai, China, [3]Northern Sydney Cancer Centre, Royal North Shore Hospital, St Leonards, Australia, [4]Medical Oncology, N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation, [5]Medical Oncology, AstraZeneca, Beijing, China, [6]CDU (China Development Unit) B&I, AstraZeneca, Shanghai, China, [7]Global Medicines Development, AstraZeneca, Alderley Park, UK

Background: NSCLC is highly prevalent in Asia. Differences in outcomes to therapy, including longer survival and higher response rates, have been noted in Asian vs Caucasian NSCLC patients due to the higher prevalence of targetable oncogenes (i.e. *EGFR* sensitizing mutation or *ALK* translocation) in the Asian population. Until recently, standard of care (SoC) first-line treatment of *EGFR*/*ALK* wild-type advanced NSCLC comprised systemic platinum-based doublets. However, over recent years, immune checkpoint blockade has also become an important option, including in the first-line setting where pembrolizumab is approved in the US, EU and Japan in patients whose tumours express high levels of PD-L1. Durvalumab is a selective, high-affinity, anti-PD-L1 antibody that has shown antitumour activity and manageable tolerability across multiple tumour types, including NSCLC. The PEARL study aims to assess first-line durvalumab vs SoC in predominantly Asian populations with *EGFR*/*ALK* wild-type advanced NSCLC and high tumour PD-L1 expression.

Trial design: PEARL (NCT03003962) is a randomised, open-label, multicentre Phase 3 study. Eligible patients are immunotherapy- and chemotherapy-naïve with Stage IV, *EGFR*/*ALK* wild-type NSCLC, high PD-L1 expression (≥25% tumour cells with membrane staining using the Ventana PD-L1 [SP263] Assay) and ECOG performance status of 0 or 1. ~440 patients will be stratified by level of PD-L1 expression, histology and smoking status, and randomised 1:1 to receive either durvalumab (20 mg/kg i.v. every 4 weeks [q4w]) or SoC platinum-based chemotherapy until disease progression. The co-primary endpoints are PFS using blinded independent central review assessments according to RECIST v1.1 and OS. Secondary endpoints include ORR; duration of response; proportion of patients alive and progression free at 12 months; PFS after subsequent anticancer therapy; disease-related symptoms and HRQoL; immunogenicity; safety (CTCAE v4.03) and tolerability. Tumour assessments will be performed q6w for the first 48 weeks and then q8w as defined by RECIST v1.1 until confirmed

disease progression. Recruitment is ongoing in Australia, China, Republic of Korea, Russia, Thailand and Vietnam.

Background: EGFR-mutated NSCLC patients treated with EGFR TKI ultimately develop resistance to therapy. Mechanisms of resistance include aberrant signalling of MET, AXL and FGFR. Inhibition of these receptors should thus abrogate their downstream signalling and restore sensitivity to EGFR TKI. S 49076 is a potent ATP-competitive TKI, which targets MET, AXL and FGFR1/2/3 at clinically relevant doses. It showed strong activity in preclinical assays against EGFR mutated MET amplified cell lines to overcome the resistance to EGFR TKI. This study evaluates the relevance of targeting MET and/or AXL dysregulation to overcome acquired non EGFR-T790M-mediated resistance to EGFR-TKI.

Trial design: The phase I/II is an international, open-label study to evaluate the safety and activity of S 49076 in combination with gefitinib in stage IIIb-IV NSCLC patients who progress on EGFR TKI (1st and 2nd generation), harbouring MET and/or AXL dysregulation without EGFR-T790M mutation. The phase I is a single arm dose-finding part of S 49076 in combination with standard dose of gefitinib. The primary objective is to determine the recommended phase 2 dose (RP2D) based on the dose-limiting toxicities and safety assessments. The secondary objectives are to evaluate the pharmacokinetic profile of both drugs and the anti-tumour activity of the combination. S 49076 and gefitinib are administered orally once daily over a continuous 28-day cycle with doses ranging from 500mg to 600mg. Dose levels are allocated using a modified Bayesian Continual Reassessment Method. This study part is active and recruiting over 5 countries across Asia and Europe. The end of phase I is expected in Q3 2017. A non-randomised and non-comparative phase II part will then evaluate the anti-tumour activity of S 49076 at the RP2D in combination with gefitinib in cohorts of patients with MET and/or AXL dysregulation. The primary objective will be to determine the objective response rate according to RECIST and the secondary objectives will be to evaluate survival rate, progression free survival, clinical benefit rate and response duration as well as safety. An interim analysis will be performed in each cohort for futility.

1380TiP A randomized, open-label comparison of lorlatinib versus crizotinib as first-line treatment for advanced anaplastic lymphoma kinase (ALK)-positive non-small cell lung cancer

A.T. Shaw[1], T.M. Bauer[2], T. Takahashi[3], C.S. Baik[4], A. Polli[5], M. Carpentieri[6], J-F. Martini[7], B.J. Solomon[8]

[1]Cancer Center, Massachusetts General Hospital, Boston, MA, USA, [2]Medical Oncology, Sarah Cannon Research Institute, Nashville, TN, USA, [3]Division of Thoracic Oncology, Shizuoka Cancer Center, Shizuoka, Japan, [4]Medical Oncology, University of Washington/Seattle Cancer Care Alliance, Seattle, WA, USA, [5]Statistics, Pfizer Oncology, Milan, Italy, [6]Global Oncology Research and Development, Pfizer Oncology, Milan, Italy, [7]Translational Oncology, Pfizer Oncology, La Jolla, CA, USA, [8]Medical Oncology, Peter MacCallum Cancer Center, Melbourne, Australia

Background: Lorlatinib and crizotinib are oral tyrosine kinase inhibitors with activity against ALK and ROS1 fusion proteins. Crizotinib is well tolerated and has superior efficacy compared to chemotherapy for treatment of patients (pts) with advanced ALK^+ NSCLC. However, resistance to crizotinib can develop, and the central nervous system (CNS) is often a site of disease relapse. Lorlatinib is a CNS penetrant and has potent activity against de novo fusions and kinase domain resistance mutations. Lorlatinib has shown clinical activity in pts previously treated with crizotinib and other ALK inhibitors, including pts with progressive CNS metastases. This study aimed to determine if lorlatinib is superior to crizotinib in prolonging progression-free survival (PFS) in treatment-naïve pts with advanced ALK^+ NSCLC and to identify candidate biomarkers predictive of clinical efficacy or treatment resistance.

Trial design: This global, multicenter, open-label phase 3 study will enroll ~280 treatment-naïve pts. Eligible pts must be aged ≥18 years, have Eastern Cooperative Oncology Group performance status of 0–2 and ≥1 measurable extracranial target lesion not previously treated with radiotherapy. Pts with asymptomatic brain metastases are eligible. Pts will be randomized (1:1) to lorlatinib 100 mg once daily or crizotinib 250 mg twice daily and stratified by presence of brain metastases (yes/no) and ethnicity (Asian/non-Asian). Treatment will continue until disease progression, pt refusal, or unacceptable toxicity. Crossover between treatment arms will not be permitted. The primary endpoint is PFS based on blinded independent central review (BICR) using RECIST v1.1. Secondary endpoints include PFS based on investigator assessment (IA), overall survival, objective response (OR) by BICR and IA, intracranial (IC) OR, IC time to progression, duration of response, time to response by BICR, tumor tissue and peripheral blood circulating free DNA biomarker assessment, safety, and pt-reported health-related outcomes. The first pt was screened on April 14, 2017. This study is registered with ClinicalTrials.gov as NCT03052608.

Background: Poly (ADP-ribose) polymerase inhibitors (PARPi) have demonstrated impressive efficacy in BRCA-mutated gynaecological malignancies. Several lines of evidence now support that the DNA repair (DDR)-deficient populations that benefit from PARPi go far beyond BRCA-deficiency. Non-small cell lung cancer (NSCLC), the first cause of cancer death worldwide, displays frequent DDR defects, the most frequent being ERCC1. This defect leads to platinum and PARPi sensitivity. Beyond ERCC1, DDR defects leading to platinum sensitivity widely overlap with those underlying PARPi sensitivity. Maintenance PARPi could therefore benefit to patients (pts) with platinum-sensitive NSCLC. Olaparib (Lynparza®, Astra Zeneca), a potent and selective PARPi, was the first-in-class approved PARPi in BRCA-mutated ovarian cancer.

Trial design: PIPSeN is a randomized double-blind phase II investigator-initiated study evaluating maintenance Olaparib versus placebo in pts with platinum-sensitive advanced NSCLC. Chemonaïve ECOG PS 0-1 pts with stage III-IV NSCLC with no *EGFR* mutation or *ALK* translocation are eligible. Treatment consists of an "induction phase" of 4-6 cycles platinum-based therapy (any doublet), followed by a "randomized phase" where pts presenting with partial or complete response are randomized between Olaparib maintenance (tablets; 300mg bd) and placebo until progression or unacceptable toxicity. Primary objective is to assess the efficacy of maintenance Olaparib as measured by Progression-Free Survival from randomisation (RECIST v1.1). Secondary objectives include comparison of overall survival, disease control rate and safety. Randomization is stratified according to age, histology and country. With an anticipated HR = 0.65 (bilateral $\alpha = 0.2$; $\beta = 0.2$), approximately 500 enrolled pts will be required to randomize 144 pts and observe 97 events. Recruitment is ongoing since the 5th of Feb. 2016 across 21 centres in France and Spain; 95 (19) pts have been enrolled (randomised) to date. Translational studies looking notably for biomarkers of platinum and PARPi sensitivity (using WES, RNAseq, proteomics and ctDNA) are associated.

1382TiP Investigation of biomarkers in patients with adenocarcinoma of the lung receiving nintedanib according to approved label: Non-interventional LUME-BioNIS study

M. Reck[1], A.J. Staal-van den Brekel[2], A. Mellemgaard[3], N. Morsli[4], K. Pietzko[5], T. Kitzing[5], J. Braunger[5], K.M. Kerr[6]

[1]Department of Thoracic Oncology, Lung Clinic Grosshansdorf, Airway Research Center North (ARCN), Member of the German Center for Lung Research (DZL), Grosshansdorf, Germany, [2]Department of Pulmonary Diseases, Twente Hospitals, Almelo, Netherlands, [3]Department of Oncology, Herlev University Hospital, Herlev, Denmark, [4]-, Boehringer Ingelheim France S.A.S., Paris, France, [5]Boehringer Ingelheim GmbH & Co. KG, Biberach an der Riss, Biberach, Germany, [6]Department of Pathology, Aberdeen Royal Infirmary, Aberdeen, UK

Background: In the Phase 3 LUME-Lung 1 trial, the addition of nintedanib to docetaxel significantly improved overall survival (OS) vs docetaxel alone in patients with adenocarcinoma non-small cell lung cancer (NSCLC) treated with one prior line of chemotherapy. No tumour or serum biomarkers are validated to predict nintedanib efficacy in this setting.

Trial design: LUME-BioNIS (NCT02671422) is an ongoing, prospective, European, multicentre, non-interventional study (N≈300) investigating whether tumour-based genomic or proteomic alterations (± clinical covariates) can predict OS in adults with advanced adenocarcinoma NSCLC initiating nintedanib + docetaxel according to the nintedanib label. Tumour tissue obtained before first-line therapy will be used for biomarker analyses. To ensure sample quality and tumour content across all slides, the first, middle and last slides will be haematoxylin/eosin-stained and assessed by a certified pathologist for tumour content, extent of necrosis and immune cell infiltration. Tumour DNA and RNA will be co-isolated from unstained slides (AllPrep® DNA/RNA FFPE Kit) and quantitated with PicoGreen® and RiboGreen® reagents, respectively. Tumour DNA sequencing libraries will be prepared using a capture-based targeted gene panel covering whole exons of NSCLC-related genes (e.g. EGFR, KRAS, ALK, BRAF, PIK3CA, TP53) and nintedanib target genes (VEGFR1–3, FGFR1–3, PDFGR α/β) and analysed by Illumina® next-generation sequencing (NGS). Transcriptomics analyses will be conducted to: (1) complement DNA analyses by providing further information on gene fusions; and (2) enable tumour classification into transcriptional subtypes. Tumour RNA libraries will be prepared and analysed by NGS or, if RNA quantity/quality is insufficient for sequencing, digital gene expression analysis (nCounter® Gene Expression Panels) will be performed. Unstained slides will also be analysed by immunohistochemistry for immune- and proliferation-related protein expression (PD-L1, Ki-67). The primary endpoint is OS, which will be analysed according to biomarker status.

Background: Several clinical trials have confirmed the safety and efficacy of atezolizumab (atezo; anti–PD-L1) monotherapy in advanced NSCLC, including in PD-L1–selected 1L patients (pts). Independent of PD-L1 status, high TMB is associated with atezo efficacy. Alectinib is a potent, selective ALK/RET kinase inhibitor currently approved for NSCLC pts previously treated with crizotinib and is expected to have activity in 1L NSCLC pts with *ALK* or *RET* alterations. Currently, molecular diagnostics require tumor biopsies which can be difficult to obtain. Here we present trials in progress that aim to clinically evaluate and prospectively validate novel blood-based diagnostic assays that measure TMB in the blood (bTMB) and somatic mutations (e.g., *ALK*/*RET*), and to determine the efficacy and safety of 1L atezo or alectinib in NSCLC pts.

Trial design: B-F1RST (NCT02848651) is a single-arm study to evaluate the efficacy and safety of atezo and the association between bTMB and efficacy in biomarker-unselected pts. BFAST is a screening and interventional umbrella trial for pts selected based on bTMB or somatic mutations. Eligible pts must have previously untreated, stage IIIB-IVB NSCLC of any histology and measurable disease per RECIST v1.1. Pts will continue treatment until disease progression (all arms) or loss of clinical benefit (atezo only). In B-F1RST, mandatory blood samples will be prospectively collected and retrospectively tested for bTMB. In BFAST, pre-enrollment screening will identify pts who harbor oncogenic somatic mutations (*ALK*/*RET*) or are bTMB + (above a prespecified cutoff); pts will be assigned to the appropriate cohort based on screening results. Study treatments and key endpoints are shown in the table. Additional BFAST cohorts may be added in the future to address other somatic mutations.

Table: 1383TiP B-F1RST and BFAST Study Details

Study	Treatment	Planned Enrollment, n	Primary Endpoints	Key Secondary Endpoints
B-F1RST Phase II	Atezo 1200 mg IV q3w	150	ORR per RECIST v1.1 (INV-assessed) for the efficacy objective Relationship between PFS per RECIST v1.1 and various bTMB quantiles for the biomarker objective	PFS and DOR per RECIST v1.1 (INV-assessed) OS
BFAST Phase II/III				
Cohort A *ALK*+	Alectinib 600 mg PO bid	78	ORR per RECIST v1.1 (INV-assessed)	DOR, CBR and PFS per RECIST v1.1 (INV-assessed) ORR, DOR, CBR and PFS per RECIST v1.1 (IRF-assessed) OS
Cohort B *RET*+	Alectinib 900 mg & 1200 mg dose escalation	52-62	ORR per RECIST v1.1 (INV-assessed)	DOR, CBR and PFS per RECIST v1.1 (INV-assessed) ORR, DOR, CBR and PFS per RECIST v1.1 (IRF-assessed) OS
Cohort C bTMB+	Atezo 1200 mg IV q3w or platinum-based chemotherapy[a]	440 (R, 1:1)	PFS per RECIST v1.1 (INV-assessed)	OS PFS, ORR and DOR per RECIST v1.1 (IRF-assessed) ORR and DOR per RECIST v1.1 (INV-assessed) 6- and 12-month PFS rates

[a]Cisplatin or carboplatin + pemetrexed for non-squamous histology, and cisplatin or carboplatin + gemcitabine for squamous histology. Administered per standard of care. INV, investigator; IRF, independent review facility; R, randomized;
[b]TMB, blood Tumor Mutational Burden.

Background: Targeted therapy improves clinical outcomes in pts with advanced NSCLC harboring specific genetic alterations. Guidelines recommend tissue-based assessment of markers, but this approach may be limited by access to sufficient tissue and tumor heterogeneity, making it difficult to identify all pts who may benefit from these treatments. An alternative approach is to assess somatic mutations in circulating cell-free tumor DNA (cfDNA). The aim of this study is to demonstrate that cfDNA is non-inferior to tissue-based genotyping in detecting clinically actionable tumor biomarkers in pts with newly diagnosed metastatic non-squamous NSCLC.

Trial design: This is a multi-center, prospective, single-cohort study. Major inclusion criteria are: (1) metastatic, biopsy proven, non-squamous NSCLC, (2) candidate for first line systematic therapy, (3) no prior targeted therapy. Peripheral blood (20 mL) is collected for cfDNA sequencing prior to and 2 weeks after treatment initiation and at the time of disease progression (maximum 12 months follow-up). cfDNA sequencing is performed using Guardant360, a comprehensive next-generation assay (Guardant Health, Inc., Redwood City, CA USA). Pre-treatment tissue samples archived at local sites are centrally analyzed. Pts are treated according to investigator standard of care criteria. Tumor response is assessed centrally per RECIST v1.1 on pts who received targeted therapy. Primary endpoint is the detection rate, in either blood or tissue, of a clinically actionable somatic biomarker, defined as mutations in EGFR, BRAF, MET and ERBB2, copy number of MET and rearrangement of the ROS1, RET and ALK genes. A total of 182 pts are needed to test a 10% non-inferiority margin. We assumed a 20% detection rate, with a 19% discordant pairs and 10% dropout rate. The one-sided asymptotic test has 90% power, at a nominal significance level of 5%. Secondary objectives are to compare turn-around time, time to treatment initiation, rates of insufficient tissue for testing or tumor not detected in cfDNA, and tumor response to targeted therapies. Genomically acquired resistance to targeted therapies is also investigated.

Background: Treatment in NSCLC is quickly evolving and new agents make it to the routine practice at a rapid pace. Whether outcome and PRO data generated from clinical trials with often narrow inclusion and exclusion criteria will hold up in the routine practice is of high interest, especially due to the increasing costs of new drugs. Therefore registry data are of ever increasing importance to patients, physicians and reimbursement institutions.

Trial design: We have started a prospective, clinical registry to document representative data on molecular testing, sequences of systemic therapies and other treatment modalities, and course of disease in patients with metastatic NSCLC in Germany (CRISP, NCT02622581). A particular focus is on molecular biomarker testing of patients before the start of first-line treatment. The data shall be used to assess the current state of care and to develop recommendations concerning topics that could be improved. PRO assessment will provide large-scale data on quality of life and anxiety/depression for real-life patients in routine practice. In addition, two questionnaires (concerning individual quality of life and patient-caregiver communication) will be validated in German patients with metastatic NSCLC. Furthermore CRISP will set up a decentral tissue annotation for future collaborative, investigational scientific biomarker testing. CRISP will be carried out in up to 150 representative cancer centers in all therapeutic sectors in Germany. More than 5000 patients will be recruited and followed up until death or for a maximum of 3 years. The first patient has been included in December 2015. Currently, 104 centers have been initiated, and 765 patients have been recruited. Preliminary data will be presented at the meeting in terms of molecular test rates, demographic data as well as treatment stratification in the 1st line setting. In conclusion: The registry CRISP will be the first to present representative real life data, covering all treatment settings of patients with NSCLC in Germany. CRISP is supported by AstraZeneca, Boehringer Ingelheim, BMS, Celgene, Lilly, MSD, Novartis, and Pfizer.

Background: Since publications highlighting the role of sarcopenia, weight loss (WL) is no longer the corner stone of malnutrition assessment. An international consensus proposed in 2011 a definition and a staging of CAX, mainly based on WL, sarcopenia, inflammation and anorexia (Fearon). We initiated this study to fill the gap of epidemiological data on CAX in NSCLC in France and Belgium.

Methods: This cross-sectional, prospective, multicentric study was conducted in Patients (pts) with NSCLC regardless of the tumor stage and the treatment line. Skeletal muscle mass (SMM) was assessed by analyzing L3 CT-scan image. Pts completed Anorexia/CAX subscale of FAACT and EORTC QLQ-C30 health related quality of life (QoL) questionnaires. Primary endpoint was the frequency of CAX according to Fearon criteria. Secondary endpoints were the frequency and the characteristics of the other stages of CAX focusing on early and discrete malnutrition changes (pre-CAX).

Results: 539 NSCLC pts were recruited within 3 months in 2016 by 56 sites, analysis population was of 531 pts and 312 had SMM assessment. Median age was 66 years, 66.5% were males, 79.9% were PS < 2, and the tumor stage was mainly IIIB-IV (87.3%). 38.7% of pts had CAX, 33.8% pre-CAX and 0.9% refractory CAX. CAX was associated with molecular tumor profiles: 23.9% in patients EGFR, ALK, ROS1, BRAF or HER2 positive, 41.4% in K-RAS+ and 43.2% with no molecular abnormality ($p = 0.003$). Interestingly, the more advanced the CAX stage is, the poorer the score of functional scale (except cognitive) of the QoL questionnaire ($p < 0.0001$). Sarcopenia was present in 66.7% of CAX pts and 68.5% of pre-CAX pts (all without WL or WL $\leq 2\%$). Notably, 25.8% of pre-CAX pts had only sarcopenia with limited WL ($\leq 2\%$) and no anorexia (questioning the mechanisms of sarcopenia). In pts with limited WL ($\leq 2\%$), the loss of appetite was associated with sarcopenia in 44% of the cases.

Conclusions: This is the first study showing an association between molecular abnormality in NSCLC and cachexia. It has also shown that it may be useful to detect sarcopenia in pts with limited WL ($< 2\%$), especially in those with loss of appetite. Cachexia stages were associated to functional QoL items.

Background: There is growing concern in society about aggressiveness of cancer care near the end of life (ACCEoL), mainly in metastatic disease. This study aims to determine prevalence and recent time trend of ACCEoL of adult cancer patients in a European country, comparing metastatic with others.

Methods: Cohort study of adults with ICD-9-CM diagnosis of cancer, who died in public hospitals in mainland Portugal (Jan'10 - Dec'15), identified from the Hospital Morbidity database (HMD). HMD provided data on primary cancer site, presence of metastatic disease and primary outcome: a composite ACCEoL indicator aggregating presence of 1 of 14 individual indicators in the last 30 days of life or chemo, immunotherapy or biological agents in the last 14 days of life (expansion of Earle et al 2004 framework). We calculated the prevalence of composite and individual indicators and examined time trends (chi2 test for trend) for the whole cohort, in metastatic disease and for main primary cancers. We considered clinically meaningful $> 5\%$ change.

Results: 92,155 patients were included (median age 73 yo, IQR 62-81; 61.9% male; 53.0% metastatic). The prevalence of the ACCEoL was 71.1%, 69.9% in metastatic patients vs. 72.6% in others ($p < 0.001$), and varying by primary cancer from 62.7% in breast to 79.3% in haematological ($p < 0.001$). The most prevalent individual indicators were > 14 days in hospital (42.7%; 42.3% in metastatic) and surgery (27.8%; 26.4% metastatic). The least prevalent were permanent tracheostomy (0.1%) and percutaneous gastrostomy (0.3%). Primary outcome remained stable overtime and despite some individual indicators showed statistically significant changes in study timeframe, none of these had $> 5\%$ change.

Conclusions: Surprisingly, we found unchanged trends of high ACCEoL among adult patients and no clinically meaningful difference for metastatic disease group. A lack of integrated palliative care, even with growing resources in the timeframe analysed, suggest that these have not been enough to reduce ACCEoL. The reduced ACCEoL in patients who died with slow progressive cancers (e.g. breast) suggests that better knowledge of disease trajectories can contribute towards reducing ACCEoL.

1388PD Open-label randomized study of individualized pharmacokinetically (PK)-guided dosing versus body surface area (BSA) dosing of paclitaxel (PTX) in advanced Non-Small Cell Lung Cancer (NSCLC) NCT02058433

S.J. Salamone[1], J. Zhang[2], H. Qi[2], H. Ni[2], Y. Li[1], J.B. Courtney[1], C. Zhou[3]

[1]*Research and Development, Saladax Biomedical, Inc., Bethlehem, PA, USA,* [2]*Department of Oncology, Shanghai Pulmonary Hospital, Shanghai, China,* [3]*Department of Oncology, Shanghai Pulmonary Hospital, Tongji University, Shanghai, China*

Background: Variability of PTX exposure using BSA dosing is well documented and often leads to severe toxicities. While carboplatin is dosed to obtain a specific exposure, paclitaxel is conventionally dosed by BSA, leading to a wide range of exposure. This study compared PTX PK-guided dosing to BSA dosing in a PTX-carboplatin regimen treating stage IIIB/IV NSCLC. This is the final analysis of interim results presented at ASCO 2015 (Poster #375). ClinicalTrials.gov Identifier NCT02058433.

Methods: 309 patients with stage IIIB/IV NSCLC were randomized to receive up to 4 cycles of first line 3-weekly carboplatin (AUC 5) and a PTX dose of 175 mg/m^2 (Arm A), or a PTX PK-guided dose (Arm B) to achieve a time above a PTX plasma concentration of 0.05μM ($T_{c>0.05}$) for 26 to 31 hours. Response was classified according to Response Evaluation Criteria in Solid Tumors Group. PTX concentrations were

measured by immunoassay; $T_{c>0.05}$ was calculated with PK software. The primary endpoint was reduction of grade 4 hematological toxicities.

Results: There were 164 patients in Arm A and 155 patients in Arm B, with 191 males and 128 females participating. PK-guided dose adjustment resulted in doses that were widely distributed 73 – 175 mg/m^2, and statistically lower than in the BSA arm (by 24%, $p < 0.001$). Compared to Arm A, PK-guided dosing significantly reduced grade 4 neutropenia by 35% ($p = 0.002$, 23% vs. 16%) over 4 cycles. The incidence of severe (grade $\geq$3) neutropenia was also significantly reduced by 25% in Arm B over all cycles ($p = <0.001$). Additionally, neuropathy ($\geq$ grade 2) was reduced from 20% in Arm A to 8% in Arm B ($p = 0.008$), representing a 60% reduction over all cycles. Response rates were not significantly different; objective response rates were 23% in Arm A and 29% in Arm B ($p = 0.285$); stable disease rates were 49% in Arm A and 42% in Arm B ($p = 0.0.240$).

Conclusions: Results of this study are in agreement with a previous report, and present further evidence that PK-guided dosing reduces severe toxicities. This is accomplished by an overall lowering of dose intensity, while still maintaining efficacy. PK-guided dosing personalizes chemotherapy, and may be useful in patient management.

1389PD Prognostic impact of drug interactions in patients with advanced cancer

M. Joerger[1], A. Hömme[2], M. Haschke[3], S. Krähenbühl[3], F. Strasser[1], C. Lehner[4], A. von Kameke[5], T. Wälti[6], B. Thürlimann[7], M. Früh[1], C. Driessen[1]

[1]Medical Oncology & Hematology, Cantonal Hospital, St. Gallen, Switzerland, [2]Institute of Pharmacology & Toxicology, University of Ulm, Ulm, Germany, [3]Clinical Pharmacology & Toxicology, University Hospital Basel and Department of Biomedicine, University of Basel, Basel, Switzerland, [4]Pharmacy, Cantonal Hospital, St. Gallen, Switzerland, [5]Information Technology (IT), Cantonal Hospital, St. Gallen, Switzerland, [6]HCI Solutions Inc., HCI Solutions Inc., Bern, Switzerland, [7]Breast Center, Cantonal Hospital, St. Gallen, Switzerland

Background: The risk of drug-drug interactions (DDI) increases with the number of comedications. The prognostic impact of DDI in oncology is poorly understood.

Methods: We included 105 patients with advanced NSCLC, 100 patients with advanced ER-negative breast cancer (BC) and 100 hospice inpatients (HO) with advanced malignancies between 2010 and 2015. Data collected included all anticancer and non-anticancer drugs received, age, gender, presence of CNS metastases, smoking status, ECOG performance status (PS), Charlson comorbidity score and overall survival (OS) from the time of incurable cancer. Potential DDI were assessed using the hospINDEX of all drugs approved in Switzerland in combination with the DDI software - flycicle mode (HCI Solutions, Bern, Switzerland). Primary study objective was to assess the prognostic value of the severity of DDI per patient cohort using Kaplan-Meier statistics, uni- and multivariate Cox regression models. The study had a power of 84% to detect a survival difference of 25%.

Results: The median number of drugs was 5 (range 0 to 15) in all patients, lowest in BC (4) and highest in HO (6). A major risk for DDI was detected in 74 patients (24.3%) overall, including 29 NSCLC patients (27.6%), 25 BC patients (25.0%) and 20 HO patients (20%). The number of drugs was significantly associated with the risk of DDI ($p < 0.0001$). The risk of a major DDI increased from 14% in patients with <4 drugs to 24% in patients with 4-7 drugs, 40% with 8-11 drugs and 67% in patients with >11 drugs. Median OS was 8.6 months in NSCLC, 33 months in BC and 1.2 months in HO. The severity of DDI was significantly associated with inferior OS in BC (HR = 1.34, $P = 0.018$), but not in NSCLC or HO. The severity of DDI remained significantly associated with OS in BC (HR = 1.34, $P = 0.017$) after correcting for patient age and ECOG PS.

Conclusions: Severity of DDI is a significant and clinically relevant prognostic factor in advanced BC patients. Prospective trials should evaluate the potential benefit of avoiding polypharmacy in this group of patients. In the meantime, increased caution with polypharmacy seems warranted when treating patients with advanced cancer.

1390P Efficacy of anamorelin in advanced non-small cell lung cancer (NSCLC) patients with anorexia/cachexia and modified Glasgow Prognostic Score (mGPS) of 2: Pooled analysis of two phase 3 trials

S. Kaasa[1], B. Laird[2], M. Fallon[2], D. McMillan[3], R. Skipworth[4], D. Currow[5], R. Giorgino[6]

[1]Department of Oncology, Oslo University Hospital and University of Oslo, Oslo, Norway, [2]Institute of Genetics and Molecular Medicine, University of Edinburgh, Edinburgh, UK, [3]Academic Unit of Surgery, Glasgow Royal Infirmary, University of Glasgow, Glasgow, UK, [4]Clinical Surgery, University of Edinburgh, Edinburgh, UK, [5]ImPACCT – Improving Palliative Aged and Chronic Care through Clinical Research and Translation, Faculty of Health, University of Technology Sydney, Sydney, Australia, [6]Research and Development Innovation and Strategy Department, Helsinn Healthcare, Lugano, Switzerland

Background: Anorexia/cachexia occurs in patients with advanced NSCLC. In 2 randomized, double-blind, placebo-controlled phase 3 trials in cachectic NSCLC patients, the ghrelin receptor agonist anamorelin was well tolerated and significantly improved body composition parameters and anorexia/cachexia symptoms over 12 weeks (Temel JS et al, *Lancet Oncol* 2016). The mGPS (0–2) has independent prognostic value; patients with mGPS 2 have worse prognosis. This analysis determined anamorelin's efficacy in cachectic NSCLC patients with mGPS 2 (C-reactive protein levels >10mg/L and albumin levels <3.5g/dL).

Methods: Stage III/IV NSCLC patients with cachexia (BMI<20 kg/m^2 or $\geq$ 5% weight loss during prior 6 months) were randomized 2:1 to once-daily oral anamorelin 100 mg or placebo up to 12 weeks. An ad-hoc efficacy analysis was performed in the modified intent-to-treat population (N = 829) to assess whether mGPS score at baseline may predict differences in anamorelin treatment effect size at end of study (or last observation carried forward since week 6 or 9).

Results: Anamorelin treatment effect was statistically significantly better, compared with placebo, for all body composition parameters in all mGPS subgroups. This effect was numerically larger in patients with mGPS 2 and statistically significant, compared with placebo, for all analyzed parameters, except fatigue subscale score (Table). In patients with mGPS 2, the placebo-adjusted mean increase in body weight exceeded the 5% weight loss cutoff used as an official criterion for cancer cachexia diagnosis.

Table: 1390P

	Treatment Effect of Anamorelin in patients with mGPS 2 (n = 123)		
	Mean	95% CI	*P* value, compared with placebo
Body weight, kg	3.07	1.47–4.68	<0.001
Body weight change, %	5.40	2.82–7.97	<0.001
Lean body mass, kg	1.84	0.62–3.06	0.003
Appendicular lean body mass, kg	1.04	0.32–1.77	0.005
Fat mass, kg	1.35	0.38–2.31	0.007
Handgrip strength, kg	2.44	0.35–4.52	0.022
FAACT Anorexia/Cachexia subscale score	5.23	1.55–8.90	0.006
Fatigue subscale score	0.67	−3.24–4.58	0.736

CI, confidence interval; FAACT, Functional Assessment of Anorexia/Cachexia Therapy.

Conclusions: In cachectic NSCLC patients with mGPS 2, anamorelin leads to significant improvements in body composition parameters and symptom burden. The extent of weight improvement in this population suggests that treatment with anamorelin may on average reverse pathologic weight loss.

1391P Prognostic Nutritional Index (PNI) for cost effective utilisation of newer, expensive radiation technology for palliative treatment of all cancer patients with limited life expectancy

S. Sundar, J. Price, T. Wolfe, D. Thurairasa, E. Shawcroft

Department of Oncology, Nottingham University Hospitals NHS Trust-City Hospital Campus, Nottingham, UK

Background: Novel, complex, resource intensive, radiation technology is increasingly used for palliative therapy even though they are not cost effective in poor prognosis pts. (Kim IJROBP 2015;556). Since nearly half of all radiotherapy (RT) activity is palliative (Hoskin Cl Onc 2013;531), objective, validated prognostic tools are urgently needed to guide cost effective utilisation of RT. As advanced cancer is associated with poor nutritional status and immune dysfunction, we assessed prognostic role of PNI-which is based on serum albumin & peripheral blood lymphocytes.

Methods: Mortality of 233 unselected cancer pts treated over a 3 month at Nottingham was assessed. All tumour sites & histology were included. Overall Median age 68 yrs. Sites of RT field: Chest=29% Vertebrae=26% Pelvis=20% Brain=12% Limbs=6% Abd=3% Miscell=3%. 95% completed RT as planned. 93% had stage 4 cancer. PNI available for 131 pts. Majority not suitable for systemic therapy following palliative RT; only 15% and 28% had further hormones and chemo respectively.

Results: Overall Median survival was 5.82 months; 38% died within 90 days of completing RT; Pts with low PNI (<38) had statistically significant higher 30 day and 90-day mortality (table). On Cox regression, low PNI was strongly predictive of poor survival, (p 0.01; Exp(B) 0.538; [95.0% CI for Exp(B) 0.336 to 0.862]. Pts who received systemic therapy following palliative RT had better survival. (Hormones and chemo P values <0.005 & <0.001 respectively). By contrast, total RT dose, and number of RT fractions were not predictive of survival (p values 0.213 and 0.379 respectively). No survival advantage for multifraction over single fraction RT.

Conclusions: For terminally ill cancer patients, who are not fit for further systemic therapy and whose PNI is < 38, Single fraction RT should be the standard of care.

Table: 1391P

	PNI		
	<38	>38	P value
Median Age -Yrs	68	66	0.26*
Median RT dose- Gy	20	20	0.21#
Median No RT fractions	5	5	0.37
30 day mortality	10%	4%	0.05
90 day mortality	25%	15%	0.03
Median Survival	3.21 mths	10.45 mths	<0.001@

1392P Characterization of cachectic patients with non-small cell lung cancer (NSCLC) according to their modified Glasgow Prognostic Score (mGPS)

B. Laird[1], D. McMillan[2], S. Kaasa[3], M. Fallon[1], R. Skipworth[4], D. Currow[5], R. Giorgino[6]

[1]Institute of Genetics and Molecular Medicine, University of Edinburgh, Edinburgh, UK, [2]Academic Unit of Surgery, Glasgow Royal Infirmary, University of Glasgow, Glasgow, UK, [3]Department of Oncology, Oslo University Hospital and University of Oslo, Oslo, Norway, [4]Clinical Surgery, University of Edinburgh, Edinburgh, UK, [5]ImPACCT – Improving Palliative Aged and Chronic Care through Clinical Research and Translation, Faculty of Health, University of Technology Sydney, Sydney, Australia, [6]Research and Development Innovation and Strategy Department, Helsinn Healthcare, Lugano, Switzerland

Background: Patients with advanced NSCLC often develop anorexia/cachexia, a comorbidity characterized by decreased body weight or low body mass index (BMI), which negatively impacts quality of life and life expectancy. Weight loss and BMI were suggested to have independent prognostic value (Martin L et al, *JCO* 2015). The mGPS (0–2) has independent prognostic value, where patients with mGPS 2 (C-reactive protein levels >10mg/L and albumin levels <3.5g/dL) have worse prognosis. Here, we investigated the characteristics of NSCLC patients with cachexia according to their mGPS, and whether mGPS can be used to differentiate patients with cachexia.

Methods: Patients with unresectable stage III/IV NSCLC and cachexia (BMI<20 kg/m^2 or ≥ 5% weight loss during prior 6 months) were enrolled in two phase 3 studies of the ghrelin receptor agonist anamorelin (ROMANA 1 and ROMANA 2). A pooled post-hoc data analysis was performed in the modified intent-to-treat population (N = 829), irrespective of treatment arm, to investigate the baseline characteristics of patients with mGPS 0–2.

Results: At baseline, 36% patients had mGPS 0 (n = 296), 49% mGPS 1 (n = 396) and 15% mGPS 2 (n = 123). Patients who lost <10% body weight during the prior 6 months had mainly mGPS 0–1; in contrast, among patients who lost >10% body weight, a higher percentage had mGPS 2. Patients with mGPS 2 had on average substantially lower values of body weight, body composition parameters, handgrip strength and anorexia/cachexia and fatigue scores than the other mGPS subgroups (Table).

Conclusions: While patients with cachexia present mGPS scores that vary from 0–2, a higher percentage of patients with mGPS 2 was observed among those with >10% body weight loss. The baseline characteristics observed in patients with mGPS 2 are worse than in the other mGPS subgroups, suggesting that mGPS may be helpful in identifying patients with more-advanced cachexia.

1393P Chemotherapy in advanced cancer patients with poor performance status (PS) initiated in an integrated oncology and palliative care (PC) setting: an observational comparative study

F. Strasser[1], N. Kalbermatten Magaya[2], D. Hehli[1], M. Früh[1], D. Blum[3]

[1]Clinic Oncology/Hematology, Dept. Internal Medicine, Kantonsspital St. Gallen, St. Gallen, Switzerland, [2]Internal Medicine, Cantonal Hospital, Münsterlingen, Switzerland, [3]Onkologie, Universitätsklinimum Hamburg-Eppendorf, Hamburg, Germany

Background: Advanced cancer patients (ACP) with poor PS often get systemic anticancer treatment (SAT). A combined PC and medical oncology structured approach involving double boarded palliative oncologists (PallOnc) is investigated.

Methods: Medical chart review over 2½ years, with locally developed (adapted from Blum D JPSM 2014) tool, of all ACP PS > 1 in a tertiary PC unit (330 pts/year, death rate 40%, length of stay [LOS] 12 days) receiving intravenous SAT (pharmacy orders). ACP with new initiated SAT were compared with continued SAT for tumor history, PS, and outcomes; in new SAT the PallOnc processes decisional process, Palliative Interventions (PIs), and primary dose reduction were analysed.

Results: Of 95 ACP receiving SAT 65 (68%) were PS > 1. In 36 ACP a new SAT was initiated, in 29 continued. Comparable were age (years, mean: 65 vs 63), gender (% female: 39 vs 43), PS (PS3/4: 64% vs 65%)), time since diagnosis of stage 4 (months, mean: 16 vs 14), number of anticancer treatment lines (mean: 2 vs 2) and LOS (days, mean: 26 vs 24). New vs continued SAT differed for tumors not responding (never PR or SD) to last chemotherapy (55% [7 PS2, 4 PS3] vs 27% [1 PS2, 2 PS3], monotherapies (67% vs 45%), death at PC unit (14% vs 41%), overall survival (1 patient alive, 1 lost-to-follow-up; days, median: 83 vs 58, mean 152 vs 128), PS at demission compared to admission (stable PS: 33% vs 24%; improved PS: 50% vs 24%), and ACP who died ≤14 days after last SAT (22% vs 14%). No G3/4 non-hematological toxicity was reported. In the new SAT group the decisional process took 11 days (median, range 0-48), explicit goals of SAT were documented in 81% (44% specific tumour-related symptoms), attitude towards SAT in 86% ACP (unwilling, ambiguous 4/31, wants, imperative 17) and 42% physicians (0, 15). Of 5 PIs Illness understanding, symptom control, end-of-life preparation, network & family support, spiritual needs) all were delivered in 21 ACP (58%), 4 and 3 in 7, 2 in 1. Primary dose reduction was applied in 2/4 PS4 patients (1: 5-25%,1: 26-50%), 13/19 PS3 (5, 8) and 11/13 PS2 (7, 4) ACP.

Conclusions: In a setting with PallOnc anticancer treatment in poor PS patients seems feasible. The encouraging data may foster prospective research.

1394P Previous palliative care encounter is associated with lower total hospital charge and shorter length of stay in patients with metastatic cancer

Y. Liu

Medicine, Mount Sinai St Luke's and Roosevelt Hospital, New York, NY, USA

Background: Patients with metastatic cancer require substantial heath care resources. Palliative care has been increasingly recognized for improvement of quality of life and reducing healthcare costs. Here, we examined the effect of prior palliative care encounters on the total hospital charges (TOTCHG) and length of stay (LOS) during the subsequent hospitalization.

Methods: We used National Inpatient Sample (NIS) 2014 to extract data for patients non-electively hospitalized with corresponding ICD9 code of previous palliative care visit (ICD9 code V667) and metastatic cancer. NIS is a nationally representative survey of hospitalizations conducted by Heathcare Cost and Utilization project. It represents 20% of all hospital data in the US. Univariate regression screening (threshold P > 0.1) and hybrid selection were used to create multivariate regression models. Relationship between TOTCHG and previous palliative care encounter as well as LOS and previous palliative care encounter were analyzed by using established models.

Results: A total number of 136591 patients admitted non-electively with metastatic cancer was identified among which 24736 had been coded for previous palliative care encounter. Teaching hospital admission, rural hospital admission, self-pay, increased age and increased Charlson score were associated with higher rate of previous palliative encounter. The multivariate regression model for LOS and previous palliative care visit were adjusted for survival outcome, number of procedures during hospitalization, number of previous chronic conditions, and number of the diagnosis during hospitalization. The model for TOTCHG and previous palliative care visit were adjusted for survival outcome, number of procedures and length of stay. We found that previous palliative care encounter was associated with both lower total hospital charge (P < 0.0001) and shorter length of stay in patients with metastatic cancer (P < 0.0001).

Conclusions: Prior palliative care visit has been associated with decreased length of stay and total hospital charges. Future studies are needed to determine if early outpatient palliative care encounter will especially benefit patients with certain tumor types.

1395P Specialized ambulatory palliative care: (SAPV) 5-year results of a multi-professional care model by HomeCare linker Niederrhein gGmbH (HC) in the Lower Rhine region

U. Grabenhorst

SAPV, HomeCare linker Niederrhein gGmbH, Viersen, Germany

Background: In recent times, German legislation has given terminally ill patients the right to receive SAPV, a multi-professional palliative care model which is aimed at prevention of hospital admission and enabling patients to die at home despite severe symptoms and a high need for palliative care. This new type of care raises the question about the best implementation and impact of SAPV. HC provides SAPV to 560.000 inhabitants of the city of Mönchengladbach and the district of Viersen.

Methods: Data collected during daily care from 2012 to 2016 are summarized and analysed in order to describe the implementation and results of SAPV.

Results: 1798 patients were treated in 5 years. The first contact with SAPV was initiated by a GP in 30% of patients and by a specialist in 4.5%; in 26% through a hospital, in 6% by a palliative care unit and in at least 30% by non-medical participants, such as relatives, nursing services, counseling centers etc. 20% of all patients were treated only temporarily by SAPV. 6% were admitted to a hospice, 14% were transferred to regular care after counseling or crisis intervention. Of the remaining patients, only 3.3% had to be hospitalized at the end and 96.7% were able to remain in their chosen home environment. That was at home for 80%, at a relative's home for 3%, in a nursing home for 14%, and miscellaneous for the remaining 3% of patients. Sonography, thoracic and abdominal paracentesis, patient-controlled analgesia etc. were performed in the patient's home by the SAPV team. Of all 1798 patients, 112 had to be hospitalized; 64 were subsequently retreated with SAPV and 48 were not. The main reasons for hospitalization were palliative interventions due to ileus and urinary retention in the upper tract, radiation of a fracture, psychosocial decompensation of the supporting relatives and confirmation of the palliative concept. The average treatment duration was 19 days, the median was under 10 days. In detail, 112 patients were treated for less than 24 hours, 271 patients for less than 48 hours, 57 patients were treated for more than 90 days and 4 patients for over 200 days.

Conclusions: The wish of patients to die at home and to avoid unnecessary hospitalization can be achieved with this model of specialized care. Further comparative investigations are necessary to identify the optimal implementation and impact of SAPV.

1396P Increasing palliative interventions at the end of life: patterns in metastatic colorectal cancer (mCRC)

R. Prince[1], A. Easson[1], S. Liang[2], M. Brar[3], S. Ramkumar[2], A. Scheer[4], R. Wong[5], J. Hallet[6], C. Zimmermann[7]

[1]DMOH, Princess Margaret Cancer Centre, Toronto, ON, Canada, [2]DSO, University of Toronto, Toronto, ON, Canada, [3]DSO, Sinai Health System, Toronto, ON, Canada, [4]DSO, St Michael's Hospital, Toronto, ON, Canada, [5]Radiation Medicine Program, Princess Margaret Cancer Centre, Toronto, ON, Canada, [6]DSO, Sunnybrook Health Sciences, Toronto, ON, Canada, [7]Palliative Care, Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: Advances in chemotherapy for mCRC have improved median survival to more than 24 months. This has resulted in increased opportunity to undergo more frequent interventions for symptom relief at the end of life. We explored patterns of palliative interventions (surgery, endoscopy, interventional radiology (IR), drainage procedures, radiotherapy) in mCRC patients over a time of evolving chemotherapy regimens.

Methods: A retrospective review was undertaken of all mCRC patients referred to palliative care at a tertiary cancer center in Toronto, Canada. Patients treated 2000-2004 (early cohort) were compared to 2006-2010 (later cohort) as more effective palliative chemotherapy was available in the later time period. Descriptive statistics, t-tests, and chi-squared tests were employed.

Results: A total of 542 (212 early and 330 later cohort) patients were included. Compared to the early cohort, the later cohort was significantly younger (62 vs 65 years, p = 0.012), had more Stage 4 disease (47 vs 42%, p = 0.029), fewer curative surgeries (58 vs 70%, p = 0.005) and fewer had adjuvant chemotherapy (26 vs 38%, p = 0.002). Palliative care referral was delayed for the later cohort with longer times between diagnosis of unresectability and referral (13 vs 8 mths, p = 0.0019) and shorter times between referral and death (6 vs 8 mths, p = 0.019). More patients in the later cohort had palliative surgery (31 vs 22%, p = 0.015), palliative IR procedures (15 vs 4%, p < 0.0001) and did not receive any chemotherapy (44 vs 29%, p < 0.0001). The later cohort underwent more interventions in the last months of life with more chemotherapy and drainage procedures closer to death (7 vs 12 mths, p = 0.002 and 2 vs 9 mths, p = 0.006 respectively). There was no difference in survival (calculated from date of diagnosis to death) between the cohorts (median survival 35 months).

Conclusions: In their final months of life, palliative mCRC patients are undergoing more interventions requiring multi-disciplinary input with the aim of improving quality of life than previously. Increasing use of interventions in the last months of life has significant ramifications for patients, service provision, staffing and funding.

1397P Chronic pleural effusion in malignancy: A single center's ten years expertise with indwelling pleural catheters

N. Frost[1], M. Brünger[2], B. Temmesfeld-Wollbrück[1], D. Schürmann[1], N. Suttorp[1]

[1]Department of Infectious Diseases and Pneumonology, Charité Universitätsmedizin Berlin, Berlin, Germany, [2]Institute of Medical Sociology and Rehabilitation Science, Charité Universitätsmedizin Berlin, Berlin, Germany

Background: Chronic and recurrent pleural effusion (PE) in malignant diseases is a common cause of dyspnea, cough and chest pain. The vast majority is malignant pleural effusion (MPE), nevertheless disease-associated but not directly disease-caused paramalignant pleural effusions (PPE) have also been described. Talc pleurodesis had been the only treatment option for decades, while for 20 years indwelling pleural catheters (IPC) have emerged as an alternative leading to spontaneous pleurodesis without any chemical agent in 40-50%.

Methods: Our aim is to explore patient characteristics, procedural variables and outcomes in a large population of patients with IPC due to PE in malignancy. Further, our objective is to identify factors associated with outcome.

Results: From 2006 until 2016 448 IPC were inserted in 395 patients, 52 received bilateral drainages (12.7%). 77.0% of the effusions were malignant (n = 304), 14.9% paramalignant (n = 59), in 8.1% the etiology could not be clarified (n = 32). The most common underlying diseases were ovarian cancer (30.6%, 121 patients), lung cancer (23.0%, 91 patients) and breast cancer (11.4%, 45 patients). The median length of insertion was 1.2 months (0.03-23.6), the median survival time after insertion 2.4 months (lung cancer 1.6 months, ovarian cancer 2.8 months, breast cancer 4.0 months). Spontaneous pleurodesis was observed in 28.6% (128/448 catheters) and was significantly associated with overall survival (HR 0.54, 95%-CI 0.39-0.75, $p < 0.001$). Complications occurred in 12.3% of all procedures (55/448 catheters), in 6.5% the catheter had to be removed (29/448 catheters). The most common complications were superficial infections (n = 14), empyema (n = 11; 1 grade 5 complication) and mechanical obstruction of the catheter (n = 13).

Conclusions: In conclusion, our retrospective series is the largest to date to report on IPC in malignancy and showed a manageable safety profile. Spontaneous pleurodesis was significantly associated with survival.

1398P Aggressiveness of care at the end of life in children with cancer: A nationwide cohort study

A. Cardoso[1], D. Martins Branco[2], A. Lacerda[2], B. Gomes[3], S. Lopes[4]

[1]Paediatric Department, Centro Hospitalar do Tâmega e Sousa, Penafiel, Portugal, [2]Medical Oncology Department, Instituto Português de Oncologia de Lisboa Francisco Gentil, E.P.E. (IPOLFG EPE), Lisbon, Portugal, [3]Department of Palliative Care, Policy and Rehabilitation, King's College, Cicely Saunders Institute, London, UK, [4]Escola Nacional de Saúde Pública e Centro de Investigação em Saúde Pública, Universidade NOVA de Lisboa, Lisbon, Portugal

Background: Cancer remains the leading medical cause of death in children. Ensuring quality of life should be a priority, but it may be difficult to stop treatments, particularly in settings where palliative care is scarce. Little is known about how many children dying from cancer experience aggressive care near the end of life (ACCEoL) in such settings (the most common worldwide). Our study aims to determine time trends in the prevalence of ACCEoL in this population.

Methods: Cohort study of children (0-17yo) who died with ICD-9-CM diagnosis of cancer in public hospitals in mainland Portugal (Jan'10 to Dec'15), identified from the Hospital Morbidity database. Based on previous studies and clinical experience, measures of ACCEoL comprised: in last 14 days of life: a) intravenous chemo/immunotherapy; in last 30 days of life: b) >14 days spent in hospital, c) >1 hospitalization, d) intensive care unit (ICU) admission, e) advanced life support (e.g. cardiopulmonary resuscitation), f) insertion of devices (e.g. central vascular access, CVA), g) total parenteral nutrition (TPN). We calculated prevalences and tested for time trends using chi2 for trend.

Results: The study included 300 patients (median age 9 yo, IQR 4-14, 58.7% male). The prevalence of ACCEoL was stable over time, with 87.8% of the children experiencing at least one ACCEoL measure (85.2% in 2010, 88.4% in 2015; $p = 0.816$)). The most prevalent individual ACCEoL measures were >14 days spent in hospital (51.0%) and >1 hospitalization (43.3%). Most measures showed no statistically significant time trend.

Conclusions: In a setting in early stages of pediatric palliative care development, we found that eight in ten children dying from cancer experience ACcEoL in their last month of life. This estimate is higher than those found in countries in more advanced developmental stages and may indicate a need to increase paediatric palliative care availability. The findings also prompt healthcare professionals to reflect on their current practice, balancing treatments and hospitalisations with patients' quality of life in the days they have to live.

PREVENTION AND SCREENING

1401PD Fluctuating cancer screening uptake in France: results of the 5th EDIFICE survey

J. Viguier[1], S. Couraud[2], L. Greillier[3], J-Y. Blay[4], C. Touboul[5], C. Lhomel[6], A. Cortot[7], J-F. Morere[8], F. Eisinger[9]

[1]Public Health and Care, The French National Cancer Institute (INCa), Boulogne-Billancourt, France, [2]Respiratory Diseases and Thoracic Oncology, Centre Hospitalier Lyon Sud, Pierre Bénite, France, [3]Multidisciplinary Oncology and Therapeutic Innovations, Hopital St. Marguerite Assistance Publique Hopitaux de Marseille, Marseille, France, [4]Medical Oncology, Centre Leon Berard, Lyon, France, [5]Statistics, Kantarhealth, Paris, France, [6]Medical, Roche - France, Boulogne-Billancourt, France, [7]Pneumology-Oncology, Hospital Albert Calmette, Lille, France, [8]Medical Oncology, Hopital Paul Brousse, Villejuif, France, [9]Aix Marseille Univ, INSERM, SESSTIM, Institute Paoli Calmettes, Marseille, France

Background: The EDIFICE nationwide surveys assess attitudes to cancer screening in France. All 5 self-reported surveys (2005, 2008, 2011, 2014 and 2016) focused on breast (BC), colorectal (CRC), prostate cancer (PC) screening; the 4th and 5th editions also included cervical (CC) and lung cancer (LC) screening.

Methods: The 5th survey recruited a representative sample of 1299 subjects (men [M], women [F]; age, 50-74 y; no history of cancer) and focused on target populations of the national screening programs for BC and CRC (50-74 y), and on specific subpopulations for PC (M, 50-75 y), CC (F, 50-65 y) and LC (M and F, 55-74 y) screening. Participants were questioned about uptake of at least 1 lifetime screening test and compliance to recommended intervals. Data analysis encompassed nationwide screening programs, opportunistic screening, and vulnerability (assessed by the EPICES score).

Results: Rates for at least 1 lifetime BC screening test (screening rate) were 93%/94%/95%/97%/97% in 2005/2008/2011/2014/2016, respectively. In line with recommendations, 75%/83%/83%/81%/75% women reported having had a mammogram in the past 2 years (compliance), with a significant drop in 2016 *vs* 2014 (P=0.02). Vulnerability had a negative impact on compliance in 2016, though not previously. For CRC, screening rates were 25%/38%/59%/60%/64%. Compliance (FOBT or FIT in the past 2 years) increased steadily from 7% (2005) to 33% (2014), and rose significantly to 38% in 2016 (P=0.02). The rise was mainly observed in the 50-54 y age group, among men, and in non-vulnerable subjects. In 2016, a significant drop in overall CC screening uptake was observed (99% in 2014 vs 94% in 2016, P<0.01), particularly among unemployed women (98% in 2014 vs 92% in 2016; P=0.03). Figures for at least 1 lifetime PC screening test were 36%/49%/50%/49%/42%, with the 2016 survey showing a significant decline, notably among unemployed (P=0.02) and non-vulnerable populations (P=0.05). LC screening rates (M,F) remained stable between 2014 and 2016.

Conclusions: In 2016, compliance to national programs was seen to be high for BC screening (despite a decline), and on the rise for CRC, possibly due to the use since 2015 of the new FIT test. Although a national program is due to be implemented in France, uptake of CC screening is on the decline.

1403P Community-based lung cancer screening of high-risk population with low-dose computed tomography in China

F. Qian[1], W. Yang[1], H. Wang[1], J. Teng[1], Y. Zhang[1], Q. Chen[2], J. Ye[2], J. Lou[1], R. Shi[3], L. Jiang[1], A. Gu[1], Y. Zhao[1], B. Jin[1], X. Zhang[1], J. Xu[1], Y. Lou[1], B. Han[1]

[1]Department of Pulmonary Medicine, Shanghai Chest Hospital, Shanghai, China, [2]Department of Radiology, Shanghai Chest Hospital, Shanghai, China, [3]Department of Preventive Medicine, Shanghai Jiaotong University, Shanghai, China

Background: Low-dose computed tomography (LDCT) screening for lung cancer has been recommended for high-risk individuals meeting the National Lung Screening Trial (NLST) criteria. However, there still is a debate concerning respective recommendations for Asian countries. Meanwhile, the proper duration and interval for lung cancer screening remains uncertain.

Methods: From November 2013 to July 2016, participants from Xuhui district of Shanghai were aged 45-70 years, and with either of the following risk factors: 1) smoking history ≥20 pack-years, and, if a former smoker, had quit within the past 15 years; 2) cancer history in immediate family members; 3) personal cancer history; 4) professional exposure to carcinogens; 5) long term exposure to second-hand smoke; 6) long term exposure to cooking oil fumes. The eligible participants were randomly assigned to a screening arm with two rounds of alternate years LDCT screens and a control arm.

Results: A total of 6659 eligible participants were enrolled, 3147 participants were randomly assigned to control arm, 3512 were assigned to LDCT prevalence screening (S1), of which 1516 participants underwent the second round of LDCT screening (S2) in the alternate year. Positive screening results were observed in 849(24.2%) participants in S1 and 380 (28.0%) in S2. 80 (2.3%) cases were highly suspected of lung cancer in S1 and 31 (2.0%) in S2 according to the suggestions from multiple disciplinary team. By April 2017, lung cancer was diagnosed in 44 participants (1.3%) after S1, 12 (0.8%) after S2, and 10 (0.3%) in the control group (stage 0 to I: 97.7%, 91.7% vs 20%; stage II to IV: 2.3%, 8.3% vs 80%). Only 18 (32%) of these 56 lung cancer patients detected by LDCT would have qualified as NLST high-risk patients. There were 2 lung cancer-specific deaths in control group, whereas 0 in the screening arm participants.

Conclusions: LDCT screening increased the detection of early-stage lung cancer and reduced lung cancer-specific mortality. In China, lung cancer CT screening may also benefit patients outside the NLST criteria with great efficiency. Screening done at biennial intervals could be taken into consideration due to few advanced-stage diseases.

1404P Colon cancer screening by fecal immunochemical testing in Iran

H. Salimzadeh[1], F. Bishehsari[2], C. Sauvaget[3], M. Amani[1], R. Hamzeloo[4], A. Nikfarjam[4], M. Maziar[4], S. Merat[1], A. Delavari[1], R. Malekzadeh[1]

[1]Digestive Oncology Research Center, Digestive Disease Research Institute, Tehran University of Medical Sciences, Tehran, Iran, [2]Department of Internal Medicine, Division of Gastroenterology, Rush University Medical Center, Chicago, USA, [3]Screening Group, Early Detection and Prevention, International Agency for Research on Cancer, Lyon, France, [4]Tehran University of Medical Sciences, Tehran, Iran

Background: Colorectal cancer (CRC) is the third-most common cancer in Iran. We aimed to measure the uptake and feasibility of a pilot CRC screening programme based on fecal immunochemical test (FIT) in population aged between 45 and 75 years and the implications for scaling-up at the national level.

Methods: This pilot study was conducted in Tehran and individuals aged between 45 and 75 years in rural and urban areas were enrolled in the screening programme. The FIT was offered by health navigators in primary health centers by collecting one single sample directly in to buffer kits by each participant. Health navigators aimed at increasing uptake and handled the whole screening programme from invitation to the referrals and provided the participants with information regarding the nature and importance of the CRC screening and details as to how to collect stool samples and send them back to the laboratory for analysis. If the first kit was not returned within 48 hours, a reminder call was sent. Those participants who had a positive FIT were referred to undergo a colonoscopy.

Results: A total of 1044 asymptomatic average-risk individuals were enrolled. The age mean was 54.1 and nearly 63.0% (n = 657) were female. Only small fraction of participants had awareness about CRC (13.7%) or polyps (8.3%) or screening tests (9.2%). Likewise their prior screening practice was extremely weak (2.2%). In multivariate regression analysis, awareness about CRC and screening tests significantly varied according to the ethnic groups, years of schooling, and family history of cancers ($P < 0.05$). In sum, 1002 returned the FIT kit, of which stool sample in six participants (0.6%) was deemed unsatisfactory for testing. The FIT uptake was 96.0%, the positivity rate was 9.1% and the detection rates were 11.9% for adenomas and 7.1% for advanced adenomas. No cancer was detected.

Conclusions: This is the first study on minimal quality metrics within a CRC screening process for the pilot phase and indicates that FIT modality as a test of choice is a safe and highly acceptable method of CRC screening in average-risk asymptomatic people. We suggest FIT as an initial CRC screening tool along with other preventive services in primary health care system in the nation.

1405P Diagnostic analysis of patients referred from general practitioner with serious non-organ-specific symptoms and signs of cancer: A retrospective cohort study

B.M. Jørgensen[1], C. Dehlendorff[2], C.M.N. Kistorp[3], S.E. Bojesen[4], J.S. Johansen[5], C.L. Feltoft[3]

[1]Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark, [2]Statistics and Pharmacoepidemiology, Danish Cancer Society Research Center, Danish Cancer Society, Copenhagen, Denmark, [3]Internal Medicine, Herlev and Gentofte Hospital, Herlev, Denmark, [4]Clinical Biochemistry, Herlev and Gentofte Hospital, Herlev, Denmark, [5]Medical Oncology, Herlev and Gentofte Hospital, Herlev, Denmark

Background: Recently, a diagnostic fast track for patients with serious non-organ-specific symptoms and signs of cancer was established in Denmark. For patients without cancer diagnosed within the first month, the prognosis is currently unclear.

Methods: A retrospective cohort study of 926 patients referred to Diagnostic Outpatient Clinic (DOC) at Herlev Hospital from April 2012 to December 2013. Baseline clinical parameters were collected from patient records. Time to cancer, death, cancer specific mortality (CSM), and death due to other causes were recorded until May, 2016. 724 patients were identified without cancer one month after examination and divided into 2 sub-cohorts based on the initial assessment: true negatives (TNs; patients diagnosed without cancer at DOC and after 1 month) and false positives (FPs; patients referred from DOC with suspicion of cancer, but without cancer the 1. month). Cumulative incidence of cancer, death, CSM, and death from other causes were estimated by the Aalen-Johansen estimator using 31 days after initial assessment as baseline. Hazard radios (HR) and 95% confidence intervals (CIs) for the initial evaluation were estimated in Cox models with cancer and mortality, respectively, as outcomes.

Results: Clinical characteristics of the 724 patients: median age 65 years (range 17-92); 44% were men; 70% were referred from their general practitioner; 43% were former/current smokers; 18% were former/current alcohol abusers. The median age ($p < 0.01$) and comorbidity score ($p < 0.01$) were highest among the FPs. TNs vs. FPs had a lower risk of subsequent cancer (HR: 0.08; 95% CI: 0.05-0.13; $p < 0.01$), mortality (HR: 0.26; 95% CI: 0.16-0.41; $p < 0.01$) and CSM (HR: 0.07; 95% CI: 0.03-0.16; $p < 0.01$). Mortality from other causes was similar in the two groups (HR: 0.58; 95% CI: 0.29-1.19; $p = 0.14$). The negative predictive value (NPV) was 0.94 and the positive predictive value was 0.46. However, around 40% of the FPs was diagnosed with cancer within the first year.

Conclusions: Ruling out cancer by investigation at DOC was associated with low risk of subsequent cancer and the NPV was high. The FPs had higher risk of cancer, mortality, and CSM compared to the TNs.

1406P Increased mutation burden in high-risk lung tissues: Toward precision cancer risk diagnosis

E. Kubo[1], H. Takeshima[1], S. Yamashita[1], N. Motoi[2], T. Ushijima[1]

[1]Division of Epigenomics, National Cancer Center Research Institute, Tokyo, Japan, [2]Department of Pathology and Clinical Laboratories, National Cancer Center Central Hospital, Tokyo, Japan

Background: Mutations are believed to accumulate in normal tissues at extremely low levels as a result of exposure to various carcinogenic factors. The degree of accumulation, namely mutation burden, is likely to be associated with cancer risk. However, owing to the limits of current detection methods for such extremely low frequency mutations, the mutation burden present in normal human lung tissues has been unclear. To overcome this limitation, we established a novel method for the quantification of extremely low frequency mutations in DNA samples. Using this method, we aimed to reveal the presence of mutation burden in normal lung tissues and its association with cancer risk.

Methods: Somatic mutations were quantified in normal lung tissues without smoking history (n = 11) ("entirely normal lung tissues":G1), normal lung tissues with smoking history (n = 11) ("smoking-exposed normal tissues":G2), and non-cancerous lung tissues of patients with lung cancer and smoking history (n = 11) ("smoking-exposed non-cancerous tissues":G3). A sequence library (15,724 bases of 291 regions of 55 cancer-related genes) was prepared by multiplex PCR using 100 DNA molecules. Libraries were sequenced using a next generation sequencer.

Results: The mutation burden in G3 ($2.7 \pm 0.8 \times 10^{-5}$ mutations/base) was significantly higher than that in G1 ($1.8 \pm 0.5 \times 10^{-5}$ mutations/base) ($p = 0.0189$). Accumulation of somatic mutations tended to be associated with increased cancer risk (OR = 3.75; 95% CI = 0.54–26.046). C>T mutations were significantly more frequent in G2 and G3 than in G1, which is in accordance with reported mutation signatures in cancer tissues [Alexandrov *et al.*, Science, 354:2016]. GCC>GTC and CCC>CTC mutations, signatures of exposure to the nitrosamines contained in tobacco smoke, were significantly enriched in G2 and G3.

Conclusions: To the best of our knowledge, this is the first study showing that mutations accumulate in high-risk lung tissues due to exposure to tobacco smoking. This will lead to a novel approach to precision cancer risk diagnosis.

1407P Change of natural history of hereditary diffuse gastric cancer after identification of a novel CDH1 mutation

N. Stjepanovic[1], S. Castro[2], N. Gadea[1], E. Carrasco[1], M. Codina[1], A. Lopez[1], M.E. Semidey[3], I.M. De Torres[3], M. Alsina[4], M. Urioste[5], L. Pena[5], F. Mercadillo[5], S. Landolfi[3], J. Balmana[1]

[1]Cancer Genetics Clinic, Medical Oncology Department, Vall d'Hebron Hospital, Barcelona, Spain, [2]Gastro-esophagic Unit, General Surgery Department, Vall d'Hebron Hospital, Barcelona, Spain, [3]Anatomic Pathology Department, Vall d'Hebron Hospital, Barcelona, Spain, [4]Gastric Cancer Clinic - Medical Oncology Department, Vall d'Hebron Hospital, Barcelona, Spain, [5]Familial Cancer Clinical Unit, CNIO, Madrid, Spain

Background: *CDH1* germline mutations are the major cause of hereditary diffuse gastric cancer (DGC). Carriers of *CDH1* mutations can present multiple signet ring cell carcinoma foci at early age. Therefore, prophylactic total gastrectomy (PTG) is widely recommended. We report a family with a novel *CHD1* mutation and analyze endoscopic and PTG findings among the mutation carriers.

Methods: Genetic *CDH1* testing by Sanger was performed in a three-generation family with multiple relatives with DGC. Direct sequencing was offered to individuals at risk >18 years. Unaffected carriers were recommended PTG and preoperative esophagogastroduodenoscopy with random gastric biopsies (RGB). Each PTG specimen was wholly sectioned (median # cassettes: 203) to look for occult cancer and histopathology was compared to RGB findings.

Results: A novel pathogenic variant in *CDH1* c.48G>A (p.Q16Q) was identified in 28 family members, 16 male/12 female. Prior to variant identification, 6 obligate carriers were diagnosed with an advanced DGC, median age 56 (53-62) years and all died of the disease. After genetic testing, 8 asymptomatic carriers were found early-stage DGC in the PTG specimen, median age 25 (19-59) years. Age-specific frequency of DGC in carriers according to PTG is shown in the Table.

Table: 1407P

	No PTG		PTG	
	n = 8		n = 20	
Age	DGC n = 6	Cumulative frequency	DGC n = 8	Cumulative frequency
10-20			1	5%
21-30			3	20%
31-40			1	25%
41-50			1	30%
51-60	5	62%	1	35%
61-70	1	75%	1	40%

Histopathological RGB and PTG correlation was performed in 17 carriers attended at our institution (May 2013-Sept 2015). Median age at PTG was 34 (19-63) years. All preoperative RGB were negative, but one, which identified a single milimetric DGC foci. PTG specimens revealed one Tis and six T1a DGC, conferring RGB a predictive negative value (PNV) of 66% for DGC. Stage IA DGC had a median of 2.8 foci/gastrectomy, localized in the body (83%) and atrium (17%), with average diameter 0.73 mm and e-cadherin expression in 100% of the foci. No severe postoperative morbidity was recorded after a median follow-up of 29 (16-44) months.

Conclusions: PTG has changed the natural disease history in c.48G>A *CDH1* carriers. Endoscopic RGB showed a low PNV for DGC and PTG is still highly recommended. More reliable screening methods are required in order to delay PTG in *CDH1*-mutation carriers.

1409P Cervical cancer screening in France: recent change in behaviors

T. de la Motte Rouge[1], J. Viguier[2], J-F. Morere[3], L. Brignoli-Guibaudet[4], J-Y. Blay[5], C. Lhomel[6], F. Eisinger[7]

[1]Medical Oncology, Centre Eugene - Marquis, Rennes, France, [2]Medical Oncology, CHRU Bretonneau, Tours, France, [3]Medical Oncology, Hopital Paul Brousse, Villejuif, France, [4]Statistics, Kantarhealth, Paris, France, [5]Medical Oncology, Centre Leon Berard, Lyon, France, [6]Medical, Roche - France, Boulogne-Billancourt, France, [7]Aix Marseille Univ, INSERM, SESSTIM, Institute Paoli Calmettes, Marseille, France

Background: Cervical cancer (CC) is the fourth most common cancer in women in France. Human papillomavirus vaccination and screening are complementary secondary prevention measures against CC. Screening by conventional Pap smear is recommended every three years for women aged 25-65y.

Methods: The EDIFICE nationwide observational surveys assess population attitudes to cancer screening in general. Representative samples of the French population aged 50-75 years are interviewed by phone using the quota method. Although the French CC screening program covers all women aged 26-65y, the present analysis pertains to a subpopulation aged 50-65y (N = 356 in 2014 and N = 460 in 2016). Interviewees, with no personal history of cancer, were asked if they had ever had a smear test during a gynecological exam. The date of the last test was noted. Data analysis focused on age group, socioprofessional categories (SPC) and social vulnerability (defined by the EPICE score).

Results: In 2016, 94% of interviewees reported at least one lifetime smear test vs. 99% in 2014 ($P<0.01$). In line with current interval recommendations, 74% in 2016 and 75% in 2014 ($P=0.81$) had had the latest test done in the past three years. Younger age groups were significantly more likely to be compliant with the recommendations in 2014 ($P<0.01$) though not in 2016 ($P=0.18$). SPC also had a significant impact on compliance rates in 2016 ($P=0.01$) but not in 2014. Vulnerable women were less likely to be screened at least once in their lifetime; this trend was non-significant in 2014 (98% vs 100% in non-vulnerable, $P=0.14$) but significant in 2016 (89% vs. 97%, $P<0.01$). Vulnerable women were also significantly less likely to be compliant with the recommendations (64% vs 81%, $P<0.01$ in 2014; 63% vs.79%, $P=0.01$ in 2016).

Conclusions: Between 2014 and 2016, participation in CC screening decreased and compliance rates stagnated. Compliance with screening recommendations was negatively affected by the following: unemployment, low SPC or classification among vulnerable populations. Additional analysis will further investigate these findings, which highlight the need for generalized population-based screening programs and targeted actions for non-participants, as advocated earlier this year by the French National Cancer Institute (INCa).

1411P Genetic counseling, screening and risk reducing practices in patients with BRCA mutations

R. Saroufim[1], S. Daouk[2], I. Abou Dalle[2], F. Kreidieh[2], Y. Bidet[3], N. El Saghir[1]

[1]Internal Medicine/Oncology, American University of Beirut, Beirut, Lebanon, [2]Internal Medicine, American University of Beirut, Beirut, Lebanon, [3]Genetics and Molecular Biology, Centre Jean Perrin, Clermont-Ferrand, France

Background: Worldwide practices of genetic counseling remain variable. We present genetic counseling, mammography and MRI screening & risk-reducing surgeries on patients with BRCA mutations & VUS of our BRCA mutations study (El Saghir et al, Oncologist 2015).

Methods: Chart review & phone calls for collection of information were done on 45 pts out of the 250 pts tested. IRB approval obtained. 14 pts (5.6% of total) with deleterious mutations & 31 pts (12.4% of total) with VUS were included. 7 pts had metastatic breast cancer. 4 pts were not reachable. We present results on 33 pts for whom we collected information about genetic counseling, screening, Contralateral Prophylactic Mastectomy (CPM) & Risk Reducing Salpingo-oophorectomy (RRSO).

Results: 14 pts with deleterious mutations (7 BRCA1 & 7 BRCA2 positive pts) & 19 pts with 20 VUS mutations (4 BRCA1 & 16 BRCA2; 1 pt had both BRCA1 & BRCA2) were examined. Of the 14 pts with BRCA deleterious mutations, 57.14% (8/14 pts) said they received some genetic counseling from their own oncologist and not a specialized genetic counselor. 85.71% (12/14) are undergoing regular screening mammography, 35.71% (5/14) are undergoing regular screening breast MRI. 50% (7/14) underwent CPM & 57.14% (8/14) underwent RRSO. Also, 57.14% (8/14) advised their family members, namely sisters & daughters, to undergo BRCA mutation testing. Of the 19 pts with VUS mutations, only 10.5% (2/19 pts) of the pts said they received some genetic counseling. 78.9% (15/19) are undergoing regular screening mammogram, 31.5% (6/19) are undergoing regular screening MRI breasts. 1 pt underwent CPM & 2 pts RRSO. Also, only 21.0% (4/19) advised their family members to undergo BRCA mutation testing.

Conclusions: The majority of pts with BRCA mutations continue to undergo screening mammography & breast MRI. Only 50% of pts with BRCA deleterious mutations underwent CPM & 60% RRSO, while a few pts with VUS mutations underwent CPM & RRSO. Genetic counseling is mostly done by medical oncologists. Our data supports recommendations to include genetic counseling in the training and Continuing Medical Education CME of Oncologists, and to improve patient education. More importantly, there is an urgent need for more certified professional genetic counselors in Lebanon & worldwide.

1413P Gastric cancer detected after Helicobacter pylori eradication at one private screening center in Japan

T. Nakamura, Y. Kon, K. Konuma, T. Sanada, S. Shibata, H. Gonda, Y. Suto, Y. Amagasa, A. Suzuki, M. Fukuda, C. Aoyagi

Health Evaluation and Promotion, Ota Memorial Hospital, Ota, Japan

Background: *Helicobacter pylori* eradication (*Hp*-er) has become widespread in Japan since Japanese public insurance started covering that treatment.

Methods: The data of the esophagogastroduodenoscopy (EGD) screening program from June 2012 through February 2017 at Ota Memorial Hospital (OMH) in Japan was reviewed. All cases of gastric cancer (GC) with *Hp*-er history (*Hp*-er Hx) detected in the EGD screening program were analyzed to reveal their characteristics.

Results: 21,817 individuals were enrolled in EGD screening program of OMH during the above period. 5,563 of them (25.5%) have *Hp*-er Hx. Fifty cases of GC were found in that program (detection rate 0.23%) and 27 of them (54%) have *Hp*-er Hx (detection rate 0.49% in participants with *Hp*-er Hx). The intervals between *Hp*-er and GC detection were ascertained in 19 cases. Median duration is 3 years and the longest interval is 20 years. Anti-*Hp* IgG antibody (*Hp*-Ab) was measured in 26 GC cases with *Hp*-er Hx. Although 6 cases still had 10 or more than 10 U/ml (*Hp*-Ab "positive"), other 20 showed less than 10 U/ml (*Hp*-Ab "negative") and 5 of them revealed less than 3 U/ml. Seventeen cases (63%) of GC with *Hp*-er Hx were the current or former smoker. The median of their Brinkman index is 690. Other 10 cases were non-smoker and 8 of them (80%) had family history of GC although only 23.5% had such a family history among current or former smokers with *Hp*-er Hx. All 27 cases of GC with *Hp*-er Hx suffered from chronic atrophic gastritis (CAG). Twenty-five of them were diagnosed as the open type (or advanced type) CAG. Other two had the closed type CAG but C-3 (nearly advanced atrophy) in Kimura-Takemoto's CAG classification. Although GC lesions were localized at any part of the stomach, all of them were found in atrophic gastric mucosa by EGD. Five of them were diffuse type and other 22 were intestinal type on Lauren's classification in their histopathologic findings.

Conclusions: It is important for individuals with *Hp*-er Hx to take periodic or annual EGD screening to search for GC because more than half cases of GC had *Hp*-er Hx in EGD screening program of OMH. Among them, ones with smoking or family history of GC have high risk. It is necessary for such individuals to have meticulous EGD inspection of the whole stomach, especially the area of atrophic gastric mucosae.

1415P NGS and Sanger screening for BRCA1/BRCA2, CHEK2 and TP53 in Argentinian high-risk breast/ovarian cancer families and bioinformatic studies: Initial results

L. Bruno[1], P. Jablonski[2], M. Ozkul[2], G. Mercado[3], J. Sendoya[4], A. Llera[4], L. Núñez[5], R. Valdez[6], D. Mansilla[7], V. Cólica[8], P. Kalfayan[5], C. Ruggiero[3], M. Reyes[9], R. Cerretini[2]

[1]Departamento de Oncología Clínica, Instituto Alexander Fleming, Ciudad Autónoma de Buenos Aires, Argentina, [2]Departamento de Genética Experimental, Centro Nacional de Genética Médica, Ciudad Autónoma de Buenos Aires, Argentina, [3]Departamento de Genética Clínica, Centro Nacional de Genética Médica, Ciudad Autónoma De Buenos Aires, Argentina, [4]Consorcio Argentino de Tecnología Genómica, Fundación Instituto Leloir, Ciudad Autónoma De Buenos Aires, Argentina, [5]Plan Nacional de Tumores Familiares y Hereditarios, Instituto Nacional del Cáncer, Ciudad Autónoma De Buenos Aires, Argentina, [6]Servicio de Oncología, Hospital Alemán, Ciudad Autónoma De Buenos Aires, Argentina, [7]Departamento de Patología Mamaria, Instituto de Oncología Angel H. Roffo, Ciudad Autónoma De Buenos Aires, Argentina, [8]Servicio de Oncología, Hospital Durand, Ciudad Autónoma de Buenos Aires, Argentina, [9]Jefatura, Centro de Estudios Genéticos, Ciudad Autónoma de Buenos Aires, Argentina

Background: In this study, we aimed at reporting the frequency of BRCA, CHEK2 and TP53 mutations in our high risk breast/ovarian cancer population, in order to determine the role of these genes testing in breast cancer risk assessment.

Methods: Total DNA of 484 unrelated cases and 180 relatives were sequence using either Sanger (564) or NGS (100) for BRCA1/BRCA2, CHEK2 and TP53 mutations. While 64.5% (312/484) of the population studied belong to jewish ethnicity, the remaining patients were european-amerindians.

Results: Of the 484 probands analyzed, 15.9% were BRCA1/BRCA2 mutation carriers, 9.7% in BRCA1, 6% in BRCA2 and one patient was double heterozygous. Overall, 18.9% of the jewish patients presented ashkenazi founder mutations and 9.9% of european-amerindian population was positive for BRCA mutations. The c.66_67delAG was the most frequent alteration, representing 34.2% of all mutations identified. Pathogenic variants in CHEK2 and TP53 genes were present in 4% and 1.1% of our european-amerindian cases. Eighteen pathogenic variants different from ashkenazi panel were identified in BRCA, three were novel and twelve not previously reported in argentinian population. Twenty-seven variants of uncertain significance were found.

Conclusions: An association between genetic ancestry and mutational profile was observed only in the Jewish population. The 66.7% of the pathogenic variants found in our non-jewish cohort were in BRCA2. Our results confirm the high level of admixture present in argentinian population, and highlight the detection of novel variants that could be typical of our region. The knowledge of them is relevant to improve patient risk assessment.

1416P The change in self-perceived characteristics of health and lifestyle due to colorectal cancer screening invitation and attendance

M. Jäntti, S. Heinävaara, N. Malila, T. Sarkeala

Mass Screening, Finnish Cancer Registry, Helsinki, Finland

Background: Previous research implies that colorectal cancer (CRC) screening may have an effect on lifestyle. The aim of the current study was to evaluate the effect of CRC screening on self-perceived health and lifestyle among men and women within a randomized health-services study in Finland.

Methods: A random sample of 31951 Finnish men and women born in 1951 were randomized 1:1 for CRC screening for the first time in 2011. A random third received a questionnaire on lifestyle before and after screening in 2010 and 2012 (n = 10271). The current study population responded to the questionnaire on both years (n = 4895). Self-rated health (SRH), perceived healthiness of diet and perceived physical fitness were assessed with logistic and ordered logistic models using calendar time (2010, 2012), screening randomization and demographic characteristics as covariates.

Results: SRH, healthiness of diet and physical fitness improved over time (OR 1.32, CI 1.17–1.48, OR 1.23, CI 1.08–1.41 and OR 1.44, CI 1.28–1.60, respectively). CRC screening invitation had no effect on these measures compared to controls (OR 0.91, CI 0.74–1.12, OR 0.95, CI 0.75–1.20 and OR 1.09, CI 0.87–1.37, respectively). Women reported better health than men. However, further analysis showed that the attender women reported weaker and the attender men better health than the corresponding control groups.

Conclusions: CRC screening did not have an effect on self-perceived health and lifestyle. However, the difference between men and women both in controls and in CRC screening attendees needs further research. The randomized setting enables us to generalize of the results to the whole screening target population.

1417P Multi-gene panels: new clinical experience in hereditary breast and ovarian cancer

T. Ramon y Cajal[1], A. Lasa[2], G. Llort[3], C. Lopez[1], C. Yagüe[4], M. Cornet[2], A. Gisbert[2], D. Fisas[1], N. Calvo[1], A. Vethencourt[1], A. Barba[1], S. Quero[2], E. Martinez[2], I. Hernan[5], A. Ruiz[6], A. Arcusa[4], E. Saigi[7], A. Barnadas[1], J. Surralles[2]

[1]Medical Oncology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [2]Genetics, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [3]Medical Oncology, Parc Tauli University, Barcelona, Spain, [4]Medical Oncology, Consorci Sanitari Terrassa, Terrassa, Spain, [5]Unitat Genètica Molecular, Hospital Terrassa, Barcelona, Spain, [6]UDIACT-centre diagnostic, Parc Tauli University, Barcelona, Spain, [7]Medical Oncology, Hospital Sabadell, Barcelona, Spain

Background: Mutations in BRCA1 and BRCA2 genes explain about 22% of families meeting testing criteria for hereditary breast/ovary cancer (HBOC). Next-generation sequencing based multi-gene panels allow the analysis of a high number of genes simultaneously with a high sensitivity and are currently integrated into clinical practice.

Methods: A total of 177 women/families with clinical criteria for HBOC underwent genetic testing with a 26-gene commercial panel related to hereditary cancer. The analysis included 150 women with a personal diagnosis of BC/OC meeting national consensus for testing except 7 patients that did not comply these criteria, 6 healthy women at high-risk with ≥1 BC/OC affected first-degree relative and 21 patients with a previous BRCA1/2 negative result by other techniques.

Results: A total of 11 BRCA1/2 mutations were identified three of which were previously undetected by other techniques. Mutations in other high or moderate BC/OC risk genes were found: one new mutation in RAD51D gene, two mutations in CHEK2 gene, one mutation in ATM gene, one mutation in PALB2 gene and two probably pathogenic variants in PALB2 and CHEK2 genes (according to predictors in silico). In addition, 8 variants of uncertain significance were detected. Subsequently, members of any of these 18 HBOC families started presymptomatic genetic diagnosis and prevention strategies.

Conclusions: In contrast to traditional sequential testing, the incorporation of multigene panels in our clinical practice has allowed us to obtain a more efficient genetic diagnosis on a greater number of families. Detecting actionable mutations in either previous BRCA1/2 negative or other HBOC associated families will optimize candidate identification for changes in medical management. The determination of the pathogenicity of frequent variants of uncertain significance in high or moderate penetrance genes remains the main challenge for cancer geneticists.

1418P Clinical features and outcomes of reversible posterior encephalopathy syndrome following bevacizumab treatment

M. Iwamoto, H. Fujioka, K. Kimura, K. Uchiyama, R. Terasawa

Breast Surgery, Osaka Medical College, Osaka, Japan

Background: Reversible posterior leukoenchephalopathy syndrome (RPLS), also known as Posterior reversible encephalopathy syndrome (PRES) is a distinct clinicoradiological entity characterized by a constellation of clinical features, and a potentially devastating complication of bevacizumab treatment.

Methods: Patients were identified from the published literature using 'PubMed' databases using the terms 'bevacizumab' or 'RPLS' and 'RPES' from January 2006 to December 2016, who developed RPLS (RPES) features within 3 weeks of bevacizumab treatment, who had brain imaging findings of focal vasogenic edema and radiologic proof of reversibility.

Results: To date, a total of 22 cases of RPLS (PRES) following the administration of bevacizumab have been reported in the literature. The mean age at presentation of these patients was 50 years (range 34–74 years), 6 of whom were male and 14 female. Headaches ($n = 11$), seizures ($n = 10$), visual disturbances ($n = 9$) and nausea and vomiting ($n = 8$) were the common presenting symptoms. In a majority of patients, an increase in blood pressure from their baseline values was observed during their hospitalization. RPLS occurred in 3 patients who received bevacizumab as monotherapy and the rest had received bevacizumab in combination with other chemotherapeutic agents (oxaliplatin, $n = 8$; fluorouracil, $n = 6$; leucovorin, $n = 5$; gemcitabine, $n = 3$; paclitaxel, $n = 3$; capecitabine, $n = 3$; doxorubicin, $n = 2$; carboplatin, $n = 2$; and irinotecan, $n = 1$). In 20 out of 22 patients, PRES resolved following withdrawal of bevacizumab and strict control of blood pressure. 3 patients also received prednisolone and mannitol as part of their treatment for RPLS. However, 2 out of 22 patients could not recover from severe coma, and died.

Conclusions: A high level of suspicion for RPLS is advisable in patients who develop headache, seizures, visual disturbances, during bevacizumab treatment, either as monotherapy or in combination with other chemotherapeutic agents. These data support the need for close vigilance of neurological features and blood pressure monitoring of patients undergoing bevacizumab treatment. Prompt withdrawal of bevacizumab and blood pressure control appear to portend favorable outcomes in these patients.

1419P Deliberative democracy and cancer screening. The use of citizens' s juries in health policy decision-making

A. Cutillas[1], P. Rosado-Varela[2], V. Luque-Ribelles[3], S. Márquez Calderón[1], E. Benitez-Rodríguez[1], J.M. Ribera-Bautista[1], J.M. Baena-Canada[4]

[1]Medical Oncology, Hospital Puerta del Mar, Cadiz, Spain, [2]Medical Oncology, Hospital Puerto Real, Puerto Real, Spain, [3]Psicología, Universidad de Cádiz, Puerto Real, Spain, [4]Medical Oncology, Puerta del Mar Hospital, Cadiz, Spain

Background: Participants in breast cancer screening programmes may benefit from early detection but may also be exposed to the risks of overdiagnosis and false positives. It is argued that citizens's juries offer important insights into how democratic deliberation could be institutionalised in contemporary political decision making processes. The aim of this deliberative democracy study was to know if Andalucia's Public Health System should offer screening mammography for women aged 50 and 69 years. We selected a citizens's jury to evaluate the reasons for their decision and to know the recommendations for politicians.

Methods: Thirteen women aged 50 and 69 years, who regularly participate in the breast cancer screening programme, agreed to participate as a jury to deliberate of the harms and benefits of this controversial topic. The participants were assembled on three consecutive days. On the first day a neutral expert trained the jury to understand the exposures during the second day of two expert witnesses positioned in favor of and against screening mammography, respectively. The third the jury deliberated, extracted its conclusions, cast its vote and exposed its recommendations for politicians. Transcription

of the text and the qualitative analysis of the information was done with the support of the ATLAS.ti software.

Results: We observed an improvement in the knowledge using analysis quantitative design. The Citizen's Jury voted 11-2. Eleven women voted yes and two did not. Women thanks for it, but there are still ignorance and confusion about breast cancer screening. There are three reasons for voting yes, for their health, for the nature of the test and for their individual freedom. There are women who argue the lack of effectiveness and the cost to justify their negative vote to mammography, at least with a universal character. Women make proposals to policymakers related to improving information, psychological care and research.

Conclusions: Spanish women have a very positive attitude to breast cancer screening although the information transmitted changes the opinion of some women, who want an informed decision making. They bet to maintain or increase the medicalization of their lives.

1420P Genetic landscape in HBOC families from Brazil: A mutational analysis

E. Dos Santos[1], B. Rossi[1], E.M.M. Santos[1], E. Rouleau[2], S.M. Caputo[3], C. Urbeteli de Sa[1], M. F. Sa Ribeiro[1], N.F. Vaz[1], B. Garicochea[1]

[1]Oncology, Hospital Sírio-Libanês, Sao Paulo, Brazil, [2]Département de Biologie et Pathologie Médicales, Gustave Roussy, Villejuif, France, [3]Genetics, Institut Curie, Paris, France

Background: Even if 10% of breast cancers are diagnosed in the context of hereditary predisposition, for a great proportion of families the molecular mechanism of cancer predisposition remains unclear. Founder mutations with increased risk for breast and other cancers have been described in some latin American countries, but the hereditary breast and ovarian cancer (HBOC) mutational landscape remains understudied in this population of highly mixed genetic contributions. Our study aims to evaluate the contribution of germline BRCA1/2 and moderated penetrance genes mutations in the incidence of HBOC brazilian families.

Methods: This is a retrospective analysis of a series of 666 consecutive patients with HBOC syndrome who underwent genetic test between March 2007 and March 2017 in Sirio-Libanes Hospital. Clinical, pathological and sequencing available data on mutations and unclassified variants in high, moderate and low penetrance genes was analysed.

Results: The majority of the patients were tested in the context of multigene NGS pannels (69%), 205 of the patients had only access to *BRCA1/2* full gene screening. A pathogenic mutation was identified in 227 index cases (34%). Unclassified variants (UV) were present in 139 tests (19%). *BRCA1/2* mutations could explain the molecular mechanism of cancer predisposition of 133 cases (20%) while TP53 gene was the second most commonly mutated gene in our cohort (46 patients, 7%). 83% of *TP53* mutation corresponded to the brazilian *TP53* founder mutation R337H (c.1010G>A). Intermediate penetrance genes mutations were present in 22 cases (3,3%): 11 for *PALB2*, 6 for *ATM*, 4 for *CHEK1*, 1 for *BRIP1*. Mismatch repair genes were mutated in 3% of the patients. The index cases were in majority women (98%) diagnosed with breast cancer under 50 years (34%), 68 (10%) of them with bilateral breast tumors.

Table: 1420P

Gene	Pathogenic mutations (n)	UV
BRCA1	90	17
BRCA2	43	39
TP53	46	6
PTEN	0	1
CDH1	0	6
STK11	0	0
PALB2	11	5
ATM	6	13
BRIP1	2	5
CHEK2	4	10
RAD51C	1	3
BARD1	2	3
BAP1	0	3
MLH1	8	7
MSH2	7	6
PMS2	5	6
MSH6	0	11
EPCAM	0	0
BMPR1	0	0

Conclusions: For the majority of the patients the mechanism of predisposition remains unknown. All together BRCA1, BRCA2 and TP53 mutations could explain the predisposition of 27% of the index cases in our cohort.

1421P Recommended cancer screening and vulnerable populations: results from the EDIFICE 5 survey

J-F. Morere[1], F. Eisinger[2], J-Y. Blay[3], S. Couraud[4], L. Brignoli-Guibaudet[5], C. Lhomel[6], A. Cortot[7], L. Greillier[8], J. Viguier[9]

[1]Medical Oncology, Hopital Paul Brousse, Villejuif, France, [2]Aix Marseille Univ, INSERM, SESSTIM, Institute Paoli Calmettes, Marseille, France, [3]Medical Oncology, Centre Leon Berard, Lyon, France, [4]Respiratory Diseases and Thoracic Oncology, Centre Hospitalier Lyon Sud, Pierre Bénite, France, [5]Statistics, Kantarhealth, Paris, France, [6]Medical, Roche - France, Boulogne-Billancourt, France, [7]Pneumology-Oncology, Hospital Albert Calmette, Lille, France, [8]Multidisciplinary Oncology and Therapeutic Innovations, Assistance Publique - Hopitaux de Marseille, Marseille, France, [9]Medical Oncology, CHRU Bretonneau, Tours, France

Background: Based on data from the 2011, 2014 and 2016 EDIFICE surveys, we sought to identify potential links between impoverished living conditions and participation in screening in the context of organized programs (colorectal [CRC], breast [BC] and cervical cancers [CC]).

Methods: The EDIFICE observational phone surveys were conducted among representative population samples (age 40-75 yrs in 2011 [N = 1603] and 2014 [N = 1602]; age 50-75 years in 2016 [N = 1501]) using the quota method. Attitudes regarding screening were assessed in subgroups of individuals within the target age-groups for each screening program. Participation in screening and follow-up rates were assessed by asking if respondents had undergone at least one screening examination in their lifetime and within the recommended time frame (2 yrs for CRC and BC, 3 yrs for CC). Data were analyzed according to the validated EPICES vulnerability score.

Results: For CRC, over the period 2011/2014/2016, participation increased in non-vulnerable subgroups (60% vs. 63%, NS and 63% vs. 68%, $P = 0.05$) as did follow-up rates (34% vs 33%, NS and 33% vs 40%, $P = 0.01$). Participation (60%/54%/53%) and follow-up (31%/30%/31%) were stable among vulnerable individuals. Participation was lower in vulnerable vs. non-vulnerable individuals in 2014 ($P = 0.02$) and 2016 ($P < 0.01$). For BC, participation rates were stable over 2011/2014/2016, in non-vulnerable (97%/98%/98%) and vulnerable individuals (94%/96%/93%), but follow-up rates decreased (87%/85%/79% and 81%/76%/65%, respectively). In 2016, participation and follow-up rates were lower in vulnerable vs. non-vulnerable groups ($P = 0.01$, $P < 0.01$). For CC, participation rates decreased significantly from 2014 to 2016, in non-vulnerable (100%/97%, $P = 0.02$) and vulnerable individuals (98%/89%, $P = 0.02$), and follow-up stabilized (81%/79% and 64%/63%). Participation and follow-up were lower in vulnerable vs. non-vulnerable groups in 2016 ($P < 0.01$, $P = 0.01$).

Conclusions: The 2016 EDIFICE survey confirms the increasing impact of social vulnerability on recommended screening programs, particularly for CRC.

1422O CTCA toxicity scoring and EORTC quality of life questionnaire: A comparison of physicians' and patients' scoring of toxicity in the "Panther trial"

Y. Brandberg[1], S. Loibl[2], T. Foukakis[1], H. Johansson[3], M. Gnant[4], C.F. Singer[5], G. von Minckwitz[2], N-O. Bengtsson[6], E. Karlsson[7], B. Mlineritsch[8], M. Hellström[3], G. Steger[9], L. Carlsson[10], D. Egle[11], R. Greil[12], J. Bergh[1]

[1]Oncology-Pathology, Karolinska Institutet, Stockholm, Sweden, [2]Medicine and Research, German Breast Group (GBG) Forschungs GmbH, Neu-Isenburg, Germany, [3]Department of Oncology, Karolinska University Hosptial, Stockholm, Sweden, [4]Department of Surgery and Comprehensive Cancer Center, Medical University of Vienna, Vienna, Austria, [5]Department of Obstetrics and Gynecology, Medizinische Universitaet Wien (Medical University of Vienna), Vienna, Austria, [6]Department of Oncology, University Hospital, Umeå, Sweden, [7]Oncology Department, Central Hospital Karlstad, Karlstad, Sweden, [8]Universitätsklinik für Innere Medizin III der PMU, UNIKLINIKUM Salzburg, Landeskrankenhaus, Saltzburg, Austria, [9]Department of Internal Medicine I, Medical University of Vienna, Vienna, Austria, [10]Onkologi, LANDSTINGET VÄSTERNORRLAND, Umeå, Sweden, [11]Department of gynecology, Univ. hospital Innsbruck, Innsbruck, Austria, [12]Internal Medicine IV, Landeskrankenhaus Salzburg - Universitätsklinikum der PMU, Salzburg, Austria

Background: A debate on health-related quality of life (HRQoL) by patients' assessment and the assessment of toxicity by physicians in clinical trials is ongoing. The relations between these two assessments is therefore of importance. The aim of this study was to investigate the relations between toxicity items (Common Terminology Criteria for Adverse Events, version 3.0.) and items in the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire (EORTC QLQ-C30).

Methods: Data was collected in a randomised phase 3 trial, comparing dose dense vs standard administration of adjuvant chemotherapy in high-risk breast cancer patients with mostly node positive disease (Foukakis et al., 2016). Data from the assessment at the end of treatment was used. Items from the EORTC QLQ-C30, considered to be associated with CTCAE, were chosen individually by three researchers. Relations based on ordinal data were analysed by Goodman and Kruskal gamma.

Results: A total of 1428 event-free patients were included. Relations between 13 toxicities and 36 EORTC QLQ-C30 items (some with more than one toxicity) were investigated.

Table: 1422O Strong or moderate relation between toxicity and HRQoL item

Toxicity	HRQoL item	Relation
Diahorrea	q17. Have you had diarrhoea	0.53^{S} (0.47 to 0.59)
Vomiting	q15. Have you vomited?	0.50^{S} (0.39 to 0.62)
Fatigue	q10. Did you need to rest?	0.35^{M} (0.28 to 0.41)
	q12. Have you felt weak?	0.35^{M} (0.28 to 0.41)
	q18. Were you tired?	0.41^{M} (0.36 to 0.47)

^{S} = Strong relation (0.50-1.00) ^{M}= Moderate relation (0.30-0.49) There were no or weak relations between all the other toxicities and HRQoL items.

Conclusions: Few relations were found between CTCAE and HRQoL items, indicating that CTCAE does not mirror the total patient experience. Some toxicities, however, are not related to patients scoring of HRQoL and therefore have to be reported by physicians. These findings should raise concerns on how to best evaluate HRQoL/toxicities in clinical trials.

1423P Loneliness and cognitive dysfunction in elderly cancer patients

A. Alkan[1], H. Selvi Öztorun[2], E. Karcı[3], G. Tuncay[4], A. Yaşar[3], E. Çınar[2], Y. Ürün[3], S. Aras[2], M. Varlı[2], F. Çay Şenler[3]

[1]Medical Oncology, Osmaniye Public Hospital, Osmaniye, Turkey, [2]Geriatrics, Ankara University School of Medicine, Ankara, Turkey, [3]Medical Oncology, Ankara University School of Medicine, Ankara, Turkey, [4]Internal Medicine, Ankara University School of Medicine, Ankara, Turkey

Background: The number of geriatric cancer patients is progressively increasing. The evaluation of cognitive functions is important. Loneliness is an emotional experience that results from unmet personal or social requirements. The association between loneliness and cognitive dysfunction has been well documented in elderly patients. However, there is no data in elderly cancer patients. The purpose of this study is to evaluate the association between loneliness and cognitive dysfunction in geriatric cancer patients.

Methods: Patients, more than 65 years of age, in departments of medical oncology and geriatrics were included. Patients were evaluated with structured questionnaires to define sociodemographic and clinical characteristics. In addition, patients were tested with multidimensional Scale of Perceived Social Support (PSC), UCLA loneliness Scale (ULS), standardized mini mental state examination (SMMSE), Clock drawing test and geriatric depression scale (GDS).

Results: 314 elderly patients (214 with a diagnosis of cancer and 120 without cancer) were evaluated. Scores of PSC, ULS, SMMSE were higher in patients without cancer. Median score of GDS in cancer patients was higher than non-cancer patients (4 vs 2, $p < 0.001$). The analysis of ULS and SMMSE showed a negative correlation between

Table: 1423P

Risk Factor	High Loneliness Score		Cognitive Impairment	
	RR(95%CI)	p	RR(95%CI)	p
Presence of depression	1.98(1.0- 3.6)	0.02	2.64(1.3-5.1)	0.004
Low social support	2.01(1.1-3.4)	0.01	1.1(0.5-2.1)	0.75
Educational status- low	3.0(1.3-6.6)	0.007	1.93(0.8-4.4)	0.12
>75 years old	1.46(0.8-2.6)	0.21	1.36(0.6-2.7)	0.36
Female	1.24(0.5-2.6)	0.56	0.88(0.3-2.3)	0.81
High income	1.36(0.7-2.4)	0.27	1.1(0.6-2.2)	0.63
Retired	0.64(0.2-1.4)	0.30	0.54(0.2-1.4)	0.22
Cancer diagnosis	0.93(0.5-1.6)	0.81	1.79(0.8-3.6)	0.11
Live in Rural	1.61(0.7-3.3)	0.20	1.5(0.6-3.3)	0.29
Comorbidity			1.38(0.68-2.8)	0.36
High Loneliness score			1.18(0.6-2.2)	0.61

loneliness and cognitive functions (r= -0.185, p = <0.001). The negative correlation was observed both in cancer patients (r= -0.206, p = 0.001) and non-cancer patients (r= -0.262, p = 0.002). In multivariate analysis; presence of depression, low PSC scores and low educational status were associated with high ULS scores. In the multivariate analysis of factors associated with cognitive dysfunction concluded that depression was associated with increased risk of cognitive dysfunction. (RR: 2.64 (1.3-5.1), 95% CI), p = 0.004) (Table).

Conclusions: In elderly cancer patients, cognitive functions are negatively effected by increased loneliness. However, the association between cancer diagnosis, loneliness and cognitive dysfunction couldn't be demonstrated in multivariate analysis.

1424P The study of emotional distress in oncology patients

K. Kondrateva[1], C. Valentina[1], T. Semiglazova[2], M. Vagaitseva[2], A. Karitskiy[2], E. Pestereva[2], A. Belyaev[2]

[1]Klinikal, Scientific Research Institute of Oncology na N.N. Petrov, Saint-Petersburg, Russian Federation, [2]Innovative Methods of Therapeutic Oncology and Rehabilitation, Scientific Research Institute of Oncology na N.N. Petrov, Saint-Petersburg, Russian Federation

Background: A study of the levels of emotional distress in patients during diagnostics and hospitalization was conducted at Petrov Oncology Scientific Research Institute in 2016. The work presented analyzes the results of the study of emotional distress in oncology patients. Groups of oncology patients, who most acutely require professional psychological aid, have been allocated.

Methods: The study is based on the modified distress self-evaluation method of International Psycho-Oncology Society (IPOS).

Results: 4,113 patients have been studied in total, of them 2,113 at the stage of diagnosis and 2,000 during hospitalization. The percentage of outpatients who report an abnormal anxiety level on the self-evaluation scale is distributed among nosology as follows: breast – 22%, gynecology – 18%, urology – 16%, unspecified diagnosis – 13%, digestive tract – 11%, lungs – 7%, soft tissue and skin tumors – 5%, and bones – 3%. The analysis of the data distribution between in-patient departments has shown that, among the patients reporting abnormal anxiety levels, 21% are hospitalized in the breast tumors department, 16% in the gynecology department, 10% in the head and neck tumors department, 9% in the radiology department, while the chemotherapy, thoracal surgery and urology departments admit 8% each, 6% are in the oncohematological department, and 5% are in the general oncology department during hospitalization.

Conclusions: More than 40% of oncology patients experience abnormal anxiety levels related to the disease, the treatment and related changes in lifestyle. The majority of patients who describe their anxiety as abnormal have breast cancer.

1425P Risk of mood disorders in long-term cancer survivors: A population-based cohort study

W-K. Huang

Department of Internal Medicine, Division of Hematology-Oncology, Chang Gung Memorial Hospital-Linkou, Taoyuan, Taiwan

Background: Evidence regarding whether long term survivors ($\geq$ 5 years) of adult cancers (LSAC) have a higher risk of mood disorders than the general population is not consistent. We aimed to compare the mood disorder rates between the two cohorts and to identify potential risk factors.

Methods: We conducted a retrospective population-based cohort study using the Taiwan National Health Insurance Research Database. We identified LSAC who were newly diagnosed between January 1, 2000 and December 31, 2007. One control was matched per patient for age, sex, index date, and the Charlson comorbidity index (CCI). The primary outcome was diagnosis of mood disorders during the follow-up period. Cumulative incidences and sub-hazard ratios (SHR) were calculated and multivariate analyses were conducted after adjusting for mortality.

Results: We identified 190,748 LSAC and 190,748 controls. The mood disorder risk was significantly higher in the LSAC cohort than in the control cohort (adjusted SHR = 1.16, 95% confidence interval [CI] = 1.13–1.18, P < 0.0001). Patients with certain cancer types were at increased risk, particularly in the first 2 years after diagnosis. However, patients with head and neck cancers or esophageal cancers had a higher risk after the 5-year follow-up period (incidence rate ratio = 1.40, 95% CI = 1.18–1.67; 2.46, 95% CI = 1.29–4.69, respectively). Multivariate analysis indicated that being female, aged 40–59 years, with more than two primary cancers, receiving two or more treatment modalities, having CCI scores higher than 3, a higher urbanization level, and lower monthly income were independently associated with an increased risk of mood disorders.

Conclusions: Long-term cancer survivors have an increased risk of mood disorders and therefore should be followed-up for depresison especially in those with certain site-specific cancer types.

1426P What oncologists should know about the screening of psychological distress: One example of pilot study in Ancona

M. Romeo, R. Giampieri, L. Burattini, M. Di Pietro Paolo, A. Bittoni, S. Rinaldi, M. Torniai, R. Berardi

Clinica Oncologica, AOU Ospedali Riuniti Ancona Università Politecnica delle Marche, Ancona, Italy

Background: Screening for psychological distress is one of the most important steps in Psycho-Oncology research and clinical assistance. In our Institution, before the present study, four studies have been carried out in this area from 2013 to 2016: 441 people were screened and 881 questionnaires were administered.

Methods: The study has been carried out using the following tools: Needs Evaluation Questionnaire (investigates five areas: informative needs, needs related to assistance and care, relational needs, needs for psycho-emotional support, material needs); Beck Depression Inventory II (BDI II), both for caregivers and for patients; Mini Mental Adjustment to Cancer (MiniMac, for the copying style); State-Trait Anger Expression Inventory–2 (for the expression of anger).

Results: From February to April 2017, 78 people have been screened (44 patients and 34 caregivers; Male/female ratio was 29/49; median age was 54 years (range 21-84); 32% of patients showed informative needs, 48% indicated a psychological need, 18% assistance needs. Depression was more present in patients (30%) than in the caregivers (22%) and problems concerning sleep (65%) and fatigue (60%) were more common; only 61% of patients had a fighting spirit while 24% of caregivers showed a high expression of anger. Fischer test showed a correlation between anxious preoccupation (MiniMac) and symptomatic depression (P = 0,000432860); moreover, Helpless-Hopeless copying style was also related (P = 0,005396636) to depression; caregiver's expression of aggressiveness (P = 0,114394682) to patients' anxious preoccupation. The relationship between patients' depression to caregivers' aggressiveness requires further investigation (P = 0,247399740).

Conclusions: Psychological screening can fulfill the following aims: discover expressed needs, coping styles, depression, familiar distress, burden. The results and the correlations underline the importance of managing the patients' anxiety and the expression of the caregivers' aggressiveness and the relationship of such issues with depression. Moreover, informative needs are associated to the most diffused psychological needs.

1427P Biopsychosocial factors underlying older patients treated for an incurable cancer in a two-tiered health care system in Brazil

C.D. Bergerot[1], K.T. Ashing[2], E. Philip[3], P.G. Bergerot[1], N. Dizman[1], S.K. Pal[1], W. Dale[4]

[1]Department of Medical Oncology & Experimental Therapeutics, City of Hope, Duarte, CA, USA, [2]Department of Population Sciences, City of Hope, Duarte, CA, USA, [3]The Notre Dame Laboratory for Psycho-Oncology Research, University of Notre Dame, Notre Dame, IL, USA, [4]Department of Supportive Care Medicine, City of Hope, Duarte, CA, USA

Background: Patients with advanced cancer experience symptoms that include pain, fatigue, and depression. We sought to describe prevalence and identify factors associated with biopsychosocial distress in older patients (65+) diagnosed with cancer stage IV.

Methods: Participants were recruited from two different types of health care facilities, public [PUB] and private [PRI] institutions, in Brazil. A cross-sectional analysis of common biopsychosocial symptoms (anxiety, depression, pain, and fatigue), and quality of life reported by older patients undergoing chemotherapy treatment was performed.

Results: Older patients (n = 167) were enrolled (Mean age=73; SD = 5.6); 59.3% from PUB. Majority were female (56.3%; 38.9% PUB), white (68.9%; 35.7% PRI, p<.01), married (59.3%; 32.1% PUB, p<.01); and diagnosed with GI (29.9%; 15.8% PUB), GU (16.2%; 4.9% PUB), and hematologic (13.8%; 7.5% PRI) cancers. Almost 16% of patients reported depression symptoms (9.6% PUB) and 12% of anxiety (8.4% PUB). PUB patients also reported associated lower QOL, which is at 50th percentile of the US

norm (PRI is at 75th percentile). PUB patients reported significantly more biopsychosocial problems including distress (21.6% vs 7.2%), pain (28.1% vs 12.0%), fatigue (34.7% vs 16.8%), sleep (22.8% vs 15%), neuropathy (22.8% vs 8.4%), and financial toxicity (16.2% vs 5.4%), compared to patients treated at PRI (all $p < 0.05$). Mostly pain (B = 1.8; B=-6.6), fatigue (B = 0.8; B=-6.5) and sleep (B = 1.2; B=-8.3) were associated with moderate to severe distress and worst QOL (all p<.01).

Conclusions: Older patients with late-stage cancer in Brazil suffer substantial unrecognized morbidity which impacts their distress and QOL. Biopsychosocial screening for older patients should be included in quality cancer care. Moreover, patients treated within PUB show worse outcomes than PRI counterparts, and they are at higher risk for multiple physical, psychological, and financial morbidity. Earlier initiation of biopsychosocial screening with appropriate supportive care may improve their QOL.

1428P Family-associated factors influence the postoperative prognosis in patients with non-small cell lung cancer

S. Takamori, G. Toyokawa, H. Ueo, F. Kinoshita, Y. Kozuma, T. Matsubara, N. Haratake, T. Akamine, F. Hirai, T. Tagawa, F. Shoji, T. Okamoto, Y. Maehara

Department of Surgery and Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan

Background: The relationship between family-associated factors and the postoperative prognosis is unknown in patients with non-small cell lung cancer (NSCLC). We hypothesized that family-associated support was associated with postoperative prognosis via nutritional pathway. The aim of this study is to elucidate the relationship between family-associated factors and postoperative prognosis in patients with NSCLC.

Methods: We selected 195 patients with NSCLC who underwent curative surgery between 2005 and 2010 whose computed tomography images within 1 month preoperatively and after 1 year postoperatively were available. The nutritional indices such as prognostic nutritional index (PNI), controlling nutritional status (CONUT), modified Glasgow prognostic score (mGPS) and skeletal muscle area (SMA) were used to estimate the change in nutritional condition after 1 year postoperatively. Paravertebral muscle area at the 12th thoracic vertebra level was used to analyze the SMA.

Results: One hundred and forty-four patients (73.8%) had both children and a partner. Twenty-seven (13.8%) only had children and 14 (7.2%) only had a partner. Childless patients showed a significantly shorter overall survival (OS) and disease-free survival (DFS) than those with children ($p<0.05$ and $p<0.05$, respectively). The postoperative exacerbation of PNI, CONUT, mGPS and SMA were found to be significantly correlated with childless patients compared with those with children ($p=0.002$, $p=0.001$, $p<0.001$ and $p=0.029$, respectively). Childless patients with a partner showed a particularly shorter OS and DFS than those with children ($p<0.001$ and $p<0.001$, respectively). The childless patients with a partner showed significant postoperative exacerbation of PNI, CONUT, mGPS and SMA compared with those with children ($p=0.037$, $p<0.001$, $p<0.001$ and $p=0.039$, respectively).

Conclusions: The patients without any children had a significantly poorer postoperative prognosis than those with children. The childless partner-present patients showed a particularly shorter OS and DFS than those with children. It was suggested that the childless patients were significantly associated with postoperative exacerbation of the nutritional status.

1430P Sexual functioning and quality of life in Egyptian premenopausal patients receiving treatment for breast cancer

H. Elghazaly[1], M. Kelany[1], O. Abdel-Rahman[1], N. Naguib[1], S. Alsirafy[2]

[1]Clinical Oncology, Ain Shams University Faculty of Medicine, Cairo, Egypt, [2]Center of Clinical Oncology & Nuclear Medicine, Kasr Al-Ainy School of Medicine, Cairo University, Cairo, Egypt, Cairo, Egypt

Background: In Egypt, due to cultural reasons, breast cancer patients may suffer in silence struggling with their sexual problems. This is the first study to explore the sexual functioning of Egyptian breast cancer patients receiving anti-cancer treatment.

Methods: The study included 105 married premenopausal patients aged ≤55 years, who underwent surgery and were receiving adjuvant treatment. We used the Arabic validated versions of the EORTC quality of life questionnaire (EORTC QLQ-C30, v 3.0) and the breast cancer module (EORTC QLQ-BR23) to assess quality of life and the female sexual function index (FSFI) to assess sexual functioning.

Results: The median age of patients was 43 years, 11% of them were employed, 81% were literate and 98% were circumcised. The average FSFI score was 16 (±9). The FSFI differed significantly according to systemic treatment ($p = 0.007$). Patients receiving chemotherapy had the lowest score (12 ± 8.5) and those receiving tamoxifen had the highest (18 ± 8.5). The FSFI score did not differ according to the type of surgery ($p = 0.892$). However, the body image scale of EORTC QLQ-BR23 was significantly better among patients who underwent breast conservative surgery compared to modified radical mastectomy ($p = 0.004$). There was a significant positive correlation between the FSFI score and the scores of global health status ($p < 0.001$), physical functioning ($p = 0.002$), role functioning ($p < 0.001$), emotional functioning ($p = 0.004$), social functioning ($p = 0.041$) scales of EORTC QLQ-C30 and body image ($p < 0.001$) and future prospective ($p < 0.001$) scales of EORTC QLQ-BR23. There was a significant negative correlation between the FSFI score and scores of fatigue ($p = 0.001$), pain ($p = 0.006$) and appetite loss ($p = 0.028$) scales/items of EORTC QLQ-C30 and systemic therapy side effects ($p = 0.003$) scale of EORTC QLQ-BR23.

Conclusions: The current results suggest that Egyptian breast cancer patients receiving chemotherapy experience significant sexual dysfunction. The type of surgery has no direct effect on sexual functioning, but may affect it indirectly through its impact on body image satisfaction. Overall, sexual dysfunction is strongly related to the quality of life in this group of patients.

1431P Primary results of a study to evaluate a decision aid for women offered neoadjuvant systemic therapy for breast cancer

N. Zdenkowski[1], P. Butow[2], A.J. Spillane[3], C. Douglas[4], C. Beckmore[5], M. Jones[6], F.M. Boyle[3]

[1]Medical Oncology, Calvary Mater Hospital Newcastle, Newcastle, Australia, [2]Psychology, University of Sydney, Sydney, Australia, [3]Medicine, University of Sydney, Sydney, Australia, [4]Medicine, University of Newcastle, Newcastle, Australia, [5]Trials Coordination, Australia and New Zealand Breast Cancer Trials Group, Newcastle, Australia, [6]Clinical Research and Statistical Support Unit, Hunter Medical Research Institute, Newcastle, Australia

Background: Women diagnosed with large or highly proliferative operable breast cancer may be offered neoadjuvant systemic therapy (NAST) for reasons including downstaging, prognostication or expanding surgical options. We aimed to systematically develop, and evaluate a DA for women who had been offered NAST.

Methods: Eligible women who were considered candidates for NAST, from four Australian recruiting centres were enrolled in a single arm longitudinal study. Participants completed online questionnaires prior to accessing the DA, and on three occasions post-DA. Primary outcomes were feasibility of use, and acceptability to patients and clinicians. Secondary outcomes were patient reported measures relevant to patient decision-making.

Results: Seventy-nine women were offered study participation and 59 enrolled. Patients were typically well educated, married, had health insurance and were information seekers (mean information needs: 7.5/10; SD 1.84). 59/79 (74.7%) patients who were offered study participation accessed the DA and 49 (79.7%) of those 59 participants reported having read it. 41/51 (80.4%) participants who completed the post-DA assessment reported that the DA helped them with their decision about NAST. 51/59 (86%) participants elected to receive NAST. 16/18 (88.9%) investigators would continue to use the DA in routine practice. Post-DA, decisional conflict decreased significantly across all subscales ($p < 0.01$); anxiety and distress decreased significantly; 86.3% achieved at least as much decisional control as they desired; a high level of knowledge was demonstrated; and 39/51 (76.5%) patients had a high (≥24) Satisfaction with Decision score (mean 25.5, SD 3.6). 84.4% reported that they shared responsibility for the decision about NAST. Investigators reported that the DA was able to be integrated into patient care.

Conclusions: Study primary outcomes were positive, showing the DA was feasible and acceptable to patients and clinicians. Improvements in decision-related outcomes were demonstrated, and the DA could be included in routine workflow. This DA can be implemented into routine clinical practice for women with operable breast cancer who are candidates for NAST.

1433P Burnout syndrome: What impact on clinical research?

C. Cagnazzo[1], S. Campora[2], S. Pirondi[3], A. Guarrera[4], A. Nuzzo[5], G. Gentili[6], C. Taverniti[7], M. Manuela[6], R. Filippi[8]

[1]Gruppo Italiano Data Manager (GIDM), Meldola, Italy, [2]ICON plc, Milan, Italy, [3]Ospedale di Sassuolo, Sassuolo, Italy, [4]AOU Careggi, Florence, Italy, [5]Clinical Research Office, IRCCS Istituto di Candiolo, Candiolo, Italy, [6]Unità di Biostatistica e Sperimentazioni Cliniche, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (I.R.S.T.), Meldola, Italy, [7]Medical Oncology, AOU Citta della Salute e della Scienza di Torino, Turin, Italy, [8]Medical Oncology, IRCCS Istituto di Candiolo, Candiolo, Italy

Background: Burnout is a job-related psychological syndrome causing depersonalization, emotional exhaustion and lack of personal accomplishment. Albeit studies mainly focus on professionals who have a direct contact with patients, physicians and nurses, little is known about burnout among other professionals employed in clinical research, that requires stressful efforts to maintain quality standards. We decided to evaluate perceived and actual burnout levels experienced by professionals who are at the "bottleneck" of research: Clinical Research Coordinators (CRCs).

Methods: The Gruppo Italiano Data Manager spread an anonymous questionnaire among about 130 CRCs. The survey consisted of 8 items on workload and perceived stress levels and a specific burnout test developed by a group of Italian psychologists.

Results: The survey was completed by 36% of subjects. On average, interviewed CRCs work 42 hours/week and follow 25 studies; 89% feel stressed and 64% believe that this affects negatively the quality of their work. Moreover, 57% of CRCs declare that this condition may soon cause a job change. The major sources of stress are: contract type (43%); workload (17%); lack of skills recognition (11%). Interestingly, the factor that most frequently has been identified among the first 3 causes of stress is the contract type (81%), followed by lack of skills recognition (32%). Based on the psychological test, the average stress level of the sample is 68 points out of overall 225; the highest levels pertain the emotional (average: 17.0/45) and physical spheres (16.3/45), while the social area is the least affected (9.7/45). Stress levels show only a very weak correlation with workload (Pearson coefficient = 0.062) and hours worked (0.095).

Conclusions: Albeit almost all CRCs perceive high levels of stress, psychological testing shows a medium-low degree of burnout. An explanation could be that CRCs are settled into distressing work conditions, so this no longer results in burnout. Burnout was substantially uncorrelated to quantitative estimates of workload, rather depending on other, qualitative, factors, such as lack of skills recognition and contractual instability. Lastly, our data suggest that current workload evaluation methods, mainly based on the number of followed studies, are no longer appropriate.

1434TiP Effectiveness of the HuCare Quality Improvement Strategy on health-related quality of life in patients with cancer: Study protocol of a stepped wedge cluster randomized controlled trial (HuCare2 study)

R. Passalacqua[1], C. Caminiti[2], E. Iezzi[2]

[1]Oncology, Istituti Ospitalieri di Cremona, Cremona, Italy, [2]Research and Innovation Unit, University Hospital of Parma, Parma, Italy

Background: Our group previously demonstrated the feasibility of the Hucare Quality Improvement Strategy – HQIS, aimed at integrating into practice 6 psychosocial interventions recommended by international guidelines. This trial will assess whether the introduction of the strategy in oncology wards improves patient Health-related quality of life (HRQoL).

Trial design: Multicenter, incomplete stepped-wedge cluster randomized controlled trial, conducted in three clusters of 5 centers each, in three equally spaced time epochs. The study also includes an initial epoch when none of the centers is exposed to the intervention, and a final epoch when all centers will have implemented the strategy. The intervention is applied at a cluster level, and assessed at an individual level with cross-sectional model. 720 patients who received a cancer diagnosis in the previous 2 months and about to start medical treatment will be enrolled. Primary aim is to evaluate the effectiveness of the HQIS vs standard care in terms of improvement of at least one of two domains (emotional and social functions) of HRQoL using the EORTC QLQ-C30 questionnaire, at baseline and at 3 months. This outcome was chosen because cancer patients generally exhibit low HRQoL, particularly at certain stages of care, and because it allows to assess the strategy's impact as perceived by patients themselves. The HQIS comprises three phases: 1) clinician training - to improve communication-relational skills and instruct on the project; 2) center support – 4 on site visits by experts of the project team, aimed to boost motivation, help with context analysis and identification of solutions; 3) implementation of EBM recommendations at the center.

1440PD The European Cancer Patient Coalition's white policy paper on the value of innovation in oncology

L. Makaroff[1], F. De Lorenzo[2], K. Apostolidis[1], J. Pelouchova[3], A. Winterbottom[1], S. Chrostowski[4], D. Cimpoeru[1], N. Bolanos Fernandez[5], A. Rek[1], I. Manneh-Vangramberen[1], L. Baker[6], F. Florindi[1]

[1]European Cancer Patient Coalition (ECPC), Brussels, Belgium, [2]F.A.V.O. - Federazione Italiana delle Associazioni di Volontariato in Oncologia, Rome, Italy, [3]General Faculty Hospital, VFN Charles University, Prague, Czech Republic, [4]Let's Win Health Foundation, Warsaw, Poland, [5]GEPAC, Madrid, Spain, [6]Public Affairs, Interel, Brussels, Belgium

Background: Each year, over 3 million Europeans are diagnosed with cancer, and over 1 million Europeans die from the disease. With a growing and ageing population, action is urgently needed to address this major global health and societal concern. Action is needed to help policy-makers understand how they can improve access to innovative cancer care and treatment. Aim: To produce a policy white paper that summarised the major recommendations to improve access to innovative cancer care and treatment for Europeans diagnosed with cancer.

Methods: The European Cancer Patient Coalition developed the white paper over a one-year period, in collaboration with Interel Public Affairs, oncology experts, and the patient organisations that form the membership of the European Cancer Patient Coalition.

Results: The "Value of Innovation in Oncology" white paper presented the position of the European Cancer Patient Coalition on innovation in oncology, and offered recommendations to help reduce variations in access to innovation and to involve patients in decision-making. It summarised the European Cancer Patient Coalition's stance on topics related to innovation in oncology, with the overarching goal to shrink international variations in the time to patients' access to innovation in oncology, while, at the same time, it considered the sustainability of health systems and how to ensure innovation is celebrated and accessed appropriately. Finally, the paper focused on recommendations to increase the involvement of patients in key aspects of innovation, including assessment and access.

Conclusions: More work is needed at the European and national level to improve the access of Europeans with cancer to innovative treatment and care and to ensure that people with cancer are actively involved in decisions throughout the care pathway.

1441PD Magnitude of clinical benefit of randomized controlled trials supporting US Food and Drug Administration approval of drugs for solid tumours

C. Molto Valiente[1], E. Amir[2], A. Ocana Fernandez[3], A. Templeton[4], L. del Carpio Huerta[1], J. Del Paggio[5], A. Barnadas[1], C. Booth[6], A. Tibau[1]

[1]Oncology Department, Hospital de la Santa Creu i Sant Pau and Universitat Autònoma de Barcelona, Barcelona, Spain, [2]Department of Medical Oncology and Hematology, Princess Margaret Cancer Centre and the University of Toronto, Toronto, ON, Canada, [3]Medical Oncology Department and Translational Research Unit, Albacete University Hospital, Albacete, Spain, [4]Department of Medical Oncology, St Claraspital and Faculty of Medicine, University of Basel, Basel, Switzerland, [5]Division of Cancer Care and Epidemiology, Queen's University Cancer Research Institute, Kingston, ON, Canada, [6]Departments of Oncology and Public Health Sciences, Queen's University Cancer Research Institute, Kingston, ON, Canada

Background: The European Society for Medical Oncology Magnitude of Clinical Benefit Scale (ESMO-MCBS) is a validated and reproducible tool to assess the magnitude of clinical benefit from drugs for solid tumors. Here, we evaluate characteristics and outcomes of clinical trials supporting approval by the FDA and their association with ESMO-MCBS.

Methods: We searched the Drugs@FDA website for applications of anticancer drugs from January 2006 to December 2016. Drug labels and reports of registration trials were reviewed and study characteristics, efficacy, toxicity and quality of life outcomes as well as regulatory pathways were collected. For randomized controlled trials (RCTs) ESMO-MCBS grades were applied. Meaningful clinical benefit was defined as a grade of A or B for trials of neo/adjuvant intent and 4 or 5 for those of palliative intent. Comparisons between groups were assessed using Logistic regression and the Mann Whitney U test.

Results: We identified 137 studies; 109 (80%) of which were RCTs. These led to the approval of 63 individual drugs for 118 licensed indications. Among the 105 RCTs for which the ESMO-MCBS could be applied, 7 (6%) were in the neo/adjuvant setting and 98 (94%) in the palliative setting. Only 46 (44%) met the ESMO-MCBS clinically meaningful benefit threshold (100% of neo/adjuvant trials and 41% of palliative trials). In multivariable analysis of palliative therapy trials, meaningful ESMO-MCBS grades were associated with phase III trials (compared to phase II; OR 38.45, $P = 0.004$), those with overall survival as their primary endpoint (compared to intermediate endpoints; OR 8.28, $P = 0.001$) and trials of targeted drugs with companion diagnostics (OR 11.62, $P < 0.001$). Over time, there has been an increase in the number of trials meeting the ESMO-MCBS threshold (33% in 2006 vs. 67% in 2016, P for trend = 0.04). There was an insufficient number of neo/adjuvant studies to perform statistical analysis.

Conclusions: In patients with advanced solid tumours, fewer than half of RCTs supporting FDA approval meet the threshold for clinically meaningful benefit using validated scales.

1442PD Review on adherence to breast cancer guidelines in Europe

L. Neamtiu[1], L. Pylkkanen[1], C. Freeman[2], Z. Saz Parkinson[1], S. Deandrea[1], A. Uluturk Tekin[1], N. Dimitrova[1], D. Lerda[1]

[1]Health in Society, JRC Joint Research Center - European Commision, Ispra, Italy, [2]Barcelona, Spain

Background: Morbidity and mortality from breast cancer in Europe, as well as costs associated with the disease, remain high. Patients treated according to existing guidelines have better survival. The European Commission Initiative on Breast Cancer (ECIBC) aims to improve quality of care by developing evidence-based breast cancer guidelines and supporting their implementation via a quality assurance scheme for breast cancer services. The goal of this study is to give an overview on compliance with breast cancer guidelines in Europe.

Methods: Studies assessing adherence to guidelines on breast cancer screening, diagnosis, treatment and follow-up were searched via Pubmed. Studies published between 1990 and 2016 were included.

Results: In total, 127 studies (mainly observational, retrospective, prospective, and cross sectional) were analysed. The number of participants varied from 56 to 72 000—with studies based on cancer registry data typically including more than 10 000 patients. Overall, adherence to guidelines was variable. Regarding treatment, (e.g. chemotherapy) adherence ranged from 70% to 96% and was approximately 50% for follow-up. Additional or 'unnecessary' procedures were cited as the main causes of non-compliance to follow-up. On the other hand, adherence with respect to radiotherapy (e.g. compliance with technical guidelines) and some safety-related aspects (e.g. cardiac monitoring during adjuvant trastuzumab therapy and prophylaxis with colony-stimulating factors) was substantially lower. Elderly patients were treated less frequently according to existing guidelines. Professionals with less experience (i.e. < 8 years) complied better with guidelines. Use of computerised decision support systems (CDSS) and implementation of a multidisciplinary breast cancer pathway led to better compliance.

Conclusions: In Europe, adherence to guidelines is variable. Implementation of guidelines can help decrease variability in clinical practice, and improve treatment effectiveness and patient safety. Fortunately, adherence can be monitored through the use of quality assurance schemes (e.g., the ECIBC). Incorporating a CDSS within the clinical workflow could reduce the workload of physicians and thus increase their compliance with guidelines.

1443PD Analysis of compliance factors for colorectal cancer screening using a Bayesian network

F. Eisinger[1], J. Viguier[2], J-Y. Blay[3], A. Cortot[4], C. Touboul[5], C. Lhomel[6], L. Greillier[7], S. Couraud[8], J-F. Morere[9]

[1]Aix Marseille University, INSERM, SESSTIM, Institute Paoli Calmettes, Marseille, France, [2]Medical Oncology, CHRU Bretonneau, Tours, France, [3]Medical Oncology, Centre Leon Berard, Lyon, France, [4]Pneumology-Oncology, Hospital Albert Calmette, Lille, France, [5]Statistics, Kantarhealth, Paris, France, [6]Medical, Roche - France, Boulogne-Billancourt, France, [7]Multidisciplinary Oncology and Therapeutic Innovations, Assistance Publique - Hopitaux de Marseille, Marseille, France, [8]Respiratory Diseases and Thoracic Oncology, Centre Hospitalier Lyon Sud, Pierre Bénite, France, [9]Medical Oncology, Hopital Paul Brousse, Villejuif, France

Background: Compared to standard explanatory analyses based on multivariate regressions, Bayesian network analyses enable multiple hypotheses and clear graphical representations of complex interactions. They provide visual descriptions of causal pathways to distinguish between direct/indirect factors. We compared multivariate regression and a Bayesian network to assess factors associated with colorectal cancer (CRC) screening.

Methods: The 5th French observational survey, EDIFICE 5, was conducted (Nov 22-Dec 7, 2016) by phone interviews of a representative sample of 1501 individuals (age, 50-75 y). The present analysis focuses on 1299 individuals with no history of cancer (50-74 y). Bayesian analysis was performed with the bnlearn R Package. Parameters of the Bayesian analysis were based on the literature and our own data (logistic regression). "Blacklist/whitelist"-type restrictions were used to reset current understanding of the correlations between variables. We also analyzed the network topology.

Results: In our sample, 36% (N = 469) declared never having undergone CRC screening (colonoscopy, fecal occult blood test) in their lifetime. The Bayesian model revealed 5 direct correlating factors: age, smoking status, social vulnerability, psychological reassurance in the screening test (PRST), and confidence in the efficacy of the test. The latter 2 account for 43% of the observed sum of the mutual informations. Other relevant factors typically seen in the literature and regression analysis had an indirect impact: level of education, self-perception of own risk of CRC, gender, temporal perspective, confidence in their physician and fear of the disease. Multiple regression analysis identified PRST (OR = 0.84, 95% CI 0.80-0.88, $P < 0.01$) and fear of the disease (OR = 0.90, 95% CI 0.84-0.96, $P < 0.01$) as the two main criteria.

Conclusions: We showed that Bayesian network analysis provides a novel representation of factors associated with CRC screening, and may explain why interventions focusing on indirect factors might be ineffective if the next step of the causal pathway remains unchanged. We suggest that Bayesian networks should be used more often to drive timely interventions (short term vs long term).

1444PD Cancer Clinical Practice Guidelines: Evaluation of ESMO, NICE and SIGN diversity

E. Pallari[1], A. Fox[2], G. Lewison[3]

[1]Health Service and Population Research, King's College London, London, UK, [2]Pharmaceutical Medicine, King's College London, London, UK, [3]Division of Cancer Studies, King's College London, London, UK

Background: This research study is on the critical appraisal of the impact of cited research evidence underpinning the development of cancer clinical practice guidelines (CCPGs) by the professional bodies of the European Society for Medical Oncology (ESMO), the National Institute for Health and Care Excellence (NICE) and the Scottish Intercollegiate Guidelines Network (SIGN).

Methods: A total of 101 CCPGs were identified from ESMO, NICE and SIGN websites across 13 cancer sites. Their 9,486 cited references were downloaded from the Web of Science© Clarivate Group database and analysed on Excel© (2016) using VBA macros.

Results: ESMO CCPGs mostly cited research from Western Europe while the NICE and SIGN ones from the UK, Canada, Australia and Scandinavian countries. The ESMO CCPGs cited more recent and basic research (e.g. genetics), in comparison to NICE and SIGN CCPGs where older and more clinical research (e.g. drugs treatment) papers were referenced. This chronological difference in the evidence-base is also in line with that ESMO has a shorter gap between the publication of the research and its citation on the CCPGs. It was demonstrated that ESMO CCPGs report more chemotherapy research while the NICE and SIGN more surgery, with the results being statistically significant. Also, breast cancer research was explored individually across the analysed evidence-base, with a similar pattern to overall oncology CCPGs. Additionally, the volume of breast cancer research cited by ESMO was slightly higher than the fraction of the oncology population suffering from breast cancer in Europe; for the NICE and SIGN the citation percentage was twice as much as the UK disease burden, indicating a potential preference on breast cancer among other oncology types.

Conclusions: This study showed that ESMO, NICE & SIGN differ in their evidence-base. Healthcare professionals should be aware of this heterogeneity in effective decision-making of tailored-treatments to patients irrespective of geographic location across Europe. Considering the potential of the United Kingdom exiting the European Union, a closer collaboration between these professional bodies can lead to the use of more evidence-based, relevant and updated clinical practice guidelines.

1445P Inclusion of older patients with colorectal cancer in clinical trials: the SAGE prospective multicenter cohort study

F. Canouï-Poitrine[1], A. Lievre[2], F. Dayde[1], D. Lopez-Trabada-Ataz[3], I. Baumgartner[4], O. Dubreuil[3], F. Brunetti[5], T. Aparicio[6], R. Coriat[7], K. Maley[8], O. Colussi[9], C. Tournigand[10], E. Paillaud[11], S. Bastuji-Garin[1]

[1]Public Health, Centre Hospitalier Universitaire Henri-Mondor, Créteil, France, [2]Service Gastro-Entérologie, CHU Rennes, Rennes, France, [3]Service d'Oncologie Médicale, APHP, Paris, France, [4]Medical Oncology, Centre hospitalier Universitaire Henri-Mondor, Créteil, France, [5]Department of Digestive Surgery, CHU Henri Mondor, Créteil, France, [6]Gastroenterology, Saint Louis Hospital, Paris, France, [7]Gastroenterology and digestive oncology, Hôpital Cochin, Paris, France, [8]Service de Geriatrie, APHP, Paris, France, [9]Service Gastro-Entérologie, APHP, Paris, France, [10]Medical Oncology, CHU Henri Mondor, Creteil, France, [11]Geriatrics, Centre hospitalier Universitaire Henri-Mondor, Créteil, France

Background: Whereas older patients represent the major part of new cancer cases, their underrepresentation in clinical trials leads to weak external validity. The main objective was to assess the proportions of older patients for whom there is an ongoing clinical trial available, eligible to at least one trial, invited to participate and finally included. Secondary objective was to investigate associated factors.

Methods: The SAGE multicenter prospective cohort study settled up in 7 centers in Paris Area between 2013 and 2016. All patients aged 65 years or more with a colorectal cancer were included. The endpoints were 1) the presence of at least one ongoing clinical trial available regarding stage and tumor location 2) the patient's eligibility 3) invitation and 4) inclusion.

Results: 577 patients (mean age: 75.6 years +/-7; 56% of men; 74% of colon tumor; 40.9% with metastasis) were included; 37 trials were ongoing (9 trials in median per center; academic sponsors: 62.2%; phaseI/II: 59.5%; chemotherapy: 75.7%). Overall, 12.3% of patients were included in a trial (65-69 yrs class: 19.1%; 70-75 yrs: 14.9%; 75-79 yrs: 12.8%; 80 yrs or more: 2.6%; $p < 0.001$). 18% (103/577) had none available trial for his/her stage and tumor location; among patients with available trial, 73% (347/577) were non-eligible; from the remaining, 34% (43/127) were not invited; from the remaining, 19%(17/88) refused to participate. Non-eligibility was, by order of frequency, related to tumor characteristics (31%), requested para-clinical exams (19%), history of anti-cancer treatment (15%), comorbidities (13.5%), functional status (10%) and age (5%). Among eligible patients, increased age, Performans Status and decreased Body Mass Index were independently associated with non-invitation (Table). Among patients invited to participate, patient's refusal was not associated with age.

Table: 1445P Factors independently associated with non-invitation to clinical trials in older eligible patients

Variables	Adjusted Odds Ratio (95%CI)*	P
Age, years 65-60	Reference (1.00)	0.01
70-75	0.26 (0.07-0.90)	
75-80	0.23 (0.06-0.96)	
> 80	0.05 (0.01-0.29)	
PS 0	Reference (1.00)	0.02
1	0.19 (0.06-0.62)	
≥ 2	0.50 (0.09-2.75)	
Body Mass Index, kg/m^2 21-24.9	Reference (1.00)	0.09
< 21	0.25 (0.07-0.90)	
≥25	0.76 (0.24-2.42)	

*Hierarchical multivariate logistic regression with the patient at the level 1 and the center at the level 2 and adjustment for all variables listed in the table, the number of trials in the center and the number of chemotherapy trials.

Conclusions: Inclusion of older cancer patients decreased dramatically after 80 years. Non-eligibility was the main reason for non-inclusion but rarely related to chronological age. Moreover, one-third are non-invited to participate and one-fifth refused.

Clinical trial identification: NCT01754636

1446P Risk of second primary cancers and competing mortality in survivors of adult-onset cancer: changing pattern over three decades

Y. Ye, P. Otahal, K. Wills, A. Neil, A. Venn

Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia

Background: Survivors of first adult-onset cancers are at risk of developing second primary cancers (SPCs) and are at risk of death from their subsequent cancers and other competing causes. Here we investigated patterns of incident SPC risk and cause-specific mortality in survivors of adult-onset cancer during the past three decades.

Methods: Data were extracted from the population-based Tasmanian Cancer Registry in Australia. Patients diagnosed with a first primary cancer between 1980 and 2009 were followed for incident SPCs to December 31, 2013 and for deaths to December 31, 2014. SPC risks were quantified by using standardised incidence ratios (SIRs). Trends in SPC risk over time were assessed in multivariable Poisson models. The cumulative incidence and subdistribution hazard ratios (SHR) of cause-specific deaths were estimated using competing risk models.

Results: 5,339 SPCs were observed from 51,802 cancer survivors. The SIRs for any SPC increased from 0.98 with a first cancer diagnosis in 1980-1984 to 1.12 in 2005-2009. The increase in SIRs was significant in multivariable Poisson models (Ptrend$<$ 0.001). Deaths were identified in 39,976 (69.8%) of 57,288 patients. The 5-year cumulative incidence of death due to first primary cancer gradually decreased from 57.2% for a first cancer diagnosis in 1980-1984 to 30.7% in 2005-2009. However, the 5-year cumulative incidence of deaths due to subsequent cancers varied across periods of first cancer diagnosis, with an increase from 1.0% in 1980-1984 to 1.7% in 1995-1999, and a decrease to 1.4% in 2005-2009. The SHR of deaths due to first primary gradually decreased over time in multivariable competing risk models, but varied over time for deaths due to subsequent cancers: the SHR increased from 1.00 (reference) in 1980-1984 to 1.19 (95%CI 1.03-1.36) in 1995-1999, then decreased to 0.80 (95%CI 0.69-0.94) in 2005-2009.

Conclusions: The risk of SPC has increased in Tasmania over the last three decades. While the risk of death due to first primary cancer decreased over time, the risk of death due to subsequent cancers did not. The increased risk of deaths from subsequent cancers might be an outcome of overdiagnosis of first primary cancer in the 1990s.

1447P Reporting of results of randomized trials in common cancers in the lay media

D. Ribnikar[1], H. Goldvaser[1], A. Ocana Fernandez[2], A. Templeton[3], B. Seruga[4], E. Amir[1]

[1]Division of Medical Oncology and Hematology, Princess Margaret Cancer Center, Toronto, ON, Canada, [2]Research Unit, Albacete University Hospital, Albacete, Spain, [3]Department of Oncology, St. Claraspital Basel, Basel, Switzerland, [4]Department of Medical Oncology, Institute of Oncology Ljubljana, Ljubljana, Slovenia

Background: Limited data exist about the role of the lay media (including the financial press) in the dissemination of results of randomized controlled trials (RCTs) in common cancers.

Methods: We searched clinicaltrials.gov to identify phase III RCTs evaluating new drugs in breast, colorectal, lung and prostate cancer. We included all completed and active trials that have completed accrual between 1 January 2005 and 31 October 2016. Reporting of trials in the lay media was identified by a systematic search of Lexis-Nexis Academic using the name of the drug and trial. Scientific reporting was defined as presentation at a conference or publication in full in the scientific literature. Associations between reporting in the lay media before scientific reporting and study design, results and sponsorship were evaluated using logistic regression.

Results: Of the 180 RCTs identified, 55% were positive, 79% were performed with palliative intent and 79% evaluated targeted therapies (including endocrine and immunotherapy). We identified 93 (52%) reports in the lay media (66% of positive trials and 38% of negative trials). In 49 cases (27%) reporting in the lay media occurred before scientific reporting with an increasing trend over time ($p = 0.009$). Among these, 53% presented quantitative data. The median time between lay media reporting and scientific reporting was 16 weeks (range 1-220 weeks). Reporting in the lay media before scientific reporting was associated with positive results (OR 3.12, $p < 0.001$), industry compared to academic sponsorship (OR 3.20, $p = 0.04$), palliative intent (OR 2.84, $p = 0.04$), journal impact factor of full publication (OR 1.02, $p = 0.03$), evaluation of targeted therapy compared to chemotherapy (OR 3.70, $p = 0.05$) and prostate cancer compared to breast cancer (OR 4.86, $p = 0.003$). There was no association between early reporting in the lay media and study endpoint, or quantitative reporting.

Conclusions: Over a quarter of all RCTs in common cancers are reported in the lay media before they are reported scientifically. Positive trials, industry sponsorship, palliative intent, journal impact factor and evaluation of new targeted therapy, especially in prostate cancer are associated with early reporting in the lay media.

1448P Effect of rural residence (RD) and distance travel to the cancer center (DTC) on neoadjuvant chemoradiation (NCRT) in localized rectal cancer

A. Suo[1], A. Talat[2], D. Le[3], N. Iqbal[2], S.C. Kanthan[4], S. Ahmed[2,5]

[1]Oncology, University of Calgary, Calgary, AB, CA, [2]Medicine, University of Saskatchewan, Saskatoon, SK, CA, [3]Oncology, Saskatchewan Cancer Agency, Saskatoon Cancer Center, University of Saskatchewan, Saskatoon, CA, [4]Surgery, University of Saskatchewan, Saskatoon, SK, CA, [5]Oncology, Tom Baker Cancer Center, Calgary, AB, CA

Background: Neoadjuvant chemoradiation therapy (NCRT) has been associated with a lower rate of local recurrence and represents an accepted standard of care. Yet, access to treatment or decisions about treatment can be affected by contextual factors such as rural residence (RD) and distance travel to cancer center (DTC). In the current study, we evaluated relationship between RD and DTC and NCRT.

Methods: A cohort of patients diagnosed with localized rectal cancer during 2009-2013 in the province of Saskatchewan was studied. The logistic regression analyses were performed to assess relationship between RD and DTC and lack of NCRT.

Results: Total 279 patients were identified with median age of 66 yrs (IQR:59-76) and M:F of 1:0.71. 94 (33.6) had a major comorbid illness. 183 (65%) were rural resident. The median DTC was 141 km (IQR 7-233). Of 279 patients, 116 (41%) were referred for NCRT, 161 (58%) underwent upfront surgery, and 2 declined surgery. The mean DTC for group treated with NCRT was 111.5 $\pm$122km compared with 169.0$\pm$176km if they did not receive NCRT ($p = 0.001$). Of urban resident, 52/96 (54%) were referred for NCRT compared with 64/183 (35%) of rural resident ($p = 0.002$). After excluding 33 (12%) patients who had clinical stage I disease and underwent upfront surgery, a univariate regression analysis revealed that both DTC (OR 1.92, 95% CI: 1.15-3.20) and RD (OR 2.51, 95%CI: 1.46-4.32) were significantly correlated with lack of NCRT. On multivariate analysis following relationships were noted with lack of NCRT. Age $\geq$ 70 yrs (OR 1.45, 95%CI: 0.84-2.45), comorbid illness (OR 1.52, 0.86-2.67), ECOG performance status of $>$ 1 (OR 1.25, 0.49-3.17), DTC (OR 1.07, 0.51-2.23), and RD (OR 2.56, 1.17-5.57).

Conclusions: Our results revealed that RD but not DTC is associated with a lower rate of NCRT in patients with localized rectal cancer. Future studies are required to explore the underlying cause of differential referral.

1450P European survey of 907 people with cancer about the importance of nutrition

M. Muscaritoli[1], A. Molfino[1], F. Scala[2], F. De Lorenzo[3], K. Christoforidi[4], I. Manneh-Vangramberen[4]

[1]Internal Medicine, Sapienza University of Rome, Rome, Italy, [2]Strategy, Healthware, Salerno, Italy, [3]ECPC Board, European Cancer Patient Coalition (ECPC), Brussels, Belgium, [4]Projects, European Cancer Patient Coalition (ECPC), Brussels, Belgium

Background: Nutritional and metabolic disorders are highly prevalent among cancer patients. We aimed to analyse the dimension of nutritional alterations among cancer patients and survivors in Europe by using a structured questionnaire encompassing the perspectives of patients and their physicians on nutritional issues.

Methods: A structured questionnaire was designed to analyse the importance of nutrition for people with cancer. The questionnaire was subdivided in specific areas of interest, such as the presence of feeding problems, perception of nutrition importance, role of food supplements, and their view of their physician's approach to nutrition. All cancer patients and survivors were eligible to answer the questionnaire, except for people diagnosed with brain and breast cancer. The study was conducted by the European Cancer Patient Coalition (ECPC), Sapienza University of Rome, and Healthware International. ECPC ensured the dissemination of questionnaire to its Members in 10 countries, who translated and disseminated the questionnaire.

Results: The survey was answered by 907 cancer patients and survivors. 59.2% (n = 537) of respondents were diagnosed with cancer less than 3 years ago, and 46.2% (n = 419) were treated for cancer for 1 year or less (46.2%; n = 419). 82.4% of respondents (n = 689) believed it was important to maintain physical activity during cancer treatment, although only 53.8% (n = 450) of the respondents reported that their physicians advised them to do so. 72.9% (n = 603) of the respondents didn't know the meaning of the term "cachexia", and 92.4% (n = 764) did not receive any information about cachexia from their health professionals. 69.7% (n = 586) of respondents reported that they lost weight after the cancer diagnosis, and for 36.7% (n = 309) of respondents this loss was moderate to severe.

Conclusions: Most people with cancer surveyed reported that they would like to receive more information about how to improve their nutrition during and after treatment. There is a need to empower individual patients and patient associations by producing more information on cancer patients' nutritional needs. Such information material should be produced by patients in close collaboration with medical oncologists and other healthcare professionals.

1451P Breast cancer specific survival (BCSS) in young women <40 years with node negative luminal breast cancer (BC) treated based on tumor gene expression

S. Shak[1], M. Roberts[2], D. Miller[1], A. Kurian[3], V. Petkov[2]

[1]Translational Sciences, Genomic Health Inc, Redwood City, CA, USA, [2]Cancer Control and Population Sciences, National Cancer Institute, Bethesda, MD, USA, [3]Departments of Medicine (Oncology) and of Health Research & Policy, Stanford University School of Medicine, Stanford, CA, USA

Background: BC at a young age is generally associated with poor prognosis, more aggressive treatment, long-term toxicities, and unique psychosocial concerns. Little data is available on outcomes defined by molecular profiles. We characterized BCSS in female patients (pts) <40 y with node negative (N0), hormone receptor positive (HR+), HER2 negative disease who were treated based on 21-gene assay Recurrence Score (RS) result.

Methods: RS results were provided electronically to SEER (US population based cancer registries) per their linkage methods (Petkov et al, npj Breast Cancer, 2016). Eligible pts were diagnosed (Jan 2004 - Dec 2012) with N0 HR+ BC, and had no prior malignancy or multiple tumors. BCSS was analyzed for female pts <40 and ≥40 y with RS results, excluding HER2+ disease. Survival was compared using a log-rank test.

Results: 1,761 of 7,186 pts <40 y (24.5%) had RS results. The proportion of pts <40 with RS < 18, RS 18-30, and RS ≥ 31 was 47%, 42%, and 11%, respectively. 47,644 of 203,033 pts ≥40 y (23.5%) had RS results. The proportion of pts ≥40 y with RS < 18, RS 18-30, and RS ≥ 31 was 56%, 37%, and 8%, respectively. The distribution of tumor size and tumor grade was similar in younger and older pts. Reported CT use increased with increasing RS, and was higher for pts <40 y ($p < 0.001$). Continuous RS result was associated with BCSS for both <40 and ≥40 y ($p < 0.001$). 5-y BCSS with RS < 18 was excellent for 820 younger pts <40 y, even in those without reported CT use (Table). Similar results were observed for ages <30 y (n = 120), 30-34 y (n = 411), and 35-39 y (n = 1,230).

Conclusions: This large population-based study of N0 HR+ HER2- BC indicates not all young women have aggressive tumor biology and poor prognosis. Nearly half (47%) of women <40 y have RS < 18 and favorable 5-y BCSS with limited CT use. An important minority (11%) with high RS have worse outcomes despite CT. Longer term follow-up is planned.

1452P Risk of malignant mesothelioma in Spain from environmental asbestos exposure

J.S. Torres-Roman[1], G. Lopez-Abente[2], J.M. Sanz-Anquela[3]

[1]Faculty of Medicine, Universidad Nacional San Luis Gonzaga, Ica, Peru, [2]Cancer and Environmental Epidemiology Unit National Center for Epidemiology Carlos III Institute of Health. Madrid, Spain, [3]Cancer Registry and Pathology Department Hospital Universitario Principe de Asturias, Department of Medicine and Medical Specialties University of Alcalá, Alcalá de Henares, Madrid, Spain

Background: The link between malignant mesothelioma (MM), and asbestos exposure (AE), is very high. AE may have occupational or environmental non-occupational source. The highest levels of AE occur in the workplace and mainly affect men. However, environmental AE, affect men and women equally. As the occupational AE prevails over the environmental non-occupational, a sex-ratio < 2 alert of possible environmental AE. The objective of this study is to evaluate the spatio-temporal distribution of the sex-ratio, in order to identify those areas with possibly higher environmental AE.

Methods: We conducted an analysis of the 6,143,124 deaths in Spain during the period 2000–2015, looking for those deaths caused by MM. Information regarding sex, year of death, age at death, province, and cause of death (ICD-10) was extracted from the deceased registry of the National Institute of Statistics. We calculated the sex-ratio between the deceased by MM according to its distribution by provinces and years, and the ratio of mortality rates adjusted for age (European standard population). We also obtained the proportion of MM among the total deceased (MM per 10,000 deaths).

Results: MM deaths were 5,345. Men 4,025 and women 1,329 (sex-ratio: 3.31). During the 2000- 2015 period the sex-ratio remained relatively stable, ranging from 2.21 in 2007 to 4.31 in 2005. In the years 2000 and 2015 the sex-ratio was 3.34 and 3.07, respectively. Likewise, in the years 2000 y 2015 the men/women age-adjusted rates was 2.83 and 3.93, respectively. The variations by provinces were more pronounced. The lowest sex-ratio (1.5) corresponded to the 140 deaths of Navarra and the highest (12.67), to the 41 deaths of Vitoria. Other low sex-ratio values were detected for Almeria (2,07), Donostia (2,02), Huesca (2) and Tarragona (1,97). Among these provinces with a possible higher environmental AE risk (sex-ratio equal to or < 2.07), Donostia and Navarra have a high MM mortality (more of 13/10,000 deaths), but the other have a low or medium mortality.

Conclusions: The high provincial variability in Spain of the proportion of women who died of MM, makes necessary the carry out of new research focused in the provinces detected as with a possible greater risk of environmental asbestos exposure in the general population.

1453P Tobacco exposure and adverse pathological features in oral cancer: Does age impact survival?

V. Srinivasalu[1], N. Subramaniam[2], D. Balasubramaniam[2], N. Kumar[3], S. Murthy[2], A. Susan[1], A. Philip[1], K. Thankappan[2], S. Iyer[2], P. Keechilat[1]

[1]Department of Medical Oncology, Amrita Institute of Medical Sciences, Kochi, India, [2]Department of Head and Neck Oncology, Amrita institute of Medical Sciences, Kochi, India, [3]GCSRT program, Harvard Medical School, Cambridge, UK

Background: The role of tobacco in oral cancer is well established, however there is a wide variation in the incidence of tobacco - related oral cancer in the literature, ranging between 70-90%. Our data shows that only half of the patients with oral cancer have any history of tobacco exposure (smoking, chewing or others). Younger patients with oral cancer (<50 years) are being shown to be a distinct subset of patients, with more aggressive disease, possibly due to an underlying immunological basis. No previous literature has shown if the effect of tobacco exposure is similar in all age groups.

Table: 1451P

	RS < 18			RS 18-30			RS ≥ 31		
	N	CT (%)	5-y BCSS (95% CI)	N	CT (%)	5-y BCSS (95% CI)	N	CT (%)	5-y BCSS (95% CI)
All Pts (N = 49405)	27308	7%	99.6% (99.4%,99.7%)	18268	35%	98.7% (98.5%,98.9%)	3829	70%	95.4% (94.4%,96.2%)
<40 y (N = 1761)	820	17%	100.0% (100.0%,100.0%)	744	56%	99.8% (98.8%,100.0%)	197	80%	93.8% (85.9%,97.3%)
≥40 y (N = 47644)	26488	6%	99.5% (99.4%, 99.6%)	17524	34%	98.7% (98.4%, 98.9%)	3632	70%	95.5% (94.4%,96.3%)

Methods: From a prospectively maintained database of patients treated for oral cancer in our institution, we extracted details for 643 patients of oral cavity squamous cell carcinoma. We divided these patients into four groups, younger patients (<55 years) with or without tobacco exposure and older patients (≥55 years) with or without tobacco exposure and compared the effect of any tobacco exposure on prognostically relevant variables (like diameter, depth of invasion, extranodal extension). We also compared the progression free survival (PFS) and overall survival (OS) between those with and without tobacco exposure in each age group separately.

Results: The percentage of those with tobacco exposure was comparable in both age groups. Tobacco exposure correlated with tumour thickness ($p = 0.001$), perineural invasion ($p = 0.002$), lymphovascular invasion ($p = 0.004$) and local recurrence ($p = 0.006$) in the younger patients but not in the older patients. In younger patients, those with tobacco exposure also had a positive trend for poorer differentiation ($p = 0.07$) and extranodal extension ($p = 0.06$). Patients <55 years who had a history of tobacco exposure, had a significantly worse PFS and OS ($p = 0.03$). In patients ≥55 years, the PFS and OS between the cohorts with and without tobacco exposure was comparable ($p = 0.10$).

Conclusions: Younger patients with exposure to tobacco have worse clinical outcome, possibly as a result of adverse pathological features like perineural invasion and lymphovascular invasion. Whether this relationship is due to an underlying immune mechanism requires further study. Younger tobacco users with oral cancer are more likely to have a poor prognosis.

1455P Initiation of systemic anti-cancer treatment in the inpatient setting in a tertiary hospital in London

J. Lam[1], K. Ng[2], T. Emms[2], R. Gillmore[2]

[1]Oncology Department, UCL School of Clinical Medicine, London, UK, [2]Medical Oncology, Royal Free Hospital, London, London, UK

Background: The landscape of adult medical oncology care has shifted across the past three decades from the hospital to the outpatient setting, reflecting factors such as patient preference, technological advancements in the delivery of therapeutics, and cost-effectiveness. There are no recent guidelines to indicate when systemic treatment should be initiated as an inpatient. This clearly presents difficulties, particularly since inpatients are associated with a poorer performance status.

Methods: We retrospectively generated data of patients at the Royal Free Hospital commencing cycle 1 of chemotherapy as an inpatient, with a particular focus on 30-day mortality, overall survival, performance status recorded prior to initiation, treatment dose and line of therapy. Data was collected over a period of 24 months from January 2015 to December 2016.

Results: We identified 34 patients across a range of tumour types and with varying performance status who fulfilled our criteria The median age of patients treated was 54.5 years. Of these, the 76% (26/34) were administered full dose therapy, with 17.6% given a 25% dose reduction, and 5.8% given with a 50% dose reduction. Of the 34 cases, 76% (26/34) were first line therapy. The treatment intent in all cases was palliative, except one case where the intent was neoadjuvant. There was a positive correlation between performance status, full-dose therapy, and first line therapy with survival (Table 1). The outcomes of inpatients were significantly worse than outpatients. 7 of 34 in our cohort died with 30 days (20.5%), while only 38.3% of them were alive at 6 months. This is compared to the overall 30-day mortality rate of our department at 2.9%.

Table: 1455P Correlation between PS, line of therapy and dose of therapy with survival (days)

Performance Status	Medial Survival (Days)
0	200
1	101.5
2	61
3	64
Line of Therapy	Median Survival (Days)
1st line	107.5
2nd line	68
3rd line	12
Dose of Therapy	Median Survival (Days)
Full Dose	110
80%	46
75%	24
50%	38

Conclusions: 1) Inpatients commenced on systemic treatment are associated with poorer overall survival compared with outpatients. 2) We would suggest adherence to the new '2016 UK CQUIN: Optimising Palliative Chemotherapy Decision Making', which recommends peer discussion within the MDT when o chemotherapy is commenced or continued when PS is greater or equal to 2 o decisions regarding commencement of 2nd line treatment or beyond are required, when there is outright progression through the first cycle of chemotherapy.

1456P Young-age onset colorectal cancer: Analysis of incidence, clinical features and outcomes

F.K. Fujiki, M.F.B. Vicentini, A.C.B. Silva, E.M. Zambrano, L.G. Fonseca, M.I. Braghiroli, J. Sabbaga, P.M. Hoff

Oncology, ICESP - Instituto do Câncer do Estado de São Paulo, Sao Paulo, Brazil

Background: Recent studies suggest an increase in the incidence of colorectal cancer (CRC) in young-age patients. Data concerning clinical behavior, pathologic findings and prognosis are still poorly understood for this age group. The aim of this study is to analyze clinical features and survival of the young-onset CRC population in our institution.

Methods: We retrospectively reviewed records of 5,806 patients diagnosed with CRC between January/2011 and November/2016 in *Instituto do Câncer do Estado de São Paulo* and identified 781 patients aged 50 years or younger Kaplan-Meier method was used to estimate overall survival (OS) and uni/multivariate analysis were carried out to identify factors associated with OS.

Results: We found an absolute increase in the incidence of CRC in patients < 50 years by 1.88% to 2.23% annually (2011-2012: 11.6%; 2013-2014: 13.5%; 2015-2016: 15.7%) with a relative increase of 35.3% between 2011 and 2016. Median age was 42 years (17-49), 57.4% were female and 20.9% reported family history (FH) of CRC. Mismatch repair (MMR) protein immunohistochemical analysis were performed in 466 patients and 78 (16.7%) had MMR deficient CRC. Left-sided tumors were more frequent (left colon 8.2%, sigmoid 33.7% and rectum 31.5%), whereas the incidence of right-sided tumors was 19.4%. Almost all of patients were symptomatic (93.9%) and abdominal pain (39.6%) and rectal bleeding (28.7%) were common. MMR deficiency was associated with better OS ($p = 0.029$). The stage distribution was stage I 2.6%, II 25.8%, III 34.1% and IV 37.5%. The median OS of stage IV was 25 months (CI95% 20.7-29.3) and not reached for I-III ($p < 0.001$). FH of CCR ($p = 0.021$) and adjuvant chemotherapy ($p < 0.001$) were independently associated with better OS in stage IV. For stages I-III, wild-type KRAS ($p = 0.003$), FH of CCR ($p = 0.024$) and absence of lymphovascular invasion ($p < 0.001$) were associated with better OS.

Conclusions: In our experience, the incidence of early-onset CRC is increasing. Young patients were more likely to be diagnosed with metastatic disease, left-sided/rectum site and symptoms at presentation. These findings highlight the emerging importance of young-age onset CRC and the need to discuss strategies to early diagnosis.

1457P Improved provision of written information on metastatic spinal cord compression to at-risk cancer patients at a tertiary referral centre

P. Mahaligam, K. Ng, A. McLaren, K. Fordham, J. King

Medical Oncology, Royal Free Hospital, London, London, UK

Background: Metastatic spinal cord compression (MSCC) affects up to 10% of patients with disseminated malignancies, and early diagnosis correlates with improved clinical outcomes. Up to 85% of patients who present with MSCC already have motor deficit by the time of presentation. We investigated our Trust's compliance with national guidelines on providing at-risk patients with written information on the signs and symptoms of MSCC. Following a period of educational intervention we re-audited our practice.

Methods: All Oncology doctors and Specialist Nurses at the Royal Free Hospital were completed an online survey on their knowledge of national guidelines and their clinical practice. We delivered an educational intervention (including formal teaching and presentation at Departmental meetings, case discussions and providing patient information leaflets to clinicians) and re-audited our practice after 3 months.

Results: There were 29 and 20 respondents to the baseline and repeat surveys respectively. 57% vs 84% reported being moderately or very familiar with the MSCC guidelines; 32% vs 47% reported knowing where the information leaflets were kept; 3% vs 15% reported providing written information on MSCC to at risk patients at least every month. (baseline and repeat surveys, respectively)

There was a consensus amongst the clinicians that patients with spinal metastases should be considered at "highest risk", and verbal information about the risks of MSCC was most commonly given to this group. There was a 42% increase in the proportion of respondents who provided written information on the risk of MSCC to patients with spinal metastases (19 vs 61%) following the intervention.

Conclusions: 1) Provision of written patient information leaflets, formal education sessions and case discussions with clinicians resulted in increased knowledge of guidelines on MSCC at 3 months, and positive changes in clinical practice. 2) There was a significant increase in the provision of written information to the highest risk patient groups (19 to 61%). 3) By increasing patient awareness, we can increase the proportion of early self-presentations and diagnosis. This will lead to prompt intervention and improvement of neurological outcomes.

1458P Impact of mastectomy on the social well-being and family dynamics of breast cancer female patients in the Gaza Strip

M. Elshami, E. Alaloul, E. Khader, I. Awad, A. Alhelu, H. Baraka, H. Abu Nemer, B. Böttcher, K. Elessi

Faculty of Medicine, Islamic University of Gaza, Gaza, Palestinian Self-Rule Area

Background: The impact of mastectomy on social well-being (SWB) and family dynamics (FD) may involve the individual, social role and perception of the usefulness of social and family support affects. The purpose of the current study is to identify that impact and its related implications on SWB and FD.

Methods: This was a cross-sectional study in which a total of 173 female patients who had mastectomy in GS hospitals completed a face-to-face questionnaire designed by the researchers; which contains 3 sections including: socio-demographic data, SWB and FD. All measures utilized a five-point Likert-type scale ranging from 1 (worst outcome) to 5 (best outcome). The study was conducted at European Gaza Hospital ($n = 60$) and Alshifaa Hopsital ($n = 113$) in the GS from August 2015 to September 2016. The data was analyzed using SPSS software.

Results: Among 173 female patients, the mean age was 51 years $\pm$ 10. About 91% were unemployed, 52% had low income and 73% were of low educational level. The overall SWB score was negatively affected by 44.2% (mean score= 2.21 $\pm$ 1.33). Seventy percent of patients had a financial impact and decreased home activities. Interestingly, 57.8% claimed that involvement in family activities was not affected after mastectomy. Shockingly, 95.4% of women worried of getting divorced due to their illness. The overall impact on FD is estimated to be by 49.2% (mean score= 2.46 $\pm$ 1.64). Surprisingly, the diagnosis of BC had an impact on sexual performance in 27.1% compared to 19.1% after mastectomy.

Conclusions: Improving patients' quality of life should be one of the primary goals of BC treatment. Involving patient's family in the process of medical care may promote their SWB and FD. However, the great fear of divorce found in this study, demonstrates the insecurity of women within the society of Gaza and is possibly an expression of the lack of security in the Gaza-Strip. Assessing and addressing the SWB and FD among BC patients may enhance providing a holistic medical care and further research in the future can help in implementing this.

1459P Cancer incidence and mortality trends in Crete, Greece during the last two decades (1992-2013): Results from the cancer registry of Crete

V-E. Chatzea[1], D. Sifaki-Pistolla[1], F. Koinis[2], E. Saloustros[3], L. Vamvakas[4], G. Pitsoulis[5], N. Tzanakis[6], D. Mavroudis[4], V. Georgoulias[2], C. Lionis[1]

[1]Social and Family Medicine Clinic, University of Crete, School of Medicine, Heraklion, Greece, [2]Medical Oncology, University of Crete, School of Medicine, Heraklion, Greece, [3]Oncology Unit, General hospital of Heraklion 'Venizelio', Heraklion, Greece, [4]Medical Oncology, University Hospital of Heraklion, Heraklion, Greece, [5]Region of Crete, Regional Council, Heraklion, Greece, [6]Respiratory Medicine, University Hospital of Heraklion, Heraklion, Greece

Background: Cancer registration is the systematic collection of data about cancer and tumor diseases and is a valuable tool for understanding what causes cancer and how best to diagnose and treat it. In Greece, this data collection is managed only in the island of Crete, by the Cancer Registry of Crete (CRC;) . In this study, we present data on the cancer incidence and mortality for all neoplasms in Crete, during 1992-2013. Secondary objectives were to map the longitudinal trends of all MN and per type.

Methods: Data were obtained from the Cancer Registry of Crete which is the only population-based registry in Greece since 1992 (permanent residents=623.000). Data were coded according to the ICD-10O and included several parameters on demographics, medical history, and lifestyle factors. Age-standardized incidence/mortality/100,000/year (ASIR, ASMR) were estimated, while Bayesian models were performed to assess any longitudinal variations ($a = 0.05$).

Results: ASIR and ASMR for all cancers in Crete were 302.8 and 150.5 respectively. Cancer of the lung and bronchus is the most common invasive cancer and cause of cancer mortality in males and females (40.2 new cases/100,000/year and 36.5 deaths/100,000/year). Colorectal cancer accounted for 25.1 new cases/100,000/year and 14.7 deaths/100,000/year, and breast cancer for 28.6 new cases/100,000/year and 11.1 deaths/100,000/year. The invasive neoplasms that presented the greatest statistically significant increasing trends during the past 22 years were: lung and bronchus (in women), colorectal cancer (in both sexes), cervical cancer, leukemia (in men) and thyroid cancer (in both sexes).

Conclusions: Although the Cretan cancer rates are still lower than the mean European ones, significant increasing trends were identified; indicating the urgency for clinical and public health measures. Since the cancers that account the most in this increase are preventable by smoking cessation, screening, and vaccination. High priority should be given to the development of population-based interventions.

1460P Robotic anticancer drug compounding assist system for the preparation of injectable antineoplastic drugs

S. Masuda, H. Watanabe, T. Irisa, K. Hata, A. Kumagai, C. Tanaka, N. Ozawa, K. Nakashima

Department of Pharmacy, Kyushu University Hospital, Fukuoka, Japan

Background: Many antineoplastic drugs are known to be mutagenic or teratogenic. Medical personnel handling antineoplastic drugs are at a high risk of occupational exposure. Therefore, in collaboration with Yaskawa Electric Corporation and Nikka Micron Co., Ltd, we developed the Cancer Drug Compounding Assist System (CDCAS). The CDCAS is an automated robotic system designed to efficiently facilitate the accurate preparation of drugs based on dose. In this study, we evaluated the CDCAS for accuracy, site contamination, and washing performance in the preparation of antineoplastic drugs.

Methods: 5-Fluorouracil (5-FU; 600, 800, or 1200 mg) was added to 100 mL of saline; 5 samples of each formulation were prepared. The weight of the mixed drugs prepared using the CDCAS was compared to those prepared by a pharmacist, and the accuracy of each preparation was calculated in terms of percentage relative error. The acceptable variance was set at $\pm$ 5%. To test for contamination, cyclophosphamide (800 mg) was continuously added to 50 bags of 100 mL saline solution. Then, 25 locations inside the isolator were identified for measurement. Cyclophosphamide was collected from those sites by using a sampling sheet method. Twenty of those samples revealed adherence of 5-FU (300 μL) to the infusion bag surface. Ozonated water was used to wash 5-FU from the surface of the infusion bags. After the washing process, any 5-FU remaining on the infusion bag surface was recovered via a wiping method.

Results: The average weight error ratio for the CDCAS and the pharmacist was −0.62% and 2.69%, respectively. Contamination of cyclophosphamide was confirmed at eight sites. Pollution of 5-FU was confirmed for two samples, and the removal rate was $\geq$ 99.9%.

Conclusions: Our study demonstrated that the CDCAS's preparation accuracy and cleaning performance are within acceptable limits. Thus, the CDCAS could be used to potentially reduce occupational exposure to antineoplastic drugs.

1461P Monitoring of contamination with cytostatics in pharmacies and hospitals in the Czech Republic

S. Kozakova

Pharmacy, Masaryk Memorial Cancer Institute, Brno, Czech Republic

Background: Monitoring of contamination with cytostatics was introduced in practice in the Czech Republic by CYTO project managed by the pharmacy of Masaryk Memorial Cancer Institute (MMI) in years 2006-2010. The number of prescriptions of cytostatic drugs increased within the Czech Republic from 23000 bags and syringes in 2010 up to 38000 in 2015. So as to set up standards for the protection of healthcare professionals, it is necessary to monitor contamination regularly at all work sites engaged in compounding or administration - both in the pharmacy (Pharm) and at the hospital departments (HD)/stationaries (S). We have introduced the monitoring of cyclophosphamide (CP) and Pt cytostatics (Pt) to routine practice in 2007. In 2015, there was also implemented monitoring of 5-fluorouracil (FU). These drugs belong to the most frequently used cytostatics in MMI (49.0% of compounded units).

Methods: The samples for detection of contamination of surfaces were collected with a nonwoven swab. CP and FU were assessed with HPLC with TQ-S MS, with limits of detection 1.1pg.cm^{-2} for CP und 7 pg.cm^{-2} for FU. Pt cytostatics were analyzed by MS with inductively coupled plasma proving LOD 0.7 pg.cm^{-2}.

Results: Maximal levels of FU detected on floors were: 775 pg.cm^{-2} at HD, 564 pg.cm^{-2} in P, at compounding units and 25 pg.cm^{-2} in P, in storage rooms. Similarly, maximal detected levels of CP on floors were found at the HD: 3244 pg.cm^{-2}, 638 pg.cm^{-2} in the P, compounding units and 235 pg.cm^{-2} in P, in the storage rooms. Maximal detected levels of Pt on floors was again found in the HD, with levels of 5390 pg.cm^{-2}, then 84 pg.cm^{-2} in P, compounding units, and 57 pg.cm^{-2} in P, in the storage rooms.

Conclusions: According to our findings, hospital pharmacists are able to decrease the contamination on their workplaces. On the other hand, improvement is needed at the hospital departments and stationaries, where hospital pharmacists may co-operate on setting the safety standards.

1462P New treatments in Oncology: Clinical practice regarding the management of Adverse Events (AEs). Results from a survey conducted by the Hellenic Group of Young Oncologists (HeGYO)

M. Liontos[1], F. Koinis[1], G. Chatsidis[2], K. Kamposioras[1], G. Papaxoinis[1], M. Nikolaou[1], K. Tsigaridas[1], E. Voulgaris[1], E. Pantavou[1], G. Aravantinos[1], A. Ardavanis[1], I. Boukovinas[1], E. Galani[1], S. Angelaki[1], G. Mountzios[1], Z. Saridaki[1], I. Varthalitis[1], N. Tsoukalas[1]

[1]On behalf of the Hellenic Group of Young Oncologists (HeGYO), under the auspices of the Hellenic Society of Medical Oncology (HeSMO), Athens, Greece, [2]Hellenic Group of Young Oncologists (HeGYO), Hellenic Group of Young Oncologists (HeGYO), Athens, Greece

Background: Targeted therapies with distinct toxicities have revolutionized treatment of advanced cancer. Aim of this study was to assess patterns of practice for the management of these AEs, which can impair patient's(pts) quality of life and hamper compliance, potentially leading to treatment failure.

Methods: Between March 2017 and May 2017, an online questionnaire was distributed by HeGYO to oncologists to provide their answers anonymously.

Results: 79 oncologists participated in the survey. The majority were medical oncologists (80%), 18% were clinical/radiation oncologists and 2% haematologists oncologists. Of them, 30% were in specialty training and 72% were ESMO members. Although 64.6% stated that they are very familiar with the new treatments in oncology, the majority (67.1%) spend less than 30% of their treatment initiation visit to inform pts on AEs. Only a minority (29.1%) gives diaries to pts for self reporting of AEs, but 59.4% offers educational material and 89.8% reaches proactively to pts. 53.2% do not make follow up phone calls between scheduled visits, while 58.2% report that there is not a call center service available in their institution for the pts to report AEs. More than 80% of oncologists described their practice to treat toxicities as more guideline-based than empiric and 92.4% of them were keen to refer pts to other medical specialties to optimize management of toxicities. 60.8% reported that a dose reduction or discontinuation was necessary in 10-30% of their pts and 59.5% reported that at least 1 of their pts discontinued treatment without informing them. Time constraints and the chaotic nature of web information were the predominant barriers interfering with doctor's education.

Conclusions: This survey emphasizes the unmet need for continuous education among health professionals and pts and effective multidisciplinary collaboration for the optimization of AEs management. The majority of participants acknowledged the importance of informing their pts and treating their side effects according to guidelines. However, they describe significant obstacles in their daily practice.

1463P Oncologists' perspectives on biologic substitution

M. Reilly[1], A. Spiegel[2]

[1]Alliance for Safe Biologic Medicines, Washington, DC, USA, [2]Global Colon Cancer Alliance, Bala Cynwyd, PA, USA

Background: Biosimilars are similar but not identical to originator biologics. As more biosimilars are approved, pharmacy or hospital-level substitution of biologics is becoming more common, potentially excluding physicians from decisions regarding the treatment of their patients.

Methods: The Alliance for Safe Biologic Medicines (ASBM) conducted regional, 15-minute web-based surveys among biologics prescribers around the world to determine their opinions on biologic substitution. Prescribers were asked to rate: (1) the importance of authority to decide the most suitable biologic for their patients, (2) the importance of designating a biologic as "dispense as written" (DAW, or equivalent), (3) the acceptability of biologic substitution, and (4) the importance of notification of biologic substitution.

Results: A total of 1,856 responses were received: 470 (25%) Europe, 427 (23%) Canada, 400 (22%) US, 399 (21%) Latin America, and 160 (8.6%) Australia. Across regions, most prescribers were from the hospital setting, and most had $\geq$ 11 years in practice. Between 10% and 25% of prescribers were oncologists (16% Europe, 10% Canada, 16% US, 18% Latin America, and 25% Australia). Across regions, most oncologists (75%) feel that it is critically/very important to have sole decision-making authority regarding the suitability of a biologic, and 71% that it is critically/very important to have DAW authority. Only 6% of oncologists feel that pharmacy-level substitution is totally acceptable; 58% consider switching to a biosimilar unacceptable, and 36% consider switching acceptable provided it has been agreed to in advance. Most (76%) also feel that it is critically/very important to be notified of pharmacy-level substitution. Responses were mostly aligned across regions; however, one notable difference was the relatively low percentage of Australian oncologists (23% vs 58% overall) who feel that substitution is unacceptable.

Conclusions: Our survey indicates that most oncologists believe it is important for them to be able to control which biologic—original product vs biosimilar—they prescribe for their patients. This is likely to become increasingly important with the availability of biosimilars used for curative intent.

1464P Ukrainian Association for helping patients with lymphoproliferative diseases: Patients support care program

I. Kryachok, O. Novosad, T. Skrypets, T. Kadnikova, I. Titorenko, O. Aleksik, K. Filonenko, A. Martynchyk, Y. Pastushenko, Y. Stepanishina, E. Kushchevyy, K. Ulianchenko, M. Surkis, V. Jurchishina, E. Gingsburg

Oncohematology, National Cancer Institute of the MPH Ukraine, Kiev, Ukraine

Background: Treatment patients with cancer, including chronic lymphoproliferative diseases (CLPD), includes not only special therapy, such as surgery, chemo- and radiation therapy, as well as psychological and social support to this group of patients. With this goal, the first Ukrainian Association for helping Patients with Lymphoproliferative Diseases (UAPLPD) was founded in 2006.

Methods: 1) To cooperate with various institutions and doctors who treat patients with CLPD. 2) To create programs which promote social assistance and protection for patients with CLPD 3) To create an appropriate financial framework for solving diagnosis and treatment difficulties.

Results: Currently, there are 18 centers in 24 regions of Ukraine and 1000 members (25% of health professionals and researchers and 75% of patients and their family members) in UAPLPD. Each year, the number of association members is growing rapidly Since 2006, the association has been carrying out a lot of activities aimed to support patients, their relatives and of course, doctors. Nowadays, we have 6 ongoing projects: "Lymphoma day", "Psychological help for patients and relatives", social project with Ukrainian pop-stars "I will survive. . .", program which help to reduce prices for expensive drugs "Support patient", "Art against cancer" and "Survivors day". Within the framework of all projects, the association provides a lot of charity concerts, art exhibitions, shoot video for promo-actions, provide art-therapy, therapeutic horse riding. There are also many educational events for patients and doctors. The UAPLPD pays attention to the assistance for diagnosing and treating patients and partially allocates money for reagents purchasing, perform PET/CT scans for free to over 40 patients annually and could cover cost-effective treatment. The Association has printed out a lot of informational material such as patient brochures on nutrition, physical therapy with our patients' stories and examples. We update and edit this information annualy, including the scientific editions as well. The latter one include guidelines for diagnostic and treatment multiple myeloma, anemia, the evaluation of response after treatment in patients with lymphoma. Since 2015, a psychologist has been working for a full time at the oncohematology department.

Conclusions: The work of the Association for helping patients is very important and necessary for effective treatment and patient rehabilitation.

1466P Feasibility and barriers to optimal oncological treatment in solid organ transplant patients with de novo cancer

B. Rousseau[1], A. Jobard[1], C. Duvoux[2], C. Neuzillet[1], P. Compagnon[3], D. Azoulay[3], A. de la Taille[4], L. Salomon[4], I. Cholley[4], M. Matignon[5], P. Grimbert[5], C. Tournigand[1]

[1]Medical Oncology, CHU Henri Mondor, Creteil, France, [2]Hepatology, CHU Henri Mondor, Creteil, France, [3]Hepatobiliary Surgery and Transplantation, CHU Henri Mondor, Creteil, France, [4]Urology, CHU Henri Mondor, Creteil, France, [5]Nephrology, CHU Henri Mondor, Creteil, France

Background: Transplanted patients (tpts) display higher cancer incidence rates compared to general population. Anti-tumor treatment after transplantation remains scarcely described. This study aimed to report oncological therapy feasibility and outcome in tpts with *de novo* cancers.

Methods: We retrospectively analyzed all consecutive cases of de *novo cancer* in renal and liver tpts treated in our center. Pts were identified based on systematic research in tpts databases from 2000 to 2016. Pts presenting with non-melanic cutaneous tumors only were excluded. Clinical features, treatments, toxicity and survival data were collected. Active optimal treatment was assessed by comparing treatment that was actually administered with guidelines.

Results: Among 4637 tpts, 209 cases of *de novo* cancer were identified in 176 (3.8%) pts. Mean age was 52.5+/-11.3 at transplantation and 59+/-10.6 at cancer diagnosis; 122 (69%) were men; 96 (55%) were renal tpts and 80 (45%) liver tpts. At cancer diagnosis, performance status (PS) was 0-1 in 89% (n = 142/160). Tumor type was mainly epithelial (75%, n = 150/200); tumor stage was localized in 80% (n = 163/205) and advanced in 20% (n = 42/205) . Among pts with initially localized tumors, 13% (n = 22/163) had cancer recurrence. Median overall survivals of pts with localized and advanced cancer were of 166 (CI95%: 100.3-ND) and 8.8 (CI95%: 5.0-47.2) months, respectively Among pts with localized tumors, 80% (n = 134/156) received optimal treatment. Reasons for non-optimal treatment were comorbidities in 36% (n = 8/22), risks for the transplant in 36% (n = 8/22), and/or toxicity in 36% (n = 8/22). In contrast, at advanced/recurrent stage, only 36% (n = 19/53) of pts received optimal treatment, and 28% (n = 15/53) best supportive care only. Barriers to optimal treatment were comorbidities in 19% (n = 6/32), risks for the transplant in 22% (n = 7/32), toxicities in 19% (n = 6/32), and poor PS in 33% (n = 17/32).

Conclusions: Oncological treatments are feasible in tpts and survival seems similar to general population. Concerns about the risk of toxicity for the transplanted organ and comorbidities were the main reasons for non-optimal treatment. These observations warrant confirmation in a prospective multicenter study.

1467P Generating patient reported outcome norms for an EU cancer population using real world data (FACT-G)

A. Rider[1], S. Simpson[2], B. Bennett[2], K. Byrne[1], P. Hallworth[1], T. Desai[2], K. Cocks[2]

[1]Adelphi Real World, Adelphi Group, Bollington, UK, [2]Patient Centred Outcomes, Adelphi Values Ltd., Bollington, UK

Background: The main aim of this analysis was to generate population norms from an EU sample of cancer patients for the FACT-G instrument using real world data. Comparisons were made between existing norms based on a US population and the newly developed EU norms.

Methods: Data was collected through the Adelphi Real World Disease-Specific Programmes (DSPs) across breast, gastric, melanoma, non-small cell lung and prostate cancers. Cross-sectional surveys were administered to physicians and patients between January 2015 and March 2017, resulting in a total sample of 4899 patients. The US population norms outlined by Brucker et al. (Evaluation & the Health Professions. 2005;28(2):192-211) are commonly used to aid interpretation of FACT-G scores but there are no large sample norms specifically derived for the EU population. Analysis included checking internal reliability of the FACT-G sub-scales in the EU sample and comparisons between the EU and existing US population norms using minimum important differences (MIDs) of 3 points for FACT-G sub-scales and 7 points for total FACT-G score (Yost et al. Evaluation & the Health Professions. 2005;28(2):172-191).

Results: The EU sample had similar population characteristics to the US sample with respect to age, gender and ECOG status but consisted of a wider sample of cancer types (including haematological cancers). Internal consistency was met ($\alpha > 0.7$) for all subscales within the FACT-G for the EU population. Comparisons between the population norms indicate differences in FACT-G scores between the EU and US samples based on MIDs. Differences exceeding MIDs were noted across social well-being (SWB), emotional well-being (EWB), functional well-being (FWB) and overall FACT-G, but not for physical well-being (PWB). Further analysis was undertaken to explore differences by gender.

Table: 1467P

	SWB	EWB	FWB	PWB	FACT-G
EU mean score	17.4	13.3	12.3	18.5	61.5
US mean score	22.1	18.7	18.9	21.3	80.9
Population difference	4.7*	5.4*	6.6*	2.8	19.4*

*Indicates MID exceeded.

Conclusions: Differences highlighted between FACT-G scores for the EU and US cancer populations indicate that population norms may be region-specific or specific to cancer type. The resulting EU population norms can be used to aid interpretation of FACT-G scores across a range of cancer types.

1468P Development of a web-based application using machine learning algorithms to facilitate systematic literature reviews

H-L. Wong[1], T. Luechtefeld[2], A. Prawira[3], Z. Patterson[4], J. Workman[4], D. Day[3], N. Chooback[1], L. Nappi[1], H.H. Samawi[1], J-M. Lavoie[1], A. Spreafico[3], A.R. Hansen[3], S. Sahebjam[5], L.L. Siu[3], S.P. Ivy[6], C. Paller[7], D. Renouf[1]

[1]Department of Medical Oncology, British Columbia Cancer Agency, Vancouver, BC, Canada, [2]Johns Hopkins Bloomberg School of Public Health, Johns Hopkins University, Baltimore, USA, [3]Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada, [4]Insilica LLC, Washington, DC, USA, [5]Department of Medical Oncology, H. Lee Moffitt Cancer Center University of South Florida, Tampa, USA, [6]Cancer Therapy Evaluation Program, National Cancer Institute, Bethesda, USA, [7]Department of Medical Oncology, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, USA

Background: Systematic review is an important element of medical research but rapid proliferation of published literature presents challenges to manual review. Computer science advances can improve workload by using algorithms to automatically select and extract data from articles. We initiated a systematic review of phase I immunotherapy clinical trials and used natural language processing to aid article screening.

Methods: A literature search was performed across MEDLINE, Embase and CENTRAL in September 2016 using 100+ search terms in the categories "neoplasm", "immunotherapy" and "phase I clinical trial". Only English language studies published since 1990 were included. We developed a web-based interface that allowed human reviewers to apply inclusion/exclusion labels based on title and abstract screening. Articles were screened by two independent reviewers who were blinded to results. An article similarity based algorithm using weighted logistic regression to predict "include" and "exclude" labels is being trained and herein we report interim results.

Results: 28,235 articles were identified from the literature search; 19,000 remained after duplicates and conference abstracts were excluded. 4,034 (21.2%) were screened, of which 532 (13.2%) were labeled "include" by at least one reviewer. 1,944 (10.2%) were screened by two reviewers with concordance of 93.7%. The prediction algorithm was weighted to improve the detection of "include" labels, and achieved 80.6% sensitivity and 78.2% specificity when compared to manual review results. The positive and negative predictive values were 34.4% and 96.6%, respectively.

Conclusions: A machine learning algorithm trained on manual reviews was able to predict systematic review article inclusion with approximately 80% accuracy. Algorithm performance was affected by the low rate of included articles, but irrelevant articles were able to be excluded with high confidence. Further development is ongoing to optimize the algorithm to improve sensitivity. Once optimized, this innovative machine learning process could transform the conduct of systematic reviews.

1469P Survival patterns for different types of cancers in the United States (1973-2012)

M.A. Gouda

Department of Clinical Oncology, Faculty of Medicine - Menoufia University, Shebin El Kom, Egypt

Background: Most studies addressing survival patterns focus on 5-years survival data due to difficulties in long-term patients' follow up. The aim of this study was to explore data on survival making use of the main advantage of SEER (National Cancer Institute Surveillance, Epidemiology, and End Results) program; that is long-term follow up of patients' records. This enabled reporting 5-years relative survival, 10-years relative

Table: 1469P showing relative survival data as a function of time and tumor type

	1973-1982	1983-1992	1993-2002	2003-2012	1973-2012
All Cases					
5-Year RS	51%	57.8%	65.7%	68.9%	64.6%
10-Year RS	43.6%	51.1%	60.5%	63.7%	58.7%
20-Year RS	36.9%	44.4%	54.1%		51.4%
Solid Malignancies					
5-Year RS	51.8%	58.7%	66.6%	69.2%	65.2%
10-Year RS	44.8%	52.4%	61.8%	64.4%	59.7%
20-Year RS	38.3%	46%	55.6%		52.7%
Hematological Malignancies					
5-Year RS	42.4%	48.4%	56.2%	65.5%	58.1%
10-Year RS	30.9%	37.5%	47.5%	56.6%	48%
20-Year RS	22.7%	29.4%	38.6%		37.9%

survival, and 20-years relative survival for different types of cancers. Survival trends as a function of time and tumor types were also provided.

Methods: SEER*Stat version 8.3.4 was used for data acquisition and analysis, where (SEER 18 Regs Nov 2015 Submission) database was used as the data source. Only cases diagnosed between 1973-2012 with malignant behavior, known age, and microscopic confirmation were included. Relative survival was calculated using Ederer II method. Tumors were classified according to ICD-O-3 into either solid malignancies (8000/3-9581/3) or hematological malignancies (9590/3+).

Results: Cancer cases diagnosed between 1973 and 2012 showed a 5-years relative survival of 64.6% (CI: 64.5%-64.6%), a 10-year relative survival of 58.7% (CI: 58.6%-58.7%), and a 20-years relative survival of 51.4% (CI:51.3%-51.5%). All of these percentages were much higher with solid malignancies than hematological ones [Table].

Conclusions: Long-term follow up data were suggestive of 20-years relative survival of 51.4% for all cancers. Data were also suggestive of improved relative survival over time. Unexpectedly, hematological malignancies, despite most of them being thought of as curable ones, appeared to have lower relative survival than solid tumors.

Background: We conducted a national survey of cancer patients (pts) to determine what factors influence their decision to participate in a cancer clinical trial (CCT) and what supports they use(d).

Methods: Pts with a diagnosis of malignancy, $\geq$ 18 years, able to provide informed consent and complete a questionnaire independently were eligible. Questionnaires were administered to pts attending 14 cancer centres from 22nd April to Nov 23rd 2016.

Results: 1,090 pts completed the questionnaire (386 (35.6%) men and 697(64.4%) women). Median age was 60 years (IQR 50-69). 311 (29.5%) had previously been offered a CCT and 303 pts had participated. Factors most frequently ranked as important regarding decisions about CCT participation included; chance to advance research (n = 846, 81.0%); living longer/feeling better (n = 851, 81.5%); recommendation by cancer doctor (n = 797, 76.3%); closer monitoring (n = 528, 50.5%); fear of more side-effects (381,36.5%) or death (n = 337,32.3%); concerns about the treatment not working (n = 446,42.7%); increased hospital visits (n = 292, 28.0%); age (n = 355, 34.0%). Only 83 pts (9.3%) independently asked about participating in a CCT. Pts were asked about hypothetical participation in a CCT of a new drug that appeared safe but which could be better than/similar to/or worse than standard treatment (ST). 687 (65%) pts reported they would consider participation but more than half 336 (51.1%) of those re-considered when a subsequent question re-stated the possibility the study drug could be worse than ST. Of those previously offered a CCT most (n = 214, 68.8%) had decided without help. When making decisions about CCT participation; family (n = 175, 56.2%), internet (n = 67, 21.5%) and GP (n = 48, 15.4%) were frequent sources of support. Most sources encouraged (n = 169, 54.3%) or were neutral about participation (n = 72, 23.2%). Cancer doctors and specialist nurses scored highest in terms of pts' trust about CCT information; 250 (69.8%) and 196 (59.4%) pts gave them full scores respectively.

Conclusions: Decisions about CCT's are complex, based on personal and altruistic factors and may be influenced by the type and detail of information given and by who provides it. Few pts we surveyed asked about a CCT, but most who had been offered a CCT had participated.

1471P Academic clinical research: Enough players to get out there?

C. Cagnazzo[1], S. Campora[2], S. Pirondi[3], G. Gentili[4], A. Guarrera[5], C. Taverniti[6], M. Manuela[4]

[1]Gruppo Italiano Data Manager (GIDM), Meldola, Italy, [2]ICON plc, Milan, Italy, [3]Ospedale di Sassuolo, Sassuolo, Italy, [4]Unità di Biostatistica e Sperimentazioni Cliniche, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (I.R.S.T.), Meldola, Italy, [5]AOU Careggi, Florence, Italy

Background: The European Regulation 536/2014 definitively establishes the equality between pharma-sponsored and academic clinical research, raising the bar of standards for no profit trials. Italy has always been known for the quality of its studies: our researchers have produced the 3.9% of world scientific papers in 2015-16 and 44 were among the 2016 world's most influential scientific minds. However, the new compelling rules imposed by law make these great minds lacking in the absence of well-arranged staff, with dedicated professionals as clinical research coordinators (CRCs). Unfortunately, the national collective health contracts allow the employment of these experts only through atypical contracts that, due to new government requirements, will

soon be banned. We have decided to map how much the problem was widespread among Italian CRCs.

Methods: In November 2016 a web survey, focused on the imminent contracts' expiration problem, has been sent to about 300 CRCs.

Results: Our survey was completed by 231 CRCs (77%). The majority of respondents (78%) work thanks to atypical contracts, while few can count on more stable ones (7.4% fixed term and 14.6% open-ended). Public hospitals have the more difficulties to ensure stable employment: only 25% of permanent contracts come from this type of structures and purely thanks to loopholes; indeed, despite their educational background, CRCs are employed almost exclusively as non-qualified administrative personnel. The 67.5% of respondents will be affected by the contract problem, with multiple expiration timing: 32% Jan-Apr 17; 23% May-Aug 17; 23% Sep-Dec 17; 17.3% from Jan 18. Interestingly, about 50 CRCs were unwilling to participate, demoralized from the age-issue of the lack of professional recognition.

Conclusions: The need for clinical trials units officially and contractually recognized by competent authorities is a priority. The new government dispositions about atypical contracts could create a vacuum of skilled work force, which can hardly be covered by physicians. Since data are understated and the problem also affects another "big ghost" of clinical research (study nurse), in the absence of a permanent solution, Italy is unlikely to meet the required standards with a loss of appealing, but mostly with a slump of therapeutic options.

SARCOMA

1473O Encouraging activity of novel pan-KIT and PDGFRα inhibitor DCC-2618 in patients (pts) with Gastrointestinal Stromal Tumor (GIST)

F. Janku[1], A.R.A. Razak[2], M.S. Gordon[3], D. Flynn[4], M. Kaufman[4], J. Pitman[5], B. Smith[4], N. Somaiah[6], J. Jennings[7], S. Salah[2], D. Westwood[5], D. Greensmith[5], J. Jacobson[5], O. Rosen[5], S. George[7]

[1]Investigational Cancer Therapeutics, MD Anderson Cancer Center, Houston, TX, USA, [2]Cancer Clinical Research Unit, Princess Margaret Cancer Centre, Toronto, ON, Canada, [3]Medical Oncology, HonorHealth Research Institute, Scottsdale, AZ, USA, [4]Research, Deciphera Pharmaceuticals, Lawrence, USA, [5]Clinical Research and Development, Deciphera Pharmaceuticals, Waltham, USA,[6]Department of Sarcoma Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA, [7]Center for Sarcoma and Bone Oncology, Dana Farber Cancer Institute, Boston, MA, USA

Background: Approved TKIs primarily inhibit either the KIT ATP binding pocket (exon 13/14) or a subset of activation loop mutations (exon 17/18) and do not demonstrate activity across both regions known to cause imatinib resistance in GIST. This leaves significant liabilities in inhibitory coverage of known KIT resistance mutations. DCC-2618 is a potent kinase switch control inhibitor active across a broad range of mutations which emerge on treatment with approved TKIs.

Methods: This is a dose-escalation study of oral DCC-2618 (QD or BID q28 days) followed by an expansion cohort in pre-treated TKI resistant GIST. During the escalation phase, FDG-PET scans were performed at baseline and after 3 wks of therapy; CT scans every 2 cycles. Next generation sequencing (NGS) of plasma cell-free (cf) DNA was performed throughout the study to quantify KIT, PDGFRa and other molecular alterations. Concordance of mutational status between plasma cfDNA and tumor tissue was assessed.

Results: 33/42 pts enrolled had KIT (30) or PDGFRa- (3) driven GIST and received daily doses ranging from 40-400 mg. Mean prior lines of therapy was 4.8. The dose selected for expansion was 150 mg QD. Safety for all 42 pts was as follows: grade (G) 3/4 adverse effects (regardless of attribution, occurring in > 1 pt) included anemia (15), asymptomatic lipase increase () (7), hypertension (4), creatine phosphokinase (CPK) (2), lower GI hemorrhage (2). Two of the G3/4 lipase at 100 mg BID and 200 mg BID and one CPK at 150 mg QD were DLTs. Of 19 pts with KIT mutant GIST assessed by FDG PET, 15 (79%) had a partial metabolic response per EORTC criteria. 2 out of 23 evaluable patients showed RECIST partial responses (PRs) and 6 out of 11 evaluable patients at doses of ^{3}100 mg/d had RECIST progression free survival of > 6 months (5 pts on therapy at ^{3}Cycle 10). NGS of plasma cfDNA revealed a reduction of mutation allele frequency (MAF) in exons 9, 11, 13, 14, 17 and 18.

Conclusions: DCC-2618 showed encouraging disease control with objective responses and prolonged stable disease in heavily pre-treated GIST patients. The notable decreases in MAF of resistance mutations across all exons supports the use of DCC-2618 beyond imatinib resistance.

Background: Sarcomas are rare but aggressive diseases. Specialized multidisciplinary management is not implemented for all patients in most countries. We investigated the impact of the surgery in a reference center on relapse and survival in the nationwide NETSARC/RREPS study.

Methods: NETSARC (netsarc.org) is a network of 26 reference sarcoma centers with specialized MDTB, funded by the French National Cancer Institute to improve the outcome of sarcoma patients. Since 2010, presentation to an MDTB and second pathological review are mandatory for sarcoma patients. Patients' characteristics and follow-up are collected in a database regularly monitored. Uni and multivariate analysis of prognostic factors for local relapse free survival (LRFS), relapse free survival (RFS) and overall (OS) were conducted.

Results: Out of the 9,594 non-metastatic pts aged > =15, with a first diagnosis of soft tissue and visceral sarcoma obtained between Jan 2010 and Dec 2014, 3505 (37%) and 6089 (63%) were operated within vs outside of one of the 26 NETSARC reference center. The former group had worse prognostic characteristics (age, size, grade, depth $p < 0.0001$ all). In univariate analysis, surgery within a reference center was associated with a better LRFS & RFS (median 60 vs 41 mos, and 25 vs 21 mos, respectively, logrank $p < 0.001$). LRFS and RFS were significantly better for pts operated in reference centers in all individual subgroups of quality of resection, (R0, R1, R2, R unknown) ($p < 0.001$). Surgery in reference center was an independent good prognostic factor for LRFS (HR: 0,60), RFS (HR:0,79) as well as OS (HR:0,68) using Cox model ($p < 0.001$ all).

Conclusions: In this nationwide unselected population, the LRFS and RFS of sarcoma patients is worse than that reported in expert centers series. Surgery in reference center is associated with significant reduction of the risk of relapse and death.

Background: There is no proven benefit of adjuvant treatment in uterine sarcoma (US). SARCGYN was a phase-III study which compared adjuvant polychemotherapy followed by pelvic radiotherapy (RT) (arm A) *versus* RT alone (arm B). The study met its primary end point (3-year progression-free survival (PFS)) and showed a statistical increase of the 3-year PFS in the chemo+RT arm (A) *vs* radiation arm (B) (55% and 41% respectively, [$P = 0.048$]) after a median follow-up of 4.3 years (Ann Oncol 2013). Secondary end-point was overall survival (OS) that required a longer follow-up.

Methods: Patients with FIGO stage ≤III US, and physiological age ≤65 years were randomized after complete surgery and normal thoracic, abdominal and pelvic CT scans between CT and no CT, with a stratification between carcinosarcomas (CS) *versus* others. Study was stopped earlier because of lack of recruitment. All patients received pelvic RT (45 grays); vaginal brachytherapy was optional. Chemotherapy consisted in four cycles of doxorubicin 50 mg/m^2, d1; ifosfamide 3 g/m^2/day d1-2; cisplatin 75 mg/m^2, d3; + G-CSF q 3 weeks.

Results: Eighty-one patients were included: 39 in arm A and 42 in arm B; 52 stage I, 16 stage II, and 13 stage III; 53 leiomyosarcomas, 9 undifferenciated sarcomas, and 19 carcinosarcomas. API was toxic with two toxic deaths and one acute leukemia. After a median FU of 9.9 years [0.3-15.1], 42/81 patients relapsed, 16 in arm A, and 26 in arm B, and 38 died, 16 in arm A, and 22 in arm B. The 5-year OS is 74% in arm A and 60% in arm B, and the difference is not significant ($p = 0.16$).

Conclusions: In this trial interrupted at an early stage and with a longer follow-up, there is no statistical impact of API adjuvant CT on OS. The two toxic deaths and the integration of carcinosarcomas may have impacted on the global prognosis. A selection

of a specific uterine population and a less toxic chemotherapy for future studies are mandatory.

1476PD Tumour necrosis and clinical outcomes following neoadjuvant therapy in soft tissue sarcoma (STS)

J. Lewin, S. Salah, E. Amir, A.R.A. Razak

Department of Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: Tumour necrosis following chemotherapy is prognostic in bone sarcoma, but remains undefined in STS.

Methods: We searched MEDLINE, MEDLINE in progress, EMBASE and Cochrane to identify studies that investigated neoadjuvant therapy in STS. Eligible studies were required to have data on survival outcomes based on tumor necrosis in the resected specimen, or provided individual patient data. Hazard ratios (HR) for relapse free (RFS) and overall survival (OS) as well as odds ratios (OR) for recurrence at 3 years and for death at 5 years were pooled in a random effect meta-analysis. Association between patient characteristics and attainment of $\geq$ 90% necrosis were explored with logistic regression.

Results: 21 studies comprising 1644 patients were included in this analysis. Location of the tumor included the extremities in the majority (n = 1459; 89%). Induction regimens included chemotherapy/radiation (n = 813; 49%), chemotherapy alone (n = 418; 25%), chemotherapy/caffeine (n = 81; 5%), radiotherapy alone (n = 78; 5%), isolated limb perfusion (ILP) with (n = 28; 2%) or without radiation (n = 208; 13%), and targeted therapy/radiotherapy (n = 18; 1%). Utilizing a cut-off of 90%, patients with $\geq$ 90% tumour necrosis had significantly reduced risk of recurrence at 3 years (OR0.30; 95% CI: 0.20-0.44; $p < 0.0001$) and had improved 5-year OS (OR 0.38; 95% CI: 0.23-0.63; $p < 0.001$). Limiting the analysis to studies with reported HR (n = 6), patients with $\geq$ 90% tumor necrosis also had a lower risk of recurrence (HR 0.68; 95% CI: 0.49-0.94; $p = 0.02$) and death (HR 0.54; 95% CI: 0.41-0.71; $p < 0.001$). There was no significant association between age, gender, and histologic subtype with attainment of $\geq$ 90% necrosis. Compared to other neoadjuvant modalities, ILP was associated with higher odds of achieving $\geq$ 90% necrosis (OR 12.1; 95% CI: 3.69-39.88; $p < 0.001$).

Conclusions: Tumour necrosis $\geq$ 90% following neoadjuvant therapy is associated with reduced recurrence risk and improved overall survival in patients with STS.

Background: Desmoid tumours are locally aggressive mesenchymal tumours that lack metastatic potential. Tumour behaviour is unpredictable and varies along a spectrum from remission to growth. Recently, active surveillance has been increasingly adopted as initial management. The aim of this study is to analyse the need and indications for treatment in desmoid patients initially managed with surveillance only.

Methods: Patients with a desmoid tumour at any anatomical location diagnosed between 1998 and 2016 were selected from a prospectively maintained database. Differences between patient groups were analysed with independent t-tests or Chi-square tests. Inverse univariate cox proportional hazard regression analyses were conducted to assess factors associated with start of treatment, tumour behaviour and pain.

Results: A total of 168 patients initially managed with surveillance only were identified. The tumours were located in an extremity (51), in the abdominal wall (61), intra-abdominally (15), in the chest wall (30) or at other locations (11). From these patients, 33% (n = 55) developed progressive disease, 38% (n = 64) had stable disease and 28% (n = 47) had a remission. Tumours in patients <50 years old were more likely to show progressive disease after surveillance in an univariate analysis ($p = 0.046$). A total of 78 patients (46%) eventually had some form of treatment, while 90 patients (54%) continued on surveillance only. Median time to treatment was 31 months. Patients with tumours >5 cm were more likely to undergo treatment ($p < 0.01$), while no significant differences were found between the different anatomical locations. Treatment consisted mainly of surgery (n = 40, 44%) or systemic therapy (n = 36, 40%). The indications to start treatment were pain (32%), growth (31%) or both (13%). Tumours located in the chest wall or upper extremity caused significantly more pain than other locations ($p = 0.01$), while pregnancy-associated desmoid tumours caused significantly less pain ($p = 0.04$).

Conclusions: Patients with desmoid tumours can be managed with surveillance only, but a large minority still needs treatment after an initial period of surveillance. Pain and tumour growth are the most common indications to start treatment after initial surveillance.

Background: To better characterize the TRS patterns compared to other sarcomas.

Methods: Retrospective multicenter study of 12,262 patients treated between 01/1980 and 12/2013 in one of 22 French Referral Sarcoma Center and enrolled in the "Conticabase". Diagnoses were systematically reviewed by expert pathologists and entities classified according to the 2013 WHO Classification.

Results: The median follow-up was 4.9 years (95%-CI: 4.7-5.0). TRS included 13 entities: synovial S (760 cases; 7.4%/5-y OS: 64%), myxoid LPS (436; 4.2%/5-y OS:88%), PNET (205; 2.0%/5-y OS:58%), round cell LPS (183; 1.8%/5-yOS: 70%), alveolar RMS (122; 1.2%/5-yOS: 25%), malignant SFT (86; 0.8%/5-yOS: 77%), clear cell sarcoma (63; 0.6%/5-yOS: 67%), LGFMS (60; 0.6%/5-yOS: 82%), desmoplastic round cell tumor (56, 0.5%/5-y OS: 11%), ESMCS (54; 0.5%/5-yOS:78%), ASPS (48; 0.5%/5-yOS: 66%), EHE (42; 0.4%/5-yOS: 55%), and sclerosing epithelioid fibrosarcoma (28; 0.3%/5-y OS: 70%). All TRS (2,143 cases; 20.8%) are associated with younger age (40.6 versus 60.0; $p < 0.0001$), low rate of predisposing conditions (0.01% vs 22.3%, $p < 0.0001$), and higher rate of N involvement (4.7 vs 1.3%, $p < 0.0001$ and higher rate of synchronous metastasis (11.9 vs 6.7%, $p < 0.001$). R0 resection (41.6 versus 31.9%, $p < 0.0001$), use of (neo)adjuvant radiation therapy (62.6 vs 42.2%, $p < 0.0001$) and use of (neo)adjuvant CT (36.6 versus 22.3, $p < 0.0001$) were significantly more frequent. At the end, TRS are associated with a lower rate of local relapse (18.1 vs 26.0%, $p < 0.0001$) but a higher rate of metastasis relapse (42.0 vs 30.7%, $p < 0.0001$).

Conclusions: TRS display specific pattern compared to other sarcomas. Second opinion by expert pathologist and use of molecular biology confirmatory test are of major importance to recognize this population and discuss multimodal approach at early stage of the disease.

1479PD Phase II study of TAS-116, an oral inhibitor of heat shock protein 90 (HSP90), in metastatic or unresectable gastrointestinal stromal tumor refractory to imatinib, sunitinib and regorafenib

Y. Kurokawa[1], T. Doi[2], A. Sawaki[3], Y. Komatsu[4], M. Ozaka[5], T. Takahashi[1], Y. Naito[6], S. Okubo[7], T. Nishida[8]

[1]*Department of Gastroenterological Surgery, Osaka University Graduate School of Medicine, Suita, Japan,* [2]*Department of Experimental Therapeutics, National Cancer Center Hospital East, Kashiwa, Japan,* [3]*Department of Medical Oncology, Fujita Health University Hospital, Toyoake, Japan,* [4]*Cancer Center, Hokkaido University Hospital, Sapporo, Japan,* [5]*Department of Gastroenterology, The Cancer Institute Hospital of Japanese Foundation For Cancer Research, Tokyo, Japan,* [6]*Division of Developmental Therapeutics/Breast and Medical Oncology, National Cancer Center Hospital East, Kashiwa, Japan,* [7]*Taiho Pharmaceutical Co. Ltd., Tokyo, Japan,* [8]*National Cancer Center Hospital, Tokyo, Japan*

Background: Mutated KIT and PDGFRA in gastrointestinal stromal tumor (GIST) rely on HSP90 for their functional stability; therefore, HSP90 is a rational therapeutic target in treating GIST in patients (pts) acquired resistance to approved tyrosine kinase

inhibitors. TAS-116 is an oral non-ansamycin, non-purine, non-resorcinol, highly selective inhibitor of HSP90α/β with antitumor activity in an imatinib-resistant human GIST xenograft mouse model. In a phase I study, TAS-116 demonstrated the acceptable safety and the efficacy signs in radiological imaging in pts with GIST including 1 partial response. Here, we conducted a phase II study to evaluate the safety and efficacy of TAS-116 in metastatic or unresectable GIST refractory to standard therapies.

Methods: This was a phase II, open label, single-arm, multi-center study. The key eligibility criteria were histologically confirmed GIST refractory to imatinib, sunitinib, and regorafenib; a measurable lesion per RECIST ver. 1.1; and adequate organ function. Pts received 160 mg/day TAS-116 on a 5-days-on/2-days-off schedule. The primary endpoint was progression-free survival (PFS); secondary endpoints included objective response rate, disease control rate, overall survival, and adverse events. An independent central review (ICR) committee assessed all responses. Sample size was 40 for full analysis set.

Results: From 12 May 2016 to 26 April 2017, 40 pts were enrolled in this study. The numbers of prior treatments was 3 in 24 pts, 4 in 9 pts, and ≥5 in 7 pts. In 34 pts evaluated as of 26 April 2017, the most common adverse events were diarrhea (82%), anorexia (50%), increased serum creatinine (44%), and eye disorders (21%). All eye disorders recovered or resolved following dose interruption, and were limited to Grade 1. There were no treatment-related deaths. According to ICR, median PFS was 4.5 months (95% CI, 2.9–6.1 months). Although none had a partial response, 27 out of 34 pts (79%) had stable disease for ≥6 weeks.

Conclusions: TAS-116 was well tolerated and the initial efficacy results in a ≥ 4th-line treatment setting for metastatic or unresectable GIST, are encouraging. Updated data will be presented at the meeting.

Background: CMB305 is an active immunotherapy designed to generate and expand anti-NY-ESO-1 immune response (IR). CMB305 consists of a dendritic cell-targeting lentiviral vector encoding NY-ESO-1 (LV305), and a boost with an NY-ESO-1 recombinant protein plus GLA-SE (G305), a TLR-4 agonist. Phase 1 studies of LV305 and CMB305 showed this approach is safe, generates IR and appears to impact survival with 81% 1-yr survival in NY-ESO-1+ sarcoma patients (pts) following LV305 treatment. We evaluated efficacy and IR for combination of CMB305 (C) and atezolizumab (A) or A alone in NY-ESO-1^{+} synovial sarcoma (SS) and myxoid round cell liposarcoma (MRCL).

Methods: A prospective randomized open label phase 2 study of C (LV305 Intradermal Days 0, 14, 42, 70 + G305 Intramuscular Days 28, 56, 84 then q6wk up to one year) + A (1200mg IV q3wk) vs. A alone in locally advanced or metastatic NY-ESO-1+ SS/MRCL. Primary endpoints are progression free survival (PFS) and overall survival (OS) with secondary endpoints of safety, IR, and response rate.

Results: As of December 30, 2016, 58 patients were enrolled. A prespecified interim analysis of PFS included the first 36 pts with median 7.0 mos follow up (Arm A+C: median age 47 yrs, 78% SS, 100% metastatic, 78% = >2 chemotherapy; Arm A: median age 44 yrs, 56% SS, 67% metastatic, 56% = >2 chemotherapy). Combination A+C was well tolerated. Clinical benefit was similar between arms (Arm A+C: 8/18 pts with SD, 1 pt unconfirmed PR, 6 mos PFS rate 17%; Arm A: 10/18 pts SD, 6 mos PFS rate 22%). In addition, anti-NY-ESO-1 IR seen in 10/19 (53%) pts Arm A+C vs. 3/12 (25%) pts Arm A by T Cell ELISpot, and 9/22 (41%) pts Arm A+C vs. 0% Arm A by antibody ELISA. Pts with IR had target lesion increase of 2% compared to 18% in pts without IR based on preliminary ANOVA-model based analysis. No deaths observed in pts with induced anti-NY-ESO-1 T cell IR (0/13 deaths IR^{+} pts vs. 5/18 deaths IR^{-} pts).

Conclusions: In the interim analysis, Arm A+C resulted in a higher level of anti-NY-ESO-1 IR when compared to Arm A; pts with IR tend to have better target lesion control. Early data indicate that induction of anti-NY-ESO-1 IR may be associated with better survival.

1481PD Efficacy and safety of palbociclib in patients with advanced gastrointestinal stromal tumors refractory to imatinib and sunitinib

A. Italiano[1], A. Adenis[2], J-Y. Blay[3], F. Duffaud[4], M. Rios[5], E. Bompas[6], O. Bouche[7], M. Pulido[8], A. Le Cesne[9]

[1]Medical Oncology, Institute Bergonié, Bordeaux, France, [2]Medical Oncology, Centre Oscar Lambret, Lille, France, [3]Medical Oncology, Centre Leon Berard, Lyon, France, [4]Oncology, CHU La Timone Adultes, Marseille, France, [5]Med, Institut de Cancérologie de Lorraine - Alexis Vautrin, Vandoeuvre Les Nancy, France, [6]Medical Oncology, ICO Institut de Cancerologie de l'Ouest René Gauducheau, Saint-Herblain, France, [7]Oncology, CHU de Reims - Hôpital Robert Debré, Reims, France, [8]Biostatistics, Institute Bergonié, Bordeaux, France, [9]Department of Medical Oncology, Gustave Roussy Cancer Campus, Villejuif, France

Background: p16/CDKN2A loss play a crucial role in GIST progression. Therapeutic options after *progression* to *imatinib* and *sunitinib* are limited. Palbociclib, an oral small-molecule inhibitor of cyclin-dependent kinases 4 and 6, was recently approved for postmenopausal women with advanced hormone receptor–positive, her2-negative breast cancer. Preclinical studies show that palbociclib inhibits the cell cycle and growth in cells with decreased p16.

Methods: This is a multicenter single-arm phase 2 clinical trial based on 2-stage Simon's design which assesses safety and efficacy of palbociclib in patients (pts) with advanced GIST having failed at least on imatinib and sunitinib and with CDKN2A loss assessed by CGH array. All pts had to have documented progressive disease (PD) as per RECIST 1.1 before study entry. Pts receive palbocilcib 150mg day 1-day 21 (oral route), daily until PD or unacceptable toxicity. The primary endpoint is the 4-month non-PD rate according to RECIST 1.1. Based on the following hypotheses: 25% 4-month non-PD rate (H0), 45% acceptable 4-month non-PD rate (H1), 5% type I error rate, 90% power, a total of 57 assessable pts are necessary (22 for the first stage + 25 for the second stage). Following the inclusion of the first 22 pts, if ≥ 7 pts are progression-free at 4 months, the accrual will continue. In order to account for not assessable pts (+/- 10%), 63 pts will be of the French Sarcoma Group.

Results: As of May 2017, 72 pts (52 males, 20 females) have been included in the study. Median age is 66.0 years out of the first 22 first evaluable patients had progressive

disease at 4 months indicating that palbociclib had not reached the primary endpoint to justify continuing accrual after the 1st step of the study.

Conclusions: Palbociclib has no significant activity as a single agent in advanced GIST with p16/CDKN2A loss. Prognostic value of CDKN2A loss in the whole population will be presented at the meeting.

Clinical trial identification: NCT01907607

1482PD Notch pathway inhibition with LY3039478 in soft tissue sarcoma (STS) and gastrointestinal stromal tumours (GIST)

O. Mir[1], A. Azaro[2], J.R. Merchan[3], R. Chugh[4], J.C. Trent[5], J. Rodon[6], U. Ohnmacht[7], C. Smith[8], G.J. Oakley III[7], A. Le Cesne[1], J-C. Soria[9], K. Benhadji[7], C. Massard[1]

[1]Department of Medical Oncology, Gustave Roussy Cancer Campus, Villejuif, France, [2]Molecular Therapeutics Research Unit, Vall d'Hebron University Hospital, Barcelona, Spain, [3]Department of Medicine, Sylvester Comprehensive Cancer Center, Miami, FL, USA, [4]Medical Oncology, University of Michigan, Ann Arbor, MI, USA, [5]Department of Medical Oncology, University of Miami Health System, Miami, FL, USA, [6]Department of Oncology, MD Anderson Cancer Center, Houston, TX, USA, [7]Department of Medical Oncology, Eli Lilly and Company, Indianapolis, IN, USA, [8]Department of Medical Oncology, Eli Lilly and Company, Windlesham, UK, [9]Department of Drug Development, Gustave Roussy Cancer Campus, Villejuif, France

Background: LY3039478 (LY) is an orally bioavailable selective Notch inhibitor (Notch 1-4). Here we report on safety, pharmacodynamics (PD), and anti-tumour activity of LY in patients (pts) with STS/GIST.

Methods: This ongoing, multi-part, phase 1 trial enrolled pts with refractory advanced or metastatic STS and GIST, measurable disease, ECOG score $\leq$1, and baseline tumour tissue. Eligible pts received LY 50 mg three times per week (TIW), for a 28-day cycle until disease progression. Safety assessments were based on CTCAE V4.0. Tumour responses were assessed using RECIST 1.1 and Choi criteria. Primary objectives are to confirm the recommended phase 2 dose of LY and document antitumour activity. Secondary objectives are safety and toxicity, PD, progression-free survival (PFS) and overall survival (OS).

Results: 63 pts have been enrolled and received LY (24 males, 39 females; median age 58, range 31-76). 26 pts had leiomyosarcoma (LMS), 9 liposarcoma, 7 pleomorphic sarcoma, 6 angiosarcomas, 5 rhabdomyosarcoma and 10 GIST. 18 out of 39 (46%) pts with evaluable tumour samples were positive for Notch 1 ICD. 5% and 13% were positive for Notch 2 ICD, and Notch 3 respectively. Per RECIST, 2 out of 53 pts with STS had unconfirmed PR, and 20 SD. In GIST group, 4 pts had SD. Using Choi Criteria, 5 pts in STS had unconfirmed PR. Overall median PFS was 1.74 months (95% CI: 1.68-2.60) and consistent across histology groups (median PFS=2.23, 1.91 and 1.68 months for LMS, GIST and other STS, respectively). PFS rate at 3 months was 42% in LMS, 39% in GIST and 15% in other STS respectively. OS and biomarker/histologic analyses of pre and post treatment biopsies will be presented at the meeting. Most frequent related adverse events (all grades) occurring in $\geq$ 20% of pts included diarrhoea 44 (70%), vomiting 24 (38%), nausea 21 (33%), decreased appetite 17 (27%), fatigue 17 (27%) asthenia 16 (25%), hypophosphataemia 14 (22%).

Conclusions: LY suggested activity in pts with STS and GIST and had a manageable safety profile.

1483PD Imatinib in combination with everolimus in patients with progressive advanced chordoma: results form an Italian phase 2 clinical trial

S. Stacchiotti[1], C. Morosi[2], A. Casale[2], E. Palassini[1], A.M. Frezza[1], A. Messina[2], A. Gronchi[3], G. Garrone[4], E. Venturelli[4], S. Pilotti[5], E. Tamborini[6], P.G. Casali[1]

[1]Adult Mesenchymal Tumor Medical Oncology Unit, Cancer Medicine Dpt, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [2]Radiology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [3]Department of Surgery, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [4]Epidemiology and Prevention Unit, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [5]Pathology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [6]Molecular Biology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy

Background: To evaluate the antitumor activity of imatinib in combination with everolimus in patients (pts) with advanced PDGFB- and/or PDGFRB-positive chordomas with evidence of mTOR and/or of its effectors (i.e. S6, 4EBP1) activation.

Methods: Within an Italian academic prospective phase II clinical study carried out from January 2011 to March 2015, 45 patients with advanced PDGFB/PDGFRB and mTOR/S6/4EBP1 positive chordoma received imatinib 400 mg/day in combination with everolimus at the starting dose of 2.5 mg/day, until progression or limiting toxicity. Eligible pts had to have evidence of progression in the 6 months prior to study entry. The primary endpoint was overall tumor response rate (ORR), defined by the Choi criteria applied also to MRI. Secondary endpoints were RECIST response, progression-free survival (PFS), overall survival (OS).

Results: Fifteen of 45 pts included in the study were pretreated with imatinib (as a single agent). All pts completed their treatment (22 progression; 16 toxicity; 7 other). Among 38/46 patients evaluable by Choi criteria, the best response was: 8 partial response (PR) (ORR, 21%), 23 stable disease (60%) and 7 progression. 42/46 pts were evaluable by RECIST with 1 PR (2%), 36 SD (85%) and 3. Median PFS by Choi criteria was 10 months (range 1-45), with 36% and 17% pts disease-free at 12 and 24 mos, respectively. Median PFS by RECIST was 13 months. At a median follow-up of 31 months, median OS was 47 months.

Conclusions: Although formally negative (the planned target was a Choi ORR $\geq$60%), this study showed that imatinib + everolimus is active in a proportion of progressive advanced chordoma pts. Major dimensional responses were uncommon but disease stabilization was apparently longer than observed with imatinib as a single agent. Toxicity was not negligible.

1484PD A matching-adjusted indirect comparison of trabectedin and pazopanib for the treatment of advanced, metastatic, leiomyosarcomas

R.L. Jones[1], J-Y. Blay[2], A. Lecesne[3], J. Martin-Broto[4], M.J. Pontes[5], J.M. Fernandez Santos[6], B. García San Andrés[7], G. Wang[8], S. Wang[9], C.R. Shin[10], R. Maki[11], S. Patel[12], G.D.S. Demetri[13]

[1]Sarcoma Unit, Royal Marsden Hospital/Institute of Cancer Research, London, UK, [2]Département d'Oncologie Médicale Adulte, Centre Léon Bérard, Lyon, France, [3]Department of Medical Oncology & Surgery, Institut Gustave Roussy, Villejuif, France, [4]MusculoSkeletal Tumor Board of Excellence Sevilla, Hospital Univ. Virgen de Rocio, Seville, Spain, [5]Oncology, Pharma Mar SA, Madrid, Spain, [6]HECOR Oncology, Pharma Mar SA, Madrid, Spain, [7]Marklet Access, Pharma Mar S.A., Madrid, Spain, [8]Biostats, Janssen Research & Development, LLC, Spring House, PA, USA, [9]HECOR, Janssen Pharmaceuticals, Horsham, PA, USA, [10]Med Group Oncology, Janssen Scientific Affairs, LLC, Horsham, PA, USA, [11]Medical Oncology and Hematology, Monter Cancer Center, Lake Success, NY, USA, [12]Oncology, The University of Texas, MD Anderson Cancer Center, Houston, TX, USA, [13]Center for Sarcoma and Bone Oncology, Dana-Farber Cancer Institute and Ludwig Center at Harvard, Boston, MA, USA

Background: Trabectedin (T) and pazopanib (P) are approved treatments for locally advanced or metastatic leiomyosarcoma (L-mSTS). In the absence of head-to-head randomized controlled trials (RCTs); a matched indirect comparison (MAIC) was performed to assess potential differences in clinical efficacy between the treatment groups.

Methods: MAIC was performed by extracting baseline characteristics from two phase III RCTs: SAR 3007 (T) and PALETTE (P): individual patient level data (IPD) was available forT only aggregated was published for P. Excluding those T patients who did not meet inclusion criteria for PALETTE, a sample size of 372 L-mSTS patients (T = 263, P = 109) was generated. Of all baseline characteristics, only time since diagnosis ($\geq$30 vs. < 30 months), age ($\geq$65 vs. < 65 years), and body weight ($\geq$77 vs. < 77 kilograms), were statistically significant outcome predictors with T. The generalized method of moments (GMM) was used to optimally match cohorts for evaluation of

differences in overall survival (OS), progression-free survival (PFS), and safety. Statistical analysis was performed using "R".

Results: There was no statistically significant difference in PFS [HR = 0.82, (95%CI 0.63-1.06, p = 0.13)], or OS [HR = 0.86, (95% CI 0.64-1.18, p = 0.36)]. The percentage of patients with post-progression therapies was higher in T (74.5%) vs. P (59%) group. In the subgroup with PFS ≥6 months, patients treated with T experienced significantly improved median PFS (11.2 months vs PFS 8.4 months HR: 0.47 (95% CI: 0.3007 – 0.7434), p = 0.002 and were significantly more likely to achieve long term survival (OS ≥ 18 months): 45.8% vs. 33.7% (95%CI: 23.5%-48.3%), p = 0.025. Increased myelosuppression and hepatotoxicity observed with T whereas diarrhea, hypertension, pulmonary toxicity/pneumothorax, and neurotoxicity were observed with P.

Conclusions: The MAIC model warrants further investigation and validation. No differences in mPFS or mOS were noted in a MAIC comparison. Among patients achieving long term disease control (PFS > 6 mo), T significantly increased mPFS and the proportion of patients achieving prolonged overall survival (OS ≥ 18 mo). Differences in the safety profile were highlighted by this indirect comparison.

1485P Localized undifferentiated endometrial sarcomas (LUES): Results of a French Sarcoma Group (FSG) retrospective series of 39 patients (pts)

M. Meurer[1], F. Duffaud[2], S. Salas[2], F. Bertucci[3], A. Floquet[4], N. Penel[5], I. Ray-Coquard[6], A. Italiano[7], J-Y. Blay[8], P. Pautier[9], M. Delannes[10], S. Piperno-Neumann[11], J. Mancini[1], M. Auriche[9]

[1]CHU La Timone Adultes, Marseille, France, [2]Oncology, CHU La Timone Adultes, Marseille, France, [3]Institute Paoli Calmettes, Marseille, France, [4]Medical Oncology, Institute Bergonié, Bordeaux, France, [5]Medical Oncology, Centre Oscar Lambret, Lille, France, [6]Medical Oncology, Centre Léon Bérard, Lyon, France, [7]Medicine, Institute Bergonié, Bordeaux, France, [8]Medical Oncology, Centre Leon Berard, Lyon, France, [9]Medical Oncology, Gustave Roussy Institut de Cancérologie, Villejuif, France, [10]IUCT, Toulouse, France, [11]Medical Oncology, Institut Curie, Paris, France

Background: UES are tumors of very bad prognosis. Although large surgical resection is the cornerstone of curative intent treatment, the optimal post-operative strategy remains unclear.

Methods: We conducted a retrospective analysis of LUES pts (Stade I-III) over the last 8 years in 10 FSG centers, from Netsarc and RRePs databases.

Results: Thirty-nine pts with primary LUES treated from 2008 to 2016 were included, with median age of 61 years (range, 43-80), and median ECOG of 0 (range, 0-3). Metrorrhagia, abdominal pain, and pelvic mass bleeding were the most common symptoms. The locoregional extension report usually included: gynecological examination (71%), and/or pelvic MRI (83%) and/or abdomino-pelvic CT scan (43%). The remote extension report was performed preoperatively for only 17/39 (50%) pts. Among 39 LUES, 24 (67%) were stage I, 3 (8%) stage II and 9 (25%) stage III. All the patients were operated on and surgical procedures were radical hysterectomy and bilateral oophorectomy for 26/39 (70%).Tumor resections were mostly R0, 23/39 (74%) and R1, 6/39 (19%). Tumor rupture occurred in 6 pts. For 7/39 LUES there was a positivity of hormonal receptors and/or cyclin D1. Twenty-two (56%) received post-operative radiotherapy (11 of them with complementary brachytherapy) and 11 (31%) adjuvant chemotherapy. With a median follow-up of 33 months (0.3-112), 17/39 pts are alive, 21/39 (54%) relapsed (7 local relapse and 13 metastases). The 3- and 5-year Overall Survival (OS) rates are 49.8% and 31.1% respectively. Median OS and Relapse-Free Survival (RFS) are 32.7 (16.3-49.1) and 23 (4.4-41.6) months, respectively. In univariate analysis; early FIGO stage (p < 0.0001), complete resection (R0-R1 vs R2; p = 0.027), ECOG (p = 0.02) and adjuvant radiotherapy (p < 0.0001) were associated with a better OS; vascular invasion (p = 0.024) and adjuvant radiotherapy (p = 0.021) were associated with a better RFS.

Conclusions: Treatment of primary LUES is radical hysterectomy and bilateral oophorectomy. Adjuvant radiotherapy appears beneficial for RFS and OS. The FIGO stage seems to have an impact on OS. A prospective study could be carried out to validate this therapeutic management.

1486P An epidemiological insight into epithelioid sarcoma (ES): The open issue of distal-type (DES) versus proximal-type (PES)

A.M. Frezza[1], L. Botta[2], S. Pasquali[3], S. Stacchiotti[1], A. Gronchi[3], P.G. Casali[1], A. Trama[2], W.G. Rarecarenet[2]

[1]Adult Mesenchymal Tumour and Rare Cancer Medical Oncology Unit, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [2]Evaluative Epidemiology Unit, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [3]Department of Surgery, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy

Background: ES is a rare sarcoma with distinctive pathologic and clinical features as well as the potential to respond to new targeted agents. We used the RARECAREnet and the SEER18 cancer registry (CR) databases (DB) to highlight the epidemiological hallamrks of ES in the EU and in the US.

Methods: The ICD-O3 code 8804 applies both to the DES and PES. Thus we broke down the primary sites using the ICD-O3 topography codes, to separate the anatomically proximal and distal forms, as a partial surrogate for the two entities of DES and PES. Incidence rate (IR), world-age adjusted IR and relative survival (RS) were calculated for ES patients diagnosed in the period 2000-07 and followed-up at least up to 31st Dec 2008. RS was estimated by the Ederer II method. 497 new cases of ES were identified from available registries in the EU, 301 in the US.

Results: Crude IR was 0.03/100,000 in the EU and 0.05/100,000 in the US. Age-adjusted IR were 0.02/100,000 and 0.05/100,000 respectively. M:F ratio was 1.6 in both sets of registries. Mean age at diagnosis was 46 in the EU and 44 yrs in the US. IR increased with age (higher in > 75-yr patients). IR in the childhood population (<14 yrs) was 0.01, i.e., 5% of all new ES cases. IR was similar for anatomically distal and proximal groups, but the latter was more incident in older patients. 5-yr RS was 50% and 52% in the EU and US, respectively. In both registries, 5-yr RS was higher in anatomically distal than in anatomically proximal (EU: 65% vs 38%; US: 69% vs 34%), evenly across all age groups (Table).

Conclusions: ES is a very rare cancer, exceedingly low in childhood. Prognosis is serious, making the identification of new treatments a priority. New targeted agents are currently under study. However, the distinction between DES and PES is likely to be of major prognostic significance. In fact, using anatomical location as a proxy, though inappropriate, we could see clear-cut differences in the epidemiological outcome. An effort to stratify ES patients by their pathologic subtype is warranted in all studies, all the more on new agents.

1487P Natural history of alveolar soft part sarcoma (ASPS): Impact of brain metastases and role of anti-angiogenic therapies (AAT)

G. Malouf[1], G. Beinse[1], O. Mir[2], J. Adam[3], P. Terrier[3], J-P. Spano[1], C. Honore[4], A. Italiano[5], J-M. Coindre[6], J-Y. Blay[7], A. Lecesne[2]

[1]Medical Oncology, Groupe Hospitalier Pitié Salpetriere, Paris, France, [2]Department of Cancer Medicine, Gustave Roussy Cancer Campus, Villejuif, France, [3]Department of Pathology, Gustave Roussy Cancer Campus, Villejuif, France, [4]Department of Surgical Oncology, Gustave Roussy Cancer Campus, Villejuif, France, [5]Early Phase Trials and Sarcoma Units, Institute Bergonié, Bordeaux, France, [6]Department of Biopathology, Institute Bergonié, Bordeaux, France, [7]Department of Adult Medical Oncology, Centre Leon Berard, Lyon, France

Background: ASPS is a rare sarcoma subtype with clinical specificities, such as an indolent behavior, brain metastasis and resistance to doxorubicin. AAT have shown clinical activity in this setting, but little is known on the optimal therapeutic strategy, and the management of brain metastasis (BM).

Methods: We retrospectively analyzed patients (pts) treated in 3 referral centers of the French Sarcoma Group. Factors associated with BM development and overall survival (OS) were analyzed. In addition, progression-free survivals (PFS) under AAT in patients with and without BM were reported.

Results: We identified 75 pts [median age at diagnosis: 23 (5-96 years), 61% females]. Among those, 31 (41%) pts had documented synchronous lung metastasis (LM), and none had BM. Median OS in pts with localized and metastatic disease were 279 months, (95% CI, 279-NR) and 74 months (95% CI, 62-144) (Log-rank, $p = 0.002$), respectively. Only surgical complete resection (R0) was associated with better OS in localized disease (HR = 4.3; (95% CI, 1-19.3), $p = 0.056$). Fifty-two (69%) pts had documented LM in the course of the disease; among those, 13 (17%) pts developed BM within a median interval of 35 months (95% CI, 17-48) from LM. Initial tumor size was associated with BM-free-survival ($\geq$5cm *vs* <5 cm): HR = 6.7 (95% CI, 1.7-26). Twelve pts were treated with AAT (sunitinib, n = 10) including 5 (42%) with documented BM; median PFS under AAT were 2 months (95% CI, 1.3-2.7) for pts with BM and 11 months (95% CI, 9-18) for pts without BM, respectively (p=0.004). BM was the cause of death or major contributing factor to it in 36% of pts.

Conclusions: These data highlight the indolent course of the disease leading to BM, which turned a shift in the course of the disease, along with limited efficacy of AAT in this setting. Furthermore, they suggest that the appropriate timing for AAT introduction has to be discussed in an individual basis considering the PFS/OS ratio in pts with metastatic disease.

Background: We previously reported on the real world treatment and outcomes of 423 angiosarcoma pts in Asia. In this current report, we focus on the 173 pts with V-AS and evaluate the treatment patterns and prognostic factors associated with this disease subset.

Methods: This is a retrospective chart review of V-AS pts seen at 8 Asian academic study sites. Survival analysis is measured from date of presentation to the study site.

Results: Median study follow-up was 8.7 mths. Median age 52 yrs; 86% of pts presented with primary disease to study site. 42% (n = 73) had localized disease and 56% (n = 97) had locally advanced/unresectable or metastatic disease; disease status was unknown for 3 pts. Distribution of primary site as follows, liver (n = 38, 22%), cardiovascular system (n = 30, 17%), breast (n = 25, 14%), spleen (n = 18, 10%) and others (n = 62, 36%) from a myriad of organ systems each representing <10% of cases. More pts with breast AS presented with localized disease. For pts with localized disease, primary treatment was surgery in 74% (n = 54) of pts. Of 38 pts with known margins, R0 and R1 were achieved in 71% and 21% respectively. In pts who had surgery, 43% developed subsequent disease relapse/progression with a median PFS of 9.5 mths. Of 97 pts with advanced/unresectable disease, 59% of pts received chemotherapy as part of treatment while 22% and 20% had surgery/radiation only or supportive care only respectively. 46% of chemotherapy-treated pts had 1 line of treatment while 35% and 19% had 2 or > 3 lines of treatment respectively. The most common first line chemotherapy used was paclitaxel (53%) followed by liposomal doxorubicin (18%). Median OS was 11.9 mths in the overall V-AS cohort, with median OS 29.2 mths and 6.3 mths in the localized and advanced/unresectable cohort respectively. In the univariate analysis of pts with unresectable/metastatic disease, only ECOG was associated with OS.

Conclusions: This study highlights the heterogeneity and treatment challenges of visceral angiosarcoma. Overall prognosis is poor, in particular in pts with advanced/unresectable disease.

1489P High dose loco-regional chemotherapy for locally advanced angiosarcoma: A multicenter study

E. Huis in 't Veld[1], D.J. Grunhagen[2], K. Verhoef[2], H.G. Smith[1], A. van Akkooi[3], R.L. Jones[4], F. Van Coevorden[3], A.J. Hayes[1], W.J. van Houdt[1]

[1]Surgical Oncology, Royal Marsden Hospital NHS Foundation Trust, London, UK, [2]Surgical Oncology, Erasmus MC - Cancer Institute, Rotterdam, Netherlands, [3]Surgical Oncology, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, [4]Medical Oncology, Royal Marsden Hospital NHS Foundation Trust, London, UK

Background: Angiosarcomas are rare aggressive sarcomas that count for 2% of all soft tissue sarcomas. The only potential curative treatment is complete surgical excision, but a large subset of patients present with locally advanced disease. The aim of this study was to evaluate the effectiveness of Isolated Limb Perfusion (ILP) as an alternative treatment option for locally advanced angiosarcoma in the extremities.

Methods: All patients who underwent an ILP for angiosarcomas between October 1991 and October 2016 in three tertiary referral centres were identified from 3 prospectively maintained databases. Demographics, tumour, treatment and response characteristics and the disease course were all obtained from either the database or patient files. Statistical analysis was performed using SPSS statistics 24.

Results: A total of 39 patients were included. The median age was 66 (range, 24-95) years. Of these patients, 23 (59%) patients had a complete resonse after ILP, 10 (25.6%) patients had a partial response, 4 (10.3%) had stable disease and 2 (5.1%) patients had local progression immediately after ILP. Of all patients, a total of 22 patients developed local progression (56,4%) while 10 (25.6%) developed distant metastases. Median time to progression; 7,4 months (IQR 3-14,9) and median time to distant metastasis of 6,4 months (IQR 1,5-44,9). The 10 (25,6%) patients with a complete response (compared to PR/SD/PD) had a non-significant trend towards better median overall survival (81,2 vs 14,5 months) (p = 0,054), and had a significantly prolonged median progression free survival (15,4 vs. 7,3 months) (p = 0,015). A total of 5 patients underwent multiple ILP's whereby the complete response rate of the first, second and third ILP were 60% (n = 4/6), 80% (n = 4/5) and 67% (n = 2/3) respectively. Only 13 (33,3%) patients needed further surgical intervention, consisting of wide local excision in 8 patients (20,5%) and amputation in 5 patients (12,8%).

Conclusions: ILP should be considered as treatment option in the multidisciplinary management of patients with locally advanced limb angiosarcomas, resulting in a high limb salvage rate, high number of complete responses and prolonged progression-free survival.

1490P Primary cardiac sarcoma (PCS): A multi-national retrospective review of clinical experience

T.W-W. Chen[1], H.H. Loong[2], A. Zer[3], R. Barua[4], J. Buttany[5], R.J. Cusimano[6], Y-C. Liang[7], C-H. Chang[8], Z. Iakobishvili[3], A.R.A. Razak[9], J. Lewin[9]

[1]Department of Oncology, National Taiwan University Hospital, Taipei, Taiwan, [2]Department of Clinical Oncology, The Chinese University of Hong Kong, Hong Kong, China, [3]Rabin Medical Center, Tel Aviv University, Tel Aviv, Israel, [4]Department of Medicine, University of Toronto, Toronto, ON, Canada, [5]Division of Pathology, University Health Network, Toronto, ON, Canada, [6]Division of Cardiovascular Surgery, University Health Network, Toronto, ON, Canada, [7]National Taiwan University College of Public Health, Institute of Epidemiology and Preventive Medicine, Taipei, Taiwan, [8]Department of Medical Research, National Taiwan University Hospital, Taipei, Taiwan, [9]Department of Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: Primary cardiac sarcoma (PCS) is a rare but often fatal disease. The current study aimed to analyze the impact of baseline demographics, local and systemic therapies in a contemporary cohort.

Methods: Clinical records of PCS across five institutions in three continents were reviewed and collected. Kaplan-Meier method was used to estimate survival. Cox proportional hazard model was used to associate variables to progression-free survival (PFS) or overall survival (OS).

Results: 47 pts with PCS (1996-2016) with a median follow-up time of 12.9 months (ms) were identified. The median age at diagnosis was 41 (range 18-79); 43% (n = 20) presented with metastatic disease. Tumor equally originated from right- (n = 23) and left-sided heart (n = 23). The common histologies were angiosarcoma (n = 18, 38%), intimal sarcoma (n = 8, 17%), and sarcoma NOS (n = 10, 21%). 66% (n = 31) had surgical (S) treatment for PCS, and only 4 (13%) pts had R0 resection. The median primary lesion size was 49 mm (20-84 mm). 70% (n = 33) of pts received at least one line of chemotherapy (C), and 51% (n = 24) received multi-modality treatment (45% S + C, 4% S + XRT, 2% S + C + XRT). The median OS was 17.7 ms (95% CI 12.4-21.8 ms). For all pts, age $\geq$ 65 was the only significant negative prognostic factor (HR 7.43, $p < 0.01$, Table 1). In localized PCS, angiosarcoma histology was a significant factor for worse PFS (HR 3.05, $p = 0.04$) and OS (HR 2.56, $p = 0.11$). 29 metastatic or relapsed pts received C. For first-line palliative C (52% combination, 48% single agent), the median PFS was 3.8 ms (95% CI 1.5-6.9 ms). The best response for first-line C was PR 10 (35%), SD 4 (14%), PD 12 (41%). 60% (6/10) of pts with PR were treated with anthracycline (angiosarcoma n = 5; intimal sarcoma n = 1). No significant improvement in OS was identified in pts presenting throughout the 20 year period of this review (pre- vs post 2012; HR 1.1, $p = 0.81$).

Table: 1490P Prognostic factors for all pts

Variable	HR (95% CI)	P Value
Age $\geq$ 65	7.43 (2.54-21.72)	0.0002
Metastatic disease at diagnosis	1.87 (0.90-3.88)	0.09
Multi-modality treatment	0.64 (0.32-1.27)	0.20
Angiosarcoma histology	1.58 (0.72-3.47)	0.26

Conclusions: The prognosis of PCS remains poor without significant improvement in OS compared to historical levels. Further research is required for this rare entity.

1491P Primary cardiac sarcoma: A retrospective study in two Korean tertiary centers

H. Ahn[1], H.K. Kim[2], K.H. Yoo[1], Y.S. Kim[1], S.J. Lee[2]

[1]Hematology and Oncology, Gachon University Gil Hospital, Incheon, Republic of Korea, [2]Division of Hematology-Oncology, Departments of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea

Background: Primary cardiac sarcoma(PCP) is a rare diasease with dismal prognosis. Optimal treatment strategy for PCP is not clear.

Methods: We retrospectively reviewed patients diagnosed with PCS in two institutions in Korea, between 1996 and 2013. A total of 41 patients were identified. Clinical characteristics and treatment outcomes were investigated. Survival was estimated and compared by Kaplan-Meier method and Log-rank test.

Results: Median age was 44 years. Eighteen patients (43.9%) were male. The most common type was angiosarcoma (N = 20, 48.7%), followed by poorly-differentiated sarcoma (N = 7, 17.1%). Most tumors were located in atriums (N = 27, 65.9%). At diagnosis, 31 patients (75.6%) had localized disease. Surgical resection of primary cardiac tumor was performed in 28 cases (68.3%) and microscopic complete resection were achieved in 12 localized cases. Median overall survial was 13.2 months for entire patients, 17.0 months after complete resection, 17.9 months after incomplete resection and 5.7 months in non-resected cases. Patients who received adjuvant chemotherapy and/or radiotherapy after surgery had significantly better median OS of 21.6 months than 11.0 months of those received surgical resection alone without adjuvant treatment ($p = 0.007$).

Conclusions: Surgical resection and multidisciplinary treatment were associated with better survival in patients with primary cardiac sarcomas. Aggressive multidisciplinary approaches may have a role in subset of patients with primary cardiac sarcomas.

1492P The differences in recurrence and survival of extremity liposarcoma subtypes

M. Vos[1], H. Kosela Paterczyk[2], P. Rutkowski[2], G.J.L.H. van Leenders[3], M. Normantowicz[4], A. Lecyk[4], S. Sleijfer[5], K. Verhoef[6], D.J. Grünhagen[6]

[1]Medical Oncology/Surgical Oncology, Erasmus MC Cancer Institute, Rotterdam, Netherlands, [2]Soft Tissue/Bone Sarcoma and Melanoma, The Maria Sklodowska-Curie Memorial Institute and Oncology Centre, Warsaw, Poland, [3]Pathology, Erasmus MC Cancer Institute, Rotterdam, Netherlands, [4]First Faculty of Medicine, Medical University of Warsaw, Warsaw, Poland, [5]Medical Oncology, Erasmus MC Cancer Institute, Rotterdam, Netherlands, [6]Surgical Oncology, Erasmus MC Cancer Institute, Rotterdam, Netherlands

Background: Liposarcomas (LPS) are most frequently located in the extremity and recur often, locally as well as on distant sites. There are currently no studies comparing the differences between the different LPS subtypes specifically on this primary site. The aim of this study is to map the differences in recurrence and survival of extremity LPS.

Methods: Two retrospective databases (Rotterdam-R, Warsaw-W) of patients treated for primary LPS located in the extremities from 1985-2015 in two tertiary referral centers were used to analyze recurrence patterns (local/distant) and survival.

Results: In total, 456 patients were identified: 192 with well differentiated LPS (WDLPS), 172 myxoid LPS (MLPS), 54 pleomorphic LPS (PLPS), 23 dedifferentiated LPS(DDLPS) and 15 other subtypes (excluded from further analysis). A difference between the two datasets was the frequency of (neo)adjuvant radiotherapy (R: 34.9% vs. W: 81.5%). In the Rotterdam cohort, local recurrence (LR) was observed most frequent in DDLPS (4/13, 5-year LR free survival 56.6%), followed by WDLPS (26/113, 64.9%), PLPS (3/20, 78.6%) and MLPS (10/77, 84.0%, $p = 0.136$). In the Warsaw cohort, 5-year LR free survival was the lowest in PLPS (9/34, 67.7%), followed by DDLPS (1/10, 83.3%), MLPS (12/95, 84.9%) and WDLPS (3/79, 94.1%, $p = 0.001$). Distant metastases (DM) were most commonly observed in PLPS in both datasets (5-year DM free survival R: 9/20, 50.3% and W: 16/34, 44.5%), but in the Rotterdam cohort MLPS (16/77, 76.3%) was the second most common subtype with DM, compared to DDLPS (2/10, 62.5%) in Warsaw. DM in WDLPS was rare in both datasets (R:3/113, 96.3%, W: 1/79, 98.5%). 5-year overall survival (OS) did not significantly differ between the two datasets (R: 38/223, 78.5% vs. W: 32/218, 80.9%, $p = 0.561$), but did significantly differ between the subtypes (R: $p = 0.005$, W: $p < 0.001$). In both datasets, 5-year overall survival was poorest in PLPS (R: 8/20, 57.5%, W: 15/34, 38.8%) and DDLPS (R: 4/13, 59.9%, W: 3/10, 44.4%), followed by MLPS (R: 16/77, 75.6%, W: 13/95, 83.1%) and WDLPS (R: 10/113, 88.2%, W: 1/79, 98.5%).

Conclusions: Patients with the four LPS subtypes show distinct patterns of LR, DM and OS. Despite the differences in recurrence, treatment and follow up, OS did not differ significantly between the two expertise centers.

1493P The sarcoma policy checklist: Focusing policy efforts on sarcoma

B. Kasper[1], P.G. Casali[2], N. Drove[3], S. Dumont[4], M. Eriksson[5], A. Gronchi[6], E. Lecointe[7], C. Valverde Morales[8], R. Wilson[9], S. Boldon[10], S. Wait[10], M. Wartenberg[11]

[1]Mannheim University Medical Center, University of Heidelberg, Mannheim, Germany, [2]Adult Mesenchymal Tumour and Rare Cancer Medical Oncology Unit, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [3]Oncology, Eli Lilly and Company, Madrid, Spain, [4]Department of Cancer Medicine, Institut de Cancérologie Gustave Roussy, Villejuif, France, [5]Skåne University Hospital, Department of Oncology, Lund, Sweden, [6]Department of Surgery, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [7]InfoSarcomes, Rennes, France, [8]Medical Oncology, Vall d'Hebron University Hospital, Barcelona, Spain, [9]The Sarcoma Patients Euronet (SPAEN), Shropshire, UK, [10]The Health Policy Partnership, London, UK, [11]SPAEN, Wölfersheim, Germany

Background: The Sarcoma Policy Checklist was developed by a multi-stakeholder group of experts to help policymakers prioritise actions to close the gap in access to high-quality information and care for sarcoma patients in Europe.

Methods: Experts defined five key areas where policy efforts are most needed to improve the care of sarcoma patients across Europe. A pragmatic review of the published literature was then conducted to determine to what extent recommendations were implemented in practice. Research focused on six countries (France, Germany, Italy, Spain, Sweden and the United Kingdom) and was complemented by local expert interviews.

Results: Five key priority areas were identified by experts: Each country should have designated, accredited centres of reference for sarcoma; specialised professional training should be provided to all health care professionals involved in sarcoma care; a multidisciplinary approach to care should be offered to every patient; greater incentives for research and innovation, and more rapid access to effective treatments are needed. Most countries have specialist sarcoma centres, however, there is often a lack of defined criteria to designate specialist centres and evaluate the quality of care. Professional training is a gap in all countries, as training on rare cancers is most often not included in the general medical curriculum or in oncologists' training. More basic research is needed to understand the underlying epidemiology of sarcomas, and help focus research on effective treatments. Greater alignment between regulatory frameworks and access frameworks such as Health Technology Assessment is needed, particularly in terms of evidentiary requirements for new treatments.

Conclusions: The heterogeneity of sarcomas poses particular challenges to research, professional training and patient access to quality treatment and care. The creation of the European Reference Network (ERN) on sarcoma, and recent advances in defining essential requirements and patient-driven principles for sarcoma care will help improve the situation of sarcoma patients across Europe. This policy paper hopes to contribute to those efforts and help drive meaningful policy change to improve patient care.

1494P Dermatofibrosarcoma protuberans might not benefit from postoperative radiotherapy after local resection with negative margin

J. Chen, K.X. Du, J.Y. He, Q.Q. Peng, L.R. Tan, J.L. Li, K.X. Du

Department of Radiation Oncology, Fujian Provincial Cancer Hospital, Fuzhou, China

Background: To evaluate the role of postoperative radiotherapy (RT) in the treatment of dermatofibrosarcoma protuberans (DFSP) after local resection with negative margin.

Methods: We retrospectively analyzed 84 consecutively treated DFSP patients who received local resection ($\leq$2cm) with negative margin from 2000 to 2016 in our institution. Statistical analysis was performed with a commercially available statistical software package.

Results: The median follow-up was 60 months (range, 10-201). For patients (28/84) with postoperative RT, four (4/28) patients were found to had local relapse, while three of them had $\leq$ 1 cm surgical margin. For patients without postoperative RT, four (4/56) patients had local failure. Postoperative RT failed to improve the local recurrence-free survival (LRFS) of DFSP after local resection with negative margin (Fisher=0.431). Patients with fibrosarcomatous DFSP (FS-DFSP) were found to have higher local recurrent rate than DFSP (66.7% vs. 7.4%, Fisher=0.023). Twenty-six patients were examined for ki-67, and positive range is 1-30%. Patients with high ki-67 expression (>15%) were found to have higher local recurrence rate than the others (80.0%vs0%, Fisher=0.000).

Conclusions: Postoperative RT did not improve the LRFS of DFSP after local resection with negative margin. FS-DFSP was more likely to have a local relapse than the other types. Ki-67 might become a good predictor for local control of DFSP.

1495P Low-dose chemotherapy with methotrexate and vinblastine for desmoid tumors: A single institution experience

J. Souza, H.M. Lourenço, G. Mendes

Medical Oncology, INCA - Instituto Nacional de Cancer, Rio de Janeiro, Brazil

Background: Desmoid tumor (DT) is a rare and locally invasive proliferative disease. Although, the absence of metastatic potential, it has the propensity for locally invasive growth and recur. Chemotherapy may be considered in inoperable and/or recurrent disease.

Methods: Patients with histological diagnosis of DT and treated with weekly low-dose chemotherapy with vinblastine and methotrexate between January 1998 and December 2015 were identified and their medical records were analyzed.

Results: Of 23 patients analyzed, most of them were women (female-to-male ratio 2.8:1). The median age at presentation was 29 years (range, 18-59 years). Tumors location was: thoracoabdominal wall (n: 11, 47.8%), extremities (n: 7, 30.4%), abdominal cavity (n: 1; 4%), and head and neck (n: 4, 17.3%). Tumor sizes were documented in 18 cases and ranged from 3 to 20 cm in largest linear dimension (median, 10 cm). Eight (34.7%) female had pregnancy history and 2 (8%) had familial adenomatous polyposis history. Eleven (47,8%) underwent surgery as first-line treatment. Five (21.7%) patients received first-line treatment with vinblastine and methotrexate, four (17.3%) patients as second-line, and 14 (60.8%) patients as third and fourth-line. Fourteen (60.8%) patients had stable disease, four (17.3%) had partial response, and five (21.7%) patients had progressive disease during chemotherapy treatment. After a median follow-up of 58 months, 12 patients had progression disease and 2 patients died. The median PFS was 29 months, without any progression after 32 months.

Conclusions: Discussion: Weekly low-dose chemotherapy with vinblastine and methotrexate appears to have significant activity. Chemotherapy could be an acceptable alternative to radical surgery in selected patients with desmoid tumors.

1496P EORTC experience with advanced/metastatic epithelioid sarcoma patients treated in prospective trials: Clinical profile and response to systemic therapy

N. Touati[1], P. Schoffski[2], S. Litière[3], I. Judson[4], S. Sleijfer[5], W.T.A. van der Graaf[6], A. Italiano[7], N. Isambert[8], T. Gil[9], J-Y. Blay[10], D. Stark[11], T. Brodowicz[12], S. Marreaud[13], A. Gronchi[14]

[1]Statistics, EORTC, Brussels, Belgium, [2]General Medical Oncology, UZ Leuven, Leuven, Belgium, [3]Statistics, EORTC - European Organisation for Research and Treatment of Cancer, Brussels, Belgium, [4]Medical Oncology, Royal Marsden Hospital NHS Foundation Trust, London, UK, [5]Medical Oncology, Erasmus MC Cancer Institute, Rotterdam, Netherlands, [6]Medical oncology, Royal Marsden Hospital NHS Foundation Trust, London, UK, [7]Medicine, Institute Bergonié, Bordeaux, France, [8]Oncologie 3, Centre Georges-François Leclerc (Dijon), Dijon, France, [9]Medical Oncology, Jules Bordet, Brussels, Belgium, [10]Medical Oncology, Centre Leon Berard, Lyon, France, [11]Medical Oncology, St. James's University Hospital Leeds, Leeds, UK, [12]Medical Oncology, Vienna General Hospital (AKH) - Medizinische Universität Wien, Vienna, Austria, [13]Medical, EORTC, Brussels, Belgium, [14]Department of Surgery, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy

Background: Epithelioid sarcoma (ES) is a soft-tissue sarcoma (STS) associated with a high local recurrence rate after primary resection and high incidence of distant metastasis. Little is known about clinical course and response to systemic treatments. This retrospective analysis aims to provide a reference for future ES-specific studies.

Methods: Data from patients with locally advanced/metastatic ES entered in prospective multi-sarcoma phase II/III trials were pooled: EORTC trial 62012 (doxorubicin vs. doxorubicin/ifosfamide), 62043 (pazopanib), 62072 (pazopanib vs. placebo) and 62091 (doxorubicin vs. trabectedin). Patients had either a local or centrally confirmed diagnosis of ES, inoperable/metastatic disease at study entry and were eligible for the respective trial. Response was assessed using RECIST 1.1. Progression-free survival (PFS) and overall survival (OS) were calculated from date of study entry.

Results: Among 1099 patients with advanced STS, 27 ES patients (2.5%) were eligible (17 male (63%), median age at diagnosis 50 yrs, range 19-72). 18 (66.7%) received chemotherapy as 1st line treatment (5 doxorubicin, 8 doxorubicin/ifosfamide, 2 pazopanib, 3 trabectedin) and 9 (33.3%) received pazopanib in 2nd line or later. Primary tumor was located in lower extremity (N = 8; 29.6%), upper extremity (N = 5; 18.5%), retro/intra-abdominal (N = 4; 14.8%), other locations (N = 10; 37.0%). At study entry, metastases were mainly found in lung (N = 17; 63%), lymph nodes (N = 9; 33.3%), bone (N = 8; 29.6%) and soft tissue (N = 7; 25.9%). Best response for 1st line patients was 4 partial responses (PR, 22.2%), 10 stable disease (SD, 55.6%) and 4 progressive disease (PD, 22.2%). In subsequent lines, pazopanib achieved 1 PR (11.1%), 4 SD (44.4%) and 4 PD (44.4%). All patients but one progressed. Median PFS and OS were 3.8 (95% CI: 2.2-4.8) and 10.8 months (95% CI: 8.1-21.3), respectively. 5 patients were still alive at time of the according trial analysis.

Conclusions: With all limitations of a retrospective analysis of such small dataset, objective response and survival outcomes of this locally advanced/metastatic ES population are relatively poor. The clinical testing of novel agents remains a high priority.

1497P Efficacy and safety of patients treated long-term with trabectedin (t) on the expanded access program: A retrospective analysis

E. Davis[1], S. Schuetze[2], S. Patel[3], R. Maki[4], R.L. Jones[5], C.R. Shin[6], R. Knoblauch[7], G. Wang[8], M. Smith[7], G.D.S. Demetri[9], P. Merriam[10]

[1]Division of Hematology/Oncology, Vanderbilt University Medical Center, Nashville, TN, USA, [2]Division of Hematology/Oncology, University of Michigan, Ann Arbor, MI, USA, [3]Department of Sarcoma Medical Oncology, The University of Texas, MD Anderson Cancer Center, Houston, TX, USA, [4]Medical Oncology and Hematology, Monter Cancer Center, Lake Success, NY, USA, [5]Medical Oncology, Royal Marsden Hospital, London, UK, [6]Med Group Oncology, Janssen Scientific Affairs, LLC, Horsham, PA, USA, [7]Clin Oncology, Janssen Pharmaceuticals, Raritan, NJ, USA, [8]Biostats, Janssen Research & Development, LLC, Spring House, PA, USA, [9]Center for Sarcoma and Bone Oncology, Dana-Farber Cancer Institute and Ludwig Center at Harvard, Boston, MA, USA, [10]Center for Sarcoma and Bone Oncology, Dana-Farber Cancer Institute, Boston, MA, USA

Background: Treatment of soft tissue sarcoma (STS) with long-term systemic therapy can be limited by cumulative toxicity. Treatment with T for prolonged courses without the cumulative toxicity has been previously described from clinical trials. Here we report the efficacy and safety for patients (pts) treated long term (≥ 6 months) in a real world setting in the T Expanded Access Program from 2005-2010.

Methods: In this retrospective analysis of pts with pre-treated, relapsed/refractory STS of multiple histologies treated ≥6 mo with T (1.5 mg/m2 iv q3wk), we compared pts treated 6-12 mo and >12 mo.

Results: Of 1803 pts, 401 (21.6%) remained on treatment ≥6 mos; 268 (14.5%) for 6-12 mo and 133 (7.2%) >12 mo. Demographics did not differ. Leiomyosarcoma or liposarcoma were the most common histologies. The mOS (mo) was 18.1 and 47.0, ORR was 7.8% and 6.8%, and clinical benefit rate (CR+PR+SD) (95%CI) was 47.4% (41.3;53.6) and 38.3% (30.1;47.2) in the 6-12 mo and >12 mo groups, respectively. The incidence of adverse events (AE)s and serious adverse events (SAE)s were similar in both groups (Table). The most common grade 3/4 AEs occurring in ≥ 5% were neutropenia, thrombocytopenia, anemia, ALT/AST increase, fatigue and nausea. A majority received dose reduction or delay; the primary reason for treatment discontinuation was disease progression. The longest observed duration of treatment was 55 mo (64 cycles; synovial sarcoma) and 54 mo (73 cycles; uterine leiomyosarcoma).

Table: 1497P Safety and Efficacy

	6-12 Months (N = 268)	>12 Months (N = 133)
Median Treatment Duration (mo), range	8.4(6; 12)	16.3 (12; 55)
Treatment Response,		
Complete response, n (%)	1 (0.4)	3 (2.3)
Partial response, n (%)	20 (7.5)	6 (4.5)
Stable disease, n (%)	106 (39.6)	42 (31.6)
Progressive disease, n (%)	20 (7.5)	12 (9.0)
Not available, n (%)	121 (45.1)	70 (52.6)
Treatment-emergent adverse events (TEAEs)	225 (84.0)	119 (89.5)
Serious TEAEs	88 (32.9)	47 (35.3)
Treatment discontinued	255(95.1)	103 (77.4)
Due to disease progression	192(71.6)	72 (54.1)
Due to adverse event	10 (3.7)	2 (1.5)
Patients with cycle delay	154 (57.5)	82 (61.7)
Patients with dose reduction	172 (64.2)	104 (78.2)

Conclusions: T can be safely administered and well tolerated in pts who receive a prolonged duration (≥6 mo) of therapy. Improved mOS may be achieved in pts who experience prolonged disease stabilization following T but adjustments in dose or schedule is frequently required.

1498P Efficacy and safety of trabectedin in an elderly patient subgroup (≥65 years) with advanced leiomyosarcoma (LMS) or liposarcoma (LPS) from the Expanded Access Program (EAP)

R.L. Jones[1], R. Maki[2], S. Patel[3], G. Wang[4], C.R. Shin[5], R. Knoblauch[6], G.D.S. Demetri[7]

[1]Sarcoma Unit, Royal Marsden Hospital/Institute of Cancer Research, London, UK, [2]Medical Oncology and Hematology, Monter Cancer Center, Lake Success, NY, USA, [3]Oncology, The University of Texas, MD Anderson Cancer Center, Houston, TX, USA, [4]Biostats, Janssen Research & Development, LLC, Spring House, PA, USA, [5]Med Group Oncology, Janssen Scientific Affairs, LLC, Horsham, PA, USA, [6]Clinical Oncology, Janssen Research & Development, LLC, Raritan, NJ, USA, [7]Center for Sarcoma and Bone Oncology, Dana-Farber Cancer Institute and Ludwig Center at Harvard, Boston, MA, USA

Background: Elderly patients (pts) (≥65 yrs) with soft tissue sarcoma may have limited treatment options due to increased comorbidities and toxicities from available therapeutic agents. Previous retrospective analyses have suggested that trabectedin (T) has similar safety and efficacy outcomes irrespective of pt age.

Methods: In this multicenter, open-label study, pts received IV T (1.5 mg/m2) every 3 wks. We retrospectively analyzed the efficacy and safety of T in pts ≥65 yrs treated from 2005-2010 on this EAP.

Results: Mean age was 71 and 49 in the ≥65 (n = 350) and <65 (=1453) groups respectively. Pt demographics and disease characteristics were similar in ECOG score, race, gender, and histology. Median duration of therapy was 3 cycles in both groups. Pts receiving prolonged therapy (>12 mo) was 26 (7.4%) and 107 (7.4%) in the ≥65 and <65 groups, respectively. Elderly patients treated with T experienced similar median OS, ORR, and CBR (Clinical Benefit Rate, CR+PR+SD) compared to the <65 group with a median OS of 11.5 mo and 12.3 mo, ORR of 7 (3.9%) and 41 (5.4%), and CBR of 78 (43.1%) and 313 (40.1%) in the in the ≥65 and <65 groups, respectively. Toxicities in the elderly group were consistent with previously reported safety profiles, and incidence in the elderly group were comparable to those of the <65 group. Treatment-emergent adverse events (TEAEs), and serious TEAEs were similar in both groups. The percentage of pts requiring dose reduction and dose delay in pts who received ≥2 cycles was also similar with 96 (33.6%) and 444 (36.2%) of pts requiring dose delay and 135 (47.2%) and 563 (46.0%) requiring dose reduction in the ≥65 and <65 groups, respectively. In both groups, the majority of pts discontinued treatment due to disease progression with only 32 (9.1%) and 118 (8.1%) of pts discontinuing treatment due to an AE in the >65 and <65 groups, respectively.

Conclusions: The efficacy and safety profile of T in pts ≥65 was similar to that observed in pts <65 in this EAP. Based upon this real world experience, T should be considered as a treatment option for elderly pts with soft tissue sarcoma and good performance status irrespective of age.

1499P The routine real-life use of trabectedin (T) in patients with advanced soft tissue sarcoma (STS) across Europe: An analysis of overall vs. per country results from Y-IMAGE study

N. Penel[1], C. Benson[2], B. Kasper[3], A. Buonadonna[4]

[1]Medical Oncology, Centre Oscar Lambret, Lille, France, [2]Medical Oncology, Royal Marsden Hospital NHS Foundation Trust, London, UK, [3]Interdisziplinäres Tumorzentrum, Universitätsklinikum Mannheim, Mannheim, Germany, [4]Medical Oncology, Centro di Riferimento Oncologico, Aviano, Italy

Background: The prospective, non-interventional, phase IV Y-IMAGE study evaluated the use of T in real-life clinical practice across Europe in patients with advanced STS.

Methods: Data from adult STS patients treated with T 1.5 mg/m^2 given as 24-h i.v. infusion q3w were collected. Patients must have received at least 1 cycle of T and currently be on T treatment. The primary endpoint was progression-free survival (PFS) as defined by investigators. The analyses were conducted in the overall population (OP)

Table: 1499P

	Full analysis set, n (%)				
	France (n = 26)	Germany (n = 29)	Italy (n = 69)	UK (n = 26)	Overall population (n = 218)

Cumulative dose received mg/patient	12.1 (3.7-48.2)	20.8 (5.6-51.0)	14.3 (1.9-60)	26.2 (3-116.4)	14.7 (1.8-116.4)
Cycle duration (days)	24.9 (21-41)	26.8 (21-44.4)	23.7 (20.5-32.5)	24.2 (21-30.6)	24.1 (20-47.5)
Dose intensity (mg/m^2/week)	0.7 (0.2-1.0)	0.6 (0.4-1.1)	0.6 (0.3-1.0)	0.7 (0.5-1.0)	0.7 (0.2-1.1)
Median PFS (months) [95% Confidence interval]	7.6 [3.3-NR]	5.9 [3.4-11.2]	6.8 [3.4-10.2]	8.3 [5.5-11.4]	5.9 [4.9-7.8]
Objective response rate (ORR) (Complete + partial response) [95% Confidence interval]	6 (23.1) [9.0-43.6]	9 (31.0) [15.3-50.8]	15 (21.7) [12.7-33.3]	10 (38.5) [20.2-59.4]	58 (26.6) [20.9-33.0]
Disease control rate (DCR) (ORR + stable disease) [95% Confidence interval]	17 (65.4) [44.3-82.8]	20 (69.0) [49.2-84.7]	48 (69.6) [57.3-80.1]	22 (84.6) [65.1-95.6]	143 (65.6) [58.9-71.9]
Time to progression (TTP), median (months) [95% Confidence interval]	7.8 [4.9-NR]	6.9 [4.2-11.2]	6.8 [3.4-10.2]	8.3 [5.5-11.4]	5.9 [4.9-8.1]
Overall survival (OS), median (months) [95% Confidence interval]	20.3 [9.6-NR]	27.3 [9.2-NR]	22.5 [19.0-NR]	20.0 [18.2-23.6]	21.3 [18.8-24.3]
Growth modulation index (GMI), median [a] Range (min-max) ≤1.1, n (%) >1.1 - <1.33, n (%) ≥1.33, n (%)	0.7 (0.1-16.3) 15 (65.2) 1 (4.3) 7 (30.4)	0.9 (0.0-15.0) 12 (50.0) 2 (8.3) 10 (41.7)	0.7 (0.0-16.7) 35 (62.5) - 21 (37.5)	2.3 (0.1-15.4) 11 (42.3) - 15 (57.7)	0.8 (0.0-42.5) 110 (56.1) 10 (5.1) 76 (38.8)

[a]The GMI (TTP trabectedin/TTP prior chemo) was assessed on 196 patient: France, n = 23; Germany, n = 24; Italy, n = 56; UK, n = 26. NR, not reached.

and separately in countries with the highest recruiting rate to cover inter-country variations: France (F), Germany (G), Italy (I) and the UK.

Results: A total of 218 patients from 41 centers and 9 European countries were evaluated. Demographics and baseline characteristics of patients recruited in the 4 countries of interest were well-balanced and comparable to those observed in OP. Patients received a median of 6 cycles of T (range: 1-44), mostly on an outpatient basis (n = 132; 60.6%). Across all centers the median cycle duration, and median dose and dose intensity were similar to those observed in OP. Analysis of PFS data showed a similar outcome in G (median PFS: 5.9 months) to that observed in OP (5.9 months), and a rather higher PFS in the UK (8.3 months), F (7.6 months) and I (6.8 months). The patients from the UK received the highest median number of cycles (10.5) and cumulative dose of T (26.2 mg) as compared to F, G and I. This was associated with favorable efficacy outcomes in those patients, particularly in terms of improved PFS (8.3 months), responses (ORR: 38.5%; DCR: 84.6%) and a high growth modulation index of 2.3. T treatment resulted in a comparable median overall survival in all patients (21.3 months), being somewhat larger among patients treated in sites across G (27.3 months). Febrile neutropenia (2.3% of patients), neutropenia, nausea, and pneumonia (1.4% each) were the most common T-related grade 3/4 adverse drug reactions.

Conclusions: In real-life setting T confers meaningful benefits to patients with multiple STS histotypes with a manageable safety profile regardless of small country variations.

1501P Safety and efficacy of pazopanib (PAZ) in advanced soft tissue carcinoma (aSTS) by prior lines of therapy, age, and dose modifications: PALETTE subgroup analyses

A. Le Cesne[1], S. Bauer[2], G.D.S. Demetri[3], W.T.A. van der Graaf[4], G. Han[5], L. Dezzani[5], Q. Ahmad[5], H. Gelderblom[6]

[1]Medical Oncology & Surgery, Gustave Roussy Institut de Cancérologie, Villejuif, France, [2]Department of Medical Oncology, University Hospital Essen Westdeutsches Tumorzentrum, Essen, Germany, [3]Center for Sarcoma and Bone Oncology, Dana-Farber Cancer Institute and Ludwig Center, Harvard Medical School, Boston, MA, USA, [4]Sarcoma Unit, The Institute of Cancer Research and the Royal Marsden Hospital, Sutton, UK, [5]Novartis Oncology, Novartis Pharmaceuticals, East Hanover, NJ, USA, [6]Medical Oncology, Leiden University Medical Center (LUMC), Leiden, Netherlands

Background: PALETTE was a randomized phase 3 trial (NCT00753688) that demonstrated single-agent activity of PAZ in advanced STS (aSTS). We evaluated the relationship between age, prior lines of therapy, and dose modifications on the safety and efficacy of PAZ in aSTS.

Methods: Median progression-free survival (mPFS) was evaluated in subgroups of prior lines of therapy (1 prior line; 2+ prior lines), age (<65 y; ≥65 y), and dose reductions and interruptions (no dose reduction/interruption; ≥1 dose reduction/interruption). Adverse events (AEs) were also compared in subgroups of prior lines of therapy and age. All analyses were descriptive and exploratory and require cautious interpretation.

Results: A total of 246 patients received pazopanib in the PALETTE study. Median PFS and median overall survival (OS) were longer in patients receiving PAZ who had only 1 prior line of therapy vs 2+ prior lines of therapy (mPFS, 24.7 vs 18.9 weeks [Table]; OS, 13.7 vs 11.3 months). In patients receiving PAZ, mPFS was similar in ages <65 and ≥65 y (20.0 and 20.1 weeks, respectively). In patients receiving PAZ, mPFS was maintained in patients requiring dose reductions or dose interruptions to manage toxicities

(Table). Regardless of number of prior lines of therapy, patients receiving PAZ had similar AE rates. The AEs leading to study discontinuation in patients receiving PAZ were higher in ≥ 65 vs < 65 y group (30% vs 17%, respectively). Rates of dose reductions, dose interruptions, and serious AEs leading to study discontinuation were similar between the 2 age groups.

Table: 1501P

Subgroups	N	Pazopanib, mPFS, weeks (95% CI)
Lines of therapy		
1 prior line	110	24.7 (19.6-27.4)
2+ prior lines	136	18.9 (11.9-20.1)
Age		
<65 y (range: 18-64)	184	20.0 (17.9-22.0)
≥65 y (range: 65-83)	62	20.1 (11.7-31.6)
Dose reduction		
No dose reduction	154	11.9 (8.9-19.3)
≥1 dose reduction	92	27.7 (21.1-35.7)
Dose interruption		
No dose interruption	107	11.0 (8.1-19.3)
≥1 dose interruption	139	21.3 (20.1-27.7)

mPFS, median progression-free survival; CI, confidence interval

Conclusions: Longer mPFS was observed in patients receiving PAZ following only 1 line of therapy. Additionally, mPFS with PAZ was maintained regardless of patient age or if dose modification was required to manage toxicity.

1502P Evolution in neutrophil-to-lymphocyte ratio (NLR) among advanced soft tissue sarcoma (STS) patients treated with pazopanib within EORTC 62043/62072 trials

E. De Maio[1], N. Touati[2], S. Litière[3], S. Sleijfer[4], W.T.A. van der Graaf[5], A. Le Cesne[6], L. D'Ambrosio[7], P.G. Casali[8], A. Italiano[9], I. Desar[10], A. Gronchi[11]

[1]EORTC, European Organisation for Research and Treatment of Cancer, Brussels, Belgium, [2]Statistics, EORTC, Brussels, Belgium, [3]Statistics, EORTC - European Organisation for Research and Treatment of Cancer, Brussels, Belgium, [4]Medical Oncology, Erasmus MC Cancer Institute, Rotterdam, Netherlands, [5]Medical Oncology, Royal Marsden Hospital NHS Foundation Trust, London, UK, [6]Department of Medical Oncology, Gustave Roussy Cancer Campus, Villejuif, France, [7]Medical Oncology, IRCCS Istituto di Candiolo, Candiolo, Italy, [8]Adult Mesenchymal Tumour and Rare Cancer Medical Oncology Unit, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [9]Medicine, Institute Bergonié, Bordeaux, France, [10]Medical Oncology, Radboud University Medical Centre Nijmegen, Nijmegen, Netherlands, [11]Department of Surgery, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy

Background: A high NLR has been shown to be associated with a poor prognosis in several solid tumors including STS and might be helpful for patient stratification and individual risk assessment. The aims of this study were to confirm that higher NLR at baseline is associated with worse prognosis in STS and to evaluate if an early decline of NLR during treatment with pazopanib is associated with a more favorable prognosis.

Methods: The single-arm phase II EORTC 62043 and placebo-controlled phase III EORTC 62072 were both investigating the effect of pazopanib in patients with advanced STS. We evaluated NLR at baseline and 50 days later. Multivariate analyses on pazopanib-treated patients investigated the prognostic value on both Progression-Free Survival (PFS) and Overall Survival (OS) of NLR at baseline as well as the predictive value of changes in NLR from baseline to the 50-days landmark. Sensitivity analyses were conducted on the placebo-treated patients.

Results: Among the 333 eligible patients treated with pazopanib, a NLR at baseline ≥3 was associated with shorter PFS and OS in comparison to NLR <3 (HR 1.44; 95% confidence interval {CI} = 1.14-1.82; p-value 0.002 and HR 1.86; 95% CI = 1.43-2.41; p-value <0.001, respectively). Changes in NLR ratio were defined as a difference of at least 40% with baseline. Compared with no changes, an increase or decrease in NLR did not affect PFS (HR 1.19; 95% CI = 0.71-1.98 and HR 0.94; 95% CI = 0.71-1.24; p-value 0.685, N = 262 patients) or OS (HR 1.40; 95% CI = 0.90-2.16 and HR 0.96; 95% CI = 0.7 2- 1.28; p-value 0.255, N = 302 patients). Thresholds other than 40% difference to define NLR change did not impact the result and no association between changes in NLR and outcome was seen in placebo-treated patients. The median NLR change in patients treated with pazopanib was a decrease of 30.4% compared to an increase of 14.5% in placebo.

Conclusions: In this study, limited by its retrospective design, the prognostic value of NLR at baseline was confirmed in advanced STS patients, irrespective of treatment. Changes in NLR during the first 50 days of treatment with pazopanib were not associated with patient outcome and can therefore not be used as an early marker for response.

Background: Treatment options for pts with advanced STS are limited. STS, like other proliferating malignancies, are dependent on the formation of new blood vessels to support their growth, invasion and metastasis. Growth Modulation Index (GMI) has been demonstrated as a relevant endpoint to assess clinical in patients with advanced STS. There are no data related to GMI in STS patients treated with anti-VEGFR targeted therapy.

Methods: Pts with metastatic STSs diagnosed between 1990 and 2013 and documented in the prospectively maintained database of the French Sarcoma Group who have received at least one TKI during their treatment were analysed. GMI, defined as the ratio of the Time To Progression (TTP2) under the TKI/TTP under the previous line of treatment (TTP1) was calculated.

Results: 209 pts (102 male) were included in this study. Median age was 50 (11-83). 234 lines of TKI were administrated. The drugs used were: Pazopanib (77, 33%), Sorafenib (70, 30%), Sunitinib (45, 19%), Regorafenib (30, 13%), Others (12, 5%). The most frequent histology subtypes were: leiomyosarcoma (64, 30.6%), undifferentiated sarcoma (28, 13.4%), synovialosarcoma (20, 9.6%), desmoplastic round cell tumor (14, 6.7%) and angiosarcoma (11, 5.3%). Median of previous lines was 2 (0 – 4). Median TTP under TKI was 4.1 months (0 – 131.1). GMI was available for 201 pts. Median GMI was 0.76 (0.02 - 12.49). GMI was ≥ 1 in 87 (41.6%) pts and ≥ 1.3 in 65 (31.1%) pts. 17 pts received 2 consecutive lines of TKI. For these pts, median GMI (TTP under TKI2/TTP under TKI1) was 1 (0.12 – 8.77). Seven (41.2%) had a GMI ≥ 1.3.

Conclusions: Targeting VEGFR was associated with significant clinical benefit (GMI ≥ 1.3) in about one third of STS pts. Up to 41% of patients progressing on a TKI experienced clinical benefit with another TKI suggesting the lack of absolute cross-resistance between TKI.

1504P Response to apatinib in advanced alveolar soft part sarcoma

C. Tu, F. Tang, Y. Zhou, L. Min, Y. Luo, W. Zhang, R. Shi, H. Duan

Department of Orthopedics, West China Hospital, Sichuan University, Chengdu, China

Background: Alveolar soft part sarcoma (ASPS) is a rare, hypervascular and chemoresistant soft tissue sarcoma. Apatinib, a novel tyrosine kinase inhibitor that highly selectively binds to the ATP-binding site of VEGFR-2 within cells resulting in inhibition of tumor angiogenesis, has shown a substantial potential in angiosarcoma, malignant fibrous histiocytoma and round cell liposarcoma. This study aimed to review the clinical efficacy and safety of apatinib in ASPS.

Methods: The clinical information of 6 patients with advanced ASPS who received apatinib were collected. The median age of them was 26.5 years old (17y-32y). Five patients were found with multiple lung metastases and one (case 4) was with locally advanced unresectable tumor. The maximum diameters of locally advanced tumor and metastatic nodules were measured by MRI and thin-section CT, respectively. All cases received apatinib at initial continuous daily dosing of 500 mg every 4 weeks. Clinical efficacy was evaluated according to RECIST v1.1. The adverse events (AEs) were graded according to CTCAE v4.03.

Results: Median follow-up from start of apatinib treatment was 10.2 months (range, 1-21 months). Five of 6 patients who received at least 1 complete cycle of apatinib treatment were eligible for the efficacy analysis (Table). One patient achieved RECIST complete response and stop apatinib treatment after six cycles. Four patients got partial response. No disease progression was found. The current objective response rate to apatinib treatment was 100% (5/5). The most common grade 3/4 treatment-related AEs were hand-foot syndrome (60.0%), hypertension (20.0%), and hepatotoxicity (20.0%). No drug-related severe AEs occurred. At the time of analysis, all patients were still alive and five patients continued to receive apatinib.

Conclusions: Our analysis confirms the short-term efficacy and safety of apatinib in patients with advanced ASPS. This result supports future randomized controlled trial to further verify anti-tumor activity of apatinib in stage IV sarcomas.

Background: Alveolar soft-part sarcoma (ASPS) is an exceedingly rare entity. We previously reported on a series of 12 ASPS the expression of PD-1/PD-L1 and lymphocytic infiltrates. PD-L1 staining was positive in 50% of the cases, suggesting a role for immunomodulatory interventions. We now enlarge the series and explore the expression of immune-related genes with the HTG EdgeSeq System and analyze their possible prognostic role.

Methods: Patients (pts) diagnosed with ASPS from Dec 1994 to Jul 2016 were reviewed. Clinical characteristics and outcome were collected. Immunohistochemical expression was tested on archived Formalin-Fixed Paraffin-Embedded (FFPE) blocks using PD-L1 (ab205921; Abcam), CD8 (ab4055; Abcam) antibodies. An ImmunOncology (IO) panel of 549 mRNAs was evaluated with the HTG EdgeSeq System from one 5µm FFPE section. This novel technology consists in a tissue digestion followed by a pre-hybridization with specific probes using quantitative nuclease protection assay (qNPA) and quantified by a standard RNA-seq protocol in a NGS sequencer.

Results: We identified 16 ASPS pts: median age 23y (6-62), M/F=5/11. Stage localized/metastatic in 11/5. With a median FU of 91 mos (4-151), 6/11 pts (54%) relapsed, with a median RFS of 19 mos (95% CI 1-75) and 2 pts died. PD-L1 was pos in tumor in 10/16 (62%) pts. HTG showed differential expression of immune-related genes according to stage (localized vs metastatic) in MNDA (log2 fold change: -3.01, $p < 0.00001$) and PRAME (log2 fold change: 1.9, $p < 0.0002$). Pts relapsing differentially expressed ABCC2 (log2 fold change -1,64, $p < 0.04$) when compared with those not relapsing. PD-L1 pos vs neg tumors (pos>5% membrane staining for PD-L1) differentially expressed TNFSF11 (fold change: -1,77, $p = 0.05$). Tumors infiltrated/not for CD8 lymphs (pos>10% of CD8) had a differential expression of CCL18 (log2 fold change: 4,89, $p < 0.0001$) and SLAMF7 (log2 fold change 2,37, $p < 0.0089$).

Conclusions: PD-L1 is expressed in more than a half of ASPS of our series. Differential expression in immune-associated genes suggest an immune related gene profile on this entity with clinical and pathological implications. Further exploration of immune-modulation in ASPS is ongoing.

1506P PD-L1 inhibition – a new therapeutic opportunity in cutaneous angiosarcoma?

R. Hamacher[1], D. Kämpfe[2], M. Ahrens[3], K. Reuter-Jessen[4], M. Schuler[1], H-U. Schildhaus[4], S. Bauer[1]

[1]Department of Medical Oncology, West German Cancer Center, University Hospital Essen, University of Duisburg-Essen, Essen, Germany, [2]Practice, Hematology and Oncology, Lüdenscheid, Germany, [3]Medizinische Klinik II, Hematology and Oncology, Universitätsklinikum Frankfurt (Johannes-Wolfgang Goethe Institute), Frankfurt am Main, Germany, [4]Institute of Pathology, University Hospital Göttingen, Göttingen, Germany

Background: Cutaneous angiosarcomas (cAS) represent a particularly challenging sarcoma subtype that frequently occurs in pretreated patients as a consequence of radiation therapy or chronic lymphedema. Local treatments are complicated as affected sites are often compromised by previous surgery and irradiation and tumor lesions lack a clear delineation. Novel treatments are therefore urgently needed to improve the outcome of these patients.

Methods: We identified 130 angiosarcomas from our institutional database of which 37 originated in the skin. Clinical characteristics and outcome was analyzed and available tumor tissue was tested for expression of PD-L1 and infiltration of immune cells, including CD8+ cells.

Results: Response to classical chemotherapeutic drugs was highest for taxanes, but frequent responses were also seen with liposomal doxorubicin, gemcitabine or oral cyclophosphamide. Despite promising chemotherapy responses, most patients eventually died of disease with often dismal local complications. Using IHC we observed several cases of cAS that showed a significant expression of PD-L1 between 10-20% on tumor cells. In addition, infiltration of immune cells with the presence of CD8+ cells was regularly observed. One of the patients with PD-L1-positive angiosarcoma of the scalp who had progressed after several lines of chemotherapy was treated with pembrolizumab. Following the second application the patient already showed a dramatic improvement of symptoms with complete healing of a large area of ulcerating and bleeding skin and ongoing remission after 6 months of treatment.

Table: 1504P Clinical data of six patients with alveolar soft part sarcoma who received apatinib

Case	Age/gender	Local tumor location	Local tumor size (cm)	Local tumor resection (Yes/No)	Chemotherapy	Cycles	Clinical efficacy
1	17/male	Left thigh	4.5	Yes	Gemcitabin + Docetaxel	Stop 6	CR
2	27/female	Right thigh	10.5	No	None	Ongoning 2	PR
3	29/male	Left thigh	11.3	No	Ifosfamide	Ongoing 4	PR
4	32/male	Right thigh	16.9	No	Ifosfamide+ Cisplatin	Ongoing 4	PR (Local tumor volume decrease)
5	26/male	Left thigh	9.6	Yes	None	Ongoing 6	PR
6	28/Female	Right thigh	5.8	No	None	Ongoing <1	–

Conclusions: Based on this study, PD-L1-directed therapy may represent a particular opportunity for angiosarcomas of the skin given the frequency of PD-L1 expression and infiltration of immune cells. Our findings suggest prospective immunotherapy studies in this sarcoma subtype.

1507P Pembrolizumab (PEM) in patients with advanced/metastatic bone sarcoma (BS) or soft tissue sarcoma (STS): Named patient use by the Medical University of Vienna

S. Schur[1], T. Brodowicz[1], B. Gad[1], R. Hamacher[1], G. Amann[2], S. Lang[2]

[1]Clinical Division of Oncology, Medizinische Universitaet Wien (Medical University of Vienna), Vienna, Austria, [2]Department of Pathology, Medizinische Universitaet Wien (Medical University of Vienna), Vienna, Austria

Background: Treatment options in locally advanced/metastatic BS and STS are limited. PEM has shown first signs of promising activity in some histologic subtypes. In this named patient use BS and STS patients who either failed standard therapy or where no standard therapy was established were treated with PEM.

Methods: This retrospective analysis includes efficacy/safety data from 18 pts. with advanced/metastatic BS/STS treated with PEM 200mg d1, q21d between May 2016 and April 2017.

Results: 10 pts. were female (56%), 8 pts. male (44%). Median age was 45 yrs. (range 18-84 yrs.). Extent of disease at initial diagnosis was localized in 15 pts. (83%) and advanced/metastatic in 3 pts. (17%). The median number of previous lines of systemic treatment before PEM was 3 (range 0-7 lines). In total, 71 cycles of PEM were administered (median 3 cycles per pt., range 1-11 cycles). Immune-related side effects were hypothyroidism in two pts. and uveitis in one pt. PD-L1 assessment on tumor samples is ongoing.

Table: 1507P

patient ID	histology	n PEM cycles	status	status PEM
1	fibromyxoid sarcoma	4	*	1
2	OSA	11	0	0 NED
3	fibrosarcoma	3	*	1
4	myxofibrosarcoma	8	0	0 PR
5	myxofibrosarcoma	2	*	1
6	angiosarcoma	3	0	1
7	dedifferentiated LPS	7	0	0 PR
8	EMC	3	0	1
9	EMC	3	0	1
10	chondrosarcoma	5	0	0 SD
11	myxoid LPS	3	0	0 PR
12	angiosarcoma	1	*	1
13	dedifferentiated LPS	5	0	0 SD
14	synovialsarcoma	3	0	0 SD
15	epitheloid sarcoma	3	0	0 PR
16	OSA	2	0	0 ie
17	OSA	3	0	0 ie
18	myxoid LPS	2	0	0 ie

Abbreviation: OSA = osteosarcoma, EMC = extraskeletal myxoid chondrosarcoma, LPS = liposarcoma, status 0 = alive, * = dead; status PEM 0 = PEM ongoing, 1 = PEM discontinued to PD (progressive disease); NED = no evidence of disease, PR = partial remission, SD = stable disease, ie = response in evaluation.

Conclusions: In this unselected cohort, PEM seems to have some activity in advanced/metastatic BS/STS. However, longer follow up of treated patients and prospective clinical trials of PEM in BS/STS patients will define the value of PEM in this patient cohort. Updated efficacy and toxicity data as well as PD-L1 expression levels will be presented at the meeting.

1509P Characteristics and prognosis of gastrointestinal stromal tumor in the pre-imatinib era: An analysis based on the Kinki GIST registry in Japan

T. Hashimoto[1], T. Takahashi[1], Y. Kurokawa[1], J. Fujita[2], S. Hirota[3], T. Nishida[4], T. Tsujinaka[5]

[1]Department of Gastroenterological Surgery, Osaka University Graduate School of Medicine, Suita, Japan, [2]Department of Surgery, Sakai Medical Center, Sakai, Japan, [3]Surgical Pathology, Hyogo College of Medicine, Nishinomiya, Japan, [4]National Cancer Center Hospital, Tokyo, Japan, [5]Department of Surgery, Kaizuka City Hospital, Kaizuka, Japan

Background: Recent breakthroughs regarding the oncogenesis of gastrointestinal stromal tumor (GIST) have led to the wider use of imatinib (IM). In addition, since perioperative IM has been established, more accurate information regarding the clinical behavior of GIST is mandatory. However, there is no big data about the clinicopathological characteristics and prognosis of GIST in Japan. The aim of this study was to clarify them based on an analysis of the GIST registry conducted by the Kinki GIST Study Group in Japan.

Methods: The registry was designed to collect data on background characteristics, treatment methods, pathologic characteristics, and prognosis of primary GIST from 2003 through 2007 at 40 participating institutions.

Results: The study enrolled 346 male patients and 332 female patients. The median [range] age was 66 [18-93] years. The primary sites were stomach (74%), small intestine (19%), rectum (3%), esophagus (1%), colon (1%), and others (1%). Fifty-eight percent were asymptomatic and 42% were symptomatic e.g. bleeding (17%), pain (10%), and digestive symptoms (9%). None of the patients was received perioperative IM therapy. Pathological examination revealed that the tumor size was 4.0 [0.1-35]cm and the mitotic count was 3 [0-300] per 50 high-powered fields. There were 91.0% KIT positive GISTs and 82.9% CD34 positive GISTs. Ninety-seven (14.5%) patients showed recurrence and the common recurrent sites were liver (n = 58) and peritoneum (n = 33). According to the modified-Fletcher criteria, the recurrence rates were 0% (0/93, very low-risk group), 2.6% (6/230, low-risk,), 4.6% (4/87, intermediate-risk), and 38.9% (75/193, high-risk), respectively. The 5-years overall survival rate was 89.0%. The 5-years recurrent free survival rate (RFS) of gastric GISTs was significantly better than that of other sites' GISTs (5-years RFS:82.7% vs. 63.9%, $P < 0.001$).

Conclusions: We reported the clinicopathological characteristics of GIST in multicenter registry study in Japan. Currently applied GIST risk classification system is comparable to predict high- or low-risk patients with primary non-metastatic and completely resected GIST in pre-IM era.

1510P Early response evaluation by 18F-FDG-PET influences management in gastrointestinal stromal tumor patients treated with neo-adjuvant intent

S. Farag[1], L-F. de Geus-Oei[2], W.T.A. van der Graaf[3], F. Van Coevorden[4], D.J. Grunhagen[5], A. Reyners[6], P. Boonstra[6], I. Desar[7], H. Gelderblom[8], N. Steeghs[1]

[1]Medical Oncology, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, [2]Department of Radiology, Leiden University Medical Center (LUMC), Leiden, Netherlands, [3]Sarcoma Unit, The Institute of Cancer Research and the Royal Marsden Hospital, Sutton, UK, [4]Surgical Oncology, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, [5]Surgical Oncology, Erasmus MC - Cancer Institute, Rotterdam, Netherlands, [6]Medical Oncology, University Hospital Groningen (UMCG), Groningen, Netherlands, [7]Medical Oncology, Radboud University Medical Centre Nijmegen, Nijmegen, Netherlands, [8]Medical Oncology, Leiden University Medical Center (LUMC), Leiden, Netherlands

Background: Early response evaluation by ^{18}F-fluorodeoxyglucose (FDG) positron emission tomography (PET) is effective in gastrointestinal stromal tumors (GISTs) treated with imatinib and recommended in GISTs treated with neo-adjuvant intent. Yet, it is unclear whether this effects treatment decisions.

Methods: All patients in the Dutch GIST Registry treated with imatinib with neo-adjuvant intent were identified. Only FDG-PETs made within 8 weeks after initiation or change (in dose or switch) of imatinib were included. Responses were derived from radiological reports and defined in 3 categories: 1) complete response; 2) partial response; 3) no response. Change in management was defined as a difference between pre-PET and post-PET treatment plans. Four categories were defined: change in 1) surgical management; 2) systemic treatment; 3) treatment objective (from curative to palliative); 4) management regarding a second tumor.

Results: Seventy FDG-PETs for early response evaluation in 63 patients treated with neo-adjuvant intent were identified. Forty-one patients (65.1%) had a KIT exon 11 and 22 (34.9%) had a non-KIT exon 11 mutation (15 other and 7 unknown mutations). Of the 70 scans 64 (87.1%) had a baseline, 50 (71.5%) showed metabolic response (partial and complete), and 18 (25.7%) led to change in management. Change in management was strongly correlated with a lack of response ($p < 0.001$) and a non-KIT exon 11 mutation ($p < 0.001$). Mutational status and response were strongly correlated ($p < 0.001$). Out of 29 FDG-PETs conducted in non-KIT exon 11 GISTs, 15 (51.7%) led to change in management: 1 (3.4%) in surgical management, 6 (20.7%) in systemic treatment, 7 (24.1%) in both and 1 (3.4%) regarding a second tumor. Out of 51 FDG-PETs conducted in KIT exon 11 GISTs, change in management was seen 3 times (5.9%): twice in systemic treatment (dose increase after partial response was seen) and once regarding a second tumor. No change in treatment objective was seen.

Conclusions: In contrast to GIST patients harboring a KIT exon 11 mutation, in non-KIT exon 11 mutated GISTs treated with neoadjuvant intent early response evaluation by FDG-PET often leads to change in management.

1511P Surgery in the treatment of metastatic and recurrent Gastrointestinal Stromal Tumors

M. Gluzman, R. Orlova, V. Kashchenko

Medical Department, Saint-Petersburg State University, Saint-Petersburg, Russian Federation

Background: Gastrointestinal stromal tumors (GISTs) are the most frequent mesenchymal tumors of the gastrointestinal tract. Surgery is the method of choice in treatment of localized GISTs but it also plays a great role in the treatment of advanced forms. The main goal of our study is to define the role of surgery for locally advanced and metastatic/recurrent lesions.

Methods: We have performed a retrospective analysis from a prospectively documented database. All histologically proven GISTs, diagnosed and treated between 2003 and 2016, were enrolled from 4 clinics in Saint-Petersburg, Russia. Cases of recurrent or metastatic GISTs were selected from the registry, and baseline characteristics and survival outcomes were analyzed. Patients were classified into two groups. The surgical treatment group (ST group) included those who underwent surgical treatment in addition to tyrosine kinase inhibitor (TKI) therapy after recurrence or metastasis, whereas the drug treatment group (DT group) included those who were treated only with TKI therapy.

Results: Metastasis or recurrence developed in 34 (22,8%) of the 149 patients with GISTs who had undergone surgery for primary localized or locally advanced tumors, 13 (38,2%) of whom were assigned to the ST group and 21 (61,8%) to the DT group. Median follow-up was 68 (4-162) months. In the ST group the 3-year overall survival rate (OS) was significantly higher than in DT group (92,3 vs. 61,9%, $p < 0,05$) but these groups didn't differ with respect to the 5-year overall survival rate (61,5 vs. 52,4%, $p > 0,05$). Median time to progression (TTP) was 23,9 months in the DT group and 29,7 months in the ST group ($p > 0,05$). OS was correlated with the pattern of recurrence: local-regional recurrence *vs.* distant metastasis – 3-year OS (94,4 vs. 50%, $p < 0,05$), 5-year OS (77,8 vs. 31,25%, $p < 0,05$). Median TTP didn't differ in both groups (18,5 vs. 20 months, $p > 0,05$).

Conclusions: Continuous TKI therapy appears to be important primarily for the prognostic improvement of patients with recurrent/metastatic GISTs. Surgical resection may have benefits when combined with TKI therapy for patients with stable disease or disease responsive to TKI therapy especially in the cases of local-regional recurrence.

1512P Clinicopathologic features and long-term follow-up of metastatic gastrointestinal stromal tumor (GIST) patients (pts) with durable response (≥ 5 years) to frontline imatinib (IM): A case-control study from GEIS

C. Serrano[1], A. Lopez Pousa[2], I. Pajares[3], C. Valverde Morales[1], J. Duran[4], J. Rubió-Casadevall[5], M.J. Safont[6], V. Martínez[7], R. Díaz Beveridge[8], A. Estival[9], D. Vicente Baz[10], A. Sebio Garcia[2], N. Hindi[11], S. Landolfi[12], D. Olivares[1], A. Garcia-Valverde[1], P. Ledesma[13], J. Arribas[14], J. Carles Galceran[1], J. Martin Broto[11]

[1]Medical Oncology, Vall d'Hebron University Hospital, Barcelona, Spain, [2]Medical Oncology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [3]Medical Oncology, Hospital Miguel Servet, Zaragoza, Spain, [4]Medical Oncology, Hospital Universitario Son Espases, Palma, Spain, [5]Medical Oncology, Hospital Josep Trueta, Gerona, Spain, [6]Medical Oncology, Hospital General de Valencia, Valencia, Spain, [7]Medical Oncology, Hospital La Paz, Madrid, Spain, [8]Medical Oncology, Hospital Universitari i Politècnic La Fe, Valencia, Spain, [9]Medical Oncology, Catalan Institute of Oncology (ICO Badalona), Hospital Germans Trias i Pujol, Badalona, Spain, [10]Medical Oncology, Hospital Universitario Virgen Macarena, Seville, Spain, [11]Medical Oncology, Hospital Universitario Virgen del Rocio, Seville, Spain, [12]Surgical Pathology, Vall d'Hebron University Hospital, Barcelona, Spain, [13]Sofpromed Investigación Clínica, GEIS, Palma, Spain, [14]Preclinical program, Vall d'Hebron University Hospital, Barcelona, Spain

Background: IM achieves disease control in most metastatic GIST pts, typically about 18 months. Interestingly, ∼15% GIST pts remain on IM beyond 5 years of continuous treatment. To date, clinicopathologic features predictive of long-term benefit to IM remain largely unknown.

Methods: We analyzed clinical, pathological and molecular characteristics, and long-term outcomes in metastatic GIST pts treated with continuous daily dosing of frontline IM in a cohort of pts benefiting ≥ 5 years, compared with a control group obtained from a national GEIS database.

Results: We found 41 IM long-term responders (IM-LTR) and 71 control cases (CC) with a median time on IM of 90.6 and 18.2 months, respectively. Compared to CC, IM-LTR were younger (59 vs 64 years, $p = 0.040$), fitter at diagnosis (performance status (PS) 0-1: 100% vs 82.2%, $p < 0.001$), had fewer metastasis prior to IM initiation (2.6 vs 7.5, $p < 0.001$), and primary tumors were bigger (10.4 vs 9 cm, $p = 0.005$) but had lower mitotic count (5.5 vs 15 per 50HPF, $p = 0.005$). There were no differences in terms of primary tumor location, disease status or metastases location at diagnosis. Mutational profile from IM-LTR (KIT ex 11, 81%; KIT ex 9, 0%; PDGFRA, 8%; wild-type, 11%) did not differ significantly from CC. IM-LTR had significantly better response pattern (complete response 34.1%; partial response 43.9%; stable disease 22%) and overall survival (not reached) over CC (9.2%, 40%, 26.2%; and 63 months, respectively). Only 7 pts (18%) receiving IM ≥ 5 years withdrew IM due to progression (69% CC, $p < 0.001$). Eight pts (25%) developed ≥ 1 new toxicities after ≥ 5 years on continuous IM; only 1 pt withdrew IM due to toxicity (grade 3 anemia). Univariate analyses show that pts with better PS ($p = 0.002$), low mitotic count ($p = 0.025$), low number of metastases ($p < 0.001$), and better response to IM ($p < 0.001$) achieve durable benefit from frontline IM.

Conclusions: Clinical and inherently biological tumor characteristics define a subset of GIST pts with increased likelihood to achieve durable benefit from IM. Molecular studies are needed to better identify these pts at treatment initiation.

1513P Tumor growth rate analysis of progression-free survival (PFS) and overall survival (OS) for patients with metastatic and/or unresectable gastrointestinal stromal tumors (GIST) receiving placebo or regorafenib in the phase 3 GRID trial

C. Kappeler[1], A. Wagner[2], G.D.S. Demetri[3]

[1]Clinical Statistics, Global Clinical Oncology, Bayer AG, Berlin, Germany, [2]Global Clinical Development, Bayer AG, Berlin, Germany, [3]Center for Sarcoma and Bone Oncology, Dana-Farber Cancer Institute and Ludwig Center, Harvard Medical School, Boston, MA, USA

Background: In the randomized, controlled phase 3 GRID trial (NCT01271712), regorafenib (REG) significantly improved PFS versus placebo (PBO) in patients with advanced GIST (HR 0.268; $P < 0.0001$). Here we report an analysis exploring prognostic characteristics of early tumor growth rate (eTGR) for PFS and OS.

Methods: The primary endpoint of GRID was PFS; OS was a secondary endpoint. Target lesions were assessed by central radiologic review based on RECIST (v1.1). Changes in target lesions over time were approximated by a parabola-like 3-parametric model. eTGR was defined as the percentage change per month of the sum of target lesion diameters from the start of double-blind treatment. To explore the association between eTGR and PFS and OS, values of eTGR were split into quartiles (Q) separately by treatment arm. PFS (cut-off in 2012) and OS (cut-off in 2015) were compared in each subgroup population by median times derived from Kaplan–Meier curves and from modeling with a Weibull distribution.

Results: For PBO and REG, there is a nearly inverse relationship between eTGR and median times of PFS and OS from Q1 to Q4 eTGR. For the REG subgroup in Q1 eTGR, this trend is lost, as it has similar or worse median times than the subgroups around zero eTGR, which show the best prognosis.

Table: 1513P

	PBO				REG			
	Q1	Q2	Q3	Q4	Q1	Q2	Q3	Q4
Mean eTGR	–0.063	0.064	0.147	0.279	–0.128	–0.022	0.024	0.135
Median PFS*	2.7	1.5	1.0	0.8	5.5	7.8	6.0	1.6
Median OS*	45.5	21.8	12.3	9.7	29.1	28.9	17.4	11.5

*By Weibull model of Kaplan–Meier curves; durations in months.

Conclusions: In this exploratory analysis, stabilization of tumor lesions at treatment start seems to be prognostic for better PFS and OS outcomes. A strong reduction of eTGR, which is seen for some REG patients, is not necessary for further disease stabilization and improvement. eTGR may be an additional efficacy parameter to consider when monitoring REG and other tyrosine kinase inhibitor (TKI) treatments in TKI-resistant GIST.

Clinical trial identification: NCT01271712

1514P Serum miRNA abundances discriminate imatinib-naive patients with advanced gastrointestinal stromal tumors (GIST) from those in remission on Imatinib therapy

H. Kosela Paterczyk[1], A. Paziewska[2], M. Kulecka[2], J. Karczmarski[3], M. Dabrowska[3], A. Kluska[3], A. Balabas[3], M. Piatkowska[3], M. Mikula[3], P. Rutkowski[1], J. Ostrowski[2]

[1]Soft tissue/Bone Sarcoma and Melanoma, The Maria Sklodowska-Curie Memorial Institute and Oncology Centre, Warsaw, Poland, [2]Department of Gastroenterology, Hepatology and Clinical Oncology, Centre of Postgraduate Medical Education, Warsaw, Poland, [3]Department of Genetics, The Maria Sklodowska-Curie Memorial Institute and Oncology Centre, Warsaw, Poland

Background: Deregulation of microRNAs (miRNAs) expression is observed virtually in all major types of neoplasm and miRNAs level in blood circulation are investigated as a potential diagnostics or prognostics biomarkers for neoplastic disorders. Gastrointestinal stromal tumors (GISTs) is the most common sarcoma of the gastrointestinal tract and to date performed studies on GISTs have provided mounting evidence on altered miRNA association with clinical, pathological features and Imatinib resistance in GIST. However, the utility of circulating miRNA as response markers of GIST progression and for Imatinib treatment have not been evaluated

Methods: 36 metastatic or unresectable CD-117-positive GIST patients, were enrolled and serum sample was collected prior to Imatinib treatment. All patients responded initially to imatinib therapy. In 12 patients an additional serum sample was collected following targeted treatment at the time of remission. Control group comprised 30 healthy individuals. MiRNAs were isolated from serum with MirVANA miRNA Isolation Kit and then analyzed using deep sequencing on Ion Torrent PGM. Reads were mapped to miRBase miRNA collection with miRDeep2. Differential expression was evaluated with edgeR.

Results: Deep sequencing identified 1284 miRNAs. The pair-wise comparison between Imatinib treated and Imatinib-naive GIST samples uncovered 22 miRNAs with differential expression (adjusted p value <0.05) of which 10 (miR-142-5p, let-7d-3p, miR-30e-5p, miR-194-5p, miR-223-5p, miR-223-3p, miR-125a-5p, miR-199b-5p, miR-24-2-5p, miR-641) yielded AUCs (areas under Receiver Operating Characteristic curves) ranging 0.81 and 0.9, thus having a high discriminative properties. A comparison of imatinib-naive GIST and control healthy samples revealed 99 differentially expressed miRNAs (adjusted p value <0.05) of which four (miR-582-5p, miR-150-5p, miR-450b-5p, miR-450a-5p) reached AUCs with high discriminatory power ranging 0.81-0.84.

Conclusions: Circulating miRNA abundances can distinguish GIST patients from those in remission following Imatinib therapy as well as from the healthy controls. However, further studies evaluating the potential of designated microRNAs as response markers for treatment or as predictive markers of GIST are warranted.

1515P LncRNA H19, HOTAIR and MALAT1 as prognostic molecular biomarkers in GIST

N. Barraco[1], L. Incorvaia[1], G. Badalamenti[1], F. Passiglia[1], A. Listì[1], R. Maragliano[1], E. Musso[1], E. Bronte[1], D. Cabibi[2], V. Calò[1], M. Castiglia[1], D. Fanale[1], A. Galvano[1], V. Gristina[1], S. Ingrao[2], L. Insalaco[1], D. Massihnia[1], A. Perez[1], V. Bazan[3], A. Russo[1]

[1]Department of Surgical, Oncological and Oral Sciences, Section of Medical Oncology, University of Palermo, Palermo, Italy, AOU Policlinico "Paolo Giaccone", Palermo, Italy, [2]Department of "Scienze per la Promozione della Salute e Materno Infantile "G.D'Alessandro", University of Palermo, Palermo, Italy, AOU Policlinico "Paolo Giaccone", Palermo, Italy, [3]Department of "Biomedicina Sperimentale e Neuroscienze Cliniche (BIONEC)", University of Palermo, Palermo, Italy, AOU Policlinico "Paolo Giaccone", Palermo, Italy

Background: Long non-coding RNAs (lncRNAs) are emerging as essential regulators of genetic and epigenetic networks. Their deregulation may underlie carcinogenesis suggesting their potential involvement in tumorigenic and metastatic processes, as well as their role as prognostic/predictive biomarkers for clinical use in patients with several solid tumors. Few studies evaluated lncRNAs expression in rare tumors such as Gastrointestinal Stromal Tumors (GISTs). Indeed, the upregulation of HOTAIR has been associated with tumor aggressiveness and metastasis, and poor survival of GIST patients. In order to gain more detailed insight on the molecular role of lncRNAs, we analyzed the expression levels of lncRNAs H19, MALAT1 and HOTAIR in tissue specimens of surgically resected GIST patients to evaluate the potential role of lncRNAs as prognostic biomarkers.

Methods: The expression of the lncRNAs H19, MALAT1 and HOTAIR was evaluated in a total of 40 pairs of disease formalin-fixed paraffin-embedded tissue and adjacent normal tissue from 40 GIST patients with localized and locally advanced disease using quantitative real-time reverse transcriptase.

Results: H19 was overexpressed in 50% GIST patients (p-value: 0.0496). MALAT1 was overexpressed in 45% GIST patients (p-value: 0.032). None of them had the related date with HOTAIR. Furthermore, the up-regulation of H19 has been found in 74% patients harboring cKIT mutations compared to 57% wild type patients (p-value: 0.042). Conversely the up-regulation of MALAT1 has been found in 76% patients harboring cKIT mutations compared to 100% wild type patients (p-value: 0.027). Finally, the up-regulation of H19 has been found in 100% patients with TTP < 3 months compared to 25% patients with TTP >3 months, while the up-regulation of MALAT1 has been found in 25% patients with TTP < 3 months compared to 75% patients with TTP >3 months.

Conclusions: H19 and MALAT1 appear upregulated in GIST patients according to the KIT- mutation status. These data would suggest a potential opposite prognostic value of both H19 and MALAT1 lncRNAs in these patients. The results of HOTAIR expression levels were indeterminated in all analyzed tumor samples, probably because HOTAIR has been degraded during its isolation. Further analyses are needed to confirm these data.

1516P Predictive factors of response to Sunitinib in metastatic Gastrointestinal Stromal Tumors (mGISTs): A retrospective analysis

L. Incorvaia[1], G. Badalamenti[1], E. Musso[1], I. de luca[1], A. Casarin[1], G.M. Assanto[1], A. Galvano[1], F. Passiglia[1], N. Barraco[1], B. Vincenzi[2], G. Grignani[3], M. Pantaleo[4], L. Gatto[5], S. Rizzo[1], D. Fanale[1], M. Castiglia[1], A. Guarini[1], A. Russo[1]

[1]Department of Surgical, Oncological and Oral Sciences, Section of Medical Oncology, University of Palermo, Palermo, Italy, AOU Policlinico "Paolo Giaccone", Palermo, Italy, [2]Medical Oncology Unit, Campus Bio-Medico di Roma, Rome, Italy, [3]Medical Oncology Unit, IRCCS Istituto di Candiolo, Candiolo, Italy, [4]Medical Oncology Unit, Policlinico S. Orsola-Malpighi, Bologna, Italy, [5]Medical Oncology Unit, Policlinico Sant'Orsola Malpighi, Bologna, Italy

Background: Imatinib is currently the standard therapy for first line treatment of metastatic GIST. Although this treatment has demonstrated durable responses with PFS and OS benefit, most patients develop resistance and experience subsequent disease progression. Current treatment available in second line are Imatinib high-dose (800 mg/day) or Sunitinib. The presence of two options in this setting, in the absence of direct comparisons, raises many questions on the choice.

Methods: A total of 128 patients with metastatic GIST were collected in our analysis in this large database. We analyzed the validity of several parameters as possible predictors of response to treatment with Imatinib high-dose vs Sunitinib in patients progressing at the standard dose of Imatinib 400 mg/day. The parameters analyzed were: anatomic

site of primary GIST, site of metastasis, KIT and PDGFRa mutational status, and FDG-PET status at progressing disease. Every factor has been correlated with Progression Free Survival (PFS) for Imatinib 800 mg/day and Sunitinib treatment, measured in months. Datas collected have been analyzed with software "Medcalc", performed by using the Kaplan-Meier method.

Results: Univariate analysis showed Sunitinib more active then Imatinib in gastric GISTs (median PFS: Sun 12 months vs Ima 800 6 months; p < 0,0001), in pts with peritoneal metastasis (median PFS: Sun 10 months vs Ima 800 5 months; P = 0,2429), in wild-type (median PFS: Sun 20 months vs Ima 800 17 months; P = 0,1361) and PET-negative GIST patients (median PFS: Sun10 months vs Ima 800 7 months; p = 0,0874).

Conclusions: with the limitations of a retrospective analysis, this study identifies the gastric site of primary tumor as a predictive factor to efficacy of Sunitinib treatment in second line. The mutational status (GIST WT), the site of metastasis (peritoneum) and the FDG-PET status (negative), although not statistically significantly, seem to be elements of increased activity for Sunitinib treatment in second line.

1517P Analysis of PD-L1 Expression in Patients with Gastrointestinal Stromal Tumors

A.B. Kinupe Abrahao[1], R. Jamani[2], E. Hsieh[3], Y-J. Ko[2]

[1]Medical Oncology, Sunnybrook Odette Cancer Center, Sunnybrook HSC, Toronto, ON, Canada, [2]Medical Oncology, Sunnybrook Odette Cancer Centre, Toronto, ON, Canada, [3]Anatomic Pathology, Sunnybrook Odette Cancer Centre, Toronto, ON, Canada

Background: The immune system is believed to have an important role in solid tumor progression. The development of monoclonal antibodies targeting immune checkpoints, such as programmed cell death 1 (PD-1) and programmed cell death ligand 1 (PD-L1), have revolutionized the treatment of some cancers. Recent efforts have attempted to elucidate the relevance of the PD-1/PD-L1 pathway in gastrointestinal stromal tumors (GIST).

Methods: Formalin-fixed, paraffin-embedded specimens were obtained from resected GIST at Sunnybrook Health Sciences Centre between March 2008 and August 2015. PD-L1 analysis was based off a tissue microarray of the cases using the Roche Ventana SP263 antibody. Each case had 1mm cores taken from different areas of the tumor block. Normal controls used for PD-L1 were placenta and tonsil (epithelial and inflammatory). CD117 was assessed via immunohistochemistry in all tumor specimens.

Results: Of twenty-nine patients who underwent surgical resection, eight had insufficient tumor tissue for analysis, and three cases were excluded due to CD117 negativity after preoperative imatinib treatment, leaving 18 patients for analysis. Three of these 18 cases were positive for PD-L1 expression: 2 patients with moderate PD-L1 staining in 85% of the stromal cells and 1 with weak staining in 15% of the stromal cells. Fifteen patients were negative for PD-L1 expression. Analysis of PD-L1 expression in tumor-infiltrating lymphocytes was not feasible due to the lack of inflammatory cells in tumor environment. The patients whose samples had significant PD-L1 expression had gastric primaries, with tumour size <10cm. They did not require preoperative treatment, and did not have metastatic disease despite two having a high mitotic rate. The clinicopathologic characteristics of patients by PD-L1 expression status is demonstrated in Table 1.

Table: 1517P

	PD-L1 negative (N = 15)	PD-L1 positive (N = 3)
Age (± SD)	62 (14)	63 (14)
Gender M F	10 5	1 2
Location Gastric Small Bowel Colon Rectum	7 5 - 3	3 - - -
Metastasis No Yes	11 4	3 -
Preoperative Imatinib No Yes	7 8	3 -
Size (cm) Preoperative imatinib Upfront surgery	6.2 (1.3-16) 5.8(1.5-11)	– 9.5 (1.5-9.5)
Mitotic Rate (50 HPF) < 5 = or > 5	12 3	1 2

Conclusions: In this cohort, PD-L1 may be a favorable prognostic biomarker. Further studies to examine the clinical benefit of immunotherapy in GIST patients with or without PD-L1 expression are warranted.

1518P Gastrointestinal stromal tumors secrete Ghrelin and express ghrelin receptors – needs linguistic correction

C. Zhu

Department of General Surgery, Peking Union Medical College Hospital, Chinese Academy of Medical Science and Peking Union Medical College, Beijing, China

Background: Gastrointestinal stromal tumor (GIST) mainly occurs in the fundus ventriculi. Ghrelin is a multifunctional protein polypeptide, which can promote the occurrence and development of tumor. It is mainly produced in the fundus ventriculi. But the misdiagnosis rate and postoperative recurrence rate is high. This study was to determine the serum ghrelin level in the normal population, patients with GIST before and after operation. And The expression of ghrelin and its receptor was determined in GIST tissue and The expression of ghrelin in adjacent normal tissue in the same patient. We hope that ghrelin can provide a new idea for the diagnosis and prognosis of GIST.

Methods: Preoperative and postoperative serum of 78 patients with GIST and 69 normal persons was collected and determined the level of serum ghrelin by ELISA. Expression of ghrelin and ghrelin receptors in GIST tissue (47 cases) was determined and Expression of ghrelin in adjacent normal tissue was determined at same time by immunohistochemical. We observed whether there were statistically significant differences in statistical analysis.

Results: the average ghrelin in the serum of normal people was 20.14 pg/ml, and 31.25 pg/ml for GIST patients. P = 0.034. The mean value of serum ghrelin in 78 patients with GIST was 31.25 pg/ml before operation and 22.5 pg/ml after operation . P = 0.023. Ghrelin and its receptor expression positive rate was 100% in GIST (47 cases). Among them, Ghrelin: (+) 12%, (++) 29%, (+++) 38%, (++ ++) 20% Ghrelin receptors:(+) 4%, (++) 23%, (+++) 27%, (++ ++) 46% 4) The expression of ghrelin in tumor tissue was about 2.23 times than that of adjacent normal tissues.

Conclusions: Gastrointestinal stromal tumors secrete Ghrelin and express ghrelin receptors. Ghrelin may serve as an effective indicator for the diagnosis and prognosis of GIST.

1519P Primary pleomorphic sarcoma (PS) and leiomyosarcoma (LMS) of bone: Retrospective analysis of an original series

G.G. Baldi[1], A. Franchi[2], G. Soccianti[3], D.A. Campanacci[3], D. Greto[4], L. Livi[5], G. Roselli[6], F. Galardi[7], S. Bazzurri[1]

[1]Medical Oncology Unit, Nuovo Ospedale di Prato, Prato, Italy, [2]Pathology Department, University of Florence, Florence, Italy, [3]Orthopedics Oncology Department, Azienda Ospedaliero-Universitaria Careggi, Florence, Italy, [4]Radiotherapy Department, University of Florence, Florence, Italy, [5]Radiotherapy, Azienda Ospedaliera Universitaria Careggi, Florence, Italy, [6]Radiology Department, Azienda Ospedaliero-Universitaria Careggi, Florence, Italy, [7]"Sandro Pitigliani" Translational Research Unit, Nuovo Ospedale di Prato, Prato, Italy

Background: To describe the clinico-pathological features of 23 patients affected by primary PS and LMS of bone, to confirm the diagnosis by molecular analysis, to evaluate the clinical outcome and to explore the prognostic impact of these features on disease-free (DFS) and overall survival (OS).

Methods: Primary PS and LMS of bone surgically treated from 2004 to 2015 were retrospectively reviewed. We analysed: age, sex, stage, histotype, histological-grade and surgical and/or medical therapy. IDH1 mutational status was evaluated and immunohistochemical staining was performed for smooth muscle actin and desmin. For molecular analysis tumor DNA was extracted from freshly cut FFPE sections by GeneRead^{TM} DNA FFPE (Quiagen) and ddPCR (Bio-rad) was used to determine the presence of IDH1H and IDH1C mutations. DFS and OS rates were calculated according to the Kaplan-Meier method. The differentiation (myogenic, MD, versus non-myogenic, NMD) was correlated with the outcome using Kaplan-Meier method.

Results: 23 patients with primary PS or LMS of bone were included in the study. Median age was 49 years (range 13-90), male/female 14/9, 18 had localised disease and 5 metastatic disease, 17 received surgery, 14 received adjuvant therapy, 1 received neo-adjuvant chemotherapy and 5 received up-front chemotherapy for advanced disease. All cases were histologically and radiologically reviewed: 17 PS and 6 LMS were identified. All cases were high-grade (FNCLCC grading system). Mutational analysis is currently underway and it will be presented at the meeting. 5-year OS of the whole series was 60% (95% CI; 3,1 – NE) and 5-year DFS was 50% (95% CI; 1,6 – 12,2). Patients with advanced disease are 13: 5-year OS in this subgroup was 38% (95% CI; 2,5 – NE). We identified MD in 11 cases. There were no significant differences between the MD and NMD groups in terms of DFS (logrank p-value=0,6788) and OS (logrank p-value=0,7389).

Conclusions: These primary malignant bone tumours are very rare with poor prognosis after relapse or when radical surgery is not feasible. MD did not predict a worse outcome than NMD in terms of OS and DFS.

1520P Development of a new promising rescue agent for high dose methotrexate (HDMTX) treatment in osteosarcoma: A safety and dose finding study

M. Eriksson[1], M. Rychłowska-Pruszyńska[2], M. Csoka[3], E. Kabickova[4], P. Mudry[5]
[1]Skåne University Hospital, Department of Oncology, Lund, Sweden, [2]Paediatric Surgical Oncology Clinic Warsaw, Institution of Mother and Child, Warsaw, Poland, [3]2nd Department of Paediatrics, Semmelweis University, Budapest, Hungary, [4]Department of Paediatric Haematology and Oncology, Motol University Hospital, Prague, Czech Republic, [5]University Hospital Brno and School of Medicine, Masaryk University, Department of Pediatric Oncology, Brno, Czech Republic

Background: HDMTX followed by calcium folinate (CF) rescue is established as part of MAP chemotherapy to manage toxicity during osteosarcoma treatment. A problem with HDTMX is the variability in plasma exposure of both MTX and CF leading to an unpredictable response. A potentially superior rescue agent methylenetetrahydrofolate (Modufolin®), containing the active metabolite of CF, has been evaluated to identify a safe and effective dose for further development.

Methods: This exploratory study performed in Hungary, Poland, Sweden and Czechia involved osteosarcoma patients, 12-40 years, planned for MAP chemotherapy. All patients received one MAP cycle (two HDMTX courses) with standard CF rescue of 15 mg/m^2. Those that completed this MAP cycle successfully according to six defined criteria subsequently received Modufolin® in the following cycle (two HDMTX courses). There were two Modufolin® dose cohorts, 15 mg/m^2 (1) and 7.5 mg/m^2 (2). A Data and Safety Monitoring Board evaluated safety before initiation of the second dose cohort and suggested the dose for further development.

Results: Eight patients 12-17 years were included. Four patients were treated in cohort 1 and four in cohort 2. In cohort 1, no MTX toxicity or delayed elimination with subsequent treatment delay was reported. In cohort 2 one patient reported mucositis grade 3 and failed successful advancement after first course of Modufolin®. In both cohorts and after both types of rescue, there were cases with significantly increased s-creatinine levels.

Conclusions: Modufolin® seems to be a safe and effective rescue agent after HDMTX. The study design however precludes a comparison between Modufolin® and CF, since only patients with successful CF rescue received Modufolin®. The higher dose of 15 mg/m^2 seemed more effective as rescue and was selected for further development.

1521P Role of intraarterial cisplatin and intravenous adriamycin as neoadjuvant and adjuvant chemotherapy in non-metastatic osteosarcoma

A.N. Mishra[1], J. Gill[2], Y. Mishra[3]
[1]Surgical Oncology, Gandhi Medical College, Bhopal, India, [2]Medical Oncology, Gandhi Medical College, Bhopal, India, [3]Medical Oncology, Peoples Medical College & Research Centre, Bhopal, India

Background: Primary bone sarcomas are rare tumors, comprising approximately 0.2% of all cancers. Because of distant metastasis, cure after surgical treatment alone is uncommon. The development of effective adjuvant or induction chemotherapy regimens has dramatically improved the prognosis and cure rate of 50%–70% and limb salvage in > 90% of cases. For nonmetastatic osteosarcoma(NMO), optimal treatment consists of multiagent neoadjuvant/adjuvant chemotherapy and limb-sparing surgical procedures. The degree of tumor necrosis (TN) after neoadjuvant chemotherapy is one of the most important pronostic indicators. Intraarterial cisplatin and intravenous adriamycin (IC-IA) could achieve a good tumor response.

Methods: Based on achievement of a maximized angiographic response, 106 patients with NMO of the extremities received IC-IA monthly for 3-6 courses between January 1995 and December 2008 followed by limb salvage surgery then adjuvant intravenous (IV) chemotherapy with adriamycin and cisplatin. After resection, if patients had a good response (the extent of TN was ≥ 90%), the same regimen was administered IV every 3 weeks for a total of 6 courses of chemotherapy. Poor responders (tumor necrosis < 90%) were treated with a regimen of high-dose methotrexate with leucovorin rescue (HD-MTX) or ifosfamide, cisplatin, and etoposide (ICE).

Results: Patients received an average of 5 cycles of neoadjuvant IC-IV chemotherapy. 96 patients underwent limb-preservation surgery and 72 had > 90% TN. With an average follow-up of 8years, 60 patients were continuously disease free, 32 died of disease and 14 had no evidence of disease within 5 years after relapse. The 5-year overall survival rate was 70%. No patient developed clinically detectable cardiac toxicity or ototoxicity after adriamycin and cisplatin administration. Febrile neutropenia occurred in few.

Conclusions: This study shows the effectiveness of treating primary NMO of extremities with IC-IA infusion. Advanced bone and soft tissue sarcomas are challenging diseases to treat with an unmet need for effective systemic therapy. Checkpoint inhibitors and Adoptive T cell therapy based immunotherapy could be a new ray of hope in treating bone sarcomas.

1522P Biomarkers of malignant cell growth used to assess the risk of osteosarcoma development

B.B. Sultonov, D. Polatova, K. Abdikarimov, U. Islamov
Muscle-sceletal Oncosurgery, National Cancer Research Center, Tashkent, Uzbekistan

Background: The aim of our study was a comprehensive study of molecular-genetic, pathologic and clinical symptoms in patients with osteosarcoma to enhance the effectiveness of early diagnosis, treatment and prevention of osteosarcomas.

Methods: We studied the immunophenotypic characteristics of tumor cells in 212 patients with osteosarcoma. Results of antibody reactions to Ki-67, bcl-2, p53 (mutant gene) localized in the nuclei and the mitochondrial matrix expressed in % based on the number of stained cells per 100 examined.

Results: Our results revealed that the expression profile of p53 +, bcl-2-, Ki 67+ in 34.9% (74/212) patients with osteosarcoma is considered as poor prognosis, presented as early metastasis, progression of tumor growth and early relapses (15 months), advanced processes (III and IV stage), low grade pathomorposis (1 and 2), the relative duration of lifespan in patients (up to 3 years), it is associated with a low degree of differentiation (G3), an increase in tumor size up to 550 cm3 with chondroblastic type of osteosarcoma. These data should be considered when looking for and isolating the most promising groups for molecular genetic markers that are would be predictive valuable in the clinic for monitoring the treatment of patients with osteosarcoma.

Conclusions: Thus, it is obvious need for clinical medicine in the implementation and expansion of molecular testing for effective decision-making on the appointment of molecular targeted therapy of patients with osteosarcoma. These requires optimization the approach based on consideration of the specifics of the population, the objective conditions related to the presence of intratumoral characteristics. The data reveals a group of patients with osteosarcoma at high risk with unfavorable prognosis at the stage of examination and choose for these kind of patients effective therapy.

1523P Efficacy of second line treatment with etoposide and ifosfamide in adult patients with advanced Ewing Sarcoma family tumors

M. Nardo, E.M. Zambrano, M.F. Vicentini, D. Toloi, V.P. Camargo, O. Feher, R. Munhoz
Clinical Oncology, ICESP - Instituto do Câncer do Estado de São Paulo, Sao Paulo, Brazil

Background: Ewing Sarcoma family tumors (ES) are rare subtypes of sarcomas, and even less common in adult patients. For those not amenable to treatment with curative intent, sequential therapy with multi-agent combinations is the standard of care, usually followed by ifosfamide/etoposide (IE) at the time of progression, largely based on protocols that included pediatric patients. Nevertheless, less is known about the efficacy of this approach for adult patients with ES refractory to first-line therapy.

Methods: We assembled a retrospective cohort of patients aged 18 or older diagnosed with metastatic/inoperable ES refractory to first-line combinations, treated with IE between 2010 and 2016. Patient́s characteristics, tumor variables, treatment outcomes and toxicity data were evaluated. Kaplan-Meier method was used to estimate overall survival and uni/multivariate analysis were carried out to identify factors associated with survival.

Results: Among 18 adult patients, the mean age of diagnosis was 22 years, 73% were male and 84% had an ECOG of 0-1 at commencement of IE. Pelvis and thorax were the most common primary sites. The mean number of cycles of IE was 4. The disease control rate was 27%, with partial responses occurring in 16% of the patients (there were no complete responses). The median OS was 4,8 months (IC 95% 0,7-8,8). Toxicities [3] grade 3 occurred in 61% of the patient, including two treatment-related deaths. The main grade 4 toxicity was febrile neutropenia. Hospitalization were required in 55% of the cases.

Conclusions: IE has limited efficacy and significant toxicity when used in the second-line setting for adult patients with advanced ES, and different approaches should be investigated for these patients.

1524P AG-120, a novel IDH1 targeted molecule, inhibits invasion and migration of chondrosarcoma cells in vitro

V. Heredia[1], M. Mendiola[1], E. Ortiz[2], D. Bernabéu[3], J.J. Pozo-Kreilinger[4], M. Miguel[1], R. Crespo[5], A. Berjón[4], V. Martínez-Marín[6], A. Redondo[6]

[1]Molecular Pathology and Therapeutic Targets Laboratory, IdIPAZ – Hospital Universitario La Paz, Madrid, Spain, [2]Orthopedic Traumatology Surgery Department, Hospital Universitario La Paz, Madrid, Spain, [3]Radiology Department, Hospital Universitario La Paz, Madrid, Spain, [4]Pathology Department, Hospital Universitario La Paz, Madrid, Spain, [5]Translational Oncology, IdIPAZ – Hospital Universitario La Paz, Madrid, Spain, [6]Medical Oncology Department, Hospital Universitario La Paz, Madrid, Spain

Background: Chondrosarcoma (CS) is the second most frequent primary malignant bone tumor in adults. Surgery is the best treatment option for these patients since most subtypes are resistant to chemotherapy and radiotherapy, thus novel systemic therapies are needed for patients with unresectable tumors. The majority of cases correspond to the conventional central CS histology, were recurrent mutations in isocitrate dehydrogenases *(IDH1/2)* coding genes are found. Therefore, *IDH1* has been reported as a potential therapeutic target and several selective inhibitor molecules, such as AGI-5198 and, more recently, AG-120, have been developed and are currently being evaluated in clinical trials. In this work, we have explored the *in vitro* effects of AG-120 on a central CS cell line, JJ012, which carries a mutation in *IDH1*.

Methods: JJ012 cells were cultured both in monolayer and three-dimensional (3D) spheroids and treated with increasing concentrations of AG-120. *IDH1* mutation in arginine residue R132G was verified by PCR sequencing. Proliferation and cytotoxic screening were done with Sulforhodamine B (SRB) assay. Monolayer invasion and migration assays were performed with FluoroBlok and wound healing assays respectively and 3D experiments were developed using a Matrigel matrix.

Results: R132G mutation of *IDH1* was confirmed by PCR sequencing. Previous reports with AGI-5198 inhibitor show contradictory results regarding their effect on CS cells. In this work, we show how novel molecule AG-120 inhibits both invasion and migration of CS *IDH1* mutated JJ012 cell line in monolayer and 3D cell culture, although it does not affect their proliferation. Minor effects on viability were only detected at high dose (100 μM).

Conclusions: These results support AG-120 as a new possible therapeutic agent for patients with metastatic CS, and further research is needed to understand its action mechanisms in this pathology.

1525TiP Geriatric assessment of elderly chemotherapy-naïve patients treated with trabectedin for advanced soft tissue sarcomas (STS): The E-TRAB study of the German Interdisciplinary Sarcoma Group (GISG-13)

B. Kasper[1], P. Reichardt[2], M. Schuler[3], P. Hohenberger[1]

[1]Interdisziplinäres Tumorzentrum, Universitätsklinikum Mannheim, Mannheim, Germany, [2]Interdisziplinäre Onkologie, HELIOS Klinikum Berlin-Buch, Berlin-Buch, Germany, [3]Onkologie, HELIOS Klinikum Emil von Behring, Berlin, Germany

Background: More than half of soft tissue sarcoma (STS) patients are diagnosed older than 60 years and prognosis for advanced disease is unfavourable with a median overall survival (OS) of ∼12 months remaining substantially unchanged during the last 20 years. Quality of Life (QoL), especially when collected directly from the patients as Patient Reported Outcome (PRO) measures, has gained increasing interest in cancer care; however, existing data among elderly STS patients are scarce. The rationale of the E-TRAB study is to analyze QoL and PRO data in the elderly population (aged ≥ 60 years) with advanced STS, considered to be unsuited to receive anthracycline-based chemotherapy, and treated with trabectedin as a 1st line therapy.

Trial design: The E-TRAB (GISG-13) study is designed as a non-interventional trial ($n = 110$). Primary endpoints to be evaluated are OS and QoL. It is hypothesized that OS will not be < 10 months in this population. As secondary endpoints a comprehensive geriatric assessment is performed, and whenever feasible captured as PRO, in order to predict for safety parameters consisting of the Instrumental Activities of Daily Living (IADL), the Mini Nutritional Assessment (MNA), the Charlson Comorbidity Index (CCI), the Geriatric Depression Scale (GDS) and Time up & Go. The predictive value of two geriatric screening tools (G8, CARG prediction tool) is investigated with regards to unplanned hospitalizations, grade 4 toxicities and early death within the first six months. The EORTC QLQ-C30 and 18 PRO-CTCAE items are used to evaluate PRO. As translational research the tumour microenvironment is analyzed immunohistochemically using a new multicolor-immunofluorescence-histology technology (OPAL). This trial benefits from a cooperation of sarcoma centers in Austria, Germany and Switzerland under the German Interdisciplinary Sarcoma Group (GISG). The recruitment of patients is ongoing.

[1]Translational Oncology, Nationales Zentrum für Tumorerkrankungen (NCT), Heidelberg, Germany, [2]Pathology, University of Ulm, Ulm, Germany, [3]Medical Oncology, Nationales Zentrum für Tumorerkrankungen (NCT), Heidelberg, Germany, [4]University Cancer Center, Medical Dept. I, University Hospital Carl Gustav Carus, Dresden, Dresden, Germany, [5]Internal Medicine I, Universitätsklinikum Carl Gustav Carus, Dresden, Germany, [6]Internal Medicine, University of Ulm, Ulm, Germany, [7]Surgery, University of Ulm, Ulm, Germany, [8]Dept. of Medical Oncology, University Hospital Essen Westdeutsches Tumorzentrum, Essen, Germany, [9]Solid Tumor Translational Oncology, University Hospital Essen Westdeutsches Tumorzentrum, Essen, Germany, [10]NCT Trial Center, German Cancer Research Center, Heidelberg, Germany, [11]Medical Oncology, NCT Heidelberg, University Hospital Heidelberg, Heidelberg, Germany

Background: Chordoma is a rare bone tumor with slow growth. The standard treatment is en-bloc excision, but the site of origin of the disease (skull base, sacrum) often prevents complete resection. For these patients, debulking surgery followed by radiation therapy (RT) or high-dose RT alone can be an alternative. However, local relapses and, more rarely, metastatic disease occur, and there is no efficient systemic therapy available. Only very limited responses are seen with chemotherapy or targeted agents (e.g. imatinib, lapatinib). In chordoma cell lines and patient biopsies, the p16 (cyclin-dependent kinase inhibitor 2a, encoded by *CDKN2A*) tumor suppressor is consistently deleted. Experiments with patient-derived chordoma cell lines demonstrated aberrant CDK4/6 activity downstream of p16 loss, which can be efficiently inhibited by the CDK4/6 inhibitor palbociclib, resulting in reduced proliferation and growth of neoplastic cells (von Witzleben et al. Cancer Res 2015;75(18):3823-31).

Trial design: Patients ≥ 18 years of age with locally advanced or metastatic chordoma with at least one measurable tumor lesion, ECOG Performance Status 0-2, adequate organ function, and loss of p16 (as determined by immunohistochemistry) or *CDKN2A* (as determined by genetic analysis) who have no response or have lost response to treatment with a tyrosine kinase inhibitor are eligible. Key exclusion criteria are prior treatment with palbociclib, uncontrolled CNS involvement, cytopenia/s, significant cardiovascular disease including prolongation of the corrected QTc interval >470 ms. Based on previous experience with 125 mg palbociclib once daily for 21 days followed by 7 days of rest in patients with other solid-organ malignancies, this regimen is chosen. Based on a Simon optimal 2-stage design, the disease control rate is the primary endpoint, whereby response is defined as complete response, partial response, or stable disease according to RECIST v1.1 after 6 cycles. For sample size calculation, we estimate a poor response with 10% and a good response with 25% (power, 80%; alpha, 5%), resulting in a first stage of 18 patients and, if 3 or more patients respond, a second stage with 25 additional patients (total, $n = 43$).

Klinikum Koblenz-Montabaur, Koblenz, Germany, [11]Division of Respiratory Medicine and Thoracic Oncology, University Hospital of Munich, Munich, Germany, [12]Medizinische Klinik IV, Klinikum Kassel, Kassel, Germany

Background: The immune surveillance reactivator lefitolimod (MGN1703), a DNA-based TLR9 agonist, is currently in a comprehensive clinical development program including a phase 3 trial in mCRC. The phase 2 IMPULSE study was designed to evaluate the efficacy and safety of lefitolimod in small-cell lung cancer (SCLC).

Methods: IMPULSE is a randomized, international, multicenter, open-label trial to assess the effect of lefitolimod-mediated immune surveillance reactivation on overall survival (OS) in extensive-disease SCLC. 102 patients with objective tumor response following 4 cycles of platinum-based first-line induction therapy were randomized 3:2 to receive either lefitolimod maintenance therapy or local standard of care (control). Upon relapse, patients have received appropriate second-line therapy.

Results: Out of 102 patients, 61 were randomized to the lefitolimod, 41 to the control arm. Distribution of patients to the two arms was balanced regarding patient demographics. Even though in this highly challenging indication the primary endpoint OS of the overall study population was not met, IMPULSE showed positive results in two pre-defined and clinically relevant subgroups: An OS benefit was shown in comparison with the control arm in patients with a low count of activated $CD86^+$ B cells (HR 0.59, 95%CI 0.29-1.21, n = 38 of 88) as well as in patients with reported chronic obstructive pulmonary disease (COPD), (HR 0.54, 95%CI 0.21-1.38, n = 25 of 102). Immunologic parameters confirmed lefitolimod's mode-of-action with a clear activation of $CD169^+$ monocytes and production of IP-10 in response to lefitolimod treatment. Lefitolimod showed a favorable safety profile in this vulnerable population.

Conclusions: The IMPULSE study showed (1) the expected pharmacodynamic response to lefitolimod, (2) positive efficacy signals in two pre-defined and clinically relevant subgroups regarding OS and (3) a favorable safety profile. This data provides significant guidance for defining patient populations most likely to benefit from treatment with lefitolimod.

[1]Department of Medical Oncology, Cross Cancer Institute, University of Alberta/Alberta Health Services, Edmonton, AB, Canada, [2]Department of Medical Oncology, Radboud University Medical Center Nijmegen, Nijmegen, Netherlands, [3]Department of Medical Oncology, Princess Margaret Cancer Centre, Toronto, ON, Canada, [4]Department of Oncology, Monash Health and Monash University, Melbourne, Australia, [5]Department of Medical Oncology, Royal North Shore Hospital, St Leonards, Australia, [6]Department of Medical Oncology, Juravinski Cancer Centre, Hamilton, ON, Canada, [7]Early Assets, Bristol-Myers Squibb, Princeton, NJ, USA, [8]Department of Medicine, Duke University Medical Center, Durham, NC, USA

Background: Given the burden of comorbidities, lack of curative agents, and high mortality in pts with SCLC, novel treatment options with limited toxicity are needed. BMS-986012 is a first-in-class, fully human mAb with enhanced antibody-dependent cell-mediated cytotoxicity that binds to fucosyl-GM1, a ganglioside highly expressed on SCLC. BMS-986012 monotherapy is well tolerated and has shown evidence of antitumor activity in some pts with rel/ref SCLC in a phase 1/2 study (NCT02247349; Chu et al. Ann Oncol. 2016;27(6 suppl) [abstract 1427PD]). Here we present initial results of BMS-986012 + nivolumab (anti–programmed death-1 mAb) in pts with rel/ref SCLC (NCT02247349).

Methods: Pts with SCLC who relapsed after or were refractory to first-line therapy received BMS-986012 400 or 1000 mg + nivolumab 360 mg IV Q3W. Dose escalation was based on a modified toxicity probability interval design. Primary objectives were safety and tolerability and determination of dose-limiting toxicities (DLT) and maximum tolerated dose. Secondary objectives included pharmacokinetics, antitumor activity, and immunogenicity.

Results: To date, 16 pts received BMS-986012 (400 mg, n = 8; 1000 mg, n = 8) + nivolumab. Demographic and safety data are based on 14 pts treated as of the April 3, 2017 cutoff. Median age was 64 y (range, 49-79 y), ECOG status was 0 (29%) or 1 (71%), and all pts were current (29%) or former (71%) smokers. All pts had prior platinum-based first-line therapy. The most common treatment-related AEs (TRAEs) were generalized pruritus (71%), vulvovaginal pruritus (21%), and dry skin (21%). Only 2 pts, both treated with 1000/360 mg, had G3/4 TRAEs (G3 pruritus with G4 lipase increase; G3 hepatic failure [DLT; led to discontinuation]). As of May 1, 2017, 4 of the 16 pts evaluable for efficacy achieved partial responses (2 unconfirmed). Updated efficacy data as well as data from ongoing biomarker analyses will be presented.

Conclusions: BMS-986012 in combination with nivolumab is well tolerated in pts with rel/ref SCLC, with no evidence of additive toxicity. Promising initial antitumor activity was observed with BMS-986012 + nivolumab in pts with rel/ref SCLC.

1529PD Activity of lurbinectedin as single agent and in combination in patients with advanced small cell lung cancer (SCLC)

M.E. Olmedo Garcia[1], M. Forster[2], E. Calvo[3], V. Moreno[4], M.P. Lopez Criado[5], J.A. Lopez-Vilarino de Ramos[6], C. Kahatt[6], P. Lardelli[6], X.E. Luepke-Estefan[6], A. Soto-Matos[6]

[1]Oncologia, Hospital Universitario Ramon y Cajal, Madrid, Spain, [2]Oncology, University College London Hospital, London, UK, [3]Oncology, Centro Integral Oncologico Clara Campal - Hospital Madrid-Norte San Chinarro, Madrid, Spain, [4]Oncology, Fundacion Jimenez Diaz, Madrid, Spain, [5]Oncology, MD Anderson Cancer Center Center, Madrid, Spain, [6]Clinica, PharmaMar, Madrid, Spain

Background: Lurbinectedin (PM01183, L) is a novel anticancer drug that inhibits activated transcription, induces DNA double-strand breaks generating apoptosis, and modulates tumor microenvironment. Relapsed SCLC still remains an unmet medical need.

Methods: Antitumor activity and safety of Lurbinectedin in SCLC was reviewed in three clinical trials (n = 83 patients): two phase I in combination with doxorubicin (L+DOX; n = 48, two cohorts) or paclitaxel (L+TAX, n = 7), and a phase II single-agent basket trial (n = 28).

Results: Median age was similar in these three studies. CNS was involved in 33% (L+DOX cohort A), 4% (L+DOX cohort B), 29% (L+TAX) and 0% of patients (L alone). Patients with sensitive disease were 52%, 64%, 71% and 71%, respectively. Activity was seen in the three studies (see Table). The most reported toxicity was hematological (G3-4 neutropenia/thrombocytopenia/febrile neutropenia: L+DOX Cohort A 96%/34%/34%; L+DOX Cohort B 89%/11%/14%; L+TAX 86%/0%/14%, and L alone 32%/4%/4%). Non-hematological toxicity was mainly G1-2 and included fatigue, nausea/vomiting, and transaminase increase.

Conclusions: Lurbinectedin shows activity as a single agent and in combination with other agents (DOX and TAX) in relapsed SCLC. Results were remarkable in terms of PFS, DCR and duration of response, especially in platinum-sensitive SCLC. Toxicity mainly consisted of transient myelosuppression, which was manageable with dose reductions and G-CSF use. A randomized Phase III with L+DOX is ongoing (ATLANTIS Study).

Table: 1529PD

Response Evaluable patients	Lurbinectedin+DOX (q3wk)		Lurbinectedin + TAX (q3wk)	Lurbinectedin alone (q3wk)
	Cohort A L 3-5 mg FD D1 + DOX 50 mg/m^2 D1 (n = 21)	Cohort B L 2 mg/m^2 D1 + DOX 40 mg/m^2 D1 (n = 27)	L 2.2 mg/m^2 D1 + TAX 80 mg/m^2 D1 & D8 (n = 7)	L 3.2 mg/m^2 D1 (n = 24)
CR	2 (10%)	1 (4%)	1 (14%)	–

Background: Notch signaling is implicated in cancer stem cell biology and is an appealing target in the treatment of SCLC. TRXT, a fully human anti-Notch2/3 antibody, has shown preclinical efficacy in SCLC. A randomized phase 1b/2 study was conducted.

Methods: This was a randomized, placebo-controlled, multi-center study. Pts were randomized 1:1 to platinum (cisplatin 75 mg/m^2 or carboplatin AUC of 5 mg/ml*min on day 1, investigator's choice) + etoposide (EP) 100 mg/m^2 on days 1-3 + TRXT 15 mg/kg on day 1 or EP + placebo (pbo) every 21 days. Chemotherapy was used for 6 cycles, and TRXT/pbo was continued until disease progression. Primary endpoint was progression-free survival (PFS). Secondary endpoints included overall survival (OS), overall response rate (ORR), safety, and PFS/OS in 5 biomarker groups.

Results: 145 pts were enrolled (137 treated). Demographics and baseline pt characteristics were balanced between arms. PFS was similar between the treatment arms (median 5.5 mo in EP+pbo vs 5.5 mo in EP+TRXT, HR = 0.97, p = 0.94). OS was also similar between the treatment arms (median 10.3 mo in EP+pbo vs 9.3 mo in EP+TRXT, HR = 1.01, p = 0.95). ORR was 70.8% in EP+pbo vs 68.6% in EP+TRXT (p = 0.83). There were no statistically significant differences in OS or PFS according to Notch3, Hes1, Hey2, Hey1, or Hes6 gene expression levels. Adverse events (AE) were more common in EP+TRXT; most commonly increased drug-related AEs included diarrhea (33.8/76.8%), thrombocytopenia (17.6/58.0%), decreased appetite (23.5/37.7%), hypokalemia (7.4/33.3%), and vomiting (13.2/31.9%). Most commonly increased grade 3 or higher AEs in the EP+TRXT arm included thrombocytopenia (10.3/40.6%), anemia (20.6/27.5%), pneumonia (4.4/15.9%), diarrhea (0/18.9%), and hypokalemia (4.4/13%). AEs with fatal outcome were more common in EP+TRXT (4.4/8.7%).

Conclusions: Tarextumab in combination with platinum-based therapy did not improve PFS, OS, ORR in previously untreated SCLC. Biomarker analysis failed to establish a predictive marker for TRXT efficacy. Pts treated with TRXT experienced more toxicity. Clinical development of TRXT has been discontinued.

1531PD Clinical outcomes for EGFR-mutant adenocarcinomas (AC) that transform to small cell lung cancer (SCLC)

N. Marcoux[1], Z. Piotrowska[1], A.F. Farago[1], A.N. Hata[1], M.J. Mooradian[1], B.J. Drapkin[1], A. Muzikansky[1], S.N. Gettinger[2], M. Mino-Kenudson[1], L. Sequist[1]

[1]Thoracic oncology, Massachusetts General Hospital, Boston, MA, USA, [2]Oncology, Yale Cancer Center, New Haven, CT, USA

Background: About 5-10% of EGFR-mutant lung ACs transform to SCLC at the time of acquired resistance. The clinical course of patients (pts) with this finding is poorly characterized.

Methods: We retrospectively reviewed the records of all 16 pts with EGFR-mutant SCLC that have been seen at our center under an IRB-approved protocol and summarized demographics, disease features, and clinical outcomes.

Results: Among 16 pts, 10 were women. 15 had AC histology at diagnosis; one had *de novo* SCLC with EGFR del19. 11 were never-smokers. All but the *de novo* case received an EGFR tyrosine kinase inhibitor (TKI) prior to transformation (7 had > 1 prior TKI; 6 received a 3rd-gen TKI) and 14/15 were on a TKI when the SCLC was noted. Median time from diagnosis to SCLC was 29.6 mo (95% CI 10.8-38.1). 15/16 of the SCLC tumors were genotyped; all kept their founder EGFR mutation and none had T790M, including 5 pts with prior T790M-positivity. Not all samples were assessed for genotype by the same assay, though recurrent mutations observed in at least 25% of cases were TP53, PIK3CA and RB1 (full genetic data will be shown at meeting). The most common therapy given directly after SCLC diagnosis was platinum-etoposide (n = 9); all SCLC treatment lines considered, platinum-etoposide had a clinical response rate of 72% (8/11) and progression-free survival of 4.6 mo (95% CI 2.0-5.5). Seven pts also had a taxane at some point after the diagnosis of SCLC, and 4/7 (57%) responded. Median overall survival (mOS) from initial cancer diagnosis was 38.2 mo (95% CI 24.5-43.9) and mOS from time of SCLC diagnosis was 12.4 mo (95% CI 4.0-16.6).

Conclusions: EGFR-mutant AC that transforms to SCLC uniformly maintains its founder EGFR mutation and is mutually exclusive with T790M (though both can be observed sequentially). In our cohort, the median time from initial lung cancer diagnosis to transformation was 2.5 years. The mOS of 12.4 mo following diagnosis of SCLC is

similar to that seen among pts with non-EGFR-mutant SCLC. Likewise, responses to platinum-etoposide were frequent, but transient. 4 pts also responded to a taxane. Interestingly, mOS from diagnosis was similar to expected mOS for pts that never transform to SCLC at 38.2 mo. Further investigation is needed to better elucidate optimal strategies for this group.

1532P The role of thoracic radiotherapy on peripheral lymphocyte subsets in patients with limited-stage small cell lung cancer

Y. Chen[1], Y. Jin[2], M. Chen[3]

[1]Zhejiang Key Laboratory of Radiation Oncology, Zhejiang Cancer Hospital, Hangzhou, China, [2]Department of Medical Oncology, Zhejiang Cancer Hospital, Hangzhou, China, [3]Department of Radiation Oncology, Zhejiang Cancer Hospital, Hangzhou, China

Background: Over the past decades, there has been a lack of significant breakthroughs in small cell lung cancer therapy, the current standard care is still concurrent chemoradiation. Recently, immune checkpoint inhibitors in anti-tumor clinical application has achieved remarkable results. There is evidence suggest that radiation and chemotherapy can alter the immune microenvironment, many clinical trials combing radiation or chemotherapy with checkpoint inhibitors are underway. But how chemotherapy or radiotherapy affects any existing anti-tumor immune response and how that response is changed following clinical treatment are still not elucidated fully. In this study, we investigated the changes of immune subsets in patients with LS-SCLC.

Methods: Blood samples were obtained from 48 patients before and after radiotherapy and 31 patients before and after induction chemotherapy. PBMCs were purified using standard Ficoll density gradient centrifugation. The percentage of circulating lymphocyte subsets were measured by flow cytometry. Patient data include clinical characteristics, disease prognostic information, survival information etc. The SPSS 22.0 software was used for the data analysis.

Results: Among the 31 patients, most values of T-lymphocyte subsets showed no statistically significant difference before and after induction chemotherapy. Among the 48 patients, remarkable elevation of CD3+, CD8+ T cells were noticed, CD4+, CD56+, CD4+CD45RA+ cells and CD4+/CD8+ ratio were significantly decreased after radiotherapy. Then we further analyzed the changes of lymphocyte subsets in 17 patients before and after induction chemotherapy as well as radiotherapy, which further confirmed the changes of immune subsets caused by radiotherapy but not induction chemotherapy.

Conclusions: This study suggest that thoracic radiotherapy but not induction chemotherapy has an immunomodulatory effect on LS-SCLC patients, which provides new insights relevant for designing more optimal combination of immunotherapy in such cohort, especially for the appropriate time and sequence of immunotherapy, radiotherapy and chemotherapy.

1534P Antidepressants simulate enriched environment enhance platinum chemosensitivity of small cell lung cancer

Y. Wu, Q. Wang, H. Tang

Internal Medicine-Oncology, Henan Cancer Hospital, Zhengzhou, China

Background: Small cell lung cancer (SCLC) is one of the most lethal malignancies with rapid chemoresistance. Numerous studies have been devoted to reversing chemoresistance. However, it is still far from successful with a clear way to reverse the effect of chemoresistance. Based on our previous study, enriched environment (EE) has a clear effect on improving the mental state of mice and can reduce chemotherapy resistance caused by platinum regimens. In this study we investigated the complex links between benign mental stress (EE) and chemosensitivity of SCLC, and use anti-depressants to improve the mental state of mice to observe its impact on chemosensitivity to platinum regimens, and the underlying mechanism was explored.

Methods: The mental state of mice was comprehensive evaluation by behavior tests include: elevated plus maze (EPM), open field experiment (OF), forced swimming (FS). Then, the mice were transplanted subcutaneously and treated with cisplatin, carboplatin and oxaliplatin. Tumor growth and the results of behavior test were analyzed. The tumor was analyzed by gene expression profiling and the differential genes were screened. The expression level of differential genes were examed by real-time PCR, and verified by western bolt and immunohistochemistry, respectively. And then we examined the effects of antidepression drugs inducing chemoresistance in NCI-H69 cell, and ABCG2 blocker was used for chemosensitivity verification in vivo and in vitro.

Results: EE significantly increased the time of movement of the in the EPM (35.24 sec V.S. 16.78 sec, $P < 0.01$), increased the center area time in OF test (54.25 sec V.S. 35.24 sec, $P < 0.05$), significantly increased the struggling time in the FS test (46.02 sec V.S. 25.81 sec, $P < 0.01$). For antidepressants, its can also significantly improve the state of depression of mice, improve the behavior results, but can not achieve the effect of EE (EPM: 30.25 sec V.S. 35.24 sec, OF: 49.84 sec V.S. 54.25 sec, FS: 37.28 V.S. 46.02 sec). For platinum chemosensitivity test, the antidepressant drugs (Diazepam, Quetiapine and Clomipramine) without direct inhibition to NCI-H69 cells. Antidepressants and EE have significantly increased the sensitivity of chemotherapy in mice, but antidepressants can not achieve the inhibitory effect of EE. We detected the serum of mice and found that the serum BDNF levels significantly decreased in EE mice. Similarly, antidepressants also significantly reduced serum BDNF levels in mice. Gene expression profiles showed that a variety of genes were downregulated in the tumor tissue of EE and antidepressants mice, mainly in ABC transporters and drug metabolic pathways. The expression level of ABCB1, ABCC2, ABCG2, ABCC9, PPARa, DPYD, GST-P1 and GSTM1 in NSCLC sample were examedby real-time PCR, and verified by western bolt and immunohistochemistry, respectively. ABCG2 expression in tumor of EE and antidepressants mice were even 3-fold higher than control ($P < 0.001$), and the same results were obtained by WB and IHC verification. Nicardipine blocks ABCG2 expression can restore chemosensitivity to platinum based drugs ($P < 0.001$).

Conclusions: Antidepressants can partially mimic the chemotherapeutic effect of EE and we confirm that the mechanism is partially achieved by increasing BDNF and reducing the expression of ABCG2.

1535TiP KEYNOTE-604: Phase 3 trial of pembrolizumab plus etoposide/platinum (EP) for first-line treatment of extensive stage small-cell lung cancer (ES-SCLC)

C.M. Rudin[1], L. Shen[2], M.C. Pietanza[2]

[1]Medicine, Memorial Sloan Kettering Cancer Center, New York, NY, USA, [2]Clinical Research, Merck & Co., Inc., Kenilworth, NJ, USA

Background: Therapeutic options for SCLC remain limited, with EP as the standard first-line chemotherapy regimen. However, patients (pts) with ES-SCLC experience high relapse rates within months after initial therapy. Pembrolizumab, a humanized monoclonal antibody against PD-1, has shown antitumor activity as monotherapy in heavily pretreated pts with PD-L1–positive SCLC in the phase 1b KEYNOTE-028 study. KEYNOTE-604 (ClinicalTrials.gov, NCT03066778) evaluates EP plus either pembrolizumab or placebo (pbo) as first-line therapy for ES-SCLC.

Trial design: In this international, double-blind, phase 3 trial, adults with newly diagnosed ES-SCLC, ECOG PS ≤ 1, and no previous systemic therapy for SCLC are randomized 1:1 to receive either EP plus a 200-mg fixed dose of pembrolizumab intravenously (IV) once every 3 weeks (Q3W) or EP plus pbo IV Q3W. Randomization is stratified by the chosen platinum therapy (carboplatin vs cisplatin), ECOG PS (0 vs 1), and baseline lactate dehydrogenase concentration ($\leq$ upper limit of normal [ULN] vs $>$ ULN). Study treatment includes a total of 4 cycles of EP and 2 y of pembrolizumab/pbo and continues until documented PD, intolerable toxicity, or withdrawal of consent. Pts with a response after 4 cycles of EP plus pbo or pembrolizumab may receive prophylactic cranial irradiation. Pts who complete 2 y of pembrolizumab treatment or stop pembrolizumab for reasons other than PD/intolerability, but subsequently have documented PD, may receive an additional 1 y of pembrolizumab. Tumor response is assessed every 6 wk for 48 wk, and every 9 wk thereafter by RECIST version 1.1 by blinded independent central review. AEs occurring during treatment and 30 d thereafter (90 d for serious AEs) are graded per Common Terminology Criteria for Adverse Events, version 4.0. Primary endpoints are PFS and OS. Secondary endpoints are ORR, duration of response, safety, and patient-reported outcomes. Enrollment is ongoing with a planned enrollment of approximately 430 pts.

1536TiP An open-label study on safety and tolerability of rovalpituzumab tesirine in Japanese patients with advanced, recurrent small cell lung cancer

I. Okamoto[1], H. Udagawa[2], S. Kanda[3], T.H. Han[4], I. Lakatos[4], F. Zhang[4], S. Okubo[5], C. Scripture[4], M. Takeda[6], H. Akamatsu[7], T. Tamura[8]

[1]Research Institute for Disease of the Chest, Graduate School of Medical Sciences, Kyushu University Hospital, Fukuoka, Japan, [2]Department of Thoracic Oncology, National Cancer Center Hospital East, Chiba, Japan, [3]Department of Thoracic Oncology, National Cancer Center Hospital, Tokyo, Japan, [4]Clinical Development, AbbVie Stemcentrx LLC, South San Francisco, CA, USA, [5]Clinical Development, AbbVie Japan GK, Osaka, Japan, [6]Department of Medical Oncology, Kindai University Hospital, Osaka, Japan, [7]Third Department of Internal Medicine, Wakayama Medical University Hospital, Wakayama, Japan, [8]Thoracic Center, St. Luke's International Hospital, Tokyo, Japan

Background: Small cell lung cancer (SCLC) is a chemoresponsive malignancy with high response rates in early lines of therapy, but will inevitably recur. For patients (pts) with progressive SCLC following treatment with at least two prior therapies, standard treatment has not been established. Rovalpituzumab tesirine (Rova-T^{TM}) is an antibody-drug conjugate that targets Delta-like protein 3 (DLL3), an atypical Notch receptor family ligand and a marker specific for tumor-initiating cells in SCLC and other neuroendocrine cancers. Rova-T is comprised of a humanized DLL3-specific IgG1 monoclonal antibody tethered to a toxic DNA cross-linking agent by a cleavable linker. Rova-T binds DLL3 on target-expressing cells, is internalized, and the toxin released to induce cell death. A Phase 1 study of Rova-T in SCLC demonstrated robust antitumor activity in DLL3-high pts and a manageable safety profile[1]. The safety, tolerability, pharmacokinetics (PK), and pharmacodynamics of Rova-T has not been evaluated in Japanese SCLC pts, thus a study of Rova-T in this population is warranted.

Trial design: This is a Phase 1, multicenter, Japanese, open-label dose escalation study (NCT03086239). Primary objective: to assess safety and tolerability of Rova-T in Japanese pts with advanced, recurrent SCLC. Secondary objectives: to explore antitumor activity of Rova-T; to study PK and pharmacodynamics of Rova-T. Pt eligibility: histologically or cytologically confirmed advanced, recurrent SCLC with measurable disease and documented disease progression after at least 2 prior systemic regimens, including at least 1 platinum-based regimen; ECOG 0-1; no prior exposure to a pyrrolobenzodiazepine-based drug. A standard 3 + 3 dose escalation will be used with $\leq$ 18 pts enrolled (6/dose level x 3 levels) and $\leq$ 60 pts if expansion cohorts are executed (20/dose level x 3 levels). Pts will receive Rova-T 0.2, 0.3, or 0.4 mg/kg intravenously on Day 1 of each 6-week cycle x 2 doses and dexamethasone 8 mg orally twice daily on Day -1, Day 1, and Day 2 of each 6-week cycle. Dose escalation will proceed until a single maximum tolerated dose (MTD) is determined (not to exceed 0.4 mg/kg). 1. Rudin et al., Lancet Oncol, 2016.

1537TiP A phase 3 trial of rovalpituzumab tesirine vs topotecan in patients with advanced small cell lung cancer following frontline platinum-based chemotherapy

P. Komarnitsky[1], H-J. Lee[2], M. Shah[2], S. Wong[2], S. Gulbranson[2], J. Dziubinski[2], L. Caffrey[2], P. Tanwani[2], M. Motwani[2], F. Zhang[2]

[1]Oncology Development, AbbVie Inc., Cambridge, MA, USA, [2]Clinical Development, AbbVie Inc., North Chicago, USA

Background: Small cell lung cancer (SCLC) represents ~15% of lung cancers. Patients (pts) are staged with limited or extensive stage disease (ES). ES standard therapy consists of a platinum-based therapy + a second agent (etoposide). Initial response rates are high but not durable. Treatment for relapsed pts is limited, but includes topotecan. However, efficacy of topotecan is suboptimal and there is a high unmet need in this population. Delta-like protein 3 (DLL3) is an atypical Notch receptor family ligand identified as a target in SCLC and neuroendocrine carcinomas (NECs). DLL3 is highly expressed in SCLC and NECs but not normal tissue. Rovalpituzumab tesirine (Rova-T^{TM}) is an antibody-drug conjugate composed of a DLL3-targeting IgG1 monoclonal antibody tethered to a toxic DNA crosslinker. Rova-T has antitumor activity in relapsed ES SCLC pts, and was well-tolerated[1]. Thus, we are investigating Rova-T vs topotecan as a 2nd line therapy in advanced SCLC.

Trial design: This is a Phase 3, randomized, open-label, multicenter study (NCT03061812) to assess efficacy, safety, and tolerability of Rova-T vs topotecan. Approximately 411 pts will be enrolled and randomized 2:1 between 2 arms. Arm A regimen: 0.3 mg/kg Rova-T intravenous (IV) on Day 1 + 8 mg dexamethasone orally, twice daily on Day -1, 1 and 2 of a 42-day cycle; administered for 2 cycles with up to 2 additional cycles permitted. Arm B: 1.5 mg/m^2 topotecan (or per local label) IV on Days 1-5 of each 21-day cycle; administered until disease progression. Pt eligibility: $\geq$ 18 years; confirmed, advanced/metastatic SCLC with first disease progression following frontline standard therapy; DLL3-high tumor expression; ECOG 0-1; no prior exposure to a pyrrolobenzodiazepine-based drug or topotecan, irinotecan, or other topoisomerase I inhibitor. Primary objectives: to determine if Rova-T improves objective response rate and overall survival vs topotecan. Secondary objectives: to assess if Rova-T improves progression-free survival vs topotecan; to compare duration of objective response between arms; and to assess effect on patient-reported outcomes. 1. Rudin et al., Lancet Oncol, 2016.

1538TiP A phase 1/2 study on safety of rovalpituzumab tesirine in combination with nivolumab or nivolumab + ipilimumab in small cell lung cancer

C. Scripture[1], G. Selvaggi[2], I. Lakatos[3], K. Boynton[3], S. Lally[3], T.H. Han[3], S.L. Peng[3], S.J. Dylla[3]

[1]Clinical Development, AbbVie Stemcentrx LLC, South San Francisco, CA, USA, [2]Oncology Clinical Development, Bristol-Myers Squibb, Lawrenceville, NJ, USA, [3]Clinical Development, AbbVie Stemcentrx LLC, South San Francisco, CA, USA

Background: Small cell lung cancer (SCLC) is an unmet medical need, representing ~15% of lung cancer diagnosed/year. Two-thirds of patients (pts) are diagnosed with extensive stage (ES) SCLC with a 2-year survival rate of 5%. Delta-like protein 3 (DLL3), an atypical Notch receptor family ligand, is highly expressed in SCLC and other neuroendocrine tumors with little to no expression in normal tissue. Rovalpituzumab tesirine (Rova-T^{TM}) is an antibody-drug conjugate composed of a humanized DLL3-specific IgG1 monoclonal antibody tethered to a toxic DNA cross-linking agent. A Phase 1 study of Rova-T in SCLC pts showed encouraging progression-free and overall survival and a manageable safety profile[1]. Studies show that nivolumab (nivo, anti-PD-1 antibody) +/- ipilimumab (ipi, anti-CTLA-4 antibody) has antitumor activity and is well-tolerated in 2nd line SCLC. Given the complementary mechanisms of action and non-overlapping toxicities, futher study is warranted to evaluate if a combination of Rova-T and nivo, or all 3 agents leads to more pts with long-term responses and prolonged survival.

Trial design: This Phase 1/2 study (NCT03026166) will enroll ~90 pts in 3 cohorts. Each cohort will receive Rova-T 0.3 mg/kg IV on Day 1 of the 1st and 3rd 3-week cycle in combination with: nivo 360 mg/kg IV q3wk x 2 cycles (cohort 1) or nivo 1 mg/kg q3wk + ipi 1 mg/kg (cohort 2) or 3mg/kg (cohort 3) IV q3wk x 4 cycles. Maintenance nivo will be administered in all cohorts at 480 mg IV q4wk. The dose limiting toxicity (DLT) evaluation period is 12 weeks. Pt eligibility: $\geq$ 18 years; histologically or cytologically confirmed 2nd line or later ES SCLC; confirmed DLL3-positive status based on immunohistochemistry of baseline tumor tissue (for DLT evaluable pts); ECOG 0-1; no autoimmune disease; no prior exposure to immuno-oncology or pyrrolobenzodiazepine-based drugs. Primary and secondary objectives: assess safety and efficacy of Rova-T in combination with nivo or nivo + ipi. Exploratory objectives: assess expression of DLL3 and PD-L1 and their relationship to clinical outcome, pharmacokinetics, incidence of neutralizing antibodies, and effects on pharmacodynamic biomarkers. 1. Rudin et al., Lancet Oncol, 2016.

1539O Pre-chemotherapy nutritional status and chemotherapy response: An observational study

R. Rao[1], N. Saha[2], V. Mani[1], R. Amritanshu[1], R. Geetha[1], N. Radheshyam[3], S. Patil[3], H.P. Shashidhara[4], T.C. Satheesh[3], V. Agarwal[3], B.S. Ajaikumar[3]

[1]Healthcare Global Enterprises Ltd., CARE, HCG Foundation, Bangalore, India, [2]Nutrition, Healthcare Global Enterprises Ltd., Bangalore, India, [3]Medical Oncology, Healthcare Global Enterprises Ltd., Bangalore, India, [4]Medical Oncology, HCG Bangalore Institute of Oncology Speciality Centre, Bangalore, India

Background: Cancer patients undergoing chemotherapy suffer from nausea, vomiting, low blood counts and electrolyte disturbances that impose stress on the nutritional needs of cancer patients. Nutritional status has been shown to reflect not just the patient's general condition but also to predict patient survival. In this study, we evaluate the predictive effects of pre-chemotherapy nutritional status in patients with solid malignancies on chemotherapy response and quality of life.

Methods: Two hundred adult patients with localized solid malignancies (Except GI and Brain malignancies) undergoing Neoadjuvant/adjuvant chemotherapy were analyzed for their nutritional status before the therapy. Nutritional status was assessed using Subjective Global assessment (SGA), Nutritional risk index (NRI), Body mass Index (BMI), Platelet lymphocyte ratio (PLR), neutrophil-lymphocyte ratio (NLR), and Albumin-globulin ratio (AGR) prior to their chemotherapy treatment. Patients were also assessed for Hand grip strength, Quality of life using Functional assessment of Chronic illness Therapy (FACIT) and EUROQol C30 and radiological response using RECIST criteria following chemotherapy.

Results: Mean age of study population was 51.65 $\pm$ 10.1years. Multivariate regression analysis was done on Chemotherapy outcomes such as Response criteria, FACIT scores, Quality of life scores and handgrip strength using, SGA, NRI, NLR, BMI and Albumin/Globulin ratio as predictors. SGA score emerged as a significant primary predictor for hand grip strength (β=-7.3, $p < 0.001$) followed by BMI ($\beta = 1.3$, $p < 0.001$) and NRI (β=-0.73, $p < 0.001$). SGA emerged a significant primary predictor for FACIT score ($\beta = 16.1$, $p < 0.001$) followed by NLR (β=- 0.43, $p = 0.008$). SGA emerged as a significant primary predictor for physical activity ($\beta = 1.73$, $p < 0.001$) followed by BMI (β=-0.19). SGA emerged as a significant predictor of quality of life score (β=-3.13, $p < 0.001$). Multinomial logistic regression for a complete response to RECIST criteria showed lower NLR to be a significant predictor ($\beta = 0.90$, $p = 0.04$).

Conclusions: The results suggest that pre-chemotherapy nutritional status and NLR influence the functional quality of life, strength and chemotherapy response in patients with solid malignancies.

1540O Fosaprepitant reduces the impact of nausea on daily function during five weeks of chemo-radiotherapy: A sub-study of the GAND-emesis trial

C.H. Ruhlmann[1], T.B. Christensen[2], L. Hammer Dohn[3], M. Paludan[4], E. Roennengart[2], F. Hilpert[5], P. Feyer[6], G. Kristensen[7], O. Hansen[1], D. Keefe[8], J. Herrstedt[1]

[1]Department of Oncology, Odense University Hospital, Odense, Denmark, [2]Department of Oncology, Herlev Hospital, Herlev, Denmark, [3]Department of Oncology, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark, [4]Department of Oncology, Aarhus University Hospital, Aarhus, Denmark, [5]Department of Oncology, Universitätsklinikum Schleswig-Holstein, Campus Kiel, Kiel, Germany, [6]Department of Radiation Oncology, Vivantes Clinics Neukoelln, Berlin, Germany, [7]Department for Gynecologic Cancer, Oslo University Hospital, Oslo, Norway, [8]RAH Cancer Centre, Royal Adelaide Hospital, Adelaide, Australia

Background: The GAND-emesis trial, a multinational, randomised, double-blind, placebo-controlled phase III trial, in women with cervical cancer receiving fractionated radiotherapy and weekly cisplatin 40 mg/m^2, demonstrated an increase of 17% in the proportion of patients completing five weeks of treatment without vomiting when fosaprepitant (FOS) was added to palonosetron (PAL) and dexamethasone (DEX) (Ruhlmann et al, Lancet Oncol, 2016). As a secondary endpoint we investigated whether there was any difference in impairment of daily functional life between groups as a result of nausea or vomiting.

Methods: The validated Functional Living Index – Emesis (FLIE) questionnaire consists of 18-items to measure the impact of nausea (9 items domain) and vomiting (9 items domain) on daily functional life. The FLIE-questionnaire was completed at baseline and again at end of study (EoS). The scores for each domain and the total score were calculated according to the FLIE Manual. Domain scores $\geq$ 54 and total score $\geq$ 108 indicate no or minimal impact on daily life. The Kruskal-Wallis H test was used to test the difference between groups.

Results: Two hundred and thirty-four patients from four countries were randomised and received study medication. Nine patients were excluded due to invalid questionnaires. Included were 115 patients receiving FOS and 110 patients receiving placebo (PLA). The point scores at baseline were similar across groups (FOS vs PLA); nausea domain: 59.9 vs 60.3 ($p = 0.31$); vomiting domain: 61.9 vs 62.1 ($p = 0.16$); and total score: 121.8 vs 122.4 (0.37). At EoS, a statistically significant difference was demonstrated for the point scores for the nausea domain and the total score (FOS vs PLA); nausea domain: 54.9 vs 53 ($p = 0.02$); vomiting domain: 61.4 vs 60.9 ($p = 0.10$); and total score: 116.3 vs 113.9 ($p = 0.01$).

Conclusions: This is the first study to investigate safety, efficacy, and impact on daily function of a neurokinin-1 receptor antagonist during the entire course of concomitant chemo-radiotherapy. The addition of FOS to PAL and DEX not only improved emetic control but also gave a clinically and statistically significant reduction of the impact of nausea on patients' daily functional life.

Clinical trial identification: EudraCT number: 2009-014691-21. ClinicalTrials.gov: NCT 01074697.

1542PD Anticipative approach to improve safety: An innovative daily hospital organisation

F. Scotté[1], R.T. Elaidi[2], H. Haboudagga[3], C. Thibault[2], J. Stevens[4], B. Bonan[5], S. Oudard[2]

[1]Medical Oncology and Supportive Care Unit, Foch Hospital, Suresnes, France, [2]Medical Oncology, Georges Pompidou European Hospital, Paris, France, [3]Pharmacy, Georges Pompidou European Hospital, Paris, France, [4]Medical Oncology, Direct Medica, Boulogne, France, [5]Pharmacy Department, Foch Hospital, Suresnes, France

Background: The PROCHE [Programme for optimisation of the chemotherapy network] initiative is an innovative oncology-monitoring program designed to reduce patient waiting time and chemotherapy wastage, ultimately improving patient care. A nurse calls patients 48 hours before anticancer treatment at the daily hospital to anticipate chemotherapy preparation.

Methods: Primary objective was to evaluate the incidence of different symptoms reported by grade (NCI-CTC AE: from 0 to 4) prospectively collected from 2008 to 2016. Secondary objective compared the 2009-2016 patients to the control cohort (2008 period) quantified using Mantel-Haenszel khi^2 and exact *p-values.*

Results: From January 2009 to December 2016, 3012 patients were enrolled in the program, representing 36 803 questionnaires completed over the whole period. Main adverse events (AE) were collected and compared to the control cohorts (2008, n = 513),

Table: 1542PD

Adverse Event	2008 (%)	2009-2016 (%)	p-value
Fatigue	82.4	62.01	<0.0001
Pain	49.69	28.31	<0.0001
Neuropathy	35.77	39.06	0.0784
Nausea	29.92	11.38	<0.0001
Vomiting	8.03	2.26	<0.0001
Infection	7.91	3.48	<0.0001
diarrhea	13.56	7.88	<0.0001
Constipation	34.42	19.28	<0.0001
Dry Skin	38.72	25.21	<0.0001
Hand Foot Syndrome	15.28	2.47	<0.0001
Mucositis	15.54	9.87	<0.0001

resulting in a significant decrease in majority of topics. Global incidence comparison is presented in table 1, with the p-value according to khi2 test. Details of severity levels scores using NCI CTC-AE V4.0, will be reported at ESMO meeting. For some of the toxicities, severe or life threatening toxicities (grades 3-4) were higher in the PROCHE cohort, while global incidence decreased.

Conclusions: The PROCHE initiative resulted in adverse events decrease and improved patient quality of care and improved hospital as well as pharmacy efficacy.

1544PD Development of an online drug-drug interaction resource to support prescribing of oncolytics

N.A.G. Lankheet[1], F.G. Jansman[2], S.E. Gibbons[3], D.M. Burger[1], K. McAllister[3], S.H. Khoo[3], N.P. Van Erp[1]

[1]Department of Pharmacy, Radboud University Medical Centre Nijmegen, Nijmegen, Netherlands, [2]Department of Pharmacy, Deventer Hospital, Deventer, Netherlands, [3]Department of Molecular and Clinical Pharmacology, University of Liverpool, Liverpool, UK

Background: Patients treated for cancer are at high risk of drug-drug interactions (DDI), which affects nearly 60% of patients on therapy. We developed a freely available DDI resource (www.cancer-druginteractions.org) to support anti-cancer drug prescribing, based on successful implementation for HIV (www.hiv-druginteractions.org) and hepatitis (www.hep-druginteractions.org) treatments.

Methods: A review of literature and registration documents was performed to evaluate the available evidence for potential DDIs of several oncolytics. Decision trees based on the FDA guideline on DDI studies were used to assess clinical relevance of DDIs. Comedications that are frequently used by cancer patients were selected. Interaction potential of drug combinations was classified using a straightforward 'traffic light' classification and quality of evidence was classified using the GRADE system. Advice on management of the interaction was included where appropriate. All records were reviewed by an expert panel of clinical pharmacists/pharmacologists.

Results: Thus far, twelve targeted oncolytics for the indications renal cell, hepatocellular and ovarian carcinoma, gastrointestinal stromal tumors, neuroendocrine tumors and sarcoma have been reviewed. Potential DDIs between oncolytics and > 450 comedications have been classified (Table). Tyrosine kinase inhibitors (TKI) show potential interactions which require action of prescribers in more than 20% of reviewed drug combinations. Monoclonal antibodies (MoAB) show clinically relevant DDIs in only 0.7% of reviewed drug combinations.

Table: 1544PD Overview of evaluated DDIsc

Drug class	TKI	MoAB
Number of comedications screened for interaction potential (mean)	458	478
Interaction classi˚cation 'traf˚c light' (%)		
Green: No clinically significant interaction	64.8	80.6
Yellow: Interaction of weak/moderate intensity; no a priori dosage adjustment required	14.4	18.7
Amber: Potential interaction which may require dosage adjustment or close monitoring	17.5	0.6
Red: Do not co-administer	3.3	0.1

Conclusions: The DDI checker currently includes comprehensive and ready-to-use advices for DDIs with oncolytics for six indications (these are due to be expanded in the coming months). The freely available, independently developed website with 'traffic light' classification will facilitate health care professionals' and patients' awareness of potential DDIs between oncolytics and frequently used comedications.

1545PD The effect of cannabis use on tumor response to nivolumab in patients with advanced malignancies

T. Taha, S. Talhamy, M. Wollner, A. Peer, G. Bar-Sela

Oncology, Rambam Health Care Campus, Haifa, Israel

Background: In recent years, immunotherapy, which enhances the immune system's response to tumors, has come into clinical use. At the same time, the use of cannabis, which has potential immune-suppressive effects, is increasing in oncology patients, mainly for palliative indications. A large number of patients is being treated with these two modalities and interaction is possible. The aim of this study was to evaluate the influence of cannabis use during immunotherapy treatment on response rate (RR), progression-free survival (PFS) and overall survival (OS).

Methods: In this retrospective, observational study, data was collected from the files of patients treated with Nivolumab in the years 2015-2016 at Rambam Health Care Campus in Haifa, Israel. Nivolumab was given to 140 patients (89 Nivolumab alone, 51 Nivolumab plus cannabis) with advanced melanoma, non-small-cell lung cancer, and renal clear cell carcinoma. The groups were homogenous regarding demographic and disease characteristics. A comparison of patients treated with Nivolumab plus cannabis to Nivolumab alone was made.

Results: In a multi-variant model, cannabis was the only significant factor which reduced RR to immunotherapy (37.5% RR in Nivolumab alone compared to 15.9% in the Nivolumab plus cannabis group ($p = 0.016$, OR = 3.13, CI95% 1.24-8.13). Cannabis use was not a significant factor for PFS or OS. Factors affecting PFS were smoking (adj HR = 2.41), brain metastases (adj HR = 2.04), and response to therapy (adj HR = 4.89). Factors that reduced OS were smoking (adj HR = 2.41), brain metastases (adj HR = 2.83), hypertension (adj HR = 2.28), low performance status and disease progression (adj HR = 2.83).

Conclusions: In this retrospective analysis, the use of cannabis in combination with immunotherapy decreased RR to treatment, without affecting PFS or OS. This information can be critical for a large group of patients, and requires caution when starting immunotherapy. Considering the limitations of the study, further prospective clinical study is needed to investigate possible interaction.

Background: Evidence is increasing that severe skeletal muscle (SM) loss (sarcopenia) is associated with reduced overall survival (OS) in mCRC pts. We recently found, using data of the randomized phase 3 CAIRO3 study (*Lancet, 2015*), that SM loss was related to shorter time to progression during first line maintenance treatment (Tx) with capecitabine+bevacizumab (CAP-B) or observation. Subsequently, SM loss during more intensive reinduction Tx by adding oxaliplatin (CAPOX-B) was associated to shorter overall survival (*ASCO, 2017*). As a potential risk factor for reduced survival we explored whether sarcopenia was associated with dose reductions at start of CAPOX-B reinduction Tx and dose limiting toxicities (DLT) during CAPOX-B reinduction Tx.

Methods: Here, CAIRO3 pts were included who received CAPOX-B reinduction Tx. DLT were defined as any dose delay, reduction, or discontinuation of systemic treatment because of reported CTCAE (v3.0) toxicities at start or during Tx. Poisson regression models adjusted for relevant confounders were used to study the association between sarcopenia and DLT.

Results: A total of 254 pts received CAPOX-B reinduction Tx. 39% of pts were sarcopenic and compared to normal SM pts we found no statistically significant differences in age and sex (sarcopenic vs normal SM: mean age 63.6±9.1 vs 61.9±8.5 yrs, p=.20 and 39% vs 31% females p=.31). BMI was significantly lower in sarcopenic pts, but pts were on average still overweight (25.9±3.8 vs 27.2±3.8 p=.01). Overall, 67% experienced ≥1 DLT. At start of CAPOX-B, 25% had already received a dose reduction and the risk of dose reduction at start was significantly higher for sarcopenic compared to

normal SM pts (RR 1.8 95%CI 1.08-2.90). Despite more frequent dose reductions at start, sarcopenic pts did not have a significantly lower risk of DLT during CAPOX-B Tx (RR sarcopenic vs normal SM pts 0.86 95% CI 0.46-1.45).

Conclusions: Sarcopenia was significantly associated with dose reductions at start of CAPOX-B reinduction Tx, and not with DLT during CAPOX-B reinduction Tx. Possible explanations for dose reductions at start might be more frequent toxicities during previous Tx including neuropathy.

1547PD Phase 3 safety evaluation of an intravenous formulation of NEPA, a novel fixed antiemetic combination of fosnetupitant and palonosetron

L. Schwartzberg[1], Z. Andric[2], D. Kowalski[3], D. Voisin[4], G. Rizzi[5], M. Karthaus[6]

[1]Hematology & Oncology, West Cancer Center, Germantown, TN, USA, [2]Medical Oncology Department, Clinical Hospital Center Bezanijska Kosa, Belgrade, Serbia, [3]Department of Lung & Thoracic Cancers, The Maria Sklodowska-Curie Memorial Institute and Oncology Centre, Warsaw, Poland, [4]Clinical Development, Helsinn Healthcare Switzerland, Pazzallo - Lugano, Switzerland, [5]Statistics & Data Management, Helsinn Healthcare Switzerland, Pazzallo - Lugano, Switzerland, [6]Department of Hematology, Oncology, and Palliative Medicine, Klinikum Neuperlach-Staedtisches Klinikum Muenchen, Munich, Germany

Background: NEPA, an oral fixed combination of the highly selective NK_1RA netupitant (300 mg) and clinically/pharmacologically distinct 5-HT_3RA palonosetron (PALO, 0.50 mg) is the first fixed-dose antiemetic combination to have been approved. A single oral NEPA capsule plus dexamethasone (DEX) given prior to AC and non-AC highly emetogenic chemotherapy (HEC) showed superior prevention of chemotherapy-induced nausea and vomiting (CINV) over PALO plus DEX for 5 days post-chemotherapy; the safety of NEPA was also well-established in the Phase 2/3 clinical program in 1442 NEPA-treated patients. An intravenous formulation of the NEPA combination (fosnetupitant 260 mg/PALO 0.25 mg) is under development.

Methods: This randomized, multinational, double-blind, stratified (by gender and country) Phase 3 study in chemotherapy-naïve patients with solid tumors was designed to assess the safety of a single 30-minute infusion of IV NEPA prior to initial and repeated cycles of HEC. Patients received either IV NEPA or oral NEPA, both with oral DEX on days 1-4. Safety was assessed primarily by treatment-emergent adverse events (TEAEs) and also by laboratory tests, vital signs and ECGs.

Results: 404 patients were included in the safety population (203 IV NEPA, 201 oral NEPA) for a total of 1312 exposures. Overall, 53% of patients were male, 99% were white and the mean age was 60 years. Cisplatin was the most frequent HEC (96% of patients) and lung cancer was most common (55% of patients). The TEAE profiles for cycle 1 (**Table**) and in all cycles were similar for the two treatment groups. There was no increased incidence of TEAEs in subsequent cycles. No clinically relevant changes in QTc and no cardiac safety concerns were seen. No infusion site reactions related to IV NEPA occurred.

Table: 1547PD

Cycle 1 n (%) patients with	IV NEPA (N = 203)	Oral NEPA (N = 201)
At least one treatment emergent adverse event (TEAE)	120 (59.1%)	135 (67.2%)
Severe TEAEs	50 (24.6%)	51 (25.4%)
Serious TEAE	29 (14.3%)	21 (10.4%)
Any treatment-related TEAE (TRAE)	18 (8.9%)	19 (9.5%)
Most common (≥2%) TRAE Constipation	10 (4.9%)	11 (5.5%)
Serious TRAE	0	0
Any TRAE leading to discontinuation	1 (0.5%)	0
Any TRAE resulting in death	0	0

Conclusions: Intravenous NEPA was shown to be safe and well-tolerated with a similar safety profile to oral NEPA in patients with various solid tumors receiving HEC.

Clinical trial identification: NCT02517021

1548PD Quality of life (QOL) evaluation of patients in a phase 3 study comparing NEPA with an aprepitant regimen for prevention of chemotherapy-induced nausea and vomiting (CINV)

L. Zhang[1], S. Lu[2], J. Feng[3], A. Dechaphunkul[4], S. Chessari[5], C. Lanzarotti[6], K. Jordan[7], M. Aapro[8]

[1]State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University Cancer Center, Guangzhou, China, [2]Shanghai Lung Cancer Center, Shanghai Chest Hospital, Shanghai, China, [3]Jiangsu Cancer Hospital, Medical Oncology, Nanjing, China, [4]Internal Medicine, Division of Medical Oncology, Prince of Songkla University, Songkhla, Thailand, [5]Corporate Clinical Development, Helsinn Healthcare, Lugano, Switzerland, [6]Statistics & Data Management, Helsinn Healthcare, Lugano, Switzerland, [7]Department of Medicine V, University of Heidelberg, Heidelberg, Germany, [8]Breast Center, Cancer Center, Clinque de Genolier, Genolier, Switzerland

Background: Suboptimal CINV prevention can negatively impact patients' (pts) QOL by interfering with daily functioning. Antiemetic guidelines recommend co-administration of a NK_1 receptor antagonist (RA)/5-HT_3RA/corticosteroid to optimize CINV control in pts at high risk for CINV. NEPA, a fixed combination of the NK_1RA netupitant and 5-HT_3RA palonosetron (PALO) has shown superior CINV prevention and improvement in QOL over PALO. A single dose of NEPA recently showed non-inferiority to a 3-day aprepitant/granisetron (APR/GRAN) regimen in preventing CINV in the first head-to-head comparison of NK_1RA-containing regimens. The impact of CINV on pts' QOL in this study was explored.

Methods: This randomized, double-blind, Phase 3 study in chemotherapy-naïve pts receiving cisplatin-based chemotherapy (CT) assessed the non-inferiority of NEPA versus APR/GRAN for complete response (CR: no emesis/no rescue medication [RM])

Table: 1548PD

% Patients	NEPA (N = 412)	APR/GRAN (N = 416)	Risk Difference (95% CI)
NIDL (overall domain) Acute (0-24h) Delayed (25-120 h)	86.2% 76.0%	83.2% 70.7%	3.3 (-1.6%, 8.1%) 5.8% (-0.1%, 11.8%)
NIDL (nausea domain) Acute Delayed	81.8% 71.1%	80.0% 65.1%	2.0% (-3.3%, 7.3%) 6.5% (0.2%, 12.8%)*
NIDL (vomiting domain) Acute Delayed	87.9% 81.3%	86.8% 77.4%	1.4% (-3.1%, 5.9%) 4.5% (-1.0%, 9.9%)
No Emesis Acute Delayed	85.2% 79.4%	87.5% 76.2%	−2.2% (-6.9%, 2.4%) 3.3% (-2.4%, 8.9%)
NSN Acute Delayed	89.8% 78.2%	87.3% 72.8%	2.6% (-1.7%, 6.9%) 5.4% (-0.4%, 11.2%)
No RM Acute Delayed	98.8% 97.6%	98.3% 94.7%	0.5% (-1.2%, 2.1%) 2.9% (0.2%, 5.5%)*

*statistically significant difference NEPA: fixed combination netupitant/palonosetron, APR: aprepitant, GRAN: granisetron, NIDL: no impact on daily life, NSN: no significant nausea, RM: rescue medication

rates during the overall (0-120 h) phase post-CT. All pts received dexamethasone on days 1-4. Secondary endpoints included proportion of pts with no emesis, no significant nausea (NSN: <25mm on 100mm VAS), no RM use, and no impact on daily life (NIDL) as assessed by the Functional Living Index—Emesis (FLIE), comprised of vomiting- and nausea-specific questions/domains. The Cochran-Mantel-Haenszel test was used for between group comparisons; non-inferiority testing was not done for secondary endpoints.

Results: Treatment groups were similar for the 828 pts analyzed: male (71%); mean age 55 years; lung cancer (58%). NIDL rates were higher for NEPA, particularly during the delayed phase; similar results were seen for no emesis, NSN, and no RM.

Conclusions: In this first study comparing NK_1RA regimens, NEPA administered only on day 1 was numerically similar to a 3-day oral APR/GRAN regimen in maintaining functional status in patients receiving highly emetogenic CT.

1549PD Multicenter randomized controlled trial to evaluate the efficacy of frozen gloves for the prevention of chemotherapy-induced peripheral neuropathy

A.J.M. Beijers[1], F. Mols[2], J. Ophorst[1], J. Pijs[3], J. de Vos-Geelen[4], E. Jacobs[5], L.V. van de Poll-Franse[6], G. Vreugdenhil[1]

[1]Internal Medicine, Maxima Medical Center -Veldhoven, Veldhoven, Netherlands, [2]Department of Medical and Clinical Psychology, Tilburg University, Tilburg, Netherlands, [3]Faculty of Health, Medicine and Life Sciencese, Maastricht University, Maastricht, Netherlands, [4]Department of Medical Oncology, Maastricht University Medical Center, Maastricht, Netherlands, [5]Department of Internal Medicine, Elkerliek, Helmond, Netherlands, [6]Netherlands Cancer Registry, Netherlands Comprehensive Cancer Organisation (IKNL), Eindhoven, Netherlands

Background: Chemotherapy-induced peripheral neuropathy (CIPN) is a common side effect of oxaliplatin and taxanes with a negative impact on quality of life (QOL). This study investigates the efficacy of wearing frozen gloves (FGs) during chemotherapy for the prevention of CIPN due to oxaliplatin or taxanes and the influence on patients' QOL.

Methods: Patients with newly diagnosed cancer starting treatment with oxaliplatin, docetaxel or paclitaxel were eligible for this multicenter randomized controlled trial. Patients were randomized between wearing FGs on both hands during treatment or not wearing FGs. Self-reported CIPN and QOL were measured with the validated EORTC-QLQ CIPN20 and EORCT-QLQ C30 at four time points; baseline (T0), after three cycles (T1), end of chemotherapy (T2) and after 6 months (T3). Subscales were analyzed with analysis of covariance and neuropathy symptoms with logistic regression analysis.

Results: Between February 2013 and May 2016, 180 patients were included, 90 patients in both arms. Thirty-one patients (34%) discontinued the FGs before end of chemotherapy mainly due to discomfort. Intention to treat analyses showed that patients in the FG-group experienced less tingling in fingers/hands at T1 (11% vs. 24%; p=.009) and T2 (28% vs. 43%, $p = 0.038$) compared to controls. At T3 these differences disappeared (28% vs 24%, p=.0884). FG patients also experienced a trend towards less interference in handling small objects (2% vs 10%, $p = 0.06$) and opening a bottle (9% vs. 6%, $p = 0.06$) at T1. FG patients also reported significantly lower motoric problems (mean 8.3 (SD 9.7) vs. 12.8 (SD 13.6), $p = 0.013$) compared to controls at T1. At T1, those treated with FGs reported statistically significant better QOL on EORTC QLQ-C30 subscales physical (mean 82 vs.74), role (mean 66 vs. 51), cognitive (mean 85 vs. 78), and social functioning (mean 79 vs. 67), and symptom scales fatigue (mean 40 vs. 49) and appetite loss (mean 21 vs. 34), all $p < 0.05$.

Conclusions: No long-term differences in neuropathy were found, but FGs reduced neuropathy symptoms with better QOL during chemotherapy. Future studies should focus on the biological process of cooling to prevent CIPN.

1550P Primary prevention of nausea and vomiting induced by moderately emetogenic chemotherapies: findings from the French CONVINCE-ME survey

F. Scotté[1], R. Chevrier[2], H. Bertucat[3]

[1]Medical Oncology and Supportive Care Unit, Foch Hospital, Suresnes, France, [2]Pharmacy Department, Centre Jean Perrin, Clermont-Ferrand, France, [3]Pharmacy Department, Centre Jacques Lacarin, Vichy, France

Background: Despite the considerable progress achieved in the last 30 years vomiting and especially nausea continue to be two of the most distressing side-effects of cancer chemotherapy. The objective of this survey was to assess the compliance of anti-emesis prescriptions with the ESMO 2016 and French AFSOS 2013 guidelines (French speaking association for supportive care in cancer), in primary prophylaxis of moderately emetogenic chemotherapies (MEC) as defined by ESMO guidelines.

Methods: Between February and November 2016, 35 pharmacists and 41 nurses from 35 French centers specialized in cancer treatment completed a 13-item questionnaire drawn up by a scientific committee about their anti-emesis practices. Concurrently, the nurses at each center recorded prospectively treatments prescribed to 10 to 20 patients starting the first cycle of MEC.

Results: Data were gathered on 448 patients with gastrointestinal cancers and 166 with lung cancers; 29% and 47% of all patients were treated with carboplatin or oxaliplatin respectively. The most frequent CINV preventive treatments for the acute phase were the combination of 5HT3 antagonist + corticoid (52% of patients) and the combination of 5HT3 antagonist + corticoid + anti-NK1 (33%). For the delayed phase, 5HT3 antagonist only (23%), anti-NK1 only (17%) and the combination of 5HT3 antagonist + anti-NK1 (17%) were the most prescribed treatment. Overall, 49% and 33% of patients in the acute phase and 10% and 17% in the delayed phase were treated in compliance the ESMO and AFSOS guidelines respectively.

Conclusions: The CONVINCE-ME survey shows inadequate use of existing recommendations at specialized centers and highlights the need for improved understanding and guideline application.

1551P Risk factors of chemotherapy-induced nausea and vomiting during cisplatin regimen in antiemetic triplet regimen including palonosetron or granisetron: TRIPLE study (phase III)

K. Suzuki[1], D. Tsuji[2], K. Ito[2], Y. Kawasaki[3], T. Yamanaka[4], H. Hashimoto[5], K. Goto[6], R. Matsui[7], N. Seki[8], T. Hama[1], N. Yamamoto[9]

[1]Department of Pharmacy, Cancer Institute Hospital of JFCR, Tokyo, Japan, [2]Department of Clinical Pharmacology & Genetics, School of Pharmaceutical Sciences University of Shizuoka, Shizuoka, Japan, [3]Department of Pharmacoepidemiology, Graduate School of Medicine and Public Health, Kyoto University, Kyoto, Japan, [4]Department of Biostatistics, Yokohama City University School of Medicine, Yokohama, Japan, [5]Department of Pharmacy, National Cancer Center Hospital, Tokyo, Japan, [6]Department of Thoracic Oncology, National Cancer Center Hospital East, Kashiwa, Japan, [7]Department of Pharmacy, National Cancer Center Hospital East, Kashiwa, Japan, [8]Division of Medical Oncology, Teikyo University School of Medicine, Tokyo, Japan, [9]Third Department of Internal Medhicine, Wakayama Medical University, Wakayama, Japan

Background: Current antiemetic guidelines recommend antiemetic triplet regimen for cisplatin-based chemotherapy. Although several prior studies have identified risk factors for chemotherapy-induced nausea and vomiting (CINV), only a few have evaluated antiemetic triplet regimen, particularly with palonosetron. Therefore, the purpose of the present study was to confirm and compare the risk factors for CINV when using palonosetron or granisetron.

Methods: A total of 825 patients in the phase III clinical trial on cisplatin regimen were evaluated. The primary endpoint was complete response (CR) rate in the overall period (0–120 h). All patients were evaluated for CINV risk factors. Using a post-hoc analysis, the impact of antiemetic treatment on CR was assessed, and odds ratio (OR) with 95% confidence intervals (CIs) for antiemetic treatment failure were evaluated by using multivariate logistic regression models. CINV risk factors were also evaluated separately in each treatment group.

Results: The multivariate analysis revealed that female (OR: 2.572; 95% CI: 1.855–3.566), less than 60 years old (OR: 1.717; 95% CI: 1.252–2.355), the cisplatin dosage (OR: 1.017; 95% CI: 1.001–1.033), and granisetron use (OR: 1.357; 95% CI: 1.013–1.817) were all significantly associated with antiemetic treatment failure in the entire

study group. Similarly, female and age were also identified as the risk factors associated with treatment failure in both groups ($P < 0.0001$). Kaplan–Meier plots of time to event classified each treatment group and revealed no significant difference between the groups for patients with zero risk factors ($P = 0.353$). For patients with one or more risk factors, those treated with palonosetron experienced significantly higher CR rates than those treated with granisetron ($P = 0.049$).

Conclusions: This analysis revealed risk factors of CINV when using triplet antiemetic regimen Including palonosetron or granisetron for cisplatin. Palonosetron might be preferred for patients with one or more risk factors.

1552P Evaluation of Antiemetic Practices for Prevention of Chemotherapy-induced Nausea and Vomiting (CINV): Results of a European Oncology Nurse Survey

P. Dielenseger[1], S. Borjeson[2], C. Vidall[3], A. Young[4], P. Jahn[5]

[1]Early Drug Development, Gustave Roussy Institute of Oncology, Villejuif, France, [2]Department of Medical and Health Sciences, Division of Nursing Science, Linköping University, Linköping, Sweden, [3]Nursing and Governance, Alcura UK Ltd, Northampton, UK, [4]Cancer Research Centre, University Hospitals Coventry and Warwickshire, Coventry, UK, [5]Nursing Research Unit, University Hospital Halle (Saale), Halle, Germany

Background: Preventing CINV in most patients is possible when guideline-recommended prophylactic antiemetics are utilized. Because oncology nurses play a critical role in risk assessment and management of CINV, a survey of European nurses was conducted to evaluate antiemetic practices, determine awareness of and adherence to current guideline recommendations, and explore barriers to adherence.

Methods: Between March 2016 and March 2017, 212 oncology nurses in 16 European countries completed a 20-question online survey.

Results: Respondents had 15 years (median) experience as an oncology nurse and most were able to suggest or prescribe antiemetics. Most (n = 169, 80%) worked in the public not-for-profit hospital setting, seeing both in- and outpatients (n = 107, 50%). While nurses were most familiar with ASCO (n = 97, 46%) and MASCC/ESMO (n = 84, 40%) guidelines, individual institution guidelines were used most (n = 99, 47%). Key discrepancies between antiemetic use and guideline recommendations were: i) under-utilization of NK_1RAs, 5-HT_3RAs and a steroid on Day 1 in the HEC setting and ii) high use of 5-HT_3RAs during days 2-5 when guidelines recommend a steroid (Table 1). Metoclopramide use (not guideline recommended) was also high, with ~30% and ~50% of nurses reporting usage for acute and delayed phases, respectively, for both HEC and MEC settings. The most common barrier to the use of guideline-recommended agents was reported as physician preference (n = 84, 40%). Product cost and formulary inclusion also played a role. The 2 most common challenges in managing CINV were "controlling nausea and vomiting in the delayed phase" (n = 135, 64%) and "reducing the impact of CINV on patients' quality-of-life" (n = 130, 61%).

Conclusions: This survey highlights many opportunities to improve utilization of guideline-recommended antiemetics, thereby optimizing prevention of CINV and quality-of-life for patients receiving emetogenic chemotherapy.

1553P A pooled analysis evaluating the combination antiemetic therapy on chemotherapy-induced nausea and vomiting in patients with colorectal cancer receiving oxaliplatin-based chemotherapy of moderate emetic risk

M. Shimokawa[1], T. Kogawa[2], J. Nishimura[3], T. Satoh[4], K. Nakata[5], T. Hayashi[6], R. Matsui[7], K. Aiba[8], K. Tamura[9]

[1]Clinical Research Institute, National Kyushu Cancer Center, Fukuoka, Japan, [2]Department of Developmental Therapeutics, National Cancer Center Hospital East, Kashiwa, Japan, [3]Department of Gastroenterological Surgery, Osaka University Graduate School of Medicine, Suita, Japan, [4]Department of Frontier Science for Cancer and Chemotherapy, Graduate School of Medicine, Osaka University, Suita, Japan, [5]Department of Surgery, Sakai City Medical Center, Sakai, Japan, [6]Department of Pharmacy, National Kyushu Medical Center, Fukuoka, Japan, [7]Department of Pharmacy, National Cancer Center Hospital East, Kashiwa, Japan, [8]Division of Clinical Oncology/Hematology, The Jikei University School of Medicine, Tokyo, Japan, [9]General Medical Research Center, Fukuoka University, Fukuoka, Japan

Background: The incidence and risk factor of delayed chemotherapy-induced nausea and vomiting (CINV) for colorectal cancer (CRC) patients receiving oxaliplatin-based chemotherapy has not been clearly controlled. To evaluate the efficacy and risk factor of combination antiemetic treatment for delayed CINV in CRC patients receiving oxaliplatin-based chemotherapy.

Methods: Aggregated data were pooled from the two prospective observational studies and one clinical trial; A nationwide survey of CINV study group, the other prospective observational study in Japan and SENRI Trial in Japan. We assessed whether delayed CINV were controlled with 3 antiemetic treatment. We also evaluated risk factors by logistic regression analysis.

Results: A total of 661 patients were evaluable in this study. The median age was 64 (range:19-85) with 391males and 270 females. Three antiemetics were used in 220 (33.3%) patients. Delayed CINV were experienced more commonly in women than in men. Delayed nausea was well controlled with 3 antiemetics than with 2 antiemetics for women (38.3% vs. 52.8%; P=0.0295). Delayed vomiting was well controlled with 3 antiemetics than with 2 antiemetics for overall (4.1% vs. 15.9%; P<0.0001) and for women (5.3% vs. 24.4%; P<0.0001). We identified several risk factors; women (odds ratio [OR], 1.853; 95% confidence interval [CI], 1.326 to 2.591; P=0.0003), motion sickness (OR, 1.947; 95%CI, 1.230 to 3.082; P=0.0044) and age (OR, 0.976; 95%CI, 0.961 to 0.991; P=0.0020) for delayed nausea, and women (OR, 2.447; 95%CI, 1.475 to 4.059; P=0.0005), motion sickness (OR, 1.892; 95%CI, 1.024 to 3.494; P=0.0417), 2 antiemetics (OR, 4.890; 95%CI, 2.362 to 10.122; P<0.0001) and FOLFOX regimen (OR, 1.680; 95%CI, 1.028 to 2.747; P=0.0384) for delayed vomiting.

Conclusions: Three antiemetics combination are encouraged for CRC female patients treated with oxaliplatin-based chemotherapy to alleviate delayed CINV. Identification of individual risk factors will assist in the development of personalized treatments for delayed CINV.

1554P Efficacy of neurokinin-1 receptor antagonists in the prevention of Chemotherapy-Induced Nausea and Vomiting in patients receiving carboplatin-based chemotherapy: a systematic review and meta-analysis

M. Di Maio[1], C. Baratelli[1], P. Bironzo[2], F. Vignani[1], E. Bria[3], E. Sperti[4], M. Marcato[1], F. Roila[5]

[1]Division of Medical Oncology, "Ordine Mauriziano" Hospital, Department of Oncology, University of Turin, Turin, Italy, [2]Division of Medical Oncology, Azienda Ospedaliera Universitaria San Luigi Gonzaga, Department of Oncology, University of Turin, Orbassano, Italy, [3]Medical Oncology, University of Verona, Verona, Italy, [4]Division of Medical Oncology, "Ordine Mauriziano" Hospital, Turin, Italy, [5]Medical Oncology, Azienda Ospedaliera Sta Maria, Terni, Italy

Background: According to current ESMO – MASCC guidelines, a combination of a neurokinin-1 receptor antagonist (NK1RA), dexamethasone and a 5-HT3 receptor antagonist (5-HT3RA) is recommended to prevent carboplatin-induced emesis, with moderate level of confidence and not unanimous consensus. Our aim was to perform a meta-analysis of all randomized trials (RCTs) evaluating the role of a NK1RA in the prevention of emesis for patients receiving carboplatin.

Methods: A systematic review was performed in January 2017, including RCTs comparing NK1RA + dexamethasone + 5-HT3RA vs. dexamethasone + 5-HT3RA in patients receiving first cycle of carboplatin-based chemotherapy. Primary outcome was complete response (CR), defined as no emesis and no use of rescue medication. CR was measured in day 1 (acute phase), days 2-5 (delayed phase) and days 1-5 (overall period). A random effects model was applied.

Results: 9 trials were potentially eligible (7 aprepitant, 1 fosaprepitant, 1 rolapitant): 6 were RCTs including only patients receiving carboplatin, and 3 were subgroup analyses of patients receiving carboplatin within RCTs including various moderately emetogenic regimens. Data of CR were available in 8 trials (1598 patients). Addition of NK1RA improves CR in all phases: acute phase, 94.5% vs. 90.1% (Odds Ratio 1.75, 95%CI 1.19-2.59, $p = 0.005$); delayed phase, 76.4% vs. 61.7% (Odds Ratio 2.04, 95%CI 1.64-2.55, $p < 0.0001$); overall period, 75.3% vs. 60.4% (Odds Ratio 2.04, 95%CI 1.64-2.54, $p < 0.0001$). There was no significant heterogeneity among trials. Sensitivity analyses, performed excluding subgroup analyses and excluding open-label trials, produced similar results.

Conclusions: In patients receiving carboplatin-based chemotherapy, triple antiemetic therapy with NK1RA, dexamethasone and 5-HT3RA is associated with a statistically significant and clinically relevant improvement in CR, compared to 5-HT3RA plus dexamethasone. Individual patient data meta-analysis could help to identify patients who are likely to obtain the highest improvement from the addition of NK1RA.

1555P Pharmacokinetic (PK) study of a single oral dose of NEPA in Chinese healthy volunteers (HVs)

R. Chen[1], S. Chessari[2], C. Lanzarotti[2], A. Bernareggi[3], P. Hu[1]

[1]Clinical Pharmacology Research Center, Peking Union Medical College Hospital (PUMCH), Beijing, China, [2]Corporate Clinical Development, Helsinn Healthcare SA, Lugano, Switzerland, [3]R&D Innovation and Strategy, Helsinn Healthcare SA, Lugano, Switzerland

Background: NEPA, a combined neurokinin-1 receptor antagonist (RA) netupitant (NETU; 300 mg) and 5-HT_3–RA palonosetron (PALO; 0.50 mg), is the first approved oral combination antiemetic. NEPA has shown superior efficacy over PALO in preventing chemotherapy-induced nausea and vomiting (CINV), in cisplatin and AC-chemotherapy settings, leading to its approval in the US and Europe (with 85% of patients Caucasian in the clinical trials). A recent phase 3 registration trial in Asian patients demonstrated non-inferiority of a single oral dose of NEPA in preventing CINV compared with a 3-day oral aprepitant/granisetron regimen. The present study was undertaken to assess the PK profile of NETU and PALO in Chinese HVs.

Methods: Eligible HVs received a single oral dose of NEPA administered as a hard gelatin capsule on day 1, after 10-h fasting. Blood samples for PK analysis were collected pre-dose and at 1, 2, 3, 4, 4.5, 5, 5.5, 6, 8, 12, 24, 48, 72, 96, 120, 144, 168, 192, and 240 h post-dose. The plasma concentration of NETU and PALO was determined by liquid chromatography-tandem mass spectrometry (LC-MS/MS). PK parameters were estimated via non-compartmental analysis using the WinNonlin 6.3 software (Certara Inc., Princeton, NJ, USA).

Results: A total of 18 subjects were enrolled (16 male; median body weight 62.7 kg [52.6–75.2 kg]; median age 27 y [21–37 y]). After a single oral dose of NEPA, mean (±SD) values of peak plasma concentration (C_{max}) for NETU were 698±217 ng/mL at a median of 4.5 h (T_{max}; 3–6 h), with mean (±SD) overall exposure up to the last measurable concentration (AUC_{0-t}) of 20.2±3.93 h*mg/L. PALO plasma concentrations reached mean (±SD) C_{max} of 1800±252 ng/mL at 3 h (2–6 h) with mean (±SD) AUC_{0-t} of 77.6±13.3 h*µg/L. NEPA was well tolerated in all HVs.

Conclusions: In Chinese HVs the PK profile of NETU was comparable to that previously observed in Caucasians. For PALO, C_{max} and AUC_{0-t} were higher in these Chinese HVs compared to Caucasians, which may be explained by CYP2D6 (involved in the metabolism of PALO) polymorphism. However, the similar efficacy and safety for PALO and NEPA in pivotal studies in both populations suggests that the higher exposure to PALO in Chinese HVs is unlikely to be clinically relevant.

1556P Iron deficiency anaemia in oncology: an epidemiological prospective study

J. Barriere[1], J-M. Ferrero[2], B. Hoch[3], R. Largillier[3], C. Hebert[2], D. Borchiellini[2], P. Follana[2], V. Mari[2], L. Evesque[2], E. Saada-Bouzid[2], R. Schiappa[4], V. Raimondi[5], E. Chamorey[4], J. Viotti[4]

[1]Oncology, Polyclinic Saint Jean, Cagnes-sur-Mer, France, [2]Medical Oncology, Centre Antoine Lacassagne, Nice, France, [3]Medical Oncology, Centre Azuréen de Cancérologie, Mougins, France, [4]Biostatistics and Epidemiology Department, Centre Antoine Lacassagne, Nice, France, [5]Laboratory, Laboratoire Cerballiance, Nice, France

Background: Anaemia in oncology is frequent, decreasing quality of life and prognosis. Its causes are multiples and still largely unknown, among them, iron deficiency (ID) is seldom studied. Associated with inflammatory syndrome, ID leads to the sequestration of iron in macrophage, making it unavailable for erythropoiesis. Prevalence of ID needs to be specified in oncology as it could be easily corrected by intravenous iron, avoiding use of EPO or blood transfusion and their side effects.

Methods: In this prospective, multicentre cohort study (NCT01968304), anaemia and ID were evaluated in patients with locally advanced or metastatic solid tumour and lymphoma newly diagnosed before starting a chemotherapy regimen. Blood samples were collected at the inclusion (week 0 - W0), 6 weeks (W6) and 12 weeks (W12) after. Prevalence was evaluated for both functional ID (FID) and absolute ID (AID) in the general population and according to the tumours location. ID was correlated with tumour response (RECIST criteria).

Results: 129 patients were enrolled between 2013 and 2015. 119 had solid tumours (breast 36, colorectal 27, lung 28, prostate 12, others 16) and 10 had lymphomas (not shown).

Table: 1556P

Location N (%)	Anaemia N (%)			Functional iron deficiency N (%)			Absolute iron deficiency N (%)			Functional ID associated with Anaemia N (%)		
	W0	W6	W12	W0	W6	W12	W0	W6	W12	W0	W6	W12
Breast 36 (30)	13 (36.1)	20 (64.5)	17 (63.0)	15 (41.7)	20 (64.5)	2 (5.6)	1 (3.2)	2 (7.4)	6 (16.7)	11 (35.5)	11 (35.5)	9 (33.3)
Colorectal 27 (23)	20 (74.1)	16 (72.7)	11 (68.8)	14 (51.9)	8 (36.4)	5 (18.5)	3 (13.6)	2 (12.5)	10 (37.0)	10 (37.0)	6 (27.3)	5 (31.2)
Lung 28 (24)	16 (57.1)	22 (88.0)	14 (93.3)	13 (48.1)	8 (32.0)	1 (3.7)	0 (0.0)	0 (0.0)	8 (29.6)	8 (29.6)	8 (32.0)	4 (26.7)
Prostate 12 (10)	9 (75.0)	11 (91.7)	9 (81.8)	6 (50.0)	3 (25.0)	0 (0.0)	0 (0.0)	0 (0.0)	4 (33.3)	4 (33.3)	2 (16.7)	2 (18.2)
All solid tumours 119 (100)	63 (52.9)	75 (72.8)	56 (71.8)	62 (48.0)	49 (43.0)	9 (7.0)	5 (4.0)	4 (5.0)	32 (26.9)	32 (26.9)	32 (31.1)	23 (29.5)

At W0, 62 patients (48%) had FID, 32 (26.9%) had FID associated with anaemia and 9 (7%) had AID. FID prevalence remains constant from W0 to W12, so as FID anaemia and AID. Also, ID incidence remains constant between W6, 17 (15.2%) and W12 10 (11.6%). Localization was not correlated with FID or FID anaemia but prevalence of AID is higher for colorectal tumours. ID (evaluated at W12) was significantly correlated ($p = 0.04$) with tumour response at W12, 51.2% of responders among patients with no ID versus only 33.3% among patients with ID.

Conclusions: Our data confirm the high prevalence of ID in cancer patients. Localization is not correlated with the prevalence of ID whereas absolute ID is of higher rate in colorectal cancer. Also, ID at W12 without supplementation seems to be predictive of chemotherapy response.

Clinical trial identification: NCT01968304. Release date: October 1, 2013

1557P Nutritional risk as a predictor of short-term outcomes in a prospective cohort of elderly patients with cancer

L.T. Sales[1], J.T. Oliveira Lima[1], A. Bergmann[2], M.J.G. Mello[1], M. Rebello[1], Z. Cavalcanti[1], D. Sales[1], N. Cruz[1], L.C.S. Thuler[2]

[1]Oncogeriatry, Hospital IMIP, Recife, Brazil, [2]INCA -National Cancer Institute, Rio de Janeiro, Brazil

Background: To determine if the nutritional risk identified by the Mini NutritionalAssessment Short-Form (MNA®-SF) is an independent predictor of short-term outcomes (infection, hospitalization and premature death).

Methods: prospective cohort study of elderly patients (≥60 years) with a recent diagnosis of cancer admitted to an outpatient oncology unit was performed. Sociodemographic and clinical variables and MNA®-SFwere collected at baseline. The outcomes were healthcare-associated infection, hospitalization and death. Data were analysed using the multivariateCoxproportional hazards models. Overall survival was estimated using the Kaplan–Meier method and survival curves were compared using theLog rank test.

Results: he cohort consisted of 608 elderly patients followed for 180 days. The mean age was 71.9 years (range: 60–96) and 50.2% participants were at risk of malnutrition as measured by the MNA®-SF. During follow-up, 35.5% of participants were hospitalized, 29.4% had healthcare-associated infections and 16.4% died. After adjustment for age, site and stage of cancer, the multivariate regression Cox model showed that being undernourished was an independentpredictor of infection (adjusted Hazard Ratio [aHR]=1.88, 95%CI 1.32–2.67, $p < 0.001$) hospitalization (HR = 1.5, 95% CI:1.10–2.06, $p = 0.012$) and death (HR = 3.12, 95% CI: 1.74–5.78, $p < 0.001$).

Conclusions: Nutritional risk at admission was identified as a significant predictor of risk forpremature death, infection, and need for hospitalization in elderly cancer patients. The use of MNA®-SF should be incorporated into regular geriatric assessment of olderpatients with cancer.

1558P A patient-centered approach to the re-development of supportive care services for oncology adolescent and young adult (AYA) patients (pt(s)) across McGill University hospitals (Rossy Cancer Network-RCN)

P. Kavan[1], R. Fox[2], G. Raskovic[2], I. Barrera[2], W. Sateren[2], G. Batist[2], M. Palumbo[2], T. Muanza[2], N. Johnson[1], A. Mamo[2], T. Alcindor[3], R. Turcotte[3], A. Meguerditchian[3]

[1]Oncology Department, Jewish General Hospital McGill University, Montreal, QC, Canada, [2]Oncology Department, Jewish General Hospital McGill University, Montreal, Canada, [3]Oncology Department, MUHC, Montreal, Canada

Background: Most AYA pts (age 18-44) across the RCN are seen in adult oncology settings tailored to the medical and supportive care needs of the general cancer population. The purpose of this study is to conceptually re-develop the delivery of supportive care services to this pt population and create a care model that could be used as a framework for AYA clinics in Canada and abroad.

Methods: An analysis of the Ambulatory Oncology Patient Satisfaction Survey (AOPSS) 2012-2015 was conducted to better understand AYAs' satisfaction with the current level of care in RCN. A Chi-square test was employed to investigate differences between AYAs (ages 18-34 vs 35-44) and pts age 45 and over (n = 2,438).

A Delphi study, composed of two panels (pts vs. health care professionals), was conducted. Panelists were asked to select a set of strategies proposed by Zebrack et al. (2010) to address the service gaps identified through AOPSS. Selection was made by rank ordering strategies based on scores of importance (7 point Likert scale). Analysis of variance (ANOVA) was used to examine study results.

Results: The analysis of the AOPSS results revealed important differences related to i) the overall satisfaction and perception of quality of care; ii) access to services and iii) satisfaction with specific aspects of care such as emotional support, communication, access to information and physical comfort.

Both Delphi panels have identified access to 1) age-appropriate education programs; 2) standardized symptom management, pain control, palliative care; and 3) fertility preservation as important strategies to enhance delivery of supportive care services to AYAs (Table).

Conclusions: Evidence gathered through the AOPSS and Delphi studies will be used to inform health administrators of strategies needed to better respond to the unique supportive care needs of oncology AYAs.

1559P Multidimensional telemonitoring of cancer patients (pts) receiving chronomodulated (chrono) Irinotecan (I), 5-fluorouracil (F), leucovorin (L) and oxaliplatin (O; chronoIFLO4) combination at home

P. Innominato[1], S. Komarzynski[1], M. Bouchahda[2], A. Ulusakarya[3], M. Haydar[2], A. Karaboué[4], F. Levi[1]

[1]Medical School, University of Warwick, Coventry, UK, [2]Oncology, Paul Brousse Hospital, Villejuif, France, [3]U935, INSERM, Villejuif, France, [4]Research & Therapeutic Innovation, AK-SCIENCE, Vitry-sur-Seine, France

Background: FOLFIRINOX is an active yet toxic regimen against intestinal cancers. Improving its tolerability could widen its use in routine clinical practice. Circadian-based chrono administration of this triplet can be performed using a multichannel programmable-in-time pump. Here, we show the safety of chronoIFLO4 at home, through real-time multidimensional telemonitoring of circadian rest-activity rhythm (CircAct), sleep, patient-reported outcome measures (PROM) and body weight changes (BWC) using 1st generation e-Health platform inCASA.

Methods: Pts received Day (D)1 chrono I (180 mg/m2, over 6-h; peak rate at 5:00), and D 2-4 chrono O (25 mg/m2/d, over 11.5-h; peak rate at 16:00) and F-L (800 mg/m2/d and 400 mg/m2/d, respectively, over 11.5-h; peak rate at 04:00), q2 weeks at home. Pts completed the 19-item MD Anderson Symptom Inventory (MDASI) on an interactive electronic screen, weighed themselves on a dedicated scale, and continuously wore a watch-sized wrist-accelerometer for CircAct and sleep monitoring. Daily data were securely teletransmitted via Internet to a specific server accessible by the hospital team. The validated and clinically-relevant CircAct parameter I<O and sleep efficiency (SE) were calculated. The dynamic patterns over time of PROMs, BWC, I<O and SE inform the oncology team on tolerance in real time.

Table: 1558P Sample Strategies for Improving Patient Quality of Life and Quality of Care Throughout the Cancer Care Continuum (Zebrack et al, 2010)

	Patient Panel (n = 31)		Health Care Professionals Panel (n = 31)	
	Rank Order (round 1)	Importance Score (0-7 Likert scale)	Rank Order (round 1)	Importance Score (0-7 Likert scale)
Patient education programs that provide AYAs with knowledge regarding treatment options and the potential physical and QOL implications of cancer therapy	1	6.55	4	6.45
Inform reproductive-age patients of cancer- related fertility risks as early in the treatment planning as possible (as per ASCO guideline) and refer as needed to an appropriate fertility preservation specialist	2	6.42	2	6.58
Provide access to a systematic and standardized symptom management, pain control, and palliative care program	3	6.35	1	6.65

Results: Eleven patients (48-72 years; 45% males; 27% PS = 0) received 26 cycles (cy) of chronoIFLO4, and provided 5,891 data points/8,736 expected (67.4%). No grade 3-4 clinical toxicity occurred. The most severe MDASI scores remained low: interference with work (mean: 5.1/10) or general activity (4.9); fatigue (4.9); distress (4.2) and appetite loss (3.6). Mean BWC was -0.9% and mean SE remained above 82%. CircAct disruption (I<O $\leq$97.5%) was observed in 4 (15%) cys before chronoIFLO4 start and in 5 (19%) cys at D14.

Conclusions: ChronoIFLO4 represents a safe therapeutic option at home, and the pt-centered multidimentional telemonitoring solution allows the design of innovative management approaches, ultimately improving pt experience with chemotherapy, safety and outcomes.

1560P A pilot study to evaluate the feasibility, usability, and perceived satisfaction with eCO (eCediranib-Olaparib), a mobile application for side effect monitoring and reporting, in women with recurrent ovarian cancer

J. Liu[1], C. Whalen[1], S. Morrissey[1], E. Komatsu[1], J-M. Lee[2], N. Houston[2], R.M. Wenham[3], D.M. O'Malley[4], E. Strock[5], R. Phillips[6], K. Mari[7], S.P. Ivy[8], B. Killam[9]

[1]Medical Oncology, Dana Farber Cancer Institute, Boston, MA, USA, [2]Women's Malignancies Branch, National Institutes of Health, Bethesda, USA, [3]Gynecologic Oncology, Moffitt Cancer Center, Tampa, USA, [4]Gynecologic Oncology, The Ohio State University Medical Center, Columbus, OH, USA, [5]Medical Affairs, Voluntis, Boston, MA, USA, [6]Medical Affairs, Voluntis, Cambridge, MA, USA, [7]Biostatistician, RCTS, Lyon, France, [8]IDB, National Cancer Institute, Bethesda, USA, [9]User-Centered Design, Inc., Ashburn, USA

Background: Cediranib inhibits VEGFR1-3 with significant but treatable side effects of hypertension and diarrhea. High frequency of these events occurred in a trial of cediranib with olaparib (C+O). Effective control of these side effects is therefore important for C+O therapy. eCO, a cloud-based mobile medical device, was developed to provide secure capture, storage, and transmission of accurate BP and diarrhea data to aid in remote monitoring. Pts receive automated reminders and instructions for self-management based on severity. HCPs monitor pt status via a secure web portal and email alerts.

Methods: Pts enrolled in a Ph 2 study of C+O (NCT02345265) could opt to participate in this pilot study. Pts received eCO-based prompts, used eCO to record BP via a Bluetooth-linked BP cuff and to enter diarrheal events, and received eCO-based reminders and recommendations. Pts completed a 17-item usability and satisfaction questionnaire after 4 weeks of eCO use. The primary objective was to evaluate the feasibility, usability, and satisfaction of eCO use. Data were analyzed by Wilcoxon Rank Sum Analysis.

Results: 15 pts completed the pilot study. Pts indicated they felt closely monitored, connected with the healthcare team, involved in their own care, and satisfied with ease of learning and use of many eCO functions (alpha < .01). Pts were satisfied with diarrhea entry and finding past recommendations (alpha < .05) and were not satisfied with reporting diarrhea side effects. eCO captured 98.1% of expected BP values (94.2% direct upload; 5.8% manual entry). BP events ($\geq$2 consecutive BP > 140/90 mmHg) occurred in 11 pts (6 with 1 event, 2 with 2 events, 3 with 3 events) with median duration 5 days (range 3-28 days). 12 pts reported 20 diarrhea events (range 1-4 events); median duration was 1.4 days (range 1.0-2.7 days); 31 entries were made (28 Gr 1, 3 Gr 2).

Conclusions: In this initial pilot, eCO captured accurate BP and diarrhea events from pts for remote monitoring. Pts reported overall usability and satisfaction with eCO, especially feeling closely monitored, more connected, involved in self-care and ease-of-use. Use of eCO in other studies is planned.

1561P Study of the satisfaction level of an education program for cancer patients

Y. Kim[1], H.Y. Lee[2], B.G. Seo[3], Y.H. Choi[3], K.A. Kwon[3], E.J. Son[4]

[1]Patient Education Team, Dongnam Institute of Radiological and Medical Sciences-DIRAMS, Busan, Republic of Korea, [2]Patient Education Team, Medical Oncology & Hematology department, Dongnam Institute of Radiological and Medical Sciences-DIRAMS, Busan, Republic of Korea, [3]Medical Oncology & Hematology department, Dongnam Institute of Radiological & Medical Sciences, Busan, Republic of Korea, [4]Nutrition Team, Dongnam Institute of Radiological and Medical Sciences-DIRAMS, Busan, Republic of Korea

Background: As the demand for cancer patient education has increased lately, the administrative body of the universal health insurance in South Korea has decided to include the cost for cancer patient education to its insurance coverage. Dongnam Institute of Radiological Medical Sciences (DIRAMS) in Busan, South Korea, created its cancer patient education program in 2016 and has educated cancer patients about their treatments according to the program since then. This paper will discuss the study conducted at the hospital in order to estimate the level of satisfaction among the patients who participated in the education program.

Methods: The program consists of an 80-minute long education session led by a doctor, a nurse, and a clinical dietitian before each cancer patient receives his or her chemotherapy, radiation therapy, or a surgery. questionnaire survey was conducted on patients who participated in the education program from July 2016 to March 2017.

Results: Among the patients who participated in the survey, the number of patients who had chemotherapy education is 663. Stomach cancer was the most prevalent cancer type in this group, followed by cholangiocarcinoma. 75.3% of the patients in this group received palliative chemotherapy, and the rest received adjuvant chemotherapy. The satisfaction level of the chemotherapy education was 4.98 on a five-point Likert scale. The number of patients who had the radiotherapy education was 195. Breast cancer represents the largest portion in this group. The satisfaction level of the radiotherapy education was 4.3. The number of patients who received the surgery education was 70. The satisfaction level of the surgery education was 4.6.

Conclusions: The total 928 patients who participated in the education program rate their level of satisfaction as 4.8 in average on a scale of 1 to 5. This high rating can be seen as an indication of high satisfaction in the quality of the education about their treatments. To enhance the education program further, it will be worthwhile to investigate improvements in each part of the program and in the perspective of patients. Subsequently, it is also worthwhile to investigate how the education program affects cancer patients.

1562P Factors influencing the use of thromboprophylaxis in cancer outpatients: CAT AXIS, a case-vignette study on clinical practice

F. Scotté[1], I. Elalamy[2], D. Mayeur[3], G. Meyer[4]

[1]Medical Oncology and Supportive Care Unit, Foch Hospital, Suresnes, France, [2]Biological Hematology, INSERM U938, Paris, France, Tenon University Hospital, Paris, France, [3]Medical Oncology, Centre Hospitalier de Versailles - Hopital Andre Mignot, Le Chesnay, France, [4]Pneumology, Hopital European George Pompidou, Paris, France

Background: Data on long-term venous thromboembolism (VTE) prophylaxis in cancer outpatients remain scarce. In the absence of consistent treatment guidelines, our objective was to describe clinical practice and to identify factors influencing the use of thromboprophylaxis.

Methods: CAT AXIS was a multicenter cross-sectional study based on the completion of physician-profile questionnaires and the assessment of 10 e-mailed credible clinical scenarios of lung, colon and breast cancer by each of participants using the case-vignettes validated method.

Results: A total of 224 physicians participated allowing the completion and the analysis of 2,085 case vignettes corresponding to 765, 703 and 617 fictive clinical scenarios on lung, colon and breast cancers, respectively. The overall rate of thromboprophylaxis was 680/2085 (32.6%) among participants with a comparable proportion for the three types of cancer. Low-molecular-weight heparin (LMWH) was the most frequently used, by 92.7%, 93.8% and 83.9% of participants for lung, colon and breast cancer, respectively; treatment duration of $\geq$ 3 months was prescribed by 74.4% of participants. Multivariate analysis of factors influencing thromboprophylaxis based on patient's characteristics is summarized in Table.

Table: 1562P Factors influencing the prescription of thromboprophylaxis

	Lung cancer		Colon cancer		Breast cancer	
	OR [95% CI]	p	OR [95% CI]	p	OR [95% CI]	p
ECOG index score: 3 vs 0-2	3.3 [2.4; 4.6]	<0.01	2.4 [1.7; 3.6]	<0.01	2.2 [1.5; 3.1]	<0.01
Antineoplastic treatment Chemotherapy+targeted therapy (TT) vs TT only Chemotherapy only vs TT only	2.1 [1.3; 3.6] 2.8 [1.5; 5.2]	0.01 0.01	2.2 [1.2; 3.9] 2.1 [1.2; 3.8]	0.012 0.015	1.6 [0.8; 3.2] 1.1 [0.6; 1.9]	0.17 0.84
History of VTE: Yes vs no	1.9 [1.3; 2.5]	<0.01	1.7 [1.2; 2.4]	<0.01	1.3 [0.9; 1.9]	0.10
Cancer stage: Metastatic vs local	1.6 [0.9; 2.7]	0.088	NI		2.3 [1.5; 3.5]	<0.01

NI: not included in the analysis.

Conclusions: In the absence of clear guidance, the use of thromboprophylaxis remains low and rather empiric even though the selection of LMWH by the majority of participants and treatment duration seems appropriate based on available data to date. ECOG index, metastatic malignancy, chemotherapy and history of thrombosis were significantly associated with the decision to use thromboprophylaxis in most situations.

1563P Literature review of TPOR agonists for CIT

G.A. Soff[1], I. Ray-Coquard[2], L.J. Marfil-Rivera[3], J. Fryzek[4], M. Mullins[4], L.C. Bylsma[4], J.K. Park[5]

[1]Hematology Service, Memorial Sloan Kettering Cancer Center, New York, NY, USA, [2]Oncologie Médicale, Université Claude Bernard Lyon I, Lyon, France, [3]Hematology, Universidad Autónoma de Nuevo León, San Nicolás de los Garza, Nuevo León, Mexico, [4]Epidemiology, EpidStat Institute, Ann Arbor, MI, USA, [5]Oncology Therapeutic Area, Amgen (Headquarters) - USA, Thousand Oaks, USA

Background: Chemotherapy-induced thrombocytopenia (CIT) can lead to dose delay/reduction. Currently there are no specific treatment recommendations beyond transfusion. We performed a systematic literature search on the use of thrombopoietin receptor (TPOR) agonists for CIT.

Methods: We searched the Cochrane Central Register of Controlled Trials, Cochrane Database of Systematic Reviews, PubMed, EMBASE, clinicaltrials.gov, and Health Technology Assessments from 1995-2017 for studies of TPOR agonists [eg, romiplostim, eltrombopag, TPO, and megakaryocyte growth and development factor (MGDF)] for CIT. Each publication was independently reviewed by two people and data extracted into Excel.

Results: We screened 892 titles/abstracts, assessed 52 articles, and abstracted data from 14 articles and 15 abstracts/posters from 1997-2016 (10 TPO, 7 MGDF, 8 romiplostim, and 4 eltrombopag), which included 18 randomized trials. TPOR agonist regimens varied widely. Common cancers included leukemia/lymphoma (n = 8 studies) and non-small cell lung cancer (n = 4), and common chemotherapies were platinum-based (n = 15) or included cytarabine (n = 5). Median or mean baseline platelet counts were 56×10^9/L-324×10^9/L in studies to treat CIT (N = 7) and 109×10^9/L-597×10^9/L in studies to prevent CIT (N = 22). The 16 placebo-controlled or crossover studies (MGDF n = 6 studies, TPO n = 5, romiplostim n = 3, eltrombopag n = 2) generally found that TPOR agonists increased platelet counts and reduced transfusions and dose delays/reductions (Table). Safety measures included thromboses (n = 19 studies) and bleeding (n = 8).

Table: 1563P Study Design and Endpoints TPOR Agonist vs. Control (Range study incidences)

CIT Prevention: Vs. Placebo/Observation or Crossover (n = 16 studies)	TPOR Agonist (N = 625)	Control (N = 428)
Efficacy Endpoint		
Chemotherapy dose delay/reduction	3% - 40%	58% - 75%
Grade 3-4 thrombocytopenia	0% - 100%	0% - 42%
Platelet transfusions	6% - 58%	8% - 83%
Safety Endpoint		
Thrombosis	0% - 29%	0% - 33%
Bleeding	0% - 100%	0% - 50%
CIT Treatment: Vs. rhIL-11 (n = 2 studies)	**TPOR Agonist (N = 63)**	**Control (N = 71)**
Efficacy Endpoint		
Chemotherapy dose delay/reduction	N/A	N/A
Grade 3-4 thrombocytopenia	Grade 3: 54% Grade 4: 14%	Grade 3: 85% Grade 4: 41%
Platelet transfusions	11%	30%
Safety Endpoint		
Thrombosis	N/A	N/A
Bleeding	N/A	N/A
CIT Treatment: Vs. PBO/Observation or Crossover (n = 2 studies)	**TPOR Agonist (N = 172)**	**Control (N = 65)**
Efficacy Endpoint		
Chemotherapy dose delay/reduction	N/A	N/A
Grade 3-4 thrombocytopenia	N/A	N/A
Platelet transfusions	N/A	N/A
Safety Endpoint		
Thrombosis	5% - 13%	7% - 21%
Bleeding	2% - 9%	9%

Conclusions: While TPOR agonists have not been approved for use in CIT, this literature review suggests that TPOR agonists may increase platelet counts and decrease chemotherapy dose delay/reduction. Further study with well-characterized bleeding and platelet thresholds is needed to explore the possible benefits of TPOR agonists for CIT compared with current care options (eg, transfusions, dose reduction).

1564P Random optimization interactive system based on Kernel learning (RISK) for venous thromboembolism risk assessment in chemotherapy-treated cancer patients

P. Ferroni[1], F.M. Zanzotto[2], N. Scarpato[1], S. Riondino[3], F. Guadagni[1], M. Roselli[4]

[1]Dept. of Human Sciences and Quality of Life Promotion, San Raffaele Roma Open University, Rome, Italy, [2]Dept. of Enterprise Engineering, University of Rome Tor Vergata, Rome, Italy, [3]Biomarker Discovery and Advanced Biotechnologies (BioDAT) Laboratory, IRCCS San Raffaele, Rome, Italy, [4]Dept. of Systems Medicine, Policlinico Tor Vergata, Rome, Italy

Background: Using a combined approach of Kernel machine-learning (ML) and random optimization (RO) techniques we recently developed a set of predictors (ML-ROs) for VTE risk assessment. Aim of this study was to validate a model incorporating the two best ML-ROs to devise a web-based graphical interface for VTE risk stratification.

Methods: Pre-chemotherapy age, sex, tumor site and stage, hematological attributes, fasting blood lipids, glycemic indexes, liver and kidney function, BMI, ECOG, supportive and anti-cancer drugs of 608 cancer outpatients were entered in the model, with numerical attributes analyzed as continuous values. Variables were clustered into groups according to clinical significance, and RO was used to devise their relative weight in final prediction.

Results: VTE occurred in 7.1% of patients. Overall, 6% were at high-risk for VTE, as per current guidelines (Khorana Score (KS) $\geq$3), 11% of which had VTE during treatment. 42% and 52% were at intermediate (KS 1/2) or low-risk (KS = 0), with VTE rates of 9% and 5%, respectively. Accordingly, the performance of KS, despite a 94% specificity, was characterized by a 9% sensitivity with an area under the ROC curve (AUROC) of 0.589, translating into non-significant positive (+LR) [1.58 (0.48-4.30)] or negative likelihood ratio (-LR) [0.96 (0.83-1.04)]. Conversely, the VTE risk prediction performance of the combined ML model showed a 0.716 AUROC, which was significantly higher than that observed with KS (difference between areas: 0.127, $p = 0.0044$). At a criterion >1 (risk estimate achieved by both predictors) this combined approach showed significant +LR [2.30 (1.70-2.82)] and -LR [0.46 (0.28-0.69)] and a 4.9 Hazard Ratio (95%CI: 2.5-9.4) with a 6-month VTE rate of 3.4% in the low-risk, compared with 14.9% in the high-risk category.

Conclusions: These results demonstrate that a ML approach, optimizing the relative weight (by RO) of groups of clinical attributes, is of clinical value for VTE risk prediction, performing better than KS. We are now finalizing the architecture of a web service with a graphical interface helping oncologists in the critical phase of decision making.

1565P Association between systemic inflammation and symptoms in advanced cancer patients

D. Viñal Lozano[1], A. Alonso-Babarro[2], Y. Vilches-Aguirre[2], L. Diez-Porres[2], M. Varela-Cerdeira[2], J. Villamayor Sanchez[1], L. Gutierrez Sainz[1], R. Madero-Jarabo[2]

[1]Medical Oncology, Hospital Universitario La Paz, Madrid, Spain, [2]Acute Palliative Care Unit, Hospital Universitario La Paz, Madrid, Spain

Background: There is growing evidence relating inflammation as a prognostic factor in cancer patients. Previous reports have found a small but significant association between systemic inflammation and symptoms in advanced cancer patients. The aim of this study was to analyse the relationship between systemic inflammatory response markers with the symptoms and performance status of advanced cancer patients that have been admitted to an Acute Palliative Care Unit (PCU).

Methods: We conducted an observational study including all cancer patients admitted in the PCU between January 2012 and April 2015. We performed a correlation analysis (spearman's rho) between serum C-reactive-protein (CRP), the modified Glasgow Prognostic Score (mGPS) and Neutrophil-to Lymphocyte Ratio (NLR) with patients symptoms recorded as the Edmonton Symptom Assessment Sytem (ESAS) and performance status recorded as Eastern Cooperative Oncology Group (ECOG), Barthel Index and Palliative Performance Scale (PPS). All data were collected within the first two days of admission.

Results: Data of 951 patients were available. The median survival was 17 days. CRP was significantly correlated with ECOG (ρ:0.180, P:0.000), dyspnoea (ρ:0.079, p:0.019), fatigue (ρ:0.162, $p < 0.001$), anorexia (ρ: 0.103, p:0.002), somnolence (ρ:0.096, p.0.009), wellbeing (ρ:0.012, $p < 0.001$), Barthel (ρ:-0.178, $p < 0.001$) and PPS (ρ:0.173, $p < 0.001$). In relation to mGPS, a significant correlation was found with ECOG (0.116, p:0.001), fatigue (ρ:0.184, $p < 0.001$), anorexia (ρ:0.107, p.0.003), somnolence (ρ:0.080, p.037), Barthel (ρ:-0.127, $p < 0.001$) and PPS (ρ:-0.125, $p < 0.001$). Finally, NLR was significantly correlated with ECOG (ρ:0.112, p0.001), dyspnoea (ρ:0.117, $p < 0.001$), fatigue (ρ:0.107, p:0.002), Barthel (ρ:-0.115, $p < 0.001$) and PPS (ρ:-0.100, p:0.002).

Conclusions: There is a small but significant correlation between systemic inflammation and symptoms. Further studies are needed to confirm the results and to test this relation in earlier phases of the disease.

1566P Outcomes of patients with malignancy admitted to the intensive care units (ICU): A prospective study

H. Assi[1], V. Nohra[2], F. Sukhon[1], N. Moukalled[1], I. Bou Akl[3], D. Mukherji[1], M. Charafeddine[1], N. Abdul Halim[1], C. El Mouhayyar[1], Y. Medlej[1], P. Bou Khalil[3]

[1]Hematology and Oncology, American University of Beirut Medical Center, Beirut, Lebanon, [2]Internal Medicine, American University of Beirut Medical Center, Beirut, Lebanon, [3]Pulmonary Medicine and Supportive Care, American University of Beirut Medical Center, Beirut, Lebanon

Background: Decisions regarding whether advanced cancer patients should be admitted to the intensive care units (ICU) is based on a complex suite of considerations, including short and long term prognosis, quality of life, and options to treat cancer. We set to describe demographic, clinical, and survival data and to identify factors associated with short and long term mortality in critically ill advanced cancer patients with non-elective admissions to general ICUs.

Methods: Critically ill adult cancer patients non-electively admitted to the ICUs at the American University of Beirut Medical Center (AUBMC) between August 2015 and 2016 were included. Demographic, clinical, and laboratory data was prospectively collected from first day of ICU admission up to 30 days after discharge. This study was observational and clinical decisions were left to the ICU team and attending physician.

Results: 91 patients were enrolled between August 2015 and 2016, with 41 patients (46%) dying in the ICU, and 12 patients (13.5%) within 30-days post-discharge. 7 patients were lost to follow-up. Mean OS was 137 days, and median OS was 31 days since date of admission to the ICU. Most common reasons for ICU admission were sepsis (68.5%) and respiratory failure (19%). Cox regression showed direct admission from the ED (2.4 times more likely to die), those with uncontrolled malignancies (1.8 times), chemotherapy within the last 30 days prior to ICU admission (2.3 times), and development of multi-organ failure (MOF) (2.5 times) in the ICU are major predictors of poor prognosis.

Conclusions: Our study showed receiving chemotherapy within thirty days prior to admission as a predictor of poor outcome in univariate and multivariate analyses. This has not been reported in a study population of this kind before. Also, many studies state that developing MOF, whether in the ICU or prior to admission negative prognostic factor. Finally, our study found that direct admission from the ED is a negative prognostic factor, which has only been reported for hematological malignancies in other studies. Thus, there is a need for the development of proper admission criteria for this population.

1568P Management of thrombosis in cancer patients in Greece

N. Tsoukalas, E. Bournakis, A. Adamidis, C. Andreadis, K. Arvaniti, A. Christopoulou, S. Douna, J.D. Moreno, G. Goumas, L. Kostadima, P. Makaronis, T. Makatsoris, D. Doufexis, G. Papatsimpas, I. Sgouros, E. Stergiou, P. Thalassinou, I. Boukovinas, P. Papakotoulas, I. Varthalitis

Hellenic Society of Medical Oncology (HeSMO), Athens, Greece

Background: Venous thromboembolism (VTE) is a common cause of adverse outcomes in patients with cancer. The risk of VTE varies with cancer type, stage, grade, therapy and other patient characteristics. Low-molecular-weight heparin (LMWH) remains the standard therapy for VTE in cancer patients.

Methods: This is an observational study conducted by the Hellenic Society of Medical Oncologists (HeSMO) that aims to record and highlight the current clinical practice and management of VTE in patients with cancer in 18 Greek centers, with nationwide dispersion.

Results: The participating centers reported a total of approximately 4300 cancer patients managed on a monthly basis, where the vast majority (80%) were treated in an outpatient setting. For this study, 340 patients with active cancer were enrolled, with the following characteristics: 53,2% male; mean age 64,3; 62.1% of patients had PS of 0-1; tumor types: lung 22,3%, pancreas 16,3%, colon 13,6%, breast 11%, stomach 8,3%, ovarian 6,5% and other tumors 21,7%. The majority of patients (95,3%) received anticancer treatment; 21,3% were inpatients and 78,6% outpatients. Among these 340 patients, 86 were diagnosed with VTE: 81,4% had symptomatic VTE while 18,6% had incidental VTE. Regarding patients with VTE,94,2% received anticancer treatment and the majority of these (65,1%) were treated in an outpatient setting. Of the patients diagnosed with VTE, 76,9% had performance status 0-1 and 74,4% had metastatic disease. In the metastatic stage there was no differences in the incidence of symptomatic or incidental VTE, 75% vs 74,3% respectively ($p = 0,99$). Highest percentage of incidental VTE observed was in patients with lung cancer (43,8%), followed by pancreatic (18,8%) and colon cancer (12,5%). All patients with VTE received antithrombotic treatment with LMWH according to the current clinical guidelines.

Conclusions: The majority of patients who developed VTE were outpatients undergoing anticancer treatment with metastases. Incidental VTE was more frequent in patients with lung cancer. Our findings of 18,6% incidental VTE further confirm the previously described results in similar studies.

1569P Incidence and outcome of Incidental Pulmonary Embolism (IPE) in oncology patients with current macroscopic disease

M.M.M. Moe

Oncology, Yeovil District Hospital, Yeovil, UK

Background: IPE is defined as a PE detected on a CT scan (not a pulmonary angiogram) done for reasons other than suspected PE. This study is to evaluate the incidence of IPE in oncology patients with current macroscopic disease, and the outcome that could potentially be affected by a delay in starting anticoagulation therapy due to delayed reporting of these routine (non-urgent) scans.

Methods: CT thorax with iv contrast done on oncology patients between 01.01.15 – 31.12.15 in two district general hospitals in a cancer network were identified from the database. The scan reports and clinic letters were reviewed for data on cancer diagnosis, macroscopic disease, PE, treatments and survivals.

Results: 2147 scans were identified. 543 scans were excluded due to absence of macroscopic disease (No IPE was reported in any of these scans.) leaving 1604 scans eligible for this study. Incidence for different tumour is shown in the table 1. 26 IPE patients are female = 15; median age = 66 (range 32 – 90); main artery = 9; lobar artery = 5; average time from CT scan to anticoagulation (LMWH) therapy is 9.7 days (median = 5 days; range = 0 – 61 days; no treatment in 3 patients) mainly due to the delay in reporting (median = 1 day; range = 0 – 60 days). The median survival from the scan date is 7 months (range = 1 – 22) with 9 patients still alive and 2 lost to follow up. None of the patients whose anticoagulation started 5 or more days after the CT scan died within 3 months. IPE was absent in all subsequent CT scans. This happened without any anticoagulation therapy in one patient who had a segmental IPE. Table 1. Incidence of IPE for different tumour types

Table: 1569P

	Patients	Scans	Scans with IPE (% of total scans)
Lung	235	587	9 (1.5%)
Breast	148	267	5 (1.9%)
Colorectal	142	310	5 (1.6%)
Oeso/gastric	72	163	2 (1.2%)
Mesothelioma	8	19	1 (5.3%)
CUP	15	30	1 (3.3%)
Bladder	15	31	1 (3.2%)
NET	1	1	1 (100%)
Prostate	41	87	1 (1.2%)
Anal	1	2	0
Brain	1	1	0
H & N	8	18	0
Heptaobiliary	10	20	0
Melanoma	3	4	0
Ovary	3	4	0
Pancreas	26	58	0
Skin	2	0	0
Total	731	1604	26 (1.6%)

Conclusions: Incidence of IPE in oncology patients with current macroscopic disease is low (1.6%) in daily practice. Most patients are likely to have lung, breast and colorectal cancers. This is probably due to the fact that these are common tumours, and the frequency of scanning in their management. No sudden death or mortality within 30 days was noted among patients who had anticoagulation therapy started 5 or more days after the CT scan. Spontaneous resolution of PE happened in one patient with segmental PE. More research is needed to select patients who may not get any meaningful benefit from anticoagulation in the presence of advanced malignant disease.

1570P Immune related adverse events associated with ipilimumab and nivolumab

B. Rapoport, R.I. Van Eeden, T. Smit

Medical Oncology, The Medical Oncology Centre of Rosebank, Johannesburg, South Africa

Background: Immune related adverse events (IrAEs) are unique and completely different from what we have seen previously. There is no prospective data on these toxicities and guidelines are based on symptomatic management from the ongoing clinical trials. Ipilimumab and nivolumab induce irAEs to the skin, gastrointestinal, liver, endocrine and other systems.

Methods: A **retrospective** review of data from 45 patient records were used to describe the IrAE's associated with 19 patients treated with Ipilimumab and 25 patients treated with Nivolumab and 1 patient with combination of ipilimumab and nivolumab. This is a single centre review in an expanded access programme/clinical trial setting.

Results: A total of 45 patients (28 males, 17 females) were analyzed. The median age was 63 years. Three patients with metastatic melanoma, 18 with non-small cell lung cancer (NSCLC), 2 with renal cell carcinoma and 2 with Hodgkin's disease were treated with nivolumab and 19 with metastatic melanoma received ipilimumab. One patient with combination of ipilimumab and nivolumab. In total 167 cycles of nivolumab (median = 4, range 1-16) and 60 cycles of ipilimumab (median = 4 cycles, range 1-4) were administered. The patient receiving combination of ipilimumab and nivolumab received 1 cycle. Seven IrAEs are described in 15 ipilimumab treated patients. These include endocrinopathy in 3 patients (hypophysitis in patient and hyphothyroidsm in 2 patients), colitis in 3 patients (1 required infliximab) and hepatitis in 1 patient. Among the patients treated with nivolumab, 7 IrAEs were documented. These included pneumonitis in 2 patients, skin rash in 3 patients, mild diarrhea in 1 patient and mild uveitis in 1 patient. One patient developed autoimmune thrombocytopenia, and nephritis. Three chest infections were documented including pulmonary tuberculosis in a NSCLC patient. The patient receiving combination ipilimumab and nivolumab had grade 4 skin toxicity requiring treatment discontinuation. No IrAE related deaths were document.

Conclusions: A plethora of irAEs are described with anti-PD1 and anti-CTLA4 antibodies. Colitis was more common with ipilimumab while pneumonitis more common with nivolumab. Prompt IrAE's diagnosis will result in decreased morbidity and mortality.

1571P Febrile Neutropenia: a systematic review of the first 5 years of a cancer unit

J. Pinto[1], I. Leão[2], F. Branco[1], J. Godinho[1], P. Simões[1], F. Lopes[1], A. Escária[1], F. Costa[1], I. Galvão[1], J.L. Passos-Coelho[1]
[1]Medical Oncology, Hospital Beatriz Angelo-Loures, Loures, Portugal, [2]Medical Oncology, Centro Hospital Vila Nova de Gaia/Espinho, V. N. Gaia, Portugal

Background: Febrile Neutropenia (FN) is a potentially life-threatening and dose-limiting complication of myelosuppressive chemotherapy (CT) that often requires hospital admission (HA). Patients (pts) with FN must initiate antibiotic (atb) therapy promptly and delay in diagnosis and subsequent treatment are associated with higher mobility and mortality.

Methods: Retrospective single institution review of all FN episodes that occurred in the years 2012 to 2016 in pts with solid tumors with an absolute neutrophil count (ANC) <1.000/µl and blood cultures (BC) collected within 30 days of an IV CT treatment. With a population base of 278.000 individuals, and 550 new solid tumor pts in Medical Oncology per year, we reviewed all BC collected during the first 5 years of Hospital Beatriz Angelo (2012-2016) and crossed with the registry of pts treated with IV CT. FN was defined as a tympanic temperature > 38 °C and ANC <1.000/µl and expected to decrease to < 500/µl in the following 7 days. Pts with hematologic malignancies were excluded.

Results: Among 1.947 eligible pts, 152 had a NF (8%) with a total of 173 NF episodes. Median age was 67yo; 90 were males (59%). Median initial ANC was 310/µl, range 20-990 (<500/µl in 69% and <100/µl in 17%). In the emergency room, median time from hospital nurse triage to medical observation (MO) was 38 min (range 4min-6h11m), MO to blood count specimen withdrawal 55min (range 10min-6h43m) and MO to arrival of BC to the lab 5h51min (range 24min-23h41m). 33 NF episodes were associated with positive BC (19%, 6 with two agents), 11 BC with Gram positive and 28 with Gram negative bacteria. 157 episodes led to HA (90%), 15 were treated as outpatients and in 1 NF episode the pt died at presentation from E. coli pneumonia. Median days of hospitalization was 8 (range 0-36). Median time on atb was 9 days (range 1-31), with first-line regimen including piperacilin/tazobactam in 110, amoxicilin/clavulanic acid + ciprofloxacin in 17, meropenem in 9, other agents in 11 and 1 with no treatment. Mortality during the NF episode was 20% (n = 34) from 173 NF episodes.

Conclusions: FN is a serious and common complication of CT treatment which must be diagnosed and treated rapidly. Delays in the evaluation of febrile cancer pts on systemic treatment may compromise the outcome of these pts.

1572P G-CSF and G-CSF biosimilars: a meta-analysis of randomized clinical trials in breast cancer patients

E. Botteri[1], A. Krendyukov[2], G. Curigliano[3]
[1]Norwegian National Advisory Unit on Women's Health, Oslo University Hosp., Oslo, Norway, [2]Industriestr 25, Hexal AG, Holzkirchen, Germany, [3]Division of Experimental Therapeutics, European Institute of Oncology, Milan, Italy

Background: The granulocyte colony-stimulating factors (G-CSFs) filgrastim and pegfilgrastim are widely used to prevent neutropenia in cancer patients undergoing myelosuppressive chemotherapy. Several G-CSF biosimilars are available, their development involving a step-wise approach including analytical comparison with the reference and iterative process development. Randomized clinical trials (RCTs) have confirmed that the reference product and its biosimilar provide the same clinical efficacy and safety and play pivotal role in the totality of evidence concept. However some heterogeneity exists among the studies. For G-CSF biosimilars, patients with breast cancer (BC) are the most sensitive population in which to confirm similarity. The aim of this meta-analysis was to compare the clinical efficacy of approved or proposed G-CSF biosimilars (filgrastim or pegfilgrastim) with reference G-CSF in patients with BC.

Methods: A Medline literature search up to March 2017 identified randomized clinical trials (RCTs) comparing biosimilar G-CSF to reference in BC patients. Primary efficacy endpoint was mean difference in duration of severe neutropenia (DSN). Secondary efficacy measures were differences in depth of absolute neutrophil count (ANC) nadir and time to ANC recovery. Random effect models were fitted to obtain pooled estimates of the mean difference and their corresponding 95% confidence intervals (CIs).

Results: Eight eligible RCTs were included. Overall difference in DSN between reference and biosimilar medicines was not statistically significant (0.06 days [95% CI -0.05, 0.17]) (Table). The secondary efficacy endpoints also showed no significant differences between reference and biosimilars.

Conclusions: This meta-analysis showed no differences in clinical efficacy between biosimilar and reference G-CSF in breast cancer patients.

1573P Pharmacokinetic and pharmacodynamic comparability of B12019: A proposed pegfilgrastim biosimilar

K. Roth[1], H. Wessels[1], J. Hoefler[2], R. Jankowsky[3]
[1]Clinical Development, Cinfa Biotech, Munich, Germany, [2]Biostatistics, Staburo, Munich, Germany, [3]Management, Cinfa Biotech, Munich, Germany

Background: B12019 is being developed as a biosimilar to Neulasta® (INN pegfilgrastim), a pegylated, long-acting form of recombinant human granulocyte-colony stimulating factor (G-CSF) for the prevention of chemotherapy-induced neutropenia. A clinical development program was conducted with B12019 in comparison to EU-authorised Neulasta to confirm the biosimilarity as established by analytical, functional and preclinical data.

Methods: The clinical development program for B12019 consisted of two clinical studies. Study B12019-101 investigated pharmacokinetics (PK) and pharmacodynamics (PD) comparability of B12019 to Neulasta. The 6mg single-dose, randomised, double-blind, two-way crossover study enrolled 172 healthy volunteers. The primary PK endpoints were the area under the plasma concentration-time curve ($AUC_{0\text{-last}}$) and the maximum concentration (C_{max}) as well as the area under the effect curve ($AUEC_{0\text{-last}}$) for absolute neutrophil count (ANC) for PD. In study B12019-102 immunogenicity and PD comparability of B12019 and Neulasta were investigated in a 3mg multiple-dose, randomised, double-blind, three-period, two-sequences crossover study in 96 healthy volunteers. Primary endpoints were $AUEC_{0\text{-last}}$ for PD and anti-drug antibody rate (ADA) for immunogenicity.

Results: Study B12019-101, using 6 mg, confirmed PK and PD comparability (compare also *Roth et al, Blood, Dec 2016*). In study B12019-102, 82 subjects were included in the model-based PD comparison. PD comparability was demonstrated, with the $AUEC_{0\text{-last}}$ geometric mean ratio with a CI of 99.6; 103.6 being within the pre-specified acceptance range. In both studies, no imbalance of ADA-positive samples after single or repeated dosing were observed. Neither anti-G-CSF nor neutralising antibodies were detected for B12019 or Neulasta.

Table: 1572P Mean and mean difference on duration of severe neutropenia* during chemotherapy Cycle 1

			Biosimilars		Reference products			Mean difference
Study and year of publication	Reference G-CSF	Biosimilar G-CSF	Mean	No. of patients	Mean	No. of patients	Weight	IV, Random, 95% CI
Blackwell 2015	Filgrastim	Filgrastim	1.17	107	1.2	107	14.2%	−0.03 [-0.32, 0.26]
Blackwell 2016	Pegfilgrastim	Pegfilgrastim	1.36	155	1.19	153	20.2%	0.17 [-0.07, 0.41]
Del Giglio 2008	Filgrastim	Filgrastim	1.1	140	1.1	136	6.4%	0.00 [-0.43, 0.43]
Harbeck 2016	Pegfilgrastim	Pegfilgrastim	0.75	155	0.83	155	28.1%	−0.08 [-0.28, 0.12]
Park 2016	Filgrastim	Pegfilgrastim	2.28	36	2.08	38	5.6%	0.20 [-0.26, 0.66]
Waller 2010	Filgrastim	Filgrastim	1.6	165	1.3	85	13.4%	0.30 [0.01, 0.59]
Waller 2016	Pegfilgrastim	Pegfilgrastim	1.2	127	1.2	67	12.2%	0.00 [-0.31, 0.31]
Pooled estimate (95% CI)				**885**		**741**	**100%**	**0.06 [-0.05, 0.17]**

Heterogeneity:$Chi^2 = 6.27$ ($P = 0.39$); $I^2 = 4\%$ *Days with absolute neutrophil count less than 0.5×10^9/L (<500/μL)

Conclusions: · The clinical program confirmed the biosimilarity of B12019 and Neulasta in highly sensitive clinical study settings. · PK comparability of B12019 and Neulasta was demonstrated at the clinical dose of 6 mg. · PD comparability of B12019 and Neulasta was shown at the clinical dose of 6 mg and the reduced dose of 3 mg. · The safety and immunogenicity profile of B12019 did not show any clinically meaningful differences to Neulasta.

1574P Efficacy and safety of RGB-02, a proposed biosimilar pegfilgrastim to prevent chemotherapy-induced neutropenia: Results of a randomized, double-blind, phase III clinical study vs. reference pegfilgrastim in patients with breast cancer receiving docetaxel/doxorubicin

K. Horvat-Karajz[1], D. Grecea[2], M. Smakal[3], A. Illes[1], Z. Kahan[4]

[1]Clinical Development of Biologics, Gedeon Richter Plc., Budapest, Hungary, [2]Radiotherapy I. Department, Ion Chiricuta Oncology Institute-IOCN, Cluj-Napoca, Romania, [3]Oncology Station, Hospital Horovice, a.s., Horovice, Czech Republic, [4]Department of Oncotherapy, University of Szeged, Szeged, Hungary

Background: Treatment with recombinant human granulocyte-colony stimulating factor (G-CSF) is accepted standard for prevention of chemotherapy-induced neutropenia. RGB-02, a pegylated G-CSF (pegfilgrastim) developed by Gedeon Richter is a proposed biosimilar to the reference pegfilgrastim product Neulasta®. Here we are presenting the results of a randomized, comparative, double-blind, multicenter study to evaluate efficacy and safety of RGB-02 in breast cancer patients receiving cytotoxic regimen (EudraCT nr: 2013-003166-14).

Methods: 239 women presenting with breast cancer were randomized to RGB-02 (n = 121) and to the reference pegfilgrastim, Neulasta® (n = 118). All patients received up to 6 cycles of docetaxel/doxorubicin and a once-per-cycle injection of a fixed 6 mg dose of pegfilgrastim. Primary endpoint was the duration of severe neutropenia (ANC $< 0.5 \times 10^9$/L) in Cycle 1 (2-sided CI interval 95%). Secondary endpoints included incidence and duration of severe neutropenia, incidence of febrile neutropenia, time to ANC recovery, depth of ANC nadir, and safety outcomes.

Results: The mean duration of severe neutropenia in Cycle 1 was 1.7 (RGB-02) and 1.6 days (reference), with a difference (LS Mean) of 0.1 days (95% CI -0.2, 0.4). Therapeutic equivalence could be established as the CI for the difference in LS Mean lay entirely within the pre-defined range of ± 1 day. The incidence of severe neutropenia decreased from cycle 1 to 2 in both groups with no statistical significant differences, for RGB-02 from 84.6% (99 patients) to 54.1% (60 patients) and from 77.0% (87 patients) to 43.7% (45 patients) in the comparator group. Both groups were similar regarding mean time to ANC recovery with 3.4 ± 1.84 days (RGB-02) and 3.7 ± 1.88 days (reference) during Cycle 1. Safety profiles were comparable between groups.

Conclusions: Therapeutic equivalence and similar safety profiles between RGB-02 and Neulasta® as once-per-cycle administration could be demonstrated. RGB-02 can provide a biosimilar alternative for the prevention of neutropenia.

Clinical trial identification: EudraCT nr: 2013-003166-14

1575P Impact of resistance exercise on metabolic syndrome (MetS) parameters in men receiving androgen deprivation therapy (ADT) for prostate cancer

T. Dorff[1], M. Gross[1], D.I. Quinn[1], J. Pinski[1], T. Schroeder[2], S. Groshen[3], C. Dieli-Conwright[2], J. Kiwata[2]

[1]Keck School of Medicine, Division of Medical Oncology, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA, USA, [2]Division of Biokinesiology and Physical Therapy, University of Southern California, Keck School of Medicine, Los Angeles, USA, [3]Preventive Medicine-Biostatistics, University of Southern California, Keck School of Medicine, Los Angeles, USA

Background: Cardiovascular disease is the leading cause of death in men with prostate cancer. ADT is effective treatment, but can adversely impact MetS components, which may contribute to excess cardiac risk. We tested whether a resistance exercise program, designed to increase skeletal muscle mass during ADT, could offset adverse changes.

Methods: Prostate cancer patients on ADT were randomized to exercise (EX) or no exercise (noEX). EX was supervised, periodized resistance training followed by stretching 3x/week for 12 weeks, 45 min/session. noEX did home-based stretching 3x/week. Baseline and post-intervention measurements included weight, waist circumference (wCirc), lean body mass, lipids, insulin, glucose. Mean differences in changes were compared with intent-to-treat linear regression models adjusted for baseline values. Cohen's D effect sizes were calculated for these pilot data to estimate effects for a fully powered trial.

Results: Thirty-two men (EX n = 13, noEX n = 19) completed the protocol. Age (mean ± SD) was 67.3 ± 8.7 yr (range 52 - 84). Mean duration ADT was 14.4 ± 13.4 months (range 3 – 57). EX patients had higher baseline BMI with 63% >25 kg/m2 compared to 25% in the NoEX group, p = 0.024. wCirc decreased significantly (p = 0.032) in EX (-1.18 cm 95%CI [-3.3, -1.0] cm) compared to NoEX (+1.97 cm [0.2, 3.7]). Lean mass increased and body fat decreased in EX compared to NoEX. Moderate effect sizes (D = 0.2-0.5) were seen between groups for other parameters (see Table).

Conclusions: Supervised resistance exercise for 12 weeks improves wCirc and body composition in men receiving ADT for prostate cancer with moderate effect on other MetS parameters.

life (QoL), fatigue and survival (OS). Multivariable logistic regression models evaluated the association of BMI 1 year prior to diagnosis with behaviour changes and perceptions.

Results: Of 1269 patients, 205 smoked at diagnosis and 44% quit at 1 year; 350 (at diagnosis) and 238 (at follow-up) met PA guidelines; 661 drank alcohol at diagnosis while 50% reduced consumption after. Median BMI was 25.8 (22% obese); 75%+ patients perceived PA as improving QoL and OS, while 70%+ described smoking and 55%+ described alcohol as worsening QoL and OS. At diagnosis, increased BMI was associated with ex-smoking (vs current smoking; P = 0.003), never using alcohol (vs former use; P = 0.05) and not meeting PA guidelines (P = 0.01). Among smokers at diagnosis, increased BMI was associated with smoking cessation (aOR = 1.08 per 1 unit BMI, P = 0.03) and perceptions that smoking worsens OS (aOR = 1.10, P = 0.04) and fatigue (aOR = 1.08, P = 0.08). Among those not meeting PA guidelines at diagnosis, increased BMI was associated with perceptions that PA worsens fatigue (OR = 1.02, P = 0.06) and is unsafe (OR = 1.04, P = 0.06), but were not associated with PA levels changes after diagnosis. Among drinkers at diagnosis, increased BMI was associated with perceiving alcohol to be less harmful (aOR = 0.93, P = 0.002) and less likely to worsen OS (aOR = 0.96, P = 0.04) and fatigue (aOR = 0.97, P = 0.09), but not with alcohol use changes after diagnosis. BMI was not associated with counselling rates; however, 66% of current smokers received cessation counselling while only 14% of current drinkers and 13% of those not meeting PA guidelines received counselling on their respective behaviours.

Conclusions: Obese patients were more likely to quit smoking and perceive it to be harmful but less likely to perceive alcohol as harmful. Survivorship programs should consider focusing on PA and alcohol counselling in obese patients.

1577P Barriers to improving awareness of the importance on exercise and dietary intervention, impact of it on lung cancer survivors' behavior

J-A. Sim[1], Y.H. Yun[2], S.H. Yoo[3]

[1]Department of Biomedical Science, Seoul National University College of Medicine, Seoul, Republic of Korea, [2]Department of Family Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea, [3]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea

Background: Awareness of the importance on exercise and dietary intervention can provide significant benefits for lung cancer patients and survivors. This study first aimed to identify the barriers and preferences to improving awareness of the importance on exercise and dietary education. In addition, the study also explored the impact of patients' awareness of the importance on exercise and diet education toward the stage of behavior change, intention of actual participation to the programs.

Methods: Total 830 lung cancer survivors from two hospitals in South Korea participated in this postal questionnaire–survey. Standardized measures including patients' socio-demographic variables, preferences for appropriate education time and place were identified as the barriers for their awareness of the importance of exercise and diet counseling program. In addition, the impacts of it on each intention of actual participation to both programs and maintaining regular exercise and balanced diet were analyzed in order.

Results: Patients who recognized exercise education program very important had more intention of actual participation to the program (adjusted Odds Ratio [aOR], 2.11; 95% Confidential Interval [CI], 1.57-2.83). In addition, subjects who recognized diet counseling programs very important maintained their behavior of balanced diet more than 6 months (aOR, 2.57; 95% CI, 1.92-3.61). However, significant differences based on the socio-demographic variables and program preferences (i.e., lower education and income, preferred time and place etc.) were identified as main barriers for survivors' awareness of the importance of the exercise and diet counseling program.

Conclusions: Identification of main barriers provides valuable information regarding improving survivors' awareness of the importance on exercise and dietary intervention, which should be targeted in maintaining future physical activity and balanced diet, and encouraging the intention of actual engagement to the programs.

1578P Current perspectives of healthcare providers on weight loss and supportive nutritional care in cancer patients

F. Strasser[1], J. Arends[2], A. Laviano[3], N. Georgiou[4], R. Audisio[5], M. Sawyer[6], S. Kaasa[7]

[1]Clinic for Oncology/Hematology, Cantonal Hospital St. Gallen, St. Gallen, Switzerland, [2]Klinik für Innere Medizin I, Universitätsklinikum Freiburg, Freiburg, Germany, [3]Department of Clinical Medicine, Sapienza University, Rome, Italy, [4]Global Medical Affairs, Nutricia Advanced Medical Nutrition, Schiphol Airport, Netherlands, [5]St. Helens Teaching Hospital, Department of Surgery, University of Liverpool, St. Helens, UK, [6]Medical Oncology, Cross Cancer Institute, University of Alberta, Edmonton, AB, Canada, [7]European Palliative Care Research Centre (PRC), Department of Cancer Research and Molecular Medicine, Faculty of Medicine, NTNU, Norwegian University of Science and Technology and St. Olavs Hospital, Trondheim University Hospital, Oslo University Hospital, Oslo, Norway

Background: Malnutrition and cachexia occur in most cancer patients (pts) impacting quality of life (QoL) and anticancer treatment (Tx) outcomes. Nutritional care can help reverse weight loss and improve pt outcomes; however, previous surveys at ESMO (2014, 2015) suggest nutritional care/assessment is insufficiently implemented in clinical practice, despite educational and academic efforts.

Methods: This survey created by the authors, including questions from prior surveys, was completed by ESMO 2016 delegates visiting the Nutricia booth.

Results: Of 2,011 respondents, 78% were medical oncologists, 56% were Europe based; 61% always discuss nutritional aspects during multidisciplinary tumor boards. To assess malnutrition, 44% measure weight, 30% evaluate systemic inflammation, and 14% assess muscle loss. Eligibility of pts to receive nutritional support is assessed before (48% [44% in 2015; 47% in 2014]) or during (54%) initiation of anticancer Tx, at primary diagnosis (28%), if weight loss is visible during outpatient visits (42%), and when anticancer Tx ends (26%). Main impacts of malnutrition are increased anticancer Tx toxicity (58%; 2015: 53%; 2014: 53%), surgery/radiotherapy complications (40%; 37%; 36%), anticancer Tx discontinuation/decreased effectivity (54%; 40%; 40%), decreased QoL (58%; 56%; 54%), impaired physical function (47%; 44%; 45%), or distress of family members (35%; 32%; 32%). Main goals of nutritional support include QoL (65%; 69%; 64%), completion of anticancer Tx (54%; 52%; 45%), or stabilizing weight (48%; 44%; 47%). Popular approaches to minimize weight loss are antiemetics (48%; 56%), appetite stimulants (41%; 48%), more-effective anticancer Tx (39%; 47%), anticachexia drugs (38%; 43%), and timely and individually tailored dietary advice (36%). During systemic Tx, 85% apply physical exercise programs (either alone or in combination with nutritional care).

Conclusions: Compared with our previous surveys, awareness and assessment of malnutrition in cancer pts seems slightly increased. HCPs recognize impacts of malnutrition but may need better guidance on how to improve nutritional care in the supportive and palliative setting.

1579P A survey of patient acceptance of skin toxicities from cetuximab-based therapy

B. Tischer[1], M. Bilang[1], P. Ronga[2], M.E. Lacouture[3]

[1]Oncology, Kantar Health, Munich, Germany, [2]Global Medical Affairs Oncology, Merck KGaA, Darmstadt, Germany, [3]Oncology, Memorial Sloan Kettering Cancer Center, New York, NY, USA

Background: Inhibition of the epidermal growth factor receptor (EGFR) extends patient survival in multiple tumor types. However, EGFR inhibition is associated with skin toxicities such as mild to moderate acneiform rash, which can be severe in up to 18% of patients. A previously performed structured literature search revealed an unmet need for research regarding the influence of dermatologic adverse events (dAEs) on patients' quality of life (QoL), patient acceptance of cancer treatments, and therapeutic risk/benefit tradeoff from the patients' perspective. This survey reports on these topics in patients who received the anti-EGFR monoclonal antibody cetuximab.

Methods: Using a multinational survey that included 195 patients, we conducted a subanalysis of 66 patients who previously received cetuximab-based cancer therapy (44 with metastatic colorectal cancer [mCRC] and 22 with squamous cell carcinoma of the head and neck [SCCHN]) to gauge attitudes regarding skin toxicities.

Results: 64/66 patients (43/44 with mCRC and 21/22 with SCCHN) experienced dAEs. Skin toxicities were cited as causing pain and physical discomfort as well as impairing QoL. Despite the negative social, physical, and functional impacts of dAEs, 70% of patients with mCRC and 64% of patients with SCCHN who received cetuximab stated that they would prefer a more efficacious cancer therapy that induced more severe skin reactions over a less efficacious therapy associated with less severe skin reactions. Furthermore, in an efficacy-safety tradeoff exercise, nearly two-thirds of patients (65%) stated that they would accept a new therapy with improved efficacy, even if 1 out of every 2 patients experienced a severe skin rash on this therapy.

Conclusions: Patients with mCRC or SCCHN who previously received the anti-EGFR antibody cetuximab as part of their cancer therapy were willing to accept skin toxicities as an AE if these toxicities were the anticipated byproduct of a more effective therapeutic regimen.

1580P Increase in cetuximab-induced skin rash and hypomagnesemia in patients receiving concomitant treatment with proton pump inhibitors (PPIs): A possible drug interaction?

M. Abu Amna[1], G. Bar-Sela[2]
[1]Oncology, Rambam Health Care Center, Haifa, Israel, [2]Oncology, Rambam Health Care Campus, Haifa, Israel

Background: Proton pump inhibitors (PPIs) may interact with several orally administered drugs, possibly by raising gastric pH levels, leading to altered dissolution and absorption. In a previous study, we found that co-administration of PPIs with cetuximab was associated with increased skin toxicity. To confirm this preliminary observation, we tested this observation retrospectively. Since both these drugs can induce hypomagnesemia, the possibility of synergism between them was also tested.

Methods: The files of patients with metastatic colorectal carcinoma (mCRC) or head and neck (H&N) carcinoma treated at our center with cetuximab as a single agent or in combination with chemotherapy or radiotherapy were reviewed. All eligible patients treated with cetuximab during 2015 and 2016 were included in the study. The concomitant use of PPIs was defined if a drug belonging to that class was included in the patient's chronic medications list.

Results: One hundred eighteen patients (61 with H&N carcinoma, 57 with mCRC) were included in the study. Median follow-up from onset of cetuximab was 12.6 months [range, 0.5-63.2 months]. Fifty-eight patients received PPIs concomitantly with cetuximab. Skin toxicity of any grade was reported in 33/58 (56.9%) patients on PPIs compared with 22/60 (36.7%) patients not on PPIs ($p = 0.08$). Grade 3-4 skin toxicity was reported in 19/58 (32.8%) patients on PPIs compared to 2/60 (3.3%) not on PPIs ($p = 0.001$). Median time to detection of severe skin toxicity was 0.7 months [range, 0.2-11.0 months]. Hypomagnesemia (Mg serum level <1.2 mg/dL) was reported in 14/58 (25.9%) PPIs treated patients compared with 5/60 (10.4%) patients not on PPIs as a chronic medication ($p = 0.08$). Median time to detection of hypomagnesemia was three months [range, 0.4-52.8 months]. Complications of all grade skin toxicity or hypomagnesemia were reported in 40/58 (69%) patients on PPI compared to 23/60 (38.3%) patients not on PPIs ($p = 0.04$). Grade 3-4 skin toxicity or hypomagnesemia (Mg < 0.9mg/dL) were reported in 23/58 (39.7%) patients on concomitant treatment with PPIs compared with 3/60 (5%) patients not on PPIs ($p = 0.001$).

Conclusions: Both the rate and the severity of cetuximab-induced skin toxicity and hypomagnesemia were increased by chronic concomitant administration of PPIs. A prospective study is needed to confirm the possible interaction between cetuximab and PPIs.

1582P NeuroCog-FX study: A multicenter cohort study on cognitive dysfunction in patients with early breast cancer

O. Rick[1], M. Reuß-Borst[2], T. Dauelsberg[3], H. Hass[4], V. König[5], R. Caspari[6], G. Götz-Keil[7], J. Pfitzner[8], C. Kerschgens[9], K. Fliessbach[10], C. Hoppe[10]
[1]Oncological Rehabilitation, Klinik Reinhardshoehe, Bad Wildungen, Germany, [2]Oncological Rehabilitation, Klinik am Kurpark, Bad Kissingen, Germany, [3]Oncological Rehabilitation, Winkelwald Klinik, Nordrach, Germany, [4]Oncological Rehabilitation, Klinik Scheidegg, Scheidegg, Germany, [5]Oncological Rehabilitation, Klinik Oexen, Bad Oeynhausen, Germany, [6]Oncological Rehabilitation, Bayerwaldklinik, Cham, Germany, [7]Bad Nauheim, Klinik am Kurpark, Bad Nauheim, Germany, [8]Oncological Rehabilitation, Klinik Graal Müritz, Graal Müritz, Germany, [9]Oncological Rehabilitation, Vivantes Klinikum, Berlin, Germany, [10]Neurology, University Bonn, Bonn, Germany

Background: Many breast cancer patients complain about cognitive dysfunction (CD) with mnestic and attentional deficits. These complaints persist even after completion of therapy in approximately one third of the patients and affects both social life and working capacity. The exact nature and genesis of CD in breast cancer patients is still not fully understood and risk factors are not yet described.

Methods: To determine CD and risk factors, we used the computer-based neuropsychological test NeuroCog-FX during a three weeks oncological rehabilitation in breast cancer patients. Eight subtests addressed attention, working memory, verbal and figural memory, and language. Test duration was <30 minutes. A cognitive deficit was diagnosed if at least one subtest was clearly below average (score < M - 1.5 SD) of the normative age group. The data on cognitive function were correlated with the level of depression (PHQ-9 test), QoL (EORTC QLQ-30) and clinical parameters (nodal status, chemo-/radiotherapy and endocrine therapy).

Results: From February 2013 to December 2014 a total of 476 patients were recruited in 9 oncological rehabilitation centers in Germany. NeuroCog-FX was used to examine 439 patients. Median age was 50 years (range: 24-62 years); 93% of patients had early tumor stage (T0-T2) and 67% were node-negative. Sixty-one percent of the patients received chemotherapy while 84% of the subjects underwent radiotherapy. CD was found in 59% and a moderate to severe depression in 38% of the patients. The severity of depression was correlated with slower reaction times and reduced verbal memory performance. These two cognitive parameters were also associated with a reduced global health status and a reduced physical function score on the EORTC-QLQ30 questionnaire suggesting an impact of cognitive deficits on quality of life. Cognitive function was not associated with type of treatment or node status.

Conclusions: In this large and homogeneous cohort of breast cancer patients, CD has been shown in most of the subjects using a valid test method. CD was associated with depression and reduced quality of life. Neither tumor therapy nor other clinical parameters had a significant impact on development of CD.

1583P Autonomic neuropathy in geriatric patients with gynecologic cancer receiving taxanes and platinum chemotherapy

G.S. Bhattacharyya[1], G. Babu[2], P.M. Parikh[3], A. Vora[4], G. Biswas[5], H. Malhotra[6]
[1]Medical Oncology, Salt Lake City Medical Center, Kolkata, India, [2]Medical Oncology, Kidwai Memorial Institute of Oncology, Bangalore, India, [3]Medical Oncology, ICON, Mumbai, India, [4]Medical Oncology, Max Healthcare, New Delhi, India, [5]Medical Oncology, Sparsh Hospital and Critical Care, Bhubaneshwar, India, [6]Medical Oncology, SMS (Sawai Man Singh) Medical College & attached Hospital, Jaipur, India

Background: The standard of care for ovarian cancer in elderly is using paclitaxel and carboplatin, an effective and efficient combination, but has serious toxicities. Peripheral neurotoxicity is one of the commonest toxicities which are seen occurring in 60% to 90% of patients. It is debilitating and vexing. Unfortunately, there is very little or no data regarding autonomic neuropathy in this setting. This study is an attempt to highlight this problem.

Methods: Single center cohort study of patients for the period 2013-2015. All patients were above the age of 65 years. 88 patients were tested for. All patients were screened for neuropathy using standard forms and methods including positional sense and stereognostic sense for neuropathy. NCI scales of grading peripheral neuropathy were followed. Autonomic neuropathy assessments were done by cardio vascular autonomic reflex test and gastro-intestinal autonomic neuropathy by using gastric phase emptying test. Genito-urinary autonomic neuropathy was tested for erectile dysfunction and bladder dysfunction. The tests were administered at baseline after 2nd, 4th and 6th cycle or if the patient complained of suggestive symptoms.

Results: 37% of patients developed grade 3/4 peripheral neuropathy. 59% of patients developed symptomatic autonomic neuropathy. Cardio vascular autonomic neuropathy occurred in 30% while gastric neuropathy was seen in 19%. Combined was seen in 10%. Constipation, diarrhoea and reeling of head were the most common complaints. Autonomic neuropathy was more common in diabetics 60% vs 48% ($p > 0.05$). Attempts to intervene using pharmacotherapy methods and non-pharmacotherapy methods were attempted.

Conclusions: Autonomic neuropathy seems to be common in geriatric population treated by this drug combination although there is not much mention either in real life or in clinical trials or if available as data attributed to other causes. Caution must be exerted in patients in diabetics and proper screening should be done in this patient population for autonomic neuropathy and peripheral neuropathy.

1586P Potential drug interactions in older patients with cancer: Updated data from the ELCAPA cohort survey

G. Beinse[1], D. Reitter[2], L. Segaux[3], M. Carvalho-Verlinde[2], C. Tournigand[4], B. Rousseau[4], T. Cudennec[5], E. Paillaud[6], F. Canouï-Poitrine[3], P. Caillet[1]
[1]Geriatric Oncology, Centre Hospitalier Universitaire Henri-Mondor, Créteil, France, [2]Department of Pharmacy, Centre Hospitalier Universitaire Henri-Mondor, Créteil, France, [3]Public Health, Centre Hospitalier Universitaire Henri-Mondor, Créteil, France, [4]Medical Oncology, Centre Hospitalier Universitaire Henri-Mondor, Creteil, France, [5]Geriatric Oncology, Centre Hospitalier Universitaire Ambroise Paré, Boulogne-Billancourt, France, [6]Geriatrics, Centre Hospitalier Universitaire Henri-Mondor, Créteil, France

Background: Because of polypharmacy, older cancer patients are at risk of adverse events related to potential drug interactions (PDI). We aim to identify PDI in daily medications, between daily medications and chemotherapy (CT), and related potential clinical outcomes (PCO).

Methods: All cancer patients aged ≥70 years, referred for geriatric assessment at Henri Mondor Hospital (Paris' area, Créteil, France), included in the prospective ELCAPA cohort survey (2007–2014), and who received CT were included. PDI were identified using Lexicomp® (LexiComp, Hudson, USA) software and the Theriaque® website. PDI were classified as: A, no interactions; B, no action needed; C, monitor therapy; D, consider therapy modification; X, avoid combination. Factors associated with grade C or D/X PDI were analyzed using ordered multivariate logistic regression.

Results: We analyzed 442 patients (median age: 78 years; 49% women). Main tumor sites were upper digestive tract (23%), colorectal (21%), urological tract (19%), lymphoid malignancies (15%), and breast (12%); 23% had metastasis. Median number of drugs/patients/day was 3 (Q1-Q3 [1-6]). We identified 1742 PDI: 87% in daily medications (183 patients had grade C PDI (41%), 128 grade D/X (29%)), and 13% between daily medications and CT (66 patients had grade C PDI (15%), 56 grade D/X PDI (13%)). Main PCO involving daily medications were hypotension risk (33%), psychotropic effects (17%), glycemic (12%) and hemostasis (9%) dysregulations. Main PCO related to PDI involving CT were risk of CT over-exposure (34%), hypotension risk (20%), and hemostasis dysregulation (11%). In multivariable analysis, adjusted for

number of drugs, factors associated with grade D/X PDI, both with or without CT were: ≥2 metastatic sites ($p = 0.01$) and lymphoid malignancies ($p = 0.01$). Patients living alone had less grade D/X PDI in daily medications ($p = 0.003$), while breast cancer ($p = 0.04$) was associated with more grade D/X PDI in daily medications. Higher body mass index was associated with grade D/X PDI involving CT ($p = 0.03$).

Conclusions: The high prevalence of PDI in older cancer patients highlights the need to assess precisely the iatrogenic risk before anti-cancer treatment.

Background: Many cancer patients experience transient exacerbations of severe pain, known as breakthroughcancer pain (BTcP), a complex pain state that negatively impacts patients' quality of life. We evaluated the knowledge of BTcP management according to the Spanish Society of Medical Oncology (SEOM) clinical practice guideline.

Methods: Fundación ECO (Foundation for Excellence and Quality in Oncology) conducted a survey regarding knowledge of managing BTcP focusing on: awareness of SEOM guidelines, agreement with recommendations, and implementation in clinical practice.

Results: A total of 83 oncologists responded: 65% were female, mean age was 40-year-old and mean time in practice was 13 years. Overall, 82% were aware of guidelines and the agreement with recommendations ranged from 99-100%. Regarding implementation, 87.6% declared full compliance, nonetheless adherence in clinical practice ranged from 30.1% to 86.7% for documentation of BTcP episodes in medical records, and 75.9% to 91.6% for therapeutic management.100% of oncologists agreed on the prescription of specific medication for BTcP and most of them (91.6%) that rapid onset fentanyl formulations should be considered the first line of treatment.

Conclusions: Our results support efforts and targeted education of medical oncologists in BTcP management. However, our study raises concerns about guidelines dissemination deficiencies as well as vague statements that underscore a need for more effective dissemination policy and more effective detailed recommendations.

1588P Enhanced supportive care in early phase clinical trials

N. Cook[1], L. Carter[1], S. Aruketty[1], C. O'Brien[1], F. Thistlethwaite[1], E. Dean[1], M. Krebs[1], M. Warren[2], R. Berman[2]

[1]Experimental Cancer Medicine Team, Christie NHS Trust/University of Manchester, Manchester, UK, [2]Supportive Care Team, The Christie NHS Foundation Trust, Manchester, UK

Background: Enhanced Supportive Care (ESC) is a fresh approach to supporting patients through cancer treatment and recognised nationally by NHS England. The Supportive Care Team (SCT) and Experimental Cancer Medicine Team (ECMT) at the Christie Hospital applied the validated 'Integrated Palliative care Outcome Scale' (IPOS; http://pos-pal.org/) in a pilot study examining the impact of ESC for patients (pts) entering early phase clinical trials. The main aims of this study were to maximise patient recruitment and retention and enhance the patient experience within the context of experimental cancer medicine clinical trials.

Methods: The IPOS tool was used to assess the effect of ESC on patient outcomes in pts on an ECMT trial. It was administered by the SCT healthcare professionals to any pts with baseline symptoms thought to be related to their underlying cancer diagnosis and at all pt visits as per trial protocol. Analysis is based on patient data where both an initial and subsequent form had been completed. Three aspects of the IPOS tool were reviewed; the overall IPOS score, the score for all symptoms as a whole and individual pain score.

Results: Data was collected from 24 pts within ECMT trials during a four-month period in 2016. The mean age was 56 years (31 to 79); 10 male and 14 female. Performance status at initial assessment was 0 (3 pts); 1 (18 pts); 2 (1 pt); unknown (2 pts). 16 pts had no previous contact with SCT services. The commonest reason for referral to the SCT was for optimisation of pain control (24/24 pts) followed by general symptom control (8/24) and psychological issues (2/24). 21 pts were seen on the day of referral, 3 pts seen ≤ 8 days of referral. 16/24 pts (67%) reported improvement in pain (and IPOS scores) within 4 weeks and 17/24 pts (71%) reported improvement in overall symptom control within 4 weeks.

Conclusions: This study has demonstrated the effectiveness of ESC on the outcomes of patients being reviewed by the SCT on ECMT clinical trials. There were considerable reductions in the overall IPOS scores and in pain score specifically. ESC has now been adopted into routine practice by our ECMT, and we are the first unit to do so in the UK. We next plan to measure the impact of ESC on patient experience, adverse events on trials, hospital admissions and treatment duration.

1589P Cancer patient interest and perceptions of lifestyle behavior programs

L. Eng[1], S. Liu[2], Q. Zhang[3], D. Farzanfar[1], S. Yeung[1], C.M. Brown[2], W. Xu[4], D. Howell[2], D.P. Goldstein[5], J.M. Jones[1], P. Selby[6], M.E. Giuliani[7], G. Liu[1]

[1]Department of Medical Oncology and Hematology, Princess Margaret Hospital, Toronto, ON, Canada, [2]Department of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University of Toronto, Toronto, ON, Canada, [3]Department of Biostatistics, Princess Margaret Cancer Centre, Toronto, ON, Canada, [4]Department of Biostatistics, Ontario Cancer Institute, Princess Margaret Cancer Centre, University of Toronto, Toronto, ON, Canada, [5]Otolaryngology-Head and Neck Surgery, Princess Margaret Cancer Centre, Toronto, ON, Canada, [6]Addictions, Centre for Addiction and Mental Health, Toronto, ON, Canada, [7]Department of Radiation Oncology, Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: Lifestyle behaviors including smoking cessation, physical activity (PA) and alcohol moderation are important aspects of a cancer survivorship program. We assessed cancer patient (pt) interest and perceptions of programs for these behaviours.

Table: 1587P

CPG AWARENESS 81.93% (68/83)	AGREEMENT	IMPLEMENTATION (in medical records)	IMPLEMENTATION (ranked drug of choice characteristics)
SEOM 97.1%	100% documentation	Episodes (n) 73.5%	Rapid onset
ESMO 63.2%	99% best evidence	Pain intensity 66.3%	High potency
NCCN 58.8%	99% specific medication	Duration 45.8%	Short duration
Instit 19.1%	99% fentanyl 1st choice	Time to peak 30.1%	Route of administration
Other 7.3%		Triggers 75.9%	Ease of use
		Relief strategies 73.5%	Minimum side effects
		Etiopathogenia 86.7%	

Table: 1589P

Program	% at risk interested in program	Believe Program is Beneficial			Believe in Routine Care Program		
		Agree	aOR of being interested (95% CI)	*P*	Agree	aOR of being interested (95% CI)	*P*
Smoking Cessation	53%	57%	2.85 (1.0-7.9)	0.04	63%	4.80 (1.7-13.9)	0.004
Household Smoking Cessation	37%	55%	2.73 (1.1-6.7)	0.03	58%	4.60 (1.8-11.9)	0.002
PA	53%	70%	4.73 (2.5-9.0)	< 0.001	71%	3.33 (1.8-6.3)	< 0.001
Alcohol Moderation	25%	55%	2.54 (1.3-5.1)	0.01	61%	2.27 (1.2-4.6)	0.02

Methods: 501 cancer pts from all subtypes were surveyed on their smoking, PA and alcohol consumption patterns along with their interest and perceptions for programs for these behaviors. Multivariable logistic regression models identified factors associated with pt interest and perceptions.

Results: At diagnosis, 115 pts smoked; 41% had second hand smoke (SHS) exposure; 238 were drinking alcohol; 313 did not meet PA guidelines. At risk individuals' (e.g, smokers for smoking cessation, exposed to SHS for household smoking cessation) survey results are shown in the table. Perceptions of how these behaviors impact quality of life, survival and fatigue was not associated with program interest ($P > 0.05$). However, pts perceiving that alcohol worsened and PA improved these outcomes were more to likely believe associated programs are beneficial (alcohol aORs = 2.1-2.2 $P < 0.03$; PA aORs = 1.9-3.2 $P < 0.02$) and should be routine care (alcohol aORs = 1.9-3.5 $P < 0.03$; PA aORs = 1.7-2.4 $P < 0.1$). Pts with more pack-yrs less likely perceived benefit in a household cessation program (aOR = 1.02 $P < 0.007$) or in a routine care program (aOR = 1.01 $P < 0.02$). Pts preferred discussing programs with doctors (35%+) or counsellors (42%+).

Conclusions: About half of pts feel that lifestyle behavior programs would be beneficial and should be part of routine care. These factors were more important than perception of the behaviors on outcomes in influencing pt interest. Initial discussions with pts should focus on discussing benefits of these programs.

1590P The investigate relationship between severe neutropenia and ABCB1and ABCG2 gene polymorphisms with esophageal cancer patients receiving docetaxel, cisplatin and 5-fluorouracil chemotherapy

H. Nomura[1], D. Tsuji[2], K. Demachi[1], S. Suzuki[1], N. Mochizuki[1], T. Yano[3], H. Daiko[4], S. Fujii[5], T. Kojima[6], K. Ito[2], M. Yamaguchi[1]

[1]Pharmacy, National Cancer Center Hospital East, Kashiwa, Japan, [2]Clinical Phrmacology & Genetics, University of Shizuoka, Shizuoka, Japan, [3]Gastroenterology, Endoscopy Division, National Cancer Center Hospital East, Kashiwa, Japan, [4]Esophageal Surgery, National Cancer Center Hospital, Chu-o, Japan, [5]Pathology, Exploratory Oncology Research and Clinical Trial Center, National Cancer Center, Kashiwa, Japan, [6]Gastrointestinal Oncology, National Cancer Center Hospital East, Kashiwa, Japan

Background: The combination of docetaxel, cisplatin and 5-fluorouracil (DCF) is a newly developed chemotherapy for esophageal cancer (EC) patients (pts). Severe neutropenia is one of the major adverse events that necessitate chemotherapy dose reduction. This study aimed to investigate relationship between grade 3 and 4 neutropenia and genetic polymorphisms in EC pts received DCF.

Methods: EC pts who had undergone DCF chemotherapy at National Cancer Center Hospital East from August 2011 to December 2016 were enrolled in this study. Prophylactic administration of granulocyte-colony stimulating factor was not conducted for the all EC pts during the above chemotherapy. Seven polymorphisms in the genes encoding docetaxel-metabolizing enzymes and transporters were genotyped, and then relationship between these genotypes and the grade 3 and 4 neutropenia was then investigated. Risk factors that enable to predict grade 3 and 4 neutropenia after first cycle of chemotherapy were explored using multivariate logistic regression analysis.

Results: A total of 170 pts treated with DCF were enrolled in this study period. The median age was 64 years, median body mass index was 22.0 (15.3 - 31.0), median serum hemoglobin level was 13.5 (8.7 - 17.1) g/dL, median prognostic nutritional index was 50.1 (36.7 - 68.7) and baseline absolute neutrophil count (ANC) was 4305 (1660 - 11020)/mm^3. The proportion of pts with grade 3 and 4 neutropenia was 56 (32.9%) and 34 (21.2%), respectively. Multivariate logistic regression analysis adjusted for potential risk factors revealed *ABCB1* 3435C > T ($p = 0.015$), *ABCG2* 34G > A (p=0.044), age (60<) ($p < 0.001$) and baseline ANC (< 4305) ($p = 0.001$) were independent and significant risk factors for grade 3 and 4 neutropenia.

Conclusions: We identified that genetic polymorphisms in ABCB1 3435 C > T and ABCG2 34 G > A was a significant predictor for grade 3 and 4 neutropenia of EC pts receiving DCF.

1591P Hepatitis B and C reactivation rates due to cytotoxic chemotherapy in patients with solid tumors

M. Karaca[1], D. Tural[2], I. Cil[2], G. Ozet[3], O.K. Yucel[4], A. Ozet[1]

[1]Department of Medical Oncology, Gazi University Medical School, Ankara, Turkey, [2]Department of Medical Oncology, Istanbul Bakirkoy Dr Sadi Konuk Education and Research Hospital, Istanbul, Turkey, [3]Department of Haematology, Yildirim Beyazit University, Ankara, Turkey, [4]Department of Haematology, Akdeniz University, Antalya, Turkey

Background: We tried to determine the incidence of the reactivation rates of chronic HBV and HCV infections in cancer patients who received different types of chemotherapy or immunosuppressive therapy. Also we tried to identify the chemotherapy regimens though to be associated with this reactivation of chronic HBV and HCV infections.

Methods: Between 2000 and 2014, 8322 cancer patients who were admitted to oncology departments were evaluated retrospectively and 3890 patients in whom hepatitis serology were available were included in this study. Their mortality rates, chemotherapy regimens, cancer types, number of positive hepatitis serology and reactivation rates were also obtained.

Results: In all 8322 cancer patients, only 3890 (47%) patients had hepatitis serology results and 355 patients had positive hepatitis serology results (HBsAg, anti-HBcAg, anti-HCV). Of them, 4.24% had anti-HBcAg positivity, 3.65%had HBsAg positivity, and 1.23% had anti-HCV positivity. Nineteen patients with HBsAg positive (13.38%), 4 patients with anti-HBcAg positive (2.42%), and 2 patients with anti-HCV positive (4.16%) had reactivation. hepatitis reactivation was seen significantly higher in lymphoma patients ($p = 0.032$). Reactivation rate of hepatitis B in those patients (HBsAg positive) was detected as 57.14%. In patients with hepatitis reactivation, the rates of usage of 5-FU, cisplatin, cyclophosphamide, doxorubicin, steroid, rituximab, and vincristine were determined as significantly higher than patients with positive hepatitis serology results but without hepatitis reactivation ($p > 0.05$ for all).

Conclusions: An association between hepatitis reactivation and the usage of 5-FU, cisplatin, cyclophosphamide, doxorubicin, steroid, rituximab, and vincristine was detected. Thus physicians should consider antiviral prophylaxis before initiating these chemotherapeutics.

1592P Meta-analysis of individual patient safety data from six randomized, placebo-controlled trials with the antiangiogenic VEGFR2-binding monoclonal antibody ramucirumab

D. Arnold[1], C.S. Fuchs[2], J. Tabernero[3], A. Ohtsu[4], A.X. Zhu[5], E.B. Garon[6], L. Paz-Ares[7], A.D. Baron[8], T. Okusaka[9], T. Yoshino[4], H.H. Yoon[10], M. Das[11], D. Ferry[12], Y. Zhang[12], Y. Lin[11], P. Binder[12], A. Sashegyi[11], I. Chau[13]

[1]Oncology, Instituto CUF de Oncologia (I.C.O.), Lisbon, Portugal, [2]Internal Medicine, Yale Cancer Center, Yale School of Medicine, New Haven, CT, USA, [3]Medical Oncology Department, Vall d'Hebron University Hospital and Institute of Oncology (VHIO), Barcelona, Spain, [4]Department of Gastrointestinal Oncology, National Cancer Center Hospital East, Kashiwa, Japan, [5]Department of Medicine, Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA, USA, [6]Hematology Oncology, David Geffen School of Medicine at UCLA/Translational Research in Oncology-US Network, Santa Monica, CA, USA, [7]Medical Oncology Department, Hospital Universitario Doce de Octubre, Madrid, Spain, [8]Division of Hematology Oncology, California Pacific Medical Center, San Francisco, CA, USA, [9]Department of Hepatobiliary and Pancreatic Oncology, National Cancer Center Hospital, Tokyo, Japan, [10]Division of Medical Oncology, Mayo Clinic, Rochester, MN, USA, [11]Oncology, Eli Lilly and Company, Indianapolis, IN, USA, [12]Oncology, Eli Lilly and Company, Bridgewater, NJ, USA, [13]Deaprtment of Medicine, Royal Marsden Hospital, Sutton, UK

Background: Ramucirumab, a human IgG1 monoclonal antibody receptor antagonist of vascular endothelial growth factor receptor 2 (VEGFR-2), has been approved for treatment in gastric/gastroesophageal junction, non-small cell lung, and metastatic colorectal cancers. A total of 6 global, randomized, double-blind, placebo-controlled, phase 3 trials across multiple tumor types and a large patient population have currently been completed. To further establish the safety profiles of ramucirumab, a meta-analysis has been performed based on the data from these 6 trials and the results are presented here.

Methods: Fixed-effects or mixed-effects models were used to conduct an individual patient meta-analysis across the 6 completed phase 3 trials and derive the relative risk (RR) and associated 95% confidence intervals (CIs) for all-grade and high-grade (Grade $\geq$3) adverse events (AEs) possibly related to VEGF pathway inhibition.

Results: This meta-analysis included a total of 4996 treated patients (2748 patients in ramucirumab arms, 2248 in control arms). Proteinuria, gastrointestinal (GI) perforation, hypertension, wound-healing complications, infusion-related reactions, and low-grade (Grade 1-2) bleeding were observed at a higher percentage in the ramucirumab arms compared to control. However, our data did not demonstrate a definite increased risk with ramucirumab in high-grade bleeding (RR: 1.1, 95% CI 0.8-1.5), high-grade GI bleeding (RR: 1.1, 95% CI 0.7-1.7), venous thromboembolic events (VTE, all-grade, RR: 0.7, 95% CI 0.5-1.1; high-grade, RR: 0.7, 95% CI 0.4-1.2), or arterial thromboembolic events (ATE, all-grade, RR: 0.8, 95% CI 0.5-1.3; high-grade, RR: 0.9, 95% CI 0.5-1.7).

Conclusions: The risk of developing certain AEs with ramucirumab is consistent with other antiangiogenic agents; and, the safety profile is consistent with the ramucirumab labels. Our results showed no clear evidence for an increased risk of high-grade bleeding, high-grade GI bleeding, VTE, or ATE in this large and patient level meta-analysis.

1593P The preventive role of intravenous L-alanyl L-glutamine in reducing the incidence of oral mucositis in head and neck cancer patients receiving radiotherapy with or without chemotherapy

A.M. Elfeky, N. Sabry, A. Barakat

Clinical Oncology and Nuclear Medicine, Tanta University Hospital, Tanta, Egypt

Background: The current prospective comparative phase 2 study aimed to assess the role of intravenous L-alanyl L-Glutamine in reducing the rate of oral mucositis for squamous head and neck cancer patients receiving radiotherapy with or without concurrent chemotherapy.

Methods: From September 2014 to Septemper 2016, 100 head and neck cancer patients were treated with radiotherapy or combined chemo-radiation at the Clinical Oncology Department, Tanta University Hospitals. Patients were randomized in 1:1 ratio into Group A (n = 50 patients) treated by radiotherapy or concurrent chemo-radiotherapy and Group B (n = 50 patients) to receive same treatment in addition to intravenous Glutamine. The investigational drug was infused daily at dose of 0.3-0.4 g/kg diluted in NS and administered at rate of 0.1g/Kg/hr. All patients received total dose of 65-70 Gy using Linac 6MV photon beam supplemented with electron beam when needed. For concurrent chemotherapy, Cisplatin (40mg/m2) was administered weekly.

Results: Mucositis was assessed by WHO grading system. A significantly higher incidence of mucositis was reported in 45% of Group A patients compared with patients in group B who received glutamine 10% $P < 0.001$). Group B patients had significantly longer period free from mucositis in comparison to group A with median time (12 weeks vs 8 weeks) $P < 0.001$. A significant lower rate of radiotherapy interruption was reported in group B compared to group A (50% vs 15%) $P < 0.001$. More Patients needed hospitalization in group A (20%) vs (5%) in group B $P = 0.059$. No adverse effects were observed in relation to glutamine.

Conclusions: Intravenous L-alanyl L-Glutamine may be an effective measure to lower incidence or prevention of oral mucositis in head and neck cancer patients treated by radiotherapy or combined chemo-radiation.

1594P Biosimilar epoetin alfa (HX575) for the treatment of chemotherapy-induced anaemia: Development, approval and 10 years' clinical experience

M.S. Aapro[1], A. Krendyukov[2], N. Höbel[3], A. Seidl[4], P. Gascón[5]

[1]Cancer Center, Clinique de Genolier, Genolier, Switzerland, [2]Oncology Biosimilars, Hexal AG, Holzkirchen, Germany, [3]Biostatistics Medical Affairs/Late Phase, Hexal AG, Holzkirchen, Germany, [4]Bioanalytics, Hexal AG, Overhaching, Germany, [5]Department of Hematology-Oncology, Hospital Clínic de Barcelona, Barcelona, Spain

Background: Patent expirations for biological products have prompted the development of biosimilars, which have comparable quality, safety and efficacy to a licensed biological medicine (the 'reference' medicine). HX575 (Binocrit®, epoetin alfa biosimilar) was approved in Europe in 2007 for the treatment of chemotherapy-induced anaemia (CIA).

Methods: The development and approval of HX575 included extensive analytical characterisation and comparison with the reference epoetin alfa, followed by a clinical development programme; this included phase I pharmacokinetic/pharmacodynamic studies to show bioequivalence to the reference medicine, and a confirmatory phase III study to confirm therapeutic effectiveness in CIA. Since approval, HX575 has been extensively used in real-world clinical practice.

Results: An array of analytical methods confirmed the similarity of HX575 and the reference epoetin alfa in terms of primary protein structure, higher-order protein structure, isoform pattern, post-translational modifications, receptor binding and biological activity. Phase I studies showed that HX575 and the reference medicine were bioequivalent following intravenous and subcutaneous administration. In a confirmatory phase III study (n = 114), HX575 was effective in treating CIA in cancer patients, and had a safety profile consistent with the therapeutic class and as expected for the therapeutic area. Post-approval data are also available for a range of cancer types; positive results have been reported from a multi-centre retrospective clinical study, single-centre experiences from several countries, and a large-scale prospective observational study. No additional/unexpected safety issues have emerged after 10 years of pharmacovigilance. A pilot study has suggested that HX575 may also be effective for the treatment of anaemia in low-/intermediate-1 risk myelodysplastic syndromes.

Conclusions: As of Feb 2017, HX575 has generated >252,000 patient years' experience in CIA worldwide. Accumulated data and experience over a decade are reassuring that

HX575 is effective and well tolerated for the treatment of CIA in patients with different cancer types.

1595P Experience with the implant of vascular access devices by medical oncologist in a non-surgical scenery

A. Revuelta[1], D. Rodríguez Rubí[2], M.L. Sánchez Lorenzo[3], L. Ruiz Echeverria[4], W. Li[1], M.P. Solís Hernández[1], L. Fáez García[1], S. Fernández Arrojo[1], C. Iglesias Gómez[2], N. Villanueva Palicio[1], P. Jimenez Fonseca[1], M. Luque Cabal[1], C. Álvarez Fernández[1], M. Izquierdo[5], J.M. Viéitez[1], E. Esteban[1]

[1]Medical Oncology, Hospital Universitario Central de Asturias, Oviedo, Spain, [2]Oncología Médica, Centro Médico Asturias, Oviedo, Spain, [3]Medical Oncology, MD Anderson Cancer Center Madrid, Madrid, Spain, [4]Medical Oncology, Hospital de Burgos, Burgos, Spain, [5]Medical Oncology, Hospital de Cabueñes, Gijón, Spain

Background: Totally implantable central venous catheters are widely used in the management of patients (pts) with malignant diseases in order to facilitate drug delivery for the new therapeutic protocols. These are based on continuous administration and higher doses of chemotherapeutic agents with relative phlebitis problems and supportive treatment. Staff of our department, specially trained on the routinely implant of central venous accesses were in charge of the procedure. The technique was carried out under local anesthesia in a special suite of day hospital, under strict aseptic measures without fluoroscopic control.

Methods: From Sep 94 to January 2017, 1665 devices (port-a-cath systems [PS]) were implanted in 1627 pts, with a median age of 50.5 yr (range 14-81), and median K.I. 70% (50-100), female 982/male 683. Venous access: right interior jugular 983, left subclavian 316, right subclavian 333, left interior jugular 33. A thorax X-ray was performed after each procedure and in 216 pts prophylactic antibiotics were given.

Results: The venous access remained implanted a median of 438 days (1- +2210). Complications occurred in 266 placements (16%): Infections 116 (7%); deep venous thrombosis 66 (4%) obstruction 10 (0.6%); malpositioned 16 (2%); fractures/migration 28 (1.7%); pneumothorax 6 (0.32%); local skin necrosis 7 (0.6%). Five hundred and twenty devices were removed, three hundred and forty-seven (66%) after completing planned therapy and 173 (34%) due to complications [Infections (92), migration (22), malposition (12), venous thrombosis (26), obstruction (11) and skin necrosis (10)]. Cost-effectiveness of venous catheters in a non-surgical scenery compared to devices implanted by interventional vascular radiologists in operating room turned out to be 1000 euro cheaper for each device.

Conclusions: Our experience suggests that implant of vascular access devices by medical oncologist in a non-surgical scenery has similar or even less complications and is more cost effective with regard to radiology suite and operating room placement procedures.

1596P Management of chemotherapy-related side effects- do patients know where to get help?

R. Prince[1], E. Amir[1], S. Blacker[2], S. McEwen[3], M. Morey-Hollis[3], C. Mothersill[2], U. Saha[1], L. Wayment[4], M. Wyatt[1]

[1]DMOH, Princess Margaret Hospital, Toronto, ON, Canada, [2]Medical Oncology, St Michael's Hospital, Toronto, ON, Canada, [3]Medical Oncology, St Joseph's Health Centre, Toronto, ON, Canada, [4]Medical Oncology, Sinai Health System, Toronto, ON, Canada

Background: Timely access to oncology healthcare providers for advice about chemotherapy-related symptom management is a provincial priority in Ontario, Canada. The aim is for all chemotherapy patients to have access to an oncology care provider for urgent advice thereby reducing unscheduled visits such as emergency room (ER) attendance and hospitalizations which are common during chemotherapy. Here, we explore patients' knowledge about how to access urgent advice for side effects.

Methods: Between September and November 2016, 4 hospitals providing systemic therapy in Toronto, Canada (one academic & three community centers) performed a program evaluation for quality improvement purposes. A paper survey was developed. Patients with breast, lung, gastrointestinal, hematological cancers and sarcoma $\leq$4 weeks after their first chemotherapy cycle were questioned in chemotherapy day units. The survey explored patients' knowledge about where to get help for chemotherapy related side effects at different time points (weekdays 9am-5pm, weekdays 5pm-9am, weekends). Descriptive statistics and Chi square were used to describe results.

Results: A total of 140 surveys were administered to 32 lung, 38 breast, 39 GI, 22 hematology and 9 sarcoma patients. Overall, 81% of patients stated they knew where to go to get help for side effects; 56% of patients were told where to get help by a staff member, usually a nurse (44%) or oncologist (23%), while 19% reported they were not told where to get help by anyone. Across all time points the majority of patients stated they would present to ER for side effect management (41, 76 & 81% respectively). The only exception was the academic hospital where 69% of patients reported calling the clinic/nursing telephone line on weekdays 9am-5pm (comparison between academic and community centers $p < 0.001$). Qualitative analysis of comments revealed that patients want more resources and education in easily accessible formats and prefer to speak to a person rather than leaving voice messages.

Conclusions: Significant gaps in patient care and education are highlighted by these results. Site specific quality improvement projects are currently underway to address these findings prior to re-administering the survey.

1597P The effects of nurses' empathy skills on attitudes towards patients with cancer

A. Alkan

Medical Oncology, Osmaniye Public Hospital, Osmaniye, Turkey

Background: Empathy is sine qua non-ability of nurses and the positive effects of empathy on clinical management have been documented. In addition, its positive effects have also been reported in oncology practice. The purpose of this study is to evaluate the predictors of empathy skills and attitude towards cancer patients and association between nurses' empathy skills on attitudes towards patients with cancer.

Methods: A structured questionnaire was used to evaluate the nurses' empathy skills and their attitudes towards to patients with cancer. Jefferson Scale of Empathy(JSE) and Attitudes Towards Cancer Scale (ATCS) were used. The predictors of JSE/ATCS scores and correlation between JSE and ATCS were analyzed.

Results: 305 nurses participated in the study (84.2% of all nurses). The median age was 33 (20-52) and most of the nurses were female (82.6%). Most of the participants were married (188,61.6%) and 40.3% of nurses had an job experience more than 10 years. Female sex, being married, having job experience more than 10 years or caring more cancer patients were associated with higher JSE scores. Nurses caring more cancer patients weekly, experience with cancer patients, participation in educational activities about cancer care or presence of relative with a diagnosis of cancer were found to have more positive attitudes towards cancer patients. Spearman correlation analysis showed a positive, weak correlation between JSE and ATCS ($r = 0.017$, $p = 0.38$)

Conclusions: Empathy skills are important while caring patients, especially in oncology practice. Although a direct correlation between empathy skills and attitudes towards cancer patients couldn't be demonstrated, health care workers caring cancer patients should be both evaluated for empathy skills and educated.

1598P Can postponement of death be used in shared decision making in patients treated with adjuvant chemotherapy?

N.D. Trabjerg[1], T.F. Hansen[1], K.D. Steffensen[2], A. Jakobsen[1], L.H. Jensen[1]

[1]Department of Oncology Vejle Hospital, Center of Clinical Excellence, Danish Colorectal Cancer Center South Denmark, Vejle Hospital Sygehus Lillebaelt, Vejle, Denmark, [2]Department of Oncology Vejle Hospital, Center for Shared Decision Making, Institute of Regional Health Research, Faculty of Health Sciences University of Southern Denmark, Vejle, Denmark

Background: Standard adjuvant treatment to patients with stage III colon cancer is six months of adjuvant combination chemotherapy with a 5-fluorouracil derivate (5-FU) and oxaliplatin. In some cases, 5-FU monotherapy may be an option. The aim is to develop a different way of explaining the benefit of different treatment options by using the concept of "postponement of death".

Methods: We identified pivotal phase III publications about adjuvant treatment for stage III colon cancer. Data regarding overall survival was extracted for observation versus 5-FU monotherapy and combination chemotherapy versus 5-FU. Data about the impact of N1 and N2 category was extracted if available. Data was used for restricted mean survival analysis. Postponement of death was defined as the mean difference in survival time between the two randomized treatment arms. Survival curves was plotted

into the tool WebPlotDigitizer and the area under the curve (AUC) was calculated for each treatment.

Results: AUC for patients receiving 5-FU was 69.1 months and for combination chemotherapy 71.9 months. The mean survival difference at 10 years was 2.8 months. For the subgroup of patients with N1 category, the postponement of death was 0.5 months if treated with combination chemotherapy instead of 5-FU. For patients with N2 category the difference was 11.6 months when treated with combination chemotherapy compared to monotherapy. In the trial comparing 5-FU with observation, the AUC was 73.7 months and 63.3 months, respectively, at 8.5 years. The overall postponement of death between 5-FU and observation was 10.4 months not adjusted for N status.

Conclusions: Postponement of death can be calculated using restricted mean survival analysis and published survival curves. Patients with colon cancer stage III can be advised that up to 6 months of 5-FU will postpone death on average 10 months compared to observation alone. Adding oxaliplatin will postpone death an additional 3 months with no adjustment for N status. Oxaliplatin has minor effect in N1 category (2 weeks) and major effect in N2 category (12 months). Future studies should investigate how the concept of postponement of death can be implemented in daily clinical practice.

1599P Cancer patient attitudes and preferences towards smoking status assessment

L. Eng[1], S. Liu[1], Q. Zhang[2], D. Farzanfar[3], R. Milne[4], S. Yeung[3], C.M. Brown[3], D. Howell[2], W. Xu[5], D.P. Goldstein[6], J.M. Jones[3], P. Selby[7], M.E. Giuliani[4], G. Liu[3]

[1]Department of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University of Toronto, Toronto, ON, Canada, [2]Department of Biostatistics, Princess Margaret Cancer Centre, Toronto, ON, Canada, [3]Department of Medical Oncology and Hematology, Princess Margaret Hospital, Toronto, ON, Canada, [4]Department of Radiation Oncology, Princess Margaret Cancer Centre, Toronto, ON, Canada, [5]Department of Biostatistics, Ontario Cancer Institute, Princess Margaret Cancer Centre, University of Toronto, Toronto, ON, Canada, [6]Otolaryngology-Head and Neck Surgery, Princess Margaret Cancer Centre, Toronto, ON, Canada, [7]Addictions, Centre for Addiction and Mental Health, Toronto, ON, Canada

Background: Continued smoking after a cancer diagnosis is associated with poorer outcomes. As smoking cessation is an important part of cancer care, understanding cancer patient (pt) attitudes towards smoking status assessment will help with integrating smoking cessation programs into cancer care.

Methods: Cancer pts from all subtypes were surveyed on their smoking history, assessment rates and attitudes/preferences towards smoking status assessment. Multivariate logistic regression models helped assess for factors associated with screening preferences.

Results: Among 501 pts, 115 smoked at diagnosis and 60% quit after; 53% had a tobacco related (lung/head and neck) cancer (TRC); 64% were treated curatively; 40% reported that their smoking status was assessed only on their first clinic visit, while 32% were assessed at a few visits and 12% all visits. Most felt that smoking status should be assessed at the first visit (95%), while half (58%) felt it should be assessed every visit. Most felt comfortable with being assessed (96%), felt it was important for clinicians to be aware of smoking status (98%) and that smoking cessation discussions should occur at the first visit (87%). Most preferred being assessed by their oncologist (88%); less than half preferred being asked by another healthcare provider (44%), on paper (29%) or electronic surveys (32%). When compared to ex/never smokers, current smokers were assessed more often at every/most visits (36% vs 20% $P = 0.001$); fewer felt assessment should occur at the first visit (89% vs 97% $P = 0.008$) and were less comfortable with being assessed (88% vs 98% $P < 0.001$). Among current smokers, lung cancer pts were more agreeable (54%) to being assessed every visit compared to head and neck (aOR = 2.45 95% CI [0.9-6.5] $P = 0.06$) and non TRCs (aOR = 2.63 [1.0-6.8] $P = 0.05$). Among all, pts who are older (aOR = 1.03 [1.0-1.1]), curative (aOR = 1.92 [1.1-3.2]) and smoked less (aOR = 0.98 per pkyr [0.97-0.99]) were more agreeable to assessment at each visit.

Conclusions: Most cancer pts felt that assessment of smoking status was important, were comfortable with being assessed and preferred being assessed directly by their oncologist. Routine screening of those currently smoking is recommended to help with cessation.

1600P Optimizing Physician Surveys in Pharmacovigilance Using ecancer Online Community

J-J. Body[1], O. Nicolatou-Galitis[2], J.M. Sprafka[3], A. Stepto[4], R.A. Gleave[4], C. Hartley[4], D. Niepel[5], A. Liede[6]

[1]Dept of Medicine, CHU Brugmann ULB, Brussels, Belgium, [2]School of Dentistry, University of Athens, Athens, Greece, [3]Center for Observational Research, Amgen - USA, Thousand Oaks, CA, USA, [4]E-Learning, Ecancer, Bristol, UK, [5]Clinical Development, Amgen - Austria, Vienna, Austria, [6]Center for Observational Research, Amgen - USA, South San Francisco, CA, USA

Background: Physician knowledge surveys have increasingly been requested of drug manufacturers in the post-authorization setting as part of risk minimization plans. Surveys in pharmacovigilance require considerable time and resource, and result in low response rates and questionable representativeness. After EMA consultation, an educational programme was initiated with *e*cancer to evaluate the potential of online communities in measuring knowledge of drug safety risks. Here, we describe the baseline survey used to measure basic knowledge of osteonecrosis of the jaw (ONJ) risks among prescribers of bone targeting agents (BTAs).

Methods: Clinical experts developed 8 multiple choice questions on BTAs and ONJ risk as described in the summary of product characteristics. BTAs included denosumab, zoledronate, or pamidronate. Invitations were sent out to ecancer and ECCO members. Eligible were physicians who treated ≥5 new/continuing adult patients with bone metastases from solid tumours in the last 3 months (mos), currently practicing as an oncology specialist in the European Union, Switzerland or Norway, and prescribed a BTA in the last 12 mos. Responses for eligible and ineligible were compared.

Results: Among visits to the online survey, 87% completed the questions: 336 eligible/ineligible respondents from 52 countries, 292 from 26 European countries. Ineligibility was driven by the criterion of treating ≥5 patients in last 3 mos. Eligible respondents (n = 182) had higher level of correct responses than those who did not meet eligibility: mean 81% vs. 73% ($p < 0.01$) (Table). Question 3 yielded lowest correct responses on the topic of ONJ incidence as reported in BTA clinical trials.

Table: 1600P

Question Number	Eligible (n = 182), Correct Responses	Ineligible (n = 110), Correct Responses
1	83%	80%
2	93%	91%
3	52%	43%
4	85%	61%
5	91%	84%
6	80%	92%
7	81%	77%
8	85%	73%

Conclusions: Online professional communities offer a pragmatic and efficient approach for recruitment of physicians for knowledge assessments. Basic knowledge of ONJ risks was high overall in this ecancer proof of concept. The strategy can achieve responses representative of today's physicians who seek information online. These findings may be compared with knowledge among physicians who may not seek information online.

1601P Ideal cardiovascular health (ICVH) in patients with a recent diagnosis of colorectal cancer (CRC)

J. Ramos[1], A. Álvarez-Bustos[1], M. Soriano[1], B. Nuñez[1], J. Ros[1], P. Osorio[1], L. Gutierrez[1], R. Gómez[1], F. Hidalgo[2], A. Leon[2], M. Mendez[1], C. González[1], A. Sanchez[1], S. Martínez[1], I. Pagola[3], L. Brea[3], C. Fiuza-Luces[4], A. Lucia[2], A. Ruiz-Casado[1]

[1]Medical Oncology, Hospital Universitario Puerta de Hierro, Madrid, Spain, [2]Physiology, Universidad Europea de Madrid, Madrid, Spain, [3]Biomechanics, Universidad Europea de Madrid, Madrid, Spain, [4]Area 3, Research Institute I + 12, Madrid, Spain

Background: Cardiovascular events are an important cause of mortality in patients cured of colorectal cancer and are also potential complications of new therapies for metastatic CRC. The American Heart Association's "Simple 7" offers a practical public health conceptualization of cardiovascular health. They include healthy behaviours: non-smoking, active physical activity (MVPA > 150 min/w), healthy diet and low body mass index (BMI); and health factors: no hypertension, no diabetes, no hypercholesterolemia. Whereas factors are non-modifiable, behaviours can be changed. Studies have shown that prevalence of ideal cardiovascular health in the US is only 0.1%.

Methods: Patients with a recent diagnosis of CRC who accepted to participate were prospectively evaluated. BMI, blood pressure, glucose and cholesterol were measured at the hospital. Physical activity was objectively evaluated with accelerometers. Adherence to a healthy diet was evaluated through the PREDIMED (adherence to Mediterranean diet) questionnaire. Information about smoking and past cardiovascular disease or risk factors was obtained from the clinical record.

Results: 91 patients were recruited between March 15 and March 17. 36% were metastatic. Age 65 (25-81), 69% male 31% female, BMI 26.2 ±3.6, Waist 95,6 ±12 cm, mean MVPA 350±248 min/wk, mean sedentarism 3394±1123. 9% had a history of CV disease (ischemic, cerebrovascular, heart failure). 34% were classified as high CV risk. Only one patient showed an ICVH.

Table: 1601P

		Healthy behaviours				Health Factors		
ICVH	No CV history	Nonsmoking	BMI <25	Healthy Diet	MVPA	No HTA	No DM	No DL
1.1%	91%	90.5%	36%	67%	96%	51%	84.3%	66%

Conclusions: The prevalence of ICVH in a population of Spanish CRC patients was 1%. This population was overall compliant with PA recommendations, adhered to a healthy diet and less than 10% smoke in the last year. Hypertension was the most prevalent risk factor. Overweight was the most prevalent unhealthy behaviour. Interventions should be aimed at reducing BMI. Interventions exploring programs with vigorous physical activity and diet modifications in CRC survivors are warranted.

1602P Additive effect of vinca alkaloids as the risk factor for hearing impairments in the childhood cancer survivors

L.M-J. Cha, M. Huh, J.Y. Lim, S.M. Hahn, C.J. Lyu, J.W. Han

Department of Pediatric Hemato-Oncology, Yonsei Cancer Center, Seoul, Republic of Korea

Background: The survival rate of childhood cancer is approaching to over 80%, and survivorship is gathering more attention. The survivors receive chemotherapy, radiotherapy and surgery in their early life stages, and the risk of ototoxicity is increased. We evaluated the degree of risk of the clinical factors causing the ototoxicy, in childhood cancer survivors.

Methods: We established survivorship program for late effects in Yonsei Cancer Center, Seoul, Korea. In all 531 enrolled survivors in the clinic, 105 patients were invited to evaluate otoxocitity in their bi-annual visits and the clinical risk factors were reviewed retrospectively.

Results: The median age at diagnosis was 6.0 (0∼26). Most common diagnosis was leukemia/lymphoma (N = 30, 30%), and brain tumor was the next (N = 29, 29%). Platinum agents were used in 64%, alkylating agents was in 83% and vinca alkaloid was in 78%. Severe hearing impairments defined as over than 60 dB loss were observed in 37% of left ears and 39% of right ears. The proportion of the survivors who had 20 dB loss in any side of ears was 28%. The 69% of abdomen tumor survivors and 56% of brain tumors had any of hearing impairments, but only 28% of leukemia/lymphoma survivors showed hearing loss ($P < 0.001$). The class of platinum agents use, vinca alkoids were adverse factors, however, the class of antimetabolites use or antibiotics use were all protective factors for hearing impairments ($P < 0.001$, <0.001, 0.006, <0.001, respectively). Both use of platinum and vinca alkaloids showed significantly higher risk of hearing impairments compared with use of none or one class of two classes of agents ($P < 0.001$ for right ear and $P < 0.001$ for left ear). Young age at diagnosis (<7.5 years old) showed higher risk of hearing loss in abdomen tumor and brain tumor group ($P = 0.006$ for right, $P = 0.051$ for left). Total 5000 cGy or more of head and neck region radiation showed increased risk ($P = 0.001$ for right, $P = 0.007$ for left). In multivariate analysis, both use of platinum and vinca alkaloids was independent risk factor (O.R.=8.1, $P = 0.004$ for right; O.R.= 8.7, $P = 0.004$ for left).

Conclusions: Hearing impairments were common late effects in childhood cancer survivors, and vinca alkaloids had additive adverse effects on the platinum use for the hearing loss.

1603P Development and validation of chewing swallowing inventory (CSI) in head and neck cancer patients

Y-H. Lai

School of Nursing, National Taiwan University & Hospital, Taipei, Taiwan

Background: Chewing and swallowing dysfunction are the common problems in head and neck cancer patients. They may interfere patients' eating and lead to malnutrition. An easily used tool to assess the problems is needed. The purposes of the study were to (1) develop the Chewing Swallowing Inventory (CSI) and (2) examine the psychometric properties of CSI.

Methods: This is an instrument development and testing study. We recruited adult patients with head and neck cancers in the head and neck cancer outpatient clinics in the medical center in northern Taiwan. The items of CSI was developed based our previous research results, clinical observation, literature review and preliminarily validated by experts panel. Psychometric testing includes content validity, internal consistency reliability, construct validity by examining of its factor structures (exploratory factor analysis), theoretical supported correlation and discriminated constructs by groups.

Results: The CIS was a 21-item 0 to 4 Likert's typed scale with 0 representing "no problem/difficulty at all" and 4 representing "having extremely severe difficulty". We recruited 175 patients. The results showed that (1) CSI has good internal consistency reliability with Cronbach's α value as 0.93. (2) The factor analysis suggest that CSI contains four clear factors which are chewing, swallowing, tongue moving/stirring and taste and saliva changes which explained 70.32% of variances. (3) CSI has good construct supported correlation with nutrition. (4) CSI had good discriminate validity to differentiate patients with different diagnosis, surgical modalities, treatments, and disease stages.

Conclusions: CSI is a simple, easily used, reliable and validated tool to assess patients' eating difficulties. It will better support health care professionals to detect HNC patients' eating related chewing and swallowing problems and provide personalized intervention to prevent malnutrition.

1604P The Relationship between Oral Supportive Care and Oral Complications in Cancer Patients Receiving Chemotherapy: A Retrospective Study

T. Kataoka

Dental Oncology, Kobe Minimally Invasive Cancer Center, Kobe, Japan

Background: Oral supportive care for cancer patients received medical insurance coverage in 2012 in Japan. Management includes not only prevention of wound infection and perioperative pneumonia but also treatment of oral complications during chemotherapy and radiotherapy in cancer patients. We conducted a retrospective study to analyze the efficacy of oral supportive care for cancer patients receiving chemotherapy.

Methods: We retrospectively analyzed consecutive 1,142 cases received anticancer chemotherapy in our hospital from April 2013 to March 2017.

Results: Patients were 633 males and 509 females aged 23-92 years (median 66). Primary sites were lung in 246, esophagus in 193, breast in 137, head and neck in 112, and others in 454. Treatment was chemotherapy in 752, and concurrent chemoradiotherapy in 390. Before beginning chemotherapy, all patients received a dental check and acquired tooth brushing techniques. We compared the oral hygiene status in 752 patients before the beginning of therapy and at the 1-month check. Rates of improved, stable and regression status were 56.9%, 23.5%, and 19.6%. Regression appeared due to worsening of general condition, and also to oral mucositis among head and neck cancer patients. Oral supportive care was continued to maintain good oral hygiene, detect oral

complications early and manage them with dental treatment, dental extraction, mechanical cleaning, medicine, mouthwash and topical ointment and analgesics. Oral complications of ≥ Grade 3 (NCI-CTC AE ver. 3.0) were antiresorptive agents-related osteonecrosis of the jaw, teeth infections, and oral mucositis occurred during treatment. There was a significant difference in the incidence of oral complications between more and less than 3 months from the latest dental visit at the start of chemotherapy ($p < 0.02$).

Conclusions: Oral supportive care for cancer patients receiving chemotherapy should begin before the start of treatment and continue until the successful completion of treatment, especially for the deteriorated patients, head and neck cancer patients, and patients who did not receive dental checkups and cleaning for more than 3 months.

1605P Safety and effectiveness of sensor-controlled scalp cooling in women receiving chemotherapy for primary breast cancer

C.M. Kurbacher, S. Herz, G. Kolberg, N. Kettelhoit, A.T. Kurbacher, C. Schweitzer, J.A. Kurbacher

Gynecologic Oncology, Gynecologic Center Bonn-Friedensplatz, Bonn, Germany

Background: Sensor-controlled scalp cooling (SCSC) to prevent chemotherapy-induced alopecia (CIA) in patients (pts) with primary breast cancer (PBC) is approved by the FDA. However, SCSC isl infrequently used in many countries due to concerns regarding both safety and feasibility. This retrospective analysis sought to obtain more detailed information about the effectiveness and safety of SCSC using the Paxman system (Paxman, Huddersfield, UK) in PBC pts exposed to neoadjuvant (NACT) or adjuvant Ctx (ACT) in the clinical routine.

Methods: 79 pts were identified from our database: NACT, 41 (51.9%); ACT, 38 (48.1%); dose-dense (dd) Ctx, 56 (70.9%); non-dd Ctx 23 (29.1%); premenopausal, 44 (55.7%); postmenopausal, 35 (44.3%). The following Ctx regimens were used: anthracycline-based (A), 1 (1.3%); taxane-based (T), 21 (26.6%); AT-based, 55 (69.6%); non AT-based, 2 (2.5%). Pts were subjected to SCSC during each Ctx cycle. CIA was quantified using the Dean score (DS) determined 3 wks after the last Ctx cycle. Data were analyzed regarding the SCSC completion rate, quality of hair preservation (success: DS 0-2, failure: DS 3-4), reasons of SCSC discontinuation, and toxicity. Moreover, the following parameters were investigated in regard to the success of SCSC: menopausal status, NACT vs ACT, dd Ctx vs non-dd Ctx, AT-based Ctx vs A-/T- or non-AT-based Ctx.

Results: 55 pts (69.6%) completed SCSC with 36 (45.6%) showing complete (DS 0), and 19 (22.8%) showing partial success (DS 1-2). 24 pts (30.4%) discontinued SCSC with CIA seen in 18 pts (22.8%). Headache and local discomfort ("feeling cold") were reported in 4 pts (5.1%) each. Side effects were all not severe and resolved quickly after cessation of SCSC. SCSC was equally effective in all analyzed subgroups. The relative risk (RR) to experience CIA was 1.11 (CI: 0.82-1.54) for post- vs premenopausal pts; 1.11 (CI: 0.83-1.53) for ACT vs NACT; 1.31 (CI: 0.96-1.72) for AT vs other Ctx protocols, and 0.99 (CI 0.72-1.43) for dd Ctx vs non-dd Ctx.

Conclusions: In our study, SCSC was safe and effective to prevent CIA in PBC pts. The success rate in our study is in good agreement to previous randomized trials of SCSC in PBC arguing in favor that SCSC is a valuable supportive treatment in the clinical routine.

1606P Pharmacokinetics and safety of FOLFOX therapy in patients undergoing hemodialysis

T. Funakoshi[1], T. Horimatsu[1], A. Yamada[1], T. Kirishima[2], T. Mizukami[3], Y. Harada[4], M. Nakajima[5], S. Nakagawa[6], T. Matsubara[7], M. Yanagita[7], M. Muto[1]

[1]Therapeutic Oncology, Graduate School of Medicine, Kyoto University, Kyoto, Japan, [2]Gastroenterology, Kyoto City Hospital, Kyoto, Japan, [3]Clinical Oncology, St. Marianna University School of Medicine, Kawasaki, Japan, [4]Hematology, Respiratory Medicine and Oncology, Faculty of Medicine, Saga University, Saga, Japan, [5]Nephrology, Hitachi, Ltd., Hitachinaka General Hospital, Ibaraki, Japan, [6]Clinical Pharmacology and Therapeutics, Kyoto University Hospital, Kyoto, Japan, [7]Nephrology, Graduate School of Medicine, Kyoto University, Kyoto, Japan

Background: Due to a lack of information, there is no guideline regarding the dosage and timing of chemotherapy in cancer patients undergoing hemodialysis (HD). Therefore, we studied the pharmacokinetics of 5-fluorouracil (5-FU) and oxaliplatin (L-OHP) in cancer patients undergoing HD.

Methods: HD patients (HD group) and patients with normal renal function (control group) who had received either modified FOLFOX6 therapy or modified FOLFOX7 therapy were prospectively enrolled. The blood concentrations of 5-FU and 5-FU metabolites, including α-fluoro-β-alanine (FBAL), fluoroacetic acid, and ammonia were measured using inductively coupled plasma-mass spectrometry. The blood concentrations of total and ultrafilterable platinum were measured in the HD group. To estimate the amount of L-OHP removal by dialysis, we also measured the platinum concentration in dialysate.

Results: There were six patients in the HD group and eight patients in the control group. In the HD group, L-OHP was administered just before the HD session in four patients, and on a non-dialysis day in two patients. The amount of L-OHP removal by dialysis was 10% or less of the administered dose, and did not depend on the timing of L-OHP administration. Regarding the 5-FU metabolites, the blood concentration of FBAL was significantly higher in the HD group than in the control group ($p < 0.01$). We observed hyperammonemia in two patients in the HD group, which was accompanied by elevated blood levels of FBAL and fluoroacetic acid, and was therefore considered to be related to 5-FU administration. Conscious level deterioration was observed in one patient with hyperammonemia.

Conclusions: The amount of L-OHP removal by dialysis was up to 10% regardless of the timing of L-OHP administration. Hyperammonemia should be monitored during FOLFOX therapy among HD patients.

1607TiP J-FORCE study: A randomized, double-blind, placebo-controlled phase III study evaluating olanzapine (5 mg) combined with standard antiemetic therapy for the prevention of chemotherapy-induced nausea and vomiting in patients receiving cisplatin-based, highly emetogenic chemotherapy

H. Hashimoto[1], S. Iwasa[2], M. Abe[3], T. Yanai[1], S. Zenda[4], T. Yamaguchi[5], H. Kaba[6], H. Fukuda[7], H. Terakado[1], Y. Ohe[8]

[1]Pharmacy, National Cancer Center Hospital, Tokyo, Japan, [2]Department of GI Medical Oncology, National Cancer Center Hospital, Tokyo, Japan, [3]Department of Gyne Oncology, Shizuoka Cancer center, Shizuoka, Japan, [4]Department of Radiation Oncology, National Cancer Center Hospital East, Chiba, Japan, [5]Biostatistics, Tohoku University Graduate School of Medicine, Sendai, Japan, [6]Data Management Section, National Cancer Center, Tokyo, Japan, [7]Data Management Section, National Cancer Center Hospital, Tokyo, Japan, [8]Department of Thoracic Oncology, National Cancer Center Hospital, Tokyo, Japan

Background: In the Alliance A221301 study, olanzapine (OLZ; 10 mg) significantly improved the prevention of nausea in patients who were receiving highly emetogenic chemotherapy (HEC). However, growing concerns exist concerning somnolence and sedation. We previously reported on the efficacy and safety of two doses (5 mg and 10 mg) of OLZ in combination with aprepitant (APR), palonosetron (PALO), and dexamethasone (DEX) in patients receiving HEC. OLZ (5 mg) seemed to lead to lower somnolence than OLZ (10 mg) and was equally effective in preventing nausea. The aim of this phase III study is to evaluate the efficacy and safety of 5 mg OLZ doses as compared with placebo, in combination with APR, PALO, and DEX, for the control of nausea in patients receiving HEC.

Trial design: Eligibility criteria for patients include those who are aged 20–75 years, have an Eastern Cooperative Oncology Group (ECOG) performance status between 0–2, and have malignant disease who will be scheduled to receive HEC with cisplatin at a dose ≥ 50 mg/m^2. Having diabetes mellitus or being treated with antipsychotic agents within 48 hours before enrollment make patients ineligible for the study. Patients are randomly assigned to receive either a 5 mg OLZ dose or placebo orally after supper on days 1–4, in combination with APR (125 mg p.o. on day 1, 80 mg p.o. on days 2–3), PALO (0.75 mg i.v. on day 1) and DEX (9.9 mg i.v. on day 1 and 6.6 mg i.v. on days 2–4). The primary endpoint is a complete response (CR), defined as no emetic episodes and without the use of rescue medications in the delayed phase (24 to 120 hours). Secondary endpoints include a CR during acute (0 to 24 hours) and overall phases (0 to 120 hours), complete and total control rates, and the level of nausea, appetite and somnolence. A total of 690 patients are required to achieve 80% power for a one-sided significance level of 0.025. We expect the CR rate of the placebo and olanzapine arms to be 65% and 75%, respectively.

1608TiP Heath related quality of life (HRQOL) assessment for patients with advanced renal cell carcinoma (mRCC) treated with tyrosine kinase inhibitor (TKI) using electronic patient reported outcome (PRO) in daily clinical practice

G. Mouillet[1,2], A. Pozet[1], J. Fritzsch[1], I. Es-Saad[1], S. Paget-Bailly[1], A. Foubert[1], D. Berthod[2], A. Anota[1], F. Bonnetain[1,3], A. Thiery-Vuillemin[2,3]

[1]Methodological and Quality of Life Unit in Oncology (INSERM UMR 1098), Besançon University Hospital, Besançon, France, [2]Medical Oncology, Besancon University Hospital, Besançon, France, [3]Bourgogne - Franche-Comté University, UMR1098, SFR IBCT, Besançon, France

Background: In mRCC, two therapies are mainly used in first line setting: pazopanib and sunitinib. These two TKI are equally effective in terms of survival however they are responsible for frequent adverse events. Physician mainly use RECIST progression-free survival (PFS) and NCI CTCAE safety as a guide to evaluate treatment efficiency and tolerance. In contrast HRQOL assessment is often restricted to clinical trial. It could be of particular interest to evaluate HRQOL in daily clinical practice in order to adequately choose and manage therapy. Currently the development of Information and Communication Technology may allow HRQOL monitoring in routine practice. The objective of the QUANARIE Study is to evaluate the feasibility of HRQOL assessment in daily clinical practice for patients with mRCC treated with TKI using electronic PRO.

Trial design: QUANARIE study (NCT03062410) is an interventional, prospective, multicenter trial involving 9 french oncological centers. Patients diagnosed with mRCC initiating TKI anti-VEGF treatment (Sunitinib or Pazopanib) will be invited to complete the European Organisation for Research and Treatment of Cancer (EORTC) QLQ-C30 cancer specific questionnaire and the EQ-5D before each visit with the physician. Questionnaires completion will be done by patients on tablets and/or computer terminals via the CHES software (Computer-based Health Evaluation System) at hospital before consultation or at home via secured portal. Physician will immediately have access to a visual summary of HRQOL evaluation. Primary objective is to assess the feasibility of routine assessment of HRQOL evaluated by the rate of filled questionnaires at 12-months. Key secondary objectives are: exhaustiveness, acceptability and effectiveness. Physician's satisfaction with electronic HRQOL evaluation will be assessed. We hypothesized that 80% of filled questionnaires at 12-months would be meaningful. A sample size of 56 patients would be needed. Enrollment is expected to last for 6 mo. Study started in April 2017. Update will be display on poster during ESMO congress.

1609TiP Impact of a cancer care coordination program based on health information technologies for patients treated by oral anticancer therapy: The CAPRI randomized trial

M. Ferrua[1], M. Di Palma[1], F. Lemare[2], A. Fourcade[1], B. Lalloue[1], F. Daumas - Yatim[3], M. Guillet - Lacaze[1], E. Minvielle[1]

[1]Research Department, Gustave Roussy, Villejuif, France, [2]Pharmacy Department, Institut Gustave Roussy, Villejuif, France, [3]EA 7348 Management des Organisations de Santé, EHESP, Rennes, France

Background: The emergence of oral delivery in cancer therapeutics results in an increased need for better coordination between all treatment stakeholders, mainly to ensure adequate treatment delivery to the patient. There is a significant interest in cancer care coordination programs, especially those combining Nurse Navigators (NN) and the use of new technologies. However, the potential impact of these combined strategies is limited by a lack of rigorous evidence.

Trial design: A monocentric randomized trial (1,000 patients, 1:1) is designed to assess the impact of a cancer care coordination program namely CAPRI. This program is based on two NN and a web application. NN ensure remote patient monitoring, via phone calls and email. They also provide a link between hospital professionals, patients and primary care professionals (GP, private nurse, pharmacist, etc.) by giving them access to the web application with the patient's authorization. Patients can enter data related to their health. Alerts are sent to the NN in case of abnormal data. NN evaluate the alert level on the basis of algorithms and determine the necessary action. The study will evaluate CAPRI's efficacy in comparison with regular care during a 6-month period for adult patients with metastatic cancer. Hypothesis is that with a closer monitoring of the patient, the management of toxicities is more efficient and results in fewer dose adjustments of oral cancer therapeutics and avoids unnecessary hospital visits. The primary research aim is to assess the impact of the CAPRI program on treatment delivery for cancer patients who started oral cancer therapy, as measured by Relative Dose Intensity. The trial involves several secondary outcomes: patient adherence, tumor response, survival, toxicities, patient quality of life and patient experience. An economic evaluation adopting a societal perspective will be conducted, in order to estimate the use of healthcare resources. A parallel process evaluation will be conducted to describe the implementation of the CAPRI program. Of the 1,000 patients to be recruited, 109 patients are currently enrolled since November 2016.

1610TiP Oncological Home-Hospitalization: Prospective randomized trial to evaluate its implications for patient and society

L. Cool[1], J. Missiaen[1], P. Debruyne[1], K. Geldhof[2], T. Lefebvre[1], M. Desmedt[3], V. Foulon[4], H. Pottel[5], D. Vandijck[6], K. Van Eygen[1]

[1]Cancer Centre, General Hospital Groeninge, Kortrijk, Belgium, [2]Oncology, AZ Groeninge (Kortrijk) & Jan Yperman Ziekenhuis (Ieper), Kortrijk, Belgium, [3]Faculty of Medicine and Life Sciences, Hasselt University, Hasselt, Belgium, [4]Pharmaceutical and Pharmacological Sciences, Catholic University Leuven, Leuven, Belgium, [5]Public Health and Primary Care, Catholic University Leuven, campus Kulak, Kortrijk, Belgium, [6]Public Health, Ghent University, Ghent, Belgium

Background: Home-based cancer treatment offers an integrated and patient-centered approach to deal with the challenges oncological day (care) units are facing. Current cancer therapies require frequent hospital visits that are known to be stressful for the patient and generate a high workload for hospital staff. Furthermore, these hospital visits are associated with significant costs for patients and the society, this against the background of increasing attention towards more cost-effective healthcare. Consequently, the general hospital Groeninge (Belgium) has initiated a research project to assess both, the clinical and economic impact of oncological home hospitalization. The project is supported by "Kom op tegen Kanker", a non-profit organization.

Trial design: Ambulatory treated adult cancer patients (EGOG ≤ 2 and living within a 30-minute drive of hospital) are visited at home by a clinical nurse specialist to conduct the necessary measures prior to therapy administration; that is nursing review, toxicity scoring, vital signs monitoring, blood collection, and IV line access provision. These assessments are performed one day prior to the actual therapy administration at the hospital, enabling the oncologist to prescribe and pharmacy to prepare cancer therapy before arrival of the patient. In addition, some safe experienced subcutaneous cancer therapies (i.e. bortezomib, azacitidine and trastuzumab) are administered directly at the patient's home. This new care model will be evaluated in terms of patient's quality of life, safety and cost-efficiency by performing a single-center randomized clinical trial allocating leastways 100 subjects to either home-hospitalization or standard ambulant hospital care. Currently, a non-randomized pilot study is launched in which the sensitivity of several validated patient reported outcome measuring tools is examined in both treatment settings ($n = 50$). Those instruments that show sufficient sensitivity will be included in the randomized trial. A second objective of the pilot study is to gather an extensive costs-inventory that will be used to set up an appropriate and reliable cost-analysis of home-based cancer treatment.

Background: Cancer cachexia is a multifactorial syndrome characterized by an ongoing loss of skeletal muscle mass that cannot be fully reversed by conventional nutritional support alone. Cachexia has a high prevalence in cancer and a major impact on patient physical function, morbidity and mortality. Despite the consequences of cachexia, there is no licensed treatment and no standard of care. It has been argued that the multifactorial genesis of cachexia lends itself well to therapeutic targeting through a multimodal treatment. Following a successful phase II trial, a phase III trial is underway.

Trial design: MENAC is a multicentre, open, randomized phase III study comparing multimodal intervention and standard cancer care versus standard cancer care alone. Patients treated for incurable lung and pancreatic cancer will be allocated randomly to receive the multimodal intervention, either immediately, or after endpoint at six weeks. The intervention is based on evidence to date and consists of Non-steroidal Anti-inflammatory Drugs (NSAID) and an EPA containing oral nutrition supplement to reduce inflammation, a physical exercise progamme consisting of both resistance and aerobic exercises to increase anabolism, as well as dietary counselling aiming to promote energy and protein balance. The overall aim is to reduce weight loss, improve food intake and maintain physical function by establish basic supportive care for cachexia. From a patient perspective, a short-term effect will be to improve physical and psychological function and reduce symptom burden. Change in body weight is primary endpoint. Secondary endpoints are change in muscle mass (CT technique) and physical activity (ActivPAL activity meter). There are several exploratory endpoints. The trial is ongoing and patients are recruited from several sites in Europa and Canada, we aim for 240 patients. If positive, the results will be practice changing for supportive treatment of patients with cancer.

Background: We previously reported that S-1 chemotherapy for gastrointestinal cancer (GI cancer) induced the high incidence of eye disorders (EDs), regardless of primary cancer site, treatment regimen and administration schedule (Yagisawa M, et al. 2017 Gastrointestinal Cancers Symposium). However, because this report showed a retrospective data from single institutional small cohort by reviewing medical records, we might have underestimated the incidence of EDs. So, we have conducted this prospective cohort study to confirm the incidence of EDs induced by S-1 more precisely.

Trial design: This is a multicenter prospective cohort study to evaluate the incidence of EDs and ophthalmologic changes in GI cancer patients received S-1 chemotherapy. The key eligibility criteria are as follows: 1) Histologically confirmed carcinoma in GI cancer, including esophageal, gastric, colorectal, pancreatic, and biliary tract cancer.; 2) The patient who receives chemotherapy including S-1.; 3) No prior medication of S-1.; 4) No lachrymal duct obstruction and less than three points of corner conjunctiva epithelium disorder score. All participants receive four times of ophthalmological examinations. The primary endpoint is cumulative incidence of epiphora in periods from start of S-1 chemotherapy to 12 weeks after induction S-1. The secondary endpoints are cumulative incidence of epiphora in overall S-1 chemotherapy periods, the time of onset and severity of epiphora, the situation of ophthalmological intervention, ophthalmological changes, risk factors of epiphora, and QOL. Because we supposed that incidence of epiphora at 12 weeks after induction S-1 is 10% as already reported, we calculated the sample size as 160 based on precision of the 95% confidence interval and aimed to recruit 180 patients considering the possibility of 10% dropouts. This study is sponsored by Non Profit Organization Hokkaido Gastrointestinal Cancer Study Group.

1613TiP Outpatient monitoring with an eTool: self managed or with pro active intervention?

S. Rauh[1], L. Hoechstenbach[2], C. Schmitz[1], A. Hagemann[3], I. Denine[4]

[1]Oncology, Centre Hospitalier Emile Mayrisch, Esch, Luxembourg, [2]Centre of Expertise for Innovative Care and Technology (EIZT), Zuyd University of Applied Sciences, Maastricht, Netherlands, [3]EHealth, Sananet, Sittard, Netherlands, [4]Assistente en Recherche Clinique, Centre Hospitalier Emile Mayrisch, Esch, Luxembourg

Background: Cancer outpatients (OP) will face a maximum of potentially serious side effects (SAEI) and complications (C) at home and at distance from their caregivers (CG). This may lead to insufficent management as the care takers ignore complications and will not carry out early intervention. Worsening of quality of life (QoL) and (prolonged) hospitalisation may be the consequence. Studies have provided evidence that e-tools inquiring about the patients' well-being at home may be useful for early intervention, thus providing better quality of life and less hospitalisations. It is unclear whether these benefits could be obtained by patients' self-management or require pro active intervention (PAI) by CG. We therefore carry out a study (PRO-ELECTS= PE) using a web-based e-tool we developed based on the Edmondson Symptom Scale (ESAS). A pilot study had proved feasability in OU of the Oncology Outpatient Unit (OOU) of the CHEM general hospital.

Trial design: This prospective randomized study compares: - I. OP documenting QoL, hospital stays/consult. during treatment intervals while under OOU visits, with:- II. P receiving daily inquiries, automated advice and alerts to contact OOU in the case of SAE, with: III. P receiving daily inquiry superised by the OOU CG and intervention in case of alarming sypmtoms. All P apart from I receive daily customized questionnaires integrating an algorithm with automated answers to standard situations and alert messages inviting the P to contact the OOU tal in case of SAE. In group III, CG of the OOU will be notified of the daily response and alerted in case of SAE. They are mandated to contact the P to provide advice or convocate him to the hospital.PRO-ELECTS should be able to determine whether active electronic patient surveillance and pro active intervention is superior to patient self -management assisted by a web tool in maintaining good quality of life and limit the severity of complications. The study will also determine which strategy provideds more patient adherence and satisfaction. So far 15 of a total of 120 P have been randomized. Patient acceptance is excellent. 3 serious side effects have been anticipated through active intervention. Data concerning P adherence, satisfaction, QoL ad complication data will be presented.

1614TiP A Phase I safety study of topical Calcitriol (BPM 31543) for the prevention of chemotherapy-induced alopecia (CIA)

B. Berman[1], J. Konner[2], V.R. Belum[2], H. Dion[3], K. Ciccolini[2], S. Kitts[2], R. Ye[3], S. Ravipaty[3], V.R. Akmaev[3], R. Sarangarajan[3], J.J. Jimenez[4], N. Narain[3], S.B. Goldfarb[2], M.E. Lacouture[2]

[1]Dermatology, Center for Clinical and Cosmetic Research, Miami, FL, USA, [2]Oncology, Memorial Sloan Kettering Cancer Center, New York, NY, USA, [3]Biosystems, BERG, LLC, Framingham, MA, USA, [4]Dermatology, University of Miami, Miami, FL, USA

Background: Chemotherapy-induced alopecia (CIA) may lead to significant psychosocial and quality of life issues. Currently there are no FDA approved therapeutic agents available to prevent CIA. In murine studies, topical calcitriol reduced CIA, likely due to arrest of cell cycle in healthy hair follicles and reducing sensitivity of follicular epithelium to chemotherapy.

Trial design: A 3 + 3 dose-escalation Phase 1 study with 3 to 6 patients at each dose level (5/10/20/40/60/80 μg/mL) to determine the maximum tolerated dose (MTD) and the overall safety and tolerability of a topical compound BPM31543 (Calcitriol) in patients with a diagnosis of breast cancer, gynecologic cancer and sarcomas. Eligible patients receiving a taxane-based chemotherapy regimen applied 1mL of BPM31543 twice/daily at each cohort dose level 14 or 7 days prior to initiation of chemotherapy and then continued twice daily for 3 months or until termination of chemotherapy. In order to determine the MTD, dose escalation occurred in stepwise increments of the immediate prior dose group, in the absence of grade 3 or greater toxicities attributed to the topical calcitriol. Dose-limiting toxicity (DLT) was determined during Cycle 1 (i.e., the first 28 days of topical agent application). Patients were managed with adequate safety monitoring and pharmacokinetic (PK) analysis in order to determine levels of exposure. The potential efficacy (secondary objective) of the topical calcitriol was evaluated by photographic assessment using a Canon digital camera system (to ensure standardization and uniformity among all enrolled patients) in addition to patient self-assessments.

Background: Available 2nd line chemotherapies for relapsed malignant pleural mesothelioma (MPM) have limited activity. Results from early clinical trials - including the mesothelioma cohort of the KEYNOTE-028 phase I/II trial - show promising activity of various PD-(L)1 checkpoint inhibitors in MPM. Pembrolizumab has been used off-label in Switzerland as 2nd and further line treatment in patients with MPM.

Methods: Cancer centers in Switzerland entered data on patients having received pembrolizumab for MPM into this retrospective registry. Patient characteristics including age, gender, histology, stage at diagnosis and previous treatments were collected. Outcomes of pembrolizumab were assessed by the local investigators using standard RECIST v1.1 criteria. PD-L1 expression was determined centrally.

Results: We collected data on 48 patients (median age 68 years) having received pembrolizumab for relapsed MPM between September 2015 and April 2017. Pembrolizumab was the 2nd line of treatment (after platinum-pemetrexed +/- bevacizumab) in 30 patients (63%). Twenty-eight patients (59%) had an ECOG of 0-1 at the beginning of pembrolizumab (as in the KEYNOTE-028 trial). Responses and survival outcomes are listed in Table. Investigator-reported toxicity was as follows: 15 treatment-related adverse events occurred in 14 patients (29%). Five events (10%) were G3-4 (2 patients with hepatitis, 1 with heart failure, 1 with non-cardiac chest pain and 1 with nephrotic syndrome). Seven patients (15%) discontinued treatment due to an adverse event.

Conclusions: This is the largest reported cohort of mesothelioma patients treated with pembrolizumab thus far, and the first with any kind of anti-PD(L)1 antibody in a "real-life" setting. Compared to available second-and-beyond line treatment options, response rates and survival outcomes were promising in the unselected population, while patients with ECOG 0-1 receiving pembrolizumab in 2nd line seemed to benefit substantially. Response rates as well as the incidence of treatment-related adverse events were consistent with the KEYNOTE-028 report. Further results including subgroup analysis by PD-L1 expression will be presented at the meeting.

Background: Fibroblast growth factor (FGF) signaling has a fundamental role in cancer development and tumor maintenance. FP-1039/GSK3052230 is a soluble decoy receptor that sequesters FGFs, including FGF2, blocking their ability to bind to and activate FGFRs, particularly FGFR1. This unique mechanism of action should avoid the on-target toxicities associated with small molecule pan FGFR kinase inhibitors, such as hyperphosphatemia and retinal, nail, and skin changes. MPM remains a disease with poor prognosis and few effective therapies, and preclinical models of MPM are particularly sensitive to inhibition of FGF/FGFR signaling by FP-1039/GSK3052230.

Methods: Herein, the analysis of patients with untreated, unresectable MPM is reported. The MPM arm of the study evaluated the safety and efficacy of FP-1039/GSK3052230 (IV weekly) in combination with standard pemetrexed+cisplatin. The study design involved dose escalation until MTD followed by a cohort expansion phase. Endpoints included safety, overall response rate by modified RECIST 1.1, disease control rate (DCR), PFS, and exploratory translational objectives.

Results: As of the cutoff date of 17 Mar 2017, 36 patients were dosed at 10, 15 and 20 mg/kg doses of FP-1039/GSK3052230. Three DLTs were observed at 20 mg/kg but none occurred at 15 mg/kg; therefore, MTD was declared at this dose. Most common related adverse events (all grades) were: nausea (56%) decreased appetite (36%), fatigue (33%), and infusion reaction (33%). The confirmed objective response rate (ORR) of all evaluable patients at or below the MTD was 48% (13/27 PRs), with disease control rate (DCR) of 100%. The median PFS was 7.4 months. As of 8 May 2017, six patients stayed on the study for over 1 year, of which 3 were still ongoing. Results of exploratory biomarker analyses will also be presented.

Conclusions: The MTD of FP-1039/GSK3052230 (15 mg/kg) in combination with pemetrexed+cisplatin in MPM was well tolerated, and durable responses were observed. Importantly, AEs associated with small-molecule pan FGFR kinase inhibitors were not observed, as predicted by the unique mechanism of action of this drug. Study sponsored by GSK; clinical trial information: NCT01868022.

Clinical trial identification: NCT01868022

1617PD Multiplexed targeted proteomics signature for serum diagnostic of malignant pleural mesothelioma

F. Cerciello[1], M. Choi[2], K. Lomeo[1], J.M. Amann[1], E. Felley-Bosco[3], R.A. Stahel[4], B. Robinson[5], J. Creaney[5], H.I. Pass[6], O. Vitek[2], D.P. Carbone[1]

[1]James Thoracic Center, James Cancer Center, The Ohio State University Medical Center, Columbus, OH, USA, [2]College of Science, College of Computer and Information Science, Northeastern University, Boston, MA, USA, [3]Laboratory of Molecular Oncology, University Hospital Zürich, Zurich, Switzerland, [4]Laboratory of Molecular Oncology, Department of Oncology, University Hospital Zürich, Zurich, Switzerland, [5]National Centre for Asbestos Related Disease, University of Western Australia, School of Medicine and Pharmacology, Nedlands, Australia, [6]Langone Medical Center, New York University, New York, USA

Background: Detection of mesothelioma from blood is challenging. Current proposed biomarkers mainly rely on single protein cancer products detected in serum or plasma. Here, we investigate if a mass spectrometry based multiplexed proteomic biomarker signature can improve accuracy of mesothelioma detection in serum.

Methods: We used targeted proteomics technology to investigate more than 400 serum samples from cohorts of mesothelioma and asbestos exposed donors from USA, Australia and Europe. Serum samples were processed for enrichment of N-linked glycoproteins on 96-well plates before peptide separation on ultra performance liquid chromatography (UPLC) followed by targeted analysis on a triple quadrupole type of mass spectrometer. The software Skyline was used for data visualization. Workflow for quantitative large scale data analysis was based on the software package MSstats.

Results: We applied logistic regression models for a multiplexed signature of six peptides from six different proteins, including the biomarker mesothelin. In the receiver operating curve, signature had an area under the curve (AUC) of 0.76 in discriminating mesothelioma from asbestos exposed donors in a training set of 212 donors. AUC in a separated validation set of 193 donors was 0.72. In the validation set, AUC was 0.74 in separating mesothelioma early stages I/II from asbestos exposed. In comparison, single mesothelin peptide assessed by mass spectrometry discriminated mesothelioma from asbestos exposed with AUC of 0.71 in training and AUC of 0.64 in validation set, and mesothelioma early stages I/II were separated from asbestos exposed with AUC of 0.66 in the validation set.

Conclusions: Diagnostic strategies based on multiplexed targeted proteomics biomarkers bear potential of an increased accuracy for detection of mesothelioma in serum.

KG, Biberach, Germany, [18]Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, USA, [19]Boehringer Ingelheim France S.A.S., Paris, France

Background: N targets MPM by inhibiting VEGFR 1–3, PDGFR α/β, FGFR 1–3, Src and Abl kinases. In a Phase II/III, double-blind, randomised LUME-Meso trial, primary Phase II analysis showed improved progression-free survival (PFS) with N and a trend for prolonged interim OS. FVC, a common pulmonary function test reflecting pt performance and quality-of-life, was also evaluated.

Methods: Pts with unresectable MPM (ECOG PS 0–1), stratified by histology, were randomised 1:1 to ≤ 6 cycles PEM (500 mg/m^2)/CIS (75 mg/m^2, Day 1) + N or P (200 mg bid, Days 2–21), followed by N/P monotherapy until progression/unacceptable toxicity. The primary endpoint was PFS; OS was the secondary endpoint. FVC was a further endpoint, evaluated as percentage change from baseline for cycle (C)1–8 using a mixed-effect model with repeated measures.

Results: 87 pts were randomised (N = 44; P = 43). At the primary OS analysis (71% of events), OS benefit favoured N (hazard ratio [HR]=0.77; 95% confidence interval [CI]: 0.46–1.29; p = 0.319) and primary PFS results were confirmed (HR = 0.54; [95% CI]: 0.33–0.87; p = 0.010). Benefit of N was greatest in epithelioid MPM for PFS (HR = 0.49; 95% CI: 0.30–0.82; p = 0.006; median [m] 9.7 vs 5.7 months [mo]) and OS (HR = 0.70; 95% CI: 0.40–1.21; p = 0.197; mOS 20.6 vs 15.2 mo). Adjusted mean (standard error [SE]) FVC change at C8 favoured N over P (all pts: +10.0 [SE: 3.5]% vs + 2.8 [SE: 3.7]%; mean treatment difference [TD]: 7.2 [SE: 4.5]%; pts with epithelioid histology: +14.1 [SE: 2.9]% vs + 4.2 [SE: 3.3]%; mean TD: 9.9 [SE 4.5]%). A trend towards improved FVC with N over P was observed from C2 in all pts and epithelioid histology. Neutropenia was the most frequent Grade ≥3 adverse event (AE; N, 43%; P, 12%); febrile neutropenia rate was low (4.5 vs 0%). AEs leading to discontinuation were lower with N than P (7 vs 17%).

Conclusions: Addition of N to PEM/CIS resulted in a substantial improvement in PFS, a trend for prolonged OS and improvement in the pulmonary function measure FVC. Treatment effect was most pronounced in pts with epithelioid histology; Phase III is recruiting in this population (NCT01907100).

1619PD Malignant pleural mesothelioma immune microenvironment and checkpoint expression before and after systemic cytotoxic treatment

G. Zago[1], F. Lunardi[2], F. Calabrese[2], S.E. Vuljan[2], L. Urso[3], S. Frega[1], A. Pavan[1], V. Polo[3], L. Bonanno[1], I. Attili[1], F. Rea[2], P.F. Conte[1], G. Pasello[1]

[1]Medical and Experimental Oncology Department, Medical Oncology 2, Istituto Oncologico Veneto IRCCS, Padua, Italy, [2]Cardiologic, Thoracic and Vascular Sciences Department, University of Padova, Padua, Italy, [3]Surgical, Oncological and Gastroenterological Sciences Department, University of Padova, Padua, Italy

Background: Tumor immune microenvironment (TME) plays a role in Malignant Pleural Mesothelioma (MPM) pathogenesis and patients outcome. PD1/PDL1 checkpoint inhibitors are currently under investigation as innovative promising treatment of MPM, even though no definitive predictive markers have been defined so far. PDL1 expression and TME are dynamic in tumor samples. The object of this preliminary analysis is a subset of MPM paired samples analyzed before and after induction chemotherapy (ct) in order to assess TME and PDL1 heterogeneity and dynamism over time.

Methods: Inflammatory cells in the intratumoral (IT) e peritumoral (PT) stroma were characterized by immunohistochemistry (IHC) using monoclonal anti-CD20 (B lymphocytes), CD3, CD4 and CD8 (T lymphocytes) and CD68 (macrophages) antibodies, and quantified as percentage in neoplastic area. PDL1 expression in tumor cells (TC) and immune cells (IC) was evaluated by IHC using Ventana SP263 antibody (Roche) and quantified as percentage of expressing cells. Difference between naïve and treated samples was assessed through Mann-Whithey test.

Results: 15 paired MPM specimens (14 epithelioid and 1 biphasic) obtained for diagnostic purpose before platinum-pemetrexed ct and at the time of resection were analyzed. After ct MPM samples showed PT and IT increase of CD68+ macrophages and CD3+ T lymphocytes, even though only peritumoral CD3+ lymphocytes significantly increased (p=0.008). CD4+ and CD8+ lymphocytes were lacking in naive samples, while CD8+ significantly increased after ct (median value PT pre *vs.* post-ct: 5% *vs.* 30%, p=0.02; median valule IT pre *vs.* post-ct: 5% *vs.* 15%, p= 0.007). CD8+/CD68+ ratio increased after ct, even though without statistical significance. No IT B lymphocytes were observed, a small increase at PT level was shown after ct. Ct induced PDL1 expression in tumor cells and even more in lymphomonocitic infiltrate (median value pre *vs.* post-ct 0% *vs.* 50%, p=0.003).

Conclusions: Ct significantly increases cytotoxic T lymphocytes at PT and IT level in MPM samples and PDL1 expression in IC. These data confirm the strong rationale for the combination of checkpoint inhibitors and ct as promising treatment of MPM.

1620P Outcomes of malignant pleural mesothelioma (MPM) patients (p) treated with immune-oncology drugs (IO) in clinical trials

S. Cedres[1], A. Martinez Marti[1], A. Navarro[1], N. Pardo[1], J. Remon[1], I. Matos[1], M. Ochoa de Olza[1], C. Hierro[1], J. Martin Liberal[1], J.M. Miquel[1], C. Viaplana[2], G. Villacampa Javierre[2], R. Dienstmann[2], E. Felip Font[1]

[1]Medical Oncology, Vall d'Hebron University Hospital/Vall d'Hebron Institute Oncology, Barcelona, Spain, [2]Oncology Data Science (ODysSey) Group, Vall d'Hebron Institute of Oncology, Barcelona, Spain

Background: The increasing incidence and poor outcome associated with MPM requires identification of effective treatment options. Initial data have demonstrated beneficial effects of IO in MPM, however recent results of clinical studies with immune checkpoint inhibitors (CPI) are not so encouraging. The aim of this study is to evaluate the outcomes of p with MPM treated with immunotherapy in clinical trials at our institution.

Methods: 20 MPM p treated with IO at Vall dHebron Institute of Oncology between September 2012 and December 2016 were reviewed. Survival data were calculated by the Kaplan-Meier method. The associations of type of immunotherapy with outcomes were assessed with Cox regression models.

Results: Patient's characteristics: median age 63 years (45-77 years), males: 62%, performance status (PS) 1:86%, asbestos exposure: 82%, stage III at diagnosis: 51%, epithelial subtype: 82%. All p were treated with chemotherapy, 90% received cisplatin plus pemetrexed as first line with median progression free survival (PFS) of 9.1 months (m;CI95% 7.6-10.7). Clinical trial with IO was offered as second-line regimen in 65% and third line in 35%. Target of IO was CTLA4: 60%, PD-1: 25% and other CPI single agent 15% (LAG3, GITR, CD40). Overall, disease control rate at 4 months was 40%. Reason for treatment discontinuation was toxicity in 20% of cases. Median PFS with IO in second line was 5.6 m (2.7-NR) and in third line 3.7 m (1.4-NR, $p = 0.77$). Different outcomes were seen according to target selected: with PD-1 median PFS of 8.6 m (4.2-NR) and with CTLA4 of 4.2 m (2.2-NR), significantly longer than 1.9 m (0.7-NR) with other CPI ($p < 0.05$). Overall, median survival (OS) was 26.9 m (21.8-NR). Survival after initiation of IO was 9.6 m (7.2-NR) if given in second-line and 4.9 m (4.5-NR) in third line ($p = 0.67$). Baseline and dynamic changes in LDH and lymphocytes were not predictors of outcomes to immunotherapy ($p > 0.05$ all comparisons).

Conclusions: In our single institution series of previously treated MPM, IO associates with prolonged disease control in a subgroup of patients, with longest benefit seen with anti PD-1 therapies. Further research with predictive biomarkers of IO in MPM is needed.

1621P Baseline hyperglycemia was predictive of poor outcome in pleural malignant mesothelioma

J.C. Ruffinelli[1], J.C. Pardo[2], S. Recalde[1], J.C. Benítez[3], L. Cancel[1], R. Palmero[1], R. Llatjós[4], M.R. Escoda[5], S. Padrones[6], I. Brao[1], E. Dalmau[2], Y. Garcia[2], F. Cardenal[1], E. Nadal[1]

[1]Medical Oncology, Catalan Institute of Oncology, L'Hospitalet, Spain, [2]Medical Oncology, Hospital Parc Taulí, Sabadell, Spain, [3]Medical Oncology, Hospital Mútua de Terrassa, Terrassa, Spain, [4]Pathology, Hospital Universitari de Bellvitge, L'Hospitalet, Spain, [5]Pathology, Hospital Parc Taulí, Sabadell, Spain, [6]Respiratory Medicine, Hospital Universitari de Bellvitge, L'Hospitalet, Spain

Background: Although numerous prognostic biomarkers were described in malignant pleural mesothelioma (MPM), the role of hyperglycemia has not been studied. We examined reported prognostic variables and glycemia as predictors of overall survival (OS) in a cohort of MPM patients.

Methods: This retrospective study included 148 consecutive patients diagnosed with MPM in two hospitals from Catalonia between 2007 and 2016. Clinicopathological characteristics and baseline analytical results were recorded. OS was calculated using Kaplan-Meier method and multivariate Cox model was adjusted by clinical variables that were statistically significant in the univariate Cox regression.

Results: Most patients were male (73%) and 56% were $\geq$ 70 years. The most frequent histological subtype was epithelioid (59.5%), followed by sarcomatoid (18%), biphasic (13.5%) and not specified (10%). Disease stages at diagnosis were: stage I, 11.5%; stage II, 16%; stage III, 33%; stage IV, 34%; not specified, 1.5%. Most patients had good ECOG performance status (PS 0-1, 63%) and 63% of patients received chemotherapy. Median baseline glycemia was 5.8 mmol/l (3.9-15.9) and patients 34 (23%) had hyperglycemia ($\geq$7 mmol/l) and 26 (18%) previous diagnosis of diabetes. The median overall survival (OS) was 10.5 months (95% CI 7.6 – 13.4). In the univariate analysis for OS, histological subtype, stage, PS, chemotherapy treatment, hyperglycemia ($\geq$7 mmol/l), high neutrophil and platelets count, low lymphocytes and and high neutrophil to lymphocyte ratio (NLR) were significantly associated with survival outcome. In the multivariate Cox model adjusted by histological subtype, stage and PS, baseline glycemia (HR 1.80, 95% CI 1.08-2.98, $p = 0.023$, Table) and neutrophil count (HR 1.42, 95% CI 1.01-1.98, $p = 0.042$) remained as independent prognostic factors for shorter OS.

Table: 1621P Multivariate Cox Regression Analysis of Overall Survival

	HR (95% CI)	p-value
Histology (non-epithelioid vs. epithelioid)	2.16 (1.42 - 3.26)	**<0.001**
Stage, continuous	1.28 (1.04 - 1.56)	**0.017**
ECOG PS, continuous	1.82 (1.42 - 2.32)	**<0.001**
Baseline glycemia, continuous	1.80 (1.08 - 2.98)	**0.023**

Conclusions: Baseline hyperglycemia was independently associated with shorter survival in this cohort of patients with MPM. Confirmation of its prognostic role in larger cohorts is warranted.

1622P Evaluation of quality of life in survivors with malignant pleural mesothelioma in Japan

I. Oze[1], Y. Nagamatsu[2], K. Aoe[3], K. Hotta[4], K. Kato[5], J. Nakagawa[6], K. Hara[6], T. Kishimoto[7], N. Fujimoto[8]

[1]Division of Molecular and Clinical Epidemiology, Aichi Cancer Center Research Institute, Nagoya, Japan, [2]College of Nursing, St. Luke's International University, Tokyo, Japan, [3]Department of Medical Oncology, National Hospital Organization Yamaguchi-Ube Medical Center, Ube, Japan, [4]Center for Innovative Clinical Medicine, Okayama University Hospital, Okayama, Japan, [5]Department of Radiology, Kawasaki General Medical Center, Okayama, Japan, [6]Department of Nursing, Okayama Rosai Hospital, Okayama, Japan, [7]Department of Medicine, Okayama Rosai Hospital, Okayama, Japan, [8]Department of Medical Oncology, Okayama Rosai Hospital, Okayama, Japan

Background: Malignant pleural mesothelioma (MPM) is the malignancy with poor prognosis. Most patients with MPM present severe symptoms such as pain, dyspnea and fatigue. Because of the symptoms and poor prognosis, MPM survivors would have poor Quality of Life (QOL), however, their QOL has not been well evaluated.

Methods: Subjects were the survivors of MPM. We asked the cancer hospitals in Japan and MPM Patients' Association to distribute the self-administered questionnaire. QOL was evaluated using scales of the EORTC QLQ-C30 and QoQoLo short version. In addition to the QOL, clinical factors were collected using the questionnaire. Mean and its standard deviation were used to evaluate QOL scores. Wilcoxon rank sum test was used to compare the QOL scores. Factors affecting the QOL score were evaluated by multiple regression model.

Results: In total, 133 survivors with MPM participated in the study. Regarding the QOL evaluated by QLQ-C30: functional scales were poor (scores >50), while symptom scales were not so poor (scores <50). When stratified by performance status (PS), functional scores were worse in survivors with good PS than those with poor PS, while symptom scales were better in good PS survivors than those with poor PS. CoQoLo scale showed MPM survivors had good relationships with their doctors, whereas, they suffered from physical and psychological pain, and had the feeling to be a burden to others. Global health status score evaluated by QLQ-C30 were significantly better among survivors with good PS, >2 years from diagnosis, and female. Similarly, good PS and >2 years from diagnosis were the factors caused higher total score of CoQoLo core domein.

Conclusions: Survivors with MPM had physical and psychological difficulties. Even the survivors with good PS had functional difficulty. Individualized supports are required for survivors with MPM.

1623P Staging and assessment of the response to PET-CT treatment in non-small cell lung carcinoma

M. Mendez Garcia[1], M.A. Brenes[2], R. Gómez[2], M. Soriano[2], M. Torrente[1], C. Maximiano[2], G. Díaz[3], B. Rodríguez[4], M.D.M. Córdoba[5], M. Provencio Pulla[6]

[1]Medical Oncology, Hospital University Puerta de Hierro, Majadahonda, Spain, [2]Oncologia Medica, Hospital Universitario Puerta de Hierro, Madrid, Spain, [3]Neumologia, Hospital Universitario Puerta de Hierro, Madrid, Spain, [4]Medicina Nuclear, Hospital Universitario Puerta de Hierro, Madrid, Spain, [5]Thoracic Surgery, Hospital Universitario Puerta de Hierro, Madrid, Spain, [6]Servicio de Oncología Médica, Hospital Universitario Puerta de Hierro Majadahond, Majadahonda, Spain

Background: Non-small cell lung cancer (NSCLC) is the leading cause of death from tumors in Western countries. Mediastinal involvement is the most important factor to determine treatment and prognosis. The aim of this study was to analyze the concordance between histological mediastinal staging with that demonstrated by positron emission tomography and computed tomography (PET-CT), in addition to defining the characteristics of this population.

Methods: We prospectively evaluated 244 patients diagnosed with NSCLC at Puerta de Hierro Hospital, from 2009 to 2016. Mediastinal staging was determined by imaging (CT and PET- CT) and anatomo-pathological examination (endobronchial ultrasound, mediastinoscopy or lymphadenectomy). Variables collected included tumor size by CT and PET- CT, lymph node involvement, treatment, and survival. The findings of PET-CT were compared with the histological findings to determine the sensitivity, specificity, and positive (PPV) and negative (NPV) predictive values.

Results: Median of age was 66 years, 74% patients were male,22% were non-smokers. Most common histologies were adenocarcinoma (45%) and squamous (37%). 12% patients presented EGFR mutations (64% 19del) and 3%were ALK-translocated. Staging results by PET-CT were: I (26%), II (21%), III (A 26% and B 14%) and IV (10%).

The correlation in staging between CT and PET-CT, obtaining a kappa index of 0.9 ($p < 0.0001$)(Landis and Koch κ values: almost perfect agreement). In stages I and II the correlation between PET-CT and final outcome after surgery was0.61 ($p < 0.0001$)(κ values: substantial agreement). For mediastinal assessment, PET- CT has a sensitivity of 85% and specificity of 45%, PPV 61% and NPV 74%.

Conclusions: According to the data observed in our series, there is a strong concordance between the two radiological tests for staging of NSCLC (PET-CT and CT). There is also agreement between PET-CT and subsequent pathological findings in NSCLC in initial stages (I and II). Because of the high sensitivity and NPV of the PET-CT for mediastinal staging, a positive result of this test requires an histological correlation.The increase in the use of PET- CT contributes to more accurate selection of patients for appropriate treatment.

1624P "Liquid Withdarw" technique prominently reduced the incidence of pneumothorax and improved tumor tissue amount of CT-guided cutting needle lung biopsy: A retrospective study

R. Li[1], W. Ren[1], J. Gao[2], Y. Zhang[3], P. Jiang[1], X. Zhou[1], H. Zhang[2], X. Shen[2], J. Liu[1], S. Gao[1], L. Wang[1], B. Liu[1]

[1]The Comprehensive Cancer Center of Drum-Tower Hospital, Medical School of Nanjing University & Clinical Cancer Institute of Nanjing University, Nanjing, P.R. China, Nanjing, China, [2]Nanjing Drum Tower Hospital, Clinical College of Nanjing Medical University, Nanjing P.R. China, Nanjing, China, [3]Nanjing Drum Tower Hospital, Medical School of Southeast University, Nanjing P.R. China, Nanjing, China

Background: CT-guided cutting needle lung biopsy is important for the diagnosis of lung cancer. In the area of precision medicine, it has become important to obtain adequate tumor tissue for the molecular testing. Pneumothorax is one of the most prevalent complications of the biopsy. In previous study, we found that "liquid withdraw" technique (to inject small amount of liquid durimng the withdrawal of the needle) can prominently reduce the incidence of pneumothorax. In this report, we retrospectively studied 92 CT-guided lung biopsy to investigate the role of this technique in reducing complications and promoting biopsy effevtiveness.

Methods: From Jan 1st, 2014 to Nov 30th, 2016, we retrospectively studied 92 CT-guided lung biopsy using liquid withdraw techniques in 90 patients. The pathologies (cytology, histology and EGFR mutation status) and complications secondary to biopsy procedure (pneumothorax, bleeding, etc.) were noted. Pneumothorax and bleeding was graded as mild (mild and very mild), moderate, and severe.

Results: 88 cases were diagnosed out of 92 biopsies (95.7%), of which 60 cases were adenocarcinoma. Among 52 cases of adenocarcinoma who consented EGFR mutation test, only 1 case (1.9%) was failed due to insufficient tissue. Among all the biopsies, when cutting tumor tissue 4-6 times per procedure, the incidence of pneumothorax was in 18 cases (19.6%), among which 13 cases (14.1%) were very mild pneumothorax (lung surface retraction of ≤ 1 cm), mild and moderate pneumothorax accounted for just 4.3%. No severe pneumothorax occurred. No other severe complications happened.

Conclusions: Compared to lung biopsy without liquid withdraw, the incidence of pneumothorax using "liquid withdraw technique" was reduced from approximately 35% to 19.6% (14.1% were very mild pneumothorax and 0% were severe pneumothorax). The liquid withdraw technique also resulted in low rate of other complications and adequate tissue for diagnosis and treatment planning of lung cancer. Next, we are planning to conduct a prospective study to further evaluate the role of liquid withdraw technique in the precision diagnosis and treatment of lung cancer.

1625P Phase II trial of S-1 treatment as palliative-intent chemotherapy for previously treated advanced thymic carcinoma

Y. Okuma[1], Y. Goto[2], F. Ohyanagi[3], K. Sunami[4], Y. Nakahara[1], S. Kitazono[3], Y. Tambo[3], N. Yanagitani[3], S. Kanda[2], H. Horinouchi[2], A. Horiike[3], Y. Fujiwara[2], H. Nokihara[2], N. Yamamoto[2], M. Nishio[3], Y. Ohe[2], Y. Hosomi[1]

[1]Department of Thoracic Oncology and Respiratory Medicine, Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Tokyo, Japan, [2]Department of Thoracic Oncology, National Cancer Center Hospital, Tokyo, Japan, [3]Department of Thoracic Medical Oncology, The Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, Japan, [4]Department of Pathology and Clinical Laboratory, National Cancer Center Hospital, Tokyo, Japan

Background: Thymic carcinoma (TC) is a rare cancer with minimal evidence of survival with palliative-intent chemotherapy. Sunitinib and everolimus monotherapies have been proposed as active molecular-targeted approaches based on phase II (Ph II) trials, and S-1, an oral fluoropyrimidine, has been described in the NCCN guideline as an active cytotoxic agent for refractory TC based on a case series. Therefore, we conducted a Ph II trial to study the result of S-1 treatment in patients with refractory TC.

Methods: In this Ph II study performed at three cancer centers in Tokyo, we aimed to enroll 26 TC patients previously treated with platinum-based chemotherapy. The patients received S-1 orally twice daily at a dose of 40–60 mg/m^2 for 4 weeks, followed by 2 weeks off until progressive disease or unacceptable toxicities. S-1 was used off-label. The primary end-point was determining the objective response rate, and secondary endpoints were progression-free survival (PFS), overall survival (OS), and toxicities.

Results: Twenty-six patients (10 males) were recruited between November 2013 and May 2016. The median age was 63 (27–74) years. Among the 26 patients, 23 had squamous cell carcinoma histology and 10 had an ECOG performance status of 0. Additionally, one patient showed complete response and seven patients showed partial responses, resulting in a 30.8% response rate (95% confidence interval [CI], 16.5–50.0) and a 65.4% disease control rate (95% CI, 46.2–80.6). After a median follow-up of 13.4 months, the median PFS was 4.3 months (95% CI, 2.3–7.6 months) and median OS was 23.4 months (95% CI, 12.8–not reached). Treatment-related adverse events (AEs) of grade $\geq$3 included neutropenia (12%), skin rash (8%), elevated ALT, decreased WBC count, and fatigue (4%). No treatment-related death was observed. However, treatment was discontinued in three patients (12%) because of AEs.

Conclusions: S-1 as palliative-intent chemotherapy and a cytotoxic agent for refractory TC confirmed clinical activity with good tolerability.

1626P Detects esophageal squamous cell carcinoma via liquid biopsy of circulating exosomes

A. Zhou[1], A.P. Chen[1], J.S. Zhang[1], W.L. Guo[2], Z.Q. Ling[1], W. Mao[3]

[1]Zhejiang Cancer Research Institute, Zhejiang Cancer Hospital, Hangzhou, China, [2]Institute of Medicine, Zhejiang University, Hangzhou, China, [3]Department of Thoracic Oncology, Zhejiang Cancer Hospital, Hangzhou, China

Background: As with many cancers, survival rates for esophageal squamous cell carcinoma (ESCC) are poor when the disease is diagnosed at a later stage whitout any symptoms. Exosomes are 40-150nm small vesicles in blood and other body fluids and have been described as promoters of tumor progression. Although the secretory mechanisms of tumour-associated exosomes are still unclear, the use of circulating exosomes as potential non-invasive biomarkers might become promising. The object of this stduy was to determine whether the circulating exosomes can serve as biomarkers in ESCC.

Methods: Serum samples were obtained from 100 patients with ESCC and 100 healthy volunteers. Exosomes were extracted by Total Exosome Isolation Reagent, and purified to selectively capture tumor-asscociated epithelial cell adhesion molecule (EpCAM) positive exosomes by magnetic-bead technique. ELISA was performed to measure the expression of CD9 protein. Cell invasion was measured using transwell chamber. Expression levels were compared by using the Mann-Whitney U test, Friedman or Wilcoxon test., Receiver-operating characteristics (ROC) curve was established to evaluate the diagnostic value of exosome for the differentiation between ESCC patients and controls. Univariate analysis of OS and DFS was performedas outlined by Kaplan-Meier test.

Results: Expression levels of exosomal CD9 were significantly higher in ESCC patients than in healthy individuals ($p < 0.05$). The expression levels of exosomal CD9 in different TNM stages and grades were significantly higher than in the controls ($p < 0.05$, respectively). ROC analysis demonstrated that expression levels of exosomal CD9 distinguished patients with ESCC from healthy individuals with 76% sensitivity and 84% specificity. Kaplan-Meier analysis demonstrated that increased expression of exosomal CD9 was associated with poor OS and PFS in ESCC patients ($P < 0.05$). In addition, the experiments of delayed processing, freezing and thawing did not affect the expression levels of exosomal CD9. Transwell and wound scratching assay showed that the exosomes could promote cell invasion and migration.

Conclusions: Serum exosomal CD9 might represent potential diagnostic and pronostic biomarkers in ESCC in the future.

1627TiP ONCOS-102 and pemetrexed/cisplatin in patients with unresectable malignant pleural mesothelioma

S. Ponce Aix[1], S. Viteri[2], J. Bosch-Borrera[3], L. Kuryk[4], T. Hakonen[4], S. Vetrhus[5], M. Jäderberg[5], L. Paz-Ares[1]

[1]Department of Medical Oncology, University Hospital 12 de Octubre, Madrid, Spain, [2]Medical Oncology, QuirónSalud Dexeus University Hospital, Instituto Oncológico Dr Rosell (IOR), Barcelona, Spain, [3]Oncologia Mèdica, Institut Català D'Oncologia (I.C.O), Girona, Spain, [4]R&D, Targovax OY, Helsinki, Finland, [5]R&D, Targovax ASA, Oslo, Norway

Background: Mesothelioma is a rare cancer with poor prognosis and limited treatment options, including surgery, radiotherapy and chemo (pemetrexed + cisplatin/carboplatin). Adenoviruses are excellent immunotherapeutic agents with a unique ability to prime and boost immune responses. ONCOS-102 is a granulocyte-macrophage colony stimulating factor (GM-CSF) – expressing oncolytic adenovirus (Ad5/3-D24-GMCSF). In a prior phase I study of 12 patients (pts) with advanced solid tumors, 40% had stable disease (SD) at 3 months, 11/12 pts had infiltration of CD8+ lymphocytes in lesions, and 10/12 had intralesional PD-L1 expression increase. Lesional immune activation was seen in two pts with mesothelioma.

Trial design: A randomized Phase II study (n = 24) with a non-randomized Phase Ib safety lead-in cohort (n = 6). The study will compare ONCOS-102 and chemo with chemo alone (control arm). Eligible pts have histologically confirmed unresectable disease and are not candidates for curative surgery. Pts can be naïve to chemo, or have received and responded to chemo, but relapsed after at least 6 months thus eligible for renewed chemo treatment. Pts must have measurable disease with tumour accessible to intratumoural injections of ONCOS-102 and biopsies. A Data Safety Monitoring Committee will review data when the first 3 and all 6 pts have completed the Day 64 visit (i.e. after 2 cycles of chemo and 4 injections of ONCOS-102). If safety is acceptable, phase II will start with 10 pts in the control arm, and 14 pts in the experimental arm. Primary objective: Safety. Secondary objectives: 1) Tumour specific immunological activation in peripheral blood and biopsies 2) Response Rate 3) Progression Free Survival 4) Overall Survival and 5) Correlation between immune activation and clinical outcome. Treatment: Single cyclophosphamide dose followed by intratumoral injection of ONCOS-102 at 3x10^{11}viral particles (VPs) on days 1, 4, 8, 36, 78 and 120. Pemetrexed (500mg/m^2)/cisplatin(75mg/m^2) is given on day 22 and every 3 weeks for a maximum of 6 cycles. Imaging at baseline, Day 64 and 148. Tumor biopsies from both injected and non-injected lesions at baseline and Day 36.

Background: Advances in Next Generation Sequencing (NGS) are enabling detailed molecular analysis of tumour and circulating tumour DNA (ctDNA). Combined with the expanding development of targeted therapies we are in the era of Precision Medicine. Molecular Tumour Boards (MTB) are needed to interpret genomic data and inform on clinically relevant matched therapies. We describe our experience of setting up a MTB to deliver a world-class genomic driven oncology programme.

Methods: Patients referred to the Experimental Cancer Medicine Team were consented for analysis of ctDNA and tumour under the TARGET (Tumour ChAracterisation to Guide Experimental Targeted Therapy) protocol. ctDNA was subjected to NGS and bioinformatic analysis for alterations in 650 cancer associated genes. Tumour was analysed by NGS for a panel of 24 genes regarded as relevant for treatment of solid tumours. We established a MTB comprising medical oncologists, clinical geneticists, bioinformaticians, scientists and bioethicists to interpret results and advise on clinical relevance and trial options. The aim of Part A of TARGET was to establish workflow and process.

Results: From Apr 2015 to Nov 2016 we recruited 100 patients to Part A. Main tumour types were colorectal (24%), breast (20%) and lung (18%). In 41% of patients a potentially actionable aberration was identified. The main challenges were i) optimisation of a bioinformatic pipeline for ctDNA, ii) linking clinical data with genomic data in a single portal, iii) interpretation of unknown variants and iv) linking results to available clinical trials in UK/Europe.

Conclusions: We have successfully implemented a comprehensive molecular profiling programme. The bioinformatic pipeline for ctDNA has evolved through real-life data collection and comparison with tumour/germline DNA. We are developing a web-based interface for linking clinical and genomic data for visualisation and annotation within the MTB. Variant interpretation software packages are being evaluated for data curation and ability to link with matched clinical trials. Recruitment of 450 patients to Part B of TARGET is underway to match patients with early phase trials in real-time.

1629O A systematic rapid autopsy program tracks temporal and spatial heterogeneity of human tumors and identifies mechanisms of resistance to targeted therapies

C.S. Walmsley[1], D. Juric[1], A. Bardia[1], L. Henderson[1], J. Gurski[1], J.R. Stone[2], C. Pinto[1], S.J. Isakoff[1], D.M. Fitzgerald[1], J.F. Gainor[1], L. Goyal[1], M. Broudo[1]

[1]Termeer Center for Targeted Therapies, Massachusetts General Hospital Cancer Center, Boston, MA, USA, [2]Department of Pathology, Massachusetts General Hospital, Boston, MA, USA

Background: Temporal and spatial heterogeneity of human tumors pose a significant barrier in the identification of effective anticancer therapies. Rapid autopsy, defined as post-mortem examination with collection of tissues for diagnosis and research within 6 hours of death, is a critical tool offering insight into this phenomenon.

Methods: Since January 2014, an on-call rapid autopsy team consisting of a pathologist, medical oncologist, pathology assistant and a tissue collection coordinator performed rapid autopsies on 51 patients with genomically-defined advanced solid tumors. Samples were collected from the primary tumor when present, multiple metastatic lesions, blood, as well as multiple uninvolved sites. All samples were recorded in a centralized database linked to patient's treatment history, as well as all previously collected tissue and liquid biopsies, under one clinical data and sample collection protocol. Samples meeting minimum viability and tumor cellularity criteria were selected for downstream analyses, including next-generation sequencing and protein-based assays.

Results: In 51 rapid autopsies, a median of 12 tissue samples were collected per autopsy (range 5-24), after a median of 2 hours and 50 minutes post mortem (range 32 minutes - 9 hours). 47 autopsies (92.2%) were completed $<$ 6 hours post mortem, and 4 autopsies (7.8%) were completed $>$ 6 hours post mortem due to delays in the confirmation of the autopsy consent from the patient's healthcare proxy and transportation delays. Tumor cellularity of collected samples ranged from 0-90% (median 60%), making these samples highly suitable for subsequent genomic analyses. Full analysis of 3 autopsy series revealed molecular alterations driving resistance to PI3K-alpha inhibitors, CDK4/6 inhibitors and FGFR inhibitors in patients with PIK3CA-altered metastatic breast cancer and FGFR2 fusion positive cholangiocarcinoma.

Conclusions: Rapid autopsies complement serially collected tissue and liquid biopsies, providing invaluable samples for analysis of tumor heterogeneity, evolutionary dynamics and determination of resistance mechanisms to targeted therapies.

Background: PD-L1 is the only validated predictive biomarker for use with immune checkpoint inhibitors targeting the PD-1 pathway in advanced NSCLC.

Methods: Correlation of PD-L1 expression with that of MET, ALK, PTEN proteins by IHC (MET+:$\geq$2+ and % staining$\geq$50%, ALK+: $\geq$1+, PTEN+: H-score$>$0) and mutations in *KRAS*, *EGFR*, *PIK3CA* or *MET* genes was explored in the large international ETOP Lungscape cohort of resected, stages I–III, NSCLC. The DAKO 28-8 immunohistochemistry assay was used to assess PD-L1 expression, and gene mutations testing was based on Fluidigm technology, a microfluidics-based multiplex PCR platform. PD-L1 expression was defined with alternative cut-offs ($\geq$1%, 5%, 50%) for neoplastic cell membrane staining.

Results: PD-L1 expression was assessed in 2182 pts, from 15 centers, 51/42/7% adenocarcinomas (AC)/squamous cell carcinoma (SCC)/other, 49/29/22% stage I/II/III, 32/54/11% current/former/never smokers, 4% unknown smoking status. For the 1% cut-off, a significant association was detected between PD-L1 and MET expression both for AC and SCC (PD-L1 positivity in AC: 61% in MET + vs 33% in MET-, $p < 0.001$; SCC: 57% vs 42%, $p = 0.005$). PD-L1 positivity was more frequent in PTEN expressing AC (48% vs 37% in PTEN loss subgroup, $p = 0.0017$), but not in SCC ($p = 0.62$). The association of ALK expression and PD-L1, explored only in the AC, was not significant ($p = 0.42$). Significant associations were also detected in AC between PD-L1 and *KRAS*

and *EGFR* genes. PD-L1 positivity was higher in *KRAS* mutated pts (AC: 46% vs 38% in KRAS wild-type (wt), p = 0.022; SCC: p = 0.88), and less frequent in *EGFR* mutated pts (AC: 27% vs 42% in EGFR wt; p = 0.012; SCC: only 8 mutated pts, no inference can be drawn). No significant correlation was detected between PD-L1 and *PIK3CA* or *MET* mutations. Results were analogous for the 5% and 50% cut-offs, with the exception of non-significant association between PD-L1 and *EGFR* in AC.

Conclusions: In this large NSCLC cohort, PD-L1 positivity (with 1%, 5% or 50% cut-off) is found to be significantly associated with IHC MET overexpression, expression of PTEN and *KRAS* mutation.

1631PD Prominent immune suppressive tumor microenvironment in female never-smoker lung cancer patients with EGFR mutations

B. Park[1], D-E. Ryu[2], H.K. Kim[1], J.H. Cho[1], J. Lee[1], J. Lee[3], H-O. Lee[2], J-G. Joung[2], W-Y. Park[2], J. Kim[1]

[1]Thoracic and Cardiovascular Surgery, Samsung Medical Center Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [2]Molecular Cell Biology, Samsung Genome Institute, Samsung Medical Center Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [3]Biomedical Science, Samsung Biomedical Research Institute, Samsung Medical Center Sungkyunkwan University School of Medicine, Seoul, Republic of Korea

Background: According to genetic and genomic analysis as well as previous clinical research, lung cancer in never-smokers might have pathogenesis and progression different from that of lung cancer among smokers. There has been indirect evidence that different types of mutations in tumors might be related to the altered immune functions.

Methods: Tissues from 110 female patients with lung adenocarcinoma (never-smokers: 102 & smokers: 8) at the Samsung Medical Center, were analyzed by next-generation genomic sequencing including whole-exome seq and RNA-seq. Somatic mutations and gene expression levels of immune signature genes were profiled. The significance for clinical outcome of the selected genes was plotted using Kaplan-Meier method and log-rank test.

Results: Expression biomarkers of immune suppressive cells such as mast cells, macrophage and Treg were prominent in female never-smokers compared to female smokers of lung adenocarcinoma. The data suggest that cells of cytotoxic functions are deactivated in smokers, whereas cells of immune suppressive functions are activated in never-smokers. Specifically as expression of immune markers specific for B-cells, dendritic cells, mast cells and Treg was especially up-regulated ($p<.05$) in tumors from patients with EGFR mutation (42%), its mutation status may play an important role in augmenting the immune suppressive activity. EGFR mutation–positive adenocarcinoma was significantly associated with low level of expression of an immune checkpoint molecule, programmed death-ligand 1 (PD-L1), in contrast with high level of cytotoxic T-lymphocyte–associated antigen 4 (CTLA-4) in female never-smokers.

Conclusions: This overall immune suppression in lung adenocarcinoma patients with EGFR mutation might explain the lower response rate of anti-PD-1/PD-L1 blockade to the female never smokers, which suggests that other approaches to block the immune suppressive microenvironment would be necessary.

1632PD A novel radiomic based imaging tool to monitor tumor lymphocyte infiltration and outcome of patients treated by anti-PD-1/PD-L1

R. Sun[1], E.J. Limkin[2], L. Dercle[3], S. Champiat[4], S. Reuzé[2], D. Brandao[5], L. Verlingue[4], S. Ammari[6], S. Aspeslagh[7], A. Schernberg[1], S. Postel-Vinay[7], A. Hollebecque[4], C. Massard[7], A. Marabelle[7], C. Robert[2], J-C. Soria[7], E. Deutsch[1], C. Ferté[8]

[1]Radiotherapy Department, Radiomics INSERM U1030, Institut Gustave Roussy, Villejuif, France, [2]Radiomics INSERM U1030, Institut Gustave Roussy, Villejuif, France, [3]Nuclear Medicine, Institut Gustave Roussy, Villejuif, France, [4]Drug Development Department (DITEP), Institut Gustave Roussy, Villejuif, France, [5]INSERM U1170, Gustave Roussy Cancer Campus Grand Paris, Villejuif, France, [6]Radiology, Institut Gustave Roussy, Villejuif, France, [7]Drug Development Department (DITEP), Gustave Roussy Cancer Campus, Villejuif, France, [8]Head and Neck, Gustave Roussy, Villejuif, France

Background: Tumor infiltrating lymphocytes (TIL) appears necessary to trigger anti-cancer activity of anti-PD-1/PD-L1. Radiomics consists in the analysis of quantitative data extracted from standard medical imaging to generate imaging biomarkers. We developed a radiomics-based predictor of TIL and investigated whether such signature could predict the outcome of patients treated by anti-PD1/PD-L1.

Methods: We first developed a predictive model of tumor infiltrating CD8 T cells with RNA-Seq and raw imaging data (CT –Scan) using random forest in 69 HNSCC patients from the TCGA (The Cancer Genome Atlas)/TCIA (The Cancer Imaging Archive) database. CD8 T cells were estimated by the Microenvironment Cell Populations-counter signature. To validate our tool, this signature was applied to a first independent cohort of 100 patients for which the pathologic TIL was assumed as either high (lymphoma, melanoma, lung, bladder, renal and MSI+ cancers; 30 patients) or low (adenoid cystic carcinoma, low-grade neuroendocrine tumors, uterine leiomyoma; 70 patients). Finally, we applied our signature on a second cohort of 139 patients prospectively enrolled in anti-PD-1/PD-L1 phase 1 trials to infer its relation with patient outcome (Overall Survival).

Results: We developed a CD8 radiomics-based signature with six out of the 80 extracted features from CT-scans. As an internal validation, the correlation of this signature with the estimated TCGA CD8 was: spearman's rho=0.81 ($P < 1e-5$). In the first external cohort, this signature was associated with the assumed lymphocyteness (Wilcoxon test, $P < 0.001$). When validating our signature in the second external cohort, the median of the CD8 signature predicted score was used to separate patients into two groups. Patients with high predicted CD8 score had significantly better OS (HR = 0.55, 95%CI=0.36-0.86, P = 0.009) and the CD8 signature remained significant after multivariate analysis including RMH score and the number of previous lines of treatment (HR = 0.48, 95%CI=0.31-0.76, P = 0.002).

Conclusions: The radiomics-based signature of TIL was validated in two external cohorts. It appears a promising tool to estimate TIL and to infer the outcome of metastatic patients treated with anti-PD1/PD-L1.

Background: The 4q12 amplicon (4q12amp) which harbors the tyrosine kinases KIT, KDR and PDGFRA has been thought to occur as frequently as 3-7% in lung adenocarcinoma (LA) (Ramos et al, 2009) and 5-15% in glioblastoma (GBM) (Holtkamp, 2006; Szerlip, 2012) as assessed by a variety of techniques. As 4q12amp is hypothesized to be an oncogenic driver, it remains unclear whether all three kinases participate equally in oncogenesis, or if one kinase can be preferentially targeted by a tyrosine kinase inhibitor (TKI) for patient benefit. We undertook a large-scale genomic analysis to describe the frequency of 4q12 across solid tumors.

Methods: We prospectively analyzed 114,200 primarily advanced stage solid tumors in the course of clinical care using hybrid-capture based comprehensive genomic profiling (CGP) of 186 to 315 genes plus introns from 14 to 28 genes commonly rearranged in cancer.

Results: 4q12amp was present in 0.65% of all cases (740/114,200), with a median copy number of 10, and was most abundant in the following cancers: 4.8% of GBM (155/3,222), 0.83% of lung cancers (191/22,857, 2/3 approximately being LA), 1.9% of sarcomas (106/5,391), and 0.77% of breast cancers (92/11,980). Of sarcomas, 7.1% of osteosarcomas (26/367) and 2.82% of soft tissue sarcomas NOS (22/780) harbored 4q12amp. Of 4q12amp lung cancer cases, the supramajority (86%) did not harbor known oncogenic drivers of NSCLC (alterations of EGFR/HER2/MET, ALK/ROS/RET fusions, or BRAF V600E). Index cases of durable responses to pazopanib and imatinib will be described in undifferentiated sarcoma, synovial sarcoma, and head and neck/salivary cancers.

Conclusions: 4q12amp is significantly less frequent in GBM and lung cancer than previously reported by non-sequencing techniques, but is enriched in osteosarcoma and undifferentiated sarcomas. The driver status of 4q12amp is supported both by the predominant mutual exclusivity with other known drivers in lung cancer, and responses to various multi-TKIs. The specificities of the latter may help shed insight into whether singly or multiply targeting KIT/KDR/PDGFRA is a preferred approach for patient benefit.

1634P FGFR pathway genomic aberrations and response to FGFRs inhibitors

M. Faure[1], A. Hollebecque[1], R. Bahleda[1], J-C. Soria[1], V. Dyevre[2]
[1]Medical Oncology, Institut Gustave Roussy, Villejuif, France, [2]Biostatistics and Epidemiology, Institut Gustave Roussy, Villejuif, France

Background: Fibroblast growth factor receptors (FGFRs) are broadly distributed transmembrane tyrosine kinase receptors. They promote cell development, differentiation, survival, migration, angiogenesis, and carcinogenesis. Specific FGFR aberrations was observed in certain cancers, some are known to be driver for tumor progression, and related to prognosis or sensitivity to cancer treatments. It is consistent to hypothesize that targeting these cancers with FGFR inhibitors would be therapeutically beneficial.

Methods: We lead a retrospective, descriptive, monocentric study, involving results of three phase I trials of Institut Gustave Roussy, for patients with refractory various solid tumors, previous selected on FGFR abnormality (amplification, single nucleotid variant (SNV), translocation). Primary endpoint was tumor response. Secondary endpoints were difference in tumor according to the type of mutation, and time to failure (TTF).

Results: 55 patients with median age of 55 years and various solid tumors were enrolled between February 16, 2011 and October 26, 2016. All patients had advanced or metastatic cancer with a median of 3.5 metastatic sites. They were heavily pretreated, in median 3 prior regimens of chemotherapy, 0 to 2 lines of targeted therapy, and one patient had immunotherapy. For patients with FGFR fusion proteins, 43% achieved partial response (PR). Median tumor response was - 46%, sustained response until 17 months. Response of SNV group depended on the type of mutation and degree of pathogenicity, in the different tumor locations. 20% had PR. Whereas some pathogenic mutations lead to dramatic response until 18 months; others failed to achieve tumor shrinkage or stabilization. 5% of patient with FGFR amplification had tumor response for 3 months only. Main clinical and biological toxicities were grade 1/2 and resolved after interruption. Treatment was resumed, at same or lower dose, excepted for 3 patients with permanently discontinuation. There was no death due to toxicity.

Conclusions: We identified genetic alterations in various members of the FGF/FGFR system that represent suitable predictive biomarkers to guide patient selection for treatment with selective pan FGFRs targeting agents.

Background: Pt selection is critical for the future development of FGFRinh. Our institution aimed to implement a translational platform to obtain samples of FGFRalt pt included in phase 1 trials.

Methods: Prospective generation of a collection of pt samples with molecularly-selected FGFRalt tumors [amplified(amp)/mRNA high expression(mRNAh)/mutated(mut)/translocated(trans)]. We developed a protocol to obtain serial biopsies (bx) during therapy with an FGFRinh, including warm autopsies, for patient-derived xenografts (PDXs) generation. We collected plasma for analysis of circulating tumor DNA (ctDNA). Clinical benefit (ClinBen) was defined as any tumor shrinkage or disease control for 4 months.

Results: From 2014 to 2017, 40 FGFRalt pt were included [FGFRamp (20)/mRNAh (7)/mut(17)/trans (3)]. 30 cases received an FGFRinh [multi-tyrosin kinase (7), selective reversible-(8) or irreversible-FGFR1-4inh (14) or FGFR4inh (1)]. 8 cases achieved ClinBen (5 breast - 2 FGFR1amp, 2 FGFR1mut, 1 11q+FGFR2amp-/1 biliary tract FGFR2trans/1 head&neck FGFR1mRNAh/1 mullerian carcinosarcoma FGFR2mut). PDXs/bx after progression to FGFRinh (10) and warm autopsies of responding pt (2) will serve to study tumor heterogeneity and resistance mechanisms using novel high-throughput technologies. All PDXs (16 growing/14 in observation) will help in identifying potential predictive biomarkers and further characterizing the mechanism of action of FGFRinh *in vivo. In vitro* functional profiling of oncogenic activity of FGFRmut (17) will be performed. Blood samples will serve for developing in-house cfDNA analysis to monitor genomic evolution of these 40 pt.

Conclusions: We have succesfully developed a powerful precision medicine framework for linking the molecular biology with the best tumor models in parallel with early clinical research. By integrating the knowledge obtained from the analysis of relevant samples, we aim to validate future hypothesis-driven therapies for selected FGFRalt pt and guide the successful development of FGFRinh. 1636P EPHA2 receptor is involved in in vivo acquired resistance to anti-Epidermal Growth Factor Receptor (EGFR) treatment in metastatic colorectal cancer (mCRC)

G. Martini[1], V. Belli[1], P.P. Vitiello[1], T. Troiani[1], C. Cardone[1], S. Napolitano[1], N. Matrone[1], V. Sforza[1], R. Franco[1], F. Morgillo[1], D. Ciardiello[2], E. Giunta[3], V. De Falco[2], N. Zanaletti[3], P. Vitale[3], E. Martinelli[2], F. Ciardiello[1]
[1]Dipartimento Medico-Chirurgico di Internistica Clinica e Sperimentale "F. Magrassi E A. Lanzara", Università degli Studi della Campania "Luigi Vanvitelli", Naples, Italy, [2]Oncologia Medica, Dipartimento di Internistica Clinica e Sperimentale "F. Magrassi", Università degli Studi della Campania Luigi Vanvitelli, Naples, Italy, [3]Oncologia ed Ematologia, Università della Campania "Luigi Vanvitelli", Naples, Italy

Background: EPHA2 tyrosine kinase receptor is implicated in cell growth, migration, and invasiveness in a wide range of cancers. We studied its role as a potential marker of resistance to anti-EGFR drugs in colorectal cancer (CRC). We previously demonstrated that EPHA2 was differently activated among a panel of CRC cell lines with primary and acquired resistance to cetuximab and the use of ALW-II-41-27 (EPHA2 selective inhibitor) in combination with cetuximab was able to revert this resistance in *in vitro* experiments (abstract presented at 2016 ESMO Congress in Copenhagen). Here we present the study on *in vivo* models.

Methods: EGFR dependent SW48 and LIM1215 cell lines were engrafted into nude mice and treated with cetuximab until disease progression. Once tumors became resistant (SW48-CR and LIM1215-CR) mice were randomized in groups of 10 mice each and assigned to receive ALW- II-41-27 as single agent or in combination with cetuximab, no treatment and cetuximab alone group served as control. ALW- II-41-27 was administered daily at 30 mg/kg by oral gavage and cetuximab intraperitoneally at 1 mg/kg two days a week. Treatment was performed for three weeks, then mice were euthanized and protein expression in tumors was analysed by Western Blot.

Results: The combination of the two drugs induced a significant reduction of tumor volume since the first administration. A reduction of 50% of tumor volume was found in 5 out 10 LIM1215-CR mice treated with ALW-II-41-27 as single agent. This effect was maintained after cessation of therapy and induced prolonged survival. Tumor protein analysis by WB demonstrated a strong reduction of EPHA2 expression and activation in mice treated with the combination of ALW-II-41-27 and cetuximab, accompanied by a significantly inhibition of activated pMAPK and pAKT.

Conclusions: These results highlight the role of EPHA2 as a potential therapeutic target in mCRC treatment.

1637P Eph A2 expression is a predictive biomarker of poorer activity and efficacy of FOLFIRI + cetuximab in RAS WT metastatic colorectal cancer (mCRC) patients (pts) in the CAPRI GOIM trial

C. Cardone[1], M.C. Paul[2], V. Moreno-Viedma[2], G. Martini[1], P.P. Vitiello[1], D. Ciardiello[1], V. Sforza[1], T. Troiani[1], S. Napolitano[1], P. Vitale[1], N. Zanaletti[1], A.M. Rachiglio[3], D. Rizzi[4], E. Maiello[5], N. Normanno[6], M. Sibilia[2], F. Ciardiello[1], E. Martinelli[1]

[1]Oncologia Medica, Dipartimento di Internistica Clinica e Sperimentale "F. Magrassi", Università degli Studi della Campania Luigi Vanvitelli, Naples, Italy, [2]Department of Medicine I, Institute of Cancer Research, Vienna, Austria, [3]Laboratory of Pharmacogenomics, Centro di Ricerche Oncologiche di Mercogliano (CROM), National Cancer Institute 'Fondazione Giovanni Pascale', Naples, Italy, [4]Trial office, GOIM, Bari, Italy, [5]Oncologia, IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy, [6]Cell Biology Unit, Istituto Nazionale Tumori – I.R.C.C.S - Fondazione Pascale, Naples, Italy

Background: Eph A2 promotes tumor growth, invasiveness and angiogenesis in mCRC. Targeting Eph A2 could overcome resistance to anti-epidermal growth factor receptor treatment in colon cancer preclinical models.

Methods: Formalin-fixed paraffin-embedded tumor specimens from 82 RAS wild type (WT) mCRC pts treated with cetuximab + FOLFIRI as first line therapy in the CAPRI GOIM trial were assessed for Eph A2 expression by immunohistochemistry. Eph A2 levels were evaluated developing an HSCORE [1 × (% cells 1+) + 2 × (% cells 2+) + 3 × (% cells 3+)] (range: 0-300). A cut off was set by ROC analysis to define high (>50) and low (≤50) Eph A2 levels.

Results: Eph A2 expression was found in 55/82 (67%) cases. According to HSCORE Eph A2 levels were low in 54 (66%) and high in 28 (34%) samples. Eph A2 expression resulted in mostly complete membranous staining. Tumor stroma was positive in 15/82 (18%) cases. In most of these cases an intense immune infiltrate was observed. Non-tumor adjacent normal mucosa was assessable in 34/82 samples. Eph A2 was expressed in 16/34 (47%), more frequently in dysplastic epithelial areas. A significant correlation between Eph A2 expression in tumor and stroma was found ($p < 0.0001$). Eph A2 was more frequently expressed in less differentiated tumors ($p = 0.02$), as well as in left-sided tumors compared to right-sided tumors [17/28 (61%), 11/28 (39%), respectively $p = 0.04$]. Eph A2 expression was associated with higher rate of disease progression (PD) 8/28 (29%) vs 5/54 (9%) ($p = 0.02$), and with worse median PFS [8.6 m (CI95% 6.4-10.8) vs 12.3 m (CI95% 10.4-14.2) $p = 0.030$], both in left and right-sided tumours. Moreover, median OS was 28.4 m (CI95% 13.1-43.7) vs 39.8 m (CI95% 30.2-49.4), although this result did not reach statistical significance ($p = 0.23$).

Conclusions: Eph A2 levels were significantly associated with a worse PFS and an increase in PD in RAS WT mCRC pts treated with cetuximab + FOLFIRI as first line therapy in the CAPRI GOIM trial, in both right- and left-sided tumors. A similar trend was observed for OS. Eph A2 might represent an additional predictive biomarker of lack of efficacy in RAS WT mCRC pts treated with cetuximab + FOLFIRI.

Quirón Dexeus, Barcelona, Spain, [5]Servicio de Oncología Médica, Hospital General Universitario de Valencia-CIBERONC, Valencia, Spain, [6]Laboratorio de Oncología Molecular, Fundación para la Investigación, Hospital General Universitario de Valencia, Valencia, Spain, [7]Laboratorio de Oncología Molecular, Fundación para la Investigación, Hospital General Universitario de Valencia-CIBERONC, Servicio de Oncología Médica, Hospital General Universitario de Valencia; Departamento de Medicina, Universidad de Valencia, Valencia, Spain

Background: Targeted inhibition of EGFR represents a milestone in lung cancer treatment. Development of sensitive and accurate techniques allows the detection of EGFR mutations in liquid biopsies. CTCs and ctDNA analysis may be useful in treatment selection, response monitoring, and early resistance detection. The aim of this study was to correlate the EGFR mutational status of CTCs and cfDNA at diagnosis and during follow-up in non-small-cell lung cancer (NSCLC) patients.

Methods: The study included 22 EGFR mutated NSCLC patients, blood samples were collected and repeated sampling was performed during follow-up and at progression. cfDNA was obtained from plasma; whereas CTCs were isolated by size using a filtration-based device (ScreenCell), characterized and enumerated by H&E. CTC and cfDNA genotyping was performed by PNA-Taqman assay for EGFR 19del, L858R, G719X and T790M detection.

Results: Patient's median age was 65 years, 81.8% were female, 70% never-smokers and 94% were ADC. The follow-up ranged from 3 to 48 months. Out of the 22 *EGFR* mutated tumors identified, 12 harbored exon 19 deletion, 7 L858R mutation in exon 21, 2 G719X mutation and one presented exon 19 deletion and T790M together at diagnosed. All patients were treated with EGFR-TKIs. 110 blood samples were evaluated at baseline and during follow-up. CTCs were observed by H&E with a range 1-30/3 ml. Our results confirm that detected mutations can provide early outcome information. Early undetectable blood mutations after EGFR-TKI might predict a large clinical response, whereas in TKI-responders patients, *EGFR* mutation remained undetectable, its reappearance preceded disease progression. In case of persisted mutation during treatment, a rapid progression and exitus was observed. A baseline T790M mutation in EGFR TKI-naïve patient has been reported with rapidly progression and exitus.

Conclusions: Results suggest that analyses of EGFR mutations in CTC and cfDNA have important clinical implications and can be a useful biomarker of diagnoses, response to therapy and early detection of mechanisms of TKIs resistance, in advance of clinically detection. 1639P Tucatinib, a HER2 selective kinase inhibitor, is active in patient derived xenograft (PDX) models of HER2-amplified colorectal, esophageal and gastric cancers

S. Peterson, P. de Vries, J. Piasecki, R. Rosler

Research and Development, Cascadian Therapeutics, Seattle, WA, USA

Background: Tucatinib, an orally bioavailable and HER2 selective small molecule tyrosine kinase inhibitor, is currently being developed for HER2+ metastatic breast cancer in combination with capecitabine + trastuzumab (HER2CLIMB study). In addition to breast cancer, HER2 is amplified in subsets of patients with other malignancies, including gastrointestinal cancers (colorectal, esophageal and gastric cancers). To test whether tucatinib might have utility in treating HER2-amplified cancers originating from the gastrointestinal tract, tucatinib was tested alone, and in combination with trastuzumab, in cell line derived and PDX models of colorectal, esophageal and gastric cancer.

Methods: *In vitro* assays were performed to evaluate the combination of tucatinib and trastuzumab in HER2-amplified cell lines by measuring changes in signal transduction (pHER2, pHER3, pAKT) and cell survival. The *in vivo* activity of tucatinib (50 mg/kg BID) and trastuzumab (20 mg/kg Q3D) was evaluated alone, or in combination, in established HER2-amplified tumor models, including PDX models of colorectal, esophageal and gastric cancers.

Results: As a single agent, or in combination with trastuzumab, tucatinib demonstrated significant anti-tumor activity, including tumor regressions, in the N87 gastric cancer cell line xenograft model and in PDX models of HER2 amplified colorectal, esophageal and gastric cancers. The combination of tucatinib and trastuzumab was consistently more active than either single agent alone, and resulted in tumor growth inhibition from 85-139%, including complete tumor regressions in HER2+ gastric PDX models.

Conclusions: The activity of tucatinib in HER2-amplified colorectal, esophageal and gastric tumor xenograft models supports the exploration of using tucatinib to treat HER2+ gastrointestinal cancers in the clinical setting. To this end, an open label phase II clinical study combining tucatinib with trastuzumab in HER2+/RAS wild type metastatic colorectal cancer (MOUNTAINEER) has recently been initiated.

1640P PI3K/RICTOR-mTORC2 axis as a driver of prognosis and potential druggable target in squamous cell lung carcinoma (SqCLC)

S. Pilotto[1], M. Simbolo[2], A. Gkountakos[3], C. Vicentini[2], I. Sperduti[4], V. Ludovini[5], R. Chiari[5], S. Novello[6], M. Milella[7], A. Mafficini[2], L. Carbognin[1], E. Caregnato[1], A. Santo[1], M. Infante[8], M. Brunelli[3], V. Corbo[2], A. Scarpa[2], G. Tortora[1], E. Bria[1]

[1]*Medical Oncology, University of Verona, Verona, Italy,* [2]*ARC-Net Centre for Applied Research on Cancer, University and Hospital Trust of Verona, Verona, Italy,* [3]*Department of Pathology and Diagnostics, University and Hospital Trust of Verona, Verona, Italy,* [4]*Biostatistics, Regina Elena National Cancer Institute, Rome, Italy,* [5]*Medical Oncology, Ospedale S. Maria della Misericordia, Perugia, Italy,* [6]*Department of Oncology, University of Turin, Turin, Italy,* [7]*Medical Oncology, Regina Elena National Cancer Institute, Rome, Italy,* [8]*Thoracic Surgery, University of Verona, Verona, Italy*

Background: We built a risk classification model for resected SqCLC (R-SqCLC) by combining clinicopathological predictors to discriminate patients' (pts) prognosis (*Pilotto JTO 2015*), we externally validated this model in a pts' cohort of > 1,300 R-SqCLC (*Bria WCLC 2016*) and we performed an integrated multi-platforms genome analysis of prognostic outliers to identify potentially druggable modulators as the PI3K/RICTOR-mTORC2 axis (*Pilotto WCLC 2016*). Here, we validate our molecular findings and we enhance our rationale with *in vitro* studies.

Methods: Next Generation Sequencing (NGS) analysis of somatic mutations (SM) and copy number alterations (SCNA) was performed (Ion AmpliSeq Lung & Colon Cancer Panel: 22 genes, a SqCLC customized targeted NGS panel: 20 genes, the commercial Ion AmpliSeq Comprehensive Cancer Panel: 409 genes). In vitro experiments were performed using the SqCLC cell line H-1703 (Rictor amplified-6 copies). PF-05212384 [PI3K/mTOR inhibitor (inh)], AZD2014 (mTORC1/2 inh), MK-2206 (panAkt inh), everolimus (mTOR inh) and chemotherapeutic drugs (Docetaxel, Gemcitabine) were tested. Cell viability was assessed by crystal violet assay and the half maximal inhibitory concentration (IC50) was estimated to evaluate drug efficacy.

Results: Main results of overall 97 pts (Training/Validation: 60/37) are presented in the Table.

Table: 1640P

	Gene	Training Set [%]	Validation Set [%]
SM	TP53	53 [88.3]	27 [72.9]
	TIE1	4 [6.7]	2 [5.4]
	PTEN	6 [10]	4 [10.8]
	PIK3CA	3 [5]	3 [8.1]
SCNA Gains	RICTOR	13 [35.1]	14 [23.3]
	PIK3CA	17 [45.9]	26 [43.3]
	FRS2	8 [21.6]	7 [11.7]
	FGFR1	14 [37.8]	18 [30]
SCNA Losses	PTEN	5 [13.5]	19 [31.7]
	TSC2	8 [21.6]	7 [11.7]

The *in vitro* results support a significant inhibition of H-1703 cells proliferation by Gemcitabine, Docetaxel, PF-05212384, MK-2206 and AZD2014 with IC50 values of 0.4 nM, 0.45 nM, 10 nM, 66 nM, 110 nM, respectively. Everolimus was not effective.

Conclusions: Our multi-step genomic analysis performed in almost 100 R-SqCLC pts allowed us to identify altered pathways with a biological impact in SqCLC oncogenesis, as the *PI3K/RICTOR-mTORC2* axis. Moreover, our *in vitro* results justify pursuing mTOR inhibition, focusing on mTORC2 complex, in RICTOR-aberrant tumors.

Background: The anti-HER2 monoclonal antibody Trastuzumab is central to the treatment of HER2-positive gastric cancer (GC); however, its responses are limited due to some poorly understood mechanisms of resistance. The aim of this study was to asses the antitumortal activity of Duligotuzumab, an anti HER3 antibody or Taselisib, a Pi3k inhibitor combined with Trastuzumab IN a panel of HER2 positive human gastric cancer cell lines (GCC), to improve anti HER2 treatment efficacy.

Methods: We evaluated in vitro the effect of Duligotuzumab, Taselisib and Trastuzumab in single agent and in combination treatments in HER2-positive GCG (NCI-N87, KATOIII, OE19) and in negative HER2 GCC (MKN28), through proliferation, migration and apoptosis assays. We also investigated the effect of combined treatment on downstream intracellular signaling, by western blot analysis.

Results: After establishing, through a dose response curve, the IC50 for each drug used ($\approx 0.5\ \mu M$), a significant synergistic effect of Duligotuzumab, Taselisib and Trastuzumab treatments in HER2-positive GCG was observed by reduction of proliferation and migration in KATOIII, OE19 and N87 cell lines; the same effect was found analyzing the apoptotic rate. At cellular level, in particular in KATOIII and OE19 cell lines, the combined treatment with Duligotuzumab or Taselisib plusTrastuzumab completely inhibited the activation of proteins downstream of HER3, PI3K and MAPK pathways.

Conclusions: Targeting both HER2 and HER3 or HER2 and PI3K with the combination of anti-HE3 antibody or Pi3k inhibitor with Trastuzumab results in an improved treatment effects on HER2-positive GCG. These important findings can be utilized to facilitate the design of future clinical trials.

1642P The TLR9 agonist lefitolimod modulates tumor microenvironment and improves anti-tumor effect of checkpoint inhibitors in vivo

K. Kapp[1], B. Volz[1], D. Oswald[1], B. Wittig[2], M. Schmidt[1]

[1]*Translational Research, Mologen AG, Berlin, Germany,* [2]*Foundation Institute Molecular Biology and Bioinformatics, Freie Universitaet Berlin, Berlin, Germany*

Background: Preclinical and ongoing clinical studies support the use of TLR9 agonists for immunotherapeutic approaches. Lefitolimod (MGN1703) is a covalently-closed dumbbell-like immune surveillance reactivator with broad immunomodulatory effects on the innate and adaptive immune system. Lefitolimod is currently evaluated in a phase 3 trial in mCRC patients (IMPALA), a phase 2 trial in SCLC patients (IMPULSE) and in two phase 1/2 trials, (i) in solid tumors in combination with the checkpoint inhibitor ipilimumab and (ii) in HIV patients (TEACH).

Methods: In several murine tumor models lefitolimod reduced tumor growth. Since the mode-of-action of lefitolimod starts upstream of the initiation points of checkpoint inhibitors like anti-CTLA-4 or anti-PD-1/anti-PD-L1 combinatory approaches may result in an enhanced anti-tumor effect. Therefore, two syngeneic murine models – the colon carcinoma CT26 and the lymphoma A20 model – were used for evaluation of the anti-tumor effect of lefitolimod with checkpoint inhibitors. In the CT26 model the influence of lefitolimod on tumor microenvironment (TME) was analysed.

Results: Treatment with anti-PD-L1 (i.p.) had no effect on tumor growth in the CT26 model, whereas addition of lefitolimod (s.c.) to anti-PD-L1 led to a clear anti-tumor effect (tumor growth inhibition, TGI 48%). This combinatory effect was even more pronounced in the A20 model where treatment with anti-PD-1 (i.p.) alone had a moderate anti-tumor effect which was vastly increased by the combination (TGI – anti-PD-1: 46%, anti-PD-1/lefitolimod 99%). Moreover, in the CT26 model an anti-tumor response to lefitolimod (i.tu.) was associated with increased infiltration of CD3 T-cells –more specifically CD8 T-cells – into the tumor of a CT26 model.

Conclusions: We showed that the member of dSLIM family of TLR9 agonists, lefitolimod, can enhance the limited anti-tumor effects of checkpoint inhibitors in murine colon carcinoma and lymphoma tumor models in vivo. The anti-tumor effect of lefito-

limod is associated with TME modulation with increased T-cell infiltration. These data clearly support the combination of lefitolimod with checkpoint inhibitors in clinical trials.

1643P Circulating immune-profile as predictor of outcome in advanced NSCLC patients treated with nivolumab

M. Tiseo[1], F. Facchinetti[1], F. Gelsomino[1], S. Buti[1], M. Veneziani[1], A. Squadrilli[1], P. Bordi[1], M. Bersanelli[1], A. Cosenza[1], L. Ferri[1], E. Rapacchi[1], G. Mazzaschi[2], F. Leonardi[1], F. Quaini[2], A. Ardizzoni[3], G. Missale[4]

[1]Medical Oncology Unit, University Hospital of Parma, Parma, Italy, [2]Department of Medicine and Surgery, University Hospital of Parma, Parma, Italy, [3]Medical Oncology Unit, University Hospital Sant'Orsola, Bologna, Italy, [4]Malattie Infettive ed Epatologia, University Hospital of Parma, Parma, Italy

Background: Detection of predictive markers of anti-PD-1/PD-L1 antibodies activity is of pivotal interest in non-small cell lung cancer (NSCLC). This study aimed to identify a circulating immuno-profile as predictor of outcome in NSCLC patients treated with nivolumab.

Methods: A peripheral blood immuno-profile evaluation was performed at baseline (T0), after 2 (T1) and 4 cycles (T2) of bi-weekly nivolumab in advanced pre-treated NSCLC patients from two Italian Institutions. First tumor assessment was performed after 4 cycles and then every 2 months. FACS analysis of lymphocyte subpopulations [CD3, CD4, CD8, NK (CD56), Treg (FOXP3) and MDSC] was performed. Absolute and % changes of lymphocyte subsets together with their functional and proliferative activity were assessed. Quali-quantitative leucocyte composition at baseline and its variation during therapy were correlated with tumor response and survival.

Results: In the overall population of 54 treated patients, baseline Neutrophil-to-Lymphocyte ratio and NK count, lymphocyte count and CD4 variations during therapy showed a statistically significant prognostic role ($p < 0.001$; $p = 0.012$; $p < 0.001$; $p = 0.010$, respectively). Among 31 patients (squamous carcinoma, n = 17; adenocarcinoma, n = 14) in which all 3 time-points samples were available, 19 were *responders* (response and stable disease) and 12 *non-responders*. In *responders*, absolute numbers of total NK and NKCD56dim subset were higher at baseline and their increase between T0 and T1 was statistically significant ($p < 0.05$). *Responders* also displayed increased cytotoxic capability as shown by a higher baseline expression of CD3ζ, perforin and granzyme in NKCD56dim subset. No significant variation was documented in absolute number and functional activity of CD4+ and CD8+ lymphocytes. A higher percentage of CD8+PD-1+ cells at baseline was observed in *responders*, while *non-responders* showed a statistically significant increase in the absolute number of MDSC during therapy ($p < 0.05$).

Conclusions: The number and function of NKs and the frequency of PD-1 expression in CD8+ cells could represent predictive peripheral immuno-biomarkers for nivolumab treatment in advanced NSCLC.

1644P Monitoring the effect of cytostatic treatment by immune activity

T.F. Hansen[1], L. Nederby[2], T. Bechmann[1], E. Jakobsen[1], A. Zedan[1], I. Mejlholm[1], J. Henriksen[1], K. Steffensen[1], C. Thomsen[1], L. Raunkilde[1], L.H. Jensen[1], A. Jakobsen[1]

[1]Oncology, Vejle Hospital, Vejle, Denmark, [2]Immunology and Biochemistry, Vejle Hospital, Vejle, Denmark

Background: Early prediction of effect remains an unsolved problem in cytostatic treatment of malignant tumors. The aim of the present study was to analyze the potential relationship between immune activity as measured by the NK Vue® system and response in patients with different tumors and different cytostatic regimens.

Methods: The study included six different trials encompassing patients with breast, prostate, ovarian and colorectal cancer. All protocols are still recruiting and so far 108 patients have been included. The preliminary results are based on 54 patients with response data available from the first evaluation. Blood samples were collected at baseline and prior to each treatment cycle into NK Vue™ Promoca tubes and placed in an incubator at 37 °C within 15 minutes of sampling. Following 24 hours of stimulation the plasma in each tube was harvested and analyzed for the level of interferon-gamma, as a surrogate for immune activity, by enzyme-linked immunosorbent assay using the NK Vue® Gold Kit.

Results: Similar results were seen between immune response and tumor types receiving different treatments. Consequently, data were pooled for preliminary evaluation. The outcome suggested a classification into three groups. The interferon-gamma dropped to an abnormal level (<200 pg/ml) in group 1 (27 patients) or remained at an abnormal level during treatment. In group 2 (12 patients) the level remained within a normal range (>500 pg/ml), while in group 3 (15 patients) it was raised from an abnormal to a normal level. The response rates were 11%, 42%, and 80% in the three groups, respectively. The difference was highly significant ($p < 0.001$). Accordingly, the positive and negative predictive values of a raising level were 80% and 79%.

Conclusions: The results suggest a relationship between the ability to mount an immune response upon stimulation and treatment effect comparable among different tumor types and treatments. Increasing levels of interferon-gamma shortly after initiation of treatment seems to predict treatment effect. Updated results will be presented at the meeting.

1645P Analysis of programmed death-ligand 1 (PD-L1) expression, transforming growth factor (TGF)-β gene expression signatures (GES) and tumor-infiltrating immune cells (IC) in hepatocellular carcinoma (HCC): Rationale for targeting PD-L1- and TGF-β

Y. Zhang[1], B.J. Naughton[2], P.A. Rolfe[1], E. Frick-Krieger[3], I. Dussault[4], L. Terracciano[5], C. Ihling[6]

[1]R&D Global Early Development, EMD Serono Research & Development Institute, Billerica, MA, USA, [2]Bioinformatics, EMD Serono Research & Development Institute, Billerica, MA, USA, [3]RD-EBP-H, Merck KGaA, Darmstadt, Germany, [4]Clinical Biomarkers and Companion Diagnostics, EMD Serono Research & Development Institute, Billerica, MA, USA, [5]Pathology, Institute of Pathology, University Hospital Basel, Basel, Switzerland, [6]CBD, Merck KGaA, Darmstadt, Germany

Background: HCC evades antitumor immune responses via multiple mechanisms, including the PD-L1 and TGF-β pathways. PD-L1 expression correlates with tumor aggressiveness and recurrence. Increased TGF-β activity corresponds with poor clinical outcomes. Using immunohistochemistry (IHC), we previously showed that PD-L1 expression in HCC stems primarily from IC. To further assess the HCC immune milieu, we measured IC, TGF-β-associated GES, and PD-L1 expression using IHC/RNAseq.

Methods: We assessed protein expression in 50 resected HCC specimens by quantitative (Q) IHC (primary antibodies: PD-L1, CD8, CD68) using standard techniques and automated software. For RNAseq, we prepared strand-specific libraries from extracted RNA, which were sequenced and compared to GES from published papers, CIBERSORT and Ingenuity Pathway Analysis.

Results: All cases had typical morphology (low- to high-grade trabecular, pseudoglandular, or solid with common cytoplasmic features). Q CD8 IHC significantly correlated with CD8 mRNA expression and CD8 T cell GES, supporting the utility of RNAseq to evaluate the role of $CD8^+$ T cells in HCC. RNAseq identified TGF-β1 as the main TGF-β isoform in HCC. Predefined TGF-β GES correlated strongly with EMT GES. There was a trend toward increased TGF-β1 activity and EMT marker expression in the S1 molecular subtype, which has previously been associated with TGF-β-driven aberrant Wnt signaling. Q CD8 IHC correlated with PD-L1 mRNA and protein levels in IC. In samples with high CD8, there was a trend of increased tumor-associated macrophages (TAMs); the presence of TAMs strongly correlated with TGF-β GES. Interestingly, few tumor cells displayed membranous PD-L1 staining as confirmed by PD-L1/pan-cytokeratin double labeling.

Conclusions: We used RNAseq and IHC to better understand the immunosuppressive environment in HCC driven by TGF-β and PD-L1, which may mediate different mechanisms to inhibit preexisting $CD8^+$ IC.

Methods: We assessed somatic MB in surgical tumor specimens with whole exome sequencing (WES) using an ion torrent proton platform (Thermo Fisher Scientific). Two hundred forty-six NSCLC patients were randomly divided into training (n = 123) and validation (n = 123) cohorts. We defined patients with a greater than median number of non-synonymous (n-syn) mutations as the higher MB group. To detect higher n-syn MB in the training cohort, clinical data was assessed using a stepwise regression model. The validation cohort was subsequently analyzed. Also, the detected factors were validated via 100 repetitions of this procedure with different randomly divided cohorts using bootstrapping method.

Results: Out of 250 NSCLC patients with tumors surgically resected between September 2014 and September 2015, we analyzed tumors from 246 patients. Patient background: median age (range) 70 (39-87), male 63%, smoker 71%, pathological stage (p-stage) (I/II/III) 67/21/12% respectively, histological type (Ad/Sq) 78/22%, EGFR mutation (positive/wild type) 31/69%, median serum CEA level (range) 3.3 ng/ml (0.5-491.8), median serum CYFRA 21-1 level (range) 1.2ng/ml (1-38), median exonic MB (range) 62.5 (4-2144) [1.79 mt/Mb (0.1-61.4)], and median n-syn MB (range) 41 (1-1510) [1.17 mt/Mb (0.02-43.2)]. Stepwise regression analysis identified four factors [histological type: squamous, smoking status: smoker, age: greater than or equal to 70, and elevated serum CEA level (greater than 5ng/ml)] associated with high n-syn MB (p=.069, p=.0001, p=.106 and p=.037 respectively). In the receiver operating characteristic curves predicting high MB, the area under the curve for the four variables in the training and validation cohorts was 0.82 and 0.84, respectively. Squamous histology, smoker, and elevated CEA level showed highly reproducible in repeated random simulations (p = 0.93, 1.0, and 0.72).

Conclusions: Along with squamous histology and smoking, elevated CEA level may be an independent predictive factor for higher MB in NSCLC.

1646P Integrative analysis of NSCLC identifies tumor genetic profiles associated with PD-L1 expression

M. Saigi[1], C. Pereira[1], E. Pros[1], E. Brambilla[2], J. Alburquerque[1], N. Baixeras[3], M. Sánchez-Céspedes[1], E. Nadal[4]

[1]*Cancer Epigenetics and Biology Program, IDIBELL, Hospitalet de Llobregat, Spain,* [2]*Pathology Department, CHU Grenoble - Hopital Michallon, La Tronche, France,* [3]*Pathology Department, Hospital de Bellvitge-ICO, Hospitalet de Llobregat, Spain,* [4]*Thoracic Oncology Unit, Institut Catala d'Oncologia ICO, Hospitalet de Llobregat, Spain*

Background: PD-L1 expression is associated with clinical benefit from anti-PD1/anti-PD-L1 therapies in advanced NSCLC. However, additional biomarkers are needed to predict which patients will benefit most. The aim of this study is to correlate specific genomic alterations with immunological biomarkers in a cohort of NSCLC.

Methods: Patients diagnosed with NSCLC from 2000 to 2005 were retrospectively reviewed. Genetic mutations and copy number of selected genes were determined by Sanger and FISH. Immunophenotype was defined by PD-L1, HLA-1 and TILs CD8+ immunostaining and scored as follows: PD-L1 positivity $\geq$ 5% on membrane tumor cells; HLA-1 intensity: 0+,1+,2+; TILs CD8+ score: low or high infiltration. Statistical analysis using Chi-square test and logistic regression were performed.

Results: From 150 patients: 87% males; stage: 90% I-II, 10% III-IV; histology: 42% adenocarcinoma (ADC), 44% squamous (SCC), 14% sarcomatoid carcinoma (SaC). Genomic alterations according to histologic subtype are summarized in **Table**. PD-L1 was positive in 47% of tumors (49% of ADC, 43% of SCC, 58% of SaC), and correlated with TILs CD8 + (p <.001) and HLA-1 (p=.002). PD-L1 positivity was associated with *MET* alterations (4.5% MET amp, 2% METexon14 skipping), OR = 5.4 (1.4-21.2), p=.015. ADC harbouring *STK11* loss of function were correlated with negative PD-L1 (p = .01) and associated with immunosupressive phenotype (negative PD-L1, low CD8+), OR = 11.6 (2.1-64), p=.005. Distinct PD-L1 expression was evidenced in

KRAS mutant tumors according to additional co-mutations: 25% of *KRAS*+*STK11* were PD-L1+ whereas 75% of *KRAS*+*TP53* were PD-L1+, despite no statistically significance.

Conclusions: *MET* and *STK11* alterations were correlated with differential expression of tumor PD-L1. *STK11* mutant tumors were more likely to have an immunosupressive phenotype. Tumors harbouring specific genomic alterations might be enriched for distinct immunophenotypes which might contribute to rational use of immunotherapies.

1648P B7-H3 (CD276) on circulating epithelial tumor cells (CETCs) correlates with proliferation marker Ki-67 and may be associated with aggressiveness of tumor in breast cancer patients

M. Pizon, D. Schott, U. Pachmann, K. Pachmann

TZB Bayreuth, Bayreuth, Germany

Background: CETCs in the peripheral blood are a prerequisite for the development of metastases. B7-H3 is an important immune checkpoint member of the B7 family and inhibits T-cell mediated anti-tumor immunity. It is highly overexpressed on a wide range of solid cancers and often correlates with both negative prognosis and poor clinical outcome in patients. Based on the clinical success of the inhibitory immune checkpoint blockade, mAbs against B7-H3 appear to be promising therapeutic strategy. In order to better understand the role of B7-H3 in cancer development we used a non-invasive, real-time biopsy for determining B7-H3 on CETCs in breast cancer patients.

Methods: Blood from 50 patients suffering from breast cancer were analyzed for CETCs. The number of vital CETCs and the expression of B7-H3 and Ki-67 were evaluated using the maintrac® method.

Results: CETCs were detected in all examined patients (ranged from 2-676 CETCs in 100 µl of blood). B7-H3 expression on the surface of CETCs was found in 82% of patients. Triple negative breast cancer patients had statistically significantly more B7-H3 positive CETCs than patients with hormone receptor positive tumor tissue (median 50 vs. 26.3; $p < 0.05$). The frequency of B7-H3 positive CETCs was significantly higher in patients who received radiation therapy compared to patients without irradiation (mean 42 vs. 29; $p < 0.05$). B7-H3 positive CETCs seem to be more aggressive because the percentage of B7-H3 positive CETCs correlated with the percentage of proliferation marker Ki-67 positive CETCs ($r = 0.689$ and $p < 0.001$). Interestingly, a significant relationship between Ki-67 expression level on the CETCs and nodal status was found.

Conclusions: Breast cancer patients have detectable CETCs with high frequency of B7-H3 expression regardless of stage of disease. B7-H3 seems to be an important factor in immune evasion and may be a promising target of anticancer therapies. Furthermore, radiation leads to an up-regulation of B7-H3 expression on CETCs, which could be a possible mechanism of acquired radio-resistance.

1649P Survival of non-small cell lung cancer patients predicted from expression of PD-L1, HLA class I and MICA/B on tumor cells

R. Okita, A. Maeda, T. Yukawa, K. Shimizu, Y. Nojima, S. Saisho, M. Nakata

General Thoracic Surgery, Kawasaki Medical School Hospital, Kurashiki, Japan

Background: Several groups have reported that programmed death-1 (PD-1) ligand 1 (PD-L1) overexpression on tumor cells predicts a poor prognosis in patients with non-small cell lung cancer (NSCLC). Although recent studies have shown that PD-L1 overexpression on tumor cells predicts for improved clinical outcome in NSCLC patients treated with anti-PD-1/PD-L1 immunotherapy, PD-L1 low/negative tumors also benefit from anti-PD-1/PD-L1 immunotherapy. These findings suggest that study on multiple immune parameters should be considered. We recently reported that the overexpression of PD-L1 in tumor predicted a poor prognosis while overexpression of NK cell activating ligand MICA/B predicted improved clinical outcome in patients with resected NSCLC. It is well known that both T cell- and NK cell-mediated tumor recognitions are influenced by HLA class I molecules, however, the roles of HLA class I molecules are different between T cells and NK cells; HLA class I/T cell receptor immune synapse induces antigen-specific cytotoxicity by T cell, while HLA class I/killer cell immunoglobulin-like receptor synapse attenuates NK cell-mediated cytotoxicity. Here, we assessed the multiple immune parameters (PD-L1, MICA/B, and HLA class I) in NSCLC tissues to assess the prognostic factors in patients with resected NSCLC.

Methods: We examined resected tumor tissues from 91 patients with pathological stage IA-IIIA NSCLC using immunohistochemical reaction for the expression of PD-L1, MICA/B, and HLA class I then assessed whether the multiple immune parameters impact on the clinical outcome of patients with NSCLC.

Results: PD-L1^{low}/MICA/B^{high} tumors have an excellent disease free survival time (DFS) compared with PD-L1^{low}/MICA/B^{low} (p=0.010 by log-rank test) or PD-L1^{high} (p<0.01) tumors. Additionally, MICA/B^{high}/HLA class I^{high} tumors have improved DFS compared with MICA/B^{low}/HLA class I^{high} tumors (p=0.035).

Conclusions: Multiple immune parameters using the expression status of MICA/B and PD-L1 or HLA class I on tumor cells are useful prognostic factors for NSCLC. We should have more concerns to NK cell-mediated tumor elimination in anti-PD-1/PD-L1 immunotherapy.

1650P YKL-39 induces monocytes migration and angiogenesis and inversely correlates with metastasis in patients with breast cancer

I. Mitrofanova[1], L. Tengfei[2], M. Zavyalova[3], N. Litviakov[4], M. Buldakov[5], N. Cherdyntseva[5], J. Kzhyshkowska[6]

[1]Laboratory of Translational Cellular and Molecular Biomedicine, Tomsk State University, Tomsk, Russian Federation, [2]Medical Faculty Mannheim, Institute of Transfusion Medicine and Immunology, University of Heidelberg, Mannheim, Germany, [3]Department of Pathological Anatomy, Siberian State Medical University, Tomsk, Russian Federation, [4]Laboratory of Virusology, Tomsk Cancer Research Institute RAMS, Tomsk, Russian Federation, [5]Laboratory of Molecular Oncology and Immunology, Tomsk Cancer Research Institute RAMS, Tomsk, Russian Federation, [6]Institute of Transfusion Medicine and Immunology, German Red Cross Blood Service Baden-Württemberg – Hessen, Mannheim, Germany

Background: Human chitinase-like proteins are considered as biomarkers of cancer and chronic inflammation.YKL-39 is a unique member of chitinase-like protein family due to its presence only in humans but not in rodents both on gene and protein levels. However, its biological activity and association with tumor progression remains unknown.

Methods: YKL-39 expression and secretion in human monocytes-derived macrophages was measured by RT-PCR and ELISA. Monocyte migration was analyzed in a transwell system. In vitro tube formation assay was performed using HUVEC cells.112 female patients with nonspecific invasive breast cancer of stage IIA-IIIC (T1-4N0-3M0) were included in the study. Confocal microscopy analysis was used to identify cell type expressing YKL-39 in tumor samples.YKL-39 expression level was measured by RT-PCR in tumor biopsy specimens.

Results: Human monocytes-derived macrophages differentiated in the presence of IL4 and TGFbeta, but not IL4 alone, were found to express high levels of YKL-39 mRNA and protein. Purified YKL-39 significantly enhanced the migration of human CD14+monocytes by 1.9 fold ($p < 0.01$) after 1 h, and 4.9 fold ($p < 0.01$) after 3 h that was comparable with the effect of MCP-1. In vitro tube formation assays using HUVEC cells demonstrated that YKL-39 has a strong pro-angiogenic effect. In human samples of breast cancer YKL-39 was found to be expressed in CD68+ macrophages but not in cancer cells or other stromal cell types. In breast cancer biopsy specimens it was found that high YKL-39 gene expression correlated with the significantly reduced frequency of lymphatic and hematogenous metastasis. Furthermore, high level of YKL-39 expression associated with 100% metastatic-free survival rate ($p = 0.015$).

Conclusions: TGFbeta is a key cytokine inducing production of YKL-39 in macrophages. YKL-39 stimulates critical for tumor progression processes: chemotaxis of monocytes and angiogenesis. However high levels of YKL-39 expression in tumor samples are predictive for metastatic-free survival in patients with breast cancer, suggesting that YKL-39 can program monocytes and newly growing vessels to inhibit metastatic spread.

1651P Pre-treatment neutrophil lymphocyte ratio/platelet lymphocyte ratio as surrogate markers of survival in non-metastatic head and neck cancer patients: An observational study

V. Agarwal[1], R. Rao[2], H.R. Abin[3], V. Rao[4], R.C. Nayar[4], V. Mani[2], A. Ram[2], B.S. Ajaikumar[1]

[1]Medical Oncology, Healthcare Global Enterprises Ltd., Bangalore, India, [2]Healthcare Global Enterprises Ltd., CARE, HCG Foundation, Bangalore, India, [3]Clinical Pharmacology, Acharya & BM Reddy College of Pharmacy, Bangalore, India, [4]Surgical Oncology, Healthcare Global Enterprises Ltd., Bangalore, India

Background: Neutrophil lymphocyte ratio (NLR) and platelet-lymphocyte ratio (PLR) are known to be surrogate markers of inflammation and have been shown to predict mortality in patients with heart disease and cancer. In this study, we evaluate the

influence of pre-treatment NLR and PLR on overall survival in head and neck cancer patients.

Methods: In this observational correlational study, subjects with a diagnosis of non-metastatic head and neck cancer were analyzed for neutrophil-lymphocyte ratio and the platelet-lymphocyte ratio at baseline before the start of their cancer-directed therapy.

Results: In this study, 189 subjects were analyzed for neutrophil-lymphocyte ratio and platelet-lymphocyte ratio before their treatment. The mean age of the study sample was 54.5±11.8. Forty-two percent underwent surgery followed by adjuvant chemoradiation while remaining underwent concurrent chemoradiation. Neoadjuvant chemotherapy was done in 29.4% of the study population. Mean NLR was 3.4±3.13 and PLR was 12.7±8.8. ROC analysis revealed 2.23 as the cutoff for NLR and 9.49 as the cutoff for PLR. Based on these cutoffs a Kaplan-Meir analysis on overall survival showed significantly improved survival (67.5% vs 58% at their mean estimates of 52 and 36 months) in those with <2.23 NLR ratio compared to > 2.23 (Log Rank $\chi2$=5.3, p = 0.02). Similarly, those with <9.49 PLR had better overall survival (69% vs 56% at their mean estimates of 46 and 39 months) compared to > 9.49 (Log Rank $\chi2$=8.1, p = 0.005). Lower NLR also showed better disease-free survival (44 vs 33 months, Log Rank $\chi2$=4.8, p = 0.03) and lower PLR also showed better disease-free survival (44 vs 33 months, Log Rank $\chi2$=8.2, p = 0.004).

Conclusions: Both NLR and PLR are inflammatory biomarkers in cancer. The results from this study suggest pretreatment NLR and PLR as predictive markers of survival in non-metastatic head and neck cancer patients.

1652P Enhanced antitumor activity of fixed-dose combinations of celecoxib and antihypertensives

C. Lee[1], L. Hwang[2], O. D'Cruz[1], K. Ng[1], V. Trieu[2]

[1]Clinical Research, Autotelic Inc., Costa Mesa, USA, [2]Clinical Research, Marina Biotech, City of Industry, CA, USA

Background: Inflammation and hypertension have recently emerged as causal factors for tumor progression and anti-hypertensive agents have been shown to reduce inflammation and suppress tumor growth and metastasis. Cyclooxygenase-2 (COX-2) is upregulated in most human tumors and is a potent inducer of cancer-associated inflammation. This preclinical study evaluated a novel combination of a COX-2 inhibitor with three antihypertensive drugs to suppress tumor growth and metastasis.

Methods: Three anti-hypertensive drugs: i) Lisinopril [LIS], an inhibitor of Ang I converting enzyme (ACE); ii) Olmesartan medoxomil (OLM), an Ang II receptor blocker (ARB); and iii) Hydrochlorothiazide (HCTZ), a thiazide diuretic along with Celecoxib [CEL], a COX-2 inhibitor were evaluated either alone or in combination for tumor growth suppression and metastatic spread in an orthotopic inflammatory breast cancer (IBC)/SUM149 model and subcutaneous melanoma/MDA-MB-435, glioblastoma/U87, and IBC/SUM159 models. Luciferase-tagged SUM149 and MDA-MB-435 cell lines were used to determine the incidence and the burden of locoregional and systemic spread. Mice were monitored for weight loss, tumor volume and survival outcome. Metastasis was measured as luciferase expression in lymph nodes and lungs and normalized to total protein.

Results: In the orthotopic SUM149 model, OLM and CEL plus OLM, had a statistically significant decrease in tumor burden (2.4 ± 0.6 x10^4 RLU/mg of protein, p = 0.01 by Mann-Whitney test) in the ipsilateral lymph nodes versus the saline-treated control (17.6 ± 8.6 x10^4 RLU/mg of protein). Similar trend was observed for LIS, but not for HCTZ. In the subcutaneous model, synergistic antitumor activity was observed with OLM (p = 0.026) at low dose but not with LIS and CEL (p = ns). At high dose, LIS, OLM, and CEL showed significant inhibition of tumor growth but no synergy. HCTZ, an antihypertensive diuretic which has no direct impact on the vascular wall had no effect on tumor growth.

Conclusions: These preclinical data strongly suggest a hitherto unappreciated role of ACE/ARB in tumor growth control and support the further exploration of combinations of CEL with ACE/ARB in cancer, especially inflammatory breast cancer.

1653P Overexpression of toll-like receptor 9 (TLR9) in elderly cancer patients when compared to cancer-free elderly control group

L. Torres[1], L.T. Sales[1], M. Santaliz de Godoy Moreno[1], C.C. Resende Lira[1], G. Delgado Soriano[1], E. Bezerra Cintra Jr[1], K. Jatahy[1], M.J.G. Mello[2], L.C.S. Thuler[3], J.T. Oliveira Lima[2]

[1]Laboratório Translacional, IMIP, Recife, Brazil, [2]Oncogeriatry, Hospital IMIP, Recife, Brazil, [3]PHD Program, INCA -National Cancer Institute, Rio de Janeiro, Brazil

Background: the genes of toll-like receptors (TLR) have been described as related to the immunosenescence process and carcinogenesis. The relationship of this gene family with carcinogenesis and immunoregulatory responses seems a promising field. The aim of this study is to compare the expression of TLR9 between geriatric cancer patients and elderly patients without any personal or familiar history of cancer, establishing if there are significant differences that may be explained by the carcinogenesis process rather than the immunosenescence one.

Methods: Between 2015 and 2016, a prospective cohort study including 195 elderly patients (≥ 60 years), 120 with incident cancer at the time of admission and 75 without any personal or familiar cancer history, assessed and collected sociodemographic and clinical variables and performed analysis of the peripheral blood in translational exploratory study. Determination of TLR9 was performed by flow cytometry with monoclonal antibodies anti-TLR9. Statistical analysis of the data was performed with GraphPad Prism.

Results: 120 patients with incident prostate or breast cancer and 75 patients without any personal or familiar history of cancer, both with ≥ 60 years, were included. Most of the cancer patients were male (60%), while most of the patients without any cancer history were female (75%). Comparing the percentage and fluorescence values of TLR9 expression, there are significant differences (p < 0,0001) between the cancer patients group and the one without any personal or familiar cancer history.

Conclusions: There is significant difference between the expression of TLR9 in elderly cancer patients and elderly patients without personal or familiar history of cancer.

1654P NSCLC patient immune cell profiling and response of tumor antigen specific CD8 T cells to checkpoint receptor antagonists

J. Lee[1], X. Wu[2], L. Liu[2], M.D. Breyer[2], H.K. Kim[1], J.H. Cho[1], J. Lee[3], Y.S. Shin[3], J. Kim[1], Y. Zhao[2]

[1]Thoracic and Cardiovascular Surgery, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [2]Biotechnology Discovery Research, Eli Lily and Company, Indianapolis, IN, USA, [3]Biomedical Science, Samsung Biomedical Research Institute, Samsung Medical Center Sungkyunkwan University School of Medicine, Seoul, Republic of Korea

Background: The breakthrough in cancer immunotherapy of targeting PD-1 or PD-L1 and enabling T cells to attack tumor has opened new window for cancer treatment of many tumor types. Many of these immunotherapeutic approaches involve targeting specific immune checkpoints. To better understand the role of checkpoint receptors in cancer immunotherapy and explore new treatments, we analyzed cancer patient PBMCs and dissociated tumor samples from non-small cell lung cancer (NSCLC).

Methods: Transcripts of Cancer Testis (CT) antigens (NY-ESO-1, MAGE-A1, and MAGE-A3), a novel T cell inhibitory checkpoint receptor (TIGIT), and its respective ligands (PVR and PVRL2) as well as PDL1 from a cohort of NSCLC patients was analyzed. Immune cells from these patient samples were profiled and NYESO1/HLAA2 tetramer was used to detect NYESO1 specific CD8 T cells in HLAA2+ patients. Intracellular cytokine secretion was analyzed using a specially designed multiparameter flow cytometry panel for both general and NYESO-1^+ CD8 T cells.

Results: The correlation between CT antigens, immune checkpoints, and effector T cell signature (CD8A, IFN-gamma, and Granzyme A) may help us understand 1) why certain patients have inflamed tumors and others have "cold" tumors; 2) why certain patients respond to anti-PD(L)1 therapy and others do not respond. Antibodies targeting both PD1 and another novel immune checkpoint receptor TIGIT showed best stimulatory effect on both antigen specific CD8 T cell number and intracellular IFN-gamma staining of those cells.

Conclusions: The data suggest that immune checkpoint receptor antibodies can be screened in real patient immune cells. Cotargeting multiple immune checkpoint receptors may provide superior efficacy to targeting single immune checkpoint receptor.

1655P Effect of neoadjuvant chemotherapy on correlation of tumor-associated macrophages with angiogenesis and lymphangiogenesis in human breast cancer

I. Mitrofanova[1], M. Zavyalova[2], M. Buldakov[3], N. Cherdyntseva[3], J. Kzhyshkowska[4]

[1]Laboratory of Translational Cellular and Molecular Biomedicine, Tomsk State University, Tomsk, Russian Federation, [2]Department of pathological anatomy, Siberian State Medical University, Tomsk, Russian Federation, [3]Laboratory of Molecular Oncology and Immunology, Tomsk National Research Medical Center of the Russian Academy of Sciences, Tomsk, Russian Federation, [4]Medical Faculty Mannheim, Institute of Transfusion Medicine and Immunology, University of Heidelberg, Mannheim, Germany

Background: Promoting role of tumor-associated macrophages (TAM) in angiogenesis and lymphangiogenesis was demonstrated in mouse tumor model sand human cancers. However, our latest studies revealed that amount of TAM in patients with breast cancer before as well after neoadjuvant chemotherapy (NAC) reversely correlated with

lymphatic metastasis. Our aim was to analyse the effect of NAC on correlation of TAM in intratumoral compartments with angiogenesis and lymphangiogenesis.

Methods: 115 female patients with breast cancer T1-4N0-3M0 were included in the study. 36 patients did not receive NAC, 79 received NAC. Expression levels of CD68 (general macrophage marker), stabilin-1 (marker of M2 macrophages), CD31 (marker of blood vessels) and LYVE1 (marker of lymphatic vessels) were identified by immunohistochemistry in 5 distinct areas of tumors: 1) soft fibrous stroma; 2) coarse fibrous stroma; 3) areas of maximum stromal-and-parenchyma lrelationship; 4) parenchymal elements; 5) gaps of ductal tumor structures.

Results: In breast cancer samples of patient who did not receive NAC direct correlation of CD68 expression in soft fibrous stroma and CD31 expression in coarse fibrous stroma ($r = 0,87$;$p=0,02$) was identified. However, reverse correlation was found between CD68 expression in gaps of ductal tumor structures and LYVE1 expression in soft fibrous stroma ($r=-0,89$;$p=0,04$). In contrast, in patients after NAC we identified a direct correlation between expression of CD68 and LYVE1 expression in the gaps of ductal tumor structures ($r = 0,80$;$p=0,02$). Expression of stabilin-1 in coarse fibrous stroma directly correlated with amount of LYVE1+ cells in areas with maximum stromal-and-parenchymal relationship ($r = 0,76$;$p=0,04$), but reversely correlated with the amount of CD31+ vessels in soft fibrous stroma ($r= - 0,52$;$p=0,001$).

Conclusions: Our data suggest that TAM before treatment support tumor angiogenesis however protect against lymphangiogenesis. After NAC TAM can switch their functional phenotype, do not support angiogenesis anymore but support lymphangiogenesis. The mechanism of chemotherapeutic programming of TAM remains to be identified.

1656P Myeloid-derived suppressor cells are associated with a decrease of tumor antigen-specific Th1 immunity in non-small cell lung cancer

O. Adotevi[1], E. Lauret Marie Joseph[1], C. Laheurte[1], M. Dosset[1], E. Fabre-Guillevin[2], P. Jacoulet[3], G. Eberts[3], G. Helluin[1], L. Boulleret[1], L. Rangan[1], Y. Godet[1], V. Westeel[3]

[1]Thérapeutique Immuno-Moléculaire des Cancers, UMR1098, Besançon, France, [2]Medical Oncology, Dr. Elizabeth Fabre-Guillevin, La Défense, France, [3]Pneumology, CHRU Jean Minjoz, Besançon, France

Background: Myeloid Derived Suppressor cells (MDSC) are immune suppressive cells associated with poor survival in several cancers. In this study, we investigated their impact on spontaneous tumor antigen specific Th1 responses in Non-Small Cell Lung Cancer (NSCLC).

Methods: Monocytic MDSC (M-MDSC) ($Lin^{-}HL\text{-}DR^{-/lo}CD11b^{+}CD14^{+}CD33^{+}$) were measured in peripheral blood of 122 NSCLC patients and 34 healthy donors by flow cytometry. The presence of spontaneous anti-tumor Th1 response was measured by IFN-ɤ ELISPOT assay using mixture of peptides derived from lung cancer-associated tumor antigens such as telomerase, NY-ESO1 and Wilms Tumor-1. Patients' samples were collected at baseline before any treatment.

Results: Higher percentage of circulating M-MDSC was found in NSCLC patients compared to healthy subjects (mean: $3.9\pm0.4\%$ vs $1.5\pm0.4\%$, $p < 0.01$). Most patients presenting high level of M-MDSC in blood ($\geq$ 5%: $M\text{-}MDSC^{hi}$) belonged to metastatic stage (34%, 21/61) compared to 14%, 9/61 in localized disease ($p < 0.01$). However, $M\text{-}MDSC^{hi}$ status was associated with poor survival regardless the tumor stage (median OS: 11 vs 27 months in $M\text{-}MDSC^{hi}$ and $M\text{-}MDSC^{lo}$ groups respectively, $p < 0.001$). The IFN-ɤ+ antitumor specific T cell response was detected in 55.8% of patients and this frequency significantly dropped to 20% in $M\text{-}MDSC^{hi}$ group. Furthermore, the magnitude of this response changed according to M-MDSC level (231 vs 116 IFN-ɤ+ specific T cells in $M\text{-}MDSC^{lo}$ and $M\text{-}MDSC^{hi}$ respectively $p < 0.05$). Finally, patients having both $M\text{-}MDSC^{hi}$ status plus low anti-tumor T cell response exhibited a very poor survival (median OS of 6 months).

Conclusions: Our results show that high levels of circulating M-MDSC is associated with a decrease of pre-existing antitumor T cell response. The level of M-MDSC combined with antitumor T cell responses could predict distinct clinical outcome. Thus, monitoring M-MDSC in blood could be used as relevant immune biomarker in NSCLC.

1657P Revealing potential immune responses (IRs) in patients with advanced colorectal cancer (aCRC) on first line chemotherapy: A prospective study of neutrophil to lymphocyte ratio, immune function and outcome

S. Turnbull[1], E. West[2], K. Scott[2], E. Tidswell[2], A. Melcher[3], M. Seymour[1], C. Ralph[4], J. Seligmann[1]

[1]Institute of Cancer and Pathology, University of Leeds, Leeds, UK, [2]Section of Infection and Immunity, Institute of Cancer and Pathology, University of Leeds, Leeds, UK, [3]Translational Immunotherapy Team, The Institute of Cancer Research, London, UK, [4]Section of Clinical Cancer Research, Institute of Cancer and Pathology, University of Leeds, Leeds, UK

Background: Neutrophil to lymphocyte ratio (NLR), a broad measure of inflammation and immune function, predicts outcome including overall survival (OS) in aCRC but the underlying mechanisms are unclear. Better understanding of IR in these patients may identify potential responders to novel immunotherapy. We investigated whether immune function correlated to NLR and how this altered during chemotherapy.

Methods: Peripheral blood was taken from 29 aCRC patients receiving 1st line chemotherapy (baseline and 6 weeks). NLR of ≥ 5 was defined as high. Immune function of peripheral blood mononuclear cells (PBMCs) was determined by NK cell activity (degranulation by CD107 expression and cytotoxic potential by ^{51}Chromium release) against target tumour cells, T cell activity by IFN-γ ELISpot, cytokine secretion (Luminex) and immune cell activation (flow cytometry).

Results: High baseline NLR was associated with shorter OS compared to low NLR (6.6 vs. 18.8 months; HR = 3.6 [1.25 to 10.35] $p = 0.0024$). High NLR also correlated with a depressed IR, including decreased cytolytic activity of PBMCs ($p = 0.046$), NK cell degranulation at baseline and decreased levels of certain immune stimulatory cytokines. Low baseline NLR correlated with increased T cell activity against tumour-associated carcinoembryonic antigen (CEA) after 6 weeks of chemotherapy. Higher cytotoxic activity of PBMCs against target tumour cells at baseline (seen in the majority of patients with NLR <5) was associated with increased OS ($p = 0.04$). A drop in NLR during chemotherapy was associated with increased innate immune function as determined by NK cell degranulation ($p = 0.004$). Irrespective of NLR, frequency of Tregs reduced during chemotherapy and there was an increase in PD-1 expression on CD8+ T cells ($p = 0.043$), NK cells ($p = 0.035$) and monocytes ($p = 0.016$).

Conclusions: This study supports the poor prognosis of a high baseline NLR in aCRC and demonstrates its association with an attenuated IR. Chemotherapy can partially reverse this phenomenon, potentially enhancing anti-tumour immunity. If chemotherapy leads to a more effective anti-tumour IR, sequential immunotherapy could exploit this.

1658P Somatic loss of the wild-type BRCA1 allele is not necessarily the first event in the pathogenesis of hereditary ovarian cancer: Implications for novel mechanism of acquired platinum resistance

E. Imyanitov[1], E. Savonevich[2], A. Ivantsov[1], G. Raskin[3], E. Kuligina[1], T. Gorodnova[4], E. Preobrazhenskaya[1], M. Kleshchov[1], V. Tiurin[1], A. Togo[1], A. Sokolenko[1]

[1]Department of Tumor Biology, N.N. Petrov Institute of Oncology, St.-Petersburg, Russian Federation, [2]Department of Obstetrics and Gynecology, Grodno State Medical University, Grodno, Belarus, [3]Department of Pathology, Russian Research Centre for Radiology and Surgical Technologies, St.-Petersburg, Russian Federation, [4]Department of Oncogynecology, N.N. Petrov Institute of Oncology, St.-Petersburg, Russian Federation

Background: Ovarian cancers (OC) arising in BRCA1 germ-line mutation carriers usually demonstrate high sensitivity to neoadjuvant chemotherapy (NACT), but almost inevitably relapse even after complete cytoreduction and continuation of systemic platinum treatment after surgery.

Methods: Changes in the somatic BRCA1 loss-of-heterozygosity (LOH) status were monitored in OC samples obtained before NACT, after NACT and at disease relapses.

Results: Loss of the wild-type BRCA1 allele was documented in 19 out 28 chemonaive OC samples included in the study. Surprisingly, 13 (68%) of these 19 OC demonstrated the retention of BRCA1 heterozygosity in the tumor tissue, which was surgically removed after median 3 cycles of NACT. TP53 mutations were easily detectable in some of the post-NACT samples thus confirming the good quality of microdissection. FISH assay and the analysis of adjacent SNPs revealed that the reversion of LOH status was attributed to selection of preexisting BRCA1-proficient clones but not to the second mutation in BRCA1 gene. Four tumor relapses were available for analysis; 3 out of these 4 tumors "restored" BRCA1 LOH during platinum-free interval. Next-generation sequencing analysis identified additional molecular events associated with evolution of OC clones upon platinum exposure and during treatment-free periods.

Conclusions: Isolated BRCA1 proficient cells are still present in chemonaive ovarian carcinomas with BRCA1 LOH, indicating that the somatic loss of the wild-type BRCA1 is not necessarily the first event in the pathogenesis of hereditary OC. These clones rapidly expand during even short-term systemic therapy. BRCA1-deficient cells have selective advantage in the absence of drug exposure and repopulate the tumor mass during platinum-free intervals. These fluctuations of BRCA1 LOH status explain why conventional platinum-based therapy, being capable to produce excellent tumor responses in BRCA1 germ-line mutation carriers, is not curative when considering long-term outcomes.

1659P Role of UBR5 mutations in DNA damage response in mantle cell lymphoma

O. Kutovaya, S. Hung, E. Vigano, R. Gascoyne, G.B. Morin, C. Steidl

Department of Lymphoid Cancer Research, British Columbia Cancer Agency, Vancouver, BC, Canada

Background: Mantle cell lymphoma (MCL) accounts for 7% of non-Hodgkin lymphomas and represents a particularly challenging disease with patient outcomes inferior to most other lymphoma subtypes. We recently reported frequent mutations (18%) in *UBR5*, a gene encoding an E3 ubiquitin-protein ligase that has not been previously implicated in lymphomagenesis. All mutations were clustered within 100bp in or around exon 58 of UBR5 and are predicted to result in the loss of the conserved cysteine residue, which is responsible for binding the ubiquitin molecule. The recurrence and clustering of *UBR5* mutations suggest their critical pathogenic nature in MCL that might be therapeutically targetable. The aim of this study is to determine the specific role of *UBR5* mutations in the pathogenesis of MCL.

Methods: Mutations clustering in exon 58 of *UBR5, a*s seen in MCL patients, were generated in three MCL cell lines (Granta-519, Jeko-1, and Mino) using the CRISPR-Cas9 genome engineering tool. First, global proteomes of *UBR5* mutants and WT were analyzed by Tandem Mass Tag (TMT)-based mass spectrometry to identify proteins with differential expression due to the *UBR5* mutations. Next, mass spectrometry-based immunoprecipitation proteomics (IP-MS) was employed to identify *UBR5* interacting partners. Candidate *UBR5* interacting proteins were functionally validated by flow cytometry, western blotting, co-immunoprecipitation, and immunofluorescence.

Results: The global proteome and IP-MS analyses identified a number of DNA damage response, chromosome organization, and cell cycle response proteins as the predominant proteins affected ($p < 0.05$). Our functional validation experiments show differential G2/M checkpoint activation and aberrant DNA damage response in *UBR5* mutants *vs* WT through association of UBR5 with ATM interactor ATMIN.

Conclusions: The proteome and functional analyses are consistent with *UBR5* functioning as a key regulator of cell signalling and point to the critical role of *UBR5* as a novel regulator of DNA damage response. Next, our goal is to develop mouse xeno-transplantation MCL models and identify therapeutic agents that render sensitivity in xeno-transplantation models with UBR5 mutations.

Background: Germline and/or somatic aberrations in *ATM* gene have been recently identified in up to 5% of PrCa cases. It has been also described that mutations in DNA repair genes predispose individuals to more aggressive and lethal phenotypes. For these reasons, our goal is to investigate the role of *ATM* in PrCa progression.

Methods: To study the cooperation of *Atm* in prostate cancer progression *in vivo*, we crossed the transgenic mouse model TRAMP with *Atm* null mice in C57BL/6 background. This model allows us to elucidate the progression of prostate cancer in wild-type (+/+), heterozygous (+/-), and homozygous (-/-) *Atm* loss in mice. PIN, invasive and metastatic prostate cancer as well as survival curves were compared for the three arms. In addition, in a large cohort of mCRPC (n = 419) from the prospective PROREPAIR-B study (NCT03075735), in which a large panel of germline DNA repair genes were studied, we compared the clinico-pathological characteristics at baseline and mCRPC diagnosis between germline *ATM* mutation carriers and non-*ATM* carriers. Chi-Square and Exact Fisher test, the Kaplan-Meier method and Long-rank test were used for statistical analyses.

Results: Twenty eight $TRAMP^{(T/+)}$; $Atm^{(+/+)}$ and 45 $TRAMP^{(T/+)}$; $Atm^{(+/-)}$ mice were follow-up until sacrifice-endpoint. Heterozygous *Atm* loss mice presented higher frequency of metastasis in the necropsy compared to *Atm* wild-type (44% vs. 21%, $p = 0{,}045$) and shorter median survival (26 vs. 32 weeks, $p = 0{,}008$). There were not significant different observed in PIN or invasive tumour prevalence. $TRAMP^{(T/+)}$; $Atm^{(-/-)}$ mice were excluded from analyses due to the early development of lethal thymomas requiring sacrifice before week 16. On the other hand, 8 patients out of 419 were found to harbour germline pathogenic *ATM* mutations (1.9%), and compared with non-*ATM* carriers presented higher frequency stage IV at diagnosis (63% vs. 34%, $p = 0.2$), bone metastasis (100% vs. 82%, $p = 0.4$) without other relevant differences found in these preliminary analyses.

Conclusions: Aberration in the *ATM* gene may favour metastatic progression in PrCa in prostate cancer preclinical models, although its clinical implication will require further clarification in the future.

Clinical trial identification: Part of the results came from the prospective PROREPAIR-B study (NCT03075735)

1661P Synergistic inhibition of CEP55 induces mitotic catastrophe and specifically targets aggressive breast cancer

D. Sinha, M. Kalimutho, A.J. Lopez, K.K. Khanna

Cell and Molecular Biology, QIMR Berghofer Medical Research Institute, Brisbane, Australia

Background: Triple negative breast cancers (TNBCs) are the most aggressive and profoundly heterogeneous form of breast cancer (BC), treatment of which is a prevalent challenge faced in clinics. *CEP55*, discovered first by our laboratory, is a key regulator of cytokinesis, error in which roots to multi-nucleation. Function of CEP55 is critically delimited by ERK2/PLK1 dependent phosphorylation, for accurate cytokinesis. Research has demonstrated connotation of CEP55 with numerous cancers including BC as higher CEP55 mRNA expression is allied to worse prognosis and poor survival. We hypothesised that, CEP55 controls fate of aneuploid cell population among aggressive BC that are heavily reliant on mitotic genes for tumour progression, thus can be targeted for therapy development.

Methods: Using *in vitro* studies we demonstrated that depletion of CEP55 sensitizes TNBC cells to anti-mitotic drugs like PLK1 inhibitor to induce CDK1-Caspase 3-dependent mitotic catastrophe due to unscheduled CDK1/Cyclin B activation. Also we showed ERK1/2 transcriptionally controls CEP55 hence inhibition of MEK1/2 using the small molecule inhibitor Selumetinib, can mimic depletion of CEP55 *in vivo*.

Results: We rationalised the usage of a MEK1/2 inhibitor in combination with a PLK1 inhibitor across a series of BC cell lines. We observed synthetic lethality among the aggressive hormone receptor negative lines with higher CEP55 expression compared to normal like and receptor positive lines with lower CEP55 level. The combination synergistically amplified apoptosis of aneuploid population via premature entry of these cells into mitosis in the presence of antimitotic drugs due to exhaustion of CEP55. We have also validated this synergistic effect of MEK1/2 and PLK1 inhibition using xenograft models, results of which imitated the *in vitro* findings.

Conclusions: We propose a novel treatment tactic of MEK1/2 -PLK1 dual combination for selectively targeting CEP55 over-expressing BC in the clinics.

1662P Synergistic antitumor effects of OT-101 (trabedersen), a transforming growth factor-beta 2 (TGF-β2) antisense oligonucleotide (ASO) and chemotherapy in preclinical tumor models

O. D'Cruz, C. Lee, V. Trieu, L. Hwang

Clinical Research, Autotelic Inc., Costa Mesa, CA, USA

Background: Overexpression of TGF-β2 has been implicated in the malignant progression of tumors by inducing immunosuppression, proliferation, angiogenesis and

metastasis. OT-101 (Trabedersen) is a phosphorothioate ASO designed to specifically target human TGF-β2 mRNA. Herein, we report the synergizing effect of OT-101 with chemotherapy in multiple human tumor xenograft models for further exploration of clinical combination strategies.

Methods: OT-101 was administered as single agent (1-64 mg/kg, qdx3/wk or qdx21) and in combination with Gemcitabine (GEM, 15 mg/kg, qdx2/wk), Dacarbazine (DTIC, 1-10 mg/kg, qdx4/wk) or Paclitaxel (PTX, 10 mg/kg, qdx5) to nude mice (10/subgroup) bearing either (i) orthotopic human L3.6pl pancreatic cancer (PAC), (ii) human metastatic C8161 melanoma, (iii) SC glioblastoma (U87) or (iv) SC ovarian (SKOV-3) tumors. Mice were monitored for adverse effects, body weight loss, tumor size and survival outcome. Lymph node and liver surface and micro-metastases as well as size and weight of the pancreatic tumors were determined. Tumor sections were stained with anti-BrdUrd and CD31 antibodies to determine tumor cell proliferation and vascularization, respectively.

Results: OT-101 significantly reduced tumor growth ($p = 0.0084$), lymph node metastasis ($p = 0.023$), and tumor angiogenesis ($p < 0.0001$) versus untreated control in the PAC model. OT-101 demonstrated synergy in tumor growth inhibition and increased survival in human malignant melanoma (C8161, $p = 0.038$, vs. DTIC alone), glioblastoma (U87, $p = 0.001$ vs. PTX) and ovarian (SKOV-3, $p < 0.05$ vs. PTX) cancer models when combined with either DTIC (C8161) or PTX (U87 and SKOV-3). No synergy was observed with GEM (PAC). The combination regimen tested was effective and tolerable. Significant antitumor activity was achieved at HED of 80 mg/m^2/day which is well below the optimized clinical dose used for IV infusion of patients at 140 mg/m^2/day.

Conclusions: The preclinical data laid the groundwork for establishing combination therapies in the clinic. Of interest is the preferential synergy between OT-101 and PTX or DTIC, but not with GEM.

1663P Targeting thioredoxin reductase 1 in novel combination therapies in p53 mutant triple negative breast cancer

P. Raninga[1], M. Kalimutho[1], D. Sinha[1], A. Bain[1], K. Tonissen[2], K.K. Khanna[1]

[1]Cell and Molecular Biology, QIMR Berghofer Medical Research Institute, Brisbane, Australia, [2]School of Natural Sciences, Griffith University, Brisbane, Australia

Background: The TP53 gene is frequently mutated in human cancers including triple negative breast cancers (TNBCs) (~84% patients). Although TP53 mutation is the only oncogenic driver in TNBCs, no targeted therapies for mutant p53 (mtp53) TNBCs are available. We aim to identify novel therapeutic targets and combination therapies for mtp53 TNBCs.

Methods: A large-scale genomic analysis was performed using the TCGA database to analyse the expression of various antioxidant genes in Mt and wild-type (wt) p53 BC cells. Thioredoxin reductase 1 (TrxR1) protein levels and redox activity were measured by western blot and DTNB reduction assay, respectively. Mt and wt p53 cells were treated with gold-based TrxR1 inhibitor and APR-246 and subsequently analysed for cell proliferation, apoptosis, and cell cycle progression. Phospho-histone H3 (pHH3) Ser10 expression was analysed by FACS.

Results: We observed significant upregulation of TrxR1, a redox gene, in mtp53 BC patients compared to wt patients. TrxR1 protein levels and redox activity were higher in mtp53 cells compared to wt cells. Notably, TrxR1 inhibition selectively induced apoptosis in mtp53 BC cells, but not in wt cells. Upon treatment with TrxR1 inhibitor, a significant proportion of mtp53 cells arrested in the G2/M phase with a concomitant increase in pHH3 Ser10, a marker of mitotic chromatin condensation. Thus, TrxR1 inhibition may lead to mtp53 TNBC cell death by causing mitotic catastrophe. APR-246, known to restore wild-type activity of mtp53 in many cancers, alone failed to induce apoptosis in mtp53 BC cells. However, co-treatment of APR-246 with a sub-lethal concentration of TrxR1 inhibitor resulted in a synergistic effect in mtp53 cells.

Conclusions: Inhibiting TrxR1 may represent an effective therapeutic strategy for mtp53 TNBCs. These results warrant the clinical evaluation of a novel combination therapy using APR-246 and TrxR1 inhibitors for mtp53 TNBC patients.

1664P Liprin-α4 could be a potential therapeutic target for pancreatic cancer

A. Yamasaki, H. Onishi, M. Kawamoto

Cancer Therapy and Research, Kyushu University Hospital, Fukuoka, Japan

Background: In pancreatic cancer whose microenvironment is extremely hypoxic condition, the analysis of signal transduction under hypoxia is thought to be significantly important. By investigating microarray analysis of pancreatic cancer cultured between under normoxia and under hypoxia, we found that the expression of leukocyte common antigen related (LAR)- interacting protein (liprin)-α4 was extremely increased under hypoxia compared to under normoxia. In the present study, the biological significance of liprin-α4 in pancreatic cancer was investigated and whether liprin-α4 could be a therapeutic target for this refractory cancer was estimated.

Methods: Three pancreatic ductal adenocarcinoma cell (PDAC) lines (ASPC-1, SUIT-2, and PANC-1) were cultured under normoxia (20%O_2) and under hypoxia (1%O_2), and were used as target cells. Inhibition of liprin-α4 was performed using liprin-α4 siRNA. Expression of liprin-α4 was analyzed by real time RT-PCR, western blot and immunofluorescent staining. Proliferation was estimated by cell count and MTT assay. Invasion was estimated by matrigel invasion assay. Mice xenograft experiments were performed using BALB/c nude female mice. Surgically resected human pancreatic cancer specimens were used for immune staining.

Results: 1) Expression of liprin-α4 was increased in PDAC under hypoxia compared to normoxia. 2) Liprin-α4 suppression decreased invasion through inhibition of endothelial mesenchymal transition in PDAC under hypoxia. 3) Liprin-α4 inhibition decreased proliferation of PDAC under hypoxia *In vitro*. 4) Tumor volume in mice injected with liprin-α4-inhibited PDAC was significantly lower than that in control mice. 5) Signaling from liprin-α4 was through PI3K and MAPK signaling pathways. 6) Relation between hypoxia inducible factor-1α (HIF-1α) expression and liprin-α4 expression was observed by immunofluorescent staining using surgically resected pancreatic cancer specimen.

Conclusions: These results suggest that liprin-α4 which is more expressed under hypoxia, plays pivotal role for inducing malignant phenotype such as proliferation and invasion in pancreatic cancer, and that liprin-α4 could be an effective therapeutic target for pancreatic cancer.

1665P Dual targeting of cystathionine β-synthase (CBS) and cystathionine γ-lyase (CSE) by miR-4317 displays a synergistic efficacy in repressing breast cancer progression

R.A. Youness[1], R.A. Assal[2], E. Khallaf[3], H.M. Hafez[3], A.A. Abdelmotaal[1], M.Z. Gad[4]

[1]Pharmaceutical Biology Department, Faculty of Pharmacy and Biotechnology, German University in Cairo, Cairo, Egypt, [2]Pharmacology and Toxicology Department, Faculty of Pharmacy and Biotechnology, German University in Cairo, Cairo, Egypt, [3]General Surgery Department, Faculty of Medicine, Cairo University, Cairo, Egypt, [4]Biochemistry Department, Faculty of Pharmacy and Biotechnology, German University in Cairo, Cairo, Egypt

Background: Recently, hydrogen sulphide (H_2S) and its synthesizing enzymes, CBS and CSE, have been casted as pleiotropic regulators in the malignant transformation process. H_2S paradoxically acts as oncogenic mediator in ovarian and liver cancers, and as tumor suppressor in prostate and gastric carcinomas. However, the link between H_2S and Breast cancer (BC) remains unclear. Thus we aimed at unraveling the association between H_2S and its synthesizing enzymes in BC progression. Furthermore, it was essential to evaluate their possible adoption as therapeutic targets in BC through their dual targeting by short non-coding RNAs.

Methods: Breast tissues were collected from 30 BC patients. Ki67 levels were quantified using immunohistochemistry. MDA-MB-231 and MCF7 cells were cultured and transfected with different oligonucleotides and/or treated with NaHS, an exogenous source of H_2S. Total RNA was extracted and quantified by qRT-PCR. Cellular viability, proliferation, and migation were measured using MTT, BrdU and scratch assays respectively. Bioinformatic analysis was performed to predict novel miRNAs that could target both CBS and CSE.

Results: CBS and CSE were significantly upregulated in BC tissues. Patients with high Ki67 scores showed the highest expression levels of CBS and CSE. Knocking down of CBS and CSE using siRNAs resulted in a significant attenuation of different hallmarks of BC. On the other hand, NaHS resulted in an increase in BC progression. miR-4317 was found to putatively target both CBS and CSE oncogenes with high binding scores. Ectopic expression of miR-4317 in BC cell lines resulted in a simultaneous reduction of CBS and CSE transcripts which was associated with a concomitant reduction in cellular viability, proliferation and migration. Finally, co-treatment of miR-4317 and NaHS resulted in abrogation of miR-4317 tumor suppressor activity.

Conclusions: This study showed a marked upregulation of CBS and CSE in BC tissues and characterized them as aggressive oncogenic drivers in BC. Moreover, miR-4317, a novel tumor suppressor in BC, displayed a synergistic effect in halting BC progression via twin-targeting CBS and CSE and diminishing H_2S levels in BC cell lines.

1666P Met/Axl system as a dual target in the mesothelioma pathway and invasiveness

G. Viscardi, V. Ciaramella, C.M. Della Corte, F. Papaccio, G. Esposito, R. Di Liello, T. Troiani, M. Orditura, F. Ciardiello, F. Morgillo

Medical Oncology, Department of Clinical and Experimental Medicine "F. Magrassi", University of Campania "Luigi Vanvitelli", Naples, Italy

Background: Malignant pleural mesothelioma is an aggressive and highly lethal disease. Conventional chemotherapies and radiation therapy have limited efficacy. Many evidences suggest the roles of receptors tyrosine kinase (RTKs) in mesothelioma pathogenesis, in particular epidermal growth factor (EGFR), Met and Axl. Axl activation is involved in proliferation and inhibition of apoptosis, and its over-expression represents a key molecular determinant underlying the development of acquired resistance to targeted anticancer agents.

Methods: Different histological types, epithelioid, sarcomatoid and mixed, of human mesothelioma cell lines were used. Protein levels of Met, Axl and its ligand, growth arrest-specific 6 (Gas6) were evaluated by Western Blot analysis. We conducted *in vitro* treatments with different doses of Foretinib, dual inhibitor of Met and Axl, in order to demonstrated the variation of cell proliferation and migration through MTT and Colony Forming Assay at the range dose 0.5-1 μM of Foretinib. Lastly, the rate of cell apoptosis was quantified by flow cytometry.

Results: The presence of Met, Axl and Gas6 proteins were found in all cell lines analyzed with different expression pattern. The dose escalation of Foretinib from 0.01 μM to 2 μM strongly inhibited cell proliferation and migration of mesothelioma cell lines. Treatment with Foretinib (at the dose 0.5 μM and 1 μM), determining a significantly increase of apoptosis rate (up to 50%) in specific histological type suggesting a different cell sensibility.

Conclusions: The co-activation of MET and AXL in mesothelioma cell lines suggests that these kinases could serve as novel therapeutic targets. MET and AXL inhibitors could be used as novel anticancer therapies influence clinically meaningful end points including metastatic recurrence and survival in the majority of tumour types.

1667P Targeting CXCR4 and FAK in non-small cell lung carcinomas with co-inactivated p53 and PTEN tumor suppressors

A. Podolski-Renic[1], M. Dragoj[1], S. Stojkovic[1], J. Dinic[1], J. Bankovic[1], E. Sereti[2], S. Jovanovic Stojanov[1], K. Dimas[2], M. Pesic[1], T. Stankovic[1]

[1]Department of Neurobiology, Institute for Biological Research "Sinisa Stankovic", University of Belgrade, Belgrade, Serbia, [2]Department of Pharmacology, Faculty of Medicine, School of Health Sciences, University of Thessaly, Larissa, Greece

Background: In this study we evaluated potential of targeting CXCR4 and focal adhesion kinase (FAK) in suppressing metastatic spread of p53/PTEN deficient non-small cell lung carcinomas (NSCLCs).

Methods: We first examined the invasive characteristics of NSCLC cells with suppressed p53 and PTEN activity using wound healing, gelatin degradation and invasion assays. Namely, NCI-H460 cells with applied pharmacological inhibition of wild type p53 and PTEN activity (NCI-H460$^{p53-/PTEN-}$) were analyzed along with COR-L23 cells that have intrinsically inactive both tumor suppressors. Further, changes in the expression of CXCR4 and FAK were evaluated by RT-qPCR and Western Blot analysis. Finally, we tested the ability of CXCR4 and FAK inhibitors (WZ811 and PF-573228, respectively) to suppress the migratory and invasive potential of p53/PTEN deficient NSCLC cells, in vitro and in vivo using orthotropic metastatic lung carcinoma mouse model.

Results: Our results showed that cells with mutually inactive p53 and PTEN have significantly increased migratory and invasive potential. Such invasive phenotype is associated with hyperactivation of CXCR4 and FAK and their downstream AKT and ERK signaling pathways. Treatments with WZ811 and PF-573228 significantly reduced migratory and invasive capacity of NCI-H460$^{p53-/PTEN-}$ and COR-L23 cells that was accompanied by the downregulation of AKT signaling. In addition, these two inhibitors showed trend to improve survival of SCID mice with orthotopicaly inoculated COR-L23 cells that extensively invaded lung parenchyma and developed distant metastases compared to NCI-H460 derived tumors.

Conclusions: Overall, we demonstrated that p53/PTEN deficient NSCLCs have extremely invasive phenotype and provided a rationale for the use of CXCR4 or FAK inhibitors for the suppression of NSCLC dissemination.

1668P Pin1 protein: A druggable target in high grade serous ovarian cancer

C. Russo Spena[1], L. De Stefano[1], B. Salis[2], F. Rizzolio[3]

[1]Graduate School in Chemistry, University of Trieste, Trieste, Italy, [2]Graduate School in Molecular Biomedicine, University of Trieste, Trieste, Italy, [3]Molecular Science and Nanosystems Department, Ca'Foscari University, Venice, Italy

Background: Epithelial Ovarian cancer (EOC) is the 5th leading cause of cancer death in the USA and the High Grade Serous-EOC is the most common and aggressive type characterized by mutations in the p53 gene (>90%). Pin1 has been demonstrated to activate a mutant p53 transcriptional program. It binds specific phosphoSer/Thr-Pro-motifs and catalyses the cis/trans conformational switch of target proteins. In HGS-EOC, Pin1 is overexpressed in about 50% of cases suggesting that it may be a potential therapeutic target. The Pin1 inhibition affects cellular proliferation, migration, invasion, new angiogenesis and apoptosis suggesting a pivotal role in cancer. Nevertheless, there are still deficiencies in producing Pin1 ligands: Pfizer has reported inhibitors that have poor permeability and low efficacy. Here, it is reported that the encapsulation of these inhibitors in liposomes increases the cytotoxic activity on ovarian cancer cells.

Methods: The inhibitor was encapsulated in ionisable cyclodextrins via a pH gradient. PEG-liposomes were prepared using different molar ratio of cholesterol and lipids. Cell viability was tested with an MTT-like assay. The liposome characteristics were evaluated by DLS and zeta potential. The loading efficiency of drug was calculated via UV-Visible method and the release with a dialysis membrane.

Results: Pegylated liposomes of about 100 nm were synthesized for the encapsulation of drug. This complex has a promising loading efficiency and release rate. These characteristics allow an efficient delivery in different ovarian cancer cells line achieving the IC50 values in the low micromolar range. Instead, inhibitor alone did not change the cell viability.

Conclusions: In summary, we have created a new formulation of Pin1 liposomal inhibitor that can be used to kill ovarian cancer cells. Therefore, for further application in vivo, the inhibitor retention would enhance antitumor efficacy. In fact, the liposome system could have a high concentration in the tumour, thanks to enhanced permeability and retention effect, overtake the tumoral barrier and represents an option for the therapy of ovarian cancer.

1669P RalB GTPase: A potential novel target for RAS mutant colorectal cancer

H. Khawaja, P. O'Reilly, D. McArt, T. Harrison, P. Johnston, S. Van Schaeybroeck

Centre for Cancer Research and Cell Biology, Queen's University Belfast, Belfast, UK

Background: Colorectal cancer is the 3rd most common cancer in the UK, with around 40,000 new cases diagnosed annually. CRC patients have a 5-year overall survival rate of < 10% and more than 50% will die of metastatic disease. Intrinsic or acquired resistance to chemotherapeutic drugs is a major problem in CRC and developing an effective treatment strategy is therefore of the utmost importance. CRC cases harbouring *RAS* mutations (>50% cases) are associated with poor prognosis; this mutation has proven to be an important predictive factor for response to EGFR targeted therapies. Failure to target the *RAS* oncogene has resulted in a concentrated effort to discover targets within the downstream components of this pathway. In this study, we evaluate the roles of the small GTPases, RalA and RalB, as novel targets in *RAS* mutant (MT) CRC. The RALGDS/RAL pathway constitutes a RAS effector pathway and mediates cell survival, proliferation and tumorigenesis. RalB in particular contributes to cell survival through TBK1 signalling.

Methods: We used an siRNA-based approach silencing RALA and RALB both individually and simultaneously in a panel of *KRAS*MT and WT cells with and without the addition of the MEKi AZD6244 (Selumetinib). Knockdown efficiency and subsequent signalling events were assessed by western blotting. Flow cytometry and MTT assays were used to measure cell death and cell viability respectively. Connectivity mapping using data from microarray experiments was used to identify drugs mimicking the phenotype observed with siRALB, subsequently leading to the investigation of a TBK1 inhibitor which is currently ongoing.

Results: We found that silencing RALB but not RALA, led to the greatest amount of cell death in *RAS*MT but not WT CRC cells. In addition, a significant increase in cell death was observed when RALB silencing was combined with MEK inhibition. Cell death was found to be mediated by Caspase 8 and involved an upregulation of death receptor 5

(DR5). Furthermore, TBK1 inhibition was found to mimic the phenotype observed with siRALB.

Conclusions: RalB but not RalA, is associated with cell survival and may contribute to drug resistance in *RAS*MT CRC. Thus, the development of novel RalB-specific therapies may lead to new treatment strategies for *RAS* MT CRC.

1670P Serial genotypic characterization of circulating tumor cells (CTCs) in patients with metastatic castration resistant prostate cancer (mCRPC) undergoing treatment with abiraterone acetate (abi) or enzalutamide (enza)

N. Dizman[1], J. Patel[2], M. He[1], B. Foulk[2], D.A. Smirnov[2], J. Hsu[1], P. Twardowski[1], M. Kortylewski[3], V. Bhargava[2], J. Jones[1], S.K. Pal[1]

[1]Department of Medical Oncology and Experimental Therapeutics, City of Hope, Duarte, CA, USA, [2]Janssen Pharmaceuticals, Janssen Pharmaceuticals, Spring House, PA, USA, [3]Department of Cancer Immunotherapeutics and Tumor Immunology, City of Hope Comprehensive Cancer Center, Duarte, CA, USA

Background: While enza and abi have substantially improved outcomes for patients (pts) with mCRPC, de novo and acquired resistance mutations are increasingly recognized.

Methods: Pts receiving abi or enza in the course of routine clinical care were consented for blood collection at weeks 0, 4, 8 and 12 of therapy, and at the time of progression (based on Prostate Cancer Working Group 3 [PCGW3] criteria). CellSearch was used for CTC enumeration; individual cells were isolated and subsequently classified for EpCAM and C45 positivity. RNA sequencing (RNA-seq) was performed on pools of up to 10 CTCs.

Results: Amongst 36 pts enrolled, median age was 71 (range, 54-84) and median PSA was 21.9 ng/dL (range, 0-918.3). Regarding treatment, 21 pts received abi and 15 received enza. By PCWG3 criteria, 23 pts met the definition of progression on abi or enza. Mean/median CTC count was 158/5 (IQR 25%-75%, 0-15). On RNA-seq of CTCs collected at the time of progression, AR was the most mutated gene followed by ATRX, GNAS, FOXA1, KMT2A and CNOT1. Several deleterious mutations in the DNA damage response genes were noted including frameshift mutations in PRKDC, MSH2 and MLH1. Differential gene expression analysis between abi/enza sensitive and abi/enza resistant samples revealed 2100 differentially regulated genes in drug-resistant CTCs. Ingenuity pathway analysis was used to identify pathways altered due to differential regulation of these genes. Among these pathways, TGFβ and CCDN1 signaling were found to be significantly up-regulated in drug resistant CTCs. In vitro enza-resistant models will be presented, offering validation of our clinical findings.

Conclusions: RNA-seq of CTCs representing abi/enza sensitive and resistant states can identify potential mechanisms of resistance. Therapies targeting the downstream signaling mediated by CCND1, such as CDK4/6 inhibitors (e.g., palbociclib or ribociclib), could avert resistance. Targeting TGFβ, another putative mediator of resistance, may be warranted.

1671P A novel circulating cell free DNA-based assay can predict tumor response to systematic chemotherapy

T. Toshima[1], T. Nagasaka[1], Y. Mori[1], T. Kawai[1], K. YASUI[1], T. Fuji[1], F. Taniguchi[1], K. Kimura[1], H. Kishimoto[1], Y. Umeda[1], A. Goel[2], T. Fujiwara[1]

[1]Gastroenterological Surgery, Okayama University Hospital, Okayama, Japan, [2]Center for Gastrointestinal Research, Center for Translational Genomics and Oncology, Baylor Scott & White Research Institute, Charles A. Sammons Cancer Center, Baylor University Medical Center, Dallas, TX, USA

Background: Although circulating cell-free DNA (cfDNA) in blood is being touted as a frontier noninvasive approaches, its clinical utility still remains questionable. The purpose of this study was to compare the efficacy of cfDNA by comparing with blood CEA levels and radiological evaluation in patients with unresectable metastatic colorectal cancer (mCRC) during treatment of systemic chemotherapy.

Methods: In this study, 12 patients with mCRC who were intended to receiving systemic chemotherapy were enrolled. Methylation status of CpG sites, considered as cancer-specific alteration, and concentration of cfDNA were evaluated from blood plasma obtained before administration of systemic chemotherapy in each treatment cycle. To analyze aberrant cancer-specific methylation, we modified the highly sensitive assay for bisulfite DNA (Hi-SA) followed by fluorescence-based PCR, as reported previously (JNCI 2009). Our modified methodology can detect 8 loci of target promoters, therefore methylation score (MS) could be ranged from 0 to 8 at a given time.

Results: Of the 12 patients enrolled, 10 patients experienced radiological progressive disease (PD). Plasma MS was significantly increased before radiological PD in 8 of 10 patients with PD. Thus MS had the median lead time of 73 days (range: 0-231 days) before documentation of radiological PD. In contrast, serum CEA level could predict PD only in the 2 patients before documentation of their radiological PD. Consequently, plasma MS could predict radiological PD with the median lead time of 9 days (range: 0-21 days) compared with serum CEA. We also examined whether cfDNA concentration level in plasma was associated with radiological PD. Of the 12 patients, only 3 patients increased cfDNA concentration level before radiological PD with the median lead time of 88 days (range; 21-140 days).

Conclusions: Our circulating cell free DNA-based assay is a robust methodology for capturing DNA methylation in circulating cell-free DNA in plasma, and is useful for the early identification of CRC patients that are at risk of developing PD prior to radiographic documentation.

1672P ctDNA might expand therapeutic options for second line treatment of KRAS mutant mCRC

P. Gazzaniga[1], C. Raimondi[1], C. Nicolazzo[1], A. Gradilone[1], E. Cortesi[2]

[1]Medicina Molecolare, Sapienza Università di Roma, Rome, Italy, [2]Scienze Radiologiche, Oncologiche ed Anatomo-patologiche, Policlinico Umberto I, Rome, Italy

Background: KRAS mutations predict failure of anti-EGFR therapies, thus genotyping colorectal cancer (CRC) is crucial for personalized treatments. Cancer heterogeneity hamper the assessment of KRAS mutational status in tumor tissues, leading to the search for alternative sources of cancer genetic information. ctDNA of patients treated with anti-EGFR drugs exhibit pulsatile levels of KRAS mutations, revealing that the CRC genome adapts dynamically to intermittent EGFR blockade. These data support the use of liquid biopsy to monitor the molecular underpinnings of resistance to anti-EGFR agents. Research has been selectively concentrated on the emergence of resistant clones in the blood of patients with wtKRAS CRC as biomarker of anti-EGFR therapy resistance. Conversely our group demonstrated that patients with metastatic CRC harboring mutated primary tumors, thus not candidate to EGFR inhibitors, frequently have wtKRAS circulating tumor cells in blood. To explain the prevalence of wtKRAS clones in these patients, the generation of hypoxia has been suggested. We aimed to determine if anti-angiogenic drugs might drive the biological evolution of mKRAS clones towards a prevalent wtKRAS disease, by ctDNA.

Methods: Ten patients with histologically confirmed mKRAS mCRC candidate to first-line anti angiogenic drugs were prospectively enrolled. To investigate whether wtKRAS clones emerge as dominant under treatments, serial blood draws were performed at baseline and at 3 months months of treatment. Idylla™ (Biocartis) ctKRAS Mutation Assay was used to track KRAS mutational status in serial ctDNA determinations for each patient.

Results: At baseline, KRAS mutational status in ctDNA was found concordant with tumor tissues in all patients analysed. At 3 months,3/10 (30%) of mKRAS CRC patients treated with antiangiogenic drugs switched to wtKRAS ctDNA in peripheral blood.

Conclusions: These preliminary data suggest that patients with mKRAS colon cancer not unfrequently switch to a prevalent wtKRAS disease in course of treatment with anti-angiogenic drugs. if confirmed in a large patients population, these results might shift second-line therapeutic options for KRAS mutant mCRC patients from insufficient to promising.

1673P Ex vivo expansion of circulating tumor cells for individualized drug susceptibility in patients with advanced or recurrent oesophageal cancer

V. Kumar[1], R.C. Sagar[1], P. Kumar[2]

[1]Surgical Oncology, Kidwai Memorial Institute of Oncology, Bangalore, India, [2]Bioinformatics, Institute of Bioinfomatics, Bangalore, India

Background: Esophageal cancer (EC) is the eighth most common cancer in the world. The incident rate of EC is significantly high in Asian countries compared to rest of the world. Circulating tumor cells (CTCs) derived from EC have the potential to be precursors of metastasis. It is therefore of paramount interest to isolate and characterize CTCs from EC patients to monitor and detection of recurrence. The aim of present study is to evaluate drug response using patient-derived CTC cultures obtained from EC.

Methods: Custom microfabricated tapered microwells will be integrated with microfluidics to expand CTC clusters without any prior pre-enrichment. The established CTC cluster assay will be used to screen anticancer drugs. The drug concentrations selected will be centered on the IC50 that had previously established for each drug across EC cell lines. Cluster formation in culture will be correlated with overall patient survival. 50 patients with a proven diagnosis of EC attending the Department of Surgical Oncology, Kidwai Institute of Oncology will be enrolled into the study.

Results: Our initial results showed CTC clusters formation in the patients with metastatic EC. This cluster formation was affected by the presence and duration of systemic therapy. We observed a progressive reduction in cluster formation in samples from patients who had undergone increasing longer treatment.

Conclusions: Our result suggests that CTC cluster can be used to rapid evaluation of drug response. We would further use the CTC cluster assay as a potential tool for evaluating patient prognosis during treatment. The study will be employed to determine the drug susceptibility pattern in individual patients and also provide therapeutic choices for personalized treatment.

[1]Prostate Cancer Clinical Research Unit, Spanish National Cancer Research Centre, Madrid, Spain, [2]Medical Oncology, Hospital Universitari i Politècnic La Fe, Valencia, Spain, [3]Oncology, The Institute of Cancer Research/Royal Marsden NHS Foundation Trust, Sutton, UK, [4]Prostate Cancer Unit, CNIO- Spanish National Cancer Center, Madrid, Spain, [5]Drug Development Unit, The Institute of Cancer Research & Royal Marsden, Sutton, UK, [6]Department, Peter MacCallum Cancer Center, Melbourne, Australia, [7]Early Drug Development Department, Institut de Gustave Roussy, Villejuif, France, [8]CNIO-IBIMA Genitourinary Research Unit, Hospitales Universitarios Virgen de la Victoria y Regional de Málaga, Málaga, Spain, [9]Medical Oncology, Hospital Universitario Virgen de la Victoria y Regional de Málaga, Malaga, Spain, [10]Section of Medicine, Institute of Cancer Research Royal Marsden Hospital, Sutton, UK, [11]Prostate Cancer Clinical Cancer Research Unit, Spanish National Cancer Research Centre (CNIO), Madrid, Spain

Background: A drop in CTCs counts as early as 4 weeks following treatment initiation have been suggested as an indicator of overall survival (OS) benefit. DOC remains a pivotal treatment in mCRPC for which there are no early pharmacodynamic (PD) markers of its activity in patients (pts). CTCs may be used as surrogate tumor tissue to study PD markers of apoptosis (CK-M30) or mitosis arrest (pHH3) in mCRPC pts receiving DOC.

Methods: We conducted a prospective 2-cohort multicenter exploratory study in mCRPC pts progressing by PCWG2 criteria who were eligible for DOC 75 mg/m2. Pts were prescreened using the CellSearch system and selected if CTCs≥5/7.5mLs of blood (Basal 1). A 2nd blood sample (Basal 2) was drawn in eligible pts within 0-7 days prior to C1D1 of DOC and further samples were collected at 8h, 24h, 7d and 21d. Directly conjugated mAb against pHH3 and CK-M30 were used in combination with CellSearch. Statistical analyses were performed to evaluate the baseline and post-treatment variability. Increases in % of biomarker CTC+ greater than the median baseline variability were correlated with achieving a 50% PSA response (PSA50) and OS from DOC start using chi-square and long-rank test, respectively.

Results: 60 mCRPC pts (CK-M30 = 30; pHH3 = 30), 95% ECOG 0-1, 95% and 17% have bone and visceral metastases respectively, received a median of 7 cycles (range 2-10) of DOC. Biomarker results are summarised in Table.

Conclusions: pHH3 in CTC+ may be a potential PD biomarker of a favourable response to DOC treatment.

1675P Risk of recurrence prediction and optimum treatment planning for early stage breast cancer patients: A cost-effective, accurate and broad based solution for Asia

S. Somashekhar[1], M.M. Bakre[2], C. Ramkumar[2], C. Basavaraj[2], A. Arun Kumar[2], L. Madhav[2], C. Prakash[2], N. Naidu[2]

[1]Surgical Oncololgy, Manipal Comphrehensive Cancer Center, Bangalore, India, [2]Clinical Research, Onco Stem Diagnostics, Bangalore, India

Background: Current molecular risk stratification tests have helped clinicians to optimize Chemotherapy for early stage breast cancer patients leading to huge savings in treatment costs and improved quality of life. However, current tests are not impactful in the Asia due to the extreme cost-sensitivity of the market. Aim of this study was to develop and validate a cost-effective, broad based and robust test to stratify early stage hormone receptor positive patients based on individual risk of recurrence.

Methods: A retrospective cohort of 300 patients, was used to develop 'CanAssist-Breast'- a Morphometric Immunohistochemistry based test comprising 5 biomarkers plus three clinical parameters (Tumor size, node status and grade) using SVM based algorithm. CanAssist-Breast biomarkers belong to key signaling pathways involved tumor invasion and chemotherapy resistance.

Results: CanAssist-Breast classifies patients into 'low or high' risk of recurrence based on "CanAssist-Breast Score" score. Test validation in a 800+ sample cohort demonstrated that it is useful in both node negative and positive patients, as well as chemotherapy naïve and treated patients. CanAssist-Breast Score, is a strong independent predictor of disease recurrence by multivariate analysis. The majority of patients in 'low risk' had Stage 2, Grade 2/3 disease over Stage 1, Grade 1 disease. Comparison with commonly used prognostic tools including Ki67, the online tool PREDICT and Oncotype Dx showed that CanAssist-Breast test was superior in determining prognosis.

Conclusions: CanAssist-Breast is a low-cost, prognostic and chemotherapy predictive test to predict risk of recurrence and enable optimal treatment planning in patients with early stage Breast Cancer in Asia.

1676P Comparison of progression-free survival (PFS) on comprehensive multiplatform profiling-guided therapy to PFS on prior therapy: A pooled analysis from 4 contemporary prospective studies

A. Seeber[1], G. Chahine[2], F. Nasr[2], A. Dean[3], M. Miranova[3], G. Jameson[4], N. Robert[5], G. Gastl[1], H. Zwierzina[1]

[1]Haematology and Oncology, Innsbruck Medical University, Innsbruck, Austria, [2]Centre Hospitalier de l'Universite Saint Joseph de Beyrouth, Hotel-Dieu de France, Beirut, Lebanon, [3]Oncology, St John of God Hospital, Subiaco, Australia, [4]Clinical Trials Program at Scottsdale Healthcare, Virginia G. Piper Cancer Center, Scottsdale, AZ, USA, [5]Oncology, Virginia Cancer Specialists, Fairfax, VA, USA

Background: It is expected that the progression-free survival (PFS) for patients with refractory cancers will decline over subsequent lines of therapy. Patients with refractory metastatic cancer have previously been shown to derive some clinical benefit from comprehensive multiplatform profiling (CMP) of tumor tissue. Data from four

independent physician-led prospective and prospective/retrospective studies was pooled in an exploratory manner to determine if PFS was improved when patients were treated with molecular profiling-guided therapies compared to PFS on the prior therapies.

Methods: Tumor tissue specimens from 202 patients were submitted for CMP to a certified referral laboratory (Caris Life Sciences, USA) between March 2010 and December 2016. Treatment selections were based on predictive biomarker status associated with agents with potential clinical benefit. Clinical benefit was defined as a PFS ratio (= PFS upon treatment according to CMP/PFS on the prior therapy) ≥ 1.3.

Results: As of December 2016, 157 of 202 (77.8%) profiled patients were treated according to the predictive results, of whom 140 were evaluable. Patients had received a median of three prior therapies (range 1-12). The most common tumor types were breast (n = 35), colorectal (n = 14), non-small cell lung (n = 11) and gastric cancer (n = 9). A median PFS of 120.0 days was observed with CMP-directed therapies compared to 89.5 days for prior therapies (HR = 0.70, p = 0.012). Seventy-three of 140 patients (52%) had a PFS ratio ≥ 1.3. Over 70% of treated patients received chemotherapy alone, while 21% of patients received targeted therapies, either alone or in combination with chemotherapy or hormone therapy.

Conclusions: Contrary to the expected decline in PFS, patients had a better outcome when treated with CMP-guided treatments. This was interestingly driven by the precision use of available chemotherapeutic resources rather than sometimes inaccessible targeted therapies. Further prospective trials in specific tumor types may help to highlight particular patient populations who might benefit most from CMP guidance.

1677P Effect of enoxaparin, omeprazole, gemcitabine and bortezomib in refractory patients

J.P. Marquez-Manriquez

Clinic of Refractory Tumors and Relapse Prevention, Centro de Investigacion de Cancer en Sonora Campus Seattle, Seattle, WA, USA

Background: Repurposing drugs and immunogenic chemotherapy for cancer is an emerging field, especially the combination of drugs with validated data. Several studies have shown that enoxaparin, omeprazole, gemcitabine and bortezomib have immunomodulatory properties that synergize with several chemotherapeutic protocols and decrease chemoresistance in several tumors. We treated refractory patients with ECOG=0 with this combination. We demonstrated significant clinical response that correlated with the immune response after 2 months of weekly treatment.

Methods: CICS IRB approved this protocol and inform of consent was signed. We included 10 patients, median age 45 years old of each tumor with at least 2-4 relapses. The patients receive intravenous 0.5 gr/m^2 of gemcitabine, 3.5 mg of bortezomib, 80 mg of omeprazole and enoxaparin was administrated subcutaneously in the area with more tumor activity according with the CT SCAN, Granzyme B ELISPOT and cytokine ELISA that were performed before, during and after the treatment. We analyzed the data with prism graph pad and by multivariate analysis using SAS/STAT.

Results: We had a significant correlation between increased levels of CD8 cells (p = 0.0003) and PFS in the 100% of the patients. The cytokines measured were downregulated after the treatment with significant correlation with IL-6 (p = 0.001), IL-8 (p = 0.001), IL-18, (p = 0.01) and TNF alpha (p = 0.005) and CR after the third CT scans. The laboratory tests before, during and after the treatment did not demonstrate clinical significant toxicity.

Conclusions: The results obtained in this pilot study gave relevant data to prepare a phase I trial. We conclude that this combination is feasible to overcome chemoresistance and improve the anti-tumor immune response by CD8 cells and decreasing cytokines associated with tumor progression.

1678P A new chemotherapy-based combination to prevent osteosarcoma progression

M. Monchanin[1], P. Berchard[1], M. Vienne[1], J.B. Langlois[2], N. Gadot[3], A. Bernet[4], J-Y. Blay[5], A. Dutour[6]

[1]Equipe C. Caux et J-Y. Blay, CRCL, Lyon, France, [2]In Vivo Imaging, CERMEP, Bron, France, [3]Anipath Platform, CRCL, Lyon, France, [4]Apoptosis and Cancer, CRCL, Lyon, France, [5]Département d'Oncologie Médicale Adulte, Centre Léon Bérard, Lyon, France, [6]CRCL, Centre Léon Bérard, Lyon, France

Background: Despite the intensification of chemotherapy regimen, 5 years survival rates for patients with metastatic or relapsed osteosarcoma (OS) remains of 20%. The secreted factor netrin 1 (Nt1) is overexpressed in many human cancers to block apoptosis. Recent studies showed that blocking Nt1 interaction with its receptors potentiates chemotherapy efficacy suggesting that combining chemotherapies with Nt1 interference could be a promising approach for chemoresistant tumors like OS.

Methods: Analyses of the ATGSarc database (http://atg-sarc.sarcomabcb.org/), indicate that Sarcoma with complex genomic (SCG) with a higher expression of Nt1 have a poorer outcome (p < 0.002). In addition, q PCR performed on human sarcomas samples showed that Nt1 is higher expressed in OS compared to other SCG (7.75 fold increase - p < 0.02). These data indicated that Nt1 could be a potential target for OS treatment. Thus, we evaluated the antitumoral effects of anti Nt1 monoclonal antibody (aNt1) combined to doxorubicin (Dox) in a rat syngeneic and metastatic OS model. In this model, treatments were administered either on progressive OS or post operatively to prevent OS relapse. At the end of the experiments tumors and lung were collected for IHC analyses.

Results: As pre operative treatment, Dox/aNt1 combination caused a marked delay in OS progression (median end point reached at day 17 and day 22 respectively in Dox and Dox/aNt1 group, (p < 0.02) and dramatically slowed down metastatic spreading: lung metastases (d > 5mm) were found respectively in 75% and 17% of Dox and Dox/aNt1 treated rats As post operative treatment, Dox/aNt1combination significantly increased animals survival (median end point reached at day 15 and day 21 respectively in Dox and in Dox/aNt1 group; (p < 0.02). Moreover, 19 days after tumor resection, 10% of the Dox treated tumors hadn't relapsed versus 40% in the Dox/aNt1 treated group. A variation in tumor vascular density caused by the treatment was found in the Anti Nt1 treated groups as shown by CD146 staining.

Conclusions: Our study reporting the antiproliferative and antimetastatic effects and of Dox/aNt1 Combination in OS indicate that this combined treatment could be a way to overcome OS chemoresistance.

1679P Mutant KIT translocates into the nucleus and induces NFKBIB expression that leads to KIT expression in imatinib-resistant gastrointestinal stromal tumors

Y-S. Hsueh[1], H.H. Chang[2], Y-S. Shan[3], H.S. Sun[4], J.A. Fletcher[5], C-F. Li[6], L-T. Chen[1]

[1]National Institute of Cancer Research, National Health Research Institutes, Tainan, Taiwan, [2]Institute of Clinical Pharmacy and Pharmaceutical Sciences, College of Medicine, National Cheng Kung University, Tainan, Taiwan, [3]Department of Surgery, National Cheng Kung University Hospital, Tainan, Taiwan, [4]Institute of Molecular Medicine, College of Medicine, National Cheng Kung University, Tainan, Taiwan, [5]Department of Pathology, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, USA, [6]Department of Pathology, Chi-Mei Foundation Medical Center, Tainan, Taiwan

Background: Gastrointestinal stromal tumor (GIST) is a dominantly mutant KIT-driven tumor. Prolonged tyrosine kinase inhibitor (TKI) treatment may result in a resistant phenotype through acquired secondary KIT mutation. Increasing evidences show that membrane-bound receptors, as EGFR, can translocate into the nucleus, mediate genes expression, and lead to tumor survival and drug resistance. However, it's barely known the nuclear role of KIT in GIST.

Methods: In this study, two imatinib (IM)-resistant GIST cell lines, GIST48 and GIST430, were used as a model.

Results: In this study, we first showed that KIT is distributed both in the cytoplasm and the nucleus in IM-resistant GIST cells. Using ChIP-seq and ChIP assay, we identified that nuclear KIT bound to the *NFKBIB* promoter region and regulated its expression. The expression levels of NFKBIB and phosopho-KIT were significantly correlated with NCCN-risk category in surgically resected GISTs stained by immunohistochemistry. The cell viabilities were inhibited as accompanying with KIT reduction in GIST cells while NFKBIB was silenced or RELA was overexpressed. Moreover, RELA was activated, translocated into the nucleus, and bound to *KIT* promoter region in NFKBIB-silenced or RELA-overexpressed GIST cells. Valproic acid, acted as a NFKB inducer, could induce RELA nucleus translocation and binding to *KIT* promoter region that led to the reduction of protein and RNA expression level of KIT and the cell viabilities of GIST cells. Furthermore, the combination of IM with low-dose valproic acid showed synergistically inhibitory effect on cell viabilities of GIST cells and comparable effects on reducing phospho-KIT level and inhibiting tumor growth as high-dose valproic acid did in GIST430 xenograft model.

Conclusions: Taken together, we first demonstrated that phosphorylated KIT could translocate into the nucleus and drive itself expression in IM-resistant GIST cells through mediating NFKBIB expression. In addition, our findings identified a novel and druggable KIT-NFKBIB-NFKB regulatory axis that provides a new insight on tumorigenesis and therapeutic option for IM-resistant, mutant KIT-expressing GISTs.

1680P Reversion of epithelial–mesenchymal transition (EMT) as a mechanism of action of cabazitazel in castration-resistant prostate cancer

N. Jiménez[1], M. Marín-Aguilera[1], O. Reig[1], P.L. Fernández[2], S. García-Recio[1], M.V. Pereira[1], A. Prat[1], B. Mellado Gonzalez[1]

[1]Medical Oncology/Translational Genomics and Targeted Therapeutics in Solid Tumors Lab, Hospital Clínic of Barcelona/Institut d'Investigacions Biomèdiques Agust Pi i Sunyer/Fundació Clínic per a la Recerca Biomèdica, Barcelona, Spain, [2]Medical Oncology/Translational Genomics and Targeted Therapeutics in Solid Tumors Lab, Hospital Clínic of Barcelona/Institut d'Investigacions Biomèdiques Agust Pi i Sunyer, Barcelona, Spain

Background: The epithelial to mesenchymal transition (EMT) process is involved in *de novo* and acquired resistance to hormone-therapy and docetaxel (D) in metastatic castration resistant prostate cancer (mCRPC). Cabazitaxel (CZ) it active after D-progression and prior second-line hormone-therapies. Here we investigated the differences between CZ and D resistance related to the EMT phenotype acquisition and its potential clinical value.

Methods: D and CZ resistant (R) cells lines were derived from parental DU-145 and PC-3. Cell line Molecular characterization was performed using Affymetrix GeneChip Human Gene 2.0 ST microarrays. Gene expression analysis was performed by quantitative real-time PCR in cell lines and in FFPE tumors from mCRPC treated with CZ. Protein levels were measured by Western Blot. Cell migration was assessed using the Cultrex cell migration kit (Trevigen) andcell viability by MTT assay. Gene inhibitory experiments were performed by siRNA transfection.

Results: Microarray data, pathway analysis and EMT gene data *in silico* validation showed that EMT occurred in both D-R and CZ-R cells, being *ZEB1* one of the top deregulated genes. However, we identified 55 EMT genes differentially deregulated between D-R and CZ-R vs parental cells. Among them *CDH1*, and *ESRP1* (lost in D-R but maintained in Cz-R), and *AXL* (overexpressed in D-R and downregulated in CZ-R). D-R cells presented a more pronounced mesenchymal phenotype (morphology, higher migration and lower proliferation rates, higher expression of EMT markers at mRNA and protein level) than CZ-R. Dose-response experiments showed that CZ induced *CDH1* and *ESRP1* expression in different cell lines models. *ZEB1* inhibition reverted D- resistance, but not CZ-resistance, and restored *ESRP1* expression in D-R cells. In 29 CRPC patients treated with CZ, low level of expression of ESRP-1 in tumor correlated with a better PSA-PFS (6.2 vs 2.7 months, P = 0.006; HR: 0.31 P = 0.009) and radiological PFS (7.9 vs 3.3 months, P = 0.047; HR: 0.39 P = 0.055) and the EMT phenotype was not associated to resistance.

Conclusions: The reversion of EMT phenotype, trough induction of *CDH1* and *ESRP1*, may be a novel mechanism of action of CZ, which may explain its activity in patients progressing to prior therapies in CPRC.

1681P Globally optimizing therapeutic combinations against bortezomib-resistant multiple myeloma using a quantitative parabolic optimization platform (QPOP)

M. Rashid[1], T.B. Toh[2], N.L. Abdullah[2], A. Silva[3], Y. Zhang[2], P.F. Tan[4], A.L. Teh[4], N. Karnani[4], S. Jha[2], C-M. Ho[5], W.J. Chng[2], H. Dean[6], E.K-H. Chow[2]

[1]Department of Pharmacology, Yong Loo Lin School of Medicine, Singapore, [2]Cancer Science Institute of Singapore, National University of Singapore, Singapore, [3]Department of Mechanical Engineering, University of California, Los Angeles, CA, USA, [4]Brenner Centre for Molecular Medicine, Singapore Institute for Clinical Sciences (SICS), A*STAR, Singapore, [5]Department of Mechanical Engineering, Henry Samueli School of Engineering and Applied Science, University of California, Los Angeles, CA, USA, [6]Department of Bioengineering, Henry Samueli School of Engineering and Applied Science, University of California, Los Angeles, CA, USA

Background: Multiple myeloma is an incurable hematological malignancy that relies on drug combinations as first and secondary lines of treatment. The inclusion of proteasome inhibitors, such as bortezomib, into these drug combination regimens has improved median survival. Resistance to bortezomib, however, is a common occurrence that ultimately contributes to treatment failure. Thus, there remains a need to identify improved drug combinations that may serve as later lines of treatment.

Methods: We have developed the quantitative parabolic optimization platform (QPOP) to optimize drug combinations against bortezomib-resistant multiple myeloma. By mapping phenotypic output data to parabolic response surfaces, QPOP is able to deterministically optimize drug combinations as well as drug dosages.

Results: We have successfully identified potential optimal drug combinations against bortezomib-resistant RPMI 8226 (P100v) cell line as projected via QPOP, with these combinations exhibiting synergistic response surface maps. The drug combinations displayed lower half-maximal inhibitory concentrations (IC_{50}) *in vitro* as compared to single drug administration. While QPOP does not rely on molecular mechanism prediction, the identified optimal drug combinations can reverse DNA hypermethylation and silencing of tumor suppressors that occurs following acquired bortezomib-resistance. Prolonged survival of P100v tumor-bearing mice was observed when these optimized combinations were validated *in vivo*, further highlighting the importance of treating *in vitro* and *in vivo* as two separate entities. Moreover, the drug combination is broadly effective across a range of primary multiple myeloma patient samples.

Conclusions: These results collectively show that QPOP is a robust platform that is able to eradicate the bortezomib-resistant clones of multiple myeloma. Beyond bortezomib-resistant multiple myeloma, global optimization of drug combinations by QPOP can serve to improve drug combination design across a range of other cancers and diseases through a continuous optimization process across the entire drug development pipeline.

1682P Compartmentalized activities of the pyruvate dehydrogenase complex sustain lipogenesis in prostate cancer

J. Chen, I. Guccini, D. Di Mitri, D. Brina, A. Alimonti

Molecular Oncology, Institute of Oncology Research, Bellinzona, Switzerland

Background: Metabolism in cancer serves to provide energy and key biomolecules that sustain cell growth, a process that is frequently accompanied by decreased mitochondrial use of glucose. Importantly, metabolic intermediates including mitochondrial metabolites are central substrates for post-translational modifications at the core of cellular signalling and epigenetics. However, the molecular means that coordinate the use of mitochondrial metabolites for anabolism and nuclear protein modification are poorly understood.

Methods: We constructed prostate specific Pten; Pdha1 double knockout mice by crossing transgenic mice with flox elements flanking exon 8 of Pten gene and exon 4 and exon 5 of Pdha1 gene. Gene expression profiling analysis and metabolic analysis between Pten; Pdha1 double knockout and Pten knockout tumours were performed to investigate the metabolic pathways altered upon Pdha1 inactivation. Lipidomics analysis between these two genotypes of tumours were performed to reveal the difference on the lipid and cholesterol ester species in response to Pdha1 inactivation.

Results: We found that genetic and pharmacological inactivation of Pyruvate Dehydrogenase A1 (PDHA1), a subunit of pyruvate dehydrogenase complex (PDC) that regulates mitochondrial metabolism inhibits prostate cancer development in different mouse and human xenograft tumour models. Intriguingly, we found that lipid biosynthesis was strongly affected in prostate tumours upon PDC inactivation. Mechanistically, we found that nuclear PDC controls the expression of Sterol regulatory element-binding transcription factor (SREBF) target genes by mediating histone acetylation whereas mitochondrial PDC provides cytosolic citrate for lipid synthesis in a coordinated effort to sustain anabolism. In line with the oncogenic function of PDC in prostate cancer, we find that PDHA1 and the PDC activator, Pyruvate dehydrogenase phospatase 1 (PDP1), are frequently amplified and overexpressed at gene and protein level in these tumours.

Conclusions: Taken together, our findings demonstrate that mitochondrial and nuclear PDC sustains prostate tumourigenesis by controlling lipid biosynthesis thereby pointing at this complex as a novel target for cancer therapy.

1683P Metabolomics in cancer cachexia

J.A. Lopez-Martin[1], M. Cala[2], E. Prieto-García[1], C. Gonzalez Riano[2], C.V. Díaz-García[1], A. García[2], V. Pardo Marqués[1], F. Ruperez Pascualena[2], I. García-Ruiz[1], C. Pernaut[1], I. Otero[1], L. Parrilla Rubio[1], M.C. Riesco[1], J. Adeva Alfonso[1], C. Barbas[2], M.T. Agulló-Ortuño[1]

[1]Oncology, Hospital Universitario 12 de Octubre, Madrid, Spain, [2]Pharmacy, CEMBIO, Boadilla Del Monte, Spain

Background: Cancer cachexia (CC) is a frequent unmet medical need. CC affects up to 80% of cancer patients, and it is indirectly responsible for at least 20% of cancer deaths. The pathophysiology is characterized by a variable combination of reduced food intake and abnormal metabolism, including systemic inflammation and negative protein and energy balance. Despite its high clinical significance, definite diagnostic criteria of cachexia are lacking. The 'omics' technologies provide a global view of biological systems. Among these, blood-based metabolomics is a promising method for cachexia study.

Methods: This study is part of a pilot, observational, cross-sectional, case-control, hypothesis generating, IRB-reviewed, research project. Objective: discovery and selection of biomarkers of cancer cachexia. Anthropometric, clinical and biochemical data from consenting eligible cancer patients were collected. Plasma proteome was assessed by 2D gel electrophoresis and MALDITOF mass spectrometry. Metabolomics was evaluated by means of a multiplatform non-targeted approach of plasma samples (LC –MS, GC-MS and CE-MS), to increase metabolite coverage. Data were analysed by univariate

and multivariate methods, using principal component analyses and error adjustments for multiple comparisons.

Results: from metabolomics study are shown. Subjects: 15 cancer (ca) patients (pts), distributed as follows: Cachexia (CX): 8 pts (male:female 7:1; pancreatic ca: 3, melanoma: 3, biliary duct ca: 2); control (CN): 7 pts (M:F 6:1; colon ca: 1, esophageal ca: 1, gastric ca: 2, pancreatic ca: 1, melanoma: 1, sarcoma:1). Median age: CX 62 y (36-81), CN 64 y (48-80); median body mass index: CX 20 Kg/m2 (17-27), CN 25 Kg/m2 (21-27); median albumin: CX 3.4 mg/dL (2.1-4.1), CN 3.9 mg/dL (3.5-4.8). A total of 89 metabolites (Mbl) were significantly altered in CX pts. The Mbl with highest increase was cortisol (fold change 1.67, $p = 0.03$). The largest affected group of Mbl was 'amino acids and derivatives', all decreased. Glycerophospholipids, sphingolipids, steroid derivatives, fatty acids, aldehydes, phenylacetamides, carboxilic acids and derivatives, and indoles were also decreased.

Conclusions: These finding suggest that plasma amino acids and lipids profiling has great potential for improving cachexia cancer screening and diagnosis, and understanding disease pathogenesis. Of note, the increased values of cortisol should lead us to revisit the use of glucocorticoids in this setting. Substitutive therapy for some of the observed deficiencies might deserve clinical exploration.

1684P Association between the Dietary Inflammatory Index (DII), urinary enterolignans and C-reactive protein in the National Health and Nutrition Examination Survey-2003-2008

N. Shivappa[1], M. Wirth[1], A. Murphy[2], T. Hurley[1], J. Hebert[1]

[1]Epidemiology, University of South Carolina, Columbia, SC, USA, [2]Pathology, University of South Carolina, Columbia, SC, USA

Background: Enterolignans are important biomarkers of microbiome diversity. Higher levels, indicating greater diversity, have been shown to reduce cancer risk. Diet and inflammation have been shown to play a role in maintaining microbiome diversity. This study examined whether inflammatory potential of diet, as measured by the Dietary Inflammatory Index™ (DII) has an impact on levels of urinary enterolignans in the National Health and Nutrition Examination Survey (NHANES) 2003-2008. We also carried out validation of the DII with C-reactive protein (CRP).

Methods: Data came from NHANES 2003-2008. Enterolignans (enterodiol and enterolactone) and CRP were assayed from urine and serum specimens, respectively. DII scores were calculated from food intakes assessed using 24-hour dietary recalls and expressed per 1,000 calories consumed. Associations were examined using survey-based multivariable linear and logistic regression.

Results: After adjustment, higher DII scores (i.e., relatively more pro inflammatory) were associated with lower levels of creatinine normalized enterodiol ($b_{DIIquartile4vs1} = -1.22$; 95% CI = -0.69, -1.74; $P_{trend} = <0.001$) and enterolactone ($b_{DIIquartile4vs1} = -7.80$; 95% CI = -5.33, -10.26; $P_{trend} = <0.001$). A positive association also was observed when enterolignans were dichotomized at the 90th percentile value. In this same sample DII scores also were associated with CRP $\geq$3mg/l ($OR_{DIIcontinuous}$=1.12; 95% CI = 1.05, 1.19).

Conclusions: In these NHANES data, there was an association between DII and enterolignans. This study also provided a successful construct validation of the DII using CRP in a nationally representative sample. Using enterolignans as a proxy for gut microbiome, these results indicate that diet-associated inflammation modifies gut diversity.

1685P Fullerenol/iron nanocomposite modulates doxorubicin-induced cardiotoxicity

M. Seke[1], D. Petrovic[2], M. Labudovic Borovic[3], D. Jović[4], I. Borisev[4], Z. Kanacki[5], D. Zikic[5], A. Djordjevic[4]

[1]Department of Radiobiology and Molecular Genetics, Institute of Nuclear Research VINCA, Belgrade, Serbia, [2]Department of Natural Sciences and Mathematics, Faculty of Education Sombor, University of Novi Sad, Sombor, Serbia, [3]Department of Pathology, Institute of Histology and Embryology "Aleksandar Dj. Kostic", Faculty of Medicine, University of Belgrade, Belgrade, Serbia, [4]Department of Chemistry, Biochemistry and Environmental Protection, Faculty of Sciences, University of Novi Sad, Novi Sad, Serbia, [5]Department of Veterinary Medicine, Faculty of Agriculture, University of Novi Sad, Novi Sad, Serbia

Background: Doxorubicin is a first line cancer chemotherapeutic. Unfortunately, its clinical use is limited by its cardiotoxicity. It is known that iron overload aggravates anthracycline toxicity. Fullerenol is a 1 nm size molecule and in aqueous solutions is in the form of polyanionic nanoparticles, which enables them to serve as a good carrier of positively charged ions such as Fe^{2+}. Fullerenol's antioxidant activity through scavenging free radicals has already been proved in different biological systems.

Methods: The aim of our study was to investigate the effects of the fullerenol/iron nanocomposite as a pretreatment to doxorubicin on the rat's heart in comparison to doxorubicin alone. After the 24h-treatment, adult male Wistar rats were sacrificed and hearts were collected for ultrastructural and qRT-PCR analysis. Considering the ability of doxorubicin to induce oxidative stress, and the fullerenol's capability to mitigate it, we had chosen to monitor gene expression of enzymes involved in antioxidant defense.

Results: Ultrastructural study revealed that in the group pretreated with the nanocomposite prior to doxorubicin application cardiomyocytes were with preserved morphology and the structure of intercalated discs. On the other hand, the heart tissues of animals treated with doxorubicin alone were significantly more damaged. Intensive interstitial edema was observed, as well as vacuolization of cardiomyocytes, hypercontraction of sarcomeres, mitochondria of irregular shapes. qRT-PCR results have shown that neither treatment with doxorubicin alone nor the pretreatment with the nanocomposite did cause significant increase in mRNA levels of catalase and superoxide dismutase.

Conclusions: Our results indicate that the fullerenol/iron nanocomposite applied as pretreatment to doxorubicin induces less damage to the hearth tissue in comparison to doxorubicin alone.

Carles[4], F. Racca[4], N. Sala-González[6], A. González del Alba[7], P.L. Fernández[8], A. Prat[1], B. Mellado[1]

[1]Medical Oncology/Translational Genomics and Targeted Therapeutics in Solid Tumors Lab, Hospital Clínic of Barcelona/Institut d'Investigacions Biomèdiques Agust Pi i Sunyer/Fundació Clínic per a la Recerca Biomèdica, Barcelona, Spain, [2]Medical Oncology, Institut Català d'Oncologia, Badalona, Spain, [3]Medical Oncology, Hospital del Mar, Barcelona, Spain, [4]Medical Oncology, Vall d'Hebron Institute of Oncology, Vall d'Hebron University Hospital, Universitat Autònoma de Barcelona, Barcelona, Spain, [5]Medical Oncology, Fundació Althaia, Barcelona, Spain, [6]Medical Oncology, Institut Català d'Oncologia, Girona, Spain, [7]Medical Oncology, Hospital Universitario Son Espases, Palma de Mallorca, Spain, [8]Medical Oncology/Translational Genomics and Targeted Therapeutics in Solid Tumors Lab, Hospital Clínic of Barcelona/Institut d'Investigacions Biomèdiques Agust Pi i Sunyer, Barcelona, Spain

Background: TMPRSS2-ERG (TE) results in androgen-driven overexpression of ERG, which is involved in resistance to taxanes in preclinical models. In prior work we showed that TE expression in blood correlated with taxanes resistance in metastatic castration-resistant prostate cancer (mCPRC). Here, we studied if the detection of TE in primary tumors predicts taxanes activity in CPRC. We also explored the impact of prior abiraterone or enzalutamide (A/E) in blood TE detection and in TE predictive value.

Methods: mCRPC patients (pts) treated with taxanes in a multicenter biomarker study were included. Formalin-fixed paraffin-embedded (FFPE) tumors and peripheral blood mononuclear cells (PBMCs) fraction were tested for TE presence by RT-qPCR. FFPE were retrospectively obtained. PBMCs were prospectively collected prior to taxane initiation. PSA-PFS was evaluated by Kaplan-Meier analysis using log-rank test. Univariate analysis of TE status (+ vs-) was performed with Cox regression.

Results: 124 pts were included: 111 (89.5%) received docetaxel (Dx), 13 (10.5%) cabazitaxel (Cz) and 27 (21.8%) both. Fifty-seven (45.9%) tumors were *TE*+. Overall, no correlation between tumor *TE* expression and taxane benefit was observed in the whole population, or in the Dx or Cz group separately. However, in Dx-treated pts without prior A/E (N = 80, 72.1%), tumor *TE*+ correlated with lower PSA-PFS (median 8.6 vs 13.6 months; HR 1.7, $p \leq 0.05$). No differences were observed in Dx treated pts with prior A/E (N = 31, 27.9%) according to tumor *TE* expression. In 44 pts, matched tumor and PBMC samples were available. Concordance between tumor an blood was 92.8% and 63.3% for pts with and without prior A/E, respectively. *TE* in blood was + in 1 (7%) pts with prior A/E and in 7 (23.3%) pts without prior A/E. As observed in FFPE samples, in patients without prior A/E to Dx (N = 28; 63.6%), blood *TE*+ correlated with lower PSA response (0% vs 61.9%, $p \leq 0.01$) and reduced median PSA-PFS (3.34 vs 8.2 mM; HR 4.1 $p \leq 0.01$).

Conclusions: The predictive value of *TE* in taxane resistance may be different depending on prior exposure to A/E. This is being tested in a multicenter prospective study.

1688P Identification of patient population with longer survival when treated with S-1 plus cisplatin via predictive enrichment strategy analysis of the FLAGS and DIGEST phase III trial

M. Takeuchi[1], M. Takeuchi[2], J.A. Ajani[3]

[1]Faculty of Environment and Information Studies, Keio University, Kanagawa, Japan, [2]Research Center for Clinical Pharmacology, Kitasato University, Tokyo, Japan, [3]MD Anderson Cancer Center, University of Texas, Houston, TX, USA

Background: The FLAGS trial, a randomized phase III trial, compared S-1, an oral fluoropyrimidine, plus cisplatin (SP) with 5-fluorouracil plus cisplatin (FP) in the first-line treatment for advanced gastric cancer (AGC). The results led to the approval of SP by EMA, and it is now marketed in Europe. The purpose of this analysis was to establish a clinical covariate(s) model using the Predictive Enrichment Strategy Analysis (PESA) identifying patients who benefit from SP.

Methods: PESA is a new robust methodology with guidelines by the United States Food and Drug Administration. Consensus-based 15 clinical covariates were selected for PESA and a large cohort with no missing data (FLAGS trial: 889 patients (pts)) was analyzed. The models generated were cross-validated and the results analyzed were validated in the DIGEST trial, a phase III trial comparing SP to FP in diffuse type advanced gastric cancer. From the DIGEST trial, 333 patients and 14 clinical covariates were used in the analysis.

Results: In FLAGS, ECOG Performance status (PS = 1) was the strongest covariate in the enrichment group showing benefit for SP. In the population with PS = 1, the OS in the SP group was significantly longer than the FP group (Hazard Ratio [HR]=0.798, 95%CI = (0.66-0.96) p = 0.0166). Other covariates with high potential to be associated with SP benefit included: diffuse-type histology, positive peritoneal metastases, and the lack of liver metastases. In DIGEST PS = 1 also showed to be most associated with SP benefit. While there was no strong signal from the variables positive peritoneal metastases, and the lack of liver metastases, there appeared to be a signal from the neutrophil variable. In the DIGEST population of diffuse type, patients with PS = 1 and low baseline neutrophil count may benefit from SP.

Conclusions: Presence of PS = 1 was associated with SP benefit in both the FLAGS and DIGEST trial. Although peritoneal and liver metastases resulted in slightly different signals in the trials, further analyses will be done to look at the impact of low baseline neutrophil count on the benefit of SP for PS = 1 and diffuse type histology patients.

1689P HMGA1 is a new biomarker of liposarcoma progression

R. Loria[1], V. Laquintana[1], G. Bon[1], D. Trisciuoglio[1], R. Covello[1], C.A. Amoreo[1], V. Ferraresi[2], C. Zoccali[2], M. D'Incalci[3], R. Biagini[2], R. Falcioni[1]

[1]Department of Research Advanced Diagnostic and Technological Innovation, Regina Elena National Cancer Institute, Rome, Italy, [2]Department of Experimental Clinical Oncology, Regina Elena National Cancer Institute, Rome, Italy, [3]Department of Oncology, Mario Negri Institute, Milan, Italy

Background: Liposarcoma (LPS) is the most common type of soft-tissue sarcoma that includes a heterogeneous class of tumors classified according to histologic appearances, protein expression pattern and molecular genetics. Molecular subtyping is not only important for accurate diagnosis but may be necessary as a basis for the identification of therapeutic targets. Lipoma is characterized by extensive High Mobility Group A1 (HMGA1) protein aberrations suggesting a role of this protein in the mechanisms of liposarcoma progression as well as previously demonstrated in other tumors.

Methods: Cell lines derived from different liposarcoma subtypes and a cohort of 68 patients were used to analyze in vitro and in vivo the role of HMGA1 in liposarcoma progression.

Results: Our data revealed that HMGA1 is highly expressed in liposarcoma cell lines and that is strongly involved in the mechanism of cell proliferation, mobility and invasion of this subtype of tumor. The *in vitro* results were confirmed *in vivo* by the RT-PCR and IHC analyses of 68 specimens of different subtypes of liposarcoma derived from patients surgically treated at Regina Elena National Cancer Institute. The aggressive subtypes de-differentiated and myxoid liposarcoma showed higher HMGA1 levels than well-differentiated liposarcoma. Furthermore, trabectedin, a marine alkaloid isolated from the tunicate *Ecteinascidia turbinata*, down-regulates HMGA1 and E2F1, as well as its downstream targets Vimentin and ZEB1 in sensitive myxoid liposarcoma cells, suggesting a critical role of the transcriptional complex HMGA1/E2F1 in the regulation of the mesenchymal compartment. These data were further confirmed *in vivo* by the IHC analysis of myxoid sarcoma specimens derived from patients that received trabectedin therapy before surgery. On the other hand, trabectedin treatment down-regulates the activity of HER3 receptor that in turn inhibits Nf-kB pathway in sensitive myxoid liposarcoma cells but not in resistant counterpart cells demonstrating that the activation of Nf-kB pathway is involved in the mechanisms of drug resistance.

Conclusions: Overall, our data suggest that HMGA1 may represent a new biomarker of liposarcoma progression and that it could be a new potential therapeutic target for the more aggressive liposarcoma subtypes.

1690P hsa_circ_0004870 is related to AR-V7 expression and may confer resistance to enzalutamide in castration-resistant prostate cancer

J. Greene[1], A-M. Baird[2], L. Brady[3], S. Gray[4], S. Finn[4], R. McDermott[5]

[1]Medical Oncology, AMNCH Adelaide and Meath Hospital, Dublin, Ireland, [2]Department of Medicine, Queensland University of Technology, Brisbane, Australia, [3]Department of Histopathology, Trinity College Dublin, Dublin, Ireland, [4]Department of Medicine, St James's Hospital, Dublin, Ireland, [5]Genito-Urinary Oncology, Tallaght & St. Vincent's University Hospital and Cancer Trials Ireland, Dublin, Ireland

Background: Androgen deprivation therapy is the mainstay of prostate cancer treatment, however, resistance inevitably develops, resulting in a more aggressive disease, known as castration-resistant prostate cancer (CRPC). While, enzalutamide provides a substantial survival benefit by targeting the AR, it is not curative and many patients develop resistance to therapy. Although not yet fully understood, resistance can develop through multiple mechanisms, such as AR copy number gain or the generation of splice variants such as AR-V7. circular RNAs (circRNA) are a type of non-coding RNA that have an important function in gene regulation and may play a role in drug resistance, through the regulation of miRNA circRNAs are tissue specific, stable and may represent a novel marker of drug resistance in PCa.

Methods: circRNA profiling was performed on an isogenic PCa cell line model consisting of enzalutamide sensitive and resistant subtypes using a high throughput microarray assay. Subsequently, bioinformatic analyses predicted five miRNA binding sites (miRNA Response Elements) for each circRNA and these were stratified based on known associations with PCa. Targets were validated using qPCR.

Results: circRNAs were more often downregulated in resistant cell lines compared to sensitive lines (588 versus 278). hsa_circ_0004870 was significantly downregulated in enzalutamide resistant cells compared with control. RBM39 was determined as the parental gene, which encodes a member of the U2AF65 family of proteins. Previous studies have shown that, U2AF65 results in the expression of AR-V7, by binding to AR pre-mRNA. Expression of all genes were confirmed within our enzalutamide model.

Conclusions: hsa_circ_0004870 is linked to the generation of AR-V7 and may play a key role in the development of enzalutamide resistance in CRPC via a miRNA mediated mechanism.

1691P Analysis of DPYD and UGT1A1 genotype in patients with advanced pancreatic cancer treated with modified FOLFIRINOX

C. Vivaldi[1], E. Arrigoni[2], R. Morganti[3], S. Catanese[1], L. Fidilio[2], I. Pecora[1], G. Restante[2], L. Fornaro[1], S. Crucitta[2], M. Lencioni[1], E. Rofi[2], E. Vasile[1], A. Falcone[1], R. Danesi[2], M. Del Re[2]

[1]University Hospital of Pisa, Medical Oncology Unit, Pisa, Italy, [2]Department of Clinical and Experimental Medicine, University Hospital of Pisa, Clinical Pharmacology and Pharmacogenetics Unit, Pisa, Italy, [3]Department of Clinical and Experimental Medicine, University Hospital of Pisa, Section of Statistics, Pisa, Italy

Background: Modified FOLFIRINOX (mFOLFIRINOX) is a standard treatment in advanced pancreatic cancer (aPC). Because of the presence of either loss-of-function mutations in DPYD (c.1679T>G, IVS14 + 1G>A, c.2194G>A, c.2846A>T) or UGT1A1*28 variant associated with reduced UGT1A1 expression, deficiency of DPD and UGT may result in drug accumulation and severe toxicities caused by fluoropyrimidines and irinotecan, respectively.

Methods: The present study analyzes the association between DPYD and UGT variants and adverse drug reactions (ADRs) in aPC patients (pts) treated with mFOLFIRINOX. Blood samples were collected from 104 pts, and analyses of DPYD c.1679T>G, IVS14 + 1G>A, c.2194G>A, c.2846A>T and UGT1A1*28 were performed by automatic sequencing. Statistical analysis was performed by chi-square, Mann-Whitney and Spearman's rho tests on SPSS v.23s.

Results: None of the pts was carrier of the c.1679G and c.2846T alleles. Only one IVS14 + 1GA was found and 8 pts had c.2194GA genotype. ADRs grade (G) ≥3 were neutropenia (42.3%), diarrhea (7.7%) and stomatitis (7.7%). The statistical analysis of the IVS14 + 1GA has not been performed due to the extremely low frequency of the mutant allele (0.96%), however IVS14 + 1GA patient experienced G4 hematological and gastrointestinal ADRs after the first cycle. We observed a trend toward significant association between c.2194GA genotype and the risk of thrombocytopenia ($p = 0.080$) and hand-foot syndrome (HFS) ($p = 0.096$). The UGT1A1*28 allele was found in 56 (54.4%) pts (*1/*28, n = 38; *28/*28, n = 18) and it was correlated with the risk of developing thrombocytopenia ($p = 0.006$) and neutropenia ($p = 0.044$). Moreover, this risk increased as the number of *28 alleles increased (*28/*28 > *1/*28 > *1/*1, $p = 0.003$). No significant correlation with diarrhea was found.

Conclusions: Our data confirm that DPYD IVS14 + 1A is associated with life-threatening toxicities and that the c.2194A allele could be possibly associated with thrombocytopenia and HFS, but validation in larger cohorts is needed. UGT1A1*28 allele is associated with a higher risk of G3/4 thrombocytopenia and neutropenia, and should be implemented in routine practice to personalize treatment in aPC.

1692P Clinical significance of the expression of membrane receptors of the alternative nuclear factor-kappaB pathway in non-small cell lung cancer

F-I. Dimitrakopoulos[1], V. Tzelepi[2], A. Kottorou[3], A. Antonacopoulou[3], A. Koutras[3], T. Makatsoris[3], H. Kalofonos[3]

[1]*Oncology, University Hospital of Patras, Rion, Greece,* [2]*Department of Histopathology, University of Patras, Patras, Greece,* [3]*Division of Oncology, Department of Medicine, University of Patras, Patras, Greece*

Background: During the last decade, the alternative pathway of Nuclear Factor-kappaB (NF-κB) has gained importance due to its implication in cancer initiation and development where it has been shown to be deregulated. It is mainly activated thgough the membrane receptors Lymphotoxin β Receptor (LTβR), CD40, B-cell activating factor receptor (BAFFR) and Receptor Activator of NF-κB (RANK), having an important role in immune response and multiple cancer cell functions.

Methods: Immunohistochemical analysis of the expression of these 4 receptors was performed on 130 tumour and adjacent non neoplastic formalin fixed and paraffin embedded tissue samples from patients with non-small cell lung cancer (NSCLC).

Results: CD40 and BAFFR expression was higher in neoplastic compared to adjacent non-neoplastic tissue ($P = 0.006$ and 0.001, respectively) while no such differences were observed for RANK and LTβR. Moreover, CD40 levels in tumour infiltrating lymphocytes (TILs) correlated with development of metastases in adrenals ($P = 0.003$), liver ($P < 0.001$) and in brain ($P = 0.048$), while CD40 levels in stromal cells correlated with liver metastasis ($P = 0.013$). Cytoplasmic BAFFR expression in cancer cells was associated with T status while BAFFR levels in stromal cells were related to 2-year survival ($P = 0.034$). Cytoplasmic RANK expression was associated with membrane levels in cancer cells ($P < 0.001$) but was independent of any clinicopathological characteristics. Finally, nuclear detection of LTβR was related to histological subtypes with squamous cell carcinoma having higher levels cmpared to adenocarcinomas ($P = 0.026$).

Conclusions: Protein levels of CD40 and BAFFR are altered in NSCLC in agreement with a deregulation of the alternative NF-κB pathway previously shown by our team. CD40, BAFFR and LTβR tissue protein levels appear to constitue biomarkers for specific clinicopathologcal parameters including survival, stage and histological subtype.

1693P Development of TP53 signature diagnostic system using multiplex RT-PCR and observational study to confirm the prognostic value of TP53 signature in breast cancer

S. Takahashi[1], T. Fukui[2], T. Nomizu[3], Y. Kakugawa[4], T. Ishida[5], S. Yamaguchi[6], S. Kato[6], N. Ohuchi[5], N. Gondo[2], C. Ishioka[7]

[1]*Department of Medical Oncology, Tohoku University Hospital, Sendai, Japan,* [2]*Biomedical Business Department, FALCO Biosystems, Kyoto, Japan,* [3]*Department of Surgery, Hoshi General Hospital, Koriyama, Japan,* [4]*Department of Breast Oncology, Miyagi Cancer Center Hospital, Natori, Japan,* [5]*Department of Surgical Oncology, Tohoku University Graduate School of Medicine, Sendai, Japan,* [6]*Department of Clinical Oncology, Juntendo University Graduated School, Tokyo, Japan,* [7]*Department of Clinical Oncology, Institute of Development, Aging and Cancer, Tohoku University, Sendai, Japan*

Background: The structural mutation status of *TP53* gene is well known independent prognostic factor of breast cancer. We have reported that status of the *TP53* mutation is predictable by expression profile of 33 genes ('*TP53* signature') in breast cancer. The *TP53* signature was reported to be one of the best predictors of prognosis and therapeutic effect by meta-analysis (BMC Cancer, 2015). The aim of this study is to develop a simple diagnostic system for *TP53* signature using multiplex RT–PCR and confirm the prognostic value of *TP53* signature.

Methods: We made the multiplex RT-PCR system consists of 26 genes, 23 genes from the *TP53* predictive genes and 3 internal control genes. *TP53* signature status was determined by the ratio of the sum of expression levels of 16 genes that were upregulated in tumors with *TP53* mutation to the sum of expression values of 7 genes downregulated in tumors with *TP53* mutation. Cutoff value was set at 1.11 to maximize the sensitivity to detect the *TP53* mutant signature. Using a 217 breast cancer case cohort, which was prospectively collected from 2007 to 2010, the relationship between the *TP53* signature status and clinicopathological features and *TP53* structural mutations were analyzed. And we validated the prognostic value of *TP53* signature in 191 stage I-II patients.

Results: Of 217 patients, 102 patients were assigned to the *TP53* mutant signature. *TP53* structural mutation was observed in 35.1% of patients with *TP53* mutant signature and 6.3% of patients with *TP53* wild-type signature. In 191 stage I-II patients, RFS of the patients with *TP53* mutant signature showed significantly shorter than the patients with wild-type signature. Similar result was observed in 164 ER positive patients. In both univariate and multivariate analyses, *TP53* signature status showed independent and better correlation to RFS than tumor size, LN status, stage, ER status and *TP53* structural mutation status in stage I-II patients.

Conclusions: We developed the diagnostic system to determine *TP53* signature status using multiplex RT-PCR. The *TP53* status diagnosed by this system could be one of the prognostic biomarker of breast cancer.

1694P Expression of estrogen receptors and beta-III tubulin in non-small cell lung cancer tissue

E.A. Ponomarenko[1], I.A. Mamichev[1], T.A. Bogush[1], O.M. Ryabinina[1], J.B. Dyakova[1], D.V. Novikov[1], B.E. Polotsky[2], M.M. Davydov[2]

[1]*Laboratory of Medical Chemistry, N.N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation,* [2]*Thoracic Surgery Department, N.N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation*

Background: Estrogen receptors beta (ERβ) are highly expressed in different normal and neoplastic tissues that, until recently, has been considered to be ER-negative based on ERα expression evaluation. Among the genes, regulated via estrogen signaling there is one, coding microtubule protein beta-III tubulin (TUBB3). TUBB3 expression is found in many solid tumors and is linked to poor prognosis and resistance to taxanes. Since it is little known about mechanisms behind TUBB3 expression in non-small cell lung cancer (NSCLC), we decided to find out if there is a correlation between ER and TUBB3 expression in this type of cancer.

Methods: 104 surgical samples of NSCLC were converted to single-cell suspension, stained with primary anti-ERα (abSP-1), anti-ERβ (ab14C8), anti-TUBB3 (ab7751) antibodies and secondary fluorescent antibodies. Immunofluorescent estimation was performed using flow cytometry. Expression level was determined as the ratio (%) of specifically fluorescent cells to the number of cells stained with secondary antibodies. Spearman rank correlation was used to test the association between variables.

Results: Both ER were revealed in all NSCLC specimens. Mean expression level of ERβ was significantly higher compared with ERα (46,6 ± 17,0% vs 23,2 ± 14,2%, respectively). Mean TUBB3 expression level was 43,1±15,7%. In all the tumors investigated only weak correlation observed between and ER status and TUBB3 expression level ($rs = 0,3$ and $rs = 0,4$ for ERα and ERβ, respectively). In the group of squamous cell cancer specimens ($n = 68$) the association was strong ($rs = 0,5$ and $rs = 0,5$ for ERα and ERβ, respectively). In the group of adenocarcinoma specimens ($n = 36$) the correlation between ERα and TUBB3 was very weak ($rs = 0,3$) and there was no correlation between ERβ and TUBB3.

Conclusions: 1. Strong correlation between TUBB3 and ER expression was found only in squamous cell cancer tissue. 2. The dominant type of estrogen receptors is ERβ. 3. In clinical terms high ERβ expression means that in case of resistance to standart platinum/taxane duplets, patients with high tumor ERβ expression may benefit from antiestrogen therapy. Supported by RFBR grants (№№15-04-06991-a, 16-34-01049-mol-a) and grant of the President of RF MK-7709.2016.7.

1695P Deciphering the antitumor efficacy and mechanistic delineation of epigenetic inhibitors in AML using patient tumor derived ex vivo phenotypic assay based platform

P.K. Majumder[1], P. Radhakrishnan[1], S. Thiagarajan[2], M. Biswas[3], D.G. Malhotra[3], B. Ulaganathan[1], B. Majumder[2], G. Babu[4]

[1]Cancer Biology, Mitra Biotech, Woburn, MA, USA, [2]Cancer Biology, Mitra Biotech, Bangalore, India, [3]Molecular Pathology, Mitra Biotech, Bangalore, India, [4]Medical Oncology, Kidwai Cancer Institute, Bangalore, India

Background: Epigenetic inhibitors have demonstrated tumor efficacy by modulating genes involved in growth, proliferation, and invasiveness in hematological malignancies like AML. Preclinical evidences suggest therapeutic benefit by combining epigenetic drugs along with other therapeutics like JAK2 inhibitors. However, there is a huge unmet need to understand the disparities in response at the individual patient level.

Methods: We developed a novel functional assay based platform called CANscript™ to predict the efficacy of anticancer drugs in clinic, which mimics patient tumor microenvironment (Majumder B et al., *Nature Communications*, 2015). Utilizing samples from AML patients we interrogated response to HDAC and DNA MTase inhibitors by assessing tumor viability, proliferation, morphology, and death in this platform. To elucidate the mechanisms of response, we delineated the pharmacodynamic and pathway modulation by immunohistochemistry and mRNA microarray.

Results: Thirty-two AML patients samples were analyzed in this platform. HDAC and DNA MTase blockade resulted antitumor response, which was demonstrated by differential and quantitatively distinct patterns of target engagement. mRNAs and pathway specific protein expression profiling is suggestive of JAK2 pathway deregulation in many of the non-responders. Treatment with JAK2 inhibitor in this cohort led to efficacy in 40% of these non-responders, suggesting the critical role of this pathway. Interestingly, unique JAK2 signatures associated with single agent vs. combination therapy was observed (10%), hinting at functionally distinct mechanisms of antitumor effects at individualized levels.

Conclusions: These findings demonstrate the utility of this ex vivo platform to predict therapeutic response of epigenetic modulators at the individual patient tumor. It also highlights that, within a contextually heterogeneous framework, distinct mechanisms orchestrate response to HDAC and DNA MTase inhibitors as a single agent or in combination with JAK2 inhibitors. Insights gained from these findings can re-shape our strategic thinking of drug selection for the treatment of AML.

1696P Proteomics of triple negative breast cancer developing metastases to central nervous system

K. Rojas[1], L. Trilla-Fuertes[2], A. Gámez[3], J. Sepulveda Sanchez[1], L. Manso Sánchez[1], G. Prado-Vásquez[3], C. Chiva[4], A. Zapater-Moros[3], S. Llorente-Armijo[3], D.C. Mendiola[1], E. Sabidó[4], J.A. Fresno[3], E.M. Ciruelos Gil[1], L. Paz-Ares[1]

[1]Medical Oncology, University Hospital 12 de Octubre, Madrid, Spain, [2]Biology, Biomedica Molecular Medicine, Madrid, Spain, [3]Molecular Oncology&Pathology Lab. INGEMM., Hospital La Paz, Madrid, Spain, [4]Proteomics Unit, Barcelona Institute of Science and Technology(BIST), Barcelona, Spain

Background: Breast cancer (BC) is the most frequent tumor in woman, representing 20-30% of all malignancies and continues being the first reason of death for cancer in European women. Triple negative (TN) BC present minor survival rates than other BC subtypes. Key reasons for that is the absence of predictive markers of response to current therapy and the absence of targeted therapies. This study aims to identify proteins with predictive value of central Nervous System (CNS) metastases and therapeutic target candidates.

Methods: This is a case-control retrospective study comparing patients (pts) with metastases to CNS vs pts without them after adjuvant treatment. Sample selection included 50 samples. Formalin-fixed, paraffin-embedded samples were retrieved from Hospital 12 de Octubre Biobank. Proteins were quantified by parallel reaction monitoring.

Results: The average age was 55 years (range 25-85). Forty-seven pts (88.67%) had ductal histology and presented high grade tumors (40 pts; 75.47%). Eight women in the case group presented as first distant recurrence CNS (34.80%), local recurrence (3pts, 13.04%), lung (2pt; 8.7%), bone (1pt; 4.34%) and other locations (7pts; 30.38%). In the control group, first distant recurrence occurred locally (6pts; 46.1%), bone (2pts; 15.4%), lung (1pt; 7.7%) and other sites (4pts; 23.1%). Protein expression data was successfully obtained from 50 samples. ISG15 ubiquitin-like modifier, (P05161) was overexpressed in triple negative breast cancer tumors that develop metastases to CNS ($p = 0.036$) compared to tumors that do not develop these CNS metastases.

Conclusions: TN tumors frequently metastasize to visceral organs, particularly lungs and brain, and are less likely to metastasize to bone. The interferon-stimulated gene 15 ubiquitin-like modifier (ISG15) encodes an IFN-inducible, ubiquitin-like protein. The ISG15 protein is involved in numerous cellular functions, including interferon-induced immune responses and the regulation of cellular protein turnover. Therefore, ISG15 may represent a novel breast tumor marker helpful in selecting pts who will develop CNS metastases. It also should be explored as a therapeutic target in this clinical context.

1697P Assessing functional Androgen Receptor (AR) pathway activity using a computational model

A. van Brussel[1], M.A. Inda[1], E. Den Biezen[1], D. van Strijp[1], J. Wrobel[1], H. van Ooijen[1], R. Hoffmann[2], W. Verhaegh[1], A. van de Stolpe[1]

[1]Precision & Decentralized Diagnostics, Philips Research, Eindhoven, Netherlands, [2]Oncology Solutions, Philips Research, Eindhoven, Netherlands

Background: Cellular signal transduction research identified 10-15 signaling pathways responsible for driving tumor growth. Defining pathway activity in tumor tissue is necessary to optimize targeted therapy choice. Verhaegh *et al* (Cancer Research 2014) used a Bayesian network approach to model transcriptional programs of signaling pathways. These pathway models use mRNA expression levels of validated direct pathway target genes to infer a probability of pathway activity in individual patient samples. Here, initial results of the AR model are presented.

Methods: 28 bona fide AR target genes were selected and a Bayesian network model for the AR pathway was built and calibrated. The model uses target genes mRNA levels (Affymetrix HG-U133Plus2.0 array) as input to infer probability of AR pathway activity. Evaluation was done using multiple public datasets from clinical studies. The model was also adapted for qPCR data as input, using a subset of most informative target genes.

Results: Biological validation on androgen stimulated LNCaP cultures showed expected AR activity (GSE7868), which was inhibited by the anti-androgen bicalutamide (GSE7708). In cell line xenograft models (GSE21887, GSE33316, GSE966), AR was active in the presence of androgen and inactive in castrated mice. In prostate hyperplasia and 90% of primary prostate cancer (PCa) samples (GSE17951, GSE28403, GSE32982, GSE3325, GSE45016) AR was active; in contrast, AR was inactive in 30-50% of castration resistant or metastatic samples. AR was active in primary PCa samples, but not in samples taken 3 days after surgical castration (GSE32982). In other cancer types AR was mostly inactive, except for a subset of Her2 subtype Breast Cancer (BCa), Luminal BCa (EM-TAB-365, GSE12276, GSE17097, GSE21653), and meningioma samples (GSE16581, GSE9438). Translation to qPCR-RNA measurement as input was successful, underscoring the portability of our approach to other measurement platforms

Conclusions: Our biologically validated computational AR model enables assessing functional AR pathway activity in individual patient tissue samples, based on mRNA microarray or qPCR input from respectively FF or FFPE material. Other pathway models and clinical validation studies are in progress.

1698P Evaluation of deamination bias from formalin-fixed tissues of small cell lung cancer with a dual strand targeted amplicon sequence

T. Amano[1], H. Nishihara[2], H. Yokouchi[3], H. Suzuki[4], H. Akita[5], N. Sato[1]

[1]Clinical Research and Medical Innovation Center, Hokkaido University Hospital, Sapporo, Japan, [2]Cancer Genome Medical Center, National Hospital Organization Hokkaido Cancer Center, Sapporo, Japan, [3]Department of Respiratory Medicine, National Hospital Organization Hokkaido Cancer Center, Sapporo, Japan, [4]Department of Chest Surgery, Division of Surgery, Fukushima Medical University, Fukushima, Japan, [5]Department of Medical Oncology, Faculty of Medicine and Graduate School of Medicine, Hokkaido University, Sapporo, Japan

Background: Precision medicine is dependent on identifying actionable mutations in tumors. Accurate detection of mutations is often problematic in formalin-fixed paraffin-embedded (FFPE) tissues, as it causes DNA damage such as fragmentation and cytosine deamination. These Sequence artifacts can be difficult to distinguish from true mutations, and are an increasing interpretive issue. Understanding of the characteristics of these sequence artifacts in FFPE tissues is critical to improve the accurate detection of actionable mutations.

Methods: We reviewed the clinical courses of 156 small cell lung cancer (SCLC) patients who had undergone surgery at 17 institutions in Japan between January 2003

and January 2013. In these patients, we obtained the FFPE tissues of 79 cases which were histopathologically confirmed as SCLC and fitted for sequencing analysis with suitable DNA quality. Targeted amplicon sequence was conducted with MiSeq and TruSight panel (Illumina) which is a dual stranded amplicon kit for detecting cytosine deamination. We evaluated the characteristics of deamination bias and the relations with institutions and age of the tissue block.

Results: We could evaluate sequence of 73 samples data from 14 institutions. Target region of the sequencing was 26 genes, total 14686 bp. The total discordant single nucleotide variant (SNV) between forward and reverse strand were 690 cases, 16.4 cases per sample. The highest number of discordant SNV was 132 per sample. The most part of discordant SNV was the deamination change (C>T/G>A), 589 (85.4%) of 690 cases. The highest discordant SNV frequency was 0.25 with read depth 1876 in deamination change pattern, and 0.10 with read depth 4196 in the others. The frequency of the deamination change was different by institutions more than age of the tissue block.

Conclusions: Cytosine deamination from formalin fixation can be a major issue in diagnostic test of genome DNA for cancer samples. Procedures that assess, minimize or remove formalin-induced influences is important in the interpretation of genomic DNA analysis leading to better practice.

1699P Functional genomic mRNA (FGmRNA) profiling of > 18,000 tumor samples identifies potential new indications for antibody-drug conjugates (ADCs) in a broad range of tumor types

K.L. Moek, D.J. de Groot, E.G.E. de Vries, R.S.N. Fehrmann

Medical Oncology, University Hospital Groningen (UMCG), Groningen, Netherlands

Background: ADCs, consisting of an antibody designed against a specific antigen at the cell membrane linked with a cytotoxic agent, are an emerging class of therapeutics. Since ADC targets do not have to be drivers of tumor growth, ADCs are potentially relevant for a wide range of tumor types. Therefore, we aimed to define the landscape of ADC target expression in a broad range of tumor types.

Methods: PubMed and ClinicalTrials.gov were searched for ADCs that are or were evaluated in clinical cancer trials. Gene expression profiles of 18,055 patient derived tumor samples representing 60 tumor (sub)types and $\geq$ 3,520 samples representing 22 healthy tissue types were collected from the public domain. Next, we applied FGmRNA-profiling (Fehrmann *et al.* Nat Genet 2015;47:115-25) to predict per tumor type the overexpression rate at the protein level of ADC targets with healthy tissue samples as reference.

Results: We identified 87 ADCs directed against 59 unique targets. 17 ADC targets showed predicted overexpression of $\geq$ 75% of samples in at least 1 tumor (sub)type, 38 $\geq$ 50% and 56 $\geq$ 25%. A predicted overexpression rate of $\geq$ 10% of samples for multiple ADC targets was observed for high incidence tumors like breast cancer ($n = 31$ with $n = 23$ in triple negative breast cancer), colorectal cancer ($n = 18$), lung adenocarcinoma ($n = 18$), squamous cell lung cancer ($n = 16$) and prostate cancer ($n = 5$). In rare tumor types we identified targets showing high predicted overexpression, for example in uveal melanomas we found 95% predicted overexpression for c-MET.

Conclusions: This study provides a data driven prioritisation of available ADCs for clinical evaluation in 60 tumor (sub)types. This comprehensive ADC target landscape can support clinicians and drug developers in trial design.

TUMOUR BIOLOGY AND PATHOLOGY

1700O Genomic profiling of 114,200 advanced cancers identifies recurrent kinase domain duplications (KDD) and oncogenic rearrangements (RE) across diverse tumor types

L.M. Gay[1], D. Pavlick[2], J. Chung[3], S. Ramkissoon[1], S. Daniel[1], J.A. Elvin[1], E. Severson[1], T. Bivona[4], K.L. Reckamp[5], S.J. Klempner[6], S-H.I. Ou[7], A.B. Schrock[1], V.A. Miller[1], P.J. Stephens[1], J.S. Ross[8], S. Ganesan[9], C. Lovly[10], A. Mansfield[11], S.M. Ali[1]

[1]Pathology, Foundation Medicine, Cambridge, MA, USA, [2]Cancer Genomics, Foundation Medicine, Cambridge, MA, USA, [3]Clinical Development, Foundation Medicine, Cambridge, USA, [4]Department of Medicine, University of California, San Francisco, USA, [5]Clinical Research Operations, City of Hope, Duarte, CA, USA, [6]Oncology, The Angeles Clinic, Los Angeles, USA, [7]Chao Family Comprehensive Cancer Center, University of California Irvine School of Medicine, Orange, CA, USA, [8]Pathology, Albany Medical Center, Albany, NY, USA, [9]Cancer Institute of New Jersey, Rutgers University, New Brunswick, USA, [10]Department of Medicine, Vanderbilt University, Nashville, TN, USA, [11]Division of Medical Oncology, Mayo Clinic, Rochester, MN, USA

Background: Kinase fusions (KFN) are well recognized as targetable drivers in some cancers, and KFN common in one disease can be found in unrelated histologies, as for *BRAF*. Recently, oncogenic KDD in *BRAF* and *EGFR* were reported, along with responses to tyrosine kinase inhibitors (TKI). We assessed the frequency of KDD and KFN across 114,200 advanced cancers to reveal the landscape of oncogenic KFN and non-canonical rearrangements (KRE) in a wide variety of subtypes.

Methods: CGP was performed on DNA and/or RNA from 114,200 solid tumors or heme malignancy samples for 184-406 cancer-related genes and select introns from 14-28 genes commonly rearranged in cancer. RNA sequencing for 265 genes was available for some cases. Selected genomic events were confirmed by manual inspection.

Results: KDD were observed in 598 cases (0.62%): *BRAF* (127), *EGFR* (115), *FGFR3* (94), *FGFR1* (40), *RET* (37), *ERBB2* (35), *PDGFRA* (35), *FGFR2* (28), *MET* (19), *ROS1* (14), *ALK* (13), *KIT* (8), *NTRK1* (8), *FLT3* (6), *FGFR4* (5), *ERBB4* (4), *PDGFRB* (3), *NTRK2* (2). KDD were seen in 2.7% of brain tumors, most often *EGFR* (66), *BRAF* (52), *PDGFRA* (13), and *FGFR3* (26). In extracranial tumors, KDD were common for *RET* (13-16% of breast, lung, and thyroid KDD+ cases), *MET* (15-20% of uterine and brain KDD+ cases), and *ALK* (54% of lung KDD+ cases). KDD possibly related to TKI resistance were seen in *BRAF* V600E-positive melanoma and *ALK*-related NSCLC. Table 1 summarizes KFE and KFN for *ALK*, *FGFR2/3*, *RET*, and *ROS1*; 48-57 tumor types are affected per gene. KFN partner varied by tumor site; for *ROS1*, *GOPC* KFN predominate in gliomas and CRC, *TFG* KFN in sarcomas, and *CD74* and *EZR* in NSCLC.

Conclusions: KDD are enriched in brain tumors. Diverse KDD are found extracranially and may underlie acquired resistance. Index cases with clinical responses to matched TKIs suggest KDD, KFN and KRE can be targeted therapeutically in many histological subtypes. Recurrent KFN are found widely in cancer, with gene partner varying by subtype.

1701O Comprehensive Genomic Profiling (CGP) of Thymic Gland Carcinomas

J.S. Ross[1], P. Vanden Borre[2], N. Almog[2], A.B. Schrock[3], J. Chung[2], J-A. Vergilio[4], J. Suh[4], S. Ramkissoon[4], E. Severson[4], S. Daniel[4], S.M. Ali[4], V.A. Miller[4], P.J. Stephens[4], J.A. Elvin[4], L.M. Gay[2]

[1]Pathology, Albany Medical Center, Albany, NY, USA, [2]Pathology, Foundation Medicine, Cambridge, MA, USA, [3]Clinical Development, Foundation Medicine, Cambridge, MA, USA, [4]R&D, Foundation Medicine, Cambridge, MA, USA

Background: Thymic gland carcinomas include a variety of histologic subtypes with variable clinical aggressiveness and response to local and systemic therapies. We queried whether CGP could refine tumor subtypes and uncover new targeted and immunotherapy options for patients with relapsed and metastatic disease (mTC).

Methods: FFPE sections of 174 consecutive cases of mTC was sequenced using hybridization-captured, adaptor ligation-based libraries to a mean coverage depth of > 500X for up to 315 cancer-related genes plus 37 introns from 28 genes frequently rearranged in cancer. Total mutational burden (TMB) was determined on 1.1 Mb. Clinically relevant genomic alterations (CRGA) were defined as GA linked to drugs on the market or under evaluation in mechanism driven clinical trials.

Results: All mTC were clinically advanced and included 4% adenocarcinomas (TAC), 3% basaloid (TBC), 3% lymphoepitheliomatous (TLEC), 17% neuroendocrine

Table: 1700O

		ALK		FGFR2		FGFR3		RET		ROS1	
	All Samples	FN	RE	FN	RE	FN	RE	FN	RE	FN	RE
NSCLC	20868	590	76	10	5	32	5	240	30	189	7
Brain	6317	3	–	7	2	82	5	3	1	24	6
Pancreatobiliary	7934	8	1	178	50	7	2	7	5	2	5
Bladder	1458	–	–	1	–	39	10	–	–	–	2
Thyroid	972	5	–	2	–	–	–	38	2	1	–
All Other	76651	132	27	122	65	89	14	71	34	38	53

Table: 1701O

	TAC	TBC	TLEC	TNEC	TNOS	TSCC	TSRC
Patients	7	5	5	30	54	69	4
Median Age (y)	48	58	50	48	57	57	61
Gender	43% F	60% F	20% F	37% F	24% F	34% F	50%F
GA/tumor	4.0	2.8	1.0	3.3	4.1	4.1	4.8
CRGA	0.9	0.3	0	0.9	0.8	1.0	1.0
Significant GA	*PDGFRA FGFR3 KIT MET PTCH1*	*CDKN2A FBXW7*	*CDKN2A MEN1*	*KIT BRCA2 IDH1 ERBB2 ERBB3*	*KIT PTEN PIK3CA*	*KIT FGFR3 PIK3CA*	*ERBB2 IDH1 KIT*
TMB >10 mut/Mb	14%	0%	0%	3%	5%	9%	0%
TMB >20 mut/Mb	0%	0%	0%	3%	5%	9%	0%

(TNEC), 31% non-NE undifferentiated (TNOS), 40% squamous and 2% sarcomatoid (TSRC) carcinomas (Table). mTC were twice as common in men than women, had a peak incidence in late middle age, and featured an average of 4 GA/case and 0.9 CRGA/case. The most common molecular targets were *KIT* and *PIK3CA*. Other targets were *PDGFRA*, *FGFR3*, *PTCH1*, *FBXW7*, *BRCA2*, *IDH1*, *ERBB2* and *ERBB3*. The more frequent subtypes (TNEC, TSCC and TNOS) tended to have more GA, with *KIT* targets in ~ 10% of cases. Low TMB in mTC was common; only 6% of cases had >10 mut/Mb and 3% had >20 mut/Mb. Examples of mTC with responses to targeted therapies will be presented.

Conclusions: mTC histologic subtypes have varying GA and TMB status. The more common TSCC, TNEC and TNOS feature more GA, and when combined with TAC have more CRGA including KIT mutations and higher TMB. CGP shows promise to guide both targeted and immunotherapy selection for patients with this rare malignancy.

1702O Clinical implications of genomic variants identified in over 30,000 advanced-stage cancer patients by next-generation sequencing of circulating tumor DNA

S.K. Pal[1], C. Brooks[2], D. Chudova[2], J. Odegaard[2], D.R. Gandara[3], P. Mack[4], S. Mortimer[2], K. Banks[2], R.J. Nagy[2], A. Baca[2], R. Lanman[2], H. Eltoukhy[2], A. Talasaz[2]

[1]Medical Oncology, City of Hope, Duarte, CA, USA, [2]Medical Affairs, Guardant Health, Inc, Redwood City, CA, USA, [3]Thoracic Oncology, UC Davis Comprehensive Cancer Center, Sacramento, CA, USA, [4]Internal Medicine, University of California Davis Cancer Center, Sacramento, CA, USA

Background: Next-generation sequencing (NGS) of circulating tumor DNA (ctDNA) enables non-invasive profiling of solid tumor cancers. Over the past few years, research and clinical practice guidelines have highlighted a role for liquid biopsy in patient care; however, few large datasets on clinical use have been published.

Methods: Somatic genomic profiles of 35,492 plasma samples from 30,024 advanced cancer patients were determined by a ctDNA NGS test targeting up to 73 genes (Guardant360®). Accuracy of ctDNA-detected driver alterations (PPV) was assessed by comparing to available matched tissue tests for 646 patients (lung, colon, and other cancer types). A pooled response rate analysis was performed across published/in press datasets presenting response data to alterations detected by Guardant360®.

Results: The full cohort consisted of non-small cell lung cancer (NSCLC) (39%), breast (16%), colorectal (CRC) (10%) and multiple other solid cancer types (35%), with ctDNA alterations detected in 88%, 86%, 88%, and 82%, respectively (86% overall). 19% of patients had 1 or more ctDNA alterations associated with an FDA-approved therapy. Resistance variants were identified in 18% of NSCLC, breast, CRC, prostate, melanoma and GIST patients. PPV ranged from 92-100% for EGFR L858R/E19del/E20ins (98%), ALK/RET/ROS1 fusions (92%), BRAF V600E (95%), KRAS G12/G13/Q61 (94%), and MET E14 skipping mutations (100%). Pooled response rate to 1st line EGFR TKIs (n = 43 NSCLC): 86% [95% CI: 71-94%]; to osimertinib (n = 19 NSCLC): 94% [72-99%]; to rociletinib (n = 63 NSCLC): 54% [41-67%]; to crizotinib (n = 11 NSCLC): 82% [48-97%]; to anti-HER2 agents (n = 7 breast): 86% [49-97%]; (n = 5 gastric): 80% [37-96%].

Conclusions: Use of liquid biopsies is increasing in clinical care, providing an option of obtaining genomic information non-invasively. This dataset, derived from liquid biopsy use in clinical practice, highlights the clinical impact of identifying alterations that are targetable by drugs with regulatory approval, including emergent resistance alterations.

Background: DDR deficiency is a hallmark of cancer. We aimed at describing in 2 prospective trials run at Gustave Roussy Cancer Campus the molecular and clinical characteristics of patients (pts) harboring DDR gene alterations with special focus on mismatch repair (MMR).

Methods: Pts with metastatic solid tumors enrolled in MOSCATO (NCT01566019) and MATCHR (NCT02517892) trials had on-purpose tumor biopsy; molecular profiling was performed using Targeted Next Generation Sequencing (TGS) and Comparative Genomic Hybridization array (CGHa), or Whole Exome Sequencing (WES). Alterations in 46 genes involved in DNA repair were searched. After review by molecular geneticist, pathogenic variants (PV) were defined as variants causing protein truncation (frameshift indels, nonsense or splice site variants) or known to be deleterious missense variants according to databases such as LOVD, BRCAshare and OncoKB. Variants without deleterious prediction were excluded.

Results: Molecular data of 1092 pts of various histologies enrolled between Dec. 2011 and Oct. 2016 was used. Analysis of TGS (N = 1090), CGHa (N = 838) and WES (N = 304) data allowed identifying 156 alterations in 107 pts (9.8%) and 30 DDR genes: 60 PV, 86 variants of unknown pathogenicity (VUP) and 10 focal deletions (CGHa). Most frequent altered pathways were homologous recombination (47 PV, including 30 BRCA1/2 PV and 7 ATM PV in 13 primary sites) and MMR. The 27 pts with 35 MMR and POLE alterations (12 PV, 20 VUP and 3 deletions) had 11 different primary types including most frequently colorectal, genito-urinary and breast. Only one pt was previously known to have Lynch syndrome. Missense PV occurred most frequently in POLE, MLH1, MSH2, PMS1 (2 each), as well as, MSH3 and MLH3 (1 each); 14/27 pts received immunotherapy (IO). Median PFS was 6.5 months with IO and 6.2 months with conventional therapy. Correlation of MMR aberrations with immune infiltrates and outcome (response, PFS and OS) on IO will be presented at the congress time.

Conclusions: DDR genes alterations occur regularly in solid tumors. Systematic analysis of DDR alterations could allow customizing treatment of pts that specifically benefit from IO or DNA repair inhibitors through synthetic lethality.

Clinical trial identification: NCT01566019 and NCT02517892

1704PD Tumor microenvironment biomarkers as therapeutic strategies for TNBC

F. Rojo[1], M. Ruiz Borrego[2], M. Hui[3], J.M. Trigo Perez[4], A. Cazet[3], M.A. Karsdal[5], A. Urruticoechea[6], S. Antolin[7], J.A. García-Saenz[8], S. O'Toole[3], A. Blach[9], L. Perez-Ramos[10], S. Bezares[11], M. Sánchez-Aragó[9], R. Caballero[11], C.L. Bager[5], A. Swarbrick[12], M. Martin Jimenez[13]

[1]Cancer Institute, Hospital Universitario Fundación Jimenez Diaz, GEICAM, CIBERONC-ISCIII, Madrid, Spain, [2]Clinical Oncology, Hospital Virgen del Rocío, Sevilla, Spain, [3]Translational Breast Cancer Research, Garvan Institute of Medical Research, Darlinghurst, Australia, [4]Clinical Oncology, Hospital Universitario Virgen de la Victoria, IBIMA, Malaga, Spain, [5]Biomarkers & Research, Nordic Bioscience A/S, Herlev, Denmark, [6]Clinical Oncology, Fundación Onkologikoa, Donosti, Spain, [7]Clinical Oncology, Complejo Hospitalario U A Coruña, Coruña, Spain, [8]Medical Oncology, Hospital Universitario Clínico San Carlos, Madrid, Spain, [9]Translational Research, GEICAM, San Sebastian de los Reyes, Spain, [10]Statistics, GEICAM, San Sebastian de los Reyes, Spain, [11]GEICAM, San Sebastian de los Reyes, Spain, [12]Tumour Progression, Garvan Institute of Medical Research, Darlinghurst, Australia, [13]Medical Oncology, Hospital General Universitario Gregorio Marañón, GEICAM, CIBERONC-ISCIII, Madrid, Spain

Background: Patients with triple negative breast cancer (TNBC) comprise a heterogeneous and poor-prognosis subgroup. Biomarkers for targeted therapy development remains a challenge. Progression of TNBC is associated with extracellular matrix (ECM) remodeling and reactivation of the paracrine Hedgehog (Hh) pathway, highlighting the relevance of tumor microenvironment (TME) in tumorigenesis. We investigated whether TME biomarkers could determine clinical response in TNBC patients treated with the Hh pathway inhibitor sonidegib in combination with docetaxel.

Methods: Patients enrolled in GEICAM/2012-12 (EDALINE) trial were included (n = 12). To evaluate Hh pathway activation, the expression of SHH and GLI1 was centrally examined by immunohistochemistry in pre-treatment primary tumors. A Hh Pathway Activation Signature (HPAS) was defined when SHH expression in epithelium and GLI1 in stroma were high (> median). Biomarkers involved in formation and degradation of ECM (C1M, C3M, C4M, C6M, pro-C3, pro-C6, CRPM, Loxl-2 and VCANM) were evaluated by ELISA (Protein Fingerprint^{TM}) in sequential plasma samples. ECM signature (ECMS) was defined when C4M and VCANM were high at baseline (> median).

Results: Related to Hh pathway activation, only 10 tumors had IHC results. Three patients had high HPAS, 2 of them experienced a clinical benefit, 1 complete response (CR) and 1 stable disease (SD) lasting 7.3 and 5.5 months, respectively. All patients with low HPAS expression progressed. An additional patient had clinical benefit but the status of Hh pathway activation was unknown. For ECM biomarkers, a maintained reduction was observed in the expression along treatment (C2D1-0.5h, C2D2-25h and C4D1) vs baseline for pro-C3 (12.8, 10.2 and 9.4 vs 16.6, $p = 0.05$, $p = 0.03$, $p = 0.25$, respectively), and pro-C6 (9.2, 7.5 and 8 vs 9.95, $p = 0.13$, $p < 0.01$, $p = 0.03$, respectively). Interestingly, patients with high ECMS had better Progression Free Survival ($p = 0.02$). Moreover, 4 patients out of 12 had high ECMS, 3 of them experienced a clinical response, 1 CR and 2 SD. All patients with low ECMS progressed.

Conclusions: Hh pathway activation and ECM remodeling might be associated with improved benefit to sonidegib in combination with docetaxel in TNBC metastatic patients.

1705PD Detection of therapeutic targets in carcinomas of unknown primary

B. Clynick[1], B. Dessauvagie[2], G. Strerrett[2], N. Harvey[2], S. Subramaniam[3], J. Herron[4], R. Allcock[1], B. Guo[1], C. Saunder[5], W. Erber[6], K. Meehan[6]

[1]Biomedical Sciences, University of Western Australia, Perth, Australia, [2]Anatomical Pathology, PathWest, Perth, Australia, [3]General Surgery, Royal Perth Hospital, Perth, Australia, [4]Radiology, Sir Charles Gardiner Hospital, Perth, Australia, [5]Surgery, Fiona Stanley Hospital, Perth, Australia, [6]Biomedical Sciences, University of Western Australia, Perth, Australia

Background: Current cancer treatment paradigms are based on features of the primary tumour and extent of disease. Carcinoma of unknown primary (CUP) is a histologically confirmed metastatic cancer in the absence of an identifiable primary tumour. As such it is difficult to determine the optimal treatment strategy and 5-year survival rates are less than 20%. This poor survival rate is due to both the unclassifiable metastatic malignancy and the use of empirical broad-spectrum chemotherapy. A shift towards personalising cancer management based on mutation profiling has been explored in many cancer types including CUP. Small studies have reported durable treatment responses in CUP patients receiving targeted therapies, specifically when EGFR and KIT variants are detected. The present study has explored whether biologically important oncogenic driver mutations and potentially actionable targets are present in CUP that have potential to better inform treatment decisions.

Methods: CUP cases (n = 32) diagnosed on histopathology criteria were selected for study. Sections were cut from paraffin blocks of formalin-fixed tissue and DNA isolated. Extracted DNA was amplified with the Ion AmpliSeq Cancer Hotspot panel and Oncomine Focus panel for the identification of biologically relevant and actionable mutations, respectively. Amplified DNA was sequenced using the Ion Torrent platform and data was processed using a stringent variant filtration pipeline.

Results: Biologically relevant or therapeutically druggable variants were detected in 88% (n = 28) of cases. The most common variants were in *TP53* (47%), *KRAS* (19%), *MYC* (6%), *BRAF* (6%) and *CDKN2A* (6%). There were potentially actionable targets in 14/32 (44%) cases, with the most common druggable variants being in the *KRAS* gene (exon 1) (6 cases) and *MYC* gene amplifications (2 cases).

Conclusions: This retrospective study successfully identified biologically relevant variants in 88% of CUP cases. 50% of these variants were potentially actionable with drugs currently approved for use in known primary cancer types or undergoing clinical trials. This would give a novel treatment option to patients with a currently incurable disease with poor survival. The data therefore supports the use of NGS at diagnosis to give biological insight into the drivers leading to the malignancy, and to allow consideration of novel targeted treatment options.

Background: Characterization of the immune phenotype of tumors during progression could aid in developing patient-tailored therapy strategies. Here, we sought to identify differences in immune markers comparing paired tumors from primary and metastatic sites from the GEICAM/2009-03 (ConvertHER) study.

Methods: Matched primary and metastases were analyzed by immunohistochemistry as described by Herbst et al., 2014 for PDL1 expression. The nanostring gene expression platform was used to profile and identify differences in the expression of 805 immune-related genes. Significant features (p-value <0.05) were assessed for functional enrichment of KEGG pathways and GO terms.

Results: Out of 44 pairs analyzed for PDL1, 29 (65%) were ER+/HER2-, 3 (7%) ER-/HER2+, 6 (14%) ER+/HER2+ and 6 (14%) ER-/HER2- (TN). PDL1 expression (^{3}1%) was observed in the immune cell (IC) compartment in 11 (19%) ER+/HER2-, 4 (33%) ER+/HER2+, 2 (33%) ER-/HER2+ and 11 (92%) TN samples. No significant differences were observed between primary and metastases. Out of 60 pairs analyzed by nanostring, the most, (40; 67%) were ER+/HER2-, 5 (8%) ER-/HER2+, 7 (12%) ER+/HER2+ and 8 (13%) TN. In the global population, we found that 102 genes were differentially expressed (fold-change >2) between primaries and metastasis. For the ER+/HER2- subgroup, expression of 98 genes significantly differs in metastasis compare to primaries. No clear changes in pre-specified immune signatures were observed, probably due to the high tumor heterogeneity, different treatments and small sample size. Interestingly, analyses of pre-specified gene signatures suggest that metastases have decreased Notch pathway, innate inflammation and TGFb-activated fibroblasts signatures. Moreover, GO-enriched signature analyses suggest that B cell differentiation and type 1 IFN pathway are also reduced in metastases both in the global population and in ER+/HER2- tumors, thus suggesting a decreased immune defense during progression.

Conclusions: Our analysis failed to identify novel immune biomarkers of BC metastases. However, these data pointed out that tumors could relax the immune system response during progression.

Clinical trial identification: NCT01377363.

1707PD Orthotopic versus subcutaneous NET: tumor tissue characteristics result in different answers when ADC is used to validate early therapy response following Peptide Receptor Radionuclide Therapy (PRRT)

E.J. Koziolek[1], J. Albrecht[1], S. Exner[2], V. Prasad[3], C. Grötzinger[2], W. Brenner[3]

[1]Berlin Experimental Radionuclide Imaging Center (BERIC), DKFZ Heidelberg, DKTK Partner Site, Charite-Universitätsmedizin Berlin, Berlin, Germany, [2]Department of Hepatology and Gastroenterology and Molecular Cancer Research Center, Universitätsklinik Charité, Campus Virchow Klinikum, Berlin, Germany, [3]Department of Nuclear Medicine, Universitätsklinik Charité, Campus Virchow Klinikum, Berlin, Germany

Background: Preclinical studies in oncology are often performed in subcutaneous tumor models, where therapy success is validated by measuring changes in tumor size. We first characterized subcutaneous (sc) versus orthotopically grown neuroendocrine tumors of the pancreas (NET) with high versus low somatostatin receptor subtype 2 (SSTR2) by multimodal imaging and validated the apparent diffusion coefficient (ADC) as a potential biomarker for early therapy response following SSTR2-specific PRRT.

Methods: NET cells (native, SSTR2-transfected BON) were inoculated sc or orthotopically ($n = 20$) in SCID mice. Tumor characteristics were monitored using a small animal nanoScanPET/MRI: (T1/T2w anatomy, diffusion-weighted imaging, dynamic contrast-enhanced MRI, angiography; PET: Ga-68-DOTATOC, F-18-FDG. PRRT: ADC values and tumor growth were measured to monitor PRRT effects following Lu-177-DOTATOC injection.

Results: Native BON tumors showed different morphologic and metabolic patterns between sc and orthotopic tumors. Sc BON/SSTR2 tumors were similar to native sc BON tumors, while orthotopic BON/SSTR2 tumors were strongly growth delayed and developed necrosis at an early stage compared to native orthotopic BON tumors. Accept of the orthotopic BON/SSTR2 tumors, small tumors appeared solid with high FDG uptake. During tumor growth necrosis increased and FDG decreased. Perfusion was increased in orthotopic versus sc tumors (ktrans = 0,49 min^{-1} and 0,31 min^{-1}). Interestingly, Lu-177-DOTATOC uptake was ~4 times higher in sc than in orthotopic BON/SSTR2 tumors. While the ADC reflected the early effects of PRRT (first 9 days) precisely in orthotopic tumors, therapy response could not be validated by ADC in sc tumors due to initial high liquid content in the tissue.

Conclusions: Successful therapy validation presupposes precise knowledge about the used xenograft und the tumor morphology in order to allow correct interpretation of therapeutic effects. In particular, the orthotopic SSTR2- tumors do reflect the physiological situation better than sc tumors and allow to use the ADC as a potential biomarker for early validation of PRRT effects.

1708P Anti-tumor activity of alectinib in the orthotopic in vivo imaging model with NCOA4-RET fusion positive tumor cells

S. Yano, S. Arai, K. Kita, A. Tanimoto, S. Takeuchi

Division of Medical Oncology, Kanazawa University, Kanazawa, Japan

Background: The rearranged during transfection (RET) gene was discovered in 1985 as an oncogene produced by recombination during the transfection of NIH 3T3 cells with human lymphoma DNA. RET fusion genes were recently identified in a population of non-small cell lung cancers (NSCLCs). The most common (>80%) fusion partner for RET is KIF5B, followed by CCDC6, NCOA4, TRIM33, CLIP1, and ERC1. Recent clinical trials for RET fusion-positive NSCLC using vandetanib or cabozantinib demonstrated positive clinical response and considerable differential activities for RET inhibitors among fusion partners. Alectinib, an approved ALK inhibitor, is reported to inhibit KIF5B-RET and CCDC6-RET. However, the activity of alectinib with respect to RET with other fusion partners is unknown.

Methods: In the present study, we investigated the effects of alectinib on NCOA4-RET fusion-positive tumor cells (EHMES-10, a mesothelioma cell line) *in vitro* by MTT assay. We also examined the effect of alectinib utilizing orthotopic implantation model with EHMES-10 cells in the in vivo imaging model.

Results: Alectinib inhibited the viability of NCOA4-RET-positive EHMES-10 cells, as well as CCDC6-RET-positive LC-2/ad and TPC-1 cells. This was achieved via inhibition of the phosphorylation of RET and induction of apoptosis. Moreover, alectinib suppressed the production of thoracic tumors and pleural effusions in an orthotopic intrathoracic inoculation model of EHMES-10 cells. *In vivo* imaging of an orthotopically inoculated EHMES-10 cell model also revealed that alectinib could rescue pleural carcinomatosis.

Conclusions: These results suggest that alectinib may be a promising RET inhibitor against tumors positive for not only KIF5B-RET and CCDC6-RET, but also NCOA4-RET.

1710P Cathepsin S regulates cell migration and invasion through mediating store-operated calcium entry and the focal adhesion proteins

H-H. Lin[1], M-R. Shen[2], J-Y. Chang[3]

[1]Basic Medical Sciences, National Cheng Kung University, Tainan, Taiwan, [2]Obstetrics and Gynecology, National Cheng Kung University Hospital, Tainan, Taiwan, [3]Internal Medicine, National Cheng Kung University Hospital, Tainan, Taiwan

Background: Cathepsin S (CTSS), a lysosomal cysteine protease, plays an important role in inflammation, and it has been reported that it is also associated with angiogenesis and extracellular matrix (ECM) degradation promoting cell migration and invasion. Since CTSS is stably overexpressed in the different types of cancer cells, we explored a novel intracellular mechanism other than ECM degradation that regulates cell migration and metastasis.

Methods: Human oral cancer cells, OEC-M1, and breast cancer cells, MDA-MB-231, were used for this study. The expressions of CTSS were knockdown by siRNA transfection and the enzymatic activities were inhibited by highly-selective CTSS inhibitor, 58. The migratory and invasive abilities were determined by wound healing assay and transwell invasion assay, respectively. Microarray data and promoter prediction analysis were used to determine the intra-cellular targets of CTSS. Immunofluorescence assay was executed to evaluate STIM1 puncta formation and calcium influxes from store-operated calcium entry (SOCE) were measured by fura-2 calcium imaging. Western blot analysis was performed to detect the alteration of focal adhesion proteins.

Results: Our data showed that either CTSS knockdown with siRNA or activity inhibition could significantly decrease cell spreading area, and suppress cell migratory and invasive activities in both OEC-M1 and MDA-MB-231 cells. Moreover, inhibition of CTSS enzymatic activity resulted in the suppression of STIM1 aggregation and decreasing calcium influx from SOCE. Furthermore, downregulation of CTSS expression with siRNA could reduce the protein expression of three focal adhesion proteins, including CD29, CD104 and vinculin, which could be restored by CTSS transfection.

Conclusions: These results exhibit a novel intracellular molecular mechanism of CTSS mediating STIM1 aggregation and the calcium influx from SOCE to regulate the focal adhesion proteins, which are crucial for ECM interactions, cell migration and invasion.

1711P Type VI collagen (COL6) as part of tumorgenesis: Focus on quantifying specific COL6 protein fragments in serum

A. Wardak[1], N. Willumsen[2], D.J. Mogensen[1], S.H. Nielsen[1], C. Jensen[1], S. Kehlet[1], M.A. Karsdal[1]

[1]Biomarkers & Research, Nordic Bioscience A/S, Herlev, Denmark, [2]Cancer, Nordic Bioscience A/S, Herlev, Denmark

Background: Type VI collagen (COL6) is emerging as an important component of the tumor microenvironment. The rationale that COL6 derived protein fragments may possess pro-tumorigenic properties has ample precedent (e.g. endothrophin). Little is however known, regarding COL6 degradation fragments as biomarkers for cancer. Here we address the biomarker potential of three specific COL6 degradation fragments measured in serum: Pro-C6 (C-terminal of the α3 chain/endotrophin), C6Ma3 (MMP-generated neo-epitope on the α3 chain), C6M (MMP-generated neo-epitope on the α1 chain).

Methods: Pro-C6, C6Ma3 and C6M were measured by validated competitive ELISAs in serum from patients with various stage solid tumors prior to treatment and healthy controls (table).

Results: C6M and C6Ma3 were significantly elevated (Kruskal-Wallis test) in most cancer types compared to controls, whereas Pro-C6 was not (table). A trend ($p = 0.098$) toward higher Pro-C6 was seen in the late (3/4) vs early (1/2) stage (Mann-Whitney test), whereas no difference was seen with C6M ($p = 0.822$) and C6Ma3 ($p = 0.458$). AUROC was 0.89 ($p < 0.0001$) and 0.86 ($p < 0.0001$) and 0.59 ($p = 0.216$) for C6M, C6Ma3 and Pro-C6, respectively, when comparing all cancer types combined to healthy controls.

Conclusions: Specific type VI collagen fragments were increased in serum from cancer patients compared to healthy controls, and showed promising clinical accuracy. This clearly support COL-6 remodeling/degradation as an important component in understanding tumorgenesis. Future studies will determine biological and clinical applicability of quantifying various COL-6 fragments in serum in relation to cancer.

1712P The combination analysis of tumor infiltration lymphocyte with Neutrophil to lymphocyte ratio may predict prognosis of colorectal cancer in stage I-III

S.M.R. Mortazavizadeh[1], Y. Ayoughi[2], M. Moghimi[3]
[1]Internal Medicine, Islamic Azad University Branch Yazd, Yazd, Iran, [2]General Medicine, Islamic Azad University Branch Yazd, Yazd, Iran, [3]Pathology, Shaheed Sadoughi Medical Science University, Yazd, Iran

Background: The tumor infiltration lymphocyte as local inflammation and neutrophil to lymphocyte ratio as systemic inflammation have been known as prognostic factors in colorectal cancer. But little is known about the correlation and impression of the local and systemic inflammation together on the prognosis of colorectal cancer. This study aimed to evaluate the effects of this combination on prognosis.

Methods: In a retrospective study, 206 patients from 2006-2015 with colorectal cancer after curative surgery have been investigated. the patients diagnosed with stage IV or simultaneously had secondary cancers were excluded. The pathological samples after surgery were studied for tumor infiltration lymphocytes (TIL) and other pathological features. Also neutrophil to lymphocyte ratio (NLR>2.38) was calculated from up to 3 days before surgery from peripheral blood. For analysis the combination of these markers, patients were divided to four groups for local inflammation or systemic inflammation predominantly (high TIL/High NLR, high TIL/Low NLR, Low TIL/High NLR and Low TIL/Low NLR) and then the overall survival (OS) and Disease free survival (DFS) for each group were calculated. Then compared with each other.

Results: For these identified patients the number of death events was 73and 133 were alive the median OS was 68 months(Range1 to 122) months .There was significant relationship between local and systemic inflammation (TIL and NLR) (p-value=0.0003), so that, when the local inflammation was predominantly and the systemic inflammation was dramatically low simultaneously, (high TIL/Low NLR) was associated with the best outcomes and improved the overall survival (mean OS = 72.56 month and HR:0.45) also low TIL was significant associated with poor prognosis on OS and DFS (p-value<o.ooo1) for both.

Conclusions: The analysis of combination of local and systemic inflammation may predict the prognosis of colorectal cancer in patients who underwent the curative surgery. So in future this unexpansive and available methods seem can be used for determining the prognosis for these patients and used as markers.

1713P Prognostic value of NK and T-lymphocyte markers in operable non-small cell lung cancer (NSCLC)

M. Skrzypski[1], A. Szymanowska-Narloch[2], A. Kowalczyk[1], A. Maciejewska[3], M. Marczyk[4], J. Polańska[4], W. Biernat[5], W. Rzyman[6], J. Jassem[1]
[1]Oncology and Radiotherapy, Medical University of Gdansk, Gdansk, Poland, [2]Pneumonology and Allergology, Medical University of Gdansk, Gdansk, Poland, [3]Forensic Medicine, Medical University of Gdansk, Gdansk, Poland, [4]Data Mining Group, Silesian University of Technology, Gliwice, Poland, [5]Department of Pathology, Medical University of Gdansk, Gdansk, Poland, [6]Thoracic Surgery, Medical University of Gdansk, Gdansk, Poland

Background: New therapies aimed at activation of T and NK cells expand NSCLC treatments options. It is conceivable that markers designating 'immune ignorant', 'immune excluding' or 'inflamed' tumor phenotypes may influence the effectiveness of specific immune therapies.

Methods: qRT-PCR was used to assess the levels of 48 mRNAs in frozen tumor tissue sections from 115 stage I-IIIA NSCLC patients (33% never-smokers, 75% lung adenocarcinoma) who underwent pulmonary resection, and in matched normal lung parenchyma. mRNA expression (normalized vs. 4 reference genes) was compared between groups that did (45%) and did not relapse.

Results: Low expression of *TIGIT* (p.adj=0.031) and *CTLA4* (p.adj=0.048) was correlated with shorter distant metastasis free survival after correction for multiple comparisons. In the subset of 75 lung adenocarcinoma cases, low expression of *TIGIT, NCR3, CXCR3, FASLG, CD96, CTLA4, PD1, FYB* and *FOXP3* was correlated with shorter distant metastasis free survival after correction for multiple comparisons (p.adj<0.042). Expression of *PD-1* (p = 0.016), *PDL-2* (p = 0.029) and *CTLA4* (p = 0.002) was significantly lower in relapsed vs. non-relapsed NSCLCs, whereas there was no difference for *PDL-1*. Expression of NK markers: *NCR3* (p = 0.006) and CD96 (p = 0.005), but not *NCR3-ligand 1* or *NKG2D, NKG2C* and *NKG2A* was significantly lower in relapsed vs. not relapsed NSCLCs. Expression of *CXCR3* and its ligands: *CXCL9* and *CXCL10* (chemoattractants for lymphocytes), but not *endothelin receptor type B*, was significantly lower in relapsed NSCLCs (p < 0.03), which could provide a plausible explanatory mechanism for lower expression of lymphocyte markers in tumours with propensity for metastases. *GITR, FOXP3 and CXCL9* expression was significantly higher in tumor samples vs. normal lung parenchyma (p.adj.<0.02). *NCR3, CXCR3 and FASLG* expression was significantly lower in tumor samples from smokers vs. never-smokers (p.adj<0.02). Samples of normal lung parenchyma from smokers were marked by higher expression of *PD-1* and *CD96* in reference to never-smokers (p.adj<0.04).

Conclusions: Non-inflamed NSCLC phenotype is associated with higher risk of distant metastases in early stage NSCLC. The non-inflamed phenotype is accompanied by lower expression of chemoattractants for lymphocytes. Expression of immune tolerance markers is increased in NSCLC compared to normal lung tissues.

1714P KRAS in non-small cell lung cancer

I. Amanam, R. Gupta, I. Mambetsariev, M. Koczywas, M. Cristea, E. Massarelli, K.L. Reckamp, R. Salgia
Medical Oncology and Therapeutics Research, City of Hope, Duarte, CA, USA

Background: Disease heterogeneity with variable molecular mutations is one of the main contributory factors in non-small cell lung cancer (NSCLC). The goal of this study was to better understand the KRAS patients with co-occurring mutations.

Methods: We identified 60 patients with a diagnosis of NSCLC and a KRAS mutation in the COH Cancer Registry from 2009 to 2016. Next generation sequencing was performed.

Results: Of the 60 patients identified, 42 (70%) were Stage IV at diagnosis, 7 (12%) Stage I and 7 (12%) stage II and 4 (6%) Stage III. 47% (78) patients were smokers. Caucasian was the most common 44 (73%) racial group, followed by Asians 9 (15%), African-Americans 3 (5%), other 3(5%) and Pacific Islander 1 (1.7%). The average age at diagnosis was 67 (median 69.5) years; 30 patients (50%) were > 70 years, 23 (38%) patients were 51-69 years, and 7 (12%) 50 years or less. The most common histology was adenocarcinoma 52 (87%), then adenosquamous 3 (5%), large cell 2 (3%) and small cell, squamous cell and carcinosarcoma (1 each, less than 2% each). Majority had metastatic disease 52 (87%) with 20% (12) metastasis to brain, with average 1.6 metastatic sites. An average of 1.97 (range = 0-5) lines of therapy including chemotherapy, biologic agents or immunotherapy were received. 12 (20%) patients received immunotherapy, radiation in 28 (47%) and surgery in 22 (37%) with a median overall survival at 15 months. The most frequent molecular alteration was codon 12 mutation (47, 78%), followed by codon 13 (7, 12%) and codon 61 (6, 10%) mutations. The most

common co-occurring mutations in this cohort were TP53 (15, 25%), ATM (9, 15%), LRP1B (9, 15%), ARID1A (8, 13%), STK11 (8, 13%), ARID1B (7, 12%), TERT (7, 12%), EGFR (6, 10%), RBM10 (6, 10%), SPTA1 (6, 10%). We are currently evaluating the relevance of the Circos plot analysis for these mutations, clinical response to immunotherapy and potential biomarkers.

Conclusions: *KRAS* mutations are among the most common molecular alterations identified in NSCLC. The discovery of effective treatments targeting *KRAS* mutations has represented a challenge so far. Understanding the significance of co-mutations and their therapeutic implications, especially in response to immunotherapy agents represents an important step to develop better treatment options for *KRAS* mutated lung cancers.

1715P PIK3CA mutation and PDL1 expression in lung squamous cell carcinoma surgically resected

L. Gutierrez Sanz[1], C. Salas[2], I. Martinez[3], D. García[3], F.F. Franco[1], I. Curto[1], M. Mendez[1], L. Gonzalez[4], M. Provencio[1], P. Martin[3]

[1]*Medical Oncology, Hospital Puerta de Hierro Majadahonda, Majadahonda, Spain,* [2]*Pathology, Hospital Universitario Puerta de Hierro, Madrid, Spain,* [3]*Pathology, IIS Puerta de Hierro, Madrid, Spain,* [4]*Medical Oncology, Hospital Quiron, Madrid, Pozuelo De Alarcon, Spain*

Background: Squamous-cell carcinoma (SCC) of the lung is the second most frequent histology in non-small cell lung cancer (NSCLC). Over the last decade new approaches targeting specific pathways in NSCLC have emerged but very few advances were made in its treatment. The PI3K-AKT-mTOR pathway is implicated in multiple cancer processes and *PIK3CA* mutations are being investigated in SCC as potential therapeutic target. The aim of the study was to evaluate the histological characteristics, mutations in *PIK3CA* and PD-L1 expression in these tumors.

Methods: Surgically resected lung SCC samples (FFPE) from 100 patients, stage I-III, were included in this study. Clinicopathologic characteristics included tumor size, TNM, smoking status, lymphovascular and pleural invasion, histopathological grade, stromal lymphoplasmacytic reaction and type of tumoral growing. DNA was isolated from 92 samples according to standard procedures and *PIK3CA* mutation analysis was done using Cobas 4800 platform. PD-L1 expression was analyzed in 74 cases by immunohistochemistry with PDL1 22C3 pharmDX assay. The PD-L1 expression was evaluated by tumor proportion scores (TPS) as IASLC guidelines.

Results: The mean age was 68 years (53-86), 14 females and 86 males. About staging: 53 patients had stage I, 27 stage II, and 19 stage III. 53% and 35% showed vascular and pleural invasion respectively. Low to moderate stromal lymphoplasmacytic reaction was found in 34% and severe in 11%. PI3KCA mutation was found in 9/92 (9,8%) patients: E545X (n = 2), E542K (n = 5), H1047X (n = 1), C420R (n = 1). PD-L1-expression was found in 31 out of 74 cases (42%): 14 cases with TPS between 1-49%; 17 cases with TPS >50%. 5/9 (55%) of PIK3CA mutated cases were PD-L1 positive (2 of them >50%). In PIK3CA non-mutated cases 26 out of 67 (39%) showed PD-L1 expression: 11 cases with TPS between 1-49%; 15 cases with TPS >50%.

Conclusions: *PIK3CA* mutation was found in 9,8% of SCC of the lung, most of them in exon 9. PD-L1 expression was found in 42% of the SCC in our series. 55% of *PIK3CA* mutated patients were positive for PD-L1 expression. No correlation has been found between PD-L1 expression and *PIK3CA* mutation in SCC. It is important to know more about the relation of these factors to select the patients for immunotherapy and new target agents.

1716P TRKA expression and NTRK1 gene copy number across solid tumors

G. Mauri[1], E. Valtorta[2], A. Sartore-Bianchi[1], G. Cerea[1], A. Amatu[1], M. Schirru[1], G. Marrapese[1], V. Fiorillo[2], P. Recchimuzzo[2], I. Stella[2], S. Veronese[2], F. Tosi[1], M. Maiolani[1], M. Truini[2], S. Siena[3]

[1]*Hematology and Oncology, ASST Grande Ospedale Metropolitano Niguarda, Niguarda Cancer Center, Milan, Italy,* [2]*Pathology, ASST Grande Ospedale Metropolitano Niguarda, Niguarda Cancer Center, Milan, Italy,* [3]*Hematology and Oncology, ASST Grande Ospedale Metropolitano Niguarda, Niguarda Cancer Center; Università degli Studi di Milano, Milan, Italy*

Background: Neurotrophic Tropomyosin Kinase Receptor 1 (NTRK1) gene encodes for the protein Tropomyosin-related kinase A (TRKA). A deregulated activity of TRKA has been detected in cancer, leading to oncogenic activity. This can result from translocations, amplifications, deletions and point mutations involving the NTRK1 gene. The incidence of NTRK1 gene copy number gain (GCN) across solid tumors has not been investigated. We present here the results of an immunohistochemistry (IHC) screening for TRKA expression within the phase I ALKA-001 clinical trial. Clinical results of ALKA-001 clinical trial are not presented here.

Methods: Formalin-fixed paraffin-embedded (FFPE) consecutive samples of different solid tumors were tested for TRKA IHC staining. Samples showing TRKA IHC staining in at least 10% of cells were further studied by fluorescence in situ hybridization (FISH) to assess whether NTRK1 gene rearrangements were present and to assess GCN. All patients signed informed consent for molecular screening according to the phase I ALKA-001 clinical trial.

Results: 1043 samples were tested; annotation for histology was available in 1023. Most of the samples were colorectal adenocarcinoma (CRC) (n = 550, 53.8%) or lung adenocarcinoma (312, 30.5%). 24 samples (2.3%) were biliary tract carcinoma (BTC). Seventeen (1.6%) samples were characterized by TRKA IHC expression (4 weak, 8 moderate, 5 strong). By FISH, 1/17 (5.9%) displayed *NTRK1* gene rearrangement and 15 (88.2%) *NTRK1* GCN gain. Among samples harboring *NTRK1* GCN gain, 8 (53%) were lung adenocarcinoma, 3 (20.0%) BTC and 2 (13.3%) CRC. Five (33.3%) samples had concomitant ALK and ROS1 GCN gain. None of the lung adenocarcinoma (n = 8) had concomitant EGFR mutations. Both CRC samples (n = 2) harbored *KRAS* mutation. No correlation was found between grading of TRKA IHC staining and the number of *NTRK1* GCN.

Conclusions: NTRK1 GCN gain can be found in 1.6% of solid tumors. In particular, we found GCN gain in 2.6% of lung adenocarcinomas, without EGFR mutations, 0.4% of CRC and 17.6% of BTC even though a limited number of the latter histology was included in the analysis. The prognostic and translational therapeutic impact of this genetic alteration remains to be established.

1717P The correlation between MMR gene expression MSH2/MSH6 and VEGF A/VEGF B in gastro-esophageal cancer

A. Dracea[1], M. Danciulescu[2], A. Dricu[3], F. Burada[1], M. Ioana[1]

[1]*Human Genomics Laboratory, University of Medicine and Pharmacy of Craiova, Craiova, Romania,* [2]*Department of Oncology, University of Medicine and Pharmacy of Craiova, Craiova, Romania,* [3]*Unit of Biochemistry, University of Medicine and Pharmacy of Craiova, Craiova, Romania*

Background: VEGF proteins are key regulators of angiogenesis and targeting VEGF A led to inhibition of new blood vessels formation, with important therapeutic effects in various cancers. The roles of VEGF B are controversial; this peptide expression seems to inhibit apoptosis by suppressing many apoptotic/cell death-related genes and to facilitate metastasis by inducing vascular leakiness, leading to a high degree of tissue hypoxia that consequently activates DNA damage signalling pathways. MSH2/MSH6 is an important complex of proteins in DNA mismatch repair system and their altered expression could represent a response to the rapidly growing number of replication errors in a tissue with a high index of proliferation.

Considering that in certain conditions, DNA damage response products, such as H2AX, promote tumor growth and angiogenesis, in the present study we aimed to identify a common pattern of expression behavior between MMR genes MSH2/MSH6 and VEGF components (VEGF A and VEGF B), in order to use these genes as diagnostic markers in gastro-esophageal cancer.

Methods: mRNA levels of MSH2, MSH6, VEGF A, VEGF B were evaluated in tumoral and peritumoral tissues samples biopsied from 36 patients using qRT-PCR with specific TaqMan gene expression assays.

Results: VEGF A/VEGF B and MSH2/MSH6 mRNAs were expressed in both tumour and peritumour mucosa, with a tendency of tumoral up-regulation for VEGF A and MSH2/MSH6. When comparing the differences between tumoral/peritumoral expression level among the studied genes, we found that MMR and VEGF have a similar pattern of expression as follows: VEGF A gene expression correlates with MSH2 (rho Spearman = 0.4562; $p < 0.05$) and also, is similar to MSH6 (rho Spearman = 0.5082 $p < 0.05$); furthermore, VEGF B gene expression is correlated with MSH2 expression (rho Spearman = 0.5350 $p < 0.05$), with a very strong correlation between MSH6/VEGF B expression (rho Spearman = 0.6730 $p < 0.0001$).

Conclusions: Our results indicate a possible crosstalk between DNA mismatch repair and VEGF signaling pathways, providing new insight into understanding the potential connection of VEGF B and MSH6 in carcinogenesis.

1718P Liver-type glutaminase (GAB) suppresses malignant phenotype of glioblastoma cells

E.J. Majewska[1], M. Szeliga[1], J. Márquez[2], J. Albrecht[1]

[1]Department of Neurotoxicology, Mossakowski Medical Research Centre, Polish Academy of Sciences, Warsaw, Poland, [2]Department of Molecular Biology and Biochemistry, Faculty of Sciences, Campus de Teatinos, University of Málaga, Malaga, Spain

Background: Glutamine (Gln) plays a pivotal role in the metabolism of tumors of different including glioblastoma (GBM), the most aggressive brain tumor. Glutaminase (GA, EC 3.5.1.2) converts Gln to glutamate (Glu) and ammonia. GA is encoded by two genes: *GLS* and *GLS2*, encoding kidney-type isoforms (KGA and GAC) and liver-type isoforms (GAB and LGA), respectively. Kidney-type isoforms promote cell proliferation, while the liver-type isoforms relate to quiescent state of cells. In GBM *GLS* is highly expressed, while *GLS2* is hardly detectable. Transfection of human GBM T98G cell line with a sequence encoding GAB is known to decrease their survival, proliferation index and migration and sensitizes them to damage by hydrogen peroxide. To examine whether the mode of action of GAB extends to other GBM cell lines, the effect of GAB transfection of U87MG, U251MG and LN229 cells with GAB was assessed.

Methods: Mitochondrial activity was determined by 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) conversion (details in M. Szeliga et al., Glia, 2009). Cell proliferation was measured by a commercially available ELISA kit based on the detection of BrdU (5-bromo-2'-deoxyuridine) incorporated into the genomic DNA. Migration was analyzed using the scratch assay. The tip scratch of cell monolayer was photographed under Juli Smart cell analyzer and measured after 0 and 24 h. Ability to form colonies was assessed after 14 days of culture following Giemsa staining of fixed cells.

Results: Transfection with GAB: i) decreased mitochondrial activity, proliferation and colony formation ability of U87MG cells ii) inhibited ability of U251MG cells to form colonies iii) decreased mitochondrial activity, proliferation, migration and colony formation ability of LN229 cells. All transfected cells were more sensitive to hydrogen peroxide as compared to the controls.

Conclusions: Suppression of malignant phenotype and their sensitization to hydrogen peroxide damage by GAB transfection appears to be a feature common to all the glioblastoma cell lines so far studied.

1719P Alteration of p53 mRNA expression in neuroblastoma and its impact in disease outcome

M. Inomistova[1], N. Khranovska[1], O. Skachkova[1], G. Klymniuk[2], S. Pavlyk[2]

[1]Laboratory of Experimental Oncology, National Cancer Institute of the MPH Ukraine, Kiev, Ukraine, [2]Department of Paediatric Oncology, National Cancer Institute of the MPH Ukraine, Kiev, Ukraine

Background: Neuroblastoma is frequent childhood malignant tumor with high clinical heterogeneity. Despite the rare mutations of *TP53* gene, p53-mediated pathway is often inactivated in neuroblastoma. The significance of MDM2, p53 direct antagonist, overexpression in neuroblastoma clinical course and outcome has been already established. But still remain patients with favorable clinical features and poor disease outcome.

Methods: The case group comprised 68 children with neuroblastoma (mean age: 36.7±4.7 months; primary tumors: 88%; MYCN+: 39%; MDM2 overexpressed: 70%). p53 mRNA expression level (EL) was analyzed in tumor samples with qRT-PCR and evaluated by the ΔΔCt method according to control *GAPDH* mRNA EL.

Results: We established that the value of p53 EL in neuroblastoma cells varied in wide limits. Significantly lower p53 EL was detected in recurrent and metastatic tumor samples comparing to primary tumors ($P = 0.001$). Insignificant increase of p53 EL in patients with unfavorable clinical and biological features (late occurrence age, IV stage, MYCN amplification) was observed. However, we revealed significant increase of p53 EL in MDM2 overexpressed tumors ($P = 0.007$). With ROC-analysis we assessed the optimal criterions for distribution of patients according to p53 expression (OC:>1.18 a.u., $P = 0.04$, AUC:0.69 for high and OC:<0.09 a.u., $P = 0.006$, AUC:0.84 for low MDM2 expression). We have analyzed 3-year event-free survival (EFS) of patients with neuroblastoma and established 100% EFS survival for patients with low MDM2 and high p53 expressions, while in other groups significant decrease in survival was observed ($P < 0.05$). EFS rates of patients with low p53/high MDM2 and high p53/low MDM2 expressions were similar (27.7% and 33.3%) and for p53/MDM2 overexpressed tumors it was only 18.2% ($P < 0.05$).

Conclusions: Regulation of p53-mediated pathway is complex and multicomponent system. Alteration of p53 EL is independent from clinical features marker of neuroblastoma. Analysis of p53/MDM2 co-expression provides the possibility for better neuroblastoma outcome prediction.

1720P Downregulation of BRCA1 protein in clear cell renal cellular carcinoma

E. Sarnowska[1], N. Rusetska[1], M. Szymanski[2], I. Jancewicz[1], M. Chmielarczyk[1], R. Konopinski[1], M. Leszczynski[1], A. Chrzan[3], M. Ligaj[3], A. Maassen[4], T. Sarnowski[5], J. Siedlecki[1]

[1]Department of Molecular and Translational Oncology, Maria Sklodowska-Curie Cancer Center, Warsaw, Poland, [2]Department of Urology, Maria Skłodowska-Curie Cancer Center, Warsaw, Poland, [3]Department of Pathology, Maria Skłodowska-Curie Cancer Center, Warsaw, Poland, [4]Department of Protein Biosynthesis, Institute of Biochemistry and Biophysics, Warsaw, Poland, [5]Protein Biosyntesis, Instytut of Biochemy and Biophysic, Warsaw, Poland

Background: Around 75% of renal cancer in adult kidney is clear cell renal cellular carcinoma (ccRCC). This type of cancer is characterized by lipids overacumulation and mutations in VHL (around 90% cases), BAP1 and PBRM1 genes as well as stabilization of HIF1α transcription factor. Additionally, metabolic switch to aerobic glycolysis and aberration in TCA cycle was observed in ccRCC independently on the stage of the disease. Moreover, the mTOR pathway hyperactivation and downregulation of AMPK pathway featured the ccRCC. This type of cancer is highly resistant to classical chemotherapy. BRCA1 is tumor suppressor gene, mutation in this gene is associated with breast and ovarian cancer. BRCA1 is a protein involved in DNA repair and apoptosis also interacts with BRG1 – core subunit of SWI/SNF chromatin remodeling complex. BRCA1 is transcribed from bidirectional promoter together with NBR2 – lncRNA. Interestingly, NBR2 interacts with AMPK and is downregulated in ccRCC. CTCF is a protein which binds Topologicaly Associated Domains, and CTCF binding site was found in BRCA1/NBR2 promoter region.

Methods: Immunohistochemistry (IHC) on paraffin embedded clinical samples for BRCA1 and BRG1 core subunit of SWI/SNF complex, comparative transcriptomic study, co-immunoprecipitation (Co-IP) and chromatin immunoprecipitation (ChIP) method were used in this work.

Results: In this study we found downregulation of BRCA1 and BRG1 proteins in ccRCC patient samples independently on stage of the disease. Interestingly, downregulation of BRG1 was more severe in samples with strong lymphocyte infiltration. By contrast, downregulation at the transcript level was observed for BRG1 encoding gene but not for BRCA1. BRG1 and CTCF co-precipitated from cancer cells, indicating the existence of co-interaction between CTCF, BRG1 and BRCA1 proteins. Additionally, overexpression of BRG1 caused increased expression of CTCF in human cells. We also found that BRG1 targets both CTCF and BRCA1 genes.

Conclusions: BRCA1, BRG1 and CTCF module is dysregulated in ccRCC cells independently on Fuhrman grade and stage of the disease. This missregulation can have a brought spectrum of changes including 3D chromatin structure, transcription, epigenetic and others.

1721P The role of PD-L1 in a high-grade invasive human oral squamous cell carcinoma microenvironment

M. Hirai, H. kitahara, Y. Kobayashi, S. Kawashiri, H. Nakamura

Oral and Maxillofacial Surgery, Kanazawa University Graduate School of Medical Science, Kanazawa, Japan

Background: Blockade of the programmed-death 1 receptor (PD-1)/programmed-death ligand (PD-L1) pathway efficiently reduces tumour growth and improves survival. Durable tumour regression with blockade of the PD-1/PD-L1 checkpoint has been demonstrated in recent clinical studies. Oral squamous cell carcinoma (OSCC) is highly immunosuppressive, and PD-L1 expression has been proposed as a potential mechanism responsible for this phenotype. Despite the fact that anti-PD-1 treatment can produce durable responses, such therapy appears to benefit only a subset of patients. Thus, it is important to understand the mechanisms underlying the regulation of PD-L1 expression in the OSCC microenvironment.

Methods: The subjects were patients with primary OSCC who underwent surgical resection at the Kanazawa University Hospital between 1998 and 2008. And, three human oral squamous cell carcinoma cell lines established from tumor biopsies with different grade of invasive abilities were used: OSC-20, OSC-19 and TSU.

Results: We showed that PD-L1 expression in high-grade invasive OSCC cell lines was lower than that in a low-grade invasive OSCC line and found a close correlation between PD-L1 expression and the epithelial-mesenchymal transition (EMT). PD-L1 expression was upregulated in macrophages and dendritic cells (DCs) in high-grade invasive human OSCC tissues or co-cultured with mesenchymal-phenotype OSCC cells in vitro. TLR4-inhibitory peptide successfully suppressed PD-L1 upregulation on macrophages and DCs co-cultured with mesenchymal-phenotype OSCC cells, suggesting that some EMT-induced tumour antigen is critical for PD-L1 induction on tumour-associated macrophages and DCs.

Conclusions: Further studies are necessary to explore the impact of EMT on the tumour immune microenvironment and to identify potential biomarkers for selecting

patients who might preferentially benefit from PD-1/PD-L1 blockade or immunotherapies more broadly.

1722P Loss of SWI/SNF chromatin remodelling complex is linked to advanced urinary bladder cancer

M. Szymanski[1], E. Sarnowska[2], A. Ornoch[2], N. Rusetska[2], S. Abramowicz[2], A. Chrzan[3], M. Ligaj[3], A. Maassen[4], J. Siedlecki[2], T. Sarnowski[3]

[1]Urology, Marii Skłodowska-Cure Cancer Center, Warsaw, Poland, [2]Molecular and Translational Oncology, Marii Skłodowska-Cure Cancer Center, Warsaw, Poland, [3]Pathology Department, Marii Skłodowska-Cure Cancer Center, Warsaw, Poland, [4]Department of Protein Biosynthesis, Institute of Biochemistry and Biophysics, Warsaw, Poland

Background: Bladder cancer originated from urothelium belongs to the top ten among all tumors. Various factors like genetic and molecular defects, appearance of different tumors in the family, previous genitourinary disorders and exposure to chemical compounds are reported as potential causes of this type of cancer. It has been reported that TP53, p21 or Ras mutations and epigenetic alterations of genes coding for these oncogenes are involved in the aetiology of urothelium originating bladder cancer. Additionally, the TCGA study indicated that such important regulatory pathways/machineries like these controlling cell cycle; (PI(3)K)/AKT/mTOR signaling involved in the metabolism control; and chromatin modificators including SWI/SNF chromatin remodeling complex (CRC) are affected in this disease.

Methods: Immunohistochemistry (IHC) on paraffin embedded clinical samples for SWI/SNF core subunits and key enzymes involved in metabolism control, comparative transcriptomic study and confirmatory quantitative real-time PCR (qRT-PCR) were used in this work.

Results: In this study we found a substantial decrease of protein levels of SWI/SNF core subunits in bladder cancer clinical samples. Subsequently, we performed reanalysis of transcriptomic data for clinical samples obtained from GEO database and confirmatory assessment of the transcript level in clinical samples. This analysis showed that the reduced protein level of SWI/SNF core subunits observed in advanced bladder cancer is likely caused by the decreased abundance of corresponding transcripts. We also found that the SWI/SNF complex interacts in human cells with key proteins involved in the control of energy status and glucose metabolism. The IHC analysis indicated altered abundance of these enzymes in cancer cells when compared to normal urothelium consistently to strong metabolic alterations characteristic for this type of cancer.

Conclusions: The down-regulation of SWI/SNF complex on both transcript and protein level, and decreased activity of its partner proteins link the molecular features with metabolic alterations observed in this type of cancer.

1723P The role of hepatocyte nuclear factor 1 homeobox B (HNF1B) loss in chromophobe RCC (ChRCC) development

E. Jonasch[1], G. Fuller[2], I. McCutcheon[3], Z. Ding[1], L. Zhou[1], X. Liu[4], W. Kong[5], R. Powell[6], I-Y. Park[6], N. Tannir[1], W.K. Rathmell[7], B. Dong[5], S. Matin[8], X. Tong[6], Y. Huang[5], P. Tong[9], J. Wang[10], C. Walker[6], M. Sun[11]

[1]Genitourinary Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA, [2]Pathology, MD Anderson Cancer Center, Houston, TX, USA, [3]Neurosurgery, MD Anderson Cancer Center, Houston, TX, USA, [4]GU Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA, [5]Urology, Shanghai Jiaotong University School of Medicine, Shanghai, China, [6]Precision Environmental Health, Baylor College of Medicine, Houston, USA, [7]Medical Oncology, Vanderbilt University, Nashville, TN, USA, [8]Urology, MD Anderson Cancer Center, Houston, TX, USA, [9]Bioinformatics, MD Anderson Cancer Center, Houston, TX, USA, [10]Bioinformatics & Comp Biology, MD Anderson Cancer Center, Houston, TX, USA, [11]Experimental Therapeutics, MD Anderson Cancer Center, Houston, TX, USA

Background: ChRCC is characterized by dramatic chromosomal copy number (CN) changes. Currently, no model is available to precisely elucidate the molecular drivers of this rare tumor. HNF1B is a master regulator of gene expression, and both mutated *HNF1B* and downregulated HNF1B protein levels have previously been described in ChRCC.

Methods: We queried The Cancer Genome Atlas ChRCC database and analyzed tissue microarray data to determine the relative levels of HNF1B in ChRCC versus other RCC subtypes, and assessed the prognostic impact of dual *HNF1B* and *TP53* loss. We knocked out *Hnf1b* in proliferating murine embryo fibroblasts (MEFs) and human ACHN cells and measured the effect on gene and protein expression of checkpoint regulatory proteins, spindle integrity, and aneuploidy. We then performed dual knockdown of *HNF1B* and *TP53* and assessed cellular behavior.

Results: We found that *HNF1B* transcript and HNF1B protein were downregulated in the majority of ChRCC in TCGA, and the magnitude of *HNF1B* loss is unique to ChRCC. Additionally, we observed a strong correlation between reduction of *HNF1B* expression and aneuploidy in ChRCC patients. In MEF cells deficient in *Hnf1b*, we observed the development of aneuploidy. *Hnf1b* deficiency also reduced spindle checkpoint protein (MAD2L1, BUB1B) and cell cycle checkpoint protein (RB1 and p27) expression, and altered chromatin access of *Mad2l1*, *Bub1b* and *Rb1* genes. Coordinate loss of *Bub1b* and *Rb1* recapitulated the polynuclearity and larger cell size seen with *Hnf1b* depletion. TCGA data also showed that *TP53* is mutated in 33% of ChRCC whose *HNF1B* expression was repressed, and the combination of *HNF1B* loss with *TP53* mutation was associated with poor prognosis. The combination of *HNF1B* loss with *TP53* inactivation led to increased cell proliferation and increased aneuploidy, providing evidence that coordinate loss of *HNF1B* and *TP53* may enhance cellular survival and engender an aggressive ChRCC tumor phenotype.

Conclusions: *HNF1B* deficiency is a major driver of chromosomal instability in ChRCC and lethality is associated with subsequent *TP53* loss. Further development of model systems with combined *HNF1B/TP53* loss will accelerate the development of treatments specific for ChRCC.

1724P Some mechanisms of increasing malignancy of B16/F10 melanoma in female mice with chronic pain

I.M. Kotieva[1], O.I. Kit[2], E.M. Frantsiyants[1], I.V. Kaplieva[1], L.K. Trepitaki[1], V.A. Bandovkina[1], N.D. Cheryarina[1], Y.A. Pogorelova[1], L.Y. Vladimirova[3]

[1]Laboratory of Study of Malignant Tumor Pathogenesis, Rostov Research Institute of Oncology, Rostov-on-Don, Russian Federation, [2]Department of Abdominal Oncology, Rostov Research Institute of Oncology, Rostov-on-Don, Russian Federation, [3]Drug Therapy Department, Rostov Research Institute of Oncology, Rostov-on-Don, Russian Federation

Background: The impact of chronic pain (CP) on the growth and development of tumors is poorly studied. However, one of the main goals of cancer therapy is the relief of chronic pain, a complex symptom based on combined pathophysiological mechanisms. Our aim was to study the influence of CP on melanoma growth in female mice and to determine levels of the VEGF family members in the tumor (T), its perifocal zone (PZ) and in the skin.

Methods: The study included 64 female C57BL/6 mice; B16/F10 melanoma was transplanted under the skin on the back of animals in the main group 2 weeks after sciatic nerve ligation. Mice with melanoma without CP were used as the controls. Levels of VEGFs: A, C, R1 and R3 were determined by ELISA (BenderMedSystem, Austria).

Results: The life span of mice with melanoma and CP was 1.5 times shorter than the control group. Melanoma in mice with CP was more aggressive, and metastases occurred after 1 week vs. 4 weeks in the controls. The rate of metastasis was higher (100% vs. 60% in the controls); melanoma with CP spread to multiple organs and caused unusual metastases to the heart and uterus. The rapid and specific development of B16/F10 melanoma in mice with CP was accompanied by increased levels of VEGF-A, -C and -R1 in T, PZ and the skin, with their maximal accumulation in T in week 1. The VEGF-A level continued to increase in T and PZ (PZ<T) in week 2; VEGF-C and VEGF-R1 levels increased in PZ only and decreased in T and skin (T<PZ). The VEGF-A levels were equally highest in both T and PZ, while VEGF-C and VEGF-R1 content in T was higher than in the skin and higher in PZ than in T. The VEGF-R3 level increased in T of mice without CP and was higher in T than in PZ, while in mice with CP its content in T was lower than in PZ. Levels of VEGF-R1 (in all tissues) and VEGF-R3 (in the skin and PZ) decreased in mice with CP in week 3.

Conclusions: CP shortened the life span of female mice with melanoma and enhanced the aggressiveness of B16/F10 melanoma metastases. The activation of angiogenesis in T and PZ can be considered as one of the mechanisms of the neoplastic progression.

1725P Impact of global epigenetics machinery on clinical outcome of colorectal cancer patients treated with fluoropyrimidine-based therapy

M.A. Fouad[1], S.E. Salem[2], M. Hussein[2], A-R. Zekri[1], D. Mohammed[1], H. Hafez[1], S. Shouman[1]

[1]Cancer Biology, National Cancer Institute-Cairo University, Cairo, Egypt, [2]Medical Oncology, National Cancer Institute-Cairo University, Cairo, Egypt

Background: The pathogenesis of colorectal cancer (CRC) is complex and influenced by many factors related to genetic, epigenetics and chronic inflammatory processes.

Methods: This is a prospective study, conducted on 102 Egyptian patients, diagnosed with CRC. Blood samples were collected at baseline and after 3 & 6 months of receiving fluoropyrimidine (FP) based therapy. DNA methylation was measured by LC/MS/MS

spectroscopy, acetylated histones (H3) and (H4) were measured by ELISA and RNA expression of FP metabolizing enzymes (TS, TP and DPD), DNA methyl transferases (DNMT3A and B) in addition to inflammatory markers (COX2, IL6, and IL1B) by qRT-PCR.

Results: The median age of the studied patients was 46 years, 47% of them were ≤ 45 years. Forty patients (38.8%) had rectal cancer, they exhibited significant H3 hyperacetylation and upregulation of COX2 and IL1B along with significantly lower median overall survival compared to colonic patients *(14.6 versus 23 months respectively)*. FP therapy produced significant decrease in global methylation, acetylated H3 & H4 levels, downregulation in TP and DNMT3B but significant upregulation in TS and DPD over treatment time. Significant positive correlations were found between global methylation and IL1B (r^2= *0.25, P= 0.01)*, acetylated H3 with DPD and COX2 (r^2= *0.28, P= 0.02 and* r^2= *0.27, P= 0.03 respectively*) and 5 methylated cytosine content (5MC) with DNMT3A and IL6 (r^2= *0.25, P= 0.04 and* r^2= *0.34, P= 0.004 respectively)*. Overexpression of COX2 > 17 had a significant poor prognostic effect on overall and event free survivals (HR = 0.58, *P= 0.003* and HR = 0.72, *P= 0.008* respectively). Also patients who had global methylation> 30 showed significant reduced event free survival by 39% (*P= 0.04*).

Conclusions: Global methylation and H3 acetylation regulated COX2, IL6 and IL1B which were not affected by the therapy, however H3 upregulated TS and DPD. Rectal cancer patients showed significant H3 hyperacetylation, upregulation of COX2 and IL1B along with significant lower overall survival.

1726P Comparison of breast cancer subtypes between young and elderly women

I. Kiladze[1], A. Mariamidze[1], M. McHedlishvili[2], K. Tsomaia[2], F. Todua[1]

[1]Medical Oncology, Research Institute of Clinical Medicine, Tbilisi, Georgia, [2]Pathology, TSU, Tbilisi, Georgia

Background: Breast cancer(BC) are increasingly recognized as heterogeneous disease based on expression of receptors for estrogen (ER), progesterone (PR), and human epidermal growth factor receptor 2 (HER2). There are four main subtypes of BC with differing tumor characteristics and different risk factors, treatment options and prognoses. Few data exist on the frequency of molecular subtypes in young and older women. The purpose of this study is to compare the distribution of the BC subtypes in young and elderly patients.

Methods: BC during the period 2013 to 2015 including ER/PR and HER2 status, was obtained from the Georgian main histopathology laboratories all over the country. We analyzed 1003 women with BC included 85 women aged 20 to 39 years (YA's), 118 women aged 40 to 45 years (older premenopausal),665 women aged 46-70 (postmenopausal) and 135women older than 70 years (elderly group) at diagnosis. Incidence rates were calculated by subtype (triple-negative; HR +/HER2 -; HR +/HER2 +; HR -/HER2 +), and differences in subtype characteristics by age groups were evaluated.

Results: The incidence of BC in YA's was 8,5%. The most common BC subtype was HR +/HER2- among all age groups, and HR -/HER2 + was the least; however, the relative contribution of each subtype varied within age categories. In YA's HR +/HER2 - was the most commonly diagnosed subtype (62%), followed by HR +/HER2 + (15%), triple-negative (12%) and HR -/HER2 + (11%). Statistically no significant difference of BC subtypes was observed in age groups. HR +/HER2 - subtype was lesser in YA's than in elder population (62% vs 73%), but statistically non-significant (p = 0.19) and there was not significant difference in prognostically "unfavorable" subtypes (HR-/HER2+ and triple-negative) (23% vs 17%) (p = 0.134; (CI) 95%: 0.09 to 1.71). Surprisingly no difference of Triple-negative BC was observed in YA and elderly groups (12% vs 13%).

Conclusions: The distribution of breast cancer subtypes among young adults didn't vary from that observed in older women. Our study results seem to be in contradiction with other studies previously reported in literature. Future studies should consider whether distribution of breast cancer subtypes influences long-term survival in young compared with older women.

1727P Distribution of the PAM50 breast cancer subtypes within each pathology-based group: a combined analysis of 15,339 patients across 29 studies

J.M. Cejalvo, T. Pascual, A. Fernández-Martínez, B. Adamo, N. Chic, M. Vidal, L. Rodelo, M. Muñoz, A. Prat

Medical Oncology, Hospital Clinic y Provincial de Barcelona, Barcelona, Spain

Background: Current classification of breast cancer in the clinical setting is based on pathology-based biomarkers such as hormone receptors (HR) and HER2. More recently, identification of the intrinsic molecular subtypes (IS) within each pathology-based group (i.e. HR+/HER2-, HR+/HER2+, HR-/HER2+ and triple-negative [TN]) is revealing clinical value. The objective of this study is to assess the distribution of the IS within each pathology-based group in a large series of breast cancer.

Methods: Twenty-nine studies were identified from the literature (2009–2017) in which IS and pathology-based data were reported. HR was evaluated by immunohistochemistry (IHC) and HER2 by IHC and/or FISH according to standard criteria. Pathology-based groups were divided into 4 groups: HR+/HER2-, HR+/HER2+, HR-/HER2+ and TN. IS (Luminal A [LumA], Luminal B [LumB], HER2-enriched [HER2-E], Basal-like [BL] and Normal-like) were identified using the research-based, or the standardized, PAM50 gene expression-based assay.

Results: PAM50 and pathology data was available in 15,339 patients. The distribution of the PAM50 IS within each IHC-based group is shown in Table 1. Within HR+/HER2- group (n = 9,768), non-luminal subtypes (HER2-E and BL) represented 5.6% and 2.2%, respectively. Within HR+/HER2+ group (n = 1,727), HER2-E and BL represented 29.2% and 2.1%, respectively. Within HR-/HER2+ group (n = 1,332), non-HER2-E subtypes (Luminal A/B and BL) represented 9.3% and 13.8%, respectively. Finally, within TN (n = 2,512), non-BL subtypes (Luminal A/B and HER2-E) represented 5.9% and 11.1%, respectively.

Conclusions: Our results confirm previous observations that all IS are represented within each pathology-based group. Based on our observations, future clinical trials in unselected breast cancer patient populations should be sufficiently powered to address the prognostic and predictive ability of the IS.

1728P Genetic association of matrix metalloproteinase MMP- 1, MMP-3 and MMP-9 Genes with HCV-related hepatocellular carcinoma in Egyptian patients

A.M. Alhanafy[1], B. Montaser[2], W. Fathy[2], N.S. Elabd[3], S. Tayel[4]

[1]Department of Clinical Oncology and Nuclear Medicine, Menoufia University, Faculty of Medicine, Shebin El Kom, Egypt, [2]Department of Clinical Pathology, Menoufia University, Faculty of Medicine, Sheben El Kom, Egypt, [3]Department of Tropical Medicine, Menoufia University, Faculty of Medicine, Sheben El Kom, Egypt, [4]Department of Medical Biochemistry, Menoufia University, Faculty of Medicine, Sheben El Kom, Egypt

Background: Hepatocellular Carcinoma (HCC) is one of the most frequent cancers in Egypt where there is high prevalence of infection with the Hepatitis C virus (HCV). Matrix metalloproteinases (MMPs) are multifunctional proteins that play an important role in cell development, differentiation, inflammation and angiogenesis. Polymorphisms in MMPs genes might be involved in development of HCV related HCC. The aim of this study was to explore the relationship of gene polymorphisms in MMP-1,3 & 9 with liver cirrhosis and HCC patients.

Methods: The study included 128 subjects enrolled from Menoufia University Hospital inpatients and outpatients clinics from the Department of Clinical Oncology & Nuclear Medicine and Department of Tropical Medicine in the period between October 2015

Table: 1727P

IHC-Based		PAM50 intrinsic subtype distribution (%)				
n = 15,339	%	LumA	LumB	HER2-E	BL	Normal
HR+/HER2-	63.68	54.47	34.41	5.64	2.24	3.24
HR+/HER2+	11.26	34.45	30.57	29.18	2.08	3.71
HR-/HER2+	8.68	6.91	2.40	69.74	13.81	7.13
HR-/HER2-	16.38	3.53	2.39	11.15	78.23	4.70

and August 2016. Patients were classified into three groups. Group I: 48 patients with HCC in addition to liver cirrhosis, including 26 males and 22 females with a mean age of 58.60±5.29; Group II: 50 patients with liver cirrhosis, including 26 males and 24 females with a mean age of 56.74±5.21; Group III: 30 healthy subjects as controls, including 15 males and 15 females with a mean age of 56.30 ±7.30. Diagnosis of HCC was performed using two imaging methods (abdominal US & triphasic CT). All subjects except controls were positive for serum HCV RNA. Liver function tests, AFP & CHILD score were assessed. Gene polymorphisms were analysed using PCR-RFLP.

Results: HCC patients had higher mutant G2G2 (35.4%) and G2 allele (62.5%) of the MMP-1 gene than patients in both cirrhotic ($P < 0.05$) and control groups ($P < 0.001$). In addition, for the MMP-3 gene, HCC patients had the most noteworthy predominance of mutant 5A/5A (22.9%) and 5A allele (52.1%) compared to the cirrhotic ($P < 0.05$) and control groups ($P < 0.001$). The results of MMP-9 gene analysis uncovered a higher frequency of the mutant TT genotype and T allele in both HCC (56.3% and 74% respectively) and cirrhotic groups (10% and 35% respectively) compared to the control group. In HCC patients, we detected a significant correlation between heterozygote G1/G2 and G2/G2 of the MMP-1 gene and homozygote TT of MMP-9 with a higher CHILD score, tumor size and stage ($P < 0.05$). Moreover, MMP-3 5A/6A was associated with a higher CHILD score, portal vein thrombosis and stage ($P < 0.05$) compared to other genotypes.

Conclusions: Gene mutations in MMP-1,3, 9 may be involved in progression of liver cirrhosis and risk relationship for HCC development.

1729P Heterogenity of epigenetic and EMT marks observed in hepatocellular carcinoma with keratin 19 proficiency

T. Okada[1], T. Nagasaka[1], N. Yokomichi[2], F. Taniguchi[1], T. Toshima[1], K. Yasui[1], T. Fuji[1], Y. Mori[1], T. Kawai[1], Y. Umeda[1], T. Yagi[1], T. Fujiwara[1], A. Goel[3]

[1]Department of Gastroenterological Surgery, Okayama University Hospital, Okayama, Japan, [2]Palliative Medicine, Seirei Mikatahara General Hospital-Hamamatsu, Hamamatsu, Japan, [3]Center for Gastrointestinal Research, Center for Translational Genomics and Oncology, Baylor Scott & White Research Institute, Charles A. Sammons Cancer Center, Baylor University Medical Center, Dallas, TX, USA

Background: The expression of keratin 19 (K19) has been proposed as a novel predictor for poor prognosis in patients with hepatocellular carcinoma (HCC). However, the cell origin of K19-proficient HCC remains unclear. Herein we tried to reveal the cell origin of K19-proficient HCC by tracing epigenetic footprints in cultured cells and clinical materials.

Methods: The KRT19 gene, which encodes K19, has a CpG island in promoter region and therefore implicates DNA methylation as a potential epigenetic process for K19 expression. Firstly, we examined epigenetic alterations in K19-positive HCC cell lines. Next, from a panel of 564 surgically resected HCCs, we clarify the clinicopathological relevance of K19-preficent HCCs by analyzing robust methylation analyses in KRT19 promoter region and LINE-1 in comparison with other cholangiocytic (K7), hepatocytic markers (HepPar-1 and Arginase-1), EMT markers (E-cadherin and vimentin), and a signal pathway associate with biliary differentiation (NOTCH-1).

Results: In vitro, although methylation in KRT19 promoter was associated with K19 deficiency, 5-aza-dC treatment failed to re-expression of K19. From 564 surgically resected HCCs, a cohort of 125 HCC patients was selected and analyzed after exclusion of HCC with recurrence, TNM stage as IIIB or more, preoperative therapy, transplantation, and combined hepatocellular-cholangiocarcinoma. In this cohort, K19 expression was found in 29 HCCs (23.2%), and corresponded with poor survival following surgery ($P = 0.025$) and extrahepatic recurrence free survival ($P = 0.017$). Compared with K19-deficient HCCs, the lower methylation level in KRT19 promoter was observed in K19-proficient HCCs ($P<.0001$). Instead, HCC with genome-wide hypermethylation in LINE-1 was frequently observed in K19-proficient HCCs ($P = 0.0079$). Additionally, K19 proficiency was associated with K7 proficiency ($P = 0.043$), and reduced both E-cadherin and HepPar-1 expression ($P = 0.043$ and$<.0001$, respectively).

Conclusions: K19-proficient HCC showed the poor prognosis owing to extrahepatic recurrence and the molecular signatures were different from K19-deficeint HCC, providing novel insights of heterogeneity underlying development of HCC with extrahepatic metastasis.

1731P Rare malignancy rare site: Extranodal lymphomas

S. Gupta, A.N. Murali

Oncology, Sarvodaya Hospital, Faridabad, India

Background: Extranodal Non Hodgkins Lymphoma (NHL) constitutes one quarter of all NHL cases. Oral cavity and breast represent 2 such uncommon sites.

Methods: Clinical and treatment details of patients with extranodal lymphomas who underwent treatment at our center were collected. Diagnosis was established by excision biopsy or by punch biopsy from the lesion. Histopathological examination (HPE) and immunohistochemistry (IHC) were performed. For staging, patients underwent positron emission tomography (PET) with computed tomography (CT) scan of the whole body.

Results: Case 1: A 32-year old male presented with complaints on the right-side base of tongue and difficulty in swallowing since 20 days. On examination, a nodular swelling was seen over the right side posterior one third of tongue going up to base of tongue. Punch biopsy from the tongue lesion was suggestive of NH. IHC showed CD 3 - positive, CD 30 - positive, ALK 1 - positive and CD 20 - positive with a final report of anaplastic lymphoma kinase (ALK) positive ALCL. Whole body PET-CT showed localized metabolic uptake in the tongue and in the right cervical lymph node - level II. A final diagnosis of ALK positive ALCL - stage IE was made. Case 2: A 22-year old female presented with complaints of lump in the right breast since 10 weeks. On examination there was a lump in the right breast measuring 3 x 2 cm in the lower outer quadrant and no other palpable lymphadenopathy. On evaluation, wide local excision of the lump was suggestive of a round cell tumor. IHC done showed the neoplastic round cells to be positive for CD 20, PAX5, CD 10 with a Ki 67 of 80% and BCL 2, MUM 1 - negative. Bone marrow examination was positive for lymphomatous deposits. Whole body PET-CT showed metabolically active sub-centimetric right axillary lymph node enlargement with diffuse hypermetabolism along axial bone marrow.

Conclusions: Only 11 previous cases of oral ALCL have been reported. Primary breast lymphoma is a rare disease, accounting for only 0.4-0.5% of all breast malignancies, 0.38-0.7% of all NHL. Extranodal NHL can occur at any site and keeping an open mind is the most important pre-requisite for making a diagnosis. Modern diagnostic tools such as IHC is mandatory for diagnosis and management of extranodal NHL.

1732P Descriptive analysis of families with TP53 mutations: Is there a genotype/phenotype correlation?

J.P. Silva[1], B. Filipe[2], A. Luís[3], A. Clara[3], S. Bento[3], P. Machado[2], P. Rodrigues[3], J. Parreira[3], F. Vaz[3]

[1]Medical Oncology, Instituto Português de Oncologia de Lisboa Francisco Gentil, E.P.E. (IPOLFG EPE), Lisbon, Portugal, [2]Molecular Pathobiology Investigation Unit, Instituto Português de Oncologia de Lisboa Francisco Gentil, E.P.E. (IPOLFG EPE), Lisbon, Portugal, [3]Familiar Cancer Risk Clinic, Instituto Português de Oncologia de Lisboa Francisco Gentil, E.P.E. (IPOLFG EPE), Lisbon, Portugal

Background: Li-Fraumeni syndrome (LFS) is a rare and serious hereditary cancer syndrome caused by germline mutations in the TP53 gene. Our objective is to review the molecular and clinical characteristics of our LFS families.

Methods: Retrospective descriptive analysis. Molecular germinal diagnosis was done either by Sanger or NG Sequencing (Trusight Cancer, Illumina); Large Genomic rearrangements were tested by MLPA (MRC Holland).

Results: Among 4952 non-related families registered in our multidisciplinary program, 395 are *BRCA1/2* families and 36 haver other molecular diagnoses with 7/36 confirmed *TP53* families. Twenty-nine pts were reviewed, including 2 male carriers, (36, 40 years) that haven't developed cancers yet. Forty-one tumours were registered (median of 1,41 tumours/carrier, 0–4). Female/male was 2:1. Median age for the first tumour was 24 years (1-45) in the index cases and 35 (1,5-61) in relatives ($p > 0,05$). Breast cancer (BC) (34% of cancers/48% pts) and sarcomas (31% of cancers/44% pts) were the most common malignancies. For BC cases hormone receptor status was confirmed in 8/14 (positive in 6/8, simultaneous HER2 positivity in 2 cases). Median age of death was 40 (34-58). Most mutations were missense (5 - 2 dominant-negative affecting the DNA binding domain: c.743G>A, p.R248Q and c.725G>A, p.C242Y), none was recurrent and the only frequent mutation observed was c.743G>A, p.R248Q. One of the missense and the 2 frameshift mutations have never been described as germinal: c.481G>A, p.A161T; c.86del, p.N29Tfs*15 and c.990del, p.Q331Rfs*14 Chompret criteria were met in 6/7 (85%) of cases and didn't identitfy a breast cancer only family, with 3 consecutive generations affected.

Conclusions: Our data confirms the heterogeneity and complexity of malignancies and mutations in LSF. Breast cancer and sarcomas were the most frequent cancers and missense, non-recurrent mutations were mostly observed. In this study c.481G>A, p.A161T; c.86del, p.N29Tfs*15 and c.990del, p.Q331Rfs*14 are, for the first time, identified as germinal mutations. At this time no genotype-to-phenotype correlation could be confirmed. Chompret's criteria had only 85% sensitivity for the identification of TP53 families.
