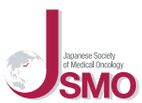
Annals of Oncology

Abstract Book of the
42nd ESMO Congress (ESMO 2017)



Madrid, Spain
8–12 September 2017

Guest Editors: ESMO 2017 Congress Scientific Committee

Annals of Oncology

Official Journal of the European Society for Medical Oncology and the Japanese Society of Medical Oncology

Executive editor: Lewis Rowett
Editorial office: Vanessa Marchesi, Paola Minotti Bernasconi, Giovannella Porcu, Annals of Oncology, Via Luigi Taddei 4, CH-6962 Viganello-Lugano, Switzerland

Annals of Oncology is covered in C.A.B. International, Current Clinical Cancer, Current Contents/Clinical Medicine®, Current Contents/Life Sciences, Elsevier BIOBASE/Current Awareness in Biological Sciences, EMBASE/Excerpta Medica, IBIDS, Index Medicus/MEDLINE, The International Monitor in Oncology, Medical Documentation Service, Science Citation Index® and Science Citation Index Expanded.

Subscriptions

A subscription to *Annals of Oncology* comprises 12 issues plus supplements in each volume. Prices include postage, and for subscribers outside the UK delivery is by Standard Air.

Annual Subscription Rate (Volume 28, 12 issues, 2017)

Institutional - Academic / Non profit only
Print and Online £1655.00/$3310.00/€2482.00
Online Only £1204.00/$2408.00/ €1806.00
Print Only £1525.00/$3050.00/€2288.00

Institutional - Corporate
Print and Online £2069.00/$4137.00/€3103.00
Online Only £1505.00/$3010.00/€2258.00
Print Only £1906.00/$3813.00/€2860.00

Personal
Print and Online £1237.00/$2476.00/€1856.00
Please note: US$ rate applies to US & Canada, Euros applies to Europe, UK£ applies to UK and Rest of World.

There may be other subscription rates available, for a complete listing please visit https://academic.oup.com/annonc/subscribe

Full prepayment, in the correct currency, is required for all orders. Orders are regarded as firm and payments are not refundable. Subscriptions are accepted and entered on a complete volume basis. Claims cannot be considered more than FOUR months after publication or date of order, whichever is later. All subscriptions in Canada are subject to GST. Subscriptions in the EU may be subject to European VAT. If registered, please supply details to avoid unnecessary charges. For subscriptions that include online versions, a proportion of the subscription price may be subject to UK VAT. Personal rate subscriptions are only available if payment is made by personal cheque or credit card and delivery is to a private address.

The current year and two previous years' issues are available from Oxford Journals. Previous volumes can be obtained from the Periodicals Service Company at http://www.periodicals.com/oxford.html or Periodicals Service Company, 11 Main Street, Germantown, NY 12526, USA. Email: psc@periodicals.com. Tel: (518) 537-4700. Fax: (518) 537-5899

Methods of payment. (i) Cheque (payable to Oxford University Press, to Oxford University Press, Cashiers Office, Great Clarendon Street, Oxford OX2 6DP, UK) in GB£ Sterling (drawn on a UK bank), US$ Dollars (drawn on a US bank), or EU€ Euros. (ii) Bank transfer to Barclays Bank Plc, Oxford Group Office, Oxford (bank sort code 20-65-18) (UK), overseas only Swift code BARC GB 22 (GB£ Sterling to account no. 70299332, IBAN GB89BARC20651870299332; US$ Dollars to account no. 66014600, IBAN GB27BARC20651866014600; EU€ Euros to account no. 78923655, IBAN GB16BARC20651878923655). (iii) Credit card (Mastercard, Visa, Switch or American Express).

Annals of Oncology (ISSN 0923-7534) is published monthly by Oxford University Press, Oxford, UK and distributed in the USA by Central Mailing Services c/o UKP Worldwide, 1637 Stelton Road B2, Piscataway, NJ 08854. The US annual print subscription or price is $3310.00. Airfreight and mailing in the USA by agent named Central Mailing Services c/o UKP Worldwide, 1637 Stelton Road B1-2, Piscataway, NJ 08854. Periodicals postage paid at Piscataway, NJ and additional mailing offices.

Subscription records are maintained at Oxford University Press, Oxford, UK.

Supplements, reprints and corporate sales

For requests from industry and companies regarding supplements, bulk article reprints, sponsored subscriptions, translation opportunities for previously published material, and corporate online opportunities, please email: special. sales@oup.com, fax: +44 (0) 1865 353774 or visit http://www.oupmediainfo.com/#!/reprints-eprints.

Permissions

For information on how to request permissions to reproduce articles/information from this journal, please visit https://academic.oup.com/journals/pages/access_purchase/rights_and_permissions.

Advertising

Advertising, inserts and artwork enquiries should be addressed to Advertising and Special Sales, Oxford Journals, Oxford University Press, Great Clarendon Street, Oxford, OX2 6DP, UK. Tel: +44 (0)1865 354767; Fax +44 (0)1865 353774; E-mail: jnlsadvertising@oup.com

Environmental and ethical policies

Oxford Journals, a division of Oxford University Press, is committed to working with the global community to bring the highest quality research to the widest possible audience. Oxford Journals will protect the environment by implementing environmentally friendly policies and practices wherever possible. Please see https://academic.oup.com/journals/pages/about_us/ethical_policies for further information on environmental and ethical policies.

Notice

The content of the abstracts contained in this Abstract Book is subject to an embargo.

Abstracts accepted for presentation at ESMO 2017 as **Proffered Paper** (oral presentation), **Poster Discussion** and **Poster** will be published online on the ESMO website at 00:05 CEST on **Thursday, 31 August 2017**.

Late-breaking abstracts and abstracts selected for the **Press Programme** will be made public at 00:05 CEST (Central European Summer Time) on the day of the official Congress session during which they are presented.

Disclaimer

No responsibility is assumed by the organizers for any injury and/or damage to persons or property as a matter of products liability, negligence or otherwise, or from any use or operation of any methods, products, instructions or ideas contained in the material herein. Because of the rapid advances in medical sciences, we recommend that independent verification of diagnoses and drug dosages should be made.

Every effort has been made to faithfully reproduce the abstracts as submitted. However, no responsibility is assumed by the organizers for any omissions or misprints.

Typeset by Cenveo Publisher Services, Bangalore, India.

The European Society for Medical Oncology (ESMO)

ESMO is the leading professional organisation for medical oncology, with the overarching goal of improving outcomes for cancer patients everywhere. We are the society of reference for oncology education and information, and are committed to supporting our members to develop and advance in a fast-evolving professional environment.

Founded in 1975, ESMO has European roots with a global reach: we welcome oncology professionals from around the world. We are a home for all oncology stakeholders, connecting professionals with diverse expertise and experience, and speaking with one voice for our discipline. Our education and information resources support an integrated multi-professional approach to cancer care, from a medical oncology perspective. We seek to erase boundaries in cancer care, whether between countries or specialities, and pursue our mission across oncology, worldwide.

The ESMO community brings together more than 16,000 oncology professionals from over 130 countries. Drawing on 40 years of experience and around 500 expert committee members, ESMO serves its members and the oncology community through:

- Post-graduate oncology education and training
- Career development and leadership training for the next generations of oncologists
- International congresses and workshops to share expertise and best practice, learn about the most up-to-date scientific advances, and connect with colleagues in related disciplines.
- Continuously reviewed, evidence-based standards for cancer care in Europe
- Advocacy and consultation to foster a favourable environment for scientific research

Cancer care is rapidly becoming more integrated and more specialised; whether their field is research, diagnosis, treatment, care, or advocacy, oncology professionals need to both build their specialist knowledge and connect with the best practitioners in other disciplines worldwide. ESMO membership makes this possible.

Please visit **esmo.org** to learn more. **Across Oncology. Worldwide.**

The European Association for Cancer Research (EACR)

The European Association for Cancer Research is a professional membership society for cancer researchers with more than 10,000 members worldwide. The EACR was founded in 1968 and has one guiding aim: 'The advancement of cancer research for the public benefit'. Membership is open to anyone actively working or studying in cancer research. Our members work across the full spectrum of the field, from basic through to translational and clinical research, and range from postgraduate students to winners of the Nobel Prize. Researchers who are members of one of the 14 EACR affiliated 'National Societies' automatically become members of the EACR as part of the wider benefits of belonging to their national society. The membership fee for active members is just 40 Euros per annum or 120 Euros for 4 years, and special reduced membership fees are available to postgraduate students and those with less than 4 years' post-doctoral experience.

We facilitate communication and collaboration within the cancer research community. We also set out to raise the profile of cancer research in Europe and to make the case for sustained political and economic support. We organise scientific conferences of the highest quality, open to members and non-members. Our Conference Series of small, focused meetings is highly regarded for its focus on the latest research topics and for the provision of opportunities for interaction between speakers and participants. In 2018 we will celebrate our 50th anniversary and invite you to join us at EACR25, our biennial Congress to be held in Amsterdam, Netherlands, 30 June - 03 July 2018.

Find out more about the EACR at **www.eacr.org**

ESMO 2017 Congress Officers

ESMO and Congress President
Fortunato Ciardiello, Naples, Italy

Scientific Committee Co-Chairs
Alberto Sobrero, Genoa, Italy (ESMO)
Richard Marais, Manchester, UK (EACR)

Educational Chair
Andrés Cervantes, Valencia, Spain

Press Officer
Solange Peters, Lausanne, Switzerland

Local Officer
Miguel Martin, Madrid, Spain

Scientific Committee

Basic science
Chairs: Anton Berns, Amsterdam, Netherlands and
Christof von Kalle, Heidelberg, Germany
Alberto Bardelli, Candiolo, Italy
Raffaele Califano, Manchester, UK
Karin de Visser, Amsterdam, Netherlands
Kristian Helin, Copenhagen, Denmark
David Huntsman, Vancouver, BC, Canada
Clare Isacke, Cambridge, UK
Richard Marais, Manchester, UK
Ultan McDermott, Cambridge, UK
Pier Guiseppe Pelicci, Milan, Italy
David Tuveson, Cold Spring Harbor, NY, USA

Breast cancer, metastatic
Chair: Fabrice André, Villejuif, France
Joan Albanell, Barcelona, Spain
Thomas Bachelot, Lyon, France
Fatima Cardoso, Lisbon, Portugal
Rob Clarke, Philadelphia, PA, USA
Sherene Loi, Melbourne, Australia
Sibylle Loibl, Neu-Isenburg, Germany
Frederique Penault-Llorca, Clermont-Ferrand, France
Aleix Prat, Barcelona, Spain
Roman Rouzier, Paris, France
Peter Schmid, London, UK
Britta Weigelt, New York, NY, USA
Lucy Yates, Cambridge, UK

Breast cancer, early stage
Chair: Nadia Harbeck, Munich, Germany
Herve Bonnefoi, Bordeaux, France
Fatima Cardoso, Lisbon, Portugal
Marco Colleoni, Milan, Italy
Javier Cortes, Madrid, Spain
Carlos Caldas, Cambridge, UK
Carsten Denkert, Berlin, Germany
Angelo di Leo, Prato, Italy
Doug Easton, Cambridge, UK
Michael Gnant, Vienna, Austria
Jos Jonkers, Amsterdam, Netherlands
Olivia Pagani, Bellinzona, Switzerland
Elzbieta Senkus, Gdańsk, Poland
Andrew Tutt, London, UK

CNS tumours
Chair: Michael Weller, Zurich, Switzerland
Carmen Balaña, Barcelona, Spain
Alba Brandes, Bologna, Italy
Louis Chesler, London, UK
Pim French, Rotterdam, Netherlands
Emilie Le Rhun, Lille, France
Roger Henriksson, Stockholm, Sweden
Stefan Pfister, Hedielberg, Germany

Annals of Oncology 28 (Supplement 5): v1–v21, 2017
doi:10.1093/annonc/mdx361

BASIC SCIENCE

1O Wild-type KRAS mediates growth inhibition and resistance to MEK inhibitors through dimerization with mutant KRAS in lung adenocarcinoma

C. Ambrogio[1], J. Kohler[1], Z. Zhou[2], H. Wang[3], R. Paranal[1], M. Capelletti[1], C. Caffarra[1], S. Li[1], Q. Lv[3], D. Santamaria[4], K.D. Westover[2], P.A. Jänne[1]

[1]*Medical Oncology, Dana Farber Cancer Institute, Boston, MA, USA,* [2]*Biochemistry and Radiation Oncology, University of Texas Southwestern Medical Center, Dallas, TX, USA,* [3]*School of Life Science and Technology, Tongji University, Shanghai, China,* [4]*U1218, ACTION Laboratory, University of Bordeaux, INSERM, Pessac, France*

Background: Mutations in *KRAS* are the most frequent *RAS* alterations in human cancers and the prevalent driver event in lung adenocarcinoma (LUAD). There are no effective targeted therapies for KRAS-driven LUAD and chemotherapy remains the standard of care. Small-molecule inhibitors of the MAPK pathway, one of the prominent downstream KRAS mediators, show minimal clinical activity either as single agents or in combination with chemotherapy. Recently, wild-type KRAS ($KRAS^{WT}$) was shown to enhance tumor fitness in *KRAS* mutant AML and CRC cell lines while concomitantly increasing sensitivity to MEK inhibition. We hypothesized that dimerization between KRAS proteins could be a key regulator for lung adenocarcinoma biology and determinant of treatment response.

Methods: To study the role of wild-type *KRAS* in the context of KRAS-driven cancer cells, we used genetically inducible models of *KRAS* loss of heterozigosity (LOH). We developed an isogenic $KRAS^{MUT}$ inducible system that lacks endogenous *HRas/NRas* but harbors conditional CRE^{ERT2}-controlled $KRas^{lox}$ alleles. Furthermore, we reconstituted $KRAS^{WT}$ and dimerization-deficient $KRAS^{D154Q}$ in KRAS-driven murine and human LUAD cell lines lacking the wild-type *KRAS* allele and evaluated the *in vitro* and *in vivo* impact on tumor progression and response to MEK inhibition.

Results: $KRAS^{WT}$ decreased *in vitro* and *in vivo* fitness of human and murine *KRAS* mutant LUAD tumor cells. However, this phenotype was reverted upon MEK inhibition, with *KRAS* LOH cells being more sensitive than $KRAS^{WT}$ expressing cells. Interestingly, both effects were dependent on wild-type/mutant KRAS dimerization and not observed with the dimerization-deficient $KRAS^{D154Q}$. We provide a mechanistic model of the ambivalent function of $KRAS^{WT}$, linking its tumor suppressor function with increased MEK inhibitor resistance through dimerization with mutant KRAS.

Conclusions: • $KRAS^{WT}$ affects cellular fitness in KRAS-driven LUAD • $KRAS^{WT}$ impairs response to MEK inhibitors in KRAS-driven LUAD • $KRAS^{WT}$ inhibitory effect is dependent on dimerization with mutant KRAS • Impaired wild-type/mutant KRAS dimerization restores sensitivity to MEK inhibitors *in vivo*.

2O CDCP1 initiates tumorigenesis and cooperates with PTEN loss to promote senescence evasion and prostate cancer progression

A. Alajati[1], J. Chen[1], A. Alimonti[2]

[1]*Cancer, IOR - Institute of Oncology Research, Bellinzona, Switzerland,* [2]*Molecular Oncology, IOR/IOSI, Bellinzona, Switzerland*

Background: Elevated levels of CUB domain-containing protein 1 (CDCP1) have been reported to be associated with poor prognosis in several human malignancies, including prostate cancer. However, its oncogenic role remains unexploited. Taking an advantage of multiple cross species genetic models, we demonstrate that CDCP1 *per se* is an oncogene. Particularly in mice, overexpression of CDCP1 in prostatic epithelial cells initiates hyperplasia, which eventually develops high-grade prostatic intraepithelial neoplasia. The functional importance of CDCP1 in tumuorigenesis was further fortified based on the evident display of invasive and metastatic prostate tumors upon its overexpression concomitantly with loss of *Pten* in mouse prostates. Mechanistically, we demonstrate that CDCP1 leads to the activation of SRC that further enhances the level of the transcription factor c-Myc *in vivo*. In turn, enhanced Myc triggers transcriptional activation of *Cyclin D1* and *COUP transcription factor II (COUPTF-II)* that bypasses the TGF-β-dependent checkpoint and senescence barrier driven by *Pten*-loss. Following on, we demonstrate that targeting CDCP1 antagonizes *c-Myc* expression to block tumourigenesis by reactivating cellular senescence in human prostate cancer cells.

Methods: CDCP1, transgenic mouse model, PTEN, prostate cancer.

Results: -Conditional overexpression of CDCP1 promotes tumourigenesis in different transgenic model systems -CDCP1 cooperates with *Pten*-loss in driving full malignant prostate tumourigenesis -Overexpression of CDCP1 overcomes *Pten*- loss induced cellular senescence by activating Myc-Targeting CDCP1 induces cellular senescence and growth arrest by downregulating Myc.

Conclusions: In sum, our findings highlight a crucial role for CDCP1 in 1) driving tumourigeneis in several transgenic models and 2) inducing full malignant progression of *Pten*-null prostate tumourigenesis by eliciting an oncogenic and tumour suppressive network that results in senescence evasion and metastasis. As CDCP1 is a cell surface protein which can be targeted by currently available monoclonal antibodies, our study also put forth a novel therapeutic strategy to target SRC and MYC tumours in metastatic human prostate cancer.

3PD New targets in triple negative breast cancer: Role of oncostatin M receptor pathway

M. Muñoz Caffarel[1], A. Araujo[1], C. Lawrie[1], I. Álvarez López[2], R. Rezola[3], A. Abaurrea[1]

[1]*Oncologia, Asociación Instituto Biodonostia, San Sebastian, Spain,* [2]*Medical Oncology, Hospital Universitario Donostia, Donostia, Spain,* [3]*Department of Pathology and Anatomy, Onkologikoa, San Sebastian, Spain*

Background: Triple Negative (TN) breast tumours have poor prognosis, lack of targeted therapies and are often refractory to conventional chemotherapy treatments. Therefore, finding new therapeutic targets for those tumours is an unmet need with high clinical impact. In this context, Oncostatin M receptor (OSMR) is a promising therapeutic target as it is over-expressed in this tumour subtype and its activation promotes invasiveness[1,2]. We previously showed that OSMR is frequently copy-number gained and over-expressed in squamous cell carcinoma, where it induces migration, invasion and metastasis[3,4,5]. We now investigate the role of OSMR in breast cancer progression. 1. Guo L, *et al.* (2013) *Oncogene* 32: 5272–5282. 2. West NR, *et al.* (2014) *Oncogene* 33: 1485-1494 3. Caffarel MM, Coleman N. (2014) *Journal of Pathology* 232:386-90 4. Caffarel MM, *et al* (2013) *Journal of Pathology* 231:168-79 5. Kucia-Tran, *et al.* (2016) *Brit J Cancer* 115:212-222.

Methods: To address this issue we use a wide array of tools including *in vitro* cell cultures and *in vivo* models. The expression of OSMR pathway was analysed in FFPE samples and large datasets of publicly available breast cancer samples (METABRIC, n = 1462; and TCGA, n = 547).

Results: OSMR and its ligand Oncostatin M (OSM) are over-expressed in basal tumours, where they associate with shorter overall survival ($p = 0.015$). While OSMR is expressed by breast cancer cells, the main source of OSM seems to be the tumour stroma, primarily cancer associated macrophages and fibroblasts. OSM treatment of breast cancer cells induces the expression of important mediators of angiogenesis and invasion. Importantly, OSMR activation accelerates tumour onset, tumour growth and metastasis in orthotopic xenografts in nude mice.

Conclusions: Our results support that OSMR pathway may have an important role in the initiation and progression of breast cancer and that it could be a promising candidate for therapeutic targeting in Triple Negative Breast Cancer. OSMR could be blocked by antibody based inhibition, strategy that has had a major impact on breast cancer.

4PD GGNBP2 suppresses tumor growth and cancer stem cell load of triple negative breast cancer by controlling STAT3 pathway

J. Zhang

The 3rd Department of Breast Cancer, Tianjin Medical University Cancer Institute & Hospital, Tianjin, China

Background: Gametogenetin binding protein 2 (GGNBP2) is encoded in human chromosome 17q12-q23, a region known as a breast and ovarian cancer susceptibility locus. GGNBP2 has a single C2H2 zinc finger and a consensus LxxLL nuclear receptor (NR) binding motif. We have reported that GGNBP2 suppresses ERα-positive breast tumorigenesis by acting as a nuclear receptor co-repressor to restrain ERα activity.

However, the detailed molecular mechanisms of GGNBP2 and its role in triple negative breast cancer (TNBC) remain largely unclear.

Methods: A human breast cancer tissue array containing 138 human breast tumor tissues were utilized to examine *GGNBP2* expression in breast cancer samples by IHC. To address the potential anti-breast tumor activity of GGNBP2 *in vitro*, we expressed exogenous *GGNBP2* in TNBC cells, including MDA-MB-231 and Cal51 cell lines. Cell proliferation and cell cycle were assessed by cell growth curve/EdU assays and flow cytometry after propidium Iodide staining. Apoptosis was determined by flow cytometry after annexin V staining, by caspase 3/7 and caspase 9 activity assays. Cancer stem cell properties were determined by expression of CD44/CD24/ALDH1 markers. The levels of phosphorylated STAT3 and total STAT3 were determined by western blot. Quantitative PCR and Western blot were carried out to evaluate the effects of GGNBP2 overexpression on STAT3 target genes, CCND1, Mcl-1, survivin, bax and bim expression.

Results: GGNBP2 expression is down-regulated in TNBC cells and patient tumors and it is associated with poor patient survival. Overexpression of GGNBP2 significanly induces cell cycle G0/G1 phase arrest and apoptosis in TNBC cell lines. Expression of cancer stem cell markers also decreased in GGNBP2-overexpressed TNBC cells. GGNBP2 reduces the expression levels of CCND1, Mcl-1 and survivin, promotes the expression levels of bax and bim proteins. Importantly, overexpression of GGNBP2 inhibits STAT3 phosphorylation and STAT3 downstream garget gene expression, including CCND1, Mcl-1 and survivin.

Conclusions: GGNBP2 serves as a critical nuclear negative regulator of STAT3-mediated gene expression and tumorigenesis.

5PD The acquired resistance to the combination of the anti-EGFR cetuximab and the MEK-inhibitor refametinib in KRAS mutated colorectal cancer cell lines depends on PI3K-signalling

P.P. Vitiello[1], G. Martini[1], C. Cardone[1], D. Ciardiello[1], V. Belli[1], N. Matrone[1], T. Troiani[1], S. Napolitano[1], V. Sforza[1], G. Papaccio[2], V. Desiderio[2], V. De Falco[1], E. Giunta[1], F. Morgillo[1], M.R. Diadema[1], P. Vitale[1], N. Zanaletti[1], F. Ciardiello[1], E. Martinelli[1]

[1]Clinical and Experimental Medicine "F. Magrassi", University of Campania "Luigi Vanvitelli", Naples, Italy, [2]Experimental Medicine, University of Campania "Luigi Vanvitelli", Naples, Italy

Background: Previous studies showed that the combination of an anti-epidermal growth factor (EGFR) and a selective MEK-inhibitor displays a significant anti-tumour activity in RAS-wild type colorectal cancers (CRCs), while the same combination partially reverts anti-EGFR primary resistance in KRAS mutated colorectal cancer cell lines. However, mechanisms of resistance to this combination are still unexplored.

Methods: We generated KRAS mutated CRC cell lines (HCT15 and HCT116) resistant to a combination of cetuximab (an anti-EGFR antibody) and BAY86-9766 (refametinib, a selective MEK1/2-inhibitor) after continuous exposure to increasing concentration of the drugs for 8 months. Resistant clones had an IC_{50} 20-100-fold higher than the parental cells. We evaluated by Western Blot (WB) analysis and quantitative Reverse Transcriptase Polymerase Chain Reaction (qRT-PCR) the expression and activation status of a panel of receptor tyrosine kinases (RTKs) and intracellular transducers. We further analysed by MTT assay the sensitivity of these cetuximab-MEKi resistant (CM-res) cell lines to GDC-0941 (pictilisib, a selective PI3Kα inhibitor) and afatinib (BIBW 2992, an irreversible pan-HER inhibitor) either used alone or in combination.

Results: We found consistent hyperactivation of the PI3K-AKT pathway and concurrent inactivation of the MAPK pathway, coupled to the activation of multiple RTKs of the HER family such as HER2 and HER3 in resistant cells when compared to parental cells. Treatment with GDC-0941 was able to partially restore the sensitivity to the drug combination, suggesting a central role for this pathway in mediating resistance in this setting, while afatinib was not capable of reverting the resistant phenotype when used alone but showed synergistic activity when combined to GDC-0941.

Conclusions: These preliminary results suggest that PI3K activation plays a central role in the acquired resistance to the combination of anti-EGFR and MEK-i. PI3K activation depends at least in part by the activation of the HER family of RTK, but it can also be activated by other receptors. In vivo experiments on mice are currently ongoing.

6PD FPA150, a novel B7-H4 therapeutic antibody with checkpoint blockade and ADCC activities

C.D. Kaplan[1], D. Houser[1], F. Kemp[2], N. Nielson[3], A. Hsu[4], K. Legris[5], G. Brattich[6], H. Xiang[7], A. Ahene[4], U. Jeffry[8], D. Bellovin[2], L. Borges[1]

[1]Immuno-Oncology Research, Five Prime Therapeutics, San Francisco, CA, USA, [2]Pharmacology, Five Prime Therapeutics, San Francisco, CA, USA, [3]Flow Cytometry, Adimab, Lebanon, NH, USA, [4]Bioanalytics, Five Prime Therapeutics, San Francisco, CA, USA, [5]Molecular Biology, Five Prime Therapeutics, San Francisco, CA, USA, [6]Protein Chemistry, Five Prime Therapeutics, San Francisco, CA, USA, [7]Clinical Pharmacology, Five Prime Therapeutics, San Francisco, CA, USA, [8]Toxicology, Five Prime Therapeutics, San Francisco, CA, USA

Background: B7-H4, a member of the B7 family of immune modulators, negatively regulates both T cell immune responses and anti-tumor immunity. While B7-H4 is highly expressed in a range of solid tumors, expression in heathy tissues is limited. Hence, we sought to generate a therapeutic antibody that both blocks the T cell inhibitory checkpoint activity of B7-H4 and mediates potent antibody-dependent cell-mediated cytotoxicity (ADCC) against B7-H4-expressing tumor cells.

Methods: Fully human B7-H4 antibodies raised by screening Adimab's yeast-based platform were evaluated for protein and cell binding, epitope specificity, and species cross-reactivity. We assessed these B7-H4 antibodies for checkpoint blockade activity using our proprietary in vitro assay, comprised of primary human T cells and B7-H4-expressing artificial antigen presenting cells. We used primary human cell-based and reporter cell line-based assays to assess the in vitro ADCC activity of B7-H4 antibodies against B7-H4-expressing target cell lines. We assessed the in vivo anti-tumor efficacy of our lead B7-H4 antibody in mice bearing syngeneic tumor cell lines engineered to display mouse B7-H4.

Results: After generating a panel of B7-H4 antibodies, we found that 12 out of 41 antibodies reverse B7-H4-mediated inhibition of T cell proliferation and IFNg production in vitro. Importantly, 11 of these antibodies with checkpoint blockade activity belong to the same epitope bin, recognize the B7-H4 IgV domain, and fully cross-react with cynomolgus monkey and rodent B7-H4, suggesting that these antibodies bind and block an evolutionarily conserved functional domain. When glycoengineered for enhanced FcgRIIIa binding, selected checkpoint blockade antibodies also mediate potent ADCC activity against cells exhibiting a range of B7-H4 expression. In a murine tumor model expressing B7-H4, our selected therapeutic candidate FPA150 significantly impairs tumor growth in a dose-dependent manner.

Conclusions: We generated a therapeutic candidate B7-H4 antibody, FPA150, which possesses both T cell immune checkpoint blockade and ADCC activity. We initiated IND-enabling studies and plan to file an IND application by the end of 2017.

7P GSKJ4, an H3K27me3 demethylase inhibitor, effectively suppresses the breast cancer stem cells

N. Yan[1], Y. Cao[2], F. Zhang[1,3], L. Xu[2]

[1]Department of Oncology, Ruijin Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China, [2]Prevention and Cure Center of Breast Disease, Third Hospital of Nanchang, Nanchang, China, [3]Department of Oncology, Suzhou Kowloon Hospital, Shanghai Jiaotong University School of Medicine, Suzhou, China

Background: Breast cancer stem cells (BCSCs) are responsible for breast cancer metastasis and treatment failure. Hence, eliminating BCSCs poses possibility to eradicate breast cancer. Recently, studies have been suggested that H3K27me3 is implicated in maintenance of cancer stem cells (CSCs), however, the roles of H3K27me3 in BCSCs remain poorly investigated. Hence, we aimed to explore the functionality of H3K27me3 in BCSCs.

Methods: Here, we firstly determined the global level of H3K27me3 in mammosphere-derived cells. Then, we detected the effect of GSKJ4 in cell viability through CCK8 assay. Next, we tested the impact of GSKJ4 on BCSCs expansions with CD44+CD24- phenotype and ALDH1-positive via flowcytometry. In addition, the impact on self-renewal capacity of BCSCs were also asked using mammosphere formation assay and colony formation assay. Further, western blot and Q-PCR were conducted to explore the effect of GSKJ4 in the expression level of stemness-related markers. Finally, we determined the influence of GSKJ4 on tumorigenicity using a xenograft model and investigated the underlying mechanisms.

Results: We identify H3K27me3 as a negative modulator of stemness of BCSCs and suggest GSKJ4 is a promising drug targeting BCSCs. we show that the H3K27me3 level is decreased in mammosphere-derived BCSCs. In breast cancer cells, we demonstrate that GSKJ4 could markedly inhibit the proliferation. Strikingly, we show that GSKJ4 could effectively suppress BCSCs including its expansion, self-renewal capacity, and the expression of stemness-related markers. Additionally, our xenograft model confirms that GSKJ4 is able to effectively inhibit the tumorigenicity of MDA-MB-231. Mechanistically, the inhibition effect of GSKJ4 in BCSCs is via inhibiting JMJD3 and UTX thus causing increment of H3K27me3 level, which results in suppressing stemness factors including NANOG, SOX2 and OCT4.

Conclusions: Our results provide strong supports that epigenetic modification is associated with maintenance of properties of BCSCs and reveal that GSKJ4 is capable to be a prospective agent targeting BCSCs.

8P The impact of rotenone-modulated oxidative stress on the survival of human breast cancer stem cells (CD24-/CD44+)

S.I. Wanandi[1], R.A. Syahrani[2], S.W.A. Jusman[1]

[1]Biochemistry and Molecular Biology, Faculty of Medicine, Universitas Indonesia, Jakarta, Indonesia, [2]Master Program in Biomedical Sciences, Faculty of Medicine, Universitas Indonesia, Jakarta, Indonesia

Background: Cancer stem cells (CSCs) have been proven to be tumorigenic and may be responsible for the resistance to chemo-radiation therapy, disease recurrence and metastasis. Chemo-radiation therapy modulates oxidative stress in cancer cells, leading to cellular adaption response including modulation of cell survival and antioxidant defense mechanisms. However, the redox status alteration of breast CSCs is not yet clearly understood. The aim of this study was to elaborate the impact of rotenone-modulated oxidative stress on the survival of human breast CSCs (CD24-/CD44+) which might be beneficial to understand the underlying mechanism of chemo-radiation therapy resistance.

Methods: Human breast CSCs (CD24-/CD44+) and non-CSCs (CD24-/CD44-) were treated with rotenone and DMSO (vehicle) for 6 hours, respectively. The effects of rotenone on oxidative stress were assessed by analysing intracellular reactive oxygen species (ROS) level using dihydroethidium assay, as well as mRNA expression and specific activity of MnSOD antioxidant. Finally, cell survival was determined using MTS assay, as well as through analysis of survivin mRNA expression.

Results: Our results showed that rotenone could not modulate the superoxide level of human breast CSCs (CD24-/CD44+), in contrast to that of non-CSCs (CD24-/CD44-). Albeit MnSOD synthesis in human breast CSCs has been excessively enhanced following rotenone treatment, the enzyme activity was still lower than in non-CSCs. Importantly, the cell viability of CSCs was higher than that of non-CSCs, which related to the increase of survivin.

Conclusions: We conclude that human breast CSCs (CD24-/CD44+) could survive better than their counterpart non-CSCs (CD24-/CD44-) when treated with rotenone. This impact might be associated with the increase of antioxidant MnSOD expression and survivin mRNA expression.

9P Kynurenine-3-monooxygenase (KMO) protein promotes triple negative breast cancer progression

C-Y. Liu[1], T-T. Huang[1], C-H. Lee[1], W-L. Wang[1], H-C. Lee[2], L-M. Tseng[3]

[1]Oncology, Taipei Veterans General Hospital, Taipei, Taiwan, [2]Department and Institute of Pharmacology, National Yang-Ming University, Taipei, Taiwan, [3]Surgery, Taipei Veterans General Hospital, Taipei, Taiwan

Background: Triple-negative breast cancer (TNBC) remains a difficult-to-treat cancer and the biology beneath TNBC is a research interest. Tryptophan-kynurenine metabolism plays an important role in epithelial-mesenchymal transition (EMT), cancer stem cells (CSCs) and immune escape. Previous studies have focused on the expression and function of the first step and the rate-limiting enzyme in tumor cells, whereas the second step catabolic enzyme kynurenine 3-monooxygenase (KMO) was rarely addressed in tumorigenesis. Hence, we sought to investigate of the mechanism and functions of KMO in TNBC carcinogenesis.

Methods: KMO gene alteration and mRNA transcripts were analyzed from the The Cancer Genome Atlas (TCGA) database. MDA-MB-231 and MDA-MB-468 TNBC cell lines were used for *in vitro* studies. Cell proliferation, colony formation, transwell migration/invasion assays and tumorsphere forming ability were used for functional study. Signal transduction pathways were assessed by Western blot, quantitative real-time PCR and reporter assays. The effect of KMO on tumor growth was tested in nude mice with breast cancer xenografts.

Results: TCGA analysis showed high-frequency of KMO amplification alterations, which was related to poor overall survival in breast cancers. KMO transcripts were up-regulated in the tumor tissues of breast cancers, especially in TNBC. The functional assays showed that ectopic KMO expression promoted tumorigenesis, including cell growth and abilities of colony formation, migration, invasion, and tumorsphere formation. Moreover, western blot analysis revealed expressions of epithelial marker E-cadherin were decreased and mesenchymal markers N-cadherin, and Twist were increased by KMO overexpression in MDA-MB-468 cells. Interestingly, the mRNA and protein levels of pluripotency genes including CD44, Nanog, Oct4, and SOX-2 were also suppressed by KMO knockdown. Data of reporter gene assay showed that the activities of Nanog, Oct4, and SOX-2 promoters were enhanced by KMO overexpression. Furthermore, knockdown KMO decreased the xenografted tumor growth of MDA-MB-468 cells, suggesting its oncogenic role in TNBC.

Conclusions: Our data highlight the novel and critical roles of KMO in TNBC progression and metastasis.

10P PIM1 kinase promotes cell migration via SHP2 in triple-negative breast cancer

F. Braso Maristany[1], J. Quist[1], C. Wells[2], A. Grigoriadis[1], P. Marra[1], A. Tutt[1]

[1]Breast Cancer Now Research Unit, Division of Cancer Studies, King's College London, London, UK, [2]Cancer Cell Biology & Imaging, Division of Cancer Studies, King's College London, London, UK

Background: Triple-negative breast cancers (TNBCs) are aggressive and associated with poor prognosis. We have recently demonstrated that PIM1 regulates cell death, tumour growth and chemotherapy response in TNBC. This study aims to further explore the molecular mechanisms by which PIM1 promotes malignant phenotypes in TNBC, in particular cell migration.

Methods: The HumanHT-12 v4 expression array was used to interrogate changes in gene expression upon PIM1 knockdown in TNBC cell lines. Transwell migration assays and time-lapse live-cell imaging were used to study the role of PIM1 in cell migration. To assess the morphology of TNBC cells we stained F-actin with 488-phalloidin. Phospho-kinase arrays were used to elucidate the pathway by which PIM1 may control cell migration.

Results: Gene expression analysis revealed PTPN11 as the most downregulated gene upon PIM1 knockdown in TNBC cell lines. These results were validated by qRTPCR in 3 TNBC cell lines. PTPN11 encodes for the phosphatase SHP2, known to be relevant for the migration of TNBC cells. We therefore studied whether PIM1 was also required for this phenotype in TNBC cell lines. PIM1 knockdown led to a defect on 2D-transwell migration in MDA-MB-231 and SUM159 cells, similar to that observed upon SHP2 knockdown. Interestingly, SHP2 knockdown did not affect short-term cell population growth of TNBC cells, suggesting that PIM1 exerts its role in cell population growth via different mechanisms, as demonstrated previously. Upon PIM1 knockdown, MDA-MB-231 showed lower motility persistence, increased circularity and a reduction of F-actin filaments. To understand the common downstream targets of PIM1 and SHP2 and elucidate the pathway by which PIM1 may control cell migration, we used phospho-kinase arrays. These revealed decreased phosphorylation of PLCg1, FAK and PYK2, proteins involved in cell migration, upon either PIM1 or SHP2 knockdown.

Conclusions: These data suggest that PIM1 regulates cell migration by controlling *PTPN11*/SHP2 expression and provide further evidence for PIM1 as a target for TNBC therapy, not only to induce apoptosis and prevent tumour growth, but also to prevent TNBC migration.

11P SHP-1 agonist SC-43 enhanced the anti-tumor effect of docetaxel through suppressing p-STAT3 in triple negative breast cancer cells

K-F. Chen[1], C-Y. Liu[2], T-I. Chao[1], P-Y. Chu[3], T-T. Huang[2], W-L. Wang[2], C-H. Lee[2], K-Y. Lau[2], W-C. Tsao[2], C-W. Shiau[4], L-M. Tseng[5]

[1]Medical Research, National Taiwan University Hospital, Taipei, Taiwan, [2]Oncology, Taipei Veterans General Hospital, Taipei, Taiwan, [3]Pathology, Show Chwan Memorial Hospital, Changhua City, Taiwan, [4]Biopharmaceutical Sciences, National Yang-Ming University, Taipei, Taiwan, [5]Surgery, Taipei Veterans General Hospital, Taipei, Taiwan

Background: Triple negative breast cancer (TNBC) is an aggressive cancer and its prognosis remains poor. Combinational therapies are a promising strategy for enhancing treatment efficacy. Blockade of STAT3 signaling have been shown to enhance the response of cancer cells to conventional chemotherapeutic agents. Here we used a SHP-1 agonist SC-43 to dephosphorylate STAT3, thereby suppressing oncogenic STAT3 signaling, and tested it in combination with docetaxel in TNBC cells.

Methods: TNBC cell lines (HCC-1937, MDA-MB-468, MDA-MB-231) were used for in vitro studies. Cell viability was examined by MTT assay. Combination index was determined using Calcusyn anaysis. Apoptosis was examined by flow cytometry and western blot. Signal transduction pathways in cells were assessed by western blot. In vivo efficacy of SC-43 in combination with docetaxel was tested in nude mice with breast cancer xenografts.

Results: To exam expression of SHP-1 in clinical samples, we analyzed mRNA expression of SHP-1 gene (ptpn6) in a public TNBC dataset (The Cancer Genome Atlas, TCGA). We found that higher SHP-1 mRNA expression is associated with better overall survival in TNBC patients. Sequential combination of docetaxel and SC-43 in vitroshowed enhanced anti-proliferation and apoptosis associated with decreased p-STAT3 and decreased STAT3-downstream effector cyclin D1 in the TNBC cell lines MDA-MB-231, MDA-MB-468 and HCC-1937. Ectopic expression of STAT3 reduced

theincreased cytotoxicity induced by the combination therapy. In addition, this sequential combination showed enhanced SHP-1 activity compared to SC-43 alone. Furthermore, siRNA against SHP-1 reduced apoptosis induced by the combination treatment. Moreover, by ectopic expression of SHP-1 mutants that caused SC-43 to lose its SHP-1 agonist capability, the SC-43-induced p-STAT3 signaling inhibition was reduced in the cells subjected to the combination treatment, suggesting SHP-1 plays a crucial role in docetaxel-SC-43-mediated TNBC cell apoptosis, Importantly, combination of docetaxel and SC-43 showed enhanced anti-tumor growth compared to single-agent therapy in MDA-MB-231 xenografted tumor mice.

Conclusions: SHP-1 agonist SC-43 enhanced the anti-tumor effect of docetaxel by SHP-1 dependent STAT3 inhibition in human TNBC cells. We suggest a therapeutic potential of SHP-1 agonist in combination with docetaxel for TNBC.

12P Delineating the mechanisms of resistance to panHER inhibitors in HER2+ breast cancer cells

O. Kutuk[1], H. Basaga[2], Y. Ozmay[1], B. Karakas[2]

[1]Department of Medical Genetics, Baskent University Faculty of Medicine Adana Uygulama Ve Arastirma Mer., Adana, Turkey, [2]Molecular Biology, Genetics and Bioengineering Program, Sabanci University, Istanbul, Turkey

Background: Despite the increase in patient survival rates promoted by increased screening and prevention efforts, much faster tumor genome sequencing and developed smart targeted therapies, de novo or acquired chemoresistance remains to be a significant factor for treatment failure in breast cancer therapeutics. Conventional chemotherapy, radiotherapy as well as targeted therapies activate mitochondrial cell death machinery to eliminate cancer cells. BCL-2 protein family members regulate mitochondrial cell death pathway by controlling mitochondrial outer membrane permeabilization. Neratinib and dacomitinib are potent and irreversible pan-EGFR inhibitors, which block their autophosphorylation and downstream signaling. Moreover, neratinib and dacomitinib have been shown to activate cell death in HER2-overexpressing cell lines. The aim of our study was to identify molecular pathways responsible for panHER2 inhibitor resistance in HER2+ breast cancer cells.

Methods: The expression of EGFR and BCL-2 protein family members was determined by immunoblotting and qPCR. CellTiter-Glo was used to measure cell viability and AnnexinV/PI staining and flow cytometer was used to evaluate apoptotic response. BH3 profiling was used to determine the apoptotic blocks and mitochondrial cell death priming in breast cancer cells.

Results: Here we showed that increased MCL-1 and decreased BIM mediate resistance to neratinib in ZR-75-30 and SKBR3 cells while increased BCL-XL and BCL-2 and decreased BIM promoted neratinib resistance in BT474 cells. Cells were also cross-resistant to dacomitinib. BH3 profiles of HER2+ breast cancer cells efficiently predicted anti-apoptotic protein dependence and development of resistance to panHER2 inhibitors. Adding specific ERK1/2 inhibitor SCH772984 to neratinib or dacomitinib led to increased apoptotic response in SKBR3 and ZR-75-30 cells, but we did not detect a similar response in BT-474 cells. Reactivation of ERK1/2 was primarily responsible for acquired resistance in SKBR3 and ZR-75-30 cells. Intriguingly, both ERK1/2 and Akt/NFkappaB pathways were responsible for neratinib resistance in BT474 cells.

Conclusions: Our results showed that different mitochondrial apoptotic blocks mediated acquired panHER2 resistance in HER2+ breast cancer cell lines as well as highlighted the potential of BH3 profiling assay in prediction of panHER2 resistance in breast cancer cells.

13P AXL as a potential primary and secondary trastuzumab resistance mechanism in breast cancer cells with HER2 overexpression

J.M. Cejalvo[1], E. Tormo[1], A. Adam[1], F. Rojo[2], B. Pineda[1], S. Zazo[2], P. Gonzalez-Alonso[2], M. Sabbaghi[3], E. Alonso[1], A. Rovira[3], J. Albanell[3], B. Bermejo De Las Heras[1], O. Burgues[4], A. Lluch[1], J.A. Perez Fidalgo[1], P. Eroles[1]

[1]Oncology, Hospital Clinico Universitario de Valencia, Valencia, Spain, [2]Cancer Institute, University Hospital "Fundacion Jimenez Diaz", Madrid, Spain, [3]Medical Oncology Department, Hospital del Mar, Pompeu Fabra University, Barcelona, Spain, [4]Pathological anatomy, Hospital Clínico Universitario de Valencia, Valencia, Spain

Background: Breast cancer (BC) is a heterogeneous disease, HER2+ represents between 15-30% of all subtypes. Trastuzumab (T), a monoclonal antibody able to inhibit HER2 activation, has been successfully employed in HER2 amplified tumors both in adjuvant and in metastatic settings, conferring an improvement in DFS, PFS and OS. Despite these results, many patients experience primary or secondary resistance to therapy. The mechanism of resistance is unclear, our aim is to assess AXL, a receptor tyrosine kinases (RTK) implicated in epithelial-to-mesenchymal transition, as potential mechanisms of resistance.

Methods: We used two cell lines to investigate possible mechanisms of primary and secondary resistance to T in HER2+ and hormone receptor negative BC. AU565 sensitive to T (AU565-S), and HCC1954 a primary T-resistant cell line. A third cell line with acquired resistance to T (AU565-R) was generated by treating AU565-S cells with constant dose of T (15mg/mL) for 4 months. Cell viability was estimated by MTT assay. We explored the expression of AXL by Western blot (WB) and quantitative reverse transcriptase PCR (qRT-PCR).

Results: The cell viability analysis at 7 days assay confirmed AU565-S as sensible to T, HCC1954 as primary resistant and the development of a secondary resistance to T (AU565-R) (50% of increased viability from AU565-S). HER2 overexpression in all three cells lines were confirmed by WB and FISH. qRT-PCR indicated an important up-regulation of AXL at mRNA levels in AU565-R and HCC1954 compared to AU565-S ($p < 0.05$). In the same line, WB analyses showed a significantly increase in AXL protein expression in AU565-R and HCC1954 (2.03 and 7.37 fold, respectively). Finally, a selective AXL inhibitor (TP-0903) has demonstrated reduction of viability in all cell lines and significant restoration of sensitivity to T in AU565-R ($p < 0.01$).

Conclusions: Our results suggest: 1) AXL could be a potential mechanism of both primary and secondary resistance to T; 2) combination therapy with AXL inhibitor plus T restored T sensitivity in in vitro model with AXL overexpressed. These results merit further study and to explore this RTK as possible therapeutic targets in case of anti-HER2 treatment failure.

14P Alterations to trastuzumab-induced antibody-dependent cell-mediated cytotoxicity (T-ADCC) in a lapatinib-resistant HER2+ breast cancer cell line model

N. Gaynor[1], M. Guibourdenche[1], B. Browne[1], L. O'Driscoll[2], N. O'Brien[3], N. O'Donovan[1], J. Crown[4], D. Collins[1]

[1]National Institute for Cellular Biotechnology, Dublin City University, Dublin, Ireland, [2]School of Pharmacy and Pharmaceutical Sciences, Panoz Institute & Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland, [3]Department of Medicine, Division of Hematology/Oncology, The University of California, Los Angeles, Los Angeles, CA, USA, [4]Dept of Medical Oncology, St Vincents University Hospital, Dublin, Ireland

Background: Lapatinib is a dual targeting (EGFR/HER2) small molecule tyrosine kinase inhibitor (TKI) approved for the treatment of HER2+ breast cancer. Lapatinib treatment can often lead to acquired resistance and refractory disease. There is no data available on the sensitivity of lapatinib-resistant breast cancer cells to immune cell-mediated cytotoxicity. To investigate the consequences of a lapatinib resistant phenotype on the immune response, we examined T-ADCC and the expression levels of immune-related proteins in a cell line model of lapatinib-resistant HER2+ breast cancer.

Methods: Lapatinib-resistant SKBR3 cells (SKBR3-Lap) were generated by continuous exposure to 250nM lapatinib for 6 months alongside untreated parental cells (SKBR3-Par). FACS-based assays employing peripheral blood mononuclear cells (PBMCs) isolated from healthy volunteers were used to measure direct PBMC-mediated cytotoxicity and T-ADCC. Comparative DNA microarray studies (SK-Par vs. SK-LAP) identified differentially expressed immune-related genes which were subsequently examined at the protein level by Western blot.

Results: T-ADCC was 45-50% lower in SKBR3-Lap compared to the SKBR3-Par cell line at the three effector to target cell ratios examined - 1:1 ($p = 0.01$), 5:1 ($p = 0.001$) and 10:1 ($p = 0.024$). Direct immune cell-mediated cytotoxicity was low (<7% at 10:1) for both cell lines. Microarray data identified significant alterations in the growth factor receptor EGFR, the immunosuppressive adenosine receptor A2AR and immune response modulating MHC Class I, HLA-E, and NKTR in SK-LAP compared to SK-Par. Western blots established changes to these targets at the protein level. In addition, protein levels of HER2 were not significantly reduced and programmed death ligand 1 (PD-L1) levels were increased ($p = 0.045$) in SKBR3-Lap.

Conclusions: Resistance to lapatinib is associated with an attenuated T- ADCC response and an altered profile of immune-related proteins in this HER2+ breast cancer model. Further investigation is warranted to explore if targeting proteins such as A2AR or PD-L1 could play a role in ADCC response in this model.

15P Estrogen-dependent breast cancer: The importance of androgen receptor in exemestane treatment

C. Amaral[1], T. Augusto[1], F. Roleira[2], E. Tavares-Da-Silva[2], G. Correia-Da-Silva[1], N. Teixeira[1]

[1]Laboratory of Biochemistry, Department of Biological Sciences, UCIBIO, REQUIMTE, Faculty of Pharmacy, University of Porto, Porto, Portugal, [2]Pharmaceutical Chemistry Group, Faculty of Pharmacy, University of Coimbra, Coimbra, Portugal

Background: Exemestane (Exe) is a third-generation steroidal aromatase inhibitor (AI) that is a standard therapeutic approach for post-menopausal women with estrogen-receptor positive (ER+) breast cancer. Besides its clinical benefit, acquired resistance may develop. Thus, to avoid this drawback it is urgent to find new targets that can improve breast cancer treatment. It is known that 85-95% of the ER+ breast cancers, overexpress androgen receptor (AR), that has a dual function in breast cancer depending on hormonal cell status. It has been described that in AIs-sensitive breast cancer cells this receptor promotes cell death. Several clinical trials are ongoing to study the efficacy of combining AR antagonists, as bicalutamide (CDX), with Exe, but the benefit of targeting AR is not well defined. In that way, this work will investigate the biological significance of AR in Exe-treated breast cancer cells and the effectiveness of targeting AR.

Methods: In ER+ breast cancer cells that overexpress aromatase (MCF-7aro), it was investigated the in vitro effects of the AR antagonist CDX in Exe-treated cells. The cell impact in viability and cell proliferation was studied using MTT assay and flow cytometry, respectively. The cell death was explored by evaluating caspase activities. The expression/activation of AR and the effects on PI3K and MAPK pathways were studied by Western-blot.

Results: Exe induces an overexpression and hyperactivation of AR in MCF-7aro cells. By blocking AR with CDX, it was observed an increase in the reduction of viability and proliferation of Exe-treated cells, when comparing to Exe alone. An increase in activation of caspases-9, -8 and -7 was also observed for the combination. In addition, CDX inhibits the Exe-induced activation of cell proliferation/survival MAPK pathway and caused no effect on PI3K pathway.

Conclusions: This study suggests that, contrary what is described for other AIs, the AR as a pro-survival role in sensitive breast cancer cells treated with Exe and that by targeting AR it is possible to improve the clinical efficacy of Exe, by inhibiting cell proliferation and inducing apoptosis. This work contributes to the understanding of the link between AR and Exe and will highlight new targets to improve breast cancer treatment.

16P Phosphatidylinositol 3-kinase (PI3Kα)/AKT axis blockade with taselisib or ipatasertib enhances the efficacy of anti-microtubule drugs in human breast cancer cells

A. Diana[1], F. Morgillo[1], C.M. Della Corte[1], C. Di Mauro[2], V. Ciaramella[1], G. Barra[3], V. Belli[1], E. Franzese[1], R. Bianco[2], E. Maiello[4], F. De Vita[1], F. Ciardiello[1], M. Orditura[1]

[1]Dipartimento Medico-Chirurgico di Internistica Clinica e Sperimentale "F. Magrassi e A. Lanzara", Università degli Studi della Campania "Luigi Vanvitelli", Naples, Italy, [2]Dipartimento di Medicina Clinica e Chirurgia, Università degli Studi di Napoli "Federico II", Naples, Italy, [3]Immunologia Clinica, Università degli Studi della Campania "Luigi Vanvitelli", Naples, Italy, [4]Oncologia, IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy

Background: The phosphatidylinositol 3-kinase (PI3Ks) pathway is commonly altered in breast cancer patients, but its role is still unclear. Taselisib, a mutant PI3Kα selective inhibitor, and ipatasertib, an AKT inhibitor, are currently under investigation in clinical trials in combination with paclitaxel or hormonal therapies in breast cancer. The aim of this study was to evaluate if PI3K or AKT inhibition can prevent resistance to chemotherapy and potentiate its efficacy.

Methods: The efficacy of combined treatment of ipatasertib and taselisib plus vinorelbine or paclitaxel or eribulin was evaluated in vitro on human breast cancer cells (with different expression profile of hormonal receptors, HER2, and of PI3Kα mutation) on cell survival by using MTT (3,(4,5-dimethylthiazol-2)2,5 difeniltetrazolium bromide) and on cell apoptosis by flow-cytometry analysis. We also investigated the effect of combined treatment on downstream intracellular signaling, by western blot analysis, and on metastatic properties, by migration assays. Finally, we analyzed changes in cell cytoskeleton by immunofluorescence.

Results: A significant synergism of ipatasertib or taselib plus anti-microtubule chemotherapy in terms of anti-proliferative, pro-apoptotic and anti-metastatic effect was observed. The combined treatment completely inhibited the activation of proteins downstream of PI3K and MAPK pathways and affected the expression of survivin. Combined treatments completely disorganized the cytoskeleton in human breast cancer cells, thus suggesting a potential mechanism for this combination.

Conclusions: Targeting PI3K may enhance the efficacy of anti-microtubule drugs in human breast cancer.

18P Potential miRNAs involved in molecular pathways mediating the anticancer effects of short term starvation in breast cancer cells treated with doxorubicin

D. Fanale, L. Incorvaia, R. Maragliano, N. Barraco, A. Listì, A. Galvano, S. Rizzo, V. Calò, V. Bazan, A. Russo

Department of Surgical, Oncological and Oral Sciences, Section of Medical Oncology, University of Palermo, Palermo, Italy

Background: In recent years, increasing evidences showed that several types of dietary approaches restricting food intake, including Short Term Starvation (STS), may exert a protective role against aging and other age-related pathologies as well as cancer. Interestingly, the dietary restriction showed significant anticancer effects able to prevent cancer onset, slow its progression and improve therapy response. Since recent studies showed that miRNAs may modulate sensibility/resistance to antiblastic therapy, the aim of our study was to investigate the STS-induced molecular changes in breast cancer cells treated with doxorubicin, focusing our attention on miRNA expression profile.

Methods: Vitality assays were used to assess the effects of STS on cell proliferation. Using a TaqMan Low Density Array A human microRNA microarray analysis, the expression profile of 377 miRNAs was analyzed in healthy and malignant breast cells, MCF10A and MDA-MB-231 respectively, treated for 24h with 1μM doxorubicin under STS conditions for 48h. In addition, the expression of mRNAs and miRNAs specifically induced by STS was analyzed in MCF-7, MDA-MB-231 and SkBr3 cells using Real-time PCR analyses.

Results: *In vitro* cell vitality assays showed that STS, in association with doxorubicin treatment, significantly reduces breast cancer cell proliferation and viability, whereas it appears to protect healthy breast cells from chemotherapeutic treatment. Microarray analysis showed that a subset of miRNAs involved in molecular pathways related to drug sensitivity/resistance was found to be differentially expressed in breast cancer cells following the doxorubicin treatment and STS. Finally, expression analysis of hypothetical miRNA gene targets involved in therapy response have confirmed the coherence of our results.

Conclusions: This work establishes, for the first time, an interesting link between anticancer effects of STS and miRNA expression changes in doxorubicin-treated breast cancer cells, suggesting the potential involvement of some miRNAs in molecular pathways mediating the effects of STS in breast cancer.

19P An endothelial premetastatic-like niche is promoted by tumor-secreted factors derived from highly metastatic breast cancer cells in vitro

M.A. Gallardo Vera, A. Zentella Dehesa

Medicina Genómica y Toxicología Ambiental, Instutito de Investigaciones Biomédicas/UNAM, Cd De MÉxico, Mexico

Background: It is well established that primary tumour can modify secondary organs long before the circulating tumor cells reach their metastatic targets. These modifications are mainly exerted through tumor-secreted factors and can act on several cell types to form what is called the pre-metastatic niche. Pre-metastatic endothelial niche play a key role in the extravasation process during metastasis. Here we describe the effect of the mixture of secreted factors by tumor cells over endothelial changes that facilitates tumor cell transendothelial migration.

Methods: Adhesion assay Human umbilical vein endothelial cells (HUVEC) cells were stimulated or not with TNF-α [10ng/ml] or Tumor Secreted Factors (TSFs) [10 μg/ml] from MDA-MB-231 or MCF-7 cell lines. HUVEC monolayers were co-cultured with a U937(^{3}H) cells. After 3h firm attached U937(^{3}H) were lysed and radioactivity was measured. Vascular permeability assay HUVEC monolayers were cultured in Boyden chambers. Cells were stimulated or not with TNF-α [10ng/ml] or TSFs [10 μg/ml] and incubated for 12h. Afterwards a dextran-FITC solution was added for 20 min and the bottom well fluorescence was quantified. Transendothelial migration assay HUVEC monolayers were cultured in Boyden chambers. Cells were stimulated or not with TNF-α [10ng/ml] or TSFs [10 μg/ml] and incubated for 10h. Fluorescent labeled MDA-MB-231 cell suspension 2x10^4 was added (24h) and the migrant cells were counted under an epifluorescence microscope.

Results: Adhesion assay revealed that HUVEC stimulated with MDA-231 TSFs attached U937 cells 6-fold comparing to the MCF-7 TSFs or control, in a similar way as

TNF-α did. The MDA-TSFs were able to increase the HUVEC monolayer permeability exceeded about 30% of the TNF-α induced permeability. A 1.5-fold increase of transendothelial migration cells was observed in HUVEC stimulated with MDA-MB-231 TSFs.

Conclusions: Tumor secreted factors derived from highly metastatic cell line MDA-MB-231 are capable to induce a premetastatic-like endothelial state, increasing the tumor cell transendothelial migration, adhesion to the HUVEC monolayer as well as vascular permeability enhancement.

20P Selective accumulation of the rat adherent natural killer cells in mammary tumor tissues

S. Gu

School of Rehabilitation Sciences, Seirei Christopher University, Hamamatsu, Japan

Background: In the present study, we attempted to clarify what kind of adhesion molecules and tumor cytotoxic killer activity A-NK cells can express, when cultured for long period in vitro, and then tried experimentally to augment the selective accumulation the A-NK cells into rat mammary tumors, in combination with the prior injection of various kinds of adjuvants into the tumor region. The mechanisms by which the effector cells accumulate in tumor tissue will be discussed.

Methods: 1. Animals: Specific pathogen-free (SPF) female rats. 2. Preparation of A-NK cells: A-NK cells were isolated from splenic lymphocytes. 3. Antibodies: Monoclonal antibodies, and Anti adhesion molecule antibodies. 4. Immunohistochemical staining and Flow cytometric analysis. 5. Preparation of mammary tumor bearing rats.

Results: Immunocytochemical and flow-cytometric analysis revealed that most of the A-NK cells strongly expressed lymphocyte-function-associated antigen 1 throughout the incubation. All A-NK cells from 8-150-day cultures, particularly those cultured for 8 days, showed significant cytolytic activity against all targets. Peritumoral injection of various kinds of adjuvant, particularly Freund's complete adjuvant plus bacillus Calmetee-Guerin, resulted in a marked accumulation of A-NK cells in mammary tumor tissues 24 h after injection, and simultaneously in the formation of vessels resembling high-endothelium venules, and expression of the ICAM-1 molecule on the tumor cells in the sites of tumor tissues. When A-NK cells were intravenously administered, significant retardation of tumor growth and prolongation of survival of tumor-bearing rats were observed in the groups that received the prior injection of adjuvants.

Conclusions: These results indicate that the prior injection of proper adjuvant into the peritumoral region is effective for the selective accumulation or infiltration of A-NK cells into the sites of tumor tissues, and results in the marked retardation of tumor growth.

21P Inhibition of nitric oxide synthase (NOS) reduces the effect of stress hormone signalling in breast cancer

R. Flaherty, B.A. Patel, M.C. Allen, M.S. Flint

Pharmacy and Biomolecular Sciences, University of Brighton-Moulsecoomb Campus, Brighton, UK

Background: Expression of nitric oxide synthase (NOS) has been found to correlate with tumour progression in breast cancer, indicating that NO activity may drive malignant growth. Previously we have shown that the stress hormone cortisol acts through a nitric oxide synthase (NOS) mediated pathway to induce production of nitric oxide (NO), and can induce DNA damage in breast cancer.

Methods: Breast cancer cell lines MCF-7 and MDA-MB-231 as well as the mouse mammary tumour cell line 66CL4 were exposed to cortisol and levels of intracellular NO were measured using composite electrochemical sensors. DNA damage was quantified using immunofluorescence and expression of iNOS and metastatic markers VEGF and TWIST were examined using qPCR. An *in vivo* syngeneic breast cancer model was also used to examine the effect of L-NAME, a NOS inhibitor, on tumour aggressiveness and metastasis in conjunction with daily restraint stress (2hrs) (n = 4/group, repeated in duplicate).

Results: Cortisol significantly increased the expression of iNOS, the generation of NO and DNA damage in breast cancer cells and this was blocked by the NOS inhibitor L-NAME. A significant increase in VEGF and TWIST expression was also observed in response to cortisol. Furthermore, L-NAME also significantly reduced primary tumour growth in stressed mice and reduced the number of metastatic sites/mouse. Tumour microvasculature (as evidenced by CD31 expression) was significantly increased in stressed mice and this was reduced with L-NAME treatment.

Conclusions: We demonstrated that L-NAME, through inhibition of NO signalling, is effective in reducing primary tumour formation and metastatic potential in stressed mice. This data may have impact for patients with breast cancer experiencing extreme stress and further genomic analysis are ongoing.

22P The interplay between TP53 and mevalonate pathway in ovarian cancer

M.I. Abdullah, M.N. Abed, A. Richardson

School of Pharmacy-ISTM, Keele University, Stoke on Trent, UK

Background: TP53 gene is the most commonly mutated tumour suppressor in human malignancies. TP53 is mutated in more than 50% of all human cancers, with over 96% of high-grade serous ovarian cancer displaying changes at this locus. Mutations of TP53 gene is associated with malignant transformation and resistance to chemotherapy. In addition, previous studies have shown that ectopic expression of TP53 mutant form in breast cancer cells leads to increased transcription of 3-hydroxy-3-methylglutaryl-coenzyme A reductase (HMGCR). This enzyme regulates the synthesis of geranylgeraniol which is used to post-translationally modify small GTPase oncogenes. HMGCR is itself considered to be a metabolic oncogene. Statins, which inhibit HMGCR, are potential cancer therapeutics which can cause ovarian cancer (OC) cell apoptosis and regression of xenografts.

Methods: The level of mevalonate pathway (MP) enzymes evaluated in panel of OC cell lines using immunoblotting. in addition, MP enzymes expression were evaluate using qPCR following ectopic expression of wild-type and R248W, R175H, and R273H p53 variants in Skov-3 cells and after inhibition of TP53 expression using siRNA directed to TP53 mRNA in Ovcar-3 cells.

Results: We confirmed that the expression of HMGCR is higher in OC cell lines than in normal epithelial ovarian cells. The level of geranylgeranyl transferase I-β (GGTI-β) and Geranylgeranyl transferase II-β (GGTII-β) was significantly higher in a subset of OC cell lines. The ectopic expression of TP53 variants in Skov-3 cells, which lack endogenous p53 protein, led to significantly increased expression of HMGCR, GGTI-β, GGTII-β and Farnesyltransferase-β (FT-β) enzymes compared to cells transfected with vector. The inhibition of the pre-existing mutations in TP53 encoding R248Q in Ovcar-3 cell line significantly decreased p53 protein and also HMGCR, GGTI-β, GGTII-β and FT-β mRNA.

Conclusions: These data suggest that TP53 mutations play critical role in regulation of the activity of MP enzymes, providing a rationale for the evaluation of the pathway inhibitors such as statins and bisphosphonates in the treatment of OC.

23P Epigenomic landscape of breast cancer in very young women

S. Sanchis[1], M.P. Chilet[1], M. Martinez[2], K. Flower[3], E. Alonso[2], O. Burgues[4], A. Lluch[5], J. Flanagan[3], G. Ribas[1]

[1]*Oncología Médica, INCLIVA Instituto de Investigación Sanitaria, Valencia, Spain,* [2]*Oncología Médica, Hospital Clínico Universitario de Valencia, Valencia, Spain,* [3]*Department of Surgery and Cancer, Imperial College London, London, UK,* [4]*Pathological Anatomy, Hospital Clínico Universitario de Valencia, Valencia, Spain,* [5]*Medical Oncology, Hospital Clinico Universitario de Valencia, Valencia, Spain*

Background: Although less frequent than in older women, breast cancer in very young women (BCVY) (≤35 years old) presents more aggressive and complex biological features. Epigenetic modifications such as miRNA regulation or DNA methylation are reported to play an important role in the onset and progression of cancer. The aim of this work is to identify the epigenetics mechanisms characteristics of BCVY that may be conferring more aggressive features to this group of patients.

Methods: We analysed methylation (Infinium MethylationEPIC BeadChip) from 26 BCVY and 15 samples from women >45 years old. Methylation differences were assessed using Wilcoxon rank sum test. We selected from The Cancer Genome Atlas (TCGA) those genes regulated by significantly different methylated sites and their expression was analysed. MiRNA expression data from TCGA, METABRIC and data previously published from our group was evaluated in a meta-analysis. We then selected those target genes which expression was more affected by miRNA deregulation. Pathway enrichment analysis was performed with most relevant genes from the epigenetic study by Enrichr.

Results: We detected a global hypomethylation profile in BCVY samples and hypermetilation of 502 specific CpG sites exclusive of this group of age. Hypomethylated CpG sites were regulating genes mainly involve in neuronal processes, extracellular matrix and cell communication. Whereas specific hypermethylation was located in genes related to immune system, NOTCH signalling, vesicular trafficking, DNA repair and senescence. MiRNA expression meta-analysis revealed a profile of 22 miRNAs significantly deregulated in BCVY. Pathway enrichment analysis of most affected target genes showed an involvement in neural processes, glucose metabolism, vesicular trafficking,

DNA repair, histone and chromatin related proteins, apoptosis, cell cycle, response to DNA damage and senescence.

Conclusions: Our work highlights the presence of epigenomic profile distinctive of BCVY. Both methylation and miRNAs studies points to deregulation of pathways related to neural processes, vesicular trafficking, DNA repair and senescence. All these processes may lead to cancer development and progression, thus genes in these pathways may be potential candidates for further studies.

24P Evaluation of cell free circulating DNA in plasma by digital PCR for early diagnosis in Peruvian breast cancer patients

A. Aguilar[1], A. Murillo[2], J. Ponce[3], J. Araujo[1], J. Pinto[1], C. Vigil[3], R. Fujita[2], J. Buleje[2]

[1]Unit of Basic and Traslational Research, Oncosalud SAC, Lima, Peru, [2]Facultad de Medicina, Universidad de San Martin De Porres, Lima, Peru, [3]Breast Unit, Oncosalud SAC, Lima, Peru

Background: New diagnostic tools can be useful and give clinical benefits, including diagnosis, prognosis, treatment and monitoring of the disease. A new non-invasive method is the study of liquid biopsies, performed in fluids containing cell-free circulating DNA (cfDNA). Analyses with digital PCR technique (dPCR) allows to establish the levels of cfDNA as well as the absolute quantification of mutant alleles with accuracy. This system scatters the sample among twenty thousand wells (microfluids on the chip), where amplification reactions occur independently and are recorded by a reader.

Methods: Peripheral blood samples were obtained from breast cancer patients and healthy controls. From each sample, the cfDNAs were extracted from plasma using the MagMAX™ Cell Free DNA Isolation Kit and dPCR was done for quantification of samples. We evaluated two genes, *PUM1* and *RNaseP*. For amplification of fragments, master mix 1X (Applied Biosystems) and PCR detection assays of both genes were combined with 1.5 µl of plasma cfDNA, dispersed in the chips and placed in a ProFlex ™ thermocycler (Applied Biosystems) following the program pre-established by the manufacturer, with additional five cycles. Finally, quantification data were obtained with QuantStudio® 3D AnalysisSuite™ Cloud Software. Comparison of DNA concentration in copies per microliter and other statistical calculations were performed with InfoStat 2015.

Results: Significant differences were found in the values of cfDNA between patients and controls for PUM1 ($p = 0.0001$) and RNase P ($p = 0.0003$). These results allowed to establish cut-off points between groups at 78,995 and 51,154 copies/uL, respectively. These values can be considered in the classification of groups for further analysis of others samples. Statistical support for the use of markers in diagnosis was also evaluated using the ROC curve that favors the PUM1 marker, with a sensitivity of 75% and a specificity of 95.2%.

Conclusions: Based on the significant differences found between breast cancer patients and controls, cell free DNA is a good biomarker that can be used in the diagnostic of breast cancer. On the other hand, digital PCR has been established as a good tool to check cfDNA levels from plasma of breast cancer patients.

25P Breast cancer predisposing germline mutations identified by exome sequencing

E.S. Kuligina[1], A.P. Sokolenko[1], I.V. Bizin[2], M.O. Anisimova[1], A.A. Romanko[1], E. Imyanitov[1]

[1]Department of Tumor Biology, NN Petrov Research Institute of Oncology, Saint Petersburg, Russian Federation, [2]Bioinformatics, St. Petersburg State Polytechnical University, Saint Petersburg, Russian Federation

Background: A significant portion of hereditary predisposition to breast cancer (BC) is attributed to yet unknown factors. Russian population is characterized by surprisingly strong founder effect, therefore whole exome sequencing (WES) for a limited number of these genetically homogenous patients has a potential to identify novel BC-predisposing genes.

Methods: WES was performed for 32 Russian BC cases, which demonstrated strong clinical signs of the hereditary disease (family history, BC bilaterality, young onset) and lacked germline mutations in "canonical" BC genes (*BRCA1, BRCA2, CHEK2, PALB2,* and *NBS1/NBN*).

Results: Eight patients carried potentially pathogenic mutations in BRCA1 network genes (3 truncations (*BLM p.Q548*, RAD51C c.904 + 1G>A, FANCM p.S497fs)* and 5 missense mutations (*FANCM (p.R100W, p.Q891P), ERCC4 p.R799W, RAD54L p.R394W, RAD50 p.D515G)).* The remaining 24 patients were analyzed for the presence of rare non-silent genetic variants; in total, 15437 alleles had ExAC frequency <1%. Use of ACMG-guided bioinformatic pipeline classified these variants for 64 'pathogenic/likely-pathogenic', 12844 of 'uncertain significance', and 2529 'benign/likely-benign'. Prevalence of 69 top candidates was compared in 640 genetically enriched BC patients, 1200 consecutive BC, 1200 middle-aged healthy females and 460 elderly healthy women. Several likely pathogenic mutations were overrepresented in the BC groups: nonsense *PZP p.R680** [9/1845, OR = 13.2]; heterozygous missense *LEPREL1 p.P636S* [6/1778; OR = 4.4] and *ING1 p.P319L* [3/1792; OR = 3.9]; homozygous missense *BRCA1 p.Q356R* [12/1683; OR = 5.5] and *EXO1 p.G759E* [9/1606, OR = 4.3]. Some potentially pathogenic variants occurred only in the index cases but were absent in other BC patients (rare ExAC alleles: *HELLS p.R53C* and *TP53INP1 p.E27D*; newly identified variations: *MLH3 p.C1393F*, *EMSY p.G934** and *ATRIP p.R760**).

Conclusions: This study revealed several alleles, which may be associated with increased BC predisposition. However, in contrast to well-known Slavic BRCA founder mutations, newly identified candidates are exceptionally rare and therefore are unlikely to be responsible for a significant share of BC morbidity. 26P Global transcriptome deregulation of breast cancer in very young women samples

V. Vidal Tomas[1], S. Sanchis[1], M. Martinez[2], E. Alonso[2], O. Burgues[3], A. Lluch[2], M.P. Chilet[1], G. Ribas[1]

[1]Medical Oncology, Biomedical Research Institute INCLIVA - University of Valencia, Valencia, Spain, [2]Medical Oncology, Hospital Clinico Universitario de Valencia, Valencia, Spain, [3]Pathological Anatomy, Hospital Clínico Universitario de Valencia, Valencia, Spain

Background: Breast cancer in young women (under 35 years) (BCVY) often presents distinct clinic-pathological features: more aggressive phenotype and worse prognosis than older women. Genomic and molecular alterations play a significant role in breast cancer biology. Due to the low incidence of BCVY (2-5%) these women are underrepresented in most molecular studies. This work presents a comprehensive study of the transcriptome in BCVY, focusing in the search of gene expression biomarkers characteristic of this group of patients.

Methods: We analysed the transcriptome by Clariom™ D (Affymetrix) from 31 BCVY and 11 samples from women >45 years old. Global gene expression was filtered and normalized by RMA method. After initial pre-processing we analysed expression in 3,639 mRNAs, 66,457 lncRNA and 3,271 pre-miRNA and differences were assessed using t-test. We performed a meta-analysis with gene expression data from The Cancer Genome Atlas (TCGA) for validation of results. Pathway enrichment analysis was performed by Enrichr.

Results: showed a specific transcriptomic landscape in BCVY. Clariom D study revealed 134 significant mRNA with p-value< 0.05 that pointed out towards pathways related with olfactory receptors, GPCR signalling, tight junction and cell-cell communication. After meta-analysis with TCGA gene expression data and own data, 43 genes were statistically significant and 15 of those withstood FDR correction (FDR< 0.05). Among those we found PIK3CB, HOXD10, ZNF654, TMEM204, IRX5, PF4, MAGEA2 and TSR2 deregulated in BCVY compared with older women. Pathway enrichment analyses and GO search highlight pathways related to cell-cell communication, cancer processes, chemokine and PI3K signalling pathways, cell differentiation, extracellular matrix, vesicular trafficking, neuronal processes among others.

Conclusions: We find the presence of a distinctive transcriptomic profile of the BCVY samples. Our study points to deregulation of pathways related to cell migration, proliferation and differentiation that promote cancer development and progression. Genes obtained in meta-analyse might be potential target genes for further studies in BCVY which could help to clarify the biological background for the development of the disease in this group of age.

27P Integrated system-level analyses of androgen receptor variant networks to identify novel prostate cancer-relevant genes that serve as prognostic biomarkers

F. Magani, E. Bray, S. Peacock, N. Zhao, K. Burnstein

Molecular and Cellular Pharmacology, University of Miami Miller School of Medicine, Miami, FL, USA

Background: Castration resistant prostate cancer (CRPC) is a rapidly progressing disease state for which there is no cure. The constitutively active androgen receptor (AR) splice variant AR-V7 represents a well-established mechanism of therapeutic resistance and disease progression. This variant lacks the AR C-terminal ligand binding domain and, as such, is not inhibited by androgen deprivation therapy. Designing high-affinity drugs to target the amino terminus of AR and AR-V7 is a major challenge due to the intrinsic disorganized structure of this region. Thus, there is an imperative need to identify novel AR-V7 hub genes in PC that may serve as novel therapeutic targets.

Methods: We performed a highly robust gene expression meta-analysis on PC patient samples. We defined gene modules correlated with PC progression using a Weighted Gene-Co-expression Network Analysis (WGCNA), a powerful systems biology approach. Further, we identified AR-V7 downstream target genes using gene expression profiling and mapped the AR-V7 functional interactome for the first time using a novel high-throughput synthetic genetic array screen in yeast. Finally, we combined the results from our three independent system-level analyses with experimental data to identify hub genes that were upregulated in PC patients, upregulated by AR-V7, and that also functionally interacted with AR-V7.

Results: The identified genes not only included select genes previously linked to PC, such as members of the topoisomerase and cyclin families, but also novel genes that had not been previously linked to PC progression. The identified gene-signature expression correlated with patients' Gleason score and had a prognostic value that predicted disease free-survival at the time of patient biopsy in large independent cohorts.

Conclusions: In sum, we show here an unbiased integrated system-level analysis of AR-V7 networks, where we combined bioinformatic analysis of patient samples and cell-based approaches to identify new candidate genes in CRPC that may serve as novel prognostic markers and future targeted therapies.

28P ODM-208, a novel CYP11A1-inhibitor as a therapeutic approach for the treatment of castration-resistant prostate cancer

R. Oksala[1], M. Karimaa[1], M. Ramela[1], R. Riikonen[1], R. Huhtaniemi[2], P. Rummakko[3], G. Wohlfahrt[3], A. Vuorela[3], M.V. Mustonen[4], P. Kallio[1]

[1]*Research and Development, Orion Corporation Orion Pharma, Turku, Finland,* [2]*Medicine, University of Turku, Institute of Biomedicine, Physiology, Turku, Finland,* [3]*Research and Development, Orion Corporation Orion Pharma, Espoo, Finland,* [4]*Research and Development, Orion Corporation Finland, Espoo, Finland*

Background: Androgen receptor (AR) plays a central role in prostate cancer and continues to be a driver in castration-resistant prostate cancer (CRPC), with increased AR expression in most cases. Approximately half of the men with CRPC respond initially to abiraterone or enzalutamide, but most relapse within 1 to 2 years. Majority of the abiraterone and enzalutamide-resistant tumors have still high AR expression and persistent AR activity. Several precursor steroids, like testosterone (T) and dihydrotestosterone activate AR, are synthesized in adrenal glands and de novo in tumours. CYP11A1 (cytochrome p450scc) is a mitochondrial enzyme catalysing the conversion of cholesterol to pregnenolone (Preg), which is the first rate-liming step in steroid hormone biosynthesis. ODM-208 is a novel, oral, non-steroidal and selective inhibitor of CYP11A1 enzyme and suppresses the synthesis of all steroid hormones and precursors.

Methods: The inhibition of CYP11A1 was measured in vitro by detecting the formation of radiolabelled isocapronic acid in a human adrenal cortex cell line (H295R), and further analysing Preg and T formation by ELISA. Inhibition of the adrenal and testicular hormone production in vivo was tested in the intact male rat assay by analysing plasma concentrations of progesterone (P), corticosterone (C) and T (with LS-MS/MS) after single oral dose of ODM-208. The tumor growth inhibition was studied by using androgen dependent VCaP cells, which were subcutaneously grafted to intact male nude mice. When tumor volumes reached on average 200 mm3, mice were castrated, and after regrowth of the tumors, the oral treatment of ODM-208 was started.

Results: ODM-208 potently inhibits CYP11A1 enzyme and formation of Preg and testosterone with low nM concentrations in vitro. In male rats, clear decreases of P, C and T concentrations can be detected already after single oral administration of ODM-208. In the murine VCaP CRPC xenograft model ODM-208 significantly inhibited tumor growth.

Conclusions: ODM-208 shows promising antitumor activity in preclinical CRPC models and suggests that ODM-208 may have the potential to be an effective treatment in CRPC. Clinical trial in patients with metastatic CRPC is planned to be started in the 2018.

29P Determining the role of the ETS factor ELF3 in normal and malignant prostate

L.K. Archer, F.M. Frame, N.J. Maitland

Deaprtment of Biology, Cancer Research Unit, University of York, York, UK

Background: Aberrations in the ETS transcription factor family members are a common feature of multiple cancers including prostate cancer (PCa), such as the TMPRSS2:ERG fusion. ELF3, also known as ESE-1, is an epithelial-specific ETS transcription factor involved in regulating cell differentiation in various tissues, however, its role in the prostate is controversial. The aim of this study was to identify the function of ELF3 in normal prostate development and to explore its role in PCa.

Methods: Three model systems were used: prostate cell lines, primary prostate epithelial cells cultured from patient tissue and paraffin-embedded human tissue sections. The function of ELF3 was investigated using knockdown via siRNA transfection and overexpression via lentivirus transduction. Western blots, immunofluorescence and immunohistochemistry were used to measure protein localisation and levels of expression. Other assays measured cell viability, colony forming ability and migration.

Results: ELF3 expression was restricted to the basal layer of the normal prostate epithelium and was not expressed in stroma. Analysis of a prostate tissue microarray indicated that whilst ELF3 is expressed in benign prostate tissue, its expression is lost in low-grade prostate tumours and re-expressed in some more advanced tumours. ELF3 knockdown resulted in decreased migration, cell viability and did not induce stem cell characteristics, whilst promoting basal cell gene expression. ELF3 overexpression increased cell migration. ELF3 was induced in primary prostate epithelial cells following treatment with the clinically approved HDAC inhibitor Vorinostat, which can promote neuroendocrine differentiation.

Conclusions: ELF3 expression correlates with the normal prostate epithelial cell differentiation hierarchy, and may have a role in advanced PCa. Analysis of total gene expression following knockdown of ELF3 will give an indication of transcriptional networks that are regulated by ELF3. In addition, a lentivirus that expresses an ELF3 mutant, which alters its localisation, will be used to assess any cytoplasmic function of ELF3. This comprehensive and clinically relevant approach will allow complete elucidation of the role of ELF3 in prostate cell differentiation and PCa.

30P Treatment-induced hypoxia attenuates enzalutamide response and promotes resistance in pre-clinical models of prostate cancer

P.J. Maxwell[1], M. Labonte[1], M. McKechnie[1], O. Duddy[1], C. Armstrong[1], C.W. Ong[1], A. Zoubeidi[2], J. Worthington[3], D. Waugh[1]

[1]*Centre for Cancer Research and Cell Biology, Queens University Belfast, Belfast, UK,* [2]*Vancouver Prostate Centre, University of British Columbia, Vancover, BC, Canada,* [3]*Axis Bioservices, Axis Bioservices, Coleraine, UK*

Background: Inhibition of androgen signalling remains the therapeutic mainstay in castrate-resistant prostate cancer. Retention of active AR signalling or acquisition of splice variants have been reported as mechanisms of resistance to the anti-androgen Enzalutamide. Other non-AR dependent mechanisms of resistance have also emerged including acquisition of a hypoxic microenvironment. We propose treatment-induced hypoxia and the induction of angiogenesis may define a novel mechanism of relapse to Enzalutamide.

Methods: Preclinical experiments were conducted in LNCaP tumors and established human prostate cancer cell lines. Tumour growth, intra-tumoral hypoxia and blood vessel density were measured *in vivo*. AR expression, activation and target gene expression were measured *in vitro*. Effects of Enzalutamide on hypoxia-driven, disease-progressing pathways and genes of interest and the role of these genes in resistance to Enzalutamide was investigated.

Results: Enzalutamide promoted persistent hypoxia in LNCaP tumours *in vivo*, followed by increased blood vessel density and restoration of oxygen tension (>14 days). *In vitro*, hypoxia increased AR expression and transcriptional activity in LNCaP cells and sustained but did not further potentiate high basal AR and ARv7 activity in 22Rv1 cells. Enzalutamide failed to attenuate the concurrent hypoxia-induced HIF-1 and NF-κB signalling, resulting in up-regulation of disease-progressing genes and pathways. Administration of neutralizing antibodies to two hypoxia-regulated genes, IL-8 and VEGF prolonged Enzalutamide-mediated LNCaP tumour growth control over 28 days *in vivo* ($p < 0.001$) and re-sensitised enzalutamide-resistant LNCaP cells *in vitro*.

Conclusions: Enzalutamide-induced hypoxia upregulates the expression of VEGF and IL-8, whose multi-model signalling effects contribute to microenvironment-promoted resistance in prostate tumours.

32P Prognostic impact of KRAS mutation in cell-free DNA in patients with pancreatic cancer

M.K. Kim[1], S.M. Woo[2], B. Park[3], K-A. Yoon[4], Y.H. Kim[5], J. Joo[3], S.J. Park[2], S-Y. Kong[6]

[1]Cancer Biomedical Science, Graduate School of Cancer Science and Policy, National Cancer Center, Goyang, Republic of Korea, [2]Center for Liver Cancer, National Cancer Center, Goyang, Republic of Korea, [3]Biometric Research Branch, National Cancer Center, Goyang, Republic of Korea, [4]College of Veterinary Medicine, Konkuk University, Seoul, Republic of Korea, [5]Molecular Imaging & Therapy Branch, National Cancer Center, Goyang, Republic of Korea, [6,7]Center for Hematologic Malignancy, National Cancer Center, Goyang, Republic of Korea

Background: Cell-free DNA (cfDNA) has been known to be released from tumor cells and evaluated potential biomarkers for therapeutic responses. However, the role of cfDNA in pancreatic cancer has not been well studied. Here we selected *KRAS* mutation which has been known common over 95% of pancreatic ductal adenocarcinoma (PDA) and evaluated applicability as a prognostic marker through the quantitative analysis of cfDNA and *KRAS* mutation in the patients with PDA.

Methods: Total of 106 PDA patients were enrolled in the study. The concentration and fraction of *KRAS* mutation were measured by *KRAS* screening multiplex droplet digital PCR kit (Biorad, USA) in plasma samples.

Results: KRAS mutation was detected in 97.4% of tissue samples and the correlation with cfDNA was 0.561 with 80.5% positivity. KRAS mutation concentration and fractional abundance showed the association with poor survival in both PFS ($P < .001$ and $P = 0.001$) and OS ($P = 0.003$ and $P = 0.006$) in the entire stage groups. Specially, the impact for survival of KRAS mutation concentration and fractional abundance was obvious in PFS in resectable group ($P = 0.016$ and $P = 0.02$). When we analyzed the receiver operating characteristic (ROC) curve to determine whether KRAS mutation in cfDNA have additive benefits with well-known tumor markers CA19-9, combined with KRAS mutation concentration or KRAS fractional abundance, the value of area under the curve (AUC) was significantly higher than the value calculated as CA19-9 alone.

Conclusions: This study represents that KRAS mutation concentration and fractional abundance in cfDNA could be prognostic marker in pancreatic cancer especially in resectable group.

33P Isoform-specific functions in pancreatic adenocarcinoma

H. Arasanz[1], M. Zuazo-Ibarra[2], M. Gato-Cañas[2], M. Ibáñez-Vea[2], G. Fernández-Hinojal[1], J. Fernández-Irigoyen[3], E. Santamaria[3], G. Kochan[2], R. Vera[1], D. Escors[2]

[1]Medical Oncology, Complejo Hospitalario de Navarra, Pamplona, Spain, [2]Immunomodulation, Navarrabiomed, Pamplona, Spain, [3]Proteomics, Navarrabiomed, Pamplona, Spain

Background: AKT/PKB is a protein kinase that plays a key role in cancer, which is expressed as 3 isoforms: AKT1 (PKBα), AKT2 (PKBβ) and AKT3 (PKBγ). Although these isoforms are remarkably similar, there is evidence that each isoform yields specific functions which may vary depending on the cell type. Even so, the underlying molecular pathways specifically regulated by each one of them are unknown.

Methods: To gain insight into the role of each isoform in the biology of human pancreatic adenocarcinoma cells, we have silenced each AKT isoform individually using short hairpin RNAs (shRNAs) delivered by lentiviral transduction. Cells transduced with an unspecific shRNA were used as controls. Then, high-throughput quantitative proteomic analyses were performed to evaluate the differential signaling routes altered by silencing of each AKT isoform.

Results: AKT1 silencing induced the upregulation of 57 proteins and downregulation of 58. AKT2 silencing up-regulated and down-regulated 78 and 101 respectively. AKT3 silencing resulted in the upregulation of 88 and downregulation of 93. The expression levels of 45 proteins were altered exclusively after AKT1 knockdown, while 74 proteins and 89 were specifically altered for AKT2 and AKT3 silencing, respectively. AKT1 silencing up-regulated RNA splicing, GPCR and mTOR pathways, and mitochondrial functions such as the respiratory chain, fatty acid metabolism or mitochondrial DNA synthesis. Pathways related to apoptosis and cell migration were inhibited. AKT2 silencing caused the activation of pathways related to apoptosis, splicing, protein folding and some mitochondrial functions. In contrast, other key metabolic pathways such as nucleic acid synthesis, pentose phosphate pathway, cell adhesion and PI3K signalling were down-modulated. Lastly, AKT3 silencing induced increased splicing and mitochondrial functions, regulation of gene expression and snRNA processing. In this case, the pentose phosphate pathway, cell adhesion, apoptosis, protein synthesis and nucleic acid synthesis were also inhibited.

Conclusions: AKT isoforms have specific functions in pancreatic adenocarcinoma. The individual silencing of each isoform induces a differential alteration of molecular pathways involved in main cellular processes.

34P High chemopreventive and therapeutic efficacy of Id1 inhibition in KRAS-mutant (KM) adenocarcinoma (AD) non-small cell lung cancer (NSCLC)

M. Roman Moreno[1], S. Vicent[2], I. Lopez[2], I. Baraibar Argota[1], E. Fraile[2], I. Gil Bazo[1]

[1]Medical Oncology, Clinica Universitaria de Navarra, Pamplona, Spain, [2]Tumores Solidos y Biomarcadores, Centro de Investigacion Medica Aplicada (CIMA), Pamplona, Spain

Background: Id1 is an independent prognostic factor in NSCLC-AD. Id1 silencing impairs cell viability and migration of NSCLC-AD cell lines. KRAS is the most frequently mutant gene in NSCLC with no specific therapies clinically available. Here we evaluate Id1 as a potential chemopreventive and therapeutic target in a humanized mouse model of KM NSCLC-AD.

Methods: Several human lung AD cell lines with known mutations (H1792-604, H2009, H358, H1568, H1437, H1703 and H2126) were selected for Id1 silencing using inducible short hairpin RNA (shRNA). Humanized AD xenograft mouse models were generated by subcutaneous injection of H1792-604 and H2009 cell lines (Id1 silenced or Id1 wild type) in flanks of immunodeficient mice. Id1 silencing was activated at the time of tumor cell inoculation (chemoprevention assay) or once the tumors were established (therapeutic assay).

Results: Id1 inhibition was achieved in all selected cell lines compared to their controls. In vivo, in the chemoprevention assay we observed a significant decrease in tumor volume in mice injected with Id1 silenced H1792-604 cells (60% ± 32.39) compared to the control group (356.29% ± 115.32) ($p < 0.001$). Moreover, mice injected with Id1 silenced H2009 cells never developed tumors compared to control mice (168.35 ± 68.71) ($p < 0.001$). In the therapeutic assay, the activation of inducible silencing of Id1 in established tumors induced a significant reduction of tumor volume in both xenograft models. Id1 inhibition induced a partial response in 40% of the tumors after injection of H1792-604 cells and in 100% of tumors in H2009 inoculated mice.

Conclusions: These findings encourage further evaluation of *Id1* as a potential therapeutic target in KM NSCLC-AD patients.

36P Synergistic effect of vismodegib and cisplatin in NSCLC models via autophagy

F. Papaccio[1], L. Mele[2], C.M. Della Corte[1], D. Liccardo[2], M. La Noce[2], V. Desiderio[2], V. Tirino[2], F. Ciardiello[1], F. Morgillo[1]

[1]Medical Oncology, Department of Clinical and Experimental Medicine "F. Magrassi", University of Campania "Luigi Vanvitelli", Naples, Italy, [2]Department of Experimental Medicine - Section of Biotechnology, Medical Histology and Molecular Biology, University of Campania "Luigi Vanvitelli", Naples, Italy

Background: Platinum-based chemotherapy still represents the standard first-line approach for NSCLC patients, although primary or secondary resistance is frequently observed. Recently the Shh pathway has been associated with resistance to platinum-based chemotherapy in NSCLC. The aim of this work is to investigate whether a combined treatment with cisplatin and the Hedgehog-pathway inhibitor vismodegib could potentiate the anti-tumour effect and to explore possible mechanisms of this synergy.

Methods: Two Human NCSLC cell lines A549 and H460 were treated with single agent Cisplatin, single agent Vismodegib and a combination of the two drugs. MTT cytotoxicity assays were performed and the data were analysed with CompuSyn software. Experiments of apoptosis and cell cycle were done by using flow cytometer. Immunofluorescence with lysoTracker as well as western blot (WB) analysis for the LC3B protein were performed to analyse autophagy.

Results: The CompuSyn analysis showed an important synergistic effect of cisplatin + Vismodegib. Combined treatment induced a significant increase in cellular apoptosis compared with single agent cisplatin. The cell cycle analyses revealed a block in S-phase with the combination treatment. The lysoTracker immunofluorescence assay showed that cisplatin induces an increase of autophagy, while the combination with vismodegib strongly reduces it, finally reverting this effect. These findings were confirmed by WB analysis for LC3B which is significantly increased by single agent cisplatin and reduced by the combined treatment.

Conclusions: Combined treatment with cisplatin and vismodegib has a synergistic effect with an increase in cancer cell apoptosis. Autophagy has been described as a mechanism through which cancer cells escape cisplatin-induced cytotoxicity. Combining cisplatin with vismodegib leads to an inhibition of autophagy, so that it could suggest a new therapeutic approach.

37P Association of the rs4567312 variant in the leptin receptor gene with plasma leptin concentrations and lung cancer incidence in the PREDIMED study

J.B. Ramirez Sabio[1], J.V. Sorlí[2], C. Ortega-Azorín[2], P. Carrasco[2], E.M. Asensio[2], R. Barragán[2], R. Fernández-Carrión[2], C. Gallego[2], J.I. González-Arráez[2], J.A. Perez Fidalgo[3], Ó. Coltell[4], D. Corella[2]

[1]Medical Oncology Unit, Hospital de Sagunt, Pto. Sagunto, Spain, [2]Preventive Medicine and CIBER Fisiopatología de la obesidad y nutrición, University of Valencia, Valencia, Spain, [3]Medical Oncology, Hospital Clinico Universitario de Valencia, Valencia, Spain, [4]Computer Languages and Systems, School of Technology and Experimental Sciences, Jaume I University, Castellón, Spain

Background: Many studies have found leptin related genes involved in tumorigenesis and have suggested it may play a role in the pathogenesis of lung cancer. Leptin Receptor (LEPR) is expressed in many tissues and cells, including lung mucosal cells. LEPR was reported to be associated with tumor cell proliferation and angiogenesis. Our objective has been to estimate the association between the rs4567312-LEPR gene and lung cancer incidence in a Mediterranean population.

Methods: We analyzed 1094 participants (398 men, 696 women) recruited in the PREDIMED-Valencia Study. Participants were high cardiovascular risk subjects aged 67±6 years at baseline. PREDIMED is a multicenter randomized, controlled trial aimed at assessing the effect of the Mediterranean diet (MedDiet) on cardiovascular prevention (primary outcome). Cancer incidence was a secondary outcome in this trial. Demographic, clinical, life-style, biochemical, and genetic variables were obtained. Subjects were followed-up prospectively from 2003 to 2014 (in the extended-follow-up).

Results: We detected 12 new cases of lung cancer from 2003 to 2014 (1.1% cumulative incidence). Tobacco smoking was strongly associated with lung cancer incidence (91.7% of current or former smokers in lung cancer subjects vs 41.5% in the non-cancer participants ($p = 0.001$). In the whole population, prevalence of the rs4567312 polymorphism was: 95.5% CC, 4.4% CT and 0.1% TT. We also detected in the whole population an association between this polymorphism and plasma leptin concentrations, 26.9±22.9 ng/mL in CC vs 18.4±16.7 ng/mL in T carriers ($p = 0.013$). We found a strong association between the rs4567312-LEPR polymorphism and lung cancer risk, being higher in carriers of the T-allele. This association remained statistically significant (OR = 7.61; 95% CI: 1.74-33.37 for T-carriers vs CC) even after adjustment for gender, age, tobacco smoking, dietary intervention group (MedDiet vs control diet) and leptin levels.

Conclusions: T-carriers allele in the rs4567312-LEPR polymorphism presented a higher incidence of lung cancer in this Mediterranean population even after adjustment for tobacco smoking and dietary intervention.

38P Two-step microarray analysis of cell-free miRNA in plasma of lung cancer patients

I. Zaporozhchenko[1], E. Morozkin[1], A. Ponomaryova[2], E. Rykova[1], N. Cherdyntseva[2], V. Vlassov[3], P. Laktionov[3]

[1]Laboratory of Molecular Medicine, Institute of Chemical Biology and Fundamental Medicine SB RAS, Novosibirsk, Russian Federation, [2]Laboratory of Molecular Oncology and Immunology, Tomsk Cancer Research Institute RAMS, Tomsk, Russian Federation, [3]Institute of Chemical Biology and Fundamental Medicine SB RAS, Novosibirsk, Russian Federation

Background: Lung cancer (LC) is causing more than 1.3 million deaths worldwide annually. Early detection of LC is critical for survival but despite recent advancements in LC diagnostics most patients are still diagnosed at advanced stages of the disease. The situation is further complicated by high intratumor heterogeneity and general diversity of lung malignancies. Insights into cancer genetics have kindled interest in molecular cancer diagnostics. One of the lucrative sources of prospective LC biomarkers is cell-free circulating miRNAs. These small non-coding RNAs are frequently deregulated in LC. It is also known that miRNAs can travel in bodily fluids for extended periods of time, shielded from degradation by membrane vesicles or other biopolymers. Recently, specific subsets of miRNAs associated with tumor phenotypes and disease progression have been found circulating in blood of cancer patients and suggested as potential biomarkers for LC.

Methods: In the present study, we have investigated the profiles of circulating miRNAs in blood plasma of LC patients and healthy individuals (HD) in order to identify potential markers for lung cancer diagnostics. Small RNAs were isolated from blood plasma of 20 LC patients and 10 healthy individuals (HD) using protocol reported earlier (Zaporozhchenko et al, Anal Biochem, 2015). Profiles of miRNA expression were obtained using miRCURY LNA miRNA qPCR Panels Plasma/Serum (Exiqon). Ratio based normalization was applied to all miRNA's with call rate higher than 80%.

Results: Statistical comparison using two-way ANOVA identified 241 ratios (98 individual miRNAs) with significantly different expression between LC patients and HD ($p < 0.05$ after Benjamini-Hochberg correction). Using LASSO penalization models and manual filtering of miRNAs associated with haemolysis, 7 miRNA ratios were identified as best predictors of cancer. Extended set of miRNAs ($n = 19$) was selected for further verification in an independent sample of 30 LC patients, 20 HD and 10 patients with hyper- and metaplastic endobronchitis using custom miRCURY LNA miRNA qPCR Pick & Mix Panel.

Conclusions: Based on expression in both data sets 5 ratios containing 7 miRNAs were selected for further validation in an extended cohort of LC and cancer-free individuals.

39P DNA methylation of the CYP1A1 and GSTP1 genes and incidence of major cancers (lung, breast and colon) in the PREDIMED-Valencia study

J.B. Ramirez Sabio[1], J.V. Sorlí[2], C. Ortega-Azorín[2], I. González-Monje[2], E.M. Asensio[2], R. Barragán[2], R. Fernández-Carrión[2], C. Gallego[2], R. Estruch[3], Ó. Coltell[4], O. Portolés[2], D. Corella[2]

[1]Medical Oncology Unit, Hospital de Sagunt, Pto. Sagunto, Spain, [2]Preventive Medicine and CIBER Fisiopatología de la obesidad y nutrición, University of Valencia, Valencia, Spain, [3]Internal Medicine, Hospital Clinic de Barcelona, Barcelona, Spain, [4]Computer Languages and Systems, School of Technology and Experimental Sciences, Jaume I University, Castellón, Spain

Background: DNA methylation is an epigenetic determinant of gene expression. Cytochrome P450 (CYP1A1) is a phase 1 xenobiotic metabolizing enzyme. Glutathione S-transferase P1 (GSTP1) detoxifies metabolites and regulates cellular chemical stress and death. Methylation changes in these genes could play a role in the incidence of cancer. Our aims were to analyze DNA-methylation of selected CpG islands in the CYP1A1 and GSTP1 genes at baseline in subjects who had incident cancer and paired controls, and to determine if DNA methylation in cancer patients changed from baseline to the time close to cancer diagnosis.

Methods: We followed-up 1094 subjects (aged: 67±6years) of the PREDIMED-Valencia study prospectively from 2003 to 2014. Cancer incidence was a secondary outcome in our trial. We analyzed 69 cases of incident cancer (lung, breast and colon) during this follow-up period, and 69 paired controls free of cancer. We analyzed DNA-methylation levels of the CYP1A1 and GSTP1 genes at baseline in both groups. Quantitative DNA methylation analysis was undertaken by MALDI-TOF mass spectrometry. We evaluated methylation levels on chromosome 15 (region: 74726090 - 74726460 base pairs from promoter) and chromosome 11 (region: 67583556-67583896 base pairs from promoter).

Results: We detected statistically significant differences in DNA methylation levels at baseline in the CYP1A1 and GSTP1 genes between cancer cases and controls (P=0.008 for the CpG site 26-27 of the CYP1A1 gene and P=0.049 for the CpG 10-11 island at the GSTP1 gene). We detected statistically significant changes in DNA methylation prospectively in cancer patients. DNA methylation at the CpG 4 (CYP1A1 gene) was 0.020±0.034 at baseline vs 0.006±0.013 close to cancer diagnosis (P=0.044). For the GSTP1 gene, methylation of the CpG 34-39 prospectively increased from 0.327±0.046 at baseline to 0.345±0.053 (P=0.014) close to cancer diagnosis.

Conclusions: We have detected differences in DNA-methylation of selected CpG Islands of the CYP1A1 and GSTP1 genes at baseline, between future diagnosed cancer subjects and cancer-free controls. Moreover, in patients subsequently diagnosed with cancer, a change in DNA methylation was observed between baseline and close to the time of cancer diagnosis. This suggests a dynamic influence of DNA methylation that could be modulated for prevention.

40P Regulation of glucose transporters by protein kinases in cancer cells

A.A. Henriques, P. Matos, P. Jordan

Human Genetics Department, Instituto Nacional de Saúde Doutor Ricardo Jorge, Lisbon, Portugal

Background: Cancer cells require increased glucose supply to sustain proliferation. One mechanism involves increased expression of glucose transporter (GLUT) genes. But insulin has revealed that protein phosphorylation is another key mechanism in glucose uptake regulation: insulin binding to responsive cells triggers a signalling cascade with phosphorylation of TBC1D4, a negative regulator of endosomal GLUT trafficking,

so that more transporters are inserted into the plasma membrane. Previous work from the host lab has identified the family of WNK protein kinases and shown that WNK1 can also phosphorylate TBC1D4 and promote GLUT translocation to the cell surface. Our objective is to understand the contribution of WNK1 to glucose uptake in colorectal cancer cells. Our objective is to understand the contribution of WNK1 to glucose uptake in colorectal cancer cells.

Methods: To characterize the role of WNK1, various colorectal cell lines were first cultivated with different glucose concentrations. Levels of GLUT1 at the cell surface were compared under these conditions and the effect of depleting WNK1 expression by siRNA determined.

Results: For selected conditions, key cell cycle or apoptotic marker proteins were analysed by Western blot and revealed higher apoptotic and cell-cycle arrest phenotypes in WNK1-depleted cells cultured in low glucose medium. In order to dissect key phosphorylation events involved in GLUT1 regulation, mass spectrometry analysis revealed that WNK1 phosphorylates TBC1D4 and the functionally related TBC1D1 at unique Serine residues. The corresponding phospho-mimetic mutants are currently being tested for their ability to increase GLUT1 translocation.

Conclusions: Together, these studies will elucidate the molecular details regulating the translocation of glucose transporters in cancer cells and have the potential to identify novel therapeutic targets.

41P Signal transduction pathways regulating alternative splicing of tumor-related RAC1b

V. Gonçalves, P. Matos, A.A. Henriques, J. Pereira, P. Jordan

Human Genetics Department, Instituto Nacional de Saúde Doutor Ricardo Jorge, Lisbon, Portugal

Background: In colon cancer distinct genetic subtypes have been described, one of which involves overexpression of RAC1b, a variant generated by alternative splicing. Aberrant splicing is known to occur in cancer and can be caused by mutation in a gene or splicing factor but also represents a dynamic response to oncogene-induced cellular signaling and in this case it may be pharmacologically targeted. Here we explore how signaling pathways are involved in the deregulation of alternative RAC1b splicing in colorectal tumor cells.

Methods: HT29 colorectal cells represent serrated colorectal tumors with *BRAF* gene mutation V600E in one allele and RAC1b overexpression. Cells were transfected with shRNA vectors directed against target candidate protein kinase transcripts and their effects on RAC1b levels analyzed 24h later by Western Blot and qRT-PCR. Treatment with kinase inhibitors or anti-inflammatory drugs was performed 24h prior to cell lysis.

Results: Two kinases, SRPK1 and GSK3β, were found required to sustain RAC1b levels and both were shown to act upon the phosphorylation of splicing factor SRSF1, which binds to and promotes the inclusion of the alternative exon in RAC1b. SRPK1 knockdown or pharmacological inhibition reduced SRSF1 phosphorylation decreasing its nuclear translocation and concomitantly RAC1b splicing. The same regulatory pathway was also found to be controlled by GSK3β. Interestingly, GSK3β phosphorylation was identified to serve as target for the anti-inflammatory drug ibuprofen, which inhibits RAC1b overexpression.

Conclusions: Together, our results demonstrate that oncogenic signal transduction pathways deregulate alternative splicing and this may be drug revertable.

42P Preserving tumor heterogeneity: A microfluidic reactor for ex vivo preservation of colorectal cancer biopsies

G.A. Llamazares[1], C. Sostres[2], A.E. Vigueras[1], A. Lué[2], J.L. Calavia[1], C. Alcaine[1], R. Guerrero[1], A.G. Gonzales[3], M.T. Ramírez[3], A. Lacueva[1], S. González[1], A. Lanas[3], I. Ochoa[1], L.J. Fernández[1]

[1]Aragón Institute of Engineering Research (I3A), University of Zaragoza, Zaragoza, Spain, [2]Service of Digestive Diseases, Univeristy Clinic Hospital Lozano Blesa, Zaragoza, Spain, [3]Service of Pathological Anatomy, Univeristy Clinic Hospital Lozano Blesa, Zaragoza, Spain

Background: Foreseeing treatment outcome in cancer patients is still a challenge that needs to be addressed. Tumors are complex structures, where the interaction between the tumor cells and the surrounding microenvironment regulates key processes in cancer progression, such as angiogenesis, evasion and modulation of the immune system response, and invasiveness. These interactions confer tumors a high heterogeneity not only inter-patient but also intra-patient. In vitro experimental models have been developed to preserve this heterogeneity present on tumor biopsies by the use of rotary wall and perfused bioreactors. However, the complexity and size of the bioreactors prevent from visual inspection of the sample and the realization of a high-throughput screening. The present work focuses on the combination of microfabrication techniques and microfluidics to downsize classic experimental models. The developed methodology requires only microliter size sample, and allows real time optical inspection.

Methods: A microscopy slide size optically transparent microfluidic bioreactor (μbioreactor) was designed and developed to preserve high cellularity on complex samples through constant perfusion. Colorectal carcinoma (CRC) biopsies were taken after previous patient consent was obtained. CRC biopsies were perfused by cell culture media in the μbioreactor during one week. After perfusion, CRC biopsies were histologically processed, stained and characterized by immunofluorescence.

Results: High cellularity was observed in CRC biopsies after one week of perfusion. Stromal and parenchymal preservation was confirmed by both, histological staining and immunofluorescence.

Conclusions: The use of microfluidic bioreactors can be successfully used to preserve CRC biopsies, maintaining cell heterogeneity while allowing optical inspection. The use of small sample volumes (microliters) allows high throughput screening using regular biopsy samples, a key feature to achieve personalized treatments in cancer.

44P Role of ICAM-1/LFA-1 interaction in the angiogenic and desmoplasic response in liver metastasis

A. Herrero-Alonso, I. Romayor, A. Benedicto, I. Hernandez-Unzueta, J. Marquez, B. Arteta

Cell Biology and Histology, Faculty of Medicine and Nursery, Universidad del País Vasco UPV/EHU, Leioa, Spain

Background: The colorectal cancer is one of the most common cancers in the world being the main cause of death the metastatic spread to the liver. During metastatic progression, a stromal and tumor cell crosstalk mediated by hepatic ICAM-1 and tumor LFA-1 interaction modulate the tumor microenvironment through an inflammatory and immune response. Additionally, a matrix remodeling and angiogenic response is also associated with tumor progression. The main cell type associated to these processes is the fibroblast associated to the tumor. Thus, the aim of this work is to elucidate the effect of ICAM-1/LFA-1 interaction during the angiogenic and desmoplasic response during liver metastatic progression.

Methods: To do so, the effect of ICAM-1/LFA-1 interaction on the tumor progression and recruitment of cancer associated fibroblasts was analyzed by an experimental metastasis assay in vivo and a modified Boyden chamber migration assays in vitro, after either activation of tumor cells with sICAM-1 or blocking of ICAM-1/FA-1 interaction. In addition, the effects of LFA-1 tumor depletion on tumor migratory potential induced by tumor-activated fibroblasts derived factors were analyzed. Also, the effect of the modulation of this pathway on MMPs protein and angiogenic gene expression levels was measured by zymography and qPCR, respectively.

Results: In vivo and in vitro assays showed an increase on fibroblast and tumor cells recruitment after activation of tumor LFA-1 activation by binding with sICAM-1 which was abrogated after blocking of LFA-1. Moreover, the expression levels of MMPS and other proangiogenic factors were decrease after the blockage of ICAM-1/LFA-1 interaction. Also, the collagen deposition was increased after LFA-1 activation and diminished by LFA-1 blocking.

Conclusions: The interaction of ICAM-1 with tumor LFA-1 favors the recruitment of fibroblast within the tumor mediated by a modulation of pro-desmoplasic factors. This favors the remodeling of the tumor stroma and the angiogenic response and promotes tumor metastatic progression. Thus, LFA-1ICAM-1 interaction might be pointed out as a potential target for therapy of the metastatic disease.

45P Role of discoidin domain receptors in extracellular matrix remodeling during tumor-host interaction in liver metastasis

I. Romayor, A. Herrero-Alonso, I. Hernandez-Unzueta, A. Benedicto, J. Marquez, B. Arteta

UrseryCellular Biology and Histology, School of Medicine and N, Basque Country University (UPV/EHU), Leioa, Spain

Background: Metastasis is the main cause of death for most solid tumors. The liver is a metastasis-susceptible organ and represents the first most common site for colorectal cancer (CRC). During tumor progression, the unique hepatic microenvironment suffers a reorganization involving the interaction between the tumor, the different hepatic stromal cells and the extracellular matrix (ECM), which is under an extreme remodeling. Among the receptors involved, discoidin domain receptors (DDR-1 and -2), a class of tyrosine kinase receptors for fibrillar collagen, are emerging as new therapeutic targets in cancer treatment, including colorectal. Aim: We aim to elucidate the implication of DDRs in the prometastatic properties of the CRC cells and stromal cells in the liver.

Methods: First, the expression of DDRs on the stromal cells under tumor activated conditions and on tumor cells in the presence of tumor-activated stromal factors was assessed at protein levels. Second, this was related to the migratory potential under the same conditions. Finally, metalloproteinases expression, known to be induced by DDRs activation and involved in cell migration and ECM remodeling, was determined by western blot and zymography.

Results: DDRs expression was inversely altered in macrophages and fibroblasts after their activation by tumor derived factors. The expression of DDRs on CRC cells was decreased by factors derived from stromal cells. These DDRs deregulated expression was related to changes in the migratory capacity of tumor and stromal cells. Moreover, MMP-9 and MMP-14 expression increased in the stromal cells activated by tumor factors, while TIMP-2 expression was higher in fibroblasts but lower in macrophages. Also, the activation of CRC cells by either fibroblasts or macrophages derived factors induced a differential expression of MMP-2, MMP-9 and MMP-14.

Conclusions: The differential expression of DDRs by cells in the tumor microenvironment could redirect the expression of MMPs inducing the migratory capacity of CRC cells. In conclusion, tumor and stromal cells crosstalk may dysregulate the ECM deposition related to DDRs expression contributing to the extensive stroma remodeling in CRC metastatic diseases.

46P Novel role of apatinib as a multi-target RTK inhibitor in the direct suppression of hepatocellular carcinoma cells

X. Li[1], A. Xu[1], H. Li[2], B. Zhang[1], B. Cao[2], J. Huang[1]

[1]Experimental Center, National Clinical Research Center for Digestive Disease, Beijing Friendship Hospital, Capital Medical University, Beijing, China, [2]Department of Oncology, Beijing Friendship Hospital, Capital Medical University, Beijing, China

Background: Although apatinib has been demonstrated with potential antitumor activity to multiple solid tumors, the underlying mechanism of apatinib for the treatment of hepatocellular carcinoma (HCC) remains unclear. In the present study, we explore if there is any direct suppression effect of apatinib on HCC cells and its relevant targets.

Methods: To determine the role of apatinib, we investigated its effect on viability, colony formation, apoptosis, migration of 6 HCC cell lines in vitro, and HCC progression in mice model. Using a phospho-receptor tyrosine kinase pathway array with 49 different tyrosine kinases, we screened and verified the tyrosine kinase targets involved in apatinib therapy.

Results: Apatinib treatment significantly inhibited HCC cell viability, proliferation, colony formation, migration, and enhanced cell apoptosis in a concentration-dependent manner ($p < 0.05$). Furthermore, apatinib showed a favorable anti-tumor growth effect (71% of inhibition ratio, $p < 0.05$) in the established human HCC xenograft mice model with good safety. RTK pathway arrays and western blots analysis demonstrated apatinib significantly down-regulated the phosphorylation levels of several tyrosine kinase receptors, especially PDGFR-α and IGF-IR, and inhibited Akt phosphorylation.

Conclusions: These novel data suggested that the apatinib may have a direct anti-HCC effects as a direct multi-target RTK inhibitor of HCC cells and a promising potentiality in HCC clinical therapies.

47P GATA6 exhibits tumor suppressive effects in hepatocellular carcinoma

H.W. Tan[1], C. Leung[1], K. Chan[1], I. Ng[2], R. Lo[2]

[1]Pathology, The University of Hong Kong, Hong Kong, China, [2]Pathology, State Key Laboratory for Liver Research, The University of Hong Kong, Hong Kong, China

Background: GATA6 is a transcription factor that regulates endoderm differentiation and lineage specification. Dysregulation of GATA6 expression had been reported in cancers of endoderm-derived organs such as the lungs, stomach and pancreas. The aim of this study is to determine the clinical significance of GATA6 in hepatocellular carcinoma (HCC) and characterize its potential functional roles.

Methods: GATA6 mRNA expression was assessed in 74 clinical HCC samples by quantitative polymerase chain reaction (qPCR). Correlation between GATA6 expression and clinicopathological parameters was analyzed. Stable GATA6 knockdown clones were established by a lentiviral-based approach in HCC cell line Huh7, which showed relatively high endogenous GATA6 expression. Functional effects upon GATA6 manipulation were investigated by cell proliferation, migration, invasion and tumorsphere formation assays *in vitro*.

Results: GATA6 expression was significantly downregulated in HCC tumor tissues when compared with the corresponding non-tumoral liver tissues ($p = 0.007$). A lower GATA6 expression was correlated with poorer cellular differentiation ($p = 0.004$). Silencing of GATA6 stimulated HCC cell proliferation, and promoted cell invasive and migratory abilities *in vitro*. This increase in metastatic capacity was mediated through the activation of epithelial-mesenchymal transition (EMT), as demonstrated by the loss of E-cadherin and gain of vimentin protein expression levels. Suppression of GATA6 augmented the self-renewal ability of HCC cells as demonstrated by the enhanced number and size of tumorspheres formed in both primary and secondary generations. In addition, the expression of various stemness markers such as Nanog, Oct4 and Sox2 were upregulated upon GATA6 silencing.

Conclusions: Our findings suggest that GATA6 is downregulated in HCC which may help to convert HCC cells to a more poorly differentiated state and enhance proliferation, self-renewal ability and metastatic potential.

48P The effects of 5-fluorouracil (5-FU) on TGF-β-related signaling molecules

T. Wang, Y. Takikawa

Department of Gestroenterology, Iwate Medical University School of Medicine, Morioka, Japan

Background: By identifying the mechanism of therapeutic effects of the combination of interferon alpha (IFNα)-2b and 5-fluorouracil (5-FU) on advanced hepatocellular carcinoma (HCC) with portal venous invasion[1], we recently found that 5-FU increased both the expression and secretion of transforming growth factor (TGF)-β in HepG2 cells. In this study, we analyzed the effects of 5-FU on TGF-β-related signaling molecules.

Methods: Hepatoma cells (HepG2 and HuH7) were treated with 5-FU, IFNα-2b, and the combination of 5-FU and IFNα-2b. The total and/or phosphorylated protein levels of TGF-β-related signaling molecules were detected by western blot analysis. Additionally, the effects of above-mentioned treatments on the epithelial–mesenchymal transition (EMT) of the cells were evaluated by performing invasion and migration assays.

Results: With respect to the TGF-β-induced apoptosis signals, 5-FU inhibited not only the phosphorylation of SMAD2, but also reduced the total protein levels of SMAD2, SMAD4, and pINK4b. Conversely, 5-FU stimulated the phosphorylation of TGF-β-induced EMT molecules, such as ERK and JNK, but not p38MAPK. Accordingly, the protein levels of E-cadherin were reduced in the cells treated with 5-FU. On the other hand, IFNα-2b did not affect the levels of TGF-β-induced EMT molecules, whereas the combination of 5-FU and IFNα-2b neutralized the effects of 5-FU on TGF-β-related signaling molecules and restored their protein levels to those observed in the control. Interestingly, the phosphorylated protein levels of SMAD2 and the total protein levels of E-cadherin and p15INK4b increased in 5-FU-stimulated HUH7 cells, but not in HepG2 cells. Furthermore, 5-FU stimulated both cell invasion and migration in HepG2 cells, whereas the combination of 5-FU and IFNα-2b abolished these effects of 5-FU.

Conclusions: Our data suggest that 5-FU induces the EMT of hepatoma cells through TGF-β, and that the higher efficacy of the combination therapy of 5-FU and IFNα-2b results from the inhibition of these effects of TGF-β. The differences observed between HepG2 and HUH7 cells in response to the stimulation with 5-FU indicate that the efficacy of the therapy may differ between patients with hepatitis B (HBV) or C virus (HCV) background.

49P Gene mutations involved in drug resistance in liver cancer cells using a new rna-seq data analysis workflow

E. Akhan Guzelcan, M. Shojaei, A.C. Acar, R. Cetin Atalay

Informatics Institute, Middle East Technical University, Ankara, Turkey

Background: According to Global Cancer Statistics (GCS) Hepatocellular carcinoma (HCC) is the 5th most common and 2nd deadliest cancer in the world. The incidence of HCC has increased over the past decades but still an effective therapy has not been developed. Sorafenib, which is the only FDA approved agent, can improve the patient survival just for a few months, therefore liver transplantation is the most efficient way of treatment up to date. In this study, we offer potential drug targets by analyzing the relationship between mutation status and drug treatment response of well-differentiated Huh7 and poorly-differentiated Mahlavu liver cancer cells.

Methods: PI3K/Akt pathway is hyperactive in ∼%40 of HCC. We determined the characterized and determined IC_{50} values of Sorafenib, PI3Ka and b inhibitors and their combinations. RNAseq experiment were performed with the inhibitor treated cells. The RNAseq data of each cancer cell line (as control) was compared to treated samples. Somatic mutations associated with drug resistance were comparatively identified with RNAseq data workflow wrapped in our laboratory using GATK-MuTect tool (Cibulskis, 2013). The results were further filtrated to obtain the missense mutations. The mutated genes that were identified during the chemical knockdown studies were further analyzed in patient survival data. The functional studies were performed by gene silencing.

Results: SLC39A5, FRG1, PPHLN1 and SRP9 gene mutations were found to be shared among all drug resistant cells. Mutated genes were shown to be associated with cancer perseverance and aggressiveness. In addition, we found an unknown transcript called CTC512. The functional studies demonstrated that once these genes were silenced, the cellular growth was prevented. Gene silencing showed the alteration of the cell cycle progression of drug resistant cells. The affected downstream pathways were further analyzed by western blotting.

Conclusions: Our results indicate potential target genes which are critical to be addressed due to their roles in resistance to drugs in HCC. Once the mutated genes are silenced the cancer progression is prevented. The identified genes can be considered as chemotherapeutical and disease progress targets.

50P Camouflaging iRGD-EGFR anchored human cytotoxic T-lymphocyte membranes to the surface of nanoparticles combined with low-dose irradiation: New approach to enhance drug-delivery targeting in gastric cancer

L. Zhang, H. Sha, R. Li, J. Wei, X. Qian, B. Liu

The Comprehensive Cancer Centre of Drum Tower Hospital, Medical School of Nanjing University & Clinical Cancer Institute of Nanjing University, Nanjing, China

Background: We report a biomimetic delivery platform based on human cytotoxic T-lymphocyte membranes. In this platform, T-lymphocyte membranes were camouflaged to the surface of poly-lactic-co-glycolic acid nanoparticles, with local low-dose irradiation (LDI) as a chemoattractant. These carriers were further anchored with the recombinant protein anti-EGFR-iRGD, improving tumor accumulation, facilitating tumor uptake.

Methods: The T-lymphocyte membrane coating was verified by dynamic light scattering, transmission electron microscopy and confocal laser scanning microscopy. The particle phagocytosis study was performed using a human phagocytic cell line. In vivo NIR fluorescence imaging was performed to monitor the route of nanoparticles. EGFR expression of tumor cells was tested before and after LDI.

Results: This new platform reduced phagocytosis of macrophages by 23.99% ($p = 0.002$). iRGD-EGFR anchored T-lymphocyte membrane-encapsulated nanoparticles accumulated in tumor site more than unfunctionalized groups, while LDI significantly enhanced the targeting ability. LDI could up-regulate EGFR expression on tumor cells, which was important in the process of localization of iRGD-EGFR anchored T-lymphocyte membrane-encapsulated nanoparticles in tumors.

Conclusions: This new platform included both the long circulation time and tumor sites accumulation ability while LDI could significantly enhance the tumor accumulation ability.

51P Delivery of paclitaxel-loaded erythrocytes-based nanoparticles using injectable albumin hydrogel for regional chemotherapy

H. Qian, Q. Liu, R. Li, L. Yu, B. Liu

The Comprehensive Cancer Centre of Drum Tower Hospital, Medical School of Nanjing University & Clinical Cancer Institute of Nanjing University, Nanjing, China

Background: Peritoneal dissemination often occurs in advanced gastric cancer (GC) patient. However, systemic chemotherapy alone has limited effect on peritoneal metastases. The purpose of this work is to fabricate a regional nanomedicine delivery system with injectable hydrogel, to investigate the sustained drug release, biocompatibility, degradation, and the therapeutic efficacy on advanced GC.

Methods: The injectable hydrogel gelling at body temperature was synthesized by one-step esterification of albumin and polyethylene glycol. The paclitaxel-loaded nanoparticles (PRNP) were prepared by encapsulating the drug in erythrocytes membrane ghost and embedded into the hydrogel (PRNP-Gel). The physical and chemical performances were characterized by dynamic light scattering, electronic microscope and SDS PAGE. The drug loading content, hemocompatibility, degradation, drug release, drug accumulation at tumor site, and anti tumor efficacy was also investigated.

Results: The PRNP-Gel suspension gelated in 15 min after subcutaneous injection. The diameter of PRNP in hydrogel was 133.1 ± 1.6 nm, drug loading efficacy and content were $85.45 \pm 1.32\%$ and $22.10 \pm 0.25\%$, respectively. 37.9% of the loaded paclitaxel was released in 196 h *in vitro*, demonstrating the sustained release properties of PRNP-Gel. No hemolysis was detected within the concentration up to 10 mg/mL, and the PRNP-Gel degraded completely in 200 days after injection. The IC50 of PRNP against MKN45 gastric cancer cells, determined by MTT, was 15.16 ng/mL. *In vivo* antitumor evaluation found that, the tumor growth inhibition of MKN45 on tumor bearing mice was 64.5% of PRNP-Gel group, which was higher than the PRNP (40.0%, $P < 0.05$) and Taxol (33.8%, $P < 0.05$). The average tumor weight was 74.9 ± 40.1 mg, while they were 194.6 ± 90.9 mg and 199.6 ± 73.9 mg in PRNP and Taxol respectively ($P < 0.05$).

Conclusions: The biocompatible and degradable drug delivery system could release chemotherapeutics in a long-term and sustained manner, exhibited an enhanced drug accumulation at tumor site, resulting in the superior antitumor effect *in vitro* and *in vivo*. This work provided a new strategy of therapy for advanced GC.

52P Effect of apatinib combined with 5-fluorouracil (5-FU) on proliferation, apoptosis and invasiveness of gastric cancer cells

P. Zhao[1], J. Zhang[2], X. Pang[1], L. Zhao[1], Q. Li[1], B. Cao[1]

[1]Department of Oncology, Beijing Friendship Hospital, Beijing, China, [2]Department of Food Science, Shandong Medicine Technician College, Tai'an, China

Background: To investigate the effect of apatinib, a small-molecule tyrosine kinase inhibitor, combined with 5-FU on proliferation, apoptosis and invasiveness of human gastric cancer cells AGS, and provide experimental basis for the treatment of two drugs combination in gastric cancer in clinic.

Methods: The expression of vascular endothelial growth factor receptor 2 (VEGFR2) protein in human umbilical vein endothelial cells (HUVEC) and human gastric cancer cells were assessed by western blotting. 4-methyl-teerazolium (MTT) assay and flow cytometry were used to assess the cytotoxicity and apoptosis effects of the cells in response to control, single apatinib, single 5-FU, and apatinib combined 5-FU groups. Western blotting was used to evaluate the expression of p-Akt, proliferating cell nuclear antigen (PCNA), Caspase-3 and the invasiveness differences of the four groups were detected by wound healing assay and matrix metalloprotein-2 (MMP-2), E-cadherin gene amplification were measured by RT-PCR.

Results: AGS had the expression of VEGFR2. Compared with single drug groups, apatinib combined with 5-FU could significantly suppress the growth, proliferation and induce apoptosis of human gastric cancer cells in time and dose-dependent manners ($P<0.05$). Western blotting dispalyed p-Akt and PCNA expression decreased after AGS cells treated with apatinb combined 5-FU. Wound-healing assay showed the invasiveness of AGS cells was inhibited and probably through down-regulating MMP-2 and E-cadherin amplification in combined group ($P<0.05$).

Conclusions: Our study points that apatinib combined 5-FU could inhibit the proliferation of AGS gastric cancer cells by down-regulating the expression of p-Akt. The invasiveness of AGS cancer cell was inhibited by reduced expression of MMP-2 and E-cadherin genes, and provides a theory basis for 5-FU and apatinib combination in clinic with advanced gastric cancer patients who failed to second-line treatment but still had a good performance status.

53P One tumour, two clones: An in vitro model of intra-tumour heterogeneity

A. Salawu[1], M. Fernando[2], D. Hughes[2], M. Reed[3], P. Woll[1], K. Sisley[4]

[1]Academic Unit of Clinical Oncology, Weston Park Hospital Cancer Research Centre, Sheffield, UK, [2]Histopathology, Sheffield Teaching Hospitals, Sheffield, UK, [3]Brighton and Sussex Medical School, University of Sussex, Brighton, UK, [4]Oncology and Metabolism, University of Sheffield, Sheffield, UK

Background: Eradication of advanced disease remains elusive in the majority of cancers including soft tissue sarcomas (STS) despite advances in our understanding of the molecular mechanisms that drive them. Targeted treatment development to date has largely relied upon data derived from all cells within a tumour sample and/or tumour cell lines. These approaches however, do not account for inherent heterogeneity of cancer cells within a single tumour and is considered an important factor that leads to treatment failure. Understanding intra-tumour heterogeneity is therefore a priority for cancer research and appropriate tumour models with sufficient availability would greatly facilitate the identification of newer targets and factors that lead to treatment resistance. We therefore aimed to develop *in vitro* models of STS that reflect intra-tumour heterogeneity.

Methods: We obtained tissue from patients having surgery for STS in Sheffield Teaching Hospitals and established primary tissue cultures. Short Tandem Repeat (STR) confirmed the same origin of both clones in both cases. DNA copy number profiling and gene expression microarray analysis were used for molecular characterisation of self-immortalised primary cell lines.

Results: One leiomyosarcoma (Shef-LMS 01) and one myxofibrosarcoma cell line (Shef-MFS 01) established two morphologically-distinct tumour cell types (culture variants) in separate long term cultures. Karyotyping and growth characteristics confirm that both variants in each case are tumour cells and they have remained in culture for over 100 passages. STR profiling confirms that in each case, both clones are derived from the same tumour. DNA copy number analysis with microarray-based comparative genomic hybridisation and gene expressson analysis shows many identical somatic copy number abnormalities (SCNA) between variants, but also numerous genomic and transcriptomic differences.

Conclusions: We believe that these genomic and transcriptomic differences provide clues to clonal evolution in these tumours and may explain the development of resistance to targeted treatment. These cell lines are therefore useful for the identification of novel targets and development of effective therapies for these tumours.

54P Docosahexaenoic acid mediates susceptible cell death through differential regulation of p62/p-eIF2alpha/NRF2 in LMP1-expressing nasopnaryngeal carcinoma cells

K. Lim[1], K. Jing[2], S. Shin[3], S-H. Han[4], Y-S. Yoo[4], Y-J. Jeon[4], J-Y. Heo[4], G-R. Kweon[4], S-K. Park[5], J-I. Park[5]

[1]Department of Biochemistry and Medical Science, Cancer Research Institute, Chungnam National University College of Medicine, Daejeon, Republic of Korea, [2]Stem Cell Research and Cellular Therapy Center, Affiliated Hospital of Guangdong Medical College, Zhanjiang, China, [3]Department of Biochemistry and Cancer Research Institute, Chungnam National University College of Medicine, Daejeon, Republic of Korea, [4]Department of Biochemistry and Medical Science, Chungnam National University College of Medicine, Daejeon, Republic of Korea, [5]Department of Biochemistry, Chungnam National University College of Medicine, Daejeon, Republic of Korea

Background: Docosahexaenoic acid (DHA) induces apoptotic cell death through several mechanisms in cancer cells. We have previously demonstrated that DHA triggers apoptosis by increasing reactive oxygen species (ROS) accumulation and the ROS-mediated apoptosis caused by DHA is associated with Nrf2 signaling activation. Here we report that DHA-induced cell death is more susceptible through p62/p-eIF2alpha/NRF2 regulation in LMP-1-expressing nasopharygeal carcinoma (NPC) cells.

Methods: Viability of CNE-LMP1 and HONE-EBV cells was compared with CNE and HONE after DHA treatment by MTT assay. DHA-induced apoptosis was analyzed using the TUNEL assay and Western blot of cleaved form of PARP. Tissue expression of LMP-1 and p62 were observed by immunohistochemistry.

Results: Treatment of four human NPC cells (CNE, CNE-LMP1, HONE, HONE-EBV) with DHA for 24 hr resulted in a dose-dependent inhibition of cell growth. The DHA effect was due to the induction of apoptosis, given that DHA increased the cleaved form of PARP as well as the number of TUNEL-positive cells. The inhibition of CNE-LMP1 and HONE-EBV cells after DHA treatment is more susceptible. compared with CNE and HONE cells without LMP1 by MTT assay. The level of p62 and NRF2 of LMP1-NPC cells were increased after DHA pretreatment cpmpared to control NPC cells. On the other hand, the level of p-eIF2alpha produced reverse result. The activation of Nrf2 signal seems to result from decreased Nrf2 inhibitor, Kelch-like ECH-associated protein 1 (Keap1), because DHA remarkably attenuated Keap1 expression levels. Moreover, silencing Nrf2 by small interfering RNAs inhibited the cytotoxic effect of DHA, indicating that Nrf2 activation plays a positive role in the process of DHA-induced apoptosis. Increased staining for LMP1 and p62 was observed in NPC tissues when compared with the nonneplastic (chronic inflammation) tissues.

Conclusions: These results suggest that differential regulation of p62/p-eIF2alpha/NRF2 contributes to susceptible cell death by DHA in LMP-1-expressing NPC cells. Thus, utilization of DHA may represent a promising therapeutic approach for chemoprevention and treatment of human NPC.

55P Inhibition of the ubiquitin-conjugating enzyme E2B restores the BCNU sensitivity of cancer cells by regulating MGMT ubiquitination

S.H. Hsu[1], S-H. Chen[2], L-T. Chen[2], J-Y. Chang[1]

[1]Institute of Basic Medical Sciences, College of Medicine, National Cheng Kung University, Tainan City, Taiwan, [2]National Institute of Cancer Research, National Health Research Institutes, Tainan, Taiwan

Background: O^6-Methylguanine-DNA methyltransferase (MGMT) is a DNA repair enzyme that removes the mutagenic O^6-alkyl groups from guanines. 1, 3-Bis (2-chloroethyl)-1-nitrosourea (BCNU), a DNA damage reagent, is known to induce cell death of tumors and the ubiquitin dependent proteolysis of MGMT. The present study aims to enhance BCNU cytotoxicity toward cancer cells by modulating MGMT dynamics.

Methods: Human nasopharygeal carcinoma cells, including HONE-1 and TW01, and human colon carcinoma HT-29 cells were used for the BCNU treatments, siRNA knockdown, immunoprecipitation and western blot experiments. The BCNU cytotoxicity was determined using methylene blue assay. Proteins involved in MGMT ubiquitination were confirmed with immunofloresence staining and *in vitro* protein ubiquitination assays.

Results: We previously identified ubiquitin-conjugating enzyme E2B (UBE2B), a DNA repair enzyme with ubiquitin-conjugating abilities, as a critical regulator of the cell cycle in oral cancer cells. A novel role of UBE2B was further revealed in regulating MGMT dynamics in nasopharygeal carcinoma cells and colon carcinoma cells. Increased colocalization of UBE2B with MGMT was found in BCNU treated cancer cells. Depletion of MGMT or UBE2B in cancer cells resulted in decreased IC50 for BCNU. Lower MGMT expression levels were observed in UBE2B deficient cells. Overexpression of MGMT rescued the UBE2B-depleted cells from the cytotoxic concentrations of BCNU, suggesting that MGMT is a downstream target of UBE2B. The E3 ubiquitin ligase RAD18, that is known as a partner of UBE2B in facilitating PCNA ubiquitination, was analyzed to investigate the mechanism of the UBE2B regulation on MGMT. Interaction of RAD18 and MGMT was observed in cancer cells, and was enhanced under the BCNU treatments. Our results also showed that UBE2B and RAD18 contribute to MGMT ubiquitination under *in vitro* conditions.

Conclusions: Our study indicated that the UBE2B-RAD18 regulation on MGMT plays an important role in BCNU-induced cancer cell death. Thus, UBE2B inhibition may be considered as a potential strategy for cancer treatment. (This work was supported by Taiwan Ministry of Science and Technology under the grants no. NSC 103-2320-B006-036-MY3).

56P Oral squamous cell carcinoma cells were sensitized to cetuximab by Eribulin via induction of the mesenchymal-to-epithelial transition

H. Kitahara, M. Hirai, S. Kawashiri, H. Nakamura

Oral and Maxillofacial Surgery, Kanazawa University Graduate School of Medical Science, Kanazawa, Japan

Background: Inhibition of EGFR signalling has emerged as a new treatment strategy for oral squamous cell carcinoma (OSCC). Previously, we found that loss of EGFR expression in OSCC was associated with EMT, and might have functional implications with regard to resistance to cetuximab, a monoclonal anti-EGFR antibody. Eribulin (a microtubule inhibitor) reportedly renders breast cancer less aggressive, and less likely to metastasise, by triggering the mesenchymal-to-epithelial (MET) transition. Here, we

evaluated whether eribulin-induced MET was associated with re-sensitization of resistant OSCC cell lines to cetuximab.

Methods: In vitro antiproliferative activities were determined in three human OSCC lines (OSC-20, OSC-19 and HOC313) treated with eribulin. These three human OSCC represented different EMT/MET states.

Results: Interestingly, HOC313 cells (mesenchymal phenotype) were highly sensitive to eribulin in comparison with other cell lines, and significantly enhanced the antiproliferative effect of cetuximab in response to the drug. Eribulin also underwent a MET-associated gene switch that resulted in high EGFR expression in HOC313 cells, and abrogated a TGF-β-induced EMT gene expression signature.

Conclusions: Eribulin-dependent sensitization of OSCC to cetuximab is likely due to induction of MET. Combination therapies based on eribulin and cetuximab have potential as a novel treatment regimen in OSCC.

57P In vivo study of the vaccine adjuvants prothymosin alpha and prothymosin alpha(100-109) in melanoma

P. Samara[1], K. Ioannou[1], N. Kavrohorianou[2], S. Haralambous[2], P. Selemenakis[3], A. Kotsinas[3], H. Kalbacher[4], W. Voelter[4], O. Tsitsilonis[1]

[1]Section of Animal & Human Physiology, Department of Biology, National and Kapodistrian University of Athens, Athens, Greece, [2]Laboratory of Transgenic Technology, Hellenic Pasteur Institute, Athens, Greece, [3]Molecular Carcinogenesis Group, Department of Histology and Embryology, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece, [4]Universität Tübingen, Interfakultäres Institut für Biochemie, Tübingen, Germany

Background: The TLR agonist prothymosin α (proTα) pleiotropically stimulates immune cells via generating the appropriate cytokine milieu for their activation. The C-terminal decapeptide proTα(100-109) is considered the immunologically active moiety of proTα, as it restores in vitro the deficient immune responses of cancer patients equally well to proTα. ProTα and proTα(100-109) ligate TLR-4, signal through the TRIF/MyD88-dependent pathways, and promote the maturation of dendritic cells. The latter further stimulate T_H1-type immune responses and prime tumor antigen-reactive T cell functions. We evaluated whether proTα and proTα(100-109) function correspondingly in vivo.

Methods: C57BL/6 mice were subcutaneously inoculated with the syngeneic melanoma B16.F1 cells. Upon palpable tumor formation, mice were intraperitonealy treated with 2 cycles of GM-CSF, proTα(100-109) or proTα, in conjunction with a B16.F1-specific peptide vaccine. Tumor growth and animal survival were monitored. Splenocytes from selected animals were tested for ex vivo cytotoxicity by ^{51}Cr-release assay and CD107 expression. Excised tumors were analyzed by immunohistochemistry, while serum cytokines were quantified by flow cytometry.

Results: Both peptides therapeutically administered in melanoma-bearing mice in the presence of cancer antigens, retarded tumor growth and prolonged the survival of treated animals by 25 days. Ex vivo analysis of spleen cell cytotoxicity confirmed the in vivo induction of B16.F1-specific and non-specific anti-tumor responses. Tumors of mice treated with proTα/proTα(100-109) did not show infiltration of smooth muscle fibers and vessels, produced less melanin, presented limited necrotic areas and were characterized by sparse T cell infiltration. Sera from the same animals contained more IFN-γ, whereas the concentration of IL-4 was marginally increased.

Conclusions: Our results show that proTα and proTα(100-109) induce T_H1-biased immune responses in vivo. As both peptides are non-toxic to normal cells, their ability to orchestrate and modulate the desired anti-tumor immune responses in mice, suggests their eventual exploitation as adjuvants in anti-cancer peptide vaccines in humans.

58P Melanoma affects clock gene machinery of several organs in tumor-bearing mice

L.V.M. de Assis, M.N. Moraes, K.K. Magalhães-Marques, S. Da Silveira Cruz-Machado, A.M.L. Castrucci

Physiology, University of Sao Paulo, Sao Paulo, Brazil

Background: The accumulation of soluble factors in the tumor microenvironment and their release into the bloodstream lead to systemic effects, resulting in cancer-associated syndromes such as cachexia. Another association observed in the latter scenario is chrono-disruption, which has been related with tumor onset and development. In fact, a positive relationship between master clock integrity and healthiness has already been disclosed; however, it is unclear whether the effects of chronodisruption in cancer are locally or systemically exerted. It is known that lung adenocarcinoma reprograms liver metabolism via a pro-inflammatory response without affecting liver clock genes. Our study evaluated whether a non-metastatic skin tumor can affect clock gene machinery of other organs.

Methods: Eight to sixteen-week old C57BL/6J male mice were inoculated subcutaneously with B16-F10 cells (or PBS, control animals), single housed at 22 ± 2 °C, kept under 12/12h light/dark cycle, and received food and water ad libitum. Two weeks after inoculation mice were euthanized 2 hours after lights on (ZT2) or 2 hours after lights off (ZT14). Skin of control animals and samples of non-tumoral adjacent skin, tumor, liver, lung, and brown adipose tissue (BAT) were collected to evaluate the expression of clock genes (*Per1*, *Per2*, *Bmal1*, and *Nr1d1*) by qPCR.

Results: No oscillatory profile of clock genes was detected in skin of control animals, tumor adjacent skin, and tumor itself of inoculated animals; *Bmal1* expression was reduced in adjacent skin and tumor as compared to skin of control animals. In liver and lung tissue, *Per1* and *Per2* oscillated in control animals, and tumor inoculation did not affect this oscillatory profile. Temporal oscillation of *Bmal1* and *Nr1d1* in the liver was lost in tumor-bearing mice. In BAT, *Per1* and *Bmal1* oscillatory expression was also lost in tumor-bearing mice. In all organs analyzed. *Bmal1* transcript was reduced in tumor-bearing mice when compared to control animals.

Conclusions: The presence of a non-metastatic tumor in the skin alters clock machinery in adjacent skin, liver, lungs, and BAT. These data bring new knowledge of how tumor macro-environment affects clock machinery, resulting in a likely chrono-disruption of the organism as a result of a localized tumor in the skin.

59P Is there receptor tyrosine kinases expression on lymphocytes in patients with renal cell carcinoma? First-in-human study

D. Khochenkov[1], M. Volkova[2], A. Olshanskaia[1], S. Aschuba[1], Y. Khochenkova[1], A. Anastasia Bondarenko[3], I. Tsimafeyeu[4]

[1]Laboratory of Biomarkers and Mechanisms of Tumor Angiogenesis, N.N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation, [2]Department of Urology, N.N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation, [3]General Medicine, Sechenov Medical University, Moscow, Russian Federation, [4]Moscow Office, Kidney Cancer Research Bureau, Moscow, Russian Federation

Background: To date little is known about receptor tyrosine kinases (RTK) expression on peripheral blood mononuclear cells (PBMC) and tumor infiltrating lymphocytes (TIL) in cancer patients. The aim of this study was to evaluate expression levels of major RTK: VEGFR1, VEGFR2, PDGFRα, PDGFRβ, FGFR2 in CD45+ population of PBMC and TIL isolated from patients with clear cell renal cell carcinoma (RCC).

Methods: Tumor and blood samples were obtained from 20 patients with RCC immediately after surgical resection of primary tumor. Tumors were harvested into sterile antibiotic-containing RPMI 1640 medium (Gibco). TIL isolation was performed under modified protocol [Baldan et al., 2015]. Isolated TIL and PBMC were prepared for flow cytometry. Cells were double stained with anti-CD45 FITC-conjugated mouse antibody, and with PE-conjugated mouse antibodies to VEGFR1, VEGFR2, PDGFRa, PDGFRb, FGFR2 (all Sony Biotech) and were analyzed on NovoCyte 2000R flow cytometer (ACEA Biosciences). Expression of RTK was evaluated with NovoExpress Software.

Results: Among PBMC 72.1±21.3% cells were CD45-positive. Isolated TIL contain 19.2±5.6% CD45-positive cells. PBMC and TIL express RTK. Expression levels of RTK are summarized in the table.

Table: 59P

Expression of RTK	PBMC	TIL	*P*
VEGFR1	25.6±11.4%	31.0±27.2%	0,699
VEGFR2	23.8±11.1%	53.2±29.3%	0,096
PDGFRa	48.0±18.9%	45.4±16.7%	0,833
PDGFRb	63.3±28.7%	66.7±26.1%	0,843
FGFR2	41.2±27.8%	23.6±12.3%	0,168

Conclusions: To our knowledge, this is first study that showed significant RTK expression on peripheral and RCC-infiltrating lymphocytes in RCC patients. PBMC and TIL have similar RTK expression levels.

60P Understanding and targeting Met signalling in bladder cancer

W. Badreldin, T. Powles, L. Menard, C. Ho-Yen, S. Kermorgant

Tumour Biology, Barts Cancer Institute-Queen Mary University of London, London, UK

Background: Bladder cancer affects 430,000 patients and leads to 165,000 deaths annually worldwide. With no major advances in the management of this disease in the last 2 decades, there is an urgent need to identify therapeutic targets with validated biomarkers. Overexpression of Met, a Receptor Tyrosine Kinase, was shown to correlate with poor prognosis in bladder cancer making it an attractive target. Cabozantinib, a Met inhibitor, showed clinical activity in patients with refractory bladder cancer in a clinical trial. However, little is known about how Met exactly signals in bladder cancer and there are no validated biomarkers. This study aims at unravelling Met signalling in bladder cancer.

Methods: Western blots and confocal/low light microscopy were used to assess Met signalling and its role in wound healing in Transitional Cell Carcinoma (TCC) cells. Met expression was assessed by immunohistochemistry in tissue samples ($n = 64$).

Results: Met is overexpressed in TCC cells and in 78% of invasive bladder cancer tissues. This was associated with a shorter median survival as compared to Low Met levels (12.97 Vs 18.05 months). Stimulation of TCC cells with Met ligand, Hepatocyte Growth Factor (HGF), triggered Met activation and downstream signalling as well as wound healing, all of which were reduced with Met pharmacological inhibitors including Cabozantinib. The PI3K downstream effector AKT was highly activated upon Met activation. Moreover, class I PI3K inhibition with GDC094 significantly inhibited HGF-dependent wound healing. Interestingly, HGF triggered rapid Met endocytosis in TCC cells. Furthermore, pharmacological inhibition of endocytosis reduced Met downstream signalling.

Conclusions: We report that Met is a major target in invasive bladder cancer. Our results further suggest that PI3K may be considered as a co-target of Met to improve patients' outcome. It may also be developed as a biomarker to help select patients who may respond to Met targeted therapy. Finally, we report for the first time that, upon HGF stimulation, Met gets rapidly endocytosed in TCC cells. Furthermore, inhibiting endocytosis reduced Met dependent signalling. All together, our results open the way for novel strategies to target invasive bladder cancer.

61P Integrated molecular signatures of TERT promoter deregulation predict disease outcomes in non-muscle invasive bladder cancer

R. Leão[1], D. Lee[2], A. Figueiredo[3], M. Komosa[4], C. Zhang[5], J. Apolónio[4], N.M. Nunes[4], T. Hermanns[6], P. Wild[7], C. Poyet[6], R.J. Hamilton[1], P. Castelo-Branco[4], U. Tabori[2]

[1]Surgical Oncology/Urology, Princess Margaret Cancer Centre, Toronto, ON, Canada, [2]Hematology Oncology, The Hospital for Sick Children, Toronto, ON, Canada, [3]Urology, Coimbra University Hospital, Coimbra, Portugal, [4]Brain Tumour Research Centre, The Hospital for Sick Children, Toronto, ON, Canada, [5]Brain Tumour Research Centre, The Hospital for Sick Children, Toronto, ON, Canada, [6]Urology, Zurich University Hospital, Zurich, Switzerland, [7]Pathology, Zurich University Hospital, Zurich, Switzerland

Background: Recent studies showed increased interest in telomere biology bladder cancer. These studies were mainly focused on hotspot TERT promoter mutations and their contribution for telomerase activation and clinical outcomes. However, the study of TERT promoter methylation, as an additional deregulatory mechanism of TERT expression, was not studied in this disease. We previously uncovered a region in the TERT promoter region (THOR – TERT hypermethylated oncological region) which is specifically hypermethylated and associated with telomerase activation in cancer tissue. In this study we aim to establish the value of this duet (TERT promoter mutations and THORMeth) in bladder cancer recurrence and progression.

Methods: To explore the impact of TERTpMut and THORMeth on TERT expression and clinical outcomes in UBC we studied two cohorts of UBC patients, 331 FFPE samples. THORMeth status was assessed using quantitative bisulfite pyrosequencing. Sanger Sequencing and ddPCR accessed TERTpMut status. TERT expression was evaluated by ddPCR. Cox proportional hazards models were used to correlate THORMeth and TERTpMut with disease recurrence and progression.

Results: THOR is a diagnostic marker for urothelial bladder cancer. THOR hypermethylated ($n = 127$, 53.6%) is associated with higher levels TERT expression ($p < 0.0001$) and is a risk factor for disease recurrence in NMIBC (Log rank $p = 0.034$) and is crucial for disease progression. TERT promoter mutations are present in all stages and grades ($n = 182$, 76.8%) and are a risk factor for disease recurrence amongst NMIBC (HR: 3.8, $p < 0.0001$). Genetic and epigenetic combined signatures in the TERT promoter allow for a clinical bladder cancer classification system based on underlying telomere biology.

Conclusions: THOR is a novel biomarker for UBC, and, as TERTpMut is able to predict disease recurrence in NMIBC. TERTpMut/highTHORMeth, comprises a distinct signature that is associated with disease progression and higher TERT expression. This fact suggests a hypothetical synergism between both mechanisms and highlights the merit of evaluating TERT promoter methylation as other deregulatory mechanism in TERT expression with implications in patients' outcomes.

62P Dose- and regimen-dependent effects of dexamethasone on extracellular matrix of brain tissue

A.Y. Tsidulko[1], T.M. Pankova[2], C. Bezier[3], G. de La Bourdannaye[4], A.V. Suhovskih[1], G.M. Kazanskaya[5], S.V. Aidagulova[6], E. Grigorieva[1]

[1]Laboratory of Molecular Mechanisms of Carcinogenesis, Institute of Molecular Biology and Biophysics SB RAMS, Novosibirsk, Russian Federation, [2]Laboratory of Central Regulation Mechanisms, Institute of Molecular Biology and Biophysics SB RAMS, Novosibirsk, Russian Federation, [3]Molecular and Cellular Biology, Pierre et Marie Curie University, Paris, France, [4]Biochemical engineering, Institut national des sciences appliquées de Toulouse, Toulouse, France, [5]Laboratory of Experimental Surgery and Morphology, Novosibirsk Research Institute of Circulation Pathology, Novosibirsk, Russian Federation, [6]Laboratory of Cell Biology, Novosibirsk State Medical University, Novosibirsk, Russian Federation

Background: Dexamethasone (DXM) is commonly used in the management of glioma patients to treat intracranial edema but patients often suffer from its side effects. The molecular mechanisms of these side effects are poorly studied. DXM seems to affect extracellular matrix (ECM) especially proteoglycans (PGs) known to be a major component of the ECM in brain tissue. The aim of our study was to investigate if the effects of DXM on brain tissue PGs depend on the treatment regimen or DXM dose.

Methods: Effects of different doses and regimens of DXM treatment on the brain ECM were studied using RT-PCR and IHC in the *ex vivo* model of organotypic brain tissue culture and *in vivo* experimental animal model. The *ex vivo* organotypic culture model was chosen instead of *in vitro* cell culture model as it represents the real 3D structure of the tissue and can be used to study ECM.

Results: The most expressed PGs in rat brain tissue were syndecan-1, glypican-1, decorin, biglycan and lumican. DXM treatment of organotypic hippocampus culture ex vivo led to dose-dependent suppression of brevican, perlecan and biglycan expression and increase in expression of glypican-1, NG2 and versican. In the in vivo experiments, PGs demonstrated age-specific and brain zone-specific expression patterns in normal brain of Wistar rats. The effects of DXM on cortex and hippocampus of the experimental animals were dose- and regimen-dependent. Low-dose DXM treatment led to significant decrease in expression of most PGs in cortex but 3-fold increase in syndecan-1, perlecan and brevican expression in hippocampus. Treatment with high-dose DXM resulted in 2-6-fold increase in most of PGs expression in both brain zones. Long-term treatment led to the most dramatic changes in PGs expression on both mRNA and protein levels, completely changing their expression pattern.

Conclusions: Taken together, obtained data demonstrate an importance of DXM doses/regimens during antiglioma therapy. Long-term treatment and high doses of DXM lead to the most dramatic alteration of PGs composition in brain ECM creating a favorable niche for tumor growth and relapses.

63P Clinical dysregulation of DNA repair by the polynucleotide kinase/phosphatase-XRCC4-DNA ligase IV in neurological disease

D. Aceytuno[1], C.G. Piett[2], Z. Havali-Shahriari[1], R.A. Edwards[1], M. Rey[3], R.S. Mani[4], S. Fang[2], M. Hammel[5], M. Weinfeld[4], J.A. Tainer[6], D. Schriemer[2], S.P. Lees-Miller[2], J.N.M. Glover[1]

[1]Biochemistry, University of Alberta, Edmonton, AB, Canada, [2]Biochemistry & Molecular Biology, Arnie Charbonneau Cancer Institute, University of Calgary, Calgary, AB, Canada, [3]Biochemistry & Molecular Biology, University of Calgary, Calgary, AB, Canada, [4]Oncology, Cross Cancer Institute, Edmonton, AB, Canada, [5]Molecular Biophysics & Integrated Bioimaging, Lawrence Berkeley National Laboratory, Berkeley, CA, USA, [6]Molecular and Cellular Oncology, University of Texas M. D. Anderson Cancer Center, Houston, TX, USA

Background: If not repaired, DNA double-strand breaks (DSBs) can lead to genomic instability and cell death or neoplastic transformation. The major DSB repair (DSBR) mechanism in higher eukaryotes is non-homologous end-joining (NHEJ). In NHEJ, polynucleotide kinase/phosphatase (PNKP) is the primary enzyme for processing abnormal 5'-OH and 3'-phosphate ends that prevent the final repair step by XRCC4/DNA Ligase IV (Lig IV). This processing step is thought to be mediated by an interaction between the PNKP-FHA domain and CK2-phosphorylated XRCC4 C-terminal tails.

Methods: See below.

Results: Our binding assays show tight binding between XRCC4/Lig IV and PNKP both with and without CK2-phosphorylation of XRCC4. Low-resolution ensemble structures of purified phosphorylated-XRCC4/Lig IV/PNKP ternary complex by small-angle X-ray scattering (SAXS) experiments also suggest a second phosphorylation-independent interaction between the PNKP and XRCC4/Lig IV. Hydrogen-deuterium exchange (HDX) experiments have identified a candidate for this secondary interaction site within a loop in the PNKP phosphatase domain. This site contains the clinically significant PNKP E326K mutation found in the severe form of the hereditary neurological disease MCSZ (microcephaly with early-onset intractable seizures and developmental delay). Activity assays show that the E326K mutation decreases both substrate binding and turnover in PNKP when bound to phosphorylated-XRCC4/Lig IV. Furthermore, UV laser microirradiation in cells show that the E326K mutation also disrupts recruitment of PNKP to DNA lesions.

Conclusions: We have identified a putative secondary interaction site that functionally contributes both to recruitment and catalysis of PNKP in NHEJ. Disruptions to PNKP in this region may result in decreased DNA double-strand break repair in cells and describe a molecular basis of MCSZ. Further, PNKP has other known clinical neurological significance and its presence on chromosome arm 19q has interesting implications in oligodendrogliomas. This interaction surface may prove an interesting target for small-molecule inhibition of DNA strand break repair toward novel radio- and chemo-sensitizing therapies in cancer treatment.

64P Effects of rottlerin and genistein through EF2K on proliferation, invasion and cell cycle/death in neuroblastoma cells

M.A. Erdogan, O. Alkan Yılmaz

Physiology, Ege University Faculty of Medicine Department of Physiology, Izmir, Turkey

Background: Neuroblastoma (NB) is the most common extracranial solid cancer in childhood and the most common cancer in infancy in the world. Rottlerin, a naturally occurring polyphenolic compound derived from Mallotus philipinensis, appears to have great potential in cancer therapy because of its effects on proliferation and apoptosis. Genistein is a phytoestrogen and it has been found to inhibit uncontrolled cell growth in several cancers. Recently, we learned that eukaryotic elongation factor-2 kinase (EF2K) is dramatically upregulated in many cancer cells and promotes cell survival and proliferation. Rottlerin and genistein have also showed inhibitory effects on this kinase in other solid tumours like pancreatic cancer. With this is mind, we investigated the effects of rottlerin and genistein in neuroblastoma cells.

Methods: In this study, two human neuroblastoma cancer cell lines (SH-SY5Y and Kelly) were treated with rottlerin and genistein in vitro. Cell proliferation, colony formation and invasion were assessed, and wound-healing tests, western blots (wb), cell cycle and apoptosis analysis by flow cytometry were performed.

Results: Our results showed that rottlerin and genistein treatments caused a significant reduction in cell proliferation, colony formation, and invasion/wound-healing capacity in neuroblastoma cells at concentrations of 5 μM and 30 μM, respectively ($p < 0{,}0001$). The combination of these doses also increased the level of inhibition in these analyses ($p < 0{,}0001$). Additionally, these drugs also increased the level of apoptosis and caused G1 cell cycle arrest in neuroblastoma cell lines ($p < 0{,}0001$). We showed that these treatments markedly inhibit EF2K overexpression. Our wb data suggested that EF2K may enhance tumorigenesis/metastasis through the upregulation of pro-tumorigenic/metastatic pathways in these cells and these agents may produce their anti-proliferative, anti-metastatic and apoptotic effects through EF2K downregulation.

Conclusions: In conclusion, these results indicate that rottlerin and genistein have important effects on neroblastoma cell behaviour and these effects may be caused by downregulation of EF2K.

65P Influence of emotiogenic brain structures on tumor growth in the experiment

E. Korobeynikova[1], E. Rostorguev[2], N.S. Kuznetsova[2]

[1]Laboratory Center, Rostov Research Institute of Oncology, Rostov-on-Don, Russian Federation, [2]Neurooncological Department, Rostov Research Institute of Oncology, Rostov-on-Don, Russian Federation

Background: Stress is the pathogenetic basis of many diseases. It leads to decreasing resistance of the organism, including antitumor one. Emotional stress of a cancer patient affects the quality of life and treatment outcomes by decreasing the antitumor resistance. Therefore, correction of emotional state is an urgent task. The purpose of the study was to reveal the influence of stimulation of emotiogenic brain structures on the antitumor resistance of animals with cancer.

Methods: Transplantable solid sarcoma S45 in white outbred male rats weighing 230-250 g was used as a model of tumor growth. Implantation of bipolar stimulating electrodes in the subcortical structures of the brain was performed aseptically by stereotactic coordinates. Electrodes were implanted to nucleus lateralis septi (LS) – "positive emotiogenic structure" and to Globus pallium (GP) – "negative emotiogenic structure"; the data were compared to the values in animals without electrodes (controls). The stimulation was performed daily for 2 months without changing the stimulation current.

Results: Stimulation of emotiogenic brain structures influenced the dynamics of S45 growth, and LS stimulation caused the greatest inhibition of tumor growth.

Table: 65P

Structure	LS	GP	Controls
n	9	10	10
Initial tumor V (cm^3)	3.0±0.5	3.1±1.9	2.2±1.2
Final tumor V (cm^3)	4.7±1.1	7.5±2.2	6.8±1.6
Tumor increase (%)	53.3±2.8	186±6.5	211±6.8
Effectiveness index	1.4	0.9	
Inhibition of tumor growth (%)	30.8	10.2	

Morphological study of the thymus, spleen and lymph nodes of animals with LS showed signs of high functional activity of the organs providing a high level of resistance.

Conclusions: Electrostimulation of LS influences antitumor resistance, significantly improving it. This suggests the expediency of combining specific anticancer drugs and nonspecific effects of psychotropic drugs - anxiolytics in complex treatment of cancer.

66P Systematic evaluation of the immune microenvironment of neuroendocrine tumours (NET)

C. Vesely[1], A. Childs[1], Y.N.S. Wong[1], O. Ogunbiyi[2], T.V. Luong[2], C. Thirlwell[3], M. Caplin[3], T. Marafioti[1], S. Quezada[1], T. Meyer[1]

[1]UCL Cancer Institute, UCL - University College London, London, UK, [2]Department of Surgery, Royal Free Hospital, London, UK, [3]School of Medicine, Royal Free Hospital School of Medicine, London, UK

Background: Immunotherapy is currently being explored in many tumour types with encouraging results, but has not yet been evaluated in neuroendocrine tumours (NET). Our aim is to characterise the immune landscape of NET and determine which immune-modulatory pathways control the tumour infiltrating lymphocytes (TILs) in order to develop a rational approach for immunotherapy in this tumour type.

Methods: Peripheral blood and fresh tissue was obtained from consenting patients with NET, and subjected to multicolour flow-cytometry to determine the abundance of CD8+, CD4+FoxP3- effector (CD4eff) and CD4+FoxP3+ regulatory (Treg) T cell subsets and the expression of co-inhibitory and co-stimulatory checkpoint molecules on these subsets. Additionally, matched FFPE tissue was obtained for multiparametric immunohistochemistry to investigate the distribution of the immune infiltrate.

Results: Tissue from 23 NET patients including 19 mid-gut tumours (13: G1 and 6: G2) was analysed. Overall the tumours contained a higher proportion of Tregs compared with peripheral blood (8.5% vs 5%, P = 0.02) and had a CD8:Treg ratio of 18.1:24.3 respectively (P = 0.036). The co-inhibitory molecules CTLA-4 and TIM-3 showed highest expression on Tregs, while PD-1 and LAG-3 expression was similar across all T cell subsets. Co-stimulatory molecules, including ICOS, 41BB and OX-40, were also highest on Tregs, as was the recently identified co-stimulatory receptor TIGIT. Immunohistochemistry revealed that the majority of cases have <1% intratumoural CD4+ and CD8+ T cells but a higher number of peritumoural T cells from all subsets. Where present, T cells were predominantly CD8+ and intratumoural CD163+ macrophages were also identified.

Conclusions: These preliminary results provide novel insight into the immune landscape of NET, and may inform the development of targeted combination immunotherapies. Initial results suggest that checkpoint molecules, such as PD1 and LAG-3, may be potential targets in this tumour type and work is ongoing to further elucidate the immunogenic potential of NET.

67P Developing a prediction model for response to lenalidomide treatment in refractory/relapsed multiple myeloma patients

Y-J. Chung, S-H. Yim, S-H. Jung

Precision Medicine Research Center, The Catholic University of Korea, College of Medicine, Seoul, Republic of Korea

Background: Despite improvements in treatment for Multiple myeloma (MM) achieved by novel drugs such as proteasome inhibitors (PIs) and immunomodulatory drugs (IMiDs), most patients will ultimately relapse or become refractory to their current treatment. Therefore, it is important to understand the mechanisms of therapeutic resistance in relapsed/refractory MM (RRMM) for improving treatment outcome. Recently, it was reported that serum or plasma of MM patients showed sufficiently stable miRNA signatures with prognostic impacts in MM cohorts, which can be used as minimally invasive markers for predicting and monitoring treatment outcomes. However, the expression patterns and biological implications of miRNAs are still unclear in RRMM patients receiving lenalidomide with dexamethasone (Len-dex).

Methods: We investigated the expression of serum miRNAs by genomewide miRNA array analysis and explored their predictive values in RRMM patients receiving Len-dex.

Results: We explored the associations of miRNAs with treatment outcome of Len-dex treatment and prognosis in 55 RRMMs (25 good responders and 30 poor responders) and built a prediction model for treatment response. Three miRNAs (miR-29c-3p, miR-30c-5p, and miR-331-3p) were found to be significantly down-regulated in poor responders. In survival analysis, lower expression of the three miRNAs was significantly associated with shorter time to progression (TTP) or poorer overall survival (OS). Eight clinical factors were also associated with TTP or OS. By combining the miRNA markers and clinical markers, we designed a a prediction model for response to lenalidomide treatment in RRMM patients. Our model showed better prediction power (AUC=0.855, sensitivity 84%, specificity 76%, and accuracy 81%) than international staging system (ISS) based prediction.

Conclusions: Our results suggest the potential of circulating miRNAs as minimally invasive markers for treatment response and prognosis in RRMM patients.

68P Combinatorial inhibition of mTOR and exportin-1 (XPO1) represses cell survival via metabolic modulation of pro-survival pathways in mantle cell lymphomas

K. Sekihara[1], K. Saitoh[1], H. Yang[1], T. Miida[1], M. Andreeff[2], Y. Tabe[1]

[1]Clinical Laboratory Medicine, Juntendo University School of Medicine, Tokyo, Japan, [2]Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX, USA

Background: MCL is an aggressive B-cell lymphoma with aberrant expression of several oncogenic effectors and requiring novel anticancer strategies. The nuclear transporter exportin-1 (XPO1) is highly expressed in MCL and is critical for cancer survival and proliferation. mTOR signaling is frequently activated and an important therapeutic target in MCL. In this study, we investigated the antitumor effects and molecular/metabolic changes induced by combined with dual mTOR inhibitor AZD-2014 and XPO1 inhibitor KPT-185 on MCL cells under the hypothesis that mTOR inhibition by AZD-2014 represses KPT-185 inducedupregulation of glycolysis.

Methods: Four MCL cell lines (Jeko-1, X138, JVM-2, and MINO), primary MCL cells, and normal bone marrow samples were utilized. Cell viability was evaluated by MTT assay. Cell cycle and apoptosis were determined by flow cytometric analysis. cDNA array, iTRAQ proteomic, immunoblotting and metabolome analysis using CE-TOF-MS were also performed.

Results: AZD-2014 enhanced KPT-185-induced the inhibition of cell growth and repression of cell viability in MCL cells but not in normal bone marrow cells. Different mTOR inhibitors (AZD-8055 and MLN0128) demonstrated similar effects. AZD-2014+KPT-185 decreased expression of the oncogenic mediator c-Myc andthe translational/transcriptional network regulator HSF1as detected by immunoblotting. iTRAQ proteomic analysis demonstrated thatthe combination caused repression of ribosomal biogenesis. Treatment with either AZD-2014 or KPT-185 depressed phospho-S6.CET-OF-MS metabolite assay showed that AZD-2014+KPT-185inhibited theKrebs cycle, and that AZD-2014 effectively repressed KPT-185-induced upregulation of glycolysis. cDNA array detected downregulation of NOD2which is known to trigger activation of MAP kinases and of NF-kappa-B signaling. Moreover, AZD-2014+KPT-185 activated AMPK, an energy stress marker in a cell type-dependent manner.

Conclusions: Our findings indicated that the combinatorial inhibition of mTOR and XPO1 identifies a novel synthetic lethality mechanism that could be exploited clinically, following satisfactory completion of pre-clinical in vivo studies.

69P CD200 and indoleamine 2,3-dioxygenase-1 (IDO-1) overexpresion in relapsed acute myeloid leukemia patients

A. Memarian[1], S. Abdolmaleki[2], M. Mirahmadian[2], M. Jeddi-Tehrani[3]

[1]Stem Cell Research Center, Golestan University of Medical Sciences, Gorgan, Iran, [2]Department of Immunology, Tehran University of Medical Sciences, Tehran, Iran, [3]Monoclonal Antibody Research Center, Avicenna Research Institute, Tehran, Iran

Background: Immunosuppression is one of the major causes of AML pathogenesis and progression. CD200 and IDO are immunoregulatory factors which overexpressed in some solid tumors and hematological malignancies. Distinct researches have shown CD200 and IDO expression is associated with AML progression. In the current study, we simultaneously examined the expression of these molecules, as the two important factors including in immunosuppression, in the newly diagnosed and relapse AML patients to investigate their correlation with each other.

Methods: 48 PBMC samples of newly diagnosed and relapse AML patients were tested and also 32 normal subjects were employed as control. CD200 expression level was examined on cells by Flow cytometry and quantitative real time RT-PCR was used to determine the IDO-1 gene expression. Finally, data were analyzed statistically.

Results: Data showed that CD200 and IDO-1 overexpressed especially in relapsed patients. Comparison between FAB AML subgroups demonstrated no statistical differences in the case of CD200 level but expression of IDO-1 was slightly increased only in M4 subgroup in comparison to M3. Correlation analyses showed strong association between expression of CD200 and IDO-1 in all patients particularly in relapsed AML, whereas no significant correlation was found in normal subjects.

Conclusions: According to the role and overexpression of CD200 and IDO-1 in AML patients and also their two-way correlation with T-regs in disease induction and progression, simultaneous assessment of these parameters are so valuable for more exact prognosis detection. Also inhibition of all these immunoregulatory pathways could be so useful for immunotherapy outcome, especially in relapsed AML.

70P Correlation between types of acute lymphoblastic leukemia with socio demographic factors

M. Sen[1], J. Basak[1], A. Mukhopadhyay[2]

[1]Molecular Biology, Netaji Subhas Chandra Bose Cancer Research Institute, Kolkata, India, [2]Medical Oncology, Netaji Subhas Chandra Bose Cancer Research Institute, Kolkata, India

Background: Acute lymphocytic leukemia (ALL) is the most predominant hematopoietic clonal disorder in children than adult. ALL classifies into two subtypes: B –ALLand T-ALL. The incidence of ALL subtype in urban areas is generally higher than rural areas. In the Western World, the predominant immunophenotype observed in ALL is B-ALL with 60-80% of total case, and T-ALL is only 15-20%. But in case of developing country like India the reverse is true. The objective of the present study is to examine and correlate T-ALL and B-ALL in leukemia patients with respect to socio-demographic factors.

Methods: During May 2015 - April 2017, total 427 ALL patients (male:female::1.9:1), age between 2-60 years attended OPD and IPD of Netaji Subhas Chandra Bose Cancer Research Institute, Kolkata, India. We have collected peripheral blood and/or bone marrow samples for immunophenotyping by FACS after taking written consent from the patients. Each sample is evaluated with a panel of monoclonal antibodies and compared the immunophenotyping data with socio-demographic factors (age, sex, economic and social status etc).

Results: The overall survival of ALL patients (with mean age 13.6 years) in 2 year is 73.6%. In our hospital, the economically weak patients (77.05%) are more abundant than economically sound patients (22.95%). Out of 427 patients, T-ALL (51.28%) is predominantly higher than B-ALL (48.71%). We found that immunophenotyping data is correlated with all the socio demographic data i.e., sex, economic and social status etc. Though disease free survival and event free survival is markedly higher in B-ALL compared to T-ALL, but we found the survival of T-ALL is also increasing.

Conclusions: Our unique findings emphasize that the detection of T-ALL and B-ALL by immunophenotypic analysis for better treatment and outcome of the patients and also trying to correlate the prevalence of T-ALL and B-ALL with economical status and also with other socio-demographic factors in study area.

71P CALR mutations and their link with cellular calcium during megakaryocyte hyperplasia in MPNs

M. Morlan Mairal[1], P. Papadopoulos[2], J. Hetmanski[3], P.T. Caswell[3], M. Krstic-Demonacos[1], A. Aziz[1]

[1]Environment and Life sciences, University of Salford, Salford, UK, [2]Dept of Hematology, Hospital Clinico San Carlos, Madrid, Spain, [3]Wellcome Trust Centre for Cell-Matrix Research, University of Manchester, Manchester, UK

Background: Megakaryocyte hyperplasia is a major characteristic of two myeloproliferative neoplasms (MPNs) known as essential thrombocythemia (ET) and Primary myelofibrosis (PMF). About 35% of ET and PMF patients harbour somatic *calreticulin* (*CALR*) mutations. CALR is a calcium (Ca^{2+}) buffering protein within the endoplasmic reticulum (ER). Ca^{2+} is an important element for megakaryocyte functions; however the impact of *CALR* mutations in cellular Ca^{2+} during megakaryocyte hyperplasia remains elusive.

Methods: *I-TASSER* software was used to study the aminoacid charge using the 3D structure of CALR mutant. Marimo cells and overexpressing CALR mutant HEK293T and DAMI cells were used as cellular models. CALR cellular localization was addressed by flow cytometry and confocal microscopy. Basal Ca^{2+} levels were measured by Fluo-8 staining. Furthermore cells were treated with Fendiline and BTP-2 calcium channel blockers to manipulate cellular Ca^{2+}.

Results: The present study shows that *CALR* mutations change the aminoacid charge of the Ca^{2+} binding region of CALR and that mutant CALR is localized outside the ER, within the cytoplasm and the cellular membrane. These results suggest that *CALR* mutations could be affecting the Ca^{2+} buffering activity within the ER. Therefore, we further analysed Ca^{2+} basal levels in CALR mutant cells, and our results showed that *CALR* mutations show lower cellular Ca^{2+}levels. These results lead us to think that low intracellular Ca^{2+} levels could be the driving force of megakaryocyte hyperplasia characteristic of ET and PMF. Therefore, we induced low intracellular Ca^{2+} levels in leukemic blast by using Ca^{2+} channel blockers and our results showed that treated cells display an increase of the megakaryocyte marker CD41a in the cell surface, suggesting an induction of megakaryopoiesis in these cells.

Conclusions: These findings elucidate that low intracellular Ca^{2+} caused by *CALR* mutations could be the driving force of megakaryocyte formation in ET and PMF. This study shows the relevance to understand the role of cellular calcium during megakaryocyte formation and this could unravel the pathogeny of CALR mutant in MPNs.

72P Approach based on magnetic nanocomplexes improves antitumor efficacy of dendritic cells immunotherapy in mice

M. Inomistova[1], N. Khranovska[1], O. Skachkova[1], O. Makeenko[2], V. Orel[2]

[1]Laboratory of Experimental Oncology, National Cancer Institute of the MPH Ukraine, Kiev, Ukraine, [2]Laboratory of Medical Physics and Bioengineering, National Cancer Institute of the MPH Ukraine, Kiev, Ukraine

Background: Dendritic cell (DC)-based immunotherapy represents a promising approach for cancer treatment. However, the DC homing rate to the lymphoid tissues is poor, thus hindering the activation of antigen-specific T cells and reducing their antitumor efficacy. Here, we developed an approach based on magnetic nanoparticles (NP) to manipulate DC migration and thus elicit a more robust and efficacious antitumor response in tumor-bearing mice.

Methods: Mouse spleen DCs were loaded with nanocomplexes (NC) consisting of iron oxide NP ($8x10^{-12}$ g/cell) and lyophilized tumor tissue. To investigate the presence of NP in DCs, the method of $Fe2^{+}$ and $Fe3^{+}$ detection by Prussian Blue Staining was used. DCs were injected intradermally into tumor-bearing mice three times in an amount of $2x10^{5}$ per mouse at an interval of 3 days starting from day 7 after Lewis lung carcinoma inoculation. One group of mice that received DCs loaded with NC was exposed to a magnetic field for 1 h. The number and volume of metastases and tumor weight were assessed 28 days after tumor inoculation. At the same time, the levels of INF-γ, IL-10, TGF-ß, IL-4, FoxP3 mRNA expression in the spleen and inguinal lymph nodes were determined.

Results: The iron oxide NP showed no toxic effects on the DCs and had no effect on their viability. We found that almost all DCs are able to incorporate magnetic NP after 24h of incubation. Fewest metastases were found in the mice that received DCs loaded with NC and were exposed to a magnetic field: the number of metastases in mice from this group was 1.7 times less than in control mice. It should be noted that the volume of metastatic nodes in the lungs and the mass of the primary tumor were practically the same as in the control mice. The most pronounced decrease in FoxP3 mRNA levels in the lymph nodes, indicating a decrease in the activity of regulatory T cells, was also noted in the mice receiving DCs loaded with nanocomplexes and exposed to a magnetic field. In the mice of this group, a significant decrease in the level of IL-4 in the spleen was detected.

Conclusions: Our results suggest that an approach based on magnetic NC could be a promising strategy for improving the antitumor efficacy of DC-based immunotherapy.

75P Signs of tumor-specific immune processes in the regression of large rat tumors under the influence of low-intensity EMR EHF and magnetite nanoparticles

G. Zhukova[1], A. Shikhliarova[1], T. Barteneva[1], M. Bragina[1], E. Shirnina[1], I.A. Novikova[2]

[1]Testing Laboratory Center, Rostov Research Institute of Oncology, Rostov-on-Don, Russian Federation, [2]Laboratory of Immunophenotyping of Tumors, Rostov Research Institute of Oncology, Rostov-on-Don, Russian Federation

Background: The problem of elaboration of methods for effective mobilization of immune antitumor processes remains urgent. Earlier, it was shown that regression of experimental animal tumors can be achieved under the influence of low-intensive electromagnetic radiations (EMR) and magnetite nanoparticles (NPs) (Garkavi L.H. et al, 1996; 2013).The aim of the study was to determine the possibility of regression of large transplanted tumors of white rats under the influence of low-intensity EMR of millimeter range (EHF) and magnetite NPs.

Methods: In experiments on 123 white outbred male rats (200-300g) with transplanted Pliss lymphosarcoma - low-intensity EMR EHF (42.2 GHz, 10 mW/cm^2, exposure 15-30 min, low-frequency modulation) and magnetite NPs (10 ± 2 nm) in the form of the magnetic fluid AM-01 ("AM-Cube", Ekaterinburg) were used. The EMR acted on the animal's head starting 3 days before the tumor was transplanted. NPs were injected into peritumoral zone 2-3 times a week in a single dose of 17.7 mg/kg to animals with already formed tumors. Duration of treatment was 4 weeks. We studied the dynamics of tumor size, histochemical and cytometric changes in tumor tissue. The Wilcoxon test was used to evaluate the results.

Results: When EMR EHF was used, complete regression of tumors with a size of 5-6 cm^3 and a partial regression (by 30-40%) of tumors with a size of 10-13 cm^3 were noted. The effect was obtained in 33% of the animals. In cases of using of magnetite NPs, tumor regression was observed in 40% of the animals, complete regression of tumors with a size of 5-30 cm^3 was observed. Before the regression began, the tumor growth rates did not differ from those in the control group when using as one as the other factor. In addition, the regression was characterized by a rapid rate (5-7 days) and no signs of intoxication in animals. In the peritumoral area considerable macrophage activity and increasing number of cytotoxic T-lymphocytes were noticed.

Conclusions: The timing of the onset of regression, its dynamics and the absence of signs of intoxication during rapid elimination of large tumors indicated the deployment of antigen-presentation processes and specific killing of tumor cells by inducing apoptosis.

76P Stimulation of RAC1/PAK1 signalling upregulates DNA damage repair genes via the BCL6/STAT5-switch

P. Barros[1], A.J. Amaral[1], L.B. Abrantes[1], T. Oliveira[1], H. Louro[2], M.J. Silva[2], P. Jordan[2], M. Gama-Carvalho[1], P. Matos[1]

[1]BioISI, University of Lisboa, Faculty of Sciences, BioISI – Biosystems & Integrative Sciences Institute, Lisbon, Portugal, [2]Departamento de Genética Humana, Instituto Nacional de Saúde, Doutor Ricardo Jorge, Lisbon, Portugal

Background: Colorectal cancer is one of the most prevalent types of cancer worldwide. The GTPase RAC1 and its effector PAK1 have been found overexpressed or hyperactivated in this type of cancers, particularly those with more aggressive and invasive features, which is frequently correlated with resistance to chemotherapeutics and unfavourable clinical prognosis. Previously, we described a new signalling pathway in

which activation of RAC1/PAK1 signalling promotes a transcriptional switch between the BCL6 repressor and the STAT5 transcriptional activator at a restricted subset of gene promoters.

Methods: Here we used a novel combinatory ChIP-Seq approach for the genome-wide identification of the BCL6/STAT5-switch target genes.

Results: Ontological enrichment analysis among the identified target genes revealed an overrepresentation of genes involved in DNA damage repair. Using the comet assay as readout for the extent of DNA damage, we show that the activation of RAC1/PAK1 signalling significantly accelerates DNA damage repair through the upregulation of pivotal genes.

Conclusions: This work highlights an additional role for the RAC1/PAK1 signalling axis that may contribute to the chemoresistant phenotype of aggressive colorectal tumours.

77P Deciphering the regulation of the metastasis suppressor, NDRG1 in different cancer-types and its functional implications

K.C. Park, Z. Kovacevic, D. Richardson

Pathology, The University of Sydney, Sydney, Australia

Background: The metastasis suppressor, N-myc Downstream Regulated Gene-1 (NDRG1) inhibits metastasis in a variety of cancer-types, including cancers of the breast, colon, pancreas and prostate. Its potent anti-oncogenic effects were demonstrated in multiple *in vitro* and *in vivo* studies, making it a promising therapeutic target. However, exactly how NDRG1 is regulated in different cancer-types and how different regulatory mechanisms affect NDRG1 function remain to be elucidated. Notably, post-translational modifications (PTMs), phosphorylation and cleavage of NDRG1, have been associated with its function. Therefore, it was crucial to examine whether these PTMs occur universally or selectively in different cancer-types. Further, considering the DNA repair role suggested for nuclear NDRG1, the effects of the above PTMs on nuclear NDRG1 levels was examined.

Methods: DU145 and PC3 prostate cancer cells, PANC-1 pancreatic cancer cells, HT-29 colon cancer cells, HepG2 and Hep3B hepatocellular carcinoma (HCC) cells were utilised. Full-length (FL) and truncated (T) NDRG1 isoforms were detected using a C-terminus directed antibody. The FL isoform was detected using an N-terminus directed antibody. Ser330 or Thr346 phosphorylation (p-NDRG1) was detected using specific antibodies.

Results: For the first time, we demonstrated that phosphorylation and potential cleavage of the NDRG1 protein occurs in all the various cancer cell-types examined. Although the levels varied, both the FL and T NDRG1 and its phosphorylated form were detected in all tumour cells assessed. The FL NDRG1 isoform was predominantly found in the cell nucleus. Ser330 p-NDRG1 was also highly localised in the cell nucleus, while Thr346 p-NDRG1 was mostly cytoplasmic. These cellular distribution patterns were similar in all cancer-types tested.

Conclusions: This study demonstrates for the first time that the NDRG1 protein is phosphorylated and potentially cleaved in diverse cancer cell-types. Further, FL NDRG1 and Ser330 p-NDRG1 were highly localised to the cell nucleus. These results indicate that the N-terminus region and phosphorylation at Ser330 could be crucial for nuclear expression and the well-known anti-metastatic function of NDRG1.

78P Registration-based automated lesion detection and therapy evaluation of tumors in whole body PET-MR images

H. Ahlström[1], S. Ekström[1], T. Sjöholm[1], R. Strand[1], J. Kullberg[1], E. Johansson[2], P. Hagmar[2], F. Malmberg[1]

[1]*Division of Radiology, Department of Surgical Sciences, Uppsala University, Uppsala, Sweden,* [2]*Antaros Medical, Mölndal, Sweden*

Background: Integrated PET/MR scanners can simultaneously acquire whole body functional PET data together with morphological and functional MR data. Whole-body PET-MRI datasets contain huge amounts of spatially detailed morphological, functional and metabolic information. We propose a method, based on deformable registration to a whole-body atlas, for computer aided detection of lesions in image data from an integrated PET-MRI system.

Methods: Images were acquired using an integrated 3T PET-MRI system (Signa PET/MR, GE Healthcare). Fat and water MR images were collected using a Dixon MR Attenuation Correction (MRAC) sequence (TE 1.67ms, TR 4.05ms, voxel size: 2x2x5.2 mm). Subjects underwent a PET scan after injection of [F18]-FDG (2 MBq/kg) with 3 minutes per bed, with a 100-120 minute interval between injection and scan start. PET reconstruction was performed using GE's fully 3D Time-of-Flight iterative reconstruction (2 iterations, 28 subsets, standard 5 mm filter, voxel size 3.125x3.125x2.78). Deformable image registration was used to spatially align subjects to a previously created morpphological and functional whole-body imaging atlas (Ekström et al., ISMRM 17), to allow voxel-wise comparisons between the imaged subjects and the atlas. Each voxel in the atlas contains mean and standard deviation of the PET uptake. Utilizing the knowledge that low ADC-values (low diffusion measured by MRI) and high FDG uptake (high metabolism measured by PET) is indicative of malignancy, suspected lesions can be detected by measuring how much the FDG uptake in each voxel deviates from "normality", as defined by the atlas. This approach generates a voxel-wise "lesion probability map" for the imaged subject. The same registration approach can be used to quantify longitudinal changes in detected lesions, for treatment evaluation.

Results: Lesion probability maps have been generated for patients with manually identified lesions, correctly assigning high values to the regions manually identified as suspected lesions.

Conclusions: The proposed method is promising for lesion detection in whole body PET-MRI images. Future work includes quantitative verification of the accuracy of the detected regions, comparing against manual detection by a radiologist.

79P 1,3,5 s-triazine containing analogues a prime Src family inhibitor: Design synthesis docking, anticarcinoma and angiogenic inhibition efficacy on cancer grafted CAM

P. Pathak[1], A. Balkrishna[2], P.K. Shukla[1], V. Kumar[1], A. Kumar[3], A.K. Singh[4], A. Verma[1]

[1]*Pharmaceutical Science, Sam Higginbottom Institute of Agriculture, Technology & Sciences, Allahabad, India,* [2]*Drug Design and Discovery, Patanjali Research Institute, Haridwar, India,* [3]*Pharmacy, SV Subharti University, Meerut, India,* [4]*Clinical, ESIC, Delhi, India*

Background: The importance of angiogenesis for solid tumor growth is well recognized and evident by the vast differential of research devoted to the subject for over thirty years. It is a complex process directed by growth factors, receptors, extracellular matrix (ECM)-to-cell and cellto- cell interactions. Tyrosine kinase (TKs) is the protein enzymes catalyze the transfer of a phosphate group from an ATP molecule to a tyrosine residue of the target protein, thus leading to signal transduction. Cytoplasmic TKs such as Src, Abl and Lck have been to date discovered and characterized and found that inhibition signalling pathway. A special Src protein like FAK is a non-receptor protein-tyrosine kinase which have vital role in various cellular function like cytoskeleton reorganization, migration, adhesion, spreading, configuration and destruction of FA, cell protrusions, progression, proliferation and apoptosis. The functional ateration of Src signal may be the reason for cancer and metastasis. So this can predict that Src and their signal inhibition can utilized in cancer therapy. Triazine containing hybrid analogues act as a prime skeleton to inhibit Src family TKs like FAK so in present project we constructed 1,3,5-triazine containing analogues (TCA) as an effective cancer induced angiogensis inhibitor.

Methods: TCA analogues constructed accordingly similarity field positioning and pattern through forge V10. Further more *in-silico* simulation was done using autodock for most prominent analogues. The analogues derived via multifactorial synthetic protocol. The activity evaluation proceeded via *in-vitro* assay against MCF-7 (Breast cancer) cell line and further *in-ova* antiangiogenic potency evaluated against cancer induced chick chorioallantoic membrane.

Results: The newly designed and constructed TCA heterocycles expressed more than 56% of similar field point pattern and intra atomic alignments. The prominent pattern showed by the analogue 8d (chloro-anilino) and 8k (bromo-anilino). *In-silico* docking on hydrophobic site of Src family protein (PDB: 4BRX) revealed that analogue 8d have binding with CYS502, TR503, GLU506, ILE428, ASN551 while analogue 8k shoed interaction with THR503, GLU506, ILE428, LEU567, ASN551 amino acid residue which was similar like vendatinib. Biological evaluation showed that analogues 8d and 8k have great tendency to inhibit cancer induced angiogenesis with marginal toxicity profile.

Conclusions: We have developed a significant series of anticancer analogues and propound the site of binding on the surface of Src family TKs receptor FAK.

81P A new isoquinoline alkaloid bersavine as a possible anticancer agent

K. Habartová[1], R. Havelek[1], M. Seifrtova[1], A. Hostalkova[2], L. Cahlikova[2], M. Rezacova[1]
[1]Department of Medical Biochemistry, Faculty of Medicine in Hradec Kralove, Charles University, Hradec Kralove, Czech Republic, [2]ADINACO Research group, Department of Pharmaceutical Botany and Ecology, Faculty of Pharmacy, Charles University, Hradec Kralove, Czech Republic

Background: Plants have had crucial role in the folklore of ancient cultures for over 5000 years. In addition to the use as food or spices, plants have also been utilized as medicine. Two remaining living traditions, the traditional Indian and Eastern medicine, have contributed most to the current state of knowledge related to medicinal plants. In their folklore, herbal medicines were prepared e.g. as teas or tinctures. These products are used as complementary treatment alongside conventional drugs till today. Another trend begun in the early 19th cent., which involved the isolation of active compounds from plants. This tendency led to the discovery of the analgesic alkaloids morphine and codeine or the cardiac glycoside digitoxin. Recently, a new alkaloid bersavine was isolated from *Berberis vulgaris*, along berbamine and berberine.

Methods: The dried root bark from *Berberis vulgaris* was minced and extracted with EtOH. The extract was evaporated, dissolved in HCl and extracted with nonpolar solvent. After the second extraction column chromatography on Al_2O_3 was performed. Subsequently was executed preparative TLC, which reveal a yet unknown alkaloid, later identified by MS and NMR analysis and named bersavine. Effect of bersavine on viability and proliferation was evaluated by WST assay and Trypan blue staining. Next was analysed its impact on cell cycle and apoptosis using the flow cytometry, activity of caspases and Western blot analysis of regulatory proteins was implemented.

Results: Bersavine's effect on cancer cells was first evaluated on panel of 9 different cell lines. Cancer cell lines MOLT-4, Jurkat, HT-29, HeLa and MCF-7 appear to be the most sensitive to the effect of bersavine. Follow-up experiments revealed that bersavine reduced cell viability and proliferation in a dose dependent manner within 24 h of treatment. Moreover, the reduction of cell viability was even more pronounce 48 h following the treatment. The decrease in cell viability was caused by the induction of apoptosis and activation of caspases.

Conclusions: All acquired results suggest that bersavine has very promising activity and it would be worthwhile to subject it to further evaluation.

82P Tactics of surgical treatment of tumors of the sacrum

I. Khujanazarov[1], I. Alimov[1], S. Ishmuhammedov[1], M. Gafur-Akhunov[2]
[1]Traumatology, Military Surgery and Neurosurgery, Tashkent Medical Academy, Tashkent, Uzbekistan, [2]Oncology, Tashkent Medical Academy, Tashkent, Uzbekistan

Background: Tumor lesions of the sacrum are relatively rare and account for 1-7% of all spinal tumors. Tumors of this localization are usually detected when the tumor reaches a significant size and causes gross neurologic disorders and impaired pelvic organs. Radicality of removal of tumors of the sacrum depends on the involvement of the cauda equina, pelvic organs and vascular structures in the process.

Methods: The study involved 13 pateintd TMA clinic on the basis of the Department of Traumatology, Orthopedics, Neurosurgery with GPH No2 from 2011 to 2016. There were 6 women, 7 men. Age category ranged from 17 to 50 years. 1-stage: Holographic selective angiography by Seldinger's method of small pelvic vessels with subsequent embolization of "feeding" tumor of vessels. In addition, the anatomical features of the arteries are determined taking into account the localization of the tumor process, which is important in the operation. 2-stage: After preoperative embolization, three patients underwent hemisakrumectomy with VS3-VS5, and three patients underwent VS1-VS3 sarcomectomy. In this case, patients were additionally stabilized by TPF systems by Lumbo-Pelviofixation.

Results: In 2 cases during surgery, the tumor was intimately soldered to the roots of the horse tail and their isolation led to traumatization of the horse's tail, resulting in a postoperative delay in urine and stool. These violations were resolved within 2 months. In 4 patients with neurinoma S1, S2, S3 spine, an involuntary resection of these roots was performed. In these cases complications from the pelvic organs were not observed due to the presence of a cross innervation. In 2 patients, because of the duration of the operation, suppuration of the operating wound was noted with subsequent secondary healing. There were no lethal outcomes among 13 patients during follow-up.

Conclusions: The tactics of surgical treatment of sacral tumors, including the preliminary embolization of "feeding" arteries with subsequent radical removal of volume formation, reduces the risk of intraoperative complications, and also allows to remove the tumor totally, which in turn prevents its recurrence.

83P The impact of co-culture of NSCLC tumor cells and fibroblasts on drug response

S. Abreu[1], V. Espírito Santo[1], A. Oleksijew[2], E. Oswald[3], M.F. Estrada[1], S.P. Rebelo[1], K. Vaidya[2], J. Schuler[4], P.M. Alves[1], E.R. Boghaert[2], C. Brito[1]
[1]Animal Cell Technology Unit, IBET, Instituto de Biologia Experimental e Tecnológica; ITQB, Instituto de Tecnologia Química e Biológica António Xavier, Oeiras, Portugal, [2]AbbVie, Chicago, IL, USA, [3]Cellular Science Charles River Laboratories, Oncotest, a Charles River company, Freiburg, Germany, [4]In vivo operations, Oncotest, a Charles River company, Freiburg, Germany

Background: The role of stromal cells and the tumor microenvironment has been described to modulate cancer development and tumor drug sensitivity, in part due to the interaction with fibroblasts. Therefore, it is critical to incorporate this feature in our in vitro model and to evaluate its potential impact in early stages of drug development.

Methods: Non Small Cell Lung Cancer (NSCLC) tumor cell aggregates were microencapsulated in alginate capsules, alone or in combination with fibroblasts (immortalized normal and cancer-associated fibroblasts – NFs and CAFs, and human dermal fibroblasts - hDFs), cultured during four weeks; and tumor growth and drug response, both *in vitro* and *in vivo*, were evaluated.

Results: Microencapsulation of H1650 and H1437 spheroids in mono- or co-cultures with fibroblasts resulted in viable cultures with tumor aggregate increasing continuously during culture time. However, tumor growth in in vitro co-cultures was dependent on the source of fibroblast and cell line used. When challenged with drugs, co-cultures with fibroblasts in our in vitro 3D model presented, in general, lower sensitivity to therapy after 3 weeks of treatment. H1437+hDFs co-cultures showed less sensitivity to volasertib treatment, with higher DNA concentration (2-fold higher versus mono-cultures) and higher resazurin reduction activity (35% versus 22% in mono-cultures). H1650+NFs co-cultures also demonstrated lower sensitivity to erlotinib and docetaxel treatment, with higher resazurin reduction activity (71% versus 29% in mono-cultures) and higher viable area of aggregates, respectively. Mono and co-cultures can also be injected in mice for the generation of xenografts. Evaluation of tumor growth based on the local of injection, fibroblast source and drug response was compared. In agreement with the in vitro results, only co-culture of H1437+hDFs injected in the lungs significantly enhanced in vivo tumor growth. However, co-culture of H1650 with fibroblasts did not result in altered tumor growth in vivo.

Conclusions: Altogether, we established a 3D model with co-culture of NSCLC tumor cell aggregates and fibroblasts that, depending on the pair used, presented reduced sensitivity to standard of care drugs, better reflecting the clinical observations.

Background: Antibodies targeting the PD-1 pathway have shown durable clinical benefit in multiple cancers. In the KN028 trial, the antitumor activity and safety of pembrolizumab were investigated in 20 solid tumors. Associations between PD-L1 expression and a T-cell inflamed GEP with response to anti-PD-1 therapy were also evaluated.

Methods: KN028 is a nonrandomized, phase 1b multicenter trial in patients with PD-L1 positive (≥1%, modified proportion score or interface pattern, QualTek IHC) advanced solid tumors treated with pembrolizumab 10 mg/kg Q2W for ≤2 y or until confirmed progression/unacceptable toxicity, death or withdrawal of consent. Response was assessed every 8 wk for 6 mo then every 12 wk. The primary endpoint was ORR (RECIST v1.1, investigator assessment [INV]) in patients who received ≥1 dose of pembrolizumab and had measurable disease. Secondary endpoints included safety, PFS and OS. ORR by central radiology review (IRC). Exploratory endpoints included relationships between GEP score (FFPE extracted RNA analyzed on NanoString nCounter) and PD-L1 expression levels (combined positive score, Dako IHC) with ORR and PFS. Data cutoff date was Feb 20, 2017.

Results: In the total study population (N = 475), there were 66 responders among 471 evaluable patients. ORR (95% CI) by INV ranged from 4.2% (0.1, 21.1) to 33.3% (15.6, 55.3) in 19/20 tumor types; no responders were observed in pancreatic carcinoma. ORR >10% was observed in 13/20 types (58/66 responders). ORR (95% CI) by IRC ranged from 4.3% (0.1, 21.9) to 26.3% (9.1, 51.2) in 18/20 tumor types. Treatment related AEs occurred in 65.5% of patients (14.1% grade 3-5). PD-L1 expression ($p = 0.034$) and GEP ($p = 0.012$) were associated with ORR in meta-analysis across tumors. Data for PFS, OS and relationships between PD-L1, GEP and MSI status with ORR will also be presented.

Conclusions: Pembrolizumab demonstrated favorable responses and manageable toxicity in the majority of the tumor types in KN028. Both PD-L1 and GEP score were predictive of clinical response, suggesting the utility of these biomarkers in selecting patients for immunotherapy and other novel therapies across a wide spectrum of tumor histologies.

Background: The presence of T790M mutation in *EGFR* accounts for nearly 50% of the acquired resistance to EGFR-TKIs. Earlier studies performed in small cohorts suggest that T790M was also detected in TKI-naïve NSCLC. Here, we use an ultra-sensitive ddPCR to address the incidence and clinical significance of T790M in a larger cohort of TKI-naïve NSCLC.

Methods: We analyzed 343 *EGFR* mutated patients of IFCT Biomarkers France program with available tumor DNA that were finally treated by EGFR-TKI. ddPCR™ was performed with QX200 system (BIO-RAD®, Hercules, USA). All samples were tested in duplicate. Colon cancers DNA were used negative controls.

Results: ddPCR identified a T790M mutation in 23/256 specimens (9%). T790M Fractional Abundance (FA) was ≥10%; ≥1% <10%; ≥0.1% <1%, ≥0.03% <0.1%, in 5 (22%), 7 (30%), 6 (26%) and 5 (22%) patients, respectively. The presence of a T790M mutation was not correlated with a specific type of *EGFR* mutations (exon 18, 19, 20 or 21). T790M positive and T790M negative populations were not different for clinical baseline characteristics. In a Cox model, a lower OS was associated with T790M mutated FA ≥ 10% (HR 18, IC95% 6-53, $p < 0.0001$) and 1≤FA<10% (HR 3.6, IC95% 1.6-8.2, $p < 0.002$). Median FA was 0.37, 0.48 and 1.87% for partial response, stable and progressive disease, respectively. The proportion of T790M mutations, is more frequent in patients with rapid (under 2 months)(n = 9/20, 45%) or usual median progression (12-14 months) (n = 8/20, 40%) compared to those with slow progression (more than 24 months) (n = 3/20, 15%)($p = 0.02$). In cases of rapid progression, T790M FA was over 1% in 7/9 (77%) patients.

Conclusions: Ultrasensitive detection of T790M is related in 9% of *EGFR* mutated TKI naïve NSCLC patients and has a negative prognostic value for T790M FA over 10%.

KG Biberach, Biberach, Germany, [19]Department of Pediatric and Adolescent Oncology, Gustave Roussy, Villejuif, France

Background: Dysregulation of the ErbB pathway may play a role in the development of paediatric neuroectodermal and mesenchymal tumours, suggesting that afatinib, an oral, irreversible ErbB family blocker, could be an effective treatment. A biomarker prevalence study assessed the frequency of ErbB-deregulations; in parallel, a Phase I trial (NCT02372006) was conducted.

Methods: Archived tissue samples from 277 neuroectodermal tumours and rhabdomyosarcomas were tested for protein expression of HER1–HER4, gene amplification of HER1/HER2 and mRNA expression of ErbB receptors and ligands. A Phase I afatinib trial in children aged 2 to < 18 years used a rolling 6 dose escalation design to determine the MTD/RP2D, starting at 18 mg/m^2/d (80% of the BSA-equivalent adult MTD dose), increasing to 23, 29, and 35 mg/m^2. PK was analysed after 1st dose and at steady state. Anti-tumour activity was assessed as per disease standards.

Results: In the biomarker prevalence study, ErbB deregulation markers were defined as: (A) HER1 gene amplification: HER1/Cen7 $\geq$2.0; $\geq$10% of cells with $\geq$15 copies; $\geq$40% of cells with $\geq$4 copies; or gene cluster in $\geq$ 10% of cells; (B) HER2 gene amplification: HER2/CEP17 $\geq$2.0; Protein expression (membrane); (C) EGFR H-score >150; and (D) HER2 H-score >0. Patients (pts) with tumours positive for $\geq$2 markers (A–D) will be selected to enrich the trial expansion cohorts. In the Phase I trial, 23 pts were screened, 17 treated and 12 evaluable for MTD. 1/7 pts experienced DLTs at 18 mg/m^2 and 2/5 at 23 mg/m^2. DLT events were decreased appetite, diarrhoea, dehydration, hypernatraemia, hypokalaemia, cheilitis, rash. Diarrhoea (12 pts) and dry skin (6 pts) were the most frequently reported drug-related AEs. Exploratory PK analysis suggested that exposure at 18 mg/m^2 in children was in a similar range as in adults treated with 40 mg/d. 1 pt with ependymoma had stable disease for 8 treatment cycles.

Conclusions: Afatinib was tolerable in children, with a safety profile similar to adults. The MTD was established at 18 mg/m^2/d and resulted in drug exposure considered effective in adults. The biomarker prevalence study identified exploratory screening markers being used to enrich patient selection in the ongoing expansion cohort.

Background: Since different therapeutic alternatives are reaching the clinic, we need biomarkers to guide treatment decissions in advanced Clear Cell Renal Cancer. This study explores the tumor expression of angiogenesis-related genes as potential markers of anti-VEGFR2 response.

Methods: Through an observational prospective study carried by the Spanish Oncology Genitourinary Group (SOGUG) FFPE tumor samples were collected from 159 RCC patients. A nCounter® Custom CodeSets (NanoString Technologies) was designed to measure the expression of a selected set of genes involved in angiogenesis (n = 23), immune response (n = 5) and RCC mutational landscape (n = 4), together with 4 house keeping genes. This technology was successfully applied to 135 primary tumors (81% clear cell histology), 4 metastasis, and 10 normal kidney tissues from patients treated with anti-VEGFR2 therapy. The association between the expression of the genes and PFS and OS was analyzed through cox-regression. Data provided correspond to multivariable analyses adjusted for MSKCC prognosis group, RCC histology and age.

Results: The 135 patients studied had been treated with sunitinib (91%), pazopanib (7%) or sorafenib (1%); most in first line (98%) and the median PFS was 21.0 months (95%CI=14.5-27.4). The strongest associations found corresponded to *VEGFC*, *VEGFA*, *PDGFRA* and *FGF2*. The median expression of these genes in the tumors was 28, 1075, 14 and 25 counts, respectively. High expression of *VEGFC* was associated with poor PFS (HR = 4.13, 95%CI=1.47-11.59, P = 0.0071) and the opposite occurred for *VEGFA*, which conferred longer PFS (HR = 0.05, 95%CI=0.005-0.48, P = 0.0098). *PDGFRA* and *FGF2* were associated with poor PFS (P = 0.01 and 0.012, respectively). Regarding OS, high expression of *VEGFC* was associated with poor OS (HR = 6.18, 95%CI=2.03-18.77; P = 0.0013). No significant associations were found for other genes.

Conclusions: We propose that the basal tumor expression of VEGF isoforms influences the survival of the patients treated with anti-VEGFR2 drugs.

88P PALB2 reversion mutations in breast, prostate, and ovarian carcinomas

L.M. Gay[1], S. Daniel[1], J. Suh[1], S. Ramkissoon[1], J-A. Vergilio[1], E. Severson[1], P.J. Stephens[1], J.S. Ross[2], J.A. Elvin[1]

[1] Pathology, Foundation Medicine Inc., Cambridge, MA, USA, [2]Pathology, Albany Medical Center, Albany, NY, USA

Background: Like BRCA1/2, deleterious mutations in PALB2 underlie deficiencies in homologous recombination-based DNA repair (HRD) and can underlie sensitivity to platinum (Pt) therapies and PARP inhibitors (PARPi). BRCA1/2 reversion mutations have been widely reported to cause therapy resistance. We report analogous reversion mutations in PALB2 for breast, ovarian, and prostate carcinomas (Ca).

Methods: Comprehensive genomic profiling (CGP) of DNA ($\geq$50 ng) extracted from 114,200 samples, both solid tumors and heme malignancies, was performed using hybridization-captured, adaptor ligation-based libraries (mean coverage depth >600X) for up to 315 cancer-related genes. Samples were evaluated for substitutions, indels, copy number changes and rearrangements.

Results: PALB2 mutations were found in ~1-3% of breast, ovarian and prostate carcinomas. Of 744 samples (0.7% of total) with likely deleterious PALB2 mutations, 7 (0.9%) harbored multiple alterations with at least one predicted to be a reversion. Of these samples, 4 were breast Ca, 1 a prostate acinar adenocarcinoma, 1 a high-grade ovarian serous Ca, and 1 an ovarian carcinosarcoma. For 3 samples the availability of multiple tests indicated the acquisition of the predicted reversion mutation(s) over time. Several reversion mutation types were observed: missense (1), compensatory frameshifts (3), overlapping small indels (2), and a deletion likely to disrupt splicing (1)

that may lead to skipping of exon 4 and an in-frame deletion excising a frameshift mutation. Multiple reversion mutations were observed in 2 cases. Only 1/7 cases also showed disruption of BRCA1/2.

Conclusions: In addition to the commonly sequenced genes BRCA1/2, PALB2 mutation can lead to homologous recombination deficiency. As with BRCA, the acquisition of additional mutations predicted to restore at least some PALB2 function and thus potentially confer resistance to therapies dependent on HRD, can be observed in tumors such as breast, ovarian, and prostate carcinomas. CGP is a valuable tool to identify clinically significant, albeit rare, primary PALB2 mutations in BRCA-negative tumors as well as acquired secondary resistance mutations in patients who progress on Pt and PARP inhibitor based therapies.

89P Pan-cancer genomic analysis of MSI-H tumors reveals commonly altered pathways

S.E. Trabucco[1], S.L. Maund[2], R. Hartmaier[1], K. Gowen[3], J. Sun[3], G.M. Frampton[1], P.J. Stephens[4], P.S. Hegde[5], S-M.A. Huang[2]

[1]Cancer Genomics, Foundation Medicine, Cambridge, MA, USA, [2]Oncology Biomarker Development, Genentech Inc., South San Francisco, CA, USA, [3]Biomarker Development and Analysis, Foundation Medicine, Cambridge, MA, USA, [4]R&D, Foundation Medicine, Cambridge, MA, USA, [5]Oncology Biomarker Development, Genentech, South San Francisco, CA, USA

Background: Microsatellite instability (MSI) is a hallmark of mismatch repair (MMR) deficiency and can be attributed to alterations in MMR-related genes including *MSH2*, *MLH1*, *MSH6*, and *PMS2*. Although alterations in PI3K pathway genes have been reported in MSI-High (MSI-H) colorectal carcinoma (CRC), a comprehensive enrichment analysis of the genomic landscape in MSI-H and MSI-stable (MSS) populations across tumor types is lacking. To better understand the molecular signatures of MSI and investigate new avenues for therapeutic opportunities, we sought to define the genomic landscape of MSI-H tumors across cancer types.

Methods: Comprehensive genomic profiling of 395 cancer-related genes, including MSI status, was performed on ~70,000 tumors. To identify potential driver alterations enriched in MSI-H tumors, variants in regions likely to be affected by polymerase slippage were excluded.

Results: As expected, alterations in *MSH2*, *MHL1*, *MSH6*, and *PMS2* as well as MMR deficiency variants were enriched in MSI-H specimens regardless of tumor type. We confirmed that variants in PI3K genes were enriched in MSI-H tumors in CRC. Importantly, this was observed across all MSI-H tumors, with 57% of pan-solid MSI-H tumors harboring a PI3K pathway variant compared to 24% of MSS tumors. WNT pathway variants were also enriched specifically in MSI-H tumors, except for CRC, in which frequent *APC* variants in MSS resulted in WNT enrichment in MSS tumors. Together, 84% of MSI-H tumors have at least one PI3K or WNT pathway variant (compared to 48% of MSS samples). Finally, although *ERBB2* alterations occur in both MSS and MSI-H tumors, we found that *ERBB2* amplifications occur nearly exclusively in MSS tumors, while *ERBB2* missense mutations are enriched in MSI-H tumors.

Conclusions: The genomic landscapes of MSI-H and MSS tumors suggest that they acquire alterations in distinct pathways. MSI-H tumors appear to share signaling pathway alterations across diseases, suggesting that MSI-H tumors may be more molecularly similar to one another than they are to MSS tumors of the same disease histology. These data may provide new avenues for exploration of targeted therapies in MSI-H tumors.

90P Molecular feature and clinical use development of gene expression profile "TP53 signature" in early stage breast cancer

S. Yamaguchi[1], S. Takahashi[2], T. Nomizu[3], Y. Kakugawa[4], T. Ishida[5], S. Kato[1], C. Ishioka[6]

[1]Medical Oncology, Juntendo University School of Medicine, Tokyo, Japan, [2]Medical Oncology, Tohoku University Hospital, Sendai, Japan, [3]Department of Surgery, Hoshi General Hospital, Koriyama, Japan, [4]Department of Breast Oncology, Miyagi Cancer Center Hospital, Natori, Japan, [5]Department of Surgical Oncology, Tohoku University Graduate School of Medicine, Sendai, Japan, [6]Medical Oncology, Tohoku University Hospital, Sendai, Japan

Background: There have been reported many gene expression profile which can predict prognosis of early stage breast cancer. We have reported the *TP53* signature which can predict dysfunction caused by *TP53* gene mutation in transcriptome level, and the status defined by *TP53* signature can predict more accurate prognosis of early stage breast cancer compare to the status defined by *TP53* DNA sequence. Recently, *TP53* signature was reported as robust predictor of early stage breast cancer by meta-analysis (BMC Cancer,2015). The aim of this study is to make clear the molecular feature of poor prognosis group diagnosed by *TP53* signature and to make easy and quick diagnostic kit which can be used in clinical situation.

Methods: We have done RNA-seq analysis using Hiseq2500 (Illumina) and reanalyzed TCGA data of breast cancer to make clear molecular feature of poor prognosis group defined by *TP53* signature. We made simple diagnostic kit using nCounter (Nanostring technology). Using this simple diagnostic kit, we diagnosed 234 breast cancer sample as *TP53* signature mutant or *TP53* signature wild, and we proved robust prediction power of *TP53* signature for early stage breast cancer. We used RNA-seq data to compare prediction power of *TP53* signature to Mammaprint, OncotypeDX, *TP53* structural mutation.

Results: TP53 signature mutant group have structural mutation in genes, including BRCA1, BRCA2, Rb1 except for TP53, which function is gene repair. In addition, TP53 signature mutant group shows high expression of PD-L1, high mutation burden and high copy number alternation. Analysis of 190 stage I-II breast cancer patients shows TP53 signature by simple diagnostic kit using nCounter has strong prediction power compare to Mammaprint, OncotypeDX, TP53 structural mutation, and clinical factors.

Conclusions: We have developed *TP53* signature as diagnostic system for early stage breast cancer which is useful in clinical situation. Poor prognosis group diagnosed by *TP53* signature shows molecular features which overlap good response marker of immune-check point inhibitors.

91P Potential biomarkers of response to DKK1 blockade with DKN-01 in combination with paclitaxel in advanced esophagogastric cancer (EGC) patients (pts)

D.G. Duda[1], C. Sirard[2]

[1]Radiation Oncology, Massachusetts General Hospital, Boston, MA, USA, [2]Clinical Development, Leap Therapeutics, Inc., Cambridge, MA, USA

Background: Overexpression of DKK1, a modulator of canonical WNT signaling, is frequently seen in malignant tumors and is often associated with worse survival. Preclinical studies have shown that DKK1 can augment tumorigenesis by promoting angiogenesis as well as enhancing tumor-associated immunosuppression. In this Phase I trial, DKN-01 (a humanized IgG4 monoclonal antibody against DKK1) showed encouraging early efficacy signals when combined with paclitaxel (DP) in EGC pts (Strickler et al., GI ASCO 2017). We performed correlative studies of plasma biomarkers of angiogenesis and inflammation in these pts.

Methods: Blood samples were collected from 34 patients treated with DP at baseline, and then weekly for 4 weeks (w). Plasma biomarkers were measured by multiplexed array for angiogenesis (bFGF, PIGF/PGF, sVEGFR1, sTIE-2, VEGF, VEGF-C, and VEGF-D) and inflammation (IFN-g, TNF-a, IL-1b, IL-2, IL-4, IL-6, IL-8, IL-10, IL-12p70 and IL-13) (Meso-Scale Discovery) and by ELISA for HGF and SDF-1a (R&D Systems). Biomarker changes were evaluated by Wilcoxon Sign-Rank test, and correlations with response using Kendall's test values and with survival using two-sided Wald test in the Cox regression.

Results: Six of 34 EGC pts in this subset analysis (18%) had a PR and 11/34 (32%) showed SD with preliminary median PFS and OS of 13.7w and 28.4w, respectively. DP treatment induced significant and sustained increases in plasma IFN-g, IL-8, VEGF-D and decreases in IL-10 (all $p < 0.05$). Transient increases in bFGF and PlGF and decreases in sTie2 were also observed. IFN-γ, IL-10, and VEGF-D correlated with overall response and change in target lesion size. Finally, OS was poor in pts with high IL-6, IL-8 and TNF-a (HR > 1 all time-points) and prolonged in pts with greater increases in IL-2 and VEGF-D after treatment.

Conclusions: Prospective plasma biomarker analyses showed that DP treatment changed biomarkers of systemic immunity and angiogenesis in EGC pts, and indicated potential associations between inflammation biomarkers and outcomes. These hypothesis-generating results will inform future prospective investigation of these plasma biomarkers as well as paired evaluation of tumor biopsies for this combination regimen.

92P Low expression of miR-20a-5p predicts benefit to bevacizumab in metastatic breast cancer patients treated within the TANIA trial

S.P.P. Gampenrieder[1], G. Rinnerthaler[1], H. Hackl[2], M. Steiner[1], C. Monzo Fuentes[1], C. Hufnagl[3], C. Hauser-Kronberger[3], A. Egle[1], R. Greil[1]

[1]IIIrd Medical Department with Hematology, Medical Oncology, Hemostaseology, Infectious Diseases and Rheumatology, Oncologic Center; Salzburg Cancer Research Institute (SCRI) with Laboratory of Immunological and Molecular Cancer Research (LIMCR) and Center, Paracelsus Medical University Salzburg, Salzburg, Austria, [2]Division of Bioinformatics, Biocenter, Medical University of Innsbruck, Innsbruck, Austria, [3]Department of Pathology, Paracelsus Medical University Salzburg, Salzburg, Austria

Background: Biomarkers predicting response to a bevacizumab containing therapy in metastatic breast cancer (MBC) are of urgent need. MicroRNAs (miRNAs) are involved in regulation of angiogenesis and development of treatment resistance and could therefore provide predictive information.

Methods: Profiling of 754 miRNAs was performed in FFPE tumor samples from 58 MBC patients who received bevacizumab-containing first-line treatment (learning set). Based on median PFS patients were divided into responders (R) and non-responders (NR). Differentially expressed miRNAs between R and NR were selected and validated in a cohort of 57 patients treated with first-line chemotherapy without bevacizumab (control set), to exclude miRNAs providing prognostic information only. In the learning set a multivariate analysis including clinical and pathological information was performed. MiRNAs significantly associated with PFS were further validated in 203 patients treated within the TANIA phase III trial randomizing between chemotherapy plus bevacizumab and chemotherapy alone for two consecutive treatment lines in patients pretreated with bevacizumab in first-line.

Results: Low expression of five miRNAs (miR-9-5p, miR-20a-5p, miR-21-5p, miR-210-3p, and miR-224-5p) was significantly associated with longer PFS in the learning set. For miR-20a-5p ($P = 0.035$) and miR-21-5p ($P = 0.004$) this association remained significant in multivariate analysis. In the control set no correlation between expression of those five miRNAs and PFS was seen. In tumor samples from the TANIA trial, low expression of miR-20a-5p was also significantly associated with longer second-line PFS and longer OS in the bevacizumab arm (HR 0.60, 95%CI 0.37-0.89; $P = 0.012$ and HR 0.54; 95%CI 0.32-0.83; $P = 0.007$, respectively) but not in the chemotherapy only arm (HR 0.73, 95%CI 0.48-1.09; $P = 0.119$ and HR 1.01 95%CI 0.63-1.62; $P = 0.964$, respectively). For miR-21-5p no significant association with PFS or OS in both treatment arms was observed.

Conclusions: MiR-20a-5p expression in breast cancer tissue showed a promising predictive value for identifying patients deriving greater benefit from bevacizumab-containing therapy.

93P Characterization of a novel tumor-suppressor gene CHL1 at 3p26.3 in esophageal squamous cell carcinoma

H. Wang

Internal Medicine, Henan Cancer Hospital, Zhengzhou, China

Background: The major histologic subtype of esophageal cancer, esophageal squamous cell carcinoma (ESCC), is one of the most common cancers and has been ranked as the sixth leading cause of cancer-related deaths in the world. Using human genome U133 Plus 2.0 GeneChip, we identified gene down-regulation of Cell adhesion molecule L1 like (*CHL1*) located at 3p26.3 in ESCC. We analysed its down-regulated expression, biological effects and prognostic significance in ESCC.

Methods: To determine whether the down-regulation of *CHL1* was associated with aberrant methylation. Methylation-specific PCR (MSP) was performed in ESCCs and their corresponding non-tumor tissues, as well as ESCC cell lines. Loss of heterozygosity status of *CHL1* was evaluated by fluorescence in situ hybridization (FISH). The effects of *CHL1* re-expression or knockdown were determined in proliferation, invasion and metastasis assay. *CHL1* target genes and related pathways were identified by protein mass spectrometry, co-immunoprecipitation (Co-IP), immunofluorescence (IF) and western-blot. Clinical impact of *CHL1* down-regulated expression was assessed in 287 patients with ESCC.

Results: The results showed that down-regulation of *CHL1* was significantly associated with allele loss (14/21) and promoter methylation (19/21; $P<0.05$) in 39 pairs of ESCC and their corresponding non-tumor tissues by using MSP and FISH. Biofunctional investigation of *CHL1* revealed that *CHL1* significantly decreased cell proliferation, G1-S cell cycle transition, invasion/migration abilities, and promoted xenograft tumor growth as well as lymph node metastasis in vivo. The anti-proliferation effect by *CHL1* was mediated through inducing cell cycle arrest at G1/S checkpoint by down-regulation of p21 and p53 and up-regulation of cyclin D1; the inhibiting metastasis role was by suppressing Epithelial-to-Mesenchymal Transition and F-actin formation which was the result of recruitment Merlin to cell surface expression by *CHL1*. After a median follow-up of 48.23 months, multivariate analysis revealed that patients with CHL1 protein down-expression had a significant decrease in overall survival. Kaplan-Meier survival curves showed that CHL1 down-regulated expression was significantly associated with shorter survival in patients with ESCC.

Conclusions: *CHL1* plays a pivotal tumor suppressive role in ESCC; its down-regulated expression is an independent prognostic factor of patient with ESCC.

94P The role of vitamin D receptor polymorphisms in predicting response to therapy in non-muscle invasive bladder carcinoma

K.Y. Loh[1], Z. Wang[2], Y.K. Lim[2], R. Mahendran[2], E. Kesavan[2], E. Chiong[2]

[1]Surgery, Duke-NUS Medical School, Singapore, [2]Urology, National University Hospital, Singapore

Background: Clinicopathological factors predicting for response to Bacillus-Calmette Guerin (BCG) treatment for non-muscle invasive bladder carcinoma (NMIBC) are well defined but there is a paucity of data on genetic factors. Vitamin D has been found to have immunomodulatory effects in pre-clinical bladder cancer studies. Various single nucleotide polymorphisms of the Vitamin D Receptor (VDR) gene has also been found to be associated with response to treatment for mycobacterium. In this study, we evaluated the predictive role of 3 VDR single nucleotide polymorphisms (SNP) in patients with NMIBC in assessing BCG immunotherapy outcome.

Methods: Peripheral blood DNA was prospectively obtained from 140 evaluable EORTC intermediate to high risk NMIBC patients, who underwent post-transurethral resection intravesical regimes of BCG or BCG with interferon alpha. 3 VDR SNPs commonly implicated in susceptibility to tuberculosis infections were evaluated using high resolution melt (HRM) analysis followed by DNA sequencing. Kaplan-Meier together with Log-Rank test and Cox regression methods were used to analyze the data.

Results: Genotype frequencies were similar between the NMIBC patients and controls in accordance to the Hardy Weinberg equilibrium. Mean follow-up time was 91.9 months. Overall mean time to recurrence and progression was 25.8 months and 47.0 months respectively. Kaplan-Meier analysis indicate that individuals carrying the VDR genotype rs1544410 A/G were significantly associated with lower recurrence-free survival rates after BCG therapy ($p = 0.007$). The VDR rs1544410 "A" allele frequency was found to be higher in patients with bladder cancer recurrences ($p = 0.01$). No association of VDR genotypes with progression-free survival was found.

Conclusions: Our findings suggest that polymorphisms in the VDR gene correlate with response to BCG therapy in NMIBC patients and further work should be performed to evaluate their utility as predictive markers of response to BCG immunotherapy.

95P Gene signatures as potential predictive markers of response to neoadjuvant chemotherapy in ER+/HER2+ breast cancer patients

E. Risi[1], A. Grilli[2], I. Migliaccio[3], C. Biagioni[1], C. Guarducci[3], M. Bonechi[3], A. McCartney[1], S. Vitale[4], L. Biganzoli[1], S. Bicciato[2], A. Di Leo[1], L. Malorni[1]

[1]Sandro Pitigliani Medical Oncology Department, Hospital of Prato, Istituto Toscano Tumori, Prato, Italy, [2]Center for Genome Research, Department of Life Science, Univeristy of Modena and Reggio Emilia, Modena, Italy, [3]Sandro Pitigliani Translational Research Unit, Hospital of Prato, Istituto Toscano Tumori, Prato, Italy, [4]Department of Medical Biotechnologies, University of Siena, Siena, Italy

Background: Chemotherapy (CT) combined with anti-HER2 drugs (H) is the treatment of choice for HER2+ early breast cancer (BC) patients (pts). However HER2+ tumors are clinically and biologically heterogeneous, and treatment response largely varies according to ER status. Predictive biomarkers are urgently needed in this context. We have recently developed a meta-dataset of clinical trials of neoadjuvant CT +/− H (trastuzumab, lapatinib, or both) in HER2+ BC pts annotated for gene expression, hormone receptor status and pathological complete response (pCR) rates. We have shown that a gene-signature (GS) of RB-1 loss-of-function (RBsig) seems to be predictive of response to neoadjuvant CT +/− H in ER+/HER2+ BC pts in this meta-dataset. Here we report the results of additional analyses aimed to evaluate RBsig's predictive value against 10 previously developed GSs in the subset of ER+/HER2+ BC pts.

Methods: The association of RBsig with pCR was evaluated in comparison with previously described GSs of: low ER signaling, p53 mutation, high PI3K pathway signaling, high expression of HER2 amplicon genes, PAM 50 and 5 immune-related GSs. For each GS, samples were classified as High or Low group using a previously described classifier. Odds Ratio (OR) performance was calculated using the ROCR (v. 1.0) package in R and plotted by forest plot using the survcomp (v. 1.24) package.

Results: RBsig and the HER2 amplicon GS were best at predicting response to neoadjuvant CT +/− H (211 pts; p:0.017). In the subgroup of pts treated with CT alone ($n = 94$), only the PI3K pathway GS was significantly associated with pCR (p:0.026).

In pts treated with CT + H (n = 117) only the HER2 amplicon GS significantly correlated with pCR (p:0.042). RBsig showed a similar trend in both these subgroups (p: 0.078 and 0.104, respectively) The immune GSs and PAM50 were not associated with pCR, independent of treatment received.

Conclusions: RBsig and HER2 amplicon GS are strongly associated with pCR in ER+/HER2+ tumors unselected for treatment. These results support the potential use of such GSs as predictive markers of response to CT +/−H in ER+/HER2+ BC pts. Validation studies are warranted.

96P Predictive biomarkers for adjuvant therapy in gastric adenocarcinoma

E. Pectasides[1], V. Kotoula[2], M. Bobos[2], I.D. Chatzidakis[2], S. Chrisafi[2], G. Fountzilas[2]

[1]Division of Hematology/Oncology, Beth Israel Deaconess Medical Center, Boston, MA, USA, [2]Data Office, Hellenic Cooperative Oncology Group (HeCOG), Athens, Greece

Background: Gastric cancer is a common and lethal malignancy, killing over 700,000 people worldwide. Recurrence rates are high even in early stage disease, with 5-year overall survival being < 50% for stage II disease and above. Current guidelines for adjuvant therapy include 5-fluorouracil (5-FU) chemotherapy in combination with radiation. The aim of our study is to develop immunohistochemical biomarkers to predict response to adjuvant chemoradiation in patients with resected gastric cancer.

Methods: A tissue microarray composed of 100 specimens from primary resected gastric cancer cases was constructed. All patients received 5-FU based chemotherapy, and 92% of patients received radiation. Tumors underwent immunohistochemical staining for 11 proteins (HER2, EGFR, p-AKT, PTEN, MTOR, VEGFA, IGF1R, MLH1, MSH2, MSH6, PMS2), and H-scores were calculated. Primary endpoints were progression-free survival (PFS) and overall survival (OS). Survival analysis was performed by Kaplan-Meier method with log-rank test for assessing statistical significance. Multivariate analysis was performed with Cox regression.

Results: Mean follow-up time for the cohort was 39.4 months. Ninety-one of 100 cases had sufficient tissue for biomarker analysis. Interestingly, low expression of MSH2 and MSH6 was significantly associated with shorter PFS, while there was a trend towards worse OS for patients with low MSH2 expression. In multivariate analysis, adjusting for well-characterized prognostic variables, both MSH2 and MSH6 retained their predictive significance. In addition, nuclear expression of the tumor suppressor PTEN was associated with longer OS. No other biomarkers were significantly associated with PFS or OS.

Conclusions: These results indicate that low expression of MSH2 and MSH6 predicts for poorer outcomes in patients with resected gastric adenocarcinoma, independent of other predictive markers.

97P Large-scale DNA organization is a prognostic marker of breast cancer survival

M. Guillaud[1], M. Keyes[2], Q. Ye[3], A. Carraro[3], A. Harrison[3], M. Hayes[4], A. Nichol[5], S. Leung[6]

[1]Integrative Oncology, BC Cancer Agency, Vancouver General Hospital University of British Columbia, Vancouver, BC, Canada, [2]Radiation Oncology, C Cancer Agency, Vancouver, BC, Canada, [3]Integrative Oncology, BC Cancer Research Centre, Vancouver, BC, Canada, [4]Department of Pathology, BC Cancer Agency, Vancouver, BC, Canada, [5]Radiation Oncology, BC Cancer Agency, Vancouver, BC, Canada, [6]Department of Pathology, University of British Columbia, Vancouver, BC, Canada

Background: Breast cancer is the leading cause of cancer-related deaths among women worldwide. Current clinicopathological parameters only partially encompass and predict biological diversity and therefore limit our ability to make informed treatment decisions and predict outcomes. The successful future of oncology will rely on our ability to correctly select patients who would benefit from chemotherapy or benefit from treatment intensification, and spare the rest from unnecessary exposure to toxic and expensive therapies. Tumour biology and prognostic markers may be the key to achieving the above goal. We investigated whether changes in Large scale DNA Organization (LDO) of tumour epithelial nuclei is an indicator of the aggressiveness of the tumour.

Methods: We tested our algorithm on a set of 172 TMA cores samples, coming from 95 breast cancer patients. Thirty five patients died of breast cancer and 60 were still alive 0 years after surgery. This TMA slide was stained with Feulgen-thionin and imaged using an high-resolution Imaging system. Automated segmentation of cell nuclei followed by manual selection of intact, in-focus nuclei resulted in an average of 50 cell nuclei per sample. Approximately 60 features measuring Large-scale DNA organization were calculated.

Results: Forward stepwise Linear Discriminant analysis selected 6 features that, combined linearly, gave the best discrimination between nuclei from alive patients specimens and nuclei from deceased patients specimens. Patient LDO score was defined as the percentage of cell nuclei with a high cell LDO. LDO algorithm correctly classified 82.1% patients, with a specificity of 79% and a sensitivity of 88%. Furthermore, individuals with a high LDO score had a 9x fold increase in relative risk of death. In the multivariate Cox regression model, LDO, Node status and Tumor Grade were all significant predictors of cancer death.

Conclusions: This data suggests that LDO could be used to identify patients more likely to have an aggressive disease and thus select a candidate for more aggressive or novel adjuvant therapies.

98P Telomere associated variables and their potential in CLL prognosis

N. De Pedro[1], J.C. Estrada[1], M. Chiesa[2], M. Diez[1], I. Garcia[1], R. González[1], B. Garcia[1], J. García[1], L. Esteban[3], L. Otero[1], P. Najarro[3]

[1]R&D, Life Length, Madrid, Spain, [2]Translational Research, GEICAM- Spanish Breast Cancer Group, Madrid, Spain, [3]Clinical Department, Life Length, Madrid, Spain

Background: The molecular mechanisms that determine disease progression and evolution in CLL are not completely known. Telomeres are usually short in CLL and their attrition may contribute to disease evolution. In addition, telomerase activity (TA) levels have also been associated with prognosis and response to treatment. In order to integrate telomere associated variables (TAV) in CLL disease management further studies with robust methodology are required.

Methods: Purified peripheral CD19 (+) B-cells from 19 healthy donors and 42 CLLs in different stages of disease were obtained from the National Bank of DNA (Salamanca, Spain). Samples were tested to determine full telomere length (TL) distribution-including percentage of short telomeres by a high throughput quantitative fluorescence in situ hybridization (HT-Q-FISH) technique. TA by Quantitative Telomere Repeat Amplification Protocol (Q-TRAP) was also quantified. Full statistical analysis of the results in the context of the clinical history of the patients was performed.

Results: Data from the pilot, retrospective study stablished strong correlations between key CLL variables and the severity of the disease. Overall, TL was shorter and TA presented higher values compared to normal age-matched subjects. Interestingly longer TL was observed for all CLL patients with somatic hyper-mutation (SHM) that in turn, was associated with better prognosis. Concomitantly, TA was elevated in those patients with no SHM and was linked to poor response to treatment and negative prognosis. The percentage of short telomeres was significantly higher for Binet C/Rai III and IV cases.

Conclusions: The use of reliable technologies to measure TAV should be integrated during early diagnostic in CLL to enhance the ability to predict disease evolution. This will require larger, prospective, longitudinal clinical studies.

99P Micro-RNA profile in advanced metastatic breast cancer as a predictive tool for response to bevacizumab-paclitaxel

M. Mendiola[1], V. Heredia-Soto[2], J. Herranz[3], R. Martín[3], P. Zamora Auñón[4], B. Castelo[4], A. Pinto Marin[4], M. Miguel[1], R. Crespo[5], A. Ramírez de Molina[6], D. Hardisson[7], E. Espinosa[4], A. Redondo[8]

[1]Molecular Pathology and Therapeutic Target Laboratory, IdIPAZ – Hospital Universitario La Paz, Madrid, Spain, [2]Instituto de Investigación del HULP, IdiPAZ, Hospital Universitario La Paz, HULP, Madrid, Spain, [3]Statistics Unit, IMDEA, Madrid, Spain, [4]Medical Oncology, Hospital Universitario La Paz, Madrid, Spain, [5]Translational Oncology Laboratory, IdIPAZ – Hospital Universitario La Paz, Madrid, Spain, [6]Research laboratory, IMDEA, Madrid, Spain, [7]Pathology, Hospital Universitario La Paz, Madrid, Spain, [8]Medical Oncology Department, Hospital Universitario La Paz, Madrid, Spain

Background: Bevacizumab-containing therapy improves progression-free survival (PFS) in human epidermal growth factor receptor (HER) 2-negative metastatic breast cancer (mBC), but its use has been questioned due to the lack of benefit in overall survival (OS). To date, biomarkers to predict its positive effect are not available. Interestingly, miRNAs have emerged as regulators of most processes, forming tight interconnected feedback loops with genes under their regulation. Currently, different analyses, such as microarray, are performed in order to identify miRNA biomarkers, using formalin-fixed and paraffin-embedded (FFPE) tissue samples.

Methods: In the present study we recorded clinical data from 57 mBC patients, and selected two (4 + 4) PFS extreme groups for the analysis of the miRnome. Three miRNAs were used for normalization (U6, 191-5p and 103-a-3p). miRNAs for model construction were selected by differential expression between the two groups. Candidates were

measured in the remaining 49 cases, and stepwise based Akaike criterion was used for profile generation. Additionally, integrative miRNA and mRNA analyses were done to reveal markers and pathways with potential clinical impact.

Results: We selected two groups of patients with extreme differences on PFS (2.48 ± 1.85 vs 35.43 ±8.03 months) for their miRnome study. The expression profiles of miRNAs in both groups were highly correlated, except for 13 miRNAs where statistical differences arised. These miRNAs were selected as candidates for profile generation on the 49 additional cases, and a combination of five of them (miR-362-3p, miR-150b-5p, miR-671-3p, miR-744-3p and miR-941) was able to accurately discriminate two PFS groups. Additionally, Kyoto Encyclopedia of Genes and Genomes (KEGG) analyses on miRNA possible target genes revealed interesting pathways to explore in these patients, such as cellular adhesion.

Conclusions: By combining experimental approaches and computational biology, we have identified candidate markers of outcome for bevacizumab-containing therapy. The five miRNAs included in the prognostic profile and cellular adhesion related genes should be explored as potential biomarkers.

100P Biomarkers of immune therapy in CUP

J. Xiu[1], Z. Gatalica[2]

[1]*Medical Affairs, Caris Life Sciences, Phoenix, AZ, USA,* [2]*Pathology, Caris Life Sciences, Phoenix, AZ, USA*

Background: Carcinoma of unknown primary (CUP) accounts for approximately 3% of all malignancies. Identification of common cancer pathway alterations (hallmarks of cancer) in diverse cancer lineages offers a rationale for search for biomarkers of targeted therapies in patients with CUP. Avoiding immune destruction is a more recently recognized common cancer characteristic and biomarkers associated with immune checkpoint blockade were explored in this study.

Methods: 392 cases of CUP were tested with NextSeq platform with a 592-gene panel. Tumor mutational load (TML) was calculated using only somatic nonsynonymous missense mutations; microsatellite instability (MSI) was evaluated with NGS by direct analysis of known MSI loci in the target regions of the sequenced genes. ArcherDx FusionPlex Assay was used to detect gene fusions and 52 gene targets were analyzed for 156 tumors. IHC was used to detect tumor expression of PD-L1 (SP142 antibody) and PD-1 TILs (NAT105 antibody) All tests were done in a CLIA-certified lab.

Results: Average patient's age was 62.4 years; 52% were female. TML high was seen in 12.2% (48/392) tumors using a cutoff of 17 mutations/Mb. MSI-high was detected in 10/392 (2.6%) of tumors. A total of 70 different genes were found mutated with the incidence ranging from 0.3% to 54%; the most frequent were TP53 (53.5%), KRAS (21.5%) and ARID1A (14.6%). Additional notable targetable mutations include PIK3CA (13.1%), CDKN2A (8.1%), PTEN (4.5%), BRAF (4.1%), ATM (3.3%), NOTCH1 (2.4%) and ERBB2 (1.5%). Targetable gene fusions identified included FGFR2 fusions (N = 2), RET (N = 1), RAF1 (N = 1).Tumors with fusions identified carry a lower TML (average 5.9) than the complete cohort (11.7, $p < 0.001$) with no MSI-high seen in this subgroup. Tumor expression of PD-L1 was seen in 22.5% (82/365) tumors while PD-1 expression on tumor infiltrating lymphocytes seen in 58.7% (37/63). The highest frequency of gene amplification seen were CCND1 (4.7%), FGF3 (3.4%), FGF4(3.4%), FGF19(3.4%), Her2 (3.1%), MYC (2.9%) and AKT2 (2.4%). Of note, CD274 (PD-L1) was rarely amplified (1.4%).

Conclusions: Using a multiplex testing approach, 28% of CUPs had biomarkers (TML-H, MSI-H and/or PD-L1) of response to the immune check-point blockade were identified, making CUP one of the most likely candidate to benefit from immune checkpoint inhibitors.

101P A circulating TH2 cytokines profile predicts survival in patients with resectable pancreatic adenocarcinoma

D. Melisi[1], G. Piro[1], F. Simionato[2], C. Carbone[1], M. Frizziero[2], G. Malleo[3], S. Zanini[2], R. Casolino[2], R. Santoro[1], M.M. Mina[1], C. Zecchetto[2], V. Merz[2], A. Scarpa[3], C. Bassi[3], G. Tortora[1]

[1]*Medicine, University of Verona, Verona, Italy,* [2]*Unit of Oncology, Azienda Ospedaliera Universitaria Integrata Verona, Verona, Italy,* [3]*Unit of General and Pancreatic Surgery, Azienda Ospedaliera Universitaria Integrata Verona, Verona, Italy*

Background: Surgery is the only potentially curative option for patients with pancreatic ductal adenocarcinoma (PDAC), but metastatic relapse remains common. We hypothesized that the expression levels of inflammatory cytokines could predict recurrence of PDAC, thus allowing to select patients who most likely could benefit from surgical resection.

Methods: We prospectively collected plasma at diagnosis from two-hundred eighty-seven patients with pancreatic resectable neoplasms. The expression levels of 23 cytokines were measured in ninety patients with PDAC by using a multiplex analyte profiling assay.

Results: Levels higher than cutoff identified of the T_H2 cytokines interleukin (IL)4, IL5, IL6, of macrophage inflammatory protein (MIP)1a, granulocyte-macrophage colony-stimulating factor (GM-CSF), and monocyte chemoattractant protein (MCP)1, and of IL17a, IFN-γ- induced protein (IP)10, and IL1b were significantly associated with a shorter median OS. In particular, levels of IL4 and IP10 higher than cutoff identified, and level of T_H1 cytokines TNFa and INFg, and of IL9 and IL1Ra lower than cutoff identified were significantly associated with a shorter DFS. In the multivariate analysis, high IP10 was confirmed as negatively associated with OS (HR = 3.097, P=0.014) and IL4 and TNFa remain negatively (HR = 2.75, P=0.002) and positively (HR = 0.224, P=0.049) associated with DFS, respectively. Simultaneous expression of low IL4 and high TNFa identified patients with best prognosis (HR = 0.313, P<0.0001).

Conclusions: We demonstrated that, among a series of cytokines, IL4 is the most significant independent prognostic factor for DFS in resectable PDAC patients, and it could be useful to select patients with high risk of early recurrence who may avoid an unnecessary resection.

102P Analytic validation of a next generation sequencing assay to identify tumor mutational burden from blood (bTMB) to support investigation of an anti-PD-L1 agent, atezolizumab, in a first line non-small cell lung cancer trial (BFAST)

D. Fabrizio[1], C. Malboeuf[2], D. Lieber[3], S. Zhong[3], J. He[3], E. White[2], M. Coyne[2], J. Silterra[3], T. Brennan[2], J. Ma[2], M. Kennedy[3], E. Schleifman[4], S.M. Paul[4], Y. Li[4], D.S. Shames[4], C.A. Cummings[4], E. Peters[4], M. Kowanetz[4], D. Lipson[2], G. Otto[2]

[1]*Cancer Immunotherapy, Foundation Medicine, Cambridge, MA, USA,* [2]*Product Development, Foundation Medicine, Cambridge, MA, USA,* [3]*Computational Biology, Foundation Medicine, Cambridge, MA, USA,* [4]*Oncology Biomarker Development, Genentech, South San Francisco, CA, USA*

Background: Recent data suggest that analysis of tumor mutational burden (TMB), a measure of tumor neo-antigenicity derived from tissue biopsies, has shown clinical utility in predicting outcomes for patients treated with anti-PDL1/PD1 therapies across a range of tumor types. Unfortunately, such analyses require quality tumor tissue that in many cases is not available for patients diagnosed in the metastatic setting. As such, there exists a significant unmet medical need for orthogonal diagnostic approaches that enable the analysis of TMB in patient samples without requiring tumor tissue. Herein, we describe the development of an assay to identify TMB from the circulating tumor DNA derived from blood (bTMB), and the analytical validation (AV) that supports its application in a phase III clinical trial in 1L non-small cell lung cancer comparing the anti-PD-L1 agent, atezolizumab, against standard of care platinum-based doublet chemotherapy (BFAST).

Methods: The bTMB assay delivers a count of somatic base substitutions down to 0.5% allele frequency across 394 genes from as little as 1% tumor content in a cell free DNA (cfDNA) sample. AV focused on establishing accuracy and precision, as well as the limit of circulating tumor DNA required to make precise and reliable bTMB calls. Accuracy of the two different bTMB cutoffs being evaluated in BFAST was established against an orthogonally validated TMB platform. Precision was evaluated by comparing the reproducibility of bTMB calls across replicate samples.

Results: The average PPA, NPA and PPV across both bTMB cutoffs was 95%, 100% and 100%, respectively. The average precision was 96%, with a coefficient of variation of 17% across all replicates. The assay limit of detection was defined as 1% tumor content in at least 20 ng of cfDNA.

Conclusions: We have developed and analytically validated a blood-based assay to determine bTMB with high accuracy and precision from as little as 1% tumor content in 20 ng of cfDNA. Clinical validation of bTMB will be established in a prospective, randomized phase III clinical trial, BFAST, with a primary endpoint of progression free survival.

103P Comparison of continuous measures across diagnostic PD-L1 assays using image analysis

T. Wiestler[1], M. Widmaier[1], J. Walker[2], C. Barker[2], M. Scott[2], F. Sekhavati[3], A. Budco[3], K. Schneider[4], K. Steele[5], M.C. Rebelatto[5]

[1]Service Department, Definiens AG, Munich, Germany, [2]Personalised Healthcare & Biomarkers, AstraZeneca, Cambridge, UK, [3]Professional Services, Definiens AG, Munich, Germany, [4]MedI/AZ Services, Definiens AG, Munich, Germany, [5]Biologic Safety Assessment, Pathology, MedImmune, Gaithersburg, MD, USA

Background: Tumour programmed cell death ligand-1 (PD-L1) expression is a key biomarker in identifying patients who may have an enhanced response to non-small cell lung cancer treatment using anti-PD-1 (e.g. nivolumab and pembrolizumab) or anti-PD-L1 (e.g. atezolizumab and durvalumab). Each treatment is currently used in conjunction with an individual PD-L1 diagnostic immunohistochemistry (IHC) assay and it is unclear whether immunolabelling parameters determined by pathologists are comparable across assays. We extended previous studies (Ratcliffe et al Clin Cancer Res 2017; Ratcliffe et al ASCO-SITC 2017 [abstr 7]) by performing image analysis (IA) with a customised PD-L1 scoring solution to permit a quantitative comparison of the 4 PD-L1 IHC assays.

Methods: We developed an IA scoring algorithm that enabled us to quantify the percentage of positive tumour cells on a whole slide image for 4 PD-L1 assays (Ventana SP263, Ventana SP142, Dako 28-8, Dako 22C3). The analysis was applied to 473 commercially available NSCLC cases (180 cases with SP142). We co-registered the consecutive slides per case and harmonised tumour and exclusion annotations to ensure that readouts of identical areas were compared per case.

Results: In agreement with previous reports, IA results showed concordance between 3 assays, whereas the SP142 assay was discordant. Moreover, high correlation was observed between IA results and pathologist ratings. This correlation could be further improved by matching the information the pathologist received to the same information used in the IA solution: blinding against the assay, scoring on digital scans and masking of non-comparable image regions. The remaining differences represent the differing sensitivity profiles of the assay protocols.

Conclusions: The results of our objective IA suggest differences in sensitivity between the analysed assays. Importantly, despite the observed differences, we confirm previous findings indicating concordance between 22C3, 28-8 and SP263. In addition, our analysis provides a continuous distribution of PD-L1 measurements allowing deeper characterisation of the samples. Tobias Wiestler and Moritz Widmaier are joint first authors.

Background: CEA-CD3 TCB (RG7802, RO6958688) is a novel T-cell bispecific antibody targeting CEA on tumor cells and CD3e on T cells. In mouse models, CEA-CD3 TCB displays potent anti-tumor activity, leads to increased intratumoral T cell infiltration and activation and up-regulates the PD-L1/PD-1 pathway.

Methods: Biodistribution was assessed in mice using SPECT/CT. Patient (pt) samples were from 2 dose-escalation studies in CEA-positive solid tumors. Study 1 (S1): single agent weekly (qw) (0.052-600 mg IV; n = 80), and Study 2 (S2): CEA-CD3 TCB qw (5-160 mg IV) plus atezolizumab 1200 mg q3w (n = 46). Analytics: [CEA-CD3 TCB]—bifunctional PK assay; antidrug antibodies—ELISA; immunophenotyping in peripheral blood (PB)—flow cytometry (FCM), in baseline (BSL) and on-treatment (OT; week 7) biopsies by immunohistochemistry and FCM; plasma cytokines—multiplex assay; PD-L1—SP142 assay.

Results: In mice, CEA-CD3 TCB preferentially accumulated in CEA-positive tumors. CEA-CD3 TCB showed near-linear PK in both studies (S1: 35; S2: 28). In pts with matched BSL and OT biopsies, 7/10 CRC pts treated with $\geq$ 60 mg of CEA-CD3 TCB in S1 had > 2.4-fold increase in CD8 T cells, which did not correlate with RECIST response. In S2, 2/2 CRC pts receiving $\geq$ 80 mg of CEA-CD3 TCB (with RECIST reduction $\geq$ 25%), showed > 8-fold increase in CD8/Ki67 T cells. SUVmax decrease (FDG-PET) correlated with BSL levels of CD4-OX40 and CD8-PD1 in S1 and CD8-OX40 in S2. In PB at week 4, a > 4-fold expansion of activated CD8 T cells (HLA-DR/Ki67) but not CD4, was detected in most pts at doses $\geq$ 60 mg (S1: 24; S2: 9). In most pts, increases in IL-6 were seen after the first TCB infusion and in fewer cases after the second/third infusion in both studies (S1: 62; S2: 33).

Conclusions: On-treatment increases in intratumoral CD8 T cells consistent with the mechanism of action and support that CEA-CD3 TCB is the first tumor-targeted T cell bispecific showing biological activity. The activation level of intratumoral T cells at BSL could be a predictive biomarker of response. In preclinical models, tumor targeting has been demonstrated. Updated data will be presented. Clinical data are reported separately.

105P Baseline gut microbiota in metastatic melanoma patients treated with ipilimumab: Relation with clinical response and colitis

N. Chaput[1], P. Lepage[2], C. Coutzac[1], E. Soularue[3], V. Asvatourian[4], E. Lanoy[5], C. Mateus[6], F. Carbonnel[3], C. Robert[6]

[1]Laboratory of Immunomonitoring in Oncology, Institut Gustave Roussy, Villejuif, France, [2]Micalis Institute, INRA, AgroParisTech, Jouy-en-josas, France, [3]Gastroentérologie, AP-HP, Kremlin Bicêtre, France, [4]Biostatistics, Institut Gustave Roussy, Villejuif, France, [5]Biostatistiques et Epidémiologie, Institut Gustave Roussy, Villejuif, France, [6]Dermatologie, Institut Gustave Roussy, Villejuif, France

Background: It is now demonstrated that gut microbiota composition has a determining influence not only on inflammatory bowel diseases but also more broadly on the immunological status of healthy individuals as well as in patients with cancer. We explored the potential role of baseline gut microbiota in anti-tumor response and in intestinal toxicity of patients with metastatic melanoma treated with anti-CTLA4 mAb ipilimumab. Moreover we explored how the composition of gut microbiota could influence not only local gut-immunity but also distant sites such as anti-tumor immunity.

Methods: Fecal microbiota compositions were prospectively assessed at baseline and before each ipilimumab infusion, using 16S rRNA gene sequencing. Patients were further clustered based on microbiota patterns. Peripheral blood lymphocytes immunophenotypes were studied in parallel.

Results: A distinct baseline gut microbiota composition was associated with both clinical response and colitis. As compared to patients whose baseline microbiota was driven by *Bacteroides* (Cluster B), patients whose baseline microbiota was enriched with *Firmicutes* (Cluster A) had longer progression-free survival and overall survival. Most of the baseline colitis-associated phylotypes were related to *Firmicutes*, whereas no-colitis related phylotypes were assigned to *Bacteroides*. A low proportion of peripheral blood regulatory T cells was associated with Cluster A, long-term clinical benefit and colitis. Ipilimumab led to a higher Inducible T-cell COStimulator induction on CD4+ T cells and to a higher increase in serum CD25 in patients who belonged to Cluster A.

Conclusions: Baseline gut microbiota enriched with *Firmicutes* is associated with beneficial clinical response to ipilimumab and more frequent occurrence of ipilimumab-induced colitis.

106P The association between PD-L1 expression, EGFR mutation and ALK translocation in a series of 982 lung cancers

M. Evans[1], B. O'Sullivan[1], M. Smith[1], F. Hughes[1], N. Trim[1], T. Mullis[1], L. Pallan[2], P. Taniere[1]

[1]Molecular Pathology Diagnostic Service, Queen Elizabeth Hospital Birmingham, Birmingham, UK, [2]Oncology, Queen Elizabeth Hospital Birmingham, Birmingham, UK

Background: PD-L1 expression testing is mandatory prior to pembrolizumab prescription in non-small cell lung cancer. Pembrolizumab was made available in the UK through the Early Access to Medicines Scheme (EAMS) in May 2016 and was NICE-approved in December 2016. Our Molecular Pathology Diagnostic Service has been offering PD-L1 testing using Dako's 22C3 IHC assay in parallel with EGFR and ALK testing. We present here data on the relationships between PD-L1 expression, and EGFR and ALK status in a series of 982 tumours.

Methods: PD-L1 expression testing was performed using the aforementioned assay on the 4800 Dako stainer. EGFR mutation testing was performed using the Therascreen kit on the RGQ platform and using COBAS kit (both screening for exon 19 deletions, L858R, G719X, L861Q, S768I, exon 20 insertions and T790M); ALK translocation was assessed using the D5F3 Ventana antibody on XT platform. PD-L1 was considered positive when more than 1% of tumour cells showed membranous staining.

Results: Of the 982 tumours, 492 were positive for PD-L1 (50.1%), 85 bore EGFR mutations (8.7%) and 14 bore ALK translocations (1.4%). There was no significant difference in PD-L1 expression rate with EGFR mutation status. However, whereas 39.3% tumours with a classical EGFR mutation were PD-L1 positive, 86.4% with a rare EGFR mutation (G719X, L861Q, S768I, exon 20 insertions) were PD-L1 positive ($p = 0.0006$). PD-L1 positivity rate was 52.3% and 85.7% in ALK non-rearranged and rearranged tumours, respectively ($p = 0.01$).

Conclusions: Our data show that the presence of classical or of rare EGFR mutations is associated with different degrees of PD-L1 expression, which may have future therapeutic implications. Our data also show that the presence of an ALK translocation is positively associated with PD-L1 expression.

107P Association of tumor and stroma PD-1, PD-L1, CD3, CD4 and CD8 expression with response to nivolumab treatment in NSCLC patients

S. Sahba[1], A-L. Niemeijer[1], J. De Langen[1], E. Thunnissen[2]

[1]Pulmonology, Vrije University Medical Centre (VUMC), Amsterdam, Netherlands, [2]Pathology, Vrije University Medical Centre (VUMC), Amsterdam, Netherlands

Background: PD-L1 immunohistochemistry (IHC) correlates only moderately with response to nivolumab treatment. Characterizing PD-1, PD-L1 and T-cell markers in both tumor and stroma might improve the predictive value of tissue IHC as predictive biomarker in this setting.

Methods: From 08-2015 to 12-2016 patients with stage IV NSCLC treated with nivolumab were registered and prospectively followed. A histological tumor biopsy, obtained before start of nivolumab, was required. Tumor PD-L1 expression and immune cell (IC) PD-L1, PD-1, CD3, CD4 and CD8 expression in tumor and stroma was assessed using IHC on serial sections. IC infiltration was scored semi-quantitatively indicating no, very low, low, intermediate, or high infiltration. Presence of CD4+ macrophages in between tumor cells was used to aid assessment of tumor PD-L1 expression. Nivolumab was dosed 3 mg/kg Q2W and response assessment was done by CT every six weeks.

Results: Overall response rate of pts ($n = 65$) was 23% and quantifiable ($\geq$1%) tumor PD-L1 expression was found in 25% of pts, versus <1% expression in 75% of pts. Univariate analyses showed a significant correlation between the levels of tumor PD-L1 expression (0%, 1-50%, >50%) and associated response rates of 17%, 22% and 57% respectively. Stromal IC expression of PD-L1, CD3, CD4 and CD8 also correlated with response ($p < 0.05$ for all markers). CD8+ tumor IC infiltration and stromal PD-1+ staining did not correlate with response. In the subgroup of $n = 47$ pts with negative (<1%) tumor PD-L1 expression, pts with either high CD3 or high PD-L1 stromal IC expression ($n = 45$) showed a remarkably high response rate of 59% ($p = 0.009$).

Conclusions: A clear positive correlation was found between PD-L1 expression and response. The distribution of PD-L1 expression was lower compared to historical data. Availability of CD4 IHC that identified PD-L1 positive macrophages is the explanation for lower percentage of tumor PD-L1 positive samples. Stromal PD-L1, CD3, CD4 and CD8 IC expression were all predictive for treatment response. In tumor PD-L1 negative pts, high stromal PD-L1 and/or CD3 IC expression selected pts with a remarkably high response rate.

108P Characterisation of heterogeneity in microsatellite instable (MSI) tumours associated with distinct cell types and immune phenotypes

E. Fontana, P. Poudel, G. Nyamundanda, Y. Patil, C. Ragulan, A. Sadanandam

Molecular Pathology, The Institute of Cancer Research/Royal Marsden Hospital, Sutton, UK

Background: In the immunotherapy era, a better understanding of heterogeneity in MSI cancers is required. We evaluated gene expression profiles of MSI colorectal (CRC), gastric (GC) and endometrial cancer (EC) samples with our cell-of-origin signature (CRCassigner), which is able to classify samples in differentiated (goblet-like; CMS3), differentiating (transit-amplifying – TA; CMS2) and less differentiated/mesenchymal (stem-like; CMS4 and inflammatory; CMS1) subtypes to identify whether MSI transcriptional heterogeneity exists.

Methods: Normalised RNAseq/microarrays gene expression profiles and microsatellite status were downloaded from TCGA. CRCassigner classification of samples was performed using Pearson correlation. Samples with low classification confidence were classified as "mixed" subtype. Gene selection enrichment analysis (using published immune markers) and differential protein expression analysis (of PDL1 from Cancer Proteome Atlas data) was performed between inflammatory and goblet-like MSI samples.

Results: The majority of MSI-H in all the 3 cancer types expressed the inflammatory profile. While in MSI-H CRC only two subtypes were present (inflammatory - 91% and goblet-like - 9%), 5 subtypes in MSI-H GC (inflammatory - 45%, goblet-like - 24%, stem-like - 21%, TA - 6%, enterocyte - 3%) and 4 subtypes in EC (inflammatory - 36%, stem-like - 36%, goblet-like - 14%, TA - 14%) were present. Inflammatory MSI tumours from all the three cancer types were significantly ($p < 0.05$) enriched for genes associated with checkpoint inhibition (PDL1), MHC Class I, Type I interferon response and macrophages compared to goblet-like MSI tumours. On the other hand, goblet-like MSI cancer showed enrichment of B-cells.

Conclusions: MSI tumours are heterogeneous and can be stratified by virtue of differentiation states (or cell-of-origin) and different immune phenotypes. With further studies, this heterogeneity may help select MSI cancer patients for immune checkpoint combination therapies.

109P Clinical implication of PLR and PD-L1 in breast cancer patients

S. Wang[1], Q. Lu[1], T. Qin[1], F. Xu[1], Y. Zeng[2], W. Xia[1], Q. Zheng[1], K. Lee[1], K. Zhang[1], G. Qin[1], M.T. Kong[3], R. Hong[1], Y. Shi[1], Z. Yuan[1]

[1]Medical Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China, [2]Breast Cancer, Sun Yat-sen Memorial Hospital, Guangzhou, China, [3]Internal medicine, Hospital Conde S. Januário, Macau, Macau PRC

Background: Anti-tumor action of the host immune systems and cancer-immune interaction are associated with tumor prognosis. Programmed death ligand-1 (PD-L1) expression was found as an unfavorable prognostic factor in breast cancer in our previous study. Besides, PD-L1 and biomarkers of the host immunity which included Neutrophil-lymphocyte ratio (NLR), platelet-lymphocyte ratio (PLR) have been reported in predicting prognosis of biliary tract cancer. However, combination of NLR/PLR and PD-L1 in breast cancer has not been reported. The aim of this study is to evaluate the prognostic role of NLR/PLR and PD-L1 in breast cancer.

Methods: A total of 870 patients with breast cancer treated in Sun Yat-Sen University Cancer Center from 2000 to 2012 with known PD-L1 status were included. Clinicopathological data and pretreatment complete blood count were retrospectively collected. X-tile was used to generate the optimal cut-off value of NLR and PLR. Kaplan-Meier and univariate Cox proportional hazards model analyses were used to compare the survival of patients between different groups.

Results: High PLR group achieved worse result than low PLR group in OS and DFS (5-year OS rate: 82.6% vs 88.8%, $p = 0.010$; 5-year DFS rate: 78.7% vs 85.6%, $p = 0.003$). High PLR was associated with shorter DFS (adjusted HR = 1.540, 95%CI: 1.124-2.110, $p = 0.007$), while high PLR was not an independent factor for OS (adjusted HR = 1.001, 95%CI: 0.999-1.003, $p = 0.488$). NLR was not associated with patients'

survival outcome. And we found patients with PD-L1 expression and high PLR had the worst prognosis. The 5-year DFS rates were 68.4%, and 85.8% in high PLR+PD-L1 (+) group and low PLR+PD-L1 (-) group respectively ($p = 0.002$). The 5-year OS rates were 73.4% and 90.1%, respectively ($p < 0.001$).

Conclusions: High PLR are associated with poor DFS in breast cancer patients. PD-L1 expression combined with high PLR was associated with an aggressive clinical outcome. Further studies are needed to evaluate the predictive value of combination of PD-L1 and peripheral blood immune markers.

110P Prognostic and predictive value of lymphovascular invasion and lymph node status among breast cancer subtypes

G-S. Liao[1], H-M. Hsu[1], M-S. Dai[2], J-C. Yu[1]

[1]Division of General Surgery, Department of Surgery, Tri-Services General Hospital, National Defense Medical Center, Taipei, Taiwan, [2]Division of Hematology/Oncology, Tri-Services General Hospital, National Defense Medical Center, Taipei, Taiwan

Background: Breast cancer subtype (BCS) and lymphovascular invasion (LVI) have both been independently demonstrated as prognostic factors. The objective of this investigation was to evaluate the prognostic power of LVI and lymph node status among BCSs.

Methods: From an institutional database, 2017 women with a histopathologically confirmed diagnosis of breast cancer treated between January 2006 and December 2014 were consecutively selected for participation in this study.

Results: Of the 2017 patients with breast cancer in the BCS groups, the highest OS and RFS rates were observed in luminal A subtype (93.6% vs. 95.1%, respectively) and the lowest were observed in TN subtype (85.3% vs. 83.0%, respectively). There were significant differences in OS according to the LVI status between the luminal A, luminal B and luminal HER2 subtypes. There were also a significant difference in the RFS rate of the luminal A, luminal B, luminal HER2 and HER2 subgroup. Therefore, we inferred that there were stronger links with LVI and BCS with regard to OS and RFS rates. Kaplan-Meier analysis showed that there were significant differences in the OS and RFS rates according to the LVI status among the BCS groups. There were significant differences in OS according to the LVI status in the distribution of the luminal A, luminal B, luminal HER2, and TN subtypes. There were also significant differences in the RFS rates among the luminal B, luminal HER2, and HER2 subtypes. On multivariate analysis, after controlling for age, tumor size was independently associated with LVI and lymph node status among all BCS groups. There were significant differences in OS according to the status of lymph node-negative and LVI-positive in the luminal HER2 subtype, as well as lymph node-positive and LVI-positive in the TN subtype. There were also significant differences in RFS according to the status of lymph node-negative and LVI-positive in the luminal A subgroup.

Conclusions: LVI and lymph node status were important prognostic factor for OS and RFS among all BCSs. In lymph node-negative breast cancer, luminal HER2 had greater predictive value for OS, whereas luminal A displayed greater predictability for RFS. In lymph node-positive breast cancer, the TN subtype had greater predictive value for OS.

111P PD-L1 expression in TNBC: A predictive biomarker of response to neoadjuvant chemotherapy?

A. Botticelli[1], B. Cerbelli[2], A. Pernazza[2], C.E. Onesti[1], P. Sciattella[3], L. Costarelli[4], M. Monti[2], D. Campagna[4], F. Mazzuca[1], L. Fortunato[5], P. Marchetti[1], G. D'Amati[2]

[1]Clinical and Molecular Medicine, Sapienza, University of Rome, Azienda Ospedaliera St. Andrea, Rome, Italy, [2]Radiological, Oncological and Pathological Science, Sapienza University of Rome, Rome, Italy, [3]Statistical Sciences, Sapienza University of Rome, Rome, Italy, [4]Pathology, San Giovanni Addolorata Hospital, Rome, Italy, [5]Surgery, San Giovanni Addolorata Hospital, Rome, Italy

Background: Immune system plays an important role in tumor surveillance and escape. Recently tumor infiltrating lymphocytes (TILs) have been proposed as a predictive biomarker for clinical outcome and pathological response (pR) after neoadjuvant (neoadj) chemotherapy (CT) in breast cancer. PD-L1 is expressed in about 20% of TNBC, suggesting the possibility of being a therapeutic target for this subtype of cancers. Here we studied the association between PD-L1 expression and pR in TNBC.

Methods: We enrolled 54 pts who had received neoadj CT (EC for 4 cycles followed by Paclitaxel q21 for 4 cycles) between Jan 2008 and Dec 2016 at Policlinico Umberto I and San Giovanni Hospital of Rome. We performed IHC for CD20, CD3, CD4, CD8, CD68, N-CAM and PD-L1 (Ventana SP142 clone) in basal paraffin-embedded biopsies. PD-L1 expression on tumor cells was evaluated both qualitatively (membrane staining intensity 0 to 3+) and quantitatively (% of positive cells.). The percentage of TILs positive for PD-L1 was also recorded. Statistical analysis was performed with T di Student test and χ^2 test.

Results: We enrolled 54 pts (median age: 50 y; range 28-75) affected by TNBC: 51 ductal (94.4%), 2 metaplastic (3.7%), 1 lobular (1.9%). The clinical stage before neoadj CT was as follow: 12.9% cT1 (7 pts), 72.2% cT2 (39 pts), 3.7% cT3 (2 pts), 1.85% cT4 (1 pt) and 5.5% cTx (3 pts). 23 pts were cN + (42.5%). After neoadj CT 30 pts underwent mastectomy (55%) and 24 conservative surgery (45%). 19 pts (35%) showed pCR. No significant associations were found between pR and cT, cN, age, histotype and KI-67. In 64.8% of basal biopsies (35 pts) PD-L1 was not detected on tumor cells and in 18.5% (10 pts) it was absent in the immune infiltrate. PD-L1 expression was detected in > 25% of tumor cells in 4 pts, all of which showed pCR ($p = 0.024$). No associations between intensity of membrane staining and pR were detected ($p = 0.7$). The immune infiltrate was characterized mostly by the presence of CD3+ CD8+. No statistically significant associations between and PD-L1 expression on immune infiltrate were detected.

Conclusions: Basal PD-L1 expression on cancer cells was associated with a better pR in TNBC undergoing neoadj CT. The introduction of anti PD-1/PD-L1 therapy in this setting of pts could lead to interesting results.

112P Pathological evaluation of tumor infiltrating lymphocytes and the benefit of nivolumab in advanced non-small cell lung cancer (NSCLC)

I. Gataa[1], L. Mezquita[1], E. Auclin[1], S. Le Moulec[2], P. Alemany[3], M. Kossai[3], J. Massé[4], C. CARAMELLA[5], J. Remon Masip[1], J. Lahmar[1], R. Ferrara[1], A. Gazzah[1], J-C. Soria[6], D. Planchard[1], B. Besse[1], J. Adam[3]

[1]Medical Oncology Department, Gustave Roussy, Villejuif, France, [2]Medical Oncology, Institute Bergonié, Bordeaux, France, [3]Pathology Department, Gustave Roussy, Villejuif, France, [4]Pathology, Bergonié, Bordeaux, France, [5]Radiology, Gustave Roussy, Villejuif, France, [6]Drug Development Department (DITEP), Gustave Roussy, Villejuif, France

Background: Assessment of tumor infiltrating lymphocytes (TIL) by pathologists using Hematoxylin-Eosin (H&E), has been described as a prognostic factor in resected NSCLC. We aimed to correlate TIL to the benefit from nivolumab in patients (pts) with treated advanced NSCLC.

Methods: Patients with advanced NSCLC treated with nivolumab, with biopsy available for evaluation, were included between November 2012 and February 2017 in two cancer centers. Patients characteristics and outcome were collected. The percentage of tumor infiltrating lymphocytes in the stroma was evaluated using H&E staining from archival pretreatment tumor tissue samples. Primary endpoint was to correlate TIL density with progression free survival (PFS).

Results: Out of ninety-eight patients included. 60 (61%) pts were male, with median age of 61 years and 85 (89%) were smokers. Sixty three (73%) pts were PS 0-1. Sixty tumors (61%) were adenocarcinoma, 29 (30%) squamous and 9 (10%) other histologies. Among 83 tumors with known molecular profile, 22 (27%) were KRAS mutated 7 (8%) EGFR mutated, 1(1%) ALK positive. The median treatment line was 3 (2-4). The median follow up was 8 months (m)(95%CI[6-19]). The median PFS was 2 m (95%CI[1-5]). The ORR was for 16%. The median TIL density was 5% (2-15). TIL density $\geq$5% correlated with PFS in univariate and multivariate analysis (HR: 0.48 [0.28-0.82] $p = 0.007$ and HR:0.31 [0.14-0.68] $p = 0.004$ respectively). TIL density $\geq$5% was also associated with better ORR (OR = 3.5, 95%CI [1.06-11.7], $p = 0.04$).

Conclusions: Pathological assessment of TIL allows an easy evaluation of immune infiltration in NSCLC and independently correlates PFS in NSCLC pts treated with nivolumab. Results from validation cohorts and combination with other morphological and immunohistochemical parameters will be reported.

113P Could a systemic inflammation response index (SIRI) predict overall survival (OS) in metastatic pancreatic cancer (PC)?

V. Pacheco-Barcia, O. Donnay, R. Mondejar, J. Rogado, M.D. Fenor de la Maza, R. Colomer

Medical Oncology, Hospital Universitario de La Princesa, Madrid, Spain

Background: Cancer-associated inflammation is a key molecular feature of PC and may affect the clinical course. The aim of this study was to evaluate the prognostic relevance of SIRI based on peripheral neutrophil, monocyte, and lymphocyte counts in metastatic PC and its association with the metastatic site.

Methods: Retrospective analysis of the medical records of patients with pathologically confirmed metastatic PC between January 2011 and December 2016. Patients were classified as having liver metastases (LM) or extrahepatic metastases alone (EM). Associations with overall survival (OS) were analyzed using Cox proportional models.

Results: A total of 37 patients were included (47 men; median age 63). Median TTP was 4 months and median OS was 6 months. 29 patients (78%) had LM and 8 (22%) EM. 33 patients (89%) received CT: 13 (40%) Gemcitabine (GEM) plus Nab-Paclitaxel, 9 (27%) GEM in monotherapy, 7 (21%) GEM plus Erlotinib and 4 (12%) an Oxaliplatine doublet. Mean Ca 19 9 levels in patients with LM were 199349 and with EM 9107. Univariate analysis identified SIRI scores ≥1,9 as significant risk factor for OS. Age, sex and high CA 19,9 levels had no prognostic significance for OS in all groups. Patients with LM showed a higher SIRI than those with EM (p = 0,03). Patients with SIRI scores < 1,9 (55%) compared to those who had SIRI scores ≥1,9 (45%) had a longer OS (p = 0,01). LM were significantly associated with shorter OS (hazard ratio [HR] 2.79; 95% confidence interval [CI] 1.36-5.34; p = 0,002) but not those with EM (HR 1.83; CI 0.71-4.72; p = 0,2). An SIRI ≥1,9 resulted in a shorter OS compared to an SIRI <1,9 (HR 2.13; CI 1.10–4.10; p = 0.024).

Conclusions: SIRI is associated with survival in patients with metastatic PC. In patients with LM, unfavourable SIRI may be associated with higher tumor burden. In our experience, a baseline SIRI ≥1.9 duplicates the risk of mortality and this finding may allow better risk stratification.

Background: Endocrine responsiveness in Estrogen Receptor positive (ER+) MBC is based on the level of ER expression on the primary tumor and/or metastatic lesion. In this study, nested in the ET-FES JTC 2011 TRANSCAN project, we used molecular imaging with ^{18}F-FES to explore intra-patient heterogeneity in ER expression at different metastatic sites and to identify patients who are not likely to benefit from ET.

Methods: ER+ patients at first relapse underwent at baseline a ^{18}F-FES PET/CT plus a ^{18}F-fluoro-2-deoxy-D-glucose (FDG) PET/CT. Patients were classified into 4 ^{18}F-FES/FDG subgroups based on the proportion of FDG avid metastatic tumor load with high ^{18}F-FES uptake (Gebhart Ann Oncol 2016). Subgroup A was considered positive (100% of concordance); subgroups B and C were considered partially positive or partially negative, with different degrees of ^{18}F-FES uptake; subgroup D was considered negative (100% of discordance). Patients with global SUV ≥2 received first line ET while those with SUV <2 were randomized to ET or to chemotherapy. HR for progression was calculated comparing patients with concordant ^{18}F-FES/FDG lesions (group A) with all the other patients.

Results: So far, 80 patients have been enrolled in the ET-FES trial and 79 are included in the present analysis. At baseline evaluation, 53 patien4ts (67.1%) were classified as ^{18}F-FDG/^{18}F-FES positive (A); 16 patients (20.3%) showed some degree of intra-patient heterogeneity (11 group B and 5 group C); 10 patients (12.6%) were classified as D with all lesions being ^{18}F-FES negative. In the 64 patients with a response evaluation available at time of analysis, 26 have shown progression. ET was administered in 40 patients in group A and in 24 patients in groups B + C + D. The use of ET alone in partially positive (B) or partially negative (C) or negative (D) patients was associated with a 79% absolute increase in the risk of progression (HR 1.79, p 0.2) compared to patients in group A.

Conclusions: Pretreatment ER biomarker imaging at different metastatic sites with ^{18}F-FES PET/CT indicate the presence of a significant intra-patient heterogeneity in MBC and represents a promising tool to select patients who are unlikely to benefit from ET alone.

115P Evaluation of a predictive radiomics signature for response to immune checkpoint inhibitors (ICIs)

A. Prawira[1], A.B. Stundzia[2], P. Dufort[3], J. Halankar[3], D.M. Paravasthu[3], A. Spreafico[1], A.R. Hansen[1], A.R. Abdul Razak[1], P.L. Bedard[1], M. Butler[1], S. Lheureux[1], A.M. Oza[1], R.W. Jang[1], K.M. Suta[1], S. Boross-Harmer[1], J. Cipollone[1], H. Chow[1], U. Metser[1], L.L. Siu[1]

[1]Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada, [2]Medical Image Analysis, Tomographix IP, Toronto, ON, Canada, [3]Joint Department of Medical Imaging, University Health Network, Toronto, ON, Canada

Background: Radiomics (RAD) uses advanced image processing techniques to extract a large set of quantitative texture and geometric features from tumor regions of interest, and subject these to a supervised machine learning protocol to train a classifier, which we exploit to develop a predictive signature of response to ICIs. We previously developed a lesion-based predictive RAD classifier of response for recurrent/metastatic squamous cell carcinoma of the head and neck (RM SCCHN) pts to ICIs based on RAD features extracted from their CT images (Prawira, ESMO 2016).

Methods: INSPIRE (NCT02644369) is an investigator-initiated phase II study evaluating biomarkers for pembrolizumab (anti-PD1 monoclonal antibody) in multiple cohorts of pts with advanced solid tumors. The primary endpoint of this project is to validate the previously developed RAD classifier from RM SCCHN pts, with pts from INSPIRE. Texture feature algorithm generation and accuracy determination were as previously described. Cross validation accuracy values were generated for combinations of 3 parameters: fraction, cost, and gamma, yielding a 3 dimensional (3D) accuracy space.

Results: Eighty lesions from 23 pts were available for analysis: median age 59, 22% males. Best response: 12 progressive disease, 3 partial response, 8 stable disease (median duration 18 weeks). Primary site: SCCHN/2, triple negative breast cancer/4, high-grade serous ovarian cancer/11, malignant melanoma/2, other advanced cancers/4. Twentyseven lesions were excluded as RECIST 1.1 responses were not yet available. Fiftythree target lesions were contoured. Per lesion RECIST 1.1 radiological outcome: 17 R, 36 NR. Cross validation in the 3D space yielded a set of ROC curves with an accuracy of 71.4% (AUC 0.41, p = 0.7) with 11.2% sensitivity and 99.9% specificity, where specificity corresponds to the proportion of NR tumors classified correctly, and sensitivity to the proportion of R tumors classified correctly.

Conclusions: Heterogeneous histologies and low pt numbers may account for the negative result in this study, suggesting that RAD may be histology-specific. Further validation in a large independent cohort of RM SCCHN pts treated with pembrolizumab is planned.

116P Clinical and pre-clinical biomarkers of Regorafenib (REG) efficacy in metastatic colorectal cancer (mCRC) in a phase II trial

K. Khan[1], D. Cunningham[2], G. Vlachogiannis[3], S. Hedayat[3], M. Rata[2], D-M. Koh[2], N. Tunariu[4], Y. Jamin[3], D. Collins[2], I. Chau[5], S. Rao[5], D. Watkins[5], N. Starling[6], C. Peckitt[5], N. Fotiadis[2], C. Saffery[1], J. Hahne[3], M. Fassan[7], C. Braconi[8], N. Valeri[9]

[1]GI and Lymphoma, Royal Marsden Hopsital, London, UK, [2]GI and Lymphoma Research unit, Royal Marsden Hospital NHS Foundation Trust, London, UK, [3]Biomedical Research Centre at The Royal Marsden Hospital and The Institute of Cancer Research, Institute of Cancer Research, London, UK, [4]Radiology, The Royal Marsden NHS Foundation Trust, London, UK, [5]Department of Medicine, Royal Marsden Hospital, Sutton, UK, [6]Medical Oncology, Royal Marsden Hospital NHS Foundation Trust, London, UK, [7]Department of Medicine, University of Padua, Padua, Italy, [8]Division of Cancer Therapeutics, The Institute of Cancer Research, Institute of Cancer Research, London, UK, [9]Molecular Pathology, The Institute of Cancer Research/Royal Marsden Hospital, Sutton, UK

Background: REG demonstrated efficacy in pre-treated mCRC pts. Lack of predictive biomarkers, potential toxicities and cost/effectiveness concerns highlight the unmet need for better patient selection.

Methods: *RAS* mutant mCRC pts with biopsiable metastatic deposits were enrolled in this phase II trial. Tissue biopsies (6-12 cores) were obtained at baseline (BL), after 2 months if stable disease (SD) and at disease progression (PD). Dynamic contrast enhanced (DCE) MRI was acquired pre and at day 15 post-treatment. Median values of volume transfer constant (K^{trans}), enhancing fraction (EF) and their product, KEF [K^{trans}*EF/100] were generated. Circulating tumour (ct) DNA was collected monthly until PD and tested for clonal *RAS* mutations by digital droplet PCR. PDOs derived from responders and non-responders pts were implanted orthotopically in the liver of mice and treated with REG for 5 days. Changes in tumour and fractional blood volume (fBV) were monitored by oxygen-enhanced MRI.

Results: mCRC pts (n = 27) with paired MRI scans were analysed; a single target lesion per pt was chosen (25 liver and 2 pelvic metastases). Median KEF decrease was 58.2%. In the 23 analysable pts (4 received ≤1 cycle of treatment due to toxicities),>70% drop in KEF(8/27) was associated with higher disease control rate (DCR) measured by

RECIST 1.1 at 2 months (m) ($p = 0.05$), progression free survival (PFS) [HR = 0.24 (0.07-0.86), $p = 0.03$], 6-m PFS (43.8% VS 0%) and overall survival (OS) [HR 0.08 (0.01-0.63), $p = 0.02$]. In all pts with DCR, PFS was found to be 5.6 vs. 4.2 m [HR 0.30 (95% CI 0.06-1.49), $p = 0.140$) and OS was 15.2 vs. 5.8 m [HR 0.11 (95% CI 0.01-1.06), $p = 0.057$]. KEF drop correlated with CD-31 reduction in sequential tissue biopsies ($p = 0.04$). RAS mutant clones decay in ctDNA after 8 weeks of treatment was associated with better PFS [HR 0.21 (0.06 - 0.71), $p = 0.01$] and OS [HR 0.28 (0.07 - 1.04), $p = 0.06$]. PDOs xeno-transplants treated with REG compared to controls had significant lower tumour fBV (4.5 VS 10.6, $p = 0.03$) and lower microvascular density measured by CD31 staining (4.3 VS 8.9, $p = 0.02$).

Conclusions: Combining DCE-MRI and ctDNA predicts depth and duration of anti-angiogenic response to REG with potential health economic implications.

117P Anti-HER2 therapy efficacy in HER2-negative metastatic breast cancer with HER2-amplified circulating tumor cells: results of the CirCe T-DM1 trial

F-C. Bidard[1], P. cottu[1], C. Dubot[2], L. Venat-Bouvet[3], A. Lortholary[4], H. Bourgeois[5], M. Bollet[6], V. Servent Hanon[7], E. Luporsi-Gely[8], M. Espie[9], S. Guiu[10], V. D'Hondt[11], V. Diéras[12], M.P. Sablin[1], S. Neffati[1], F. Berger[1], J-Y. Pierga[1], W. Jacot[11]

[1]Medical Oncology, Institut Curie, Paris, France, [2]Medical Oncology, Hôpital René Huguenin - Institut Curie, St. Cloud, France, [3]Medical Oncology, Limoges University Hospital, Limoges, France, [4]Medical Oncology, Centre Catherine de Sienne, Nantes, France, [5]Medical Oncology, Clinique Victor Hugo Le Mans, Le Mans, France, [6]Radiation Oncology, Clinique Hartmann, Levallois-Perret, France, [7]Medical Oncology, Centre Oscar Lambret, Lille, France, [8]Medical Oncology, Institut de Cancérologie de Lorraine - Alexis Vautrin, Vandoeuvre Les Nancy, France, [9]Medical Oncology, Hôpital St. Louis, Paris, France, [10]Medical Oncology, Institut de Cancerologie de Montpellier, Montpellier, France, [11]Medical Oncology, ICM Regional Cancer Institute of Montpellier, Montpellier, France, [12]Department of Medical Oncology, Centre Eugène Marquis Rennes, France; Institut Curie, Paris, France

Background: Changes of HER2 status has been reported in circulating tumor cells (CTC) isolated from preclinical models and metastatic breast cancer (MBC) patients. The prospective multicentric phase II "CirCe T-DM1" trial was set up to assess whether HER2-amplified CTC are detectable in HER2-negative MBC and whether these cancers would respond to anti-HER2 therapy.

Methods: HER2-amplified CTC were screened in HER2-negative (HER2-/ER- and HER2-/ER+) MBC patients starting a 3rd line or 4th line of systemic therapy. CTC were detected by CellSearch® (Janssen Diagnostics) and FISH was performed on isolated CTCs. HER2-amplification was defined by a HER2/CEP17 ratio $\geq$2.2. Patients with $\geq$1 HER2-amplified CTC, measurable disease and adequate organ function were eligible. After stratification according to amplified CTC count ($<$ vs $\geq$ 3), patients received single agent T-DM1. The primary endpoint of the study was the response rate by RECIST criteria.

Results: From 11/2013 to 08/2016, 155 MBC patients were screened. 11 (9.2%) and 3 patients (2.5%) had 1-2 and $\geq$3 HER2-amplified CTCs respectively (minimal HER2/CEP17 ratio: 2.5). In the 14 patients with HER2-amplified CTC, the fraction of HER2-amplified CTCs among all detected CTCs was low (median 1.6%, range [0.3%-35.3%]), and presence of HER2-amplified CTCs was not associated with any patients' characteristics. 11 patients were treated with single agent T-DM1. Partial response was confirmed in one patient with 1 HER2-amplified CTC (among 9 CTC detected); median PFS was 4.9 months (range: 1.8-10.1).

Conclusions: This study shows that CTCs with a true HER2-amplification can be detected in advanced HER2-negative MBC, mostly as a minor CTCs subset. Although one confirmed response was observed in our study, the overall low response rate to specific anti-HER2 therapy does not support the clinical utility of such strategy in that setting.

118P Nationwide external quality assessment (EQA) of EGFR testing in circulating tumor DNA: The French experience

M. Denis[1], A. Vallée[1], S. Charpentier[1], I. Nanni-Métellus[2], L. Lacroix[3], C. Jovelet[3], M. Francilette[3], D. Fetique[4], J-P. Bellocq[4], E. Rouleau[5]

[1]Molecular Biology, CHU Nantes, Nantes, France, [2]Laboratoire de Biologie Médicale, Faculté de Médecine, Marseille, France, [3]BMO, Institut Gustave Roussy, Villejuif, France, [4]AFAQAP, Hôpital Hautepierre, Strasbourg, France, [5]Département de Biologie et Pathologie Médicales, Institut Gustave Roussy, Villejuif, France

Background: Detection of EGFR mutation in circulating tumor DNA (ctDNA), a powerful blood-based biomarker with multiple clinical applications for lung cancer patient, is technically challenging because it requires sensitivity and specificity. In order to evaluate the performance of the french laboratories performing this assay, we set up a national EQA scheme for circulating tumor DNA.

Methods: Artificial samples were prepared by spiking DNA extracted from control FFPE sections containing specific mutations (Horizon Diagnostics, from 25 to 350 copies/mL of plasma, as determined by digital PCR) in normal plasma (Clinisciences). Aliquots (2 ml) of 10 different samples were sent in dry ice to 43 laboratories. DNA extraction and EGFR testing were performed according to local practice. Laboratories were requested to search for exon 19 deletions, p.L858R, p.G719X and p.T790M mutations. Data were collected on a web questionnaire within one month and compared to the expected results.

Results: We collected 30 complete sets of data. DNA was extracted using the QIAmp® circulating DNA kit (Qiagen; n = 13), the Cobas® cfDNA sample preparation kit (Roche; n = 9) or the Maxwell® system (Promega; n = 7). The most widely used methods were the Cobas® EGFR Mutation Test v2 (Roche; n = 10), digital PCR (n = 8) and NGS (n = 6). Among the 10 labs using the Cobas®, 9 obtained the 10 expected genotypes. This number dropped to 3 (out of 6 labs) for NGS, and 2 (out of 8 labs) for dPCR, because of false negative results, false positive results, and not contributive tests.

Conclusions: Digital PCR and NGS are known to be highly sensitive techniques. However, the results of this EQA suggest that in routine clinical practice, ctDNA analysis requires technical skill or/and validated bioinformatic pipeline to reach high sensitivy and specificity. Under the specific conditions of this scheme, the Cobas® method appeared to be the most robust approach. This external control will allow the laboratories to evaluate their practice and improve their process. A similar approach targeting other genes (BRAF, KRAS and NRAS) is being developed, and additional EQA schemes will be set up at the nationwide level. Supported by a grant from AstraZeneca.

119P IL-8 as a pharmacodynamic biomarker for TGF-β2 antisense (trabedersen) therapy: Results of a phase II trial

L. Hwang[1], W. Wang[1], S. Qazi[2], K. Ng[2], O. D'cruz[2], V. Trieu[1]

[1]Clinical Research, Oncotelic Inc, Agoura Hills, CA, USA, [2]Clinical Research, Autotelic Inc., Costa Mesa, CA, USA

Background: In a Phase I/II study of Trabedersen (OT-101), a phosphorothioate antisense specific for human TGF- β2 mRNA, patients with advanced pancreatic cancer (PAC) treated in the 2nd-line and beyond exhibited improved overall survival (OS) when OT-101 was followed with chemotherapy. Here, we examined the association between plasma levels of cyto-/chemokines and OS outcomes to identify potential biomarkers for improved OS.

Methods: 37 PAC patients were treated with continuous IV infusion in escalating doses of 2 treatment schedules (7-days-on, 7-days-off and 4-days-on, 10-days-off). Plasma levels of 31 cyto-/chemokines were measured at 8 separate time points over 3 cycles of OT-101 treatment (140 mg/m^2/day, 4-days-on, 10-days-off). Standardized maximum levels of individual cyto-/chemokines on Day 2 were subtracted from levels on Day 5 of each cycle of treatment and correlated with log10 transformed OS values. Feedback interactions with PK parameters were also investigated utilizing an ANCOVA model.

Results: A median OS of 14.5 months and 2.6 months was observed for 2nd-line patients treated with and without subsequent chemotherapies, respectively ($p = 0.0009$). Increasing difference of IL-8 levels at Day 2 vs Day 5 was positively correlated with OS ($R^2 = 0.58$, $P = 0.0066$). Stratifying for patients with and without chemo, R^2 increased to 0.99 and 0.77 respectively. Similar results were observed for IL-15, with $R^2 = 0.93$ in patients with chemo and $R^2 = 0.50$ in those without. ANCOVA models for two PK parameters exhibited significant model fits ($F_{3,7} = 7.89$, $P = 0.012$ for Simulated Vz Mean; $F_{3,7} = 8.18$, $P = 0.011$ for Simulated Cl Mean) and the interaction effects resulted in lower p-values for the correlation of OS vs IL-8 levels.

Conclusions: Increasing peak levels of IL-8 and IL-15 response on Day 2 of OT-101 treatment correlated with OS in PAC patients. This correlation with OS was evident regardless of subsequent chemotherapy or not indicating spikes in IL-8 and IL-15 as potential biomarkers for OT-101.

120P Predictive assay for anti-angiogenic agents (AADx) identifies molecular subgroups of RASwt mCRC with differential efficacy of FOLFIRI plus bevacizumab in the FIRE-3 (AIO KRK-0306) trial

S. Stintzing[1], B. Price[2], L. Knight[2], A. McCavigan[2], S. Walker[2], P. Harkin[2], R. Kennedy[2], D. Neureiter[3], S. Held[4], A. Jung[5], T. Kirchner[6], V. Heinemann[1]

[1]Medical Dept. III, Ludwig Maximilians University - Grosshadern, Munich, Germany, [2]GLOBAL & EU Headquarters, Almac Diagnostics, Craigavon, UK, [3]Universitätsinstitut für Pathologie der Paracelsus Medical University, Salzburger Landeskrankenhaus, Salzburg, Austria, [4]ClinAssess GmbH, ClinAssess GmbH, Leverkusen, Germany, [5]Pathologisches Institut-LMU München, Ludwig-Maximillians-Universität, Munich, Germany, [6]Institute of Pathology, University of Munich (LMU), Munich, Germany

Background: The FIRE-3 trial compared 1st-line therapy of FOLFIRI plus either cetuximab or bevacizumab in 592 KRAS exon 2 wildtype (wt) mCRC patients. The subgroup of extended RAS wt patients consisted of 400 patients. The AADx molecular assay has previously been shown to identify a poor prognosis angiogeneic subgroup across multiple cancer types including colorectal cancer. Both bevacizumab (through inhibition of VEGFR-activation) and cetuximab (through inhibition of EGFR-signaling) would be expected to have anti-angiogenic effects in colorectal cancer. The predictive role of AADx in FOLFIRI plus bevacizumab or cetuximab treated in colorectal cancer patients remains unclear.

Methods: Transcriptional profiling of 501 formalin fixed paraffin embedded pre-treatment samples from the ITT population was performed using the Almac Diagnostics Xcel™ array. Patients were classified by the AADx assay as ANGIO ON or OFF based on a predefined score. ORRs were compared using Fischer's exact test. Progression free survival (PFS) and Overall survival (OS) times were compared using Kaplan-Meier estimation and log-rank tests. Hazard ratios (HR) were estimated according to the Cox proportional hazard method.

Results: The AADX assay was successfully applied to 438 out of 501 specimens available from the study population (n = 752). Of those, 315 had a RAS wt tumor and 123 a RAS mutant. The correlation between RAS status and AADx score with respect to ORR; PFS, and OS were complex (Table). The addition of cetuximab to FOLFIRI was significantly superior to the addition bevacizumab in "ANGIO ON" tumors most likely reflecting the strong link between EGFR-signaling and angiogenesis in colorectal cancer.

Conclusions: Here, we present data demonstrating that it possible to define subgroups in the group of wt mCRC patients within the FIRE-3 trial that responded differently to the addition of cetuximab or bevacizumab.

121P Influence of HIF-2alpha deregulation and overexpression of VEGF ligands on the response to aflibercept: Identification of predictive biomarkers

A.K. Larsen[1], S. Thouroude[1], L. Louadj[1], M. Sabbah[1], E. Dochy[2], A. de Gramont[3], J.A. Denis[1], A. Bouygues[1]

[1]Cancer Biology and Therapeutics, Centre de Recherche Saint-Antoine, INSERM U938 and Université Pierre et Marie Curie (UPMC), Sorbonne Universités Paris, France, Paris, France, [2]Late Development Lead – R&D, Sanofi Genzyme, Bruxelles, Belgium, [3]Medical Oncology, Institut hospitalier Franco-Britannique/Franco-British Institute, Levallois-Perret, France

Background: Angiogenesis inhibitors are widely used for treatment of metastastic colorectal cancer. However, no predictive biomarkers are currently available for patient selection. Besides the tumor-associated endothelial cells, VEGF-signaling inhibitors target CRC cells that express VEGF as well as functional VEGFR1 receptors thereby mediating both paracrine and autocrine VEGF-signaling. The aims of this work is i) to establish the direct influence of aflibercept (Zaltrap®) that inhibits all three VEGFR1 ligands (VEGF-A, VEGF-B and PlGF) on CRC cells, ii) to identify tumor phenotypes associated with resistance to aflibercept in vitro and, iii) to extend these findings to human xenograft models.

Methods: A panel of 12 well-characterized CRC cell lines was used to establish the influence of VEGFR1 stimulation (VEGF-A, VEGF-B, PlGF) and inhibition (aflibercept) on VEGF-mediated tumor cell migration. Expression of VEGF ligands and receptors was determined by qRT-PCR and ELISA assays. The *in vivo* influence of aflibercept was determined in human xenograft models and complemented by IHC and Western blot analysis.

Results: Aflibercept inhibited the migration of most CRC cells under both normoxia and hypoxia including the highly sensitive HCT-116 cells. In contrast, LS174T cells did not respond to either aflibercept or to purified VEGF ligands. These cells expressed high levels of VEGF ligands and HIF2alpha, even under normoxia. Accordingly, aflibercept showed pronounced *in vivo* activity toward HCT-116 xenografts with 75% tumor growth inhibition but only 40% tumor growth inhibition toward LS174T tumors, compared to the corresponding vehicle controls. A similar trend was observed for bevacizumab with 41% tumor growth inhibition for HCT-116 and 32% inhibition for LS174T xenografts. IHC analysis of LS174T xenografts confirmed the strong expression of HIF2alpha and VEGF ligands as well as a modest inhibitory effect on the tumor-associated endothelia cells.

Conclusions: We here report that aflibercept has direct antimigratory effects on most CRC cells. Strong expression of HIF-2alpha and VEGF ligands was accompanied by aflibercept resistance in vitro as in vivo.

122P Cell-free (cf)DNA analysis identifies *PIK3CA/AKT1* mutations associated with greater PFS improvement from the addition of ipatasertib (IPAT) to paclitaxel (P) in triple-negative breast cancer (TNBC)

M. Wongchenko[1], R. Dent[2], S-B. Kim[3], C. Saura[4], M. Oliveira[4], J. Baselga[5], A.V. Kapp[6], W.Y. Chan[7], S.M. Singel[7], D.J. Maslyar[7], S. Gendreau[1]

[1]Oncology Biomarker Development, Genentech Inc., South San Francisco, CA, USA, [2]Division of Medical Oncology, National Cancer Centre, Singapore, [3]Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [4]Medical Oncology Department, Vall d'Hebron University Hospital, Vall d'Hebron Institute of Oncology, Barcelona, Spain, [5]Human Oncology and Pathogenesis Program and the Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY, USA, [6]Product Development Biostatistics, Genentech Inc., South San Francisco, CA, USA, [7]Product Development Oncology, Genentech Inc., South San Francisco, CA, USA

Background: The oral Akt inhibitor IPAT is being evaluated in cancers with a high prevalence of PI3K/Akt pathway activation. In the placebo-controlled randomised phase II LOTUS trial (NCT02162719), adding IPAT to P as first-line therapy for metastatic TNBC improved PFS in unselected patients (stratified hazard ratio [HR] 0.60 [90% CI 0.40–0.91]), with a more pronounced effect in patients with *PIK3CA/AKT1/PTEN*-altered tumours [Dent, ASCO 2017]. cfDNA sequencing was performed to assess the utility of blood samples for detecting tumour mutations in TNBC.

Methods: Pre-treatment plasma and tumour samples were evaluated for genetic alterations using Foundation Medicine's FoundationACT® and FoundationOne® next-generation sequencing assays, respectively. Samples from 88 patients were evaluable by cfDNA, 72 of whom also had evaluable tumour samples (52 primary tumour).

Table: 120P

RAS wild-type	AADx score	ORR	p OR	PFS months	p HR	OS months	p HR
FOLFIRI + Cetuximab	ANGIO ON	65.2%	0.69 0.87	10.6	0.72 1.07	29.8	0.88 1.04
	ANGIO OFF	68.3%		10.6		30.6	
FOLFIRI + Bevacizumab	ANGIO ON	46.3%	0.0038 0.39	9.1	0.0002 0.52	21.2	0.0062 0.59
	ANGIO OFF	69.1%		13.1		29.1	
RAS Mutant	**AADx score**	**ORR**	**p OR**	**PFS months**	**p HR**	**OS months**	**p HR**
FOLFIRI + Cetuximab	ANGIO ON	38.6%	0.93 0.94	8.2	0.49 1.23	23.0	0.81 0.92
	ANGIO OFF	40.0%		7.7		19.2	
FOLFIRI + Bevacizumab	ANGIO ON	58.8%	0.13 2.1	11.2	0.35 1.30	23.1	0.02 2.00
	ANGIO OFF	40.0%		10.2		18.5	

To test the prognostic effect of cfDNA mutational burden, patients were classified as having high or low variant allele fraction (VAF) in cfDNA using the median as a cutoff.

Results: In 81 patients (92%), at least one mutation was detectable by cfDNA sequencing. Concordance with tissue sequencing was 75%. High VAF was associated with shorter PFS than low VAF in both the IPAT + P arm (HR 2.39 [90% CI 1.19–4.70]) and the placebo + P arm (HR 2.68 [90% CI 1.46–5.11]). High VAF was also associated with the presence of > 1 metastatic site but not tumour volume per RECIST v1.1. In 22 patients (25%), an activating PIK3CA (n = 16) or AKT1 (n = 6) mutation was detected in cfDNA; concordance with tissue sequencing was 100%. PFS improvement with the addition of IPAT to P was more pronounced in patients with detectable PIK3CA/AKT1 mutations (HR 0.15 [90% CI 0.03–0.50]) than in those without a detectable mutation (HR 0.82 [90% CI 0.50–1.31]).

Conclusions: These results highlight the potential role of cfDNA in evaluating patient prognosis as well as identifying genetic markers associated with improved treatment outcomes. Furthermore, they support the occurrence of PIK3CA and AKT1 mutations as early genetic events present in primary tissue samples that are maintained during metastasis.

123P Genotyping circulating tumor DNA identifies metastatic colorectal cancer (mCRC) patients highly sensitive to Sym004

C. Montagut Viladot[1], A. Bardelli[2], T. Tuxen Poulsen[3], R. Dienstmann[4], M. Kragh[5], S. Kopetz[6], K. Koefoed[3], F. Ciardiello[7], C. Ding[8], J. Vidal[1], J. Clausell-Tormos[3], G. Siravegna[2], T. Lindsted[3], M.W. Pedersen[3], G. Rospo[2], G. Argilés Martinez[9], P. Nadler[3], I.D. Horak[3], J. Tabernero[10]

[1]Medical Oncology, Hospital del Mar, Barcelona, Spain, [2]Department of Oncology, IRCCs University of Torino School of Medicine, Candiolo, Italy, [3]Symphogen, Ballerup, Denmark, [4]Oncology Data Science (ODysSey) Group, Vall d'Hebron University Hospital, Barcelona, Spain, [5]Symphogen, Denmark, [6]GI Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [7]U.O.C. di Oncologia Medica e di Ematologia, Università degli Studi della Campania "Luigi Vanvitelli", Naples, Italy, [8]Symphogen, Somerville, NJ, USA, [9]Medical Oncology, Vall d'Hebrón Institut d'Oncologia (VHIO), Barcelona, Spain, [10]Medical Oncology, Vall d'Hebron University Hospital, Barcelona, Spain

Background: Acquired resistance of mCRC patients (pts) to anti-EGFR monoclonal antibodies (mAbs) is frequently due to mutations in RAS/BRAF and EGFR extracellular domain (ECD), and amplifications in MET/ERBB2. Studies suggest that some anti-EGFR mAb refractory pts retain tumor EGFR-dependency potentially targetable by more efficacious agents such as Sym004 – a mixture of two non-overlapping mAb targeting EGFR for degradation. A Phase 2b trial of Sym004 in 254 mCRC pts tissue RAS wt that relapsed on anti-EGFR blockade was recently completed.

Methods: Baseline circulating tumor (ct)DNA profiles (Guardant360, Guardant Health, N = 193 pts) were obtained from blood samples collected from pts in the Sym004 Phase2b trial. Serial blood samples during treatment were analyzed for EGFR-ECD mutation dynamics.

Results: High mutant allele frequency (MAF >20%) of *KRAS*/*NRAS* was found in 5% of pts and *BRAF* V600E and *EGFR*-ECD mutations in 6.7% and 25% of pts, respectively. At least 1 of these mechanisms of resistance was identified in 32% of the pts. Mutations in *KRAS, NRAS*, and *BRAF* V600E, and amplifications of *ERBB2* and *MET* were more likely to co-occur with *EGFR*-ECD mutations, demonstrating genomic complexity developed as a result of EGFR blockade. Comparative analysis of MAFs of driver genes indicated that *EGFR*-ECD mutations are subclonal events. The absence of any *EGFR*-ECD/*BRAF*/high *RAS* MAF mutation at baseline was associated with a significantly improved OS in the Sym004 treated pts as compared to control arm with investigator's choice chemotherapy. Sym004 has previously been demonstrated to retain *in vitro* efficacy in *EGFR*-ECD mutated cancer cells, and ctDNA monitoring demonstrated decrease in *EGFR*-ECD in Sym004 treated pts. This suggests that *EGFR*-ECD mutated cells are targeted by Sym004, but this activity does not translate into clinically meaningful OS benefit, likely due to other co-occuring resistance mechanisms.

Conclusions: Comprehensive liquid biomarker profiling of 193 mCRC pts captured high intrapatient heterogeneity following anti-EGFR therapy, and identified a highly Sym004 sensitive mCRC pts subset with a *RAS/RAF/EGFR*-ECD wild type profile. Our data indicates heterogeneous responses of different subclones to targeted agents in mCRC.

124P Role of circulating miRNAs as prognostic biomarkers in resected early-stage non-small cell lung cancer

P. Ulivi[1], E. Petracci[2], V. Ludovini[3], G. Marisi[1], A. Delmonte[4], N. De Luigi[4], D. Calistri[1], L. Crinò[4], D. Amadori[4], R. Chiari[3], S. Baglivo[3], F. Grignani[5]

[1]Biosciences Laboratory, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola, Italy, [2]Biostatistics and Clinical Trials Unit, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) - IRCCS, Meldola, Italy, [3]Medical Oncology, Ospedale S. Maria della Misericordia, Perugia, Italy, [4]Department of Medical Oncology, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola, Italy, [5]Pathology Unit, Perugia Hospital, Perugia, Italy

Background: Non-small cell lung cancer (NSCLC) is the primary cause of cancer-related death, with a 5-year survival rate < 16% mainly because of disseminated disease, even in fully resected early-stage disease. Biomarkers identifying patients at a higher risk of relapse would be useful and circulating microRNAs (miRNAs) are a promising option in this setting.

Methods: We analyzed a case series of 182 patients with resected early stage (IA-IIIA) NSCLC (99 adenocarcinoma [ADC] and 83 squamous cell carcinoma [SCC]). Peripheral blood samples were collected from each patient before surgical resection and serum was obtained after centrifugation and stored at -80 °C until miRNA extraction. A panel of 84 circulating miRNAs was analyzed by Real Time PCR. Data were normalized using an external spike-in (cel-miR-39) and the mean of the two most stable endogenous housekeeping genes chosen separately for ADC and SCC samples. miRNA expression was analyzed in relation to disease-free survival (DFS) by the Cox regression model. Results are reported as hazard ratios (HRs) and 95% confidence intervals (CIs).

Results: In ADC patients, stage was significantly associated with DFS (HR stage II-IIIA *vs* stage I = 4.94, 95% CI [2.71 - 9.02]). Multiple statistical methods were used to evaluate miRNA expression data. In univariate analysis, two miRNAs (miR-222-3p and miR-22-3p) were significantly associated with DFS (p = 0.033 and p = 0.041, respectively). However, this significance was not maintained after adjusting for multiple testing. In SCC patients, disease stage was significantly related to DFS (HR stage II-IIIA *vs* stage I = 3.31, 95% CI [1.74 - 6.33]). Five miRNAs (let-7a-5p, miR-126-3p, miR-26a-5p, miR-130b-3p, miR-21-5p) were significantly associated with DFS even after adjusting for multiple testing (False Discovery Rate q-value <0.001).

Conclusions: Pre-surgery circulating levels of let-7a-5p, miR-126-3p, miR-26a-5p, miR-130b-3p and miR-21-5p would appear to be significantly correlated with prognosis in resected early-stage SCC.

Background: Plasma cell-free DNA (cfDNA) sampling from patients with advanced cancers offers a minimally invasive source of tumor DNA for molecular testing, including methylation profiling. Tumor sequencing at disease progression offers insights into cancer biology, but is often not done because of logistical and other challenges associated with tumor biopsies.

Methods: Plasma samples were collected from patients with advanced breast, colorectal, non-small cell lung cancer (NSCLC) and melanoma at the time of disease

progression and/or on therapy. Up to 30 ng (median 18ng) of plasma cfDNA was tested with the pan-cancer methylation panel to target a total of 10,888 CpG sites using an Illumina HiSeq2500 sequencer to calculate methylation scores. Methylation scores were correlated with cancer types and clinical outcomes.

Results: Of 69 plasma cfDNA samples collected from patients (colorectal cancer, 28; NSCLC, 18, breast cancer, 12; melanoma, 11) at disease progression, methylation scores were consistent with the presence of cancer in 84% (58/69); while in 79% (46/58) of plasma cfDNA samples, methylation scores accurately classified the underlying cancer type. High methylation scores in plasma cfDNA samples collected at disease progression compared to low methylation scores were associated with shorter survival irrespective of the tumor type (3.9 vs 10.4 months, $P < 0.001$, confirmed on multivariable analysis). In addition, high methylation scores in plasma cfDNA samples collected at progression vs low methylation scores were associated with shorter time to treatment failure (TTF) on systemic therapy (1.6 vs. 2.8 months, $P = 0.007$). There was a positive correlation between RECIST response (%) to systemic therapy and methylation scores (r 0.32, $P = 0.03$). Methylations score before therapy (median 87.28) were higher than methylation scores on therapy (median 9.49, $P = 0.001$).

Conclusions: Methylation scores from plasma cfDNA collected at disease progression from patients with advanced cancers accurately classify underlying cancer types and are associated with survival, TTF and RECIST responses.

126P Single-cell combined mutation and gene expression studies of circulating tumor-associated cells in non-small cell lung cancer

J. Mong[1], J. Shi[1], T.M. Chin[2], S-W. Wong[3], A. Tee[4], D. Chan[5], K. Wong[6], S. Yeap[7], L. Ngo[8], Y-O. Tan[9], M. Hu[1], J. Ying[1], M-H. Tan[1]

[1]Biodevices and diagnostics, Insitute of Bioengineering and Nanotechnology (IBN), Singapore, [2]Department of Haematology-Oncology, National University Hospital, Singapore, [3]The Cancer Centre, Singapore, [4]Department of Respiratory & Critical Care Medicine, Changi General Hospital, Singapore, [5]Singapore Oncology Consultants, Singapore Oncology Consultants, Singapore, [6]SOC @ Gleneagles, Singapore, [7]Novena Cancer Center-Mount Elizabeth Specialist Centre, Singapore, [8]Cancer Centre, Raffles Medical Group, Singapore, [9]SOC clinic, Farrer Park Hospital & Medical Centre, Singapore

Background: Circulating tumor cells (CTC) in the bloodstream not only provide us a sampling of the tumor population but are also keys to the metastatic process. Most CTC enrichment devices are coupled to downstream marker analysis by immunocytochemistry that define CTC as CD45-negative and epithelial marker (e.g. EPCAM)-positive cells. Our group recently reported a new class of tumor-derived cells in circulation, the circulating tumor-endothelial cluster, in colorectal cancer. This demonstrated that tumor-associated cells in circulation hitherto considered malignant may instead and unexpectedly provide key insights to the tumor microenvironment. To effectively classify the circulating cell milieu in lung cancer, we used a single-cell technique RNA and mutation analysis (scrm-PCR) we have described previously to characterize DNA and RNA from the same cell.

Methods: We enriched for CTC from whole blood of non-small cell lung cancer (NSCLC) patients using silicon microsieves with uniformly spaced 8 to 10uM circular pores. We manually selected captured single cells or cell clusters for characterization. 50 single cell or cell clusters from 5 NSCLC patients and 2 healthy subjects were probed for a curated panel of 27 RNA markers and hotspot DNA mutations in EGFR, TP53 and KRAS by scrm-PCR.

Results: Classic epithelial markers such as EPCAM are largely unexpressed in CD45-negative cells in NSCLC. DNA mutations were undetected in all isolated cells except for 1 cell. CD45-negative cell clusters in NSCLC exhibit a different phenotypic profile as compared to our report of tumor-endothelial in colorectal cancer, failing to express classic endothelial markers such as VWF, MCAM and CDH5. We identified important morphological features correlating with biological phenotypic classification of these cells, allowing us to establish a map of the circulating cell milieu of NSCLC.

Conclusions: This is the first systematic same-cell combined mutation and expression analysis of circulating cells in NSCLC patients. With this novel approach, we report the presence of predominantly tumor-associated cells rather than malignant cells in circulation, and highlight the potential of these cells as biomarkers of NSCLC and its tumor microenvironment.

127P EGFR copy number aberrations detected in cfDNA from advanced NSCLC patients

G.M. O'Kane[1], T. Li[2], M. Tsao[3], G. Liu[1], T.J. Pugh[2], N.B. Leighl[1]

[1]DMOH, Princess Margaret Cancer Centre, Toronto, ON, Canada, [2]Toronto Medical Discovery Tower, Princess Margaret Cancer Centre, Toronto, ON, Canada, [3]Pathology, Princess Margaret Hospital, Toronto, ON, Canada

Background: Copy number aberrations (CNA) in the epidermal growth factor receptor (EGFR) represent a mechanism of tyrosine kinase activation and oncogenic signaling in advanced non-small cell lung cancers (NSCLC). High copy number gains (CNG) may predict TKI sensitivity but when acquired are postulated to reflect resistance. Treatment with monoclonal antibodies may have a role and therefore CNA integration in molecular diagnostics is potentially important.

Methods: Cell free (cf) DNA was from extracted from NSCLC patients undergoing treatment with EFGR-TKIs. A validated Liquid Biopsy Sequencing (LB-Seq) method for hybrid capture followed by ultra deep sequencing (> 20,000X) evaluated coding exons of KRAS, NRAS, BRAF, PIK3CA, and EGFR (18 kb). Subsequent filtering of mutation calls using a novel algorithm enabled detection of tumor-derived fragments at concentrations down to 0.2%. EGFR CNAs were assessed using a modified version of the VisCap algorithm. Mutation calls were compared to tissue biospy results for EGFR mutations.

Results: Targeted sequencing has been performed on 12 samples to date: 10 patients with classical *EGFR* mutations in L858R and del19, 1 with an exon 20 insertion and 1 with an exon 18 G718X mutation. All patients had progressed on at least one *EGFR*-TKI. % mutant reads ranged from 0.25% to 33%. *EGFR* CNGs were detected in 3 patients: 1 patient with T790M+ve disease confirmed in both tissue and cfDNA was found to have a co-occurring BRAF mutation (p.33_34insGA). The remaining 2 patients' tissue samples tested negative for T790M; T790M was detected in cfDNA in 1 patient, who is currently receiving osimertinib, and in the other patient rapid progression on gefitinib occurred with an *EGFR*-G719X mutation. Copy number losses were detected in 2 patients. 2 of 6 patients with *EGFR*-T790M positive tissue were confirmed in cfDNA, the remaining 4 negative results were verified by ddPCR. An intronic variant of unknown significance (c.747 + 9C>T), not covered in tissue testing, was also captured in cfDNA.

Conclusions: Copy number aberrations in EGFR can be detected from targeted sequencing of cfDNA in patients with *EGFR* mutated NSCLC. Longitudinal evaluation in patients receiving *EGFR*-TKIs may provide insights into mechanisms of resistance.

Background: Recent studies have reported that serum microRNAs (miRNAs) are potentially useful biomarkers for diagnosis and treatment of cancer. However, its utility for detecting esophageal squamous cell carcinoma (ESCC) has not been investigated yet. The aims of this study are to identify circulating serum miRNAs for ESCC detection.

Methods: We comprehensively analyzed serum miRNA expression profiles of 595 patients with ESCC, and 5051 non-cancer individuals using microarray (3D-Gene, Toray). Serum of non-cancer individuals was obtained from Biobank of NCGG and Health check up clinic (Yokohama Minoru clinic). Serum of ESCC patients was collected before starting any treatment such as radiotherapy, surgery and chemotherapy. Analyzed samples were randomly divided into discovery and validation sets. Serum miRNA levels were compared between ESCC and non-ESCC patients. Fisher's linear discriminant analysis was performed to construct the discriminant model for ESCC detection. Measured values of each miRNAs were extrapolated into the discriminant formulas. We performed ROC analysis to evaluate the diagnostic ability of these formulas in each validation cohort.

Results: In discovery set, 300 patients of ESCC was compared to 300 individuals of non-cancer control. We picked up 3 miRNAs, named miR-A, miR-B and miR-C, for ESCC diagnosis. Their AUC for detection of ESCC was 0.967, 0.873 and 0.650, respectively in ROC analysis. We constructed the discriminant model, called EC index, using these 3 miRNAs in discovery set. In validation set which contain 295 pts of ESCC and 4751 person of non-cancer control, EC index showed the AUC, sensitivity and specificity of the discriminant formula was 0.99, 0.98 and 0.95, respectively.

Conclusions: We identified novel serum miRNAs for ESCC detection. Our discriminant using these miRNAs can diagnose ESCC.

129P First prospective multicenter real-world RAS mutation comparison between OncoBEAM-based liquid biopsy and tissue analysis

J. Garcia Foncillas[1], J. Tabernero[2], E. Aranda Aguilar[3], M. Benavides[4], C.J. Camps[5], R. López[6], C. Montagut[7], A. Anton Torres[8], G. Lopez Vivanco[9], E. Diaz Rubio[10], F. Rojo[1], A. Vivancos[11]

[1]Cancer Institute, University Hospital "Fundacion Jimenez Diaz", Madrid, Spain, [2]Medical Oncology, Vall d'Hebron University Hospital, Barcelona, Spain, [3]Oncology, University Hospital Reina Sofia, Cordoba, Spain, [4]Oncology, Hospital Regional Universitario Carlos Haya, Malaga, Spain, [5]Oncology, Hospital General Universitario Valencia, Valencia, Spain, [6]Medical Oncology Department, Hospital Clinico de Santiago, Santiago de Compostela, Spain, [7]Oncology, University Hospital del Mar, Barcelona, Spain, [8]Oncology, Hospital Miguel Servet, Zaragoza, Spain, [9]Oncology, Hospital de Cruces, Barakaldo, Spain, [10]Oncology, Hospital Clinico Universitario San Carlos, Madrid, Spain, [11]Oncology, Vall d'Hebron University Hospital, Barcelona, Spain

Background: Liquid biopsy is a powerful tool to refine the management of cancer patients by offering a minimally-invasive alternative to tumor tissue testing and rapid evaluation of overall tumor burden mutational status. To support its clinical adoption, a rigorous real-world evaluation of this method in routine clinical practice is required. OncoBEAM RAS is the only liquid biopsy assay to attain CE-IVD status for plasma RAS mutation analysis in routine colorectal cancer (CRC) patient care. The goal of the present study was to evaluate the aggregate performance of OncoBEAM RAS in10 hospital labs where the technology is installed in Spain.

Methods: Blood samples were collected in Streck cell-free DNA BCT® or EDTA tubes from metastatic CRC patients and circulating cell-free DNA from plasma was examined for RAS mutations using the OncoBEAM platform at each hospital laboratory. Results were then compared to those obtained from DNA extracted from tissue from the same patient.

Results: The overall percentage agreement (concordance) of results from plasma and tissue RAS mutation testing of 230 patients was 90.4% (208/230); 95% CI = 0.86-0.94, with positive percent agreement of 86.9% (113/130) and negative percent agreement of 95.0% (95/100). Re-analysis of tissue from all discordant cases by BEAMing revealed 2 false negative local tumor tissue RAS results. Plasma false negative results were observed more frequently in patients presenting with peritoneal and/or lung metastases only. The prevalence of RAS mutations in plasma (51.3%) and tissue (56.5%) were in accord with the expected occurrence of RAS mutations in mCRC patients.

Conclusions: In this first prospective real-world RAS mutation performance comparison study across a network of hospital laboratories certified to perform OncoBEAM testing in routine clinical practice, a high overall agreement was observed between results obtained from plasma and tissue samples. These results are comparable to those obtained in retrospective studies. Overall, these findings indicate that plasma OncoBEAM RAS testing is a viable solution for rapid delivery of RAS mutation status to determine mCRC patient eligibility for anti-EGFR therapy.

130P EGFR plasma testing in routine practice by real-time PCR in lung cancer patients: Experience of 262 patients

P. Taniere[1], P. Taniere[1], M. Smith[1], B. O'Sullivan[1], F. Hughes[1], T. Mullis[1], N. Trim[1], S. Baijal[2], Q. Ghafoor[3], G. Middleton[4]

[1]Molecular Pathology Diagnostic Service, Queen Elizabeth Hospital Birmingham, Birmingham, UK, [2]Oncology, Heartlands Hospital-Heart of England NHS Foundation Trust, Birmingham, UK, [3]Oncology, New Queen Elizabeth Hospital Birmingham, Birmingham, UK, [4]Oncology, Queen Elizabeth Hospital Birmingham, Birmingham, UK

Background: EGFR mutation testing in lung cancer prior to tyrosine kinase inhibitor (TKI) therapy can be performed in tissue or plasma in practice. Both techniques are complementary; however, plasma testing can represent a surrogate for re-sampling a tumour in patients progressing under TKI prior to prescription of osimertinib, but clinical sensitivity of the test remains to be determined. We present our twelve-month experience of integrating EGFR plasma testing into our service with a series of 262 cases. We currently receive over 50 cases per month.

Methods: EGFR mutation testing for both tissue and plasma is performed using cobas EGFR Mutation Test v2, which covers 29 deletions in exon 19, T790M, L858R, G719X, S768I, L861Q and 5 insertions in exon 20. For plasma testing, DNA is extracted using the cobas cfDNA sample preparation kit. All samples were submitted in Paxgene ccfDNA tubes.

Results: Of the 262 cases submitted for testing, five failed (1.9%). 123 mutations, including 42 T790M, were detected. Turnaround time was two days. Clinical sensitivity is very difficult to assess because of the uncertainty of the presence of circulating tumour DNA at all. All types of primary mutation were detected: 70 exon 19 deletions, 42 L858R, 2 G719X, 5 L861Q, 3 combined S768I and G719X, and 1 singlet T790M. Clinical details were not available for all patients. A sensitising mutation was found in 51 of 92 patients (55.5%) under TKI therapy, where this was indicated on the request form; among these, an associated T790M mutation was found in 19 (37%) of patients. Several patients underwent multiple tests while they received TKI therapy; in two patients, the secondary mutation was detected prior to clinical progression.

Conclusions: We show here that EGFR plasma testing is perfectly suitable for clinical practice; it is highly specific and cost-effective due to rapid turnaround times, but the low sensitivity renders it complementary to tissue testing rather than a true surrogate.

131P Circulating tumor cells as liquid biopsy for castration resistant prostate cancer patients treated with cabazitaxel

S. Salvi[1], V. Conteduca[2], V. Casadio[1], P. Fici[1], G. Gurioli[1], F. Martignano[1], U. Basso[3], G. Fornarini[4], C. Lolli[2], G. Schepisi[2], S. Testoni[5], D. Calistri[1], U. De Giorgi[2]

[1]Biosciences Laboratory, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola, Italy, [2]Department of Oncology, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola, Italy, [3]Medical Oncology Unit 1, Department of Clinical and Experimental Oncology, Istituto Oncologico Veneto IRCCS, Padua, Italy, [4]Medical Oncology, IRCCS Azienda Ospedaliera Universitaria San Martino - IST Istituto Nazionale per la Ricerca sul Cancro, Genoa, Italy, [5]Unit of Biostatistics and Clinical Trials, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola, Italy

Background: Cabazitaxel (CBZ) has been shown to improve overall survival (OS) in metastatic castration resistant prostate cancer (mCRPC) patients (pts) and to overcome resistance to docetaxel (DOC). Circulating tumor cells (CTCs) can be useful tool for precision medicine. CTCs expression profiling before CBZ treatment could establish novel predictive biomarkers.

Methods: We prospectively enrolled 28 pts with mCRPC treated with CBZ 25 mg/mq q21 after DOC and abiraterone or enzalutamide. CTCs enrichment was assessed with Adna Test EMT/STEM. Expression analyses of AKR1C3, AKT2, ALDH1, AR, ARV7, EPCAM, FOLH1, MDK, PARP, MRP1, PIK3CA, POU5F1, PSCA, TUBB3, VIM, ACT, HPRT1 were analyzed using real time PCR. CTCs positive pts were defined when at least one marker among AKT2, AR, AR-V7, EPCAM, FOLH1, PSCA, PIK3CA was expressed. Progressive disease was defined according to PCWG2 criteria. Main endpoint was the correlation between CTCs expression profiling and outcome.

Results: Of these 28 pts, 18 (64%) had detectable CTCs before the starting of CBZ and 10 (36%) had undetectable CTCs. Detection of CTCs was associated with poor OS. However, no difference was observed for progression free survival (PFS). No correlation between CTCs assessment and PSA response rate was found. In addition, we subdivided pts according to median value of CTCs expression markers. Nine (50%) pts with ≥3 markers had a significant worse PFS compared to pts with <3 markers. Pts with ≥3 markers, reflecting heterogeneity of disease, had also a poor OS (Table).

Table: 131P

CTCs	Pts	PFS			OS		
		Median (months)	HR (95% CI)	*p*	Median (months)	HR (95% CI)	*p*
CTCs +	18/28	5.8	1.31 (0.58-3.04)	*p*=0.5220	9.7	7.03 (1.16-11.00)	***p*=0.0279**
CTCs -	10/28	7.0			–		
≥3 markers	9/18	2.5	3.59 (2.07-22.01)	***p*=0.0039**	3.9	5.92 (3.86-52.21)	***p*=0.0003**
<3 markers	9/18	10.1			16.6		

Conclusions: We prospectively confirmed a prognostic role for CTCs in mCRPC pts treated with CBZ and we also firstly showed the utility to characterize CTCs expression markers thanks to its potential predictive role. The identification of markers expressed

on CTCs may also provide additional therapeutic targets. More details on the prognostic impact of these biomarkers and *AR* status and mutations are under analysis and will be presented at meeting.

132P Biomarker analysis using circulating tumor DNA in patients treated with sorafenib for advanced hepatocellular carcinoma

S.R. Park[1], C.R. Oh[2], S-Y. Kong[3], M.K. Kim[4], K-A. Yoon[5], E. Cho[6], J-H. Jang[6], J. Lee[6], B-Y. Ryoo[1]

[1]Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [2]Department of Internal Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [3]Department of Laboratory Medicine, Hospital, National Cancer Center, Goyang, Republic of Korea, [4]Cancer Biomedical Science, Graduate School of Cancer Science and Policy, National Cancer Center, Goyang, Republic of Korea, [5]College of Veterinary Medicine, Konkuk University, Seoul, Republic of Korea, [6]Genome Research Center, Green Cross Genome, Yongin, Republic of Korea

Background: We aimed to investigate potential biomarkers in patients treated with sorafenib for advanced hepatocellular carcinoma (HCC) using circulating tumour DNA (ctDNA).

Methods: 155 patients who had started sorafenib between March 2014 and November 2016 were identified from a prospective biomarker cohort of Asan Medical Center, Korea. We quantified the concentration of ctDNA extracted from blood samples of each patient collected before sorafenib treatment and measured the copy numbers of vascular endothelial growth factor-A (VEGFA) in ctDNA. We also applied low depth whole genome sequencing from ctDNA to find copy number aberrations in HCC and employed Q-score, defined as a standard deviation regarding Z-scores of sequenced reads on each chromosome.

Results: Among 155 patients, 124 were finally included in the analysis. 82 patients achieved partial response, stable disease or non-CR/non-PD with sorafenib treatment (non-PD group) whereas 42 exhibited progressive disease (PD group). The PD group had significantly higher levels of ctDNA concentrations than the non-PD group (153.3 vs. 109.3 ng/mL; $p = 0.038$). Q-score of PD group was also higher than that of non-PD group but there was a borderline significant difference between two groups (6.10 vs. 3.80; $p = 0.058$). VEGFA copy number, which was available for only 41 patients, did not differ between PD ($n = 16$) and non-PD ($n = 25$) groups (2.56 vs. 2.48; $p = 0.467$). Divided into two groups based on the median value (119.7 ng/mL) of ctDNA concentrations, patients with high ctDNA had significantly shorter time to progression (TTP) (median, 2.3 vs. 4.1 months; $p = 0.025$) and overall survival (OS) (median, 4.5 vs. 14.8 months; $p < 0.001$) than those with low ctDNA. Similarly, patients with higher Q-score than median value of 4.12 had significantly worse TTP (median, 2.7 vs. 4.0 months; $p = 0.012$) and OS (median, 5.2 vs. 17.3 months; $p < 0.001$) compared to those with lower Q-score. After adjusting confounding factors by multivariate Cox regression analysis, the concentration of ctDNA and Q-score remained independent prognostic factors associated with both TTP ($p = 0.026$ and 0.042, respectively) and OS ($p < 0.001$ and $p = 0.001$, respectively).

Conclusions: Our results showed that ctDNA level and copy number aberrations represented by Q-score could be potential prognostic biomarkers in HCC patients treated with sorafenib.

133P Heparinase enables reliable quantification of circulating tumor DNA from heparin plasma samples by droplet digital PCR

D. Sefrioui[1], L. Beaussire[2], F. Clatot[3], A. Perdrix[4], P. Michel[5], F. Di Fiore[5], N. Sarafan-Vasseur[2]

[1]Gastroenterology, CHU Hôpitaux de Rouen-Charles Nicolle, Rouen, France, [2]Institute for Biomedical Research and Innovation, Inserm U1079, University of Rouen, Rouen, France, [3]Department of Medical Oncology, Henri Becquerel Center, Rouen, France, [4]Department of Biopathology, Henri Becquerel Center, Rouen, France, [5]Department of oncology, CHU Charles Nicolle, Rouen, France

Background: Circulating tumor DNA has been highlighted as a potential "liquid biopsy", which can be used to identify prognostic and predictive alterations in oncology. Heparin is often used as plasma anticoagulant source for tumor marker analysis such as CA19.9 or CA15.3 but corresponds also to an inhibitory of PCR not enabling ctDNA detection. We aimed to evaluate the impact of heparinase addition on heparinized plasma samples to recovery the possibility of ctDNA analysis on samples initially dedicated for tumor markers analysis.

Methods: Plasma samples were collected in heparinized ($n = 194$) and EDTA ($n = 8$) tubes from hormone receptor-positive metastatic breast cancer (HR+MBC) patients resistant to aromatase inhibitor (AI) treatment ($n = 144$) and from newly diagnosed pancreatic adenocarcinoma (PA) patients ($n = 50$). *ESR1* and *KRAS* mutations were used as targets for ctDNA detection in HR+MBC and PA patients, respectively. ctDNA was detected by droplet digital PCR after an amplification step either without or with heparinase (H- and H+ respectively). PCR efficiency and ctDNA detection rate were compared between H- and H+ subgroups as well as with EDTA subgroup.

Results: Heparinase addition improved significantly PCR efficiency for 91/144 HR+MBC and 26/50 PA patients enabling ctDNA detection in 22/91 (24%) and 13/26 (50%) of these patients. Moreover, heparinase condition did not quantitatively and qualitatively alter the ctDNA detection for patients without heparin inhibition of PCR and comparable results for ctDNA detection were obtained between H+ and EDTA subgroups.

Conclusions: Heparinase addition allows removing the heparin inhibition on cfDNA amplification and to detect and quantify accurately ctDNA levels by dPCR in the heparinized plasma samples.

134P Circulating tumour DNA (ctDNA) in the clinical management of patients (pts) with advanced non-small cell lung cancer (NSCLC): A single centre experience

M. Uccello[1], M. Kushnir[1], G. Mak[1], C. Murias Henriquez[1], C. Abbosh[2], D. Papadatos-Pastos[2], T. Newsom-Davis[3], T. Ahmad[2], C. Swanton[4], M. Forster[2], R. Lanman[5], I. Faull[6], H-T. Arkenau[1]

[1]Drug Development, Sarah Cannon Research Institute UK, London, UK, [2]Oncology, University College London Hospital, London, UK, [3]Oncology, Chelsea and Westminster Hospital NHS Trust, London, UK, [4]Translational Cancer Therapeutics, Cancer Research UK London Research institute, London, UK, [5]Medical Affairs, Guardant Health, Redwood City, CA, USA, [6]Medical Affairs, Guardant Health, Barcelona, Spain

Background: Circulating tumour DNA (ctDNA) is an emerging non-invasive method to guide personalised medicine in patients (pts) with advanced non-small cell lung cancer (NSCLC). The aim of this project was to assess the utility of ctDNA in routine clinical practice where tumour biopsy (Bx) was contraindicated or insufficient for genotyping.

Methods: A 73-gene cancer panel test using next generation sequencing for ctDNA profiling (Guardant360®) was offered at our institution to stage IV NSCLC pts. The reports obtained were discussed in a multidisciplinary Genomics Review Board (GRB) to assess potentially actionable genomic alterations and enrolment into clinical trials. All pts consented for prospective collection of demographic, clinical, and biomolecular data.

Results: Thirty advanced lung cancer pts were offered ctDNA testing. Histology included adeno- in 27 (90%) pts, squamous cell- in 2 (7%) pts, and small cell carcinoma in 1 (3%) pt. As assessed by baseline tumour Bx, EGFR status was mutant in 15 (50%) pts, wild type in 8 (27%) pts, and unknown in 7 (23%) pts. Activating EGFR mutations (mut) showed on original Bx at diagnosis were detected by ctDNA in 11 (73%) pts – lag-time 17 months (range 7-94). Primary EGFR mut were found in 2 pts with unknown EGFR status, allowing access to EGFR tyrosine kinase inhibitors (TKIs). Acquired T790M mut was found in 3 (20%) pts progressing on prior EGFR TKI, with the indication to receive Osimertinib. Only 1 pt with ctDNA-positive status for T790M mut received concomitant solid Bx which was negative for T790M mut. Other genomic alterations were detected in the overall population, more commonly involving TP53 ($n = 12$; 40%), NF1 ($n = 7$; 23%), MET ($n = 5$; 17%), BRAF ($n = 4$; 13%), PIK3CA ($n = 3$; 10%), BRCA 1/2 ($n = 3$; 10%), PDGFRA ($n = 3$; 10%), and AR ($n = 3$; 10%) genes. Critical review in the GRB was crucial in assessing genomic alterations of clinical significance.

Conclusions: Our study confirms the utility of ctDNA testing in advanced NSCLC pts where tumour Bx was not possible or insufficient for genotyping. Based on ctDNA, 5 pts received treatment with 1st- or 2nd-line EGFR TKIs while several pts were considered for clinical trial participation. Updated results of this ongoing study will be reported.

135P Genome-wide methylation analysis reveals a prognostic classifier for non-metastatic colorectal cancer (ProMCol)

M. Gündert[1], D. Edelmann[2], A. Benner[2], L. Jansen[3], M. Jia[3], V. Walter[3], P. Knebel[4], E. Herpel[5], J. Chang-Claude[6], M. Hoffmeister[3], H. Brenner[3], B. Burwinkel[1]

[1]Division of Molecular Epidemiology, German Cancer Research Center, Heidelberg, Germany, [2]Division of Biostatistics, German Cancer Research Center, Heidelberg, Germany, [3]Division of Clinical Epidemiology and Aging Research, German Cancer Research Center, Heidelberg, Germany, [4]Department of General, Visceral and Transplantation Surgery, University of Heidelberg, Heidelberg, Germany, [5]Department of General Pathology, Institute of Pathology, Heidelberg, Germany, [6]Division of Cancer Epidemiology, Unit of Genetic Epidemiology, German Cancer Research Center, Heidelberg, Germany

Background: Currently, pathological staging according to the tumor-node-metastasis system remains the gold standard for the prediction of patient survival in colorectal cancer (CRC) but this classification system provides insufficient information and therefore additional prognostic markers are needed.

Methods: A genome-wide methylation analysis was done for two independent cohorts of non-metastatic CRC patients (screening cohort n = 578 and validation cohort n = 308). Initially, genome-wide differentially methylated CpG sites between 34 pairs of tumor and normal mucosa tissue samples from the same patients were identified. A variable screening for prognostic CpG sites was performed in the screening cohort using marginal testing based on the Cox model and subsequent adjustment of the *p*-values via independent hypothesis weighting (IHW) using the difference between tumor and normal mucosa tissue as auxiliary covariate. From the 1000 CpG sites with the smallest adjusted *p*-value, the 20 CpG sites with the smallest Brier Score for 3-year overall survival (in the screening cohort) were selected. Applying principal component analysis on these CpG sites, we derived a methylation-based classifier for the prognosis of non-metastatic CRC (ProMCol).

Results: The ProMCol classifier was independently validated in the validation cohort, where it showed a significant reduction in the Brier score. Regarding the three year survival, the prediction error was reduced from 0.132 (calculated only with clinical variables), to 0.124 (combination of clinical variables with ProMCol classifier). An additional replication analysis showed that the ProMCol classifier was significantly associated with overall survival (OS) of non-metastatic CRC patients in the screening (HR = 0.22, 95%CI=0.13-0.35, *p*=6.2E-10) and the validation cohort (HR = 0.40, 95%CI=0.22-0.74, *p*=0.003), adjusted for standard clinical factors. Patients with a high methylation status, represented by higher values of the ProMCol classifier, showed a better prognosis for OS than patients with a low methylation status and lower ProMCol classifier values.

Conclusions: The usage of the ProMCol classifier could improve the prognostic accuracy for non-metastatic CRC patients.

136P Epigenetic biomarkers in breast cancer: Preliminary results from H3K27m3 assessment in endocrine-treatment resistance

M. Fontes-Sousa[1], S. Lobo[2], S. Salta[2], P. Lopes[2], J. Lobo[3], S. Sousa[1], R. Henrique[3], C. Jeronimo[2]

[1]Medical Oncology, Portuguese Institute of Oncology, Porto, Porto, Portugal, [2]Cancer Biology and Epigenetics Group, IPO Porto Research Center (CI-IPOP), Portuguese Institute of Oncology, Porto, Porto, Portugal, [3]Pathology, Portuguese Institute of Oncology, Porto, Porto, Portugal

Background: Breast cancer (BC) is an important cause of morbidity and mortality. Most BC are hormone-receptor positive and can be treated with endocrine treatment (ET), until resistance or toxicity is developed. Specifically, H3K27m3, an epigenetic marker of gene repression, has been associated with prognosis in ET resistant BC. Herein, we aim to further understand its potential role as predictive marker of ET resistance before exposure to treatment.

Methods: A cohort of BC patients diagnosed between 1995 and 2002 at our institution were enrolled after informed consent. Expression of H3K27me3 was determined by immunohistochemistry (IHC) in formalin fixed paraffin embedded tissues. GenASIs^{TM} software was used to assess cell-positivity using a custom profile from positive control. Pre-specified conditions: $\geq$ 5 frames $\geq$ 3000 cells analyzed/case. SPSS v24 was used for statistical purposes.

Results: A total of 102 cases were assessed for H3K27me3 immunoexpression. Median of 6 frames/case (range 5-10) and 3311 cells/case (range 3017-5292) were obtained. Of the total cases analyzed, a median of 80% of cells showed positivity (range 9-100%). Using a negative/positive 50% cut-off, 81% were considered positive (pos.). The analyzed cohort displayed a median age of 60 years (33-82 years), 89% were classified as ductal carcinoma (DC) and 38% were grade 3. Concerning IHC subtyping, 43% classified as Luminal A-like, whereas 57% Luminal B-like. Around 66% of the cases evaluated for H3K27me3 expression were treated with adjuvant Tamoxifen exclusively. BC cases with H3K27me3 50-60% positivity were associated with higher cancer-related death (CI 95% 1.10-34.38, p = 0.05), although not reaching significance. Grade 3 BC significantly associated with increased risk of death (p = 0.024). An intermediate H3K27me3 expression (60-70% pos.) was observed in non-DC BC (CI 95% 1.42-13.92, p = 0.04).

Conclusions: In this preliminary retrospective cohort, H3K27m3 positivity was not found to be a pre-treatment endocrine resistance biomarker. However, statistical trends were observed between H3K27m3 expression and increased cancer-related death risk. Thus, further studies with extended cohort of patients are warranted.

137P Bioinformatic estimate of biomarker-positive populations in genomics-driven trials using precision trial designer (PTD)

L. Mazzarella[1], G. Melloni[2], A. Guida[1], G. Curigliano[1], E. Botteri[3], A. Esposito[1], M. Kamal[4], C. Le Tourneau[4], L. Riva[5], P. Pelicci[6]

[1]New Drug Development, Istituto Europeo di Oncologia, Milan, Italy, [2]Biomedical Informatics, Harvard Medical School, Boston, MA, USA, [3]Norwegian National Advisory Unit on Women's Health, Oslo University Hosp., Oslo, Norway, [4]Department of Medical Oncology, Institut Curie, Paris, France, [5]Center for Genomic Science, Italian Institute of Technology, Milan, Italy, [6]Department of Experimental Oncology, European Institute of Oncology, Milan, Italy

Background: Trials that prospectively accrue based on genetics are powerful methods to test hypotheses in precision oncology, but are often difficult to conduct due to the rarity of biomarker-positive cases. This is mitigated in umbrella trials that maximize accrual by testing many hypotheses. However, multiple treatment arms frequently generate conflicting treatment allocations due to simultaneous actionable mutations; the allocation algorithm should be planned based on relative mutation frequencies to accurately estimate sample size and dropout rates. Large sequencing projects like the TCGA could be exploited but proper tools are lacking.

Methods: We developed Precision Trial Designer (PTD), a bioinformatic tool that simulates genomically-defined cohorts by iteratively sampling patient data from mutation databases (e.g. TCGA) and provides essential parameters to plan biomarker-driven trials using survival or response-rate endpoints. To show its potential, we simulated a 10-arm imaginary trial on multiple cancers, based on the Molecular Analyses for Personalized medicine (MAP) consensus. We then validated our approach by comparing simulated and real data from the SHIVA01 clinical trial.

Results: In the MAP trial, PTD predicted $\geq$1 actionable alteration in 73% patients and 32% conflicts. To adequately power each arm, we found the optimal rule that maximizes accrual (ALK inhibitors first, AKT inhibitors last) and propose various designs. In the SHIVA01 simulation, combinatorial point mutations were correctly predicted (18.9%, 95%CI 15.7-22.1 simulated vs 15.3%, 11.8-18.7 real), whereas PTD slightly overestimated copy number alterations (36.3%, 31.6-41 simulated vs 25.6%, 21.4-29.7 real), a predictable gap due to different detection techniques. Overall, 50.8% (46.2-55.7) cases were predicted as biomarker-positive, vs 37% (32.5-41.7) real. The relative contribution of each pathway of treatment (RAS/MEK, PI3K/MTOR) was conserved (47.8%, 41.7-53.9 and 25.8%, 19.9-31.5 simulated vs 53.1%, 95%CI 48.3-57.9 and 31.6%, 27.2-36.1 real, respectively).

Conclusions: PTD predicts combinatorial mutation frequencies with acceptable approximation and overcomes pressing issues in designing precision trials.

138P Detection of microsatellite instability (MSI) in colorectal cancer samples with the automated Idylla MSI Test

G. Maertens, B. De Craene, E. Rondelez, K. Peeters, L. Vandenbroeck, L. Van Puymbroeck, G. Vandercruyssen, E. Sablon

CREATE, Biocartis, Mechelen, Belgium

Background: Detection of microsatellite instability (MSI) is recommended for all colorectal cancer (CRC) patients. Current clinical reference methods to detect MSI stain for mismatch repair proteins or analyze frequently mutated DNA repeat regions. The Idylla MSI Test is being developed using a unique set of novel biomarkers (Zhao et al. 2014; eLife) capable of faster detection with greater specificity and selectivity compared to current methods.

Methods: To assess the suitability of the novel marker set to detect MSI status in CRC, we profiled 8 or more markers in 870 CRC samples. Several clinical sites and different ethnic groups (Afro American, Caucasian, East-Asian, Hispanic and Indian) were included to assess robustness of marker selection. Repeat length was determined on FFPE DNA by PCR followed by melting curve analysis. Two-hundred and one samples were additionally screened with a reference methodology for MSI detection (Promega MSI analysis system).

Results: Hundred fifty-three samples (17.6%) were classified as MSI-H and 693 samples (79.7%) as MSS with the novel set of biomarkers, while 24 samples (2.8%) could not be classified. Concordance analysis was performed on 201 samples. The overall percent agreement with results available for both methods (173/201) was 93.6%. 11/173 (6.4%) were scored MSI-H for Idylla and MSS for the reference method; conversely no MSI-H cases for the reference method and MSS for Idylla were detected. 24/201 (11.9%) samples failed with the reference method, even after repeat testing, while only 8/201 (4.0%) samples failed with the Idylla methodology.

Conclusions: This study on a diverse set of CRC samples successfully demonstrated the validity of the novel MSI biomarkers to discriminate between MSI-H and MSS status. The Idylla MSI Test is currently under development on the most performant markers. Compatibility with the fully integrated Idylla platform will allow providing accurate and reliable results, with actionable results generated within 150 minutes from just one tumor FFPE slice (no reference sample required).

139P Gene expression BIRC5, Erb-b2/Her2-neu, ESR1, PGR1, MMP11, MDR1, MRP1, MXR at the CTCs in the primary breast cancer

Y. Shliakhtunou

Oncology, Vitebsk State Medical University, Vitebsk, Belarus

Background: Distant metastases are the main cause of death of patients with breast cancer. The substrate for the development of metastasis are the circulating tumor cells (CTCs). Determination of the expression of tumor-specific genes gives a more complete picture of the course of the tumor process.

Methods: Using PCR technology in real-time, gene expression studied BIRC5, Erb-b2/Her2-neu, ESR1, PGR1, MMP11, MDR1, MRP1, MXR at the CTCs in the surgical and adjuvant treatment of 56 cases primary non-metastatic breast cancer.

Results: In 33 (59%) prior to surgery functionally active in the CTCs-enriched peripheral blood, samples expressing the targeted range of different genes have been found. Simultaneous expression of targeted genes detected in 15 (26.8%). The highest levels of expression of the genes identified for BIRC5 1.2013 ± 0.193965 (min – 0.0017; max – 10.7083) and-Erb-b2/Her2-neu 1.6886 ± 0.0939 (min – 0.1032; max – 17.4401). Expression of ESR1, PGR1 were determined in 23 patients (42.5%). Expression family of ABC transporters detected in 14 (25%). After the operation was observed decrease in the number of CTCs and including functionally active to 13 cases (23.2%), but the CTCs data determined high levels of gene expression BIRC5, c-Erb-b2/Her2-neu, and MXR. During adjuvant, treatment with anthracyclines observed decrease in the level of gene expression BIRC5, ESR1, PGR1 at the CTCs in 7 patients. However, in 6 samples marked increase in the level of gene expression MDR1, MRP1. In the course of a taxane therapy in combination with trastuzumab in a group of patients of the 14 people there was a decrease, and the complete disappearance of the expression of a-Erb-b2/Her2-neu in 9 people, but in 5 patients there was a significant increase in the level of expression of targeted genes-Erb-b2/Her2-neu, BIRC5 and MXR. Expression of the gene in MMR11 CTCs-positive samples was determined at a high level, but significant reduction in the course of chemotherapy has not been determined.

Conclusions: The data indicate a high diagnostic, prognostic and predictive value of determining the functional activity of the CTCs on the basis of determining the dynamics of gene expression of tumor progression at the stage of planning treatment of breast cancer.

Background: Metabolic syndrome (MS) and inflammation (INF) alterations are hallmarks of cancer progression. The study aimed to firstly assess the relationship between MS and INF and its impact on progression-free/overall survival (PFS/OS) in CRPC pts.

Methods: We retrospectively evaluated CRPC pts treated with abi and enza in 7 Italian Institutes between March 2011 and October 2016. MS was defined by modified Adult Treatment Panel III criteria, and INF characterized by the presence of at least 1 of these criteria: NLR≥3, elevated VES or C-reactive protein (CRP) levels.

Results: Eighty-three of 551 pts evaluated (15%) met MS criteria at baseline, whereas for 40 (8.5%) this occurred during treatment. No significant difference of MS incidence and cardiometabolic toxicities were reported between abi or enza. Pts with MS (MS+) showed a greater INF profile compared to MS- (79% vs 28%, $p < 0.0001$). We observed NLR≥3 in 70.2% of MS+ vs 38% of MS-, $p < 0.0001$, and median values of VES and CRP higher than upper normal limit (UNL) in MS+ vs MS- (53 vs 15, $p < 0.0001$, UNL<30 and 15 vs 3.3, $p < 0.0001$, UNL<5mg/L, respectively). Median PFS and OS were associated with baseline MS and INF and their combination defined clinically high- and low-risk prognostic groups (MS+/INF+ vs MS-/INF-) (Table). Multivariate analysis confirmed that MS was independently associated with PFS (HR = 2.07, 95%1.03-4.18 p = 0.041) and OS (HR = 4.87, 95% CI 2.36-10.03, $p < 0.0001$).

Conclusions: The presence of MS is strongly associated with INF. Pre-treatment identification of MS and INF alterations may represent an available and easy to perform tool for a better prognostication of CRPC pts treated with abi or enza. A prospective evaluation is warranted.

Table: 140P Univariate analyses of progression-free survival (PFS) and overall survival (OS) according to Metabolic Syndrome (MS) and In˜ammation (INF) status

	N. events/ total atient	Median PFS (months) (95% CI)	p	HR (95% CI)	p	N. events/ total atient	Median OS (months) (95% CI)	p	HR (95% CI)	p

141P Ischemic stroke and cancer correlation: A stroke unit experience

M. Rodrigues[1], R. Costa[2], S. Brito[2], A. Pissarra[1], A. Lourenço[3], F. Grenho[3], L. Campos[3]

[1]Medical Oncology, Hospital São Francisco Xavier, Lisbon, Portugal, [2]Internal Medicine, Hospital São Francisco Xavier, Lisbon, Portugal, [3]Stroke Unit/Internal Medicine, Hospital São Francisco Xavier, Lisbon, Portugal

Background: Cancer (Cr) and ischemic stroke (IS) are common causes of death in high-income regions. Cr patients present a higher probability of developing thromboembolic events, particularly IS. Measurable objective parameters may be helpful stating a neoplastic etiology: High D-dimer (DD) levels; C-reactive protein (CRP); Neutrophil–lymphocyte ratio (NLR) and platelet-lymphocyte ratio (PLR) express the severity of inflammation relating it to etiology and prognosis. Single centre retrospective study analyses patients with IS and active solid Cr (NG) with purpose of identifying clinical, laboratorial and imagological features that differentiate this from a control group (CG) without Cr.

Methods: Patients with IS admitted in a Stroke Unit from 01/2009 to 12/2014. Active cancer identified in clinical process. Transient ischemia, haemorrhagic strokes and other diagnosis excluded. For CG an age and gender matching patient was chosen. Clinical, analytical and imagological features were compared between groups. Statistical analysis using the SPSS Statistics V22.

Results: Out of 603 consecutive patients with IS, 48 (7.9%) had active solid Cr, 16 diagnosed during diagnostic work-up for IS, 24 before and 8 in the year after. Male predominance: 30 patients (62,5%). 14: metastatic disease. Most frequent Cr diagnosed were prostate and bladder (12,5% each); colon(10%) and lung(8,3%). Cardioembolism was the main subgroup in both (26 NG; 24 CG). Imagiologic pattern was similar in both groups. NG had increased laboratorial values compared to CG: LDH 602 vs 501 U/L (p 0,04); CPR 3,2 vs 1,8 mg/dL (p 0,11) and DD 0,85 vs 0,7ug/mL (p 0,28). Average NLR and PLR: 5,4 and 161,6 NG vs 2,34 and 104,1 CG ($p < 0,01$ and 0,03 respectively). NG and CG average NIHSS was 6,3 vs 4,9 (p 0,18) and mRs was 2,75 vs 1,95 (p 0.019) respectively. Higher NLR and PLR were associated with worse outcomes (higher NIHSS and mRs score).

Conclusions: Although Cr is a rare cause of stroke, it should not be devalued. There are several clinical, laboratory and imagiological signs of underlying neoplastic disease that should be considered, since they may promote an earlier diagnosis and approach to this pathology. Future prospective studies should be started in order to validate some of this parameters as indicators of subjacent neoplastic disease.

142P longitudinal exploratory analysis of prior- surgery everolimus circulating and clinical biomarkers in locally advanced and metastatic renal cell carcinoma patients (RCC)

R. Elaidi[1], D. Helley[2], L. Mauge[2], C. Badoual[1], E. Tartour[3], E. Braychenko[4], L. Albiges[5], B. Escudier[5], S. Oudard[6]

[1]Medical Oncology - Hôpital Européen Georges Pompidou, ARTIC, Paris, France, [2]Biologic Haematology, Hopital Européen Georges Pompidou, Assistance Publique-Hôpitaux de Paris, Université Paris-Descartes, Paris, France, [3]Biologic Immunology, Hopital Européen Georges Pompidou, Assistance Publique-Hôpitaux de Paris, Université Paris-Descartes, Paris, France, [4]Medical oncology, ARTIC - Association pour la Recherche de Thérapeutiques Innovantes en Cancérologie, Paris, France, [5]Medical Oncology, Institut Gustave Roussy, Villejuif, France, [6]Immunothérapie et traitement anti-angiogénique en pathologie cancérologique, Hopital European George Pompidou, Paris, France

Background: If many drugs are available in RCC, we lack predictive biomarkers of disease recurrence or progression for personalized treatment. Circulating biomarkers (CB) are attractive candidates for disease monitoring. Longitudinal assessment of CB was performed in the NEORAD clinical trial (NCT01715935).

Methods: Locally advanced (LA) and metastatic (M) patients with clear cell or papillary RCC received 6 weeks prior-nephrectomy everolimus (Ev). CB assessed were: angiogenesis factors: VEGF-A, VEGFR-1&2, bFGF, SDF1, PlGF; CEC; CTC; HSC; immune cells: CD45, CD14+VEGFR-1/Tie2, Treg, IL-6. Clinical/histological (CH): ECOG-PS, tumor burden (TB), % necrosis, % sarcomatoid. Exploratory analysis (EA): CB and CH (prior to Ev, D22, D42, 4 weeks post-nephrectomy (+ 4 weeks if Ev resumed in M pts) in PD vs non-PD pts used Bayesian Model Averaging (BMA) and regularized Cox regression (LASSO). Three modeling strategies were compared for robustness.

Results: 25 patients were included: LA = 14, M = 11. In LA and M cohorts, respectively 2 and 9 pts exhibited progression during the 12m post-surgery follow-up period. Most important predictors upon EA (by order): tumor burden, VEGF-A, LA/M, VEGFR-2, % necrosis, IL-6, VEGFR-1, age, PlGF. Higher TB at baseline and % necrosis were associated with increased risk of 6m post-nephrectomy progression. TB, IL-6, VEGF-A, VEGFR-1&2 exhibited nonlinear relationships suggesting complex underlying pathophysiological mechanisms involved in response to Ev, and are currently explored. Reduced VEGFR-2 at D42 was associated with worse PFS in both cohorts. Upon BMA and LASSO, % necrosis and TB were among the most retrieved predictors prior to nephrectomy, whereas CD45 and CD34 + 45-146+ at 4 weeks post-nephrectomy were the best CB predictors. No significant change in monocyte populations and in Treg was observed.

Conclusions: VEGF related CB, TB and % necrosis were the best candidates to discriminate PD- vs non-PD in LA and M pts. Extensive analysis of data collected using robust non-linear models could contribute to improve our understanding of mechanisms involved and suggest predictive biomarkers to be validated.

143P A comparison of treatment recommendations by molecular tumor boards worldwide

D.T. Rieke, S. Leyvraz, S. Burock, U. Keilholz

Charité Comprehensive Cancer Center, Charité - Universitätsmedizin Berlin, Berlin, Germany

Background: Precision oncology holds promise to improve patient outcome. Yet, a benefit of personalized therapy in comparison to standard therapy has not been shown in prospective trials. We asked molecular tumor boards (MTB) worldwide to make treatment recommendations for sample patients to assess standards and differences in the precision oncology approach.

Methods: 4 fictional patients with various degrees of genomic information (mutation, gene expression, copy number and gene fusion data, somatic and germline events) were created. A questionnaire was designed to identify methods and structures of the respective molecular tumor board's recommendation process. 29 molecular tumor boards from 9 countries were identified and asked to participate in the survey between August 2016 and March 2017. A qualitative interpretation of the results was performed.

Results: 5 MTBs from 4 countries completed the questionnaire and provided therapy recommendations. An identical treatment recommendation by all 5 MTB was not made for any one of the patients. In only one patient an overlapping treatment recommendation was made by three MTBs. Heterogeneity was larger for patients with more complex genomic information. The availability of clinical trials did not influence the recommendation heterogeneity. The setup of MTBs showed similarities in participating specialties (e.g. medical oncology, pathology, molecular biology), duration of discussion, testing methods and number of discussed patients. Differences were seen in the interpretation process. Further differences were identified in the interpretation of germline aberrations and interpretation of variant allele frequency. Comments by MTBs helped to identify minimum reporting standards for genetic testing.

Conclusions: Several differences in treatment recommendations were observed. In cases with obvious recommendations there was higher concordance among assessments. However, differences in treatment recommendations were observed in complex cases, and such heterogeneity contributes to the complexity of precision oncology. Larger studies are necessary for rational and stepwise development of principles and practice of MTB procedures.

144P Identification of germline mutation using 30-gene sequencing and clinical characteristic of Chinese with hereditary breast cancer

A. Kwong[1], V. Shin[1], C-H. Au[2], T-L. Chan[2], E. Ma[2]

[1]Surgery, The University of Hong Kong, Pokfulam, Hong Kong, China, [2]Molecular Pathology, Hong Kong Sanatorium & Hospital, Happy Valley, Hong Kong, China

Background: With the recent discovery of other breast cancer susceptibility genes (e.g. *CDH1*, *ATM*, *CHEK2*, *PALB2*, *RAD50)*, molecular diagnosis of hereditary breast and ovarian cancers (HBOC) using multigene panels could help to identify other moderate/low penetrance genes in patients who tested negative for *BRCA* mutation. However, the clinical management of these cancer predisposition genes have not been clearly defined, therefore only *BRCA1* and *BRCA2* are routinely included in the genetic screening. In view of the differences in the mutation spectrum across ethnicity, it is important to identify other HBOC genes to estimate the associated breast cancer risk in Chinese.

Methods: High-risk breast cancer patients who were negative for *BRCA1*, *BRCA2*, *TP53* and *PTEN* were selected from the Hong Kong Hereditary Breast Cancer Family

Registry between 2007-2016. In the study, 745 patients were subjected to 30-gene panel by next-generation sequencing (Color Genomics). All detected pathogenic mutations were further validated by bi-directional DNA sequencing. The sequencing data was co-analyzed by our in-house developed bioinformatics pipeline.

Results: Thirty-five pathogenic variants were identified in this series (4.7%), which correspond to 11 different cancer predisposition genes. Majority of the carriers (74.29%) had early-onset of breast cancer (age <45), 42.86% had ³ 2 family members with cancer and 17.14% were triple-negative. The most common mutated genes were *PALB2* (1.21%), *RAD51D* (0.94%) and *ATM* (0.67%). However, the cancer risk of *RAD51D* in breast cancer warrants further investigation. Moreover, over 28% of patients had a variant of unknown significance (VUS) in these genes (excluding *BRCA1, BRCA2, TP53* and *PTEN*), which account for 183 types of VUS. Data from large-cohort studies and international consortiums will help to define the pathogenicity and clinical interpretation/management of the variants.

Conclusions: Our findings suggested that detection of *PALB2* should be included in the genetic test panel in Chinese with breast cancer. Multigene panel testing is an efficient tool in the diagnosis of HBOC, this could help patients to understand the cancer risk and aid the development of effective treatments.

145P Selecting patients with metastatic colorectal cancer for treatment with temozolomide using proteomic analysis of MGMT

S. Schwartz[1], F. Cecchi[1], Y. Tian[1], K. Scott[1], M. Di Bartolomeo[2], F. Morano[2], G. Fucà[2], A. Martinetti[2], F. De Braud[2], F. Dominoni[2], M. MILIONE[2], M.A. Calegari[3], A. Orlandi[3], C. Barone[4], F. Pietrantonio[2], T. Hembrough[1]

[1]R&D, NantOmics, LLC, Rockville, MD, USA, [2]Department of Medical Oncology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [3]Department of Medical Oncology, Policlinico Universitario A. Gemelli, Rome, Italy, [4]Department of Medical Oncology, Università Cattolica del Sacro Cuore, Milan, Italy

Background: Temozolomide (TMZ) is a standard treatment for melanoma and glioblastoma and it has shown limited but encouraging activity in patients with metastatic colorectal cancer (mCRC). In multiple cancer types, the DNA repair protein O^6-methylguanine-DNA methyltransferase (MGMT) is a resistance marker for TMZ; MGMT promoter methylation is associated with loss of MGMT expression and response to TMZ. We hypothesized that mCRC patients whose tumors expressed quantities of MGMT protein below a pre-defined cutoff would have better outcomes on TMZ than patients with MGMT expression above the cutoff. To test our hypothesis, we assessed MGMT by mass spectrometry in the tumor samples of patients with refractory mCRC and MGMT promoter methylation receiving TMZ.

Methods: Archived formalin-fixed, paraffin-embedded tissue sections were obtained from 24 patients from two phase 2 trials. A pathologist marked the tumor areas, which were microdissected and solubilized. In each tumor sample, multiple protein biomarkers including MGMT were quantified with selected reaction monitoring mass spectrometry. An MGMT cutoff of 200 amol/ug was based on the limit of quantitation from a concentration curve. The Mantel-Cox log-rank and the Fisher's exact tests were used for survival comparisons.

Results: MGMT protein was detected in 13 of 24 (54.2%) colorectal tumor samples (range: 229.3-784.8 amol/μg). The overall response rate was 29%. Patients with MGMT protein levels below a cutoff of 200 amol/ug (n = 11) had a notably higher response rate than patients with MGMT levels above the cutoff (64% vs. 0%; p = 0.001 Fisher's test). Also a longer progression-free survival was observed (4.3 vs. 1.6 months, HR = 0.36, 95% CI = 0.13-1.10, p = 0.054). Results for overall survival were consistent but not statistically significant (8.9 vs 6.9 months, HR = 0.55, p = 0.221).

Conclusions: Patients with mCRC whose tumors expressed low or undetectable levels of MGMT protein had better outcomes following TMZ treatment than their counterparts. Quantitative proteomic analysis of MGMT could potentially be used to select CRC patients for TMZ treatment. The results of validation studies are forthcoming.

146P Predicting response to chemotherapy in gastric cancer patients randomized to docetaxel: A reevaluation of the ITACA-S trial

F. Cecchi[1], D. Catenacci[2], S. Schwartz[1], S. Sellappan[1], Y. Tian[1], R. Miceli[3], F. Pietrantonio[3], A. Pellegrinelli[4], A. Martinetti[3], M. Di Bartolomeo[3], T. Hembrough[1]

[1]R&D, NantOmics, LLC, Rockville, MD, USA, [2]Department of Medical Statistics, Biometry, and Bioinformatics, University of Chicago Medicine, Chicago, IL, USA, [3]Department of Medical Oncology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [4]Pathology and Laboratory Medicine, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy

Background: No predictive biomarker for chemotherapy has been validated for clinical use. Clinical studies suggest tumor expression of the proteins class III β-tubulin (TUBB3) and thymidine phosphorylase (TYMP) predict resistance to taxane and response to 5-FU, respectively. Immunohistochemical definitions of protein status vary widely. We evaluated relationships between survival and expression of TUBB3 and TYMP as quantitated by mass spectrometry in the archived tumor samples of 247 patients from the Intergroup Trial of Adenocarcinoma of the Stomach (ITACA-S). Patients had been randomized to monotherapy with 5-FU/LV or to FOLFIRI plus docetaxel and cisplatin.

Methods: Gastric tumor tissues were microdissected and solubilized for proteomic quantitation of 45 protein biomarkers. The cutoff for TUBB3 (750 amol/μg of total protein) was predetermined based on the assay's limit of detection. An experimental cutoff for TYMP (1335 amol/ug) was derived in the 5-FU/LV-treated patients using Monte Carlo 2-fold cross-validation. The Mantel-Cox log-rank test was used for survival comparisons.

Results: Among gastric cancer (GC) patients treated with docetaxel-containing chemotherapy (n = 125), those with TUBB3 protein levels below the cutoff had a longer median overall survival (mOS) than patients with TUBB3 levels above the cutoff (1563 vs 886 days, p < 0.04). TUBB3 level made no difference in survival among patients who received 5-FU/LV (p = 0.64). Of note, among patients with high TUBB3 levels, those treated with 5-FU/LV survived 3 years longer than patients treated with docetaxel (mOS = 1991 vs 886 days, p = 0.048). 5-FU/LV-treated patients (n = 122) with TYMP protein expression above the cutoff survived longer than those with lower TYMP levels (mOS: 2362 vs 1062 days, p < 0.02). A combination of TUBB3 and TYMP expression predicted the longest survival in patients treated with FOLFIRI plus docetaxel (p < 0.001).

Conclusions: Quantitative proteomic analysis identified subsets of trial patients who benefitted from specific adjuvant chemotherapy regimens. Personalized chemotherapy based on quantitated TYMP and TUBB3 is promising and warrants broader evaluation.

Background: We have conducted the Nationwide Cancer Genome Screening Project in Japan since April 2015 using Next Generation Sequencing in cancers of digestive system, called as the SCRUM-Japan GI-SCREEN. In this presentation, we show the result of advanced pancreatic cancer (aPC).

Methods: This study is ongoing with the participation of 20 major cancer centers. Patients who plan to or receive systemic chemotherapy were eligible. DNA and RNA were extracted from FFPE tumor samples and were analyzed by the Oncomine Cancer Research Panel (OCP) which allows to detect gene mutation, copy number variant (CNV) and fusions across 143 genes in a CLIA certified CAP accredited laboratory. The detected genomic variant data were classified according to genetic drivers of cancer including gain- and loss-of-function or single nucleotide variant based on the Oncomine Knowledgebase. In this presentation, we show the results of aPC cohort.

Results: As of 31st October 2016, a total of 179 aPC samples were analyzed. The sequence with the OCP was successfully performed in 120 (67.0%). Out of 120 patients, the proportion of location of tumor and histology type is follows; Ph = 44%, adenocarcinoma 97%. The proportion of procedure for sample collection is follows; surgical resection 35.0%, needle biopsy 38.3%, EUS-FNA 20.0%, other 5.8%, and unknown 0.8%.The frequently detected mutations (> 10%) in 120 samples of which results were available were KRAS (93%), TP53 (63%), CDKN2A (12%), and SMAD4 (11%). Other

important/druggable mutations were GNAS, BRCA2, and ATM (3%, each). Most frequently detected CNVs (≥ 7copies) was MYC (3%), and no gene fusion was detected.

Conclusions: This nationwide screening system is efficient to detect rare gene alterations in aPC. Alterations in potentially druggable genes were limited in aPC, but homologous recombination repair genes were attractive target. This novel knowledge provides an intriguing background to investigate new target approaches and represents a progress toward more precision medicine.

Background: F is a selective estrogen receptor degrader for HR+ advanced breast cancer patients (pts). We designed this trial to compare A vs. A in combination with F (A+F) to address the hypothesis that a complete estrogen blockade can prevent resistance to aromatase inhibitors in the adjuvant setting.

Methods: This was a multicenter, open label, phase III study in which HR+/HER2- EBC postmenopausal pts were randomized 1:1 to A for 5 years (y) or A+F (A concurrently with F 250mg/4 weeks for 3y followed by 2y of A). Pts were stratified for prior chemotherapy (yes/no); number of positive lymph-nodes (0/1-3/≥4); HR status (both positive/one positive) and site. Primary objective was disease-free survival (DFS). To detect an absolute 5-y DFS increase of 3% (90% A, 93% A+F) a sample size of 2716 evaluable patients was required. On 2010, when the negative results of the FACT trial were made available, the financer decided to stop the study support after the inclusion of 872 pts.

Results: From January 2008 to June 2010, 437 pts were randomized to A and 435 to A+F. Pts characteristics were well balanced between arms; median age was 62 y (40-86), 46.9% were N0, 89.5% ER+/PgR+ and 68.2% had received prior chemotherapy. Treatment was completed as planned by 72.5% and 48.5% of A and A+F pts. Median relative dose intensity was 99% for A (both arms) and 81% for F. Most relevant G2-3 toxicities (>5% in either arm) with A vs. A+F were hypertension (13.2%; 9.9%), fatigue (5.2%; 11.8%), LDL-Cholesterol increase (9.4%; 5.3%), osteoporosis (5.5%; 6.9%) and musculoskeletal bone/joint pain (26.3%; 29.4%). After a median follow-up of 6.3y, the proportion of pts disease free at 5y was 90.99% (A 90.77%, A+F 91.25%, D = 0.48%, p = 0.357); 9.4% had BC relapse (A 10.5%; A+F 8.3%, D = 2.2%) and 4.3% had secondary tumors (A 3.9%; A+F 4.6%). Survival and breast cancer-specific survival were not reached.

Conclusions: The GEICAM/2006-10 study failed to demonstrate a statistically significant increase in DFS adding F to A as adjuvant therapy, though no formal conclusion can be extracted from this trial due to the F administered dose and the actual trial sample size.

Background: In the Herceptin Adjuvant (HERA) trial, 24% of patients (pts) who received T for 1 year (y) had a disease recurrence at 11 y follow-up. The primary analysis of the ExteNET trial, performed after 2 y follow-up, showed that a 1-y course of neratinib after T-based adjuvant therapy significantly improved invasive disease-free survival (iDFS) *vs* placebo in early-stage HER2+ BC (HR 0.67; 95% CI 0.50–0.91; p = 0.0091) [Chan et al. *Lancet Oncol* 2016]. We now report updated 5-y efficacy findings.

Methods: ExteNET is an international, multicenter, randomized, double-blind, placebo-controlled phase III trial. Pts received oral neratinib 240 mg/d or placebo for 1 y. After 2 y, randomized pts were asked to re-consent to collection of data concerning disease recurrences and survival from medical records for a further 3 y. The preplanned 5-y analysis was by intention-to-treat (ITT). Non-consenting pts were censored at their last physical examination. Primary endpoint: iDFS. HR (95% CI) were estimated using Cox proportional-hazards models. Data cut-off: March 2017. Clinicaltrials.gov: NCT00878709.

Results: ITT population comprised 2840 pts (neratinib, n = 1420; placebo, n = 1420); 53 pts died during the initial 2-y follow-up. Among 2787 available pts, 2117 (76%) re-consented to additional follow-up (neratinib, n = 1028; placebo, n = 1089). Updated results after a median follow-up of 5.2 y are shown below. Secondary efficacy endpoints were supportive of the primary analysis.

Table: 1490

	n	Estimated 5-y iDFS rate, % Neratinib	Placebo	HR (95% CI)	P value
ITT	2840	90.2	87.7	0.73 (0.57–0.92)[a]	0.008
Centrally confirmed HER2+	1796	90.4	88.2	0.74 (0.55–1.00)	0.047
HR +[b]	1631	91.2	86.8	0.60 (0.43–0.83)	0.002
HR–[b]	1209	88.8	88.9	0.95 (0.66–1.35)	0.762
Completed T ≤ 1 y of randomization	2297	89.7	86.5	0.70 (0.54–0.90)	0.006

HR, hormone receptor; [a]Stratified analysis; [b]Stratification factor.

Conclusions: 1 y of neratinib after T-based adjuvant therapy significantly improves iDFS at 5 y in pts with early-stage HER2+ BC, with a long-term sustained effect. A protocol-specified subgroup analysis suggested greater benefit in HR+ pts. Overall survival data are not yet mature.

151PD Efficacy and safety of biosimilar ABP 980 compared with trastuzumab in HER2 positive early breast cancer

G. von Minckwitz[1], O. Ponomarova[2], S. Morales[3], N. Zhang[4], V. Hanes[4]

[1]Medicine and Research, German Breast Group (GBG) Forschungs GmbH, Neu-Isenburg, Germany, [2]Experimental Pathology, R.E. Kavetsky Institute of Experimental Pathology, Kiev, Ukraine, [3]Medicine, Hospital Universitario Arnau de Vilanova, Lleida, Spain, [4]Biosimilars, Amgen, Thousand Oaks, CA, USA

Background: Analytical, functional, and pharmacokinetic similarity between ABP 980 and trastuzumab (TRAS) has been demonstrated. Here we report the results of primary efficacy analysis in the corresponding clinical study.

Methods: The objective of this randomized, multicenter, double-blind study was to compare ABP 980 with TRAS on pathologic complete response (pCR) in women with HER2 positive early breast cancer. After run-in anthracycline-based chemotherapy, patients were randomized 1:1 to intravenous ABP 980 or TRAS plus paclitaxel Q3W for 4 cycles. Patients had to complete a full cycle of run-in therapy to be eligible for randomization. Patients continued to the adjuvant phase on IP Q3W for up to 1 year. The co-primary endpoints were risk difference (RD) and risk ratio (RR) of pCR in breast tissue and axillary lymph nodes of tumor samples. Clinical similarity was confirmed if the 2-sided 90% CIs for RD and RR were within the bioequivalence margin of -13% to 13% for RD and 0.759 to 1.318 for RR. Secondary endpoints included safety.

Results: Of the 827 enrolled patients, 725 were randomized (ABP 980: n = 364; TRAS: n = 361); 696 (ABP 980: n = 358; TRAS: n = 338) were included in the pCR evaluable population. Based on local review, 48.0% and 40.5% of patients in the ABP 980 arm and TRAS arm, respectively, achieved pCR. RD and RR of pCR were 7.3% (90% CI: 1.2%, 13.4%) and 1.19 (90% CI: 1.033, 1.366), with the upper bound CI slightly exceeding the equivalence margin. Based on central independent review, 47.8% and 41.8% in the ABP 980 arm and TRAS arm achieved pCR. RD and RR of pCR were 5.8% (90% CI: -0.5, 12.0%) and 1.14 (90% CI: 0.993, 1.312), contained within the equivalence margin. 292 (80.2%) and 287 (79.5%) in the ABP 980 and TRAS arm, respectively, had ≥1 adverse event (AE); 54 (14.8%) patients in the ABP 980 arm and 51 (14.1%) in the TRAS arm had a Grade ≥3 AE. Most common AEs (ABP 980 vs TRAS) were arthralgia (17.3% vs 15.2%), asthenia (14.8% vs 16.3%), neutropenia (14.6% vs 12.5%), peripheral neuropathy (13.7% vs 11.9%), and anemia (11.0% vs 10.2%).

Conclusions: Results of this study show clinical equivalence of ABP 980 and TRAS in the neoadjuvant setting and add to the totality of evidence demonstrating similarity between ABP 980 and TRAS.

Background: CT-P6 is a proposed biosimilar to Reference Trastuzumab (RTZ). This trial (2013-004525-84) evaluated the similarity of CT-P6 and RTZ in efficacy and safety for HER2+ EBC.

Methods: 549 patients with HER2+ EBC were randomized to receive CT-P6 (n = 271) or RTZ (n = 278) in combination with docetaxel (Cycles 1-4) and 5-fluorouracil, epirubicin and cyclophosphamide (Cycles 5-8). CT-P6 or RTZ was administered at 8 mg/kg (Cycle 1 only) followed by 6 mg/kg every 3 weeks. After surgery, patients received CT-P6 or RTZ monotherapy up to 10 cycles. The primary endpoint was pathological complete response (pCR) rate at surgery. Secondary endpoints were overall response rate (ORR), PK, PD and safety.

Results: The pCR rate was 46.8% in CT-P6 and 50.4% in RTZ. The 95% CIs for the estimate of treatment difference were within the equivalence margin (±0.15) in both PPS and ITT. The proportion of patients with at least 1 SAE was 7.4% in CT-P6 and 11.9% in RTZ over 1-year treatment. 6 patients (3 in CT-P6 and 3 in RTZ) withdrew treatment due to significant LVEF decrease. Infusion related reaction was reported for 11.4% of patients in CT-P6 and 10.4% of patients in RTZ.

Table: 152PD Summary of efficacy endpoints

	PPS		ITT	
	CT-P6 n = 248	RTZ n = 256	CT-P6 n = 271	RTZ n = 278
pCR (ypT0/is ypN0)				
pCR rate	46.8	50.4	43.5	47.1
(95% CI)	(40.4 – 53.2)	(44.1 – 56.7)	(37.6 – 49.7)	(41.1 – 53.2)
Difference estimate	−0.0362		−0.0358	
(95% CI)	(−0.1238 – 0.0516)		(−0.1198 – 0.0480)	
pCR (ypT0 ypN0)				
pCR rate	39.9	41.4	37.3	38.8
(95% CI)	(33.8 – 46.3)	(35.3 – 47.7)	(31.5 – 43.3)	(33.1 – 44.9)
Difference estimate	−0.0149		−0.0158	
(95% CI)	(−0.1022 – 0.0731)		(−0.0996 – 0.0685)	
ORR (independent review)				
ORR	88.3	89.5	86.3	87.1
(95% CI)	(83.6 – 92.0)	(85.0 – 92.9)	(81.7 – 90.2)	(82.5 – 90.8)
Difference estimate	−0.0115		−0.0070	
(95% CI)	(−0.0990 – 0.0764)		(−0.0911 – 0.0769)	

Conclusions: This study demonstrated the equivalence of efficacy between CT-P6 and Reference Trastuzumab in EBC patients. Secondary efficacy endpoints also supported the similarity for two study drugs. CT-P6 was well tolerated with a similar safety profile to that of Reference Trastuzumab through the neoadjuvant and adjuvant period.

Background: Equivalence for efficacy between SB3 (a proposed trastuzumab biosimilar) and originator trastuzumab (TRZ) in terms of breast pathologic complete response (bpCR) rates has been demonstrated and previously reported.[1] Here we present the one-year results on safety, immunogenicity, event-free-survival (EFS), and overall survival (OS).

Methods: Study compared neoadjuvant SB3 or TRZ for 8 cycles concurrently with chemotherapy (4 cycles of docetaxel followed by 4 cycles of 5-fluorouracil/epirubicin/cyclophosphamide). Patients then underwent surgery followed by 10 cycles of adjuvant SB3 or TRZ as randomised. The primary endpoint was bpCR rate and secondary endpoints included safety, immunogenicity, EFS, and OS up to the adjuvant period.

Results: A total of 875 patients were randomised with a median follow-up duration of 438 days, and 765 patients completed adjuvant therapy (SB3, N = 381; TRZ, N = 384). Incidences of treatment emergent adverse events (TEAEs) were comparable between arms (Table). Most frequently occurring TEAEs were alopecia, neutropenia, and nausea during the neoadjuvant period and radiation skin injury, procedural pain, and fatigue during the adjuvant period. EFS rates were 92.2% in SB3 and 91.6% in TRZ (hazard ratio 0.94; 95% CI, 0.59 to 1.51). There were a total of 6 deaths (SB3, N = 1; TRZ, N = 5). Immunogenicity was low and comparable, with anti-drug antibody positive for 3 patients (0.7%), in each arm.

Table: 153PD Safety profile

	SB3 N = 437 n, (%)	TRZ N = 438 n, (%)
Incidence of TEAEs	426 (97.5)	421 (96.1)
Grade ≥ 3 TEAEs	325 (74.3)	315 (71.9)
TEAEs of special interest*	48 (11.0)	53 (12.1)
Serious TEAEs	56 (12.8)	58 (13.2)
Death	1 (0.2)	5 (1.1)

*Includes infusion-related reaction, left ventricular systolic dysfunction, and congestive heart failure.

Conclusions: One-year safety, immunogenicity, and survival results further support the biosimilarity established between SB3 and TRZ. Reference: 1. Pivot X et al. ASCO 2017, ID509.

154PD A randomized, double-blind study of PF-05280014 (a potential biosimilar) vs trastuzumab, both given with docetaxel (D) and carboplatin (C), as neoadjuvant treatment for operable human epidermal growth factor receptor 2-positive (HER2+) breast cancer

P.E. Lammers[1], M. Dank[2], R. Masetti[3], R. Abbas[4], F. Hilton[5], J. Coiro[6], I. Jacobs[7]

[1]Division of Hematology/Oncology, Department of Internal Medicine, Meharry Medical College, Nashville, TN, USA, [2]Cancer Center, Semmelweis University, Budapest, Hungary, [3]Multidisciplinary Breast Center, Catholic University of Rome, Rome, Italy, [4]Clinical Pharmacology, Pfizer Inc, Collegeville, PA, USA, [5]Pfizer Essential Health Clinical Statistics, Pfizer Inc, Groton, CT, USA, [6]Global Biosimilars Medical Affairs, Pfizer Inc, New York, NY, USA, [7]Oncology Biosimilars, Pfizer Inc, New York, NY, USA

Background: This comparative clinical trial evaluated efficacy, safety, immunogenicity and pharmacokinetics (PK) of PF-05280014, a potential trastuzumab biosimilar, vs trastuzumab sourced from the EU (trastuzumab-EU), both given with D and C, as neoadjuvant treatment for operable HER2+ breast cancer.

Methods: Patients (pts; N = 226) were stratified by primary tumor size and hormone receptor status and randomized 1:1 to receive PF-05280014 or trastuzumab-EU (8 mg/kg at Cycle 1; 6 mg/kg thereafter), both with D (75 mg/m^2) and C (target AUC 6), every 3 wks for 6 treatment cycles. The study was powered to test whether PF-05280014 was noninferior to trastuzumab-EU in the percentage of pts with Cycle 5 C_{trough} (pre-dose Cycle 6) >20 µg/mL. Efficacy was measured by the percentage of pts with pathological complete response (pCR), defined as the absence of invasive neoplastic cells in breast and lymph nodes after neoadjuvant therapy, and objective response rate (ORR). Safety and immunogenicity were also assessed.

Results: The percentage of pts with Cycle 5 C_{trough} >20 µg/mL was 92.1% for PF-05280014 and 93.3% for trastuzumab-EU; the lower limit of the 95% CI (-8.02% to 6.49%) for the stratified difference between groups was above the noninferiority margin (-12.5%). The pCR rate was 47.0% (95% CI: 36.9-57.2) for PF-05280014 and 50.0% (95% CI: 39.0-61.0) for trastuzumab-EU. Central radiology review-assessed ORR was 88.1% (95% CI: 80.2-93.7) for PF-05280014 and 82.0% (95% CI: 72.5-89.4) for trastuzumab-EU. All causality, grade 3-4 treatment-emergent adverse events were reported by 38.1% (PF-05280014) vs 45.5% (trastuzumab-EU) of pts. No pts in the PF-05280014 and 1 (0.89%) in the trastuzumab-EU group had positive anti-drug antibody titer.

Conclusions: PF-05280014 demonstrated similarity in efficacy, safety and immunogenicity, and noninferiority in PK to trastuzumab-EU. A separate comparative safety and efficacy study (NCT01989676) is evaluating PF-05280014 vs trastuzumab-EU, both given with paclitaxel, as first-line treatment for HER2+ metastatic breast cancer.

Background: Increased number of TILs at baseline is associated with pathological complete response (pCR) and improved outcomes in HER2+ early breast cancer (BC) treated with anti-HER2-based chemotherapy. The associations in the neoadjuvant setting in the absence of chemotherapy and the effect of on-treatment TILs changes on pCR in the breast (pCR_B) are unknown.

Methods: PAMELA is a prospective study in HER2+ BC designed to evaluate the ability of the PAM50 intrinsic subtypes (IS) to predict pCR_B following neoadjuvant lapatinib and trastuzumab (with hormonal therapy if hormone receptor-positive[HR+]). Levels of TILs as continuous and categorical (TILs-low = <50%, TILs-high = >50%) variables and their changes were correlated with pCR_B.

Results: TILs evaluation was available for 148 baseline (BS) and 134 Day-15 (D15) samples of 151 recruited patients. At BS, the median (interquartile range) levels of TILs were 10% (5-20). Median TILs distribution according to IS was: HER2-E (10%), Luminal (Lum) A (7.5%), LumB (5%), Basal-like (5%) ($p = 0.02$). Levels of TILs were higher in HR- (10%, 1-20) vs HR + (5%, 1-20) tumors, although not statistically significant ($p = 0.07$). pCR_B rates were 58.3% (7/12) for TILs-high and 27.2% (37/136) for TILs-low ($p = 0.03$). At baseline, TILs were significantly associated with pCR in univariate analysis. At D15, median levels of TILs were 15% (5-30) with an increase across all the different IS ($p < 0.01$). The distribution across IS at D15 was: HER2-E (20%), Lum A (10%), Lum B (7.5%), Basal-like (20%) and Normal-Like (10%) ($p = 0.37$). At D15, TILs-high tumors showed a pCR_B rate of 65% (13/20) vs 21.1% (24/114) of TILs-low ($p < 0.01$). As a continuous variable, higher TILs levels at D15 and changes of TILs levels from BS to D15 were associated with higher pCR_B rates independently of HR status and IS ($p < 0.01$). When analysis was performed for HR-negative and HR-positive patients, separately in both cohorts, TILs at D15 was significantly associated with pCR.

Conclusions: The presence of TILs at D15 is an independent predictive marker of pCR_B in HER2+ early BC treated with neoadjuvant anti-HER2 agents without chemotherapy.

156PD Targeted NGS profiling identifies genomic alterations associated with high-risk eBC

T.R. Wilson[1], A.R. Udyavar[2], C-W. Chang[3], J. Giltnane[4], J.M. Spoerke[1], J. Aimi[1], H. Savage[1], A. Daemen[2], R. Bourgon[2], M.R. Lackner[1]

[1]Oncology Biomarker Development, Genentech Inc. - Roche - USA, South San Francisco, CA, USA, [2]Bioinformatics and Computational Biology, Genentech Inc. - Roche - USA, South San Francisco, CA, USA, [3]Biostatistics, Genentech Inc. - Roche - USA, South San Francisco, CA, USA, [4]Research Pathology, Genentech Inc. - Roche - USA, South San Francisco, CA, USA

Background: Identifying early breast cancer (eBC) patients that require adjuvant chemotherapy is defined by clinical features, which do not accurately identify high-risk patients. The USO01062 Phase 3 study enrolled 2,611 high-risk patients based on clinical features, with a 13% event rate observed. Comparing the genomic landscape of tumors between patients who had a recurrence event and those who did not may uncover genomic aberrations associated with recurrence that may be used to identify high-risk patients. The genomic landscape of TNBC subtypes is also largely unknown and NGS profiling may shed light on novel therapeutic opportunities.

Methods: The USO01062 study failed to show a benefit for the addition of capecitabine to adjuvant chemotherapy (O'Shaughnessy J. *et al.* 2015). Arms were pooled and DNA and RNA were extracted from 1,181 tumor samples, of which 145 patients had a DFS event, and were matched demographically to a set of 146 patients without an event for targeted NGS profiling using FoundationOne®. Gene expression was previously run using a breast cancer specific 800-gene panel (Wilson T.R. *et al.* 2016).

Results: Analysis of somatic alterations within IHC subtypes identified unique prognostic factors, e.g. alterations in *ATM*, *ERCC4* and *IGF2R* correlated with a worse HR in HR+ disease, whereas alterations in *MAP3K1*, *RPTOR* and *LYN* correlated with a worse HR in TNBC. Analysis of tumor mutational burden (TMB) revealed TNBC tumors had the highest burden, which did not correlate with clinical outcome or expression of *PDL1* and *CD8* genes. Molecular subtyping of TNBC (Lehmann B.D. *et al.* 2011) found distinct genetic drivers in each subtype, e.g. alterations in *TP53* and *MYC* were the most frequent in BL1 and BL2 tumors. IM tumors expressed alterations in *TP53*, *CREBBP* and *BRCA1*. LAR tumors expressed alterations in *PIK3CA* and *PTEN*.

Conclusions: TMB was not prognostic and did not correlate with *PDL1* or *CD8* gene expression, suggesting that TMB in TNBC may not be a surrogate for the immune activated subtype. TNBC molecular subtyping identified different genomic drivers providing evidence for genomic heterogeneity within subtypes. Lastly, comparison of patients that experienced a DFS event identified genomic alterations that may be used to identify high-risk patients.

Clinical trial identification: Patients were enrolled onto the parent study USO01062, (NCT00089479).

157PD 10 years follow up of the RASTER study; implementing a genomic signature in daily practice

S.B. Vliek[1], V. Retel[2], C. Drukker[3], E. Rutgers[3], H. van Tinteren[4], M.J. van de Vijver[5], J.M. Bueno-De-Mesquita[1], J. Wesseling[6], W. van Harten[2], S.C. Linn[7]

[1]Molecular Pathology, The Netherlands Cancer Institute, Amsterdam, Netherlands, [2]Health Technology Assessment, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, [3]Surgical Oncology, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, [4]Biometrics, The Netherlands Cancer Institute, Amsterdam, Netherlands, [5]Pathology, Academic Medical Center, Amsterdam, Netherlands, [6]Pathology, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, [7]Medical Oncology, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands

Background: In 2004 the 70-gene signature, MammaPrint® (MP), developed to predict High or Low Risk of distant breast cancer (BC) recurrence, was introduced in the observational RASTER trial. Patients (cT1–3N0M0) and their doctors took the clinical Dutch guideline and MP in to account to decide on adjuvant systemic treatment (AST). Five years follow-up data confirmed the prognostic value of the MP (Drukker, Int J Cancer, 2013). In this analysis we report the outcome at 10 years.

Methods: Ten year survival data was available for all 427 Raster patients, age < 61. For the current analysis, clinical high (C-high) or low (C-low) risk was scored according to the modified version of Adjuvant! Online (Cardoso, N Engl J Med, 2016). 10-year distant-recurrence-free-interval (DRFI) probabilities were compared between risk groups based on the 70-gene signature and clinical assessment.

Results: The 70-gene signature identified 51.4% (219/427) patients with a genomic Low Risk of BC recurrence (G-low). 10-year DRFI in patients with G-low or genomic High Risk (G-high) was 93.7% and 86.8% respectively (HR 1.4; 95% confidence interval{CI] 1.0-1.9). Clinical assessment identified 57% as C-low. The 10-year DRFI was 91.7% in C-low and 88.2% in C-high (HR 1.4; 95%CI 0.8-2.6). The 10-year DRFI in the combined genomic and clinical riskgroups was 94.4% in patients with a C-low/G-Low profile, only 11.6% of them received AST. In the C-low/G-High group 10-years DRFI was 88.5%, over 90% of them received AST. For C-high risk patients 10-year DRFI was 90.9% if G-Low (n = 46) and 87.3% if G-High (n = 137). In ER-positive BC (ER+) (N = 342) 10-years DRFI was 93.6% (G-Low) versus 88.8% (G-High) (HR 1.6; 95%CI 0.8-3.3). With clinical risk assessment, 10-years DRFI in ER+ was 91.6% (C-low) versus 91.9% (C-high).

Conclusions: Patients who omitted chemotherapy based on MammaPrint Low Risk had an excellent 10 year DRFI, confirming the prognostic value of the MP. When C-high, the MP identified another 10.8% (46/426) of patients as G-Low who might forego adjuvant chemotherapy if ER+. In contrast to genomic risk stratification, the clinical risk assessment was unable to differentiate for survival between ER+ C-high and C-low risk patients.

Background: In premenopausal pts with HER2+ EBC, the prognostic effect of TIA is unknown and the gonadotoxicity of trastuzumab (T) and lapatinib (L) remains largely uncertain. We aimed to assess the prognostic effect of TIA and the impact of T and/or L on the risk of developing TIA in premenopausal pts with HER2+ EBC.

Methods: ALTTO was an international, open-label, randomised phase 3 trial in pts with HER2+ EBC. Pts were randomised in 4 adjuvant anti-HER2 arms: T alone, L alone, a sequence of the 2 agents (T->L) and their combination (T+L). As per study protocol, menopausal status was collected in all pts at randomisation and at week 37. By selecting only premenopausal pts at randomisation, we investigated whether TIA in pts with hormone receptor-positive (HR+) and negative (HR-) EBC would impact on disease-free (DFS) and overall survival (OS), and the risk factors for developing TIA. Landmark and time-dependent modeling were used to account for guaranteed time bias.

Results: Out of 8381 pts randomised in ALTTO, 2862 were included in this analysis. Median age was 43 years (range 38-47); 1679 (59%) pts had HR+ EBC. Pts with HR+/HER2+ EBC who experienced TIA had significant better DFS (hazard ratio [HR] 0.64; 95% confidence intervals [CI] 0.52-0.79) and OS (HR 0.53; 95% CI 0.38-0.74) than those who did not have TIA. By contrast, pts with HR-/HER2+ EBC had similar DFS (HR 0.85; 95% CI 0.68-1.07) and OS (HR 0.89; 95% CI 0.64-1.25) regardless of whether they had TIA (interaction P for DFS=0.009 and for OS = 0.002). A similar TIA rate was observed in the T (72.6%), L (74.0%), T->L (72.1%) and 74.8% (T+L) arms ($p = 0.644$). Older age ($p < 0.001$), addition of taxanes to anthracycline-based chemotherapy ($p < 0.001$), and use of adjuvant endocrine therapy ($p < 0.001$) significantly increased the risk of TIA.

Conclusions: In premenopausal pts with HR+/HER2+ EBC, TIA was associated with significant survival benefits. Anti-HER2 agents did not impact the likelihood of developing TIA. These data are of great importance in oncofertility counseling and support the use of ovarian suppression as part of adjuvant endocrine therapy in premenopausal HR+/HER2+ EBC pts.

Clinical trial identification: The trial is registered with the clinicaltrial.gov identifier, number NCT00490139.

Background: Exploration of neoadjuvant chemotherapy with anti-HER2 therapy to achieve higher pathological complete response (pCR) is important. We focused on trastuzumab emtansine (T-DM1), pertuzumab (P) and tailored response guided therapy in HER2+ primary breast cancer (cT1c–T3, cN0–N1, M0, tumor ≤ 7 cm).

Methods: This randomized phase II study evaluated efficacy and safety of 3 regimens, A) 6 cycles TCbHP, B) 4 cycles TCbHP followed by 4 cycles T-DM1+P, and C) 6 cycles T-DM1+P: responders to 4 cycles T-DM1+P were assigned to 2 more cycles [C1] or non-responders were assigned to 4 cycles FEC [C2] (Table). Responders: $\geq$30% decrease in tumor size (MRI) and Ki67 $\leq$10% or no cancer cells in core needle biopsy. ER(+) patients received anti-hormonal therapy concurrent to T-DM1+P. HER2, ER and Ki-67 were assessed in a central laboratory. Primary endpoint was pCR rate (yT0-is, yN0; centrally confirmed). Secondary endpoints were safety, ORR and breast conservation rate.

Results: A total of 206 patients were enrolled (Aug 2014-Feb 2016; full analysis set, n = 204). Patient characteristics were comparable among all groups (median age 53.0 y,

Table: 159PD Summary of response

Variable	Group A (6-cycle TCbHP) % (n = 51)	Group B (4-cycle TCbHP switched to 4-cycle T-DM1+P) % (n = 52)	Group C1 (4-cycle T-DM1+P continued 2-cycle T-DM1+P) % (n = 80)	Group C2 (4-cycle T-DM1+P switched to 4-cycle FEC) % (n = 21)	Group C % (n = 101)
pCR rate, Overall	56.9 (29/51)	71.2 (37/52)	62.5 (50/80)	38.1 (8/21)	57.4 (58/101)
pCR rate, ER (-)	76.2 (16/21)	73.9 (17/23)	72.2 (26/36)	33.3 (2/6)	66.7 (28/42)
pCR rate, ER (+)	43.3 (13/30)	69.0 (20/29)	54.5 (24/44)	40.0 (6/15)	50.8 (30/59)
ORR	96.1 (49/51)	86.5 (45/52)	88.8 (71/80)	85.7 (18/21)	88.1 (89/101)
cCR	47.1 (24/51)	51.9 (27/52)	38.8 (31/80)	38.1 (8/21)	38.6 (39/101)
Breast conservation rate	52.0 (26/50)	51.9 (27/52)	54.4 (43/79)	38.1 (8/21)	51.0 (51/100)
Breast conservation rate from planned mastectomy	34.4 (11/32)	38.7 (12/31)	36.7 (18/49)	14.3 (2/14)	31.7 (20/63)

Dose was administered every 3 weeks as adjuvant therapy. ER (+) patients received concurrent endocrine therapy during T-DM1 treatment. ER, estrogen receptor; FEC, 5-fluorouracil/epirubicin/cyclophosphamide; ORR, overall response rate; pCR, pathological complete response; TCbHP, docetaxel/carboplatin/trastuzumab + pertuzumab; T-DM1+P, trastuzumab emtansine + pertuzumab

post-menopause 53.9%, T2 70.6%, median tumor size 26 mm, N0 63.2%, ER(+) 57.8%). In group C, 80 (79.2%) patients continued T-DM1+P due to favorable response. pCR rate in group A, B, and C was 56.9%, 71.2%, and 57.4%. By exploratory analyses, pCR rate was higher for groups B and C1 than A in ER(+), but comparable in ER(-) patients. No significant differences in secondary endpoints. No treatment discontinuation due to AEs and similar drug-related SAE profile were seen among groups. Of specific mention: low drug-related alopecia in group C1 (5.0%) than A, B or C2 (81%–94%) and less febrile neutropenia in C1 (0%) than A, B or C2 (15%–33%).

Conclusions: Addition of T-DM1+P to standard TCbHP regimen may be possibly superior to TCbHP. Tailored T-DM1+P is a promising approach with mostly equal efficacy and less toxicity compared to TCbHP.

160PD Statistical model to predict brain metastasis risk in patients with early-stage breast cancer

B. Abderrahman[1], N.K. Ibrahim[1], K.R. Hess[2]

[1]Breast Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [2]Biostatistics, The University of Texas MD Anderson Cancer Center, Houston, TX, USA

Background: Breast cancer (BC) brain metastases (BCBM) are emerging as a major factor of morbidity and poor overall survival. We hypothesized that a clinical risk prediction model could predict BCBM and allow the selection of an enriched early-stage BC patient population, who are at higher risk for BCBM, for preventive trials.

Methods: Electronic medical records were retrospectively reviewed for patients diagnosed and treated for early-stage BC at MD Anderson Cancer Center between 1997 and 2014 under a study approved by the institutional review board. The clinicopathologic prognostic features selected for analysis are: age, HER-2 receptor status and hormone receptor (HR) status, tumor histology, grade, and stage, menopausal status, vascular and lymphatic invasion. A multivariate Cox proportional hazards regression analysis was conducted.

Results: A total of 15164 patients with complete data for key variables were studied. Patients were randomly split 2:1 into training and validation sets. Of the 10026 patients in the training set, 317 developed BCBM and of the 5138 in the validation set, 133 developed BCBM. The 10-year estimated risk of brain metastasis was 4.2% (95% CI, 3.7% to 4.7%) in the training set. Younger age, HER-2 negative and HR-negative receptor status, higher tumor stage and grade, were all significantly and independently associated with BCBM. The risk prediction model had an estimated Harrell's concordance index of 81% (95%CI, 77% to 86%) in the validation set. In the 10% of validation set patients predicted to have the highest risk, the 10-year risk of brain metastasis was 15% (95% CI, 11% to 18%).

Conclusions: This risk prediction model for brain metastasis risk in early BC allows us to: (1) Identify the significant clinical risk factors for BCBM, (2) use these risk factors to develop an individualized risk score for BCBM, and (3) use this score to select patients at higher risk of BCBM to be prioritized for preventive trials.

161PD Surrogate endpoints for overall survival in randomized controlled trials evaluating adjuvant treatment for breast cancer: A meta-analysis

M. Savina[1], W. Jacot[2], S. Mathoulin-Pélissier[1], Y. Laghzali[3], C. Bellera[1], S. Gourgou[3]

[1]Department of Epidemiology and Clinical Research, Institut Bergonié Régional Cancer Institute of Bordeaux, Bordeaux, France, [2]Department of Medical Oncology, ICM Regional Cancer Institute of Montpellier, Montpellier, France, [3]Department of Biostatistics, ICM Regional Cancer Institute of Montpellier, Montpellier, France

Background: In cancer randomized controlled trials (RCT), endpoints other than overall survival (OS) such as disease-free survival (DFS) are increasingly being used as primary endpoint. Their development is influenced by the need to reduce the number of patients, the duration and ultimately the cost of the trials. Their use as primary endpoint however require a rigorous validation as surrogate endpoints for OS. In adjuvant breast cancer, only a few studies evaluated surrogate endpoints for OS, limited by the use of aggregate data. We present the results of a meta-analysis of individual-patient data assessing surrogate endpoints for OS in the context of adjuvant breast cancer.

Methods: We evaluated four endpoints as potential surrogates for OS relying on a meta-analysis of 5 phase III trials: relapse-free survival (RFS), invasive DFS, locoregional RFS and distant DFS. At the patient level, we estimated the individual-level associations by jointly modeling each surrogate with OS using a copula function. At the trial level, we estimated the association between the treatment effects using (1) a linear regression model weighted by the trial size and (2) the two-step model proposed by Burzykowski, Molenbergh and Buyse.

Results: We gathered individual-patient data from 11676 patients from 5 RCT. The endpoints were highly associated with OS at the patient level ($r \geq 0.98$). At the trial level, invasive DFS showed the higher association with OS (R^2_{WLR}=0,78; R^2_{2SM}=0,87).

Conclusions: This is the first meta-analysis on individual-patient data evaluating surrogate endpoints for OS in adjuvant breast cancer. These results suggest that the endpoints could be interesting candidate surrogates for OS, but further evaluation on a larger set of trials is required to improve the precision of our estimations of the trial-level associations.

162PD Pathological response in a triple-negative breast cancer cohort treated with neoadjuvant carboplatin and docetaxel according to Lehmann's refined classification (TNBCtype-4)

I. Echavarria Diaz-Guardamino[1], A.C. Picornell[2], S. López-Tarruella[2], Y. Jerez[2], K. Hoadley[3], E. Alvarez[2], M. del Monte-Millán[2], J. Gayarre[2], R. Ramos-Medina[2], T. Massarrah[1], I. Ocaña[2], M. Cebollero[4], F. Moreno Antón[5], J.A. García-Saenz[5], H. Gomez Moreno[6], H. Fuentes[6], A.I. Ballesteros Garcia[7], U. Bohn Sarmiento[8], C. Perou[3], M. Martin Jimenez[2]

[1]Medical Oncology, Hospital General Universitario Gregorio Marañon, Madrid, Spain, [2]Medical Oncology, Instituto de Investigación Sanitaria Gregorio Marañon (IiSGM), Madrid, Spain, [3]Genetics, University of North Carolina - Chapel Hill, Chapel Hill, NC, USA, [4]Pathology, Hospital General Universitario Gregorio Marañon, Madrid, Spain, [5]Medical Oncology, Hospital Universitario Clínico San Carlos, Madrid, Spain, [6]Medical Oncology, Instituto Nacional de Enfermedades Neoplasicas - INEN, Lima, Peru, [7]Medical Oncology, Hospital Universitario de La Princesa, Madrid, Spain, [8]Medical Oncology, Hospital de Gran Canaria Dr. Negrin, Las Palmas, Spain

Background: Triple-negative breast cancer (TNBC) is an aggressive subtype of BC in need for predictive biomarkers of response to neoadjuvant chemotherapy (NACT). We aimed to evaluate the predictive value of the TNBCtype-4 classifier in a population of TNBC treated with carboplatin and docetaxel (TCb).

Methods: Patients with stage I-III TNBC (ER and PR < 1%, HER2-negative) were accrued in a non-randomized trial of neoadjuvant carboplatin AUC 6 and docetaxel 75 mg/m2 q3 weeks (NCT01560663). Pathological complete response (pCR) was defined as the absence of invasive tumor in the breast and axillary lymph nodes (ypT0/is ypN0) and residual disease was evaluated using the residual cancer burden (RCB) method (Symmans et al 2007). RNAseq was performed from FFPE-extracted mRNA from the basal core biopsy, and RNAseq data was uploaded into the TNBCtype online tool (http://cbc.mc.vanderbilt.edu/tnbc). Correlation studies were analyzed with R studio v 3.2.1.

Results: RNAseq was available for 94 of the 121 patients enrolled. Patients included had a median age at diagnosis of 51 years (range 28-78), 69.1% had nodal involvement and 52.1% and 46.8% had stage II and III disease, respectively. pCR rate and pathological good response (pCR or RCBI) were 44.7% and 56.4%. TNBCtype-4 distribution was: 34.0% BL1, 20.2% BL2, 23.4% M and 14.9% LAR. An additional 7.4% were classified as ER-positive. BL1 was associated with a significant younger age at diagnosis and higher ki67 values. TNBCtype-4 showed a significant association with response to NACT ($p = 0.027$), even in multivariate analysis including tumor size and nodal status, with BL1 patients achieving the highest pCR rate (65.6%), followed by BL2 (47.4%). Conversely, LAR and ER-positive showed the lowest pCR rates, 21.4% and 14.3%. When compared to BL1, LAR and M subtypes had an OR of achieving a pCR of 0.14 and 0.30 respectively ($p < 0.05$).

Conclusions: TNBCtype-4 shows a significant predictive value of response in a TNBC cohort homogeneously treated with TCb, with BL1 and LAR displaying the best and worse responses to NACT respectively.

163PD Long-term survival analysis of the randomized phase II trial investigating the addition of carboplatin to neoadjuvant therapy for triple-negative (TNBC) and HER2-positive early breast cancer (GeparSixto)

M. Untch[1], A. Schneeweiss[2], C. Salat[3], M. Rezai[4], D-M. Zahm[5], P. Klare[6], J-U. Blohmer[7], H. Tesch[8], F. Khandan[9], P.A. Fasching[10], C. Jackisch[11], V. Nekljudova[12], G. von Minckwitz[12], S. Loibl[12]

[1]Frauenklinik, Helios Klinikum Berlin Buch, Berlin, Germany, [2]Division Gynecologic Oncology, National Center for Tumor Diseases (NCT) University Hospital, Heidelberg, Germany, [3]Innere Medizin, Hämatologie und internistische Onkologie, Hämato-Onkologische Schwerpunktpraxis, Munich, Germany, [4]Frauenklinik, Luisenkrankenhaus, Düsseldorf, Germany, [5]Frauenklinik, SRH Wald-Klinikum, Gera, Germany, [6]Krebsheilkunde, Praxisklinik, Berlin, Germany, [7]Klinik für Gynäkologie mit Brustzentrum, Charité-Universitätsmedizin Berlin, Berlin, Germany, [8]Onkologie, Dr. Hans Tesch - Private Address, Frankfurt am Main, Germany, [9]Frauenklinik, St. Markus Krankenhaus, Frankfurt am Main, Germany, [10]Frauenklinik, Universitätsklinik Erlangen, Erlangen, Germany, [11]Frauenklinik, Klinikum Offenbach GmbH, Offenbach, Germany, [12]Medicine and Research, German Breast Group (GBG) Forschungs GmbH, Neu-Isenburg, Germany

Background: Patients (pts) with TNBC involved in the GeparSixto study showed an improved pCR rate (ypT0 ypN0) with the addition of carboplatin (Cb) to anthracycline/taxane-based neoadjuvant chemotherapy, which translated in an improved early disease-free survival (DFS). No difference was observed in the HER2+ subgroup for pCR and DFS by adding Cb. Here, we present the results on the long-term survival analysis.

Methods: In the GeparSixto trial, pts were treated for 18 weeks with paclitaxel 80mg/m^2 q1w and non-pegylated-liposomal doxorubicin (NPLD) 20mg/m^2 q1w (PM), concurrently with bevacizumab 15mg/kg q3w if TNBC or trastuzumab 6(8)mg/kg q3w and lapatinib 750mg daily if HER2+. 595 pts were randomised 1:1 to receive concurrently Cb AUC 1.5-2.0 q1w (reduced to 1.5 by an amendment after 330 pts) vs no Cb, stratified by subtype (HER+ vs TNBC), 588 pts started treatment. Primary objective was pCR (ypT0 ypN0). DFS, distant (DDFS), loco regional recurrence-free (LRRFS) and overall survival (OS) were secondary objectives.

Results: After a median follow-up of 47.3 months (range 1.7-62.8) overall no significant difference in DFS was seen with PMCb vs PM (HR = 0.83 [95%CI 0.58-1.20]; p = 0.327). However, Pts with TNBC had a significantly better DFS (HR = 0.56 [95%CI 0.34-0.93]; p = 0.024) and DDFS (HR = 0.50 [95%CI 0.29-0.86]; p = 0.013) when treated with PMCb. No difference was seen in pts with HER2+ disease (DFS HR = 1.34 [95%CI 0.77-2.34]; p = 0.295; interaction test p = 0.022 and DDFS HR = 1.56 [95% CI 0.86-2.83]; p = 0.145; interaction test p = 0.006). A trend towards a better OS was observed in pts with TNBC (HR = 0.60 [95%CI 0.32-1.12]; p = 0.110). OS was not different between the two arms, neither overall (HR = 0.72 [95%CI 0.43-1.21]; p = 0.223) nor in HER2+ disease (HR = 1.13 [95%CI 0.44-2.93]; p = 0.800). Multivariable analysis comfirms that pCR (pCR vs no pCR) independently predicted DFS (HR = 0.23, p < 0.001), DDFS (HR = 0.21, p < 0.001), and OS (HR = 0.29, p = 0.002).

Conclusions: Long-term survival analysis supports the neoadjuvant use of Cb in TNBC. The value of pCR as a strong predictor of DFS and OS was confirmed.

164P Impact of lack of surgery on outcomes in elderly patients with non-metastatic breast cancer (BC): A population based study using the SEER 18 data base

C. Truica, M. Yin

Cancer Institute, Penn State Hershey Medical Center, Hershey, PA, USA

Background: Elderly women with non-metastatic BC do not always receive standard of care definitive surgical treatment. Both provider and patient related reasons have been cited. The impact of omitting surgery in elderly patients who otherwise would be candidates for surgery has not been addressed. We performed a population based study to evaluate the impact of lack of surgery on survival outcomes in elderly women with BC in modern era.

Methods: The Surveillance, Epidemiology and End Results database was queried from 2010 to 2013 for female patients age 60 and older with a diagnosis of invasive ductal or lobular BC with AJCC stage I, II, III. To determine the relationship between surgery at diagnosis and survival and to take into consideration the effect of comorbidities, we organized patients in the following groups: a. Surgery performed, b. Surgery recommended, but not performed; c. Surgery not recommended and not performed. The Kaplan –Meier method was used to generate survival curves and the log-rank test was performed to compare OS rates among different groups.

Results: 119,404 patients were eligible with a median age between 70 to 74 years old. 71,638 (60%) patients were stage I, 37,524 (31.42%) were stage II and 10,245 (8.58%) were stage III. 85.2% were ER +, 12.4% were Her 2 + and 8.8% were triple negative (TN). Compared with the patients who received surgery, patients who did not receive surgery had a significantly worse outcome (all patients: HR = 7.39, 95% CI, 6.98–7.83, P < 0.001. Patients who were recommended to have surgery but did not receive it had significantly inferior survival than patients who underwent surgery (HR = 5.08, 95% CI, 4.48–5.76, P < 0.001) although better OS than those who were recommended against surgery (HR = 0.62, 95% CI, 0.54–0.71, P < 0.001). Similar results were found in subgroup analyses regardless of age, tumor stage, ER or HER2 status. Patients with TNBC who did not received surgery also had a significantly worse OS than those who received surgery. (HR = 4.89, 95% CI, 4.07–5.88, P < 0.001).

Conclusions: Definitive surgery should be performed in medically-fit elderly patients with non-metastatic BC due to a significant survival benefit.

166P Eight-year follow up results of the OTOASOR trial: The optimal treatment of the axilla – surgery or radiotherapy after positive sentinel lymph node biopsy in early-stage breast cancer. A randomized, single centre, phase III, non-inferiority trial

Á. Sávolt[1], G. Peley[1], C. Polgár[2], B. Győrffy[3], Z. Mátrai[1]

[1]Department of Breast and Sarcoma Surgery, National Institute of Oncology Hungary, Budapest, Hungary, [2]Center of Radiotherapy, National Institute of Oncology Hungary, Budapest, Hungary, [3]MTA TTK Momentum Cancer Biomarker Res. Group, Hungarian Academy of Sciences, Budapest, Hungary

Background: The National Institute of Oncology, Budapest conducted a single centre randomized clinical study. The OTOASOR (Optimal Treatment Of the Axilla – Surgery Or Radiotherapy) trial compares completion of axillary lymph node dissection (cALND) to regional nodal irradiation (RNI) in patients with sentinel lymph node metastasis (pN1sn) in stage I-II breast cancer.

Methods: Patients with primary invasive breast cancer (cN0 and cT $\leq$ 3cm) were randomized before surgery for cALND (standard treatment) or RNI (investigational treatment). Sentinel lymph nodes (SN) were investigated with serial sectioning at 0.5 mm levels by haematoxylin-eosin staining. Investigational treatment arm patients received 50Gy RNI instead of cALND. Adjuvant treatment and follow up were performed according to the actual guidelines. Between August 2002 and June 2009, 1,054 patients were randomized for cALND and 1052 patients for RNI. SN was evaluated in 2,073 patients and was positive in 526 patients (25.4%). 474 cases were evaluable (244 in the cALND and 230 in the RNI arm), and in the cALND group 94 of 244 patients (38.5%) who underwent completion axillary surgery has additional positive nodes. The two arms were well balanced according to the majority of main prognostic factors. Primary endpoint was axillary recurrence and secondary endpoints were overall survival (OS) and disease-free survival (DFS).

Results: Mean follow-up was 97 months (Q1-Q3 80-120). Axillary recurrence was 2.0% in cALND arm vs. 1.7% in RNI arm (P = 1.00). OS at 8 years was 77.9% vs. 84.8% (P = 0.060), and DFS was 72.1% in cALND arm and 77.4% after RNI (P = 0.51). The results show that RNI is statistically not inferior to cALND treatment.

Conclusions: The long term follow-up results of this prospective-randomized trial suggest that RNI without cALND does not increase the risk of axillary failure in selected patients with early-stage invasive breast cancer (cT $\leq$ 3 cm, cN0) and pN1(sn). Axillary radiotherapy should be an alternative treatment for selected patients with sentinel lymph node metastases.

167P Time to surgery in early breast cancer treated with neoadjuvant chemotherapy

M. Cinausero[1], G. Galli[2], D. Basile[1], L. Gerratana[1], G. Fasola[1], F. De Braud[3], M. Sant[4], B. Paolini[5], S. Di Cosimo[6], F. Puglisi[1]

[1]Department of Oncology, University Hospital of Udine, Udine, Italy, [2]Division of Medical Oncology, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy, [3]Department of Oncology, University of Milan, Milan, Italy, [4]Analytic Epidemiology and Health Impact Unit, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy, [5]Department of Pathology, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy, [6]Biomarker Unit, Dipartimento di Ricerca Applicata e Sviluppo Tecnologico (DRAST), Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

Background: A delay between surgery and adjuvant chemotherapy (CT) has been associated with worse outcome in early breast cancer (BC), but little is known about timing-related consequences in the neoadjuvant setting. Aim of this study is to investigate the impact of the interval between the end of neoadjuvant CT and surgery (CTTS).

Methods: This retrospective study analyzed a series of 469 consecutive BC patients (pts) receiving neoadjuvant CT at the Department of Oncology of Udine (n = 222) and of the Istituto Nazionale Tumori of Milan (n = 247), between 2004 and 2015. CTTS

was defined as the time between the last CT administration and surgery. Prognostic impact was investigated through Cox regression.

Results: Luminal-like subtype was the most frequent (53.69%) followed by HER2-positive (29.26%) and triple negative BC (17.05%). Median follow-up was 55.07 months (mo). Estimated overall survival (OS) at 24 and 60 mo was 96.4% and 88.2%, respectively. Estimated relapse free survival (RFS) at 24 and 60 mo was 83.6% and 65.8%. Median CTTS was 1.08 mo (25%-75% range: 0.89 - 1.2 mo). Among the total population no statistically significant differences were observed in terms of OS and RFS between CTTS $>$ 1 vs $<$ 1 mo (HR 1.18, 95%CI 0.72-1.98; HR 1.28, 95%CI 0.89-1.85, respectively). On multivariate analysis, grade 3 and Ki67 $>=$20% were associated with worse RFS (HR 2.09, 95%CI 1.31-3.33; HR 2.77, 95%CI 1.30-5.91, respectively); on the other hand, a pathological complete response was associated with better RFS (HR 0.23, 95%CI 0.09-0.56). In terms of OS, grading and Ki67 were marginally significant. Subgroup analysis for CTTS showed no statistically significant differences when stratification for the main clinico-pathological features was applied. Notably, a trend for interaction in the nodal status stratification was observed.

Conclusions: This study explored the impact on RFS and OS of the interval between the end of neaodjuvant CT and surgery. Notwithstanding the exploratory purpose, the results suggest that an interval superior to 1 month was not significantly detrimental in terms of both RFS and OS.

168P Updated results of the Breast cancer task force phase II study of neoadjuvant weekly carboplatin (Cp) added to paclitaxel (P) followed by epirubicin (E) and cyclophosphamide (C) in triple negative breast cancer (TNBC) patients (pts)

C. Fontaine[1], N. Cappoen[1], V. Renard[2], H. Van Den Bulk[3], P. Vuylsteke[4], P. Glorieux[5], L. Decoster[6], M. Vanhoeij[7], J. De Grève[6], A. Awada[8], H. Wildiers[9]

[1]Medische Oncologie, UZ Brussels, Jette, Belgium, [2]Medische Oncologie, AZ st Lucas, Gent, Belgium, [3]Medische Oncologie, Imelda ZH, Bonheiden, Belgium, [4]Medische Oncologie, St Elisabeth, Namur, Belgium, [5]Medische Oncologie, Cliniques Sud Luxembourg, Arlon, Belgium, [6]Medische Oncologie, UZ Brussel, Jette, Belgium, [7]Oncologische Heelkunde, UZ Brussel, Jette, Belgium, [8]Medical Oncology, Jules Bordet, Brussel, Belgium, [9]General Medical Oncology, University Hospitals Leuven, Leuven, Belgium

Background: Introduction: TNBC has the highest mortality of all BC subtypes. Neoadjuvant platinum added to the taxanes-antracycline chemotherapy has been reported to improve pathologic complete response (pCR) rate and survival in TNBC. Aim: To evaluate the efficacy and toxicity of the addition of weekly Cp to Pl and dose dense EC on the pCR rate in an open-label phase II study in stage II/III TNBC pts.

Methods: Patients and methods: Sixty three pts received dose dense P (80mg/m^2/wk) concurrent with Cp (AUC=2) for 12 wks, added to two-weekly E (90mg/m^2) and C (600mg/m^2) for 4 cycles, and followed by surgery and radiotherapy. The primary endpoint was pCR in the breast and axilla. Additionally adverse events are registered. A correlative assessment of germ line mutations in HRD genes is ongoing. Pts are monitored for clinical response by magnetic resonance and mammography and also for relapse free survival and time to treatment failure. The study sample size has been calculated according to the optimal Simon's two-stage design method. The target sample size was 63 patients with 80% power to detect a pCR rate of $>$ or $=$ 47% ($\alpha = 0.05$).

Results: Accrual to the study is completed and 63 eligible pts with operable, non-inflammatory stage II/III TNBC were included. Most pts were between 40 and 60 yr old and 49 out of 63 were stage T2. Forty percent were clinically node + and 68% were G3. Seventy three percent received breast conserving surgery. Thirty eight out of 63 pts (60%) achieved a pCR rate in the breast and axilla. In 52 evaluable pts for toxicity, the main toxicity for part 1 (Cp+P) of the combination was neutropenia G3/4 in 37 pts (71%) and for part 2 (EC) febrile neutropenia G3/4 in 18 pts (34%) despite primary prophylaxis, followed by thrombocytopenia G3/4 in 11 pts (21%). Only three pts had a neuropathy G3.

Conclusions: The addition of weekly carboplatinum to neoadjuvant dose dense paclitaxel and EC is feasible and a pCR rate in the breast and axilla as high as 60% in early TNBC pts is obtained. Correlation with genomic HRD deficiency is ongoing.

Background: Neoadjuvant chemotherapy for triple negative breast cancer (TNBC) patients (pts) is mostly based on anthracycline and taxane (AT). The microtubule dynamics inhibitor eribulin mesylate (E) has been proved to increase survival in heavily pretreated metastatic breast cancer pts. We argue that sequential AT and E would benefit also non-metastatic TNBC pts.

Methods: Pts with primary TNBC$>$2 cm received doxorubicin 60 mg/m^2+paclitaxel 200 mg/m^2 day 1, q 21 for 4 cycles, followed by E 1.4 mg/m^2 days 1,8 q 21 for 4 cycles. The primary endpoint was the pathological complete response (pCR) rate; secondary endpoints included clinical response rate by RECIST 1.1, metabolic response by EORTC criteria, safety profile and biomarker analysis. Sample size was estimated to detect a 40% pCR, with 20% for a minimal hypothesis. With a type I error of 0.05 and a statistical power of 80%, 13 patients were to be initially enrolled. Observation of $\geq$ 4 pCR would justify continuation of accrual up to 43 pts.

Results: Thirteen pts were enrolled. The combination was safe with mostly G1/2 toxicities. The only G $\geq$ 3 event was neutropenia, which was related to AT in 4 pts and to E in 2 pts. An analysis of the degree of response by imaging was feasible in 11 pts. Overall 6/11 (54%) pts achieved a partial response after AT; of note 3/5 (27%) AT-unresponsive pts responded to E, 1 had stable disease and 1 pt definitely progressed. FDG PET/CT scans were available in 12 pts after AT and in 10 pts after 2 cycles of E. Median SUV_{max} values were 13, 3, and 2 at baseline, after AT and after E, respectively. Of the 4 pts with complete metabolic response (2 after AT and 2 after E), 2 achieved pCR at surgery. Immunostaining of paired pre- and post-treatment tumor bioptic specimens revealed reduction of beta-catenin, cyclin D and c-myc expression in the absence of n-cadherin modulation. The trial was halted because of the unmet primary endopoint (3 pCR).

Conclusions: Despite an unmet primary endpoint, E showed clinical and biological activity in TNBC pts. The observed modulation of beta-catenin pathway core proteins, purportedly outside the domain of epithelial mesenchymal transition, claims for further investigation and for the refinement in the definition of the clinical endpoints.

170P Impact of neoadjuvant therapy (NT) and pathological complete response (pCR) on breast-conserving surgery (BCS) in patients (pts) with breast cancer (BC): A meta-analysis

C. Criscitiello[1], M. Golshan[2], W.T. Barry[2], G. Viale[1], S. Wong[2], M. Santangelo[3], G. Curigliano[1]

[1]Division of Experimental Therapeutics, Istituto Europeo di Oncologia, Milan, Italy, [2]Breast Surgical Services, Dana Farber/Brigham and Women's Cancer Center, Boston, MA, USA, [3]Abdominal Surgery and Transplantation, Department of Advanced Biomedical Sciences, University Federico II, Naples, Italy

Background: We performed a meta-analysis of randomized trials that evaluated the pCR and surgical decisions after NT for BC.

Methods: Studies were retrieved by searching the PubMed database and the proceedings of major conferences. The primary outcome was BCS rate. Secondary outcomes were pCR rate and association to BCS. Meta-analyses were performed using random-effects (RE) models that use inverse-variance weighting for each treatment arm based on the number of evaluable pts. Point estimates are reported with 95% confidence intervals, and $p < 0.05$ was considered statistically significant.

Results: 36 studies were identified (N = 12,311 pts). 17/36 studies reported both pCR and BCT for at least 1 treatment arm, and comprise the studies in this analysis. The number of arms per study ranged from 1 to 6, such that 42 independent units were available to evaluate the association between pCR and BCT. The BCS rate ranged from

5% to 76% across arms with an average BCS of 57% (95% CI 52%-62%). Significant heterogeneity was observed among the trials (Cochrane Q = 787, p < 0.001, I^2 = 97%). In the meta-regression model, BCS rates were not significantly associated with year of first patient-in (p = 0.89), grade (p = 0.93), hormone-receptor status (p = 0.39). Clinical N-stage (p = 0.01) and HER2 status (p = 0.03) were significantly associated with BCS. pCR rate ranged from 3% to 60% across studies. The average pCR across all study arms was 24% (95% CI 19%-29%). No association was observed between pCR rate in a study arm and the resulting BCS rate in a univariate model (p = 0.34) nor after adjusting for HER2 and clinical nodal status (p = 0.82). Change in BCS with NT was further derived from the subset of 14 multi-arm trials, where 17 pairwise contrasts were made between randomized populations: 2 studies showed a significant difference in BCS. The difference in pCR rates between treatment arms ranged from -22% to 24%. However, no significant association is seen with the corresponding difference in BCS rates (p = 0.27).

Conclusions: This meta-analysis indicates that, despite increasing pCR, there is no concomitant increase in BCS. Future NT studies should reconsider using BCS as an endpoint.

Businco, Cagliari, Italy, [11]Medical Oncology, IRCCS Istituto di Candiolo, Candiolo, Italy, [12]Medical Oncology, Azienda Ospedaliera Treviglio-Caravaggio, Treviglio, Italy, [13]Medical Oncology Unit, University Hospital Sant'Orsola, Bologna, Italy, [14]Breast Unit, A.O.R.N. San Giuseppe Moscati, Avellino, Italy, [15]Medical Oncology, Ospedale SS Trinità, Sora, Italy, [16]Medical Oncology, IRCCS AOU San Martino - IST-Istituto Nazionale per la Ricerca sul Cancro, Genoa, Italy

Background: Compared with the standard interval adjuvant chemotherapy, dose-dense schedule is proved to increase disease-free survival (DFS) in node-positive early breast cancer (EBC) patients (pts). To date, GIM2 is the only trial supporting the role of dose-dense chemotherapy in pts with hormone receptor-negative (HR-) or hormone receptor-positive tumours (HR+) (Del Mastro et al. Lancet 2015). To further refine the evidence of treatment effect in the HR+ subgroup, a composite index of risk was developed including clinico-pathological features.

Methods: The randomized phase III GIM2 trial enrolled 2091 pts with node-positive EBC (primary endpoint: DFS). A continuous, composite measure of treatment benefit was determined from a Cox model incorporating potential predictive factors (age: 25-40/41-55/56-71; histological grade: 1 + 2/3; HR status: positive/negative; ki-67 levels: ≤20%/>20%). Subpopulation treatment effect pattern plot methodology was used to reveal differential treatment effects on DFS according to composite index. The study analyzed the cohort of pts with HER2- (N = 1127) disease with a special focus on HR+ disease (N = 980).

Results: On average, the magnitude of benefit with dose dense chemotherapy versus standard chemotherapy widely varied according to composite measure of specific features. In the HER2- subgroup, the highest benefit was observed in pts with G3, HR-, >10 positive nodes, age <40 yrs, ki-67 > 20% (hazard ratio for DFS 0.57, 95% CI 0.35-0.94). Notably, among pts with HR+ disease, the following clinic-pathological characteristics conferred the highest benefit: G3, ≥4 positive nodes, age ≥56 yrs, ki-67 > 20% (hazard ratio for DFS 0.66, 95% CI 0.38-1.15).

Conclusions: Composite risk evaluation and corresponding subpopulation treatment effect pattern plot methodology suggest that benefit of dose dense adjuvant chemotherapy is not confined to triple negative EBC.

[1]Medical Oncology, Gayrettepe FNG Hospital, Istanbul, Turkey, [2]Medical Oncology, Haseki State Hospital, Istanbul, Turkey, [3]Radiology, Gayrettepe FNG Hospital, Istanbul, Turkey, [4]Radiation Oncology, Gayrettepe FNG Hospital, Istanbul, Turkey, [5]Medical Oncology, Istanbul Bilim University, Istanbul, Turkey, [6]Surgical oncology, Taksim state hospital, Istanbul, Turkey, [7]Surgical oncology, İstanbul FNG Hospital, Istanbul, Turkey, [8]Surgical Oncology, Biruni University, Istanbul, Turkey, [9]Physical Therapy Specialist, Istanbul Bilim University, Istanbul, Turkey, [10]Radiology, İstanbul FNG Hospital, Istanbul, Turkey, [11]Medical Oncology, Istanbul University, Istanbul, Turkey, [12]Pathology, Gayrettepe FNG Hospital, Istanbul, Turkey, [13]Surgical Oncology, Istanbul University, Istanbul, Turkey

Background: In this study; Amenorrhea caused by chemotherapy in early stage breast cancer patients and its effects on survival were investigated.

Methods: A total of 389 patients who received adjuvant chemotherapy from 600 premenopausal patients who were treated with early stage breast cancer during 2000-2013 and followed up were included in the study. Patients who did not undergo medical ovarian ablation (OA); Amenore as developing and non-developing, two groups were separated and compared with clinicopathologic features and survival. SPSS 17. version was used.

Results: Disease-free survival (DFS): median (m) 57 months (4-197 months), overall survival (OS): m 60 (10-168 months) and follow up time m 60 months (23-168 months). During follow-up, chemotherapy induced amenorrhea (CIA) was observed in 145 (57.5%) of 252 patients who did not have any ovarian ablation (OA. The 5-year OS rate of patients with CIA was significantly higher than the patients without CIA (p = 0.042, 95.9% vs 89.7 vs 158.88 vs 135.33 months, respectively). In the subgroup analysis, the OS in patients with CIA was significantly higher than in those without CIA in patients had HR (+) (p = 0.036, 97.5% vs 91.5 vs 162.13 vs. 136.20 months, respectively). There was no significant difference in the duration of OS between with CIA and without CIA of the patients who had not HR (+) (p = 0.736, 90.9% vs 86.8% and 126.16 and 133.76 months, respectively). The duration of OS was significantly longer in patients with CIA in the luminal A molecular subtype than in those luminal B molecular subtype, but the difference was not significant in patients without CIA (p = 0.027 vs p = 0.074 respectively).

Conclusions: The development of amenorrhea due to chemotherapy provides a significant survival advantage over those patients who do not develop amenorrhea due to chemotherapy. This advantage is more pronounced in hormone receptor positive, lymph node involvement and advanced disease. The development of amenorrhea due to chemotherapy in patients with HR negative does not affect survival. Amenorrhea development further prolongs survival compared to luminal B in the luminal A molecular subtype.

173P Determinants and outcomes associated with delays in adjuvant chemotherapy among breast cancer patients

M. Chavez Mac Gregor[1], X. Lei[2], H. Zhao[2], S.H. Giordano[1]

[1]Breast Medical Oncology, Health Services Research, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [2]Health Services Research, The University of Texas MD Anderson Cancer Center, Houston, TX, USA

Background: Adverse outcomes have been associated with delays in the administration of adjuvant chemotherapy among breast cancer patients. We evaluate the determinants and outcomes associated with delays in time to chemotherapy (TTC) in a large cohort of older breast cancer patients.

Methods: We used the NCI-Surveillance Epidemiology and End Results (SEER) and Texas Cancer Registry (TCR)-Medicare linked data bases to identify patients ≥66 years old diagnosed with localized or regional breast cancer between 2001-2011. All patients received chemotherapy within 9 months of surgery. Delayed TTC was defined as > 90 days. Multivariable logistic regression was used to identify predictors of treatment delay. A Cox Proportional Hazards model was fit to determine the association between treatment delay, overall survival (OS) and breast cancer specific survival (BCSS).

Results: 25,096 patients were included, of them 2,676 (10.7%) had a TTC >90 days. In multivariable analysis factors associated with delays in TTC were: recent year of diagnosis (2011 vs 2001 OR = 1.31; 95%CI 1.03-1.67), older age (76-80 vs 66-70 OR = 1.51; 95%CI 1.33-1.72), black race (OR = 1.35; 95%CI 1.14-1.58), having state buy-in (as an indicator of poverty) (OR = 1.27; 95%CI 1.1-1.47), comorbidities (Charlson score 1 OR = 1.23;95%CI 1.09-1.37; score 2 OR = 1.57; 95%CI 1.37-1.81), mastectomy (OR = 1.49; 95%CI 1.33-1.67), mastectomy with immediate reconstruction (OR = 1.85; 95%CI 1.37-2.48), Oncotype DX testing (OR = 1.68; 95%CI 1.4-2.02), mastectomy >30 days after the initial surgery (OR = 16.91; 95%CI 12.07-23.68), brachytherapy (OR = 4.11; 95%CI 3.17-5.34) and whole breast radiation prior to

chemotherapy (OR = 31.9; 95%CI 28.05-36.49). After adjusting for potential confounders, patients with TTC >90 days had worse OS (HR = 1.37; 95%CI 1.27-1.48) and BCSS (HR = 1.34; 95%CI 1.19-1.51).

Conclusions: A delay in adjuvant chemotherapy administration >90 days is associated with adverse outcomes among older breast cancer patients. Determinants of delays were sociodemographic in nature, related to patient's characteristics and to treatment received. Every effort should be made to identify vulnerable patients and to administer chemotherapy in a timely manner.

174P Adjuvant chemotherapy in pT1ab node-negative triple negative breast carcinomas: Results of a national multi-institutional retrospective study

A. De Nonneville[1], A. Gonçalves[1], C. Zemmour[1], M. Cohen[2], J.M. Classe[3], F. Reyal[4], P.E. Colombo[5], E. Jouve[6], S. Giard[7], E. Barranger[8], R. Sabatier[1], F. Bertucci[1], J.M. Boher[9], G. Houvenaeghel[2]

[1]Medical Oncology, Institut Paoli Calmettes, Marseille, France, [2]Surgical Oncology, Institut Paoli Calmettes, Marseille, France, [3]Surgical Oncology, Institut René Gauducheau, Saint Herbain, France, [4]Surgical Oncology, Institut Curie, Paris, France, [5]Surgical Oncology, Val-d'Aurelle, Montpellier, France, [6]Surgical Oncology, Institut Claudius Regaud, Toulouse, France, [7]Surgical Oncology, Centre Oscar Lambret, Lille, France, [8]Surgical Oncology, Centre Antoine Lacassagne, Nice, France, [9]Department of Clinical Research and Investigation, Biostatistics and Methodology Unit, Institut Paoli Calmettes, Marseille, France

Background: Triple negative breast cancers (TNBC) are considered as associated with poor outcome, but prognosis of subcentimetric, node-negative disease remains controversial and evidence that adjuvant chemotherapy (CT) is effective in these small tumors remains limited.

Methods: Our objective was to investigate the impact of adjuvant CT on survival in pT1abN0M0 TNBC. Patients were retrospectively identified from a cohort of 22,475 patients who underwent primary surgery in 15 French centers between 1987 and 2013. Since rare pathological types may display very particular prognoses in these tumors, we retained only the invasive ductal carcinomas of no special type according to the last WHO classification witch is most common TNBC histologic type. End-points were disease-free survival (DFS) and metastasis-free survival (MFS). A propensity score for receiving CT was estimated using a logistic regression including age, tumor size, SBR grade, and lymphovascular invasion.

Results: Of a total of 284 patients with pT1abN0M0 ductal TNBC, 144 (51%) received post-operative CT and 140 (49%) did not. Patients receiving CT had more adverse prognostic features, such as tumor size, high grade, young age, and lympho-vascular invasion. Adjuvant CT was not associated with a significant benefit for DFS (Hazard ratio, HR = 0.77 [0.40-1.46]; $p = 0.419$, Log-rank test) or MFS (HR = 1.00 [0.46-2.19], $p = 0.997$), with 5-year DFS and MFS in the group with CT *vs.* without of 90% [81%-94%] vs. 84% [74%-90%], and 90% [81%-95%] vs. 90% [83%-95%], respectively. Results were consistent in all supportive analyses including multivariate Cox model and the use of the propensity score for adjustment and as a matching factor for case–control analyses.

Conclusions: This study did not identify a significant DFS or MFS advantage for adjuvant CT in subcentimetric, node-negative ductal TNBC. Although current consensus guidelines recommend consideration of adjuvant CT in all TNBC larger than 5 mm, clinicians should carefully discuss benefit/risk ratio with patients, given the yet unproven benefits.

175P OHERA: A real world study of cardiac events in > 3700 patients with her2-positive early breast cancer treated with trastuzumab: Final analysis

E. Lidbrink[1], J. Erfan[2], E. Chmielowska[3], B. Otremba[4], A. Bouhlel[5], S. Lauer[6], M. Liste Hermoso[5], E. Nüesch[6], M. Shing[7], V. Misra[8]

[1]Karolinska Institute, Karolinska University Hospital, Stockholm, Sweden, [2]Josa Andras, Teaching Hospital, Nyiregyhaza, Hungary, [3]Regionalne Centrum Onkologii, Bydgoszcz, Poland and Medical University Nicolaus Copernicus, Torun, Poland, [4]Onkologische Praxis, Oldenburg, Oldenburg, Germany, [5]Global Pharma Development, F Hoffmann-La Roche Ltd, Basel, Switzerland, [6]Biostatistics, F Hoffmann-La Roche Ltd, Basel, Switzerland, [7]Genentech Inc, Clovis Oncology Inc, San Francisco, CA, USA, [8]The Christie Clinic, The Christie NHS Foundation Trust, Manchester, UK

Background: As of Sept 2016, > 2.2 million breast cancer (BC) patients (pts) have received trastuzumab (Herceptin®; H) in clinical trial or real world settings. Risk of cardiac failure in pts treated with H in real world practice may differ from that observed in a clinical trial setting.

Methods: OHERA (NCT01152606) is a non-interventional post-approval safety study that investigated incidence of symptomatic congestive heart failure (CHF) and cardiac death in pts with HER2-positive early BC (EBC) receiving adjuvant intravenous H (H IV) in routine clinical practice, per the EU Summary of Product Characteristics (SmPC). Pts with HER2-positive EBC (stage I–IIIb) considered for treatment with H IV per the EU SmPC were enrolled, treated and monitored per local practice. Primary endpoints were incidence of symptomatic CHF (New York Heart Association [NYHA] class II–IV) and incidence of cardiac death. Secondary endpoints included time to onset of CHF. The final analysis included pt data collected for up to 5 years or until death, loss to follow-up or consent withdrawal.

Results: Pts were enrolled Aug 2007–Nov 2010 at 199 sites across 9 countries. The safety population included 3733 pts with EBC treated with H IV. Median treatment duration was 11.8 months; median follow-up was 60.1 months. Incidence of symptomatic CHF was 2.8% (n = 106); including severe symptomatic CHF (NYHA class III–IV) in 1.0% (n = 38) pts. Median time to onset of symptomatic CHF was 5.7 months (95% CI 5.3–6.5) and 77 (72.6%) pts achieved CHF resolution. Incidence of cardiac death was 0.2% (n = 6). 251 pts had a left ventricular ejection fraction (LVEF) drop of ≥ 10% from baseline to < 50% and 169/251 (67.3%) achieved LVEF drop resolution. Incidence of CHF was higher in pts with baseline risk factors such as pre-existing cardiac conditions, age ≥65 years or baseline LVEF ≤55%. Pts who had left-side radiotherapy at baseline did not have higher CHF incidence.

Conclusions: OHERA is the largest study investigating the cardiac safety of adjuvant H IV in a real world setting to date. Final analysis results were consistent with cardiac safety results from previous adjuvant H IV clinical trials in EBC, and the baseline risk factors for CHF reported in the H IV EU SmPC.

176P Clinical outcomes of delayed start of trastuzumab treatment in patients with early breast cancer: ml25232 study

S. Beslija[1], T. Ceric[1], B. Hasanbegovic[1], A. Kurtovic-Kozaric[2], A. Pasic[1], N. Mahic[1], M. Kalamujic[1], A. Cardzic[1], J. Alidzanovic[3], I. Marjanovic[4], A. Mekic-Abazovic[5]

[1]Oncology, Clinical Center, University of Sarajevo, Sarajevo, Bosnia and Herzegovina, [2]Pathology, Cytology and Human Genetics, Clinical Centre of Sarajevo University, Sarajevo, Bosnia and Herzegovina, [3]Oncology, University Clincal Center Tuzla, Tuzla, Bosnia and Herzegovina, [4]Oncology, University Clinical Hospital Mostar, Mostar, Bosnia and Herzegovina, [5]Oncoogy, Hematology and Radiation Unit, Cantonal Hospital Zenica, Zenica, Bosnia and Herzegovina

Background: Breast cancer patients in low and middle income countries have limited access to targeted therapies such as trastuzumab. The discontinuous availability of trastuzumab created waiting lists and subsequent very delayed treatment. Since few studies have systematically analyzed possible deleterious effect of delayed trastuzumab treatment, we designed a study to investigate its consequences on overall survival and disease-free survival.

Methods: This was a multicenter cohort study of HER2-positive early breast cancer patients (n = 223) diagnosed between 01/05/2005 and 01/05/2010 in the Federation of Bosnia and Herzegovina. The study began in 01/01/2010, and enrollment was completed in 30/06/2012. Last follow up and cut off date for analysis was 31/03/2015.

Results: A total of 223 women (median 55 years; IQR: 49-61 years) were recruited. Since 131 (59%) patients waited for > 6 months after surgery to receive trastuzumab, we categorized our patient cohort into three groups: non-waiting group (n = 92; wait time < 6 months), and waiting group 1 (n = 85; wait time between 7 to 12 months) and waiting group 2 (n = 46; > 13 month wait). OS at 5 years in non-waiting group was 84%, compared to 72% in wait group 1 and 75% in wait group 2 ($p > 0.05$). DFS at 5 years in the non-wait group was 79%, compared to 65% in wait group 1, and 68% in wait group 2 ($p > 0.05$).

Conclusions: Unfortunate and unique circumstances in developing countries have created waiting lists for trastuzumab treatment—our systematic analysis of 223 women has shown that delayed start of trastuzumab treatment does not have a statistically significant effect on clinical outcomes, but shows a trend towards worse OS and DFS for women with delayed treatment. Thus, trastuzumab treatment has a persistent benefit even when administered with delayed start.

Background: The international, randomized, placebo (P)-controlled phase III ExteNET trial (NCT00878709) showed that N for 1 y after trastuzumab-based adjuvant therapy significantly improved 2-y invasive disease-free survival in early HER2+ BC patients (pts) (HR 0.67; 95% CI 0.50–0.91; p = 0.0091) [Chan et al. *Lancet Oncol* 2016]. Detailed longitudinal evaluation of HRQoL was an exploratory endpoint of ExteNET.

Methods: 2840 pts received N 240 mg/d or P for 1 yr. Pts completed FACT-B and EQ-5D questionnaires at baseline and months (M) 1, 3, 6, 9, and 12. Changes in scores from baseline were compared between groups using ANCOVA with no imputation for missing values. Sensitivity analyses using alternative methods were applied. Changes in HRQoL scores were considered to be clinically meaningful if greater than minimal clinically important differences (MCID) reported in the literature.

Results: 2407 pts were evaluable for FACT-B (N, n = 1171; P, n = 1236), and 2427 for EQ-5D (N, n = 1186; P, n = 1241). Compliance with questionnaires exceeded 85%. N was associated with decreased HRQoL scores at M1 *vs* P, after which between-group differences diminished (Table). They were consistently less than MCIDs, except for physical well-being (PWB) subscale at M1. BC subscale (BCS) showed small improvements with N at M3–M9, all less than MCIDs. Different sensitivity methods did not alter the results.

Table: 177P

Scale	MCID range	Adjusted† mean difference in change from baseline: N *vs* P				
		M1	M3	M6	M9	M12
FACT-B total	7–8	−2.9*	0.1	−0.6	−0.5	−0.8
TOI-PFB	5–6	−2.6*	−0.3	−0.7	−0.4	−1.0*
TOI-ESB	5–6	0	1.2*	0.6	0.5	0.4
PWB	2–3	**−2.4***	−1.1*	−1.0*	−0.9*	−1.1*
BCS	2–3	0.3	0.7*	0.4*	0.6*	0.2
EQ-5D index	0.09–0.10	−0.02*	−0	−0	0	0
EQ health state	7–10	−2.7*	0.1	−1.3*	−0.7	−0.4

†For baseline score;

*Statistically significant at $p < 0.05$ without adjustment for multiple testing
TOI = trial outcome index; PFB = PWB + functional WB + BCS; ESB = emotional WB + social WB + BCS.

Conclusions: N was associated with decreased HRQoL, in particular in PWB, at M1, possibly due to N-related diarrhea. Based on their small magnitude, differences observed after M1 in PWB favoring P and in BCS favoring N, may not be clinically important.

178P Second interim analysis of HerSCin, a German non-interventional study of subcutaneous trastuzumab for HER2-positive early breast cancer in routine clinical practice

K. Lüdtke-Heckenkamp[1], S. Kümmel[2], A. Ruf-Dördelmann[3], A. Distelrath[4], J. Wacker[5], S. Schmatloch[6], S. Busch-Liles[7], M. Schmidt[8]

[1]Department of Oncology and Hematology, Niels Stensen Kliniken, Franziskus Hospital Harderberg, Georgsmarienhütte, Germany, [2]Cancer Center Essen, Klinikum Essen Mitte, Essen, Germany, [3]Department of Gynecology and Obstetrics, Municipal Clinic Karlsruhe, Karlsruhe, Germany, [4]Oncologic Centre, Clinic Fulda gAG, Fulda, Germany, [5]Gynaekologische Onkologie, Frauenklinik Bruchsal, Bruchsal, Germany, [6]Senology, Elisabeth Hospital, Kassel, Germany, [7]Medical Affairs, Roche Pharma AG, Grenzach-Wyhlen, Germany, [8]Department of Obstetrics and Gynecology, University Hospital Mainz, Mainz, Germany

Background: Compared with IV trastuzumab, subcutaneous trastuzumab (H_{SC}) showed non-inferior outcomes in the HannaH trial and was preferred by patients (pts) and healthcare professionals in the PrefHer study. The ongoing HerSCin study (NCT01959386) is evaluating H_{SC} in routine clinical practice in Germany.

Methods: Pts with HER2-positive early breast cancer treated with (neo)adjuvant H_{SC} (investigator's chosen regimen) in routine oncology practice between Nov 2013 and Nov 2016 were eligible. Pts could be enrolled retrospectively up to 9 wks after starting H_{SC}. Baseline characteristics, treatment, adverse events (AEs), clinical outcomes and quality of life (EORTC QLQ-C30/QLQ-BR23) data are collected prospectively. Primary efficacy endpoints are pCR rate (neoadjuvant setting) and 2-year disease-free survival (adjuvant setting).

Results: At the data cut-off for the second planned interim analysis (Nov 2016), 420 of 1003 pts enrolled to date from 103 German centres had completed therapy and were eligible for analysis. The median duration of follow-up was 12.2 (range 3.3–25.8) mo. Baseline characteristics are below. The mean duration of H_{SC} was 8.8 mo (neoadjuvant: 9.2; adjuvant: 8.7). All-grade and grade ≥3 AEs were reported in 63% and 15% of pts, respectively. The most common all-grade AEs were fatigue (10%), diarrhoea (9%) and arthralgia (7%). AEs led to treatment interruption/withdrawal in 48 pts (11%). Only 1 of the 4 fatal AEs was considered treatment related (cardiac/respiratory failure). The pCR rate (including carcinoma in situ) in the neoadjuvant subgroup was 60.3% (95% CI 48.5–71.2). Efficacy results in the adjuvant subgroup are not mature.

Conclusions: The 60.3% pCR rate is consistent with prospective trials of IV trastuzumab and H_{SC}. Tolerability is as expected based on results from randomised trials. H_{SC} is an active, feasible and tolerable treatment for use in routine oncology practice as well as the clinical trial setting.

179P Timing of initiation of trastuzumab (T) and long-term outcome of patients (pts) with early-stage (ES) HER2-positive (HER2+) breast cancer (BrCa): Impact of neo-adjuvant (NAdj) versus adjuvant (Adj) strategy

G. Gullo[1], N. Walsh[2], D. Fennelly[1], D. Tryphonopoulos[3], J. Walshe[1], K. O'Mahony[4], N. Silva[5], L. Hammond[4], J. Ballot[6], C. Quinn[7], C. Buckley[8], J. Crown[1]

[1]Medical Oncology Department, St Vincents University Hospital, Dublin, Ireland, [2]National Institute for Cellular Biotechnology, Dublin City University, Dublin, Ireland, [3]Medical Oncology, Agios Savas Hospital, Athens, Greece, [4]Pharmacy Department, St Vincents University Hospital, Dublin, Ireland, [5]Pharmacy Department, St Vincent's Private Hospital, Dublin, Ireland, [6]Medical Oncology Clinical Research, St Vincents University Hospital, Dublin, Ireland, [7]Pathology Department, St Vincents University Hospital, Dublin, Ireland, [8]Medical Oncology, St Vincents University Hospital, Dublin, Ireland

Background: The optimal schedule of anti-HER2 Tx for HER2+ ESBrCa with respect to chemotherapy and surgery remains undefined. We performed a retrospective analysis of a large, prospectively maintained single institution data base to study the impact of treatment schedule on clinical outcome.

Methods: Our database included all pts treated with T for Stage I to III HER2+BrCa who had a minimum follow up (FU) of 3 years. Time-to-first-T (TFT) was calculated from the date of the first diagnostic breast biopsy to the date of the first T. Pts with stage N3b and N3c or inoperable disease were excluded from the study.

Results: A total of 506 pts treated between October 2001 and March 2014 were included in the study. T was administered as part of AdjTx in 386 (76%) pts, and of NAdjTx in 120 (24%), 338 (67%) pts had TCH [docetaxel/CBDCA/T] or "TCH-like", 119 (24%) pts had delayed concomitant (i.e. AC-TH)/sequential T. Median FU is 73.3 months (range 1.4-176.3). Median TFT for the overall cohort was 12 weeks (range 1.9-122.3). Median TFT was significantly shorter in the NAdj than in the Adj cohort: 4.4 vs 14 weeks [$p<0.00001$]. In the entire cohort, DFS and OS rates were 83% and 91%, respectively. DFS and OS rates were 90% and 96% vs 75% and 85% for pts with TFT $\leq$12 weeks vs TFT >12 weeks, respectively [$p < 0.0001$]. Pts with TFT >12 weeks had a significantly higher risk of recurrence [HR 1.96; $p = 0.008$] and death [HR 2.84; $p = 0.006$] than pts with TFT $\leq$12 weeks. Pts with positive lymph nodes (LN+) and TFT >12 weeks had significantly higher risk of relapse [HR 2.40, $p = 0.001$] and death [HR 2.10, $p = 0.024$] than pts with TFT $\leq$12 weeks. However, despite NAdj pts having significantly higher rate of LN + (75% vs 53%, $p < 0.0001$), DFS and OS were superimposable in the two cohorts. Pts with LN+ had superior DFS when treated with NAdjTx compared with AdjTx [$p = 0.006$].

Conclusions: Our mature data indicate that timing of anti-HER2 Tx significantly affects long-term outcome and T should be initiated $\leq$12 weeks from first diagnosis of ES HER2+BrCa. The early institution of T in the NAdj cohort abolished the negative impact of LN+, thus suggesting that this should be considered the optimal Tx strategy for ES HER2+BrCa.

180P Adjuvant endocrine treatment: Stop or continue?

E.W. Muller[1], A. van de Wouw[2], D. van Dreuten[1]

[1]Internal Medicine, Slingeland Hospital, Doetinchem, Netherlands, [2]Internal Medicine, Vie Curie MC, Venlo, Netherlands

Background: There is currently a trend towards extending adjuvant endocrine treatment in higher risk breast cancer patients up 10 years. However, a trade off has to be made between persisting side effects of endocrine treatment vs a small advantage in recurrence risk. It is not well known if patients still suffer side effects after 5 years of endocrine treatment, and if these may be reversible. Therefore, we studied the change in side effects of endocrine treatment and overall quality of life during and 3 months after cessation, in patients who completed at least 5 years of treatment.

Methods: We included 101 patients from 2 oncological practices who underwent curative treatment for breast cancer and whose adjuvant endocrine therapy ended between 2013 and 2016. Patients willing to cooperate filled out a questionnaire before and 3 months after stopping their endocrine therapy. Hot flashes, joint pain, muscle pain and fatigue were scored as absent, a little, severe or very severe. Overall quality of life was scored on a scale from 0 to 10.

Results: 101 patients were included. Average was 61 years. Tumors were T1-T4, N0-N3, M0. Most patients received tamoxifen for 2-3 years, followed by an aromatase-inhibitor for 3-6 years. The main finding of this survey is that overall quality of life improved significantly after stopping endocrine therapy from 6.9 (range 4-10) to 7.7 (5-10) ($p < 0.01$ Wilcoxon paired rank test). 22 women improved $\geq$2 points. Patients who scored high on muscle aches and joint complaints improved the most.

Conclusions: Even patients who completed at least five years of endocrine treatment suffer side effects up to the end of treatment. After cessation these ameliorate in many, and this improves quality of life significantly. These findings are relevant when deciding

on extended adjuvant endocrine treatment in individual patients. Detailed analysis will be presented.

Clinical trial identification: Under Dutch law no obligations for protocol submission for this type of survey, only institutional approval.

181P Use and effectiveness of adjuvant ovarian function suppression (OFS) in premenopausal women with early breast cancer

A.R. Ferreira[1], J. Ribeiro[2], A. Mayer[3], M. Brito[4], A. Miranda[3], J.P. Fernandes[5], J.L. Passos-Coelho[6], L. Costa[1], I. Vaz-Luís[7]

[1]Medical Oncology, Hospital de Santa Maria and Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal, [2]Medical Oncology, Fundação Champalimaud, Lisbon, Portugal, [3]Registo Oncológico Regional do Sul, Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisbon, Portugal, [4]Medical Oncology, Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisbon, Portugal, [5]Medical Oncology, Hospitais CUF Lisboa, Lisbon, Portugal, [6]Medical Oncology, Hospital da Luz and Hospital de Beatriz Ângelo, Lisbon, Portugal, [7]Department of Medicine and Unit INSERM 981, Institut Gustave Roussy, Villejuif, France

Background: OFS either in association with tamoxifen (TAM) or an aromatase inhibitor (AI) improved disease-free survival in young women ($\leq$35) and in those premenopausal women at higher risk of recurrence. However, its survival benefit remains largely unknown. In this study we characterize real-world use of adjuvant OFS from 2006 to 2015 and analyze its overall survival (OS) impact.

Methods: Retrospective observational cohort study of premenopausal women with Stage I-III hormone receptor-positive (HR+) breast cancer treated at one of 5 large centers in Portugal and diagnosed from 2006-2015. Study outcomes were use of OFS and OS. Pearson's Chi^2 test, logistic regression and Cox proportional hazards models were used.

Results: Of 1717 eligible patients, 304 (17.3%) were treated with adjuvant OFS, of which 271 (15.4%) in combination with TAM and 33 (1.9%) with AI. Baseline characteristics differed by subgroups: patients treated with OFS were younger, had larger, less differentiated (grade III 16% vs 24% for OFS), more frequently HER2 positive (14% vs. 19% for OFS) tumors, and underwent more frequently mastectomy (48% vs 57% for OFS), radiotherapy (25% vs 31% for OFS) and (neo)adjuvant chemotherapy (73% vs 79% for OFS). Adjuvant OFS was used at least since 2006 with an increase in its use from 2014 onward (16% vs 25% since 2014), particularly for the combination with AI (0.4% vs 8% since 2014). In a multivariate model, characteristics associated with use of OFS included younger age and year of diagnosis $\geq$2014 (both $p < 0.001$). Median time on OFS was 25 mo. (interquartile range 21-27). With a median follow-up of 38 mo. (IQR 20-66) and after controlling for age at diagnosis, staging, histologic grade, HER2 status, use of (neo)adjuvant CT, type of surgery and year of diagnosis, patients treated with OFS had a better OS when compared to those not treated with OFS (adjusted-HR 0.44, 95% CI 0.19-0.96; $p = 0.040$). Absolute benefit at year 5 was 2.1% (93.2 [95% CI 90.8 – 94.9) vs 95.3 [95% CI 89.7 – 97.9]).

Conclusions: In the real-world setting, a quarter of premenopausal women with early breast cancer were already treated with adjuvant OFS in 2014. After a median follow-up of 3 years, adjuvant OFS showed an OS benefit.

182P A phase II randomised study of Adjuvant hypo-fractionated radiotherapy with concurrent vs sequential letrozole in post-menopausal women with hormone receptor positive breast cancer: Report of pulmonary toxicity and cosmetic outcome

R. Upadhyay[1], D.N. Sharma[1], P. Julka[2], G.K. Rath[3]

[1]Radiation Oncology, All India Institute of Medical Sciences, New Delhi, India, [2]Medical Oncology, B.R. Ambedkar Institute Rotary Cancer Hospital (AIMS), New Delhi, India, [3]Radiation Oncology, B.R. Ambedkar Institute Rotary Cancer Hospital (AIMS), New Delhi, India

Background: The sequence of hormonal therapy with adjuvant radiation(RT) is debated because of anticipated morbidity. We conducted a phase II study to evaluate feasibility and efficacy of concurrent and sequential letrozole along-with hypo-fractionated RT(HFRT).

Methods: A total of 50 Post-menopausal women with hormone-receptor positive, Stage I-III Breast cancer received adjuvant HFRT 42.5Gy/16fr/3weeks and were randomly assigned to either concurrent (arm A) or sequential letrozole (arm B). Letrozole was started 3 weeks before RT in the concurrent, and 3 weeks after RT in sequential group. Pulmonary toxicity was assessed by clinical examination, chest x-ray, pulmonary function tests and HRCT chest (if indicated) at baseline, at one and six months(m) post RT. Cosmetic outcome was reported in both arms with six parameters (Table) at 6 m post RT.

Results: A total of 48 patients(pts) were followed up for 6 m (25 in Arm A and 23 in Arm B). None of the pts developed acute pulmonary toxicities. Mean (R) FeV1 and FVC values at baseline, 1 and 6 m post RT were 1.8 l (1.6-1.9) and 2.2 l(2.1-2.4), 1.79 l(1.5-1.9) and 2.1 l(1.9-2.4) and 1.85 l(1.6-2) and 2.2 l(2-2.4) respectively, and were comparable. FeV1 and FVC remained within 80 to 120% of the baseline values in 37 pts (20 Arm A vs 17 Arm B, $p = 0.5$). FeV1 and FVC were reduced by more than 80% at 6 m in 3 pts of Arm A and 5 pts in Arm B, ($p = 0.7$), while this was improved by over 120% in 5 pts (2 vs 3, $p = 1$). RTOG grade 2-3 radiation dermatitis was seen in 33 pts (15 vs 18, $p = 0.55$) while 5 pts had grade 4 toxicity (2 vs 3, $p = 1$). There was no treatment interruption because of toxicity.

Table: 182P

Cosmetic Outcome

	Mild change		Marked change	
	ARM A	ARM B	ARM A	ARM B
Breast Shrinkage	6	5	2	3
Breast Hardness	2	2	1	0
Breast Swelling	1	0	0	0
Change in Skin appearance	9	8	3	3
Self-breast assessment	14	13	5	5
Photographic breast assessment	15	15	3	2

Overall, 18 pts had excellent cosmesis (7 vs 11, $p = 0.4$) while 32 had good cosmesis. (18 vs 14, $p = 0.4$).

Conclusions: HFRT along-with concurrent Letrozole is well tolerated. However, patients are being followed to assess loco-regional disease control and late toxicities.

183P Intrinsic tumor features underlying clinical subtype discordance in early breast cancer

V. Kotoula[1], E. Giannoulatou[2], K. Papadopoulou[1], I. Tikas[1], K. Manousou[1], M. Bobos[1], S. Lakis[1], G. Lazaridis[1], I. Efstratiou[1], F. Zagouri[1], G. Pentheroudakis[1], H. Gogas[1], C. Christodoulou[1], A. Koutras[1], A. Psyrri[1], C. Papandreou[3], P. Papakostas[1], D. Bafaloukos[1], D. Pectasides[1], G. Fountzilas[1]

[1]Data Office, Hellenic Cooperative Oncology Group (HeCOG), Athens, Greece, [2]Computational Genomics Laboratory, Victor Chang Cardiac Research Institute, Darlinghurst, Australia, [3]Department of Medical Oncology, University Hospital of Larissa, Larissa, Greece

Background: Despite efforts for laboratory and method harmonization, discordant clinical subtypes for ER/PgR/HER2 that determine treatment selection for breast cancer patients in clinical practice, still pose a challenge.

Methods: We investigated the clinical relevance of discordant clinical subtypes and their clinicopathological and genotype characteristics (60-gene panel) in a series of 1427 breast cancer patients treated within 4 adjuvant trials (2 in the pre- and 2 in the post-trastuzumab era; recruitment period 1997 – 2012). Treatment decisions were based on local laboratory typing; all tumors were re-typed centrally. Disease-free survival was assessed.

Results: We observed 340 (23.8%) discordant tumors for ER/PgR and/or HER2, ranging from 30% in the oldest to 19% in the most recent trial ($p = 0.004$); Cohen's K was 0.512 for all subtypes, 0.583 for ER/PgR and 0.687 for HER2. ER/PgR discordance was associated with ER ($p < 0.001$) and PgR ($p = 0.017$) heterogeneity, basal phenotype, as well as higher grade, TILs and Ki67 labeling (all $p < 0.001$). HER2 discordant tumors had lower HER2 gene and CEN17 copies, and lower HER2/CEN17 ratios (all $p < 0.001$). Triple-positive tumors were rarely (0.5%) retyped as triple-negative (TN). ER/PgR discordant tumors had mutation patterns resembling HER2+ and TN, e.g., inversed TP53 and PIK3CA mutation prevalence ($p < 0.001$). Mutation clustering and phylogenetic analysis distinguished between concordant ER+/PgR+/HER2- tumors (73% of all tumors) and all other subtypes, with strong associations between ER±/PgR±/HER2- and ER+/PgR+/HER2 ± ($p < 0.001$). More relapses were noticed in patients with ER/PgR and HER2 negative-to-positive cases who did not receive hormonotherapy and trastuzumab (multivariate $p = 0.048$ and $p = 0.016$, respectively), but not in positive-to-negative cases.

Conclusions: Apart from technical considerations, clinical subtype discordance may reflect the genetic background of breast cancers, which appear to evolve by deviating from the ER+/PgR+ status. Development and reporting of phenotypic surrogates

predictive of discordance is needed for increasing diagnostic accuracy and appropriate treatment selection.

Valentín Maganto[12], M. Martin Jimenez[1]

[1]Medical Oncology, Hospital General Universitario Gregorio Marañon. Instituto de Investigación Sanitaria Gregorio Marañón (IiSGM), Madrid, Spain, [2]Medical Oncology, Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain, [3]Medical Oncology, Hospital Universitario Ramón y Cajal, Madrid, Spain, [4]Medical Oncology, Hospital Universitario Clínico San Carlos, Madrid, Spain, [5]Medical Oncology, Hospital Universitario La Paz, Madrid, Spain, [6]Medical Oncology, Hospital Universitario Príncipe de Asturias, Madrid, Spain, [7]Medical Oncology, Hospital Universitario Infanta Leonor, Madrid, Spain, [8]Medical Oncology, Hospital Universitario 12 de Octubre, Madrid, Spain, [9]Medical Oncology, Hospital Universitario Severo Ochoa, Madrid, Spain, [10]Medical Oncology, Hospital Universitario de Fuenlabrada, Madrid, Spain, [11]Medical Oncology, Hospital Universitario Fundación Alcorcón, Universidad Rey Juan Carlos, Madrid, Spain, [12]Former Regional Oncology Coordinator, Ministry of Health, Madrid, Spain

Background: Semiquantitative inmunohistochemical (IHC) expression of progesterone receptor (PR) adds prognostic value to the current IHC-based luminal A (LA) definition, such that patients (pts) with LA (Ki67 <14% and PR > 20%) tumors can be spared from adjuvant chemotherapy (CT). Oncotype Dx® (ODX) and MammaPrint® (MP) assays have been validated as predictors of CT benefit. This study assessed the distribution of recurrence risk in LA and LB breast tumors as defined by Ki67 and PR.

Methods: A retrospective analysis was performed in 889 T1-2, N0-Nmic, M0 tumors for which ODX or MP results and local pathology data were available. Ki67 was assessed by IHC (high ≥14% and low <14%). PR was assessed by semiquantitative IHC (PR low < or = 20%, high >20%). Histological grade was defined using the Nottingham grading system.

Results: Median age 54 years (18-77). All pts had HER2 negative tumors. Median tumor size 15 mm (2-88). Three hundred (33.7%) tumors were classified as LA and 589 (66.3%) as LB. Grade 1 tumors were higher in LA (27%) than in LB (19%) pts (p < 0,001). CT was first recommended in 137 pts (45.7%) with LA vs. 361 pts (61.3%) with LB tumors. ODX was performed in 432 (48.6%) pts and MP in 457 (51.4%). Recurrence risk distribution varied significantly between groups (p < 0.001). ODX: among LA pts, 71.4%, 25.7% and 2.9% had low, intermediate and high recurrence risk respectively; among LB pts respective values were 46.2%, 44.2% and 9.6%. MP: among LA pts, 81.2% and 18.8% had low and high recurrence risk, respectively; among LB pts respective values were 54.2% and 45.8% (Table). After test results CT was recommended to 61 pts (20.3%) with LA vs. 268 pts (45.5%) with LB tumors.

Table: 184P

Recurrence Risk (%) ODX (n = 432)	LA (n = 300)	LB (n = 589)
Low	71.4	46.2
Intermediate	25.7	44.2
High	2.9	9.6
MP (n = 457)		
Low	81.2	54.2
High	18.8	45.8

Conclusions: There is a wide distribution of recurrence risk results between LA and LB tumors defined by Ki67 and PR which confirms the important role of gene-expression assays in adjuvant decision making. Of note about half of pts with LB tumors had low recurrence risk indicating minimal benefit from adjuvant CT.

185P The first report of multicenter validation study of 95-gene classifier, a multi-gene prognostic assay of estrogen receptor positive and node negative breast cancer patients

T. Kinoshita[1], K. Aogi[2], M. Takahashi[3], K-I. Ito[4], T. Oba[4], N. Shiroma[5], K. Arihiro[5], F. Tsukamoto[6], S. Shiino[1], M. Yoshida[7], S. Ohsumi[2]

[1]Division of Breast Surgery, National Cancer Center Hospital, Tokyo, Japan, [2]Division of Breast Surgery, Shikoku Cancer Center, Matsuyama, Japan, [3]Department of Breast Surgery, Shikoku Cancer Center, Matsuyama, Japan, [4]Division of Breast, Endocrine & Respiratory Surgery, Shinshu University School of Medicine, Matsumoto, Japan, [5]Department of Anatomical Pathology, Hiroshima University Hospital, Hiroshima, Japan, [6]Department of Breast and Endocrine Surgery, Japan Community Health care Organization (JCHO) Osaka Hospital, Osaka, Japan, [7]Department of Pathology and Clinical Laboratories, National Cancer Center Hospital, Tokyo, Japan

Background: 95-Gene Classifier (95GC; Curebest™ 95GC Breast) is one of the multi-gene prognostic assays of estrogen receptor (ER) positive and node negative breast cancer patients, developed 95 gene-set without overlap with that used in another RT-PCR based product (Oncotype DX®). According to the original paper, the prognostic capability of 95GC has been shown even in the "intermediate" patients by microarray-based simulation model, "Recurrence Online", of above RT-PCR product. But still 95GC has been validated only using the data from single institute and public database. Here we report the result of the first multi-center validation study for this multi-gene assay.

Methods: ER-positive and T1-2/N0/M0 breast cancer patients who received only hormonal therapy, without chemotherapy, in adjuvant were enrolled retrospectively. For each patient, fresh frozen tissue was applied to the assay and the classification result of 95GC, "L" or "H", was used for the validation on 5 year recurrence free survival (5Y-RFS).

Results: We analyzed 75 eligible cases out of 150 enrolled, and found 47 patients classified as "L" showed 96.5% of 5Y-RFS (95%CI:89.5-98.9) while 28 patients of "H" showed 79.1% of 5Y-RFS (95%CI:63.8-88.5). There was a statistically significant difference between RFS of "L" and "H" groups by Log-Rank test (p = 0.0017). Other factors having significant association with 95GC were histological grade (p = 0.0012), "Recurrence Online" (p < 0.001) and "PAM50" (p < 0.001). And the patients of histological grade 2, of intermediate group by "Recurrence Online" and of Luminal B by "PAM50" could be classified into "L" and "H" by 95GC with different trends of RFS.

Conclusions: 95GC was well validated by this first multi-centered retrospective study on 5Y-RFS of ER-positive, node-negative patients who received only hormonal therapy in adjuvant. The result indicates the usefulness of this novel multi-gene assay, as it can classify target patients into 2 groups, "L" and "H", according to the prognosis of 5Y-RFS.

186P Breast cancer PAM50 subtypes: Correlation between RNA-Seq and multiplexed gene expression platforms

A.C. Picornell[1], I. Echavarria Diaz-Guardamino[2], E.L. Alvarez Castillo[1], S. Lopez-Tarruella Cobo[2], Y. Jerez[2], K. Hoadley[3], J. Parker[3], M. del Monte-Millán[2], R. Ramos Medina[1], J. Gayarre[1], I. Ocaña[1], M. Cebollero[4], T. Massarrah[2], F. Moreno Antón[5], J.A. García-Saenz[5], H. Gomez Moreno[6], A.I. Ballesteros Garcia[7], M. Ruiz Borrego[8], C. Perou[3], M. Martin Jimenez[2]

[1]Medical Oncology, Instituto de Investigación Sanitaria Gregorio Marañon (IiSGM), Madrid, Spain, [2]Medical Oncology, Hospital General Universitario Gregorio Marañón, Madrid, Spain, [3]Genetics, University of North Carolina - Chapel Hill, Chapel Hill, NC, USA, [4]Pathology, Hospital General Universitario Gregorio Marañon, Madrid, Spain, [5]Medical Oncology, Hospital Universitario Clínico San Carlos, Madrid, Spain, [6]Medical Oncology, Instituto Nacional de Enfermedades Neoplasicas - INEN, Lima, Peru, [7]Medical Oncology, Hospital Universitario de La Princesa, Madrid, Spain, [8]Oncología, Hospital Virgen del Rocío, Seville, Spain

Background: Gene expression signatures are a key tool for decision-making in breast cancer. In 2000 Perou *et al.* identified 4 intrinsic subtypes of breast cancer from gene expression data: LumA, LumB, HER2-enriched and Basal-like. These breast cancer subtypes yielded a superior prognostic impact than classical immunohistochemistry factors. From the initial intrinsic subtype, a 50-gene signature was developed for subtype assignment. PAM50 is being successfully used in multiplexed gene expression platforms such as NanoString nCounter®, which is the basis for the Prosigna® test. The

latter was approved for the risk of distant relapse estimation in postmenopausal women with hormone receptor+, node+/- early stage breast cancer patients; and is a daily-used tool assessing the need of adjuvant chemotherapy.

Methods: The analyses were performed in paraffin embedded tissues (FFPE) from 96 patients recruited in a multicenter, prospective, non-randomized triple negative breast cancer trial (NCT01560663). Pre-treatment core biopsies were performed following clinical practice guidelines and conserved as FFPE for further RNA extraction. PAM50 was performed on both NanoString nCounter® and RNA-Seq technologies. Subtype assignment was based on the nearest centroid classification following this procedure for both platforms.

Results: Subtype calling agreed on 96% of the cases (NanoString nCounter®/RNA-Seq discordances: 3 Basal-like/HER2-enriched and 1 HER2-enriched/LumA). Both the Spearman correlation to each of the centroids and the risk of recurrence (ROR) were above 0.89 in both platforms. Furthermore, the agreement on proliferation score reached up to 0.97. In addition, 82% of the individual PAM50 genes showed a correlation coefficient >0.80.

Conclusions: The RNA-Seq is a fundamental research tool for whole transcriptome analysis. However, it cannot be massively used in the daily clinical practice, due to its processing time requirements and economic costs. We demonstrated that the RNA-Seq technology provides similar results to the NanoString nCounter®, with the latter providing lower cost and more simplicity in its use.

187P Summary of head-to-head comparisons of patient (pt) risk classifications by the 21-gene recurrence score (RS) assay and other genomic assays for early breast cancer (EBC)

Z. Varga[1], P. Sinn[2], D. McCullough[3], A. Lau[3], M.C. Stöppler[3], F.L. Baehner[3], C. Chao[3], A. Seidman[4]

[1]Departement Pathologie und Molekularpathologie, Universitätsspital Zürich, Zurich, Switzerland, [2]Sektionsleiter Gynäkopathologie, Pathologisches Institut, Heidelberg, Germany, [3]Medical Affairs, Genomic Health, Inc., Redwood City, CA, USA, [4]Department of Medical Oncology, Memorial Sloan-Kettering Cancer Center, New York, NY, USA

Background: Many genomic assays that assess recurrence risk in EBC are prognostic, but they differ in risk group stratification, which can affect clinical utility. Prospective outcomes of > 50K pts treated based on 21-gene RS results have shown that pts with low RS EBC can safely forgo chemotherapy. Because of its extensive validation and wide clinical use, the RS assay is a common comparator in head-to-head studies with other assays.

Methods: Published/presented studies of the RS assay performed on same tumor samples with Breast Cancer Index (BCI), EndoPredict (EP) or EP+clinical features (EPclin), MammaPrint (MMP), and/or Prosigna (ROR) assays were reviewed. Study findings were summarized descriptively.

Results: 14 studies were found that compared the RS assay with BCI (1), BCI, EPclin, and ROR (1), EP/EPclin (2), MMP (6), and ROR (4). Overall discordance in risk stratification ranged from 43% to 66% between assays (Table). The RS assay classifies 12% of pts as high risk, compared with EP (63%), EPclin (48%), and MMP (46%), assays with low/high risk groups, and compared with BCI (16%) and ROR (33%), assays that, like the RS assay, use three risk groups.

Conclusions: The five most common genomic assays in clinical use for EBC risk-stratify pts differently and thus are not interchangeable. Of these, the RS assay classifies the smallest proportion of pts as high risk.

Background: Gene expression profiling is increasingly being used by clinicians to help determine whether or not to offer adjuvant chemotherapy. Oncotype DX is a 21 gene panel developed to predict the risk of tumour recurrence in patients with oestrogen receptor (ER) positive, HER2 negative breast cancer. NICE has recommended its use for patients at intermediate risk of recurrence, where this information would help clinicians to assess the potential benefit of chemotherapy versus endocrine therapy alone. Our aim was to see how oncologists are interpreting Oncotype DX tests in their clinical practice.

Methods: Data on patient and tumour characteristics (size, grade, ER/PR/HER2/nodal status), Oncotype DX recurrence score, treatment options offered and treatment outcomes were collected from 14 cancer centres across the UK.

Results: Of the 628 patients tested, 317 (50%) were in the low risk category (recurrence score <18), 224 (36%) were intermediate risk (score 18-30) and 81 (13%) were high risk (≥31). Chemotherapy was recommended for 52 patients in the low risk group, and was discussed/offered to a further 21. Chemotherapy was recommended for 91.8% of high risk patients. For patients with intermediate Oncotype scores, chemotherapy was

Table: 187P

Discordance[a] Between the RS Assay and Other Assays

	BCI			ROR			EP/EPclin			MMP		
Study[b]	1-level	2-level	Overall	1-level	2-level	Overall	1-level	2-level	Overall	1-level	2-level	Overall
Sestak 2016	37%	5%	42%									
Bartlett 2016[c]				40%	10%	50%						
Alvarado 2015				37%	10%	46%						
Dowsett 2013				41%	3%	43%						
Sinn 2017				45%	20%	66%						
Varga 2013							29%/29%	18%/21%	47%/50%			
Clough 2013										38%	19%	57%
Denduluri 2011										34%	25%	58%
Maroun 2015										31%	22%	53%
Shivers 2013										26%	19%	44%

a. Overall=any discordance in risk classification between the RS assay and other; 1-level=discordance of one risk category (low ↔ intermediate or intermediate ↔ high); 2-level=discordance of two risk categories (low ↔ high). b. Four studies lacked risk classification information appropriate for inclusion in this table. c. Study used nonstandard RS cutoffs for the RS vs. MMP comparison.

recommended for 101 patients (45.9%), the option of chemotherapy was discussed/offered to 31 (14.1%) and 88 (40.0%) were not offered chemotherapy. Overall, 160 patients (25.9%) received chemotherapy. Where oncologists recommended chemotherapy to patients (n = 231), 59.7% of patients went on to receive chemotherapy. Where oncologists had offered or discussed chemotherapy as an option (n = 58), 27.6% of patients went on to receive it. The most common regimes were FEC75x6 (23.9%), ECx6 (13.8%) and ECx4 (9.4%), with 13.2% of patients receiving 3rd generation chemotherapy (FEC/T, TC or EC/taxane); other regimes included ACx4, TCx4 and weekly paclitaxel.

Conclusions: Throughout the UK, about half of patients tested had low risk Oncotype scores and the majority (74.1%) of patients tested did not receive chemotherapy. The widest variation in clinical practice was observed in interpreting intermediate risk Oncotype results, and in the chemotherapy regimens offered.

189P Enhancing decision-making about adjuvant chemotherapy in ER+, HER2- early breast cancer (EBC) following EndoPredict testing

L. Fallowfield[1], S. May[1], L. Matthews[1], V. Jenkins[1], J. Mackay[2], A. Arbon[3], B. Hack[3], J. Hall[4], C. Harper-Wynne[5], S. Hinde[6], A. Moss[7], E. Thanopoulou[8], S. Westwell[9], D. Wlaszly[3], R. Simcock[3], G. Patel[3], D. Bloomfield[3]

[1]SHORE-C/BSMS, University of Sussex, Brighton, UK, [2]Oncology, University College London Cancer Institute, London, UK, [3]Oncology, Brighton&Sussex University Hospitals, Brighton, UK, [4]Oncology, Dartford & Gravesham NHS Trust, Dartford, UK, [5]Oncology, Kent Oncology Centre, Maidstone, UK, [6]Centre for Health Economics, University of York, York, UK, [7]Oncology, Western Sussex Hospitals NHS Foundation, Worthing, UK, [8]Oncology, Surrey and Sussex HEalthcare NHS Trust, Redhill, UK, [9]Oncology, East Sussex Healthcare NHS Trust, Eastbourne, UK

Background: Chemotherapy side-effects can be substantial. There is increasing recognition that with surgery, radiotherapy and hormone treatment (tmt), many patients (pts) derive no benefit from chemotherapy and experience only iatrogenic harm. Gene expression profiling tests can help refine recurrence risk and likely chemotherapy benefit. EndoPredict is a multigene test which includes clinico-pathologic parameters to produce an EPclin score classifying risks of distant recurrence as low or high for ER+ve HER_2–ve pts treated with adjuvant endocrine tmt alone. We compared tmt decisions pre and post EndoPredict test results, pts' anxiety, decisional conflict and oncologists' confidence about decisions made.

Methods: 14 oncologists in 7 UK hospitals saw 149 pts judged to have equivocal indications for chemotherapy. Pts and oncologists discussed provisional tmt decisions based on usual prognostic factors. These decisions were reconsidered when EPclin results were available. Pre and post-test pts completed Spielberger's State/Trait Anxiety inventory (STAI) and a decision conflict scale (DCS). Oncologists additionally recorded:- basic clinical details, their agreement with, and confidence about tmt decisions (endocrine (E) therapy +/- chemotherapy(C)).

Results: 66.7% pts with an initial E alone decision and a high risk result upgraded to E+C. 9.4% pts with initial E+C decisions and high risk results down-graded to E alone. None of 46 pts initially favouring E alone who were low risk changed decisions. 82.8% who initially wanted E+C and had low risk scores downgraded to E alone. Endopredict results increased oncologists' confidence (8% 'strongly agreed' pre-test, 50% post-test). Oncologists neither agreeing nor disagreeing with decisions fell (24% to 5%). Anxiety was stable in pts with unchanged decisions. Pts whose tmt was downgraded had significantly lower anxiety scores ($p < 0.01$); those whose tmt was upgraded had increased scores ($p < 0.001$). Likewise overall uncertainty on DCS fell post-test ($p < 0.023$).

Conclusions: EndoPredict scores increased oncologists' and pts' decision-making confidence, generally improved the matching of risk with therapy decisions.

190P Circulating ESR1 mutations at the end of aromatase inhibitor adjuvant treatment and after relapse in breast cancer patients

V. Allouchery[1], L. Beaussire[2], A. Perdrix[1], D. Sefrioui[1], L. Augusto[3], C. Guillemet[1], N. Sarafan-Vasseur[2], F. Di Fiore[4], F. Clatot[4]

[1]Medical oncology, Centre Henri Becquerel, Rouen, France, [2]Institute for Biomedical Research and Innovation, Inserm U1245, University of Rouen, Rouen, France, [3]Medical oncology, Henri Becquerel, Rouen, France, [4]Oncologie Médicale, Centre Henri Becquerel, Rouen, France

Background: Detection of *ESR1* circulating mutations is associated with acquired resistance to aromatase inhibitor (AI) in metastatic breast cancer. Until now, the presence of *ESR1* circulating mutations at the end of the adjuvant treatment by AI in early breast cancer had never been clearly established. In this context, the aim of the present study was to evaluate the *ESR1* circulating mutation frequency at the end of adjuvant treatment in patients with a subsequent local or metastatic relapse.

Methods: This monocentric retrospective study was based on available stored plasmas and included all early breast cancer patients who completed at least 2 years of AI adjuvant treatment and experienced a documented relapse at least 6 months after the end of their treatment. *ESR1* circulating mutations (D538G, Y537S/N/C) were detected by droplet digital PCR in plasma samples taken both at the end of adjuvant treatment and on AI progression in patients re-exposed to AI during the metastatic phase.

Results: A total of 39 patients were included, with a median adjuvant AI exposure of 60 months (range 41-85). One patient (2.6%) had a local relapse only, while all the others (97.4%) had a metastatic relapse during follow-up. Median delay between the end of adjuvant treatment and relapse was 25 months (range 6-71). No ESR1 circulating mutation was detectable at the end of AI adjuvant therapy. In contrast, among the 25 patients (64%) who progressed on AI during the metastatic setting, 17 plasma samples were available and 7 patients (41,2%) had a detectable mutation.

Conclusions: Our results highlighted that there is no emergence of circulating *ESR1* mutation at the end of an AI-based adjuvant treatment in hormone receptor positive breast cancer patients. In contrast, and as expected, we showed that re-exposure to AI in the metastatic setting induced circulating mutation detection in a significant fraction of the patients. Our present findings point out the low interest in *ESR1* circulating mutation detection during the adjuvant setting, even for patients that will relapse.

191P Pathological proliferation score to predict genomic risk categories in early stage breast cancer

A. Bulbul[1], D. Tsao-Wei[2], E.A. Mino[1], A. Mustafa[3], S. Rashad[4], H. Abboud[5], S. Chouial[1], T. Braik[1], K. Masoud[1], D. Tripathy[6]

[1]Hematology/Oncology, Kymera Independent Physicians, Carlsbad, NM, USA, [2]Biostatistics, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA, USA, [3]Anesthesiology, Acharya Shri Chander College of Medical Sciences and Hospital, Jammu, India, [4]Medicine, All Saints University of Medicine, Roseau, Dominica, [5]Medicine, Windsor University, Monee, IL, USA, [6]Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA

Background: Five of the 16 cancer-related genes used to calculate the Recurrence score (RS) are proliferative genes. Appropriate utilization of an expensive test is important especially in areas of limited resources. A relatively inexpensive 'Pathological Proliferative score' (PrS) of a tumor may help group patients in risk categories correlating with the RS.

Methods: We retrospectively studied 205 patients with Lymph node negative, hormone receptor (HR) positive, HER2 negative status (ODX candidates) between1990-2015 treated across three rural community oncology practices. Proliferation score was calculated by combining tumor grade, visual mitotic score and Ki67 immunostaining (on a scale of 1-3, lowest score of 3; highest score of 9). Log-rank test was used for survival analysis.

Results: PrS correlated with ODX risk recurrence ($p < 0.001$, Fischer's Exact test) [Table]. PrS predicted FFP ($p = 0.014$) at 10 years with PrS (3-4) 96%±2%, PrS (5-7) 91%±5% and PrS > (7-9) 75%±1%. It did not predict PFS($p = 0.77$), OS($p = 0.84$). Type of adjuvant treatment or none did not affect Low Prs(3-4) 10 yr PFS ($p = 0.18$ and OS ($p = 0.33$). Int/High PrS (5-9) showed benefit with adjuvant hormonal therapy compared to none at 10-year OS ($p = <0.001$), PFS ($p = 0.002$) and FFP ($p = 0.003$).

Table: 191P Correlation of ODX with PrS

	Proliferative Score (n = 190)			
	3 – 4 (n = 119)	5 – 6 (n = 37)	7 – 9 (n = 40)	p-value*
Genomic Risk				<0.001
Low	41 (87%)	11 (58%)	2 (11%)	
Intermedium	6 (13%)	7 (37%)	1 (5%)	
High	0 (0%)	1 (5%)	16 (84%)	
Unknown	72	18	21	
Genomic Risk				<0.001
Low	41 (87%)	11 (58%)	2 (11%)	
Intermedium/High	6 (13%)	8 (42%)	17 (89%)	
Unknown	72	18	21	

*p-value based on Fisher's Exact test

The 10 yr OS (p = 0.75), PFS (0.76) and FFP (p = 0.88) was not influenced by addition of adjuvant chemotherapy.

Conclusions: PrS which may represent an inexpensive screening approach to identify patients with a low ODX RS that have excellent outcomes despite the type of adjuvant treatment. ODX testing is unlikely to re-categorize them. Higher (5-9) PrS was not predictive of chemotherapy benefit, unlike high ODX. Lack of standardization of Ki67 staining, retrospective nature of the study while important should be tested in an expanded and prospective setting.

192P Population sizes of patients (pts) with node negative (N0), HR+, HER2− primary breast cancer (BC), using standard and TAILORx 21-gene recurrence score (RS) cut-off values (COV)

J-U. Blohmer[1], M. Verrill[2], C. Fortmann[3], C. Chao[3], J. Gligorov[4]

[1]Klinik für Gynäkologie mit Brustzentrum, Charité-Universitätsmedizin Berlin, Berlin, Germany, [2]Northern Institute for Cancer Research, Newcastle University, Newcastle Upon Tyne, UK, [3]Medical Affairs, Genomic Health, Inc., Redwood City, CA, USA, [4]Department of Medical Oncology, APHP, Hôpital Tenon, Paris, France

Background: Whether to use adjuvant chemotherapy (CT) is a crucial decision for pts with HR+, HER2− primary BC. The 21-gene Recurrence Score® (RS) assay is validated to predict adjuvant CT benefit and risk of recurrence, using standard RS COV of < 18, 18-30, and ≥31. Of ∼59K N0/N1 pts from two real-world registries, those with RS < 18 (>50% of total) largely treated without CT had favorable 5-y outcomes. The prospective TAILORx and PlanB clinical trials showed excellent 5-y outcomes for RS < 11 and RS ≤ 11 subgroups, respectively, treated without CT. The AJCC now recommends use of RS < 11 to down-stage to 1A. The capacity to generalize regional study outcomes globally requires first that RS subgroup sizes are geographically consistent. Here, we analyze RS subgroup sizes across geographical regions using standard and TAILORx COV.

Methods: Pts with N0, HR+, HER− primary BC and RS results from 2004 to April 2017 were included (data from Genomic Health). Subgroup sizes were determined for RS < 11, 11-17, 18-25, 26-30, and ≥31 in the US, Germany, the UK, France, and the rest of the world (RoW).

Results: Of 609,247 unique RS records analyzed, 513,035 were from the US, 29,248 from EU countries, and 66,964 from RoW. The relative population sizes of RS subgroups were highly consistent across geographical regions. Deviations in percentages for each RS range were within ±3% (Table). Across all regions, >50% of pts had RS < 18.

Conclusions: Our analysis revealed highly consistent RS subgroup classifications across geographic regions, mirroring observations from registry studies, suggesting that tumor biology as characterized by RS results does not vary by geography. Our findings therefore support the generalizability of outcomes-study results using standard or custom COV across geographic regions.

193P Oncotype DX score, menopausal status and body mass index

S. Picardo[1], J. Sui[2], M. Greally[3], B. Woulfe[1], L. Prior[4], L. Corrigan[5], C. O'Leary[5], W. Mullally[2], J. Walshe[4], J. McCaffrey[6], M. O'Connor[5], D. O'Mahony[2], L. Coate[7], R. Gupta[8], S. O'Reilly[9]

[1]Department of Medical Oncology, University Hospital Limerick, Limerick, Ireland, [2]Department of Medical Oncology, Cork University Hospital, Cork, Ireland, [3]Department of Medical Oncology, Mater Misericordiae University Hospital, Dublin, Ireland, [4]Department of Medical Oncology, St Vincent's University Hospital, Dublin, Ireland, [5]Medical Oncology, University Hospital Waterford, Waterford, Ireland, [6]Medical Oncology, Mater Misericordiae University Hospital, University College Dublin (UCD) & Cancer Trials Ireland, Dublin, Ireland, [7]Department of Medical Oncology, University Hospital Limerick, Mid Western Cancer Centre, Limerick, Ireland, [8]Department of Medical Oncology, Mid-Western Regional Hospital, Limerick, Ireland, [9]Medical oncology, Cork University Hospital, Cork, Ireland

Background: The Oncotype DX assay uses expression of 21 genes to predict the risk of distant disease recurrence in patients with oestrogen receptor positive Her2 negative breast cancer. It has been demonstrated that increased intra-tumoural inflammation is associated with higher Oncotype score. An inflammatory milieu within the breast is associated with more aggressive histological cancer subtypes, and also with obesity, which is recognised as a risk factor for breast cancer. The association between obesity and breast cancer is higher in post-menopausal than pre-menopausal women. Therefore this study aimed to investigate whether there is a correlation between Oncotype score, menopausal status and obesity.

Methods: All patients with Oncotype assays performed between 2008 and 2016 in several centres in Ireland were identified. Data was retrospectively collected on weight, body mass index (BMI), menopausal status and Oncotype scores, including oestrogen (ER) and progesterone (PR) scores. Statistical analysis assessed correlation between Oncotype scores and these factors.

Results: Analysis was performed on 269 patients from a single centre with early stage breast cancer. Median age was 53.4 years and the majority of patients (58%) were post-menopausal at diagnosis. Patients who had a BMI less than 25 (normal weight) had significantly lower Oncotype score than those with BMI greater than 25 (overweight/obese) (p < 0.05). The Oncotype ER and PR scores were similar in normal weight and overweight patients, as were tumour size and grade. Post-menopausal patients had higher Oncotype scores than pre-menopausal patients (p < 0.001), with higher ER scores (p < 0.001) and lower PR scores (p < 0.001). On multivariate analysis, menopausal status remained significant as a predictor of Oncotype score. Complete analysis of an additional 600 patients will be performed.

Conclusions: Oncotype score is higher in overweight patients with early stage node-negative breast cancer. This difference appears to be independent of ER and PR scores and correlates with menopausal status. This retrospective study is the first to suggest that the body mass index and menopausal status of patients with early stage breast cancer may influence the Oncotype DX recurrence score and analysis of a further cohort of patients is ongoing.

194P Comparisons of tumor-infiltrating lymphocytes and 21-gene recurrence score in ER-positive/HER2-negative breast cancer

S.G. Ahn[1], Y.J. Cha[2], C. Yoon[1], S.J. Bae[1], J. Kim[3], J. Jeong[1]

[1]Surgery, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Republic of Korea, [2]Pathology, Gangnam Severance Hospital, Seoul, Republic of Korea, [3]Surgery, Kangnam Mizmedi Hospital, Seoul, Republic of Korea

Background: Recent meta-analysis showed that tumors with high tumor-infiltrating lymphocyte (TIL) have a higher probability of pathologic complete response even in Luminal/HER2-negative breast cancer. Also, the 21-gene recurrence score (RS) predicts the clinical benefit of chemotherapy for ER-positive/HER2-negative women. We compared two markers in those cancer.

Methods: In ER-positive/HER2-negative patients treated with primary surgery, the RS (Oncotype DX® Breast Cancer Assay; Genomic Health, Inc., USA) was obtained. We evaluated TIL in H&E slides of surgical specimens by standardized methodology proposed by the international TIL-working group. In 198 women, the percentage of stromal TIL was successfully assessed. In accordance with the recent meta-analysis, the degree of TILs were categorized as high ($>=$60%), intermediate (11-59%), and low ($<=$10%).

Results: Ninety-seven (49.0%), 88 (44.4%), and 13 patients (6.6%) had low, intermediate, and high TILs, respectively. There is a significant but weak correlation between continuous RS and continuous TIL (Pearson's R = 0.201, P = 0.004). The average of continuous RS was significantly highest in the high TIL tumors (17.8±10.7 in low TIL, 19.4±8.7 in intermediate TIL, and 26.2±8.2 in high TIL; P = 0.014). Whereas the average of continuous TILs was compared according to categorized RS, it was significantly higher in the intermediate RS or the high RS tumors (15.4±13.2 in low RS, 26.6±13.6 in intermediate RS, and 19.8±19.2 in high RS; P < 0.001). When we compared categorized RS and TIL, we found that the rates of the high TIL-tumors was significantly higher in the intermediate RS or the high RS (1.0% for low RS tumors, 12.5% for intermediate RS tumors, and 10.0% for high RS tumors; P = 0.007).

Conclusions: We found that tumors with high TIL tend to have a higher RS in ER-positive/HER2-negative breast cancer. We also noted that the rate of high-TIL tumors was significantly higher in the intermediate-RS tumors as well as in the high-RS tumors. Clinically, our findings suggest that TIL count might be referred in decision-making of chemotherapy in the intermediate RS-patients.

Table: 194P

	Low or Intermediate TIL	High TIL	P-vlaue
Low RS (N = 98)	97 (99%)	1 (1%)	0.007
Intermediate RS (N = 80)	70 (88%)	10 (12%)	
High RS (N = 20)	18 (90%)	2 (10%)

195P The 70-gene signature in node positive breast cancer: 10-year follow-up of the observational RASTER study

S.B. Vliek[1], V. Retel[2], C. Drukker[3], J.M. Bueno-De-Mesquita[1], E. Rutgers[3], H. van Tinteren[4], M.J. van de Vijver[5], J. Wesseling[6], W. van Harten[2], S.C. Linn[7]

[1]Molecular Pathology, The Netherlands Cancer Institute, Amsterdam, Netherlands, [2]Health Technology Assessment, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, [3]Surgical Oncology, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, [4]Biometrics, The Netherlands Cancer Institute, Amsterdam, Netherlands, [5]Pathology, Academic Medical Center, Amsterdam, Netherlands, [6]Pathology, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, [7]Medical Oncology, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands

Background: In early stage breast cancer patients, with axillary lymph node metastasis, the 70-gene signature, MammaPrint® (MP) identifies patients with a High or Low Risk of distant breast cancer (BC) recurrence. For MP Low Risk (G(enomic)-low) in patients with up to 3 positive lymph nodes (N1-3), the MINDACT trial (Cardoso, NEJM 2016) showed that it might be safe to forgo adjuvant chemotherapy. Here we evaluated the prognostic value of MP at 10 years follow-up in patients with lymph node positive early stage BC.

Methods: Between 2004 and 2006 812 women with early stage BC participated in the observational RASTER trial (Bueno de Mesquita, Lancet Oncol, 2007). 181 patients were node positive and not included in the primary analysis, 176 of them gave consent for future research. On 164 tumor samples (FFPE) MP was performed retrospectively. Survival data was collected and samples were allocated to clinical high (C-high) or C-low risk as used in MINDACT. Patients with over 3 axillary lymph node metastases (N4+) were all considered C-high. 10-year distant-recurrence-free-interval (DRFI) was compared between subgroups based on the MP and clinical assessment.

Results: In 3 patients the clinical assesment could not be determined. Over 95% of patients received chemotherapy, 82.9% (136/164) of tumors were ER-positive and 18.3% (30/164) of patients had N4+. MP identified 47% (n = 77/164) as Low Risk, including 16,9% (13/77) with N4+. 10-year DRFI in patients N1-3 and G-Low or G-High was 94.9% and 80.7% respectively (HR 4.7; 95%CI 1.3-16.2). With the clinical assessment 13.7% (n = 22/161) were low risk, only one was diagnosed with distant BC recurrence. 10-years DRFI was 94.4% in C-low and 85.8% in C-high (HR 3.7 95%CI 0.5-28.5). In N4+ 10-years DRFI was 69.7%. Combining the clinical assessment with MP risk assessment in patients N1-3 the 10-years DRFI in clinical high risk patients was 95.2% for G-Low (n = 44) and 79.6% for G-High (n = 65) (HR 4.83 95%CI 1.1-21.4).

Conclusions: We again confirm the prognostic value of Mammaprintin BC patients with axillary lymph node involvement after 10 years follow up. In N1-3 patients with clinical high risk, MP can identify a subgroup with excellent prognosis after standard adjuvant systemic therapy.

196P Higher expression of estrogen response genes in the primary tumor is associated with a greater risk for late recurrence in patients with ER+/HER2-breast cancer

R.D. Bense, E.G.E. de Vries, C.P. Schröder, R.S.N. Fehrmann

Department of Medical Oncology, University Medical Center Groningen, Groningen, Netherlands

Background: In patients with ER+ breast cancer, 50% of recurrences occur > 5 years after diagnosis (*i.e.* late recurrence). Clinical trials report contradicting results on the effect of extended endocrine therapy > 5 years to reduce late recurrence risk. Using publically available breast cancer gene expression profiles, we aimed to gain insight into the biology that increases the risk for late recurrences.

Methods: Gene expression profiles of primary ER+/HER2- tumors of breast cancer patients were collected with disease-free survival (DFS) data, defined as time of diagnosis to local recurrence or distant metastasis. We defined (i) a group containing all patients (n = 2,231), (ii) a group that received 5 years of endocrine therapy only (n = 591), and (iii) a group that received no systemic therapy (n = 497). For each group, genes were ranked on their association with DFS as determined by multivariate Cox regression with age, tumor size, grade, lymph node status, and therapy as covariates. Gene set enrichment analysis (GSEA) was performed on these gene lists with the Hallmark collection from the Molecular Signatures Database. Within each group, associations with early recurrence were studied in all patients with censoring at 5 years if no event occurred < 5 years after diagnosis (set I). To study associations with late recurrence, a second set was defined that contained only patients with a follow-up ≥ 5 years and no event < 5 years after diagnosis (set II).

Results: Within all patients and the group that received 5 years of endocrine treatment only, higher expression of genes belonging to the Hallmark 'estrogen response late' was associated with longer DFS in set I and shorter DFS in set II. This Hallmark contains estrogen responsive genes identified in estradiol treated ER+ breast cancer cell lines. However, in patients who received no systemic treatment, higher expression of these genes was associated with shorter DFS in both set I and II.

Conclusions: Higher expression of estrogen response genes is associated with a greater risk for late recurrence in patients with ER+/HER2- breast cancer. Potentially, patients with ER+ tumors with high expression of these genes might benefit most from extended endocrine therapy.

197P Understanding BRCA1 and BRCA2 mutated breast cancer cases in Romania: First report on founder mutations in Romanians

A. Eniu[1], L. Pop[2], A. Stoian[1], E. Dronca[2], R. Matei[1], M. Ligtenberg[3], H. Ouchene[3], A. Onisim[1], O. Rotaru[1], R. Eniu[4], N. Antone[1]

[1]Department of Breast Tumors, Cancer Institute Ion Chiricuta, Cluj-Napoca, Romania, [2]Research Center for Functional Genomics, Biomedicine and Translational Medicine, Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania, [3]Department of Human Genetics, Radboud University Medical Centre, Nijmegen, Netherlands, [4]School of Medicine, Cardiff University, Cardiff, UK

Background: First systematic analysis of BRCA 1(B1) or BRCA2(B2) mutations in high-risk Romanian breast cancer patients (pts) aiming at defining founder mutations.

Methods: This prospective study evaluated the germline B1/B2 mutations in 250 high-risk breast cancer pts tested between 02.2015-12.2016 at IOCN. Inclusion criteria selected pts diagnosed with triple negative breast cancer under the age of 50, or having conventional family history criteria. All pts signed an informed consent. B1/B2 testing was performed using an AmpliSeq-based sequencing analysis, on the Ion Torrent Personal Genome Machine at RCFG. Pathogenic mutations were validated using Sanger technology. MLPA was performed for all pts.

Results: Of the 250 pts with breast cancer, 44 (17.6%) carried pathogenic mutations, 29 pts (11.6%) in B1 and 15 (6%)in B2, while 18 patients (7.2%) carried a Variant of Uncertain Significance (VUS). Patient features analysis confirmed the prevalence of younger age, higher grade, hormone receptor negative and Her2 negative status among mutated patients (data not shown). Out of the 16 distinct deleterious mutations identified, 7 (43.75%) occurred in B1 and 9 (56.25%) in B2. The founder mutations identified in B1 gene were: c.5329_5330insC (c.5266dupC) 11 pts (37.93%), c.3607C>T 9 pts (31.03%) and c.181T>G 4 pts (13.79%). Other B1 mutations where c.1687C>T 2 pts (6.89%), and c.4218delG (3.44%), c.212 + 1G>T (3.44%), c.68_69delAG (3.44%) in one patient respectively. For B2 gene, c.9371A>T (46.66%) was identified as founder mutation (7 pts, 46.66%). Other mutations were found each in one patient (6.66%): c.1528G>T, c.4022C>G, c.7007G>A, c.8695C>T, c.9253delA, c.8680C>T, c.8755-1G>A, c.8695C>T. Of the founder mutations identified, two (c.3607C>T and c.9371A>T) have not been previously identified as founder mutations in any Eastern European country.

Conclusions: This prospective study presents the first extensive results of germline B1/B2 mutations in Romanian high-risk breast cancer pts. Our results indicate that at least four recurrent B1/B2 mutations qualify as founder mutations; two being newly identified as carrying a founder effect. ClinicalTrials.gov Identifier: NCT02317120.

Clinical trial identification: NCT02317120

198P The prevalence of CD146 expression in breast cancer subtypes and its relation to outcome

I.E. de Kruijff[1], A.M. Timmermans[1], M.A. den Bakker[2], A.M.A.C. Trapman[1], R. Foekens[1], E. Oomen-De Hoop[1], M. Smid[1], A. TjonA Fat - Hollestelle[1], C.H.M. van Deurzen[2], M.E. Meijer - van Gelder[1], J.A. Foekens[1], J.W.M. Martens[1], S. Sleijfer[1]

[1]Department of Medical Oncology and Cancer Genomics Netherlands, Erasmus MC Cancer Institute, Rotterdam, Netherlands, [2]Department of Pathology, Erasmus MC Cancer Institute, Rotterdam, Netherlands

Background: CD146 has several putative (patho)physiological roles in breast cancer. The most prominent is its involvement in the induction of epithelial-to-mesenchymal transition, which might have an effect on cancer phenotype and aggressiveness. Here, we investigated the prevalence of CD146 expression and its prognostic role in breast cancer subtypes.

Methods: In total, 1,025 breast cancer patients were available for this retrospective study. From all patients, formalin-fixed paraffin-embedded primary breast cancer tissue was collected and embedded in tissue microarrays, which were stained for CD146. CD146 expression was defined as > 1% of the tumor cells showing CD146 membrane staining. Clinical data were available from all patients (median follow up 118 months, range 4-120). For subtype analysis the Pearson chi-square test was used and the Cox proportional hazards model for survival analyses. Only patients who were lymph node negative and did not receive (neo)adjuvant systemic treatment were included in the survival analyses (n = 551).

Results: 113 (11%) out of 1,025 tumors showed CD146 expression. Of these, 43% of the tumors had > 50% of the tumor cells showing CD146 membrane staining. From the molecular subtypes, CD146 positive tumors are often of the triple negative subtype (76 out of 119 (64%), $p < 0.001$) and histologically of the medullary type (11 out of 23 (48%), $p < 0.001$). In univariable analysis, CD146 was a prognostic factor for both poor metastasis-free survival (MFS) and overall survival (OS) (respectively HR 1.65, 95% CI 1.02-2.66, $p = 0.041$ and HR 1.66, 95% CI 1.03-2.69, $p = 0.037$). When correcting for the traditional prognostic factors (including age, tumor size and grade, ER, PR and HER2) in multivariable analysis, CD146 was not an independent prognostic factor for MFS and OS (respectively HR 1.63, 95% CI 0.93-2.87, $p = 0.088$ and HR 1.46, 95% CI 0.82-2.61, $p = 0.197$).

Conclusions: CD146 protein expression is present in 11% of the primary breast cancer tumors and is most prevalent in the triple negative and medullary subtypes. CD146 is a prognostic factor for MFS and OS in breast cancer patients, but it is not independent of the traditional prognostic factors. Its potential impact on outcome to systemic treatment such as endocrine therapy, remains to be established.

199P Neutrophil-to-lymphocyte and lymphocyte-to-monocyte ratios in breast cancer

L. Gerratana[1], D. Basile[1], S. Zago[2], M.G. Vitale[1], G. Pelizzari[1], M. Bonotto[1], C. Bozza[1], M. Bartoletti[1], V. Fanotto[1], C. Lisanti[1], M. Cinausero[1], S. Barban[1], M. Lera[1], I. Venuti[1], M. Mansutti[3], A.M. Minisini[3], G. Fasola[3], F. Curcio[2]

[1]School of Medical Oncology, Department of Medicine, University of Udine, Udine, Italy, [2]Clinical Pathology Institute, University Hospital of Udine, Udine, Italy, [3]Department of Oncology, University Hospital of Udine, Udine, Italy

Background: Immunity plays a pivotal role in cancer progression and prognosis. A high neutrophil-to-lymphocite ratio (NLR) or a low lymphocyte-to-monocyte ratio (LMR) are respectively associated with systemic inflammation and immune suppression and have been associated with a poor outcome. Aim of this study is to further investigate the interaction between the immune system and breast cancer (BC) through the NLR and LMR.

Methods: This retrospective study analyzed a consecutive cohort of 657 patients (pts) with a diagnosis of pT1 BC, without restrictions regarding lymph node status (T1BC), or metastatic BC (MBC) treated between 2004 and 2017 at the Department of Oncology of Udine (Italy). Differences in terms of NLR and LMR among the two cohorts and between clinico-pathological characteristics in the T1BC subgroup were explored through the Kruskal-Wallis test. The prognostic impact in terms of OS in the T1BC population was investigated through uni- and multivariate Cox regression.

Results: Both NLR and LMR were significantly different between the T1BC and the MBC cohorts. In particular, pts with T1BC had a higher median LMR (3.9 vs 2.9; $P = 0.0001$) and lower NLR (2 vs 2.7; $P = 0.0001$). After stratification according to molecular profile, T1BC and MBC cohorts of Luminal B-like subtype were significantly different in terms of both LMR (4.2 vs 3; $P = 0.0001$) and NLR (2 vs 2.5; $P = 0.0001$). In triple negative subtype, the difference between TB1C and MBC was observed for NLR (1.9 vs 3.2; $P = 0.0272$) only. On the other hand, no differences between TB1C and MBC were highlighted for the other subtypes. When focusing on the clinico-pathological characteristics of the T1BC cohort, LMR was associated with progesterone receptor (PR) expression ($P = 0.0261$) and marginally with the estrogen receptor (ER) expression, while NLR with tumor diameter ($P = 0.0240$) and marginally with grading. Furthermore, among T1BC pts, NLR had no prognostic impact in terms of OS, while LMR was associated with a better outcome also when corrected for ER, PR and HER2 status (HR 0.44, 95%CI 0.28 - 0.71, $P = 0.001$).

Conclusions: These results suggest a role for systemic inflammation and immune-suppression in breast cancer, especially in the triple negative and luminal B-like subtypes.

200P Vitamin D as a prognostic factor in triple negative early breast cancer

S. Morales[1], A. Gasol Cudos[2], A. Novell Alvarez[2], F. Vilardell Villellas[2], M.J. Panades Siurana[2], C. Canosa Morales[2], J. Mele Olive[2], E. Iglesias Martinez[2]

[1]Breast Oncology, Hospital Universitari Arnau de Vilanova de Lleida, Alpicat, Spain, [2]Breast Oncology, Hospital Universitari Arnau de Vilanova de Lleida, Lleida, Spain

Background: Triple negative breast cancer remains without a target therapy. Interventions that could improve pathological complete response (pCR) rates are required. Metabolits of vitamin D could be involved in chemotherapy response.

Methods: A series of 147 patients with early or locally advanced triple negative breast cancers was retrospectively analyzed from 2007 to 2016. Patients from 2015 to 2016 period were supplemented with vitamin D and calcium (880UI/1000mg). Analysis of clinicopathological, immune variables and vitamin D pathway were correlated to pCR.

Results: Median age was 53, median tumor size 30mm, 48% had nodal involvement, and median ki67 expression was of 70%. Androgen receptor was expressed in 28% of tumors analyzed, EGFR in 89%, CK5/6 in 63%. Mean stromal T lymphocytes infiltrates (sTILS) was of 28%, mean PDL1 expression of 128, mean 53BP1 expression of 125, and mean VDRnuc expression of 132. pCR rate was of 40%, and within patients with vitamin D supplementation was 64% (16/25). Only VDRnuc expression was associated with pCR ($p = 0.047$) in the univariate and multivariate analysis. Patients with high expression of VDRnuc in tumor had no evidence of relapse ($p = 0.024$), with similar curves than those who achieve pCR ($p = 0.000$).

Conclusions: VDRnuc expression is a strong predictive ($p = 0.047$ with pCR) and prognostic ($p = 0.024$ with relapse) in triple negative breast cancer. Role of supplementation needs to be tested if it could improve VDRnuc levels; whereas in our series patients with supplementation had better pCR rates.

201P CDK12: New breast and ovarian cancer predisposition gene in Tatar population?

E. Shagimardanova[1], O. Brovkina[2], M. Gordiev[3], R. Enikeev[4], L. Shigapova[1], D. Khodyrev[2], O. Gusev[1], A. Kedrova[2], V. Kosiy[2], A. Nikitin[2]

[1]Extreme Biology laboratory, Kazan Volga Region Federal University, Kazan, Russian Federation, [2]Molecular genetic laboratory, Federal Research and Clinical Center, FMBA of Russia, Moscow, Russian Federation, [3]Laboratory, Tatarstan Cancer Center, Kazan, Russian Federation, [4]Chemotherapy, Kazan Clinical Oncology Center, Kazan, Russian Federation

Background: The development of hereditary ovarian and breast cancer (OC/BC) is often caused by genetic defects in the DNA repair system. However, the diagnostics in most medical centers of Russia includes PCR-based identification only the eight common mutations in BRCA1/2 for the Slavic population. Previously we established that patients of the Tatar population with OC/BC did not possess most of Slavic mutation and a significant part of the predisposition is due to other mutations in the genes of the homologous recombination (HR) system. The aim of this work is the analysis of the germline mutations in the HR genes.

Methods: The DNA from 175 blood samples from patients of the Volga District with hereditary OC/BC were analyzed by targeted NGS (Roche NimbleGen, Illumina MiSeq), the comparison groups included blood samples from patients of Slavic origin.

Results: 62% of the detected pathogenic mutations were presented in the *BRCA1/2* genes. The remaining mutations were found in other genes of the reparation system (HGMD Professional 2017.1 database). An unexpected finding was the detection of a germline splicing mutation *c.1047-2A>G* in *CDK12* gene (Chr17(GRCh37):37627130A>G, NM_016507.3) in patients of Tatar origin (Table).

Mutation *c.1047-2A>G* is more common in patients with OC/BC in comparison with healthy controls (7/224 vs 0/316, p = 0.002, OR = 21.49, CI 95% = 1.22–377.25).

Table: 201P *CDK12 c.1047-2A>G* frequency distribution

Subjects origin	BC or OC	Healthy controls
Tatar from Volga District	6/94 (6.4%)	0/32 (0%)
Non-Tatar from Volga District	1/81 (1.2%)	–
Slavic from Moscow	0/49 (0%)	0/284 (0%)
ExAC NFE	–	29/64446 (0.045%)
1000G	–	2/5006 (0.039%)

Conclusions: Gene *CDK12* is one of the most frequently altered genes in serous ovarian cancers, but significance of *CDK12* germline mutations in hereditary cancers remains to be defined. Its role in carcinogenesis of OC was established recently and *CDK12* was not included in most NGS panels of HR genes. Our study demonstrates that *CDK12* may be novel candidate gene for OC/BC genetic predisposition. Notably, frequency of *CDK12 c.1047-2A>G* (6.4%) mutation is comparable with frequency of founder-mutation *BRCA1 5382insC* (7.4%), that indicates its possible founder role in Tatar population.

202P Prognostic value of master transcriptional regulators (MTRs) in early stage breast cancer

S. Barron[1], K. Jirström[2], B. Nodin[2], H. Jernström[2], C. Ingvar[3], B. Moran[4], C-J.A. Wang[1], T. Loughman[1], B. Fender[1], P. Dynoodt[1], C. Lopez-Ruiz[1], W. Gallagher[4]

[1]Product Development, OncoMark Ltd, Dublin, Ireland, [2]Department of Clinical Sciences Lund, Oncology and Pathology, Lund University, Lund, Sweden, [3]Department of Clinical Sciences Lund, Division of Surgery, Lund University, Lund, Sweden, [4]Biomolecular and Biomedical Science, UCD Conway Institute, Dublin, Ireland

Background: Multigene prognostic signatures (MGPS) enable identification of candidate patients (pts) for treatment de-escalation in early stage BC. However, currently available MGPS do not completely address clinical needs by adequately incorporating lymph node (LN)-positive pts and clinicopathological information (CPI). Here, we present OncoMasTR, a MGPS for determining the risk of distant recurrence (DR) in ER-positive, HER2-negative BC pts with up to 3 involved LNs. OncoMasTR, discovered via a novel network analysis methodology that determines upstream MTRs has been mechanistically verified and offers improved prognostic value compared to existing MGPS. OncoMasTR has been further trained to include LN-positive pts and CPI.

Methods: Two independent sample sets: 225 pts from Malmö University Hospital and 106 pts from Skåne University Hospital were used for training, cross-validation and refinement of OncoMasTR. RNA extracted from 225 archived tissues was analysed by RT-qPCR and expression levels of the MTRs were determined by normalising against the expression levels of reference genes. The strongest prognostic combinations of MTRs were identified using statistical models of all possible combinations of MTRs. Clinical performance of the models with the best cross-validated performance in the training data were further evaluated in the 106 independent samples.

Results: OncoMasTR classifies up to 72% of LN0 pts and 60% of LN0-3 pts as low risk, with only 4.9% and 5.5% recurrence rate within the respective groups. When incorporating selected CPI, its prognostic performance further improved to a concordance index of above 0.8. Results showed that the OncoMasTR Molecular score (mS) alone adds statistically significant information to the CPI, and the Combined score (cS) also adds statistically significant information to the mS.

Conclusions: OncoMasTR offers significant prognostic information to the standard CPI and addresses the unmet clinical need of LN-positive pts. The binary output of OncoMasTR, giving no ambiguous intermediate group helps eliminate uncertainty in the formation of the final treatment decision. OncoMasTR is ready for large-scale clinical validation and, subsequently, clinical translation.

203P Survival outcomes of all patients treated with breast carcinosarcoma at a UK specialist cancer centre over a 10 year period (2004–2014)

M. Alameddine, J. Chan, F. Alam

Clinical oncology, Clatterbridge Cancer Center, Wirral, UK

Background: Carcinosarcoma of the breast is a rare and aggressive type of breast cancer presenting as a high grade tumour with lower rates of both lymph node metastasis and oestrogen and progesterone receptor (ER/PR) expression when compared to the more common types of breast cancer, carrying a less favourable prognosis. We present the clinical and pathological findings and outcomes of a series of patients diagnosed and treated for breast carcinosarcoma at a UK specialist cancer centre.

Methods: We conducted a retrospective review of data for all patients diagnosed with breast carcinosarcoma between October 2004 and October 2014 at the Clatterbridge Cancer Centre NHS Foundation Trust.

Results: Nine patients were diagnosed in the 10-year period, with a median age at diagnosis of 73 years (range 37-76 years). Seven patients (77.8%) were postmenopausal. Six patients (66.7%) presented with a palpable mass. T1, T2, and T3 were found in 1, 6 and 2 patients respectively. N0, N1, and N2 were found in 6, 2 and 1 patients respectively. All patients had G3 disease with a median diameter of 3cm (range 1.9-9.0 cm). Oestrogen receptor (ER) and progesterone receptor (PR) were both negative in 8 patients (88.9%). Whilst one patient had wide local excision, all the rest had mastectomy, of whom 4 had axillary nodal clearance and 4 had sentinel nodal biopsy. Five patients received adjuvant radiotherapy. Adjuvant chemotherapy was delivered to 5 patients (2 patients received neither treatments) and adjuvant hormone therapy was delivered to 2 patients (one of whom had a concurrent contralateral ER/PR positive tumour). Patients were followed up for a median period of 15 months (range 1-60 months). Median DFS is estimated to be 25 months and median OS is estimated to be 49 months (95% CI: 14-84 months). Two patients (22.2%) developed metastases with a DFS time of 13 and 14 months respectively, and both died within 5 months.

Conclusions: Within a 10 year period during which our specialist cancer centre were referred 16,500 new breast cancer patients, only 9 patients had carcinosarcoma. Prognosis following recurrence is poor within our limited cohort, in agreement with the published literature. In order for more meaningful analysis of survival outcomes for such a rare form of breast cancer, a multicentre collaborative approach is required.

204P ESR1, Ph-mTOR, CDK4/6 and PD-L1 expression as prognostic (and potentially druggable) drivers for pure invasive lobular breast carcinoma (ILC): Preliminary results of prognostic outliers according to a clinical-pathological model

L. Carbognin[1], M. Brunelli[2], E. Manfrin[2], A. Caliò[2], I. Sperduti[3], M.V. Dieci[4], G. Griguolo[4], V. Guarneri[4], R. Nortilli[1], S. Pilotto[1], E. Fiorio[5], V. Parolin[5], E. Orvieto[6], F. Pellini[7], G.P. Pollini[7], P.F. Conte[8], A. Scarpa[2], G. Tortora[1], E. Bria[1]

[1]Medical Oncology, University of Verona, Verona, Italy, [2]Department of Pathology and Diagnostics, University and Hospital Trust of Verona, Verona, Italy, [3]Biostatistics, Regina Elena National Cancer Institute, Rome, Italy, [4]Department of Surgery, Oncology and Gastroenterology, University of Padova, Padua, Italy, [5]Oncology, AOU Integrata Verona, Verona, Italy, [6]Department of Surgery, Oncology and Gastroenterology, Istituto Oncologico Veneto, Padua, Italy, [7]Breast Surgery, AOU Integrata Verona, Verona, Italy, [8]Medical and Experimental Oncology Department, Medical Oncology 2, Istituto Oncologico Veneto IRCCS, Padua, Italy

Background: The biological drivers of prognosis for pure ILC are not entirely clear. The aim of this analysis was to investigate the molecular and immune-related portrait of prognostic outliers to identify different patterns of expression associated with prognosis and potentially *druggable*.

Methods: Clinical-pathological multi-center data of resected early-stage pure ILC patients (pts) were correlated to disease-free and overall-survival (DFS/OS). A continuous score was derived according to multivariate Hazard Ratios, in order to derive a 3-class model (Poor/Intermediate/Good Prognosis). IHC (for Ph-mTOR, CDK6, PD-L1), FISH (for ESR1, Ph-mTOR, CDK4, PD-L1) and H&E evaluation (for stromal Tumor Infiltrating Lymphocytes, sTILs) were performed upon pts at Poor and Good Prognosis. Odds Ratio (OR) with 95% CIs for the risk of association with prognostic class of biomarkers was determined.

Results: Data from 457 pts were gathered (median age 57 years, median follow: 75 months). The 3-class cross-validated model significantly differentiated DFS and OS ($p < 0.0001$, prognostic accuracy: 0.65 and 0.71, respectively). Based on DFS, 154 and 20 pts with Good and Poor prognosis, respectively, were identified. The preliminary and exploratory analysis of the first 34 pts (Good/Poor 14/20) is reported (OR < 1: higher chance to be associated with Good prognosis; OR > 1 higher chance to be associated with Poor prognosis).

Table: 204P

Biomarker [Method]	OR	95% CIs
High sTILs [H&E]	0.22	0.01-5.8
Ph-mTOR deletion [FISH]	0.33	0.07-1.49
ESR1 gain [FISH]	0.53	0.09-3.18
PD-L1 positive [IHC]	0.67	0.08-5.4
CDK4 deletion [FISH]	1.22	0.1-15.1
PD-L1 gain [FISH]	1.25	0.19-8.2
Score 3+ CDK6 [IHC]	2.29	0.21-24.68
Score 3+ Ph-mTOR [IHC]	2.48	0.61-10.05
ESR1 deletion [FISH]	2.75	0.27-23.04
CDK4 gain [FISH]	3.18	0.15-66.36

Conclusions: Despite unpowered, these preliminary data suggest that Poor and Good prognosis are potentially associated to differential expression of a cluster of biomarkers: ESR1 deletion, CDK4 gain, CDK6 and ph-mTOR over-expression versus high sTILs, PD-L1 positive, ESR1 gain and ph-mTOR deletion, respectively.

205P The pregnancy and fertility (PREFER) study: A prospective cohort study on fertility-preserving (FP) strategies in young early breast cancer (EBC) patients (pts)

C. Dellepiane[1], M. Lambertini[2], V. Fontana[3], F. Poggio[1], E. Blondeaux[1], B. Conte[1], A. D'Alonzo[1], M. Vaglica[1], C. Bighin[1], G. Iacono[1], A. Abate[1], S. Pastorino[1], M.C. Pescio[4], P. Anserini[4], L. Del Mastro[1]

[1]Medical Oncology, IRCCS AOU San Martino - IST-Istituto Nazionale per la Ricerca sul Cancro, Genoa, Italy, [2]Breast Cancer Translational Research Laboratory, Institute Jules Bordet, Brussels, Belgium, [3]Department of Clinical Epidemiology, IRCCS AOU San Martino - IST-Istituto Nazionale per la Ricerca sul Cancro, Genoa, Italy, [4]Gynecology, IRCCS AOU San Martino - IST-Istituto Nazionale per la Ricerca sul Cancro, Genoa, Italy

Background: Premature ovarian failure and subsequent infertility are possible long-term side effects of chemotherapy (CT) in young EBC pts. Limited data are available on the number of pts who consider FP strategies and on the reasons for refusal of these procedures. To address the significant challenges related to fertility issues, the PREFER study was developed as a national comprehensive program aiming to optimize care and improve knowledge around this topic.

Methods: This is a prospective cohort study ongoing across several Italian centers affiliated to the GIM (Gruppo Italiano Mammella) study group. Oncologists offer the available FP strategies to young EBC pts undergoing (neo)adjuvant CT: oocyte cryopreservation (OC), ovarian tissue cryopreservation (OTC) and LHRH analogue (LHRHa) during CT. Eligible pts are premenopausal, $\leq$ 45 years, no previously exposed to CT and/or radiotherapy. Primary objective is to obtain data about preferences and choices of young EBC pts on the FP strategies. Secondary objectives are to evaluate the success and safety of FP strategies, hormonal changes during CT and survival outcomes. The present analysis reports preliminary results of the study including pts enrolled at the coordinating center from November 2012 to May 2017.

Results: A total of 131 EBC pts were enrolled; median age was 38.9 years (24.8-45.34). Nine pts (6.87%) refused all FP options. Reasons for refusal were no interest in fertility preservation (5 pts), previous pregnancy (3 pts), no interest in having children (1 pts). LHRHa was accepted by 120 pts (91.6%) and 27 pts (20.6%) accepted gynecologic counseling. Among these pts, 10 (7.6%) accepted OC or OTC. Main reason for refusal of cryopreservation procedures was fear of delaying cancer treatment (3 pts). No complications were observed among women who underwent OC or OTC. Median number of mature oocytes yielded and cryopreserved was 8.5 (4-13). A patient had a spontaneous pregnancy following adjuvant treatment.

Conclusions: Despite the great importance of fertility issues in young EBC pts, a minority of them (7.6%) require to access cryopreservation procedures. This is crucial information from a public health perspective and for resource allocation.

206P Incidence of permanent alopecia following adjuvant chemotherapy in women with early stage breast cancer

J. Crown[1], J. Walshe[1], D. Fennelly[2], J-C. Long[1], S. Cairney[1], D. McDonnell[1], J. Ballot[1], D. Wildes[1], E. Sills[1], G. Gullo[2]

[1]Medical Oncology, St Vincents University Hospital, Dublin, Ireland, [2]Medical Oncology Department, St Vincents University Hospital, Dublin, Ireland

Background: Alopecia is one of the most distressing toxicities of adjuvant chemotherapy for patients with breast cancer. Historically, oncologists have reassured patients (pts) that chemotherapy-induced alopecia is temporary, and followed by full hair recovery. More recently there have been troubling reports of permanent alopecia following adjuvant taxanes (Tax). We studied the incidence of long-term hair loss in patients treated on adjuvant trials in our institution. Patients who were enrolled on clinical trials involving Tax (D-Docetaxel, P-Paclitaxel) and/or Anthracyclines (A) were included.

Methods: We conducted a telephone interview survey of pts who had completed adjuvant or neo adjuvant A and/or T chemotherapy on clinical trials more than one year before. Ongoing alopecia was graded as 0 (full hair recovery), 1 (mild hair loss) or 2(severe/total). The study was approved by the hospital audit committee.

Results: We studied 295 pts who has been treated on 12 studies. Drug exposure: D-260 pts (D nonA-185, D+A-75); A-nonTax-12 pts; A+P 23 pts. The overall incidence of alopecia was 15% (11% grade 1 and 4% grade 2). For all D the incidence was 15% (12% Grade 1 and 3% Grade 2). For D+A-24% (19% Grade 1 and 5% Grade 2). For D non A the incidence was 13% (8% grade 1 and 5% grade 2). For A non T 8% (Grade 2-8%). For PA-13% (4% grade 1 and 9% grade 2). For patients receiving D non-A regimens, there were two levels of D exposure, 300mg/m^2 (90 pts) or 450 mg/m^2 (95 pts). The incidence of alopecia was significantly D dose dependent: D300- 7% (all grade 1) and D 450-19% (14% grade 1, 5% grade 2) (p=.02 chi$^{2)}$. Among the higher dose D group, the companion drug choices carboplatin for HER2 positive, (55 pts) or cyclophosphamide (40 pts) were associated with similar incidences of permanent alopecia (22% v 16%).

Conclusions: Permanent alopecia is a common complication of adjuvant chemotherapy. The risk appears to be highest in regimens which contain A and D, but it is also seen in D non-A, AP and in A non-Tax. For patients receiving D non A, the risk is dose-dependent. Our set contains few P pts, and no pts undergoing low dose weekly P. Oncologists should warn all patients undergoing adjuvant therapy of the risk of permanent alopecia.

207P Significant changes in dietary intake and physical activity after breast cancer diagnosis in a Chinese breast cancer cohort study

Y. Lei[1], W. Yeo[1], S.C. Ho[2], C-K.I. Lee[1], K.L. Cheung[1], R. Lee[1], Y-Q. He[1]

[1]Department of Clinical Oncology, The Chinese University of Hong Kong, Hong Kong, China, [2]Division of Epidemiology, the Jockey Club School of Public Health and Primary Care, The Chinese University of Hong Kong, Hong Kong, China

Background: The diagnosis of cancer can motivate survivors to modify lifestyles, typically involving diet and physical activity. Few data have reported pre- and post-diagnostic lifestyle habits in Chinese population.

Methods: In an on-going prospective cohort study which involved 1462 Chinese women with early-stage breast cancer, we evaluated dietary intake and lifestyle factors pre- and post- breast cancer diagnosis. Validated food frequency questionnaires were used to evaluate dietary intake. Leisure time physical activity was measured by a modified Chinese Baecke questionnaire. This report compared changes of dietary intake and physical activity between 12 months before and 18 months after diagnosis of breast cancer.

Results: Intake of whole grains, refined grains, fruits, vegetables, eggs, and nuts increased significantly post-diagnosis (Range, 54%-72% increase; $P < 0.001$, each; Table). Conversely, after diagnosis consumption of red meat, processed meat, poultry, dairy products, soy, sugar drinks, and coffee significantly decreased (Range, 32%-63% decrease; $P < 0.001$, each). The level of physical activity (MET-hour per week) post-diagnosis was significantly increased (median, 0.75 vs. 5.25; $P < 0.001$), with 58% of patients became more physically active. However, the proportion of women that met the WCRF/AICR Cancer Prevention recommendations about physical activity (10 MET-hour per week) was still low, only 21% women met at pre-diagnosis, increasing to 34% at post-diagnosis.

Table: 207P

Food group	Pre-diagnosis [Median (IQR), g/1000kcal/day]	Pre-diagnosis [Median (IQR), g/1000kcal/day]
Refined grains	269.9 (213.3-348.3)	319.6 (257.8-391.2)
Whole grains	3.6 (0-11.9)	7.4 (0.7-30.0)
Fruits	95.1 (54.3-137.8)	140.4 (92.0-193.6)
Vegetables	194.1 (136.8-263.2)	271.5 (197.3-359.8)
Eggs	8.3 (4.1-14.8)	10.1 (5.2-16.9)
Red meat	48.3 (29.1-72.7)	38.2 (20.3-62.0)
Processed meat	1.7 (0.3-4.8)	0.4 (0-2.4)
Poultry	20.4 (9.6-38.2)	1.1 (0-7.1)
Dairy products	15.4 (5.0-44.5)	5.7 (0.6-15.9)
Soy	28.1 (12.8-55.1)	23.3 (8.3-49.0)

*IQR, inter quartile range.

Conclusions: In this cohort study, Chinese breast cancer patients reported significant changes in dietary intake and increased physical activity level and a higher proportion met the WCRF/AICR Cancer Prevention recommendations after cancer diagnosis. These findings provided crucial information on lifestyle behaviors in Chinese breast cancer survivors, and provided information to healthcare professionals on survivors' health and quality of life.

208P Prevention of cardiotoxicity in breast cancer patients: A randomized prospective study

A.M. Elkhateeb[1], D.R. Diab[1], H. Ibrahim[1], N. Gado[1], Y.A. Ali[2], A.S. Ibrahim[3]

[1]Clinical Oncology Department, Faculty of medicine Ain Shams University, Cairo, Egypt, [2]Cardiology department, Faculty of medicine Ain Shams University, Cairo, Egypt, [3]Radiodiagnosis, Faculty of medicine Ain Shams University, Cairo, Egypt

Background: Adjuvant anthracyclin chemotherapy (ANTC) and trastusumab are documented to prolong survival in breast cancer patients. However, these drugs are well known to induce Left Ventricular Systolic Dysfunction (LVSD). Multiple studies showed that acetyl choline-esterase inhibitor (ACEIs) and beta Blockers (BBs) can prevent LVSD.

Methods: One hundred and twenty six patients with M0 breast cancer patients to be treated with ANTC ± trastuzumab were randomized to an intervention group (group 1) (n = 63 patients) which received cardioprotective drugs; (ACEI;enalapril) and (BB;carvedilol) or to a control group which did not receive cardioprotective drugs (group 2) (n = 63 patients). To evaluate systolic and diastolic functions conventional echocardiography (Simpson method and M- mode) and cardiac magnetic resonance imaging (CMR) were performed at baseline, after 3 cycles and 6 cycles of ANCT, and after 1 year of follow-up. Cardioprotective drugs received: Both enalapril and carvedilol were started at least 24 hours before the first chemotherapy cycle.

Results: In the intervention group 58 patients had 3 cycles ANTC, 6 patients received 6 cycles ANTC, and 12 patients received trastuzumab. Whereas in the control group 47 patients had 3 cycles ANTC, 16 patients were given 6 cycles ANTC and 18 patients received trastusumab. After 3 ANTC cycles, LVEF did not change in group 1 (64.35% at baseline vs. 63.59%, p 0.2) but decreased by M- mode in the control group (64.84% at baseline vs. 63.42%, p 0.03) associated with statistically significant deterioration of diastolic function grades. At 1 year follow-up, while no change was observed in LVEF in group 1, there was decrease in LVEF by CMR in group 2 (65.78% at baseline, 61.48% at 1 year, p 0.048). No cases were detected with heart failure or with final EF < 45% in either group. Compared to controls, the intervention group had a statistically significant lower incidence of decrease EF ≥ 10% after finishing ANTC by CMR(1.9% vs. 12.5%, p 0.04).

Conclusions: Combined prophylaxis with ACEI (enalapril) and BB (carvedilol) may prevent LVSD in patients with non-metastatic breast cancer treated with anthracyclines containing chemotherapy ± trastuzumab. The clinical relevance of this strategy should be confirmed in larger randomized studies.

Klinikum Graz, Graz, Austria, [15]ABCSG, Vienna, Austria

Background: In ABCSG-34, patients with HER2-negative breast cancer were randomized to preoperative standard of care therapy (SoC) with or without L-BLP25 (Stimuvax). This report describes the quality-of-life (QoL) results of the trial.

Methods: 400 patients were randomized to receive SoC with or without BLP25. Postmenopausal women with low-risk disease (ER +++/ ++, Ki67 <14%, G1/2) received 6 months of letrozole; premenopausal and postmenopausal patients with triple-negative, ER-/+/ ++, Ki67 ≥14%, or G3 tumors received 4 cycles of epirubicin/cyclophosphamide plus 4 cycles of docetaxel with or without L-BLP25. Primary end point results RCB and pCR rates were presented previously (SABCS 2016; Abstract Nr 850339). QoL was assessed with the EORTC QLQ-C30 and EORTC QLQ-BR 23 at baseline, before surgery, and up to 4 weeks thereafter. The objective was to evaluate differences of QoL in women treated with or without L-BLP25, as well as between the two regimens.

Results: 385 patients from 17 centers were included in the QoL analysis. There were no differences in QoL between patients receiving SoC only and those receiving additional L-BLP25. Impact on QoL was determined by the SoC therapy and by the timepoint of the assessment. Before surgery and 4 weeks thereafter patients receiving chemotherapy ± TL-BPL25 showed more impairment in the QoL scales role and social functioning, financial problems and body image than the patients receiving endocrine therapy ± TL-BPL25. Fatigue and hair loss were significantly more common in the chemotherapy than in the endocrine arm. At the time of surgery and thereafter, patients in both SoC arms had significantly negatively impacted QoL (physical, role, emotional, cognitive, social, sexual functioning, body image domains) as well as more fatigue, pain, dyspnoea, breast and arm symptoms. There were no differences in global health status between the arms at the different time points.

Conclusions: Addition of L-BLP25 (Stimuvax) to SoC in HER2-negative EBC patients does not impair QoL.

210P Dedicated breast PET for predicting residual disease after breast cancer neoadjuvant chemotherapy

S. Sasada[1], T. Kadoya[1], N. Goga[1], A. Emi[1], K. Kajitani[1], N. Masumoto[1], R. Haruta[2], T. Kataoka[2], M. Okada[1]

[1]*Surgical Oncology, Research Institute for Radiation Biology and Medicine, Hiroshima University, Hiroshima, Japan,* [2]*Breast Surgery, Hiroshima University Hospital, Hiroshima, Japan*

Background: Diagnostic methods to evaluate the response to breast cancer neoadjuvant chemotherapy (NAC) have been established. Dedicated breast PET (DbPET) is a high-resolution molecular breast imaging method, and we investigated the ability of DbPET to predict the presence of residual primary tumors after NAC, compared with whole-body PET (WBPET).

Methods: Forty-five patients (47 tumors) underwent WBPET and ring-type DbPET after NAC, and tumors were completely resected between January 2016 and March 2017. The pathological response was classified as complete remission (ypT0), residual intraductal disease (ypTis), or residual invasive disease (ypT≥1). Standardized uptake value (SUV) and tumor-to-normal tissue ratio (TNR) were assessed.

Results: Twelve patients achieved ypT0 and 5 developed ypTis. DbPET detected all cases of ypTis, and WBPET detected only one case of ypTis. The sensitivity, specificity, and accuracy of WBPET for ypT≥is were 54.3%, 83.3%, and 61.7%, respectively, and those of DbPET were 77.1%, 83.3%, and 78.7%, respectively. In the ypT0/ypTis/ypT≥1 groups, the median WBPET-SUV, DbPET-SUV, and DbPET-TNR were 1.0/0.9/1.1, 1.7/1.8/2.2, and 1.0/1.6/1.7 (P = .134, .077, and .008), respectively (Table). Area under the curves of WBPET-SUV, DbPET-SUV, and DbPET-TNR for predicting ypT≥is were 0.610, 0.648, and 0.807, respectively.

Table: 210P Comparison of predicting indexes for predicting pathological response

Pathological response	WBPET-SUV		DbPET-SUV		DbPET-TNR	
	Median (IQR)	*p*	Median (IQR)	*p*	Median (IQR)	*p*
ypT≥1	1.1 (0.9-1.7)	.134	2.2 (1.5-3.9)	.077	1.7 (1.1-2.9)	.008
ypTis	0.9 (0.9-1.2)		1.8 (1.4-1.9)		1.6 (1.4-1.8)	
ypT0	1.0 (0.9-1.0)		1.7 (1.5-2.1)		1.0 (0.9-1.1)	

Conclusions: DbPET was superior to detect residual primary tumors, especially noninvasive carcinoma, after NAC than WBPET. TNR was expected as the better parameter of pathological evaluation than SUV.

212TiP IMpassion031: A phase III study comparing neoadjuvant atezolizumab (atezo) vs placebo in combination with anthracycline/nab-paclitaxel (nab-pac)–based chemotherapy in early triple-negative breast cancer (eTNBC)

E.A. Mittendorf[1], C.H. Barrios[2], N. Harbeck[3], K.H. Jung[4], D. Miles[5], S. Saji[6], H. Zhang[1], A-N. Duc[7], S. Rafii[8], C. Lai[9]

[1]*Breast Surgical Oncology, University of Texas MD Anderson Cancer Center, Houston, TX, USA,* [2]*Department of Medicine, PUCRS School of Medicine, Porto Alegre, Brazil,* [3]*Breast Center, University of Munich (LMU), Munich, Germany,* [4]*Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Democratic People's Republic of Korea,* [5]*Medical Oncology, Mount Vernon Cancer Centre, Northwood, UK,* [6]*Medical Oncology, Fukushima Medical University, School of Medicine, Fukushima, Japan,* [7]*Biostatistics, F. Hoffmann-La Roche Ltd., Basel, Switzerland,* [8]*Global Oncology Product Development, F. Hoffmann-La Roche AG, Welwyn Garden City, UK,* [9]*Global Development, Genentech, South San Francisco, CA, USA*

Background: Atezo is an anti–programmed death-ligand 1 (PD-L1) monoclonal antibody that prevents PD-L1 from binding to PD-1 and B7.1 receptors, thereby restoring tumor-specific immunity. TNBC is characterized by PD-L1 expression on tumor-infiltrating immune cells (IC), a high mutation rate and high levels of tumor-infiltrating lymphocytes (TILs), suggesting a therapeutic opportunity for atezo. Atezo alone and in combination with nab-pac is well tolerated, with promising activity in metastatic TNBC, supporting its investigation in early-stage disease. IMpassion031, a global Phase III, double-blind, randomized, multicenter, placebo-controlled study, is being conducted to evaluate the efficacy and safety of neoadjuvant treatment with nab-pac → doxorubicin + cyclophosphamide and either atezo or placebo in invasive stage II/III eTNBC. The choice and sequence of chemotherapy is selected to maximize the opportunity to establish a robust immune response.

Trial design: Patients (pts) with previously untreated, central laboratory–confirmed invasive TNBC with primary tumor size > 2 cm and ECOG PS 0-1 are eligible. Exclusion criteria include history of invasive BC, stage IV disease, and prior immunotherapy or autoimmune disease. Approximately 204 pts will be randomized 1:1 to receive atezo (840 mg q2w) or placebo with nab-pac (125 mg/m^2 qw) for 12 weeks, followed by atezo (840 mg q2w) or placebo with doxorubicin (60 mg/m^2 q2w) + cyclophosphamide (600 mg/m^2 q2w) for 4 cycles before surgery. Pts will be unblinded post-surgery and pts in the atezo arm will continue to receive atezo (1200 mg q3w × 11 doses). Stratification factors include stage II vs III at diagnosis and PD-L1 expression (IC0 vs IC1/2/3). The primary endpoint is pathological CR (pCR); key secondary endpoints include pCR according to PD-L1 status, pt-reported outcomes, event-free survival and overall survival. Tumor samples will be taken at baseline, on treatment (optional), at surgery and post-recurrence and will be assessed for biomarkers associated with responses and immune escape.

Background: Recent preclinical findings have been published which provide new insights into the functional cross-talk between the estrogen receptor (ER) and the progesterone receptor (PR) in breast cancer (Mohammed et al., Nature, 2015). Addition of a PR agonist to anti-estrogens directly modifies ERa chromatin binding and the transcriptional response in breast cancer cells, and is anti-proliferative in vitro and in vivo. Megestrol Acetate (MA), an off-patent semi-synthetic derivative of progesterone, has been licensed for many years as a treatment for ER+ metastatic breast cancer. There is

also good evidence for the effectiveness of MA as a supportive therapy to ameliorate endocrine therapy-related hot flushes.

Trial design: PIONEER is a three-arm, open label, multi-centre randomised phase II pre-surgical window trial evaluating effects of 15 days of preoperative therapy with Letrozole (LET), or LET plus MA 40mg, or LET plus MA 160mg in postmenopausal women with newly diagnosed, ER+ HER2- invasive primary breast cancer. Patients are being recruited in Cambridge, with 5-6 other UK sites due to open in q3/4 2017.

Table: 213TiP 3-arm randomisation

Arm A	LET 2.5mg daily
Arm B	LET 2.5mg daily + MA 40mg daily
Arm C	LET 2.5mg daily + MA 160mg daily

The primary endpoint is % change in proliferation between baseline and day 15 tumour biopsies, measured by Ki67 immunohistochemical (IHC) assessment. Secondary endpoints include: expression of Aurora Kinase A, Caspase 3 and Androgen receptor/PR/EMT markers by IHC; and safety endpoints. Exploratory endpoints include: transcription factor mapping (ChIP-seq) on paired fresh-frozen tumour samples. Patients are randomised in a 1: 1.5: 1.5 ratio for arms A: B: C. Based on results from previous clinical trials, a mean 66% reduction in Ki67 is anticipated for LET alone (arm A), and a 77.5% reduction for combination arms B and C, based on preclinical data. A recruitment total of 189 patients is required. Pioneer will help determine if there is value in conducting a follow-on adjuvant study to investigate the longer term benefit of combining an aromatase inhibitor with MA, and if so, at what dose (40mg vs. 160mg).

Clinical trial identification: EudraCT Number: 2016-003752-79 MHRA/REC number: v2.0 5th June 2017

214TiP VENTANA (SOLTI-1501): Antiproliferative effect of the addition of oral metronomic vinorelbine to endocrine therapy in luminal/HER2-negative early breast cancer: A window of opportunity trial

B. Adamo[1], J.A. Perez Fidalgo[2], E. Ciruelos[3], M. Vidal[1], S. Blanch[4], A. Lopez[5], P. Gomez Pardo[6], L. Murillo[7], K. Amillano[8], N. Martínez Jañez[9], X. Gonzalez[10], J. Canes[11], A. Prat[1]

[1]Medical Oncology, Hospital Clínic de Barcelona, Barcelona, Spain, [2]Medical Oncology, Hospital Clinico Universitario de Valencia, Valencia, Spain, [3]Medical Oncology, Hospital Universitario 12 de Octubre, Madrid, Spain, [4]Medical Oncology, Fundación Instituto Valenciano de Oncología, Valencia, Spain, [5]Medical Oncology, Hospital de León, Leon, Spain, [6]Medical Oncology, Vall d'Hebron University Hospital, Barcelona, Spain, [7]Medical Oncology, Hospital Clínico Universitario Lozano Blesa, Zaragoza, Spain, [8]Medical Oncology, Hospital Universitari Sant Joan de Reus, Reus, Spain, [9]Medical Oncology, Hospital Universitario Ramón y Cajal, Madrid, Spain, [10]Medical Oncology, Hospital Universitario Quirón Dexeus, Barcelona, Spain, [11]Scientific, SOLTI Breast Cancer Research Group, Barcelona, Spain

Background: The cornerstone of luminal breast tumors treatment both in early and advanced settings is endocrine therapy (ET). Although extended adjuvant ET has demonstrated benefit, a significant percentage of patients relapse. In previous studies, the combination of ET with CDK4/6 inhibitors has shown unprecedented efficacy suggesting that inhibition of the cell cycle in combination with ET is a strategy to keep exploring. The efficacy and safety of metronomic VNB have been confirmed in preclinical and clinical studies and it is now considered a multi-mechanisms of action therapy that could offer advantages when combined with other drugs. VENTANA study is a "window-of-opportunity" trial designed to explore whether, similarly to CDK4/6 inhibitors, oral metronomic VNB in combination with endocrine therapy induces a superior antiproliferative effect than ET alone. We hypothesize that the synergistic biological effect of the combined treatment could be an alternative to CDK4/6 inhibitors in the treatment of luminal breast cancer patients.

Trial design: Pts are randomized (1:1:1) to receive LET 2.5mg daily, oral VNB 50mg 3 days a week, or the combination. After 3 weeks of treatment, pts undergo surgery. Pre- and post-treatment (surgical) samples will be analyzed for gene expression. The primary objective is to test if oral metronomic VNB and LET induce a superior antiproliferative effect than either drug alone in pts with early BC defined as Luminal by PAM50. This will be evaluated by the expression of 11 proliferative genes contained in the PAM50 subtype predictor (BIRC5, CCNB1, CDC20, CDCA1, CEP55, KNTC2, MKI67, PTTG1, RRM2, TYMS and UBE2C) as surrogate signature biomarker of its anticancer activity. In addition, 560 BC-related gene signatures will also be analyzed. Enrollment started in July 2016 in 10 sites across Spain. To date, 47 patients have been included. We expect to report full study results by Spring 2018.

Background: Cell cycle inhibition is a proven target for novel cancer therapeutics. Palbociclib (P) is an orally active inhibitor of CDK4/6, and arrests the cell cycle at the G1-S transition. P in combination with endocrine therapy (ET) has demonstrated efficacy in phase II and III randomized trials for patients with newly diagnosed and recurrent hormone receptor positive/HER2 negative (HR+/HER2-) metastatic breast cancer (MBC), and is approved in these settings. Given confirmed benefits of P and ET for MBC, the PALLAS study was designed to determine if the addition of P to adjuvant ET improves outcomes over ET alone in HR+/HER2- early breast cancer.

Trial design: PALLAS is an international open-label phase III trial randomizing (1:1) patients (pts) to 2 years of P (125 mg daily, 21 days on 7 days off in a 28-day cycle) combined with at least 5 years of provider choice ET (AI, tamoxifen, +/- LHRH agonist), versus ET alone. The primary objective of the study is to compare invasive disease-free survival (iDFS) for the combination of P and ET, versus ET alone. Secondary objectives include comparison of iDFS excluding cancer of non-breast origin, DRFS, LRRFS, OS, as well as safety. The principal objective of the translational investigations is to determine the predictive or prognostic utility of defined genomic subgroups with respect to iDFS and OS. Additional objectives include evaluation of cfDNA and tissue biomarkers predictive of benefit or resistance, pharmacogenomics, adherence, and patient-reported QOL. Eligible pts are pre- or post-menopausal women or men with stage II-III, HR+/HER2- breast cancer. Patients may have already initiated ET, but must be randomized within 12 months of diagnosis and 6 months of initiation of adjuvant ET. Trial sample size is 4600 pts and stage IIA pts will be capped at a total accrual of 1000 pts. Interim analyses for safety, futility/efficacy and sample size re-estimation are planned. PALLAS opened in 9/2015 and accrual is ongoing. Contact information: emayer@partners.org.

Background: In a Phase II study (NCT00494234), treatment with olaparib, a potent, orally available PARP inhibitor, exerted antitumor activity in patients (pts) with advanced BC harboring a gBRCAm. In a randomized phase III trial, olaparib significantly improved PFS compared to chemotherapy (CT) for patients with HER2-negative gBRCAm advanced BC (OlympiAD, NCT02000622, ASCO 2017). OlympiA (NCT02032823) is a phase III trial of olaparib as adjuvant therapy for pts with high risk gBRCAm HER2-negative BC who have completed local treatment and (neo)-adjuvant CT.

Trial design: OlympiA is a double-blind trial in which high risk HER2-negative pts are randomized (1:1) to receive treatment with olaparib (300 mg tablets bid [2 x 150 mg]) or placebo for 12 months. Eligible pts must have completed local treatment and at least 6 cycles of (neo)-adjuvant containing anthracyclines and/or taxanes. Pts with triple negative BC (TNBC) must have $\geq$pT2 or $\geq$pN1 in the adjuvant and non-pCR in the neoadjuvant setting. Pts with hormone receptor (HR) positive BC must have $\geq$4 positive lymph nodes in the adjuvant and non-pCR and CPS&EG score $\geq$3 in the neoadjuvant setting. Pts must also harbor a deleterious gBRCAm. Stratification factors include hormone receptor status, prior neoadjuvant versus adjuvant CT, and whether pts have received platinum therapy for current BC. The primary objective is invasive disease-free survival (IDFS). Efficacy assessments will be made by mammograms/breast MRI scans annually for 10 years, beginning 6 months from randomization, and by medical history/physical examination from randomization every 3 months for 2 years, then every 6 months for a further 3 years and annually thereafter. Secondary objectives include overall survival, distant DFS, incidence of new non-BCs, HRQoL, safety and tolerability. The primary IDFS analysis will be performed after 330 IDFS events using a stratified log-rank test. Patient enrolment began in April 2014 and is currently ongoing. The target number for randomization is 1500 patients across ~500 sites and ~25 countries worldwide. Support: U10CA12027,-69651,-37377,-69974,-180868,-180822, -189867; AstraZeneca.

Background: The extent of tumor-infiltrating lymphocytes (TILs) in the residual disease after anthracycline-based neoadjuvant chemotherapy (NACT) is associated with a better prognosis, in patients with triple-negative breast cancer (TNBC). We aimed to develop a genomic signature from pre-treatment samples to predict the extent of TILs after NACT, and then to test its prognostic value on survival.

Methods: Using 99 pre-treatment samples (training set), we generated a four-gene signature that predicts post-NACT TILs using the LASSO technique. Prognostic value of the signature on survival was first assessed on the training set ($n = 99$) and then evaluated on an independent validation set including 185 patients with TNBC treated with NACT.

Results: A four-gene signature combining the expression levels of HLF, CXCL13, SULT1E1, and GBP1 predicted the extent of lymphocytic infiltration after NACT. In a multivariate analysis performed on the training set, a one-unit increase in the signature value was associated with distant-relapse free survival (DRFS) (HR: 0.28, 95%CI: 0.13-0.63, $p = 0.0018$). For the validation dataset, the four-gene signature was significantly associated with DRFS in the entire set (HR: 0.26, 95%CI: 0.11-0.59, $p = 0.0012$) and in the subset of patients with residual disease (HR: 0.23, 95%CI: 0.10-0.55, $p = 0.0008$).

Conclusions: We developed a four-gene signature of immune-activation, which predicts outcome in patients treated with NACT for TNBC.

218P Prognostic estimates of Ki-67 percentage drop after neoadjuvant chemotherapy (NAC) in luminal B (lumB) and triple negative breast cancer (TNBC)

J. Pascual[1], B. Rojas-Garcia[1], V. Peg[2], S. Diaz-Botero[3], E. Zamora[1], E. Muñoz Couselo[1], M. Oliveira[1], P. Gomez Pardo[1], J. Perez Garcia[1], F. Ruiz-Pace[4], C. Viaplana[4], S. Escrivá[1], L. Garrigos[1], M. Arumi[1], M. Espinosa-Bravo[3], J. Cortés[1], I. Rubio[3], C. Saura[1], R. Dienstmann[4], M. Bellet Ezquerra[1]

[1]*Medical Oncology Department, Vall d'Hebron University Hospital Institute of Oncology (VHIO), Barcelona, Spain,* [2]*Anatomical Pathology, Vall d'Hebron University Hospital, Barcelona, Spain,* [3]*Breast Pathology Unit, Vall d'Hebron University Hospital, Barcelona, Spain,* [4]*Oncology Data Science Group (ODysSey), Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain*

Background: Pathologic complete response (pCR) and residual cancer burden (RCB) after NAC are validated prognostic markers in BC. We assessed the impact of adding Ki-67% drop (baseline biopsy - surgery) to distant metastasis relapse-free survival (dRFS) models containing CP factors plus post-treatment stage (MDACC CPS score), estrogen receptor status and tumor grade (MDACC CPS+EG score).

Methods: Records from 341 patients (pts) with lumB/HER2 neg (baseline Ki67 >20%) or TNBC who received NAC from 2008 to 2015 at our hospital were reviewed. Uni- and multivariate Cox models were constructed and concordance-index (c-index) calculated.

Results: Pts: median age 47 years (24-83), 60% lumB and 40% TNBC, 62% stage 2, 38% stage 3. pCR: 12% lumB, 32% TNBC ($p < 0.01$). Median Ki-67% drop: 24% lumB, 5% TNBC ($p < 0.01$), without differences by NAC regimen. dRFS at 5 year-median follow-up was 75% in lumB (CI95% 67-83) vs 62% in TNBC (CI95% 53-74, $p < 0.01$); 90% in RCB 0/1 (CI95% 81-97) vs 74% in RCB 2/3 (CI95% 65-83, $p < 0.01$). As compared to pts with RCB 0/1, those with RCB 2/3 plus Ki-67% drop $>= 20\%$ (best cut-off in univariate model) had similar dRFS at 5 years (90%, CI95% 81-100, $p = 0.48$), irrespective of molecular group. Enrichment for Ki-67 $>=$20% drop in lumB (60%) vs TNBC (30%, $p < 0.01$) was observed. Both CPS and CPS+EG scores were validated as independent prognostic factors in univariate dRFS models (c-index of 0.70 and 0.78, respectively). The addition of Ki-67% drop ($< 20\%$ vs $>= 20\%$) to CPS and CPS+EG scores in multivariable models significantly improved their performance (c-index of 0.74 and 0.81, respectively). Ki-67 $>= 20\%$ drop associates with 70-80% reduction in distant relapse risk (HR 0.27 and 0.16 in CPS and CPS+EG models, respectively, $p < 0.05$).

Conclusions: Our data support the addition of Ki-67% drop after NAC in lumB and TNBC to existing dRFS online outcome calculators. In the context of RCB 2/3, Ki-67 $>= 20\%$ drop is mainly seen in lumB/HER neg tumors. Importantly, Ki-67 $< 20\%$ drop identifies a high-risk population that may be eligible to clinical trials with novel therapeutic interventions in the adjuvant setting.

219P Immune function and response to neoadjuvant chemotherapy in hormone receptor positive, HER2-negative breast cancer

A. Matikas[1], J. Lövrot[1], A. Ramberg[2], M. Eriksson[2], T. Lindsten[2], T. Lekberg[1], I. Hedenfalk[3], N. Loman[3], J. Bergh[1], A. Erlandsson[4], T. Hatschek[1], T. Foukakis[1]

[1]*Oncology/Pathology, Karolinska Institutet, Stockholm, Sweden,* [2]*Clinical Pathology and Cytology, Central Hospital Karlstad, Karlstad, Sweden,* [3]*Oncology/Pathology, Lund University, Lund, Sweden,* [4]*Urology, Örebro University, Örebro, Sweden*

Background: Gene expression (GE) signatures and Tumor Infiltrating Lymphocyte (TILs) enumeration have shown promise as predictors of response to neoadjuvant chemotherapy in Hormone Receptor negative (HR-) and HER2+, but not in HR+/HER2- breast cancer (BC). This study aimed to explore their predictive value in HR+/HER2- BC, based on previous work from our group on the association of immune function and chemosensitivity in advanced HR+ BC.

Methods: The PROMIX phase 2 trial enrolled patients with locally advanced HER2-BC to receive six cycles of epirubicin and docetaxel, plus bevacizumab during cycles 3-6. Patients underwent tumor biopsies at baseline and after cycle 2 for GE profiling using DNA microarrays and TIL enumeration according to standard guidelines. Since pathologic complete remission (pCR) is relatively rare in HR+ BC, we also associated an immune gene module score (IMS) and TIL counts with the non-dichotomous variable of decrease in tumor size.

Results: Of the 150 enrolled patients, $n = 113$ were HR+. For $n = 71$, both TIL and GE data were available at baseline, while for $n = 78$ and $n = 49$ patients longitudinal TIL and GE data at baseline and cycle 2 were available, respectively. At baseline, on both univariate (OR = 2.29, $P = 0.037$) and multivariate analysis (OR = 2.35, $P = 0.044$) IMS was associated with pCR, while its association with tumor shrinkage was only apparent on univariate ($P = 0.047$) and not multivariate analysis ($P = 0.061$). TIL infiltration >50% ($n = 9$) was associated with neither pCR (OR = 1.812, $P = 0.61$) nor tumor shrinkage ($P = 0.99$). However, decreases in TIL counts in cycle 2 compared with baseline were associated with lesser decreases in tumor size ($P = 0.043$ for univariate and $P = 0.044$ for multivariate analysis).

Conclusions: Baseline immune function as assessed by GE analysis, but not TIL enumeration, and a preserved abundance of TILs after chemotherapy were predictive for chemosensitivity at the neoadjuvant setting in patients with HR+, HER2- BC.

220P Safe resection margins in breast-conserving surgery

Y. Kostiuchenko[1], I. Motuzyuk[1], O. Sydorchuk[1], N. Kovtun[2], M. Krotevich[3]
[1]Oncology Department, Bogomolets National Medical University, Kyiv, Ukraine, [2]Department of Statistics and Demography, Taras Shevchenko National Univeristy of Kyiv, Kyiv, Ukraine, [3]Pathology, National Cancer Institute, Kyiv, Ukraine

Background: Our first research concerning resection margins in breast-conserving surgery (BCS) for breast cancer patients (BCP) was performed in 2003-2006. In the group of BCP where after positive margins we performed mastectomy (0%) and in the group where the negative margins were achieved immediately (1.27%) the incidence of local recurrences was lower comparing to the group that had re-resections (4.76%) or the group without microscopic control of margins (8.16%). We tried to understand the causes of local recurrences after BCS, and develop recommendations on achieving safe resection margins.

Methods: To clarify the possibility of cancer spreading to the side of regional lymph nodes we were injecting a solution of aqueous methylene in four points around a tumor in 30 minutes before surgery and subsequently we were studying cuts made at the distance up to 5 cm from the tumor margin. In 12% of cases we identified tumor elements in cuts located at a distance of more than 3 cm. In this study we included 996 BCP of I-III stages who had BCS at the National Cancer Institute in 2008-2015. The main group consisted of 379 BCP who had an additional removal of tissues towards the axillary area as a monoblock during the BCS (with additional histological control as mentioned above). 617 BCP in the control group had standard BCS. The average age of BCP was $50.6 \pm 1{,}1$ in the main group, and $49{,}8 \pm 0{,}9$ in the control group ($p > 0.05$). Median follow-up was 142 weeks.

Results: Achieving negative margins at the area of possible metastasis significantly reduces local recurrence rates, especially in a stage II (5.34%) and III (3.35%) BCP. The incidence of distant metastases (diagnosed in 93 (9.34%) cases) was significantly lower in the main group – 21 (5.54%) comparing to the control group – 72 (11.67%), both in general and in each stage ($p < 0.05$). Time of distant metastases occurrence was slightly lower in the control group – $84{,}7 \pm 8{,}9$ weeks, comparing to the main group – $101{,}3 \pm 9{,}5$ weeks ($p > 0.05$).

Conclusions: BCS with the additional removal of tissues towards the axillary area and lymph nodes dissection as a monoblock is reasonable and significantly reduces local and distant metastases rates. However, more long-term research in this area is urgently needed, especially in terms of benefit in survival.

Clinical trial identification: The study is approved by the Commission on issues of ethics of the National Cancer Institute (Protocol No. 7 of 08.04.2010) and the Commission on issues of ethics of the Bogomolets National Medical University (Protocol No. 71 of 10.04.2013).

221P A clinically applicable model to predict risk of relapse in patients treated for locally advanced breast cancer: Potential utilization in future clinical trials

O. Aseyev, L. Simmonds, M. Gertler, S. Verma
Medical Oncology, The Ottawa Hospital Regional Cancer Centre, Ottawa, ON, Canada

Background: Despite advances in cancer treatment, over 25% of patients (pts) with locally advanced breast cancer (LABC) relapse during first 5 years after treatment. The primary objective was to construct a prediction tool for risk of relapse (RR) in pts with LABC after neoadjuvant therapy (NAT).

Methods: This was single center, retrospective study of 546 pts with LABC who received NAT at the Ottawa Hospital Cancer Center between 2005 and 2015. Median follow-up was 49 months. The following data collected: demographics, tumor size, nodal and receptor status, grade, HER-2, stage, treatment and clinical outcomes. Primary endpoints were local and/or distant recurrence rate and time to relapse during the first 5 years. A prediction tool was devised based on the Cox regression model.

Results: Over 60 variables were included in primary analysis. Cox regression proportional hazards model analysis resulted in only 5 factors with significant influence on risk of relapse during first 5 years of follow up. Risk factors and their risk prediction value are: 1) residual disease (yes- 4; no-0), (HR = 4.25; p-value<0.001), 2) lymph nodes status (positive-3; negative-0), (HR = 2.27; p-value=0.006), 3) Inflammatory histology (yes-2; no-0), (HR = 1.90; p-value=0.003) 4) estrogen receptors status (positive-2; negative-0), (HR = 2.07; p-value=0.001), 5) Adjuvant radiotherapy (yes-0; no-1), (HR = 1.76; p-value=0.036). When these factors are combined the following Relapse Prediction (RP) Score can be constructed. According to this simple RP score, patients can be classified into to three groups (RP score – 0-5; 6-7; 8-12). RR was 7 times higher in patients with RP Score 8-12 vs patients with score 0-5 (p-value<0.001). Internal validation of proposed model was performed. ROC analysis of the proposed model revealed a sensitivity of 75%.

Conclusions: Patients with LABC represent a heterogeneous group with diverse risk of disease recurrence that can be predicted. Patients with high risk may require additional treatment and/or more active follow-up strategies and this simple model may be used to design unique studies in LABC based on RP score. We intend to further validate this model on a larger multi center/provincial population.

222P Role of radiotherapy and its impact on survival of male breast cancer: Experience from a tertiary cancer center

R. Upadhyay[1], P. Julka[2], G.K. Rath[3]
[1]Radiation Oncology, All India Institute of Medical Sciences, New Delhi, India, [2]Medical Oncology, B.R. Ambedkar Institute Rotary Cancer Hospital (AIMS), New Delhi, India, [3]Radiation Oncology, B.R. Ambedkar Institute Rotary Cancer Hospital (AIMS), New Delhi, India

Background: Male breast Cancer (MBC) is a rare disease accounting for about 1% of all malignancies in men and 1% of all breast cancers. These patients(pts) are managed like female breast cancers. There is limited literature available defining the role of radiotherapy(RT) in management of MBC. We conducted a retrospective analysis to study the impact of adjuvant RT on outcome of MBC pts treated at our centre.

Methods: Review of MBC pts presenting to our centre from 2005 to 2015 was done. All underwent pre-treatment evaluation in a combined tumor clinic comprising radiation, surgical and medical oncologist. Most pts were treated with surgery followed by adjuvant therapy and kept on regular follow up. Overall survival (OS) was defined as time from pathologic diagnosis to last follow up or death. Disease free survival (DFS) was defined as time from diagnosis to first relapse.

Results: 96 pts of MBC were identified. Median age was 58 years (range 28-83). Clinical stage I, II, III and IV were 8, 27, 39 and 22 respectively. Of 66 pts with known receptor status, 83% were ER positive, 82% PR positive, 20% Her-2/neu positive and 7.5% triple negative. 69 pts underwent modified radical mastectomy or wide local excision. 54% were pathologically node positive. Adjuvant RT was delivered to 34% pts at 1.8-2 Gy per fraction to a median dose of 50 Gy (range 45-60 Gy). Radiation field comprised of chest wall with (75%) or without regional nodes (25%). Median follow up was 24 months (range 9-132). 16 pts had relapse out of which 4 had local and 13 had distant (most common site bone) metastases after a median duration of 19 mnths. 2 yr estimated DFS for the entire cohort was 79.2% and 2 yr OS was 85.7%. The 2 yr DFS in pts undergoing surgery was 86.4% vs 29.2% in those who did not($p = 0.001$). Pts who received adjuvant RT had better 2 yr DFS (92.4% vs 52.9%, $p = 0.002$). Adjuvant chemotherapy did not significantly affect the 2 yr DFS (93.1% vs 73%, $p = 0.123$).

Conclusions: MBC mostly present in advance stages at our centre and harbor HR positive disease with low HER-2 overexpression. Adjuvant RT provided a statistically significant improvement in outcome. Longer follow up of these cohort of pts is required for accurate evaluation of role of RT in MBC.

223P Early characteristics of breast neoplasms on contrast-enhanced ultrasonography and its clinical value

S. Qin, Z.W. Jie
Ultrasound Medicine, Nanjing Jingdu hospital, Nanjing, China

Background: To investigate the characteristics of breast neoplasms on contrast-enhanced ultrasonography and its clinical value.

Methods: 225 female patients with breast masses unable to be diagnosed by conventional ultrasonography were examined with contrast-enhanced ultrasonography (CEUS). Their ages range were 12 to 85 years, the mean age was 45.8 ± 17.6 years. 225 cases were investigated. For cases of multiple lesions, performed which was the highest classification level of BI-RADS; for the lesions of the same level, performed the largest lesion. The characteristics of these masses on CEUS were analyzed and compared with the results of pathology examination. The contrast agent(UCA) was SonoVue (Bracco, Italy).

Results: 91 cases were malignant and 134 cases were benign. The 91 malignacies displayed: irregular shapes were 80.2%(73/91), tortuous, massive or penetrating vessels were 86.8% (79/91), heterogeneous distribution of contrast enhancement were 83.5% (76/91), perfusion defect of contrast signals were 89.0% (81/91), local retention of contrast signals were 93.4% (85/91), rapidly entering and exporting from the lesions were 65.9% (60/91). Significant differences of above CEUS characteristics were found between the benign and malignant breast lesions ($P < 0.05$), The two most important features were perfusion defects and local retention of the contrast signals, with the sensitivity and specificity attained to 89.0% and 91.8%, and 93.4% and 92.5%, respectively. Poorly defined boundaries of the 91 malignacies were 64.8%(59/91), and the specificity was 47.8%. The malignant cases had enlarged maximum diameter on CEUS compared to pre-contrast ($P < 0.05$).

Conclusions: The typical features of breast cancers on CEUS were irregular shapes, tortuous, massive or penetrating vessels, heterogeneous distribution of contrast enhancement, with perfusion defect or local retention of contrast signals, rapidly entering and exporting from the lesions, enlarged maximum diameter of the lesions on CEUS compared to pre-contrast. It is valuable for CEUS in the diagnosis and differential diagnosis of breast neoplasms clinically.

224P Synchronous and metachronous breast cancer in Ukraine

I. Motuzyuk[1], O. Sydorchuk[1], N. Kovtun[2], Y. Kostiuchenko[1]

[1]Oncology Department, Bogomolets National Medical University, Kyiv, Ukraine, [2]Department of Statistics and Demography, Taras Shevchenko National Univeristy of Kyiv, Kyiv, Ukraine

Background: This study aims to evaluate the current state of multiple primary malignant neoplasms (MPMN) in Ukraine and develop decision criteria for type of surgical treatment for these patients.

Methods: The study included 2,032 patients who received special treatment at the Department of Breast Tumours at the National Cancer Institute in 2008-2015. Among them there were 195 MPMN patients where 107 (54.9%) presented synchronous cancer (SC) and 88 (45.1%) presented metachronous cancer (MC). The average age of patients was 46.6, and the number of postmenopausal women was 63.1%. Among SC patients there were 60 (56.1%) with only breast localizations and 47 (43.9%) with combination of breast and other localizations (gynaecological etc.), and among MC there were 41 (46.6%) with only breast localizations and 47 (53.4%) with combination of breast and other localizations. All the patients were evaluated in terms of aggressiveness of the disease, survival rates, as well as risk factors and treatment options.

Results: The clinical course of the disease (CCD) in MPMN patients was worse in SC patients comparing to MC patients (p=0.00162). A more aggressive CCD was observed in patients exposed to radiation from the Chernobyl accident ($p = 0.000798$). There was no influence on CCD of such factors as primary localization, type of special treatment, age and type of settlement. However, the impact of type of surgery was statistically proven, i.e. CCD in patients who underwent mastectomy was worse comparing to patients who underwent breast-conserving surgery (p=0.00048). Plastic and reconstructive surgery in SC patients was statistically proven as reasonable increasing overall survival by 29% (p=0.015). There was an influence of local recurrences on the overall survival in SC patients reducing it by 71% (p=0.033), however, there was no influence in MC patients.

Conclusions: The MPMN patients have to get an improved attentive management and treatment. Medical and surgical oncologists should concern all the risk factors that have influence on CCD in these patients and provide the best option of management. The research in this area of oncology is open and this is crucial to continue researches for better outcome of these patients.

Clinical trial identification: The study is approved by the Commission on issues of ethics of the National Cancer Institute (Protocol No. 7 of 08.04.2010) and the Commission on issues of ethics of the Bogomolets National Medical University (Protocol No. 71 of 10.04.2013).

225P Clinical outcomes of single versus double hormone receptor positive breast cancer patients treated with neoadjuvant chemotherapy

J. Raphael[1], S. Nofech-Mozes[2], M. Trudeau[1]

[1]Department of Medicine, Division of Medical Oncology, Sunnybrook Health Sciences Centre, Toronto, ON, Canada, [2]Department of Pathology, Sunnybrook Health Sciences Centre, Toronto, ON, Canada

Background: This study aimed to evaluate and compare tumor response rates and survival outcomes between single and double hormone receptor (HR) positive (+) [Estrogen Receptor (ER+)/Progesterone Receptor (PR) negative (-) or ER-/PR+ versus ER+/PR+] breast cancer (BC) patients with any HER2 status treated with neoadjuvant chemotherapy at a single institution.

Methods: A retrospective review was conducted using the Sunnybrook "Biomatrix" database to identify eligible patients. A multivariable logistic regression analysis (MLR) was performed to assess the association between HR status (single or double HR+) and pathologic complete response (pCR) rates at surgery. A Kaplan-Meier method was used to estimate Disease Free Survival (DFS) and a log-rank test was used to compare DFS between 3 subgroups of patients: single or double HR+ and HR negative patients.

Results: Three hundred and four BC patients were identified and included in the analysis with a median follow up of 43.3 months (Q1-Q3: 28.7-61.1) and a mean age of 49.7 years (Standard deviation 10.9). Forty seven percent (47/101), 31% (11/36) and 14% (24/167) of patients with HR negative, single HR+ and double HR+ disease achieved a pCR respectively (X^2 test <0.0001). In a MLR analysis, HR status and HER2 status were associated with pCR rates. Compared to HR negative patients, patients with double HR+ disease were less likely to achieve pCR (Odd ratio (OR):0.14, 95%CI 0.06-0.31, $p<0.0001$) while single HR+ patients did not differ (OR:0.51, 95%CI 0.19-1.4). The association between HR+ status (single versus double HR+) and pCR rates compared to HR negative patients remained the same in subgroup analyses of HER2+ and HER2 negative patients separately. No difference in survival (DFS) was seen between the 3 subgroups of patients: HR negative, single and double HR+ patients.

Conclusions: BC patients with single HR+ disease behave differently than double HR+ patients in terms of likelihood of achieving pCR after neoadjuvant chemotherapy and do not differ from HR negative patients. This difference does not translate into a difference in DFS. Prospective studies are needed to validate these findings before considering different treatment strategies for these 2 subgroups of HR+ BC patients.

226P The correlation between toll-like receptor genes polymorphisms, tumor microenvironment characteristics and the effectiveness of preoperative chemotherapy for locally advanced breast cancer

N. Verovkina[1], L.A. Sivak[1], S. Lyalkin[1], Z.I. Rossokcha[2], P.E. Fedorovna[2]

[1]Department of the Chemotherapy of the Solid Tumors, National Cancer Institue, Kiev, Ukraine, [2]Reference Center of Molecular Diagnostics of the Ministry of Health of Ukraine, "Reference Center of Molecular Diagnostics of the Ministry of Health of Ukraine", Kiev, Ukraine

Background: Toll-like receptor (TLR) activation may be an important event in tumor cell immune evasion. TLR2 and TLR4 gene polymorphisms correlate with increased susceptibility to cancer development, response to conventional chemotherapy in various organs.

Methods: Treatment results of 62 patients with breast cancer stages T1-3N0-3M0 treated with neoadjuvant chemotherapy were evaluated. The level of the post-treatment CD4+, CD8+, FOP3+ tumor-infiltrating immune cells and Ki-67 positive cells were studied. The polymorphisms of TLR4 (C399T) and TLR2 (G753A) genes were investigated using a PCR restriction fragment length polymorphism method. Statistica10.0 software was used to perform analysis of variance.

Results: ER+ and PR± expressing tumors were identified in 69.3% of patients, ER and PR negative tumors - in 30.6%. Pathological complete response (pCR) was identified in 14.6%. Genotype CC of TLR4 (C399T) gene was detected in 87%, whereas genotype CT - in 9.6% and genotype TT - in 3.4% of patients. Genotype GG of TLR2 (G753A) gene was detected in 88.7%, genotype GA - in 11.3% of patients. A correlation was found between polymorphisms of TLR2 (G753A) and axillary lymph nodes involvement. In carriers of GA genotype of TLR2 gene (G753A) we found more frequent axillary LN metastases ($\chi 2=5.75$; $p = 0.01$). A direct correlation was identified between level of Ki-67 and the level of regulatory FOXP3 cells in carriers of GA genotype of TLR2 gene($r = 0.96$; $p = 0.008$). There appears to be a relationship between TLR4 gene and levels of CD4 + (p=0.01) and CD8 + (p=0.02) as well as an association between TLR4 (C399T) gene and residual cancer burden (RCB) ($p = 0.04$). In carriers of TT genotype of TLR4 gene the level of CD4+ cells was significantly lower ($p = 0.03$). In carriers of CC genotype of TLR4 (C399T) gene we found a direct correlation between the level of CD8+ cells and Ki- 67 in the residual tumor ($r = 0.38$, $p = 0.01$). Higher level of CD4+ is associated with lower RCB in carriers of CC genotype of TLR4 (C399T) gene ($r = 0.3$, $p < 0.05$).

Conclusions: Preliminary results of the study indicate that further elucidation of the role of the TLRs in breast cancer development is promising.

227P Triple negative breast cancer: 10-year survival update of the applied treatment strategy in Kuwait

M.S. Fayaz[1], G. Demian[2], M. El-Sherify[3], M. Aziz[1], H. Eissa[2]

[1]Radiation Oncology, Kuwait Cancer Control Centre Al Sabah Hospital, Shuwaikh, Kuwait, [2]Radiation Oncology, National Cancer Institute, Cairo University, Cairo, Egypt, [3]Radiation Oncology Department, Kuwait Cancer Control Center, Kuwait, Kuwait

Background: Triple negative breast cancer (TNBC) is recognized as a distinct clinical and biological entity of poor outcome for almost two decades, yet its treatment strategy still needs to be better specified. The study aim is to update the 10-year survival data of our TNBC patients and to find its association with different applied treatment modalities.

Methods: We updated 10-year survival data of 359 women diagnosed with TNBC between 1999 and 2009 in Kuwait Cancer Control Center (KCCC). The overall survival (OS), disease free survival (DFS), distant metastasis free survival (DMFS) and locoregional free survival (LRFS) were estimated using Kaplan Meier method. Survival was correlated with different prognostic factors and treatment modalities. Statistical significance was calculated using the log-rank test and defined as $p < 0.05$. Cox regression was used for Multivariate analysis.

Results: TNBC represented 12% of breast cancer in Kuwait with a median age of 48 years. The stage distribution was as follow: stage I, II, III, IV in 15%, 43%, 35% and 7%

of patients respectively. Regarding surgery, 33% had Conservative surgery; 67% had mastectomy and 82% had axillary clearance. Chemotherapy was neoadjuvant in 25%, adjuvant in 56% and palliative in 5% of patients. Two-thirds of patients (67%) received adjuvant radiotherapy. After a median follow-up of 108 months, the 10-year OS, DFS, DMFS and LRFS were 66%, 59%, 72% and 77% respectively. The 10-year OS was 92%, 80%, 49% and 0% for Stage I,II,III and IV respectively ($p = 0.0000$). OS was significantly worse with the presence of lymphovascular invasion (LVI; $p = 0.003$). OS was not significantly affected by age, grade or treatment modality. In multivariate analysis, the clinical stage and LVI were still significant (P = 0.0000 and 0.04 respectively).

Conclusions: In absence of biological biomarkers, the clinical stage and LVI seems to be the only significant prognostic factors for survival of TNBC patients in our study population. Timing of chemotherapy as well as the extent of surgery do not seem to affect the TNBC patients' outcome.

228P A decade of HER2-targeted therapy in older patients with invasive breast cancer at Institut Curie

R. Geiss[1], J-Y. Pierga[2], E. Auclin[3], G. De Lempdes[4], F. Rollot Trad[5], P. cottu[2], C. Giard[6], D. Stevens[7], E. Brain[1]

[1]Medical Oncology, Hôpital René Huguenin - Institut Curie, St. Cloud, France, [2]Medical Oncology, Institut Curie, Paris, France, [3]Medical Oncology, Hopital European George Pompidou, Paris, France, [4]Geriatric Oncology, Institut Curie, St. Cloud, France, [5]Geriatric Oncology, Institut Curie, Paris, France, [6]Pharmacology, Hôpital René Huguenin - Institut Curie, St. Cloud, France, [7]Epidemiology, Hôpital René Huguenin - Institut Curie, St. Cloud, France

Background: Around 40% and 20% of breast cancers (BC) occur in women aged ≥ 65 and ≥ 75 years respectively. Although HER2-targeted therapy has profoundly improved the management of HER2+ BC, literature is short of data for frail and elderly patients reflecting the poor representation of older patients in registration trials.

Methods: We conducted a retrospective analysis of any stage HER2+ BC patients aged ≥ 65 years treated with a HER2-targeted therapy at Institut Curie between 2000 and 2012 to assess treatment feasibility. Baseline data were extracted from the institution database and patients' files were reviewed for treatment compliance and safety profile.

Results: From 2000 to 2012, 261 and 76 patients received anti-HER2 treatment in adjuvant and metastatic setting respectively. In adjuvant setting (age distribution 65-69/70-74/$\geq$75: 109/85/67; median follow-up 65 months), the median duration of trastuzumab treatment was 12 months with an 80% completion rate (defined as $>$ 9 months of treatment) decreasing significantly ≥ 75 years (70%). Grade ≥ 3 cardiac toxicity occurred in 9.6% of patients, was reversible in 72% of cases, and multivariate analysis identified the following risk factors for cardiac events: history of thromboembolic disease, valvulopathy and performance status (PS) ≥ 2 [OR 6.3 (95% CI: 1.4-27.7), 25.6 (4-162.8) and 18.2 (1.1-304.3) respectively], but not age. In metastatic setting (age distribution 65-74/$\geq$ 75: 41/35; median follow-up 27 months), median duration of HER2-targeted therapy was 22.8 months (0-109.2), with no impact of age. Trastuzumab and lapatinib (alone or in combination) were mostly prescribed, pertuzumab and T-DM1 representing $<$ 15% of cases depending on treatment line. Multivariate analysis identified the following factors for mortality: PS ≥ 2, history of thromboembolic disease [OR 3 (95% CI: 1.1-8.1) and 3.3 (0.7-16.3) respectively], but not age.

Conclusions: HER2-targeted therapy seems feasible in ≥ 65 yrs patients in both adjuvant and metastatic setting. Cardiac toxicity occurs in 10-15% but is reversible in most cases. Chronological age does not seem to affect duration of anti-HER2 treatment nor cardiac toxicity.

229P Dedicated breast PET to predict pathological complete response after neoadjuvant chemotherapy for breast cancer

M. Fujiwara, N. masumoto, S. Sasada, T. Kadoya, M. Okada

Surgical Oncology, Hiroshima University, Hiroshima, Japan

Background: Reports indicate that whole-body (WB) ^{18}F-fluorodeoxyglucose (FDG) PET can predict a pathological complete response (pCR) after neoadjuvant chemotherapy (NAC). New dedicated breast PET (DBPET) can generate high-resolution images and thus might be able to predict pCR after NAC. The present study aimed to determine whether or not DbPET can predict the effects of NAC for breast cancer more effectively than WBPET.

Methods: The clinical responses of 35 consecutive patients with breast cancer (T1–4, N0–1, M0) who underwent NAC between January 2016 and January 2017 were assessed using WBPET and DBPET. We assessed maximum standardized uptake values (SUVmax), before (pre-SUVmax) and after (post-SUVmax) NAC and rates of change in SUVmax (ΔSUVmax) before and after NAC. Relationships between these parameters and pathological responses (pCR) were assessed using each modality. We created receiver operating characteristics curves (ROC), calculated areas under them (AUC) for both WBPET and DBPET images and predicted pCR.

Results: Twelve of 35 patients achieved pCR. The median pre-SUVmax, post-SUVmax and ΔSUVmax among the 35 patients determined using WBPET and DBPET were 6.8 and 18.0, 1.7 and 3.1, and 78.2 and 77.6, respectively. Uptake of ^{18}F-FDG was indistinguishable from background in WBPET, but confirmed in DBPET after NAC in three of 23 patients with non-pCR disease. The median pre-SUVmax of WBPET and DBPET in the pCR group was higher than non-pCR group (7.88 and 21.73 vs 6.22 and 16.28, $p = 0.30$ and $p = 0.15$, respectively). In contrast, post-SUVmax of the pCR group was lower than non-pCR group (0.97 and 2.06 vs 1.54 and 3.86, $p = 0.062$ and $p = 0.032$, respectively). ΔSUVmax of pCR group was higher than non-pCR group (82.23 and 88.56 vs 76.34 and 72.55, $p = 0.27$ and $p = 0.04$, respectively). Additionally, the AUC of DBPET (pre-SUVmax: 0.543, post-SUVmax: 0.725, ΔSUVmax: 0.752) was higher than WBPET (pre-SUVmax: 0.477, post-SUVmax: 0.694, ΔSUVmax: 0.549) in either time points.

Conclusions: The diagnostic accuracy of DBPET were equal to, or better than those of WBPET. DBPET might serve as a new diagnostic modality when planning therapeutic strategies for patients with breast cancer after neoadjuvant chemotherapy.

230P Efficacy and safety profile of the adriamycin/cyclophosphamide (AC) followed by docetaxel/cisplatin (DC) in locally advanced breast cancer

T. Abdelhamid[1], M. Saber[1], A. Abdel-Samie Gaber[1], M. Selim[1], O. Youssef[2], A. Salama[3], N. Aly Eldin[4]

[1]Medical Oncology, National Cancer Institute Cairo University, Cairo, Egypt, [2]Surgical Oncology, National Cancer Institute Cairo University, Cairo, Egypt, [3]Pathology, National Cancer Institute Cairo University, Cairo, Egypt, [4]Biostatistic, National Cancer Institute Cairo University, Cairo, Egypt

Background: Neoadjuvant chemotherapy (NCT) using anthracycline - taxane based chemotherapy achieved better outcome and increase the rate of breast conservative surgery (BCS). This study evaluates the efficacy and safety profile of 4 cycles AC followed by 4 cycles of DC as NCT and detect pCR with its subsequent effect on BCS, OS, DFS and its correlation with molecular subtypes and other markers as ERCC1and Ki-67.

Methods: A prospective phase II study at the Medical Oncology Department of the National Cancer Institute (NCI), Cairo University, where 104 female patients with LABC were recruited during the period from March 2010 to July 2013 to receive eight cycles of NCT, 4 cycles of (AC) followed by 4 cycles of (DC), responding patients were referred to surgery then to radiotherapy for local control. All patients were assessable for toxicity. ER, PR, Her2neu, Ki-67 and ERCC1 were done.

Results: Median age: 51yrs, postmenopausal: 48.1%, median tumour size at presentation: 8 cm, stage IIIB: 82.7%, ER/PR positive: 78.8% and 25% were Her2neu positive. The pCR after DC according to Miller and Payne system was 20.2%, with mean tumour size:4.15$\pm$ S.D 2.703. Age and menopausal status showed statistical significant correlation with pathological response. The correlation between DFS in positive and negative ERCC1 was statistically significant; (p-value ≤ 0.01). The overall survival (OS)of the patients was 85.4% at 36 months while the disease free survival (DFS) was 85.3% at 24 months. Anaemia G2 & more was encountered in 27 patients (26%); neutropenia G2 & more was reported in 49 patients (47.1%), while Peripheral neuritis was observed in 103 patients (99%).

Conclusions: Adding Cisplatin to Docetaxel for 4 cycles after 4 cycles of Adriamycin – Cyclophosphamide improved the pCR, OS and rate of BCS. ERCC1 is a predictor marker of DFS.

232P Pregnancy associated breast cancer spotlights

M. Shalaby, S.F. Lasheen, S. Talima

Oncology Department, Kasr-Alainy School of Medicine, Cairo, Egypt

Background: Pregnancy associated breast cancer (PABC) is a rare entity of breast cancer. It is defined as breast cancer occurring during pregnancy or within 12 months from end of pregnancy. Though rare, it represents a very challenging situation to both the physician and patient. This retrospective study is an attempt to focus on PABC cases presenting at our institute regarding their personal, disease characteristics and type of treatment received.

Methods: This is a retrospective study conducted at Kasr-Al-Ainy oncology center "NEMROCK". The files of female patients diagnosed with breast cancer under the age of 40 in the period from January 2005 to December 2014 were retrospectively reviewed. A comparison has been conducted between PABC cases and non-pregnant cases concerning personal and disease characteristics, modality of treatment and outcomes.

Results: This study included a total of 175 patients 40 years old or younger, among them 40 were PABC cases. Twenty five percent of PABC presented with distant metastasis at first presentation while only 11.6% of the non-pregnant patients presented with metastasis (P value 0.039). Time from onset of symptoms till breast cancer diagnosis was more than 6 months in 55.6% of PABC cases in comparison to 36.3% in non-pregnant cases (P value 0.043). Concerning treatment; 32.4% of PABC cases received neoadjuvant chemotherapy while 20.7% of non-pregnant patients received it (P value 0.027). There was no statistical difference in personal and disease characteristics between pregnant and non-pregnant patients including family history, pathological subtypes, stage, grade and biological subtypes. There was no statistically significant difference in disease free survival between PABC cases and non-pregnant ones (P value 0.497).

Conclusions: PABC is associated with a late diagnosis. Although PABC patients present at later stages than non-pregnant ones and the use of neoadjuvant treatment is higher in pregnant cases, the outcome of patients with PABC is comparable to that of non-PABC of matched age.

233TiP KEYNOTE-522: Phase III study of pembrolizumab (pembro) + chemotherapy (chemo) vs placebo + chemo as neoadjuvant followed by pembro vs placebo as adjuvant therapy for triple-negative breast cancer (TNBC)

P. Schmid[1], J. Cortes Castan[2], J. Bergh[3], L. Pusztai[4], C. Denkert[5], S. Verma[6], H.L. McArthur[7], J. Zhao[8], G. Aktan[8], T. Dang[8], R. Dent[9]

[1]Centre for Experimental Cancer Medicine, Barts Cancer Institute-Queen Mary University of London, London, UK, [2]Oncology, Ramon y Cajal Hospital, Madrid, Spain, [3]Department of Oncology-Pathology, Karolinska Institutet & Cancer Center Karolinska and Karolinska University Hospital, Stockholm, Sweden, [4]Medical Oncology, Yale School of Medicine, Yale Cancer Center, New Haven, CT, USA, [5]Pathology, Institut of Pathology, Charité Universitätsmedizin Berlin, German Cancer Consortium (DKTK) Partner Site Berlin and DKFZ, Heidelberg, Germany, [6]Medical Oncology, Tom Baker Cancer Centre, University of Calgary, Calgary, AB, Canada, [7]Medical Oncology, Cedars-Sinai Medical Center, Los Angeles, CA, USA, [8]Medical Oncology, Merck & Co., Inc., Kenilworth, NJ, USA, [9]Medical Oncology, National Cancer Centre Singapore, Singapore

Background: Endogenous anticancer immunity may be enhanced with immune checkpoint inhibition by increased tumor-specific antigen release after chemo. Combining the anti–PD-1 inhibitor pembro with chemo may be an effective treatment strategy for TNBC in neoadjuvant and adjuvant settings. KEYNOTE-522 (NCT03036488) is a phase III study of neoadjuvant pembro + chemo followed by adjuvant pembro vs neoadjuvant placebo + chemo followed by adjuvant placebo in pts with TNBC.

Trial design: Eligible pts are aged ≥18 y with previously untreated, centrally confirmed, nonmetastatic TNBC, defined as combined primary tumor (T) and regional lymph node (N) staging per AJCC (investigator-assessed: T1c N1-2, T2-4 N0-2). Pts with bilateral or multifocal primary tumors or inflammatory breast cancer are allowed. ECOG PS 0-1 and adequate organ function are required. Pts with a history of invasive malignancy ≤5 y or prior therapy before study start are excluded. Approximately 855 pts will be randomly assigned to 1 of 2 arms and stratified by tumor nodal status (positive vs negative), size (T1/T2 vs T3/T4), and carboplatin choice (Q3W vs QW). In arm 1, pts will receive 4 cycles of pembro 200 mg Q3W + paclitaxel (80 mg/m^2 QW on d 1, 8, 15) + carboplatin (AUC 5 Q3W on d 1 or AUC 1.5 QW on d 1, 8, 15) and then 4 cycles of pembro + doxorubicin (60 mg/m^2 on d 1) or epirubicin (90 mg/m^2 on d 1) + cyclophosphamide (600 mg/m^2 Q3W on d 1) as neoadjuvant therapy. Definitive surgery will be 3-6 wk after the last cycle. In arm 2, placebo will replace pembro. Post-surgery, pts will receive 9 cycles of pembro or placebo as adjuvant therapy. One neoadjuvant/adjuvant cycle = 21 d; treatment is up to 17 cycles (pembro/placebo only) or until disease progression/unacceptable toxicity. Dual primary endpoints are pCR rate (ypT0/Tis ypN0) and EFS. Secondary endpoints include pCR rate (ypT0 ypN0) in all pts and in those with PD-L1+ tumors (ie, PD-L1 staining in ≥ 1% tumor cells or stroma), pCR rate (ypT0/Tis ypN0) in pts with PD-L1+ tumors, EFS in pts with PD-L1+ tumors, pCR rate (ypT0/Tis) in all pts and in those with PD-L1+ tumors, OS, and safety. Interim analyses are planned.

234TiP KEYNOTE-355: Randomized, double-blind, phase III study of pembrolizumab (pembro) + chemotherapy (chemo) vs placebo (PBO) + chemo for previously untreated, locally recurrent, inoperable or metastatic triple-negative breast cancer (mTNBC)

J. Cortes Castan[1], Z. Guo[2], V. Karantza[2], G. Aktan[3]

[1]Oncology, Ramon y Cajal Hospital, Madrid, Spain, [2]Oncology, Merck & Co., Inc., Kenilworth, NJ, USA, [3]Clinical Research, Merck & Co., Inc., Kenilworth, NJ, USA

Background: In the phase Ib KEYNOTE-012 study, the anti–PD-1 antibody pembro demonstrated promising antitumor activity and acceptable safety as monotherapy in pretreated patients (pts) with PD-L1+ mTNBC. Adding pembro to chemo may enhance antitumor activity. KEYNOTE-355 (NCT02819518) is a global phase III study of pembro+chemo vs PBO+chemo in pts with previously untreated, locally recurrent, inoperable TNBC/mTNBC.

Trial design: Eligible pts are ≥18 y and have centrally confirmed, locally recurrent, inoperable TNBC or mTNBC not previously treated with chemo (prior chemo in [neo]adjuvant setting allowed); measurable disease per RECIST v1.1; ECOG PS 0-1; ≥6 mo between definitive surgery or last dose of adjuvant chemo, whichever was last; and first disease recurrence (≥12 mo if prior treatment with same-class agent). Part 1 is an open-label, unblinded safety run-in of ~30 pts distributed over 3 arms (pembro+nab-paclitaxel, pembro+paclitaxel, pembro+gemcitabine/carboplatin). Part 2 is a double-blind, PBO-controlled study of ~828 pts to be randomized 2:1 to pembro 200 mg every 3 weeks + chemo (nab-paclitaxel 100 mg/m^2 on d 1, 8, and 15 every 28 d; paclitaxel 90 mg/m^2 on d 1, 8, and 15 every 28 d; or gemcitabine 1000 mg/m^2 + carboplatin AUC 2 on d 1 and 8 every 21 d) or PBO+chemo. Crossover not allowed. Stratification factors are study chemo (taxane vs gemcitabine/carboplatin), tumor PD-L1 expression (+/-), and prior therapy with same-class agent in the (neo)adjuvant setting (yes/no). Treatment will occur for ≤35 administrations (pembro/PBO only) or until confirmed disease progression, unacceptable toxicity, withdrawal of consent, or decision to discontinue. Primary end points are safety in part 1 and PFS (by RECIST v1.1, central radiology review) and OS in part 2; secondary end points include ORR (by RECIST v1.1, central radiology review), duration of response. AEs will be graded per NCI CTCAE v4.0. Response will be assessed at wks 8, 16, 24, then at 9-wk intervals up to 1 y, and at 12-wk intervals thereafter. Interim safety analysis will occur after pts complete 1 treatment cycle in part 1.

235TiP A Phase Ib trial of xentuzumab and abemaciclib in patients with locally advanced or metastatic solid tumours, hormone receptor-positive (HR+), HER2-negative (HER2-) breast cancer (BC; +/-endocrine therapy), or non-small-cell lung cancer (NSCLC)

A. Prat[1], D. Yee[2], M.P. Sablin[3], H. Iwata[4], E.L. Johnston[5], T. Bogenrieder[6], J. Serra[7], K. Stucke-Straub[8], P. Lo Russo[9]

[1]Medical Oncology, Hospital Clínic, Barcelona, Spain, [2]Medicine, Masonic Cancer Center, University of Minnesota, Minnesota, MN, USA, [3]Medical Oncology, Institut Curie, Paris, France, [4]Breast Oncology, Aichi Cancer Center Hospital, Nagoya, Japan, [5]Oncology, Eli Lilly and Company, Indianapolis, IN, USA, [6]Oncology, Boehringer Ingelheim RCV, Vienna, Austria, [7]Oncology, Boehringer Ingelheim España, S.A., Barcelona, Spain, [8]Oncology, Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, Germany, [9]Medical Oncology, Yale Cancer Center, New Haven, Connecticut, CT, USA

Background: The insulin-like growth factor (IGF) and the cyclin D-cyclin-dependent kinase (CDK) 4/6-retinoblastoma pathways have been implicated in the pathogenesis and resistance mechanisms of a variety of cancers, including HR+ HER2- BC and NSCLC. IGF-ligand dependent signalling via the IGF receptor results in upregulation of cyclin D1, and thus, progression through the cell cycle, providing rationale for the simultaneous inhibition of IGF and CDK4/6. This trial assesses the maximum-tolerated dose (MTD), safety and preliminary efficacy of the IGF ligand-neutralising antibody, xentuzumab, in combination with abemaciclib, a selective inhibitor of both CDK4 and 6, +/- hormone therapy, in pts with solid tumours.

Trial design: Study BI 1280.18 (NCT03099174) is a Phase Ib multicentre, non-randomised, open-label, dose escalation trial with four dose-finding cohorts (Cohorts A–D) followed by two expansion cohorts (Cohorts E, F). Eligible pts include adults ≥18 yrs (≥20 for Japan), with measurable or evaluable disease, adequate organ

function, ECOG PS $\leq$ 1, and unresectable advanced or metastatic solid tumours after failure on standard therapy (Cohort A), postmenopausal locally advanced or metastatic HR+, HER2- BC (Cohorts B–D, F), or stage IV NSCLC after 1–2 lines of therapy and failure after platinum-based chemotherapy (Cohort E); CDK4/6 inhibitor-naïve pts (Cohorts A–E) and pts who have received prior CDK4/6 inhibitors (palbociclib or ribociclib) plus aromatase inhibitors (Cohort F) are included. Pts will receive either xentuzumab plus abemaciclib alone (Cohorts A, E) or in combination (at MTD defined for the doublet therapy) with letrozole (Cohort B), anastrozole (Cohort C), or fulvestrant (Cohorts D, F). Primary endpoints are the MTD and/or recommended phase-2-dose (RP2D; Cohorts A–D), and objective response (Cohorts E, F). Further endpoints include antitumour activity (Cohorts E, F), and pharmacokinetic outcomes (all Cohorts). This study will be conducted in the US, Europe and Japan. Pt screening is planned to start May 17; target enrolment: N≈88.

[1]Division of Hematology-Oncology, Departments of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [2]Section of Hematology & Oncology, Department of Internal Medicine, Seoul National University Hospital, Seoul, Republic of Korea, [3]Department of Internal Medicine, Yonsei Cancer Center, Seoul, Republic of Korea, [4]Center for Breast Cancer, National Cancer Center Hospital, Goyang, Republic of Korea, [5]Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [6]Department of Internal Medicine, Seoul National University Bundang Hospital, Seoul National University College of Medicine, Seongnam, Republic of Korea, [7]Department of Internal Medicine, Chungbuk National University Hospital, Cheongju, Republic of Korea, [8]Clinical Development Division, National OncoVenture, Goyang, Republic of Korea, [9]Clinical Research and Development, Hanmi Pharmaceutical Co., Ltd., Seoul, Republic of Korea

Background: Although the introduction of HER2 directed therapy including trastuzumab, pertuzumab, lapatinib, and TDM-1 in the treatment of HER2-positive metastatic breast cancer (mBC) patients favorably changed the natural history of this disease, HER2-positive mBC will eventually progress in most patients. Poziotinib is a novel, oral pan-HER kinase inhibitor which showed potent anti-tumor activities through irreversible inhibition of HER family tyrosine kinases.

Methods: This open-label, multicenter phase 2 study was designed to evaluate the efficacy and safety of poziotinib monotherapy in patients with HER2-positive mBC who have progressed from more than 2 HER2-directed therapies. Patients received poziotinib 12 mg once daily on a 14-day on/7-day off schedule. Dose escalation up to 16 mg was allowed at appropriate time point and dose reduction to 8-10 mg were performed according to toxicities. Progression-free survival (PFS) as the primary endpoint and objective response rate (ORR), overall survival (OS), and safety were evaluated.

Results: From Apr 2015 to Feb 2016, 106 patients were enrolled in the trial from 7 institutes in Korea. The patients were median age of 50 (range: 30∼76) who had received median 4 prior anti-cancer therapies including median 2 HER2-directed therapies in the advanced or metastatic setting. Median follow up duration was 12 months. The median PFS was 4.04 months (95% CI, 2.94 - 4.40 months), and median overall survival has not been reached. The disease control rate was 75.49% (77/102) including 20 patients with confirmed partial response. The most common treatment-related AEs were (total/grade≥3) diarrhea (96.23%/14.15%), stomatitis (92.45%/12.26%), and rash (63.21%/3.77%).

Conclusions: Poziotinib showed meaningful clinical activity in heavily-treated HER2-positive mBCs. Diarrhea and stomatitis were the major toxicities leading to dose modification. Biomarker study being analyzed from pre- and on-treatment biopsies is warranted to support further on the meaningful clinical outcomes of poziotinib in HER2-positive mBC.

Clinical trial identification: NCT02418689

238PD A randomized, double-blind study of PF-05280014 (a potential trastuzumab biosimilar) vs trastuzumab, both in combination with paclitaxel, as first-line treatment for HER2-positive metastatic breast cancer

M. Pegram[1], E. Tan-Chiu[2], A. Freyman[3], A. Vana[4], F. Hilton[5], C. Zacharchuk[3], R. Ewesuedo[3]

[1]Stanford Cancer Institute, Stanford University School of Medicine, Stanford, CA, USA, [2]Medical Oncology, Florida Cancer Research Institute, Plantation, FL, USA, [3]Pfizer Essential Health, Biosimilars Clinical R&D, Pfizer Inc, Cambridge, MA, USA, [4]Pfizer Essential Health, Biosimilars Clinical R&D, Pfizer Inc, San Diego, CA, USA, [5]Pfizer Essential Health Clinical Statistics, Pfizer Inc, Groton, CT, USA

Background: A biosimilar is a biologic product that is highly similar to an approved biologic drug. The humanized monoclonal antibody PF-05280014 (a potential trastuzumab biosimilar) has previously demonstrated similarity to trastuzumab in analytical, nonclinical, and clinical pharmacokinetics (PK) and safety studies. In this randomized, double-blind, efficacy and safety study, PF-05280014 was compared with trastuzumab sourced from the EU (trastuzumab-EU) as first-line treatment for patients (pts) with HER2-positive (HER2+) metastatic breast cancer (MBC).

Methods: Between 4 Apr 2014 and 22 Jan 2016, 707 pts with HER2+ MBC were randomized 1:1 to PF-05280014 or trastuzumab-EU, both given with paclitaxel (starting dose 80 mg/m^2; days 1, 8, 15 of each 28-day cycle). Trastuzumab was administered weekly until at least Week 33 (first dose 4 mg/kg; subsequent doses 2 mg/kg), with treatment continuing until progression. The primary endpoint was objective response rate (ORR; complete or partial response according to RECIST 1.1) by Week 25 and confirmed by Week 33, based on blinded central radiology review. Secondary endpoints included safety, measures of tumor control, immunogenicity, and PK.

Results: The risk ratio for ORR was 0.940 for PF-05280014 over trastuzumab-EU, with a 95% confidence interval of 0.842–1.049, which was within the pre-specified equivalence margin of 0.8–1.25. 1-yr progression-free survival (56% for PF-05280014 vs 52% for trastuzumab-EU) and 1-yr survival (88.84% vs 87.96%) were similar between groups. The safety profile, including incidence of serious adverse events, was similar in both arms, and no new safety signals were identified. After study drug initiation, all pts tested negative for antidrug antibodies, except 1 pt receiving trastuzumab-EU. Up to cycle 5 day 8, mean trough and peak serum concentrations were similar for both agents. At the cutoff for this primary analysis (24 Aug 2016), 558 pts remained ongoing in the study.

Conclusions: In pts receiving first-line treatment for HER2+ MBC, PF-05280014 was similar to trastuzumab-EU in terms of efficacy, safety, immunogenicity, and PK.

Clinical trial identification: NCT01989676; EudraCT number: 2013-001352-34

Background: In HER2 overexpressing MBC around 40% of pts treated with T-based regimens do not respond and half of them progress within a year. The combination of the SRC inhibitor D and T is synergistic in preclinical models. We conducted a phase II trial combining D with a standard first line treatment with T/P.

Methods: Pts with HER2+ MBC (by central laboratory) were included. First line treatment consisted of 28-day cycles with T 2mg/kg weekly, P 80mg/m2 (3 weeks on/1 week off) and D 100mg once daily administered in first line until radiologic or symptomatic progression (PD) or unacceptable toxicity. Primary objective was objective response rate (ORR); secondary objectives were safety, other efficacy variables (Clinical Benefit Rate (CBR), Time to Progression (TTP), Progression Free Survival (PFS)) and pharmacodynamic biomarkers (phosphorylated (p)-AKT, and p-SRC) in peripheral mononuclear cells (PBMCs).

Results: Twenty-nine pts were included; median age was 49 years (31-81), 12 pts (41%) were premenopausal, 22 (76%) had hormone-receptor positive tumors and 23 (79.3%) had visceral disease. The median number of cycles was 12 (1-35), 9 pts discontinued treatment due to PD, 6 for adverse events, 6 due to investigator/sponsor criteria and 8 due to other reason. The ORR was 79.3% (95% CI 60.3-92) and the CBR was 82.8% (95% CI 64.2-94.2). Median TTP was 23.9 months (95% CI 14.9-not reached (NR)) and median PFS was 23.9 months (95% CI 10.3-NR). The mean relative dose intensity of D, T and P was 98.3%, 99.8% and 89.7% respectively. G2-3 decrease in ejection fraction was seen in 10.3% (n = 3) and 24.1% (n = 7) of pts. No G4 toxicity was seen. G3 toxicities were limited to: fatigue, hypertension, neutropenia and hyponatremia (6.9% [n = 2] each). Phosphorylated SRC and AKT were reduced in PBMCs after 8h (4.4 and 1.9 folds, respectively) of D administration in cycle 1 day 1 in 16 assessed pts.

Conclusions: D can be safely combined with T and P and the combination is effective with a ORR that reached almost 80% of patients. We observed decreased levels of p-SRC and p-AKT in PBMCs in patients treated with D, as previously described in preclinical models.

240PD Comprehensive genomic profiling of primary and metastatic CDH1 mutated classic and pleomorphic invasive lobular breast carcinomas reveals markers of hormonal therapy resistance and opportunities for targeted therapies

J.S. Ross[1], L.M. Gay[2], J.A. Elvin[3], J. Suh[3], J-A. Vergilio[3], S. Ramkissoon[3], E. Severson[3], S. Daniel[3], G.M. Frampton[3], D. Fabrizio[3], A.B. Schrock[4], S.M. Ali[3], V.A. Miller[3], P. Stephens[3], J. Chung[2]

[1]Pathology, Albany Medical Center, Albany, NY, USA, [2]Pathology, Foundation Medicine, Cambridge, MA, USA, [3]R & D, Foundation Medicine, Cambridge, MA, USA, [4]Clinical Development, Foundation Medicine, Cambridge, MA, USA,

Background: Although invasive lobular breast cancer (ILC) is typically combined with the far more frequent ductal disease for clinical trials and research studies. We queried whether classic (CILC) and its uncommon pleomorphic variant (PILC) featured unique genomic alterations (GA) which could influence therapy for patients with relapsed and refractory disease.

Methods: From a series of 10,784 invasive breast carcinomas DNA was extracted from 40 µm of FFPE sections of 454 (4%) *CDH1* mutated ILC including 428 classic (CILC) (94%) and 26 pleomorphic (PILC) (6%) subtypes. CGP was performed on hybridization-captured, adaptor ligation-based libraries (mean coverage depth >600X) for up to 315 cancer-related genes. Total mutational burden (TMB) was determined on 1.2 Mbp of sequenced DNA.

Results: Median age at 63 years was similar for both CILC and PILC (see Table). Clincal ER+ status (p) was higher in CILC and HER2+ status was higher in PILC ($P < 0.0001$). *ESR1* substitution GA were significantly higher in CILC and the frequency of *ESR1* GA was significantly higher in CILC exposed to hormonal therapy (metastasis biopsies) than in pre-treatment primary tumors ($P < 0.0001$). *ERBB2* GA (amp + non-amp) detected by CGP were higher in PILC than CILC in both pre-and post-treatment samples ($P < 0.0001$ for both). *ERBB2* GA nearly doubled after hormonal treatment in both CILC and PILC. *PIK3CA* GA were similarly the most frequent GA in both CILC and PILC, but *TP53* GA were significantly more frequent in PILC than CILC. Median TMB was higher in PILC than CILC and TMB $\geq$ 15 mut/MB was more than twice as frequent in PILC than CILC ($P = 0.046$). Patients with post primary therapy associated *ESR1* and *ERBB2* GA responding to precision therapies will be presented.

Table: 240PD

	CILC (428)	PILC (26)
Median Age	63	63
*ER +	98%	74%
*HER2 IHC/FISH+	12 (3%)	6 (22%)
ESR1 GA Primary Pre-Rx	6%	0%
ESR1 GA Metastatic Post-Rx	17%	0%
ERBB2 GA Primary Pre-Rx	7%	18%
ERBB2 GA Metastatic Post-Rx	12%	34%
Other Significant GA	*PIK3CA* (55%), *CCND1* (21%), *TP53* (17%), *ARID1A*, *AKT3*, *MDM4*, *PTEN* (all 11%)	*PIK3CA* (58%), *TP53* (30%), *AKT1* 22%), *FGFR4*, *CCND1*, *PTEN* (all 17%)
TMB median (mut/Mb)	2.7	3.6
TMB $\geq$ 15%	8%	19%

*when clinical status available.

Conclusions: Both CILC and PILC show differences in GA in pre-treatment primary vs metastatic lesions in important genes such as ESR1 and ERBB2 likely reflecting the impact of primary therapies. Relapsed CILC is more often driven by ESR1 GA and PILC by ERBB2 GA. Both the CILC and PILC groups have subsets with high TMB, more frequent in PILC, indicating potential for immunotherapies for these patients.

Background: AZD5363 (AZD) potently and selectively inhibits AKT1–3. *PIK3CA* mutations increase sensitivity to AZD in vitro and in vivo. We conducted a randomised Phase 2 trial (NCT01625286), to compare the efficacy of AZD versus placebo, in combination with weekly paclitaxel, in advanced or metastatic ER+ve/HER2−ve breast cancer, and in a PIK3CA mutation sub-population (*PIK3CA*+).

Methods: Female patients (N = 110) aged ≥18 years with ER+ve/HER2−ve advanced or metastatic breast cancer who had received no prior chemotherapy in the advanced or metastatic setting were enrolled. Patients were randomised 1:1, stratified by PIK3CA mutation status (*PIK3CA*+ vs *PIK3CA*− in tissue or circulating tumour DNA), to receive paclitaxel 90 mg/m^2 i.v. once weekly for 3 weeks out of 4, plus oral AZD 400 mg, or matched placebo twice daily 4 days on, 3 days off, starting on the day after each paclitaxel administration. Enrolment was capped to ensure 50 *PIK3CA*+ patients were enrolled. Progression status and tumor response (RECIST 1.1) was assessed every 12 weeks. The primary endpoint was investigator-assessed progression-free survival (PFS).

Results: Median PFS was 10.9 months (95% CI 8.3–12.4) on AZD plus paclitaxel versus 8.4 months (95% CI 8.2–10.8) on placebo plus paclitaxel (HR 0.80, 80% CI 0.6–1.06, p = 0.31). In the *PIK3CA*+ subgroup, median PFS was 10.9 months (95% CI 8.7–11.5) on AZD plus paclitaxel versus 10.8 months (95% CI 8.3–14.3) on placebo plus paclitaxel (HR 1.11, 80% CI 0.73–1.68, p = 0.76). Objective response rate was 59% on AZD plus paclitaxel versus 57% on placebo plus paclitaxel. The most common adverse events were diarrhoea (76% AZD vs 27% placebo), alopecia (52% vs 49%), nausea (39% vs 24%) and anaemia (33% vs 27%). Adverse events grade 3 or higher included diarrhoea (24% vs 2%), hyperglycaemia (13% vs 0%) and neutropenia (11% vs 9%). Discontinuation rates due to adverse events were 13% on AZD and 7% on placebo.

Conclusions: Adding AZD to weekly paclitaxel did not prolong PFS in the overall population or *PIK3CA*+ subgroup of ER+ve/HER2−ve advanced or metastatic breast cancer.

242PD Initial results of a phase 1 dose expansion cohort of M6620 (formerly VX-970), an ATR inhibitor, in combination with cisplatin in patients with advanced triple-negative breast cancer NCT02157792)

M.L. Telli[1], S. Lord[2], E. Dean[3], V. Abramson[4], H-T. Arkenau[5], C. Becerra[6], S.M. Tolaney[7], R. Tang[8], M.S. Penney[8], J. Pollard[9], G. Conboy[8], S.Z. Fields[8], G. Shapiro[7]

[1]Oncology, Stanford University School of Medicine, Stanford, CA, USA, [2]Department of Oncology, Churchill Hospital, University of Oxford, Oxford, UK, [3]Oncology, The Christie NHS Foundation Trust, Manchester, UK, [4]Division of Hematology, Vanderbilt University Medical Center, Nashville, TN, USA, [5]Oncology, Sarah Cannon Research Institute SCRI UK, London, UK, [6]Baylor Charles A. Sammons Cancer Center, Texas Oncology, Dallas, TX, USA, [7]Oncology, Dana-Farber Cancer Institute, Boston, MA, USA, [8]Oncology, Vertex Pharmaceuticals Incorporated, Boston, MA, USA, [9]Oncology, Vertex Pharmaceuticals Limited, Oxford, UK

Background: ATR is a regulator of the cellular response to replication stress and signals DNA damage repair through homologous recombination. Many cancers depend on ATR to survive DNA damage. VX-970 is a potent, selective inhibitor of ATR with preclinical anticancer activity in combination with DNA-damaging chemotherapy in TNBC models. Given the prevalence of DNA damage repair defects in TNBC, this study evaluated the safety and efficacy of VX-970 in combination with Cis in an expansion cohort of pts with BRCA1/2 wild-type mTNBC.

Methods: Eligible pts had advanced ER-, PR-, and HER2- BC with 0-2 prior non–platinum-based therapies. First line pts were eligible if relapse occurred ≥ 3 months after prior (neo)adjuvant chemotherapy. Measurable disease per RECIST 1.1 was required. Of a maximum 50 pts planned for enrollment, ≥30 were required to be BRCA1/2 germline wild-type and to have basaloid molecular subtype tumors on central testing. Pts received intravenous Cis 75 mg/m^2 on day 1 with VX-970 140 mg/m^2 on days 2 and 9 of each 21-day cycle. In pts intolerant to Cis or at investigator's discretion, treatment could be switched to carboplatin AUC 5 with VX-970 90 mg/m^2.

Results: At the time of this analysis, 35 female pts with mTNBC who received ≥1 cycle of study drug were included in the safety set (median age, 48 y [range 35-74 y]). Grade ≥3 related TEAEs occurred in 16/35 pts: neutropenia (n = 8), anemia (n = 5), vomiting (n = 4), nausea (n = 3), and 1 pt each with thrombocytopenia, neutrophil count decreased, platelet count decreased, hypokalemia, generalized weakness, rigors, and acute kidney injury. Of these 35 pts, 18 were BRCA1/2 wild-type and had basaloid TNBC with at least 1 baseline scan and 1 on-treatment scan at the time of the data cut. Preliminary objective response rate was 38.9% (n = 7 [all partial response]), and disease control rate (CR+PR+SD) was 72.2% (n = 13).

Conclusions: Combination VX-970 and Cis shows encouraging antitumor activity and tolerability in mTNBC. The study is ongoing; updated safety and efficacy results will be presented.

Background: The Phase III OlympiAD study (NCT02000622) in patients with metastatic breast cancer (mBC) and a germline *BRCA* mutation (g*BRCA*m) showed a statistically significant progression-free survival (PFS) benefit for olaparib monotherapy over chemotherapy treatment of physician's choice (TPC; hazard ratio [HR] 0.58; 95% CI 0.43, 0.80; $P<0.001$; 7.0 vs 4.2 months for olaparib vs TPC, respectively). We report further efficacy outcomes for objective response, target lesion shrinkage and tumour burden.

Methods: OlympiAD was a randomized, open-label, Phase III study of olaparib monotherapy vs TPC in HER2-negative mBC patients with a g*BRCA*m who had received ≤2 chemotherapy lines in the metastatic setting. Patients were randomized 2:1 to olaparib tablets (300 mg bid) or single-agent TPC (capecitabine, eribulin or vinorelbine). Patients had ≥1 lesion suitable for assessments according to modified RECIST 1.1. The primary endpoint was PFS by blinded independent central review.

Results: 302 patients were randomized to olaparib (n = 205) or TPC (n = 97). In patients with measurable disease, objective response rate (ORR) was 59.9% for olaparib patients (n = 167; complete response [CR] 9.0%, partial response [PR] 50.9%, stable disease ≥5 weeks [SD] 25.1%; progressive disease [PD] 15.0%) and 28.8% for TPC patients (n = 66; CR 1.5%, PR 27.3%, SD 37.9%, PD 33.3%). Median best percentage change from baseline in target lesion size was −45.1% for olaparib and −14.8% for TPC.

Table 243PD Subgroup analyses for PFS by baseline tumour burden and location are shown in the Table.

	Olaparib 300 mg bid	Chemotherapy TPC
Tumour burden		
1 metastatic site, n	46	25
Median PFS, months	8.4	4.2
HR (95% CI)	0.62 (0.35, 1.13)

*Includes both bone and other tumour locations

Conclusions: Olaparib monotherapy in OlympiAD led to a doubling of ORR vs TPC and a larger reduction in target lesion size, indicating a more pronounced depth of response in HER2-negative g*BRCA*m mBC patients. PFS was longer with olaparib than with TPC, irrespective of tumour burden and location.

Background: The BOLERO-4 study demonstrated clinical benefit and an acceptable safety profile with first-line (1L) EVE + LET in postmenopausal pts with ER+, HER2− ABC. Pre-specified subgroup analyses evaluated PFS in pt subgroups: age (<65 years vs ≥ 65 years), visceral metastases (yes vs no), and bone-only lesions at baseline (yes vs no).

Methods: BOLERO-4 is an open-label, Phase II, multicenter, international, single-arm trial. Postmenopausal pts with ER+, HER2− ABC, with no prior therapy for advanced disease, received EVE 10 mg/day + LET 2.5 mg/day until disease progression, unacceptable toxicity, or withdrawal of consent. The primary endpoint was locally assessed 1L PFS on the overall full analysis set (FAS). Here we report 1L PFS data that was assessed based on the aforementioned pt subgroups. BOLERO-4 is registered with ClinicalTrials.gov (NCT01698918).

Results: At the data cut-off (Dec 17, 2016), 202 pts with ABC were enrolled for 1L treatment with EVE + LET. Median PFS, and 18- and 24-month Kaplan−Meier-estimated PFS rates were similar to the FAS irrespective of pt age, presence/absence of visceral metastases, or presence/absence of bone-only lesions at baseline (Table). The distribution and frequency of all-grade adverse events (regardless of causality) among pts aged <65 and ≥65 years was comparable with the overall population.

Conclusions: Treatment benefit with EVE + LET in the 1L setting was maintained across pt subgroups and was consistent with that observed in the FAS of the BOLERO-4 study. EVE + LET, therefore, is an effective 1L treatment for ER+, HER2− ABC, irrespective of pt age, visceral metastases, or bone-only lesions. These data support the potentially important role of EVE in the ABC treatment landscape.

Background: The Phase 3 MONALEESA-2 study (NCT01958021) demonstrated that addition of ribociclib (RIB; cyclin-dependent kinase 4/6 inhibitor) to letrozole (LET) significantly improved progression-free survival (PFS) in patients (pts) with hormone receptor-positive (HR+), HER2-negative (HER2–) advanced breast cancer (ABC). RIB benefit was observed as early as 8 weeks. Here we evaluate duration of response (DoR) and tumor shrinkage.

Methods: Postmenopausal women (N = 668) with HR+, HER2– ABC and no prior systemic therapy for ABC were randomized to RIB (600 mg/day; 3 weeks on/1 week off) + LET (2.5 mg/day; continuous) or placebo (PBO) + LET. Pts had measurable disease or ≥ 1 predominantly lytic bone lesion. Primary endpoint was PFS; DoR was an exploratory endpoint. Tumor assessments were conducted every 8 weeks for the first 18 months. For tumor shrinkage analyses, pts were grouped by quartiles (Q) for best % change in target lesion; pts were excluded from this analysis if best % change was unavailable or contradicted by overall response of unknown/progressive disease.

Results: Of 501 pts with measurable disease, 135 (53%) vs 91 (37%) pts had a complete response or partial response in the RIB + LET vs PBO + LET arm, respectively. At a median follow-up of 15.3 months, median DoR was not reached in either arm. Tumor shrinkage was evaluable in 443 (66%) pts. Pt characteristics were well-balanced in both arms and irrespective of tumor shrinkage, apart from *de novo* ABC in Q2–Q3 (RIB + LET vs PBO + LET; 46% vs 30%) and visceral disease in ≤Q1 (64% vs 84%). A higher proportion of pts in the RIB + LET vs PBO + LET arm experienced a best % change of at least 53% (**Table**). In all evaluable pts, mean % change in tumor size was greater in the RIB + LET vs PBO + LET arm at each tumor evaluation over the first 18 months.

Table: 245PD

Q	Cut-off	Corresponding best % change in tumor size	RIB + LET n=231	PBO + LET n = 212
≤Q1	≤25%	At least –53%	73 (32%)	38 (18%)
Q1–Q2	>25% to ≤ 50%	Between –53% and –33%	64 (28%)	52 (25%)
Q2–Q3	>50% to ≤ 75%	Between –33% and –12%	52 (23%)	54 (25%)
>Q3	>75%	Less than –12%	42 (18%)	68 (32%)

Conclusions: In postmenopausal women with HR+, HER2– ABC, first-line RIB + LET prolonged PFS and was associated with a greater degree of tumor shrinkage vs PBO + LET.

Background: The primary goal of this non-inferiority trial was to determine if an intermittent treatment regimen was not inferior to a continuous regimen, in first-line treatment of patients with HER2-negative, incurable, metastatic or unresectable locally advanced breast cancer.

Methods: Patients were randomised to receive 8 cycles or 2x4 cycles of paclitaxel/bevacizumab on days 1, 8 and 15 every 4 weeks, both with continuation of bevacizumab

once every 21 days until disease progression or unacceptable toxicity. If progressive disease occurred ≥ 3 months after the initial 4 cycles with paclitaxel/bevacizumab in the intermittent arm, another 4 cycles were given. If progressive disease occurred in the continuous arm or < 3 months after the initial 4 cycles in the intermittent arm, second-line treatment was started. The primary endpoint was progression-free survival (PFS), secondary endpoints included overall survival (OS). Intention-to-treat and per-protocol analyses were performed using a proportional hazards regression model. The two-sided 95% confidence interval (CI) for the hazard ratio (HR) was calculated and the upper limit was compared with the non-inferiority margin of 1.34.

Results: The intention-to-treat population comprised of 420 patients. The total median PFS in first-line treatment was 10.7 months (95% CI 7.03 - 12.42) for the intermittent regimen and 9.7 months (95% CI 8.94 - 10.28) for the continuous regimen (HR for disease progression or death [intermittent vs. continuous], 1.006; 95% CI 0.743 - 1.361). Results on OS were similar with a HR of 1.312 (95% CI 0.959 - 1.794). The per-protocol analysis showed comparable results. Safety results and actually delivered treatments did not reveal unexpected findings and will be presented at the meeting.

Conclusions: Intermittent first-line treatment with paclitaxel/bevacizumab is not non-inferior to continuous scheduling regarding PFS in patients with HER2-negative incurable locally advanced or metastatic breast cancer. Analysis of the secondary endpoint OS supported this conclusion. Therefore, intermittent first-line treatment cannot be recommended over continuous scheduling.

Clinical trial identification: EudraCT 2010-021519-18; BOOG 2010-02.

247P A single-arm, phase ii study assessing the efficacy of pembrolizumab (pembro) plus radiotherapy (RT) in metastatic triple negative breast cancer (mTNBC)

H.L. McArthur[1], C.A. Barker[2], A. Gucalp[3], L. Lebron Zapata[4], Y.H. Wen[5], A. Phung[2], M. Wilgucki[2], M. Henrich[3], B.B. Arnold[6], Z. Zhang[7], A. Ho[6]

[1]Medicine, Breast Medical Oncology, Samuel Oschin Comprehensive Cancer Institute Cedars-Sinai Medical Center, Los Angeles, CA, USA, [2]Radiation Oncology, Memorial Sloan Kettering Cancer Center, New York, NY, USA, [3]Medicine, Memorial Sloan Kettering Cancer Center, New York, NY, USA, [4]Radiology, Memorial Sloan Kettering Cancer Center, New York, NY, USA, [5]Pathology, Memorial Sloan Kettering Cancer Center, New York, NY, USA, [6]Radiation Oncology, Samuel Oschin Comprehensive Cancer Institute Cedars-Sinai Medical Center, Los Angeles, CA, USA, [7]Biostatistics, Memorial Sloan Kettering Cancer Center, New York, NY, USA

Background: Overall response rates of 13-19% have been reported with checkpoint inhibitor monotherapy in chemotherapy-resistant, PD-L1-positive mTNBC. RT is frequently used to enhance local control in mTNBC and has been reported to induce distant (abscopal) tumor responses when combined with immunotherapy. In this study we evaluate the safety and efficacy of RT combined with the anti-PD-1 inhibitor, pembro, in a single-arm, two-stage, phase II study in mTNBC (NCT02730130).

Methods: Eligible women had biopsy-proven mTNBC, ECOG performance status 0-2, and ≥2 measurable sites of metastatic disease with at least 1 site requiring RT. A total RT dose of 3000 cGy was delivered in 5 daily fractions. IV pembro was given at 200mg within 3 days of first RT fraction then every 3 weeks until disease progression. The primary endpoint was overall response rate at week 13 in the non-irradiated lesions by RECIST v1.1. Secondary endpoints included safety and overall survival. Tumor biopsies were obtained at baseline and at week 7. PD-L1 expression was not required for study entry.

Results: As of May 1, 2017, the study has completed enrollment (N = 17) with 4 women on treatment pending 13-week evaluation. Median age was 52y (range 37-73y). Median number of prior therapies received for metastatic disease was 3 (range 0 to 8). Of the 7 women not evaluable at 13 weeks: 5 died secondary to disease-related complications (at weeks 2, 6, 7, 8, and 9) and 2 came off study due to disease progression prior to week 13. Of the 6 women evaluable at week 13, 2 (33%) had a partial response (PR), 1 (17%) had stable disease (SD) and 3 (50%) had disease progression. The 2 PRs represented 76% and 75% decreases in tumor burden by RECIST v1.1 durable for 21 and 31 weeks, respectively. SD response was durable for 30 weeks. Common toxicities were mild and included fatigue, myalgia and nausea.

Conclusions: The combination of pembro and RT was well-tolerated. This is a poor prognosis population with 5/13 (38%) evaluable patients dying within 12 weeks of study entry. However, durable responses were observed outside of the RT field in 2/6 (33%) patients who were unselected for PD-L1 expression and evaluable at 13 weeks. Safety and toxicity data for all study patients will be presented.

NE=not estimable.

Methods: Postmenopausal women (N = 666) were randomized 2:1 to receive P (125 mg QD; 3 wk on, 1 wk off) + L (2.5 mg QD; continuously) or PBO+L. Prior neo(adjuvant) ET/CT with curative intent was allowed; prior ET or CT for recurrent advanced or metastatic disease was not. The primary endpoint was investigator-assessed progression-free survival (PFS); other key endpoints included response rates and safety. Exposure to P among subgroups is also presented.

Results: At baseline, 249/444 pts (56%) in the P+L arm had received prior ET and 213 (48%) had received prior CT (Table). Pts previously treated were slightly younger vs those not previously treated. Exposure to P+L was similar across subgroups. In P+L-treated pts, median PFS was 22.2/25.7 mo with prior ET/no prior ET and 22.4/25.7 mo for prior CT/no prior CT. The significant clinical benefit of P+L vs PBO+L remained regardless of prior ET/CT exposure. Across all subgroups, the incidence of all-causality adverse events (AEs) was similar; neutropenia was the most frequent AE. AEs leading to permanent discontinuation occurred in < 10% of pts.

Conclusions: Regardless of prior (neo)adjuvant treatment, P+L significantly prolonged PFS vs PBO+L and demonstrated consistent efficacy in pre-treated and non–pre-treated subgroups of postmenopausal pts with ER+/HER2– ABC. Tolerability was similar across subgroups and consistent with the known safety profile of P.

249P Analysis of overall survival by tumor response in MONARCH 1, a phase 2 study of abemaciclib, a CDK4 and CDK6 inhibitor, in women with HR+/HER2- metastatic breast cancer (MBC) after chemotherapy for advanced disease

J. Cortés[1], H.S. Rugo[2], S.M. Tolaney[3], V. Diéras[4], D. Patt[5], H. Wildiers[6], S. Nanda[7], A. Koustenis[8], M.N. Dickler[9], J. Baselga[9]

[1]Clinical Research Department, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain, [2]Department of Medicine, UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA, USA, [3]Department of Medicine, Dana-Farber Cancer Institute, Boston, MA, USA, [4]Department of Medical Oncology, Centre Eugène Marquis Rennes, France; Institut Curie, Paris, France, [5]Medical Oncology, Texas Oncology - Central Austin, Austin, TX, USA, [6]General Medical Oncology, University Hospitals Leuven, Leuven, Belgium, [7]Statistics-Oncology, Eli Lilly and Company, Bridgewater, MA, USA, [8]Oncology, Eli Lilly and Company, Indianapolis, IN, USA, [9]Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY, USA

Background: Abemaciclib is a selective inhibitor of CDK4 and CDK6 dosed orally on a continuous schedule. Abemaciclib monotherapy (MONARCH 1) has demonstrated antitumor activity in heavily pretreated patients with HR+/HER2- MBC in terms of objective response rate (ORR= CR + PR) (19.7%; 95% CI: 13.3, 27.5), disease control rate (DCR= CR + PR + SD) (67.4%), and clinical benefit rate (CBR= CR + PR + SD ≥ 6 months [m]) (42.4%). At 18 m minimum follow-up, the median progression-free survival (PFS) was 5.95 m (95% CI: 4.21, 7.50) and median overall survival (OS) was 22.3 m (95% CI: 17.7, NR). Treatment was well tolerated. The results from exploring associations between ORR and OS are reported.

Methods: The primary objective of MONARCH 1 (NCT02102490) was to evaluate ORR per RECIST 1.1. Secondary objectives included duration of response (DoR), PFS, OS, DCR, CBR and safety. To explore whether responders have a better survival than nonresponders, a Cox proportional hazards model with responder status as a time-dependent covariate was used. A multivariable analysis using Cox regression model including baseline factors (ECOG PS, age, PgR status, liver mets, pleural/peritoneal mets, number of chemotherapies, prior capecitabine, number of metastatic sites), and response status was conducted to adjust for any differences in baseline prognostic factors in the two groups. As a supportive analysis, a landmark analysis at 6 m was performed.

Results: 26/132 patients (19.7%) achieved a best response of PR (responders). In the analysis where response was included as a time dependent covariate, patients who responded had a better OS (HR 0.31; 95% CI: 0.12, 0.77; p=.01) compared with nonresponders. After adjusting for potential baseline prognostic factors, results were consistent (HR 0.31; 95% CI: 0.12, 0.79; p=.01). Landmark analysis at 6 m supported results from previous analyses (HR 0.34; 95% CI: 0.12, 0.95; p=.04).

Conclusions: An association between ORR and OS was observed. Responders have a better OS compared to nonresponders.

Background: Paclitaxel (PTX) is a standard chemotherapy drug for metastatic or recurrent breast cancer (m/r BC). However, it presents problems such as hypersensitivity and peripheral sensory neuropathy (PSN). NK105 is a novel nanoparticle drug delivery formulation that encapsulates PTX in polymeric micelles. In a murine model, passive targeting was shown and NK105 accumulated in tumors. We expected NK105 to have similar efficacy and a better safety profile, regarding hypersensitivity and PSN, compared with PTX, considering a past phase II study in gastric cancer patients (pts). This study aimed to verify the non-inferiority of NK105 to PTX in terms of progression-free survival (PFS) in m/r BC pts.

Methods: Eligible pts were randomly assigned at a 1:1 ratio to either the NK105 (N) or PTX (P) arm. NK105 (65 mg/m^2) and PTX (80 mg/m^2) were administered via intravenous infusion weekly for 3 weeks followed by a 1-week rest period until disease progression. Tumor responses were assessed every 6 weeks by RECIST Ver. 1.1. The primary endpoint was PFS, while the secondary endpoints were overall response rate (ORR), overall survival (OS), and safety. PSN was evaluated by CTCAE Ver. 4.03 and FACT/GOG-NTX Ver. 4 (FACT).

Results: From September 2012 to July 2014, 436 pts were randomized and 422 pts were included in the efficacy analysis. The median PFS (95% CI) for the N and P arms was 256 (212–302) and 260 days (211–350), respectively. The adjusted hazard ratio (95% CI) was 1.255 (0.989–1.592), exceeding the set non-inferiority margin. The ORR and median OS for the N and P arms were 31.6% vs. 39.0%, and 950 vs. 1103 days, respectively. Adverse drug reactions occurred in 96.7% pts in the N arm and 98.1% in the P arm. PSN incidences in the N and P arms were 52.8% and 70.0%, respectively and incidence of Grade 3 or more was lower in the N arm than in the P arm pts. Cumulative PSN incidences between the N and P arms were significantly different (P < 0.01) and were favored in the N arm.

Conclusions: The efficacy of 65 mg/m^2 of NK105 could not be verified in terms of non-inferiority of PFS relative to PTX in this study. NK105 safety profile was generally similar to that of PTX, but the NK105 PSN profile was better than that of PTX. NK105 efficacy should be re-evaluated in future studies.

Background: Prognosis of metastatic TNBC is poorer compared with those of other subtypes, because of the lack of effective treatment target. TNBC contains molecularly heterogeneous phenotypes, some of which are influenced by germline (g) *BRCA*1/2 mutation. Eribulin is one of standard treatments for metastatic TNBC and olaparib (Lymparza™), a PARP (poly ADP ribose polymerase) inhibitor, has shown remarkable efficacy in BRCA mutated breast cancer. Therefore, we evaluated the efficacy and safety of the combination of these drugs in a phase I/II trial (UMIN00009498) with an expectation of synergistic effect.

Methods: In phase I, we have determined the recommended dose as 300mg bid of olaparib twice daily and 1.4 mg/m^2 of eribulin intravenously on day 1 and 8 in 21-day cycle. The primary efficacy endpoint in phase II was tumor response rate (RR) in the central review. The planned size was 24, with one-sided alpha of 0.1, power of 0.8, expected RR of 0.3 and threshold of 0.1.

Results: Twenty-four patients were enrolled from June 2014 to December 2014 in phase II. The median age was 46 years old (range: 27 to 73). The median number of prior chemotherapy regimens was 3 (range: 2 to 6). Sixteen patients (66.7%) had visceral metastasis and 8 had non visceral metastasis. Dose intensity of eribulin was 0.69 (mg/m^2-week) and that of olaparib was 2086.2 (mg/week). RR in central review was 29.2% (80%CI: 17.0-44.2), including 7 with PR, 7 with SD, 7 with PD and 3 with NE; thus, the null hypothesis was rejected. In institutional decision, RR was 37.5% (9/24; 95%CI, 18.8-59.4), including1 patient with CR. Median progression-free survival was 4.2 months (95%CI: 3.0 to 7.4). Median overall survival was 14.5 months (95%CI: 4.8 to 22.0). Safety was analyzed separately for phase I and II. Significant severe adverse events (>=G3) were leukocytopenia (87.5%, 83.3%), neutropenia (87.5%, 83.3%), febrile neutropenia (20.8%, 33.3%), anemia (16.7%, 41.7%) and thrombosis (0%, 8.3%), respectively.

Conclusions: The combination of olaparib and eribulin was well tolerated and showed a promising efficacy and safety for metastatic TNBC.

252P Phase II study of gemcitabine, trastuzumab, and pertuzumab for HER2-positive metastatic breast cancer after prior pertuzumab-based therapy

N.M. Iyengar, L.M. Smyth, D. Lake, A. Gucalp, J.C. Singh, T.A. Traina, P. Defusco, M.N. Dickler, M.N. Fornier, S.B. Goldfarb, K. Jhaveri, S. Modi, T. Troso-Sandoval, K. Jack, G. Ulaner, M. Jochelson, J. Baselga, L. Norton, C.A. Hudis, C.T. Dang

Medicine, Memorial Sloan Kettering Cancer Center, New York, NY, USA

Background: The combination of taxanes with trastuzumab (H) and pertuzumab (P) for first line treatment of HER2-positive metastatic breast cancer (MBC) is associated with improved progression-free (PFS) and overall survival (OS). Treatment per physician's choice with anti-HER2 therapy after second line therapy is associated with a median PFS of 3 months. While continued use of H in therapeutic combinations after progression on H-based therapy is standard, the efficacy of continuing HP-based treatment after progression on P-based therapy is unknown.

Methods: This is a single arm phase II trial of gemcitabine (G) with HP. Eligible patients (pts) had HER2-positive (IHC 3+ or FISH $\geq$ 2.0) MBC with prior HP-based treatment and $\leq$ 3 prior chemotherapies. Pts received G (1200 mg/m^2) on days 1 and 8 of a q 3 week (w) cycle, and H (8 mg/kg load $\rightarrow$ 6 mg/kg) and P (840 mg load $\rightarrow$ 420 mg) q3w. The primary endpoint is PFS at 3 months. Secondary endpoints include OS, safety and tolerability. An exploratory endpoint is to compare PFS by RECIST criteria versus 18-F FDG-PET response criteria. The study therapy will be considered successful if at least 27/45 (60%) patients are progression free at 3 months.

Results: As of 27 April 2017, 45 of 45 pts are enrolled; 39 are evaluable at 3 months and 6 have not had 3-month evaluation. At 3 months, 30/39 (77%) are progression free (1 CR, 8 PR, 21 SD); 9 pts progressed. There are no cardiac or febrile neutropenic events to date. 4 pts required G dose reduction (3 grade 3 neutropenia and 1 grade 3 vomiting) and the study was amended to lower initial G dose to 1000 mg/m^2.

Conclusions: The preliminary 3 month-PFS is 77% in evaluable pts (95% CI 62% to 87%). The updated 3 month-PFS results will be presented. Continuation of P beyond progression is associated with apparent clinical benefit. A randomized trial is justified to confirm this clinically important observation.

253P Abemaciclib plus fulvestrant in patients (pts) with HR+/HER2- endocrine therapy naïve (EN) advanced breast cancer - an exploratory analysis of MONARCH 2

P.A. Kaufman[1], H. Iwata[2], P. Nikolinakos[3], J.T. Beck[4], H. Koh[5], J.L. Gonzalez-Trujillo[6], Y. Lin[7], S. Barriga[8], D. Headley[9], N. Bourayou[10], A. Llombart Cussac[11], G.W. Sledge Jr.[12]

[1]Medicine, Section of Oncology, Norris Cotton Cancer Center Dartmouth-Hitchcock Medical Center, Lebanon, NH, USA, [2]Breast Oncology, Aichi Cancer Center Hospital, Nagoya, Japan, [3]Hematology and Medical Oncology, University Cancer & Blood Center, LLC, Athens, GA, USA, [4]Department of Medicine, Highland Oncology Group, Fayetteville, AR, USA, [5]Department of Medical Oncology, Kaiser Permanente Medical Group, Bellflower, CA, USA, [6]Oncology, Fundacion Rodolfo Padilla AC, Leon Guanajuato, Mexico, [7]Global Statistical Sciences, Eli Lilly and Company, Indianapolis, IN, USA, [8]Oncology Clinical Development, Eli Lilly and Company, Madrid, Spain, [9]Oncology Clinical Development, Eli Lilly and Company, Indianapolis, IN, USA, [10]Oncology Clinical Development, Eli Lilly and Company, Paris, France, [11]Medical Oncology Service, Hospital Arnau Vilanova, Valencia, Spain, [12]Department of Medicine, Stanford University, Stanford, CA, USA

Background: MONARCH 2 demonstrated that the addition of abemaciclib, dosed on a continuous schedule at 150 mg twice daily, to fulvestrant (F) significantly improved progression-free survival (PFS) and objective response rate (ORR) compared to placebo (P) plus F (PFS hazard ratio [HR], 0.553, P<.0000001; ORR in measurable disease 48.1% vs 21.3%, P<.001) in women with hormone receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2-) advanced breast cancer (ABC) who had progressed on endocrine therapy (ET). Here we present efficacy and safety findings from an exploratory cohort of EN pts from MONARCH 2 not included in the intent-to-treat (ITT) population.

Methods: Pts were randomized 2:1 to receive abemaciclib or P + F (500 mg, per label). Pre/perimenopausal women received a gonadotropin-releasing hormone agonist. Pts were not allowed to have had chemotherapy in the advanced setting. Pts were stratified by metastatic site (visceral, bone only, other). The primary endpoint for this analysis was investigator-assessed PFS which was described using the Kaplan-Meier method and a Cox model.

Results: Forty-four EN pts were randomized to abemaciclib + F (N = 28) or P + F (N = 16). 46% of pts presented with visceral disease, 77% with measurable disease, and 82% were postmenopausal. At the time of the analysis, 18 pts were still on treatment (13 [46.4%] in the abemaciclib + F arm and 5 [31.3%] in the P + F arm). 18 PFS events were observed (9 [32.1%] in the abemaciclib + F arm and 9 [56.3%] in the P + F arm). The median PFS had not been reached in the abemaciclib + F arm and was 23.1 months in the P + F arm (stratified HR, 0.454; 95% CI: 0.179, 1.154). The ORR in pts with measurable disease was 60.0% (5% complete response [CR]) in the abemaciclib + F arm and 57.1% (0% CR) in the P + F arm. The most common adverse events were diarrhea, nausea, fatigue,

and neutropenia. Diarrhea generally occurred in the early cycles and was managed with dose adjustment and conventional anti-diarrheal medication.

Conclusions: In this exploratory cohort of EN pts, the addition of abemaciclib to fulvestrant demonstrated a comparable increase in PFS and consistent safety results to those observed in the ITT population in MONARCH 2.

254P Matching-adjusted indirect treatment comparison of ribociclib and palbociclib as first-line treatments for HR+, HER2– ABC

A. Forsythe[1], D. Chandiwana[2], M. Dolph[1], G. Tremblay[1], M. Monaco[2]

[1]Purple Squirrel Economics, New York, NY, USA, [2]Oncology, Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA

Background: Ribociclib (RIB) and palbociclib (PAL) combinations with letrozole (LET) vs LET alone have been evaluated in separate Phase 3 randomized controlled trials in patients with hormone receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2–) advanced breast cancer (ABC); however, no head-to-head comparative studies have been conducted. Classic indirect treatment comparison (ITC) can lead to biased results due to differences in patient populations and trial designs. These differences can be corrected by using the matching-adjusted indirect comparisons (MAIC) technique. Here, we compare RIB and PAL in patients with HR+, HER2– ABC using MAIC.

Methods: Individual patient data were available for the RIB trial (MONALEESA-2). As only published summary data were available for the PAL trial (PALOMA-2), RIB data were adjusted to closely match the PAL data. Data for RIB-treated patients were assigned weights so that weighted mean baseline characteristics matched those reported for PAL. Overall survival data have not been reported for PALOMA-2, thus only progression-free survival (PFS) data were compared. Adjusted hazard ratios (HRs) for PFS were calculated using weighted Cox regression models and used to calculate indirect HRs with 95% confidence intervals (CIs). Classic frequentist ITC was performed before and after adjustment. ITC of Grade 3/4 adverse events (AEs) was also performed.

Results: The unadjusted PFS HR (95% CI) for RIB+LET vs LET was 0.556 (0.429; 0.721) and for PAL+LET vs LET was 0.580 (0.460; 0.720). MAIC adjustment for age, race, region, Eastern Cooperative Oncology Group status, disease stage at diagnoses, sites of metastases, and chemotherapy setting at baseline provided a RIB+LET vs LET HR estimate of 0.501 (0.365; 0.688). The HR for unadjusted ITC of RIB vs PAL was 0.959 (0.681; 1.350) and by MAIC was 0.864 (0.586; 1.274). ITC of Grade 3/4 AEs yielded a risk ratio (RR) of 0.81 (0.61; 1.08) for RIB vs PAL.

Conclusions: Using MAIC methodology due to a lack of head-to-head trials, the resulting HRs for PFS were comparable. Similarly, using ITC, AE profiles were also comparable although the RR for AEs slightly favored RIB.

255P Phase 1 dose-escalation study of single-agent ZW25, a HER2-targeted bispecific antibody, in patients (pts) with HER2-expressing cancers

M. Beeram[1], E. Hamilton[2], M. Blum Murphy[3], D. Hausman[4], J.R. Infante[2], R. Korn[5], A. Patnaik[1], S.A. Piha-Paul[3], D. Rasco[1], G. Rowse[6], J. Thimmarayappa[4], A. Tolcher[1], F. Meric-Bernstam[3]

[1]Medical Oncology, South Texas Accelerated Research Therapeutics (START), San Antonio, TX, USA, [2]Medical Oncology, Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN, USA, [3]Medical Oncology, University of Texas MD Anderson Cancer Centre, Houston, TX, USA, [4]Clinical Development, Zymeworks Biopharmaceuticals Inc, Seattle, WA, USA, [5]Radiology, Imaging Endpoints LLC, Scottsdale, AZ, USA, [6]Therapeutics Research and Development, Zymeworks Inc, Vancouver, BC, Canada

Background: HER2 is expressed on many cancers (ca) at varying levels. ZW25, a novel bispecific antibody, targets the same HER2 domains as trastuzumab (T) and pertuzumab (P). In preclinical studies ZW25 shows increased binding, internalization and anti-tumor activity relative to T in models of low to high HER2.

Methods: 3 + 3 dose escalation study in pts with HER2 IHC 1-3+ or FISH+ ca, who have progressed after standard treatment (tx) including HER2 targeted agents, and have measurable or non-measureable disease per RECIST 1.1. ZW25 was given weekly (QW; 5, 10 or 15 mg/kg) or biweekly (Q2W; 20 mg/kg) in 4 week cycles. Assessments included HER2 status (local and central read), adverse events (AEs), tumor response, PET scan, immunogenicity and PK.

Results: 16 pts (8 breast; 6 gastric/esophageal ≥; 1 colorectal [CRC]; 1 adnexal) have received ZW25 QW at 5 (n = 3), 10 (n = 6) and 15 mg/kg (n = 7); 20 mg/kg Q2W is enrolling. All pts had prior T; breast ca pts also had T-DM1 (n = 8), P (n = 6) or lapatinib (L; n = 6). 12 pts had IHC 3+/FISH+ ca (local and central read); 1 CRC ca was HER2 heterogeneous (IHC 3+/FISH+ and IHC 0/FISH -), and 3 GE were IHC 1 + (central read). No dose limiting toxicities were observed. The most common AEs were Diarrhea (44%, all grade 1), Infusion reaction (IR) (44%, grade 1 and 2), and Fatigue (31%). PK was non-linear and increased with dose of ZW25. 8/13 pts tested had anti-drug antibodies (ADA) at baseline. No increases in titers and no new detectable ADA were seen. In 7 breast ca pts (1 too early), best overall response (BoR) was 2 PR (both 10 mg with prior T, P, T-DM1, L); 2 SD (>8 cycles in 5 mg pt with prior T, P, T-DM1; >2 cycles in 15 mg pt, with T, P, T-DM1, L); and 3 PD. BoR in 5 GE pts (1 too early): 1 SD > 4 cycles (10 mg, prior T, IHC 3+) and 4 PD. BoR in adnexal (10 mg) and CRC (15 mg) pts was PD.

Conclusions: ZW25 was well tolerated with promising single-agent activity including SD > 6 mo and PR in pts with HER2 expressing ca who have progressed after standard tx, including multiple lines of prior HER2 targeted agents. These early signs of activity support the therapeutic potential of ZW25.

256P Efficacy of palbociclib plus fulvestrant in advanced Hormone Receptor-positive (HR+) metastatic breast cancer (MBC) pretreated with everolimus: Real-life data from the french temporary authorization for use (TAU) at the Institut de Cancérologie de l'Ouest

P. Du Rusquec[1], C. Palpacuer[2], L. Campion[2], A. Patsouris[3], P. Augereau[3], C. Gourmelon[1], M. Robert[1], L. Dumas[4], C. Folliard[5], M. Campone[1], J-S. Frenel[1]

[1]Medical Oncology, Centre Rene Gauducheau, Nantes, France, [2]Biostatistics, Centre Rene Gauducheau, Nantes, France, [3]Medical Oncology, Centre Paul Papin, Angers, France, [4]Pharmacy, Centre Rene Gauducheau, Nantes, France, [5]Pharmacy, Centre Paul Papin, Angers, France

Background: The CDK4-6 inhibitor palbociclib, combined with hormonal therapy is a new standard of treatment for HR+ Metastatic Breast Cancer. Before the European Medicines Agency approval, a Temporary Authorization for Use (TAU) has been set up in France restricted to patients pretreated with everolimus. We present the efficacy data of this combination in this population.

Methods: Between November 2015 and November 2016, all the patients treated with palbociclib + fulvestrant according to the TAU in our institution were prospectively included. Datas from their medical records and adverse events (AE) were collected.

Results: 60 patients received at least one dose of palbociclib in combination with fulvestrant with a median age of 61 years. 50 patients (83.3%) had visceral metastasis and 10 (16.7%) had bone only disease. Patients had received an average of 5.3 lines of treatment before palbociclib initiation, including hormonal therapy (mean = 3.0) and chemotherapy (mean = 2.3). Of note, 28 patients (46.7%) had received fulvestrant previously and all had been pretreated with everolimus. With a median follow-up of 8.1 months, median progression free survival (PFS) was 6.1 months (95% CI, 4.2 to 7.4) and median overall survival was not reached. PFS was the same according to the presence of visceral metastasis or no (HR 1.46 (95% CI, 0.57 to 3.74), p = 0.42). Interestingly, patients treated previously with fulvestrant and subsequently re-challenged with fulvestrant and palbociclib had a PFS of 6.4 months, which was similar to patients who didn't receive fulvestrant previously (HR = 1.00 (95% CI 0.55 to 1.83), p = 1.00). The most common AE were neutropenia (n = 53), thrombocytopenia (n = 25) and anemia (n = 20). At the time of this analysis (April 2017), 36 patients received a further line of treatment after progression.

Conclusions: In this heavily pretreated population, the association of fulvestrant plus palbociclib provides an interesting median PFS of 6.1 months. Patients previously treated with fulvestrant seem to derive the same magnitude of benefit compared to fulvestrant naive patients.

257P A phase 1 study of BYL719, an α-isoform selective PI3K inhibitor, in Japanese patients with advanced solid malignancies

J. Tomomatsu[1], S. Iwasa[2], H. Saka[3], S. Takahashi[1], K. Nakano[1], S. Morita[4], M. Inoue[4], H. Nakahama[2], Y. Kogure[3], T. Kakizume[5], K. Natsume[5], T. Aoki[5], C. Quadt[6], Y. Yamada[2], Y. Ando[4]

[1]Department of Medical Oncology, The Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, Japan, [2]Department of GI Medical Oncology, National Cancer Center Hospital, Tokyo, Japan, [3]Department of Respiratory Medicine, Nagoya Medical Center, Nagoya, Japan, [4]Department of Clinical Oncology and Chemotherapy, Nagoya University Hospital, Nagoya, Japan, [5]Oncology, Novartis Pharmaceuticals KK, Tokyo, Japan, [6]Oncology, Novartis Pharmaceuticals AG, Basel, Switzerland

Background: BYL719 is an oral inhibitor that selectively targets the α-isoform of class l PI3K. In a first-in-human ph1 study in mostly Western patients (pts) with *PIK3CA* alteration, the maximum tolerated dose for once-daily (qd) BYL719 was declared as 400 mg and preliminary antitumor activity was observed. Previous preliminary findings showed tolerability, safety, and pharmacokinetic (PK) results in dose escalation of the first-in-Japanese ph1 study. Here, we report results of the food effect on the PK profile of BYL719 at steady state, additional safety, and preliminary efficacy in Japanese pts.

Methods: Pts were aged ≥18 years with histologically confirmed, advanced solid tumors. Pts received BYL719 qd in 28-day cycles until disease progression, unacceptable toxicity, or investigator/pts decision. The objectives in the expansion part were to assess food effect on PK profile, preliminary antitumor activity, and safety. Pts with PIK3CA alteration were selected in the expansion part and were randomized to receive BYL719 at the recommended dose 350 mg qd in fasted or fed condition on cycle 1 day 22 and cycle 2 day 1 in a crossover fashion. Pts received BYL719 ∼1 hr following a light breakfast and continued to be fasted for 1 hr after each dose.

Results: Thirty-three pts were enrolled and all pts discontinued treatment. The median duration of exposure was 71.0 days (range, 6-462). The common BYL719-related all-grade (Gr) AEs (>30%) were hyperglycemia, rash maculopapular (48.5%, each), diarrhea (45.5%), and decreased appetite (33.3%). BYL719-related Gr 3 or 4 AEs (≥20%) were rash maculopapular (24.2%) and hyperglycemia (21.2%). Eight pts were enrolled in the expansion part; six of them were eligible for PK analysis. The geometric mean values of dose-normalized C_{max} and $AUC_{0\text{-}24}$ in fed state were 78% and 56% higher than those in fasted state, respectively. One pt experienced Gr 4-infected neoplasm meeting DLT criteria, 1 pt with uterus cancer and *PIK3CA* mutation had an unconfirmed partial response, and 18 pts had a stable disease.

Conclusions: In this ph1 study of BYL719 in Japanese pts, a positive food effect and preliminary antitumor activity were observed at steady state in pts with *PIK3CA* mutation status.

258P Phase 1 study of RX-5902, a novel orally bioavailable inhibitor of phosphorylated P68, which prevents β-catenin translocation in advanced solid tumors

J. Diamond[1], G. Eckhardt[2], L. Gluck[3], M. Gutierrez[4], C. Peterson[5], R. Pila[6], E. Benaim[7]

[1]Department of Medicine, University of Colorado Denver School of Medicine, Aurora, CO, USA, [2]Anschutz Cancer Center, University of Colorado Denver School of Medicine, Aurora, CO, USA, [3]Oncology, Clinical Research Unit ITOR, Greenville, SC, USA, [4]John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NJ, USA, [5]Clinical Operations, Rexahn Pharmaceuticals, Inc, Rockville, MD, USA, [6]Clinical Operations, Rexahn Pharmaceuticals, Inc, Rockville, MD, USA, [7]Oncology, Rexahn Pharmaceuticals, Inc, Rockville, MD, USA

Background: RX-5902 is a novel compound that targets phosphorylated p68 RNA helicase (also known as DDX5), a member of the DEAD box family of RNA helicases. Phosphorylated p68 may play a vital role in cell proliferation and tumor/cancer progression through inhibition of β-catenin translocation. We report preliminary results of the Phase 1 study of RX-5902 as a single agent to treat advanced solid tumors.

Methods: The dose finding portion of the Phase 1 study (NCT02003092) was designed to evaluate safety, tolerability and dose limiting toxicities, to identify the maximum tolerated dose and a recommended phase 2 dose and schedule (RP2D). Secondary objectives were pharmacokinetics (PK) and antitumor activity (RECIST v1.1). Eligible subjects (aged ≥ 18 years), with relapsed/refractory solid tumors that had been heavily pretreated, received oral RX-5902 ranging from 25 mg to 350 mg and administered at 1, 3, 5 or 7 times per week for 3 weeks followed by 1 week of rest or for 4 weeks without rest.

Results: As of May 2017, 35 subjects (23 Females, 12 males) were treated with oral RX-5902. The dose limiting toxicities were G4 hyponatremia (n = 1) and G3 fatigue (n = 1) at 300 mg administered daily for 4 weeks. The maximum tolerated dose of 250 mg, will be studied further in the Phase 2a portion. Of the 35 subjects treated, 15 subjects (breast ER+/PR+/Her2-, triple negative breast (n = 2), cervical (n = 2), neuroendocrine (n = 3), paraganglioma, colorectal (N = 3), pancreatic, ovarian, head and neck cancers) experienced stable disease; 2 subjects have received treatment for > 2.5 years. The most common related adverse events were G1/G2 anorexia, G1/G2 nausea, G1/G2 vomiting, G1/G2 diarrhea, G1 weight loss and G1/G2 fatigue. Oral RX-5902 was bioavailable with median T_{max} of 2 hours and median elimination half-life of 12 hours.

Conclusions: Data from this study support that RX-5902 is safe and well-tolerated at the doses and schedules tested. The RP2D of 250 mg of RX-5902 administered daily for 5 consecutive days for 4 weeks is being studied further in metastatic triple negative breast cancer in the Phase 2 portion of this study.

Background: ESO/ESMO develops consensus guidelines for MBC treatment every 2 years, potentially applicable worldwide. Aim of the present analysis is to verify the adherence to ABC recommendations for HER2-ve MBC in the context of the AMBRA study.

Methods: AMBRA is a longitudinal cohort study, aiming to describe the choice of first and subsequent lines of treatment in HER2-ve MBC pts receiving at least one Chemotherapy (CHT) (SABCS 2016, P5-15-07 & P5-14-09). For the present analysis, we selected 4 statements from the ABC1 & ABC2 Conferences, comparing them with the clinical choices of 1st-line therapy in all evaluable cases.

Results: So far, 791 pts have been enrolled, of whom 586 (74.1%) have received CHT as 1st-line treatment. 479 pts (81.7%) had Luminal tumours at diagnosis. First-line CHT was monotherapy in 89 pts (25.2%), anthra-based CHT in 45 (7.7%) and platinum-based in 38 (6.5%), mainly TNBC (20/38, 52.6%). Selected recommendations and percentages of adherence are reported in Table.

Conclusions: The adherence to clinical recommendations is very low, being only partially applied in all the clinical situations analyzed. Educational interventions are urgently needed and a confrontation with the clinical community is strongly recommended.

Table: 259P Adherence to ABC recommendations for HER2-ve pts

	n/N (%of adherence)	
1 - Anthracycline (A)- or Taxane (T)-based regimens, preferably as a single agent, would usually be considered as first-line CHT, in those pts who have not received these regimens as adjuvant treatment	A/T mono 59/270 (21.8%) A/T poly 101/270 37.4%)	160/270 (59.2%)
2 - In pts with taxane-naive and anthracycline-resistant MBC, taxane-based therapy, preferably as a single agent, would usually be considered as the treatment of choice	T mono 89/431 (20.6%) T poly 119/431 (27.6%)	208/431 (48.2%)
3 - Other options are Capecitabine and Vinorelbine	135/586 (23.0%)	
4 - If given in the adjuvant setting, a taxane can be re-used in the metastatic setting, particularly if there has been at least 1 year of disease-free survival	DFI > 12 months 74/79 (93.7%) DFI </= 12 months 5/79 (6.3%)	79/151 (52.3%)

260P M-bioscore: A practical tool for predicting outcomes among patients with previously untreated metastatic breast cancer

O. Abdel-Rahman

Clinical Oncology, Ain Shams University Faculty of Medicine, Cairo, Egypt

Background: Two prognostic models "bioscore" and "Neo-bioscore" were recently published and validated to help predict the outcomes of patients with non-metastatic breast cancer treated with either upfront surgery or upfront neoadjuvant chemotherapy. A comparable model for metastatic disease is yet to be developed. The current study thus sought to propose and validate a third model "M-bioscore" to help predict the outcomes of treatment-naïve patients with metastatic breast cancer.

Methods: Through SEER*Stat program, surveillance, epidemiology and end results (SEER) database (2010-2013) was accessed. The resulting cohort was equally split into two halves: training set (to guide model development) and validation set (to test the model prediction). Multivariate analysis for the candidate prognostic factors (extent of metastases, estrogen receptor (ER), progesterone receptor (PR), HER2 neu and nuclear grade) was conducted through a Cox proportional model. M-bioscore was then calculated for each patient. Cancer-specific survival analyses according to M-bioscore were conducted through Kaplan-Meier analysis/log-rank testing.

Results: A total of 6655 patients with previously untreated metastatic breast cancer and complete data were identified in the period from 2010-2013. The following factors were associated with better cancer-specific survival in multivariate analysis in the training set (isolated distant nodal metastases, ER positivity, PR positivity, HER 2 neu positivity and lower nuclear grade) ($P < 0.01$). This has been shown for both training and validation sets. accordingly, the M-bioscore model has been proposed as follows: an M-bioscore point is given for each of ER negativity, PR negativity, HER2 neu negativity and nuclear grade 3. The site/distribution of metastasis are given the following points: 0 for isolated distant lymph nodes, 1 for isolated bone/skin deposits, 2 for isolated liver/lung deposits, 3 for isolated brain deposits or multiple sites of metastases. A total M-bioscore was then calculated for each case in the training cohort (which may range from 0 to 7). After assignment of a total M-bioscore for each patient, cancer-specific survival was compared according to the score. Log rank testing with pair wise comparisons between all different scores was conducted. For cancer-specific survival assessment according to the M-bioscore, *P* values for pair wise comparisons among different score points were significant ($P < 0.05$) except for the comparison between score 0 and score 1/score 2/score 3 in the training cohort. These findings have been confirmed in the validation and overall cohorts. Table shows the three year cancer-specific survival (CSS) rates for patients in the overall cohort according to M-bioscore.

Conclusions: M-bioscore is a novel, easy and reliable tool for predicting the outcomes of patients with previously untreated metastatic breast cancer. Further external validation within the context of other population-based cohorts is recommended.

Legal entity responsible for the study: Omar Abdel-Rahman

Table: 260P Three-year cancer-speci˚c survival according to M-bioscore

M-bioscore	All patients	
	N (%)	CSS rate
0	22 (0.3%)	95%
1	273 (4.1%)	81%
2	1567 (23.5%)	69%
3	1202 (18.1%)	60%
4	1680 (25.2%)	52%
5	1038 (15.6%)	35%
6	590 (8.9%)	26%

261P Is PFS a more relevant endpoint than OS in 1L HR+, HER2– MBC? A systematic literature review

A. Forsythe[1], D. Chandiwana[2], J. Barth[3], M. Thabane[4], J. Baeck[2], A. Shor[1], G. Tremblay[1]

[1]Purple Squirrel Economics, New York, NY, USA, [2]Oncology, Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA, [3]Oncology, Novartis Pharma GmbH, Nuremberg, Germany, [4]Oncology, Novartis Pharmaceuticals Canada Inc., Dorval, QC, Canada

Background: Hormone receptor-positive (HR+), human epidermal growth factor 2 receptor-negative (HER2–) metastatic breast cancer (MBC) accounts for 73% of all MBC.[1] Endocrine therapy (ET) is the basis of first-line (1L) therapy for patients (pts) with HR+, HER2– MBC; however, efficacy is limited by ET resistance. Novel therapies have demonstrated improvements in progression-free survival (PFS) vs standard ET. The clinical relevance of PFS is debated due to a lack of direct correlation with overall survival (OS) benefit, and cases of asymptomatic progression. We review studies of HR+ HER2– MBC to assess factors that influence OS and treatment response, and changes in health-related quality of life (HRQoL).

Methods: The Embase®, MEDLINE®, and Cochrane databases were systematically searched to identify studies in adult women with HR+, HER2– MBC, published 2006–January 2017, and written in English. Phase (Ph) 2 and 3 randomized controlled-trials (RCTs), observational, and retrospective studies were considered and HRQoL and real-world evidence reviewed.

Results: 79 RCTs were identified: 58 (73%) in the 1L setting and 21 (27%) in the ≥second-line setting. PFS data were reported in 61 (77%) studies; 31 (51%) reported significant PFS improvement. OS was reported in 44 (56%) of studies; only 11 (14%) reported a significant OS improvement. Significant improvements in both PFS and OS were reported in only 6 (8%) studies (1 Ph 2; 5 Ph 3). Pts with HER2– MBC received on average ≥5 lines of therapy, with no defined treatment pathway. Baseline characteristics, prior therapies, and the type and number of post-progression therapies significantly impacted OS. PFS, response rates, and HRQoL decreased with each line of therapy (EQ-5D: 0.78 1L vs 0.70 post-progression).

Conclusions: Multiple HR+, HER2– MBC therapies have been investigated yet few CTs have achieved a significant improvement in OS. Multiple factors besides the choice of 1L therapy impact OS, such as post-progression therapies, which cannot be controlled in RCTs. This study emphasizes the importance of PFS improvement coupled with HRQoL maintenance in 1L treatment of HR+, HER2– MBC. 1. Howlader N *et al. J Natl Cancer Inst* 2014;106:dju055.

262P PFS/TTP as a potential surrogate for OS in HR+, HER2– MBC

A. Forsythe[1], D. Chandiwana[2], J. Barth[3], M. Thabane[4], J. Baeck[2], A. Shor[1], G. Tremblay[1]

[1]Purple Squirrel Economics, New York, NY, USA, [2]Oncology, Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA, [3]Oncology, Novartis Pharma GmbH, Nuremberg, Germany, [4]Oncology, Novartis Pharmaceuticals Canada Inc., Dorval, QC, Canada

Background: Several, recent randomized controlled trials (RCTs) in hormone receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2–) metastatic breast cancer (MBC) have demonstrated a significant improvement in

progression-free survival (PFS); however, few have reported an improvement in overall survival (OS). OS may be an imperfect endpoint due to the impact of factors such as baseline characteristics and subsequent therapies. Investigation of the use of PFS or time to progression (TTP) as a surrogate for OS in HR+, HER2– MBC has been limited. This study assesses the correlation of PFS/TTP and OS in HR+, HER2– MBC across all lines of therapy.

Methods: A systematic literature review of RCTs in HR+, HER2– MBC was conducted to identify studies that reported both median PFS/TTP and OS. The correlation between PFS/TTP and OS was evaluated using Pearson's product-moment correlation and Spearman's rank correlation. Subgroup analyses were performed to explore possible reasons for heterogeneity. Errors-in-variables weighted least squares regression (LSR) was used to model incremental OS months as a function of incremental PFS/TTP months. An exploratory analysis investigated the impact of 3 covariates (chemotherapy vs other, PFS vs TTP, and 1L vs > 1L) on the use of PFS/TTP in OS prediction. The lower 95% prediction band was used to determine the minimum incremental PFS/TTP months below which there would be no predicted OS benefit (the surrogate threshold effect [STE]).

Results: A total of 39 studies were identified. There was a statistically significant correlation between median PFS/TTP and OS (Pearson=0.741, $p < 0.000$; Spearman=0.650, $p < 0.000$). Results were unchanged for chemotherapy and hormonal or targeted therapy, and for line of therapy. Initial LSR analysis yielded an R^2 of 0.354; 1 PFS/TTP month corresponded to 1.13 OS months. The addition of 3 covariates improved R^2 to 0.569; 1 PFS/TTP month corresponded to 0.78 OS months. The STE for OS benefit was 5–6 months of incremental PFS/TTP.

Conclusions: Results of this study indicate a significant association between PFS/TTP and OS, which may justify the use of PFS/TTP as surrogate for OS benefit during regulatory approval and subsequent reimbursement of new therapies in HR+, HER2– MBC.

263P Survival gains from advances in first-line systemic therapy for HER2-positive metastatic breast cancer in the U.S., 1995-2015

J. Roth[1], P. Bajaj[2], S. Sullivan[3], C. Reyes[4], V. Antao[5], A. Stein[6], R. Mahtani[7], S. Ramsey[1]

[1]Public Health Sciences, Fred Hutchinson Cancer Research Center, Seattle, WA, USA, [2]Health Economics and Outcomes Research, Genentech Inc. - Roche - USA, South San Francisco, CA, USA, [3]Pharmacy, University of Washington, Seattle, WA, USA, [4]Health Economics and Outcomes Research, Genentech Inc., South San Francisco, CA, USA, [5]US Medical Affairs, Genentech Inc. - Roche - USA, South San Francisco, CA, USA, [6]Breast & Gyn Oncology, Genentech Inc., South San Francisco, CA, USA, [7]Hematology/Oncology, Sylvester Comprehensive Cancer Center, Deerfield Beach, FL, USA

Background: Of the approximately 67,000 women diagnosed with metastatic breast cancer (mBC) annually in the U.S., nearly 10,700 are HER2-positive (HER2+). Prior to the advent of HER2 targeted therapy, women with HER2+ mBC had a less favorable prognosis than those with HER2-negative mBC. The objective of this study was to quantify survival gains for women with HER2+ mBC from 1995-2015, a period spanning pre HER2 targeted therapy to the present, where multiple targeted therapies are available.

Methods: We developed a simulation model to estimate overall survival (OS) for successive cohorts diagnosed with HER2+ mBC from 1995-2015. OS data were derived from clinical trials referenced in NCCN guidelines and extrapolated to a lifetime horizon by fitting Weibull curves. Patients were assigned to regimens in each diagnosis year using information from the IPSOS 'Global Oncology Monitor'- a commercial treatment registry. Results were calibrated with SEER OS data. Outcomes included 5-year OS, expected OS, and total life years (LYs) for all patients with HER2+ mBC. Annual incidence of HER2+ mBC was assumed to be constant over time.

Results: Over the period 1995-2015, expected 5-year OS for women with HER2+ mBC increased by 28.9%. Mean expected per-patient OS improved by 28.1 months (25,000 population LYs) (see Table). The largest gain (15.7 months) occurred between 2010 and 2015–the period over which pertuzumab-based treatment was approved for first-line use and gained substantial market penetration. The smallest gain (2.4 months) occurred between 1995 and 2000—the period over which trastuzumab-based treatment was approved, but had not yet achieved market penetration.

Conclusions: The introduction and expanded use of targeted treatments, along with other advances in care, have provided substantial individual- and population-level survival gains for women with HER2+ mBC. A considerable proportion of the expected OS differences between 1995 and 2015 took place after the introduction and uptake of trastuzumab and pertuzumab-based regimens.

Table: 263P

Diagnosis Year	5-Year OS (%)	Mean Per-Patient OS (Months)	Population Life Years
2015	38.8	55.3	49300
1995	9.9	27.2	24300
Difference	+28.9	+28.1	+25000

Background: Brain metastases (BM) are frequent in HER2+ MBC occurring in > 30% of pts and are associated w significant neurologic morbidity and mortality. Current treatment strategies for BM primarily utilize radiotherapy (RT) and in selected instances surgical resection. Tucatinib is a highly selective oral HER2+ tyrosine kinase inhibitor that has shown promising results in HER2+ MBC both in pts w and w/o BM.

Methods: Two Phase 1b studies of tucatinib were pooled to compare PFS and sites of relapse in pts w or w/o BM.

Results: 77 pts were analyzed, all treated at the recommended Phase 2 dose of 300mg PO BID of tucatinib, 50 in the 004 trial (tucatinib + T-DM1) and 27 in the 005 trial (tucatinib + trastuzumab + capecitabine). All pts were heavily pretreated w a median of 3 prior therapies including a taxane, trastuzumab, pertuzumab, T-DM1 and lapatinib. Four cohorts of pts were identified: 46% (35) had systemic metastases only, 17% (13) had previously treated (RT w or w/o surgery) and stable BM, 19% (15) had previously treated and progressive BM and 17% (13) had asymptomatic untreated BM demonstrated by screening MRI. Median PFS across cohorts was 8.5, 6.1, 9.0 and 7.1 months, respectively. No statistically significant difference in PFS was seen when comparing the non-BM cohort to all BM cohorts (median of 8.5 vs. 6.7 months; $p = 0.65$). The risk of progression in brain in pts w baseline BM was 48.8% overall (41.5% in brain only; 7.3% in brain and body) compared to an 11.1% overall (8.3% in brain only; 2.8% in brain and body) in pts w/o baseline BM.

Conclusions: 54% of pts entered tucatinib studies w baseline BM, either previously treated (stable or progressive) or untreated. The cohorts of pts analyzed appear to differ only in the site of disease progression. Although pts w/o baseline BM primarily have progression in extraneural sites and pts w baseline BM primarily have progression in the CNS, PFS is comparable across cohorts. Furthermore, pts both w and w/o BM have durable responses w these combination therapies following multiple lines of prior HER2 targeted therapy. These data support the use of tucatinib in both pts w and w/o BM in the accruing HER2CLIMB trial.

Clinical trial identification: ONT-380-004 and ONT-380-005

Background: For HR+/HER2– metastatic breast cancer (mBC), international guidelines recommend the use of endocrine therapy (ET) as first-line (L1) treatment except in case of "visceral crisis" for which chemotherapy (CT) is advised. Few studies directly compare these two treatment options. In 2014, UNICANCER launched the Epidemiological Strategy and Medical Economics (ESME) Research program to centralize real-world data in oncology. We sought to use this database to study this question.

Methods: All patients (pts) who initiated treatment for a newly diagnosed mBC between January 2008 and December 2014 in all 18 French Comprehensive Cancer Centers were included in the ESME mBC database. ESME Research program centralized all existing data using retrospective data collection. Primary endpoint of the present study was progression free survival (PFS1) and overall survival (OS) according to L1 treatment for aromatase inhibitors sensitive (AIS) HR+/HER2- mBC pts.

Results: 6265 pts out of 16703 in ESME, had AIS HR+/HER2- mBC. As L1 therapy, 2733 pts (43.6%) received ET alone, while 3532 received CT (56.4%). Among these 3532 pts, 2073 (58.7%) received ET as maintenance treatment after CT. A Cox multivariate analysis with significant prognostic variables identified a lower risk of death in the patients with L1 ET (HR = 0.839, 95% IC [0.772-0.911], $p < 0.0001$). Patients receiving CT were younger (median age 56.0 *vs* 66.0, $p < 0.001$), more likely to have visceral metastasis (61.6% *vs* 40.1%, $p < 0.001$) and SBR III primary tumors (31.3% vs 18.8%, $p < 0.001$). Median PFS1 was 15.18 months for L1 ET (95% CI, 14.45-16.20) *vs* 12.58 months for L1 CT +/- hormone maintenance (95% CI, 11.89-13.14), $p < 0.0001$. Median OS was 60.78 months for L1 ET (95% CI, 57.16-64.09) *vs* 49.64 months for L1 CT (95% CI, 47.31-51.64), $p < 0.0001$.

Conclusions: The results show that despite guidelines, a majority of AIS HR+/HER2- mBC pts still received CT as first-line treatment in the past years. PFS1 and OS data do not suggest any advantage of this aggressive strategy over ET alone. Advanced statistical methods using the propensity score will be presented in order to control for potential selection bias.

Background: The everolimus-exemestane combination has been included in the International guidelines for advanced HR+ breast cancer (mBC) since the results of the Bolero-2 trial. Marketing authorization has been granted in France in July 2012. We evaluated the incidence and indication of everolimus (EVE) use before and after marketing authorization and reimbursement.

Methods: All patients who initiated treatment for a newly diagnosed mBC between 01/2008 and 12/2015 in all 18 French Comprehensive Cancer Centers have been included in the real life ESME database, which collects retrospective data using a clinical trial-like methodology.

Results: The ESME program included a total of 16,703 patients of which 9,921 had HR+/HER2- mBC. Median age at metastatic diagnosis was 62.0 year (range 23-96). Visceral metastases were present in 60.3% of cases. Only 4123 patients (41.6%) received endocrine therapy alone as first-line therapy, and 60% were deemed endocrine resistant. Overall, 1,217 (12.3%) pts have received EVE during therapy as of Dec. 2015 (all lines). EVE was given as first line therapy in 117 pts (10% of all EVE pts and 1.2% of pts receiving a first line therapy). In 99/117 pts (85%) EVE was combined with exemestane. Before 2012, EVE was used within clinical trials. After 2012, use of EVE increased steadily. Percentages in the Table refer to the total of pts who received any kind of treatment during a given year of observation (eg 506 pts took EVE in 2015 out of 4435). Median duration of EVE use was 6.0 months (range 0-65) as first line treatment and 3.9 months (range 0-65) in pretreated patients. Patient population and causes of EVE cessation will be detailed at the meeting.

Table: 266P

Year	2008	2009	2010	2011	2012	2013	2014	2015
N	4	7	13	11	133	391	493	506
%	0.20	0.22	0.30	0.21	2.3	6.6	8.6	11.41

Conclusions: In this very large French national and representative cohort of HR+ HER2- mBC, EVE use rose quickly as soon as marketed. EVE was mostly used in pretreated mBC albeit in probably too advanced pts. These data underline the need for physician and patient education for oral therapies.

267P Can contemporary trials in HER2-negative metastatic breast cancer (mBC) detect overall survival (OS) benefit?

S. Kümmel[1], C. Jackisch[2], V. Müller[3], A. Schneeweiss[4], S. Klawitter[5], M.P. Lux[6]

[1]Cancer Center Essen, Klinikum Essen Mitte, Essen, Germany, [2]Obstetrics and Gynecology, Sana Clinic Offenbach, Offenbach, Germany, [3]Department of Gynecology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [4]Division Gynecologic Oncology, National Center for Tumor Diseases (NTC) University Hospital, Heidelberg, Germany, [5]Biostatistics and Epidemiology, Roche Pharma AG, Grenzach Wyhlen, Germany, [6]OBGYN-Department, University Breast Center Franconia, University Hospital Erlangen, Erlangen, Germany

Background: Although several recent trials have demonstrated improved progression-free survival (PFS) or time to progression (TTP) with first-line regimens for HER2-negative mBC, OS benefit is often elusive. We calculated required sample sizes to power for OS based on published data in recent trials.

Methods: Randomised superiority trials of first-line chemotherapy or targeted therapy for HER2-negative mBC including >150 patients, meeting the primary efficacy objective and published between 2000 and 2014 were identified. The sample sizes required to power for PFS (or TTP) and OS were calculated retrospectively for each trial using the observed results and study/recruitment follow-up durations (alpha=0.05, 2-sided log-rank test, 80% power), and summarised as a factor relative to the actual sample size ($x < 1$ required x-fold fewer cases to show the same gain; $x > 1$ required x-fold more cases).

Results: Only 8 of the 14 identified trials reported all information required for retrospective sample size calculation (Table). Most would have required a far larger sample size to demonstrate an OS gain (x: 0.5–2479) with the observed results. In 10 of 13 trials, the sample size required to power for OS was at least 5-fold larger than that needed to power for PFS.

Conclusions: Designing trials to test potential new treatments for HER2-negative mBC is challenging and requires a balance of regulatory acceptability, feasibility and realistic medical assumptions to calculate sample sizes, which can be particularly difficult in heterogeneous study populations with long post-progression survival and heterogeneous subsequent therapies. However, ongoing and future trials of cancer immunotherapy (new mode of action) focusing on triple-negative mBC (a more homogeneous population with shorter OS and post-progression survival, and fewer treatment options) may show a new pattern.

268P What are the treatment patterns and overall survival (OS) in patients with metastatic triple-negative breast cancer (mTNBC) in US clinical practice?

P. Bajaj[1], D. Latremouille-Viau[2], A. Guerin[2], C. Reyes[1], A. Stein[1], A. Kurian[3], P. Cortazar[1]
[1]US Medical Affairs, Genentech Inc. - Roche - USA, South San Francisco, CA, USA, [2]Analysis Group, Montreal, QC, Canada, [3]Division of Oncology, Stanford University School of Medicine, Stanford, CA, USA

Background: mTNBC is a condition with significant unmet medical need due to limited treatment (tx) options and short survival after chemotherapy (chemo) failure. Tx patterns and OS in patients (pts) with mTNBC in US clinical practice were assessed.

Methods: This retrospective chart review study used data collected in October and November 2016 from US oncologists via an online case report form. Data of adult pts who were initiated on a pharmacological tx after a diagnosis of recurrent or de novo mTNBC between January 2012 and June 2015 were reviewed. Tx regimens used in 1st- and 2nd-lines for mTNBC were summarized. Median OS from 1st- and 2nd-line tx initiation were estimated using Kaplan-Meier analyses.

Results: 125 oncologists provided data on 411 mTNBC pts; mean age was 57 years; 298 (73%) had ≥2 lines of tx; 256 different tx sequences were identified. Mean duration of tx was 7.5 months (mos) in 1st-line and 7.3 mos in 2nd-line. The most prevalent tx regimens were single agent chemo with taxane (22%) in 1st-line and capecitabine (Cap; 20%) in 2nd-line. Median OS was 16.7 mos in 1st-line and 14.2 mos in 2nd-line.

Conclusions: Findings suggest that, in US clinical practice, there is substantial heterogeneity in the tx of pts with mTNBC. Pts had a median OS < 18 mos after tx initiation. A better understanding of the mTNBC pt subpopulation and optimal tx sequencing is warranted to improve tx strategies and prolong survival.

269P Outcomes of systemic therapy for advanced triple-negative breast cancer: A single centre experience

N. Battisti[1], D. Okonji[1], T. Manickavasagar[1], K. Mohammed[2], M. Allen[1], A. Ring[1]

[1]Breast Unit, The Royal Marsden NHS Foundation Trust, London, UK, [2]Research and Development Department, The Royal Marsden NHS Foundation Trust, London, UK

Background: Systemic treatment outcomes for advanced triple-negative breast cancer (aTNBC) are worse compared to other disease subtypes, due to aggressive behaviour, heterogeneity and lack of molecular targets. Many options are under investigation although most patients receive standard cytotoxic chemotherapy. We aimed to provide better insight into the efficacy of different lines of therapy for aTNBC (overall response rate [ORR], median progression-free survival [mPFS] and median overall survival [mOS]) to better inform discussion with patients, decision-making and referral for clinical trials.

Methods: We retrospectively identified 268 patients diagnosed with aTNBC from 01/12/2011 to 30/11/2016 from our electronic records. Patients' and tumour characteristics were recorded, along with systemic treatment outcomes. Chi-squared/Fishers exact test and Kaplan-Meier statistical methods were utilised.

Results: 186 patients treated with ≥1 line of palliative systemic treatment were eligible for the analysis with a median age at 55 (range 26-91). 53.8% had ECOG Performance Status 0 and 69.9% visceral involvement. 38.6% had a disease-free interval (DFI) <12 months following surgery and 13.4% had de novo advanced disease. 11.4% carried a BRCA mutation. 64.5% received 2 lines of therapy, 37.6% had 3 and 21.5% had 4. ORR and mPFS to first line therapy were respectively 43.9% (95% CI 36.5-51.5) and 3.7 months (95% CI 2.9-5.1), to second line was 40.2% (95% CI 31.2-49.6) and 3.5 months (95% CI 2.6-4.1), to third line 28.8% (95% CI 18.3-41.3) and 2.5 months (95% CI 2.0-3.0) and to fourth line 25.0% (95% CI 12.7-41.2) and 2.1 months (95% CI 1.6-2.8). First line patients with a DFI ≥12 months had ORR of 47.7% (95% CI 36.8-58.7) compared to 35.8% (95% CI 23.1-50.2) for those with a DFI <12 months (p 0.172). mPFS was respectively 5.2 months (95% CI 3.4-6.5) compared to 2.7 (95% CI 1.8-3.6) (p 0.005).

Table: 269P Demographics at advanced stage disease diagnosis

Median age	55 (range: 26-91)	
Age group N (%)	**< 60 years**	117 (62.9)
	≥ 60 years	69 (37.1)
ECOG Performance Status N (%)	**0**	100 (53.8)
	1	75 (40.3)
	2	11 (5.9)
Disease sites N (%)	**Visceral**[1]	130 (69.9)
	Non-visceral only	56 (30.1)
Advanced disease histology N (%)	**Invasive ductal**	112 (60.2)
	Invasive lobular	7 (3.8)
	Mixed	2 (1.1)
	Metaplastic	3 (1.6)
	Other	2 (1.1)
	Not available[2]	60 (32.3)
De novo advanced disease N (%)	25 (13.4%)	
No. of lines of systemic therapy received N (%)	**1**	186 (100)
	2	120 (64.5)
	3	70 (37.6)
	4	40 (21.5)
	5	20 (10.7)
	6	5 (2.7)
	7	1 (0.5)
DFI[3]	**≤12 months**	56 (38.6)
	>12 months	89 (61.4)
BRCA	**Wild-type**	66 (35.7)
	Mutated[4]	21 (11.4)
	Unknown	98 (53.0)

[1]: with or without non-visceral involvement; [2]: radiological diagnosis of advanced disease; [3]: 145 (80%) patients included in the DFI analysis; [4]: either BRCA1 or BRCA2.

Conclusions: The response rates observed in this population of patients are similar to those observed in published clinical trials. However, the PFS rates are short, and as a result early consideration for inclusion in clinical trials of novel approaches can be justified in these patients.

270P Untreated hormone receptor positive/HER2-negative metastatic breast cancer survival with front-line chemotherapy and maintenance endocrine therapy

R. Sabatier, A. Meskine, M.A. Cappiello, J-M. Extra, C. Tarpin, F. Rousseau, M. Provansal, F. Bertucci, P. Viens, A. Gonçalves

Medical Oncology, Institute Paoli Calmettes, Marseille, France

Background: Except some life threatening cases, combination of endocrine therapy and CDK4/6 inhibitors is becoming the standard first line treatment for women with hormone receptor (HR) positive/HER2 negative advanced and metastatic breast cancer (MBC). However cost-effectiveness analyzes are lacking concerning this therapy. As chemotherapy also targets cell cycle we wondered how sequential combination of chemotherapy and maintenance endocrine therapy could be effective as first line treatment for naive HR+/Her2- MBC.

Methods: We retrospectively collected from our institutional database ("Institut Paoli-Calmette", Marseille, France) cases with naive HR+/HER2- MBC. We selected patients treated with chemotherapy plus maintenance endocrine therapy as first line treatment between January 2000 and December 2015. Progression-free survival (PFS) and Overall Survival (OS) were analyzed using the Kaplan-Meier's method. We also conducted univariate (UV) and multivariate analyzes including menopausal status, visceral disease, pathological subtype, and progesterone receptor expression assessed by immunohistochemistry.

Results: A total of 183 female patients were included with a median age at diagnostic of 56,9 years. Most of them were postmenopausal (n = 114, 65.9%) and 108 (59.7%) had visceral metastases. Anthracyclynes-Taxanes combinations were used for 162 patients (88.5%). Median number of chemotherapy cycles was 6. Endocrine therapy was aromatase inhibitors and tamoxifen for 120 (67.8%) and 56 (31.6%) cases, respectively. Median PFS was 33 months [95CI = 25-38] and median OS was 79 months [95CI = 63-101]. In UV analysis pre-menopausal status (HR = 0.58), non-ductal non-lobular subtype (HR = 0.47), and absence of visceral disease (HR = 0.51) were correlated to better OS. All these features remained significant in multivariate analysis. We observed no death related to treatment.

Conclusions: Following these results, and with the issues of cost-effectiveness related to newly approved therapies, first-line chemotherapy plus maintenance endocrine therapy may be considered for untreated HR+/HER2- MBC.

271P Can we predict subsequent brain metastasis in patients with metastatic breast cancer?

S.F. El Zawawy,

Clinical Oncology, University of Alexandria Faculty of Medicine, Alexandria, Egypt

Background: The one year over all survival of breast cancer patients with brain metastasis is only 20%–40%. Approximately, 80% of brain metastases occur after the diagnosis of other systemic metastatic lesions. Due to this dismal prognosis, prophylactic approaches as cranial irradiation, high-dose methotrexate, or lapatinib could be evaluated as preventative measures. However, these approaches are usually toxic and cannot be applied to all patients. This study is carried out to evaluate risk factors that have an impact on subsequent development of brain metastasis in metastatic breast cancer patients and thus, those patients can be candidates for prophylactic measures.

Methods: The medical files of 267 metastatic patients were retrospectively reviewed for demographic, clinico pathological, metastatic and treatment characteristics.

Results: 46 out of 267 patients developed brain metastasis with an incidence of 17.2%. Significant risks include age <40y 28.7% patients compared to21.6% for age 40 – 50y and 11.1% for age >50y (P = 0.031), 24.2% premenopausal patients compared to 11.4% for postmenopausal (P = 0.013), Her2/neu overexpression (48.5%) and triple negative (35.3%) compared to 11.3% patients with ER positive (P = 0.0001, 0.003), high grade compared to low grade tumors (35.6% vs 12.6% P = 0.005). Patients with N2, 3 had higher risk than N0, 1 (44% vs 13.8%) (P = 0.01), 30.9% patients with disease free duration (DFD) <2 years developed brain metastasis compared to 22.1% for M1 patients and 11.1% patients with DFD >2years (P = 0.019, 0.033). 3.6% patients with bone only metastasis developed brain metastasis compared to 20.6% patients with visceral only metastasis and 27.4% patients with bone and visceral metastasis (P = 0.036, 0.014). 32.3% patients with lung containing metastasis developed brain metastasis

compared to 57.3% patients with lung and liver containing metastasis and 9.2% of patients with liver containing metastasis (P = 0.038, 0.022).

Conclusions: Young patients with lung metastases, Her2/neu overexpression or triple negative with disease free duration < 2years carried the highest risk for brain metastases. Such patients may be candidate for screening or prophylactic strategies.

272P Pathological characteristics and prognosis of a cohort of 57 patients (pts) with de novo oligometastatic breast cancer (OMBC)

S. Chretien[1], N. Kotecki[1], J. Wallet[2], C. Desmedt[3], A. Mailliez[4], C. Regis[4], D. Pasquier[5], Y-M. Robin[6], J. Bonneterre[4]

[1]Medical Oncology, Centre Oscar Lambret, Lille, France, [2]Biostatistics, Centre Oscar Lambret, Lille, France, [3]Translational Breast Cancer Laboratory, Institute Jules Bordet, Brussels, Belgium, [4]Breast Cancer Department, Centre Oscar Lambret, Lille, France, [5]Academic Department of Radiation Oncology and CRISTAL UMR CNRS 9189, Centre Oscar Lambret, Lille, France, [6]Pathology, Centre Oscar Lambret, Lille, France

Background: Management of de novo OMBC is controversial with no specific treatment guidelines available.

Methods: We reviewed 57 consecutive de novo OMBC pts defined as ≤ 5 synchronous metastatic lesions, diagnosed between 01/2000 and 12/2012 at Oscar Lambret Center. Clinicopathological (CP) characteristics and survival data were retrospectively collected. Predictors of overall survival (OS) and progression free survival (PFS) were identified by univariate analysis before being introduced into a stepwise cox regression model.

Results: Median primary tumor size was 40mm (0-150) and 79% of the cases were invasive ductal carcinoma. Estrogen and progesterone receptors were detected in respectively 76% and 56% of the cases. HER2 overexpression was observed in 26% and 12.5% were triple negative. Median KI67 was 40% (5-80). On SBR grading, 3 (6%) cases were grade I, 31 (66%) grade II and 12 (26%) grade III. 16% pts had ≥ 4 histologically involved axillary lymph nodes. The median number of metastatic lesions was 2 (1-5). 31 pts had bone metastases. 65% pts were treated surgically for the primary tumor, 42% had neoadjuvant (NA)/adjuvant chemotherapy (CT), 45% had radiotherapy (RT) for primary BC and 58% were locally treated for their metastatic lesions, while 17 pts were treated with palliative CT only. The median follow-up period was 6.4 years (0.2–12). 2 and 5-year OS and PFS were respectively 90.8%/52.1% and 45.7%/21.4%. Significant predictors of both OS/PFS in univariate analysis were SBR grade, surgery and RT of primary BC, use of NACT and hormonotherapy. In multivariate analysis (MV) both SBR ≤ 2 at diagnosis and the administration of NA CT were identified as significant predictors for better OS (p = 0.005 and 0.006 respectively). High SBR grade independently predicted for worse PFS (p = 0.006).

Conclusions: This retrospective work further highlights the CP characteristics and predictors of outcome of de novo OMBC pts. Only SBR grade at diagnosis and use of NA CT were identified as significant predictors in MV analysis. A molecular analysis of this cohort is planned to complete these findings and characterize the subset of OMBC pts who could benefit from curative therapy and those for whom alternative strategies should be adopted.

273P External validation of modified breast graded prognostic assessment for breast cancer patients with brain metastases

G. Griguolo[1], W. Jacot[2], E. Kantelhardt[3], M.V. Dieci[1], C. Bourgier[4], C. Thomssen[5], C. Bailleux[6], F. Miglietta[1], A.L. Braccini[7], P.F. Conte[1], J-M. Ferrero[6], V. Guarneri[1], A. Darlix[2]

[1]Department of Surgery, Oncology and Gastroenterology, University of Padova, Padua, Italy, [2]Department of Medical Oncology, ICM Regional Cancer Institute of Montpellier, Montpellier, France, [3]Department of Gynaecology and Institute of Medical Epidemiology, Biostatistics and Informatics, Martin Luther University Halle-Wittenberg, Halle, Germany, [4]Department of Radiation Oncology, ICM Regional Cancer Institute of Montpellier, Montpellier, France, [5]Department of Gynaecology, Martin-Luther University Halle-Wittenberg, Halle (Saale), Germany, [6]Department of Medical Oncology, Centre Antoine Lacassagne, Nice, France, [7]Department of Medical Oncology and Radiotherapy, Centre Azuréen de Cancérologie, Mougins, France

Background: Several prognostic indexes have been developed to estimate survival of breast cancer (BC) patients with brain metastases (BM). The Modified Breast Graded Prognostic Assessment (GPA) has been proposed as refinement of the Breast GPA, based on a single-institution cohort of 1,552 patients. In addition to age, tumor subtype and Karnofsky PS, the modified breast GPA comprises number of BM. The aim of this study is to validate the modified breast-GPA in an external multinational cohort.

Methods: Clinical and biological data of 668 BC patients diagnosed with BM at four European institutions between 1996 and 2016 were reviewed. Patients were classified according to breast GPA and modified breast GPA. OS was calculated from time of BM diagnosis to death or last follow up. Cox proportional models were used to calculate Hazard Ratio and 95% Confidence Intervals (CI). Performances of breast-GPA and modified breast-GPA were compared using Harrell's concordance index.

Results: At last follow-up, 632 patients (94.6%) had died. Median OS was 8.1 months (95% CI 6.9-9.4 months). Median age at BM diagnosis was 56 years (range 24-85). Tumor phenotype distribution was: triple negative (20.1%), hormone receptor (HR)-HER2 + (21.6%), HR+HER2 + (20.4%) and HR+HER2- (33.4%). KPS distribution was: 90-100 (19.6%), 70-80 (49.0%), 60 (12.8%) and ≤50 (18.6%). 355 patients (53.5%) had >3 BM. Number of BM (1,2,3,>3) was significantly associated with OS (p < 0.001). Both breast-GPA and modified breast-GPA predicted OS (Table). Concordance indices were 0.641 (95% CI, 0.6405 to 0.6422) and 0.667 (95% CI, 0.6662 to 0.6678) for breast-GPA and modified breast-GPA, respectively (p < 0.001).

Conclusions: Number of BM is a significant prognostic factor in BC patients with BM and modified breast-GPA performs better than breast-GPA in predicting prognosis of these patients.

Background: The addition of pertuzumab (P) to trastuzumab (H) and docetaxel improves survival in clinical trials of patients with HER2+ MBC, and is a guideline-recommended standard of care for this population. In the real world, however, various factors may influence treatment decisions. Systematic Therapies for HER2-positive Metastatic Breast Cancer Study (SystHERs) is a fully enrolled (June 2012–June 2016), ongoing, US-based, observational study that captures real-world data for patients with HER2+ MBC. Here, we describe the baseline characteristics and treatment patterns of patients who received 1L PH or H without P.

Methods: Eligible patients had HER2+ MBC diagnosed within 6 months of enrollment and were ≥18 years of age. Patients were compared descriptively by 1L treatment (PH vs H without P), defined as any therapy received up to first progression.

Results: As of February 10, 2017, among 978 eligible patients, 949 had received 1L treatment (PH, n = 711; H without P, n = 174; no H, n = 64) (Table). 476 (67%) and 88 (51%) of patients in the 1L PH and H without P cohorts, respectively, remain on study. Median follow-up from 1L treatment start was 22 and 25 months, respectively. In patients treated with PH, median duration of treatment with H and P were 15 and 13 months, respectively. In the H without P cohort, median duration of H was 15 months. Among all patients, 68% (648/949) received 1L PH + taxane.

Conclusions: Of patients with HER2+ MBC in the real-world SystHERs study, 68% were treated with PH + taxane. Compared with patients who received PH, those who received H without P were older, less commonly had liver metastasis, and more commonly had prior cardiovascular disease, suggesting that these characteristics may have influenced the treatment choice between PH vs H without P.

[a]In pts with recurrent MBC only. H, trastuzumab; P, pertuzumab.

examine baseline characteristics, first-line treatments, and breast cancer–specific survival (BCSS) by age.

Methods: SystHERs is a fully enrolled (Jun 2012–Jun 2016), ongoing, US-based, observational study. Pts were ≥18 years old and had HER2+ MBC diagnosed within 6 months of enrollment. Pts were grouped by age at MBC diagnosis (<50, 50–69, or ≥ 70 years) and compared descriptively. BCSS was defined as time from the date of MBC diagnosis to date of death due to MBC progression.

Results: As of Feb 10, 2017, of 978 eligible pts, 287 were <50 years old, 563 were 50–69, and 128 were ≥70 at MBC diagnosis. Median follow-up from MBC diagnosis was 23, 22, and 19 months, respectively. Baseline characteristics, first-line treatments, and BCSS are shown (Table). In pts who received chemotherapy, docetaxel was the most common agent in pts <50 (67%) and 50–69 (64%) followed by paclitaxel (29% in both groups), whereas in pts ≥70, 43% and 45% received docetaxel and paclitaxel, respectively.

Conclusions: In this preliminary real-world analysis of pts with HER2+ MBC, pertuzumab (P) + trastuzumab (H) was more commonly used than H without P across all age groups. Pts <50 and 50–69 years old more commonly received PH + taxane than those ≥70 (72% and 69% vs 43%, respectively). Compared with younger pts, those ≥70 received regimens with chemotherapy less commonly (89% and 87% vs 67%), and more commonly received regimens with H without P (13% and 17% vs 34%) or hormonal therapy (39% and 41% vs 52%). Pts <50 had longer BCSS than those ≥70 (78% vs 64% at 3 years).

276P Defining priorities for research: Interim results of the Canadian metastatic breast cancer priority setting partnership

N. Nixon[1], S. Verma[1], C. Simmons[2], J. Lemieux[3]

[1]Medical Oncology, Tom Baker Cancer Centre, Calgary, AB, Canada, [2]Medical Oncology, British Columbia Cancer Agency, Vancouver, BC, Canada, [3]Medical Oncology, Chu De Quebec, Quebec, QC, Canada

Background: Research priorities are generally determined by funders and researchers without direct involvement and input from patients and caregivers. Certain disease areas have incorporated the patient voice to determine patient driven priorities. In this study, this approach was employed to better understand the needs and priorities of metastatic breast cancer patients and their caregivers.

Methods: This study was conducted using methodology outlined by the James Lind Alliance. A steering committee of patients, physicians, patient advocates, and allied health care professionals was assembled to oversee the research study. The initial survey collected unanswered research questions from patients, caregivers, and clinicians. Responses were collected and categorized by consensus of the steering committee. Here we present the results from the national survey.

Results: Between November 2016 and April 2017, 733 responses from 311 individuals were collected (62% patients, 11% physicians, 9% caregivers or relatives, 5% nurses/allied health professionals, 2% patient organization representatives, and 10% other). The main themes for key patient priorities are: 136 (19%) related to treatment and monitoring, 78 (11%) linked lifestyle and alternative therapy, 58 (8%) regarded tumour biology, 53 (7%) regarded psychosocial aspects, 46 (6%) to diagnosis, 35 (5%) to toxicity, 24 (3%) to prevention, and 17 (2%) to young or pre-menopausal population. Two hundred and eighty-six (39%) were considered out of scope. The most frequently identified priorities included the role of alternative therapies for improving survival, the role of immune therapy for treating metastatic breast cancer, and the potential for improving outcomes with early detection/surveillance with modern treatment and diagnostic modalities.

Conclusions: Patient derived research priorities in advanced breast cancer point to an improved understanding of alternative therapies, integration of immune therapy and a focus on early detection of relapse. These priorities should be addressed by the research community to meet the needs of our patients with advanced breast cancer.

277P Real-world treatment patterns and outcomes among elderly metastatic triple negative breast cancer patients in the United States

S. Satram-Hoang[1], P. Bajaj[2], A. Stein[2], K.Q. Hoang[1], F. Momin[1], P. Cortazar[2], C. Reyes[2]

[1]Department of Epidemiology, Q.D. Research, Inc., Granite Bay, CA, USA, [2]US Medical Affairs, Genentech Inc., South San Francisco, CA, USA

Background: Triple negative breast cancer (TNBC) is more aggressive than other breast cancer (BC) subtypes and accounts for up to 20% of all BC. Despite the poorer prognosis, there are no approved targeted treatments available and chemotherapy (chemo) remains the only choice. We examined treatment patterns and outcomes among elderly metastatic TNBC patients (pts) in routine clinical practice.

Methods: Patients were identified from the linked SEER-Medicare database (1/1/2001-12/31/2013). The analysis included TNBC *de novo* Stage IV pts (n = 776) and pts with distant recurrences following an initial diagnosis of Stage I-III (n = 1851). Pts were ≥66 years and continuously enrolled in Medicare Parts A/B in the year prior to diagnosis. The analysis was stratified by age <70 (n = 359) and ≥70 (n = 2268). Kaplan Meier analyses and time-varying Cox proportional hazards regression assessed overall survival (OS).

Results: The mean age at metastatic diagnosis was 77.6 years and 1259 (48%) pts received treatment with chemo. Compared to < 70 year olds, ≥70 year olds were less likely to be diagnosed with *de novo* Stage IV disease (28% vs. 42%), had worse performance status indicators, higher comorbidity burden, were less likely to receive chemo (45% vs. 66%), but were more likely to have had BC surgery (81% vs. 70%). Pts treated with chemo had improved OS compared to untreated pts, and the survival advantage was more pronounced in the <70 year olds with a 6 month longer unadjusted OS compared to the ≥70 cohort (log rank p < 0.0001). This finding was supported in the adjusted multivariate model which showed a 46% (HR = 1.46; 95% CI: 1.08-1.96) increased risk of death for untreated pts in the <70 year olds and a 17% (HR = 1.17; 95% CI: 1.06-1.29) increased risk of death for untreated pts in the ≥70 year olds (vs. treated).

Conclusions: In this real-world analysis, 52% of elderly TNBC pts did not receive chemo following their metastatic diagnosis. Although the survival benefits of chemo were stronger in the younger cohort, the benefits of treatment were maintained among ≥70 year olds who were also less likely to receive chemo. These findings suggest opportunities exist to improve the clinical treatment of elderly TNBC pts.

278P Effect of neoadjuvant chemotherapy on disease free survival and over all survival in triple-negative breast cancer patients

J. Gill[1], A.N. Mishra[2]

[1]Medical Oncology, Gandhi Medical College, Bhopal, India, [2]Surgical Oncology, Gandhi Medical College, Bhopal, India

Background: Breast cancer (BC) is the most common cancer in India with 150000 new cases are diagnosed and 70000 women dies of it every year. Triple-negative breast cancer (TNBC) is an aggressive subtype that lack ER and PR expression and absence of overexpressed or amplified HER2. TNBC accounts for 15%-25% of all invasive BC, occurs more in younger women and is associated with higher histologic grade and advanced disease. Our goal was to study the relation between triple-negative receptor status and major determinants of clinical outcome, such as response to neoadjuvant chemotherapy (rate of pathologic complete response [pCR]), progression free survival (PFS), site-specific distribution of recurrence, postrecurrence survival (PRS) and overall survival (OS).

Methods: We included 2658 patients who received neoadjuvant chemotherapy at Jawaharlal Nehru Cancer Hospital Bhopal for stage I-III breast cancer from 1990 to 2010 and for whom complete receptor information were available. Clinical and pathologic parameters, pCR, survival measurements and organ-specific relapse rates were compared between patients with TNBC and non-TNBC.

Results: 505 patients (19%) had TNBC. Mean age for TNBC (42 years) was lesser than non-TNBC (56 years; *P*=.002). Patients with TNBC had significantly higher pCR rates (34% *v* 14%; *P*=.028) but decreased 5 year PFS rates (*P*<.0001) and 5year OS rates (*P* <.0001). TNBC was associated with increased risk for distant metastases (*P* =.0005), lower risk for bone recurrence (*P* = .034) and shorter PRS (*P* < .0001). Recurrence and death rates were higher for TNBC only in the first 5 years. If pCR was achieved, patients with TNBC and non-TNBC had similar survival (*P* = .36). Patients with residual disease (RD) had worse OS if they had TNBC compared with non-TNBC (*P* < .0001).

Conclusions: TNBC patients have increased pCR rates (excellent survival) compared with non-TNBC. However TNBC patients with RD have significantly worse survival after neoadjuvant chemotherapy in first 5 years.TNBC patients may be best treated with 3rd generation adjuvant or neoadjuvant chemotherapy regimens that achieve the highest possible pCR rates. With high risk of distant metastases, these patients require closer surveillance in initial years of follow-up.

279P Real-world everolimus experience in postmenopausal HR+ HER2- advanced breast cancer women: Treat ER+ight Canadian prospective observational study 2nd subgroup analysis

C. Doyle[1], N. Califaretti[2], S. Dent[3], E. Chouinard[4], S.R. Perri[5], S. Chia[6]

[1]Oncology, Centre des Maladies du Sein Deschênes-Fabia, Quebec, QC, Canada, [2]Medical Oncology, Grand River Regional Cancer Center, Kitchener, ON, Canada, [3]Medical Oncology, Ottawa Hospital Cancer Center, Ottawa, ON, Canada, [4]Oncology, Cambridge Memorial Hospital, Cambridge, ON, Canada, [5]Medical Affairs, Novartis Pharmaceuticals Canada Inc., Dorval, QC, Canada, [6]Medical Oncology, BC Cancer Agency - Vancouver Cancer Center, Vancouver, BC, Canada

Background: Treat ER^{+}ight is the 1st Canadian real-world study enrolling patients (pts) previously exposed to letrozole or anastrozole and currently receiving endocrine therapy (ET) alone or in combination with targeted therapy.

Methods: At data cut-off (13 Mar '17), 35 pts were enrolled in the everolimus + exemestane (EVE+EXE) subgroup out of 100 total enrolled pts since Mar '16 from 24 active sites. This sub-analysis describes baseline characteristics, treatment duration and stomatitis prevention outcomes in EVE+EXE pts.

Results: Baseline characteristics: median age – 65 (39-80); family history of breast cancer (BC) – 37%; ECOG 0-1 – 83%; median time since primary BC diagnosis – 6 yrs (2-12); median time since advanced BC diagnosis – 1 yr (0-3.5). Sites of metastases (%): bone (B) only – 26; visceral (V) only – 43; B+V – 23. Line (L) of metastatic therapy (%): 17 - 1L, 51 - 2L, 31 - 3L. EVE start dose (%): 10mg (80), 7.5mg (3), 5mg (17). Therapy ongoing n (%): 23 (66) (78% 1L & 2L). Therapy discontinued n (%): 12 (34) (50% 3L). Reason for discontinuation n (%): 9 (75) progression, 2 (17) adverse event, 1 (8) death. Median follow-up time at data cut-off 3.4 mths (0.5-9.1). Median time to treatment discontinuation (TTD) 7.0 mths (95% CI, 3.4-NR) in overall subgroup. Median TTD NR (95% CI, 2.4-NR) in 20 (57%) pts receiving prophylactic/proactive mouthwash (P/P MW) compared to 5.7 mths (95% CI, 3.2-NR) in 15 (43%) pts receiving reactive/no MW (p = 0.140, Log-rank). 1st stomatitis event related to EVE n (%): overall subgroup 10 (29) – any Grade (Gr), 7 (20) – Gr 1, 2 (6) – Gr 2, 1 (3) – Gr 3 and in P/P MW subgroup 3 (15) – any Gr. Median time to 1st stomatitis event in P/P MW subgroup (mths) NR (95% CI, 1.64-NR) and NR (95% CI, 0.33-NR) in reactive/no MW subgroup (p = 0.334, Log-rank) with majority of stomatitis events occurring early within the 1st 2 months of therapy.

Conclusions: Compared to BOLERO-2, EVE+EXE pts in Treat ER+ight had lower ECOG 0-1 (83 vs 96%), more V disease (66 vs 56%), 20% received lower EVE start dose, similar treatment duration (7.0 mths median TTD vs 7.8 mths median PFS) and lower any Gr stomatitis (29 vs 59%). This represents the 1st observation of a trend toward improved TTD in pts receiving P/P MW upon EVE initiation.

Background: Metastatic breast cancer (MBC) in young patients (pts) is traditionally considered at poor prognosis. Although current guidelines recommend endocrine therapy (ET) as first line treatment (1st trt) for HR+ HER2- MBC, younger age can lead to more extensive use of first line chemotherapy (CT). In the present analysis, we aimed to

assess overall survival (OS) of younger MBC pts compared to older ones, and to explore 1st trt choices in a large real-life multicenter cohort.

Methods: The Epidemiological Strategy and Medical Economics (ESME) Research program aims to collect high-quality real-world data in oncology from 18 French Comprehensive Cancer Centers. Pts who started treatment for a newly diagnosed MBC between Jan 2008 and Dec 2014 were selected in the MBC ESME database. The primary end point of the FICHE-Young study was to compare adjusted OS in pts diagnosed with endocrine-sensitive HR+ HER2- MBC and aged ≤45 vs > 45 at diagnosis. We also evaluated 1st trt choices in both categories and its correlation with OS. Analyses will be adjusted on a propensity score, in order to control selection biases associated with non-randomization.

Results: 6265 pts out of 16703 in ESME had HR+/HER2- MBC. Characteristics and 1st trt choices are listed in the Table. Median OS was 62.3 months (mos) (95% CI 56.5-69) in pts ≤45 and 52.8 mos in those >45 (95% CI 50.7-55), p<.0001. In pts ≤45, we did not show any statistically significant difference in OS between first line ET and CT+/-ET (68.5 mos for ET (95% CI, 56.8-NE) vs 59.0 mos for CT+/-ET (95% CI, 55.9-69), p = 0.3208).

Table: 280P

	≤ 45 yrs old	>45 yrs old
N	851	5414
Median age	40.0 [23;44]	63 [45;95]
Visceral metastases	56.3%	51.6%
De novo MBC	41%	42.4%
Median time to onset of MBC	3.28 yrs [0.50;19.53]	9.18 yrs [0.50;43.02]
1st trt: ET alone	19.4%	47.4%
Chemo +/- maintenance ET	80.6%	52.6%

Conclusions: With the limitations of a nonrandomized study population, in this real-world setting, younger HR+MBC pts did not show a poorer prognosis compared to older patients. Many young pts received CT as first line treatment, with no demonstrated benefit over ET alone.

281P Cell-free circulating DNA as independent prognostic markers in metastatic breast cancer

J. Cheng[1], H. Surowy[1], M. Wallwiener[2], T. Holland-Letz[3], K. Cuk[1], S. Schott[2], A. Trumpp[4], K. Pantel[5], C. Sohn[2], A. Schneeweiss[6], B. Burwinkel[1]

[1]Division of Molecular Epidemiology, German Cancer Research Center, Heidelberg, Germany, [2]Department of Gynecology and Obstetrics, Women's Hospital, University of Heidelberg, Heidelberg, Germany, [3]Department of Biostatistics, German Cancer Research Center, Heidelberg, Germany, [4]Division of Stem Cells and Cancer, German Cancer Research Center, Heidelberg, Germany, [5]University Hospital Hamburg-Eppendorf, Department of Tumor Biology, Hamburg, Germany, [6]Division Gynecologic Oncology, National Center for Tumor Diseases (NTC) University Hospital, Heidelberg, Germany

Background: Blood-based biomarkers like microRNAs, cell-free DNA and circulating tumor cells hold great promise as they are reproducible and easily accessible in cancer patients. Cell-free DNA variables, such as cell-free DNA concentrations (cfDNA conc) and cell-free DNA integrity (cfDI), have great potential as diagnostic and prognostic markers in breast cancer patients. Here we investigated the potential prognostic ability of cfDNA conc and cfDI in a prospective study cohort of metastatic breast cancer (MBC) patients.

Methods: Blood was collected for cfDNA extraction from patients when enrolled about to start the first cycle of systematic therapy at baseline (MBCBL) and after the first cycle of systematic therapy (MBC1C). cfDNA conc and cfDI in blood plasma were evaluated by measuring the short and long fragments of two repetitive DNA elements, ALU (ALU-111bp, ALU-260bp) and LINE1 (LINE1-97bp, LINE1-266bp), by quantitative PCR. In total, 268 patients were included in this study. cfDNA conc and cfDI was compared between these two groups. The prognostic ability of cfDNA variables was evaluated by univariate and multivariate Cox regression model.

Results: A significant increase of cfDI (P = 1.21E-7 for ALU and P = 1.87E-3 for LINE1) and decrease of cfDNA conc (P = 1.17E-3 for ALU and P = 1.60E-2 for LINE1) were observed between patients at MBCBL and patients at MBC1C. Multiple Cox regression model indicated that cfDI and cfDNA conc can be used as independent prognostic markers in patients after one cycle of therapy with odds ratio (OR) and 95% confidence interval (CI) of 0.70 (0.48 - 1.01) for ALU cfDI, 0.63 (0.44 - 0.92) for LINE1 cfDI, 2.44 (1.68 - 3.53) for ALU cfDNA conc, 2.12 (1.47 - 3.06) for LINE1 cfDNA conc for overall survival. When four cfDNA variables were combined, it can reach an OR of 2.53 (1.77-3.62) for overall survival analysis of patients.

Conclusions: In summary, our results showed a decreased cfDNA conc and increased cfDI from the enrollment of the study to the first cycle of systematic therapy in MBC patients. cfDNA conc and cfDI can serve as independent prognostic markers in MBC patients after the first cycle of systematic therapy.

Background: Olaparib (Lynparza®) shows efficacy in patients with triple negative breast cancer (TNBC). Eribulin is one of the standard therapies for metastatic breast cancer. A phase I/II study of combination therapy with eribulin and olaparib capsule (EO study) was conducted on patients with TNBC. We investigated the correlation between response to combination therapy and homologous recombination deficiency (HRD).

Methods: Tissue samples were collected from patients who participated in the EO study. Archival tissue samples were examined for gene alterations using the Foundation Medicine, Inc. (FMI) gene panel. Pathogenic or likely pathogenic gene alterations were extracted from all detected gene alterations using the FMI data dictionary. This dictionary uses the COSMIC database, relevant literature, and internal evidence to determine the reportable status of an alteration. HRD-related genes were defined as previously described (Konstantinopoulos PA, et al. Cancer Discovery, 2015). Correlation between presence of HRD and response to combination therapy was tested using chi-square test.

Results: A total of 32 tissue samples were collected. Nineteen samples were collected from the phase I and 13 samples from the phase II. Seventeen patients were treated at the recommended dose. Thirty-three gene mutations were detected. The most frequent gene mutations were *TP53* (n = 27, 84.4%), *PIK3CA* (n = 7, 21.9%), *BRCA1* (n = 5, 15.6%), *MLL3* (n = 5, 15.6%), and *AKT1* (n = 4, 12.5%). We detected 32 gene amplifications, with *MYC* being the most common (n = 6, 18.8%). Eight homozygous deletions were detected, and the most frequent was loss of *PTEN* (n = 4, 12.5%). We detected 10 gene rearrangements. HRD, including *BRCA1/2* mutations, was observed in nine patients. The overall response rate (RR) and clinical benefit rate (CBR) were 31.3% and 78.1%, respectively. The RRs in patients with HRD and without HRD were 44.4% and 26.1%, respectively (p=.4072). The CBRs for the HRD and non-HRD groups were 66.7% and 82.6%, respectively (p =.3702).

Conclusions: Eighty-three gene alterations were detected in TNBC pts receiving combination olaparib/eribulin therapy. Patients with HRD had numerically higher response rate.

283P Neutrophil-lymphocyte ratio (NLR) as a prognostic factor in metastatic breast cancer

F. Ayala de la Peña, J.C. Yufera Soler, M.A. Ivars, A. Fernandez Sanchez, E. Navarro Manzano, P. De la Morena Barrio, E. Garcia-Garre, E. Garcia-Martinez, G. Marin Zafra, R. Salguero Aguilar, T. Garcia

Hematology and Medical Oncology, Hospital Universitario Morales Meseguer, Murcia, Spain

Background: Neutrophil-lymphocyte ratio (NLR) might be a surrogate marker of the tumor microenvironment immune balance and has been proposed as a prognostic factor for different tumors. A metanalysis of NLR for breast cancer (BC) showed that higher values at diagnosis were associated with lower survival. However, these results were mainly derived from the analysis of early BC cases: only three of twelve articles included women with metastatic breast cancer (MBC), sample size was small and no differential statistical analysis was performed for MBC. The aim of this work was to determine the prognostic value of NLR for MBC.

Methods: We retrospectively collected clinical and analytical data from a series of consecutive MBC patients treated in one center between 2009 and 2016. NLR (=neutrophil count/lymphocyte count) was obtained from differential white blood cell count at diagnosis of metastasis, before starting any treatment. Non-parametric tests (Mann Whitney U, Kruskal-Wallis) were used to evaluate differences of NLR between groups. Kaplan-Meier curves and Cox regression models (univariate and multivariate) were used for overall survival analysis.

Results: 265 consecutive patients with MBC were included, 117 of them (44%) with metastatic disease at diagnosis. Median age: 59 (19-95); ECOG 0-1 (69%), 2-3 (12%); site: bone only (37%), visceral only (18%), bone+visceral (30%); tumor subtype: HR (hormone receptor)+/HER2- (59%), HR+/HER2 + (17%), HR-/HER2 + (7%), HR-/HER2- (14%); disease free interval in recurrent MBC: <24 months (48, 32%), > 24 months (100, 67%). Outcomes: 135 deaths; median overall survival (OS): 35 months (IC95%: 27.4-42.6). Median NLR was 2.31 (range: 0.70-44.33), with significant higher values in women with ECOG 2-3 ($p = 0.008$) or negative estrogen receptors ($p = 0.03$). Univariate Cox model of OS showed a HR = 1.07 (95%: 1.03-1.11; $p < 0.001$) for NLR as a continuous variable; using the median value as cut-off, HR = 1.47 (95%CI: 1.05-2.07; $p = 0.024$). A multivariate Cox model showed the independent value of NLR for OS (Table).

Table: 283P Multivariate Cox proportional hazard regression model of MBC overall survival including NLR at diagnosis of distant disease

	HR (95%CI)	p
MBC at diagnosis (M1)	1.48 (1.02-2.14)	0.036
Negative estrogen receptors	2.56 (1.75-3.76)	<0.001
LNR (continuous variable)	1.07 (1.03-1.11)	0.001
Age (continuous variable)	1.02 (1.00-1.03)	0.008

Conclusions: A higher NLR at diagnosis is a negative prognostic factor for overall survival in metastatic breast cancer. These data, if prospectively validated, may support the addition of NLR to MBC prognostic models and may lead to differential therapeutic approaches in patients with higher NLR.

284P Real-life study of BRCA genetic screening in metastatic breast cancer

G. Meynard[1], C. Villanueva[1], A. Thiery-Vuillemin[1], L. Mansi[1], P. Montcuquet[1], N. Meneveau[1], L. Chaigneau[1], F. Bazan[1], H. Almotlak[1], E. Dobi[1], T. Nguyen Tan Hon[1], E. Klajer[1], C. Fagnoni-Legat[2], S. Paget-Bailly[3], A. Meurisse[3], M-A. Collonge-Rame[4], C. Populaire-Ventron[4], X. Pivot[1], E. Curtit[1]

[1]Medical Oncology, CHU Besançon, Hôpital Jean Minjoz, Besançon, France, [2]Pharmacology Unit, CHU Besançon, Hôpital Jean Minjoz, Besançon, France, [3]Methodological and Quality of Life Unit in Oncology, University Hospital Jean Minjoz, Besançon, France, [4]Genetic Unit, CHU Besançon, Hôpital Jean Minjoz, Besançon, France

Background: Genomic instability is a hallmark of cancers and mutations in the DNA repair BRCA1 and BRCA2 genes predispose to breast and other cancers. Prevalence of BRCA1/2 mutations is known in general population, but the frequency of these mutations in patients with metastatic breast cancer has not been established.

Methods: Prospective *BRCA1* and *BRCA2* genetic testing was proposed to all patients with metastatic breast cancer treated in 7 centers (in Franche-Comte, France) between February 19th 2015 and November 30th. *BRCA True™* test (Pathway Genomics®, San Diego CA, USA) was used to analyze the coding and flanking regions of *BRCA1* and *BRCA2* genes associated with hereditary breast and ovarian cancer by next-generation sequencing-base and Sanger sequencing.

Results: Of the 407 metastatic breast cancer patients, 11 (2.7%) had pathogenic germline BRCA1/2 mutations. BRCA2 (n = 8) mutations were the most frequent. Five of 11 patients (45%) would not have been candidate for BRCA1/2 mutation screening according to genetic counseling recommendations. All patients with a BRCA2 mutation presented a luminal metastatic breast cancer whereas all patients with BRCA1 mutation had a triple-negative metastatic breast cancer.

Conclusions: This is the first study assessing the prevalence of germline *BRCA1* and *BRCA2* mutations in an unselected population of patients with metastatic breast cancer. These patients with *BRCA1*/2 germline mutation represent the targeted population for poly(ADP-ribose) polymerase (PARP) inhibitors based therapy.

285P Higher MCTS1 mRNA level in breast cancer may associate with an unfavorable outcome

Y. Shi, N. Liao, G. Zhang, C. Ren, L. Wen, W. Zhu, X. Chen

Breast, Guangdong General Hospital and Guangdong Academy of Medical Sciences, Guangzhou, China

Background: The oncogene MCTS1 was originally discovered as an amplified product in a subset of T-cell lymphoma lines. It has been involved in cell cycle progression and conferring a growth advantage in lymphomas. However, the role of MCTS1 in predicting the outcome of breast cancer patients remains unclear.

Methods: GEPIA was a newly–developed web server for gene expression profiling and interactive analyses. We analyzed the gene expression profile across the clinical and RNA-seq data of 1085 breast cancer and 291 normal breast tissue based on TCGA and GTEx data.

Results: The results showed that MCTS1 was one of the most differential survival genes, and the median expression levels of MCST1 in breast cancer and normal tissue were 51.3 and 32.7 respectively. The overall survival of breast cancer patients with high MCTS1 mRNA level was inferior to that with low MCTS1 mRNA level (Logrank p = 2.3e−06). Cox Proportional Hazards Model analysis showed that MCST1 mRNA level in tumor was an independent predictor for overall survival status in breast cancer patients (HR = 2.2, p(HR)=4.1e−06). We inquired MCST1 on UCSC Genome Browser on Human Dec. 2013 (GRCh38/hg38) Assembly, and the result showed that H3K27ac, an active enhancer mark associated with the activation of transcription, was highly modified in promoter subdomain. We further analyzed the functional protein association networks on the String database, which showed that DENR involved in the translation of target mRNAs by recognizing the initiation codon were related to breast cancer with high MCTS1 mRNA expression.

Conclusions: In conclusion, higher MCTS1 mRNA level in breast cancer may associate with an unfavorable outcome due to H3K27ac modified MCTS1 promoter hyperacylation, which promotes its expression to inhibit apoptosis and cell cycle progression. To further confirm it, the experiment about the transfection of the shRNA on target gene is undergoing.

286P Holistic therapeutic strategy of TNBC necessitates in depth molecular classification: A prospective study

R. Bhattacharyya[1], K. Banerjee[2], M. Sen[1], A. Mukhopadhyay[1]

[1]Molecular Biology, Netaji Subhas Chandra Bose Cancer Research Institute, Kolkata, India, [2]Molecular Biology, Saroj Gupta Cancer Centre and Research Institute, Kolkata, India

Background: Triple negative breast cancer (TNBC), the most heterogeneous and aggressive breast cancer has always remained a global burden. To understand the molecular pathogenesis, we stratified the seven subgroups of TNBC propounded by Lehmann et al (2011) as: [1] TNBC with alterations of the DNA damage repair and cell cycle checkpoint pathways (Basal Like 1 & 2 (BL1, BL2)), [2] with upregulation of cell signalling and cell motility pathways (mesenchymal (M), mesemchymal stem like (MSL)), [3] with upregulated cell survival pathways (BL2, M, MSL) [4] With upregulated angiogenesis pathways (BL2, MSL), [5] With upregulation of pathways associated with T cell signalling, [6] With upregulated Androgen receptor signalling pathways. Our objective was to prioritize the basic molecular heterogeneity of TNBC in redefining our choice of drugs.

Methods: Lehmann's TNBC subgroups showed deregulation of diverse molecular pathways necessitating targeted therapeutics. We conducted a Meta-Analysis on12

randomized reported trial cases (n = 1170), solely under the following classes of drug regimens: [1] DNA destabilizers, [2] PARP inhibitors, [3] Microtubule stabilizers, [4] Angiogenesis inhibitors, [5] Antimetabolite, [6] T cell targeted therapy; as single or combinational therapies. Radiotherapy recipients were excluded.

Results: Best therapeutic efficacies of DNA destabilizers with angiogenesis inhibitors in combination than monotherapy with either (OR: 5.011-7.286; p value< 0.001) indicated a significant prevalence of basal like TNBCs in populations. Statistical significance with antimetabolites as combination therapy (OR: 2.343; p value: 0.018) and not with microtubule stabilizer (OR: 0.377) were remarkable, indicating probability of less predominance of M or MSL type TNBC in a population. PARP inhibitors or T cell targeted therapies were also found promising (OR: 1.120, 1.040 respectively), warranting their targeted usage for BRCA1 deficient and IM type TNBCs respectively.

Conclusions: For TNBC treatment, personalized medicine and not a generalized treatment strategy should be considered.

287P Neutrophil-to-lymphocyte ratio in metastatic breast cancer: Association with clinico-pathological features and outcome

M. Bartoletti[1], L. Gerratana[1], S. Zago[2], D. Basile[1], M.G. Vitale[1], G. Pelizzari[1], M. Bonotto[1], C. Bozza[1], V. Fanotto[1], C. Lisanti[1], M. Cinausero[1], S. Barban[1], M. Lera[1], I. Venuti[1], M. Mansutti[3], A.M. Minisini[3], G. Fasola[3], F. Curcio[2], F. Puglisi[1]

[1]School of Medical Oncology, Department of Medicine, University of Udine, Udine, Italy, [2]Clinical Pathology Institute, University Hospital of Udine, Udine, Italy, [3]Department of Oncology, University Hospital of Udine, Udine, Italy

Background: Tumors are closely linked with systemic inflammation, of which neutrophil-to-lymphocyte ratio (NLR) represents a simple and inexpensive tool of evaluation. Previous data suggested that a high NLR is associated with poor prognosis in several tumors, including breast cancer (BC). However, few studies involved patients (pts) with metastatic breast cancer (mBC).

Methods: We retrospectively analyzed clinico-pathological features and treatment outcome of 595 consecutive mBC pts treated at the Department of Oncology of Udine, Italy, between 2004 and 2014. NLR was calculated from the blood count performed before first line therapy start. Differences in NLR according to clinico-pathological characteristics were investigated through chi-square test. Cox regression was used to determine the prognostic impact of NLR.

Results: A statistically significant higher NLR was found in pts whose tumor had the following features: high grade (P = 0.009), ductal isotype (P = 0.02), ER negativity (P = 0.003), PgR negativity (P = 0.0001), high Ki-67 (P = 0.03). There were no statistical differences in NLR between HER2-positive and HER2-negative BC (P = 0.33). Among subtypes, triple-negative BC were associated with higher NLR, while luminal HER2+ BC with lower NLR (P = 0.004). No statistical differences in NLR were found according to visceral disease (P = 0.13) nor according with bone-only disease (P = 0.24). At univariate analysis, a NLR $\geq$2.64 was associated with worse progression-free survival after first line therapy (HR 1.41, 95%CI 1.11-1.79, P = 0.005) and with worse overall survival (HR 1.76, 95%CI 1.32-2.36, P < 0.0001). The statistical significance was lost at multivariate analysis (P = 0.08 and P = 0.13, respectively). Of note, a subgroup analysis showed a significant prognostic value of NLR in HER2-positive subtype (HR 4.89, 95%CI 1.13-21.23).

Conclusions: High NLR was associated with pathological features of BC, but did not represent an independent prognostic factor at multivariate analysis. Further investigation is warranted to identify the appropriate cut-off value of NLR and the BC subtypes in which its prognostic role could be more useful.

288P Prognosis after loco-regional recurrence of breast cancer: 35 years longitudinal data from the Stockholm cancer register

C. Falato[1], L. Eriksson[1], A. Sofiadis[1], S.K. Taylor[2], A. Nordblom[1], I. Fredriksson[3], J. Hartman[1], J. Bergh[1], T. Foukakis[1]

[1]Oncology and Pathology, Karolinska University Hospital-Solna, Stockholm, Sweden, [2]Dept. of Medical Oncology, BC Cancer Agency, Kelowna, BC, Canada, [3]Molecular Medicine and Surgery, Karolinska University Hospital-Solna, Stockholm, Sweden

Background: Loco-regional recurrence (LRR) of breast cancer is a significant cause of morbidity and mortality. It is poorly described how prognosis after LRR has evolved over time at the population level.

Methods: 2272 patients diagnosed with LRR between 1980-2014 were identified within the Stockholm cancer registry and divided in 7 cohorts by the year of LRR diagnosis. Post-relapse event free survival (EFS) and overall survival (OS) were analyzed separately in local and loco-regional relapses and compared across the cohorts by Cox regression method. Primary tumor size, axillary node status, estrogen receptor (ER) status, type of surgery, adjuvant chemotherapy, LRR free survival, and age at LRR were the covariates for Cox model adjustment.

Results: In 1615 patients diagnosed with local relapse, 903 post-LRR events were registered (Table). A significant improvement in median EFS (p < .001) and OS (p < .001) was observed in patients diagnosed 2010-14 compared with previous time periods. Among 657 patients with loco-regional recurrences, 476 experienced a post-LRR event (Table). EFS and OS independently improved over time (p <.001 and p <.001, respectively). Smaller primary tumors, negative axillary lymph nodes, ER positive status, breast-conserving surgery, longer LRR-free interval and younger age at LRR occurrence were independently associated with longer survival after LRR. No association was observed between survival and type of surgery or LRR-free interval in LRRs. An improvement in survival over time was also demostrated when cohorts 1980-84 and 2010-14 were excluded from the model.

Table: 288P

	Local recurrence	Locoregional recurrence
Type of post-lLRR relapse	N (%)	N (%)
Loco-regional	117 (13%)	57 (12%)
Distant	438 (49%)	305 (64%)
Loco-regional + distant	13 (1%)	3 (1%)
Death	335 (37%)	111 (23%)
Total	903 (100%)	476 (100%)

Conclusions: Survival after LRR has gradually improved over the last 35 years regardless of other recognized prognostic factors.

289P The CAN BEAR study: A systematic review and meta-analysis investigating adverse events (AEs) of targeted agents added to endocrine therapy (ET) in patients (pts) with hormone-receptor positive (HR+) metastatic breast cancer (MBC)

S. Martel[1], M. Bruzzone[2], M. Ceppi[2], C. Maurer[1], N. Falbel Ponde[1], A.R. Ferreira[1], G. Viglietti[3], L. Delmastro[4], C. Prady[5], E. De Azambuja[1], M. Lambertini[3]

[1]Oncologie Médicale, Institut Jules Bordet, Bruxelles, Belgium, [2]Clinical Epidemiology, IRCCS AOU San Martino-IST, National Institute for Cancer Research, Genoa, Italy, [3]Breast Cancer Translational Research Laboratory, Institute Jules Bordet, Brussels, Belgium, [4]Department of Oncology, IRCCS AOU, San Martino-IST, Italy, [5]Oncologie Médicale, Hôpital Charles-Lemoyne, Greenfield Park, QC, Canada

Background: Combining targeted agents and ET improves outcomes in pts with HR+ MBC but increases the risk of AEs. However, the specific additional toxicity burden caused by these agents remains unknown. Our meta-analysis aims to better estimate the comparative risk of AEs with the combination of ET and CDK4/6 inhibitors, PI3K inhibitors, mTOR inhibitors and anti-HER2 agents in pts with HR+ MBC.

Methods: A systematic literature search of MEDLINE, EMBASE, Cochrane Library and proceedings from major conferences up to March 31st 2017 was conducted to identify randomized controlled trials investigating ET plus CDK4/6, PI3K, mTOR inhibitors and anti-HER2 agents as compared to ET alone in pts with HR+ MBC. For each class of targeted agents, two groups were considered: ET plus targeted agent vs. ET alone. Summary risk estimates (odds ratio, OR) and 95% confidence intervals (CI) were calculated for each side effect within each class of targeted agents for each trial. Pooled analysis was conducted using the random and fixed effects models.

Results: A total of 7865 pts from 15 studies were included in our meta-analysis. Overall, the addition of targeted agents to ET was associated with significant higher risk of grade 3-4 AEs: OR 2.95 (95% CI 2.47-3.53) for CDK4/6 inhibitors, 2.05 (95% CI 1.63-2.58) for PI3K inhibitors, 1.89 (95% CI 1.40-2.56) for mTOR inhibitors, and 2.33 (95% CI 1.17-4.63) for anti-HER2 agents. Anti-HER2 agents, CDK4/6 and PI3K inhibitors significantly increased the risk of grade 3-4 fatigue, but not mTOR inhibitors (OR 1.48; 95% CI 0.64-3.43). Anti-HER2 agents, PI3K and mTOR inhibitors significantly increased the risk of grade 3-4 diarrhea, but not CDK4/6 inhibitors (OR 1.15; 95% CI 0.46-2.87). Other AEs and class specific toxicities will be reported at the conference.

Conclusions: In pts with HR+ MBC, the combination of targeted agents and ET is associated with significant increased risk of AEs. The risk of developing different AEs varies largely according to the type of agent used. Potential specific toxicities should be taken into account and discussed with patients when deciding to opt for combination regimens.

290P OlympiAD: Health-related quality of life (HRQoL) in patients with HER2-negative metastatic breast cancer (mBC) and a germline BRCA mutation (gBRCAm) receiving olaparib monotherapy vs standard single-agent chemotherapy treatment of physician's choice (TPC)

M. Robson[1], K.J. Ruddy[2], S-A. Im[3], E. Senkus-Konefka[4], B. Xu[5], S.M. Domchek[6], N. Masuda[7], S. Delaloge[8], W. Li[9], N. Tung[10], A. Armstrong[11], W. Wu[12], C. Goessl[12], A. Degboe[12], P.F. Conte[13]

[1]Memorial Sloan-Kettering Cancer Center, New York, NY, USA, [2]Mayo Clinic, Rochester, NY, USA, [3]Seoul National University College of Medicine, Seoul National University Hospital, Cancer Research Institute, Seoul, Republic of Korea, [4]Medical University of Gdańsk, Gdańsk, Poland, [5]Chinese Academy of Medical Sciences and Peking Union Medical College, National Cancer Centre/Cancer Hospital, Beijing, China, [6]Basser Center, University of Pennsylvania, Philadelphia, PA, USA, [7]National Hospital Organization, Osaka National Hospital, Osaka, Japan, [8]Institut Gustave Roussy, Villejuif, France, [9]The First Hospital of Jilin University, Changchun, China, [10]Dana-Farber Harvard Cancer Center, Beth Israel Deaconess Medical Center, Boston, MA, USA, [11]Christie Hospital NHS Foundation Trust and Faculty of Biology, Medicine and Health, Manchester, UK, [12]AstraZeneca, Gaithersburg, MD, USA, [13]University of Padova and Istituto Oncologico Veneto IRCCS, Padua, Italy

Background: The Phase III OlympiAD study showed a statistically significant and clinically meaningful PFS survival benefit with olaparib monotherapy, compared with standard of care chemotherapy (median 7.0 vs 4.2 months, respectively, hazard ratio 0.58; 95% CI 0.43, 0.80; $P = 0.0009$) in patients (pts) with HER2-negative mBC and a g*BRCAm*. A key predefined secondary objective was to assess the effect of olaparib on HRQoL.

Methods: The randomized, open-label, Phase III OlympiAD study (NCT02000622) enrolled pts with HER2-negative mBC and a g*BRCA*m, after ≤2 chemotherapy lines for mBC. Pts were randomized 2:1 to olaparib tablets (300 mg bid) or single-agent treatment of physician's choice (TPC; capecitabine, vinorelbine or eribulin). Pts were asked to complete an EORTC QLQ-C30 questionnaire (analysis focused on the Global HRQoL scale with range 0–100, and higher scores indicating a better QoL), at baseline and every 6 weeks until disease progression. Changes in Global HRQoL scores were analyzed descriptively, and mean change from baseline (cfb) by a mixed model for repeated measures.

Results: 302 pts (ITT) were randomized to olaparib (n = 205) or TPC (n = 97). Overall QLQ-C30 compliance rate was 93% for olaparib vs 77% for TPC. HRQoL was better preserved with olaparib than TPC (mean cfb in Global HRQoL score across all visits was 3.9 [n = 191] vs -3.6 [n = 73], respectively, difference 7.5; 95% CI 2.48, 12.44; P=0.0035). The proportion of pts (ITT) who were free of Global HRQoL deterioration (cfb decrease in ≥ 10 points) was 81.5% in the olaparib arm vs 61.2% in the TPC arm at 6 months, and 64.0% vs 53.5% at 12 months, respectively. The median time to Global HRQoL deterioration was not reached in olaparib pts, and was 15.3 months for TPC pts. A best HRQoL response of 'improved' (cfb increase in ≥ 10 points over two visits ≥21 days apart) was observed in 34% olaparib pts vs 13% TPC.

Conclusions: Pts receiving olaparib experienced significantly less and later deterioration in Global HRQoL vs TPC. HRQoL was modestly and consistently greater in patients receiving olaparib compared with TPC.

Background: PALOMA-2 demonstrated efficacy of P+L vs placebo (PBO) + L in pts with treatment-naive ER+/HER2– ABC (Finn *NEJM* 2016). We describe clinical patterns of hematologic adverse events (AEs), with an emphasis on NP, in pts receiving P+L.

Methods: Postmenopausal women (N = 666) with no prior systemic therapy for ABC were randomized 2:1 to receive P+L (P, 125 mg/d, 3 wk on/1 wk off; L, 2.5 mg/d continuously) or PBO+L (L, 2.5 mg/d continuously) until disease progression, unacceptable toxicity, or consent withdrawal. Hematological AEs are reported based on lab results.

Results: As of 2/26/2016, median follow-up was 23.0 mo in pts receiving P+L (n = 444). Median age of P+L pts was 62.0 (range, 30–89) years; ECOG status was 0, 1, and 2 in 57.9%, 40.1%, and 2.0%, respectively; and 213 (48.0%) received prior chemotherapy. 423 (95.3%) P+L pts experienced any grade (gr) NP, including 298 (70.4%) with gr 3/4 NP, manageable with dose modification. Among pts with gr 3/4 NP, 65 (15.4%), 41 (9.7%), and 192 (45.4%) experienced 1, 2, or ≥ 3 episodes, respectively. 92 (20.7%) and 84 (18.9%) pts experienced 3–5 episodes of any grade anemia and thrombocytopenia, respectively. Median (range) times to first episode of gr ≥ 3 NP, anemia, and thrombocytopenia were 28.0 d (12 − 854 [median duration, 31.5]), 182.0 d (14 − 760 [11.5]), and 283.5 d (21 − 617 [26.5]), respectively. Although NP is associated with increased risk of infection, the rate of gr 3/4 infections was 3.5% in P+L pts with NP. Of pts with gr 3/4 NP, 68.8% did not have any overlapping infections. Febrile NP was reported in 1.8% of P+L pts and did not result in therapy discontinuation. In univariate analysis, risk of developing gr 3/4 NP was associated with Asian ethnicity (P=0.0002) and low baseline absolute neutrophil counts (P<0.0001). NP resulting in dose reduction or interruption had no impact on PFS.

Conclusions: NP occurred early during therapy, and was manageable with dose modification. Febrile NP was reported in 1.8% of P+L pts and did not result in therapy discontinuation. Withholding dose, or dose reduction does not negatively impact PFS.

292P Prospective observational study of peripheral neuropathy in breast cancer patients treated with eribulin

Y. Sakata, H. Iwata, H. Ikezawa, R. Fudetani, D. Tonoda, Y. Uchida, H. Hasegawa, T. Matsuoka

Oncology Medical Department, Eisai Co., Ltd., Tokyo, Japan

Background: Eribulin mesylate (ERI), a nontaxane microtubule dynamics inhibitor, has antitumor activity and can prolong overall survival in patients with recurrent breast cancer (BC). As data lack on peripheral neuropathy (PN) when using ERI as primary or

secondary therapy for recurrent BC, we assessed the incidence of PN, the times to PN onset and recovery, and the risk factors for PN in patients with HER-2-negative recurrent or metastatic BC treated with ERI.

Methods: We analyzed data from an ongoing 2-year multicenter prospective observational study where the same number of patients who started ERI administration as primary or secondary therapy and as tertiary or later therapy were enrolled. PN events were defined as new onset or existing PN worsened after ERI administration. Logistic regression was run to assess the risk factors.

Results: The analysis set comprised 458 patients who had completed 6-month follow-up after ERI administration. Mean age ± standard deviation was 59.4 ± 10.9 years, and 171 patients (37.3%) had a history of PN from previous chemotherapy and 190 (41.5%) had existing PN at start of ERI administration (baseline). PN events were observed in 115 patients (25.1%), with severity of Grade 1 in 55 (12.0%), Grade 2 in 51 (11.1%), and Grade 3 in 9 (2.0%) in accordance with the Common Terminology Criteria for Adverse Events version 4.0. After the PN events, 91 patients (79.1%) continued ERI, and 16 (13.9%) reduced the dose or underwent a drug holiday. Within 6 months after ERI administration, 39.0% recovered to the state at baseline. In 266 patients without PN at baseline, new PN appeared in 71 patients (26.7%), and median time to PN onset was 57.0 days (95% confidence interval, 43.0–66.0 days). Results also showed that "history of radiotherapy", "hemoglobin level", and "history of PN from previous chemotherapy" were significantly associated with PN events, but no evident association was found with the number of chemotherapy prior to baseline.

Conclusions: PN events were observed in about one-quarter of patients treated with ERI, most of which were mild, and about one-third of patients who developed PN recovered early. This suggests that ERI is well tolerated.

293P Overall survival and quality of life in patients with metastatic breast cancer treated with nab-paclitaxel: Final results of the non-interventional study NABUCCO

K. Potthoff[1], A. Nusch[2], U. Söling[3], R. Hansen[4], C. Salat[5], S. Grebhardt[6], J. Harde[7], N. Marschner[8]

[1]Medical Department, IOMEDICO, Freiburg, Germany, [2]Hämatologie und Internistische Onkologie, Krebszentrum Ratingen, Ratingen, Germany, [3]Innere Medizin, Hämatologie und Internistische Onkologie, Innere Medizin, Hämatologie und Internistische Onkologie, Kassel, Germany, [4]Hämatologie und Onkologie, Onkologische Schwerpunktpraxis Dres. Hansen & Reeb, Kaiserslautern, Germany, [5]Innere Medizin, Hämatologie und internistische Onkologie, Hämato-Onkologische Schwerpunktpraxis, Munich, Germany, [6]Clinical Operations, IOMEDICO, Freiburg, Germany, [7]Statistics, IOMEDICO, Freiburg, Germany, [8]Internal Medicine/Hematology, Praxis für Interdisziplinäre Onkologie & Hämatologie, Freiburg, Germany

Background: Nab-paclitaxel (Nab-P) is approved for the treatment of metastatic breast cancer (MBC) after first line therapy and when anthracyclines are not indicated. Clinical trials proved high efficacy and reduced toxicity of nab-P compared to standard taxanes. Real world data of nab-P in MBC, however, are still limited.

Methods: The prospective, multicenter, non-interventional NABUCCO study was designed to collect data on effectiveness including overall survival, safety, treatment patterns and quality of life (QoL) in patients (pts) with MBC in real world. QoL was assessed with the validated questionnaires Functional Assessment of Cancer Therapy-General (FACT-G) and the breast cancer and taxane specific modules (FACT-B and FACT-Taxane) at baseline (BL), 3, 6 months. Data were analyzed descriptively. Survival was analyzed with the Kaplan-Meier method.

Results: 697 of 705 pts with MBC enrolled at 128 sites in Germany from 4/2012 to 4/2015 were evaluable (median age 62.3 years (yrs) (min-max 29.2-89.3); age ≥65 yrs n = 291 (41.8%), ECOG 0/1 n = 628 (90.1%), prior taxanes n = 419 (60.1%)). 194 pts (27.8%) received 220-260 mg/m^2 q3w, 491 pts (70.4%) received weekly *nab*-P at ≤ 150 mg/m^2 (physician's discretion; 1.7% other). Median overall survival (mOS, months [95% CI]) was 15.6 [14.2-17.2]. No difference was observed with regard to treatment pattern (15.1 [12.3-17.5] q3w vs 16.3 [14.4-18.5] weekly) and age (15.7 [14.0-18.1] <65 yrs vs 15.1 [12.8 - 17.3] ≥ 65 yrs). mOS was significantly shorter in pts receiving prior taxanes (13.7 [11.7-15.5] vs. 18.3 [16.4-22.2]) or prior chemotherapy in general (19.2 [16.9-22.2], 15.1 [12.5-17.3], 14.1 [10.3-17.2], 11.3 [9.1-12.7] with 0, 1, 2, ≥ 3 prior palliative lines). Consistent with safety data, pts reported increased taxane-related symptoms after start of *nab*-P (BL vs 6 months; [range]: FACT-Taxane subscale score 52.3 [4.0-64.0] vs 40.0 [3.0-64.0]). Global and breast cancer related QoL were not affected (FACT-G 71.3 [27.0-105.0] vs 67.0 [14.0-104.0]; FACT-B subscale score 23.6 [0.0-35.0] vs 22.0 [2.0-35.0]).

Conclusions: The NABUCCO study confirms survival data from clinical trials in real world without deteriorated global and breast cancer related QoL.

[1]Oncology Clinical Pharmacology, Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA, [2]Medical Oncology, Novartis Pharmaceuticals, East Hanover, NJ, USA, [3]Achaogen, South San Francisco, CA, USA, [4]Medical Oncology, Novartis Pharma AG, Basel, Switzerland

Background: Ribociclib (KISQALI®) is a CDK4/6 inhibitor that has been approved recently in the United States for use in combination with an aromatase inhibitor as a first-line therapy for HR+, HER2− advanced or metastatic breast cancer. The recommended ribociclib dose is 600 mg/day (3-weeks-on/1-week-off) with no restrictions on food intake or concomitant proton pump inhibitor (PPI) use. Here we examine the influence of gastric pH and food intake on ribociclib bioavailability using physiology-based pharmacokinetics (PBPK) modelling, observed clinical pharmacokinetic (PK) data, and population PK (pop-PK) analysis.

Methods: *In silico* PBPK models based on *in vitro* and preclinical data were built and fitted with clinical PK data from healthy volunteers. Sensitivity analyses were performed to evaluate the effect of gastric pH (range, 0.5-8.0) on ribociclib PK and absorption. A descriptive statistical analysis of clinical PK data from patients with and without concomitant PPI use and a pop-PK analysis were used to examine the effect of PPI dose

Table: 294P Ribociclib PK parameters by PPI use[a]

Study No.	PK Parameter	n	PPI Use	Geometric Mean (Geometric Coefficient of Variation, %)
X2107	$AUC_{0\text{-}24h}$ (ng*hr/mL)	8	Yes	24,700 (30.6)
		10	No	21,100 (57.2)
	C_{max} (ng/mL)	10	Yes	1,780 (34.6)
		13	No	1,620 (53.2)
X2101	$AUC_{0\text{-}24h}$ (ng*hr/mL)	12	Yes	25,900 (79.1)
		46	No	23,700 (61.3)
	C_{max} (ng/mL)	13	Yes	2,050 (74.7)
		48	No	1,870 (60.3)
X1101	$AUC_{0\text{-}24h}$ (ng*hr/mL)	2	Yes	42,600 (28.7)
		6	No	55,100 (68.6)
	C_{max} (ng/mL)	2	Yes	2,700 (53.0)
		6	No	3,500 (65.8)

$AUC_{0\text{-}24h}$, area under the concentration-time curve from time zero to 24 hours; C_{max}, maximal concentration; PK, pharmacokinetics; PPI, proton pump inhibitor. [a]Defined by PPI use prior to and on the day of sampling on C1D15 for $AUC_{0\text{-}24h}$ and C_{max}, and on the dosing date corresponding to the $AUC_{0\text{-}24h}$ or C_{max}. "Yes" was defined as PPI use for at least 5 consecutive days; "No" was defined as no PPIs use for at least 13 consecutive days.

intensity on ribociclib bioavailability. The effect of a high-fat meal on ribociclib exposure was evaluated in a bioequivalence trial in healthy volunteers.

Results: Sensitivity analyses using validated PBPK models predicted no effect of varying stomach pH on ribociclib absorption. PK data ($AUC_{0\text{-}24h}$ and C_{max}) from several clinical studies showed similar ribociclib exposure regardless of PPI use (Table). The pop-PK analysis supported the PBPK models and clinical findings by showing that PPI use is a statistically insignificant and clinically unimportant covariate on ribociclib bioavailability. Food intake did not affect the rate or extent of ribociclib absorption.

Conclusions: *In silico* models and clinical PK data indicate that ribociclib can be administered without regard to PPI use or food intake. This lack of dosing restriction may facilitate greater patient compliance and clinical benefit.

295P Pneumocystis jiroveci pneumonia (PCP) in patients receiving weekly chemotherapy for metastatic breast cancer

S.T. Wijaya, E. Harrison, M. Moody, C. Wilson, L. Hughes-Davies, C. Caldas, H. Earl, R. Baird

Cambridge Breast Unit, Addenbrooke's Hospital, Cambridge, UK

Background: Pneumocystis jiroveci pneumonia (PCP) is thought to be a rare phenomenon in the solid tumour population, particularly in patients with breast cancer. However, it may be increasing within this population as the type and intensity of chemotherapy used changes. There is currently a lack of consensus on PCP prophylaxis in patients who are immunocompromised due to chemotherapy.

Methods: The EPIC electronic health record system was searched for metastatic breast cancer (MBC) patients treated with a weekly chemotherapy (epirubicin/paclitaxel) regimen from October 2014 – February 2016 at Addenbrooke's hospital (n = 49). A subset of patients diagnosed with PCP (n = 5) was identified. A retrospective analysis was performed on the charts of all patients.

Results: Patients received a mean of 21 weeks (SD = 15, min=1, max=62) of chemotherapy. An overall of 16% (n = 8) of patients had profound lymphopaenia (absolute lymphocyte count $<0.5*10^9$/L) at some point during their treatment. 10% (n = 5) of the patients were diagnosed with confirmed (n = 3) and probable (n = 2) PCP.

Conclusions: A high incidence of PCP was observed in MBC patients receiving weekly epirubicin/paclitaxel treatment. Additional investigation is needed to define the population of patients at the greatest risk of PCP infection, and to identify those who might benefit from antibiotic prophylaxis.

296P Detection of early cardiac effects of docetaxel plus trastuzumab and pertuzumab through strain rate imaging in patients with HER2-positive metastatic breast cancer

V. Michalaki[1], G. Koutroulis[1], I. Psychogios[1], E. Karvouni[2], I. Vasiliou[1], C. Papadimitriou[1]

[1]2nd Department of Surgery, Areteion Hospital, University of Athens, Athens, Greece, [2]Histopathology Department, Areteion Hospital, University of Athens, Athens, Greece

Background: Dual anti- HER2 therapy with trastuzumab and pertuzumab in combination with taxane-based chemotherapy improves overall survival in patients with metastatic HER2-positive breast cancer. There is a critical need to investigate the potential cardiotoxicity of dual anti-HER2 blockade, given the importance of HER2 signaling in cardiac homeostasis and stress response. Sequential left ventricular (LV) ejection fraction (EF) assessment has been mandated to detect myocardial dysfunction. Changes in cardiac function induced by this therapy, however, are subtle and difficult to quantitate by conventional imaging methods. Doppler myocardial imaging-based velocity, strain, and strain rate measurements have been shown to sensitively quantify abnormalities in cardiac function in other settings. The aim of this study was to determine if sensitive indices of left ventricular (LV) dysfunction, specifically strain rate imaging, would be useful for addressing the early detection of dual anti-HER2 mediated cardiotoxicity.

Methods: Patients with 0-1 lines of prior therapy were treated with 8 cycles of docetaxel (75mg/m(2) plus trastuzumab (8 mg/kg loading dose followed by 6 mg/kg) and pertuzumab (840 mg loading dose followed by 420 mg every 3 weeks. Conventional and Doppler myocardial imaging echocardiography were obtained at baseline and every 2 cycles of treatment. Segmental peak systolic longitudinal and radial velocity, strain, and strain rate (SR) were measured.

Results: Twenty-seven women (median age 52.2 years) were enrolled in the study. There was no overall change in Left ventricular dimensions, ejection fraction, and systolic myocardial velocity. In contrast, a significant reduction in longitudinal and radial strain and strain rate was found after 8 cycles (longitudinal strain -12.8% +/- 2.2% vs baseline (P = .001); radial strain 29.3% +/- 7.1% vs 50.3% +/- 10.6%, P < .001 vs baseline). Changes in radial function appeared earlier and were more pronounced than in longitudinal direction.

Conclusions: In contrast with conventional echocardiography myocardial velocity measurements allowed detecting subtle changes in longitudinal and radial left ventricular function after 8 cycles of therapy. We suggest that strain rate imaging identifies preclinical myocardial dysfunction earlier than conventional measures in women undergoing treatment with dual anti-HER2 therapy for metastatic breast cancer and could be used for cardiac function monitoring.

297P Evaluation of drug-drug interactions (DDI) between tucatinib and capecitabine (C) in patients with advanced HER2+ metastatic breast cancer from a phase 1b study

A. Vo[1], D. Leviten[2], M. Insko[3], T. Sierra[2], A. Dozier[2], L. Walker[4], S. Peterson[5]

[1]DMPK, Cascadian Therapeutics, Inc., Seattle, WA, USA, [2]ADME/PK, Cascadian Therapeutics, Inc., Seattle, WA, USA, [3]PK, Faraday Pharmaceuticals, Seattle, WA, USA, [4]Clinical Development, Cascadian Therapeutics, Inc., Seattle, WA, USA, [5]Research and Development, Cascadian Therapeutics, Seattle, WA, USA

Background: Tucatinib is an orally bioavailable, potent HER2 selective tyrosine kinase inhibitor. Based on the combination activity with chemotherapy and trastuzumab (Tz) in preclinical HER2+ tumor models, tucatinib was evaluated in combination with C and Tz in a Phase 1b study in patients with HER2+ metastatic breast cancer (mBC).

Methods: A phase 1b 3 + 3 dose escalation study (ONT-380-005) was conducted to evaluate the safety and tolerability of tucatinib in combination with C and Tz. Tucatinib (300 mg PO BID), C (1000 mg/m2 PO BID 14 days of a 21-day cycle), and Tz (8 mg/kg IV loading; then 6 mg/kg IV once every 21 days), were administered to HER2+ mBC patients previously treated with Tz and T-DM1. Pharmacokinetic (PK) assessments were conducted on cycle 1 day 14 (+C) and on cycle 1 day 21 (-C). PK of C and its major catabolites/metabolites were also measured. In vitro assessments of the activation of C were determined in the presence of tucatinib. The enzymes evaluated were carboxyesterase (CES), cytidine deaminase (CDA), thymidine phosphorylase (TP), and dihydropyrimidinephosphorylase (DPD).

Results: Tucatinib did not inhibit conversion of C to 5'-DFCR in vitro; at 10 μM tucatinib reduced ~30% of CES activity. Similarly, tucatinib did not have any significant effect on the activity of CDA, TP, or DPD. Results from *in vitro* inhibition studies suggested tucatinib does not have a measurable effect on the conversion of C to its active antimetabolite. The clinical PK of tucatinib was unchanged in the presence or absence of C. The PK of C and its catabolites/metabolites were also unaffected in the presence of tucatinib, and were consistent with reported literature.

Conclusions: The overall in vitro and clinical results indicate there is no evidence for DDI between tucatinib and C, including when the combination is given with Tz. The tucatinib-Tz-C triplet combination has been reported to be well tolerated and supports the evaluation of the efficacy of the combination regimen in an ongoing controlled, randomized, double-blinded registrational study (HER2CLIMB).

298P Outcomes of intracranial stereotactic radiotherapy (SRT) in metastatic breast cancer (BC)

G. Kothari[1], K. Mohammed[2], G. Ross[1]

[1]Breast Unit, Royal Marsden Hospital NHS Foundation Trust, London, UK, [2]Research and Development Department, The Royal Marsden NHS Foundation Trust, London, UK

Background: Brain metastases (BM) are a significant cause of morbidity and mortality. Advancement of systemic therapies for patients with BC has improved control of extracranial metastases and survival. Intracranial control however continues to be challenging. SRT has been shown to provide excellent local control (LC) with minimal toxicity, although breast specific data is comparatively lacking.

Methods: This study aims to describe outcomes of first SRT including LC, distant brain control (DC), time to intracranial progression (TTP) and overall survival (OS) in a cohort of patients with BC who received SRT from 2001 to 2016 at the Royal Marsden Hospital. Kaplan Meier and log-rank methods were used for statistical analysis.

Results: 64 patients underwent SRT for 129 BM. Median age was 52.4 years. 58 (91%) were ECOG 0/1. 18 (28%) were hormone receptor positive (HR+)/HER-2 negative, 38 (59%) were HER-2 enriched (HER-2+), and 8 (13%) were triple negative (TN). The median number of BM treated with SRT was 1 (range 1 - 12). Median dose and range was 20 Gy (12 – 35 Gy) in 1 fraction (1 – 10). 29 (45%) were treated using a linear

accelerator, 34 (53%) with CyberKnife and 1 with GammaKnife. 27 (42%) had prior whole or partial brain radiotherapy (WBRT). 21 (33%) had prior surgery. 30 (49%) had concurrent endocrine therapy, 25 (40%) had targeted therapy and 8 (13%) had chemotherapy. Follow-up imaging was available for 57 patients. Median follow up was 15 months. 1 year LC was 54% and DC was 56%. Median TTP was 7.1 months (95%CI: 6.1 – 10.8) and was significantly worse for TN compared to HER-2+ patients (5.3 vs 9.9 months, $p = 0.046$). Salvage radiotherapy or surgery was performed after SRT in 13 (23%) patients for local failure, and 20 (35%) for distant failure. 7 (12%) patients had radionecrosis following SRT. OS from SRT was 19.6 months (95%CI: 14.9 – 23.1), and was significantly worse for TN patients (13.6 vs 22.1 months, $p = 0.003$), age $\geq$ 60 years (14.9 vs 19.8 months, $p = 0.028$) and multiple brain metastases (14.0 vs 22.6 months, $p = 0.010$).

Conclusions: Outcomes in patients with BC and BM treated with SRT are excellent overall. Outcomes are worse in TN disease, older patients and patients with multiple BM, and should be considered in SRT decision making.

Broussais, St. Malo, France, [13]Medical Oncology, Clinique Victor Hugo Le Mans, Le Mans, France, [14]Medical Oncology, Centre Léon Bérard, Lyon, France, [15]Medical Oncology, Centre Paul Papin, Angers, France

Background: Treating metastatic breast cancer (MBC) in women of 70 years old or more is a frequent problem however few data are available describing the safety and efficacy of chemotherapy in elderly patients. Eribulin is validated for MBC from the 2nd line treatment onwards since two phase III studies. We present here a focus on safety and efficacy of eribulin in patients $\geq$ 70 years old compared to the results of younger patients in a real life cohort.

Methods: From Oct 2014 to Feb 2017, a multicentric retro-prospective study (REPROLINE) was conducted. Data concerning patient, tumor characteristics, previous treatments administered, tolerance, efficacy and outcome of eribulin were retrieved for patients treated in real life for MBC in 12 different French hospitals between Dec 2013 and Jan 2016. Data from 446 MBC patients were collected. This database was splitted in two cohorts: comparing the results from the cohort of 363 patients $<$ 70 years old (group A) to the cohort of 83 patients $\geq$70 years old or more (group B).

Results: Median age for each cohort was 56.3 and 75.4 years old. Both cohorts had similar tumour characteristics, number of metastatic sites and the median number of prior chemotherapy lines was 2. Albumine serum levels were lower in the group B with 21% of patients with albumine $<$ 30g/L versus 13% in group A, without any statistical difference. Outcomes were similar in group A and B with respectively: median PFS of 3.67 months versus 3.7 months; HR 0.972(CI 95% 0.762-1.241), $p = 0.821$. median OS 10.7 months vs 10.7 months; HR 0.997 (CI95% 0.752-1.323), $p = 0.984$. Patients in both groups received a median number of 4 cycles. The most frequent grade 3 adverse events were neutropenia (22.9% in group A and 15.7% in group B), fatigue (6.5% group A and 13.3% group B) and neurotoxicity (4.4% and 3.6%, respectively). No statistical difference between elderly and younger patients was demonstrated. 9.6% of the total patients stopped the treatment due to fatigue.

Conclusions: We present here the first study focusing retro-prospectively on the tolerance and efficacy of eribulin in elderly patients in real life. In this study, eribulin in patients $\geq$70 years old is as effective and safe as in younger patients.

300P Long-term responders to trastuzumab monotherapy in the first-line metastatic setting: characteristics and survival data (SAKK 22/99 Trial)

S. Schmid[1], D. Klingbiel[2], A. Goldhirsch[3], C. Oehlschlegel[4], E. Munzone[5], F. Nolè[3], B. Pestalozzi[6], S. Aebi[7], C. Rochlitz[8], R. von Moos[9], K. Zaman[10], C. Mamot[11], P. Weder[1], B. Thuerlimann[1], O. Pagani[12], T. Ruhstaller[1]

[1]Breast Center St. Gallen, Kantonsspital St. Gallen, St. Gallen, Switzerland, [2]Coordinating Center, SAKK, Berne, Switzerland, [3]Department of Oncology, Istituto Europeo di Oncologia, Milan, Italy, [4]Institute of Pathology, Kantonsspital St. Gallen, St. Gallen, Switzerland, [5]Division of Medical Senology, European Institute of Oncology (IEO), Milan, Italy, [6]Department of Oncology, Universitätsspital Zürich, Zurich, Switzerland, [7]Department of Oncology, Inselspital, University Hospital Bern, Bern, Switzerland, [8]Department of Oncology, University Hospital Basel, Basel, Switzerland, [9]Department of Oncology, Kantonsspital Graubünden, Chur, Switzerland, [10]Department of Oncology, Centre Hospitalier Universitaire Vaudois - CHUV, Lausanne, Switzerland, [11]Department of Oncology, Kantonsspital Aarau, Aarau, Switzerland, [12]IOSI, Ospedale Regionale Bellinzona e Valli, Bellinzona, Switzerland

Background: The prospective randomized trial SAKK 22/99 compared first-line trastuzumab plus chemotherapy with the sequential use of trastuzumab followed by chemotherapy plus trastuzumab at progression in patients with stage 4 HER2-positive breast cancer. The main results were recently published in Annals of Oncology. Here we report characteristics and outcomes of patients with long-lasting disease control with trastuzumab alone.

Methods: Long-term responders to trastuzumab monotherapy were defined as patients achieving disease control for $\geq$ 6 months. A risk score was defined as sum of negative prognostic factors (NPFs): ER negative (neg), PgR neg and visceral disease. The HER2:CEP17 FISH ratio was correlated with duration of response. Standard descriptive statistics were used. Survival analysis was done using the Kaplan-Meier method.

Results: Of 175 enrolled pts, 86 were randomised to receive trastuzumab monotherapy until PD. 24 patients (28%) were long-term responders ($\geq$6 months). In a landmark analysis excluding patients who died within 6 months, 5y-overall survival (OS) in long-term responders was 54% (95% CI 31–72) compared to 18% (95% CI 10–30) in short-term responders (log-rank $p = 0.02$). Baseline characteristics were well-balanced except for visceral disease (see Table, Fisher's exact test $p = 0.01$). With each additional NPF the proportion of long-term responders decreased: 0 NPF, 42%; 1 NPF, 40%; 2 NPFs, 35%; 3 NPFs 17%. Median FISH ratio was 4.8 (IQR 4.1–5.3) in long-term responders and 4.7 (IQR 2.5–5.3) in short-term responders; no long-term responders were in the lowest quartile of all FISH ratios.

Table: 300P Baseline characteristics

	HER2-long Responders (N = 24)	HER2-short Responders (N = 62)
Age (med)	57 years	52 years
Visceral disease (yes)	46%	76%
ER-Status (pos)	59%	60%
PR-Status (pos)	48%	41%
FISH (med. Ratio)	4.8	4.7
ALP U/l (med)	74	103
Hb g/l (med)	130	134
WBC G/l (med)	5.8	6.8
Endocrine treatment adj (yes)	33%	48%

Conclusions: Long response to trastuzumab monotherapy is prognostic with significantly higher 5y-survival rates in this cohort. Negative prognostic factors including lower FISH ratio may reduce the chance for long-term response to trastuzumab monotherapy as first line therapy.

Background: mCHT is the minimum biologically effective dose of a chemotherapeutic agent, given at regular dosing regimen with no prolonged drug free interval, that leads to anti-tumor activity. Old regimens included Cyclophosphamide-Methotrexate (CM), whereas in the last years new regimens, such as Vinorelbine (VRL) and Capecitabine (CAPE)-based have been developed. Aim of this observational retrospective ongoing study is to describe the use of mCHT in ABC pts across 5 years and the clinical characteristics of the pts together with efficacy of old (CM-like) vs new (VRL/CAPE-based) metronomic regimens in terms of response and disease control.

Methods: We retrospectively identified from clinical records those HER2-ve ABC pts who have received any kind of mCHT in the years 2011-2015, alone, or in combination with a non-metronomic drug. Standard statistical approaches were used for describing the sample characteristics. Logistic and non proportional hazard analysis were used to identify factors associated with response, and time to treatment failure and survival, respectively. This preliminary analysis focuses on Response Rate (RR) and Disease Control Rate (DCR).

Results: From June 2011 to December 2015, 267 pts have been identified till now and 233 are fully evaluable. Median age at mCHT start was 67 years. 81% was HR+ and 33% had non-visceral metastatic disease. 22% of the pts received CM, 55% VRL-based and 23% mCAPE-based regimens. mCHT use increased over the time from 15.0% (2011) to 30% (2015). As 1st-line treatment, CM was administered in 27% of compared with more than 48% of patients receiving CAPE/VRL-based regimens. Overall Response Rate (ORR) was 28% and Disease Control Rate (DCR) was 79%. Median duration of mCHT was 6.2 months. New generation metronomic regimens produced higher ORR in comparison to old ones (32% vs 13.5%), with similar duration of treatment (6.4 vs 5.4 months, respectively).

Conclusions: The use of mCHT in the treatment of HER2-ve ABC pts has deeply changed across the last 5 years, being new generation regimens used in earlier lines of treatment, producing interesting results in terms of objective response and disease control.

Background: This subanalysis of a retrospective, multicenter, cohort study of fulvestrant 500 mg (F500) in advanced/metastatic breast cancer (AMBC) patients in Japan (UMIN000015168) sought to identify clinical factors associated with prolonged time to treatment failure (TTF).

Methods: We analyzed ER+/human epidermal growth factor receptor 2 (HER2)-negative and ER+/HER2-positive patients who received F500 as 2nd- or later-line treatment. Factors investigated were age (≥65/≤65 years), treatment line (≥4th/3rd/2nd), time from AMBC diagnosis to F500 use (<3/≥3 years), prior palliative chemotherapy (no/yes), nuclear or histological grade (1/2/3), visceral metastasis (no/yes), ER expression (+/−), and progesterone receptor expression (+/−). TTF was determined using Kaplan–Meier analysis. TTF data were analyzed using univariate and multivariate analyses with a Cox proportional hazards model.

Results: We registered 1072 patients who received F500 between November 2011 and December 2014 at 16 sites in Japan. In the ER+/HER2− group (n = 828), median TTF was 5.4 months. By univariate analysis, higher age, earlier F500 use and no prior chemotherapy were associated with significantly longer TTF. By multivariate analysis, higher age, longer time from AMBC diagnosis to F500 use, no prior palliative chemotherapy and F500 treatment line were correlated with prolonged TTF (Table). In the ER+/HER2+ group (n = 132), treatment line was correlated with TTF (median 4.6 months) in the univariate analysis ($P = 0.042$); no factors significantly correlated with TTF in the multivariate analysis.

Table: 302P Factors correlated with TTF in ER+/HER2− AMBC patients

ER+/HER2−	Hazard ratio	95% confidence interval	*P*
Age (≥65/<65 years)	0.85	0.73–0.99	0.035
Treatment line (≥4th/3rd/2nd)	1.36	1.22–1.52	<0.001
Time from diagnosis (≥3/<3 years)	0.65	0.54–0.79	<0.001
Prior chemotherapy (yes/no)	1.34	1.13–1.58	<0.001

Conclusions: In ER+/HER2− patients who received F500 as a ≥ 2nd-line treatment, treatment line, advanced age, no prior palliative chemotherapy and a longer time from AMBC diagnosis to F500 use were associated with longer TTF.

Background: Though advanced and metastatic epidermal growth factor receptor 2 (HER2)-positive disease is not curable, a small proportion of patients with HER2-positive metastatic breast cancer remain in prolonged complete remission with anti-HER2 treatment. We hypothesized that some cases of human epidermal growth factor receptor 2 (HER2)-positive metastatic breast cancer may be curable by trastuzumab. In this large, multicenter retrospective study, we aimed to assess the long-term outcomes for patients with a durable response to trastuzumab.

Methods: We retrospectively evaluated the data of patients diagnosed with HER2-positive metastatic breast cancer who received trastuzumab for more than 2 years as the first-line treatment. Patients diagnosed between April 1, 2001 and December 31, 2014 at 19 institutions in Japan were included in the analysis.

Results: A total of 108 patients were evaluated. Sixteen were met to exclusion criteria. The median follow-up length was 7.7 years. Disease progression occurred in 44/108 (40.7%) patients and 13/108 (12%) patients died. The median progression-free survival was 11.2 years, and as more than 80% of patients were alive 10 years after metastatic breast cancer diagnosis. Of the 108 patients, 57 achieved a clinical complete response. Trastuzumab therapy was interrupted for 27 (47.4%) of these patients (based on the doctor's recommendation for 19 patients, owing to adverse events for 4 patients, owing to unknown reasons for 3 patients, and at the request of 1 patient). Disease progression occurred in 4 of the 27 patients after the interruption of trastuzumab treatment. The median duration of trastuzumab therapy for all 27 patients was 5.1 years (0.9-9.3 years).

Conclusions: In conclusion, we found that some patients showed no evidence of disease after the interruption of trastuzumab therapy. Discontinuation of maintenance trastuzumab in this patient population after a limited time should be explored cautiously while awaiting a global collaborative effort for a randomized trial.

304P Characterization of breast cancer responses to metformin

A. Makhtar

Oncology Department, University of Sheffield, Sheffield, UK

Background: Over the last six decades, metformin has become one of the most widely prescribed oral medications for type II diabetes. It has recently received considerable attention because of its potential role in reducing the risk of cancer development and its antineoplastic properties. However, the mechanism behind the growth-inhibitory effect of metformin on breast cancer cells remains unclear, with little consensus on which tumour subtypes benefit from treatment. Furthermore, it should be noted that much of the in vitro work published to date has used drug concentrations greatly exceeding the recommended clinical dose, and therefore may not translate directly into clinical practice.

Methods: Non-tumorigenic (MCF10A), pre-malignant (MCF10AT), pre-invasive (DCIS), the three-invasive breast cancer [MCF7, T47D and MDA-MB-231] and the fully bone-homed variant of MDA-MB-231(BM) were treated with metformin and effects on cellular proliferation were evaluated by trypan-blue exclusion and clonogenic assays. The expression levels of metformin transporters mRNA and proteins (OCT1-3, MATE1-2 and PMAT) were evaluated by qRT-PCR, western blot.

Results: The growth-curtailing effect of metformin was achieved at 0.3mM for MDA-MB-231($P = 0.0198$) in cell counting assays. Colony-forming capacity was inhibited in all cell lines tested at 0.03mM, ($P < 0.0001$). The Invasive cancer cells demonstrated strong expression of OCT2, PMAT and MATE1 but minimal positivity for OCT1 and no expression of MATE2. OCT3 is only expressed by the triple negative MDA-MB-231. The mRNA and tissue expression of metformin transporters followed the same pattern.

Conclusions: Clinically relevant doses of metformin inhibited the proliferation and colony formation of different breast cancer subtypes regardless of their receptor status and aggressiveness, including the hard to treat triple negative subtype MDA-MB-231 cells. Expression of various influx and efflux metformin-transporters is essential for cellular response and sensitivity to treatment.

305P Paclitaxel every-3-weeks versus weekly paclitaxel and versus weekly vinorelbine in metastatic breast cancer

L. Katselashvili[1], I. Kiladze[1], M. Katcharava[1], N. Jokhadze[1], T. Melkadze[2], A. Matitashvili[3], M. Zhvania[4], N. Sharikadze[5], F. Todua[6]

[1]Oncology, Research Institute of Clinical Medicine, Tbilisi, Georgia, [2]Medical Oncology, Research Institute of Clinical Medicine, Tbilisi, Georgia, [3]Oncology, Mardaleishvili Medical Centre, Tbilisi, Georgia, [4]Oncology, Conssillium Medulla, Tbilisi, Georgia, [5]Medical Oncology, MediclubGeorgia, Tbilisi, Georgia, [6]Radiology, Research Institute of Clinical Medicine, Tbilisi, Georgia

Background: Single-agent chemotherapy (CT) is widely used in the management of HER2-negative breast cancer patients (pts). As both Paclitaxel (P) and Vinorelbine (V) have demonstrated efficacy in the treatment of Metastatic Breast Cancer (MBC), they are recommended among the standard available CT agents for MBC patients. This study compares the efficacy and safety profile of most frequently used three treatment regimens: Paclitaxel every-3-weeks (3-w-P) versus weekly Paclitaxel(w-P) and versus weekly Vinorelbine (w-V) in MBC. Primary objective: Time to progression (TTP). Secondary objectives: evaluation of safety profiles, clinical benefit and response rate (RR) of all arms.

Methods: In this open-label randomized prospective study, pts were randomized (2:2:1) to receive either: intravenously 3-w-P every 21 days, w-P 80 mg/m^2/week (day 1, 8, 15) every 28 days or w-V 25 mg/m^2/week (day 1, 8, 15) every 28 days. Main eligibility criteria: age $\geq$18 years, documented metastatic disease previously untreated by CT for metastatic setting, ER/PR positive and HER2-negative disease, or triple negative disease. ECOG$\leq$2.

Results: From April 2014 to April 2015, 95 pts were included. 39 received 3-w-P; 38 received w-P and 18 received w-V per protocol. Median age was 58 years (range 38-79), median duration of treatment 11.5 weeks (range 9-24). Efficacy: with a median follow up of 24 months (m), median time to progression (primary endpoint) was 10.3m, 9.8m and 9.6m in 3-w-P arm, w-P and in w-V arm respectively ($p = 0.006$). Safety: w-V was much better tolerated with fewer G 3/4 toxicity events ($n = 2$) than w-P and 3-w-P

(n = 23 and 16). Neuropathy G3/4 was mostly reported in 3-w-P and w-P arm than in V arm (75% vs. 69% vs. 17%). G3/4 alopecia was reported in both P arms (94%) when in V arm G3 alopecia was only in 6% of pts.

Conclusions: Weekly Paclitaxel appeared as effective as every-3-weekly regimen and weekly Vinorelbine, however neurotoxicity is a treatment-limiting toxicity for both Paclitaxel regimen. Vinorelbine had fewer significant grade 3-4 toxicities than both Paclitaxel arms and had better RR. Larger randomised studies are needed to determine the efficacy and overall survival of Paclitaxel versus Vinorelbine.

306P All oral combination of vinorelbine and capecitabine as a first line treatment in patients (pts) with metastatic breast cancer (MBC)

S. Shehata, M. Khalaf

Clinical Oncology Department, Assiut University Hospitals, Assiut, Egypt

Background: Oral chemotherapy (OCT) represents a step forward in the management of MBC. It has gained an increased importance over the past years. In Egypt, cancer pts living in rural areas are often hours away from the closest treatment center. For these pts, OCT offers a convenient option and seems to be preferred. In first line MBC, oral vinorelbine (OV) with capecitabine (C) is an active full oral combination with response rates (RR) ranging from 48 to 70% in published data. Based on that, we evaluated efficacy and safety of OV-C in first line Her2 negative MBC pts.

Methods: 26 patients were treated. Eligible pts had no previous treatment for their advanced disease. All pts had measurable disease relapsing after (neo) adjuvant AC ± taxane based treatment, WHO PS $\leq$ 2. Pts were treated with OV 60 mg/m^2 D1, D8 for the first cycle and thereafter 80mg/m^2 D1, D8 in combination with (C) 825mg/m^2 twice daily from D1 to D14, every 21 days for 6 cycles. Primary endpoint (EP) was Disease Progression Rate (DPR) (%); secondary EPs were RR, 3 year survival (3YS) and safety.

Results: All 26 pts were included in the analysis. Median age was 53.2 years (range 38.8-77.1); median WHO PS 1 (range 0-2). 58% of the pts were post-menopausal. All pts were treated with AC-based therapy in the (neo)adjuvant setting and 61.5% with an AC+taxane based treatment. 21 (81%) pts had 2 or more metastatic sites; liver (39%), bone (31%) and lung (31%) being the most frequent sites. A median of 4 cycles were given (range: 1-6) with a total number of 102 cycles delivered. ORR was achieved in 14 pts (54%), including 1 complete (4%) and 13 partial responses (50%). In pts who received 6 cycles of treatment, DPR was 40%, while 3 YS was 64.3%. G3-4 neutropenia was noted in 2 (8%) of pts. G3 hand-foot syndrome, nausea-vomiting and neuropathy were seen in 1 (4%), 2 (8%) and 1 (4%) respectively. Dose escalation was possible in 83% of the pts.

Conclusions: In addition to all the benefits of OCT including convenience and prolonged infusion-free survival, our results show that OV-C is also an effective and well tolerated regimen, making it an attractive option for our pts. OCT appears to be a valid alternative to I.V treatment especially for pts and countries where accessibility to treatment centers remains an issue.

Background: Eribulin is a widely used drug for the management of HER2(-) MBC. Given HER2(+) MBC is routinely treated with combinations of anti-HER2 agents plus chemotherapy, frequent use of eribulin in this context has been published in small case series. As today, clinical trial data of eribulin plus trastuzumab comes from phase 2 study in which 1st line patients achieved objective response rates (ORR) of 71% and median progression free survival (PFS) of 12 months, with median overall survival (OS) not yet achieved. HALATRUST is a retrospective, multicentre study designed to evaluate the clinical benefit rate (CBR) and safety profile of this combination in daily clinical practice.

Methods: All known HER2+ MBC patients treated with eribulin plus trastuzumab for a minimum of 1 dose and whose medical records were available and initiated from April 2011 to May 2016 were included. No statistical hypothesis was pre-established.

Results: Of the 48 patients identified in 19 Spanish public and private centres, 47 fully complied with the inclusion criteria and were analysed for efficacy and safety. Relevant baseline characteristics of the population are as follows. Median age: 55 (35 – 86) year-old, women: 45 (96%), positive estrogen and progesterone receptor: 30 (64%) and 19 (40%) respectively, disease burden of $\geq$ 5 lesions: 35 (75%), and median number of previous treatments for MBC: 7. Efficacy and safety results of the study population (n = 47) are summarized in the Table.

Table: 307P

Category	Variable
CBR, n (%)	25 (53.2)
ORR, n (%)	11 (23.4)*
PFS, median (range)	3.6 (3.2 – 4.9)
OS, median (range)	12.1 (9.6 – 19.1)
Dose adjustments, n (%)	9 (19)
TRAE withdrawals, n (%)	3 (6)**

TRAE: treatment related adverse events.
*Including 1 complete response.
**Most TRAE were of hematologic origin.

Conclusions: HALATRUST is, to the best of our knowledge, the largest reported case series on the use of eribulin plus trastuzumab for the treatment of late-line HER2(+) MBC. Results found provide clear evidence on the efficacy and safety of the combination, and highlight the need for its inclusion within the earlier treatment options used in this patient population.

308P Lower response to T-DM1 in metastatic breast cancer patients with HER2 IHC score of 2 and FISH positive compared with IHC score of 3

S. Yazaki, J. Hashimoto, S. Ogita, E. Nakano, T. Yamauchi

Division of Medical Oncology, St. Luke's International Hospital, Tokyo, Japan

Background: Ado-trastuzumab emtansine (T-DM1) is the standard second line chemotherapy for HER2 overexpressed metastatic breast cancer (MBC). Tumor HER2 status is measured by either immunohistochemistry (IHC) or fluorescence in situ hybridization (FISH). A previous study showed no difference in objective response rate (ORR) with trastuzumab monotherapy between IHC 3+ and IHC 2+/FISH positive groups. It is not known whether response to T-DM-1 differs between IHC 3+ and IHC 2+/FISH positive patients. The aim of this study is to compare the efficacy of T-DM1 in IHC 3+ group to that of IHC 2+/FISH positive group.

Methods: We retrospectively identified and reviewed the medical records of all patients with HER2 positive MBC who received T-DM1 in our hospital from October 2013 to December 2016. In the efficacy analysis, we excluded five patients who had HER2 negative tumors at metastatic sites.

Results: A total of 44 patients were identified and 36 patients were available for efficacy analysis of ORR. Median age was 58 years old (range 28-80). 95.5% received prior trastuzumab. 45.5% received at least one chemotherapy for MBC, 29.5% received more than four lines of chemotherapy. 79.5% had IHC 3+ and 20.5% had IHC 2+/FISH positive. ORR was 16/30 (53.3%) in IHC 3+ group and was 0/6 (0%) in IHC 2+/FISH positive group (P = 0.024). Median progression free survival (PFS) was 7.0 months (95% CI, 5.58 to 8.42) in IHC 3+ group and was 2.0 months (95% CI, 0.00-4.57) in IHC 2+/FISH positive group.

Conclusions: ORR and PFS were significantly worse in HER2 IHC 2+/FISH positive patients compared with IHC 3+ patients. This is the first report to demonstrate the difference of T-DM1 efficacy by HER2 test results.

"SAN MARTINO" IST – Istituto Nazionale per la Ricerca sul Cancro- S.S. Sviluppo Terapie Innovative, Genoa, Italy, [18]Medical Oncology, Azienda Ospedaliera St. Croce e Carle, Cuneo, Italy, [19]Medical Oncology, Presidio Ospedaliero Ospedale Sant'Anna, San Fermo Della Battaglia, Italy

Background: Two randomized studies demonstrated that Nab-P produces a significantly higher overall response rate (ORR), longer Time to Progression (TTP), and greater overall survival (OS) in ABC pts treated with second-line or greater therapy compared with patients who receive conventional Paclitaxel. However, few data are available in the real-life setting, especially for the weekly schedule (wNab-P).

Methods: AMBRA is a longitudinal cohort study, aiming to describe the choice of first and subsequent lines of treatment in HER2-ve ABC pts receiving at least one CHT (SABCS 2016, P5-15-07 & P5-14-09) in the years 2012-2015. For the present analysis, we focused on the use of Nab-P, describing efficacy results according to pts' characteristics.

Results: So far, 791/1500 pts have been registered into the study and 107 (13.5%) received Nab-P in any line of treatment. Median age was 54 years, 88 (82.2%) had Luminal tumours. Twenty-two pts (20.6%) received Nab-P as 1st line, 48 (44.8%) as 2nd-line, the remaining as 3rd-line or greater. Most pts (47.7%) received the every 3 weeks (Q21) schedule, whereas 30 pts (28%) were treated with the weekly (wNab-P) schedule (days 1,8,15 Q28) at different doses: £100 mg/mq: 11 (10.3%), 125 mg/mq,: 15 (14%); 150 mg/mq: 4 (3.7%). The remaining received different schedules or doses. Median number of cycles received was 5 (1-17) and median duration of treatment was 3.5 months in the whole population. No difference has been observed in terms of number of cycles or duration of treatment according to the schedule.

Conclusions: Our results are similar to those obtained in randomized clinical trials and in a recent large real-life study, confirming that Nab-P is currently one of the most promising choice of treatment for ABC pts.

310P Everolimus-exemestane (EE) vs palbociclib-letrozole (PL) or palbociclib-fulvestrant (PF) in the treatment of metastatic HR+, HER2- breast cancer. An indirect comparison with network meta-analysis

C. Cherubini, L. Gianni, L. Stocchi, V. Arcangeli, O. Carminati, M. Papi, G. Pasini, M. Fantini, S.V.L. Nicoletti, D. Tassinari

Oncology, City Hospital, Rimini, Italy

Background: To compare the efficacy of EE to PF or PL in the treatment of metastatic HR$^+$, HER2$^-$ breast cancer pre-treated or untreated with aromatase-inhibitors (AI) for advanced disease.

Methods: An indirect comparison with a network meta-analysis comparing EE with PL or PF in the treatment of metastatic HR$^+$, HER2$^-$ breast cancer pre-treated or untreated with AI for advanced disease was performed. The Progression-Free-Survival (PFS) was the primary end point of all our indirect comparisons. The indirect comparison was performed both for patients pre-treated with AI and for patients never treated with AI for advanced disease. Efficacy data were expressed as Hazard Ratio (HR) and 95% Confidence Interval (95CI), assuming an α-error of 5% as index of statistical significance.

Results: All the data of the BOLERO-2 trial, the Bachelot et al network meta-analysis (Breast Cancer Treat Rep 2014), the PALOMA-2 and the Paloma-3 trial were analyzed and indirectly compared in a network meta-analysis. 2 orders of comparison were performed: EE vs PL for patients never treated with AI for advanced disease and EE vs PF for patients pre-treated with AI for advanced disease. The pooled HR and 95%CI were respectively 0.597 (0.355-1.005, p = 0.89) and 1.1 (0.7-1.6, p = 0.97) for EE vs PL (never treated with AI) and EE vs PF (pre-treated with AI). No major reasons of clinical and methodological heterogeneity were detected in an independent qualitative analysis, while a moderate quantitative heterogeneity was detected using the I^2 test.

Conclusions: Till today EE and PL or PF represent active treatments for patients with metastatic HR$^+$, HER2$^-$ breast cancer treated or untreated with AI, and no direct comparisons between EE and PL or PF exist in literature. Although our data have not the power to detect any definitive difference in PFS between EE and PL or PF (probably with the exception of EE vs PL, where a trend in favor of EE could bedetected), EE, PL or PF seem to be comparable in terms of PFS; it follows that the better safety or the economic profile could help physicians in daily clinical practice.

311TiP FRIEND: A randomized pilot study to compare the efficacy and tolerability of fulvestrant 500mg with exemestane as first line endocrine therapy for post-M ER positive HER2 negative ABC patients relapse after adjuvant non-steroidal aromatase inhibitors (NSAI)

J. Wang, B. Xu, Q. Li, P. Zhang, P. Yuan, F. Ma, Y. Luo, R. Cai, Y. Fan, S. Chen, Q. Li

Department of Medical Oncology, National Caner Center, Cancer Hospital, Chinese Academy of Medical Science, Beijing, China

Background: Breast cancer is one of the most common malignancies in women. It has long been acknowledged that oestrogen acts as an endocrine growth factor for hormone-dependent breast cancer. Fulvestrant is a selective estrogen receptor degrader – an ER antagonist with a novel mode of action. Confirm & China Confirm study demonstrated that the efficacy of Fulvestrant 500mg is superior to 250mg. FIRST&FALCON study results confirmed the superior efficacy of fulvestrant over anastrozole in postmenopausal women who have not received prior hormonal therapy. But in the clinical practice, AI are widely used as adjuvant ET for postmenopausal ER+ breast cancer patients. To date there are no randomized trials to compare Fulvestrant 500mg with AI in patients who have relapsed during or after adjuvant non-steroidal AI.

Trial design: The FRIEND trial is a parallel-group, multi-centre study designed to compare the efficacy and tolerability of fulvestrant 500 mg with exemestane 25 mg as first line endocrine therapy in post-M women with ER positive HER2 negative ABC who have relapsed on or after at least 2 years of adjuvant NSAI therapy. Approximately 148 postmenopausal women with ER positive HER2 negative advanced breast cancer who have relapsed whilst on adjuvant NSAI (treatment duration ≥2 years) or after completed adjuvant NSAI treatment will enter this study. Eligible patients will be randomized 1:1 to the following treatment groups: Fulvestrant 500 mg i.m. every 28 (± 3) days plus an additional 500 mg on day 15 (± 3) of first month only; Exemestane 25 mg, orally, once daily. Treatment will continue until disease progression or treatment discontinuation. The primary endpoint is progression-free survival. Secondary endpoints include objective response rate, disease control rate, time to treatment failure, duration of response and overall survival. Efficacy will be determined based on tumor assessments performed by each investigator according to RECIST version 1.1. Safety will be monitored based on the frequency and severity of adverse events (AEs). This study is currently recruiting patients.

312TiP VinoMetro: Phase II study of metronomic daily oral vinorelbine as first-line chemotherapy in advanced/metastatic hormone receptor positive (HR+)/human epidermal growth factor receptor 2 negative (HER2-) breast cancer resistant to endocrine therapy

T. Elger[1], T. Decker[2], T. Fehm[3], S. Fuxius[4], N. Harbeck[5], I. Juhasz-Böss[6], V. Möbus[7], C. Thomssen[8], M. Seehase[1], L. Schollenberger[9], C. Ruckes[9], M. Schmidt[1]

[1]Klinik und Poliklinik für Geburtshilfe und Frauengesundheit, Universitätsmedizin Mainz, Mainz, Germany, [2]Schwerpunktpraxis für Hämatologie und Onkologie, Ravensburg, Germany, [3]Frauenklinik, Universitätsklinikum Düsseldorf, Düsseldorf, Germany, [4]Onkologische Schwerpunktpraxis, Heidelberg, Germany, [5]Brustzentrum, Klinikum der Ludwig-Maximilians-Universität, Munich, Germany, [6]Klinik für Frauenheilkunde, Geburtshilfe und Reproduktionsmedizin, Universitätsklinikum des Saarlandes, Homburg, Germany, [7]Klinik für Gynäkologie und Geburtshilfe, Klinikum Frankfurt Höchst, Frankfurt, Germany, [8]Klinik und Poliklinik für Gynäkologie, Universitätsklinikum Halle, Halle (Saale), Germany, [9]Interdisziplinäres Zentrum Klinische Studien (IZKS), Universitätsmedizin Mainz, Mainz, Germany

Background: Chemotherapy (CTx) is a cornerstone in HR+/HER2- advanced/metastatic breast cancer (a/mBC) after endocrine failure. In this indication, vinorelbine

(VRL) is a well-established cytotoxic drug. There is a high medical need for new options that prolong the time between endocrine failure and intensive CTx, which is commonly associated with impaired quality of life and serious side effects. Metronomic CTx was shown to induce disease control in a/mBC with a favorable safety profile. This innovative approach involving continuous daily dosing of oral VRL, which could provide anti-angiogenic and immune-modulatory properties, has not been investigated so far in this indication.

Trial design: VinoMetro is an open-label, single-arm, phase II study (Simon two-stage minimax) of metronomic daily oral VRL (30 mg/day) as first-line CTx. The study involves strict safety monitoring with an initial safety run-in. It is accompanied by a steering committee and supervised by an independent monitoring board. The main objectives are to estimate efficacy in terms of clinical benefit rate after 24 weeks of treatment (primary endpoint) and the progression-free survival, amongst others, as well as the assessment of safety and quality of life. Patients with HR+/HER2- a/mBC having failed or being no candidate for endocrine therapy (targeted combinations allowed) and being naïve to palliative CTx are eligible, if they exhibit ECOG 0-1. The main exclusion criteria are prior vinca-alkaloids, aggressive disease requiring combination CTx and CNS involvement. Until 2017-04-30, 5 patients were enrolled. It is planned to include 45 (39 evaluable) patients at 8 German sites until 09/2018. Scheduled completion date is 09/2019. Two interim analyses are planned (first analysis: safety evaluation based on the 10 initial patients with predefined stopping rules). VinoMetro is an investigator initiated trial (NCT03007992) sponsored by the University Medical Centre of Johannes Gutenberg-University Mainz, Germany, and supported by an unrestricted grant provided by Pierre Fabre Pharma GmbH (Freiburg, Germany).

Clinical trial identification: EudraCT 2016-000284-17

Background: BOLERO-2 trial demonstrated that the mTOR inhibitor everolimus was effective in overcoming resistance to endocrine therapy, and BOLERO-4 trial is evaluating the efficacy and safety of combined use of everolimus with letrozole as initial therapy for ER positive HER2 negative metastatic breast cancer (MBC). However, there is no study to evaluate the efficacy of everolimus which can prolong the administration period of aromatase inhibitor (AI) through postponing the acquisition of drug-resistance for MBC with sensitivity to aromatase inhibitor.

Trial design: This study is conducted to examine whether additional administration of everolimus significantly prolongs progression-free survival period in post-menopausal patients with ER-positive HER2-negative MBC which have sensitivity to AI. The inclusion criteria are MBC pts with histologically confirmed ER positive and HER2 negative invasive breast cancer with one or more measurable distant metastatic lesions diagnosed by radiological examination. All patients are receiving AI as the first line hormone therapy for 5-7 months. The pts who are sensitive to AI are randomized to everolimus plus AI arm or the AI alone arm. After randomization, the same AI are continued until progression of diseases and next appropriate regimens are started after that. The primary endpoint is the progression free survival, and the secondary endpoints are overall survival, response rate, disease control rate, adverse events, time to treatment failure and the proportion of patients who continued administration of AI agents for 1 year after the randomized allocation. Sample size for randomized pts was determined to attain at least 80% of power to detect a 5.4 months' difference (10 vs. 15.4 months, HR:0.65) with one-sided alpha of 0.1. Enrollment of 130 pts for randomization is planned over a 2-year accrual period from April 2017.

Clinical trial identification: This trial was registered at UMIN-CTR[umin.ac.jp/ctr/] as UMIN 000025156.

314TiP Selecting patients with oligo-metastatic breast cancer harboring homologous recombination deficiency (HRD) for intensified chemotherapy: The OLIGO-study

T.G. Steenbruggen, A.N. Scholten, M-J.T. Vrancken-Peeters, I.A. Mandjes, M. Holtkamp, J. Wesseling, S.C. Linn, G.S. Sonke

Medical Oncology, The Netherlands Cancer Institute, Amsterdam, Netherlands

Background: About 5% of patients with metastatic breast cancer (MBC) survive more than 10 years. Long-term survival is mostly seen in patients with limited, maximum of 3-5, distant metastases, often referred to as 'oligo'-MBC. Oligo-metastatic cancer can be treated with curative intent using a multidisciplinary approach that targets the detected metastases, circulating micro-metastases, and any locoregional disease if present. Optimal patient selection is of vital importance.

Intensified chemotherapy in the treatment of breast cancer is controversial, as older studies have not shown a survival benefit in unselected patients. Recent retrospective analyses, however, have suggested that patients with HRD derive significant benefit from intensified chemotherapy compared to conventional chemotherapy.

Trial design: This study will evaluate the difference in event-free survival (EFS) between intensified chemotherapy and conventional chemotherapy as part of a multimodality treatment approach in patients with oligo-MBC harboring HRD. Patients are eligible if they have pathological proven oligo-MBC, defined as 1-3 distant metastases, either as *de novo* or recurrence for which no chemotherapy is given. All lesions must be amenable to surgery or radiotherapy with curative intent. No progression on induction chemotherapy is allowed. Lastly, the tumor has to be HRD by array comparative genomic hybridization. Patients start with 3 cycles of induction chemotherapy, which includes anthracyclines and taxanes in treatment-naïve patients and is adapted according to previously received (neo)adjuvant treatment in others. Patients are 1:1 randomized to another 3 cycles of conventional chemotherapy or 2 cycles of intensified chemotherapy (carboplatin, thiotepa and cyclophosphamide) with stem cell support. Following systemic treatment, all patients receive maximal surgery and/or radiotherapy of locoregional and distant disease. The primary endpoint is EFS at 3 years. Toxicity, time to progression, and overall survival are secondary clinical endpoints. In total 86 patients are required. At the time of abstract submission, 33 patients were randomized.

Background: Metastatic breast cancer continues to be a major cause of cancer death among women globally. In recent years, a better understanding of tumor biology, and the availability of high-throughput technologies has enabled the emergence of precision medicine bringing new expectations and giving rise to molecular screening programs worldwide. Recently, the MOSCATO trial has shown for the very first time that

prospectively sequencing a large panel of genes and utilizing this information to guide treatment choices may improve the outcome of a subset of patients. Some institutions are implementing such strategy as part of the routine treatment decision-making process. However, SOLTI, as a collaborative Spanish network, runs AGATA, the first multi-institutional molecular screening program ever implemented in this country. Patient recruitment started in October 2014 and is expected to conclude in June 2017.

Trial design: Up to 260 patients with metastatic breast cancer will be recruited in 10 participating sites in Spain. Mutation testing is performed prospectively in the genomic laboratories of Vall dHebron Institute of Oncology in Barcelona, 12 de Octubre University Hospital in Madrid, and the University Clinical Hospital of Valencia. Upon molecular characterization and collection of key clinical data, each case is reviewed by a multidisciplinary advisory board, which recommends potential experimental treatments, mainly in the context of clinical trials. During this pilot stage, our primary objective is to determine the success rate in including patients in trials based on their molecular profile. Additional aims are to identify technical and logistical barriers to the implementation of a nationwide program, describe the genomic profiles of the tumors, and assess patient outcomes. Retrospective gene expression (PAM50 + 110 genes and 20 miRNAs) and proteomic analysis (40 markers) will be performed to provide a more comprehensive molecular profile of the tumors that may help explain sensitivity or resistance to administered therapies. Data collected within this program is expected to generate hypotheses for further investigations directed to improve precision medicine.

Clinical trial identification: NCT02445482

Legal entity responsible for the study: SOLTI Breast Cancer Research Group

Funding: Novartis, Mutua Madrileña, Instituto de Salud Carlos III

316TiP BREAKOUT: A cross-sectional, prospective, observational study of germline BRCA mutation (gBRCAm) prevalence and real-world outcomes among patients (pts) with HER2-negative (HER2-ve) metastatic breast cancer (mBC)

T. Dalvi[1], K.A. Gelmon[2], R. Dent[3], M. Pegram[4], S. Loibl[5], Y. Tazir[6], A. Milner[7], J. Lewis[8]

[1]Medical Evidence and Observational Research, AstraZeneca, Gaithersburg, MD, USA, [2]Department of Medical Oncology, British Columbia Cancer Agency, Vancouver, BC, Canada, [3]Division of Medical Oncology, National Cancer Centre Singapore, Duke-NUS Medical School, Singapore, [4]Breast Cancer Oncology Program, Stanford Women's Cancer Center, Palo Alto, CA, USA, [5]Medicine and Research, German Breast Group, Neu-Isenburg, Germany, [6]Medical Evidence and Observational Research, AstraZeneca, Wedel, Germany, [7]Biostatistics and Information Sciences, AstraZeneca, Cambridge, UK, [8]Global Medicines Development, AstraZeneca, Cambridge, UK

Background: Several poly (ADP-ribose) polymerase (PARP) inhibitor therapies are currently under investigation to assess their potential for the management of breast cancer. Olaparib (Lynparza) is being evaluated in a Phase III study in HER2-ve mBC pts with a g*BRCA*m (OlympiAD; D0819C00003; NCT02000622). The prevalence of germline and somatic *BRCA* mutations or other somatic homologous recombination repair gene mutations (HRRm) in HER2-ve mBC pts is not well defined. Treatment and clinical outcomes data for pts with HRRm are also limited. The primary objective of this real-world evidence study (NCT03078036) is to estimate g*BRCA*m prevalence in a population of HER2-ve mBC pts not selected by phenotype, age or family history. Treatment patterns and survival outcomes for pts with HRRm will also be examined.

Trial design: BREAKOUT is a prospective, cross-sectional, non-interventional, observational cohort study recruiting HER2-ve mBC pts who have started first-line chemotherapy within 90 days prior to enrollment. If hormone receptor positive, eligible pts will have exhausted all hormone therapy options prior to enrollment and will not have received prior PARP inhibitor treatment. If unavailable from medical records, g*BRCA*m status will be locally determined by blood test and, if negative, archival tumor specimens may be examined with a FoundationOne Dx genomic profile. Pts with a g*BRCA*m, somatic *BRCA* mutation or other HRRm (in *ATM*, *RAD51B*, *RAD51C*, *RAD51D*, *RAD54L*, *BRIP1*, *FANCL*, *PALB2*, *BARD1*, *CHEK1*, *CHEK2*, *CDK12* or *PPP2R2A*) will be followed for ≥18 months to determine the distribution of standard-of-care treatments, progression-free survival (investigator assessed) and overall survival by line of therapy. Approximately 2000 women in 17 countries in North America, the EU and the Asia Pacific region will be enrolled to provide a global g*BRCA*m prevalence estimate with a precision of no more than ±2%. An interim analysis focusing on g*BRCA*m prevalence will be carried out once testing has been completed for all pts. The study is expected to conclude in 2019.

317TiP IMpassion131: Phase III study comparing 1L atezolizumab with paclitaxel vs placebo with paclitaxel in treatment-naive patients with inoperable locally advanced or metastatic triple negative breast cancer (mTNBC)

D. Miles[1], F. Andre[2], J. Gligorov[3], S. Verma[4], B. Xu[5], D. Cameron[6], C.H. Barrios[7], A. Schneeweiss[8], V. Easton[9], I. Dolado[10], J. O'Shaughnessy[11]

[1]Medical Oncology, Mount Vernon Cancer Centre, Northwood, UK, [2]Medical Oncology, Gustave Roussy, Villejuif, France, [3]Medical Oncology, Institut Universitaire de Cancérologie, IUC-UPMC, Sorbonne Univeristy, Paris, France, [4]Oncology, Cumming School of Medicine, University of Calgary Alberta Health Services, Calgary, AB, Canada, [5]Medical Oncology, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China, [6]MRC Institute of Genetics & Molecular Medicine, Edinburgh Cancer Research Centre, University of Edinburgh, Edinburgh, UK, [7]Department of Medicine, PUCRS School of Medicine, Porto Alegre, Brazil, [8]Division Gynecologic Oncology, National Center for Tumor Diseases (NTC) University Hospital, Heidelberg, Germany, [9]Global PDMA (Biometrics), F. Hoffmann-La Roche AG, Basel, Switzerland, [10]Global PDMA, F. Hoffmann-La Roche AG, Basel, Switzerland, [11]Texas Oncology, Baylor University Medical Center, US Oncology, Dallas, TX, USA

Background: Chemotherapy (including paclitaxel [pac]) remains the main 1L treatment for metastatic TNBC but brings limited clinical benefit, highlighting the need for new treatments. Atezolizumab (atezo) blocks the interaction of PD-L1 with receptors PD-1 and B7.1, thus restoring anti-tumor immunity. TNBC is a rational target for atezo due to high PD-L1 expression, elevated T-cell tumor infiltration and high mutational burden. Atezo alone and in combination with nab-pac was well tolerated, with no exacerbation of chemo-associated adverse events, and demonstrated promising clinical activity in mTNBC. Atezo + nab-pac is being further investigated as 1L TNBC treatment in IMpassion130. IMpassion131, a global, multi-center, randomized, double-blind, placebo (pbo)-controlled study, is comparing the efficacy and safety of 1L atezo + pac vs pbo + pac in patients (pts) with untreated, inoperable, locally advanced or metastatic TNBC.

Trial design: Eligible pts are those with inoperable, locally advanced or metastatic TNBC, histologically confirmed; de novo or recurrent disease after early BC chemo treatment completed ≥ 12 mo prior; taxane monotherapy eligible; no prior chemo or targeted systemic therapy for inoperable locally advanced or metastatic disease; ECOG PS 0-1 and measurable disease by RECIST v1.1. Exclusion criteria include known symptomatic CNS disease, prior immunotherapy and history of autoimmune disease. Approximately 495 pts will be randomized 2:1 to receive atezo (840 mg) or pbo (q2w; days 1 and 15 of 28-day cycle) plus pac (90 mg/m^2; days 1, 8, 15 of 28-day cycle) until disease progression. Stratification factors are PD-L1 expression on tumor-infiltrating immune cells (IC; IC0 [< 1%] vs IC1/2/3 [≥ 1%] with VENTANA SP142 IHC assay), prior taxane therapy, presence of liver metastases and geographical region. The primary endpoint is PFS measured by RECIST v1.1. Key secondary endpoints include OS, 12- and 18-month OS rates, 12-month PFS rate, ORR, DOR, and safety. Tumor biopsies will be investigated at baseline, on treatment and at progression to assess biomarkers of response and immune escape.

319TiP CompLEEment-1: Phase 3b study of ribociclib + letrozole for the treatment of hormone receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2–) advanced breast cancer (ABC) in patients with no prior endocrine therapy (ET) for ABC

M. De Laurentiis[1], M. Martin Jimenez[2], A. Ring[3], P. Cottu[4], K. Zhou[5], J. Wu[5], J.P. Zarate[5], C. Zamagni[6]

[1]Breast Oncology, IRCCS Fondazione G. Pascale, Naples, Italy, [2]Medical Oncology Service, Universidad Complutense de Madrid and Hospital General Universitario Gregorio Marañón, Madrid, Spain, [3]Department of Medicine, Royal Marsden Hospital NHS Foundation Trust, London And Surrey, UK, [4]Medical Oncology, Institut Curie, Paris, France, [5]Oncology Global Medical Affairs, Novartis Pharmaceuticals, East Hanover, NJ, USA, [6]Addarii Medical Oncology Unit, Orsola-Malpighi Hospital, Bologna, Italy

Background: CDK4/6 inhibitor ribociclib was recently approved in the United States in combination with letrozole for the treatment of HR+, HER2– ABC in postmenopausal women with no prior therapy for advanced disease, based on the significantly prolonged PFS versus placebo plus letrozole observed in the pivotal phase 3 MONALEESA-2 trial (Hortobagyi et al. NEJM 2016). The phase 3b CompLEEment-1 study will further evaluate the safety and efficacy of ribociclib plus letrozole as first-line therapy in an expanded patient population.

Trial design: In this open-label study, men or women of any menopausal status with HR+, HER2– ABC will receive ribociclib (600 mg/day, 3 weeks on/1 week off) + letrozole (2.5 mg/day); men and premenopausal women will receive concomitant goserelin (3.6 mg subcutaneous implant every 28 days). Treatment will continue until disease progression or unacceptable toxicity. Patients are limited to $\leq$ 1 line of chemotherapy and no prior ET for advanced disease; patients receiving (neo)adjuvant ET with a non-steroidal aromatase inhibitor must have a disease-free interval of $>$ 12 months. Exclusion criteria include Eastern Cooperative Oncology Group performance status $>$2, or prior CDK4/6 inhibitor treatment. Planned hematologic and chemistry laboratory assessments will be completed every 2 weeks for the first 2 months, then monthly to Cycle 6, and as clinically indicated to Cycle 36. Tumor assessments are recommended every 12 weeks or at intervals per local standard of care during the treatment phase. The primary outcome is safety and tolerability. Secondary outcomes include time to progression, clinical benefit rate, overall response rate, safety, and patient-reported outcomes (PROs). Adverse events and drug-drug interactions will be monitored using CT Scholar; PROs will be collected for female patients using the FACT-B questionnaire to better understand health-related quality of life and treatment side effects. Global recruitment of the planned ~3,000 patients is ongoing, with the majority occurring in Europe.

Clinical trial identification: NCT02941926

320TiP A phase II trial of mirvetuximab soravtansine in patients with localized triple-negative breast cancer (TNBC) with tumors predicted insensitive to standard neoadjuvant chemotherapy (NACT) including a lead-in cohort to establish activity in patients with metastatic TNBC

S. Damodaran[1], F. Symmans[2], T. Helgason[1], E.A. Mittendorf[3], D. Tripathy[4], K. Hess[5], J. Litton[6], S. Moulder[1]

[1]Breast Medical Oncology, The M. D. Anderson Cancer Center, Houston, TX, USA, [2]Department of Pathology, MD Anderson Cancer Center, Houston, TX, USA, [3]Breast Surgical Oncology, University of Texas MD Anderson Cancer Center, Houston, TX, USA, [4]Department of Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA, [5]Department of Biostatistics, MD Anderson Cancer Center, Houston, TX, USA, [6]Breast Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA

Background: While TNBC patients with pCR/RCB-0 or RCB-1 have excellent survival, those with extensive residual disease (RCB-II or RCB-III) after NACT have poor prognosis. At MD Anderson, through the Moonshot Initiative, we have created a biomarker-driven drug development strategy, ARTEMIS (A Randomized, TNBC Enrolling trial to confirm Molecular profiling Improves Survival) to identify novel targeted therapies for tumors that are predicted to be insensitive to standard NACT. Molecular profiling along with imaging is used to identify patients with chemo-insensitive disease and inform second phase of therapy incorporating targeted agents to improve responses. Folate receptor α (FRα) is a GPI-anchored surface protein encoded by *FOLR1* gene that is overexpressed in multiple cancers including TNBC. Mirvetuximab soravtansine is an antibody-drug conjugate that consists of a monoclonal antibody against FRα conjugated to maytansinoid, a microtubule inhibitor. Nearly 40% of TNBC express high levels of FRα, suggesting that FRα directed therapy is a viable therapeutic strategy.

Trial design: The study will include a lead in cohort (Cohort A) to establish efficacy in metastatic TNBC patients and a neoadjuvant cohort (Cohort B) to determine activity in chemo-insensitive, localized TNBC patients. If $>$ 2 patients in Cohort A have response, the neoadjuvant cohort will be activated. Patients deemed to have chemo-insensitive, FRα+ TNBC identified through the ARTEMIS are eligible for Cohort B. The primary objectives are to determine the response rate of single agent mirvetuximab in metastatic FRa+ TNBC ($>$ 2 lines of therapy) and to determine if mirvetuximab would improve the rates of neoadjuvant pathologic response (pCR or RCB-I) from 5% to 20% in patients with high risk, chemo-insensitive, FRa+ TNBC. A two-stage Gehan-type design with 14 patients in the first stage will be employed for the neoadjuvant cohort (n = 37). Mirvetuximab will be given IV every 21 days (6 mg/kg). Correlatives include assessment of FOLR1/FRα and characterization of biomarkers of immune modulation.

321TiP SOLTI-1303 PATRICIA: A phase II study of palbociclib and trastuzumab (with or without letrozole in ER+) in previously trastuzumab-pretreated, postmenopausal patients with HER2-positive metastatic breast cancer

P. Villagrasa Gonzalez[1], A. Prat[2], M. Oliveira[3], L. de la Pena[1], X. Gonzalez[4], J. Cortes Castan[5], J. Rios[6], J. Vázquez[7], N. Martínez Jañez[8], A. Perelló Martorell[9], I. Garau[10], E. Martinez de Dueñas[11], S. Morales[12], M. Melé[13], B. Bermejo De Las Heras[14], E. Ciruelos[15]

[1]Scientific Department, SOLTI Breast Cancer Research Group, Barcelona, Spain, [2]Medical Oncology, Hospital Clínic de Barcelona, Barcelona, Spain, [3]Medical Oncology, Vall d'Hebron University Hospital Institut d'Oncologia, Barcelona, Spain, [4]Medical Oncology, Hospital Universitario Quirón Dexeus, Barcelona, Spain, [5]Oncology Service, Hospital Universitario Ramon y Cajal, Madrid, Spain, [6]Medical Statistics, Hospital Clinic Barcelona, Madrid, Spain, [7]Medical Oncology, SOLTI Breast Cancer Research Group, Barcelona, Spain, [8]Medical Oncology, Hospital Universitario Ramón y Cajal, Madrid, Spain, [9]Medical Oncology, Hospital Son Espases, Palma De Mallorca, Spain, [10]Medical Oncology, Hospital de Son Llàtzer, Palma De Mallorca, Spain, [11]Medical Oncology, Hospital Provincial de Castellón, Castellon, Spain, [12]Medical Oncology, Hospital Universitario Arnau de Vilanova, Lleida, Spain, [13]Medical Oncology, Hospital Universitario Sant Joan de Reus, Reus, Spain, [14]Medical Oncology, Hospital Clinico Universitario de Valencia, Valencia, Spain, [15]Medical Oncology, University Hospital 12 de Octubre, Madrid, Spain

Background: Despite the high efficacy of anti-HER2 agents, HER2+ metastatic breast cancer remains incurable and in need of additional therapeutic options. Persistent activation of the cyclin D1/CDK4 axis has been identified as a mediator of resistance to anti-HER2 therapy but clinical data of the benefit of CDK4/6 inhibitors in combination with trastuzumab is lacking. PATRICIA is a Simon 2-Stage study to evaluate the efficacy of combining trastuzumab plus palbociclib, with or without letrozole, assessed by progression-free survival (PFS) in pretreated HER2-positive patients.

Trial design: Postmenopausal HER2-positive patients treated with 2-4 prior systemic anticancer treatment lines that must involve trastuzumab or another anti-HER2 treatment in the metastatic setting are included in three cohorts: A: HR-negative, receiving trastuzumab and palbociclib; B1: HR-positive, receiving trastuzumab and palbociclib; B2: HR-positive, receiving trastuzumab, palbociclib and letrozole. Palbociclib is administered at 200 mg/day for 14 days of 21-day cycles. Trastuzumab and letrozole are administered at usual doses. As these combinations have not been tested in phase I trials, we incorporated a 2 cycles-safety run-in phase with the first 6 patients of each regimen. The primary objective is to assess clinical efficacy measured as PFS at 6 months (PFS6). Assuming an increase of at least 20% in PFS6 by the addition of palbociclib +/- letrozole to trastuzumab, PFS6 should be $\geq$ 50% for a cohort to be successful and proceed to stage 2. According to this, it will be necessary to include 15 patients in each cohort in stage 1. In stage 2, each cohort may continue recruitment for up to 46 patients. Translational research searching for predictive biomarkers will be implemented. To date, 43 patients, 13 in A and 15 in each B cohort, have been included in 14 sites across Spain. An independent safety data committee was held twice during the study. The

committee recommended that study continue enrollment as planned. The first stage efficacy analysis is intended for December 2017.

Clinical trial identification: NCT02448420

Background: Palbociclib is an oral, potent, selective inhibitor of CDK4/6, blocking cell cycle progression from G1 into S phase. Preclinical data indicate that palbociclib has enhanced activity against luminal ER+ human breast cancer (BC) cell lines in vitro, combined with endocrine treatment. Randomized clinical trials showed significant PFS prolongation in patients with newly diagnosed and pretreated metastatic luminal BC, when palbociclib was combined with letrozole and fulvestrant respectively (PALOMA-1/2 and -3 trials). Predictive biomarkers for patient selection to receive palbociclib plus endocrine treatment are still missing.

Trial design: PYTHIA (IBCSG 53-14/BIG 14-04) is a phase II, single-arm, multicenter, study of fulvestrant and palbociclib in postmenopausal women with ER+/HER2-, advanced BC, who progressed after prior endocrine treatment (1st or 2nd line; up to 1 line of prior chemotherapy is allowed). Patients are enrolled concurrently in the AURORA program (NCT02102165), a longitudinal cohort study with extensive molecular characterization of matched primary-metastatic BC, and plasma samples. The primary endpoint is PFS, based on local assessment as per RECIST 1.1. Secondary endpoints are safety and tolerability, as well as disease control rate. Correlative objectives will assess the potential predictive value of: i) mutations and copy number aberrations in a panel of cancer-related genes, ii) gene signatures inferred by RNA sequencing, iii) early FDG-PET/CT assessment performed for a subset of 30 patients, at baseline and Day 28, and iv) a serum thymidine kinase-1 (TK1) assay, performed at baseline, Day 14 and after Cycle 1. The sample size of 120 patients was selected to have 80% power to detect a HR of 2.0 for biomarker-positive patients, with 30-50% prevalence (two-sided $\alpha = 0.05$). Enrollment opened in May 2016, with the target-recruitment being 120 patients at 21 sites in Belgium, Italy and the UK.

Clinical trial identification: NCT02536742

Background: Adjuvant ET and chemotherapy reduce the risk for recurrence of HR+, HER2– EBC. However, recurrence is still common in pts with adverse clinical and pathologic features. In the phase 3 clinical trial MONALEESA-2, the cyclin-dependent kinase 4/6 inhibitor ribociclib in combination with letrozole prolonged progression-free survival versus letrozole plus placebo in postmenopausal women with HR+, HER2– advanced breast cancer and no prior therapy for advanced disease (HR = 0.56, 95% CI, 0.43-0.72; $P = 3.29 \times 10^{-6}$; Hortobagyi et al. N Engl J Med. 2016). EarLEE-1 (NCT03078751) investigates the efficacy and safety of ribociclib with ET versus placebo with ET as adjuvant treatment in pts with high-risk EBC.

Trial design: In this double-blind, placebo-controlled, phase 3 trial, ~2000 women and men with fully resected, high-risk, HR+, HER2– EBC (defined as AJCC 8th ed. Prognostic Stage Group III for pts who received adjuvant chemotherapy, or > 2 mm residual disease in axillary lymph nodes and > 10 mm in breast after neoadjuvant chemotherapy) are being randomized 1:1 to ribociclib (600 mg/day, 3 weeks on/1 week off for ~24 months) with ET or placebo with ET. Adjuvant ET may include tamoxifen, letrozole, anastrozole, or exemestane for ≥ 60 months with ovarian suppression for premenopausal women. Randomization is stratified by menopausal status, risk group, and region. Eligible pts must have tumor tissue from the surgical specimen, adequate bone marrow and organ functions, normal serum electrolytes, QTc interval < 450 msec, and completed and recovered from acute toxicities of adjuvant radiotherapy and (neo)adjuvant chemotherapy. The primary endpoint is invasive disease-free survival. Secondary endpoints include recurrence-free survival, distant disease-free survival, overall survival, quality of life, and safety. Global recruitment is ongoing.

Background: Pre-clinical data and initial results from clinical studies point to the added benefit of CDK4/6 inhibition when combined with anti-HER2 tx. The current study is designed to evaluate the added benefit of Palbociclib when given in combination with anti-HER2 and endocrine tx maintenance in the 1st line setting of metastatic HER2+HR+ breast cancer.

Trial design: PATINA is an international, open-label, pivotal Phase III study. Primary objective is to demonstrate that the combination of Palbociclib with anti-HER2 plus endocrine tx is superior to anti-HER2 plus endocrine tx in prolonging PFS. Sample size is 496 pts. The study starts after completion of 6-8 cycles of chemotherapy-containing anti-HER2 tx for metastatic breast cancer in the 1st line setting. Pts are eligible provided they are without evidence of disease progression by local assessment (i.e. CR, PR or SD). To account for the need for less intense tx regimens for a subset of pts diagnosed with HER2+ER+ disease, clinicians may recommend the combination of trastuzumab with either a taxane or vinorelbine prior to study initiation. Clinicians might also choose a non-Pertuzumab option for pts previously treated with pertuzumab in the neo(adjuvant) setting. Secondary objectives include measures of tumor control (OR, CBR, DOR), OS, safety and QOL. The translational science main objective is to compare PFS estimates according to *PIK3CA* mutation status assessed by cfDNA analysis. Endocrine tx options are AI or fulvestrant. Premenopausal pts must receive ovarian suppression. The study has a 90% power to detect a hazard ratio of 0.667 in favor of the palbociclib arm. Pts approached to participate in AFT-38 will be asked to indicate on the informed consent forms whether remaining biospecimens and clinical data from the control arm of the study can be shared with the Mastering Breast Cancer (MBC) Initiative. The overarching purpose of the MBC is to create a mechanism for understanding the natural history of metastatic breast cancer by cataloguing longitudinally studied tumor-specific markers and treatment effects.

3250 Nivolumab (nivo) in combination with radiotherapy (RT) ± temozolomide (TMZ): Updated safety results from CheckMate 143 in pts with methylated or unmethylated newly diagnosed glioblastoma (GBM)

M. Lim[1], A. Omuro[2], G. Vlahovic[3], D.A. Reardon[4], S. Sahebjam[5], T. Cloughesy[6], J. Baehring[7], N. Butowski[8], V. Potter[9], R. Zwirtes[9], P. Paliwal[9], M. Carleton[9], J. Sampson[3], A.A. Brandes[10]

[1]Metastatic Brain Tumor Center, Johns Hopkins University School of Medicine, Baltimore, MD, USA, [2]Neurology, Memorial Sloan Kettering Cancer Center, New York, USA, [3]The Preston Robert Tisch Brain Tumor Center at Duke, Duke University Medical Center, Durham, NC, USA, [4]Center for Neuro-Oncology, Dana-Farber Cancer Institute and Harvard University School of Medicine, Boston, MA, USA, [5]Oncology, H. Lee Moffitt Cancer Center University of South Florida, Tampa, FL, USA, [6]Neurology-Oncology, University of California Los Angeles, Los Angeles, USA, [7]Neurology, Yale School of Medicine, New Haven, CT, USA, [8]Department of Neurological Surgery, University of California, San Francisco, San Francisco, USA, [9]Oncology, Bristol-Myers Squibb, Princeton, USA, [10]Neurology, AUSL-IRCCS Institute of Neurological Sciences, Bologna, Italy

Background: Prognosis is poor for pts with GBM, as nearly all have recurrence after standard-of-care therapy. Nivo, a fully human IgG4 mAb inhibitor of the programmed death-1 receptor, is approved for the treatment of multiple cancers. Exploratory cohorts 1c and 1d of CheckMate 143 (NCT02017717) assessed the safety/tolerability of nivo in combination with RT ± TMZ in pts with newly diagnosed GBM.

Methods: In cohort 1c, pts received nivo 3 mg/kg Q2W + standard RT + concurrent TMZ (75 mg/m^2 daily) followed by adjuvant TMZ (150-200 mg/m^2; 5 days/28-day cycle for ≥ 6 cycles). In cohort 1d, pts received nivo 3 mg/kg Q2W + standard RT without TMZ. All pts continued to receive nivo until confirmed progression/unacceptable toxicity. Pts (n = 58) were initially assigned to 1c or 1d based on MGMT methylation status (1c, methylated or unmethylated; 1d, unmethylated). Following the initial evaluation, a second group of 55 pts with unmethylated MGMT were randomized 1:1 to 1c or 1d. Pooled safety data for all 113 pts are described here.

Results: Twelve pts with methylated and 43 pts with unmethylated MGMT were treated in 1c, and 58 pts with unmethylated MGMT were treated in 1d. Pts discontinued treatment in 1c (67% each arm) and 1d (83%) mostly due to radiographic progression (1c, 50% [methylated], 37% [unmethylated]; 1d, 64%), study drug toxicity (8%, 9%; 10%), or pt decision (8%, 14%; 0%). AEs (all cause) are summarized in Table. The most common (≥ 30% of pts in any arm) neurological AEs were headache (42%, 47%; 41%) and seizure (25%, 16%; 31%). No deaths due to study drug toxicity were reported.

Conclusions: Nivo with RT ± TMZ was well tolerated, with the frequency of neurological AEs consistent with that in other reports in this disease. These data support continued development of nivo + RT ± TMZ in newly diagnosed GBM in the ongoing CheckMate 498 (NCT02617589) and CheckMate 548 (NCT02667587) trials.

Background: PD-L1, PD-1 expression, TILs and IDH-1 mutation associations and their prognostic importance in GBM are planned to assessed in the study.

Methods: GBM patients who were newly diagnosed and operated between February 2006 to February 2017 were included retrospectively in the study. In initial tumor specimens PD-L1, PD-1 expression, CD4(+) ve CD8(+)TILs, IDH-1 mutation were assessed. For IDH-1 mutation analysis real time PCR tecnique was used, for PD-L1 and PD-1assessment immunohistochemistry was performed by Ventana® antibody (clon-SP263, ROCHE). For PD-1, PD-L1, CD4, CD8 TILs intensity was graded as low, moderate, dense and estimated in percents. The cut off value assumed as $\geq$ 5% for PD-L1, PD-1 positivity. Kaplan Meier, Cox regression tests and SPSS 23 were used.

Results: Ninety patients were included. The mean age was 57$\pm$ 12,3 and 57 (63,3%) patients were male. Fourty eight (53,3%) patients were received chemoradiotherapy and chemotherapy with temozolamide after operation. Two different staining patterns were diagnosed for PD-L1 expression as diffuse fibrillary [29 (32,2%)] and membranous staining [15(16,7%)]. Thirty (33%) patients have IDH-1 mutation. TILs were seen intensely in the perivascular field, which is rarely found in the intratumoral area and in that TILs, PD-1 staining grade was dense. We also observed a positive correlation between the density of TILs in the intratumoral/perivascular fields and the percentages of PD-L1 positivity. ($p < 0{,}0001$, $r = 0{,}46$). The intensity of both TILs in perivascular areas were significantly lower in PD-L1 (-) tumors than in PD-L1 (+) tumors ($p < 0{,}001$). No association was found between IDH-1, PD-L1 and TILs. We didn't find any significant effect of age, sex, PD-L1 positivity and IDH-1 mutation status on survival. (log rank 0,03;0,78; 0,13; 0,64 respectively.) Presence of dense intratumoral PD-1 (+)TILs and dense membranous PD-L1 staining were found as positive; advanced age was found as negative independent prognostic factors by multivariate analysis.

Conclusions: Staining pattern of PD-L1 and the density of PD-1 positivity in TILs may be a prognostic importance in GBM.

327O Epidermal growth factor receptor (EGFR) amplification rates observed in screening patients for randomized clinical trials in glioblastoma

M.J. van den Bent[1], L.A. Roberts-Rapp[2], P. Ansell[2], J. Lee[3], J. Looman[2], E. Bain[2], C. Ocampo[2], K.D. Holen[2], E.J. Gomez[2], A.B. Lassman[4]

[1]Neuro-Oncology, Erasmus MC Daniel den Hoed Cancer Center, Rotterdam, Netherlands, [2]Oncology, AbbVie Inc, North Chicago, IL, USA, [3]Oncology, Abbott Molecular Inc, Des Plaines, IL, USA, [4]Department of Neurology and Herbert Irving Comprehensive Cancer Center, Columbia University Medical Center, New York, NY, USA

Background: EGFR is a key oncogenic target for the treatment of glioblastoma. EGFR amplification is detected in ~50% of tumors. Depatuxizumab mafodotin (depatux-m), formerly called ABT-414, is a tumor-specific antibody-drug conjugate that preferentially targets tumors with EGFR amplification. Herein, we report the frequency of EGFR amplification in 2 large-scale glioblastoma clinical trials of depatux-m.

Methods: Assays for EGFR abnormalities were performed centrally in 2077 (as of May 1, 2017) glioblastomas during screening for 2 randomized glioblastoma trials with depatux-m: INTELLANCE 1 (NCT02573324) for newly diagnosed patients ($n = 1001$), and INTELLANCE 2 (NCT02343406) for recurrent disease ($n = 1076$). EGFR amplification, required for eligibility in both trials, was determined by fluorescence in situ hybridization and defined as at least 2 copies in at least 15% of cells. EGFRvIII data will be reported at the meeting.

Results: The frequency of EGFR amplification was ~50% (Table), similar to published rates. Higher rates were observed in patients from the Americas/Europe (53–57%) than from Asia (34%).

Table: 327O Pooled Screening Results: INTELLANCE 1 (phase II/III, newly diagnosed) and INTELLANCE 2 (phase II, recurrent)

World Region	Not Amplified	EGFR Amplified	Total Patients	Positive, %
Africa	5	4	9	44.4
Americas	213	238	451	52.8
Asia	132	69	201	34.3
Europe	518	672	1190	56.5
Middle East	19	21	40	52.5
Oceania	106	80	186	43.0
Total	993	1084	2077	52.2

Conclusions: This study represents the first report of lower EGFR amplification rates in patients from Asia with glioblastoma to our knowledge. This observation requires further study.

Clinical trial identification: INTELLANCE 1: NCT02573324 INTELLANCE 2: NCT02343406

328O Low grade glioma patients with IDH mutation and 1p19q codeletion: What to do after surgery?

E. Franceschi[1], A. Mura[1], A. Mandrioli[1], S. Minichillo[1], A. Tosoni[1], A. Pession[2], D. De Biase[2], D. Danieli[3], S. Pizzolitto[4], A. Fioravanti[5], L. Volpin[6], R. Agati[7], S. Bartolini[1], A. Paccapelo[1], A.A. Brandes[1]

[1]Medical Oncology, AUSL/IRCCS Institute of Neurological Sciences, Bellaria Hospital, Bologna, Italy, [2]Department of Pharmacy and Biotechnology (Dipartimento di Farmacia e Biotecnologie) - Molecular Diagnostic Unit, Azienda USL di Bologna, University of Bologna, Bologna, Italy, [3]Departments of Pathology, ULSS Vicenza, Vicenza, Italy, [4]Department of Pathology, Santa Maria della Misericordia Hospital, Udine, Italy, [5]Neurosurgery, AUSL/IRCCS Institute of Neurological Sciences, Bellaria Hospital, Bologna, Italy, [6]Neuroscience and Neurosurgery, San Bortolo Hospital, Vicenza, Italy, [7]Department of Neuroradiology, Bellaria Hospital, IRCCS Institute of Neurological Sciences, Bologna, Italy

Background: Molecular characterization of low grade gliomas (LGG) is essential for diagnosis and treatment of these diseases. LGG patients (pts) with IDH mutation and 1p19q codeletion (codel) are characterized by a median OS (mOS) longer than 10 years. Thus, the role of treatments and side effects should be carefully evaluated.

Methods: We evaluated LGG pts from our data warehouse ($n = 679$ pts) who received surgery and had sufficient tissue to assess biomarkers characterization. Pts with gliomatosis were excluded. IDH1/2 assessment was performed on formalin-fixed paraffin-embedded samples by qPCR. In wild type cases we performed NGS. 1p/19 codel analysis was performed by FISH.

Results: 93 consecutive LGG with IDH mutation and codel were included. The median follow up (FU) was 96.1 months. Mean age was 40 yrs (range: 25-66); 8 pts (8.6%) underwent biopsy, 61 pts (65.6%) partial resection, 24 pts (25.8%) complete resection. 84 pts (90.3%) were considered high risk using RTOG criteria (> 40 years and/or incomplete resection). Fifty pts (53.7%) received only FU, 17 pts (18.3%) received chemotherapy (CT), 18 pts (19.4%) received radiotherapy (RT), 8 pts (8.6%) received RT + CT. Median PFS (mPFS) was 59.6 months (95%CI: 41.8-77.4) and was significantly longer in pts who received postsurgical treatments (79.5 months, 95%CI: 66.4-92.7) than pts who received FU (46.3 months, 95%CI: 36.0-56.5; $P = 0.001$). mPFS was 50.8 months (95%CI: 17.4-84.3), 103.6 months (95%CI: 11.7-195.6) and 120.2 months (95%CI: 40.5-199.8) in pts treated with CT alone, RT alone and RT + CT, respectively. Multivariate analysis showed that receiving a post-surgical treatment ($P < 0.001$), and the extent of resection ($P = 0.043$) were significantly correlated with PFS.

Conclusions: Our study evaluated the role of treatments in LGG pts assessed with NGS and FISH. Post-surgical treatments are crucial to extend PFS in pts with IDH mutation and codel. The choice of post-surgical treatments seems to have a role, being CT alone less effective than RT and RT+CT. Longer FU is needed to provide information about OS.

Malpighi, Bellaria Hospital, University of Bologna, Bologna, Italy, [5]Neurosurgery, AUSL/IRCCS Institute of Neurological Sciences, Bellaria Hospital, Bologna, Italy, [6]Department of Pathology, ULSS Vicenza, Vicenza, Italy, [7]Department of Neurological, Neuropsychological, Morphological and Movement Sciences, Section of Neurosurgery, University of Verona, University Hospital, Verona, Italy, [8]Neuroradiology, AUSL/IRCCS Institute of Neurological Sciences, Bellaria Hospital, Bologna, Italy

Background: Low grade glioma (LGG) is a heterogeneous disease. Recently, the 2016 WHO classification of brain tumors has underlined the role of genetic and molecular features. Molecular astrocytomas have been defined as grade II tumors with IDH mutation and without 1p19q codeletion.

Methods: We evaluated 213 consecutive patients with LGG who received surgery or biopsy and had adequate tissue to assess molecular characterization. IDH mutations were assessed by immunohystochemistry (IHC) and next generation sequencing (NGS) in IHC negative cases, MGMT methylation status was assessed by polymerase chain reaction (PCR) and 1p19q deletion was assessed by fluorescence in situ hybridation (FISH).

Results: 198 patients (93.0%) showed IDH-mutation. Ninety patients (49.2%) were 1p19q non codeleted (molecular astrocytomas). The median follow up was 98.3 months. Median age was 36 (range: 18-69), 11 patients (12.2%) underwent biopsy, 48 (53.3%) patients subtotal resection and 31 (34.4%) patients total resection. According to RTOG criteria, 68 patients (75.6%) were considered high risk (> 40 years and/or incomplete resection), and 22 patients (24.4%) were considered low risk (< 40 years and/or complete resection). 59 patients (65.5%) did not receive any post-surgical treatment, but only follow-up, 31 patients (34.4%) received post-surgical treatments: 20 (22.2%) received radiotherapy (RT), 7 (7.8%) received chemotherapy (CT), 4 (4.4%) received CT+RT. Median progression-free survival (PFS) was 44.3 months. Significant differences in PFS were observed between treated and untreated patients (64.8 vs 35.7 months $p = 0.004$) and treated with RT versus follow-up (60.0 vs 35.7 months $p = 0.004$). Multivariate analysis confirmed the treatment after surgery as an independent prognostic factor (HR 0.456, $p = 0.005$). Median overall survival (OS) was 164.0 months. At time of analysis no significant differences in OS were available.

Conclusions: Post-surgical treatment after resection of IDH mutant molecular astrocytomas is an independent prognostic factor. A longer follow-up is needed for worthy results in terms of OS.

Background: Gal-1 is a β-galactoside binding protein that plays an important role in cancer progression and has been implicated in resistance to chemotherapy and anti-VEGF therapy. Gal-1 mediates glioma aggressiveness and its expression increases with grade and correlates with worse outcome. Our aim was to evaluate the prognostic significance of Gal-1 in a homogenous cohort of GB.

Methods: GLIOCAT is a multicenter study of newly diagnosed 432 GB patients treated with Stupp regimen. Tissue from 272 patients was used to generate a tissue microarray and Gal-1 expression in cytoplasm (C) and nucleus (N) was analyzed by immunohistochemistry. Results were evaluated by three reviewers and quantified by H-Score. Expression levels were correlated with clinical characteristics, known prognostic factors and response to anti-angiogenic treatment. Preliminary results will be presented at 2017 ASCO, abstract e13526. We will report here the final results.

Results: We defined a cut off for Gal-1 H-Score of ≥ 157 (cytoplasm, C) and ≥ 123 (nucleus, N). High combined Gal-1 expression significantly correlated with worse OS. No correlation was found with PFS.

Multivariate analysis: KPS, age, MGMT methylation status, extent of resection and Gal-1 expression were independent prognostic factors for survival. High Gal-1 expression correlated with worse OS at recurrence in 61 patients with antiangiogenic treatment (13.8 vs 17.8months, $p = 0.084$) and in 80 with other therapies (17.7 vs 29.3months, $p = 0.001$).

Table: 330PD

H-Score	n	mOS (months) (range)	p value
Combined H-Score Low (C < 157 and N < 123)	213 59	16.69 (13.98-19.39)	0.008
High (others)		13.76 (9.93-17.56)	

Conclusions: Gal-1 expression represents an independent prognostic factor for GB patients treated initially with standard therapy and with other therapies at recurrence.

331PD Impact of WHO 2016 update and molecular markers in pleomorphic xanthoastrocytoma

R. Tonse, T. Gupta, E. Sridhar, J. Shastri, A. Jain, N. Bano, R. Jalali

Radiation Oncology, Tata Memorial Centre, Mumbai, India

Background: There is a relative paucity of data regarding outcomes of pleomorphic xanthoastrocytomas (PXA) particularly with respect to the impact of emerging molecular markers. We present our institutional experience of PXA and correlate their outcomes with various clinical and pathological factors.

Methods: Between 2006 to 2016, 37 patients with histologically verified PXA form the study cohort. All patients underwent maximal safe resection; those who had good resection, low MIB-1 index and young age were observed. Adjuvant radiotherapy was given in patients with atypical features on histology, high MIB-1 index and recurrence after first surgery or with significant residual disease. Patients diagnosed with anaplastic PXA were managed by multi-modality approach comprising maximal safe resection, radiotherapy and systemic therapy. BRAFV600E mutation testing was attempted in all 37 paraffin embedded tissue blocks. Progression free survival (PFS) and overall survival (OS) and potential prognostic factors affecting outcomes were analyzed.

Results: Median age at diagnosis was 20 years (range 4–45). Tumors were predominantly in the temporal lobe and seizures were the most frequent symptom at presentation. Gross total resection (GTR) was achieved in 23 cases (62%), a subtotal resection (STR) in 13 cases (35%) and biopsy in one patient. At a median follow-up of 33 months, 3-year and 5-year OS was 80.2% & 74% respectively. Patients who underwent GTR had a better PFS as compared to those who underwent STR (3-year estimates 85.6% vs. 32.3%; $p = 0.001$). 10 patients (27%) were classified as having anaplastic PXA. PFS was significantly superior in PXA grade II as compared to the anaplastic PXA group (3-year estimates 80.2% vs. 32%; $p = 0.007$). Of the 27 patients where BRAF V600E testing was successful, 13 patients showed a mutation (48%). 3-year PFS & OS survival in BRAFV600E mutated patients was 51.9% & 76.9% compared to 73% & 75% in BRAFV600E non-mutated patients, respectively. No patient had an IDH1 mutation.

Conclusions: Anaplastic PXA has worse outcomes as compared to PXA grade II. This data may provide valuable insights and set as a benchmark for imparting targeted therapies.

332PD Change of PD-L1 expression status of high grade glial tumors at recurrence and its effect on survival

B. Oyan[1], S. Eren[2], O. Sonmez[1], F. Ozkan[3], K. Yaltırak[4], U. Ture[4]

[1]Medical Oncology, Acibadem University School of Medicine, Istanbul, Turkey, [2]Internal Medicine, Yeditepe University Hospital, Istanbul, Turkey, [3]Pathology, Yeditepe University Hospital, Istanbul, Turkey, [4]Neurosurgery, Yeditepe University Hospital, Istanbul, Turkey

Background: Although immunotherapy is not an established treatment option in high grade glial tumors, trials are ongoing. One of the main predictive factor for response to

immune checkpoint inhibitors is PD-L1 expression status and this can change over time with the effect of therapies like chemotherapy and radiotherapy. The aim of this study is to determine whether PD-L1 expression status changes in recurrent gliomas after chemoradiotherapy and the impact of this change on survival.

Methods: PD-L1 expression of 29 patients was evaluated by an expert pathologist with immunohistochemistry. PD-L1 positivity was defined as expression in $\geq$ 1% of tumor cells. Change in PD-L1 expression status was defined as an absolute 5% difference between two resections.

Results: Of the 29 patients, 15 patients (51.7%) had PD-L1 expression in $\geq$ 1% of tumor cells and 7 patients (24.1%) had PD-L1 expression in $\geq$ 10% of tumor cells at diagnosis. Median survival of patients with baseline PD-L1 <%10 was 26 months, and in patients with PD-L1 $\geq$%10 was 18 mo ($P = 0.063$). The PD-L1 status did not change in 17 patients (58.6%). 8 patients had PD-L1 negative tumors both at diagnosis and at recurrence, while 9 patients had PD-L1 positive tumors both at diagnosis and at recurrence. In 6 patients (20.7%) a negative-to-positive switch and in 6 patients (20.7%) a positive to negative switch were seen. The change in PD-L1 status over time was not statistically significant. The change of PD-L1 over time did not influenced overall survival of the patients ($P = 0.45$).

Conclusions: The PD-L1expression status changes in more than 40% of high grade glial tumors at recurrence after receiving chemotherapy and radiotherapy. So immune responsiveness of glial tumors can be modified by treatments. As the patients in this study did not receive immunotherapy after recurrence, the change in PD-L1 expression probably did not affect survival.

333PD Meta-analysis of the effect of rituximab in the treatment of primary central nervous system lymphoma

S. Yavuz[1], M. Yildirim[2], G. Yazıcı[3], V. Kaya[4], S. Paydas[5]

[1]Medical Oncology, Acıbadem University, Adana, Turkey, [2]Internal Medicine, Bahçeşehir Üniversitesi, Gaziantep, Turkey, [3]Department of Radiation Oncology, Hacettepe University School of Medicine, Ankara, Turkey, [4]Department of Radiation Oncology, Medstar Antalya Hospital, Antalya, Turkey, [5]Medical Oncology, Cukurova University, Adana, Turkey

Background: Primary central nervous system lymphoma (PCNSL) is a rare subtype of agressive non-hodgkin lymphoma (NHL), and is most commonly of B cell phenotype. The standard treatment is not well established but high dose methotraxate is the most commonly used regimen. Intravenous rituximab (iv Rtx) treatment is integrated into the protocols for systemic B cell lymphomas. However there are mixed results with the use of Rtx. The aim of this meta-analysis is to investigate the role of iv Rtx in the treatment of PCNSL.

Methods: PubMed and EBSCOhost databases are searched for rituximab, primary central nervous lymphoma, rituximab, survival. Browsing databases was done in English.

Results: 580 patients were included to meta-analysis. Pooled hazard ratio showed that overall survival is correlated with iv Rtx (HR, 0,498; 95% CI, 0,366 - 0,678; p:<0,001). Pooled hazard ratio was calculated by using fixed effect model. The quality determinations of 7 studies were done by using Newcastle-Ottowa Scale. The studies were counted low quality with the score 1-3, average quality with the score 4-6, high quality with the score7-9. Median score of the studies was calculated as 5.

Conclusions: In this meta-analysis, we showed that the addition of iv Rtx as part of a treatment protocol for PCNSL has a positive impact on survival.

Background: TTFields is a novel cancer treatment modality using a patient-operated home-use device delivering alternating electrical fields interfering with cell division and selectively disrupting mitosis. Clinical trials are ongoing in various solid tumors and phase 3 trials in glioblastoma (GBM) were recently concluded.

Methods: TTFields were tested in two large phase 3 trials in patients with recurrent (EF-11; $n = 237$) and newly diagnosed GBM (EF-14; $n = 695$). Both trials aimed at improving overall survival (OS) with TTFields and included quality of life (QOL) using the EORTC QLQ C-30 with brain cancer module (BN-20) as a secondary endpoint.

Results: In recurrent GBM, TTFields monotherapy was compared to best physician's choice chemotherapy and failed to demonstrate a superior OS. However, improved response rate (14% vs 9.6%) and a comparable OS (HR 0.86 [CI 0.66–1.12]; $p = 0.27$) suggested clinical activity. The absence of systemic toxicity was favorably noted by many patients. In newly diagnosed GBM, TTFields was added to standard adjuvant TMZ chemotherapy and led to a significant prolongation of OS (HR 0.63 [CI 0.53-0.76]; $p = 0.000059$), without added systemic toxicity. OS was extended in all patient subgroups tested including MGMT unmethylated tumors and elderly GBM. More TTFields patients reported stable or improved scores on global health status, pain, physical functioning and leg weakness (all $p \leq .01$). Deterioration free survival was significantly longer with TTFields for global health, physical and emotional functioning, pain and leg weakness (all $p < .01$). Time to deterioration was shorter for itchy skin and longer for pain (both $p < .001$).

Conclusions: TTFields are an effective treatment for GBM with a novel mechanism of action and unique delivery method. Patients become rapidly independent in handling the device allowing patients to control their treatment at home with stable or improved QOL. The significant survival benefit observed in GBM serves as a proof of principle and establishes this novel modality as a promising anti-cancer therapy in a variety of solid tumors. Due to the lack of overlapping toxicities it can be easily combined with established treatments.

335PD Early platelet variation during concomitant chemo-radiotherapy predicts adjuvant temozolomide-induced thrombocytopenia in newly-diagnosed glioblastoma

M. Fontanilles[1], F. Clatot[2], C. Alexandru[3], O. Langlois[4], O. Veresezan[5], F. Marguet[6], M. David[7], A. Laquerriere[6], C. Hanzen[8], I. Tennevet Bouilly[3], F. Di Fiore[9]

[1]Medical Oncology, Centre Henri Becquerel, Rouen, France, [2]INSERM U1245 Équipe de recherche en oncologie normande IRON, Cancer Centre Henri Becquerel, Rouen, France, [3]Medical Oncology, Cancer Centre Henri Becquerel, Rouen, France, [4]Neurosurgery, Hopital Charles Nicolle, CHU Hopitaux de Rouen, Rouen, France, [5]Radiation Oncology and Medical Physics, Cancer Centre Henri Becquerel, Rouen, France, [6]Pathology, Hopital Charles Nicolle, CHU Hopitaux de Rouen, Rouen, France, [7]Biopathology, Cancer Centre Henri Becquerel, Rouen, France, [8]Radiation Oncology and Medical Physics, Centre Henri Becquerel, Rouen, France, [9]Medical Oncology, Cancer Center Henri Becquerel, Rouen, France

Background: Although temozolomide (TMZ) was known to induce thrombocytopenia with subsequent cycle delay, dose reduction and early treatment discontinuation in glioblastoma multiforme (GBM), no early predictive test of these side effects has been yet clearly established. In this context, our aim was to identify the best threshold of early platelet variation predicting TMZ-induced thrombocytopenia during the TMZ maintenance phase and to validate it in an independent series of GBM patients.

Methods: It was a retrospective trial including patients suffering from newly diagnosed GBM and treated with TMZ at 75 mg/m2/day concomitant to radiotherapy (RT) followed by TMZ maintenance, according to the Stupp protocol. In a training set, variations of platelet concentrations occurring from the first week to week 6 (ΔW6) were analyzed to identify the most relevant platelet decrease during RT-TMZ associated with at least one clinically relevant TMZ-induced thrombocytopenia ($\leq$100 G/l) in the maintenance phase. An independent validation cohort was used to validate the performance of the ΔW6 threshold.

Results: A total of 147 patients were included: 85 in the training set and 62 in the validation cohort. Twenty seven patients (18%) experienced at least one TMZ-induced thrombocytopenia in the maintenance phase, respectively 14 (16%) and 13 patients (21%) in each cohort; and was the most frequent cause of TMZ schedule changes (49%, 30/61). A platelet decrease at W6 $\geq$35% (ΔW6$\geq$35%) was identified as the best predictive variation of clinically induced thrombocytopenia with an AUC of 0.83, a sensitivity (Se) of 65% and a specificity (Sp) of 96%. In the validation set, a presence of a ΔW6$\geq$35% of platelet variation was associated with: Se 77% [95% CI 66%-87%], Sp 73% [62%-84%], positive predictive value 42% [29%-54%] and negative predictive value 92% [86%-99%].

Conclusions: Our results showed that a platelet decrease at W6 $\geq$35% during the RT-TMZ phase may be an early, widely faisable and costless marker of clinically relevant TMZ-induded thrombocyponia during the TMZ maintenance. Prospective studies are needed to evaluate the usefulness of this test for early TMZ schedule adaptation.

Background: There is no standard treatment in recurrent GB and overall survival (OS) ranges from 3 to 9 months (m). The aim of this study was to identify clinical or biological factors that guide the best therapeutic strategy.

Methods: We identified 397 patients (Pts) from GLIOCAT database (432 patients uniformly treated with Stupp's regimen) who had recurrent GB: 250 Pts received 1 or more active treatment (TT) and 147 Pts didn't. We analysed clinical and molecular characteristics, treatments received, OS and progression-free survival (PFS).

Results: The median TT lines after recurrence was 1 (0-5). At 1st recurrence surgery was performed in 51 (30 alone), RT in 8 and systemic therapy (ST) in 208 Pts (189 without any local TT): Bevazicumab (BV) $\pm$ Irinotecan (IR) 90; clinical trial (CT) 42; TMZ 27; Nitrosoureas (NU) 27]. Pts without any TT were older ($p < 0.001$), had worse KPS ($p < 0.001$), worse Mini-Mental (MM) ($p = 0.003$), more biopsies than resection ($p < 0.001$) and did not complete the 6 cycles of adjuvant TMZ ($p < 0.001$) analyzed by χ^2. In the multivariate analysis the only two variables statistically significant for OS were receiving treatment at progression (OS 2.5m vs 10.6m $p < 0.0001$) and biopsy versus partial or complete resection at diagnosis ($p = 0.005$). Methylated MGMT tumours had a worse OS from the time of relapse, irrespective of the treatment administered ($p = 0.014$). Salvage surgery did not present better OS ($p = 0.69$). 230 Pts had a 2nd recurrence: 128 received a 2nd line TT (surgery 8; RT 5 and ST 114: BV $\pm$ IR 42; NU 31; TMZ 19; CT 11; other 11). 110 Pts had a 3th recurrence: 42 received a 3th line. Pts who received TT had better OS than those who did not receive TT in 2nd ($p < 0.0001$) and in 3th recurrence ($p < 0.0001$) evaluated by Log rank test (Kaplan-Meier). BV was the TT that obtained the highest median PFS in the 1st and 2nd relapse. There were no significant differences in OS between the different TT regimens (median OS from relapse 7.7 m).

Conclusions: Pts who received TT at recurrence offered a better OS in multivariate analysis. Pts undergoing surgery did not present better OS than those who only received ST. MGMT methylation is not a predictor of better OS in recurrence. Pts treated with BV had longer PFS but not OS.

337P Molecular subtypes of gliomas defined by gene expression profiling

E. Deluche[1], F. Caire[2], V. Rigau[3], S. Durand[4], S. Robert[5], B. Bessette[6], F. Labrousse[5], M-O. Jauberteau[6], K. Durand[5], F. Lalloue[6]

[1]Oncology, CHU Limoges - Hopital Dupuytren, Limoges, France, [2]Neurosurgery, CHU Limoges - Hopital Dupuytren, Limoges, France, [3]Pathology, CHRU de Montpellier- Gui de Chauliac, Montpellier, France, [4]UMR 1061 INRA, Limoges University, Limoges, France, [5]Pathology, CHU Limoges - Hopital Dupuytren, Limoges, France, [6]EA 3842, Cellular Homeostasis and Pathologies, Faculty of Medicine of Limoges, Limoges, France

Background: Gliomas are the most common primary brain tumors in adults. The heterogeneity of tumors, the lack of reliable criteria for identifying different subtypes make their histopathological diagnosis and their management complex. The molecular classification is one of the most promising approaches to better characterize gliomas. The aim of this study was to characterize molecular markers from the differential transcriptomic analysis of high and low-grade gliomas.

Methods: Tumor samples were obtained from 81 patients diagnosed with gliomas between 1998 and 2013 at Limoges and Montpellier University Hospitals. Transcripts from brain tumor frozen samples were analyzed by Taqman Low Density Array. Cluster and principal component analyses were performed on a list of 96 selected genes belonging to glioma markers, genes coding for neurotrophins and their receptors or involved in different mechanisms such as glycosylation, autophagy, RTK signaling pathways, hypoxia and angiogenesis. Protein expressions from selected genes were achieved by immunohistochemical staining on Tissue MicroArray.

Results: Firstly, variations in gene expression were noted between the primary tumor and its recurrence and between biopsy and resected surgical specimen for a same patient. To have homogeneous series, only 64 primary brain tumors obtained from resected surgical specimens and free from radiotherapy and/or chemotherapy were presented in this work. Brain tumors were diagnosed as grade II oligo-astrocytoma ($n = 9$), grade III oligo-astrocytoma ($n = 10$), grade III astrocytoma ($n = 8$), glioblastoma ($n = 17$), grade II oligodendroglioma ($n = 9$) and grade III oligodendroglioma ($n = 11$). Using the hierarchical cluster method, we identified gene expression patterns specific of low or high grades and a set of genes of interest appeared significantly over-expressed or under-expressed according to tumor grade ($p < 0.05$). Some of them were correlated to prognosis ($p < 0.05$). Immunohistochemistry analysis confirmed the changes of protein expression between low and high grades.

Conclusions: Our results showed that high and low-grade gliomas differ in their gene expression profiles and several genes might act as new biomarkers for differential diagnosis and prognosis in gliomas.

338P Chitosan-capped gold nanoparticles impair radioresistant glioblastoma stem-like cells

M. Aldea[1], M. Potara[2], O. Soritau[3], I.S. Florian[4], G. Kacso[5]

[1]Oncology, Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania, [2]Bio-Nano-Sciences, Babes-Boyai University Interdisciplinary Research Institute in Bio-Nano-Sciences, Cluj-Napoca, Romania, [3]Tumor Biology, Ion Chiricuta Cancer Center, Cluj-Napoca, Romania, [4]Neurosurgery, Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania, [5]Radiotherapy, Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania

Background: Glioblastoma is a rapidly lethal cancer with a stringent need for new treatment strategies. In this study, we tested if chitosan-capped gold nanoparticles (Chit-GNPs) may overcome the limitations of drug concentrations by an increased cell internalisation in glioblastoma stem-like cells (GSCs) and if such GNPs could enhance the response to irradiation.

Methods: GSCs lines were isolated from glioblastoma tumor fragments and characterised with stemness and neural markers. Chitosan biopolymer was used as reducing and stabilizing agent to generate Chit-GNPs through an environmentally friendly synthesis procedure. The fabricated Chit-GNPs were characterized by UV-vis-NIR extinction spectroscopy, transmission electron microscopy and zeta potential measurements. GSCs and two normal cell lines were selected for in vitro investigations. The uptake and cytotoxicity of Chit-GNPs were evaluated relatively to that of citrate-capped gold nanospheres (GNPs) of similar size. Cell lines were treated with increasing concentrations of GNPs and Chit-GNPs and then irradiated with hypofractionated radiotherapy (3 consecutive fractions of 1, 2 Gy) and brachytherapy (one single fraction of 1 and 2 Gy). The effect was evaluated through the MTT cell viability test and confirmed with Trypan blue-based counting.

Results: GSCs proved to express stem-cell markers and were highly resistant to radiotherapy. Their cell viability and proliferation were impaired by chit-GNPs with an IC50 of 10ug/mL, while remaining unaffected by simple GNP used in similar concentrations. Chit-GNPs were 15 nm in size, with a positive zeta potential and proved a superior cell internalisation compared to simple GNPs. Normal cell lines remained unaffected by GNPs and Chit-GNPs. Radiotherapy at the tested doses failed to give an additional anti-cancer effect when combined with GNP treatment.

Conclusions: The enhanced internalisation within GSCs and the cytotoxic effect of Chit-GNPs make this compound a suitable backbone for drug delivery in glioblastoma treatment, particularly as it proved a selective toxicity for cancer cells. Surprisingly, Chit-GNPs were highly cytotoxic to glioma cell lines irrespective of irradiation.

339P Hypoxia, Inflammation and redox status as determinants of malignant progression of cancer stem cells

M. Papale

Medicina Sperimentale, Sapienza – Università di Roma, Rome, Italy

Background: Transformed cells live in a hostile environment characterized by lack of oxygen. Hypoxia produces: necrosis with alarmins release; activation of HIF1a. Recent studies have shown that HIF1a controls also the expression of membrane receptors in tumor cells. These receptors are part of the inflammatory reparative response (IRR) and have the capacity to bind and be activated by alarmins. Once activated, their signaling cascades lead to NFkB. Human tumor tissues posses 1-2% of cancer stem cells (CSCs) responsible for the metastatic potential of tumors. In particular, we investigated the overall hypothesis that, in CSCs from a primary tumor, hypoxia links the expression of IRR genes to tumor progression.

Methods: Hypoxia was achieved in a hypoxic chamber, where a 1% oxygen mix was flushed in for 4 min. Hypoxic response as well as efficacy of drugs treatments on CSCs was determined by measuring HIF1a, VEGF and other markers by WB and Immunofluorescence. Inflammation-like status was reproduced by treatment with necrotic extracts. Redox status was determined by the DCFH-DA. Expression of IRR and adhesion genes was determined by RT-PCR.

Results: Initially, two cell lines of Glioblastoma CSCs from two different tumors were selected and the protein and gene expression were analyzed by WB and RT-PCR. WB analysis showed that hypoxia promotes the expression of HIF1a and change the expression of other proteins directly related to HIF1a. Moreover the gene expression by RT-PCR showed many differences among the analyzed markers. Then we used multiple concentrations of digoxin and acriflavine in the two selected cell lines and also necrotic extracts. Both the drugs promote the reduction of the expression of HIF1a and other related markers. Moreover we used the drugs and an invasion assay kit for evaluation of invasive tumor cells. Also in this case, we observed modification in the invasiveness of CSCs.

Conclusions: Hypoxia promotes cells adaptation trough the expression of HIF1a, without new genetic mutations, and modify other HIF-target proteins such as VEGF, HKII, Rage. Using different concentrations of digoxin and acriflavine it is possible to modify protein and gene expression of HIF1a and related markers, modifing the production of ROS and the invasiveness of CSCs.

340P The prognostic role of high mobility group box protein-1 in glioblastoma and its relationship with the inflammatory response

M. Yildirim[1], D. Süren[2], A.S. Alikanoğlu[3], Ö. Çakın[4], İ.A. Karacay[3], C. Sezer[3], V. Kaya[5], A. Güzel[6]

[1]İnternal Medicine, Bahçeşehir Üniversitesi, Gaziantep, Turkey, [2]Department of Pathology, Health Science University, Antalya Education and Research Hospital, Antalya, Turkey, [3]Department of Pathology, Antalya Education and Research Hospital, Antalya, Turkey, [4]Department of Anaesthesia and Reanimation, Akdeniz University School of Medicine, Antalya, Turkey, [5]Department of Radiation Oncology, Medstar Antalya Hospital, Antalya, Turkey, [6]Department of Neurosurgery, Bahçeşehir Üniversitesi, Gaziantep, Turkey

Background: In this study, the prognostic role of HMGB expression determined with immunohistochemistry in patients with glioblastoma, and the relationship with the systemic inflammatory response indicators, NLR and PLR are studied.

Methods: This study included 30 patients who had a histopathologic diagnosis of glioblastoma and 14 patients who underwent surgery for a non-tumoural intracranial pathology in Antalya Education and Research Hospital between 2008-2012. HMGB1 expression was examined via immunohistochemical method.

Results: There were a significant difference of HMGB1 expression between the study and the control group ($p = 0.002$). HMGB1 expression was found positive in 23 patients (76.7%) and negative in 7 (23.3%) patients in the study group. In the control group, it was positive in 4 (28.6%) patients and negative in 10 (71.4%) patients. When NLR was used as the SIR indicator, it was determined as positive in 11 (36.7%) patients and as negative in 19 (63.3%) patients. When PLR was used as the SIR indicator, it was determined as positive in 10 (33.3%) patients and negative in 20 (66.7%) patients. Median follow up period of patients was 7.8 ± 7.2 (Range 0.7-26.1). Median survival of the study group was 9.6 ± 1.8 (95% Confidence Interval Range 6-13.2) (Figure 1). There wasn't any significant difference between HMGB1 expression and survival ($p = 0.692$) (Figure 2). When NLR or PLR was used as the SIR indicator, there wasn't any relation or difference determined between SIR and survival ($p = 0.692$, $p = 0.740$). A significant relation was determined between HMBG1 expression and NLR ($p = 0.29$). NLR was negative in 17 (73.9%) patients with positive HMGB1 expression, whereas it was negative in 2 (28.6%) patients with negative HMGB1 expression. HMGB1 expression suppresses SIR response. There wasn't any relationship between HMGB1 expression and PLR ($p = 0{,}127$).

Conclusions: Results we achieved in our study lead to the opinion that HMGB1 overexpression might have a role in the immune response to the developing tumour in patients with glioblastoma. While treatment strategies are developing in patients with glioblastoma, we believe that HMGB1 could be an important treatment goal.

341P Impact of hyperbaric oxygenation on the expression of PKD1 protein forms in T98G glioblastoma cell line treated with selected pentabromobenzylisothiourea (ZKK-3)

K. Stepien, R.P. Ostrowski, E.B. Pucko, E. Grzywaczewska, E. Matyja

Department of Experimental and Clinical Neuropathology, Mossakowski Medical Research Centre Polish Academy of Sciences, Warsaw, Poland

Background: Glioblastoma (GBM) is the most malignant brain tumour with poor prognosis and limited therapy effectiveness. Tumour hypoxia is considered as a main reason of GBM's resistance to medical treatment. It seems that improvement of therapeutic response can be achieved by the combination of chemotherapeutics application with refinement of oxygenation status of tumour tissue. One of the novel anti-tumour compounds is isothiourea derivative ZKK-3, which inhibits the activity of protein kinase D1 (PKD1). PKD1 promotes tumour growth and mediates detoxification of mitochondrial reactive oxygen species (ROS). The aim of this study was to examine the impact of hyperbaric oxygenation (HBO) on the expression of PKD1 protein as well as its phosphorylated forms - pPKD1 (Ser 916) and pPKD1 (Ser 744/748) in glioma cells treated with ZKK-3 in vitro.

Methods: Human glioblastoma T98G cell line was cultured in medium supplemented with ZKK-3 and exposed to the various oxygen conditions: normoxia, hypoxia, HBO, double hypoxia, hypoxia/HBO. After 24 hours of incubation cell lysis was made. The level of tested proteins in obtained lysates was examined using Western Blot technique.

Results: Increasing concentration of ZKK-3 caused diminution of PKD1, pPKD1 (Ser 916) and pPKD1 (Ser 744/748) levels in all tested oxygen conditions. Comparison of hypoxia and HBO conditions showed that hyperbaric oxygen administration resulted in enhancement of expressions of all PKD1 forms. Moreover, in groups preincubated in hypoxia conditions the levels of tested proteins were also markedly elevated after hyperbaric oxygenation (hypoxia/HBO) in comparison to the double hypoxia groups.

Conclusions: Increase of PKD1 protein expression as well as its phosphorylated forms evidenced that HBO application resulted in enhancement of oxidative stress in T98G cell line *in vitro*. This combined with ZKK-3 ability to inhibit activities of those kinases gives ground to consider ZKK-3/HBO therapy as a promising therapeutic strategy for patients with malignant gliomas. 343P The role of clinical characteristics in low grade gliomas in molecular era

A. Mura[1], E. Franceschi[1], S. Minichillo[1], A. Mandrioli[1], A. Tosoni[1], A. Fioravanti[1], A. Talacchi[2], L. Volpin[3], G. Tallini[4], D. De Biase[4], R. Agati[5], S. Pizzolitto[6], S. Bartolini[1], A. Paccapelo[1], A.A. Brandes[1]

[1]Medical Oncology, AUSL/IRCCS Institute of Neurological Sciences, Bellaria Hospital, Bologna, Italy, [2]Department of Neurological, Neuropsychological, Morphological and Movement Sciences, Section of Neurosurgery, University of Verona, University Hospital, Verona, Italy, [3]Neuroscience and Neurosurgery, San Bortolo Hospital, Venice, Italy, [4]Department of Biomedical and NeuroMotor Sciences (DiBiNeM), Section of Pathology, M. Malpighi, Bellaria Hospital, University of Bologna, Bologna, Italy, [5]Department of Neuroradiology, Bellaria Hospital, IRCCS Institute of Neurological Sciences, Bologna, Italy, [6]Department of Pathology, Santa Maria della Misericordia Hospital, Udine, Italy

Background: Low grade gliomas (LGGs) are rare tumors. Molecular characterization has been recently integrated into diagnostic workup of low grade gliomas (LGG) defining specific prognostic features. Moreover, clinical factors, such as age and the extent of resection have a prognostic role in LGG. Here we report a comprehensive analysis on clinical and molecular features impacting on outcome in a large cohort of LGG.

Methods: We evaluated adult LGG patients (pts) which occurred from 1991 to 2015, who received surgery and had sufficient tissue to assess molecular biomarkers characterization. We assessed the status of IDH mutation (using PCR or NGS) 1p19q codeletion (FISH), MGMT methylation (detected with PCR).

Results: 213 consecutive LGG were included. The median age was 38 (range:18–69). Median follow up was 98.3 months, 25 pts (11.7%) underwent biopsy, 124 pts (58.2%) subtotal resection, 64 pts (30%) grosstotal resection. According to RTOG criteria 37pts (17.4%) were low-risk (<40 years with complete resection), and 176 (82.6%) were high-risk. IDH1/2 mutation was found in 93% of pts. 1p/19q codeletion was found in 50.8% of pts, MGMT methylation in 65.3% of pts. Median progression free survival (PFS) was 47.8 months. Median survival was 211.0 months (95%CI: 185.7-236.3) and 164.0 months (95%CI: 123.0-205.0) in low risk and high risk patients patients. Significant factors in univariate analysis are listed in the Table. Multivariate analysis showed that PFS was influenced by extent of resection ($P < 0.001$), IDH mutation ($P < 0.001$) and treatment. IDH mutation ($P < 0.001$) and extent of resection ($P = 0.029$) were significantly correlated with overall survival in multivariate analysis.

Table: 343P

Variable	OS (months)	P	PFS (months)	P
IDH mutation	187.2 vs 32.2	0.001	50.8 vs 16.5	<0.001
1p19q codeletion	189.4 vs 164.0	0.015	57.1 vs 41.1	0.031
MGMT methylation	211.0 vs 148.7	0.013	56.0 vs 44.3	0.024
Surgery (complete vs biopsy)	211.0 vs 83.0	0.038	52.9 vs 40.0	0.011

Conclusions: The definition of LGG outcome is complex. Both clinical and molecular factors are needed to determine prognosis and treatment strategies.

Background: The 2016 WHO classification of CNS tumors included molecular parameters in addition to histology to redefine many tumor entities. Low-grade glioma (LGG) are divided into isocitrate dehydrogenase (IDH) wild type or mutant. Absence of IDH mutation is a rare event in LGG, and IDH wild type are considered a provisional entity. The technique used to assess IDH mutation is essential to determine the real impact of this tumor type.

Methods: The observation of a particularly favorable outcome in a group of 42 patients with a diagnosis of IDH wild type LGG (OS = 93.7 months) led us to retest IDH mutation with a more sensitive technique. Next Generation Sequencing (NGS) was used to retest IDH status in tumor samples, the results of NGS assay were compared with previous findings.

Results: Initial assessment of IDH mutation in this 42 patients had been performed using PCR in 19 cases and immunohistochemistry in 2 cases. twenty-one (50%) of the 42 initial IDH wild type LGGs were discovered to be IDH mutant when tested with NGS. Four patients had R132H mutation while in the remaining 17 cases a rare IDH mutation was detected. In particular 4 patients showed IDH2 mutation, 5 patients had IDH1 R132C mutation, 5 patient had IDH1 R132G mutation and 3 patients had IDH1 R132S mutation. Median OS of NGS confirmed IDH mutated LGG was 164.0 months vs 32.2 months for NGS IDH wild type LGG reflecting the very distinct clinical course of these two entities.

Conclusions: Repeating testing in IDH wild type LGG cases is crucial, as well as the technique used to assess this mutation. NGS is able to assess IDH mutations in 50% of patients previously misdiagnosed. IDH wild type LGG remains a rare entity with dismal prognosis.

345P Effect of ADM alone or combined with monoclonal anti-programmed death ligand-1 antibody on glioma cell lineU251 and T lymphocytes

S. Zheng[1], H. Zhang[2]

[1]Medical School, Southeast University, Nanjing, China, [2]Surgery, Nanjing Centre Hospital, Nanjing, China

Background: Glioblastoma is the most common primary brain tumor. The current standard therapy for patients with glioblastoma is surgery and combination of radiotherapy with temozolomide chemotherapy. However, the prognosis is still very poor. Much research has been done to improve patient outcomes in glioblastoma. Recently, immunotherapy with immune checkpoint inhibitors, such as ipilimumab, nivolumab, and pembrolizumab shows great clinical improvements in other advanced tumors, which make immunotherapy an attractive strategy in glioblastoma treatment.

Methods: The expression of PD-L1 was determined by flow cytometry. The concentration of adriamycin was determined by CCK-8 assay depending on the inhibition rate of U251 cells, which was set to less then 50%(IC50). After treatment with different concentrations of adriamycin, cell proliferation of T lymphocytes was detected by CCK-8 method, cell apoptosis of T lymphocytes and PD-L1 expression were analyzed by flow cytometry. Treated with different concentrations of adriamycin alone or in combination with PD-L1 inhibitors, U251 cells and T lymphocyte proliferation in co-culture were determined by CCK-8 assay.

Results: The expression of PD-L1 was nearly 70%. The IC50 of adriamycin was 4.298mg/L. Adriamycin could enhance the proliferation of T lymphocytes when concentration was less than 4.298mg/L and could up-regulate the expression of PD-L1. Adriamycin (4.298mg/L) combined with immunotherapy (PD-L1 inhibitor 1.5mg/L) could inhibit glioma cells growth obviously and the number of dead T lymphocytes in co-culture system was reduced.

Conclusions: Adriamycin combined with immunotherapy (PD-L1 inhibitor) is a promising strategy for glioma treatment and our research provides theoretical basis for combination of adriamycin and immunotherapy in glioma treatment.

346P Prognostic Impact of neutrophil to lymphocyte ratio (NLR) in patients (pts) with recurrent primary malignant brain tumours (PMBT) in phase I (Ph1) trials: The Royal Marsden (RMH) Experience

N. Coleman[1], V. Michalarea[1], S. Alken[1], R. Perez Lopez[2], N. Tunariu[2], A. Petruckevitch[1], U. Banerji[1], J. de Bono[1], L. Welsh[1], F. Saran[1], J. Lopez[1]

[1]Oncology, Institute of Cancer Research Royal Marsden Hospital, Sutton, UK, [2]Radiology, The Royal Marsden NHS Foundation Trust, London, UK

Background: The NLR is a marker of systemic inflammatory response and elevated levels have been associated with aggressive disease and poorer outcome in multiple cancers, including prostate, lung and colon cancer. In pts with GBM, elevated NLR prior to any initial therapy is predictive for worse outcomes. For pts with refractory PMBT, the role of NLR is uncertain. We aimed to assess the prognostic impact of NLR, and the impact of corticosteroids (CCS) in pts with PMBT referred for consideration of Ph1 trial.

Methods: Retrospective data were collected on treatment (tx) and tumour characteristics of pts with PMBT referred for consideration of Ph1 trial participation between 06/2004–09/2016. Survival analyses were performed using the Kaplan-Meier method, Cox proportional hazards model; chi-squared test was used to measure associations between categorical variables.

Results: 100pts with advanced, refractory PMBT were referred. All pts had received at least one line of prior tx; median no. of prior systemic therapies was 2; 76% had GBM; 63% required CCS on first assessment. Use of CCS was associated with shorter disease-free survival (HR 1.93, 95% CI 1.21-3.06, $p = 0.005$) and shorter overall survival (OS) in both univariate (HR 2.33, 95% CI 1.44-3.77, $p = 0.001$,) and multivariate analysis [MVA](HR 1.84, 95% CI: 1.05-3.24, $p = 0.034$). Pts with NLR$\geq$4 were more likely to require CCS compared to pts with an NLR$<$4 (81% vs 38%). NLR$\geq$4 was associated with poorer outcomes in all models (OS, MVA: HR 1.73, 95% CI 1.02-2.94, p-value 0.043). Use of CCS did not modify the association between NLR and outcomes. Patients with an NLR$\geq$4 and requiring CCS had the poorest outcome ($p = 0.0364$); median OS(mOS) for pts with NLR$\geq$4 on CCS was 4.1months(m)(SE 0.29, 95% CI 3.29-5.42), vs 19m mOS for pts not taking CCS (SE 8.61 95% CI.36-not reached).

Conclusions: In our advanced PMBT cohort, elevated NLR$\geq$4 remained an independent prognostic indicator for poor outcome, independent of the use of CCS. Pts with elevated NLR requiring CCS demonstrated the worst outcomes – a reminder of the potential relevance of host immunity in PMBT.

347P Prognostic value of pre-operative neutrophil-to-lymphocyte ratio in patients with glioblastoma multiforme

Y. Kemal[1], O. Oltulu[1], E. Odabasi[2], O. Ozdemir[2], I. Yucel[3]

[1]Medical Oncology, Samsun Training and Research Hospital, Samsun, Turkey, [2]Radiation Oncology, Samsun Training and Research Hospital, Samsun, Turkey, [3]Department of Medical Oncology, 19 Mayis University Hospital, Samsun, Turkey

Background: Glioblastoma multiforme (GBM) is the most common and aggressive primary brain tumour. GBM development is is closely associated with inflammation status and immune response. The neutrophil-to-lymphocyte ratio (NLR) is a marker of host immune response and its elevation has recently been shown to be a poor prognostic factor in many malignancies including colon, prostate, lung, and bladder cancer. We aimed to investigate the prognostic value of preoperative NLR in GBM patients.

Methods: Between 2010 and 2016; 104 patients had surgery for GBM and were assessed for consideration of adjuvant therapy at our institution. Of these, 80 patients with an evaluable pre-corticosteroid full blood count result were identified and included in the final analysis.

Results: The mean tumor diameter was 41mm, most of them were found in the right hemisphere (56%) and in the temporal lobe (27.5%). 85% of the patients received adjuvant chemoradiotherapy (with temozolamide). Median overall survival was 13.4 moths. Patients with NLR $<$4, had a worse median overall survival at 12.5 months versus 13.8 months in patients with NLR $>$4. But this difference was not statistically significant ($p > 0.05$).

Conclusions: Our results suggest that pretreatment NLR could be a useful marker for predicting prognosis in GBM patients but large scale trials are needed to confirm this.

Agostino-Estense, Modena, Italy, [9]Department of Medical Oncology, Azienda Ospedaliera Arcispedale Santa Maria Nuova - IRCCS, Reggio Emilia, Italy, [10]Department of Neurosurgery, St Anna University Hospital, Ferrara, Italy, [11]Neurosurgery, Bufalini Hospital, Cesena, Italy, [12]Neurosurgery, AUSL/IRCCS Institute of Neurological Sciences, Bellaria Hospital, Bologna, Italy, [13]Department of Pathology, University Hospital, Modena, Modena, Italy, [14]Department of Pathology, S. Anna University Hospital and University of Ferrara, Ferrara, Italy, [15]Department of Pathology, Bufalini Hospital, Cesena, Italy, [16]Departments of Pathology, University Hospital, Parma, Parma, Italy

Background: Glioblastoma (GBM) remains an incurable disease. Radiotherapy and temozolomide are the backbone of the treatment. Clinical and molecular factors are essential to define prognosis.

Methods: Data on all new cases of primary brain tumors observed from January 1, 2009, to December 31, 2010, in adults residing within the Emilia-Romagna region were recorded in a prospective registry in the Project of Emilia Romagna on Neuro-Oncology (PERNO). We perform a prospective evaluation about prognostic factors in GBM patients treated with temozolomide concurrent with and adjuvant to radiotherapy.

Results: One hundred sixty-nine GBM patients (median age, 60 years; range 29 – 82) were prospectively evaluated. MGMT methylation status was available in 140 patients. Combining gender and MGMT methylation status we obtained four groups of patients: 36 male pts with methylated MGMT (25.7%), 47 male pts with unmethylated MGMT (33.6%), 32 female pts with methylated MGMT (22.9%), 25 female pts with unmethylated MGMT (17.9%). Results of univariate analysis are summarized in the Table. Overall survival (OS) was significantly different between methylated male and methylated female ($p = 0.028$), methylated male and unmethylated female ($p = 0.031$), unmethylated male and methylated female ($p = 0.002$), methylated female and unmethylated female ($p < 0.001$). In multivariate analysis, gender and MGMT methylation considered together (met female vs met male HR = 0.459; 95% CI 0.242 – 0.827; $p = 0.017$), age (HR 1.025; 95% CI 1.002 – 1.049; $p = 0.032$) and Karnofsky Performance Status (KPS) (HR 0.965; 95% CI 0.948 – 0.982; $p < 0.001$) were significantly correlated with OS.

Table: 348P Results of univariate analysis

	n	mOS	95%CI
methylated male	31	16.3	9.2-23.4
unmethylated male	41	15.6	11.8-19.5
methylated female	26	nr	
unmethylated female	21	17.0	11.8-22.2
total	119	17.0	15.2-18.9

Conclusions: The median overall survival is consistently higher for female pts with methylated MGMT, treated with temozolomide concurrent with and adjuvant to radiotherapy. When considered simultaneously with MGMT methylation status, gender might impact on clinical outcome and should be considered as a prognostic factor.

349P Reduced-intensity bevacizumab in progressive glioblastoma multiforme (GBM) is associated with similar overall survival versus standard-dosing

J.P. Gleeson[1], N. Keegan[1], E. Harrold[1], D. Kamel[1], N. Karadawi[1], E. Mammadov[1], D. Kelly[2], C. O'Leary[3], P. O'Halloran[4], K. Egan[1], S. Molloy[1], S. Mac Nally[4], B.T. Hennessy[1], O.S. Breathnach[1], W. Grogan[1], P.G. Morris[5]

[1]Medical Oncology, Beaumont Hospital, Dublin, Ireland, [2]Medical Oncology, Mater Misericordiae University Hospital University College Dublin, Dublin, Ireland, [3]Medical Oncology, University Hospital Waterford, Dublin, Ireland, [4]Neurosurgery Department, Beaumont Hospital, Dublin, Ireland, [5]Medical Oncology, Beaumont Hospital & RCSI, Dublin, Ireland

Background: Bevacizumab (BEV) has demonstrated activity in glioblastoma multiforme (GBM), particularly with regard to symptom control, however overall survival

(OS) benefits have not been clearly defined in prospective randomised phase III trials. Most studies have used 10mg/Kg q 2wks as standard although some experts suggest a less intensive dose schedule might offer similar benefits at a lower cost and therefore better value.

Methods: We retrospectively analysed data from the prospective database of the national neuro-oncology centre in Ireland. All patients who received BEV at the time of progression for histologically-proven de novo GBM from 2010 to 2016 were included. At our institution there is variable practice between Neuro-Oncologists in terms of BEV dosing schedule - standard BEV dosing (10mg/kg q 2wks or 15mg/kg q 3wks) vs. reduced-intensity BEV (5mg/kg q 2wks or 7.5mg/kg q 3wks). Using the Kaplan-Meier method, we assessed OS in the entire cohort and by BEV dosing schedule.

Results: In total, 118 patients received BEV for progressive GBM. Median OS was 5.6 months for the entire population (range: 0.5-42 months) and OS was 45%, 18% and 2% at 6-, 12- and 24-months, respectively. Patient characteristics by BEV dosing schedule were similar (Table). Median OS was similar in the reduced intensity BEV group (N = 49) at 5.5 months and the standard-dose group (N = 69) at 5.6 months, p=0.55. Quality of life analyses are ongoing.

Table: 349P

	Standard Dose BEV	Reduced Intensity BEV	
	N = 69	**N = 49**	***P*-Value**
Gender	**N (%)**	**N (%)**	
Male	45 (65%)	32 (65%)	0.99
Female	24 (35%)	17 (35%)	
AGE			
< 45 years	10 (14.5%)	8 (16%)	0.92
45-65 years	42 (60.9%)	28 (57%)	
> 65 years	17 (24.6%)	13 (27%)	
MGMT	**Known (50/69)**	**Known (36/49)**	
Methylated	20 (40%)	17 (47%)	0.50
Unmethylated	30 (60%)	19 (53%)	
Time from Diagnosis to BEV start			
< 12 months	36 (52%)	24 (49%)	
12-18 Months	16 (23%)	12 (24%)	0.94
> 18 months	17 (25%)	13 (27%)	
Median Overall Survival post BEV	**5.6 Months**	**5.5 Months**	**0.55**

Conclusions: In this large heterogeneous cohort of patients, OS was similar in patients who received standard or reduced intensity BEV for treatment of progressive GBM. Given the cost of BEV, these results have important implications for value in cancer care.

350P An individualized-approach to second-line systemic anti-cancer therapy for glioblastoma

P. Gkogkou[1], K. Geropantas[1], T. Ajithkumar[2]

[1]*Oncology Department, Norfolk and Norwich University Hospital, Norwich, UK,* [2]*Oncology Department, Cambridge University Hospitals NHS Foundation Trust, Cambridge, UK*

Background: The optimal second-line systemic anti-cancer therapy (SACT) for recurrent inoperable glioblastoma (GBM) is not known. Generally, patients with a recurrence within 6 months of adjuvant temozolomide (TMZ) are treated with procarbazine/lomustine/vincristine (PCV) regimen and those with a recurrence at least 6 months after completion of TMZ are re-challenged with TMZ (rTMZ). The aim of this study is to evaluate the clinical outcomes of this individualized approach.

Methods: We treated 46 patients with second-line SACT for recurrent GB between 2009 and 2015. The Response Assessment in Neuro-Oncology (RANO) criteria were used to assess treatment response. The Kaplan-Meier method was used to calculate survival. Patient- and disease-related characteristics between the groups were compared using the Fisher exact test.

Results: 31 patients received PCV and 15 patients received rTMZ (Table). The median progression-free (PFS) (3.4 months each) and overall survival (OS) (5.2 months vs. 5.3 months p = 0.482) from the start of second-line SACT were similar for both groups. Compared with the PCV group, the median PFS (19.6 months vs. 8.7 months, p = 0.001) and OS (28 months vs. 13.7 months, p = 0.001) calculated from the date of diagnosis were better for the rTMZ group. Toxicity was acceptable in both treatment groups.

Conclusions: As the individualized approach of second-line SACT in recurrent GB leads to similar survival. Patients who recur more than 6 months after completion of primary chemo-radiotherapy generally have a better survival.

351P Levetiracetam offers a survival advantage in patients with epilepsy related to MGMT-unmethylated glioblastoma

L. Rojas[1], A. Ruiz-Patiño[2], A.F. Cardona[3], O. Arrieta[4], Z. Zatarain-Barrón[4]

[1]*School of Medicine, Pontificia Universidad Javeriana, Bogotá, Colombia,* [2]*School of Medicine, Hospital Universitario San Ignacio-Pontificia Universidad Javeriana, Bogotá, Colombia,* [3]*Clinical Oncology, Foundation for Clinical and Applied Cancer Research FICMAC, Bogotá, Colombia,* [4]*Thoracic Oncology Unit and Laboratory of Personalized Medicine, Instituto Nacional de Cancerologia - Mexico, Ciudad De México, Mexico*

Background: Epilepsy is a common symptom in patients with glioblastoma (Gb). Levetiracetam (LEV), an antiepileptic drug (AED), enhances MGMT inhibition and

Table: 350P

	PCV	TMZ	p value
Median age (years)	57 (range 29-71)	63 (range 34-80)	0.119
Excision			0.613
Debulking	25(80,6%)	13(86,7%)	
Biopsy	6(19,4%)	2(19.4%)	
Radiological Appearacne			0.182
Single	24(77,4%)	14(93.3%)	
Multifocal	7(22.4%)	1(6.7%)	
Adjuvant Treatment			0.816
Radical chemo-RT	25(80.6%)	13(86.7%)	
Radical RT alone	2(6.5%)	1(6.7%)	
Palliative RT	4(12.9%)	1(6.7%)	
Adjuvant treatment completed within 6 months	1 (3%)	11 (73%)	0.001
Median time to progression after ˚rst-line (months)	1.2 (range: 0.7-11.03)	9.8 (range: 1-24.3)	0.001

reduces chemotherapy mediated neuronal toxicity, offering a theoretical benefit over other AEDs.

Methods: 213 Hispanic patients were included. All patients underwent surgery (if feasible) followed by chemoradiation based on temozolomide. Type of AED was selected under treating physician discretion. Recorded variables included demographics, AED, dosage, MGMT status, performance status (PS) and type of surgical intervention. The relationship between overall survival (OS), AED and MGMT methylation status was explored.

Results: Mean age was 53-yo (SD+/-14.7), 56.8% were male, 73% presented with epilepsy after diagnosis and 50.7% harbored methylated MGMT (metMGMT). 41% were treated with LEV, 26% were given another AED and 33% did not require any AED. AED indication was not associated with age ($p = 0.087$), PS ($p = 0.78$) anatomic tumor site ($p = 0.34$) or MGMT status ($p = 0.98$). Median OS was 25.8 months (95%CI 21.6-31.5), 27.9 months (95%CI 23.8-33.7) for those with metMGMT, and 11.83 months (95%CI 7.73-16.67) for non-metMGMT ($p < 0.001$). OS for the group of metMGMT patients treated with LEV was 33 months (95%CI 32.6-33.7) while for the unmethylated population was 36.2 months (95%CI 31.2-37.3; $p = 0.45$). In contrast, OS for patients treated with other AEDs was 25.8 months (95%CI 20.4-31.5) for those who have methylated MGMT and 7.6 months (95%CI 6.53-11.8) for non-methylated ($p < 0.001$). Patients who achieved seizure control and had metMGMT reached an OS of 25.2 months (95%CI 17.5-32.7) compared to 5.3 months (95%CI 4.3-6.2) for non-metMGMT and seizure free patients ($p < 0.001$). By comparing the three treatment groups, LEV in non-metMGMT offered an OS advantage to other AED and non-AED treated patients ($p < 0.001$) whereas this benefit was not observed in metMGMT ($p = 0.639$).

Conclusions: Retrospective analysis of this cohort suggests that LEV modifies OS in non-metMGMT Gb patients making it comparable to those with metMGMT. Further validation of this data in clinical trials is warranted.

352P The prognostic role of indicators of systemic inflammatory response in patients with glioblastoma

V. Kaya[1], M. Yildirim[2], G. Yazıcı[3], A.Y. Yalçın[4], N. Orhan[5], A. Güzel[6]

[1]Department of Radiation Oncology, Medstar Antalya Hospital, Antalya, Turkey, [2]İnternal Medicine, Bahçeşehir Üniversitesi, Gaziantep, Turkey, [3]Department of Radiation Oncology, Hacettepe University, Ankrar, Turkey, [4]Department of Radiation Oncology, Suleyman Demirel University, Isparta, Turkey, [5]Department of Biochemistry, Medicalpark Gaziantep Hospital, Gaziantep, Turkey, [6]Department of Neurosurgery, Bahçeşehir Üniversitesi, Gaziantep, Turkey

Background: High-grade gliomas, among which glioblastomas are the most frequently observed histologic subtype, are the most common primary brain tumors in adults. The standard treatment for glioblastoma consists of maximal safe resection, followed by concomitant chemoradiotherapy. It was reported that inflammatory response plays a major role in malignancy, including tumor progression. This study aimed to determine the prognostic role of the neutrophil to lymphocyte ratio (NLR) and the thrombocyte to lymphocyte ratio (PLR)—both indicators of systemic inflammatory response (SIR)—in patients with glioblastoma.

Methods: This study retrospectively evaluated 90 patients that were treated for glioblastoma.

Results: Median follow-up time was 11.3 months (range: 1-70 months). The 1-year and 2-year overall survival rates were 55.2% and 19.5%, respectively. Univariate analysis showed that there wasn't a correlation between overall survival and gender ($p = 0.184$), comorbid diseases ($p = 0.30$), clinical presentation ($p = 0.884$), or tumor lateralization ($p = 0.159$). The prognostic factors that affected survival—other than SIR—were Eastern Cooperative Oncology Group (ECOG) performance status ($p = 0.003$), and tumor localization ($p = 0.006$). Multivariate analysis showed that overall survival was significantly correlated with SIR based on NLR (HR: 2.41), and ECOG performance status (HR: 1.53).

Conclusions: These findings confirm that the NLR value obtained from peripheral blood prior to treatment can be used as a prognostic factor in patients with glioblastoma. It is known that a high NLR value (NLR ≥ 5) is indicative of aggressive disease with decreased survival; therefore, aggressive treatment modalities can be offered to this selected patient population.

353P Which patients with recurrent glioblastoma will require a second surgery during their treatment? A machine learning solution

A. Ruiz-Patiño[1], A.F. Cardona[2], L. Rojas[3], O. Arrieta[4], Z. Zatarain-Barrón[4]

[1]School of Medicine, Hospital Universitario San Ignacio-Pontificia Universidad Javeriana, Bogotá, Colombia, [2]Clinical Oncology, Foundation for Clinical and Applied Cancer Research FICMAC, Bogotá, Colombia, [3]School of Medicine, Pontificia Universidad Javeriana, Bogotá, Colombia, [4]Thoracic Oncology Unit and Laboratory of Personalized Medicine, Instituto Nacional de Cancerologia - Mexico, Ciudad De México, Mexico

Background: Deciding upon the therapeutic approach for patients with recurrent glioblastoma (Gb) is a challenge. Although a second surgery may provide effective palliation, it has yet to be established whether it prolongs survival and/or improves quality of life; previous reported data is scarce to demonstrate that reoperation is indicated for all patients with recurrence. The few studies investigating this issue are retrospective and have been conducted on small series with heterogeneous data sets. The aim of the present study was to analyze potential predictors of outcome in patients with recurrent Gb selected for second surgery.

Methods: A statistical learning model based on artificial neural networks was performed. 144 Hispanic patients with Gb were selected; included variables were age, performance status (PS), MGMT promoter methylation (MGMTmet), IDH1/2, and extent of primary surgical resection (ESR). The objective was to identify patients who were candidates for a second surgery considering multiple variable combination models (342). Based on the overall survival (OS) 17 comparisons were made to identify the best model for later validation.

Results: 41 patients (49.7%) were female, median age was 52-years old (SD+/-14.3), 63 cases (43.8%) were older than 60 years, 125 (86.8%) had a Karnofsky Performance Index (KPS)>80%, 73 (50.7%) had methylated MGMT and 124 (86.1%) underwent total or subtotal primary resection. The best predictive variables for requiring a second surgery were age, PS, extent of surgical resection and MGMT methylation status status. With an area under the curve of 0.984, combined age plus MGMTmet had a sensitivity of 78% and a specificity of 95%. Other models including MGMTmet+IDH, age+ KPS and age+KPS+ESR yielded an AUC of 0.563, 0.861, and 0.854, respectively. All differences were statistically significant with p value <0.05.

Conclusions: The identification of patients who will require a second surgical intervention can be achieved, offering patients and clinicians an objective tool to plan and carry multiple therapeutic options.

354P The prognostic role of age in salvage re-irridiation applied patients with recurrent glioblastoma: A meta-analysis

E. Dereağzı[1], V. Kaya[2], G. Yazıcı[3], M. Yildirim[4]

[1]Faculty of Health Sciences, İstanbul Bilgi University, İstanbul, Turkey, [2]Department of Radiation Oncology, Medstar Antalya Hospital, Antalya, Turkey, [3]Department of Radiation Oncology, Hacettepe University School of Medicine, Ankara, Turkey, [4]Internal Medicine, Bahçeşehir Üniversitesi, Gaziantep, Turkey

Background: Glioblastoma is the most common primary malignant brain tumor in adults. Despite of postoperative adjuvant therapy, glioblastoma recurs in almost all the patients. After recurrence, chemotherapy, carmustine wafer intended for lesions, usage of anti-VEGF, re-operation, re-irradiation are the existent salvage therapy options. In this meta-analysis, the prognostic role of age in Salvage re-irradiation applied patients with recurrence glioblastoma was analyzed.

Methods: PubMed and EBSCOhost databases are searched for malignant glioma, high-grade glioma, recurrence, survival, re-irradiation, re- radiation. Browsing databases was done in English.

Results: 1588 patients were included to meta-analysis. Pooled hazard ratio showed that overall survival is correlated with re-operation (HR,1.042; 95% CI, 1.012-1.073; p:0,006). Pooled hazard ratio was calculated by using fixed effect model. The quality determinations of 4 studies were done by using Newcastle-Ottowa Scale. The studies were counted low quality with the score 1-3, average quality with the score 4-6, high quality with the score7-9. Median score of the studies was calculated as 5.

Conclusions: In this meta-analysis, we showed that for re-irradiation treatment, which is a salvage therapy option for recurrent glioblastoma, the age is an important prognostic factor.

355P Temozolomide combined with fractionated stereotactic radiotherapy for large brain metastases: A propensity-matched Study

Y. Ma, J. Xiao, N. Bi, Q. Liu, Y. Zhang, R. Zhao, S. Yang, Y. Li

Radiation Oncology, Cancer Institute and Hospital, Chinese Academy of Medical Sciences (CAMS), Beijing, China

Background: This study was conducted to investigate the efficacy and safety of temozolomide (TMZ) with fractionated stereotactic radiotherapy (FSRT) for large brain metastases (BMs).

Methods: From 2009 to 2016, 72 patients (pts) with large BMs (diameter>3cm or volume>6cc) undergoing concurrent TMZ and FSRT (Group A, n = 38) or FSRT alone (Group B, n = 34) were compared by using the propensity score matching method at the ratio of 1:1. Finally, 27 pts of each group were matched. FSRT was given by 52-52.5Gy/3.5-4Gy/13-15f, while TMZ was given by 75mg/m^2 concurrently. The disease control rate (DCR, CR+PR+SD) was assessed after 2-3 months from treatment. Toxicity was recorded according to CTCAE, v4.0. Local control (LC), intracranial progression-free survival (IPFS), progression-free survival (PFS) and overall survival (OS) were assessed with Kaplan–Meier method and log-rank test.

Results: The median GTV of Group A and B were 19.7cc (6.02-142.81cc) and 15.7cc (6.27-62.35cc), respectively. During treatment, more lesions in Group A shrank greatly and got re-contoured (39 VS 29, p = 0.005), and the median GTV shrinkage rate was 30.5% versus (VS) 23.1%. After 2-3 months of treatment, the DCR was 97.4% (37/38) in Group A and 85.3% (29/34) in Group B (p = 0.064). The median follow-up time was 20.6 months. Before matching, the LC (p = 0.037) and PFS (p = 0.025) of Group A were significantly greater than Group B. IPFS (p = 0.059) and OS (p = 0.059) were marginally longer in Group A. After matching, the median PFS time and 1-year PFS rate of Group A were significantly greater than Group B (12.7m VS 3.3m and 55.2% VS 26.4%, respectively, p = 0.041). The rate of intracranial progression death of Group A was significantly lower (18.2% VS 45.8%, p = 0.04). Both overall survival time and IPFS were also marginally longer in Group A (MST: 23.7m VS 17.5m, p = 0.064; 1y-IPFS: 61.6% VS 40.7%, p = 0.069), while there was no significant difference in 1-y LC (89.8% VS 84.2%, p = 0.23). There was no severe toxicity in both groups (p = 0.623).

Conclusions: The addition of TMZ to FSRT shows advantages in accelerating the shrinkage of large BMs and might improve intracranial control and overall survival, with no increase of toxicities. Further studies with large sample sizes are warranted.

356P Worsening of quality of life (QoL), cognitive functions (CF) and psychological status (PSY) can predict radiologic progressive disease (RPD) in glioblastoma (GBM) patients (PTS) treated with radiation therapy (RT) and temozolomide (TMZ): A mono-institutional prospective study

E. Bergo[1], G. Lombardi[1], P. Del Bianco[2], S. Dal Pos[3], F. Berti[4], L. Bellu[4], A. Pambuku[1], V. Zagonel[1]

[1]Clinical and Experimental Department, Medical Oncology 1, Veneto Institute of Oncology, Padua, Italy, [2]Clinical Trials and Biostatistics Unit, and Molecular Immunology and Oncology Unit, Veneto Institute of Oncology, Padua, Italy, [3]Neuroradiology Unit, University Hospital of Padua, Padua, Italy, [4]Radiation Therapy and Nuclear Medicine Unit, Veneto Institute of Oncology, Padua, Italy

Background: Almost all PTS with GBM treated with RT and TMZ relapse during or after treatment. We performed a prospective study to assess if deterioration of QoL, CF and PSY is a predictor of RPD.

Methods: PTS with newly histologically diagnosed GBM treated with RT and TMZ as first-line therapy and KPS>60 were enrolled. PTS received TMZ for 12 cycles or until unacceptable toxicity or progressive disease. All questionnaires were given to PTS for self-assessment before performing MRI. Macdonald criteria were used for radiological evaluation. We assessed QoL, CF and PSY before starting treatment, at the end of RT, and every 3 months until 9 months after the end of RT using EORTC-C30, BN-20, MMSE and HADS questionnaires. Brain MRI were performed at the same timepoints.

Results: We prospectively enrolled 111 consecutive PTS at our oncological center, Veneto Institute of Oncology, between January 2013 and December 2015. Median age was 59; 69 PTS were male and 36 PTS aged ≥65. PTS showing a RPD reported lower physical functioning (p = 0.018), minor role function (p = 0.0007) and a lower global health status (p = 0.01) than patients without RPD. In addition, they reported greater uncertainty in the future (p = 0.007), increased drowsiness (p = 0.013), increased itchy skin (p = 0.005) and greater weakness in the legs (p = 0.027) compared to PTS without RPD. PTS with RPD were more anxious (p = 0.0021) and depressed (p = 0.0001) than PTS without RPD. The two groups significantly differed in CF (p = 0.0007), especially 1 and 6 months after RT, with worse results in the MMSE for PTS with RPD.

Conclusions: Worsening of QoL, CF and PSY can predict RPD in GBM PTS treated with RT and TMZ.

357P Dose distribution after tumor cavity injection in brain glioma patients

M. Zhao, X. Fu

Department of Neurosurgery, 1st Affiliated Hospital General Hospital of PLA, Beijing, China

Background: The local delivery of drug into brain has not been widely used because the unpredictable dose distribution and dose-toxicity effects that drug may carry. This study is to investigate the efficacy of drug delivery by intra-cerebral injection.

Methods: 3 patients with deep-seated glioma underwent stereotactic biopsy and Ommaya reservoir implantation. Radioactive agent (^{131}I-chTNT) was injected at a dose of (0.8mCi/cm^3) through Ommaya reservoir. Patients were carefully observed and Post-operational PET was performed to reveal the body distribution of 131I and evaluate the distribution of drugs in whole body.

Results: After the intratumoral injection, most of the drug stayed in the brain tumor and decayed gradually for more than 4 weeks. Although the accumulation of 131I was also found in thyroid and urinary system as well as stomach and large intestine, it disappeared within 2 weeks while strong radioactivity was still seen in the brain tumor.

Conclusions: These images demonstrated excellent localization of the radiolabel in the tumor with little diffusion over time. Intra-tumoral injection of chemical or readioactive drugs is recommendable in the local treatment.

358P Retrospective analysis to ascertain whether thromboembolic events, patient gender and tumour size have prognostic implications for glioblastoma multiforme

D. Parslow, S. Pascoe

Oncology Department, Derriford Hospital Plymouth Hospitals NHS Trust, Plymouth, UK

Background: Glioblastoma multiforme is a rare grade 4 incurable brain malignancy. Well established prognostic indicators for this disease include performance status, age and cognitive function at diagnosis. Presenting with a seizure is also known to predict a better prognosis. Patient gender, tumour size and thromboembolic events have not been previously known to have prognostic significance. The rationale of this study is to identify alternative features which could be used as additional prognostic indicators.

Methods: We conducted a retrospective analysis of all patients diagnosed with glioblastoma multiforme at Derriford Hospital, Plymouth, UK between 2009 and 2016. We analysed factors such as survival time since diagnosis, patient demographics, tumour size at diagnosis, performance status at diagnosis, presenting symptom, treatment undergone and the occurrence of venous thromboembolic events since diagnosis.

Results: 92 patients were included. The occurrence of venous thromboembolism had no impact on survival time (p = 0.386). Male sex appeared to predict a better prognosis than female sex, however, this did not quite achieve statistical significance with a p value of 0.09. Cox regression analysis revealed tumour size on diagnosis to be significantly negatively correlated with survival time, with a p value of 0.012. Our analysis agreed with previous findings that multifocal disease and increased age are poor prognostic indicators, and presenting with seizures is a good prognostic indicator. Patients who underwent radical debulking surgery followed by concomitant chemoradiation had a significantly longer survival time than patients who had best supportive care alone.

Conclusions: Our analysis has shown that increasing tumour size is negatively correlated with survival duration. This link has not been previously established. Female sex may also be a poor prognostic indicator, but our data did not achieve statistical significance so further research investigating this potential link may be warranted. Venous thromboembolic events had no impact on prognosis.

359P The standard and high dose chemotherapy dose intensity and their effect on the survival of medulloblastoma using nation-wide treatment protocol

J.Y. Lim[1], L.M-J. Cha[2], S.M. Hahn[1], C-O. Suh[3], D-S. Kim[4], C.J. Lyu[1], J.W. Han[1]

[1]Department of Pediatric Hemato-Oncology, Yonsei Cancer Center, Seoul, Republic of Korea, [2]Department of Pediatric Dentistry, Yonsei University College of Medicine, Seoul, Republic of Korea, [3]Department of Radiation Oncology, Yonsei Cancer Center, Seoul, Republic of Korea, [4]Department of Neurosurgery, Yonsei University College of Medicine, Seoul, Republic of Korea

Background: Medulloblastoma is the most common type of childhood brain tumors. We conducted Korea's nation-wide protocol based treatment for medulloblastoma, and adopted tandem high dose chemotherapy for high risk disease. Here we present the result of treatment in Yonsei Cancer Center using the protocol and elucidate dose-response relationship.

Methods: The patient diagnosed and treated in Yonsei Cancer Center were reviewed retrospectively, from 2006 to 2015. We excluded the patients less than 3 years old and over 30 years old. Dose intensity (DI) was calculated as actual dose level/planned dose level divided by chemotherapy treatment duration. Ind-DI was defined as induction chemotherapy DI and HDCT-DI was as high dose chemotherapy DI. The protocol was composed of 2 cycles of neoadjuvant chemotherapy and 32.4Gy of craniospinal radiotherapy (CSRT) and 50.4 Gy of total tumor dose. After the radiotherapy, 4 cycles of chemotherapy and tandem high dose chemotherapy was done.

Results: Among total 39 patients, 16 were standard risk (SR) and 23 were high risk (HR). The 5 year overall survival (OS) was 92% for SR, and 67% for HR. Disease specific survival (DSS) for HR was 75%, and therefore 8% was treatment related mortality (TRM). The 5Y OS between M0 and M1 status was not statistically different in HR. The ind-DI did not affect in 5Y OS for SR and HR. Ind-DI was strongly correlated with HDCT-DI. The 5Y-OS for HDCT-DI<70% was statistically inferior to HDCT-DI>70%. All TRMs developed in HDCT-DI>90%. Therefore, the reduction of HDCT-DI in the protocol was suggested from this analysis. The responsiveness of induction chemotherapy (complete remission and partial remission) was predictive marker for 5Y-OS ($P = 0.026$). The complete response at the first HDCT was also predictive for 5Y-OS ($P = 0.009$).

Conclusions: The result from the nation-wide protocol was acceptable but high dose intensity was the cause of treatment related mortality. Now the dose of HDCT was reduced to achieve the ideal survival rate from the protocol.

360P Primary central nervous system germ cell tumours: A single institution retrospective study

J.P. Silva[1], M. Ramos[1], A. Azevedo[2], D. Salgado[2], I. Costa[2], J. Marques[2]

[1]Medical Oncology, Instituto Português de Oncologia de Lisboa Francisco Gentil, E.P.E. (IPOLFG EPE), Lisbon, Portugal, [2]Neurology, Instituto Português de Oncologia de Lisboa Francisco Gentil, E.P.E. (IPOLFG EPE), Lisbon, Portugal

Background: Germ Cell Tumors (GCTs) are 2% of intracranial neoplasms, mainly in the pineal/suprasellar region and in young ages. The overall prognosis, in tumors containing a non-germinomatous component, is poor with a median 5 year overall survival (OS) of under 30%. Treatment recommendations suggest a multimodal approach

Methods: We performed a retrospective review of all consecutive primary intracranial GCT patients (pts) diagnosed and treated at our Institution from 1988 to 2015. Primary aim: to characterize the clinical, demographic and treatment data. Secondary aim: to evaluate overall survival (OS) at 5 and10 years using the Kaplan-Meier method and related prognostic factors

Results: From a total of 45 pts, 30 were males, median age 11 years (P10-90: 5,75–20). The main symptoms were cephalalgia (45%), diabetes insipidus (31%) and vomiting (20%). 53% had endocrinologic disturbances, 44% visual field limitations and 20% pts Parinaud Syndrome. Sixty percent presented with intracranial hypertension. Primary location was the pineal and suprasellar in 56% and 29% of cases. Cranial and Neuroaxial Magnetic Ressonance Imaging (MRI) was the preferred imaging method used in 91 and 53% pts, respectively. The diagnosis was reached by tumour markers in 22,2%, tumour biopsy in 26,6% and surgery in 51,1% pts. Tumour markers were elevated in 69% pts. Fourty-ninve percent of pts had pure germinoma, 15,5% pts had mixed germinoma and 31% pts non-germinoma. Sixty-nine percent of pts underwent intracranial decompression techniques. Sixty-nine percent of pts had chemotherapy regimens (PEI in 18 pts) and 82,2% pts had cranial radiotherapy (with simultaneous neuroaxial irradiation in 17 pts). Complete response was achieved in 91,1% of pts with 22,2% pts recurring. The 5 and 10 OS rate was 88 and 85% respectively (98 and 98% for Germinomas and 82 and 75% for non-germinoma). OS values differences between histologies did not reach statistical significance. In the multivariate analysis only cranial radiotherapy and absence of recurrence were associated with improved survival ($p = 0.003$ and $p = 0.016$, respectively).

Conclusions: First line multimodality treatment achieves good clinical outcomes, with focus on cranial radiotherapy. Disease recurrence is associated with worse outcomes.

361P Effect of silibinin nutraceutical supplementation in brain metastases of patients with advanced lung cancer

J. Bosch-Barrera[1], E. Sais[1], A. Izquierdo[1], A. Hernández[1], D. Roa[1], E. Cuyas[2], S. Pedraza[3], N. Priego[4], P. Ortuño[3], G. Sánchez[3], N. Cañete[3], A. Roselló[5], R. Soffietti[6], J. Brunet[1], M. Valiente[4], J.A. Menendez[2]

[1]Medical Oncology Department, Catalan Institute of Oncology, Girona, Spain, [2]Metabolism and Cancer Group, Girona Biomedical Research Institute, Girona, Spain, [3]Department of Radiology, Diagnostic Imaging Institute, Doctor Josep Trueta University Hospital, Girona, Spain, [4]Brain Metastasis Group, CNIO, Madrid, Spain, [5]Radiotherapy Department, Catalan Institute of Oncology, Girona, Spain, [6]Department of Neuro-Oncology, University of Turin and City of Health and Science Hospital, Turin, Italy

Background: Silibinin is a bioactive flavonolignan extracted from milk thistle (*Silybum marianum*). We are currently evaluating the pre-clinical activity of silibinin on reactive astrocytes, a major component of the brain metastasis microenvironment shown to play important pro-metastatic functions.

Methods: We present data of patients with lung cancer and brain metastases that have received compassionate use of nutraceutical supplementation with Legasil®, a commercially available silibinin-based nutraceutical, in addition to standard oncologic treatment. We have compared our observed results with the brain GPA index of each patient calculated by Lung-molGPA tool (brain GPA Index).

Results: Eighteen patients have been treated: median age 62 y (range: 35–80); male: 11 (61%); median number of brain metastases: 4 (range: 1-20); median size of the bigger brain metastasis: 26 mm (range: 10-65 mm). Histology: Adenocarcinoma: 14, Large cell: 1, Small cell: 2, Squamous: 1. All patients have received whole brain radiotherapy. Observed overall survival (OS) was significantly superior compared with expected OS calculated by Lung-molGPA (median 22.2 months [95% CI 13.0-32.6] vs 6.9 months [4.2-9.5]; $p = 0.001$). Time to central nervous system treatment failure of silibinin was 26.9 months (95% CI 11.7-42.1 months). Brain tumor progression was observed in 6 patients (33%). Overall response rate at brain disease was 75% (Complete Response:3 patients (20%) and Partial Response: 10 patients (55%)). Only one patient presented brain tumor progression as best response. At data cutoff (May 1st, 2017), 6 (33%) patients remained alive.

Conclusions: These preliminary data suggest that silibinin supplementation contributes to the control of brain metastases in lung cancer patients. Further evaluation of the silibinin use in a phase II clinical trial is warranted.

362P Melanoma with V600 BRAF mutations and brain metastases: Experience of targeted therapy in a single center

D. Naskhletashvili[1], L. Demidov[2]

[1]Neuro-oncology, N. N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation, [2]Department of Dermatology, N. N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation

Background: The effectiveness of chemotherapy (temozolomide, fotemustine, lomustine) alone and in combination with whole brain irradiation in patients with melanoma with cerebral metastases does not exceed 7-10%, without significant impact on overall survival, which is 2-4 months. Targeted therapy has improved the survival of patients with metastatic melanoma with BRAF V600 mutations. In patients with brain metastases targeted therapies allow not only to control systemic tumor process, but also to achieve the effect of treatment of cerebral metastases. So, the efficacy (complete and partial regressions of brain metastases) targeted therapy with BRAF inhibitors vemurafenib or dabrafenib in patients with melanoma with BRAF V600 mutations in metastatic brain lesions, according to the literature, varies from 18.0% to 39.2%, with a median survival of patients from 5,3 to 8,2 months. We evaluated the efficacy of targeted therapy (BRAF inhibitors vemurafenib or dabrafenib as monotherapy and also in combinations with MEK inhibitors cobimetinib or trametinib) in patients with melanoma brain metastases.

Methods: In Russian N.N. Blokhin Cancer Research Center effect of the various schemes targeted therapy were evaluated in 45 patients with melanoma with BRAF V600 mutations and brain metastases. Patients received the following treatment options: dabrafenib (4 patients), dabrafenib + trametinib (11 patients), vemurafenib (25 patients), vemurafenib + cobimetinib (5 patients). Three patients (6,7%) targeted therapy was combined with whole brain irradiation, in eight patients (17,8%) – in combination with stereotactic radiotherapy/radiosurgery.

Results: Complete regression of brain metastases was achieved in 3 patients (6,7%), partial regression in 19 (42,2%), stabilization in 15 (33,3%). Thus, the tumor control in

the brain was observed in 37 patients (82,2%). In 43 patients (95,6%) of 45 were also established metastases in other sites (extracranial lesions). Complete regression of metastases in extracranial lesions was achieved in 1 patient (2,3%), partial regression – in 26 (60,4%), stabilization in 13 (30,2%). The median time to disease progression was 5.5 months. The median survival of patients was 8,5 months.

Conclusions: The data presented indicate that the targeted therapy with BRAF inhibitors as monotherapy and also in combination with MEK inhibitors in patients with metastatic melanoma with brain metastases provides control over the disease in most patients and has a significant advantage with a group of historical control (chemotherapy ± whole brain irradiation).

363P Radioprotective effect of xenon in radiation treatment for brain metastases

M. Zinkovich[1], T. Protasova[2], A. Shikhlyarova[2], L. Rozenko[1], Y. Arapova[2]

[1]Radiology, Rostov Research Institute of Oncology, Rostov-on-Don, Russian Federation, [2]Testing Laboratory Center, Rostov Research Institute of Oncology, Rostov-on-Don, Russian Federation

Background: Surgical treatment, whole brain irradiation (WBI) and stereotactic radiation therapy (RT) are the main treatment strategies for solitary brain metastases. Applying additional boost to the bed of removed metastatic foci seems promising for enhancing local control, but increased radiation exposure affects the central regulation and processes that maintain homeostasis. The purpose of the study was to evaluate optimization of adjuvant RT with xenon due to its neurotrophic and neuroprotective effects.

Methods: 16 patients of the control group received WBI with additional boost once a day (60 Gy in 15 fractions), while 12 patients of the main group received similar RT plus inhalations of a xenon/oxygen mixture twice a week. Clinical and neurological examination was performed and the quality of life was assessed (using QLQ-C15 and BN-20 + 2 questionnaires) for all patients during the treatment. Adaptation reactions were identified and the ratio of their anti-stress/stress types (R as/s) was calculated for integral evaluation of the body condition, individual testing tension (Ut) at the Yin Tang point was studied and EEG parameters were analyzed.

Results: Only patients receiving xenon reported reduced rates of headaches and dizziness, disorders of higher nervous activity, reduced degrees of movement disorders; RT course for these patients was performed in compliance with the accompanying therapy. Assessment of the quality of life by the end of the treatment showed significant improvement in such criteria as physical health and loss of appetite, as well as pain relief, in contrast to the control group. Negative dynamics of integral body parameters, R as/s and Ut was lower than in the control group, and some EEG parameters were normalized after xenon therapy.

Conclusions: Xenon therapy is an effective optimization method for radiation treatment of patients with brain metastases. Its radioprotective and stress-limiting effects allow reduction of adverse effects and toxicity and improvement of the quality of life of patients.

Background: Treatment for advanced HCC remains limited and outcomes are poor. However, emerging data implicate FGF19 as a key HCC driver and suggest its receptor, FGFR4 as a novel therapeutic target. A phase 1 study (NCT02508467) was initiated to assess the safety and clinical activity of BLU-554, a potent, highly-selective oral FGFR4 inhibitor.

Methods: Adult patients (pts) with advanced HCC and well-preserved liver function received BLU-554 once daily on a 4-week cycle following a 3 + 3 escalation/MTD expansion design. Adverse events (AEs) per CTCAE, PK, PD and pathway activation (tumor FGF19 IHC) were assessed. Response was determined by RECIST 1.1 every 8 weeks.

Results: At a 4/20/17 cutoff, 61 pts have been treated with BLU-554 including 25 in dose escalation (140-900 mg) and 36 in the ongoing dose expansion. 48 (79%) pts had metastatic disease, 54 (89%) had failed $\geq$1 prior systemic therapy (48 (79%) sorafenib; 11 (18%) nivolumab) and 29 (48%) had pathway activation (IHC+). Based on safety profile, PK, PD, and anti-tumor activity, 600 mg was the MTD and RP2D. Radiographic tumor reduction and objective response per RECIST 1.1 were observed in IHC+ pts in dose escalation and dose expansion. Of 19 IHC+ pts with $\geq$ 1 radiographic assessment, 11 (58%) pts had tumor reduction: 6 with SD, 4 with PR and 1 with CR (ORR 26%). 6 (32%) IHC+ pts had duration of treatment $\geq$ 6 months. In contrast, only 4 (15%) of 27 IHC negative pts had tumor reduction (all SD) and only 1 (4%) had duration of treatment $\geq$ 6 months. Most AEs (regardless of causality) were Grade (Gr) 1-2, including diarrhea (66%), nausea (43%), vomiting (39%), ALT increase (33%), fatigue, AST increase (29% each), abdominal pain (23%), anemia, and decreased appetite (20% each). AST (13%) and ALT (10%) increase, were the only BLU-554-related Gr 3-4 AEs occurring in $\geq$ 10% of pts. 2 pts experienced DLT (1 Gr 3 abdominal pain; 1 Gr 3 fatigue lasting $>$ 7 days) at 900 mg. 36 (59%) pts have discontinued treatment: 26 disease progression; 5 AE; 3 investigator's decision; 2 withdrew consent.

Conclusions: BLU-554 is well tolerated at the recommended dose of 600 mg and demonstrates important clinical activity in FGF19 IHC+ advanced HCC pts who have failed prior systemic therapy.

366PD Oncolytic herpesvirus therapy for mesothelioma: A phase I/IIa trial of intrapleural administration of HSV1716 (NCT01721018)

S. Danson[1], P. Woll[2], J. Edwards[3], K. Blyth[4], P. Fisher[2], J. Roman[5], K. Simpson[5], R. Spavin[5], K. Learmonth[5], J. Conner[5]

[1]Department of Oncology and Metabolism, Sheffield Experimental Cancer Medicine Centre, Weston Park Hospital, Sheffield, UK, [2]Sheffield ECMC, Weston Park Hospital Cancer Research Centre, Sheffield, UK, [3]CardioThoracic Surgery, Northern General Hospital, Sheffield, UK, [4]Respiratory Medicine, Queen Elizabeth University Hospital, Glasgow, UK, [5]Research and Development, Virttu Biologics Ltd, Newhouse, UK

Background: Malignant Pleural Mesothelioma (MPM) remains a major challenge with limited therapeutic options. Disease is frequently confined to the pleura, distant metastases are uncommon and intrapleural treatment is therefore appealing. HSV1716 is a 34.5null oncolytic herpes simplex virus which, in pre-clinical studies, demonstrates cancer cell-specific HSV1716 infection and oncolysis and an anti-tumor immune response. We assessed the safety and potential for efficacy of intrapleural HSV1716 in patients with inoperable MPM.

Methods: We performed an open label, dose escalation, phase I/IIa trial of intra-pleural HSV1716. Patients with a histological diagnosis of MPM and indwelling pleural catheter (IPC) were eligible if they had performance status $\leq$ 2 and adequate hematologic, renal and liver function. Patients received 1x10^7pfu HSV1716 through their IPC on 1, 2 or 4 occasions a week apart, in 3 separate cohorts. The primary objective was to determine the safety and tolerability of intra-pleural HSV1716. The secondary objectives were to assess HSV1716 replication and patient immune responses in pleural fluid and blood. An exploratory objective was to assess tumour response by CT, using modified RECIST criteria.

Results: Twelve patients were treated, 3 received 1 dose of intrapleural HSV1716, 3 received 2 doses and 6 received 4 doses. HSV1716 was well-tolerated with no HSV1716-related SAE and 17 HSV1716-related transient Grade 1-2 AEs. Evidence of HSV1716 replication (n = 9) and pleural Th1 cytokine responses (n = 8) were observed. Novel anti-tumor IgG responses were detected post treatment and their antigen targets identified by protein array. CT analysis on day 57 indicated 6 patients with stable and 6 patients with progressive disease. Median survival from treatment was 15mths for all patients and 18mths in patients with evidence of a Th1 immune response (n = 8).

Conclusions: The study demonstrated an acceptable safety profile of intra-pleural HSV1716 with evidence of viral replication and anti-tumour immunogenicity. This supports further studies in MPM, possibly involving combination with immune checkpoint inhibitors.

367PD Early FDG-PET response correlates with dose and clinical efficacy in patients with microsatellite stable (MSS) metastatic CRC (mCRC) treated with the CEA-CD3 T-cell bispecific antibody plus atezolizumab

F. Sandoval[1], D. Sabanes Bove[2], S. Bouseida[1], V. Karanikas[3], A. Keelara[1], J. Saro[3], T. Nayak[1]

[1]Roche Pharmaceutical Research and Early Development, Roche Innovation Center, Basel, Switzerland, [2]Biostatistics, F. Hoffmann-La Roche Ltd., Basel, Switzerland, [3]Roche Pharmaceutical Research and Early Development, Roche Innovation Centre, Zurich, Switzerland

Background: CEA-CD3 TCB (RG7802, RO6958688) is a novel T-cell bispecific antibody targeting CEA on tumor cells and CD3 on T cells. An ongoing phase Ib study (NCT02650713) is exploring the safety, tolerability and efficacy of CEA-CD3 TCB in combination with atezolizumab. We report preliminary results of FDG-PET imaging as an early pharmacodynamic marker for this novel cancer immunotherapy combination in MSS mCRC patients.

Methods: In this study, CEA-CD3 TCB is given QW in combination with atezolizumab 1200 mg Q3W in patients with CEA-expressing solid tumors. As of March 3, 2017, a total of 35 MSS mCRC patients have been treated with CEA-CD3 TCB doses of 5-160 mg; 15 patients were evaluable for PET image analysis. On-treatment FDG-PET scans were performed at week 4 and compared with baseline. On-treatment changes in SUV_{max}, metabolic tumor volume (MTV) and total lesion glycolysis (TLG) were

analyzed in up to 10 measurable lesions per patient, identified at baseline by an independent reviewer. The exploratory statistical analyses used semiparametric Gaussian regression models and Cox PH landmark analyses (for progression-free survival [PFS]).

Results: Early changes in FDG-PET parameters showed a dose-response relationship (MTV: $P = 0.0022$; TLG: $P = 0.0054$; SUV_{max}: $P = 0.0081$); notably all patients receiving doses $\geq$ 80 mg (n = 7) showed decreases in SUV_{max}, TLG and MTV at week 4. Furthermore, week 4 reductions in FDG uptake (MTV: $P < 0.001$; TLG: $P < 0.001$; SUV_{max}: $P = 0.0061$) correlated with later tumor shrinkage (best change from baseline per RECIST v1.1). Reduction in MTV and TLG, but not SUV_{max}, correlated with decreases in soluble CEA levels measured at week 6 (MTV: $P = 0.013$; TLG: $P = 0.034$; SUV_{max}: $P = 0.54$) and longer PFS (MTV: $P = 0.013$; TLG: $P = 0.052$; SUV_{max}: $P = 0.85$).

Conclusions: In MSS mCRC patients, changes in MTV, TLG and SUV_{max} correlated with dose and tumor shrinkage. Decreases in 2 FDG parameters (MTV and TLG) correlated with a reduction in soluble CEA levels. Early on-treatment changes in FDG-PET can serve as a pharmacodynamic biomarker related to treatment efficacy.

368PD Dose escalation/expansion study to investigate the safety, pharmacokinetics, food effect, and antitumor activity of BGB-290 in patients with advanced solid tumors

J. Lickliter[1], L. Mileshkin[2], M. Voskoboynik[1], M. Millward[3], A. Freimund[2], T. Meniawy[3], T. Tang[4], R. Wei[4], M. Li[5], V. Paton[6]

[1]*Oncology, Nucleus Network, Melbourne, Australia,* [2]*Oncology, Peter MacCallum Cancer Center, Melbourne, Australia,* [3]*Oncology, Linear Clinical Research Limited, Nedlands, Australia,* [4]*Clinical Pharmacology, BeiGene USA, Inc., Emeryville, CA, USA,* [5]*Clinical Development, BeiGene Co. Ltd, Beijing, China,* [6]*Oncology, BeiGene, Inc, Emeryville, CA, USA*

Background: Poly (ADP-ribose) polymerase inhibitors (PARPis) represent a class of antitumor agents that exert their cytotoxic effects by inhibiting PARP activity. Some PARPis are capable of trapping PARP proteins on DNA further augmenting cell death. BGB-290 is a potent and selective PARP1/2 inhibitor with strong PARP-trapping and antitumor activity in both *in vitro* and *in vivo* preclinical tumor models harboring *BRCA* gene mutations or other homologous recombination defects.

Methods: This two-staged study (NCT02361723) consists of a Phase 1A dose-escalation/dose-finding component to establish the maximum tolerated dose (MTD) and/or recommended Phase 2 dose (RP2D) of BGB-290 in patients with solid tumors and a two-part Phase 2 component that includes expansion in targeted indications (Part A) and the effect of food on the BGB-290 pharmacokinetic (PK) profile (Part B).

Results: As of 1 May 2017, Phase 1A had completed enrollment (n = 45); 3 patients remain on treatment. Objective responses were observed across the dose range (2.5–120 mg BID). Of the 23 evaluable patients with gynecological cancer, 10 (43%) achieved an objective response per RECIST 1.1 (n = 3 complete; n = 7 partial). More patients with germline *BRCA 1/2* mutated ovarian cancer achieved an objective response (n = 7/12, 58%) than patients not carrying the mutation (n = 2/8, 25%). Drug-related adverse events (AEs) reported in $\geq$ 10% of patients were nausea, fatigue, anemia, vomiting, diarrhea, anorexia and neutropenia. Anemia and neutropenia were the most common drug-related Grade 3 AEs; no Grade 4 drug-related AEs were reported. Three BGB-290-related serious AEs were reported (anemia, n = 2; nausea, n = 1). Four deaths were associated with an AE; however, none were considered drug-related. The BGB-290 RP2D was determined as 60 mg BID and is being evaluated in Phase 2 to determine antitumor activity and food effects. Dose escalation to determine MTD with QD dosing is ongoing.

Conclusions: BGB-290 has demonstrated a favorable safety profile and promising preliminary antitumor activity in phase 1A; phase 2 is ongoing evaluating in patients with ovarian, breast, prostate, gastric and small cell lung cancer.

370PD Phase I dose escalation study of M2698, a p70S6K/AKT inhibitor, in patients with advanced cancer

A.M. Tsimberidou[1], C. Verschraegen[2], A. Weise[3], J. Sarantopoulos[4], G. Lopes[5], J. Nemunaitis[6], A. Victor[7], J. Shaw[8], R. Kaleta[8], R. Kurzrock[9]

[1]*Investigational Cancer Therapeutics, MD Anderson Cancer Center, Houston, TX, USA,* [2]*Division of Medical Oncology, Ohio State Unv. Medical Center, Columbus, OH, USA,* [3]*Medical Oncology, Karmanos Cancer Institute, Detroit, MI, USA,* [4]*Institute for Drug Development, Cancer Therapy and Research Center at University of Texas Health Science Center, San Antonio, TX, USA,* [5]*Clinical Medicine, Sylvester Comprehensive Cancer Center, Miami, FL, USA,* [6]*Mary Crowley Cancer Research Center, Dallas, TX, USA,* [7]*Global Biostatistics, Merck KGaA, Darmstadt, Germany,* [8]*Clinical Oncology, EMD Serono, Billerica, MA, USA,* [9]*Clinical Science, UCSD Moores Cancer Center, La Jolla, CA, USA*

Background: Aberrant PI3K/Akt/mTOR (PAM) pathway signaling is observed in various tumors and confers resistance to standard therapies. M2698 is an oral, brain penetrant, potent and selective p70S6K/Akt1/3 inhibitor that can block signaling from Akt feedback loop activation, a possible tumor escape mechanism

Methods: Patients (pts) with advanced cancer were given oral M2698 daily (PO 15–380 mg) in 21-day (d) cycles in a 3 + 3 dose escalation [DE] design. Response was assessed every 2 cycles. An expansion phase in pts with PAM pathway tumor alterations is ongoing

Results: Overall, 50 pts received M2698 monotherapy (DE, n = 40; expansion, n = 10); DE data presented only (cut-off 10/27/16). Treated pts had a median age of 56 years. (14 men, 26 women). Tumor types included breast (n = 7), colon (n = 4), lung (n = 4) and other (n = 25). In the DE phase, 35/40 pts were evaluable. Two pts had a dose limiting toxicity (DLT; 60mg and 160mg) and drug-related Grade $\geq$3 adverse events (AEs) occurred in 6/40 (15%) of pts. AEs leading to dose reductions occurred in 1 pt at < 320 mg/d and in 3 pts $\geq$320 mg/d. Of the 32 DE pts (without DLT) who completed treatment by the data cut-off, 6 pts (19%) remained on treatment (Rx) for $\geq$ 180 days (min, max range 21 to 504 days) [Table]. Exposure of M2698 increased dose proportionally and ^{3}80% phospho-S6 inhibition in tumor was achieved in 2/7 paired biopsies from pts treated with doses ^{3}110 mg/d. Expansion phase dose was 240 mg/d PO. Tissue molecular analysis and liquid biopsies were performed. Analysis is ongoing.

Table: 370PD

Dose level mg/d	All Pts in DE set without DLT	
	N	Days on Rx
15	3	90, 126, 42
30	3	504, 126, 112
60	5	42, 42, 21, 180, 42
75	3	42, 42, 84
110	3	462, 42, 42
160	5	42, 42, 223, 42, 62
200	3	215, 73, 126
320	6	75, 256, 41, 168, 98, 70
380	2	42*

1 pt on treatment at data cut off.

Conclusions: M2698 was well tolerated and provided stable disease over a wide range of doses.

371PD A Phase 1 PK/PD Study of ASN003, a novel highly selective BRAF and PI3K inhibitor, in patients with advanced solid tumors

D. Rasco[1], R. Sullivan[2], N. Lakhani[3], S. Reddy[4], N. Rao[4], L. Denis[4], A. Tolcher[1], K.T. Flaherty[5]

[1]Medical Oncology, South Texas Accelerated Research Therapeutics (START), San Antonio, TX, USA, [2]Department of Oncology, Massachusetts General Hospital Cancer Center, Boston, MA, USA, [3]Medical Oncology, South Texas Accelerated Research Therapeutics (START), Grand Rapids, MI, USA, [4]Oncology, Asana Biosciences, Lawrenceville, NJ, USA, [5]Termeer Center for Targeted Therapies, Massachusetts General Hospital Cancer Center, Boston, MA, USA

Background: RAS-RAF-MEK and PI3K-AKT-mTOR are two major pathways involved in tumor cell signaling and growth. Components of these pathways are frequently mutated in a broad range of tumors. ASN003 is a highly selective and potent (low nM IC_{50}) inhibitor of BRAF and PI3K-α and -d (low affinity for PI3K-b). ASN003 shows strong antitumor activity in tumor models harboring BRAF and PIK3CA or PTEN mutations, and also in PDX models that are resistant to selective BRAF and MEK inhibitors.

Methods: Oral ASN003 once daily is being evaluated for safety/tolerability and preliminary efficacy in eligible patients with advanced solid tumors using an accelerated dose titration design (Part A) and enrolling cohorts of melanoma, CRC and NSCLC patients with a BRAF, PIK3CA or PTEN mutation at MTD (Part B). Eligibility criteria include HbA1c ≤ ULN or fasting glucose <140 mg/dL. Pharmacokinetic (PK) profile and the pharmacodynamic (PD) effects of ASN003 on tumor tissue biomarkers such as pERK and pS6 are investigated in both parts of the study.

Results: Patient accrual is ongoing. To date, seven eligible patients are enrolled in dose levels ranging from 10 – 120 mg QD. ASN003 has been well tolerated. Treatment-related adverse events (TRAEs) were mild (G1) to moderate (G2). TRAEs include diarrhea (G2) (n = 1), nausea/vomiting (G1) and dry mouth/lips/skin (G1). Transient G1 elevation of glucose and insulin c-peptide levels has been noted in 1 pt. No G3/4 AEs have been observed to date. The PK profile showed excellent, systemic exposure at steady state at all doses (C_{max} up to 930 ng/mL, $AUC_{0\text{-}T}$ up to 18998 ng.h/mL at 80 mg QD) and a half-life of > 12 hour. Dose escalation is ongoing.

Conclusions: ASN003 is a novel small molecule, with uniquely selective and potent inhibition of BRAF, PI3-α and -d kinases. To date, ASN003 was well tolerated at doses up to 120 mg QD and achieved good systemic exposure. Updated and detailed clinical safety/efficacy and PK/PD results will be presented.

372PD First-in-human (FIH) study of TAS-120, a highly selective covalent oral fibroblast growth factor receptor (FGFR) inhibitor, in patients (pts) with advanced solid tumors

Y. Kuboki[1], N. Matsubara[2], H. Bando[3], K. Shitara[3], K. Yoh[4], T. Kojima[3], I. Ohno[5], H. Takahashi[5], K. Harano[1], S. Kondo[6], H. Hirai[7], C. Morizane[6], T. Doi[1]

[1]Department of Experimental Therapeutics, National Cancer Center Hospital East, Kashiwa, Japan, [2]Department of Breast and Medical Oncology, National Cancer Center Hospital East, Kashiwa, Japan, [3]Department of Gastrointestinal Oncology, National Cancer Center Hospital East, Kashiwa, Japan, [4]Thoracic Oncology, National Cancer Center Hospital East, Kashiwa, Japan, [5]Department of Hepatobiliary and Pancreatic Oncology, National Cancer Center Hospital East, Kashiwa, Japan, [6]Department of Hepatobiliary and Pancreatic Oncology, National Cancer Center Hospital, Tokyo, Japan, [7]GCMO Office, Taiho Pharmaceutical Co. Ltd., Tokyo, Japan

Background: Dysregulation of the FGF/FGFR signaling pathway has been associated with many developmental disorders and varieties of cancers. TAS-120 is an oral, highly selective covalent FGFR inhibitor with potent antitumor activity *in vitro* and *in vivo* models with FGFR pathway aberration.

Methods: This FIH study consists of dose escalation phase (DE) and expansion phase (EX). The objectives of this study are to determine the maximum tolerated dose (MTD)/recommended dose (RD) and to investigate the safety, pharmacokinetics, pharmacodynamics, and efficacy. In DE, the first three cohorts were evaluated by a single patient then a 3 + 3 design is used which is currently ongoing. Pts with FGFR abnormalities can be enrolled to EX during the evaluation of DE with dose lower than maximum administered dose under evaluation. TAS-120 was administered orally three times weekly (Monday-Wednesday-Friday) in a 21day cycle.

Results: As of 3 Apr 2017, 36 pts (34% FGFR with genetic abnormalities) were enrolled (DE; 26 pts, EX; 10 pts). Tumor types enrolled were bladder cancer (n = 8), colorectal cancer (n = 7), biliary tract cancer (n = 4), gastric, esophageal and pancreas cancer (n = 3 each), and others (n = 8). Pts were treated in 8 dose cohorts of 8 -160 mg. MTD has not been reached. The most common drug-related AEs (all AEs ≥10%) were hyperphosphatemia (79%), and anorexia (12%). Grade ≥3 hyperphosphatemia has never been observed. Hyperphosphatemia was managed with dose interruption or reduction in addition of phosphate binders. Drug-related SAE has not occurred. TAS-120 exposure increased with dosage. Mean C_{max} and $AUC_{0\text{-}48}$ at 160 mg were 1,192 ng/mL and 9,972 ng*h/mL, respectively, with a mean T_{max} of 2.67 hrs and apparent $T_{1/2}$ of 6.06 hrs. Two pts showed the clinical response, one of them was gastric cancer with FGFR2 amplification at 80 mg, and the other was esophageal cancer (FGFR status is under evaluation) at 120 mg. Moreover, two biliary tract cancer with FGFR2 fusion at 56 mg, and one bladder cancer at 36 mg (FGFR status is unknown) had stable disease > 24 weeks.

Conclusions: TAS-120 was well-tolerated, and the safety profile was confirmed up to 120 mg. The ongoing DE and EX are still under evaluation and RD will be determined.

373PD Phase 1 Study of E7046, a PGE2 Receptor EP-4 inhibitor that targets immunosuppressive myeloid cells in the tumor microenvironment

D.S. Hong[1], A. Varga[2], A. Parikh[3], G. Shapiro[4], L. Reyderman[5], M. Ren[5], S. Dayal[6], T. Binder[5], C.E. Ooi[5], O. Ataman[6], A. Marabelle[2]

[1]Division of Cancer Medicine, The University of Texas M.D. Anderson Cancer Center, Houston, TX, USA, [2]Drug Development Department (DITEP), Gustave Roussy, Villejuif, France, [3]Department of Hematology/Oncology and Medicine, Massachusetts General Hospital, Boston, MA, USA, [4]Depatrment of Medicine, Harvard Medical School, Boston, MA, USA, [5]Eisai, Inc., Woodcliff Lake, NJ, USA, [6]Eisai, Ltd., Hatfield, UK

Background: E7046 is a selective small molecule antagonist of the prostaglandin E_2 receptor-type-4 that inhibits the differentiation of monocytic myeloid lineage cells towards a pro-tumorigenic phenotype in the TME. This is a first-in-human study of single-agent E7046.

Methods: Key eligibility criteria: patients (pts) ≥18 years with selected advanced cancers with high levels of myeloid infiltrate. The dose-escalation phase consisted of 6-pt cohorts of 125, 250, 500, and 750 mg (once-daily, oral, 21-day cycle) doses of E7046. Primary objectives were safety/tolerability, maximum tolerated dose (MTD) and/or RP2D. Secondary objectives included PK and initial anti-tumor activity; exploratory objectives included PD assessments on immune cells in tumor infiltrate and in peripheral blood and metabolic response by ^{18}FDG-PET.

Results: 30 pts received E7046 (median age 58 yrs [24-78]; 2-7 lines of prior therapy). Most common tumor types were colorectal cancer (40%), pancreatic cancer (20%), and SCCHN (13%). No DLTs were observed and the MTD was not reached. The most frequent drug-related adverse events (AEs) were diarrhea (20%), decreased appetite, fatigue and nausea (13% each). Drug-related AEs of Gr 3/4 occurred in 4 pts (diarrhea, anaphylactic reaction, hypersensitivity, hyperuricemia, rash, generalized rash). 2 pts had drug-related serious AEs (rash, allergic reaction, fever in 1 pt; hyperuricemia, acute renal failure [Gr 2] in 1 pt). 3 pts discontinued treatment due to AEs (bowel obstruction, allergic reaction, abdominal pain). There were no drug-related deaths. E7046 exposure was dose proportional up to 500 mg with no incremental increase in exposure at 750 mg. E7046 was extensively metabolized, elimination half-life was ∼12hr and accumulation on multiple dosing was ∼2-fold. 2 pts are ongoing and preliminary efficacy showed no objective responses, 4 pts with durable SD or clinically stable (>4 mo) and 4 pts with ^{18}FDG-PET metabolic responses.

Conclusions: Single-agent E7046 was tolerated with no MTD reached in heavily pretreated pts with myeloid-rich tumors. PD analysis of immune cell modulation to help determine the RP2D will be presented at the meeting.

374PD A first in human phase 1 study of KPT-9274, a first in class dual inhibitor of PAK4 and NAMPT, in patients with advanced solid malignancies or NHL

A. Naing[1], S. Leong[2], M.J. Pishvaian[3], A.R.A. Razak[4], A. Mahipal[5], J. Berlin[6], D. Cho[7], W. Senapedis[8], S. Shacham[8], M. Kauffman[8], J. Ellis[8], J. Meade[8], E. Baloglu[8]

[1]Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA, [2]Medical Oncology, University of Colorado Cancer Center Anschutz Cancer Pavilion, Aurora, CO, USA, [3]Lombardi Comprehensive Cancer Center, Georgetown University, Washington, DC, USA, [4]Department of Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada, [5]Medical Oncology, Mayo Clinic, Rochester, MN, USA, [6]Medical Oncology, Vanderbilt Ingram Cancer Center, Nashville, TN, USA, [7]Medical Oncology, NYU Medical Oncology Associates, New York, NY, USA, [8]Clinical, Karyopharm Therapeutics, Newton, MA, USA

Background: KPT-9274 is an oral, small molecule modulator of PAK4 (p21 activated kinase) and NAMPT (nicotinamide phosphoribosyltransferase). PAK4 is a major player in cell morphology and WNT/β-catenin signaling. NAMPT is the rate-limiting enzyme in NAD biosynthesis. Co-inhibition of these targets leads to synergistic anti-tumor effects through energy depletion, inhibition of DNA repair, cell cycle arrest, and ultimately apoptosis. Cells can utilize niacin to make NAD through an alternative pathway using NAPRT1. NAPRT1 is often absent in tumors making it a potential response biomarker. KPT-9274 demonstrates potent anti-tumor activity pre-clinically and in patient dogs with cancer.

Methods: This dose escalation study evaluates KPT-9274 as a single agent and co-dosed with niacin. KPT-9274 is given QoDx3/week (28-day cycle) at a starting dose of 10 mg. The objectives are to evaluate safety and tolerability of KPT-9274, dose-limiting toxicities (DLT), maximum tolerated dose (MTD), recommended phase 2 dose, early anti-tumor activities, pharmacokinetic (PK) and pharmacodynamic properties.

Results: As of 02-Mar-17, 14 patients (pts: 9M/5F; median age 61) with advanced solid tumors were enrolled in 4 cohorts (10 – 40 mg). One DLT (G4 anemia) at 40 mg was reported. MTD is not yet reached. Drug-related adverse events (AEs) include G2-4 anemia (6 pts, 43%) and G3 fatigue (1 pt, 7%). The most common G2 AEs are arthralgia and myalgia (3 pts; 21% each) and influenza-like illness (2 pts; 14%). Stable disease (SD) was seen in 29% of the 14 pts. Preliminary PK analysis suggests plasma exposure was dose proportional on C1D1 increasing 4 to 5-fold by C1D24. On C1D24, the mean C_{max} and AUC_{0-t} observed in 20 – 30 mg cohorts were 319 – 1,573 ng/mL and 10,456 – 59,152 ng*hr/mL, respectively. Preliminary data indicate that treatment of KPT-9274 reduces NAD levels vs. baseline in circulating leukocytes and tumor biopsies. Analyses to correlate NAPRT1 status with response is ongoing (2 of 4 SD pts are NAPRT1-).

Conclusions: Oral KPT-9274 is tolerated in pts with advanced solid malignancies. Anemia, arthralgias and myalgias are common AEs with one DLT (G4 anemia). PK is generally proportional and predictable.

375PD Phase I study of the checkpoint kinase 1 inhibitor GDC-0575 in combination with gemcitabine (gem) in patients (pts) with refractory solid tumors

A. Italiano[1], J.R. Infante[2], G. Shapiro[3], K.N. Moore[4], P. Lorusso[5], S. Postel-Vinay[6], S. Cousin[7], M. Toulmonde[7], C. Lucchesi[7], E. Blackwood[8], S. Mahrus[8], X. Lu[8], M. Tagen[8], J. Schutzman[8], J. Lauchle[8], J-C. Soria[9]

[1]Medicine, Institute Bergonié, Bordeaux, France, [2]Medical Oncology, Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN, USA, [3]Early Drug Development Center, Dana-Farber Cancer Institute, Boston, MA, USA, [4]Department of Obstetrics and Gynecology, University of Oklahoma Health Sciences Center, Oklahoma City, OK, USA, [5]Yale Cancer Center, Yale University, New Haven, CT, USA, [6]Départemement d'Innovation Thérapeutique et des Essais Précoces (DITEP), Institut Gustave Roussy, Villejuif, France, [7]Medical Oncology, Institute Bergonié, Bordeaux, France, [8]Early Clinical Development, Genentech Inc, South San Francisco, CA, USA, [9]Medical Oncology, Institut Gustave Roussy, Villejuif, France

Background: Checkpoint kinase 1 (Chk1) inhibition following chemotherapy overrides cell cycle arrest and induces mitotic catastrophe and cell death. GDC-0575 is a highly-selective oral small-molecule Chk1 inhibitor that results in tumor shrinkage and growth delay in xenograft models.

Methods: This Phase I trial enrolled pts with refractory solid tumors and ECOG 0-1 status. Patients received IV gem 1000 mg/m^2 followed ∼24 hours later by GDC-0575 (15-60 mg) PO, or IV gem 500 mg/m^2 followed ∼24 hours later by GDC-0575 (45-105 mg) PO, weekly for 2 of 3-week cycles. TP53 was evaluated in archival tumor tissue by gene sequencing. Safety, pharmacokinetics (PK), pharmacodynamics, and tumor response by RECIST v1.1 were investigated.

Results: Of 81 pts treated, 73% were female, the median age was 56 years (range 27-75), and 48% were ECOG PS 0. The most common tumor types were breast (46%), and soft tissue sarcoma and NSCLC (both 7%). Dose escalation was halted at GDC-0575 60 mg and 105 mg with gem 1000 mg/m^2 and gem 500 mg/m^2, respectively, as pts experienced Grade 4 thrombocytopenia and Grade 3-4 febrile neutropenia as dose-limiting toxicities. The most frequent adverse events (all grades) related to GDC-0575 and/or gem were neutropenia (80%), anemia (56%), fatigue (47%), nausea (46%), and thrombocytopenia (40%). Maximum concentrations of GDC-0575 were achieved within 2 hours of dosing, and its half-life was ∼23 hours. No PK drug-drug interaction was observed between GDC-0575 and gem. Among pts treated with GDC-0575 and gem 500 mg/m^2, there were 4 cPRs (2x sarcoma, NSCLC, TNBC) and 3 SDs (TNBC, NSCLC, SCLC) for $\geq$ 6 months. Exome sequencing data from tumor samples obtained at progression did not reveal mutations in Chk1 but identified mutations in genes known to regulate apoptosis.

Conclusions: The Chk1 inhibitor GDC-0575 can be safely combined with a standard or modified dose and schedule of gem. Hematological toxicities were frequent but manageable. Preliminary anti-tumor activity was observed in patients with a variety of refractory solid tumors treated with GDC-0575 in combination with gem 500 mg/m^2.

Clinical trial identification: NCT01564251

376P Preclinical evaluation of the anti-CLDN18.2 antibody, IMAB362, in pancreatic carcinoma

C. Heinz[1], R. Mitnacht-Kraus[1], M. Kreuzberg[1], S. Wöll[1], U. Sahin[2], Ö. Türeci[1]

[1]Ganymed Pharmaceuticals, AG, Mainz, Germany, [2]Translational Oncology, University Medical Center of the Johannes Gutenberg University Mainz, Mainz, Germany

Background: Claudin 18.2 (CLDN18.2) is a tight junction protein restricted to the gastric mucosa cells; however, in the context of malignant transformation CLDN18.2 can be found in tumors derived from organs that do not normally express CLDN18.2, such as the pancreas. IMAB362 is a first-in-development monoclonal antibody that specifically targets CLDN18.2-expressing tumor cells. The aims of this preclinical study were to examine CLDN18.2 expression in pancreatic cancer (PC) and to evaluate IMAB362 as a single agent or in combination with standard chemotherapy for the treatment of PC.

Methods: CLDN18.2 expression in normal and neoplastic pancreatic tissues from patients with PC was assessed by a validated, semi-quantitative, IHC assay. IMAB362 pharmacodynamics, including binding characteristics, antibody-dependent cellular cytotoxicity (ADCC), complement-dependent cytotoxicity (CDC), and IMAB362-induced antitumor activity, were assayed in vitro (human PC cell lines) and in vivo (PC xenograft mouse models).

Results: CLDN18.2 expression levels and patterns in normal and malignant pancreatic tissue were very different. Whereas CLDN18.2 was not observed in normal tissue, CLDN18.2 was expressed in about 50% of tested neoplastic pancreatic tissues and pre-malignant lesions. IMAB362 bound with high specificity and high affinity to CLDN18.2-positive (CLDN18.2$^+$) PC cells. IMAB362-induced efficient lysis of CLDN18.2$^+$ PC cells through ADCC. In vitro, pretreatment of human PC cells with chemotherapeutic agents resulted in CLDN18.2 stabilization and a higher epitope density, which led to an increase in IMAB362-induced ADCC. Repeated doses of IV IMAB362 in mice bearing CLDN18.2$^+$ PC xenografts resulted in slowed tumor growth and survival benefit. In vitro studies and animal data showed the antitumor activity of IMAB362 to be further augmented by pretreatment with gemcitabine and gemcitabine plus oxaliplatin.

Conclusions: In these preclinical studies, IMAB362 induced cell death in CLDN18.2$^+$ human PC cell lines and xenografted tumors, and demonstrated potential as a targeted treatment for PC, both as single agent and in combination with chemotherapy.

377P Preclinical characterization of IMAB362-vcMMAE, an anti-CLDN18.2 antibody–drug conjugate

M. Kreuzberg[1], R. Mitnacht-Kraus[1], U. Sahin[2], Ö. Türeci[1]

[1]Ganymed Pharmaceuticals, AG, Mainz, Germany, [2]Translational Oncology, University Medical Center of the Johannes Gutenberg University Mainz, Mainz, Germany

Background: Antibody–drug conjugates combine the specific targeting and antitumor activity of monoclonal antibodies with the potent cell killing activity of cytotoxic small molecule drugs. IMAB362 is a monoclonal antibody specific for the tight junction protein Claudin 18.2 (CLDN18.2). In normal tissue, CLDN18.2 is exclusively expressed in the gastric mucosa. In the context of malignant transformation, CLDN18.2 can be found in gastric tumors as well as tumors from organs that do not normally express CLDN18.2 (eg, pancreas). Preclinical characterization of IMAB362 conjugated to the antimitotic molecule, monomethyl auristatin E, with a valine–citrulline linker (IMAB362–vcMMAE) is presented here.

Methods: IMAB362–vcMMAE binding characteristics and internalization were assessed in CLDN18.2-expressing human cell lines. Cell viability and IMAB362–vcMMAE-mediated cytotoxic effects (direct and indirect [bystander]) were also assessed in CLDN18.2 in vitro models. Xenograft mouse models of pancreatic and gastric cancers were developed to assess the cytotoxic and antitumor effects of IMAB362–vcMMAE in vitro.

Results: IMAB362–vcMMAE showed a slightly decreased relative binding affinity on CLDN18.2-transfected cells and cells that endogenously express CLDN18.2 compared with unconjugated IMAB362. In cell lines that internalized IMAB362–vcMMAE, cell viability was reduced by 45–90%; EC_{50} negatively correlated with CLDN18.2 expression level, with the lowest EC_{50} being <30 ng/mL. By contrast, no reduction in cell viability occurred in cells without target expression. IMAB362–vcMMAE produced CLDN18.2-negative cell death via bystander effect in vitro (co-cultured tumor cells). In vivo, intravenous IMAB362–vcMMAE resulted in dose-dependent inhibition of tumor growth as well as prolonged survival in early and advanced tumors in both pancreatic and gastric cancer mouse models; significant antitumor activity was observed after a single 8 or 16 mg/kg IV bolus injection. No systemic or organ-specific IMAB362–vcMMAE-related toxicity was observed in the mice.

Conclusions: IMAB362–vcMMAE is a highly specific and potent antibody-drug conjugate against in vivo and in vitro models of gastric and pancreatic cancers.

378P Preclinical characterization of IMAB362 for the treatment of gastric carcinoma

R. Mitnacht-Kraus[1], M. Kreuzberg[1], M. Utsch[1], U. Sahin[2], Ö. Türeci[1]

[1]Ganymed Pharmaceuticals, AG, Mainz, Germany, [2]Translational Oncology, University Medical Center of the Johannes Gutenberg University Mainz, Mainz, Germany

Background: Monoclonal antibodies (mAbs) are a key component of cancer therapy. An ideal therapeutic mAb would selectively bind to cancer cells while avoiding binding to healthy tissue. In normal tissue, Claudin 18.2 (CLDN18.2) is expressed in gastric mucosal cell tight junctions, largely inaccessible to mAbs. Upon malignant transformation, perturbations in cell polarity lead to cell surface exposure of CLDN18.2 making it targetable by mAbs. This has driven the development of an anti-CLDN18.2 mAb, IMAB362, which specifically targets CLDN18.2-positive cancer cells while sparing normal tissue. The preclinical characterization of IMAB362 as a targeted therapy for gastric cancer (GC) is presented here.

Methods: CLDN18.2 expression was characterized in primary tumors and metastases (32 of which corresponded to primary tumors) from GC patients using a validated, semi-quantitative, IHC assay. IMAB362 binding characteristics and mechanism of action were assessed in vitro using CLDN18.2-expressing cell lines and in vivo in mouse tumor xenografts. Antitumor activity of IMAB362 was assessed in human GC cell line xenografts in mice treated with chemotherapy with/without IMAB362.

Results: In patient-derived GC tissue, CLDN18.2 was frequently (~80%) and robustly expressed in both primary and metastatic tumors. IMAB362 was highly selective for CLDN18.2 both in vivo and in vitro. IMAB362 mediated effective and target-selective antibody-dependent cellular cytotoxicity (ADCC) against GC cell lines with endogenous CLDN18.2 expression and induced complement-dependent cytotoxicity (CDC)-mediated lysis of CLDN18.2-expressing tumor cells. IMAB362-mediated ADCC and CDC were not affected by the presence of CLDN18.2-negative cancer cells. Treatment with chemotherapy sensitized tumor cell lines to IMAB362-mediated mechanisms by increasing CLDN18.2 expression; improved antitumor activity was observed in xenografted mice treated with IMAB362 + chemotherapy compared with mice treated with chemotherapy alone.

Conclusions: IMAB362 is a target-selective mAb with strong immune effector mediated antitumor activity (ADCC, CDC) that contributes to the elimination of CLDN18.2-expressing GC cells and synergizes with chemotherapy.

Background: Altered FGFR signaling is a potential target for anticancer therapy. Rogaratinib (BAY1163877) is an oral inhibitor of FGFRs 1-4. Screening for patients based on tumor FGFR1-3 mRNA overexpression, we reported in a phase I study that selected urothelial carcinoma patients were highly sensitive to rogaratinib treatment (NCT01976741; Joerger et al, ESMO 2016). Here we further identify patients sensitive to rogaratinib with malignancies not previously identified as being driven by FGFRs.

Methods: Subjects with treatment-refractory advanced or metastatic solid tumors were screened for high FGFR1-3 mRNA expression levels by RNA *in situ* hybridization (RNAscope®; Advanced Cell Diagnostics, Inc., Newark, CA) and Nanostring® assay (NanoString Technologies, Inc., Seattle, WA) from fresh or archival tumor specimens. FGFR-positive patients were treated with 800 mg BID on a continuous 21-day cycle. Responses were assessed by Response Evaluation Criteria in Solid Tumors (RECIST) version 1.1.

Results: More than 500 patient biopsies were screened for FGFR1-3 mRNA levels. Seventy two FGFR-positive patients were treated with rogaratinib, with 63 evaluable for response. Clinical responses were observed in tumor types not previously associated with FGFR alterations, including a partial remission (PR) in a patient with a FGFR1 mRNA-positive adenoid cystic carcinoma of the tongue and a PR in a FGFR3 mRNA-

positive head and neck squamous cell carcinoma patient. Long-lasting stable disease with tumor shrinkage was also seen in patients with a) FGFR3 mRNA-positive gastric cancer, b) FGFR3 mRNA-positive lung squamous cell carcinoma c) FGFR3 mRNA-positive lung adenocarcinoma, d) FGFR2 mRNA-positive breast cancer and e) FGFR1 mRNA-positive hemangioendothelioma with complete disappearance of edema over 18 months.

Conclusions: Patient selection for treatment with rogaratinib based on quantification of FGFR1-3 mRNA isoforms in all tumor types irrespective of underlying data on DNA alterations is feasible and yields clinically meaningful responses in tumor types not been previously associated with altered FGFR signaling.

380P A phase 1b study evaluating the safety and pharmacokinetics (PK) of regorafenib (REG) in combination with cetuximab (CTX) in patients with advanced solid tumors

C. Weekes[1], A.C. Lockhart[2], H-J. Lenz[3], J.J. Lee[4], A. Cleton[5], F. Huang[6], I. Sturm[7]

[1]Division of Hematology/Oncology, Massachusetts General Hospital, Boston, MA, USA, [2]Department of Medicine, University of Miami, Coral Gables, FL, USA, [3]Division of Medical Oncology, University of Southern California/Norris Comprehensive Cancer Center, Los Angeles, CA, USA, [4]Division of Hematology-Oncology, Department of Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA, USA, [5]Clinical Pharmacology Oncology, Bayer AG, Berlin, Germany, [6]Clinical Pharmacology Oncology, Bayer HealthCare Pharmaceuticals, Whippany, NJ, USA, [7]Translational Medicine Oncology, Bayer AG, Berlin, Germany

Background: Combining REG with CTX may overcome intrinsic and acquired resistance in EGFR-sensitive and -resistant tumors. We evaluated the safety, PK, maximum tolerated dose (MTD), and preliminary efficacy of REG plus standard dose of CTX (initial 400 mg/m^2 intravenously followed by 250 mg/m^2 weekly) in a phase 1b study. Final results from the intermittent REG dosing arm (3 weeks on/1 week off) are reported, with final results from the terminated continuous REG dosing arm (n = 11) previously presented (Weekes et al. AACR 2016, abstract CT148).

Methods: This was an open-label, dose-escalation (3 + 3 design) study in patients with locally advanced or metastatic solid tumors who progressed after standard therapy. The starting dose of REG was 120 mg once daily (QD) in a 28-day cycle (3 weeks on/1 week off) plus CTX. If tolerable, REG was escalated to 160 mg QD. If not tolerable, the REG dose was reduced to 80 mg QD. Dose-limiting toxicities (DLTs) were evaluated in Cycle 1. Adverse events (AEs) were graded according to NCI-CTCAE v4.03. Antitumor activity was assessed using RECIST v1.1.

Results: As of January 31, 2017, 31 patients received REG in an intermittent schedule plus CTX: 8 patients received REG 120 mg and 23 received REG 160 mg. One DLT of grade 3 hand–foot skin reaction was reported in 6 evaluable patients at the 120 mg dose level. No DLT was confirmed at the 160 mg dose level. The MTD was declared at the standard dose of REG 160 mg QD (3 weeks on/1 week off) plus the standard dose of CTX. The most common AEs, regardless of relationship to study drug, were hypophosphatemia (42%), fatigue (39%), and nausea (39%). The most common grade $\geq$3 REG-related AEs were hypophosphatemia (23%) and fatigue (10%). REG $AUC_{(0-tlast)}$ was 29.1 mg·h/L at 160 mg and 17.4 mg·h/L at 120 mg. CTX had no effect on the PK of REG. One patient (120 mg REG) had a partial response; 6 (160 mg REG; 29%) and 2 (120 mg REG; 25%) patients had stable disease.

Conclusions: REG at 160 mg QD (3 weeks on/1 week off) plus standard dose of CTX was tolerated with no unexpected toxicities. Observed AEs were in line with known REG and CTX safety profiles.

381P Clinical study of apatinib in the treatment of malignant pleural effusion and malignant celiac effusion

M. Xin

Radiotherapy Department, 4th Hospital Medical University, Shijiazhuang, China

Background: Malignant pleural effusion and malignant celiac effusion is a severe complication of the advanced malignant tumor, The formation of malignant pleural effusion and malignant celiac effusion relied on VEGF growth factor.Apatinib blocking vascular endothelial growth factor (VEGF) combining with the receptor and blocking signal transduction pathway, thereby inhibiting tumor and the formation of new blood vessels, inhibit the formation of the malignant pleural effusion and malignant celiac effusion. We conducted the study to exploring the single-agent oral path of Apatinib for the treatment of malignant pleural effusion and malignant celiac effusion of the clinical curative effect.

Methods: Patients were eligible for inclusion in the study if they had histologically confirmed malignancies, with malignant pleural effusion and malignant celiac effusion. Eastern Cooperative Oncology Group (ECOG) performance status of 0-2. Study Objective: Clinical curative effect. Study Design and Treatment: This study recruited 13 patients with histologically confirmed malignancies, and the patients with malignant pleural effusion and malignant celiac effusion from January 2016 to October 2016. All patients had an Eastern Cooperative Oncology Group (ECOG) performance status of 0-2. All patients were given the oral drug Apatinib, the doses of oral given is 500 mg or 425 mg everyday until progressive disease (PD) or intolerable toxicity. Assessment and Statistical analysis: The assessmet were determined according to the World Health Organization (WHO) criteria. The ORR and DCR analyses were based on frequencies.

Results:

Table: 381P Baseline patient characteristics

Characteristic Apatinib(n = 13)
Age(years)
Median(range) 58(44-84) Sex Male 7(53.85) Female 6(46.15) EGOG PS 0 2(15.38) 1 6(46.15) 2 5(38.46) Carcinoma Lung cancer 6(46.15) Pancreatic cancer 4(30.77) Breast cancer 2(15.38) Thymic cancer 1(7.7)
Efficacy: Apatinib is effective for the treatment of malignant pleural effusion and malignant celiac effusion: CR 5 cases, PR 5 cases, SD 3 cases, overall-response rate (ORR)76.92%, disease-control rate (DCR)100%.

Conclusions: Apatinib is a safe, feasible way in the treatment of malignant pleural effusion and malignant celiac effusion. Relying on the simple method and favourable rencent curative effect. Apatinib provides a new way for the treatment of malignant pleural effusion and malignant celiac effusion that deserves further research.

382P Evaluation of NRP-1 TM domain targeting peptide in melanoma

M. Pierdant, L. Aurore, V.D.H. Michael, D. Bagnard*U1109, Institut National de la Santé et de la Recherche Médicale (INSERM), Strasbourg, France*

Background: Membrane proteins and their interactions play central roles in a variety of cellular processes including nutrient uptake, signaling and cell-cell communication. Many cancers, neurological, metabolic and immune disorders can be attributed to the abnormal function of membrane proteins. All of these membrane proteins either contain one or several transmembrane (TM) strands and/or undergo some degree of oligomerization. Thus, stabilization or disruption of these protein-protein interactions is therefore of great interest for the modulation of protein function within the cell. In this context, TM domains of neuropilin-1 receptor (NRP1) and human epidermal growth factor receptor (HER2) are particularly studied in our laboratory to develop anti-cancer therapies based on the interference of the TM domains. Antitumor effects of TM peptides targeting NRP1 or HER2 has been proved in glioblastoma (Nasarre et al., 2010) and breast cancer (Arpel et al., 2016) respectively. In addition, HER2 has been proved to reduce metastasis in a metastatic model of breast cancer (Arpel et al., 2014). Moreover, NRP1 expression has been detected by immunostaining in tumor specimens obtained from patients with prostate, lung, pancreatic, colon carcinoma and melanoma.

Methods: In order to expand the therapeutic applications of these TM peptides, we evaluated its anti-tumoral activity in melanoma in an orthotopic allograft model in nude mice ($B_{16}F_{10}$ cell line).

Results: Our results show, that a local administration of MTP-NRP1 (1µg/kg, 3x/week) significantly reduces tumor development after 11 days of treatment. These results concur with the dT/dC% value at day 13 (18,3%) indicating that the treatment is efficiently impacting the tumor volume after this period. The application of the RECIST criteria identified 7.1% of mice presenting stable disease while 78,6% exhibited partial response. However 14.3% of mice were non responders to the treatment.

Conclusions: Hence, current work is conducted to analyze by gene array profiling the differences in NRP1 and other cancer promoting receptors between responder and non-responder populations. This is a prerequisite to decide whether MTP-NRP1 could be developed in this indication, particularly by associating it to another drug in the non-responding population.

383P A phase I dose-escalation study of the novel peptide ALM201 in patients (pts) with advanced solid tumours

A. El-Helali[1], R. Plummer[2], G. Jayson[3], V. Coyle[1], Y. Drew[2], N. Mescallado[4], N. Harris[2], A. Clamp[4], J. McCann[5], R. Kennedy[6], A. Cranston[7], R. Wilson[1]

[1]Medical Oncology, Centre for Cancer Research and Cell Biology, Belfast, UK, [2]Medical Oncology, Northern Institute for Cancer Research, Newcastle Upon Tyne, UK, [3]Division of Molecular & Clinical Cancer Sciences, The Christie NHS Foundation Trust, Manchester, UK, [4]Oncology, Institute of Cancer Sciences and Christie Hospital, Manchester, UK, [5]Patient Advocacy, Northern Ireland Cancer Research Consumers Forum, Belfast, UK, [6]Almac Diagnostics, Almac Diagnostics, Craigavon, UK, [7]Drug Discovery, Almac Discovery, Craigavon, UK

Background: ALM201 is a novel 23-amino acid peptide derived from FKPB-L, a human endogenous protein with inherent anti-angiogenic activity. Pre-clinically, ALM201 potently inhibits cell migration, invasion and neo-vessel formation without effects on cell cycle or proliferation.

Methods: We enrolled pts with solid tumours using a single patient (10 - 40mg) then 3 + 3 (80 - 300mg) dose escalation design. ALM201 was administered subcutaneously (S.C.) once daily on days 1-5, 8-12, and 15-19 every 21 days. All pts continued until disease progression (PD) or dose-limiting toxicity (DLT). Primary objectives were to determine the safety, tolerability and recommended phase II dose (RP2D) of ALM201. Secondary objectives were to determine the pharmacokinetics (PK) and anti-tumour activity. Plasma and urine samples were analysed by a validated LC-MS/MS method.

Results: We report interim data in 18 evaluable pts enrolled in 8 dose levels. Cancers included ovarian (5), colorectal (4), NSCLC (2), endometrial (1), gallbladder (1), cervical (1), urachal (1), renal (1), pancreatic (1) and mesothelioma (1). Doses of 10 - 300mg were well tolerated. No DLTs were observed. The only toxicity was grade 1 injection site skin reaction. Median treatment duration was 11.1 weeks (range 3-18 wks). Two patients had stable disease for up to 6 cycles prior to progression. Maximal plasma concentrations were typically observed 1.5h (0.75-4h) after dosing indicating fairly rapid absorption. Above 40mg, plasma concentrations were consistently seen up to 6h after dosing (assay LLOQ = 100ng/mL). Where the terminal phase could be defined, half-lives <2h were reported (0.9-1.8h, n = 4 pts). Plasma C_{max} and AUC tended to increase with dose; with no evidence of dose non-proportionality between 10 - 160mg and lower than proportional increases in exposure observed above 160mg. No evidence of drug accumulation was observed over successive dose cycles. No unchanged parent drug was detectable in patient urine in the 0-6h collection phase after dosing.

Conclusions: Monotherapy ALM201 administered S.C. demonstrated a very good safety profile and acceptable PK in patients with advanced solid tumors. The RP2D analysis is currently ongoing.

Clinical trial identification: EudraCT No: 2014-001175-31

385P Interim pharmacokinetic (PK) and pharmacodynamic (PD) data from the first-in-human study of NUC-3373, a pyrimidine nucleotide analogue, in patients with advanced solid tumors

E. Ghazaly[1], V.K. Woodcock[2], P. Spilipoulou[3], L. Spiers[2], J. Moschandreas[4], L. Griffiths[2], C. Gnanaranjan[1], D.J. Harrison[5], T.R.J. Evans[3], S.P. Blagden[2]

[1]Centre for Haemato-Oncology, Barts Cancer Institute, London, UK, [2]Early Phase Clinical Trials Unit, Churchill Hospital University of Oxford NHS Trust, Oxford, UK, [3]University of Glasgow, Beatson Institute for Cancer Research, Glasgow, UK, [4]Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, Oxford, UK, [5]School of Medicine, University of St. Andrews, Fife, UK

Background: NUC-3373, a phosphoramidate transformation of FUDR, is designed to bypass 5-FU and capecitabine resistance. Intracellular levels of the active 5-FU metabolite FUDR-MP in vitro were 363x higher than with 5-FU. Here, we report the interim PK and PD data from the ongoing first-in-human dose-escalation study of NUC-3373 in patients (pts) with advanced solid tumors (NuTide:301).

Methods: NUC-3373 was administered as 30- min IV infusion on days 1, 8, 15 and 22 of a 28-day cycle. The first 3 pt cohorts received NUC-3373 at 125mg/m^2, 250mg/m^2 and 500mg/m^2. The primary objective was to determine RP2D. Secondary objectives included safety, PK and PD profiles, and anti-tumour activity. Blood samples were collected pre-dose and at 11 time-points up to 48h post-dose during cycle 1. Plasma and intracellular metabolites were measured by UPLC-MS/MS; western blotting of extracted PBMCs measured thymidylate synthase (TS) within ternary complexes (TS-T).

Results: PK/PD analyses were conducted on 16 of the 17 pts recruited to the first 3 dosing cohorts pts (94%), median age 59 yrs (range 24-71), with 7 cancer types, the majority (76%) being colorectal cancer. Mean plasma Cmax and AUC of NUC-3373 were dose proportional. Linear PK was confirmed across the studied dose range with clearance of 3.4 ± 0.6 L/hr and plasma $t_{1/2}$ of 9.4h ±0.98h. Intracellular FUDR-MP was detectable at 5 minutes post-infusion with $t_{1/2}$ of 14.3h ±1.7h and was still present at 48h. In the 500mg/m^2 cohort the mean intracellular Cmax and AUC_{0-24} of FUDR-MP were 4.2pmol/10^6 cells and 16.5pmol/10^6 cells/hr. Within 1 hour of infusion, FUDR-MP was present within TS-T leading to depletion of the intracellular dTMP pool after 2-4h. Toxic metabolites FBAL and FUTP were undetectable intracellularly or in plasma. Dose escalation continues.

Conclusions: PK/PD data demonstrate NUC-3373 generates high intracellular concentrations of the active cytotoxic metabolite FUDR-MP, which efficiently sequester TS into TS-T inhibiting its activity. This and lack of toxic metabolite accumulation indicate NUC-3373 has a favorable PK profile compared to the established fluoropyrimidines.

Background: A high level of microsatellite instability (MSI-H) is indicative of a tumor deficient in mismatch repair (dMMR). Prior reports suggest that anti-PD-1 antibody therapy provides durable responses in patients (pts) with MSI-H cancers. Here we assessed efficacy of PD-1 blockade using pembrolizumab in pts with dMMR/MSI-H (hereafter termed MSI-H) advanced cancer enrolled in two ongoing, global, multicenter phase 2 studies KEYNOTE (KN)164 and KN158. We report results in 61 pts with MSI-H CRC and 77 pts with MSI-H non-CRC across 20 tumor types.

Methods: KN164 enrolled pts with MSI-H colorectal cancer (CRC) and ≥2 prior therapies, whereas the multicohort KN158 study included pts with MSI-H non-CRC and ≥1 prior therapy. MSI-H status was determined locally by IHC or PCR or centrally by PCR. Eligible pts in both studies received pembrolizumab 200 mg Q3W. Tumor response was assessed every 9 wk. Primary endpoint was ORR by independent central review per RECIST v1.1. Database cut-off date was Feb 10, 2017 for KN164 (≥54 wk follow-up) and Jan 27, 2017 for KN158 (≥27 wk follow-up).

Results: KN164 enrolled 61 pts with MSI-H CRC (90% with ≥2 prior therapies) and KN158 enrolled 77 pts with MSI-H non-CRC (52% with ≥2 prior therapies), at data cutoff. Tumor types represented in KN158 in at least 2 pts included endometrial (n = 17), gastric (n = 11), small intestinal (n = 10), pancreatic (n = 9), biliary (n = 8), mesothelioma and small cell lung (n = 3 each), adrenocortical, bladder, and thyroid (n = 2 each) cancers. ORR was 27.9% (n = 17 [all confirmed]; 95% CI 17.1%-40.8%) for MSI-H CRC and 37.7% (n = 29 [23 confirmed and 6 unconfirmed]; 95% CI 26.9%-49.4%) for MSI-H non-CRC. Median DOR was not reached for MSI-H CRC (range 2.9+ to 12.5+) or MSI-H non-CRC (range 2.4+ to 9.2+). Median OS was not reached for either MSI-H CRC or MSI-H non-CRC, with 6-mo OS rates of 87% and 73%, respectively.

6-mo PFS rates were 43% for MSI-H CRC and 45% for MSI-H non-CRC. 4 (7%) pts with MSI-H CRC and 7 (9%) with MSI-H non-CRC had serious drug-related AEs. The safety profile was consistent with that previously seen for pembrolizumab.

Conclusions: Pembrolizumab provides robust antitumor activity with durable responses in heavily pretreated pts with MSI-H cancers.

Ltd, Beijing, China, [12]Clinical Development, BeiGene (Beijing) Co. Ltd, Beijing, China, [13]Internal Medicine, Auckland City Hospital, Auckland, New Zealand

Background: BGB-A317 is a humanized IgG4 anti-PD-1 mAb that blocks PD-L1/L2 binding to PD-1 restoring T-cell-mediated tumor inhibition. The Fc-hinge region has been engineered to preclude FcγR1-mediated binding to macrophages/myeloid-derived suppressor cells (MDSCs). Upregulation of PD-1/L1 and predominance of macrophages and MDSCs have been reported in GC and EC supporting the rationale of evaluating BGB-A317 in pts with GC or EC.

Methods: This ongoing, open-label, dose-escalation/expansion study is being conducted to evaluate the safety, tolerability and anti-tumor activity of BGB-A317 in pts with advanced solid tumors. Pts with histologically confirmed advanced GC or EC were eligible and treated with BGB-A317 at 2 mg/kg or 5 mg/kg every two weeks (Q2W) or Q3W. Adverse events (AEs) were assessed per NCI-CTCAE v4.03 and tumor assessments were performed approximately every two months via RECIST v1.1.

Results: As of 6 MAR 2017, 55 pts [median age 62 yrs (22-81)] with recurrent/refractory GC (n = 28) or EC (n = 27) were treated. Most were Caucasian (n = 36) and all pts had received ≥1 prior line of anti-cancer treatment. Median treatment duration was 51 days (5–363); 19 pts remain on study. The most common treatment-emergent AEs were fatigue (n = 11), nausea (n = 9) and dysphagia (n = 8); 46% pts experienced AEs ≥Grade (Gr) 3 but none were treatment related. One serious AE (diarrhea [Gr 2]) was considered related to treatment by investigators. Of the 47 evaluable pts, the disease control rate, defined as the proportion of pts who achieved complete or partial response (CR or PR) or stable disease (SD), is 32%. PRs have been reported in 3 pts (GC = 2; EC = 1) with duration of responses being 96, 125 and 188 days respectively, 2 pts are still on treatment; 5 initial documentations of PRs awaiting confirmation (GC, n = 2; EC, n = 3) have been reported in 12 pts with SD (GC = 5; EC = 7).

Conclusions: BGB-A317 appears to be generally well tolerated in pts with recurrent/refractory GC or EC. The preliminary safety profile and anti-tumor activity appear to be consistent with other checkpoint inhibitors and support continued exploration and development of BGB-A317 in pts with advanced GC or EC.

388P Preliminary results from a subset of patients (pts) with advanced head and neck squamous carcinoma (HNSCC) in a dose-escalation and dose-expansion study of BGB-A317, an anti-PD-1 monoclonal antibody (mAb)

L. Horvath[1], J. Desai[2], S. Sandhu[3], A. O'Donnell[4], A.G. Hill[5], S. Deva[6], B. Markman[7], M.B. Jameson[8], Z. Chen[9], X. Tan[9], J. Hou[10], A. Lim[11]

[1]Medical Oncology, Chris O'Brien Lifehouse, Camperdown, Australia, [2]Medical Oncology, Peter MacCallum Cancer Centre, Melbourne, Australia, [3]Department of Oncology, Peter MacCallum Cancer Center, Melbourne, Australia, [4]Endocrine, Diabetes & Research Centre, Wellington Hospital, Wellington, New Zealand, [5]Medical Oncology, Tasman Oncology Research, Southport, Australia, [6]Internal Medicine, Auckland City Hospital, Auckland, New Zealand, [7]Department of Oncology, Monash Cancer Center, Monash Health, Melbourne, Australia, [8]Regional Cancer Center, Waikato Hospital, Hamilton, New Zealand, [9]Oncology, BeiGene (Beijing) Co. Ltd, Beijing, China, [10]Immunoncology, BeiGene USA, Inc, Emeryville, CA, USA, [11]Oncology, Linear Clinical Research, Nedlands, Australia

Background: BGB-A317 is a humanized IgG4 anti-PD-1 mAb that blocks PD-L1/PD-L2 binding to PD-1 restoring T-cell mediated tumor response. The Fc-hinge region has been engineered to preclude FcγR1 mediated binding to macrophages/myeloid-derived suppressor cells, a potential mechanism of PD-1 bound T-cell clearance. Regulatory $Foxp3^+$ T-cells and PD-1^+T-cell infiltration in the tumor microenvironment have been reported in HNSCC supporting the rationale for evaluation of BGB-A317 in pts with HNSCC. Here we present the preliminary results from a subset of pts with HNSCC treated with BGB-A317.

Methods: This ph 1, open-label, multi-center, dose-escalation/expansion study was conducted to evaluate the safety, tolerability, and anti-tumor activity of BGB-A317 in pts with advanced solid tumors. Pts with histologically confirmed advanced HNSCC who progressed following standard of care treatment were eligible to receive BGB-A317 administered at a dose of 5 mg/kg Q3W. Adverse events (AEs) were assessed per NCI-CTCAE v4.03. Tumor assessments were performed Q9W per RECIST v1.1.

Results: As of 6 Mar 2017, 18 pts with recurrent HNSCC were enrolled (median age, 63 years [25-78]). Most pts were male (89%), Caucasian (67%) and had received ≥2 prior lines of anti-cancer treatment. The median treatment duration for BGB-A316 was 104 days (30-245); 7 pts remain on study. Most treatment-emergent AEs were Grade (Gr) 1/2 in severity and the more common AEs were fatigue (n = 6), constipation (n = 3) and ear discomfort (n = 3). Eleven unique AEs ≥Gr 3 were reported in 7 pts: dysphagia, nausea salivary gland enlargement, dyspnea, pleuritic pain, aspiration pneumonia,

infection-related COPD exacerbation, parotitis, ocular hyperemia, and wound hemorrhage. A partial response (PR) has been confirmed in 1 pt, and 8 pts have stable disease (SD,) including 2 unconfirmed PRs. The disease control rate, defined as the proportion of pts who have achieved CR, PR and SD, is 50%.

Conclusions: BGB-A317 appears to be well tolerated in pts with recurrent HNSCC. The preliminary safety profile and anti-tumor activity support continued investigation of BGB-A317 in this setting.

Ltd, Beijing, China, [12]Clinical Development, BeiGene (Beijing) Co. Ltd, Beijing, China, [13]Department of Oncology, Monash Cancer Center, Monash Health, Melbourne, Australia

Background: BGB-A317 is a humanized IgG4 anti-PD-1 mAb that blocks PD-L1/L2 binding to PD-1 restoring T-cell-mediated tumor inhibition. The Fc-hinge region has been engineered to preclude FcγR1 mediated binding to macrophages/myeloid-derived suppressor cells (MDSCs). Upregulation of PD-1/L1 and predominance of macrophages and MDSCs have been reported in OC supporting the rationale of evaluating BGB-A317 in pts with OC.

Methods: An open-label, multi-center, dose-escalation/expansion study is being conducted to evaluate the safety, tolerability and anti-tumor activity of BGB-A317 in pts with advanced solid tumors. Pts with histologically confirmed advanced OC were eligible and treated at different dose levels (0.5, 2, 5, 10 mg/kg intravenously [IV] every 2 weeks [Q2W] in dose escalation, or at 2 or 5 mg/kg IV Q2W or Q3W, or 200 mg IV Q3W in dose expansion, or 5 mg/kg IV Q3W in indication expansion). Tumor assessments, including CA125, occurred approximately every 2 months and response was collected according to both RECIST 1.1 and GCIG criteria. Adverse events (AEs) were assessed per NCI-CTCAE v4.03.

Results: As of 6 Mar 2017, 51 pts [median age 62 (19–80) yrs] with recurrent/refractory OC were enrolled. Most pts were Caucasian (88%), all had received ≥1 prior line of anti-cancer treatment (median 3 [1–12]). Median duration of treatment was 68 (22–446) days; 7 pts remain on study. The most common treatment-emergent AEs were nausea (37%), fatigue (28%), and abdominal pain (28%). 49% of pts experienced an AE ≥Grade (Gr) 3; stomatitis (n = 1) and diarrhoea (n = 1) were Gr 3 AEs considered treatment-related by investigators. Mucosal inflammation, pyrexia and colitis were serious AEs considered treatment-related by investigators (n = 1, each). Among 51 evaluable pts, the disease control rate is 43%; 2 PRs have been reported including 1 pt who remains on study and to date has achieved an 89% reduction in target lesions.

Conclusions: BGB-A317 appears to be generally well tolerated in pts with recurrent/refractory OC. The preliminary safety profile and anti-tumor activity are consistent with that observed with other checkpoint inhibitors and support continued investigation of BGB-A317.

390P A phase I study of durvalumab (D) in combination with olaparib (O) and cediranib (C) in recurrent women's cancers

A. Zimmer[1], C. Peer[2], L. Cao[2], E. Kohn[2], S. Lipkowitz[3], C. Annunziata[3], J. Trepel[2], M-J. Lee[2], L. Mikkilineni[2], M. Gatti-Mays[2], A. Nunes[2], S. Soltani[2], W.D. Figg[2], N. Houston[3], E. Nichols[3], J-M. Lee[3]

[1]Women's Malignancies Branch, National Cancer Institute National Institutes of Health, Bethesda, MD, USA, [2]Center for Cancer Research, National Cancer Institute National Institutes of Health, Bethesda, MD, USA, [3]Women's Malignancies Branch, National Institutes of Health, Bethesda, MD, USA

Background: Recent data showed a PARP inhibitor, O and a VEGFR1-3 inhibitor, C together are clinically superior to O alone in recurrent platinum-sensitive ovarian cancer (OvCa). We hypothesized reduced VEGF signaling by C and DNA damage by O may complement anti-tumor activity of immune checkpoint blockade, D. We previously reported the safety data and RP2D of D in combination with O or C. We now report RP2D and PK/PD data of the D+O+C therapy (NCT02484404).

Methods: Eligible patients (pts) with PS 0-1 and good end organ function received D+O+C in a 3 + 3 design. An intermittent C schedule (C; 5 days on/2 days off) at 15 or 20 mg (dose level: 1, 2) was combined with D 1500 mg IV q28 days, and O tablets 300 mg BID. The DLT period was one 28d cycle. Safety was assessed by CTCAEv4.0 and response by RECISTv1.1. Plasma samples were collected for O and C PK analysis and for pro-inflammatory cytokines (IFN-γ, IL-10, IL-12, IL-2, IL-6, IL-8 and TNF-a) pre-treatment and on therapy (cycle 1 day 15 and cycle 3 day 1).

Results: Nine women (median age 59yr [44-73], and median 3 prior therapies [2-6]) were treated. Of the 9 pts, 7 had OvCa, 1 endometrial (EnCa) and 1 triple negative breast Ca. Grade 3/4 AEs include hypertension (1/9), anemia (1/9) and lymphopenia (3/9). No pts experienced DLTs. One patient required dose reduction during cycle 5, for grade 3 anemia. Three PRs were observed in 2 OvCa and 1 EnCa (response rate of 33%, median 5 months [4^+-6^+]), and 4 had SD (median 5 months [3^+-10^+]), yielding 78% disease control rate. There were no significant changes in O and C PK parameters caused by D and the co-administration of C or O. All cytokines plasma levels were not changed significantly by the treatment. PD-L1 expression by IHC and immune subsets by flow cytometry are under analysis.

Conclusions: The RP2D for D+O+C (D 1500 mg q28d+O 300 mg tablets BID+C 20 mg 5 days on/2 days off) is tolerable and active in recurrent women's cancers. A phase II expansion study of D+O+C is to open in OvCa.

391P Phase I expansion of olaparib (PARP inhibitor) and AZD5363 (AKT inhibitor) in recurrent ovarian, endometrial and triple negative breast cancer

S. Westin[1], J. Litton[2], R. Williams[1], P. Soliman[1], M. Frumovitz[1], K. Schmeler[1], A. Jazaeri[1], A. Sood[1], K. Lu[1], S. Moulder[3], R. Murthy[2], A. Rodriguez[1], C. Samuel[2], L. Engerman[1], A. Cyriac[1], P. Rugman[4], J. Lindemann[5], E. McMurtry[6], G. Mills[7], R. Coleman[1]

[1]Gynecologic Oncology, MD Anderson Cancer Center, Houston, TX, USA, [2]Breast Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [3]Breast Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA, [4]AstraZeneca, Cambridge, UK, [5]AstraZeneca, Melbourn, UK, [6]AstraZeneca, Macclesfield, UK, [7]Systems Biology, MD Anderson Cancer Center, Houston, TX, USA

Background: We sought to confirm the recommended phase II dose (RP2D) of the combination of olaparib and AZD5363 in women's cancers and evaluate molecular markers of response and resistance.

Methods: Olaparib tablet formulation (O) was given orally BID, AZD5363 (A) was given orally on a 4 day on/3 day off schedule. Two dose levels were planned per the ComPAKT study (Yap AACR 2015). Responses were defined using RECIST 1.1.

Patients had biopsies at baseline and after 28 days of treatment for planned correlative testing.

Results: To date, 38 patients (pts) have been enrolled. Median number of prior therapies was 4 (1-8). Only 7 (18%, 5 ovarian, 2 breast) pts had known germline BRCA mutation. The first two pts on DL1 (O 300mg; A 400mg) experienced DLTs of diarrhea and vomiting. Therefore, 6 pts were treated on DL-1 (O 300mg; A 320mg). There were no DLTs on DL-1, therefore, 6 additional pts were treated on DL1. There were no DLTs on re-explored DL1. DL1 was confirmed as the RP2D. Expansion phase was performed with an additional 24 pts. Most common adverse events (≥15%) were anemia (89%, G3/4 16%), nausea (76%, G3/4 5%), diarrhea (74%, G3/4 5%), leukopenia (61%, G3/4 11%), elevated creatinine (58%, G3/4 3%), hyperglycemia (42%, G3/4 0%), fatigue (42%, G3/4 0%),vomiting (39%, G3/4 5%), anorexia (32%, G3/4 0%), mucositis (26%, G3/4 0%), hypertriglyceridemia (18%, G3/4 0%), thrombocytopenia (18%, G3/4 0%), neutropenia (18%, G3/4 10%), hypercholesterolemia (18%, G3/4 0%), hyponatremia (16%, G3/4 5%) and constipation (16%, G3/4 0%). Of 30 pts evaluable for response, overall response rate (RR) was 24%. Seven had confirmed partial response including 1 ovarian, 4 endometrial and 2 triple negative breast cancer pts. RR among endometrial cancer pts was 50% (4/8). Six additional pts had stable disease for greater than 4 months including 4 ovarian and 1 endometrial cancer pts. Assessment of molecular correlatives of response and resistance are ongoing.

Conclusions: The combination of olaparib tablet formulation and AZD5363 is well tolerated at the confirmed RP2D and demonstrates preliminary evidence of durable tumor activity in ovarian, endometrial and triple negative breast cancer. Promising response was seen in the endometrial cancer cohort.

392P Generation of a novel preclinical PK/PD model provides insights into PARP inhibitor clinical monotherapy activity

M. O'Connor, E. Cadogan, E. Leo, A. Hughes, M. Learoyd, H. Xu, J. Li, J. Yates

Innovative Medicines and Early Clinical Development, AstraZeneca, Cambridge, UK

Background: In Phase II trials, an olaparib capsule dose that inhibits PARP (100 mg bd) was clinically inferior to the MTD (400 mg bd). Using an in vivo model, we investigated this discrepancy and the effect of dose and schedule on tumour progression.

Methods: PK, PD and antitumour activity were assessed using olaparib (100, 50, 25, 10, 2.5 mg/kg qd) in a breast cancer patient-derived xenograft (PDX) with mutated BRCA2 and TP53. We studied the relationship between PARP1 inhibition and DNA single-strand breaks (SSBs) by creating a mathematical model. We also compared PK/PD model parameters with free minimum olaparib steady-state plasma concentration ($C_{min,ss}$) in seven Phase I–III clinical studies.

Results: Only 100 and 50 mg/kg olaparib doses caused tumour regression, yet all but the lowest led to acute PAR inhibition. The differentiating factor was time over PAR IC_{95}; simulations using the mathematical model at steady state predicted a threshold where >95% reduction in PAR caused >20-fold increase in DNA SSBs. Overlaying clinical data, we saw that 400 mg bd capsule and 300 mg bd tablet doses provide continuous PAR inhibition ($C_{min,ss}$>IC_{95} upper confidence level); 100 mg bd capsule does not. Dosing schedule assessment showed PDX regression with continuous 100 mg/kg olaparib (0/10 tumours progressed by day 100). By contrast, continuous dosing at 50 mg/kg or intermittent dosing (1 wk on/1 wk off) at 100 mg/kg resulted in 2/10 and 10/10 progressions, respectively. Treatment withdrawal upon regression led to regrowth in all cases; re-challenge at continuous 100 mg/kg was effective (9/10 regressions), 50 mg/kg was not (0/10). In a maintenance setting, switching to lower or intermittent dosing resulted in tumour response more similar to that of continuous 100 mg/kg (1/10, 2/10 and 0/10 progressions, respectively).

Conclusions: Discrepancy between biologically and clinically effective olaparib doses is explained by a need for continuous >95% PAR inhibition. Both the 400 mg bd capsule and 300 mg bd tablet dose, used in the ongoing clinical programme, provide this. Dosing schedule data suggest continuous PAR inhibition is also needed for long-term responses. These data highlight important principles for treatment of patients with PARP inhibitor monotherapy.

393P Pharmacodynamic (PD) biomarkers for the p70S6K/Akt inhibitor, M2698: Translation from animal to human and relevance to dose selection

W. Xiong[1], H. Tian[2], A. Clark[2], J. Shaw[2], R. Kaleta[3], I. Celik[4], P. Girard[2]

[1]Merck Institute for Pharmacometrics, Merck Serono S.A., Lausanne, Switzerland, [2]Global Early Development, EMD Serono Research and Development Institute, Billerica, MA, USA, [3]Clinical Oncology, EMD Serono Inc., Billerica, MA, USA, [4]Global Research and Development, Merck KGaA, Darmstadt, Germany

Background: M2698 is an oral, potent and selective inhibitor of p70S6K/Akt1/3 in the PAM pathway with the potential to block signaling from the Akt feedback loop and overcome tumor resistance. Preclinical studies suggest a steep exposure – adverse event relationship. Therefore, insights into drug-dependent target modulation (S6 phosphorylation (pS6) inhibition) and its association with efficacy could inform dose selection.

Methods: Pharmacokinetic (PK) data from the phase I, first-in-human (FIH) dose escalation trial conducted in patients with advanced cancer who received daily (d) oral M2698 (15-320mg/d) were evaluated by nonlinear, mixed effect modeling. Using a PK/PD model developed with data from a breast tumor cell line derived xenograft (CLDX) in mice, tumor pS6 time profiles in humans were simulated using a mouse PD model driven by human PK. Model predictions were calibrated by comparing simulations to clinical observations, with an assumed variation in sensitivity (IC_{50}) to pS6 between CLDX and human tumors. Predicted pS6 time profiles and clinically observed pS6 inhibition in human tumors and peripheral blood mononuclear cells (PBMC) informed the dose escalation decision in the FIH study.

Results: M2698 PK profiles were best described by a two-compartment linear model with transit compartments for delayed absorption. Consistent exposure-dependent effects of pS6 inhibition in PBMCs were observed at 160-320 mg/d, with 70-80% pS6 inhibition observed in some tumors. Based on predicted pS6 inhibition, CLDX tumors were 2-3x more sensitive than human tumors. Applying a 2-3x higher IC_{50}, simulations suggested that 250-350mg/d would achieve the PD threshold of continuous tumor pS6 inhibition ≥ 80% in 90% of a human population, leading to escalation to 380mg/d.

Conclusions: Understanding inter-species variation can improve the precision of preclinical-to-clinical translation. For M2698, preliminary clinical PD data showed that human tumors were 2-3x less sensitive to pS6 inhibition than CLDX tumors in mice. Collective PMBC and tumor PD outcomes suggest that 160 -320 mg/d M2698 may result in considerable pS6 inhibition; a range for selection of a phase 2 dose.

394P Phase 1 study of ipatasertib (AKT inhibitor) for investigating safety, tolerability, pharmacokinetics (PK), efficacy, and biomarkers in Japanese patients (pts) with solid tumors including castration-resistant prostate cancer (CRPC)

S. Takahashi[1], Y. Fujiwara[2], N. Matsubara[3], J. Tomomatsu[1], S. Iwasa[2], A. Yamasaki[4], C. Endo[5], S. Yokoyama[4], T. Doi[6]

[1]Department of Medical Oncology, The Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, Japan, [2]Department of Experimental Therapeutics, National Cancer Center Hospital, Tokyo, Japan, [3]Division of Breast and Medical Oncology, National Cancer Center Hospital East, Kashiwa, Japan, [4]Clinical Development Div., Chugai Pharmaceutical Co., LTD., Tokyo, Japan, [5]Translational Clinical Research Div., Chugai Pharmaceutical Co., LTD., Tokyo, Japan, [6]Department of Experimental Therapeutics, National Cancer Center Hospital East, Kashiwa, Japan

Background: Ipatasertib is a highly selective small-molecule inhibitor of AKT showing antitumor activity. Clinical efficacy and safety in non-Japanese pts with metastatic

CRPC has been reported (ASCO, ESMO 2016). We investigated safety, tolerability, PK, efficacy, and biomarkers in Japanese pts.

Methods: Phase 1, open label, dose-escalation study; 3 + 3 design. Primary endpoints were safety, tolerability, and PK. In Stage 1, pts with solid tumors were administered 200, 400, or 600 mg ipatasertib PO daily for 21 days of a 28-day cycle. In Stage 2, pts with CRPC were administered ipatasertib (200 or 400 mg PO daily) in combination with abiraterone acetate (AA) (1000 mg PO daily) plus prednisolone (5 mg PO twice a day) for the whole 28-day cycle. In an exploratory analysis of biomarkers, we investigated the relationship between PI3K pathway alterations (PIK3CA mutation or amplification and PTEN loss) and clinical efficacy of ipatasertib.

Results: A total of 21 pts were enrolled. Stage 1: 3, 4, and 8 pts were enrolled in the 200, 400, and 600 mg cohorts. One pt in the 600 mg cohort experienced DLT [Gr3 nausea]. The most common AEs of any grade (≥30% of pts) were nausea, diarrhea, decreased appetite, vomiting, and fatigue. C_{max} and AUC of ipatasertib were dose-proportional from 200 to 600 mg. Eight pts had stable disease (SD); 2 of those 8 pts continued study treatment beyond 4 months. Stage 2: 3 pts each were enrolled in the 200 and 400 mg cohorts. No DLTs were observed. The most common AEs of any grade were nausea, diarrhea, vomiting, diabetes mellitus, dysgeusia, and dizziness. Ipatasertib C_{max} and AUC were similar to those in monotherapy. Of the 6 pts, complete response was observed in 1 pt and SD was observed in 1 pt. Three pts continued study treatment beyond 4 months; 2 of those 3 pts had previously received AA and enzalutamide. Biomarker results will be presented.

Conclusions: Ipatasertib was well tolerable for Japanese pts. Based on our results, the recommended doses of ipatasertib for further development are 600 mg for monotherapy and 400 mg for in combination with AA plus prednisolone.

395P DS-1205b, a novel, selective, small-molecule inhibitor of AXL, delays the onset of resistance and overcomes acquired resistance to EGFR-TKIs in a human EGFR-mutant NSCLC (T790M-negative) xenograft model

T. Jimbo[1], T. Taira[1], T. Komatsu[1], K. Kumazawa[2], N. Maeda[1], N. Haginoya[1], T. Suzuki[3], M. Ota[4], Y. Totoki[5], C. Wada[5], K. Inaki[5], T. Isoyama[1], M. Uno[1]

[1]Oncology Function, Daiichi Sankyo Co., LTD, Tokyo, Japan, [2]Quality & Safety Management Division, Daiichi Sankyo Co., LTD, Tokyo, Japan, [3]Biologics Division, Daiichi Sankyo Co., LTD, Tokyo, Japan, [4]Research Management Department, Daiichi Sankyo RD Novare Co., LTD, Tokyo, Japan, [5]Discovery Science and Technology Department, Daiichi Sankyo RD Novare Co., LTD, Tokyo, Japan

Background: AXL is a receptor tyrosine kinase that plays an important role in signal transduction in normal and malignant cells. Abnormal expression and/or activation of AXL can provide a survival advantage for certain cancer cells, and AXL up-regulation is associated with poor prognosis in several cancers. Recently, it has been reported that up-regulation of AXL expression is a mechanism of EGFR-TKI resistance in EGFR-mutant non-small cell lung cancer.

Methods: Kinase activity was measured by mobility shift assay. The inhibition of hGAS6-induced migration was measured in AXL-transfected NIH3T3 (NIH3T3-AXL) cells. The in vivo anti-tumor effects of DS-1205b mono- and combination-therapy with EGFR-TKI were evaluated in NIH3T3-AXL allograft and HCC827 xenograft models. Protein expression was analyzed by Western blot or immunohistochemistry and gene expression was analyzed by RT-PCR or RNA seq.

Results: We found that DS-1205b selectively inhibited AXL kinase activity with IC_{50} of 1.3 nM, and with NIH3T3-AXL cells, DS-1205b potently inhibited the hGAS6-induced migration in vitro with EC_{50} of 2.7 nM. DS-1205b monotherapy exerted significant antitumor activity in an NIH3T3-AXL allograft model. In an HCC827 xenograft model, combination treatment with DS-1205b and osimertinib significantly delayed on the onset of tumor resistance compared to osimertinib alone in a manner proportional to DS-1205b does. DS-1205b also showed a similar resistance delay effect with erlotinib combination in the same xenograft model. AXL up-regulation was associated with the development of resistance to erlotinib treatment in another HCC827 xenograft study, and DS-1205b restored the antitumor activity of erlotinib in erlotinib-resistant tumors in a dose-dependent manner.

Conclusions: In an HCC827 xenograft model of EGFR-mutant NSCLC, inhibition of AXL activity by DS-1205b restored sensitivity to erlotinib, and addition of DS-1205b to osimertinib delayed the onset of resistance to osimertinib. These findings support further non-clinical and clinical studies targeting inhibition of AXL in EGFRm NSCLC.

397P Immune related adverse events (irAEs) in early phase immunotherapy (IO) trials: Implications for recommended phase 2 dose (RP2D) determination

Y. Kanjanapan[1], D. Day[1], M. Butler[1], L. Wang[2], A.M. Joshua[1], D. Hogg[1], N.B. Leighl[1], A.R.A. Razak[1], A.R. Hansen[1], S. Boujos[3], M.A. Chappell[1], K. Chow[3], M. Paolo[3], B. Sherwin[1], L-A. Stayner[3], L. Soultani[3], A. Zambrana[1], L.L. Siu[1], P.L. Bedard[1], A. Spreafico[1]

[1]Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada, [2]Biostatistics Department, Princess Margaret Cancer Centre, Toronto, ON, Canada, [3]Drug Development Program, Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: IO agents have a unique profile of irAEs. Due to the potential of delayed severe irAEs, we examined if conventional dose-limiting toxicity (DLT) periods may underestimate the rate of clinically significant irAE (csAE), defined as an irAE that required systemic therapy, drug delay or discontinuation.

Methods: A retrospective chart review of patients (pts) on early phase IO trials at Princess Margaret Cancer Centre examined severity (CTCAE v4.0), management, timing of onset and resolution of all grade (G) irAEs. A generalized estimating equation model assessed the association between time on treatment (Rx) and csAE, adjusted for duration of IO. Potential predictors of csAEs were assessed.

Results: From 8/2012-9/2016, 239 pts across 21 trials received ≥1 dose of IO (72% single agent; 28% IO-based combination). The most common tumors were melanoma (23%) and lung (18%) cancer. Among 890 total Rx-related irAEs, 93 (10%) were csAEs, including 22 (24%) endocrine, 15 (16%) gastrointestinal [GI], 11 (12%) respiratory, 10 (11%) skin and 9 (10%) hepatic csAEs. Median onset was ≤90 days for hepatic, GI and general (eg fatigue) csAEs, and >90 days for endocrine, respiratory, skin and musculoskeletal csAEs ($P = 0.03$). One pt with G3 hepatitis and G4 hypophosphatemia met protocol-defined DLT criteria and 27 irAEs fulfilled DLT criteria but occurred after the DLT period. 61 pts had csAEs, with 21 (34%) having >1 csAE. The onset of first csAE was 0-6 weeks (wks) in 30 (49%) pts; wks 7-12 in 16 (26%); wks 13-48 in 10 (16%); and ≥49 wks in 5 (8%) pts. The odds ratio (OR) for the first csAE occurrence within first 6 wks vs ≥ 6 wks was 3.3 (95% CI 2.0-5.6, $P = 0.002$), accounting for varying Rx duration. After adjustment for time on Rx, csAE correlated only with response on univariate analysis (OR 4.3, 95% CI 2.1-8.9, $P < 0.001$), but not with single or combination IO, age, ECOG status, prior IO or prior therapy lines.

Conclusions: Risk of first-onset csAE was higher during the initial 6 wks of IO, supporting use of conventional DLT period for dose escalation decision. However, as late csAEs were also seen, RP2D determination should consider the entire temporal course of csAE. Occurrence of csAEs positively correlated with response to IO, relative to time on Rx.

398P Drug-induced electrolyte abnormalities in oncology phase I trials: Analysis of 1088 cases treated at The Royal Marsden Hospital

A.H. Ingles Garces[1], J.E. Ang[1], M. Ameratunga[1], M. Chenard-Poirier[1], D. Dolling[2], N. Diamantis[1], S. Seeramreddi[1], R. Sundar[1], J. de Bono[1], J. Lopez[1], U. Banerji[1]

[1]Drug Development Unit, The Royal Marsden NHS Foundation Trust, London, UK, [2]Oncology, Institute of Cancer Research Royal Marsden Hospital, Sutton, UK

Background: The incidence and clinical significance of electrolyte abnormalities (EAs) in phase I studies is not well documented. The objective of this study is to evaluate the incidence of EAs, graded according to CTCAE v4.03, and its correlation with factors influencing them.

Methods: A retrospective chart review was performed of 1088 cases in 82 phase 1 clinical trials consecutively treated from 2011 to 2015 at the Drug Development Unit, The Royal Marsden Hospital. Cox regression was used to examine the relationship between overall survival and baseline characteristics, treating the occurrence of grade 3/4 EAs as a time-varying covariate.

Results: The most common EAs in all grades during trials are: hyponatremia 62%, hypokalemia 40%, hypophosphatemia 32%, hypomagnesemia 17% and hypocalcemia 12%. Overall, grade 3/4 EAs occurred in 19% of cases. More specifically, grade 3/4 EAs were observed, as follow: hyponatremia 10%, hypophosphatemia 6%, hypokalemia 5%, hypomagnesemia 1%, hypermagnesemia 1%. Grade 3/4 EAs occurred during the dose-limiting toxicity window in 8.73% of cases. Overall, diarrhea was associated with hypomagnesemia in all grades (HR 1.78, 95% CI: 1.32-2.39, $p < 0.001$), with G3/G4 hypokalemia (HR 1.93, 95% CI: 1.09-3.43, $p = 0.02$) and hyponatremia in all grades (HR 0.79, 95% CI: 0.67-0.93, $p = 0.006$). Vomiting was also associated with hypomagnesemia in all grades (HR 1.45, 95% CI: 1.08-1.95, $p = 0.01$) and G3/4 hypokalemia (HR 2.91, 95% CI: 1.62-5.23, $p < 0.001$). Baseline hypoalbuminemia, hyponatremia and female gender are associated with higher risk of developing other EAs during trial in the univariate analysis. Patients who developed G3/4 EAs during follow-up had a poorer median overall survival (OS) (26 weeks vs 37 weeks, HR = 1.61; 95% CI: 1.37-1.90; $p < 0.001$).

Conclusions: Baseline EAs are common in patients with advanced cancers participating in phase I trials. This is the first study to demonstrate the clinical significance of baseline hypoalbuminemia and hyponatremia, which are predictors of development of other EAs in phase 1 patients. G3/4 EAs are adverse prognostic factors of OS independent of serum albumin levels.

400P LCZ 696, administered during doxorubicin, trastuzumab or pertuzumab treatment, prevents cardiotoxicity in our in vitro model

N. Maurea[1], R. Paciello[2], G. Piscopo[1], A. Rienzo[1], G. Sorrentino[1], C. Maurea[1], R. Caputo[3], M. De Laurentiis[3], P. Maiolino[4], C. Coppola[1], C. De Lorenzo[2]

[1]Division of Cardiology, Istituto Nazionale Tumori, IRCCS – Fondazione G. Pascale, Naples, Italy, [2]Ceinge – Advanced Biotechnology S.C.ar.l., Department of Molecular Medicine and Medical Biotechnology, University 'Federico II', Naples, Italy, [3]Department of Breast Surgery and cancer prevention, Istituto Nazionale Tumori – IRCCS – Fondazione G. Pascale, Naples, Italy, [4]Pharmacy, Istituto Nazionale Tumori, IRCCS – Fondazione G. Pascale, Naples, Italy

Background: Doxorubicin (DX), Trastuzumab (T) and Pertuzumab (P) are antineoplastic drugs used in the treatment of breast cancer. Adverse cardiovascular events related to anticancer drugs are among the leading causes of morbidity and mortality in cancer patients. Sacubitril-valsartan (LCZ 696) is a combination drug, made up of neprilysin inhibitor sacubitril and angiotensin II receptor blocker valsartan, used for the treatment of heart failure in patients with a reduced ejection fraction. Here, we aim to assess whether LCZ 696, administered during DX, T or P treatment, reduces *in vitro* anticancer drugs-related cardiotoxicity compared to Valsartan (V), used as a control drug.

Methods: The H9C2 rat cardiomyoblasts were seeded in 96-well plates at a density of 1 x 10^4 cells/well and incubated at 37 °C with 5% CO2 for 16 hours. After the addition of 200 nM of T, P or DX in the culture medium, cells were incubated for 72 hours. The cells were further treated in the absence or presence of 10 μM of LCZ 696 or V for additional 3 days. Viable cells were counted by trypan blue exclusion test and cell survival was expressed as percentage of viable cells compared to control untreated cells.

Results: LCZ 696 reduced significantly T, P and DX related toxicity in H9C2 cardiomyoblasts as evidenced by the higher percentage of viable cells treated with combinations of T, P or DX with LCZ 696 with respect to cells treated with T, P or DX alone ($p < 0.001$). V reduced significantly T and DX related toxicity in H9C2 cardiomyoblasts treated with combinations of T or DX and V with respect to the cells treated with T or DX, used as single agents ($p < 0.001$). However there was no significant reduction of toxicity when H9C2 cells were treated with P + V. Thus, both LCZ 696 and V reduced significantly DX and T related toxicity when administered to H9C2 cardiomyoblasts after the antineoplastic treatment (no significant difference between LCZ 696 and V treatment, $p = 0.6$). Moreover, LCZ 696 was significantly more effective than V ($p < 0.001$) in reducing both T and P related toxicity when administered to cultures of H9C2 cardiomyoblasts after antineoplastic treatments.

Conclusions: LCZ 696, administered during DX, T or P treatment, significantly increases the viability of treated cells, thus reducing cardiotoxic effects of these drugs, as demonstrated by our *in vitro* experiments. The future perspective aims to test LCZ 696 in *in vivo* models to assess its capability to blunt left ventricular dysfunction after antineoplastic treatments.

401P MEK inhibitor retinopathy

T. Shukair

Ophthalmology, Hospital Madrid Norte Sanchinarro, Madrid, Spain

Background: To evaluate the presence and characteristics of subretinal fluid (SRF) associated with the use of MEK inhibitors in the treatment of systemic cancer MEK retinopathy is described as symmetrical bilateral disease that develops in a time-dependent and dose-dependent manner.

Methods: In this prospective, observational study, collected data from 14 patients with locally advanced or metastatic cancer undergoing treatment with the MEK inhibitor as clinical trials between 2010-2013. They underwent regular ophthalmological examinations including determination of visual function, biomicroscopy, dilated fundoscopy and optical coherence tomography (OCT).

Results: Of the 14 participants, 10 (71%) were men; the mean (SD) age was 65 years (range, 41-80 years). Six (48%) study participants developed SRF during the study period. OCT revealed subfoveal neuroretinal elevation, serous retinal detachments often asymptomatic. In general it solves spontaneously without any apparent functional deficits or changes in structural integrity, and does not require the suspension of the treatment.

Conclusions: The presence of serous retinal detachment in patients undergoing treatment with the MEK inhibitor is common. Visual symptoms were mild and mainly transient and the presence of SRF did not lead to permanent ocular disorder. It is important to investigate all previous ocular disorders and pharmacologic interactions of MEK inhibitor that could associate with ocular effects.

402P A Phase I/II study everolimus in combination with paclitaxel-carboplatin in patients with advanced adenocarcinoma of the stomach

H.H. Loong[1], F. Mo[1], L. Li[2], C. Lee[3], K-C. Lam[2], J. Koh[1], P. Chiu[4], A. Teoh[4], A.T.C. Chan[1], E. Ng[4], W. Yeo[1]

[1]Department of Clinical Oncology, The Chinese University of Hong Kong, Hong Kong, China, [2]Department of Clinical Oncology, Prince of Wales Hospital, Hong Kong, China, [3]Department of Oncology, United Christian Hospital, Hong Kong, China, [4]Department of Surgery, The Chinese University of Hong Kong, Hong Kong, China

Background: Significant proportion of patients (pts) with adenocarcinoma of stomach (ADCS) present with advanced disease. Paclitaxel (P), either alone, or in combination with carboplatin (C) is well-tolerated, but has modest activity in ADCS. The PI3K-Akt pathway played an important role in cell proliferation and apoptosis in pre-clinical ADCS models. Everolimus (E) is a potent inhibitor of mTOR, a downstream mediator of the PI3K-Akt pathway. Combining chemotherapies with mTOR inhibition may improve outcome

Methods: A single-arm, dose-escalation study of E, in combination with P and C (E+PC) was conducted in pts with metastatic and/or loco-regionally advanced ADCS [NCT01514110]. In the phase 1 portion (P1P), the maximum-tolerated dose (MTD), recommended phase 2 dose (RP2D) and safety of E+PC, were determined using a

standard 3 + 3 design. Starting dose (dose level I) was E 5mg/d, P 175mg/m^2 and C AUC5 every 3 weeks. Dose-limiting toxicities (DLT) were defined as grade 4 haematological or grade 3 or 4 non-haematological toxicities. Preliminary efficacy of E+PC in pts with ADCS, defined by clinical benefit rate (CBR) (CR+PR+SD for 6wks or more as per RECIST), and survival were determined in the phase 2 portion

Results: 30 pts were enrolled (P1P = 12) from Jan 2008 to Nov 2014. In the P1P, 2 DLTs (G5 GI bleeding and G3 joint pain) were experienced at dose level II, thus establishing dose level I as the MTD and RP2D. 21 pts were treated at RP2D. Baseline demographics of phase 2 portion: M/F: 9/12, Median age 54 (range 40-69), ECOG PS 0/1/2: 10/10/1. Prior lines of chemotherapy 0/1/≥2: 7/12/2. Median cycles: 6 (range 1-19). Common related ≥G3 adverse events (AEs) include (%): neutropenia (48%), anaemia (43%), thrombocytopenia (29%), mucositis (10%). Febrile neutropenia occurred in 10% (n = 2) of pts. 18 pts were evaluable for response (5 PR, 9 SD, 4 PD). CBR 77.8% (95% CI 58.6-97.0%). Median PFS and OS was 6.9 and 9.0months (95%CI 3.5 – 7.6; 3.8 – 15.1months) respectively

Conclusions: E+PC administered at RP2D was well-tolerated. Comparing with prior reported series of PC alone, E+PC showed more favorable efficacy and has promising activity in pts with advanced ADCS. Acknowledgement- Supported by Novartis Pharmaceuticals Ltd

Background: CEA-CD3 TCB (RG7802, RO6958688) is a novel T-cell bispecific antibody targeting CEA on tumor cells and CD3 on T cells. Preclinically, CEA-CD3 TCB had potent antitumor activity, leading to increased intratumoral T-cell infiltration and activation, T-cell–mediated tumor cell killing and PD-L1/PD-1 upregulation.

Methods: In 2 ongoing dose-escalation phase I studies, CEA-CD3 TCB is given as monotherapy IV QW (S1) or in combination (QW) with atezolizumab 1200 mg Q3W (S2) in pts with advanced CEA positive (> 20% of tumor cells expressing moderate or high) solid tumors. In S1, 80 pts (70 CRC) were treated at dose levels of 0.05-600 mg; in S2, 45 pts (35 CRC) at 5-160 mg.

Results: At doses ≥ 60 mg (31 evaluable pts with CRC in S1; 14 in S2), CT scans revealed signs of tumor inflammation within 48 h of the first dose, consistent with CEA-CD3 TCB mode of action. 2 (6%) CRC pts in S1 (both microsatellite stable [MSS]) and 3 (21.5%) in S2 (2 MSS CRC, 1 MSI high [out of 2]) had confirmed partial response (PR; RECIST v1.1). Additionally, tumor reduction of − 10% to − 30% (stable disease) was seen in MSS CRC pts (4 [13%] in S1 and 5 [36%] in S2). At weeks 4-6, 9 (29%) CRC pts in S1 and 7 (50%) in S2 had metabolic PR (FDG PET; EORTC criteria). At all doses in S1, the most common related AEs were pyrexia (56%), infusion-related reactions (IRRs; 50%) and diarrhea (40%). In S1 (out of 59 pts > 40 mg), the most common grade ≥ 3 (G3) related AEs were IRRs (24%) and diarrhea (7%). Five pts experienced DLTs: G3 dyspnea, G3 diarrhea, G3 hypoxia, G4 colitis and G5 respiratory failure (G4 and G5 at 600 mg [exceeding MTD]). DLT events were likely associated with tumor lesion inflammation, per investigators. In S2, there was no evidence of new or additive toxicities, with 2 DLTs at 160 mg (1 G3 ALT increase in a pt with liver metastases and 1 G3 maculopapular rash). Updated data will be presented.

Conclusions: Evidence of antitumor activity in advanced CRC and other CEA-expressing tumors was observed during dose escalation with CEA-CD3 TCB monotherapy. Enhanced activity and a manageable safety profile was seen in combination with atezolizumab.

404P Dose escalation study of vemurafenib with crizotinib or sorafenib in patient with BRAF-mutated advance cancers

D. Sakamuri[1], S. Kato[2], H.J. Huang[3], A. Naing[3], V.R. Holley[3], S. Patel[4], S.A. Piha-Paul[3], A.M. Tsimberidou[5], D.S. Hong[6], F. Meric-Bernstam[7], F. Janku[3]

[1]GI Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA, [2]Center of Personalized Cancer Therapy and Division of Hematology and Oncology, Department of Medicine, UC San Diego Moores Cancer Center, La Jolla, CA, USA, [3]Department of Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [4]Department of Melanoma Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA, [5]Investigational Cancer Therapeutics, MD Anderson Cancer Center, Houston, TX, USA, [6]Phase I Unit, The University of Texas M. D. Anderson Cancer Center, Houston, TX, USA, [7]Oncology, University of Texas MD Anderson Cancer Center, Houston, TX, USA

Background: BRAF inhibitors are effective in melanoma and other cancers with *BRAF* mutations; however, patients ultimately develop therapeutic resistance through activation of alternative signaling pathways such as MET, PDGFR and CRAF. We hypothesized that combining the BRAF inhibitor vemurafenib and MET inhibitor crizotinib or PDGFR/CRAF inhibitor sorafenib can overcome resistance.

Methods: We designed a phase I study (3 + 3 design) to determine the safety of vemurafenib (240-960 mg PO BID q 28 days) with crizotinib (250 mg PO daily or BID q 28 days) in arm A or sorafenib (200 mg PO daily to 400mg PO BID q 28 days) in Arm B in patients with *BRAF*-mutant advanced cancers. Endpoints included maximum tolerated dose (MTD), dose limiting toxicities (DLT), safety, response (RECIST 1.1) and plasma cell-free DNA mutation analysis.

Results: Thirty-six patients (arm A, 13; arm B, 23), median number of 3 prior therapies (29 [81%] had prior BRAF/MEK inhibitors) were treated. Patients (melanoma 17/36, 47%; papillary thyroid cancer 5/36, 14%; colorectal cancer 3/36, 8%; lung adenocarcinoma 2/36, 6%; other 9/36, 25%) had *BRAF* V600E (30), V600K (3) or other *BRAF* mutations (3). Vemurafenib 720mg BID with crizotinib 250mg daily and vemurafenib 720 mg BID with sorafenib 400mg/200mg were identified as MTDs. DLTs included grade (G) 3 rash (2) in arm A and G3 rash and G3 hypertension in arm B. Other G3 treatment related toxicities were G3 fatigue (2), G3 anemia (1), G3 thrombocytopenia (1), G3 neutropenia (1), G3 thromboembolic event (1) in arm A and G3 hypertension (1), G3 headache (1), G3 diarrhea (2), G3 intraocular inflammation (1) in arm B. In Arm A, 3 of 13 (23%) patients (melanoma refractory to BRAF monotherapy [2] and

lung adenocarcinoma) attained a partial response (PR). In Arm B, 4 of 23 (17%) patients (ovarian cancer refractory to MEK inhibitor, melanoma, lung adenocarcinoma, papillary thyroid cancer) attained a PR. Optional longitudinal collection of plasma cfDNA to assess clonal evolution was performed and will be presented at the meeting.

Conclusions: Vemurafenib in combination with crizotinib or sorafenib is well tolerated with encouraging activity including patients previously treated with BRAF/MEK inhibitors.

405P Hepatic functional imaging and genomics to predict irinotecan pharmacokinetics and pharmacodynamics: The PREDICT IR study

M. Michael[1], W. Liauw[2], S-A. McLachlan[3], E. Link[4], A. Matera[4], M. Thompson[5], M. Jefford[1], R.J. Hicks[5], C. Cullinane[6], I. Campbell[6], P.J. Beale[7], C.S. Karapetis[8], T.J. Price[9], M.E. Burge[10]

[1]Division of Cancer Medicine, Peter MacCallum Cancer Centre, Melbourne, Australia, [2]Medical Onclogy, St Geroges Hospital, Sydney, Australia, [3]Medcial Oncology, St Vincents Hospital, Melbourne, Australia, [4]Biostatistics and Clinical Trials Centre, Peter MacCallum Cancer Centre, Melbourne, Australia, [5]Dept. Cancer Imaging, Peter MacCallum Cancer Centre, Melbourne, Australia, [6]Division of Cancer Researchcine, Peter MacCallum Cancer Centre, Melbourne, Australia, [7]Medical Oncology, Royal Prince Alfred Hospital, Sydney, Australia, [8]Medical Oncology, Flinders Medical Centre and Flinders Centre for Innovation in Cancer, Adelaide, Australia, [9]Medical Oncology, Queen Elizabeth Hospital, Woodville, Australia, [10]Medical Oncology, Royal Brisbane and Women's Hospital, Brisbane, Australia

Background: Body surface area-based dosing of Irinotecan (IR), has not accounted for its significant pharmacokinetic (PK) and pharmacodynamic (PD) variability. Given IR's unique metabolism, hepatic functional nuclear imaging (HNI) with probes for hepatic transporters correlated with its PK. This study further evaluated the utility of HNI combined with extensive excretory/metabolic/PD pharmacogenomics (PG) to predict IR PK and PD in patients (pts) treated with FOLFIRI to enable dose individualization.

Methods: Eligible pts had advanced colorectal cancer, suitable for $1^{st}/2^{nd}$-line FOLFIRI± Bevacizumab. Pts had blood analyzed by Affymetrix DMET™ Plus Array and additional SNPs were genotyped. For HNI, pts were given IV 250MBq ^{99m}Tc-IDA and imaging data analyzed for hepatic extraction/excretion parameters (clearance [CL], 1hour retention [1hRET], deconvulutional CL [DeCL], hepatic extraction fraction [HEF]). Pts treated with chemotherapy, q2-weekly, and restaged after 4 cycles. Blood taken for IR and metabolite (SN38, SN38G) analysis on day 1 cycle 1, PK parameters derived by non-compartmental analysis. Statistical correlations were evaluated between (i) IDA HNI and (2) PGs, with IR PK, toxicity, objective response (ORR) and progression-free survival (PFS).

Results: 32 pts analysed, 31 pts completed 4 cycles. (1) PK correlates: (a) HNI CL and 1hRET with SN38 Metabolic CL, ($P = 0.04$) and (b) HNI DeCL with IR $AUC_{(0\text{-}\infty)}$ ($P = 0.04$). (2) Grade 3+ diarrhea ($N = 4$, 13%) predicted by SN38 $AUC_{(0\text{-}\infty)}$ andMetabolic CL ($P = 0.04$), and gene variants for SCL22A2 and -28A3, ABCC2, UGT2B17, CYP2C18 and DPYD ($P < 0.05$) (3) Grade 3+ neutropenia ($N = 9$, 28%) predicted by SN38 PK exposure ($P < 0.02$), HNI CL and 1hRET ($P < 0.0001$) and variants for SLC7A7-, SLC22A2-, CHST1-, UGT1A1-, -2B7, ABCB1. (4) ORR ($N = 6$, 20%) predicted by Methylene tetrahydrofolate reductase (MTHFR) 677C > T ($P = 0.002$), SN38 exposure ($P < 0.003$), and variants in metabolic/transporter genes ($P < 0.05$). (5) PFS by SN38 PK exposure, MTHFR 677C > T, HNI CL, HNI HEF and variants in PK genes ($P < 0.05$).

Conclusions: Hepatic functional imaging with extensive pharmacogenomics correlated with Irinotecan PK and PD enabling the future development of nomograms to individualize its dosing.

406P Ongoing phase 1 trial of SL-801, a novel XPO-1 inhibitor, in patients with advanced solid tumors; Interim results

J. Wang[1], J. Nemunaitis[2], G. Chiorean[3], P. Lorusso[4], K. Courtney[5], A. Olguin[6], J. Bullington[7], S. Shemesh[7], J. Chen[6], C. Brooks[6], T.M. Bauer[8]

[1]Sarah Cannon Research Institute, Florida Cancer Specialists, Sarasota, FL, USA, [2]Mary Crowley Cancer Research Center, Dallas, TX, USA, [3]Seattle Cancer Center Alliance, University of Washington, Seattle, WA, USA, [4]Yale Cancer Center, Yale University, New Haven, CT, USA, [5]Internal Medicine, UT Southwestern Medical Center, Dallas, TX, USA, [6]R&D, Stemline Therapeutics, New York, NY, USA, [7]Clinical Operations, Stemline Therapeutics, New York, NY, USA, [8]Medical Oncology, Tennessee Oncology, Nashville, TN, USA

Background: Exportin-1 (XPO1) is a critical nuclear export protein involved in nuclear-cytoplasmic transport and is overexpressed in multiple malignancies. SL-801 is a novel oral small molecule inhibitor of XPO1 and has shown potent in vitro and in vivo anti-tumor activity against a broad range of hematologic and solid malignancies. SL-801 has been shown to reversibly inhibit XPO1, which may translate to selective activity and potential safety benefits. Study SL-801-0115 is a first-in-human, dose-escalation study in adult patients with locally advanced, unresectable or metastatic solid tumors that are resistant to or relapsed following available standard systemic therapy. Preliminary interim results in the ongoing dose-escalation Phase 1 clinical study are reported.

Methods: The objective of this multicenter, dose-escalation phase 1 trial is to evaluate the safety and tolerability of SL-801, identify the maximum tolerated dose (MTD), and assess pharmacokinetics (PK) with increasing doses. SL-801 is administered daily on Day 1 through Day 4 and Day 8 through Day 11 every 21 days. The starting dose cohort was 5 mg and has reached 35 mg to date.

Results: As of 3/31/17, 19 heavily pretreated (range: 1-11 prior therapies) adult patients with advanced solid tumors have received SL-801 (6 Females, 13 Males). Median age is 62 years (range: 39-75). MTD has not been reached. Median follow-up is 1.4 months (range: 0.1-4.9). Pharmacokinetic analyses are ongoing. The most frequent treatment-related Grade 1-2 AEs were fatigue and nausea (26%), diarrhea (16%), and myalgia, vomiting and decreased appetite (11% each). Grade 3 AEs, possibly treatment-related, included diarrhea ($n = 1$; 5 mg) and acute renal injury ($n = 1$; 30 mg). There were no grade 4 or 5 treatment-related events. Three patients achieved stable disease, for 3-7 cycles, by investigator assessment.

Conclusions: The initial dose-escalation of SL-801 appears to be well tolerated to date in patients with advanced solid malignancies. Enrollment continues in this ongoing Phase 1 trial and updated safety and efficacy data will be presented. Clinical trial information: NCT02667873.

407P Antitumor efficacy of triple monoclonal antibody inhibition of epidermal growth factor receptor (EGFR) with MM-151 in EGFR-dependent and in cetuximab-resistant human colorectal cancer cells

S. Napolitano, G. Martini, E. Martinelli, C.M. Della Corte, V. Belli, N. Matrone, F. Morgillo, F. Ciardiello, T. Troiani

Oncologia Medica, Dipartimento di Internistica Clinica e Sperimentale "F. Magrassi", Università degli Studi della Campania Luigi Vanvitelli, Naples, Italy

Background: Novel and more efficient anti-EGFR drugs capable to overcome acquired resistance to first generation of anti-EGFR inhibitors needs to be investigated.

Methods: MM151 is a mixture of three different monoclonal IgG1 antibodies directed toward three different, non-overlapping, epitopes of the EGFR. We performed an *in vivo* study by using human CRC cell lines (SW48, LIM 1215 and CACO2) which are sensitive to EGFR inhibitors, in order to evaluate the activity of MM-151 as compared to standard anti-EGFR mAbs, such as cetuximab, as single agent or in a sequential strategy of combination MM-151 with irinotecan (induction therapy) followed by MM-151 with a selective MEK1/2 inhibitor (MEKi) (maintenance therapy). Furthermore, the ability of MM-151 to overcome acquired resistance to cetuximab has been also evaluated in cetuximab-refractory CRC models.

Results: MM151 shown stronger antitumor activity as compared to cetuximab. The maintenance treatment with MM-151 plus MEKi resulted the most effective therapeutic modality. In fact, this combination caused an almost complete suppression of tumor growth in SW48, LIM 1215 and CACO2 xenografts with a mean tumor volume of 13 mm^3, 13 mm^3 and 75 mm^3, respectively at 30 week. Moreover, in this treatment group, mice with no evidence of tumor were more than double as compared to single agent treated mice. Its superior activity has also been demonstrated, in cetuximab-refractory CRC models.

Conclusions: These results provide experimental evidence that more efficient and complete EGFR blockade may determine better antitumor activity and could contribute to prevent and/or overcome acquired resistance to EGFR inhibitors.

408P Validation of the Royal Marsden Hospital (RMH) prognostic score on an enriched early treatment line cohort for phase I trial patients

M. Blanco Codesido, A. Calvo Ferrandiz, S. Lopez-Tarruella Cobo, R. Alvarez, Y. Jerez, I. Marquez Rodas, S. Perez Ramirez, A. Muñoz, A. Calles, P. Sabin Domínguez, C. López, A.C. Picornell, B. Puente, C. Rubio, M. Herencia, T. Massarrah, M. Martin Jimenez

Medical Oncology, Hospital General Universitario Gregorio Marañon, Instituto de Investigación Sanitaria Gregorio Marañón (IiSGM), Madrid, Spain

Background: The RMH score has been validated to predict survival in different populations of patients starting phase I clinical trials. Most of the populations where it has been validated are of heavily treated patients that lack other treatment options. The type of phase I trials is changing and we aimed to validate the score in a new cohort with more patients treated on an early line, rahter than the usual classic phase I trials heavily pretreated patient population.

Methods: We analyzed the RMH score in the patients treated in our center in a phase I trial between 2012 and 2017. We collected demographics data, overall survival after starting the trial, the RMH score (albumin, LDH, and number of metastatic sites) for all patients and the treatment line. We considered a late line anything over two treatment lines and in any case if the patient did not have any other treatment available depending on the tumor type. An early line was the first or second treatment line when the patient did have further lines available.

Results: We treated 77 patients on a phase I trial in our institution, 23 males and 54 females. Mean age was 55 years (26-77). RMH score was (0/1/2/3) in (31/23/20/3) patients. Thirty-three patients were treated on an early line. Median survival for low score (0/1) was 639 days and for high score (2/3) was 327 days $p = 0.0834$. The mean survival for patients with low RMH score was higher than those with a high RMH score in every treatment line, although due to the low number of patients in some of those categories the difference was not significant.

Conclusions: The RMH score did predict well the overall survival in our patients. The survival times in our institution are higher than those previously published, probably due to the inclusion of patients on earlier treatment lines than those used before to calculate and validate the score. Our findings support the use of the RMH score for the selection of patients entering phase I trials irrespectively of the design of the trial (early vs. late line).

Background: DS-8201a is a HER2 targeting antibody-drug conjugate of high drug to antibody ratio (7 to 8) with a novel linker and topoisomerase I inhibitor. In preclinical studies, DS-8201a showed a broad antitumor spectrum, including efficacy against low HER2 expressing breast cancer (BC) and HER2 expressing non-gastric and non-breast cancers. The current phase 1 trial includes dose escalation (Part 1) and expansion (Part 2) including BC, gastric cancer (GC) and other HER2 expressing solid tumors.

Methods: Part 1 used a mCRM to identify the recommended dose in patients (pts) with BC or GC. Part 2 was designed to evaluate the safety and efficacy in 4 expansion cohorts: HER2 positive BC, HER2 positive GC, low HER2 expressing BC, and other solid tumors expressing HER2. HER2 expression was determined by IHC, FISH, NGS or other platforms. Adverse events (AEs), objective response rate (ORR), and disease control rate (DCR: CR + PR + SD) were assessed.

Results: Twenty four pts in Part 1 and 113 pts in Part 2 were enrolled. 24 of 113 pts were HER2 expressing solid tumors other than BC and GC. DS-8201a was administered up to 8.0 mg/kg in Part 1, and dose level of 6.4 mg/kg IV every 3 weeks was chosen. DLTs were not observed in the study. In the updated Part 1 results, confirmed ORR was 35%, DCR was 91% (BC: 88%, GC: 100%), and the median duration of treatment was ≥32 weeks in heavily pretreated BC and GC pts. Non-BC and non-GC cohort consists of 11 CRC, 5 NSCLC, 4 salivary gland, 2 Paget's disease, 1 cholangiocarcinoma and 1 esophageal cancer. ORR including under confirmation and DCR were 33% and 91%, respectively in evaluable 12 pts. Two out of 5 evaluable pts with CRC and 2 out of 4 evaluable pts with salivary gland achieved PRs. Of all pts in this phase 1 study, the most common AEs of any grades were nausea (≥Gr1 60%; ≥Gr3 2%), decreased appetite (≥Gr1 55%; ≥Gr3 4%), vomiting (≥Gr1 30%; ≥Gr3 0%) and platelet count decreased (≥Gr1 30%; ≥Gr3 9%). Updated phase 1 results will be presented.

Conclusions: DS-8201a was well tolerated and is remarkably active in pts with heavily pretreated HER2 expressing BC and GC with durable disease control. Promising efficacy in HER2 expressing other tumors was observed and warrants further investigation.

Background: MAPK pathway mutations leading to signaling hyperactivation are common in many ST; as RAF kinases play a key role in MAPK signaling, they represent a valid target for therapy. As a pan-RAF inhibitor, TAK-580 is differentiated from

approved BRAF-specific RAF inhibitors. Here we report the expanded cohort data from a single-agent, first-in-human study of TAK-580 (NCT01425008).

Methods: Patients with advanced ST or inoperable stage III/IV MEL received TAK-580 Q2D or QW in 28-d cycles. Primary objectives were safety and maximum tolerated doses [MTD] of TAK-580; secondary objectives included preliminary antitumor activity, PK and PD effects. Safety and PK were compared between 2 MTD regimens (200 mg Q2D vs 600 mg QW). Preliminary antitumor activity of TAK-580 Q2D vs QW was evaluated in *NRAS*-mutation positive (mut) MEL. Activity and efficacy (PFS) were assessed in *BRAF*-mut MEL. Plasma PK were assessed pre- and post-dose between d1 and d28 of cycle 1 (C1). Tumor biopsies were taken at screening and post-dose on d21 or 22 of C1. Disease assessments were performed at baseline and every 2 cycles thereafter.

Results: 80 patients received TAK-580 200 mg Q2D (60 MEL + 20 PK-evaluable ST) and 19 MEL patients received 600 mg QW. DLTs observed were: periorbital edema and maculopapular rash (280 mg Q2D); rash and hyperbilirubinemia (800 mg QW). For Q2D and QW, 41% and 32% of patients, respectively, had Gr $\geq$ 3 drug-related adverse events (AE); 19% and 11% discontinued due to AEs. Total weekly exposure (AUC_{168h}) after TAK-580 600 mg QW was comparable to 3-fold AUC_{48h} after 200 mg Q2D. Of 14 *NRAS*-mut MEL Q2D patients, 1 achieved PR (1.5 mos). In comparison, none of 17 *NRAS*-mut MEL QW patients had an objective response. 50% of the 16 *BRAF*-mut MEL Q2D patients achieved a PR with a median PFS of 4.6 mos (range 1.0–40.8).

Conclusions: The safety and PK profiles of TAK-580 Q2D and QW at MTD were acceptable. QW dosing improved safety but not efficacy over Q2D dosing. PD results were consistent with the proposed mechanism of action of TAK-580 with observed RAF pathway inhibition. These data support the use of QW dosing in the assessment TAK-580 given in combination.

411P Pharmacological activity of CB-103: An oral pan-NOTCH inhibitor with a novel mode of action

D. Weber[1], R. Lehal[1], V. Frismantas[2], J-P. Bourquin[2], M. Bauer[1], M. Murone[1], F. Radtke[3]
[1]*Drug Development, Cellestia Biotech AG, Basel, Switzerland,* [2]*Paediatric Oncology, University Children's Hospital, Zurich, Switzerland,* [3]*Research Laboratory, EPFL Lausanne, Lausanne, Switzerland*

Background: NOTCH signalling is a developmental pathway known to play critical roles during embryonic development as well as for regulation of self-renewing tissues. Aberrant activation of NOTCH signalling leads to deregulation of the self-renewal process resulting in sustained proliferation, invasion and metastasis, all of which are hallmarks of cancer. When the NOTCH pathway is inappropriately activated by genetic lesions (over expression of NOTCH ligands/receptors, GOF mutations in NOTCH receptors as well as chromosomal translocations), it becomes a major driver for NOTCH-dependent cancers and resistance to standard of care treatment. Several therapeutic approaches have been utilized to block NOTCH signalling, e.g. a) the use of monoclonal blocking antibodies (mAbs) against NOTCH ligands and receptors and b) the use of small molecule gamma-secretase inhibitors (GSIs). Here we report the pharmacological characterization of CB-103, a first-in-class orally-active small molecule, protein-protein interaction inhibitor of the NOTCH transcriptional activation complex.

Methods: Primary pharmacodynamic (PD) studies were conducted to investigate CB-103 in relation to its desired therapeutic effect for treating advanced or metastatic haematological and solid tumour malignancies as NOTCH pathway inhibitor. Regarding the PD effect, in vitro studies demonstrated for CB-103 a dose-dependent decrease in NOTCH signalling activation with a unique mechanism compared to GSIs and mAbs. In a panel of > 120 cell lines of various malignancies CB-103 was active on a subset of 24 cancer cell lines, including different solid tumours (breast, lung, sarcomas), lymphomas and leukaemias.

Results: Moreover, CB-103 demonstrated anti-NOTCH activity in the Triple-Negative Breast Cancer HCC1187 cell line, being resistant to GSIs due to a NOTCH2 chromosomal translocation. In addition, CB-103 exhibited anti-tumour efficacy in multiple in vivo models and patients derived xenograft models.

Conclusions: Safety pharmacology and toxicology studies have been completed and revealed an excellent non-clinical safety profile of CB-103. A first-in-human Phase I/IIA clinical study in advanced solid tumours and haematological malignancies is under preparation.

412P Design and development of potent E1 ubiquitin activating enzyme inhibitor, CPL-410-005, as novel anticancer therapy

A. Stanczak, A. Górnicka, B. Stypik, M. Mroczkiewicz, J. Pieczykolan, K. Dubiel, M. Wieczorek
Preclinical Development Department, Celon Pharma S.A., Lomianki, Poland

Background: The ubiquitin-proteasome system is crucial in tumorigenesis. The division rate of cancer cells, thus protein synthesis, is increased in comparison to normal ones, what sensitizes tumors for any protein changes. Proteasome inhibitor - bortezomib was the first inhibitor registered in treatment of blood cancers. However, drugs beneficial for solid tumors are still missing. Therefore targeting of E1 enzyme as a start of UPS pathway may serve as a promising anticancer therapy.

Methods: We have designed a novel E1 small molecule inhibitor, CPL-410-005. The inhibitory potency of compound was assessed on purified E1 enzyme, using biochemical assay. Assays to measure cellular poliubiquitylation or ubiquitin-like modifications level were developed. The compound's biological activity and selectivity was evaluated in a number of cancer cells using cell viability assays, Western Blot and flow cytometry, analyzing programmed cell death, unfolded protein response or cell cycle inhibition.

Results: CPL-410-005 inhibits E1 enzyme with greater potency than MLN7243. This results in cellular polyubiquitylation inhibition, while the impact on other ubiquitin-like modifications (neddylation, sumoilation) is minor. Tumor proliferation rate inhibition was pronounced in reference to the non-malignant cells [IC_{50} values of 20 nM for HCT-116 cells vs IC_{50} values of 400 nM for HEK293 cells]. Moreover, a higher level of unfolded protein response or programmed cell death was observed in cells treated with CPL-410-005 in reference to MLN7243 (5% apoptotic cells vs 30% for MLN7243 vs CPL-410-005, respectively). In case of CPL-410-005, apoptosis rate was higher in tumor than in normal cells (80% apoptotic cells vs 20%, respectively). A high throughput study was performed, to determine the activity of CPL-410-005 on 120 human tumor cell lines, showing that >85% tested cell lines responded with IC_{50} value below 100nM. The initial in vivo studies on tumor human xenografts are ongoing.

Conclusions: We have designed and evaluated in vitro a potent E1 inhibitor - CPL-410-005, which shows promising in vitro activity. Further preclinical studies are necessary to develop this compound as a novel anticancer therapy.

413P RX-3117, a novel hypomethylating agent, shows promising therapeutic activity in combination with nab-paclitaxel and checkpoint inhibitors in preclinical models

J. Frank[1], Y.B. Lee[1], D.J. Kim[1], E. Benaim[2]
[1]*Research, Rexahn Pharmaceuticals, Rockville, MD, USA,* [2]*Clinical Trial, Rexahn Pharmaceuticals, Rockville, MD, USA*

Background: A novel nucleoside analogue, RX-3117, is being evaluated in a Phase IIa study in patients with advanced pancreatic and bladder cancer. RX-3117 shows promising antitumor activity in xenografts including patient-derived xenografts resistant to gemcitabine. Here we demonstrate the preclinical effects of combination therapy with RX-3117 + Abraxane or anti-PD1 immunotherapy.

Methods: One colorectal (MC38), pancreatic (Pan02) syngeneic xenograft and patient-derived pancreatic (CTG-0723) xenograft model were exposed to 60 mg/kg RX-3117 po, 5 days on, 2 days off for three weeks. Pan02 and MC38 received RX-3117 alone or in combination with 100ug anti-PD1, ip. PDx CTG-0723 received one cycle of RX-3117, followed by a second cycle of RX-3117 + 10 mg/kg Abraxane, iv. MC38 tumor-infiltrating lymphocytes were measured at days 5 and 12 with RX-3117.

Results: In MC38 at day 28, RX-3117 or anti-PD1 showed TGIs of 90% and 93%, whereas the combination showed 99% TGI. Differences were also observed in TILs.

Relative to vehicle (CD4+:10.6+/-1.6, CD8+: 8.6+/-1.1), %CD4 + (17.4+/-1.4) and CD8+ cells (12.3+/-1) increased. %MDSCs decreased on Day 5 in blood (42+/-7.7 vs 29+/-6). %CD8+ increased (9.6+/-3.3 vs 12.3+/-3.2) and %MDSC decreased (15.4 +/- 3.7 vs 10.6 +/- 3.3) in tumor on Day 12. In Pan02, RX-3117 + anti-PD1 resulted in a day 32 TGI of 60%. Anti-PD1 alone had a day 32 28% TGI. In CTG-0723, the first cycle of RX-3117 at 10, 30 and 60 mg/kg produced TGIs of 33%, 46% and 77%. The second cycle, RX-3117 + Abraxane, day 46 TV showed TGIs of 55%, 58% and 83%.

Conclusions: We demonstrate the antitumor effect of RX-3117 as a single agent and in combination with Abraxane or anti-PD-1. The combination of RX-3117/anti-PD1 in MC38 produced 7 tumor-free survivors out of 10 compared to 2 of 10 by anti-PD1 alone, indicating RX-3117 may mobilize the right population of lymphocytes to enable anti-PD-1 to work more effectively. In Pan02, RX-3117 exhibited better TGI than anti-PD-1. In CTG-0723, the combination of RX-3117 and Abraxane showed additive TGI. These studies demonstrate the therapeutic potential of RX-3117 in multiple cancers and validate the combination of RX-3117 with anti-PD1 in several cancer types.

414P A phase Ib trial of JX-594 (Pexa-Vec), a targeted multimechanistic oncolytic vaccinia virus, in combination with low-dose cyclophosphamide in patients with advanced solid tumors

M. Toulmonde[1], S. Cousin[1], A. Bessede[2], M. Homerin[3], N. Stojkowitz[3], M. Lusky[4], M. Pulido[5], A. Italiano[1]

[1]Medical Oncology, Institute Bergonié, Bordeaux, France, [2]IMMUSMOL, Immusmol, Bordeaux, France, [3]Clinical Research, Transgene SA, Illkirch-Graffenstaden, France, [4]Project Management, Transgene SA, Illkirch-Graffenstaden, France, [5]Biostatistics, Institute Bergonié, Bordeaux, France

Background: JX-594 (Pexa-Vec) is a targeted oncolytic vaccinia virus designed to selectively replicate in and destroy cancer cells with epidermal growth factor receptor (EGFR)/ras pathway activation. Direct oncolysis plus GM-CSF expression is accompanied by tumor vascular disruption and anti-tumoral immunity. JX-594 was well-tolerated intravenously (IV) and intratumorally (IT). Given the immunomodulatory effects of low-dose cyclophosphamide (CP), anti-tumor synergy is predicted with JX-594.

Methods: CP was delivered orally at the dose of 50 mg BID one week on one week off. JX-594 was delivered IV at day 8 of each day 28-cycle. 2 dose levels of JX-594 were explored: 3.10^8 and 1.10^9 plaque forming units (pfu). The primary objective of the study was to determine the safety of JX-594 in combination with low-dose CP in patients with advanced solid tumors. Secondary objectives include response rates, PFS, pharmacokinetics and pharmacodynamics.

Results: Ten patients entered the study. 9 were evaluable for safety. No dose limiting toxicity was observed. The combination regimen was well-tolerated. The most frequent adverse events were grade 1-2 fever/transient flu-like symptoms (n = 10), grade 1-2 nausea (n = 5), grade 1-2 anemia (n = 4) and grade 1-2 fatigue (n = 4). 2 patients (breast cancer, ovarian cancer) had stable disease as best overall response.

Conclusions: IV JX-594 was well-tolerated in combination with low-dose CP. PK and PD (immunological profiling) will be presented at the meeting. Two phase 2 studies are ongoing in patients with advanced HER2 negative breast cancer and advanced soft-tissue sarcomas, respectively.

415P Population pharmacokinetic analysis of OT-101 (trabedersen) in patients with advanced tumors

W. Wang[1], K. Ng[2], D. Nam[2], V. Trieu[1], L. Hwang[1]

[1]Clinical, Oncotelic Inc, Agoura Hills, CA, USA, [2]Clinical, Autotelic Inc., Costa Mesa, CA, USA

Background: OT-101 (Trabedersen) is a phosphorothioate antisense oligodeoxynucleotide specifically inhibiting the expression of transforming growth factor-beta 2 (TGF-b2), whose overexpression is a pivotal factor for malignant progression in solid tumors. In the clinical Phase I/II study, plasma pharmacokinetic (PK) profile of OT-101 administered intravenously was evaluated in patients with advanced tumors. A population PK model was built to further understand the factors contributing to the variability in PK of OT-101.

Methods: A total of 61 patients with pancreatic cancer (n = 37), malignant melanoma (n = 19), or colorectal carcinoma (n = 5) were treated with OT-101 with escalating doses in 2 treatment schedules (1st schedule: 7-days-on/7-days-off; 2nd schedule: 4-days-on/10-days-off; up to 10 cycles). The plasma concentration data of OT-101 were analyzed using nonlinear mixed-effect modeling (Phoenix NLME 7.0). The influence of age, gender, body mass index (BMI), body weight (BW), cancer type, treatment schedule, creatinine clearance (CrCl) and estimated glomerular filtration rate (eGFR) as covariates on PK was evaluated.

Results: With exclusion of protocol deviations, the final analysis dataset contained 92 patient cycles and 1188 plasma samples. Twenty-six patient cycles were from 7-days-on/7-days-off schedule and 66 were from 4-days-on/10-days-off schedule. The concentration time course of OT-101 was best described by a two-compartment model with combination of additive and multiplicative error. The estimates of PK parameters were as follows: total body clearance, 41.79 mL/hr; distribution volume of the central compartment, 6.30 L; inter-compartmental clearance, 4.02 L/hr; distribution volume of the peripheral compartment, 5965.83 L. eGFR were identified as the covariates on OT-101 central compartmental clearance, with K_{eGFR} as 11.45.

Conclusions: The PK profile of OT-101 was best described by a two-compartment model. The model will be used with the sparse PK samples collected from the planned phase 3 clinical trial to calculate exposure measures for use in subsequent PK-PD analysis of efficacy.

417TiP A phase 1 study of oral LOXO 292 in adult patients with advanced solid tumors, including RET-fusion non-small cell lung cancer, medullary thyroid cancer and other tumors with increased RET activity

A.E. Drilon[1], T.M. Bauer[2], V. Subbiah[3], M. Cabanillas[4], N. Lahkani[5], L. Wirth[6], G. Oxnard[7], S. Smith[8], T. Eary[8], S. Cruickshank[8], M. Nguyen[8], S. Rothenberg[8]

[1]Medical Oncology, Memorial Sloan-Kettering Cancer Center, New York, NY, USA, [2]Medical Oncology, Sarah Cannon Research Institute, Nashville, TN, USA, [3]Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA, [4]Endocrine Neoplasia & Hormonal Disorders, University of Texas M.D. Anderson Cancer Center, Houston, TX, USA, [5]Medical Oncology, START Midwest, Grand Rapids, MI, USA, [6]Hematology/Oncology, Massachusetts General Hospital, Harvard University, Boston, MA, USA, [7]Thoracic Oncology, Dana Farber Cancer Institute, Boston, MA, USA, [8]Research and Development, Loxo Oncology, Stamford, CT, USA

Background: RET is a receptor tyrosine kinase with critical roles in normal physiology. Fusions of the RET kinase with a partner protein have been identified in ~2% of non-small cell lung cancers (NSCLC) and a subset of papillary thyroid cancers and other tumors. RET mutations occur in the majority of medullary thyroid cancers (MTC). Although multikinase inhibitors with anti-RET activity are in the clinic, their activity is limited by incomplete RET inhibition in patients, toxicity from off-target effects (e.g.VEGFR2) and poor pharmacokinetics (PK). LOXO-292 is a potent and specific inhibitor of RET, including fusions, activating mutations and potential acquired resistance mutations, with minimal inhibition of off targets, including > 100-fold selectivity for VEGFR2.

Trial design: This is an open label, multi-center, dose escalation and expansion Phase 1 study in adult patients with advanced solid tumors. Major eligibility criteria for dose escalation include prior cancer treatment (prior treatment with anti-RET TKIs allowed) and normal hematopoietic and major organ function. During dose escalation, when a dose level is achieved that is safe and consistent with RET target engagement, enrollment will be limited to patients with RET-fusion NSCLC, MTC and other tumors with RET alterations or increased RET activity, as identified in tumor or blood by prior molecular assays performed locally. Once the Maximum Tolerated Dose (MTD) or recommended dose for further study is identified, patients will be enrolled to one of five dose expansion cohorts, depending on tumor type (i.e. NSCLC, MTC, other cancer), prior TKI therapy and type of RET alteration. The starting dose of LOXO-292 is 20 mg orally once per day, and dose escalation is proceeding using a 3 + 3 design. The primary endpoint is establishment of the MTD/recommended dose for further study. Key secondary endpoints include: safety and tolerability, PK parameters and preliminary assessment of anti-tumor activity. Patients undergo safety, clinical and PK assessments and radiographic evaluation for their disease at regular intervals.

Clinical trial identification: Treatment of patients has begun. The study has been submitted to the NIH (https://clinicaltrials.gov) and the ClinicalTrials.gov Identifier is pending and will be provided as soon as available.

Background: Neurotrophin ligands and their receptors TRKA, TRKB, and TRKC (encoded by *NTRK1, NTRK2, and NTRK3)* are important for growth regulation, differentiation and survival of neurons. Translocations involving the *NTRK1/2/3* kinase domain have been described in a broad range of adult and pediatric tumors, including infantile fibrosarcoma (IFS), spindle-cell sarcoma, congenital mesoblastic nephroma, pediatric papillary thyroid cancer, high- and low-grade gliomas and Ph-like acute lymphoblastic leukemia. Larotrectinib is the first small-molecule selective inhibitor of TRKA, -B, and -C in clinical development and has demonstrated tumor growth inhibition in preclinical models and clinically meaningful and durable responses in patients with *NTRK*-translocated cancers in an adult phase 1 trial.

Trial design: We have initiated an open-label, multi-center, international Phase 1/2 study with larotrectinib in pediatric patients with solid tumors and primary CNS tumors. A pediatric recommended phase 2 dose of 100mg/m^2 (caped at 100mg BID) has been established. Enrollment to phase 2 began in April 2017 and is ongoing. For the phase 2 component, patients from 1-month of age with IFS or an *NTRK*-fusion positive tumor, including those who have not undergone definitive surgery are eligible. Patients who have not undergone definitive surgery are eligible as well. Larotrectinib is administered as an oral liquid formulation or capsules twice daily on a continuous 28-day schedule. Dosing is based on body surface area. The phase 2 portion enrolls patients with *NTRK*-translocated tumors and measurable disease into three cohorts: 1) infantile fibrosarcoma; 2) other extracranial solid tumors; and 3) primary CNS tumors. The primary endpoint is objective response rate, with duration of response and progression free survival as secondary efficacy endpoints. Quality of life measures and ctDNA are exploratory endpoints. Each phase 2 cohort will enroll in a single stage of up to 10 patients. Molecular abnormalities will be characterized through the analysis of archival tissue.

419TiP Chemosensitization of carboplatin by NOX66: Pharmacokinetics and safety

I. Minns, G. Kelly

Clinical Development and Medical Affairs, Noxopharm Limited, Sydney, Australia

Background: The experimental anti-cancer drug, idronoxil, is a selective inhibitor of PI3K/AKT in tumor cells, with studies showing it to be a potent chemosensitizing agent of carboplatin *in vitro* and in animal studies across a wide range of cancer cell types. These results, however, have not translated to clinical efficacy, with a Phase 3 study of combined oral idronoxil and intravenous carboplatin in patients with late-stage platinum-refractory ovarian cancer discontinued with no efficacy seen. This lack of efficacy is now thought to be due to complete conversion of idronoxil to bio-inactive Phase 2 metabolites. NOX66 is a suppository formulation of idronoxil designed to protect the drug from Phase 2 metabolism. This first-in-human study will look at the ability of NOX66 to deliver relatively high levels of idronoxil in a bio-active form, investigating (a) PK and (b) safety of NOX66 administration both as a monotherapy and in combination with carboplatin.

Trial design: This is an open label, Phase 1 PK and safety study of NOX66 as a monotherapy and in combination with carboplatin. Patients included have end stage, refactory solid tumours, and no further therapy options available. A total of 16 patients will be recruited into the study in two cohorts of 8 patients. NOX66 suppositories are formulated using 400mg of idronoxil per 2.2g suppository. Patients are allocated to receive either one or two suppositories per day. Study Part 1: NOX66 PK: Patients receive NOX66 for 14 consecutive days as monotherapy, with a follow up period of 7 days post-dosing. Blood samples will be collected throughout the monotherapy arm to measure levels of idronoxil. If no significant adverse events are noted in this 21 day period, a patient will continue in the study. Study Part 2: NOX66 plus Carboplatin: Patients receive NOX66 at the same dose as in Part 1, for 7 days. Carboplatin is administered on Day 2 of treatment. Up to 6 cycles of chemotherapy are administered, at intervals of 28 days. For Cycles 1-3, low dose (AUC4) carboplatin is administered. Subject to safety review, standard dose (AUC6) carboplatin is administered for cycles 4-6. Safety assessment is continued throughout the study, with measures to identify efficacy signals (CT scan, ECOG) performed at baseline and after Cycles 3 and 6.

420TiP Phase 1b/2 study to assess the safety, tolerability, and clinical activity of BGB-290 in combination with temozolomide in patients with locally advanced or metastatic solid tumors

M. Johnson[1], B. Benson[2], R. Wei[3], R. Brachmann[2], M.D. Galsky[4]

[1]Tennessee Oncology, Sarah Cannon Research Institute, Nashville, TN, USA, [2]Clinical Development, BeiGene USA, Inc, Emeryville, CA, USA, [3]BioStatistics, BeiGene USA, Inc, Emeryville, CA, USA, [4]Medical Oncology, Icahn School of Medicine at Mount Sinai, New York, NY, USA

Background: Poly (ADP-ribose) polymerase (PARP) proteins are a family of DNA binding and repair proteins and are thought to play a key role in the base excision repair of DNA damage generated by temozolomide (TMZ), a DNA-alkylating agent. PARP inhibitors (PARPis) represent a class of antitumor agents that exert their cytotoxic effects by inhibiting PARP activity. Some PARPis are capable of trapping PARP proteins on DNA, further augmenting cell death. BGB-290 is a potent and selective inhibitor of PARP1/2 and has demonstrated PARP trapping capacity. Synergistic cytotoxicity has been observed *in vitro* and *in vivo* when BGB-290 is combined with low dose TMZ.

Trial design: This open-label, Phase 1b/2 dose-escalation/dose-expansion study is designed to evaluate BGB-290 at the recommended Phase 2 dose (60 mg administered orally twice daily [PO BID]) in combination with TMZ in patients with locally advanced and metastatic solid tumors. The phase 1b dose-escalation component will follow a 3 + 3 design to establish the maximum tolerated dose (MTD) of TMZ in combination with BGB-290 in ~50 patients with solid tumors. Dose escalation will evaluate the safety, tolerability and pharmacokinetics of BGB-290 (60 mg BID) plus escalating doses

Table: 420TiP

Treatment arm	Tumor type	Estimated sample size
Cohort 1	Platinum-sensitive high grade epithelial, non-mucinous, ovarian cancer, fallopian cancer or primary peritoneal cancer with either known deleterious or suspected deleterious germline or somatic BRCA1/2 mutation or with DNA HRD	20
Cohort 2	Triple negative breast cancer with either known deleterious or suspected deleterious germline or somatic *BRCA1/2* mutation or with DNA HRD	20
Cohort 3	Metastatic castration-resistant prostate cancer with either known deleterious or suspected deleterious germline or somatic BRCA1/2 mutation or with documented HRD	20
Cohort 4	Extended stage small cell lung cancer who have been treated with ≤2 prior regimens	20
Cohort 5	Gastric or gastroesophageal junction cancer who have been treated with ≤ 2 prior regimens	20

of TMZ administered once daily (QD) either on Days 1-7 (Arm A) or continuously (Arm B) of each 28-day cycle. The phase 2 component will further evaluate the safety, tolerability and antitumor activity of the recommended combination dose and schedule in ~20 patients with one of five different tumor types (**Table**). Enrollment into these expansion cohorts will occur simultaneously and independent of each other. Subjects will continue to receive treatment in 28-day cycles until confirmed disease progression, intolerable toxicity, or discontinuation/withdrawal.

421TiP Phase 1b/2 study to assess the clinical effects of BGB-290 in combination with radiation therapy (RT) and/or temozolomide (TMZ) in patients with first-line or recurrent/refractory glioblastoma

P.Y. Wen[1], K. Shih[2], D. Schiff[3], R. Brachmann[4], R. Weitzman[4], T. Cloughesy[5]

[1]Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA, USA, [2]Neuro-Oncology, Sarah Cannon Research Insititute, Nashville, TN, USA, [3]Neurology, University of Virginia Health System, Charlottesville, VA, USA, [4]Clinical Development, BeiGene USA, Inc, Emeryville, CA, USA, [5]Neurology-Oncology, University of California Los Angeles, Los Angeles, CA, USA

Background: Poly (ADP-ribose) polymerase (PARP) proteins are a family of DNA binding and repair proteins and are thought to play a key role in the base excision repair of DNA damage generated by TMZ. In glioblastoma (GB) cells, pharmacological modulation of PARP activity increased growth inhibition induced by TMZ in both p53-wild type and-mutant GB cells lowering the TMZ IC_{50}. RT used in the clinical treatment of GB generates mostly single-strand breaks (SSBs). In non-replicating cells PARP inhibition only delays the repair of SSBs induced by radiation with a minimal impact on cell survival. On the contrary, PARP inhibition markedly enhances radiosensitivity of proliferating cells generating double-strand breaks. Thus, PARP inhibitors have the potential to increase the therapeutic index of RT by increasing DNA damage mainly in highly replicating tumor cells, but sparing non-cycling normal tissues. BGB-290, a potent and selective inhibitor of PARP1/2, has demonstrated potent PARP trapping, brain penetrance and antitumor activity in preclinical intracranial xenograft models.

Trial design: This open-label, dose-escalation/dose-expansion Phase 1b/2 study was designed to determine the safety, tolerability, pharmacokinetics, pharmacodynamics, and antitumor effects of BGB-290 at the recommended Phase 2 dose (60 mg PO BID) in combination with RT and/or TMZ. The Phase 1b component will consist of 3 dose-escalation arms. Arm A: BGB-290 will be combined with RT in patients with first-line GB with unmethylated *MGMT* promoter ('unmethylated GB'); Arm B: BGB-290 will be combined with both TMZ and RT in patients with first-line unmethylated GB; Arm C: BGB-290 will be combined with increasing doses of TMZ in patients with recurrent/refractory methylated or unmethylated GB. Once a recommended Phase 2 regimen has been established, up to 60 patients may be enrolled in the dose-expansion (Phase 2) cohort for that arm. In Arm C, 2 expansion cohorts with up to 60 patients each may be opened: 1 for unmethylated GB and 1 for methylated GB.

422TiP PROCLAIM-CX-2009: A first-in-human trial to evaluate CX-2009 in adults with metastatic or locally advanced unresectable solid tumors

J. Garcia-Corbacho[1], A. Spira[2], V. Boni[3], J. Feliu[4], M. Middleton[5], H. Burris[6], A. Yang Weaver[7], M. Will[7], J. Harding[8], F. Meric-Bernstam[9], V. Heinemann[10]

[1]Oncology, Hospital Clinic Barcelona, Barcelona, Spain, [2]Oncology, Virginia Cancer Specialists Research Institute, and Oncology Research, Fairfax, VA, USA, [3]Oncology, START Madrid-CIOCC, Madrid, Spain, [4]Oncology, Hospital Universitario La Paz, Madrid, Spain, [5]Oncology, Oxford NIHR Biomedical Research Centre, University of Oxford, Oxford, UK, [6]Oncology, Sarah Cannon Research Institute, Nashville, TN, USA, [7]Oncology, CytomX Therapeutics, South San Francisco, CA, USA, [8]Oncology, Memorial Sloan Kettering Cancer Center, New York, NY, USA, [9]Oncology, University of Texas MD Anderson Cancer Center, Houston, TX, USA, [10]Oncology, Ludwig-Maximilians-University of Munich - Campus Grosshadern, Munich, Germany

Background: CX-2009 is a novel recombinant Probody™ drug conjugate (PDC) derived from a humanized monoclonal antibody (mAb) against CD166 and conjugated to N-succinimidyl 4-(2-pyridyldithio) butanoate-N2′-deacetyl-N2′-(4-mercapto-4-methyl-1-oxopentyl)-maytansine (SPDB-DM4, licensed from Immunogen), a potent microtubule inhibitor. PDCs are fully recombinant mAb prodrugs designed to remain inactive until they are cleaved into an active mAb by tumor-associated proteases. This tumor-specific activation allows PDCs to target highly and homogeneously expressed tumor antigens while avoiding binding to these same targets on healthy tissue. An example is CD166 (also referred to as activated leukocyte cell adhesion molecule [ALCAM]), which is highly expressed in multiple cancers but also in healthy tissue. In preclinical studies, CX-2009 exhibited antitumor activity and reduced peripheral binding compared to the corresponding anti-CD166 ADC.

Trial design: PROCLAIM-CX-2009 (PRObody CLinical Assessment In Man) is an open-label, multicenter, dose-escalation study to determine the maximum tolerated dose (MTD) and the recommended phase 2 dose (RP2D) of CX-2009 in 7 selected tumor types with high CD166 expression (breast, lung, prostate, ovarian, endometrial, head and neck, and biliary carcinomas). Part A ($n \leq 50$) will initiate with accelerated dose titration, followed by a standard 3 + 3 design to determine the MTD and ending in a modified toxicity probability interval 2-design cohort treated at the MTD to determine the RP2D. Part B of the study will be a dose expansion phase testing CX-2009 administered at the RP2D in the same 7 tumor types (up to 14 patients each, $n \leq 98$). Eligibility is based on confirmed refractory metastatic or locally advanced unresectable tumor. Outcome measures include assessment of safety, tolerability, pharmacokinetics, and efficacy based on RECIST 1.1. Exploratory biomarkers will characterize tumor CD166 expression and mitotic markers as well as CX-2009 activation in tumor versus peripheral blood.

Clinical trial identification: NCT03149549

Legal entity responsible for the study: CytomX Therapeutics, South San Francisco, CA, USA

Funding: CytomX Therapeutics, South San Francisco, CA, USA

Disclosure: M. Middleton: Grants: Roche, AstraZeneca, GSK. Advisory board: Amgen, Novartis, Rigontec, CytomX. Personal fees: Amgen, Roche, GSK, Novartis, Bristol-Myers Squibb, Eisai, Merck, CytomX. 423TiP The first-in-human, dose-finding PROCLAIM-CX-072 trial to assess the antitumor activity and tolerability of the probody therapeutic CX-072 as monotherapy and in combination with ipilimumab or vemurafenib in solid advanced tumors and lymphomas

V. Boni[1], J. Garcia-Corbacho[2], J. Feliu[3], J. Wydmanski[4], Z. Horvath[5], I. Bondarenko[6], B. Irving[7], M. Will[7], E.G.E. de Vries[8], F. Thistlethwaite[9]

[1]Oncology, START Madrid-CIOCC, Madrid, Spain, [2]Oncology, Hospital Clinic Barcelona, Barcelona, Spain, [3]Oncology, Hospital Universitario La Paz, Madrid, Spain, [4]Oncology, NZOZ Vegamed, Katowice, Poland, [5]Oncology, Debreceni Egyetem Klinikai Kozpont, Debrecen, Hungary, [6]Oncology, Dnipropetrovsk State Medical Academy, Dnepropetrovsk, Ukraine, [7]Oncology, CytomX Therapeutics, South San Francisco, CA, USA, [8]Oncology, Universitair Medical Center Groningen, Groningen, Netherlands, [9]Oncology, The Christie NHS Foundation Trust and University of Manchester, Manchester, UK

Background: CX-072 is a novel protease activatable prodrug (Probody™ therapeutic) derived from a human monoclonal antibody against programmed cell death ligand 1 (PD-L1). CX-072 was designed to restrict its activity to the tumor microenvironment and remain largely inactive in nonmalignant tissue. A surrogate molecule for CX-072 displayed potent antitumor activity with reduced systemic immune activation and immune-related toxicities in preclinical tumor models, potentially enabling new and more effective combination therapies. The phase 1/2 PROCLAIM-CX-072 (PRObody CLinical Assessment In Man) study will assess the safety, tolerability, and antitumor activity of CX-072, as monotherapy and in combination, in adults with advanced or recurrent solid tumors and lymphomas.

Trial design: In an open-label, multicenter, dose-escalation, 3 + 3 design, CX-072 will be administered as monotherapy (Part A) in 2 combination schedules with ipilimumab 3 mg/kg 3 weekly × 4 (Parts B1 and B2) and in combination with vemurafenib 960 mg/kg twice daily (Part C). The expansion cohort (Part D) will include CX-072

monotherapy in PD-L1–responsive tumor types. Patient recruitment was initiated on January 11, 2017. Key inclusion criteria are: Parts A and B1—advanced, refractory solid tumor or lymphoma in checkpoint inhibitor-naive patients for whom approved PD agents are not available; Part B2—advanced, refractory solid tumors or lymphomas with measurable disease that progressed on previous treatment with a PD-1/PD-L1 inhibitor but patients did not discontinue due to toxicity; Part C—checkpoint inhibitor, BRAF-inhibitor, and MEK-inhibitor-naive metastatic V600E BRAF-mutated melanoma. Efficacy will be determined according to irRECIST v1.1 criteria, and safety and tolerability will be assessed based on the incidence and nature of dose-limiting toxicities, adverse events (AEs), and serious AEs. Exploratory biomarkers will be used to characterize tumor protease activity, immune response pattern within the tumor, and CX-072 activation in tumor vs peripheral blood.

Clinical trial identification: NCT03013491

Legal entity responsible for the study: CytomX Therapeutics, South San Francisco, CA, USA

424TiP Phase 1b multi-indication study of the antibody drug conjugate anetumab ravtansine in patients with mesothelin-expressing advanced or recurrent malignancies

A. A. Adjei[1], A. Walter[2], L. Cupit[3], J. Siegel[4], A. Holynskyj[3], B.H. Childs[3], C. Elbi[3]

[1]Medical Oncology, Mayo Clinic, Rochester, MN, USA, [2]Biomarker Strategy, Bayer AG, Berlin, Germany, [3]Clinical Development, Bayer HealthCare Pharmaceuticals Inc., Whippany, NJ, USA, [4]Clinical Statistics, Bayer HealthCare Pharmaceuticals Inc., Whippany, NJ, USA

Background: Mesothelin is expressed in a wide variety of tumours, including mesothelioma, ovarian, pancreatic, gastric/GEJ, NSCLC, triple-negative breast cancer, cholangiocarcinoma, and thymic carcinomas. Anetumab ravtansine (BAY 94-9343), is a novel fully human anti-mesothelin IgG1 antibody conjugated to the maytansinoid tubulin inhibitor DM4 and has shown encouraging anti-tumor activity in mesothelioma and ovarian cancer patients in a phase I study. We will therefore conduct a signal generating study with anetumab ravtansine in six additional high unmet medical need malignancies with mesothelin expression (NCT03102320).

Trial design: Eligibility criteria include: ≥18 years, unresectable locally advanced or metastatic recurrent or relapsing disease, one or more prior lines of therapy, and availability of tumour tissue for mesothelin expression testing. Mesothelin-positive patients with selected adenocarcinomas (NSCLC, triple negative breast, gastric including gastroesophageal junction) and thymic carcinoma will receive anetumab ravtansine as monotherapy at 6.5 mg/kg IV on a 21-day cycle. Patients with cholangiocarcinoma will receive anetumab ravtansine in combination with cisplatin (25 mg/m2 IV day 1 and 8 on a 21-day cycle for up to 6 cycles) and patients with pancreatic adenocarcinoma will receive anetumab ravtansine in combination with gemcitabine (1000 mg/m2 IV day 1 and 8 on a 21-day cycle). A safety run-in phase (18-24 patients each) will be conducted for the combination regimens prior to enrolling patients in the main study phase. The primary objective of the main phase of the study is objective response rate (ORR) of anetumab ravtansine as monotherapy or combination therapy in patients with either of two mesothelin expression levels: high (≥30% positive tumor cells with moderate and stronger membrane staining intensity) and low-mid (≥5% all intensities and <30% positive tumour cells with moderate and stronger membrane staining intensity). Secondary objectives include safety, disease control rate, duration of response, durable response rate, and progression-free survival. Approximately 348 patients will be enrolled.

Clinical trial identification: NCT03102320

425TiP A phase 1 study of SY-1365, a selective CDK7 inhibitor, in adult patients with advanced solid tumors

A. Tolcher[1], K.T. Do[2], E. di Tomaso[3], N. Waters[3], K. Stephens[3], D.A. Roth[3], G. Shapiro[2]

[1]Medical Oncology, South Texas Accelerated Research Therapeutics (START), San Antonio, TX, USA, [2]Early Drug Development Center, Dana-Farber Cancer Institute, Boston, MA, USA, [3]Clinical Development, Syros Pharmaceuticals, Cambridge, MA, USA

Background: SY-1365 is a selective and potent covalent CDK7 inhibitor. CDK7 activity has been implicated in malignancies with transcriptional dependencies such as SCLC, TNBC, ovarian cancer, MYCN-amplified neuroblastoma, and various hematologic malignancies including AML and T-ALL. Preclinical studies in solid tumor and hematologic malignancies show treatment with SY-1365 leads to antitumor activity, showing apoptosis in vitro and complete regressions in xenograft models. This first clinical study is focused on patients with advanced solid tumors. The primary objectives are to assess the safety and tolerability of SY-1365 administered intravenously as a single agent, and to determine dose-limiting toxicities, maximum tolerated dose, and the recommended phase 2 dose. Secondary objectives include evaluation of pharmacokinetic (PK) properties and pharmacodynamic (PD) effects of SY-1365 in tumor and surrogate tissues, as well as assessment of preliminary anti-tumor activity.

Trial design: This is a multi-center, open-label Phase 1 trial that is expected to enroll approximately 70 patients with advanced solid tumors. The dose escalation phase of the trial is open to solid tumor patients for whom standard curative or palliative measures do not exist or are no longer effective. Initially, SY-1365 will be administered intravenously twice weekly for 3 weeks of each 4-week cycle. Regimen optimization will be based upon PK, PD, and safety data prior to an expansion phase to evaluate preliminary antitumor activity of SY-1365 in 25 patients with SCLC, TNBC or ovarian cancer. A second expansion cohort will enroll 10 patients with tumors of any histology to evaluate PD endpoints in paired tumor biopsies. SY-1365 target engagement in peripheral blood mononuclear cells and available tumor biopsies will be assessed by measuring CDK7 occupancy over the course of treatment. Downstream biological pathway impact of SY-1365 will be measured by quantifying changes in gene expression as a result of transcriptional inhibition. Induction of tumor cell apoptosis will also be investigated. This trial opened in May 2017. ClinicalTrials.gov identifier: NCT03134638.

Clinical trial identification: Study Protocol Number: SY-1365-101. ClinicalTrials.gov NCT03134638

426TiP First-in-human study of AMC303 as monotherapy in patients with advanced solid tumor of epithelial origin

E. Calvo[1], P. Aftimos[2], A. Azaro[3], M. de Miguel[1], C. Jungels[4], P. Nuciforo[5], P. Ehmer[6], H. Bender[7], K. Dembowsky[8]

[1]Medical Oncology, START Madrid, Centro Integral Oncologico Clara Campal, Madrid, Spain, [2]Clinical Trials Conduct Unit, Institute Jules Bordet, Brussels, Belgium, [3]Molecular Therapeutics Research Unit, Vall d'Hebron University Hospital, Barcelona, Spain, [4]Medical Oncology, Jules Bordet, Brussels, Belgium, [5]Molecular oncology group, Vall d'Hebron Institute of Oncology, Barcelona, Spain, [6]Analytics, Pharmacelsus GmbH, Saarbrücken, Germany, [7]Clinical Development, Amcure GmbH, Eggenstein-Leopoldshafen, Germany, [8]Management, Amcure GmbH, Eggenstein-Leopoldshafen, Germany

Background: CD44v6 is an isoform of the CD44 family of transmembrane glycoproteins for hyaluronan. High CD44v6 expression was correlated with tumor invasion, metastasis, recurrence and chemoresistance. CD44v6 is a co-receptor of the receptor tyrosine kinases c-Met, RON and VEGFR-2 that play a critical role in the development and progression of many types of cancer. Inhibition of CD44v6 efficiently blocks activation of c-Met, RON and VEGFR-2 and intracellular downstream signaling processes. AMC303 is a highly specific and selective inhibitor of CD44v6 for which strong anti-tumor activity was demonstrated *in vitro* and *in vivo*. In xenotransplantation animal models, intermittent application of AMC303 resulted in a marked reduction of the primary tumor, prevention of metastatic spread and regression of existing metastases. Good safety and tolerability were demonstrated in pre-clinical studies. The starting dose of 0.1 mg/kg and dose escalation steps are based on the safety profile and are supported by modelling of human pharmacokinetic (PK) profiles from animal exposure studies. Blocking of CD44v6 by AMC303 represents a novel and promising approach to block cancer related RTK pathways by an extracellular acting drug.

Trial design: A First-in-Human Phase I/Ib study in cancer patients was initiated (NCT03009214). The study was designed as a two part open-label, non-randomized, multicentre, dose escalation study with a 3 + 3 design (Part 1) and an expansion cohort at the Maximum Tolerated Dose (MTD)/Recommended Phase 2 Dose (RP2D) (Part 2). Inclusion and exclusion criteria are: Type of cancer (e.g. epithelial cancer for which CD44v6 is known to be highly expressed), ECOG status 0-2, and adequate hematological, renal and hepatic function. Cancer patients are enrolled after failure of conventional therapy or for whom no standard treatment is available. The primary endpoints in Part 1 are safety and tolerability and PK properties. The effects of AMC303 on RTK pathways are analysed in plasma samples (ELISA and Luminex) and mandatory tumor biopsies (immunohistochemistry, protein profiling). Part 2 will focus on selected tumor types as evaluated from the pharmacological effects of AMC303 in part 1.

Background: Among patients (pts) with advanced carcinoid/neuroendocrine tumors (NETs), expression of PD-L1 is associated with higher tumor grade. The multicohort phase 1b KEYNOTE-028 study (NCT02054806) evaluated safety and efficacy of pembrolizumab in pts with PD-L1–positive advanced solid tumors. This is the first report from the carcinoid and pancreatic NET (pNET) cohorts of this study.

Methods: Eligibility criteria included: Carcinoid tumors or well- or moderately differentiated pNETs; PD-L1–positive (≥1% modified proportion score or interface pattern, QualTek IHC); failure of standard therapy; and ECOG PS ≤ 1. Pts received pembrolizumab 10 mg/kg Q2W for up to 2 y or until confirmed progression, intolerable toxicity, or consent withdrawal. Response was assessed every 8 wk for 6 mo then every 12 wk. The primary endpoint was ORR per RECIST v1.1 by investigator review.

Results: 276 screened pts had tumor samples evaluable for PD-L1; 36% were positive. Among enrolled carcinoid (n = 25 [lung, n = 9; gut, n = 7; other, n = 9]) and pNET (n = 16) pts, respectively, median ages were 63 y and 61 y, 76% and 38% had ECOG PS of 1, and 44% and 50% had ≥2 prior therapies for metastatic disease. As of Jan 10, 2017, median (range) follow up was 18.9 (2.0–33.3) and 20.1 (4.5–30.4) mo. Treatment-related AEs (TRAEs) occurred in 17 (68%) carcinoid and 11 (69%) pNET pts; the most frequent (≥20%) were diarrhea (n = 7, 28%) and fatigue (n = 5, 20%) in carcinoid pts and fatigue (n = 6, 38%) and diarrhea (n = 4, 25%) in pNET pts. Grade ≥3 TRAEs occurred in 8 (32%) carcinoid pts (including diarrhea, n = 3; AST increased, n = 2; ALT increased; n = 2) and 0 pNET pts. One grade 4 AE (increased gamma-glutamyl transferase) and 1 death (unspecified cause) occurred in the carcinoid cohort; neither was treatment related. Three carcinoid pts (12%; 95% CI, 3%–31%) and 1 pNET pt (6%; 95% CI, 0%–30%) had objective responses; SD rates were 60% (n = 15) and 88% (n = 14). Durations of response were 6.9, 9.2, and 11.1 mo for the carcinoid responders; the pNET responder has an ongoing response of 17.6 mo.

Conclusions: In pts with heavily pretreated carcinoid/pNET tumors, pembrolizumab was generally well tolerated and, in some pts, provided clinically meaningful antitumor activity.

428O Immune landscape of pancreatic neuroendocrine tumours (PanNETs)

K. Young[1], C. Ragulan[2], G. Nyamundanda[2], Y. Patil[2], R.T. Lawlor[3], D. Cunningham[1], N. Starling[1], A. Scarpa[3], A. Sadanandam[2]

[1]GI and Lymphoma Research Department, The Royal Marsden NHS Foundation Trust, Sutton, UK, [2]Molecular Pathology, The Institute of Cancer Research, Sutton, UK, [3]ARC-Net Centre for Applied Research on Cancer, University and Hospital Trust of Verona, Verona, Italy

Background: To date little is known about the immune landscape of PanNETs and if immunotherapy could play a role in their treatment. We previously identified 3 molecular subtypes in PanNETs: Metastases like primary (MLP), intermediate and insulinoma like tumours (PanNETassigner signature, Sadanandam Cancer Discovery 2015). Here we sought to profile the immune architecture of 48 PanNET patient samples across these subtypes.

Methods: Patients were recruited by the ARC-Net Research Centre Verona, within an ethically approved protocol. Quality RNA was isolated from fresh frozen samples for immune profiling using microarrays, nCounter platform (Nanostring Technology) and RNAseq (Illumina). CIBERSORT analysis was performed to assess immune cell enrichment.

Results: 48 PanNET samples were classified using the PanNETassigner gene signature. Based on immune expression profile analysis, tumours were divided into two categories, immune high or immune dormant. The majority of the MLP subtype were immune high, whereas most of the insulinoma and intermediate samples were immune dormant. A small number of insulinoma samples were immune high reflecting the heterogeneity of this tumour. Within the MLP subtype there was increased expression of *CD8B*, *LAG3*, *CD38*, *CXCL10*, *CXCL9*, *CCL19*, *CD28* and *CD27* compared to the other subtypes. Some of these genes are associated with chronic infection (CD38, CXCL10) whilst others are markers of T cell exhaustion (*LAG3*). This pattern is consistent with CIBERSORT analysis conducted using microarray data on an overlapping cohort of PanNET samples, where the MLP subtype was associated with increased levels of infiltrating T cells but also an increase in exhausted CD8+ve T cells. PD1 was highly expressed in 2/15 MLPs. PDL1 expression was heterogeneous in MLP but high in 7/13 insulinomas. FOXP3 was highly expressed in a subset of the MLP samples (7/16).

Conclusions: We have demonstrated the differential expression of immune related genes across 3 known PanNET subtypes. The MLP subtype appears to be associated with an immune profile similar to that seen in chronic infection with increased T-cell exhaustion. Such detailed profiling is essential to inform patient selection approaches for immunotherapy and rational immunotherapy combinations for panNETs in the future.

429O A phase II trial of palbociclib in metastatic grade 1/2 pancreatic neuroendocrine tumors: The PALBONET study on behalf of the Spanish Taskforce Group of Neuroendocrine Tumors (GETNE)

E. Grande Pulido[1], A. Teule[2], T. Alonso-Gordoa[1], P. Jiménez-Fonseca[3], M. Benavent[4], J. Capdevila[5], A. Custodio[6], R. Vera[7], J. Munarriz[8], A. La Casta-Muñoa[9], R. Garcia-Carbonero[10]

[1]Medical Oncology, Hospital Universitario Ramon y Cajal, Madrid, Spain, [2]Medical Oncology, ICO Belvitge, Barcelona, Spain, [3]Medical Oncology, H. U. Central de Asturias, Oviedo, Spain, [4]Medical Oncology, H. U. Virgen del Rocío, Seville, Spain, [5]Gastrointestinal and Endocrine Tumor Unit, Vall d'Hebron University Hospital, Barcelona, Spain, [6]Medical Oncology, Hospital Universitario la Paz, Madrid, Spain, [7]Medical Oncology, Hospital de Navarra, Pamplona, Spain, [8]Medical Oncology, Hospital General de Castellón, Castellón, Spain, [9]Medical Oncology, H. U. Donostia, San Sebastian, Spain, [10]Medical Oncology, University Hospital 12 de Octubre, Madrid, Spain

Background: Overexpression or amplification of cell cycle regulators like cyclin-dependent kinase-4 (Cdk-4), phospho-Rb1, or cyclin D1 are observed in 58%, 68%, and 68% pancreatic neuroendocrine tumors (pNETs), respectively. Moreover, these alterations correlate with a more aggressive behavior. Palbociclib targets Cdk-4/6 and has shown in vitro activity in pNETs cell lines overexpressing Cdk-4.

Methods: In this non-randomized, open-label, phase II study, patients (pts) with metastatic grade (G) 1/2 pNETs were recruited from 10 centres belonging to the Spanish Taskforce Group of NETS (GETNE). Palbociclib 125 mg was given once daily for 21 of 28 days until disease progression (DP) or unacceptable toxicity. The initial planned recruitment was 21 patients based on a 2-stage Simon's phase II design, where palbociclib would be considered inactive if < 5% of patients achieved an objective response rate (ORR) by RECIST criteria. Type I error rate was 5% and the design had 85% power to reject null hypothesis when the true ORR was 5%.

Results: 21 pts were included. One pt withdrew from the study due to clinical deterioration after < 1 month (m). 54% were males, mean age was 54 years (range: 33-66), and 67% had received > 3 previous lines of therapy (23.8% pazopanib; 80.9% sunitinib; 47.6% everolimus) beside somatostatin analogs. 20 pts were evaluable for ORR with a median follow up of 10m (4.23-12.43). No responses (0%) were observed; 11 (55%) pts had stable disease and 6 of them lasted more than 6m; 7 (35%) pts had progression as best response. 1 pt had tumor shrinkage of 8%. Median PFS was 1.9m (IC95% 0 - 13). Median OS was 16.6m (IC95% 9.3 – 23.9). Most frequent toxicities of any grade were: asthenia (16.2%), diarrhea (6.4%), abdominal pain (4.7%), nausea (4.3%) and neutropenia (11.5%). 5 pts developed G3-4 neutropenia (1 case of febrile neutropenia) and 2 pts G3-4 thrombocitopenia.

Conclusions: Lack of activity was observed with palbociclib in 21 molecularly unselected and heavily pretreated patients with advanced G1/2 pNETs. Translational studies correlating activity with molecular tumor markers and Ki67 proliferation index are ongoing.

430O Different RNA expression profile defines prognosis in grade 1/2 neuroendocrine neoplasms of small intestine origin: The GETNE-NETSEQ study

J. Capdevila[1], F. Mancuso[2], S. Landolfi[3], F. Salva[4], C. Miguel[5], P. Jiménez-Fonseca[6], R. Garcia-Carbonero[7], C. López López[8], A. Casteras[9], T. Sauri Nadal[1], P. Nuciforo[10], A. Vivancos[2], I. Matos[1]

[1]Medical Oncology, Vall d'Hebron University Hospital, Vall d'Hebron Institute of Oncology, Barcelona, Spain, [2]Cancer Genomics Group, Vall d'Hebron Institute of Oncology, Barcelona, Spain, [3]Anatomic Pathology Department, Vall d'Hebron Hospital, Barcelona, Spain, [4]Medical Oncology, Mataró Hospital, Barcelona, Spain, [5]Pathology, H. U. Central de Asturias, Oviedo, Spain, [6]Medical Oncology, H. U. Central de Asturias, Oviedo, Spain, [7]Medical Oncology, University Hospital 12 de Octubre, Madrid, Spain, [8]Oncology, Hospital Universitario Marqués de Valdecilla, Santander, Spain, [9]Endocrinology, Vall d'Hebron University Hospital, Barcelona, Spain, [10]Molecular Oncology Group, Vall d'Hebron Institute of Oncology, Barcelona, Spain

Background: Neuroendocrine neoplasms (NENs) are a heterogeneous group of tumors with different prognosis. Clinical and pathological factors are used to predict outcome but there are some patients that have a poor outcome even with good classical prognostic factors. We aimed to define a different RNA expression profile (EP) that could detect patients with worse prognosis and identify possible targetable new pathways.

Methods: We identified 48 paraffin-embedded archival tumor material of patients with metastatic grade 1/2 NENs of small intestine origin for RNAseq. We generated on average 66 million paired-end reads for each sample on HiSeq2500 (Illumina). RNAseq reads were mapped against the human reference genome (hg19) with Tophat (v2.0.14) and quantified using Cufflinks tools suite (v.2.2.1). 41 samples had sufficient quality to be included in the analysis. We used multivariate Cox proportional models to study the association between EP, clinical variables (gender, age, location of metastases, hormone production and Ki67 index) and overall survival (OS). We defined as poor outcome those patients that died within the first 3 years of the diagnosis of advanced disease.

Results: 9348 transcripts were quantified. A gene signature of 329 transcripts was defined by a two-way statistical analysis between poor and long term survivors. A pathway enrichment analysis of these genes showed a deregulation in the poor prognosis group on the PI3KCA-Akt-mTOR and the Toll-like receptor signaling pathways. The hazard ratio (HR) for mOS defined by EP comparing poor and long term survivor groups was 0.33, 95% CI 0.1-1.1, p = 0.081 in the univariate analysis and HR of 0.05, 95% CI 0.005-0.51, p = 0.011 in the multivariate analysis.

Conclusions: We identified statistically different RNA-clusters and different deregulated pathways for those patients with advanced NENs of small intestine origin with poor prognosis. To our knowledge, this is the first time that Toll-like pathway is involved in the pathogenesis of NENs. These results are relevant as they may help improve the prognosis stratification of patients and involve novel targetable pathways of great clinical potential.

[1]GROW School for Oncology and Developmental Biology, Department of Pulmonology, Maastricht University Medical Center (MUMC), Maastricht, Netherlands, [2]Genetic Cancer Susceptibility Group, International Agency for Research on Cancer (IARC-WHO), Lyon, France, [3]Pathology-DNA, Jeroen Bosch Hospital, s'Hertogenbosch, Netherlands, [4]Department of Pathology, Vrije University Medical Centre (VUMC), Amsterdam, Netherlands, [5]Department of Pathology, Maasstad Hospital & Erasmus University Medical Center, Rotterdam, Netherlands, [6]Department of Pulmonary Diseases, University of Groningen and University Medical Center Groningen, Groningen, Netherlands, [7]Department of Pulmonary Diseases & Thoracic Oncology, VU Medical Center & Netherlands Cancer Institute, Amsterdam, Netherlands, [8]Department Research, Comprehensive Cancer Association, Utrecht, Netherlands, [9]PALGA Foundation, Utrecht, Netherlands, [10]GROW School for Oncology and Developmental Biology, Department of Pathology, Maastricht University Medical Center (MUMC), Maastricht, Netherlands

Background: Whether to treat LCNEC with non-small cell lung carcinoma type chemotherapy (NSCLC, i.e. platinum-gemcitabine/taxanes or pemetrexed) or small cell lung carcinoma type (SCLC, i.e. platinum-etoposide) is subject of debate. Recent molecular studies have identified two mutually exclusive genomic LCNEC subtypes, the co-mutated TP53 and RB1 (i.e. SCLC like) and the STK11/KEAP1 (predominantly RB1 wild-type, i.e. NSCLC like) subtype. We determined if genomic LCNEC subtypes are clinically relevant for chemotherapy (CT) outcome.

Methods: Clinical data and tumour specimens were retrospectively obtained from the Netherlands Cancer Registry and Pathology Registry (PALGA, 2003-2012). All first-line CT treated patients with panel-consensus diagnosed LCNEC were included for next-generation sequencing (NGS) analysis for TP53, RB1, STK11, and KEAP1 genes. Furthermore, immunohistochemistry for RB1 (pRB1, 13A10) was analysed (H-score, ≥50 considered as positive). NGS and pRB1 results were correlated with overall survival (OS) and progression free survival (PFS) by Kaplan Meier plots and Log-rank test.

Results: LCNEC was panel-consensus diagnosed in 148/232 patients; 79 passed quality control for NGS and 109 for pRB1. RB1 mutations were found in 47% (n = 37) and loss of pRB1 expression in 72% (n = 78) of the cases. Mutations in RB1 were mutually exclusive with mutations in STK11 (n = 8; P = 0.006). Due to reported resistance in neuroendocrine carcinomas, we analysed NSCLC-CT without pemetrexed-CT; OS was significantly longer for NSCLC-CT (n = 15, 9.6 [7.7-11.6] months) compared to SCLC-CT (n = 13, 5.8 [5.5-6.1] months, P = 0.026). LCNEC tumours expressing pRB1 also had longer OS when treated with NSCLC-CT (n = 14, 9.6 [7.4-11.8] vs. n = 9, 1.9 [1.7-2.1] months, P = 0.001). PFS of RB1 wild-type NSCLC-CT treated patients was significantly longer than SCLC-CT (P = 0.018) also for pRB1 (P = 0.023). In patients with a *RB1* mutation OS and PFS were not significantly different for NSCLC-CT vs. SCLC-CT.

Conclusions: In LCNEC with RB1 wild-type, NSCLC-CT correlates with a more favourable outcome compared to SCLC-CT. However, RB1 mutated LCNEC treated with NSCLC-CT have similar clinical outcomes as compared to SCLC-CT. Prospective studies should be initiated.

Background: Sorafenib has demonstrated a significant impact in progression free survival (PFS) in patients with advanced DTC in the DECISION trial. BRAF and RAS

Table: 432PD Clinical variables in each expression profiles

		BRAF like (n = 56)	RAS like (n = 28)	non-BRAF/RAS-like (n = 41)
Treatment	Sorafenib	37(66.1%)	9 (32%)	22 (53.7%)
	Placebo	19 (33.9%)	19 (68%)	19 (46.3%)
Sex	Female	26 (46.4%)	19 (68%)	15 (36.6%)
	Male	30 (53.6%)	9 (32%)	26 (63.4%)
ECOG	0	36 (64%)	15 (53.6%)	29 (70.7%)
	1-2	20 (36%)	13 (46.4%)	12 (29.3%)
Tumor histology	Papillary	53 (94.6%)	14 (50%)	6 (14.6%)
	Follicular	2 (3.6%)	7 (25%)	24(58.5%
	Poorly differentiated	1 (1.8%)	7 (25%)	10 (24.4%)
BRAF status	Mutated	31 (55.4%)	2 (7%)	0 (0%)
	Wild type	25 (44.6%)	26 (93%)	41 (100%)
RAS status	Mutated	5 (8.9%)	14 (50%)	1 (2.4%)
	Wild type	51 (91.1%)	14 (50%)	40 (97.6%)

mutation status (MS) have not shown prognostic significance on PFS and overall survival (OS) in multivariate model. The aim of this study was to correlate different RNA expression profiles with PFS and OS in a multivariate model.

Methods: We previously identified 3 expression profiles, BRAF, RAS and non-BRAF/RAS-like based on RNA-seq analysis (77 million paired-end reads for each sample on HiSeq2000) of 125 tumour samples of patients included in the DECISION trial. RNAseq reads were mapped against the human reference genome (GRCh38) with STAR (v2.5.1b) using ENCODE parameter. We used multivariate Cox proportional models to study the association between clinical variables (sex, age, thyroid cancer histology, Eastern Cooperative Oncology Group performance status), arm of treatment and biomarkers (EP and MS) with PFS and OS.

Results: The clinical variables in each expression profiles are shown in Table. Multivariable analysis indicated that only sorafenib treatment (HR: 0.39, 95% CI 0.23-0.66, $p < 0.001$), age (HR: 0.97, 95% IC 0.94-0.99, $p = 0{,}002$) and BRAF-like EP (HR = 0.41, 95% IC 0.17-0.99, $p = 0.046$) were independent prognostic factors for PFS. No significant prognostic factors we identified for OS. However, in papillary histology (PTC), only the BRAF-like EP was associated with outcome (HR = 0.32, 95% IC 0.118-0.876, $p = 0.026$).

Conclusions: RNA-seq analysis identifies 3 different expression profiles in DTC: BRAF-like, RAS-like and non-BRAF/RAS-like. BRAF-like EP includes almost all BRAF mutant tumors but also a 45% of tumors with no mutation in BRAF gene. In the multivariate analysis, BRAF-like EP has shown a better prognostic factor for PFS in DTC and for OS in PTC.

433PD Comprehensive genomic profiling of metastatic and relapsed thyroid gland carcinomas is associated with tumor type and reveals new routes to targeted therapies

J.S. Ross[1], L.M. Gay[2], P. Vanden Borre[2], N. Almog[2], A.B. Schrock[3], J-A. Vergilio[4], J. Suh[4], S. Ramkissoon[4], E. Severson[4], S. Daniel[4], S.M. Ali[4], V.A. Miller[4], P.J. Stephens[4], J.A. Elvin[4], D. Bowles[5]

[1]Pathology, Albany Medical Center, Albany, NY, USA, [2]Pathology, Foundation Medicine, Cambridge, MA, USA, [3]Clinical Development, Foundation Medicine, Cambridge, MA, USA, [4]R&D, Foundation Medicine, Cambridge, MA, USA, [5]Medical Oncology, University of Colorado Denver, South Aurora, CO, USA

Background: We queried whether CGP could differentiate the mTC subtypes of papillary (PTC), follicular (FTC), medullary (MTC) and anaplastic (ATC) carcinomas and their potential responses to targeted and immunotherapies.

Methods: CGP was performed on FFPE samples using hybridization-captured, adaptor ligation based libraries to a mean coverage depth of > 500X for up to 315 cancer-related genes. Total mutational burden (TMB) was determined on 1.1 megabases of sequenced DNA as previously described (PMID: 28420421).

Results: 778 clinically advanced mTC were studied. Median age across the subtypes was similar with male patients slightly more frequent than females except for PTC. ATC had the highest median GA/sample at 4.34. *BRAF* was a target option for 73% of PTC and 39% of ATC, and *RET* for MTC in 81% of cases. Oncogenic rearrangements of *RET*, *BRAF*, *ALK*, and *NTRK1* were detected in 8%, 3%, 1%, and 1% of PTC cases, respectively, and in 1%, 1%, 0%, and 1% of ATC cases, respectively, but not detected in any cases of FTC or MTC. At 66%, *TP53* GA were most frequent in ATC. *TERT* GA were 58-67% in PTC, FTC and ATC and 0% in MTC. TMB was extremely low for all

Table: 433PD

	PTC	FTC	MTC	ATC
No. Patients	408	77	113	180
Median age (years)	59	60	54	64
Gender (F/M)	215/193	37/40	46/67	88/92
GA/tumor	2.75	3.01	1.96	4.34
Significant genes altered	*BRAF TERT TP53 RET*	*TERT NRAS TP53 PTEN HRAS*	*RET VHL MEN1 HRAS CCND1*	*TP53 TERT BRAF NRAS PIK3CA NF1 NF2 PTEN*
TP53 GA Frequency	11%	16%	2%	66%
RET GA Frequency	9%	0%	81%	2%

BRAF GA Frequency	73%	7%	0%	39%
BRAF, RET, ALK, or NTRK rearrangemens	13%	0%	0%	3%
Total Mutational Burden ≥10 mut/Mb	2%	1%	2%	3%
Opportunity for Targeted Therapies	High (BRAF, oncogenic fusions)	Low	High (RET)	Moderate (BRAF, oncogenic fusions)

4 mTC tumor types with only 3 mTC (<1%) having ≥ 20 mut/Mb. Examples of mTC with responses to targeted therapies will be presented.

Conclusions: Refractory mTC patients are generally older than patients with classic localized primary PTC, and feature relatively more males. Advanced stage PTC, and to a lesser extent ATC, is frequently driven by *BRAF* GA or oncogenic rearrangements. Relapsed MTC is nearly universally driven by *RET* GA, whereas FTC has no dominant driver GA identified. TMB appears to be low for all subtypes of MTC, suggesting low potential for immunotherapies.

434PD Impact of duration of dose interruption on the efficacy of lenvatinib (LEN) in a phase 3 sudy in patients (pts) with radioiodine refractory differentiated thyroid cancer (RR-DTC)

M. Tahara[1], M.S. Brose[2], L. Wirth[3], T. Suzuki[4], K. Fujino[4], N. Batty[5], C. Dutcus[5], A. Gianoukakis[6]

[1]Division of Head and Neck Medical Oncology, National Cancer Center Hospital East, Kashiwa, Japan, [2]The Thyroid Cancer Therapeutics Program, Department of Otorhinolaryngology: Head and Neck Surgery, Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA, USA, [3]Hematology/Oncology, Massachusetts General Hospital, Harvard University, Boston, MA, USA, [4]Eisai Co., Ltd, Tokyo, Japan, [5]Eisai, Inc, Woodcliff Lake, NJ, USA, [6]Endocrinology Fellowship Program, UCLA School of Medicine, Torrance, CA, USA

Background: LEN prolonged progression-free survival (PFS) in pts with RR-DTC in the SELECT trial, and efficacy was maintained in all subgroups. Toxicity was manageable with dose modifications, but whether a longer period of dose interruption might impact the efficacy of LEN was unclear.

Methods: In SELECT, pts were randomized 2:1 to receive LEN 24 mg/day or placebo. Pts assigned to LEN were divided into 2 groups: pts with duration of dose interruption <10% (A) and pts with duration of dose interruption ≥10% (B) of total treatment duration. A and B were not randomized groups. PFS, objective response rate (ORR), and safety were analyzed in both groups.

Results: Of 261 LEN-treated pts, there were 134 in group A and 127 in group B. Differences in pt characteristics between groups (A and B) were, respectively: age (>65 years, 33% and 49%), race (Asian, 10% and 25%), and ECOG performance status (0, 64% and 46%). Median duration of dose interruption was 19 days (range: 0–63) and 61 days (range: 2–266) in groups A and B, respectively. Median PFS was not reached (hazard ratio [HR] to placebo: 0.14; 95% CI: 0.09–0.20, P < 0.001) in group A and 12.8 months (HR to placebo: 0.31, 95% CI: 0.22–0.43) in group B. ORR was 76% for group A and 53% for B. Disease control rate was 88% and 87% in groups A and B, respectively. Common adverse events (AEs) were similar in both groups, but incidences were different for diarrhea (A: 74%; B: 58%), decreased appetite (A: 45%; B: 62%), decreased weight (A: 57%; B: 44%), palmar-plantar erythrodysesthesia (A: 27%; B: 38%), and proteinuria (A: 23%; B: 42%). Common AEs leading to dose interruption or reduction included diarrhea (A: 24%; B: 21%), hypertension (A: 16%; B: 24%), proteinuria (A: 11%; B: 27%), and decreased appetite (A: 10%; B: 27%).

Conclusions: Longer duration of dose interruption may negatively affect the potential efficacy of LEN. Management of toxicities is essential to avoid long dose interruption. Differences in pt characteristics might confound the results. However, in this analysis LEN achieved improved PFS and ORR compared to placebo, regardless of length of dose interruption.

Background: Delta-like protein 3 (DLL3) is an atypical Notch receptor family ligand expressed in high-grade neuroendocrine carcinomas (NECs), but not in normal tissue. Rovalpituzumab tesirine (Rova-T^{TM}) is an antibody-drug conjugate targeting DLL3. A Phase 1 study of Rova-T in small cell lung cancer showed encouraging antitumor activity in patients (pts) with DLL3 expression, and was well-tolerated[1]. Rova-T may also be active in other DLL3-expressing tumors.

Methods: This is a Phase 1/2, open-label, multicenter study (NCT02709889) to determine safety and tolerability of Rova-T in 8 cohorts: malignant melanoma, medullary thyroid cancer (MTC), glioblastoma (GBM), large cell NEC (LCNEC), neuroendocrine prostate cancer (NEPC), high-grade gastroenteropancreatic NEC (GEP NEC), other NEC and other solid tumors. Eligible adults have a histologically confirmed, DLL3-expressing, advanced solid tumor relapsed/refractory to standard therapy, and no prior exposure to a pyrrolobenzodiazepine-based drug. A 3 + 3 dose escalation is used in each cohort, at doses 0.2-0.4 mg/kg of Rova-T administered intravenously on Day 1 of each 42-day cycle, and proceeding until a maximum tolerated dose (MTD) is determined. A 2-stage design will be used for disease-specific expansion cohorts.

Results: As of 3 April 2017, 31 pts (2 melanoma, 2 MTC, 3 GBM, 3 LCNEC, 3 NEPC, 3 GEP NEC, 10 other NEC, 5 other solid tumor) have been treated (26 pts at 0.2 mg/kg, 5 pts at 0.3 mg/kg Rova-T). The MTD has not been reached. Twenty-six pts (84%) had an adverse event (AE), and only 3/31 pts (10%) had a Grade 3+ AE deemed to be related to Rova-T. Common AEs were fatigue (32%), nausea (29%), and constipation (23%). Four pts had serosal effusions, 2 (6%) of which were assessed to be drug-related, and 3 pts (10%) had adverse skin reactions. Ten pts (32%) discontinued treatment, 5 for progressive disease and 4 due to AEs. Eleven pts have had post-baseline tumor assessments, and anti-tumor activity has been observed in multiple disease cohorts.

Conclusions: Preliminary safety and efficacy data of Rova-T warrant continued study in these disease populations, and will be updated at time of presentation. 1. Rudin et al., Lancet Oncol 2016.

437PD Integrative DNA methylome and miRNA transcriptome analysis for new biomarker discovery in entero-pancreatic neuroendocrine tumours (EP-NETS)

J. Barriuso[1], A. Lamarca[1], V. Heredia[2], L. Guerra-Pastrian[3], C. Alvarez-Escola[4], J. Castell[5], A. Custodio[6], M. Miguel[2], M. Mendiola[2], J. Feliu[6]

[1]Medical Oncology, The Christie NHS Foundation Trust, Manchester, UK, [2]Translational Oncology, IdIPAZ – Hospital Universitario La Paz, Madrid, Spain, [3]Pathology, IdIPAZ – Hospital Universitario La Paz, Madrid, Spain, [4]Endocrinology, IdIPAZ – Hospital Universitario La Paz, Madrid, Spain, [5]Surgical Oncology, IdIPAZ – Hospital Universitario La Paz, Madrid, Spain, [6]Medical Oncology, IdIPAZ – Hospital Universitario La Paz, Madrid, Spain

Background: Several attempts to improve the knowledge about the molecular biology of EP-NETS. However, the majority of these studies rely on alterations or pattern descriptions rather than integrative analysis of the findings derived from different platforms. We aim to identify new potential biomarkers integrating the differential expression of miRNAs and DNA methylated regions.

Methods: From a series of 115 EP-NETS formalin-fixed and paraffin embedded samples, we selected 8 cases of small intestine (SI) NETS and 8 pancreatic (P) NETS based on relapse (yes vs no) trying to identify the most phenotypically different cases within these groups in our series. DNA and RNA were extracted. The methylome *EPIC* array was used to determine differentially methylated regions (DMRs) and a transcriptomic array was used to analyse miRNA expression. Quality check (QC) of data was ran prior to analysis. False discovery rate (FDR) was applied to correct for multiple comparisons. Chromosomal regions with differentially expressed miRNAs and DMRs were plotted to perform an integrative analysis.

Results: Sample-wise and chip-wise QC were performed. DMRs were analyzed comparing patients with or without relapse (R) in SI-NETS and PNETS. The most significant differentially methylated regions for R vs non-R in PNETS were found in chromosome (chr) 2, and in chr 1 and 2 for SI-NETS. A gene set analysis of the DMRs was performed using a FDR < 0.1. Gene sets commonly represented in SI-NETS and PNETS are within CD8 TCR pathway and endothelin pathway. None of the miRNAs maintain significance using a FDR <0.2. However, one of the top10 differentially expressed miRNAs for PNETS, hsa-miR-149-5p (uncorrected $p = 0{,}014$) is found in the same region of the chr 2 were the most significant DMRs and differentially methylated promoters are located. Has-miR-9-1-5p (uncorrected $p = 0.017$) was also differentially expressed in PNETs and located close to one of significant DMRs in chr 1.

Conclusions: It is feasible to integrate the analysis of DMRs and miRNAs in EP-NETS. Certain areas of chr1 and 2 concentrated regions with different epigenetic regulation when compare R vs non-R. Validation of the findings is ongoing.

438PD Improved time to quality of life deterioration in patients with progressive midgut neuroendocrine tumors treated with 177Lu-DOTATATE: The NETTER-1 phase III trial

J. Strosberg[1], E.M. Wolin[2], B. Chasen[3], M.H. Kulke[4], D. Bushnell[5], M. Caplin[6], R.P. Baum[7], P. Kunz[8], T. Hobday[9], A. Hendifar[10], K. Öberg[11], M. Lopera Sierra[12], P. Ruszniewski[13], E. Krenning[14]

[1]GI Oncology, H. Lee Moffitt Cancer Center University of South Florida, Tampa, FL, USA, [2]Montefiore Einstein Center for Cancer Care, New York, NY, USA, [3]Nuclear Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [4]Gastrointestinal Cancer, Dana-Farber Cancer Institute, Boston, MA, USA, [5]Nuclear Medicine, University of Iowa, IA, USA, [6]Neuroendocrine Tumour Unit, Royal Free Hospital, London, UK, [7]Nuclear Medicine, Zentralklinik Bad Berka GmbH, Bad Berka, Germany, [8]Oncology, Stanford University Medical Center, Stanford, CA, USA, [9]Oncology, Mayo Clinic, Rochester, MN, USA, [10]Oncology, Cedars-Sinai Medical Center, Los Angeles, CA, USA, [11]Endocrine Oncology, University Hospital, Uppsala University, Uppsala, Sweden, [12]Advanced Accelerator Applications, New York, NY, USA, [13]Oncology, Hôpital Beaujon, Clichy, France, [14]Oncology, Erasmus Medical Center, Rotterdam, Netherlands

Background: Neuroendocrine tumor (NET) progression is associated with deterioration in quality of life (QoL). We assessed the impact of ^{177}Lu-DOTATATE treatment on the time to clinically relevant change (deterioration) in health-related QoL (HRQoL). The NETTER-1 trial is an international phase III study in patients with progressive, somatostatin receptor positive midgut NET. Patients were randomized to receive treatment with ^{177}Lu-DOTATATE versus high-dose (60 mg) Octreotide LAR (Oct). EORTC questionnaires QLQC-30 and G.I.NET-21 were assessed during the trial to determine the impact of treatment on HRQoL.

Methods: 231 patients completed EORTC QLQC-30 and G.I.NET-21 questionnaires at baseline and every 12 weeks thereafter until tumor progression centrally confirmed. QoL scores were converted to a 100-point scale according to EORTC instructions and individual changes from baseline scores were assessed. Time to QoL deterioration (TTD) was defined as the time from randomization to the first QoL deterioration $\geq$10 points for each patient in the corresponding domain scale. This magnitude of variation was considered clinically relevant. All analyses were conducted on the ITT population.

Results: TTD was significantly longer in the ^{177}Lu-DOTATATE arm ($N = 117$) vs the control arm ($N = 114$) for the following domains: global health status (hazard ratio (HR) 0.406; $p = 0.0006$), physical functioning (HR 0.518; $p = 0.0147$), role functioning (HR 0.580; $p = 0.0298$), fatigue (HR 0.621; $p = 0.0297$), pain (HR 0.566; $p = 0.0247$), diarrhea (HR 0.473; $p = 0.0107$), disease related worries (HR 0.572; $p = 0.0176$) and body image (HR 0.425; $p = 0.0058$). In the other domains TTD did not reach statistical significance between the arms. Differences in median TTD were clinically significant in several domains: 28.8 months vs. 6.1 months for global health status, and 25.2 months vs. 11.5 months for physical functioning.

Conclusions: This analysis from the NETTER-1 Phase III study demonstrates that ^{177}Lu-DOTATATE provides a significant quality of life benefit for patients with progressive midgut NETs compared to high-dose octreotide, in addition to the meaningful increase in progression-free survival already reported.

439PD Peptide receptor radionuclide therapy of neuroendocrine neoplasms using lutetium-177 and yttrium-90 labeled somatostatin analogs: A single center experience in over 1000 patients

A. Singh[1], H.R. Kulkarni[1], T. Langbein[1], C. Lehmann[1], K. Niepsch[1], D. Müller[1], M. Hommann[2], D. Kaemmerer[2], A. Jochems[3], P. Lambin[4], D. Hörsch[5], R.P. Baum[1]

[1]Theranostics Center for Molecular Radionuclide Therapy and Molecular Imaging, Zentralklinik Bad Berka GmbH, Bad Berka, Germany, [2]Department of General and Visceral Surgery, Zentralklinik Bad Berka GmbH, Bad Berka, Germany, [3]Department of Radiation Oncology, MAASTRO Clinic, Maastricht, Netherlands, [4]GROW - School for Oncology and Developmental Biology, Maastricht University, Maastricht, Netherlands, [5]Department of Internal Medicine, Zentralklinik Bad Berka GmbH, Bad Berka, Germany

Background: Peptide receptor radionuclide therapy (PRRT) of patients with somatostatin receptor expressing gastroenteropancreatic neuroendcrine neoplasms (NEN) has shown promising results in a recently published clinical trial (NETTER-1, NEJM, Jan 2017). In this study, we performed an intention to treat analysis in over 1000 patients with NEN (pancreas, mid-gut, lung and others) treated at our center.

Methods: From 2004, 1048 patients received at least one cycle of Yttrium-90 or Lutetium-177 based PRRT, and were included in an intention to treat analysis. Ga-68 somatostatin receptor (SSR) PET/CT was used for restaging and response to therapy assessment (EORTC criteria). Accordingly, overall survival (OS) and progression free survival (PFS) were calculated. Adverse events (hematotoxicity and nephrotoxicity) were determined by CTCAE (v4.03).

Results: Overall survival (95% CI) was 51 months (47.0-54.9) and differed according to tumor grade, location of primary tumor, functionality, previous therapies, and the radioisotope used for PRRT. PFS was 19 months (16.9-21.0), which was influenced by tumor grade, location of primary tumor, and the radioisotope used for PRRT. PFS after initial progression and first and second resumption of PRRT, following therapy-free intervals of $>$ 6 months, was 11 months (9.4-12.5) and 8 months (6.4-9.5), respectively. Myelodysplastic syndrome or leukemia developed in 2.1% patients. No grade 4 nephrotoxicity was observed with Lu-177. Few patients with severe renal dysfunction before PRRT, progressed to end-stage renal disease. No patient with normal renal function before PRRT developed G3 (or higher) nephrotoxicity.

Conclusions: PRRT is effective as it favorably prolongs the OS and PFS in patients with metastatic neuroendocrine neoplasms. However, this depends on the tumor grade, location of primary tumor, and the radionuclide used for therapy. Low rate of severe hematotoxicity were observed. There was no therapy associated severe nephrotoxicity in patients with normal renal function prior to commencement of PRRT.

Background: The phase III, placebo-controlled, randomized TELESTAR study evaluated efficacy and safety of telotristat ethyl (TE) in patients (pts) with diarrhea (≥4 bowel movements [BMs]/day) due to carcinoid syndrome (CS) inadequately controlled by somatostatin analogs (SSAs). TE, a tryptophan hydroxylase inhibitor, decreases peripheral serotonin levels. As add-on treatment to SSAs, TE 250 mg 3x/day (tid) and TE 500 mg tid significantly reduced BM frequency ($p < 0.001$) compared with placebo over the 12-week Double-blind Treatment (DBT) period. After Week 12, pts crossed over to a 36-week Open-label Extension (OLE) period with TE 500 mg tid; data from the full 48 weeks are presented.

Methods: Changes from baseline in BM frequency (monitored weekly), urinary 5-hydroxyindoleacetic acid (u5-HIAA; Weeks 18, 24, and 48), European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire-Core 30 (EORTC QLQ-C30) score (Weeks 24 and 48), and safety during the OLE period were evaluated.

Results: Of the 135 pts randomly assigned, 118 completed the DBT period; 115 pts subsequently entered (and 79 completed) the OLE period. Of the 36 pts who discontinued the OLE period, the most frequent reasons were adverse event (AE; 15 pts) and withdrawal of consent (9 pts). Treatment-emergent AEs led 18 pts to discontinue TE; gastrointestinal disorder was the most commonly reported reason (6 pts). Reductions from baseline in BM frequency (~2 BMs/day) and u5-HIAA levels (range –20.0 mg to –49.5 mg/24 hours) during the OLE were consistent with results of the DBT period and persisted through Week 48. Improvement in EORTC QLQ-C30 diarrhea subscale scores relative to baseline (range –18.8 to –30.6 points) was notable and persisted through Week 48. Crossover into the OLE period was well tolerated. Treatment-emergent AEs were mainly mild to moderate and occurred at a similar rate as in the DBT period.

Conclusions: Patients benefitted from TE throughout the OLE period. TE was well tolerated over 48 weeks and its efficacy was consistent with previously reported data.

441PD Follow-up recommendations for completely resected gastroenteropancreatic neuroendocrine tumours (GEP-NETs): Consensus guidelines from the Commonwealth NET collaboration (CommNETs) in conjunction with the North American NET Society (NANETS)

S. Singh[1], L. Moody[2], D. Chan[1], D. Metz[3], J. Strosberg[4], E. Segelov[5]

[1]Medical Oncology, Sunnybrook Odette Cancer Center, Sunnybrook HSC, Toronto, ON, Canada, [2]IHPME, University of Toronto, Toronto, ON, Canada, [3]Gastroenterology, University of Pennsylvania School of Medicine, Philadelphia, PA, USA, [4]GI Oncology, Moffitt Cancer Center, Tampa, FL, USA, [5]Medical Oncology, Monash University and Monash Health, Melbourne, Australia

Background: NETs are uncommon, and there is no consensus regarding the optimal follow-up frequency or modality after resection. Current follow-up guidelines for resected GEP-NETs are based on limited evidence and our large, international practice survey showed poor compliance by NET expert clinicians. A need for clear and practical guidelines was identified.

Methods: A RAND/UCLA appropriateness process was employed given the lack of published data. A systematic review was undertaken as well as a multi-national practice survey to understand current follow-up patterns. Results from two large retrospective reviews (Ontario, Canada and Tampa, Florida) examining outcome following curative surgery were obtained. An 18-member multidisciplinary international panel scored 193 clinical scenarios for appropriateness of timing of consultations and investigations for detecting recurrence on a 1-9 scale. At a face-to-face consensus conference, the final follow-up recommendations were developed.

Results: Twelve studies were identified describing follow-up strategies post-resection, with only one comparing follow-up strategies. Data from our practice survey ($n = 163$) and our population-based study ($n = 936$) are separately reported. Based on the scenario scoring, the panel resolved 14 summary statements, with the major themes of (1) less frequent follow up visits and investigations within the first five years (2) longer follow up even beyond 10 years (3) different recommendations for pancreatic versus gastrointestinal NETs (4) identification of low risk subgroups where no routine follow-up was recommended (5) no role for any serum or urine biomarkers, or chest imaging (6) the need to evaluate functional imaging in follow-up.

Conclusions: Streamlined, practical guidelines were developed for the follow-up of patients with resected GEP-NETs. These guidelines differ significantly from other current guidelines. The expert consensus was informed by previously unavailable large outcome datasets. Compliance, cost-effectiveness and patient acceptability will be evaluated in future studies.

442P Long-term survival of patients with carcinoid syndrome in clinical trials of telotristat ethyl

P. Lapuerta[1], M.H. Kulke[2], M. Caplin[3], E. Bergsland[4], L. Anthony[5], K. Öberg[6], M. Pavel[7], D. Hörsch[8], T.M. O'Dorisio[9], J.S. Dillon[9], K. Kassler-Taub[1], W. Jiang[1]

[1]Lexicon Pharmaceuticals, Inc., The Woodlands, TX, USA, [2]Gastrointestinal Cancer Treatment Center, Dana-Farber Cancer Institute, Boston, MA, USA, [3]Neuroendocrine Tumour Unit, Royal Free Hospital, London, UK, [4]Hereditary GI Cancer Prevention Program, UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA, USA, [5]Division of Medical Oncology, University of Kentucky Chandler Medical Center, Lexington, KY, USA, [6]Department of Endocrine Oncology, University Hospital, Uppsala University, Uppsala, Sweden, [7]Department of Gastroenterology and Hepatology, Endocrinology & Metabolic Diseases, Charité–Universitätsmedizin, Berlin, Germany, [8]Department of Internal Medicine, Zentralklinik Bad Berka, Bad Berka, Germany, [9]Department of Internal Medicine, Endocrinology and Metabolism, University of Iowa, Iowa City, IA, USA

Background: Patients with carcinoid syndrome (CS) in the setting of metastatic neuroendocrine tumors (NETs) experience considerable morbidity and mortality. From the time of diagnosis of metastatic NETs, median survival has been estimated to be approximately 31–75 months. CS is associated with tumoral secretion of serotonin and subsequent debilitating diarrhea, which poses a significant health risk. In previous studies, telotristat ethyl (TE), a tryptophan hydroxylase inhibitor, was effective and well tolerated in treating CS diarrhea. At enrollment, patients in these studies had already survived an average of 6–8 years with metastatic NETs since their initial diagnoses.

Methods: Adverse events reported during treatment with TE were pooled from 2 Phase 2 and 3 Phase 3 clinical trials of TE in patients with CS. The long-term safety of TE was examined, causes of hospitalization and death were reviewed, and an estimate of overall survival was obtained.

Results: A total of 239 patients with CS received treatment with TE in Phase 2 and 3 clinical trials. For these patients, as of the end of 2016, the mean duration of exposure was 1.3 years, and maximum 5.7 years. The leading causes of hospitalization were gastrointestinal disorders and surgical and medical procedures, mostly attributable to the underlying tumor and related treatment. Survival estimates at 1, 2, and 3 years were 93%, 88%, and 77%, respectively. Nearly all deaths were due to progression or complication of the underlying disease, and none were attributable to TE. There was 1 death in Year 4 and no deaths in Years 5 and 6 of patient follow-up in this data set. The median survival with TE was not reached at the end of the 6-year Follow-up period.

Conclusions: Our review of the long-term safety data for TE indicates that patients with CS treated with TE in Phase 2 and 3 studies experienced encouraging survival rates.

443P Identifying symptom and quality of life improvements in patients with carcinoid syndrome treated with telotristat ethyl: Qualitative patient exit interviews from the TELESTAR Trial

F. Marteau[1], P. Williams[2], M. Feuilly[1], B. Arnould[2]

[1]Health Economics & Outcomes Research, Ipsen, Boulogne-Billancourt, France, [2]Patient Centered Sciences, Mapi, Lyon, France

Background: Carcinoid syndrome (CS) is a rare condition in patients (pts) with neuroendocrine tumors (NETs), characterized by diarrhea, flushing, and abdominal pain that impact health-related quality of life (HRQoL). We assessed symptoms and HRQoL in pts with inadequately-controlled CS enrolled in TELESTAR (NCT01677910).

Methods: English or German-speaking pts randomized 1:1:1 to 12 wks of double-blinded (DB) treatment with telotristat ethyl (TE) 250mg, 500mg, placebo were invited to a blinded, qualitative, semi-structured exit interview after the DB period to assess symptoms, HRQoL concepts (improved/not changed/worsened), and TE treatment effects. Concepts were freely reported by pts and not solicited. EORTC QLQ-C30 and GINET21 questionnaires assessed HRQoL, daily diaries assessed baseline (BL) bowel movement (BM) frequency. Analyses compared pts with durable response (DRs; predefined as BM frequency reduction of $\geq$ 30% from BL for $\geq$50% of DB period) and without durable response.

Results: TELESTAR enrolled 135 pts, 45 per group; 34 pts (9, 16, 9 in TE 250mg, 500mg, placebo, respectively), including 10 DRs consented to interviews. BL age, gender, race, BMs/wk of interviewed pts (IPs) were similar to non-interviewed pts. Most qualitative concepts were captured, to an extent, by the QLQ-C30; most common HRQoL qualitative concepts identified were daily life activities, physical, and psychological, with most TE-treated pts improving in these over the DB period. The most common symptoms (improvement/no change) reported in all IPs were diarrhea consistency (n = 17/n=10), frequency (n = 17/n=9), urgency (n = 11/n=7); flushing (n = 11/n=7), and fatigue (n = 9/n=4). A higher proportion of TE-treated pts and DRs reported symptom and HRQoL concept improvements. Durable response ($p < 0.001$) and treatment satisfaction ($p = 0.0137$) correlated with diarrhea QLQ-C30, but no other QLQ-C30/GINET21 scores.

Conclusions: The QLQ-C30 covered most qualitative concepts, but due to the lack of emphasis on key symptoms, may not adequately reflect pt perspectives. Interviews suggested improvements in symptoms and HRQoL with TE treatment and in DRs.

Clinical trial identification: NCT01677910

444P Carcinoid syndrome: Patient outcomes from a European Neuroendocrine Tumour Society (ENETs) centre of excellence

P.D. d'Arienzo[1], E. Amir[2], A.R. Lewis[3], L. Magdalani[3], W. Mansoor[3], R.A. Hubner[3], J.W. Valle[4], M.G. McNamara[4]

[1]Medical Sciences, Sant'Anna School of Advanced Studies, Pisa, Italy, [2]DMOH, Princess Margaret Hospital, Toronto, ON, Canada, [3]Medical Oncology, The Christie NHS Foundation Trust, Manchester, UK, [4]Medical Oncology, The University of Manchester/ The Christie, Manchester, UK

Background: Carcinoid syndrome (CS), characterised by flushing, diarrhoea, wheeze and fibrotic valvulopathy, arises in patients (pts) with advanced NETs due to serotonin and kallikrein secretion.

Methods: Sequential pts with advanced well-differentiated gastroenteropancreatic NETs (GEP-NETs) treated at The Christie (1998-2017) with $\geq$1 carcinoid symptom(s) and raised serum/urinary 5-hydroxyindoleacetic acid (5-HIAA) were identified. Ratio of 5-HIAA/upper limit normal (ULN) was calculated. Progression-free (PFS) and overall survival (OS) were estimated (Kaplan-Meier method) and prognostic factors identified (Cox proportional hazards model).

Results: Of 882 pts, 139 (16%) had CS: median (med) age 64 yrs, 55% male, 80% performance status (PS) 0-1, 13% PS 2; 65% had small bowel primary, 10% large bowel, 4% pancreas, 0.7% gastric, 21% unknown primary (consistent with GEP-NET origin). Tumour grade (G) was 1 in 45%; G2 in 29%; symptoms included diarrhoea (91%), flushing (89%), wheeze (22%), and carcinoid heart disease (CHD; 35%). Fifty-seven (41%) had primary resection, and 121 (87%) had liver metastases. In first line, 66% received a somatostatin analogue (SSA), 20% debulking surgery, 14% other. Med baseline 5-HIAA levels were 8.45 x ULN (urinary: 10.56 x ULN, serum: 6.07 x ULN). Med follow-up was 45.7 months (mo). Med PFS and OS were 27.0 (95%CI 17.2-33.9) and 65.4 (95%CI 50.4-76.4) mo. On univariate analysis, small bowel primary ($P = 0.045$), liver metastases ($P = 0.03$), Ki-67 ($P < 0.01$) and 5-HIAA baseline ratio ($P < 0.001$) were prognostic for PFS; and age ($P < 0.01$), PS ($P < 0.01$), primary in situ ($P < 0.001$), CHD ($P = 0.03$), Ki-67 ($P = 0.03$), baseline 5-HIAA ratio ($P < 0.001$) and use of SSA vs surgery ($P = 0.02$) were prognostic for OS. On multivariable analysis, high Ki-67 (HR 1.06, 95%CI 1.00-1.12, $P = 0.049$) and baseline 5-HIAA ratio (HR 1.03, 95%CI 1.01-1.05, $P = 0.001$) were prognostic for worse PFS. Primary in situ (HR 2.23, 95%CI 1.09-4.54, $P = 0.03$) and high baseline 5-HIAA ratio (HR 1.02, 95%CI 1.00-1.04, $P = 0.04$) were prognostic for worse OS. Change in 5-HIAA at 6 mo was not prognostic for PFS ($P = 0.42$) or OS ($P = 0.60$).

Conclusions: Baseline 5-HIAA ratio, but not change from baseline to 6 months, was prognostic for PFS and OS. Treatment optimisation is pivotal.

445P Relationship between symptoms and health-related quality of life benefits in patients with carcinoid syndrome: Post-hoc analyses from TELESTAR

M. Pavel[1], D. Cella[2], J.L. Beaumont[2], S. Hudgens[3], F. Marteau[4], M. Feuilly[4], S. Gabriel[4], A. Houchard[4], J. Ramage[5], D. Hörsch[6], M.H. Kulke[7]

[1]Gastroenterology and Hepatology, Endocrinology & Metabolic Diseases, Charité University Medicine Berlin, Berlin, Germany, [2]Feinberg School of Medicine, Northwestern University, Chicago, IL, USA, [3]Clinical Outcomes, Clinical Outcomes Solutions, Tucson, AZ, USA, [4]Health Economics & Outcomes Research, Ipsen, Boulogne-Billancourt, France, [5]Gastroenterology, Hampshire Hospitals, Basingstoke, UK, [6]Internal Medicine, Zentralklinik Bad Berka, Bad Berka, Germany, [7]Gastrointestinal Cancer Treatment Center, Dana-Farber Cancer Institute, Boston, MA, USA

Background: The safety and efficacy of telotristat ethyl (TE) in patients (pts) with metastatic neuroendocrine tumors (NETs) and carcinoid syndrome (CS) not adequately controlled with somatostatin analogs (SSAs) have been demonstrated. TE-treated pts showed significantly greater reductions in bowel movement (BM) frequency and more presented with durable response than placebo (PBO)-treated pts. These post-hoc analyses examined the relationship between improvements in symptoms and health-related quality of life (HRQoL) in pts who were durable responders (DRs; n = 48) and non-durable responders (NDRs; n = 87), irrespective of treatment group, in TELESTAR (NCT01677910).

Methods: Pts were randomized 1:1:1 to TE 250mg, 500mg, and PBO three times daily during the 12-week (wk) double-blind (DB) treatment period; durable response was predefined as a daily BM frequency reduction of $\geq$ 30% from baseline for $\geq$50% of the DB period. Clinical symptoms were assessed via daily records, HRQoL by the EORTC QLQ-C30 and QLQ-GINET21 questionnaires. The difference in arithmetic means and associated 95% CIs were used as a descriptive measure of group effects.

Results: 135 pts were randomized, 45 in each group. The mean difference [95% CI] in change from baseline between DRs and NDRs at Wk12 was (1.8 [-2.3, -1.2]) for daily BM frequency, (-1.2 [-1.6, -0.7]) for daily flushing, (-38.7 [-70.0, -7.3] mg/24 hrs) for u5-HIAA levels, (-1.2 [-1.8, -0.6]) for abdominal pain severity and (-0.3 [-0.4, -0.2]) for urgency to defecate. DRs showed meaningful and/or significant improvements in QLQ-C30 global health (8.1 [-0.3, 16.5]), summary score (4.9 [0.6, 9.2]), social

functioning (5.1 [-4.7, 14.9]), nausea/vomiting (-7.5 [-15.4, 0.4]), pain (-16.0 [-27.0, -5.0]), dyspnea (-5.7 [-15.5, 4.1]), diarrhea (-14.7 [-26.5, -2.9]), and GINET21 gastrointestinal symptoms (-9.3 [-16.3, -2.2]) versus NDRs.

Conclusions: Durable response was associated with reductions in the symptoms and overall clinical burden of CS. DRs showed significant and/or meaningful improvements in global HRQoL, nausea, pain, diarrhea, and gastrointestinal symptoms.

446P Benefit of oral monotherapy with pazopanib in metastatic gastroenteropancreatic neuroendocrine tumours

D. Katalinic, I. Aleric, A. Vcev

Department of Internal Medicine, Faculty of Medicine Osijek, Osijek, Croatia

Background: Although standard therapy for gastroenteropancreatic neuroendocrine tumors (GEP-NETs) can provide symptom relief and delay tumour progression, new strategies are needed for patients with metastatic disease. The aim of this study was to investigate the antitumour activity and safety profile of pazopanib - a selective multitargeted receptor tyrosine kinase inhibitor of vascular endothelial growth factor receptor and platelet-derived growth factor receptor.

Methods: We enrolled 124 patients with metastatic GEP-NETs. Pazopanib was administered orally at a dose of 800 mg daily with a 28-day cycle. The primary endpoint was overall response rate (ORR) according to Response Evaluation Criteria in Solid Tumors. The secondary endpoints were overall survival (OS), progression-free survival (PFS) at 6 months and safety profile of pazopanib (general tolerability and toxicity). The third endpoint was to compare the clinicopathological features of tumours and biomarker analysis with survival of the patients.

Results: The mean follow-up time was 196±87 days with a range of 67-268 days; 26 patients died within the observation time. 69% of the patients had confirmed pancreatic GEP-NET and 51% had colorectal, gastric and duodenal GEP-NET. 59 (47.6%) patients had G1, 34 (27.4%) G2 and 31 (25%) had G3 GEP-NET. ORR was 24% (19 of 124 patients), stable disease was achieved in 49 patients (39.5%) and PFS at 6 months was 36%. Median OS was 10.2 months (95% CI, 5.4-13.2 months). The most common grade 3-4 adverse events attributed to therapy were neutropenia (11%), proteinuria (14%), diarrhea (7%), and fatigue (12%). Patients with high CgA levels had the highest mortality risk (hazard ratio 3.478, 94% confidence interval 1.313-4.727, $p < 0.001$) and worse outcomes. Furthermore, extremely high CgA levels (>3000 ng/mL, range 8300-800 ng/mL) were associated with low survival independently from the Ki-67 score in a multivariate Cox regression model.

Conclusions: Pazopanib demonstrated a comparable therapeutic efficiency as well as a satisfying safety profile compared to other targeted agents in the treatment of patients with metastatic GEP-NETs.

447P High hepatic tumor burden and cardiovascular comorbidities linked to carcinoid heart disease

M.C. Mesquita[1], C.A.C. Silva[1], C.M.P.D.C. Silva[2], M.C. Feres Almeida Soeiro[2], L.A. Hajjar[2], P.M. Gehm Hoff[1], R.S.P. Riechelmann[1]

[1]Oncology, Instituto do Câncer do Estado de São Paulo, Sao Paulo, Brazil, [2]Cardiology, Instituto do Câncer do Estado de São Paulo, Sao Paulo, Brazil

Background: One of the most common functioning syndromes associated with neuroendocrine tumors (NET) is the carcinoid syndrome (CS). By releasing vasoactive substances, these tumors can cause fibrotic complications, including right-sided valve heart fibrosis, named carcinoid heart disease (CHD). Factors associated with the onset and progression of CHD are poorly understood. We aimed to investigate prognostic factors associated with CHD.

Methods: Retrospective study of consecutive patients (pts) with advanced NET and CS and/or elevated 24h-urinary 5HIAA who performed an echocardiogram to screen for CHD. CHD was defined as echocardiographic evidence of moderate to severe tricuspid or pulmonar regurgitation.

Results: From 2009 to 2017 42 pts were included: Median age was 54.4 (19 – 85) years, 24 were female, 69% had midgut NET. The frequency of CHD was 38% (16 pts) CHD was not associated with age ($p = 0.79$), sex ($p = 0.38$), bone metastasis ($p = 0.66$), flushing ($p = 0.14$) or diarrhea ($p = 0.53$); the median urinary level of 5HIAA at diagnosis of CHD was numerically higher, albeit not significant, among CHD pts ($p = 0.20$). CHD was significantly associated with higher volume (>50% of parenchyma) of liver metastases [OR 13.86 (2.57 – 74.68), $p = 0.002$]. Time from symptoms to diagnosis of NET was borderline significant ($p = 0.08$). When CHD was defined as at least mild valve regurgitation, the frequency of CHD was 45% (19 patients) and we observed a significant association between the presence of cardiovascular comorbidities and CHD [OR 6.58 (1.09; 39.78), $p = 0.040$].

Conclusions: CHD is highly frequent among pts with CS. We found that high liver tumor burden and possibly, longer time of symptoms until diagnosis of NET were associated with CHD. Such findings probably imply that a delayed diagnosis negatively affects CS patients, increasing the risk of CHD. Interestingly, we found that concurrent cardiovascular disease was associated with CHD, as a potential predisposing factor.

Orsola, Bologna, Italy, [11]Oncology, Campus Bio-Medico di Roma, Rome, Italy, [12]Endocrinology, Policlinico di Napoli, Naples, Italy, [13]Gastroenterology, Policlinico di Milano, Milan, Italy, [14]Endocrinology, Policlinico Gemelli, Rome, Italy, [15]Nuclear Medicine, Universitàà di Bari, Bari, Italy, [16]Gastroenterology, Ospedale S. Andrea, Rome, Italy, [17]Medical Oncology, Azienda Ospedaliera Careggi, Florence, Italy, [18]Medical Oncology, Spedali Civili, Brescia, Italy, [19]Medical Oncology, Istituto Oncologico del Mediterraneo, Viagrande, Italy

Background: Bone metastases (BM) in neuroendocrine neoplasms (NEN) represent a poorly defined issue.

Methods: This is a nationwide survey among Italian institutions dealing with NEN patients. Characteristics of BM, clinical management, skeletal related events (SREs) and disease outcome were recorded.

Results: We analysed 321 patients with histological diagnosis of NEN and BM collected from 18 Italian Centers. Mean age was 59 y.o. (range 13-86). Primary sites were 47% gastroenteropancreatic (GEP), 36% lung, 4% Paraganglioma/Pheocromocytoma (Par/Pheo), 7% unknown, 5% others. The vast majority (72%) of NEN were already metastatic at diagnosis and the liver represented the second most frequent site of metastasis (in 77% of patients) during follow-up, in addition to BM. Bone was the first metastatic site in 41% of cases. Neoplasms were low/intermediate grade in 80% and high grade in 20%. SREs occurred in 32% of cases, mainly in lung and others. Median time to SRE was 4 months. It strictly correlated with the high grade, irrespective of the primary site. Bisphosphonates were administered in 32% of patients. Median survival from BM diagnosis was 65 months (range 45-78) in the whole population, with Par/Pheo at the best and high grade GEP at the worst limit. SRE, high grade (or in alternative high Ki-67) and prior lung metastases resulted significantly associated with worse overall survival at the multivariable analysis. After adjustment for tumor grade, survival of patients with GEP and lung NENs were similar.

Conclusions: This is one of the largest series of NEN patients with BM reported so far. This survey mirrors the Italian real clinical practice in this setting, as it included most Centers involved in NET patients' management. It showed that overall, BM from NEN are associated with a relatively long survival. Bisphosphonates were used in a low percentage of cases, probably related to SRE. Tumor grade confirmed its value in separating two survival categories, irrespective of primary site. The results of this analysis generated hypotheses for prospective trials in homogeneous clinical settings.

449P Financial toxicity in patients with neuroendocrine tumors: Impact of a chronic disease on patients' economic situation

L. Apostolidis[1], K. Mehlis[1], M. Kudlich[1], J. Witte[2], J. Walther[1], W. Greiner[2], E.C. Winkler[1]

[1]Department of Medical Oncology, National Center for Tumor Diseases, University Hospital Heidelberg, Heidelberg, Germany, [2]Department of Health Economics and Health Care Management, School of Public Health, Bielefeld University, Bielefeld, Germany

Background: The diagnosis of cancer imposes physical, emotional and financial burdens on patients. So far, the socio-economic impact of cancer for patients in Germany is poorly understood. The aim of the project is to provide an overview on patients' financial losses due to a neuroendocrine tumor (NET) diagnosis as well as possible psychosocial effects.

Methods: This prospective quantitative study recruited n = 123 patients with NET from November 2016 to March 2017 at the National Center for Tumor Diseases, University Hospital Heidelberg. They completed a survey on patients' income, cancer-related out-of-pocket costs, disease burden (Distress Thermometer), quality of life (EORTC-LQ 29/30), health status (EQ-5D) and demographic data.

Results: 78.0% (n = 96) of the patients stated to have higher out-of-pocket costs because of their disease, mostly in terms of travel expenses and co-payments for medication. With regard to loss of income, 29.3% (n = 36) of the participants reported a minus, which is beyond 800€per month in almost half (44.4%) of these cases. 61.5% of the persons affected by income losses cannot compensate these by savings or credits. 33.3% (n = 41) of the responding patients indicated that they have to cut back on their expenses of daily living as a result of their disease. Higher cancer-related out-of-pocket costs per month were associated with lower estimation of patient's quality of life (p = 0.003), lower self-reported health status (p = 0.013) and a more severe perception of disease burden (p = 0.036) whereas a higher monthly income was strongly correlated with better quality of life (p=.008)/health status (p = 0.008) and lower disease burden (p = 0.006).

Conclusions: Given the fact that the majority of surveyed patients has to face financial losses due to their cancer diagnosis which is accompanied by the experience of distress as well as worsened quality of life and health status, there is a need for targeted measures that could prevent financial problems and reduce emotional burdens. Further research is required to address this aim.

Clinical trial identification: The trial was approved by the Instituional Research Ethics Committee (approval S-458/2016).

450P Pancreatic exocrine insufficiency (PEI) in patients (pts) with well-differentiated neuroendocrine tumours (wd-NETs) treated with somatostatin analogues (SSAs): Incidence and impact on quality of life

A. Lamarca[1], L. McCallum[1], C. Nuttall[1], J. Barriuso[2], M. Frizziero[1], R. Leon[1], W. Mansoor[1], M.G. McNamara[2], R.A. Hubner[1], J.W. Valle[2]

[1]Medical Oncology, The Christie NHS Foundation Trust, Manchester, UK, [2]Medical Oncology, The University of Manchester/The Christie, Manchester, UK

Background: Advanced wd-NET patients (pts) are commonly treated with SSAs. PEI may be under-estimated in trials due to difficulties in distinguishing carcinoid syndrome-related diarrhoea and PEI.

Methods: In this single-institution, prospective, observational study, sequential pts with advanced wd-NET were commenced on SSAs and followed for a minimum of 12 months (or until disease progression). Toxicity was prospectively assessed monthly. Faecal elastase testing (FE) (for diagnosis of PEI) and quality of life (QoL) questionnaires (QLQ-C30 and QLQ-GI.NET21) were performed 3-monthly.

Results: Of 52 pts recruited (Jan 15-Apr 16), 50 were eligible: median age 65.8 yrs; 58% male; ECOG performance status 0 (42%), 1 (46%) or 2 (12%); primary: small bowel (60%), pancreas (22%), lung (12%) and other (6%). Baseline median Ki-67 was 3.1% (range 0.7-25), serum 5HIAA: 195 nmol/L (95%CI 145-318) and chromogranin A (CgA): 327 ng/mL (95%CI 140-582). Most pts were metastatic (92%), non-functional (66%) and started SSA first-line (88%); depot SSA was octreotide in 60%, lanreotide in 40%. Forty-one pts (82%) started full-dose SSA (4-weekly octreotide 30mg or lanreotide 120mg); 96% achieved full dose; 3 pts required dose reduction due to toxicities. Grade (G) 1-2 toxicities were flatulence (50%), abdominal pain (32%), diarrhoea (30%), fatigue (20%), PEI (22%), nausea (16%), hyperglycaemia (6%), anorexia (4%) and constipation (2%). G 3-4 toxicities were few (G3 hyperglycaemia (n = 1) and G3 PEI (n = 1); no G4). Twelve pts (24%) developed SSA-related PEI (4 clinical diagnosis, 8 FE-confirmed) at a median of 2.9 mo (95%CI 1.7-8.6) after starting SSA; 11/12 (92%) pts received enzyme replacement. Questionnaires identified fatigue, insomnia and diarrhoea as the most important baseline symptoms; SSA therapy did not negatively-affect QoL. Estimated median progression-free survival (PFS) was 29.9 mo (95%CI 21.4-not reached). High baseline CgA was an independent factor for shorter PFS (HR 1.01 (95%CI 1.001-1.1); p-value 0.001) after adjustment for other factors (baseline 5HIAA, Ki-67).

Conclusions: SSA-induced PEI occurs in 1:4 pts; clinicians should actively identify and treat.

Background: The CLARINET core study established the antitumour activity of lanreotide Autogel 120mg/28 days (LAN) in metastatic enteropancreatic neuroendocrine tumours (NETs). The vast majority of the core study population (96%) had stable disease (SD) at baseline, but the LAN open-label extension (OLE) also included patients with progressive disease (PD; while receiving placebo [PBO] in the core study). Here, we report the final analysis of time to subsequent death/PD for patients with PD switched to LAN.

Methods: In the core study, patients with metastatic well-/moderately differentiated non-functioning enteropancreatic NETs received LAN/PBO for 96 weeks or until death/PD (RECIST 1.0). Eligible patients for the OLE (NCT00842348) had SD at core-study end or PD (with PBO only) during the core study. Adverse events (AEs) were recorded at 4-weekly visits. CT/MRI scans from OLE baseline (week 1) and every 24 weeks subsequently were assessed locally for PD (RECIST 1.0). Primary objective: long-term safety. Secondary objective: long-term efficacy, with assessments including PFS and time to subsequent death/PD (from Kaplan–Meier analyses; months approximated as 4 weeks).

Results: 89 patients were treated in both core and OLE studies (42 LAN–LAN [SD, n = 41]; 47 PBO–LAN [SD, n = 15]); 40% of the LAN–LAN vs. 47% of the PBO–LAN group had treatment-related AEs. Overall median LAN PFS, based on the intent-to-treat population (n = 101), was 38.5 months. Seven PD events (no deaths) occurred during the OLE in 15 patients entering with SD from the PBO arm of core study. In total, 32 patients with PD whilst receiving PBO in the core study entered OLE (of 59 potentially eligible); NETs were in pancreas in 17 patients, midgut in 10, hindgut in one, and of other/unknown origin in four. Of these patients, 20 had subsequent PD during the OLE and three died; median time to subsequent death/PD was 19.0 months [95% CI: 10.1; 26.7].

Conclusions: The final analysis of the CLARINET OLE study suggests benefit with LAN in patients who had experienced PD when receiving no NET-specific treatment (PBO), with median time to subsequent death/PD of 19 months.

452P Temozolomide-capecitabine (TemCap) chemotherapy for neuroendocrine neoplasms (NENs): Time to maximum response and optimal treatment duration

A. Lamarca[1], J. Barriuso[2], L. McCallum[1], G. Papaxoinis[1], M. Nasralla[1], C. Nuttall[1], M. Frizziero[1], Z. Kordatou[1], M.G. McNamara[2], R.A. Hubner[1], P. Manoharan[3], W. Mansoor[1], J.W. Valle[2]

[1]Medical Oncology, The Christie NHS Foundation Trust, Manchester, UK, [2]Medical Oncology, The University of Manchester/The Christie, Manchester, UK, [3]Radiology/ Nuclear Medicine, The Christie NHS Foundation Trust, Manchester, UK

Background: TemCap is an option for treatment of NENs; benefit of treatment until progression rather than a fixed 6-month (mo) course remains unclear.

Methods: Patients (pts) diagnosed with advanced NEN (pathology-confirmed), treated with TemCap with follow-up and available radiological response data were eligible for this retrospective study. Efficacy was assessed by RECIST v1.1.

Results: Of 62 pts identified (Jan'12-Jan'17), 60 were eligible. Median (med) age at starting TemCap was 63.6 yrs; 50% were male; Performance Status (PS) 0-1 (83.3%), 2 (16.7%); with NEN of lung (33.3%), pancreas (21.7%), small bowel (16.7%), colorectal (3.3%) and other (25.0%) origin. The med Ki-67 was 12% (range 1-29); most (83.3%) were well-differentiated [grade (G)1/typical (18.3%); G2/atypical (65%); G3 (16.7%)], non-functional (75.0%) and metastatic (90.0%). Pts received TemCap as first- (33.3%) or second- (35.0%) line, for a med of 5.58 mo (95%CI 5.33-5.78). After 6 cycles, 38 pts (63.3%) were progression-free (i.e. eligible for maintenance TemCap [mTemCap]); 11 received mTemCap, 27 did not. Rationale for mTemCap was good response (n = 7), good tolerance (n = 3) or pts' wishes (n = 1). Overall, 29 pts (48.3%) had stable disease and 14 pts (23.3%) achieved a partial response (PR); med reduction in responding pts was -56.7% (95%CI -76.4 to -33.3); 4 additional pts (6.67%) achieved a reduction >20% but <30%. Time to PR was 3.9 mo (95%CI 2.45-15.24); time to maximum response was 10.7 mo (7.2-11.8). By the end of follow-up, 95% and 75% of pts had stopped TemCap and progressed, respectively; estimated med PFS and overall survival (OS) were 10.1 mo (95%CI 6.7-14.2) and 27.3 mo (95%CI 16.35-NR), respectively. Achieving a PR was an independent factor (multivariable Cox regression) impacting on PFS (HR 0.2 (95%CI 0.1-0.6); p = 0.001); landmark analysis (excluding pts with early (3 mo) progression; n = 10) confirmed such findings.

Conclusions: Achieving a PR impacts on PFS in pts treated with TemCap. Although PR is an early event, maximum response is not achieved until later in pts' treatment/ follow-up; mTemCap until progression is appropriate for pts who are progression-free at 6 mo and have good tolerance to treatment.

453P Efficacy of recombinant human endostatin combined with chemotherapy in advanced pancreatic neuroendocrine tumors

Y. Cheng

Medical Oncology, Peking Union Medical College Hospital, Beijing, China

Background: Dacarbazine or temozolomide, an oral analog of dacarbazine, showed activity against advanced pancreatic NETs when administered alone or in combination with other agents. Targeting pathways involved in angiogenesis, such as VEGFR TKI is also active in advanced pNETs. Endostatin is an endogenous angiogenesis inhibitor, rhEndostatin combined with chemotherapy prolonged overall survival compared with chemotherapy alone in advanced non-small cell lung cancer.

Methods: 14 patients with histologically confirmed, locally advanced or metastatic pancreatic well-differentiated NETs with radiologic progression within the previous 12 months received the study regimen: Temozolomide was administered orally 150-200 mg/m2/d, d1-7. Dacarbazine and 5-FU were both administered intravenously at a dose of 250mg/m2/d and 500mg/m2/d respectively, d1-5. rhEndostatin was administered intravenously at a dose of 15mg/d, d1-14, repeated every 21 days. CT/MRI was performed at baseline and every 3 cycles after initiation of treatment. Radiologic response was classified according to RECIST 1.1 criteria.

Results: Patients received a median of 6 treatment cycles (range, 2 to 8 cycles). Of the 14 patients, 6 patients received temozolomide and 8 received the DTIC + 5-FU combined with rhEndostatin. 5 patients used temozolomide as maintenance therapy, the median maintenance therapy cycles was 6 (range, 2 to 18 cycles). ORR was 43% (CR: 1 patient, PR: 5 patient), DCR was 86%, mPFS was 12 months, overall survival has not been reached. No grade 3/4 toxicity occurred.

Conclusions: rhEndostatin combined with temozolomide or darcarbazine-based chemotherapy was effective in treatment of advanced pNETs and was well tolerated.

454P Comparison of clinical efficacy of SST analogues therapy (lanreotide autogel vs. octreotide LAR) in treatment of patients with advance, non-resectable pancreatic neuroendocrine tumours (pNETs)

A. Kolasinska-Cwikla[1], A. Lewczuk[2], J. Palucki[1], L. Sawicki[1], K. Roszkowska-Purska[1], M. Kidd[3], L. Bodei[4], I. Modlin[5], J. Cwikla[6]

[1]Clinical Oncology, National Institute of Oncology-Marii Skodowskiej-Curie, Warsaw, Poland, [2]Endocrinology, Medical Univeristy of Gdansk, Gdansk, Poland, [3]Wren Laboratories, Wren Laboratories, Branford, CT, USA, [4]Nuclear Medicine, European Institute of Oncology, Milan, Italy, [5]Surgery, Yale University Scholl of Medicine, New Haven, CT, USA, [6]Radiology, Univeristy of Warmia and Mazury in Olsztyn, Faculty of Medical Sciences, Olsztyn, Poland

Background: Use of somatostatin analogues can be considered in pancreatic NET G1/ G2 as a first-line therapy. This retrospective study aimed to compare the efficacy of octreotide long-acting release (OCT) and lanreotide Autogel (LAN) in patient with advanced G1/G2 pNETs, comparison between LAN and OCT in naïve patients, based on progression free survival (PFS).

Methods: Ninety-two patients with histological proven G1 or G2 pNETs were retrospectively analyzed (41 men; 51 women; mean age 53.7years [range 21-87 years]). The patients were assigned randomly to OCT (n = 42) and LAN (n = 50) groups. Evaluations included comparison of PFS between groups with LAN and OCT administered at 28-day intervals, objective response rate (ORR) calculated based on CT/MRI imaging performed every 6 month. The clinical efficacy was based on PFS and time to subsequent death/PD using Kaplan –Meier, radiological response was classified according to RECIST 1.0 criteria.

Results: Medain PFS for all patients was 16.0 months (CI 22.8-34.9); in LAN group PFS 22 months (CI 21.9-39.5) vs OCT 15 (CI 18.1-35,1), P = 0.28 (Cox Mantel test). The significant difference was noted in group of patients with G2 tumors LAN 22 months (CI 19.5-35.0) vs. OCT 7 months (CI 8.2-22.2) P = 0.01. Even higher significant difference was obtained in males group G2: LAN 23.5 (CI 16-44.6) vs. OCT 6.0 months (CI 3.3-14.3). There was no significant difference in female patients: LAN 17.5 mo (CI 15.4-34.8) vs. OCT 13 months (CI 8.2-29.4), but the trend favorable LAN over OCT. Additional analysis in patients with liver metastasis showed similar trend, but no significant difference. There was no difference in PFS between groups with G1 tumors in male or female patients and those without liver involvement.

Conclusions: Lanreotide Autogel is preferable SST therapy in G2 pNET, especially in male patients. Additional it seems to be also more effective in female patients but without statistical significance. The trend of better efficacy in terms of increase PFS seems to be in favor of LAN in patients with liver involvement as well. There was no significant difference in groups of patients with G1 pNEN and those without liver involvement.

Background: NEN incidence increases with age. Elderly population is usually underestimated in clinical trials due to presence of co-morbidities and low performance status (PS) and thus prognosis' informations are lacking. Our study aims to analyze the outcome in a retrospective cohort of elderly metastatic NEN patients (pts) who underwent different treatments.

Methods: From June 2006 to march 2016 we collected data from pts ≥70 y with mNEN. Comorbidities were summarized by the Charlson Comorbidity Index (CCI). Kaplan-Meier method was used to estimate overall survival (OS), Cox's proportional hazard model to assess the impact of known prognostic factors. Adjusted hazard ratios (HR) were calculated with 95% confidence interval (95% CI).

Results: We identified 145 pts ≥70 y with mNEN. Pts characteristics were resumed in the table. Median follow up was 72.3 (53.2-85.1) months. First Line treatment was: somatostatin analog (SSA) in 79 pts, peptide radionuclide therapy (PRRT) in 23, chemotherapy (CHT) in 36 pts. Seven pts didn't receive first line treatment and 102 pts received more than 1 line treatment. PS ECOG and FDG PET results were identified as independent prognostic factors for OS assessed by a multivariate Cox regression model, with a higher risk for patients with PS ECOG ≥0 and with positive FDG PET, while age at diagnosis showed a hazard ratio of 1.10 (95%CI:0.99-1.26). Median OS was 5.1y (3.4-6.6). No difference in mOS were seen according to CCI. G1/G2 NEN pts who underwent PRRT as first line had a mOS of 6.5 y (3.3-NE), SSA 5.7 y (4.2-7) and CHT 5.9 y (0.4-NE) respectevely. G3NEN pts treated with CHT had a mOS of 1.5 y (1.0-2.5).

Table: 455P

Pts characteristics	N (%)
Male	86 (59.3)
Female	59 (40.7)
Age at diagnosis	
Median (range)	74 (70-87)
70-74 years	89 (61.4)
75-79 years	40 (27.6)
80+ years	16 (11.0)
PS ECOG	
0	59 (45.7)
1	60 (46.5)
≥2	10 (7.8)
Unknown(UK)	*16*

456P Modified staging classification for gastric neuroendocrine carcinomas on the basis of the American Joint Committee on cancer

J. Xie, H. Chang-Ming, C. Zheng, P. Li, J. Lin

Department of Gastric Surgery, Fujian Medical University Union Hospital, Fuzhou, China

Background: The purpose is to explore the value of the seventh edition of AJCC staging and improved AJCC staging in the evaluation of the prognosis of gastric neuroendocrine carcinoma (GNEC).

Methods: We analyzed retrospectively the clinical and pathological data of 427 GNEC patients from SEER database and 129 GNEC patients in single center. AIC and C index were used to evaluate the distinguishing capability of different TNM staging systems.

Results: In SEER database, the 5-year survival rate stratified by AJCC staging of GENC (I, IIa, IIb, IIIa, IIIb, IV) were 68%, 61%, 46%, 22%, 21%, and 10% respectively. While in single center, the 5-year survival rate of different stages were 100%, 60%, 27%, 16%, 22%, and 0% respectively. From the survival curve analysis, there are significant crossovers between the IIIB survival curves of SEER database as well as single center and those of IIIA and IIB. In SEER database, the T staging and the age of disease diagnosis were independent factors affecting the prognosis of IIIB patients. According to the T staging, the IIIB was divided into four subgroups: T1N1,T2N1, T3N1, and T4N1. According to the principle of similar survival rate, the new AJCC staging is composed of different stages: nI(T1N0M0), n IIa (T1N1M0, T2N0M0), n IIb (T2N1M0, T3N0M0), n IIIa (T3N1M0, T4N0M0), n IIIb (T3N1M0, T4N0M0) and n IV (T1-4NxM1). The survival curve of the new AJCC staging showed less crossover per stage, obtaining a smaller AIC value (1572 vs. 1583) and a smaller c-index (0.7505 vs. 0.7421). It is discovered that through employing the data of single center as external validation, the new AJCC staging can better distinguish different TNM staging.

Conclusions: Dividing IIIB of the seventh edition of AJCC staging into various substages has significant prognostic value and the new AJCC staging can better distinguish the stages of GNEC.

457P Predictive factors in GEP-NEN: The integrated role of Ki67, beta-catenin and morphology

M. Milione[1], R. Miceli[2], A. Pellegrinelli[1], G. Centonze[1], F. Barretta[2], S. Pusceddu[3], L. Giacomelli[4], J. Coppa[5], V. Mazzaferro[6], G. Sozzi[7], A. Anichini[8], F. de Braud[3]

[1]Pathology and Laboratory Medicine, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [2]Medical Statistics, Biometry and Bioinformatics, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [3]Oncology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [4]Department of Surgical Sciences and Integrated Diagnostic, University of Genova, Genoa, Italy, [5]Surgery, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [6]Surgery, Liver Transplantation and Gastroenterology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [7]Experimental, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [8]Immunotherapy Unit, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy

Background: The WHO 2010 classification divides gastro-entero-pancreatic neoplasms (GEP-NENs) into G1, G2 and G3, according to Ki67 and/or mitotic index. Several studies have proposed to further divide G3 diseases in at least two subgroups, defined by Ki67 and/or morphological features. We investigated the morphological or immunohistochemical features associated with poorer prognosis and weather the G3 category could be further divided according to such features.

Table: 457P Joint distribution of patients according to WHO 2010 classification by the results of the prognostic model

	New Prognostic model's macro groups by Ki67 grading								
WHO 2010 classification	m0,B01, Ki67 < =2	m0,B2 Ki67 < =2	m0,B01 2<Ki67 < =20	m0,B2 2<Ki67 < =20	m0,B01 Ki67>20	m0,B2 Ki67>20	m1,B01 Ki67 < =55	m1,B2 Ki67 < =55	m1 Ki67>55
G1 (Ki67 < =2)	89	0	0	0	0	0	0	0	0
G2(2<Ki67 < =20)	0	0	95	2	0	0	0	0	0
G3(20<Ki67 < =55)	0	0	0	0	17	7	12	9	0
G3 (Ki67 >55)	0	0	0	0	0	0	0	0	83

Methods: We evaluated 314 consecutive GEP-NEN patients. Surgical specimens of primitive tumors were assessed for morphology (m0: well-differentiated; m1: poorly-differentiated), Ki67 and beta-catenin (B01 absent or not-nuclear localization; B2 nuclear localization). Those features were correlated with overall survival (OS) and disease-free survival (DFS) after surgery by means of Cox multivariable models. The model performance was evaluated by means of Harrell's C index.

Results: Median follow-up was 84 months (95% CI: 74-103). Based on Ki67 only, the WHO 2010 classification allowed to distinguish three classes with different prognosis (5-year OS: ≤2%: 97.0%, 2-20%: 90.9%, >20%: 14.5%). When considering Ki67 as continuous variable, and by including also morphology and beta-catenin in the multivariable OS model, patient-specific estimates were obtained, thereby improving the prognostic classification, particularly for G3 patients, which could be split in further sub-groups (Table). Harrell's C index was 0.864. Similar results were obtained for DFS.

Conclusions: WHO 2010 classification stratifies the risk of OS and DFS for G1 and G2 diseases. On the other hand, the risk of death for G3 disease varies according to Ki67 values, morphology and beta-catenin. Morphology has the strongest predictive power, segregating two macro groups in which beta-catenin has a lower differential effect while a prognostic gradient by Ki67 (up to Ki67 ≤55) is evident.

458P The preoperative blood lymphocyte-to-monocyte ratio acts as a superior prognostic factor and predicts tumor metastasis in gastric neuroendocrine neoplasms after surgery

L. Cao, H. Chang-Ming, J. Lin, J. Lu, C. Zheng

Department of Gastric Surgery, Fujian Medical University Union Hospital, Fuzhou, China

Background: The aim of this study is to investigate the prognostic significance of the preoperative blood lymphocyte-to-monocyte ratio (LMR) in gastric neuroendocrine neoplasms (g-NENs).

Methods: We enrolled 177 patients who had been diagnosed with g-NENs and undergone radical surgery. Receiver operating characteristic curve analysis was used to identify the optimal value for the LMR. Univariate and multivariate survival analyses were used to identify prognostic factors. A nomogram was adopted to predict recurrence free survival (RFS) and overall survival (OS) after surgery.

Results: The LMR was significantly lower in patients with g-NENs than in matched normal volunteers (NVs) ($P < 0.05$) and was associated with age, tumor site, tumor size, depth of invasion, the lymph node ratio (LNR) and lymphovascular invasion (all $P < 0.05$). Multivariate analysis demonstrated that the LMR was an independent prognostic factor for RFS and OS. The concordance index (C-index) of the nomograms for RFS (OS), which included the lymph node ratio, histological type and the LMR, was 0.776 (0.760), which was higher than the C-index of the traditional TNM staging system [0.678 (0.667)]. The recurrence rate was 38.9% (69/177), and the median time to recurrence was 10 months. We noted a significant correlation between the LMR and tumor recurrence, especially liver, peritoneal and lymph node metastases (all $P < 0.05$).

Conclusions: As an independent prognostic factor for survivals in patients with g-NENs, the LMR combined with the lymph node ratio and histological type had a more superior ability to predict clinical outcomes in post-surgery patients than the traditional TNM staging system. Patients with low LMRs require close surveillance to identify tumor recurrence early.

459P Follow-up and recurrence in resected gastroenteropancreatic neuroendocrine tumours: A population-based study

D. Chan[1], E. Segelov[2], L. Moody[3], N. Liu[4], H. Fischer[4], P. Austin[4], S. Singh[1]

[1]Medical Oncology, Sunnybrook Odette Cancer Center, Sunnybrook HSC, Toronto, ON, Canada, [2]Medical Oncology, Monash University and Monash Health, Melbourne, Australia, [3]IHPME, University of Toronto, Toronto, ON, Canada, [4]Biostatistics, Institute of Clinical Evaluative Sciences, Toronto, ON, Canada

Background: Neuroendocrine tumours (NETs) are uncommon. Little data exist to guide follow-up in resected disease, with no consensus regarding the optimal follow-up frequency or modality. Follow-up imaging regimens are extrapolated from other gastrointestinal tumours. As NETs are heterogeneous, this may result in both over-use and underuse of investigations in patients.

Methods: A population-based retrospective cohort study using linked data from the Institute for Clinical Evaluative Sciences and the Ontario Cancer Registry (capturing more than 99% of incident cases in Ontario) was conducted to evaluate patients diagnosed with gastroenteropancreatic NETs in Ontario, Canada from 1994 to 2012. Recurrence-free survival and the frequency of cross sectional imaging (abdominal computed tomography (aCT), magnetic resonance imaging (aMRI) and ultrasound (aUS)) were the main outcomes.

Results: Nine hundred and thirty-six patients were identified with median follow-up 47 months. The mean age was 59, 51% were female, and distribution of primary cancers was: small intestine 47%, pancreas 20%, large intestine 21%, rectum 6.4%, stomach 6.0%. The median survival time to a composite outcome of recurrence or death was 7.2 years, and 9.5 years if censoring on death. The cumulative incidence of recurrence was 8.4% (95% CI 6.8% to 10.3%) within one year, 33.7% (95% CI 30.4% to 36.9%) within five years, and 48.5% (95% CI 44.4% to 52.4%) within 10 years. The rate of recurrence significantly increased with age (HR = 1.529 for age 50-70 compared to < 50, $p = 0.0003$) and pancreatic primary (HR = 1.463, $p = 0.0006$), but not income quintile ($p = 0.1071$), rurality ($p = 0.1931$) or gender ($p = 0.3787$). The rate of use of aCTs, aMRIs and aUS decreased over time, from 1.04 per 100 patient-days in months 1-3 to 0.22 at months 49-60. On average, 1.59 abdominal CTs per patient were performed in the first year, 0.83 in the second year and 0.52 in years 3-5.

Conclusions: Unlike colon cancer, significant numbers of NETs recur between 5-10 years after curative surgical resection. These data support the lengthening of follow-up for resected NETs to a minimum of 10 years. Future research should focus on the impact of imaging on early detection of recurrence and survival outcomes.

460P Elevated levels of 5-HIAA and CgA in patients with PanNETs from the CLARINET Study

A.T. Phan[1], E.M. Wolin[2], N. Liyanage[3], B. Mirakhur[4], S. Pitman Lowenthal[4], A. Vinik[5], G.A. FisherJr[6], M. Pavel[7]

[1]Medical Oncology, University of New Mexico Comprehensive Cancer Center, Albuquerque, NM, USA, [2]Medical Oncology, Montefiore Einstein Center for Cancer Care, Bronx, NY, USA, [3]R&D Statistics, Ipsen Innovation, Les Ulis, France, [4]Medical Affairs, Ipsen Biopharmaceuticals, Basking Ridge, NJ, USA, [5]Diabetes Research, Eastern Virginia Medical School, Norfolk, VA, USA, [6]Medical Oncology, Stanford University, Stanford, CA, USA, [7]Gastroenterology and Hepatology, Endocrinology & Metabolic Diseases, Charité University Medicine Berlin, Berlin, Germany

Background: While carcinoids frequently synthesize, and secrete serotonin into the circulation, and 5-HIAA is a common biomarker in the carcinoids, measurement of 5-HIAA in non-carcinoid PanNET patients (i.e. no hormone-related symptoms or non-functional) is not routinely recommended by international guidelines. The incidence of serotonin-producing PanNETs may be underestimated, with potential impact on clinical outcome when serotonin levels remain elevated. We sought to characterize 5-HIAA and CgA levels in PanNET patients who participated in the large placebo-controlled phase III CLARINET Study.

Methods: Evaluable data available for urinary 5-HIAA and serum CgA for patients with PanNET in CLARINET study were analyzed. Urinary 5-HIAA and Serum CgA were assessed at baseline and every 12 weeks thereafter through Week 96. Changes in urinary 5-HIAA and serum CgA levels were calculated using a non-parametric Wilcoxon 2-sample test. Biochemical response for urinary 5-HIAA or serum CgA was defined as baseline >upper limit of normal (ULN, 41.6 µmol/d 5-HIAA; 98.1 µg/L CgA) and ≥50% decrease from baseline or a decrease to a value ≤ULN on study.

Results: 91/204 patients in CLARINET had PanNETs. Evaluable data for urinary 5-HIAA and serum CgA concentrations were available in 79 and 88 patients, respectively. A substantial number of patients with PanNET had elevated (>ULN) urinary 5-HIAA levels (21/79; 27%) and/or serum CgA (63/88; 72%). Among the 21 PNET patients with baseline 5-HIAA >ULN, biochemical response was achieved in 85% (11/13) lanreotide-treated patients compared with 63% (5/8) in patients on placebo at the last available value ($p = 0.33$). Among patients with baseline CgA >ULN, biochemical response was achieved in 66% (19/29) of lanreotide vs. 18% (6/34) of placebo-treated patients ($p = 0.0002$). Limited sample sizes precluded robust analysis for statistically significant differences in the lanreotide vs. the placebo group among patients with elevated biomarkers at baseline and biochemical response.

Conclusions: The percentage of patients with elevated urinary 5-HIAA was unexpected. The concept of PanNET and secretion of serotonin may need to be redefined. The potential of 5-HIAA and CgA as biomarkers of response and follow-up in nonfunctioning PanNET is alluring, but requires further study. Data from additional prospective studies are needed to impact clinical practice guidelines.

461P The prognostic value of cytokeratin 7, 19, thyroid transcription factor-1 and CD117 expression in lung neuroendocrine tumors of various grades

L. Gurevich[1], N. Korsakova[1], I. Voronkova[1], I. Kazantseva[1], V. Ashevskaya[1], A. Titov[2], L. Kogoniya[2], M. Byakhova[1]

[1]Pathology, Moscow Regional Research and Clinical Institute ("MONIKI"), Moscow, Russian Federation, [2]Surgery, Moscow Regional Research and Clinical Institute ("MONIKI"), Moscow, Russian Federation

Background: Neuroendocrine tumors of the lung (NETL) are a wide range of tumors with various malignancy grades and prognosis.

Methods: We performed immunohistochemical assessment of the diagnostic biopsies and surgical specimens from 205 patients with NETL aged 55 ± 14 years and identified 61 (29,8%) typical carcinoids (TC), 44 (21,5%) atypical carcinoids (ATC), 84 (41%) small cell neuroendocrine carcinomas (SCNEC) and 16 (7,8%) large cell neuroendocrine carcinomas (LCNEC). Markers of neuroendocrine differentiation (synaptophysine, chromogranine A and CD56) and cytokeratins (CK) 7 and 19, thyroid transcription factor-1 (TTF-1), CD117 were used.

Results: Most often, the expression of CK7 and CK19 was found in LCNEC (71.4%, 10/14 and 91.7%, 11/12 respectively), less frequently, in ATC and SCNEC (52,8%, 19/36 and 52.4%, 22/42; 43,9%, 29/66 and 68,2%, 45/66 of cases, respectively), whereas in TC it was rare (13,3%, 6/45 and 19,3%, 11/57 respectively). The rates of CK7 and 19 expression were significantly lower in the TC, compared to the SCNEC and LCNEC ($p < 0.01$, χ.) The expression of TTF-1 was very rare in the TC (11,6%, 5/43 of cases) and significantly more often in ATC (60.5%, 23/38) and in SCNEC and LCNEC (79,2%, 57/72 and 75%, 9/12 of cases, respectively). TTF-1 expression was significantly less frequent in typical than in ATC, SCNEC and LCNEC ($p < 0.01$, χ.). The expression CD117 was absent in the TC (0%, 0/27), very rare in the ATC (17,4%, 4/23) and significantly more often in SCNEC and LCNEC (95,7%, 43/47 and 42,8%, 3/7 of cases, respectively).

Conclusions: Expression of TTF-1, CK7, 19 and CD117 in the NETL is characteristic for a less differentiated cell immunophenotype and allows for identification of the risk group with unfavorable clinical outcome among low-grade TC and ATC.

461P An open-label, multicenter Phase 1b study of radium-223 + paclitaxel in cancer patients with bone metastases

R. Geva[1], J. Lopez[2], S. Danson[3], H. Joensuu[4], A. Peer[5], S.J. Harris[6], F. Souza[7], B.A. Ploeger[8], K.M.C. Pereira[9], R. Perets[5]

[1]Research Unit, Division of Oncology, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [2]Drug Development Unit, The Royal Marsden Hospital and The Institute of Cancer Research, Sutton, UK, [3]Department of Oncology and Metabolism, Sheffield Experimental Cancer Medicine Centre, Weston Park Hospital, Sheffield, UK, [4]Department of Oncology, Helsinki University Hospital, Helsinki, Finland, [5]Oncology Division, Rambam Health Care Campus, Haifa, Israel, [6]Department of Medical Oncology, The Royal Marsden NHS Foundation Trust and Institute of Cancer Research, Sutton, UK, [7]Clinical Pharmacodynamics Expert Oncology, Bayer HealthCare Pharmaceuticals, Whippany, NJ, USA, [8]Drug Discovery, Pharmaceuticals, Clinical Pharmacometrics, Bayer Pharma AG, Berlin, Germany, [9]Pharmaceuticals Development, Bayer Pharma AG, São Paulo, Brazil

Background: Concomitant radium-223 (Ra-223) and chemotherapy is a possible option for cancer patients (pts) with bone metastases (mets). Both treatments impact hematologic parameters, and myelosuppression risk during coadministration is unknown. This phase 1b study (NCT02442063) in cancer pts with bone mets evaluated the safety of Ra-223 + paclitaxel (PTX) and the mode of interaction between treatments regarding myelosuppression.

Methods: Eligible pts had a confirmed malignant solid tumor with ≥ 2 bone mets and were candidates for PTX treatment. Treatment included 7 PTX cycles (90 mg/m^2 IV per wk as per local standard of care; 3 wk on/1wk off) combined with 6 Ra-223 cycles (55 kBq/kg IV; 1 injection every 4 wk, starting at PTX cycle 2). The primary end point was percentage of pts with neutropenia and thrombocytopenia during treatment with Ra-223 + PTX (cycles 2 and 3) vs PTX alone (cycle 1). A previously developed dose-exposure-response model describing the time course of PTX and Ra-223–induced suppression of absolute neutrophil counts was used to evaluate the mode of interaction (additive or synergistic) between Ra-223 and PTX.

Results: Of 22 enrolled pts, 15 were treated; 13 completed cycles 1-3 and were included in the pharmacodynamics analysis. Tumors in treated pts were breast (7 pts), prostate (4 pts), bladder (1 pt), non-small cell lung (1 pt), myxofibrosarcoma (1 pt), and neuroendocrine (1 pt). 7 pts had received ≥ 3 prior chemotherapy regimens. In the 13 pts who completed cycle 3, grade 3 neutropenia rates in cycles 2 and 3 were 31% and 8%, respectively, vs 23% in cycle 1; there were no cases of grade 4 neutropenia or grade 3/4 thrombocytopenia. No pts discontinued treatment due to toxicity from the treatment combination. Safety data for the breast cancer pt subset will be presented. The myelosuppression model showed an additive effect of Ra-223 to PTX-induced neutropenia, with an additional 10% average decrease in absolute neutrophil count vs PTX alone.

Conclusions: In pts with solid tumors and bone mets, Ra-223 was well tolerated when combined with PTX, with an additional 10% average decrease in neutrophil levels compared with PTX monotherapy. The combination should be explored further in pts with bone mets.

462P A nomogram based on tumor-associated neutrophil-to-lymphocyte ratio to predict survival prognosis for patients with gastric neuroendocrine neoplasms

L-L. Cao, H. Chang-Ming, J. Lu, J. Xie, P. Li

Department of Gastric Surgery, Fujian Medical University Union Hospital, Fuzhou, China

Background: This study investigated the predictive value of the tumor-associated neutrophil-to-lymphocyte ratio (TA-NLR) on clinical outcomes for patients with gastric neuroendocrine neoplasms (g-NENs) after radical surgery.

Methods: Data from 142 patients who were diagnosed with g-NENs and underwent radical gastrectomy at our department from March 2006 to March 2015 were prospectively collected and retrospectively analyzed. Receiver operating characteristic curve analysis was used to identify the optimal value for TA-NLR. Univariate and multivariate survival analysis were used to identify prognostic factors for g-NENs. A nomogram was adopted to predict RFS and OS after surgery.

Results: TA-NLR was not significantly associated with clinical characteristics (all $P > 0.05$). TA-NLR significantly correlated with tumor recurrence, especially with liver and lymph node metastasis (both $P < 0.05$). A multivariate Cox regression analysis identified the TA-NLR as an independent prognostic factor for recurrence-free survival (RFS) and overall survival (OS) (both $P < 0.05$). The concordance index (C-index) of the nomograms, including the TA-NLR, Ki-67 index and lymph node ratio, for RFS (OS) was 0.788(0.759) and was higher than the C-index of the traditional TNM staging system [0.672(0.663)].

Conclusions: TA-NLR was an independent prognostic factor for patients with g-NENs regarding RFS and OS. Nomograms with the TA-NLR, Ki-67 index and lymph node ratio had a superior ability to predict clinical outcomes for postoperative g-NENs patients, as well as the traditional TNM staging system.

463P Plasma protein fingerprinting and machine learning for the diagnosis of small intestinal neuroendocrine tumors: The nordic NET biomarker group EXPLAIN study

M.M. Kjellman[1], S. Welin[2], U. Knigge[3], H. Gronbaek[4], H. Sorbye[3], E. Thiis-Evensen[5], M. Thyregod Jørgensen[6], V. Johanson[7], C. Schalin-Jäntti[8], P. Myrenfors[9], T. Ström[9], K. Becker[9], R. Belusa[9]

[1]Department of Endocrine Surgery, Karolinska Institutet, Stockholm, Sweden, [2]Department of Endocrine Oncology, Uppsala Akademiska, Uppsala, Sweden, [3]Department of Surgery, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark, [4]Department of Clinical Medicine, Aarhus University Hospital, Aarhus, Sweden, [5]Department of Gastroenterology, Oslo University Hospital, Oslo, Sweden, [6]Department of Medical Gastroenterology, Odense University Hospital, Odense, Denmark, [7]Department of Surgery, Sahlgrenska Hospital, Gothenburg, Sweden, [8]Department of Endocrinology, Helsinki University Hospital, Helsinki, Finland, [9]Medical Department, Ipsen, Stockholm, Sweden

Background: Small intestinal neuroendocrine tumors (siNETs) are notoriously difficult to diagnose, especially in an early stage. The EXPLAIN study aimed to investigate

92 plasma proteins (PP), previously shown to be cancer related, in an attempt to improve the accuracy in diagnosis of siNETs.

Methods: This non-interventional exploratory study in the nordic countries analysed 136 patients with siNET from 17 hospitals and 144 age and sex matched controls (all with written consent). Exclusion criteria: NET not confirmed, previously treated for NET, other malignant diseases, chronic inflammatory disease, kidney or liver failure. Blood samples (4 ml) were obtained at first visit. Samples analysis used the Proseek Multiplex Oncology II assay (OLink) to measure relative levels of the 92-cancer related PP. In addition, chromogranin A (CgA) was analyzed centrally (Akademiska Lab. Uppsala). Data was subjected to statistical supervised learning techniques (SSLT): random forest and support vector machine.

Results: This is the first interim analysis. Patient characteristics: age 65±10 (mean±SD), 58% male, 48% G1 and 52% G2, 88% N1 and 65% M1, 23% >3 bowel mov/d and 11.5% >3 flushes/d. CgA (mean (SD), nmol/L) in 115 patients free from proton pump inhibitor treatment (PPI): 42.37 (86.62), in 21 NET patients with PPI: 68.41 (74.21), in 132 controls free from PPI: 3.67 (3.57) and in 12 controls treated with PPI: 11.83 (8.97). Several PP (>20) showed significant p<.005 different mean levels compared with controls (t-test with Satterthwaite correction). Ten valuable PP in the model: CgA, LYN, ABL1, DKN1A, TXLNA, MUC-16, EGF, MetAP 2, VIM and MK.

Table: 463P Comparison of SSLT models

	SVM – Radial	SVM – Linear	Random Forest
Accuracy (95% CI)	0.8429 (0.7362, 0.9189)	0.8714 (0.7699, 0.9395)	0.8857(0.7872, 0.9493)
Sensitivity	0.7647	0.7941	0.8824
Specificity	0.9167	0.9444	0.8889
AUC	0.9191	0.9428	0.9404

Conclusions: Both a high level of sensitivity and specificity (0.9) were obtained using our multi plasma protein strategy combined with SSLT for the diagnosis of siNET. Further development of the machine learning model is ongoing.

464P CXCR4 inhibition by ulocuplumab prevents EMT of pNET cells in vitro

E. Pellé, M. Cives, D. Quaresmini, D. Lovero, C. Felici, P. Cafforio, R. Palmirotta, F. Silvestris

Azienda Ospedaliero-Universitaria Consorziale Policlinico di Bari, University of Bari Aldo Moro, Bari, Italy

Background: NETs overexpress CXCR4. We have previously shown that stimulation of CXCR4 by its ligand SDF-1 promotes EMT and increases the distant tumor spread of NET cells. Ulocuplumab (Ulo) is a fully human IgG4 mAb designed to inhibit the binding of SDF-1 to CXCR4. We investigated the effects of Ulo in preventing pNET spreading *in vitro*.

Methods: Complement-dependent cytotoxicity (CDC), Ab-dependent cell cytotoxicity (ADCC), Ab-dependent cell phagocytosis (ADCP) and direct Ab-induced apoptosis were investigated using three pNET cell lines (BON1, CM, QGP1) treated with Ulo. Transcriptome profiling was performed by RNAseq following incubation with SDF-1 in the presence or absence of Ulo. Flow cytometry was used to characterize the EMT-related phenotype of NET cells, as well as their expression of immune checkpoints in response to EMT-inducing stimuli. Migration and invasion of pNET cells towards liver and bone fragments was evaluated by transwell assays. The effects of Ulo on the intracellular signaling activated by CXCR4 stimulation were investigated by western-blot (WB), while confocal microscopy assessed the nuclear expression of CXCR4 after high-quality nucleocytoplasmic fractionation.

Results: Ulo failed to induce CDC, ADCC and ADCP in pNET cell lines, in absence of significant direct tumor cell killing. Ligand stimulation of CXCR4 promoted an EMT-like transcriptional shift (upregulation of *SNAIL*, *ZEB1*, *SMAD2*), which was abrogated by Ulo. Treatment with SDF-1 induced cadherin switch, but was unable to alter the membrane expression of immune checkpoints including PD-L1, PD-L2 and CD38. Both *in vitro* migration and invasion of pNET cells towards liver and bone were significantly suppressed by CXCR4 blockade. Stimulation of CXCR4 induced the phosphorylation of Akt, ERK, and NF-kB, resulting in Vimentin overexpression as well as acquirement of mesenchymal patterns including enhanced spindle index. These effects, inhibited by Ulo, were paralleled by a substantial enrichment of CXCR4 on the nuclear membrane.

Conclusions: Ulo suppresses EMT in pNET cell lines by both disabling the intracellular signaling downstream CXCR4 activation and preventing its nuclear localization. The pathophysiology of nuclear CXCR4 needs to be investigated.

Background: RIFTOS MKI was designed to compare the time to symptomatic progression from study entry in patients with RAI-R DTC for whom there was a decision to treat or not to treat with an MKI in the real-life setting. Here, we report interim baseline characteristics for a subgroup of patients from Europe.

Methods: RIFTOS MKI is a non-interventional study enrolling patients from USA, Japan, Europe, and rest of the world with asymptomatic RAI-R DTC. The decision to initiate MKIs at study entry was at the discretion of the treating physician. Final analysis will be performed once 700 patients have been enrolled and the last enrolled patient has been followed for 24 months.

Results: Of the 80 patients enrolled from Europe, the median duration of observation was 165 days; 51% were male and the median age was 67 years. Most patients had an ECOG performance status of 0 or 1 (96%) and distant metastasis at initial visit (81%). The most frequent histology was papillary (61%). The median time from initial diagnosis of DTC to study entry was 7.7 years. RAI refractoriness was mainly due to lack of RAI uptake (70%) and the median time from RAI classification to initial visit was 25 months. The average dose per RAI treatment and median cumulative activity of RAI were 4.6 and 13.0 GBq, respectively.

Conclusions: The interim baseline characteristics results presented here are similar to those previously reported in phase III studies. The study is ongoing.

Background: MANEC is a rare entity and evidence on its prognosis and management is limited.

Methods: Demographic/clinicopathological/survival data of consecutive patients (pts) with a diagnosis of MANEC (2010 WHO criteria) from 4 European centres were retrospectively reviewed.

Results: Fifty-three pts were identified (01/06-03/17); median (med) age: 62 yrs (range 34-89), male: 70%, ECOG PS 0-1: 60%, with primary tumours from small/large bowel in 34 (64%), oesophagus/stomach: 13 (24.5%), pancreas/biliary tract: 5 (9.5%), unknown (UNK): 1 (2%). Forty percent had an adult comorbidity evaluation (ACE)-27 score of 0. The neuroendocrine (NE) component (predominant histology in 40%) was poorly-differentiated (PD) in 45 (85%) [Ki-67≥55%: 58%]. Most frequently-expressed immunohistochemical (IHC) markers were synaptophysin (100%), chromogranin A (CgA) (58.5%) and CDX2 (51%). Histology was PD NE in 64% from recurrent/metastatic sites (n = 14 pts). Of 28 (53%) pts with localised disease (LA), 26 (93%) had curative surgery (7 had neoadjuvant chemo-radiotherapy (CT-RT), 6 adjuvant CT, 1 peri-operative CT), 1 (3.5%) had definitive CT-RT and 1 (3.5%) had UNK management; 16 (57%) recurred. Forty-one pts (77%) were treated for advanced (adv) disease: 20 (49%) platinum-based CT, 3 (7%) irinotecan-based CT, 1 (2.4%) gemcitabine, 3 (7%) UNK CT regimen, 1 (2.4%) RT, 1 (2.4%) CT-RT, 11 (27%) best supportive care (BSC), and 1 (2.4%) UNK management. Med follow-up time was 10.4 months (mo) (95% Confidence Interval (CI) 5.15-13.09). Med overall survival (OS) for all pts was 18.6 mo (95% CI 11.4-40). Med recurrence-free survival and OS in pts with LA was 19.4 mo (95%CI 5.8-30.9) and 21 mo (95%CI 12.1-40). Med progression free survival (PFS) and OS in pts with adv disease was 4.6 mo (95%CI 3.3-6.7) and 13.6 mo (95%CI 8.8-33.1). On univariable analysis, ACE-27 score (0 vs ≥ 1) was prognostic for better PFS and OS (both $p < 0.05$); IHC negativity for CgA and active treatment (vs BSC) were prognostic for better PFS (both $p < 0.05$).

Conclusions: PD NE histology in MANECs was predominant in both diagnostic and recurrent/metastatic tumour samples. Active treatments were offered to most pts but more effective therapy is clearly needed.

467P Incidence of adrenal gland tumor as a second primary malignancy: SEER based database

W. Rashed[1,3], A. Saad[2], M. Al-Husseini[2], A.M. Galal[3], A.M. Al-Tayep[3], A. El Shafie[3], M.A. Ali[3], A.S. Alfaar[4]

[1]Research Department, Children's Cancer Hospital 57357, Cairo, Egypt, [2]Medicine, Faculty of Medicine-Ain Shams University, Cairo, Egypt, [3]Research Department, Armed Forces College of Medicine, Cairo, Egypt, [4]Medicine, Charité-Universitätsmedizin Berlin, Berlin, Germany

Background: Adrenal gland tumors are sporadic and heterogeneous, with an incidence (excluding childhood neuroblastoma) of 0.05% in the US. Advances in cancer treatment in the last few decades have resulted in increased survival in most paediatric and adult cancer types. The aim here is to report the incidence of adrenal gland tumors as a second primary tumor based on data from the SEER database.

Methods: Data from the Surveillance, Epidemiology, and End Results 'SEER' program of the National Cancer Institute, using the SEER*stat software (version 8.3.2) was obtained. All cancer sites using the Multiple Primary Standardized Incidence Ratios 'MP-SIR' session were selected. SEER 13 Regs Research Data from1992 to 2013 was used.

Results: Data from a total of 2,887,468 persons with cancer were reviewed, 117 of whom had suffered second primary adrenal tumors. One of these patients had two events of adrenal cancer as a second primary, resulting in a total of 118 incidences. The overall standardized incidence ratio (SIR) of adrenal gland tumor as a second primary was 1.49. A high percentage of this event was found in elderly patients, especially those of white race. High incidence of the event was detected in specific primary tumor sites: hypopharynx (O/E=44.59), stomach (O/E=4.95), small intestine (O/E=8.86), liver (O/E=8.74), breast (O/E=1.78), kidney and renal pelvis (O/E=3.19), other endocrine including thymus (O/E=38.27), nodal NHL (O/E=3.79), and Chronic Myeloid Leukemia (O/E=11.15).

Conclusions: Little is available in the literature about adrenal gland tumors as a second primary tumor. Its incidence is high in both white race and elderly cancer survivors in the US. The risk of cancer survivors suffering from a second primary adrenal gland tumor should receive more attention in the US. This would ideally be through follow-up programs at specialized national cancer networks, especially for rare tumors like those of the adrenal gland.

468P Activity of temozolomide (TMZ) in patients (PTS) with malignant pheochromocytoma or paraganglioma (MPP): A mono-institutional retrospective study

G. Lombardi[1], M.A. Ferrara[2], A. Pambuku[1], M. Lorusso[2], F. Boaretto[2], F. Schiavi[2], L. Biasini[3], F. Azzolin[2], G. Opocher[4], S. Zovato[2], V. Zagonel[1]

[1]Clinical and Experimental Oncology, Medical Oncology 1, Veneto Institute of Oncology, Padua, Italy, [2]Familial Tumor Unit, Veneto Institute of Oncology, Padua, Italy, [3]Immunology and Molecular Oncology Unit, Veneto Institute of Oncology, Padua, Italy, [4]IOV, Veneto Institute of Oncology, Padua, Italy

Background: MPP are very rare neuroendocrine tumors and, currently, there is no standard chemotherapy for their treatment. TMZ showed some benefit in digestive neuroendocrine tumors. We investigate TMZ activity in PTS with MPP.

Methods: Retrospectively, we evaluated TMZ activity in MPP PTS treated at our oncological center, Veneto Institute of Oncology, from January 2015 to March 2017. The inclusion criteria were: pathological diagnosis of MPP, ECOG PS 0-2, no haemopoietic, renal and hepatic abnormalities. TMZ schedule was 150-200mg/m^2 for 5 consecutive days every 28 days until progression disease or unacceptable toxicity. CT scan and urinary concentrations of metanephrines were performed every 12 wks; evaluation of tumor response was performed according to RECIST 1.1 criteria. Germinal mutational analysis of the genes of susceptibility to pheochromocytoma/paraganglioma (SDHx, MAX, TMEM127, RET, VHL, FH) was performed. Aberrant hypermethylation of MGMT promoter was analyzed on DNA obtained from surgical tissue. Median OS and PFS were estimated by the Kaplan-Meier method. Toxicity was evaluated by CTCAE v.4.

Results: We enrolled 12 consecutive PTS; 7 were males; ECOG PS was 1 and 2 in 9 and 3 PTS. MAX gene was mutated in 1 PT. SDHB gene was mutated in 2 PTS. MGMT promoter was methylated in 1 patient. No other genetic mutations were found. 5 PTS were already treated with a prior chemotherapy (3 sunitinib, 1 capecitabine, 1 dacarbazine) and 4 with a prior MIBG. 9 PTS were evaluable for response: 2 PTS had a partial response, 5 stable disease, 2 progressive disease. Median follow up was 9.2ms (range 1.1-28ms). 2 PTS received TMZ for more than 2 years and other 2 PTS for more than 1 year. Median PFS and OS were not reached (95% CI = 3.4ms-n.a.; 6.2ms-n. a, respectively). Urinary metanephrines levels seem to correlate with response. Hypertension descreased significantly in 5 PTS during TMZ treatment. No grade 3-4 toxicity was recorded.

Conclusions: TMZ is an active and safe treatment for MPP, regardless of previous treatment. A prospective phase II study is ongoing.

469P Neuroendocrine carcinoma of the uterine cervix: A retrospective monocentric study

M. Creoff, S. Thezenas, A. Lapierre, A. Ducteil, D. Azria, C. Bourgier, C. Kerr

Radiation Oncology, ICM Regional Cancer Institute of Montpellier, Montpellier, France

Background: Neuroendocrine cervical carcinoma (NECC) is a very aggressive and rare disease. To date, only 2 prospective studies with scarce patient numbers have been reported in the literature. Here we studied a NECC patients (pts) cohort treated with current anticancer treatment modalities.

Methods: All pts with NECC were retrieved from 1996 to 2013 in our institute (n = 14). 3D-conformal radiation therapy combined to concomitant chemotherapy (RT-CT) was performed to all pts. Chemo- regimen (CT) was cisplatin plus etoposide or carboplatin plus etoposide. Mean total dose to clinical target volume (CTV) was 48 Gy.

Results: Pts and treatments characteristics. Mean age was 48.5 years old. Most of pts had a loco regional disease (n = 11): stage IA (n = 1), IB (n = 1), IIA (n = 2) and IIB (n = 7); 3 pts were stage IVB. Pelvic and/or lombo-aortic lymph nodes involvement was observed in 42.8% pts (n = 6). Among them, 3 pts were treated with an extended lombo-aortic radiation field. Among the entire cohort, 2 treatment modalities were distinguished: (i) most of pts were treated with neoadjuvant CT followed by concurrent RT-CT (n = 9). Either pulsed-dose rate (PDR) brachytherapy (n = 4) or colpo-hysterectomy (=3) was performed according to tumor response. Adjuvant CT was performed to 3 pts in this subgroup (mean number of cycle: 3); (ii) colpo-hysterectomy followed by concomitant RT-CT and PDR brachytherapy (n = 1), adjuvant CT delivered to 1 patient (3 cycles). Pts outcome. Median follow up was 10 years (range,

0.3-11.2). Median overall survival (OS) was 1.9 years; (IC95% [0.8 –NC]); 1-, 2- and 5-y OS were 79%, 48% and 40% respectively. Median progression free survival (PFS) was 11.7 months (IC95% [6 - 59]); 1-, 2- and 5- y PFS were 50%, 29% and 21% respectively. At the time of study analysis, 5 pts were still alive without any progression disease and are considered as long patient survivor (follow up at least more than 6 years).

Conclusions: Despite the small number of pts in our study, pts outcome was consistent with the literature. This study showed a large variety of treatment modalities. To date, there is no consensus on how to treat these pts. However, owing to poor pts outcome, aggressive treatment modalities are probably required.

470TiP AGITG NABNEC: A randomised phase II study of nab-paclitaxel in combination with carboplatin as first line treatment of gastrointestinal neuroendocrine carcinomas

M. Khasraw[1], M.S. Hofman[2], L. Chantrill[3], N. Pavlakis[4], V. Gebski[1], A.J. Gill[5], B. Markman[6], S. Yip[1], E. Gibbs[1], C. Karapetis[7], S.F. Wong[8], D.T. Ransom[9], M. Michael[10], K. Wilson[1], J. Simes[1], L. Lipton[11]

[1]NHMRC Clinical Trials Centre, The University of Sydney, Sydney, Australia, [2]Department of Oncology, University of Melbourne, Peter MacCallum Cancer Centre, Melbourne, Australia, [3]The Kinghorn Cancer Centre, St Vincent's Hospital, Darlinghurst, Australia, [4]St Leonard's, Northern Cancer Institute, Sydney, Australia, [5]Department of Anatomical Pathology, Royal North Shore Hospital, Sydney, Australia, [6]Department of Oncology, Monash Health, Melbourne, Australia, [7]Department of Medical Oncology, Flinders Centre for Innovation in Cancer, Bedford Park, Australia, [8]University Hospital Geelong, Barwon Health, Geelong, Australia, [9]Department of Medical Oncology, Fiona Stanley Hospital, Perth, Australia, [10]Division of Cancer Medicine, Peter MacCallum Cancer Centre, Melbourne, Australia, [11]Western Hospital Footscray Walter and Eliza Hall Institute, Royal Melbourne Hospital, Melbourne, Australia

Background: Neuroendocrine carcinomas (NEC WHO grade 3) are aggressive cancers that are rapidly fatal. There have been no randomised trials to date to establish standard therapy for advanced gastrointestinal (GI) NECs. Etoposide and carboplatin are used by extrapolation from small cell lung cancer data. Paclitaxel is also active in NECs but there is no data on the role of nab-paclitaxel. This randomised study aims to establish if carboplatin and nab-paclitaxel combination is an effective and tolerable treatment for advanced GI NECs.

Trial design: NABNEC has commenced as a randomised phase II multicentre trial enrolling adults with advanced and/or metastatic non-resectable GI NECs. Patients are randomised to: Arm A (n = 47) IV nab-paclitaxel 100 mg/m^2 on Day 1 every week and IV carboplatin AUC = 5 on Day 1 every 3 weeks OR: Arm B (n = 23) IV etoposide 100mg/m^{2}on Days 1-3 every 3 weeks and IV carboplatin AUC = 5 on Day 1 every 3 weeks. Treatment will continue until disease progression or unmanageable toxicity. The primary endpoint is objective response rate (RR) by RECIST 1.1. At 6 months, the RR in the intervention group would need to be at least 50% to justify further investigation. A total sample size of 70 patients with a 2:1 randomisation (intervention to control) will have 80% power with 95% confidence to rule out a 30% objective RR in favour of a more clinically relevant RR of 50% at 6 months. Secondary endpoints include progression free survival, overall survival, safety as measured by NCI-CTCAE V4.03, and quality of life using EORTC QLQC30 and QLQ-GINET21 questionnaires. Translational research endpoints include (1) blood and tissue biomarkers (prognostic and/or predictive) correlated with clinical endpoints including (a) circulating tumour cells, (b) mutation profile by whole exome sequencing, (c) DNA methylation profile and (2) utility of 18-fluoro-deoxyglucose positron emission tomography (FDG-PET) imaging as an early predictor of response and association of SUV max with clinical endpoints. NABNEC has opened to recruitment at 9 study sites and is currently enrolling patients. The randomised NABNEC study will run at 20 sites in Australia and New Zealand. ANZCTR # 12616000958482.

471TiP A multicentre, randomised, double-blind, parallel-group, placebo-controlled trial of apatinib in local progressive or metastatic radioactive iodine-refractory differentiated thyroid cancer

Y. Lin[1], S. Qin[2]

[1]Department of Nuclear Medicine, Peking Union Medical College Hospital, Beijing, China, [2]People's Liberation Army Cancer Center, Nanjing, China

Background: Radioactive iodine-refractory differentiated thyroid cancer (RAIR-DTC) is a big challenge in the management of thyroid cancer. Sorafenib and lenvatinib are the 2 FDA-approved tyrosine kinase inhibitors (TKIs), which might not be affordable for most of the Chinese patients (pts). Apatinib is an oral TKI targeting VEGFR-2, with a patient assistance program available in China. It achieved a quick Tg decline of 21% 2 weeks later and an objective response rate (ORR) of 90%, showing promising efficacy in RAIR-DTC (Lin et al, ATA 2016, Short Call Poster 65; Lin et al, Oncotarget, Epub Feb. 02, 2017). Thus, this study aimed to further evaluate the efficacy and safety of apatinib in treating RAIR-DTC.

Trial design: This study is a multicentre, randomised, double-blind, parallel-group, placebo-controlled, phase III trial in China. Adult pts with locally advanced or metastatic RAIR-DTC are eligible. The inclusion criteria include at least one measurable lesion; disease progression within the past 12 months; and ECOG PS 0–2. Pts are defined as RAIR-DTC if they have target lesion(s) without iodine uptake, received one RAI treatment (≥3.7 GBq [≥100 mCi]) but progressed within the past 12 months, received two RAI treatments or more with a time interval of less than 12 months and progressed at least 12 months later), or received cumulative RAI activity over 22.2 GBq (≥600 mCi). Previous targeted therapy is not allowed. Enrolled patients will be randomly assigned to receive apatinib (500 mg qd) and placebo, respectively. Four weeks is defined as one cycle. Dose increase to 750 mg and dose reduction to 250 mg are allowed. The primary endpoint is progression free survival. The secondary endpoints include disease control rate, ORR, duration of response, changes in serum Tg and TgAb concentration, quality of life, and safety. A multiple Cox proportional hazards model is used to evaluate the hazard ratios after adjusting iodine uptake, metastatic lesion site, gender, and age. 118 pts will be recruited assuming a 106.9% increase in median PFS in the apatinib arm compared with the placebo arm. As of 2nd May 2017, 3 eligible patients have been enrolled.

472TiP Phase 2 clinical investigation of BPM31510 (ubidecarenone) alone and in combination with gemcitabine in patients with advanced pancreatic cancer

A. Niewiarowska[1], R. Sarangarajan[2], D. Lucius[2], N. Narain[2], R.K. Raminathan[3], M. Hidalgo[4]

[1]Hematology, Vita Medical Associates, Bethlehem, PA, USA, [2]Biosystems, BERG, LLC, Framingham, MA, USA, [3]Medical Oncology, Mayo Clinic Hospital, Phoenix, AZ, USA, [4]Medical Oncology, Beth Israel Deaconess Medical Center, Boston, MA, USA

Background: BPM31510 is an ubidecarenone lipid nanodispersion that switches cancer energy generation from glycolysis to mitochondrial oxidative phosphorylation to elicit anticancer effect. BPM31510 is well tolerated as a monotherapy and at an established MTD of 110mg/kg in combination with Gemcitabine in a Phase I clinical trial. Preclinical *in vivo* pancreatic models demonstrate that BPM31510 alone and in combination with gemcitabine significantly improves duration of survival; supporting the Phase 2 evaluation of BPM31510 in patients with advanced metastatic adenocarcinoma.

Trial design: Eligible patients (aged ≥ 18 y) relapsed/refractory to standard treatment (ST) and met inclusion/exclusion criteria. Each patient receives 110mg/kg IV BPM31510 in a 144-hour infusion alone or in combination with gemcitabine. Tumor response is evaluated at wk10 and then every 8 wks. Investigator observations and reports by treated patients provide clinical assessments not specifically defined in the protocol. This study initially will enroll ten (10) patients in the BPM31510 (monotherapy arm) and ten (10) patients in the BPM31510 plus gemcitabine (combination therapy arm) with intent to enroll the additional 15 patients into the applicable treatment arm(s) into the expansion stage based on RECIST v1.1 clinical response. The goal is to evaluate the Overall Response Rate (ORR) in patients treated with BPM31510 alone or in combination with gemcitabine along with Overall Survival (OS); Progression-Free Survival (PFS); Time to Progression (TTP); Tumor Response using Adaptive Molecular Responses (multi-omic molecular profiling); Evaluate Change in CA 19-9 levels and patient reported Quality of Life using the validated FACT-HEP patient-reported outcomes instrument.

Background: The International Duration Evaluation of Adjuvant chemotherapy (IDEA) collaboration was established to combine data from 6 randomized trials to assess whether 3-month (3M) of oxaliplatin/fluoropyrimidines-based adjuvant chemotherapy is non-inferior to 6-month (6M) for 3-year disease-free survival (DFS) in stage III colon cancer (CC).

Methods: IDEA France randomized patients (pts) between 3M and 6M of chemotherapy with mFOLFOX6 or XELOX (physician choice). DFS was estimated using the Kaplan–Meier method and described using a 3-year DFS rate with 95% confidence interval (CI). Cox-proportional-hazard models were performed to estimate the hazard ratios (HRs) and 95% CIs. We present here the results in the modified ITT (mITT: pts receiving at least one dose of treatment) and modified per-protocol (mPP: pts receiving 3M in the 3M arm and >5M in the 6M arm) populations. Subgroups and long lasting neuropathy results are also reported here.

Results: From May 2009 to May 2014, 2022 pts were randomized from 129 centers and 2010 (99%) and 1757 (87%) were included in the mITT and mPP populations, respectively. With a median follow-up of 4.3 years, the 3-year DFS rate was 72% and 76% (HR = 1.24; 95% CI 1.05–1.46, p = 0.01) for the 3M and 6M mITT populations, respectively and 72% and 78% (HR = 1.36; 95% CI 1.14–1.63, p = 0.0008) for the 3M and 6 M mPP populations. In the mITT FOLFOX treated population (90% of pts), 3-year DFS was 81% (3M) and 83% (6M) for T1-3/N1 pts (N = 1106, HR = 1.15 95%CI 0.89-1.49) and 58% (3M) and 66% (6M) for T4/N2 pts (N = 702, HR = 1.44 95%CI 1.14-1.82). Grade >1 neuropathy was observed in 36% and 67% of pts (p < 0.0001) in the 3M and 6M arms, respectively. With a median follow-up of 3.6 years, final residual grade >1 neuropathy was 2.8% and 7.4% (p < 0.0001), in the 3M and 6M arms, respectively.

Conclusions: The IDEA France study, with 90% of pts treated with mFOLFOX6, shows that 6M adjuvant treatment is superior to 3M. However, this difference was not significant in the mITT and mPP T1-3N1 populations suggesting that 3M of the mFOLFOX6 regimen could be an option for these pts. Clinically relevant (grade>1) neuropathy was significantly higher in the 6M arm, with long-lasting neuropathy in 7.4% of pts.

Background: Combination therapy with oral fluoropyrimidine and irinotecan (CPT-11) has not yet been established as first-line treatment for metastatic colorectal cancer (mCRC). However, several studies of S-1 and CPT-11 plus bevacizumab (Bmab) combination therapy have shown promising efficacy in mCRC, suggesting the potential to replace mFOLFOX6 or CapeOX plus Bmab. We performed a randomized phase 3 trial to determine whether S-1 and CPT-11 plus Bmab is non-inferior or superior to mFOLFOX6 or CapeOX plus Bmab in terms of progression-free survival (PFS).

Methods: The TRICOLORE trial was a randomized, open-label, phase 3 trial. Chemotherapy-naïve patients with mCRC were randomized to receive either mFOLFOX6 or CapeOX plus Bmab (group A) or S-1 and CPT-11 plus Bmab (group B; 3-week regimen: 7.5 mg/kg Bmab, 150 mg/m^2 CPT-11 on day 1, and 40 − 60 mg S-1 twice daily for 2 weeks, followed by a 1-week rest; or 4-week regimen: 5 mg/kg Bmab, 100 mg/m^2 CPT-11 on days 1 and 15, and 40 − 60 mg S-1 twice daily for 2 weeks, followed by a 2-week rest). The primary endpoint was PFS. The non-inferiority margin was a hazard ratio (HR) of 1.25 based on the assumption of a median PFS of 11/12 months in group A/group B (power 0.85, 1-sided alpha 0.025). The primary tumor RAS status of patients consented to submit tissue sample were centrally analyzed.

Results: A total of 487 patients were enrolled from June 2012 to September 2014. Data were analyzed after confirming >374 events as planned. All demographic factors were well balanced. Median PFS was 10.8 months in group A and 14.0 months in group B (HR 0.85, 95% CI: 0.70–1.03, p < 0.001 for non-inferiority, p = 0.087 for superiority). The RAS mutation status was evaluable in 67.6%. In the RAS wild-type subgroup, median PFS was 11.6 months in group A and 15.9 months in group B. In the RAS mutant-type subgroup, median PFS was 9.3 months in group A and 11.3 months in group B.

Conclusions: S-1 and CPT-11 plus Bmab was non-inferior to mFOLFOX6 or CapeOX plus Bmab with respect to PFS and has now become a recommended 1st-line treatment for mCRC irrespective of RAS status.

475O mFOLFOXIRI + panitumumab versus FOLFOXIRI as first-line treatment in patients with RAS wild-type metastatic colorectal cancer m(CRC): A randomized phase II VOLFI trial of the AIO (AIO-KRK0109)

M. Geissler[1], U.M. Martens[2], R. Knorrenschield[3], J. Greeve[4], A. Florschuetz[5], A. Tannapfel[6], S. Wessendorf[1], T. Seufferlein[7], S. Kanzler[8], V. Heinemann[9], S. Held[10], A. Reinacher-Schick[11]

[1]Oncology, Hematology, Gastroenterology, Infectious Diseases, Klinikum Esslingen, Esslingen, Germany, [2]Medical Clinic III, SLK-Kliniken Heilbronn GmbH, Heilbronn, Germany, [3]Hematology/Oncology, Universitätsklinkum Marburg, Marburg, Germany, [4]Medical Clinic I, St. Vincenz Krankenhaus, Paderborn, Germany, [5]Internal Medicine, Klinikum Dessau, Dessau, Germany, [6]Pathology, Ruhr Universität, Bochum, Germany, [7]Internal Medicine I, Ulm University, Ulm, Germany, [8]Medical Clinic II, Leopoldina Krankenhaus Medizinische Klinik II, Schweinfurt, Germany, [9]Medicine III, Ludwig Maximilians University - Grosshadern, Munich, Germany, [10]ClinAssess GmbH, Leverkusen, Germany, [11]Hematology/Oncology, Ruhr Universität, Bochum, Germany

Background: Triple chemotherapy with an anti-EGFR reported promising activity with some safety concerns in single arm phase II trials. The randomized VOLFI trial evaluated activity and safety of mFOLFOXIRI + panitumumab versus FOLFOXIRI in ECOG 0-1, primarily non-resectable mCRC patients.

Methods: Prospective 2:1 randomized, multi-center, phase II trial comparing mFOLFOXIRI (Oxaliplatin 85 mg/m2, Irinotecan 150 mg/m2, 5-FU 3000mg/m2 cont. 48h, LV 200 mg/m2) + Panitumumab 6 mg/KG (arm A) with FOLFOXIRI (Ox 85 mg/m2, Iri 165 mg/m2, 5-FU 3200mg/m2 cont. 48h, LV 200 mg/m2; arm B), both arms q2w. Cohort 1: irresectable mCRC; cohort 2: chance of secondary resection of metastatic lesions. Primary endpoint was ORR, secondary endpoints were secondary resection rate (cohort 2), DCR, PFS, OS, toxicity, quality of life. Financially supported by an unrestricted grant from Amgen.

Results: A total of 96 patients were randomized (63 arm A, 33 arm B). In arm A and B 20 (31.7%) and 11 (33.3%) patients belonged to cohort 2, respectively. ORR was 85.7% in arm A and 54.5% in arm B ($p = 0.0013$, OR 5.000; 95%-CI 1.870-13.370). DCR was 96.8% in arm A and 78.8% in arm B ($p = 0.0071$, OR 8.212). In arm A and B 53 (84,1%) and 25 (75.8%) tumors were left sided, 10 (15.9%) and 6 (18.2%) were located in the right colon, respectively. ORR in Arm A was 90.6% versus 60.0% ($p = 0.0288$, OR 6.400) and in Arm B 60.0% versus 50% (p=n.s.) for left and right located CRC, respectively. ORR between arms A and B comparing left and right sided CRC was 90.6% versus 60.0% ($p = 0.0039$, OR 6.400; 95%-CI 1.889-21.679) and 60.0% versus 50.0% (p= n.s.), respectively. Secondary resections in cohort 2 were 60% ($n = 12$) and 36.4% ($n = 4$) in arms A and B, respectively. Serious adverse advents grade 3-5 occured in 45.3% and 24.2% in arms A and B, respectively ($p = 0.0496$).

Conclusions: mFOLFOXIRI plus panitumumab results in significantly higher response rates compared to FOLFOXIRI in RAS wild-type mCRC. Response rates, however, are differential according to tumor sidedness. High secondary resection rates were observed. Toxicity is manageable in younger fit patients with ECOG 0-1. PFS, OS, QL and TR data are still immature and will be presented at the meeting.

Background: Neoadjuvant chemotherapy has proven valuable in several tumors, but not in colon cancer (CC). The present randomized phase II trial addressed this issue in patients (pts) with locally advanced CC.

Methods: Pts with resectable CC deemed as high risk T3 (extramural tumor invasion > 5 mm), T4 and/or N2 (3 or more visible lymph nodes or 1 node >10mm diameter) on initial abdominopelvic CT-scan were randomized to either receive 6 months of adjuvant FOLFOX after colectomy (arm A control), or neoadjuvant FOLFOX for 4 cycles before surgery and 8 cycles after (arm B). In RAS wild-type pts a third arm testing perioperative FOLFOX + cetuximab has been added prior to colectomy (arm C). The primary endpoint of the study was the rate of major pathological Tumor Regression Grade (TRG) as defined by Ryan centrally assessed by 2 pathologists blinded to the pts treatment. The secondary endpoints included toxicity, perioperative morbidity, carcinologic quality and completeness of the surgery. Analysis was by intention to treat.

Results: 120 pts from 37 French centres were enrolled, 94% completed preoperative chemotherapy. All but 5 pts (disease progression $n = 2$, metastatic disease at inclusion $n = 1$, non resectable tumor $n = 1$, death $n = 1$) in the preoperative arms were resected. 95% and 98% of patients underwent R0 resection in the preoperative arms and control arm, respectively. No significant differences in severe postoperative morbidity rates (Dindo Grade >3) were seen between arm A (13.7%), B (8.2%) and C (14.3%) ($p = 0.64$). Major pathological responses (TRG 1-2) were observed in 7.7%, 44.2%, and 6.3% in arm A, B and C respectively ($p < 0.001$).

Conclusions: Preoperative FOLFOX for locally advanced resectable CC is feasible with acceptable toxicity/morbidity and high TRG. A phase III trial to establish whether these encouraging results translate into improved long-term oncological outcome is now warranted.

Background: Second-line treatment with chemotherapy plus Bev or Cet is now established as a valid option in mCRC. The main objective of this French multicenter, randomized open phase II trial, was to evaluate the Progression Free Survival (PFS) rate at 4 months with chemotherapy plus Bev or Cet in patients with disease progression after Bev plus chemotherapy.

Methods: The main eligibility criterion was disease progression after bevacizumab + 5-FU with irinotecan or oxaliplatin in patients with WT KRAS exon 2 mCRC. Patients were randomized in Arm A (FOLFIRI or mFOLFOX6 plus Bev) or in Arm B (FOLFIRI or mFOLFOX6 plus Cet); the chemotherapy doublet was chosen according to the first line (cross over). Analyses were performed in ITT population. They were repeated on the KRAS + NRAS WT population and in the triple negative population (KRAS, NRAS, and BRAF negative).

Results: From October 2010 to May 2015, 133 patients were included in 25 sites (1 patient ineligible): 85 males (64%), PS 0 (74, 56%), 1 (54, 41%), unknown (4, 3%). The 4-month PFS rate was 80.3% [95%CI (68.0% - 88.3%)] in Arm A and 66.7% [95%CI (53.6% - 76.8%)] in Arm B. Median PFS was 7.1 months in Arm A vs 5.6 months in Arm B ($p = 0.060$). Median OS reached 15.8 months in Arm A vs 10.4 months in Arm B ($p = 0.073$). Tumors samples were collected by a central laboratory and 95 were analysed using the KRAS/BRAF mutation analysis panel kit (KRAS exon 2,3,4 and BRAF V600E) and NRAS mutation detection kit (exons 2,3,4; Entrogen). On the whole, 81 patients were KRAS and NRAS WT (41 in Arm A and 40 in Arm B). Median PFS was respectively 7.8 months and 5.6 months in Arm A and Arm B ($p = 0.076$); median OS was 21.0 months in Arm A vs 10.7 months in arm B ($p = 0.324$). 73 were negative for the 3 genes ($n = 36$ and 37). Their median PFS were 8.2 months in Arm A) vs 5.7 months in arm B ($p = 0.100$). Median OS was 21.1 months vs 12.6 months ($p = 0.365$).

Conclusions: PRODIGE18 study is in favour of bevacizumab continuation beyond progression with chemotherapy cross over in WT RAS mCRC initially treated with first-line Bev plus chemotherapy.

Virgen del Rocío, Seville, Spain,* [17]*Medical Oncology, Vall d'Hebron University Hospital, Barcelona, Spain,* [18]*Symphogen, Denmark,* [19]*Oncology, BHI of Omsk region Clinical Oncology Dispensary, Omsk, Russian Federation*

Background: Sym004, a mixture of 2 anti-EGFR monoclonal antibodies (mAbs), was shown to be active in a prior P1/2 trial in refractory mCRC. Due to its unique mode of action, Sym004 was developed for overcoming of acquired resistance to anti-EGFR antibodies.

Methods: 254 patients (pts) were entered to an open label, multinational, 3-arm (1:1:1) RP2S comparing 2 regimens (12 mg/kg [A] or 9 mg/kg loading dose followed by 6 mg/kg [9/6; B]) of weekly Sym004 vs investigator choice (IC) of 5-FU, capecitabine, or best supportive care [C]. Standard eligibility criteria were used; pts were to be refractory to chemotherapy and have responded to, and progressed on anti-EGFR mAb-based therapy; *RAS* exon 2 wild type in tumour archival sample. The study was designed to detect a 3-month (M) improvement in overall survival (OS) (6 vs 9 M) between either Arm A or B and Arm C.

Results: Demographic and baseline parameters were well balanced. The Sym004 adverse event (AE) profile was typical although frequency/severity of dermatologic AEs and hypomagnesemia was higher and GI AEs appeared lower than with approved anti-EGFR mAbs. Arm B was better tolerated than Arm A. OS in the ITT population and exploratory subgroups are presented. The primary outcome of the study was negative due to unexpected outcomes of Arm C. Arm B (9/6 mg dose) was not only better tolerated over 12/6 mg (Arm A), but also was associated with improved survival. Biomarker-specific analyses evaluating pts with double-negative (DN) (no *RAS* mutant allele frequency >20% in circulating tumor [ct]DNA; no *BRAF* V600E) or triple-negative (TN) (DN + no EGFR extracellular domain mutation in ctDNA) mCRC demonstrated markedly prolonged survival and established the 9/6 regimen as well-tolerated and active in DNmCRC (OS increased 3.5 M) and TNmCRC (OS increased 5.5 M).

Conclusions: Although the study was negative in ITT population, treatment with Sym004 was associated with remarkable response when compared with any 4th-line treatment of mCRC. The promising results in the molecularly selected population provide guidance to design a pivotal ctDNA-guided pivotal trial in EGFR inhibitor refractory mCRC.

479O Consensus molecular subtypes (cms) as predictors of benefit from bevacizumab in first line treatment of metastatic colorectal cancer: Retrospective analysis of the MAX clinical trial

J. Mooi[1], P. Wirapati[2], R. Asher[3], C. Lee[3], P. Savas[4], T.J. Price[5], S. Tejpar[6], J. Mariadason[1], N. Tebbutt[7]

[1]*Oncogenic Transcription Laboratory, Olivia Newton-John Cancer Research Institute, Heidelberg, Australia,* [2]*Bioinformatics Core Facility, Swiss Institute of Bioinformatics, Lausanne, Switzerland,* [3]*NHMRC Clinical Trials Centre, University of Sydney, Sydney, Australia,* [4]*Medical Oncology, Peter MacCallum Cancer Center, Melbourne, Australia,* [5]*Medical Oncology, Queen Elizabeth Hospital and University of Adelaide, Woodville, Australia,* [6]*Oncology, University Hospital Leuven, Leuven, Belgium,* [7]*Medical Oncology, Olivia Newton-John Cancer Centre and Austin Health, Heidelberg, Australia*

Background: CMS is a transcriptome-based classification of colorectal cancer (CRC) with prognostic implications, but its association with treatment outcomes, especially in the metastatic setting, remains unknown. We investigated whether CMS classification was predictive of bevacizumab treatment benefit using data from the phase 3 MAX trial. MAX previously reported progression-free survival (PFS) benefit for the addition of bevacizumab (B) to chemotherapy (capecitabine (C) +/- mitomycin (M)) in first line treatment of metastatic CRC.

Methods: Archival tumours from 256 patients (54% of trial population) were available for gene expression profiling using Almac Xcel microarray. Tumours were classified into CMS groups 1 to 4 using previously published methods. We correlated CMS groups with PFS in the MAX trial. The predictive value of CMS was demonstrated as the interaction between CMS and bevacizumab treatment, assessed by Cox proportional hazards model.

Results: After data quality control, primary tumours from 239 patients (51% of trial population) were suitable for survival analysis. Distribution of CMS groups were CMS1 18%, CMS2 48%, CMS3 12%, CMS4 23%. Hazard ratios (HR)(95% CI) of PFS in C vs CB+CBM arms for CMS 1,2,3 and 4 were 0.83 (0.43-1.62), 0.50 (0.33-0.76), 0.31 (0.13-0.75) and 1.24 (0.68-2.25) respectively (test for interaction between CMS and treatment, p = 0.03). CMS remained a significant independent predictor of PFS after adjustment for prognostic factors in a multivariate analysis (p = 0.04).

Table: 478O

Population	Arm A	Arm B	Arm C
ITT N = 254	7.9[a] (6.5, 9.9)[b] N = 83	10.3 (9.0, 12.9) N = 86	9.6 (8.3, 12.2) N = 85
US&EU[c] N = 224	7.7 (6.1, 11.3) N = 75	9.9 (8.0, 12.8) N = 74	8.5 (6.8, 10.2) N = 75

US&EU with TNmCRC N = 131 (68%)[d]	10.6 (6.8, 13.1) N = 47	12.8 (9.7, 14.7) N = 46	7.3 (6.3, 8.8) N = 38

[a]median survival in M

[b]95% confidence intervals

[c]the subgroup analyses excluded pts due to different medical practice

[d]with biomarker data

Conclusions: In metastatic CRC, CMS 2 and 3 subtypes preferentially benefit from the addition of bevacizumab to chemotherapy, compared to CMS 1 and 4. Validation of these findings in independent cohorts is required. Once validated, CMS classification could be used to guide patient selection for bevacizumab therapy.

Background: There are conflicting results concerning the prognostic value of the methylator phenotype (CIMP+ for "CpG island methylator phenotype") in non-metastatic colon cancer (CC) patients (pts). We studied this phenotype in stage III CC pts having undergone R0 resection, characterized for MSI, *RAS* and *BRAF* mutation status and treated with adjuvant FOLFOX-based treatment.

Methods: Tumor samples of 1910 pts enrolled in the PETACC-8 adjuvant phase 3 trial were analysed. The method used was methylation-specific PCR where $CIMP^+$ status was defined by methylation of at least three of the five following genes: *IGF2*, *CACNA1G*, *NEUROG1*, *SOCS1* and *RUNX3*. Association between CIMP status and overall survival (OS), disease-free survival (DFS), and survival after relapse (SAR) was assessed by Cox model and adjusted for prognostic factors (including *MSI*, *BRAF* and *RAS* mutation status) and treatment arm (FOLFOX or FOLFOX plus cetuximab). CIMP status was analyzed according to treatment efficacy.

Results: Determination of CIMP status was successful in 1870 pts (98%): 275 (14.7%) tumors were classified $CIMP^+$. Compared to $CIMP^-$ pts, $CIMP^+$ pts were significantly older ($p = 0.002$), with more frequently women ($p = 0.04$). $CIMP^+$ tumors were more frequently right-sided ($p < 0.0001$)), with histopathology grade 3-4 ($p < 0.0001$), pN2 ($p = 0.001$), MSI ($p < 10e\text{-}4$), *BRAF* mutated ($p < 0.0001$) and *RAS* wild-type ($p < 0.0001$). In multivariate analysis, $CIMP^+$ status was associated with shorter OS (HR: 1.4; 95% CI 1.02 – 1.9; $p = 0.04$) and SAR (HR: 1.8; 95% CI 1.2 – 2.6; $p < 0.0004$); but DFS was not significantly different between $CIMP^+$ and $CIMP^-$ pts (HR: 1.1; 95% CI 0.8 1.5; $p = 0.34$). Theses results were independent of the treatment received. No benefit or detrimental effect of cetuximab was observed in $CIMP^+$ patients for OS and DFS.

Conclusions: In a large clinically and molecularly well defined stage III CC population treated with standard adjuvant therapy, methylator phenotype is a prognostic biomarker for OS and SAR. However, no impact of CIMP status on DFS was observed. Finally, we did not find any predictive value of the CIMP status for the efficacy of FOLFOX versus FOLFOX plus cetuximab.

481PD Sidedness influences prognosis in stage III but not in stage II colon cancer patients receiving an adjuvant therapy: A GISCAD analysis from three randomized trials including 5234 patients

S. Cascinu[1], D. Poli[2], A. Zaniboni[3], R. Labianca[4], A. Sobrero[5], V. Torri[6]

[1]Department of Oncology/Hematology, Azienda Ospedaliero - Universitaria Policlinico di Modena, Modena, Italy, [2]Laboratory of Methodology for Clinical Research, IRCCS-Istituto Ricerche Farmacologiche Mario Negri, Milan, Italy, [3]Oncology Unit, Fondazione Poliambulanza, Brescia, Italy, [4]Department of Oncology, Ospedale Papa Giovanni XXIII, Bergamo, Italy, [5]Medical Oncology Unit, IRCCS San Martino, Genoa, Italy, [6]Department of Oncology, IRRCS Mario Negri Institute for Pharmacological Research, Milan, Italy

Background: While in the advanced setting right colon cancer is associated with a worse outcome, this negative prognostic effect has been not definitively demonstrated in the adjuvant setting. We have analyzed the outcome data from 3 large randomized trials (SITAC-1; SMAC and TOSCA) assessing adjuvant therapy in colon cancer patients with stage II and III. Furthermore, since previous trials were not powered to assess the prognostic role of transversum colon cancer, we analyzed this site independently.

Methods: In order to define the prognostic effect of sidedness we assessed three randomized trials of adjuvant therapy (SITAC, 5FU/FA vs control, 821 patients; SMAC, intraportal 5FU vs 5FU/FA, 990 patients; TOSCA, FOLFOX or XELOX three vs six months 3513 patients) carried out in Italy from 1987 to 2013 and including 5324 patients. Survival and disease-free survival, overall and in each trial, were analyzed according to right, transversum and left colon location. Right-sided was considered caecum to hepatic flexure, left-sided splenic flexure to rectum and trasversum hepatic to splenic flexure. Statistical analysis considered all randomized patients according to allocation arm, with available data on putative prognostic factors. Analysis was planned in order to provide overall and by stage results.

Results: 5324 patients were included in this analysis; 2490 patients were males and 2834 females. Median age was 64 years. 2240 patients had a stage II colon cancer and 3084 a stage III. Right tumors were 1573 (30%), trasversum 822 (15%) and left 2929 (55%). Patients characteristics were well balanced among the three trials. In all the 5234 patients DFS was not affected by tumor location (right colon versus left, HR = 1.01; 95% CI = 0.89-1.15) while right tumor was associated to a worse OS compared to left tumor (HR = 1.21; 95% CI = 1.05-1.40) In stage II patients there was no difference in terms of DFS and OS among the three different tumor location while in stage III patients, right colon cancer had a worse outcome both in DFS and OS than left tumor (HR: 1.37 95% CI = 1.16-1.64, $p < 0.001$).

Conclusions: This is the largest analysis demonstrating the prognostic effect of tumor location in colon cancer patients receiving adjuvant chemotherapy. The effect however is present only in stage III but not in stage II colon cancer.

482PD Robot-assisted vs laparoscopic vs open abdominoperineal resections for low rectal cancer: Short-term outcomes of a single-center prospective randomized controlled trial

J. Xu, Y. Wei, L. Ren, Q. Feng, J. Chen, D. Zhu, W. Chang, T. Yi, L. Yang, X. Qin

General Surgery Department, Zhongshan Hospital, Fudan University, Shanghai, China

Background: Currently, robotic surgery for rectal cancer using da Vinci System is common. However, there is almost no clinical trial reported. This randomized controlled trial aims to compare the safety and efficacy of robot-assisted, laparoscopic and open abdominoperineal resection (APR) for low rectal cancer.

Methods: From 2013-09 to 2017-03, patients aged from 18 to 75 years, with low rectal cancer within 5 cm from anal verge, clinical T1 to T3, no distant metastases, were randomly assigned to receive either robot-assisted procedures (RAP), laparoscopic procedures (LAP) or open surgery (OS) for APR in 1:1:1 ratio. The primary endpoint was postoperative complication rate.

Results: Totally 506 patients were enrolled in this study, randomly assigned to RAP (n = 169), LAP (n = 169), and OS (n = 168). Actually, 3 patients refused surgery, 173 finished RAP, 176 finished LAP, and 154 finished OS (including 4 convert from LAP to OS). The open conversion rate was 0 in RAP and 2.4% in LAP, with no significant difference ($P = 0.123$). In per-protocol analysis, no significant difference was observed in tumor location, size, differentiation and pathological TNM stage, among the three groups. RAP had significantly lower postoperative complication rate (10.4%) than both LAP (18.8%, $P = 0.027$) and OS (26.0%, $P < 0.001$). Also, RAP reduced intraoperative hemorrhage (median, 100 ml) than LAP (130 ml, $P < 0.001$) and OS (200 ml, $P < 0.001$). And RAP promoted postoperative recovery, with shorter days to first flatus (1.0 day) than LAP (2.0 day, $P < 0.001$) and OS (3.0 day, $P < 0.001$), shorter days to first automatic urination (2.0 day) than LAP (3.0 day, $P < 0.001$) and OS (3.0 day, $P < 0.001$), and shorter days to discharge (5.0 days) than LAP (6.0 days, $P < 0.001$) and OS (6.0 day, $P < 0.001$). There was no significant difference in resection margin involvement and number of lymph node harvested. More details are shown in the table.

Conclusions: Robot-assisted APR was safe, and reproduce equivalent surgical quality of conventional laparoscopic and open surgery. Also, it provided less injury and faster functional recovery.

Table: 482PD Study results in per-protocol analysis

	RAP (n = 173)	LAP (n = 176)	OS (n = 154)	P value RAP vs. LAP	P value RAP vs. OS
Operating time, min (median, IQR)	205 (200-220)	195 (160-240)	160 (140-180)	0.002	<0.001

483PD Perioperative chemotherapy with or without cetuximab in patients (pts) with resectable colorectal liver metastasis (CRLM): Mature analysis of overall survival (OS) in the New EPOC randomised controlled trial

J. Bridgewater[1], S. Pugh[2], A. Whitehead[3], L. Stanton[3], Z. Eminton[3], J. Mellor[3], A. Allen[3], M. Finch-Jones[4], S. Falk[5], T. Iveson[6], M. Rees[7], J.W. Valle[8], J. Hornbuckle[9], T. Hickish[10], D. Cunningham[11], T. Maughan[12], J. Garden[13], G. Griffiths[3], J. Primrose[2]

[1]Oncology, UCL Cancer Institute/Paul O'Gorman Building, London, UK, [2]Surgery, University of Southampton, Southampton, UK, [3]Clinical Trials Unit, University of Southampton, Southampton, UK, [4]Surgery, University Hospitals Bristol NHS Foundation Trust, Bristol, UK, [5]Oncology, University Hospitals Bristol NHS Trust Bristol Haematology and Oncology Centre, Bristol, UK, [6]Oncology, Southampton General Hospital Southampton University Hospitals NHS Trust, Southampton, UK, [7]Surgery, Hampshire Hospitals NHS Foundation Trust, Basingstoke, UK, [8]Medical Oncology, The University of Manchester/The Christie, Manchester, UK, [9]Oncology, Weston Park Hospital Cancer Research Centre, Sheffield, UK, [10]Oncology, Bournemouth University, Bournemouth, UK, [11]GI and Lymphoma Research Unit, Royal Marsden Hospital NHS Foundation Trust, London, UK, [12]Oncology, Oxford Institute for Radiation Oncology, Oxford, UK, [13]Surgery, University of Edinburgh, Edinburgh, UK

Background: The primary analysis of the New EPOC trial in 2013 demonstrated a shorter progression-free survival (PFS) when cetuximab was added to chemotherapy as perioperative treatment for CRLM. This analysis reports the mature OS data and novel exploratory analyses.

Methods: Pts with KRAS exon 2 wild-type resectable or suboptimally resectable CRLM were randomised to chemotherapy (CT) or chemotherapy and cetuximab (CTX) before and after liver resection. Trial recruitment and use of cetuximab were halted in 2012 on the recommendation of the Data Monitoring Committee.

Results: 128 pts received CT and 129 CTX between Feb 2007 and Nov 2012. At a median follow-up of 69 months (IQR 59-81), 130 events (death from any cause) had been observed. Median OS was shorter for CTX vs CT (p = 0.035) and in contrast to the primary analysis, mature analysis of PFS was not significantly different (p = 0.291). There were numerically more multi-site progressions in CTX (n = 17/83, 20.5%) than CT (n = 8/78, 10.3%) pts and survival post-progression (PPS) was particularly poor for CTX pts (p = 0.014). Predefined subgroup analyses demonstrated the adverse effect of CTX was in pts conventionally thought to have good prognostic features. Whilst OS was the same for responders and non-responders on CT, it was improved for responders vs non-responders on CTX.

Table: 483PD

	Median survival (months)		HR	95%CI
	CT	CTX		
PFS	23.9	15.5	1.17	0.87-1.57
PPS	35.4	23.5	1.60	1.10-2.33
OS				
All	81.0	55.4	1.45	1.02-2.05
OS by pre-operative response				
Yes	81.1	60.7	1.40	0.89-2.20
No	79.9	34.5	2.19	1.22-3.95
≥4 metastases/poor differentiation of primary/N2 disease				
Yes	59.2	58.3	0.95	0.61-1.51
No	not reached	45.8	2.37	1.39-4.06

Conclusions: In the context of perioperative therapy for resectable CRLM CTX confers a shorter OS and survival post progression compared to CT. This detriment is in those with conventionally favourable prognostic features suggesting that cetuximab induces adverse biology in some pts, the biomarker profile of whom is being investigated. Response to CT alone does not improve OS compared to non-responders, suggesting conferred benefit is adjuvant not neoadjuvant.

Background: In the CheckMate 142 trial (NCT02060188), NIVO + IPI demonstrated manageable safety and clinical activity characterized by an investigator-assessed objective response rate (ORR) of 55%, disease control rate (DCR; defined as CR + PR + SD ≥ 12 wk) of 79%, and encouraging survival benefit (6-mo PFS and OS rates:77% and 89%) in pts with dMMR/MSI-H mCRC (Andre T, et al. ASCO 2017). Here, we report biomarker analyses in pts who received NIVO + IPI in the CheckMate 142 study.

Methods: Pts with dMMR/MSI-H mCRC who progressed on or were intolerant of ≥ 1 prior line of therapy received NIVO 3 mg/kg + IPI 1 mg/kg Q3W × 4 doses followed by NIVO 3 mg/kg Q2W. Tumor anti-programmed death ligand 1 (PD-L1) expression was assessed using the Dako 28-8 pharmDx assay. PD-L1 positivity was defined as ≥ 1% cell membrane staining of any intensity. *BRAF* and *KRAS* mutation statuses were determined by investigators per local guidelines. Characterization of Lynch syndrome as present or absent was based on past medical history from clinical records. ORR per investigator was determined per RECIST v1.1.

Results: Tumor PD-L1 expression and *BRAF/KRAS* statuses were assessed in 84 pts. ORR and DCR by PD-L1, BRAF/KRAS mutational status, and clinical history of Lynch syndrome are reported in the Table below.

Conclusions: Confirmed responses with NIVO + IPI were observed in pts with dMMR/MSI-H mCRC who were PD-L1 expressors and non-expressors, as well as across *BRAF* and *KRAS* mutational status. Responses were also observed in pts with or without a history of Lynch syndrome. These results are consistent with previously reported biomarker analyses of the NIVO monotherapy cohort.

Table: 484PD

Pts, n (%) [95%CI]	dMMR/MSI-H mCRC N = 84 Pts With ≥ 6 Mo of Follow-Up	
	ORR	DCR
Tumor PD-L1 expression*		
≥1% (n = 16)	9 (56) [29.88, 80.25]	12 (75) [47.62, 92.73]
<1% (n = 50)	27 (54) [39.32, 68.19]	39 (78) [64.04, 88.47]
Mutation status†		
BRAF mutant (n = 21)	10 (48) [25.71, 70.22]	16 (76) [52.83, 91.78]
KRAS mutant (n = 30)	19 (63) [43.86, 80.07]	26 (87) [69.28, 96.25]
BRAF/KRAS wild type (n = 22)	13 (59) [36.36, 79.29]	17 (77) [54.63, 92.18]
Clinical history of Lynch syndrome‡		
Yes (n = 27)	20 (74) [53.72, 88.89]	22 (81) [61.92, 93.70]
No (n = 25)	12 (48) [27.80, 68.69]	19 (76) [54.87, 90.64]

*18 pts had no quantifiable PD-L1 expression at baseline;
†11 pts had unknown *BRAF/KRAS* status at baseline;
‡32 pts had unknown Lynch syndrome status at baseline

Background: We demonstrated that the second planned interim analysis (median follow-up, 23.7 months) of the JCOG0910 failed to show non-inferiority of adjuvant S-1 to capecitabine in disease-free survival (DFS: relapse, second malignancy, death are events) at ASCO2015 (abstract # 3512), and the results were opened by the recommendation of JCOG Data and Safety Monitoring Committee. We updated the follow-up data to confirm the conclusion at the interim analysis.

Methods: Key eligibility criteria were: stage III, colorectal adenocarcinoma except for lower rectal cancer, R0 with D2/3 lymph node dissection. Patients were randomized to 8 courses of capecitabine (1,250 mg/m^2 twice daily, days 1–14, every 3 weeks) or 4 courses of S-1 (40 mg/m^2 twice daily, days 1–28, every 6 weeks). Primary endpoint was DFS. Planned sample size was 1,550 in order to provide 80% power with a non-inferiority margin at a hazard ratio (HR) of 1.24 and 1-sided $\alpha = 0.05$. This trial is registered with UMIN-CTR, #UMIN000003272.

Results: 1,564 patients were randomized to capecitabine (n = 782) or S-1 (n = 782). At the end of the follow-up period of 3 years, 69% of required events (368/535) were observed, with a median follow-up for all randomized patients of 4.13 years, 3-year DFS was 81.7% (95% CI, 78.8 - 84.2%) in capecitabine and 78.3% (75.2 - 81.0%) in S-1. The HR of DFS was 1.22 (95% CI, 1.00–1.50) and the non-inferiority of S-1 was not demonstrated (P for non-inferiority = 0.448). Three-year relapse-free survival (RFS: relapse, death are events) was 84.6% in capecitabine and 81.5% in S-1. The HR of RFS was also 1.21 (95% CI, 0.96–1.53). Three-year overall survival (OS) was 96.3% in capecitabine and 95.4% in S-1. The HR of OS was 1.18 (95% CI, 0.83–1.68). In the subgroup analyses, no significant interactions were identified between the major baseline characteristics.

Conclusions: These updated results confirmed that S-1 could not be demonstrated to be non-inferior to capecitabine in DFS. Adjuvant capecitabine remains the standard treatment and S-1 is not recommended.

Background: The AIO KRK-0110 study compares a sequential application of FP+ BEV followed by IRI+ FP+ BEV at first progression (arm A) vs. initial FP+ IRI+ BEV (arm B) in patients (pts) with untreated mCRC.

Methods: The primary efficacy-endpoint was time-to-failure of strategy (TFS). The non-inferiority margin was a 90% confidence interval of a hazard ratio (HR) of 0.8 (Power 70%, $\alpha = 0.05$). Secondary endpoints of the study included response rate, progression-free survival (PFS), overall survival (OS), efficacy in molecular subgroups and quality of life (EORTC QLQ C30).

Results: The full analysis set (FAS) consists of 421 pts (212/209 Arm A/B), median age was 71 years. The primary endpoint (TFS) was not met (HR: 0.86 (0.73-1.02)). Concerning TFS, patients with *RAS/BRAF* wild-type (WT) mCRC appeared to have significant benefit from initial irinotecan while this was not observed in patients with mutant (MT) *RAS* or *BRAF*. A Cox model interaction test for study arm and *RAS*-status was significant (P = 0.03). PFS and OS were consistent with TFS (see table for details). Objective response rate favored the initial irinotecan-arm (36.8% vs 53.6%, P = 0.005). Quality of life (global health, physical functioning, etc) was not substantially different between both study arms at baseline and end of treatment.

Conclusions: In this trial comprising a more elderly population, non-inferiority for TFS of initial FP+ BEV as compared to FP+ IRI+ BEV was not shown. In detail, sequential therapy was inferior in pts with *RAS/BRAF*-WT mCRC and cannot be recommended. However, sequential bevacizumab-based therapy could be discussed as an option in elderly pts with *RAS MT* mCRC. Conclusions on *BRAF* mutant tumors are limited by sample size.

Clinical trial identification: NCT01249638

487P International comparison of stage-specific treatment of and survival from colorectal cancer: England, Norway and Sweden, 2010-2012

S. Benitez Majano, C. Di Girolamo, M. Morris, B. Rachet, M.P. Coleman, S. Walters

Non-Communicable Disease Epidemiology, London School of Hygiene and Tropical Medicine, London, UK

Background: Colorectal cancer patients in England have worse outcomes than patients diagnosed in other high-income countries with similar healthcare coverage. We aim to compare clinical characteristics and survival of colorectal cancer patients in England, Norway and Sweden to understand whether differences in stage and treatment could help to explain international differences in survival.

Methods: Information on patients aged 15-99 years diagnosed with primary malignant tumours of the colon and rectum in England, Norway and Sweden during 2010-2012 was extracted from national cancer registration and/or specialised colorectal cancer registry data. Six-month, one-year and two-year net survival was estimated for each country, stage at diagnosis, and surgical treatment status.

Results: There were 93,125 colorectal cancer diagnoses in England, 11,155 in Norway, and 17,925 in Sweden during the time period. Stage was more advanced in colon than in rectal tumours. England had slightly poorer stage distribution, and a higher proportion of missing stage, than Norway and Sweden. Overall, 64.1% of colorectal cancer patients diagnosed in England, 68.8% diagnosed in Norway and 70.3% diagnosed in Sweden had evidence of receiving potentially curative surgery. These surgically treated patients were on average younger in England than in Norway and Sweden, in each stage category. Stage-specific net survival was generally highest in patients in Sweden and lowest in those in England. The survival deficit of English patients was particularly large compared to similar patients in the other countries among those diagnosed with advanced disease and/or who did not receive potentially curative surgery.

Conclusions: Stage-specific survival from colorectal cancer in England was lower than in Norway and Sweden. This survival deficit may be partly explained by the higher proportion, and lower survival, of patients who did not receive potentially curative surgery in England. The different proportions of missing data may somewhat affect the comparability of the results; however these remain informative.

[1]Oncology, Rabin Medical Center, Petach Tikva, Israel, [2]Surgery, Rabin Medical Center, Petach Tikva, Israel

Background: Staging of patients (pts) with pathological stage III colon cancer (CC) is currently suboptimal; many pts still recur despite an unremarkable preoperative staging. We previously reported that early postoperative PET-CT can alter the stage and management of up to 15% of pts with high risk stage III CC and later reported also encouraging preliminary results in a larger cohort of consecutive pts with stage III CC, in which staging and management were altered in 14.5%. The aim of the current study was to expand the previous one to a larger cohort and to evaluate the actual impact of early postoperative PET-CT on pts outcome.

Methods: A Retrospective study of all consecutive pts with stage III CC who were treated at our institution and underwent early postoperative PET-CT between 2007-2016. Demographic and clinicopathological data were retrieved. Statistical analyses were done using standard methods.

Results: 348 pts, 166 (47.7%) males, with a median age of 66 years (range, 29-92), were included. Pathological stage was IIIA, IIIB and IIIC in 21(6%), 254 (73%) and 73 (21%) pts, respectively. The median number of lymph nodes examined and of positive ones were 14 (range, 3-54) and 2 (range, 0-32), respectively. High FDG-uptake was noted in 95 (27.3%) pts, including 23 (6.6%) with clear postoperative changes and 18 (5.2%) with a false positive uptake, of whom 6 underwent invasive diagnostic procedures. PET-CT results modified the management of 52 pts (14.9%) who were found to have true positive findings: 44 (12.6%) with overt metastatic disease and 8 (2.3%) with a second primary tumor. At a median follow-up of 45.6 months, the estimated 5y disease-free survival for true stage III pts was 81.9% and the 6y overall survival of the entire cohort was 76.4%. Interestingly, of the 44 pts found to be metastatic, 12 (27.3%) underwent curative treatments and 8 (66.7%) of those remain free of disease, with a median follow-up of 64.7 months.

Conclusions: In this large cohort, early postoperative PET-CT changed the staging and management of 14.9% of pts with resected stage III CC, with encouraging outcome results. We are conducting a prospective trial to further evaluate this strategy.

489P Role of body composition in early stage colorectal cancer (CRC) outcomes

J. Hopkins[1], D. Bigam[1], D. Eurich[2], V. Baracos[3], M. Sawyer[4]

[1]Department of Surgery, University of Alberta, Edmonton, AB, Canada, [2]School of Public Health, University of Alberta, Edmonton, Canada, [3]Department of Oncology, Division of Palliative Care Medicine, Alberta, Canada, [4]Medical Oncology, Cross Cancer Institute, University of Alberta, Edmonton, AB, Canada

Background: CRC is the 3rd most common cancer worldwide. Novel prognostic factors are needed to allow practitioners to stratify and personalize treatment and surveillance options to patients (pts). The objective of this study was to determine associations between body composition and disease-specific outcomes in early stage CRC. We hypothesized that pts with sarcopenia or reduced muscle radiodensity (SMD) at time of surgery will have worse overall outcomes, specifically in their 5-year overall (OS) and disease free survival (DFS). Also, that pts with accelerated skeletal muscle loss at their 2-year surveillance computed tomography (CT) scan will have higher recurrence rates.

Methods: This is a retrospective cohort study of early stage (I-III) CRC from 2007-09. We excluded any pt without analyzable or preoperative CT scan or if a prior diagnosis of CRC. Routine CT imaging was used to measure skeletal muscle (SMA). Total body SMA was normalized for height (skeletal muscle index, SMI). An SMI <52.4 cm^2/m^2 and <38.5 cm^2/m^2 was used as a cutoff for sarcopenia in men and women, respectively. Mean muscle radiodensity in HU was obtained as a measure of myosteatosis.

Results: A total of 2049 pts were identified, of which 1455 had available, analyzable imaging. The cohort was 59% male. The median age was 67 yrs with over 50% older than 65. Most pts presented with stage II-III disease (39%, 50%, respectively). The prevalence of sarcopenia was 45.0% in females and 56.2% in males, with an average SMI of 40 and 51 cm^2/m^2, respectively. Average SMD was 31.5 HU for females and 33.2 HU for males. Pts with disease recurrence had a significantly lower SMI (49 vs. 42 cm^2/m^2, $p < 0.001$). Pts with recurrence also had lower HU (33.3 vs. 30.3 HU, $p = 0.001$). The median time to recurrence was 538 days and average length of follow up was 5 yrs. Data collection and analysis is currently ongoing. We anticipate that pts with disease recurrence within 5 yrs of diagnosis will have a significantly faster rate of muscle loss.

Conclusions: Our study demonstrates for the first-time body composition's ability to predict recurrence of a solid tumor after curative surgery. Pts with reduced overall SMI and SMD had increased risks of disease recurrence. These findings if validated may allow better stratification of treatment and surveillance of CRC pts.

Background: FOLFOX is the standard adjuvant chemotherapy for resected stage III colon cancer. MOSAIC trial was performed outside of Japan, and we conducted a phase II study (NORTH/HGCSG1003) to assess the efficacy and safety of FOLFOX as adjuvant chemotherapy for Japanese patients (pts) with resected stage III colon cancer (UMIN ID: 000004590). In 2017 ASCO-GI, Shichinohe, et al. reported that the 3-year disease-free survival rate (3y-DFS rate) as the primary endpoint was 75.2%. Recent analysis of pts with metastatic colorectal cancer has shown that primary tumor location correlates with different outcome. However, with regard to adjuvant chemotherapy for resected stage III colon cancer, there are few reports of treatment outcomes by primary tumor location.

Methods: This phase II study enrolled patients with resected stage III colon cancer. Patients received 12 cycles of FOLFOX4 or mFOLFOX6. We analyzed 264 patients registered in this phase II study. This study was analyzed by CTCAE v4.0 for adverse events (AEs) and Kaplan-Meier method for DFS and relapse-free survival (RFS). To compare with right-sided tumor (RT: Cecum to Transverse colon) and left-sided tumor (LT: Descending colon to Rectosigmoid colon), Fisher's exact test was used in terms of patient characteristics, AE, and Log-rank test was used in DFS and RFS.

Results: Patients with RT and LT were 93 and 171, respectively. The patient characteristics between RT and LT were generally balanced except for pathological stage (IIIA/IIIB/IIIC; 6.4/78.5/15.1% in RT, 18.1/71.9/10.0% in LT; $p = 0.019$), number of harvested lymph nodes (median; 23 in RT, 16 in LT; $p = 0.001$), and perforation (0% in RT, 4.1% in LT; $p = 0.054$). There were no significant differences in AEs ($\geq$Grade 3) and relative dose intensity between RT and LT. 3y DFS rate was 75.9% in RT and 73.8% in LT (HR 1.122, $p = 0.636$). 3y RFS rate was 77.6% in RT and 76.0% in LT (HR 1.193, $p = 0.490$).

Conclusions: There were no significant differences between RT and LT in the efficacy and safety of FOLFOX as adjuvant chemotherapy. This analysis suggested that FOLFOX might provide benefit for resected stage III patients regardless of primary tumor location.

491P Factors predicting adherence to a tailored-dose adjuvant treatment based on geriatric assessment in elderly people with colorectal cancer: A prospective study

M. Antonio[1], J. Saldaña[1], A. Carmona-Bayonas[2], R. Salazar[3], V. Navarro[4], C. Tebé[5], J.M. Borras[6]

[1]Medical Oncology, Institut Català d'Oncologia Hospital Duran i Reynals, L'Hospitalet de Llobregat, Barcelona, Spain, [2]Medical Oncology, Hospital Universitario Morales Meseguer, Murcia, Spain, [3]Medical Oncology, Institut Català d'Oncologia Hospital Duran i Reynals, Barcelona, Spain, [4]Translational Research Laboratory, Institut Català d'Oncologia Hospital Duran i Reynals, Barcelona, Spain, [5]Statisical Assessment Service, Institut d'Investigació Biomèdica de Bellvitge (IDIBELL), L'Hospitalet de Llobregat, Barcelona, Spain, [6]Department of Clinical Sciences, University of Barcelona, Barcelona, Spain

Background: Selecting elderly people with colorectal cancer (CRC) for adjuvant chemotherapy is challenging. Comprehensive geriatric assessment (CGA) can help by classifying them according to their frailty profile. The supposed benefit of chemotherapy is based on the rate of treatment adherence. This study evaluated tolerance and adherence to tailored-dose adjuvant therapy based on CGA in a cohort of older patients with high-risk stage II and stage III CRC.

Methods: Prospective study in 193 consecutive patients aged 75 or older. Based on CGA results, we classified patients as fit, medium-fit, or unfit, administering standard therapy, adjusted treatment and best supportive care, respectively. We recorded planned chemotherapy, toxicity, and completion of the treatment. A logistic multivariate analysis was carried out.

Results: Seventeen (15%) of the 141 candidates for chemotherapy (n = 86 fit and n = 55 medium-fit) refused treatment; associated factors included polypharmacy (odds ratio [OR] 5.34, 95% confidence interval [CI] 1.55, 18.40) and rectal location (OR 5.61, CI95%, 1.45, 21.49). Of the 105 patients receiving chemotherapy, 20 (27%) fit and 4 (13%) medium-fit patients experienced grade 3-4 toxicity (p = 0.11) without association to explanatory variables. About 55% of patients treated with chemotherapy received at least 80% of the planned dose (55% fit and 58% medium-fit patients; p = 0.7). Factors associated with completion of chemotherapy were the absence of toxicity (OR 7.67, CI95% 2.41, 24.43) and social support (OR 2.29, CI95% 0.08, 1.04).

Conclusions: CGA is useful for selecting elderly patients for adjuvant chemotherapy, adapting the dose to their frailty profile, and identifying adherence-related factors amenable to modification through CGA-based interventions.

University Hospital Reina Sofia, CIBERONC Instituto de Salud Carlos III, Cordoba, Spain

Background: UPTR remains controversial in the initial management of unresectable asymptomatic mCRC patients (pts), whereas right sidedness is a bad prognostic factor.

Methods: Retrospective pooled analysis of KRAS WT mCRC pts treated with 1st line EGFR inhibitors (EGFRI) + chemotherapy (CT) from two phase II randomised trials (MACRO-2 & PLANET). We analysed UPTR effect on overall survival (OS) and progression free survival (PFS) by tumour sidedness (right/left) and stage (I-III/IV) at diagnosis. All stage I-III pts underwent UPTR at diagnosis as standard procedure.

Results: 260 pts were included in the analysis (Table). In pts with stage IV at diagnosis, UPTR was associated with a better OS, although differences were only significant in right sided tumours (mOS (m): 20.9 vs 10.6; HR non-UPTR vs UPTR 2.1 (1.0, 4.3); P = 0.038). Conversely, left sided tumours had a significantly better OS vs right sided tumours regardless of UPTR: UPTR HR 0.4 (0.2, 0.8); P = 0.006; no UPTR HR 0.2 (0.1, 0.4); P < 0.0001. In pts with stage I-III at diagnosis (all UPTR), there were no differences in OS according to sidedness. After UPTR, OS was significantly higher in stage I-III tumours vs stage IV only in right sided tumours. Similar results were observed for PFS.

Conclusions: In mCRC *KRAS* WT pts treated in 1st line with EGFRI + CT, UPTR seemed to improve outcomes particularly in right sided tumours. Table: 492P Median (95%CI) OS and PFS

Background: The New EPOC study demonstrated a shorter progression-free survival (PFS) with the addition of cetuximab to chemotherapy for operable colorectal liver metastasis. The combination of a liver resection with EGFR inhibition is unique to this study. This analysis explores both surgical quality and the impact of volume of liver resected on outcome.

Methods: Data is presented for 263/271 patients (early study withdrawals excluded). Details of surgery were completed by the operating or lead surgeon in 19 UK specialist centres. The report of no residual tumour in the pathological specimen was queried in each case. Volume of liver resected was estimated and patients divided into tertiles (tertile 1: ≤20.5%, tertile 2 20.6-44.1%, tertile 3: 44.2-84.8%) to investigate association with PFS.

Results: Operations were performed on 233/263 patients (118 chemo alone CT, 115 chemo and cetuximab CTX) of which 205 (108 CT, 97 CTX) underwent resection. A further 18 had surgery that included ablation (6 CT, 12 CTX). 155 had major resections (87 CT, 68 CTX) and the median estimated volume of total liver volume resected was the same in both groups (CT 27.8% IQR 17.0-63.4, CTX 27.8% 17.4-63.4). In the CT group PFS was significantly associated with the volume of liver resected (tertile 1 median PFS not reached, tertile 2 28 months, tertile 3 18.7 months, p = 0.02). Those with a smaller resection volume (tertile 1, ≤20%) appeared to have a shorter PFS with cetuximab (median PFS for CT not reached, CTX 15.2 months, HR 2.15 95%CI 1.00-4.57 p = 0.06). By contrast those with a larger volume of liver resected (tertiles 2 & 3) had similar outcomes irrespective of the use of cetuximab (median PFS for CT 20.2 months, CTX 16.9 months, HR 1.06 95%CI 0.65-1.71 p = 0.83). When analysis was restricted to just those with a R0 resection the shorter PFS with cetuximab persisted (HR 1.68 95% CI 1.04-2.71 p = 0.035). Examination of the pathological specimen revealed no residual tumour in 22 patients (14 CT, 8 CTX) of whom 8 have disease progression (6 CT, 2 CTX).

Conclusions: These exploratory analyses suggest the technical aspects of surgery are similar between the treatment groups and that those patients having smaller volume resections may be disadvantaged by the addition of cetuximab.

Background: The no-touch isolation technique (NTIT) aims to reduce cancer cells flowing from the primary tumor site to liver and other organs by first ligation of blood vessels that feed the primary tumor. A previous randomized controlled trial (RCT) failed to prove its efficacy with statistical significance because of insufficient sample size and many patients being lost to follow-up. We conducted a phase III trial to confirm the superiority of NTIT in patients with cT3/T4 colon cancer.

Methods: Eligibility criteria included histologically proven colon cancer; tumor located in the cecum, ascending, transverse, descending, sigmoid or rectosigmoid colon; T3 or T4; N0-2 and M0; patients age 20-80 years. Patients were randomized preoperatively to either conventional technique (CoT) arm or NTIT arm. Patients with pathological stage III received adjuvant chemotherapy with capecitabine. The primary endpoint was disease-free survival (DFS), and planned sample size was 850 to detect 6% difference in 3-year DFS with one-sided alpha of 5% and power of 80%. Short-term clinical outcomes were compared between the arms. (UMIN-CTR: UMIN000004957).

Results: A total of 853 patients were randomized (CoT: 427, NTIT: 426) between January 2011 to November 2015. Conversion to CoT was needed for 5 (1.2%) patients in NTIT arm. Regarding surgical procedure, there were no differences in operative time (median 172 min: CoT, 178 min: NTIT, p=0.43), and in blood loss (median 69 ml: CoT, 77 ml: NTIT, $p = 0.92$). Postoperative complications and time to pass first flatus (median 2 days: CoT, 2 days: NTIT, $p = 0.64$) did not differ between the arms. There was no hospital death in both arms. Regarding radicality of surgery, there were no differences in D3 lymph node dissection rate (96.3%: CoT, 96.2%: NTIT) and pathological R0 resection rate (98.6%: CoT, 96.7%: NTIT).

Conclusions: Operative quality, postoperative course, radicality, morbidity and mortality are similar in two arms. The primary analysis planned for 2019 is pivotal to prove superiority of NTIT to CoT in term of DFS.

495P Prognostic impact of tumor deposits in colorectal cancer with lymph nodes metastasis

F. Liu, J. Zhao, L. Yang, Y. Xu

Department of Colorectal Surgery, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Tumor deposit (TD) was an important clinical characteristic associated with adverse prognosis in colorectal cancer (CRC), reported in 4.9%-41.8% CRC patients. The frequent alteration of TDs definition and category criteria in the recent 4 versions of TNM staging system make it controversial. There are several points that are not clear in the latest TNM classification regarding the coexistence of TDs and LNMs and the comparison of the prognosis value between TDs and LNMs.

Methods: Two large-scale cohorts were collected for optimally categorizing TDs with LNM in the tumor stage. The first cohort was from the SEER database involving 65,537 patients between 2011 and 2013. The second cohort was from Fudan University Shanghai Cancer Center (FUSCC) involving 2853 patients between 2010 and 2014.

Results: TDs were observed in 6.32% of patients in SEER cohort and 14.7% in FUSCC cohort. A significantly reduced overall survival was observed for TDs in LNM positive CRC patients (hazard ratio [HR], 1.65; 95% CI, 1.54 to 1.76) in SEER cohort. Prognosis became worse as the number of LNMs increasing, but there was no significant difference in different numbers of TDs in the SEER cohort and FUSCC cohort. Therefore, whether TDs exist or not was the main point. Further analysis combining TDs with LNM shows that there is no considerable difference in the impact on overall survival between N1 and N1c, between N1 with TDs (N1TD) and N2. The 3-year survival rate was 82.3%, 72.0%, 69.9%, 55.7%, 52.1%, 39.4% for N0, N1, N1c, N1TD, N2 and N2 with TDs (N2TD) respectively in SEER cohort. Similar results were observed in the FUSCC cohort.

Conclusions: TD should not be considered as LNM, because they have different survival impact based on our study results. TDs and LNMs could be integrated into a modified pathological N category including 6 subtypes (N0, N1c, N1, N1TD, N2 and N2TD). Among these subtypes, the prognosis of N1c and N1 was similar which means that the revision concerning TDs in the 7th TNM staging system is adequate to predict the pN1c patients' outcome. For the condition of TDs and LNMs coexistence, the prognosis of N1TD and N2 was similar and the prognosis of N2TD was the worst. Therefore, the modified pathological N category was reasonable solution to of apply TDs into the pN category of TNM staging system.

496P Predictive potential of tumour-stroma ratio on benefit from adjuvant bevacizumab in high-risk stage II and stage III colon cancer

S. Zunder[1], G. van Pelt[1], H. Gelderblom[2], R. Tollenaar[1], C. Mancao[3], W. Mesker[1]

[1]Surgery, Leiden University Medical Center (LUMC), Leiden, Netherlands, [2]Medical Oncology, Leiden University Medical Center (LUMC), Leiden, Netherlands, [3]Genentech, F. Hoffmann-La Roche AG, Basel, Switzerland

Background: The tumour-stroma ratio (TSR) has proven to be an independent prognostic factor in colon cancer.

We evaluated the predictive potential of TSR on disease free survival (DFS) and overall survival (OS) in patients with high-risk stage II and stage III colon cancer who received standard oxaliplatin-based chemotherapy with or without bevacizumab.

Methods: Haematoxylin and Eosin stained tumour slides of 1212 patients (42% of intention-to-treat(ITT)) enrolled in the AVANT trial were microscopically scored for TSR and categorized as stroma-low or stroma-high.

TSR scores were correlated to the primary endpoint DFS and secondary endpoint OS.

Results: Of 1212 tumour slides, 1163 could be scored for TSR. Patients with stroma-high tumours ($n = 339$) had a significant shorter DFS ($p < 0.001$) compared to patients with stroma-low tumours ($n = 824$). In the AVANT trial addition of bevacizumab did not prolong DFS and data suggested a potential detrimental effect on OS.

In our study, the bevacizumab – FOLFOX-4 arm had a significantly shorter DFS compared to FOLFOX-4 in stroma-low tumours, with a hazard ratio (HR) of 1.94 (95% CI 1.24 – 3.04; $p = 0.004$). However, in stroma-high tumours the effect was reversed and showed a trend for better DFS when adding bevacizumab to FOLFOX-4 versus FOLFOX-4 (HR 0.61 (95% CI 0.35 – 1.07; $p = 0.08$)). For bevacizumab- XELOX versus FOLFOX-4, this was not seen (stroma-low HR 1.07 (95% CI 0.64-1.77; $p = 0.80$); stroma-high HR 0.78 (95% CI 0.47-1.30; $p = 0.35$)). For OS the same pattern was observed for bevacizumab – FOLFOX-4 versus FOLFOX-4 with a HR of 2.53 (95% CI 1.36-4.71; $p = 0.003$) for stroma-low and HR 0.50 (95% CI 0.22-1.14; $p = 0.10$) for stroma-high tumours. For bevacizumab – XELOX versus FOLFOX-4, this was 1.13 (95% CI 0.55-2.31; $p = 0.74$) for stroma-low tumours and HR 0.74 (95% CI 0.37-1.51; $p = 0.41$) for stroma-high tumours.

Conclusions: Addition of bevacizumab to intravenous oxaliplatin-based chemotherapy suggests, in accordance with AVANT ITT analysis, a pronounced shorter DFS and OS in low stromal tumours. In contrast, in high stromal tumours a (potential) beneficial trend is observed when adding bevacizumab to intravenous oxaliplatin-based chemotherapy.

497P Tumor-stroma interactions and response to targeted agents in preclinical models of colorectal cancer (CRC)

C. Bazzichetto, F. Conciatori, I. Falcone, F. Cognetti, L. Ciuffreda, M. Milella
Medical Oncology 1, Regina Elena National Cancer Institute, Rome, Italy

Background: Recent evidence suggests that genetically "normal" tumor microenvironment may react to pathway inhibitors by upregulating signaling pathways and modulating the sensitivity of cancer cells to targeted agents. The aim of this study was to uncover the mechanisms by which stromal cells modulate the sensitivity of tumor cells in response to signaling inhibitors.

Methods: We monitored the functional effects of MEK and PI3K/mTOR inhibitors (trametinib/gedatolisib) on isogenic CRC cell lines (HCT116 and HCT116 PTEN$^{-/-}$) in the presence or absence of stromal fibroblasts or fibroblast/endothelial cell conditioned medium (CM); moreover, we evaluated pathway activation under different culture conditions and analysed the cytokine/chemokine profile.

Results: Trametinib/gedatolisib combinations were additive in HCT116 (combination index, CI = 1) and strongly synergistic in HCT116 PTEN$^{-/-}$ (CI = 0.25). Under conditions of direct cell-cell contact, co-culture with HCT116 PTEN$^{-/-}$ rendered fibroblasts hypersensitive to combined trametinib/gedatolisib combinations, while co-culture with HCT116 actually protected the stromal component. CM from different types of stromal cells (fibroblasts: HFF, HF, BJ; endothelial cells: EA.hy926) differentially affected the response of HCT116 (but not HCT116 PTEN$^{-/-}$) to signalling inhibitors: in particular, HFF- and EA.hy926-CM rendered HCT116 hypersensitive to PI3K/mTOR blockade by single-agent gedatolisib moreover, EA.hy926 rendered HCT116 PTEN$^{-/-}$ more sensitive to trametinib. Pathway activation analysis showed more prominent downregulation of AKT phosphorylation in response to PI3K/mTOR inhibition in the presence of fibroblast-conditioned medium. Angiogenesis microarrays demonstrated a diversified profile of cytokine/chemokine production in stromal cells from different sources, particularly in terms of IL-6, IL-8 and MCP-1 production.

Conclusions: Stromal cells differentially affected response of CRC to agents targeting the MAPK and PI3K pathways; such effects varied depending on the genetic background of the tumor cell (PTEN-competent or PTEN-loss) and on the modality of tumor stroma interaction (direct cell contact or soluble factors).

498P Molecular profiling of colorectal tumors stratified by the histological tumor-stroma ratio

T. Sandberg[1], J. Oosting[2], G. van Pelt[1], H. Putter[3], J.T. van Wezel[2], R. Tollenaar[1], J. Morreau[2], W. Mesker[1]
[1]Surgery, Leiden University Medical Center (LUMC), Leiden, Netherlands, [2]Pathology, Leiden University Medical Center (LUMC), Leiden, Netherlands, [3]Medical Statistics and bioinformatics, Leiden University Medical Center (LUMC), Leiden, Netherlands

Background: The tumor microenvironment or tumor stroma is a dominant determinant of cancer cell behaviour and disease progression. The presence of high tumor stroma content is likely associated with cancer cells acquiring pro-metastatic capacities. The tumor-stroma ratio (TSR) is a robust prognostic tool that is scored on haematoxylin and eosin (H&E) paraffin sections at the invasive margin of the tumor. The importance of the tumor stroma was also emphasized in the colorectal cancer consensus molecular subtypes (CMS). The CMS classification described four CRC subtypes, of which the poor-prognosis CMS4 subtype is characterized by high stromal infiltration and mesenchymal gene expression. However, the biological mechanism of the tumor stroma is not well understood. We therefore aim to investigate the overall transcriptomic profiles and activated pathways of tumors classified by the TSR method using gene expression data.

Methods: Seventy-one patients with stage I-III colorectal cancer were included in the study with available gene expression data and H&E sections. Firstly, we scored the TSR on H&E sections and performed survival analysis. Secondly, we quantified the amount of stromal cells present in the tumor bulk of the gene expression analysis.Thirdly, we investigated the biological pathways differently activated between the two groups using online currated gene sets of the MSigDB. Finally, we compared the association between the TSR classification and the CMS classification assessed based on gene expression data.

Results: The TSR was an excellent prognostic marker in a multivariable analysis [OS p = 0,0001, HR = 4,59 (1,96 – 10,75)]. Tumors stratified as stroma-high based on histological TSR had significantly more stromal cells compared to stroma-low tumors (p = 2,58*10-5). Pathways related to epithelial-mesenchymal-transition, angiogenesis, extracellular matrix and integrin were significantly different in the two tumor-stroma groups. We found that the TSR and the CMS classification were associated (χ^2 test = 7,71; p = 0,005).

Conclusions: At the moment, we are validating our findings in a second cohort and further investigating genes present the relevant pathways. These results will be presented on the day of the symposium.

499P The characteristics and prognostic factors in colorectal cancer containing signet ring cell

X.Q. Kong, X.Q. Zhang, J.L. Li, Y.P. Dong, J.X. Wu
Department of Radiation Oncology, Tumor Hospital of Fujian Province, Fuzhou, China

Background: Colorectal signet ring cell carcinoma (SRCC) is a rare entity with poor prognosis. The aim of the study was to investigate the clinicopathological characteristics and identify the prognostic factors in colorectal cancer containing signet ring cell (CRC-SRC).

Methods: We retrospectively analyzed 98 CRC-SRC patients confirmed by pathology from February 1987 to December 2015 in our institute. Age, gender, clinical characteristics, laboratory findings, pathologic grade and TNM staging were studied to identify prognostic factors associated with the overall survival (OS) and progression-free survival (PFS). Statistical analysis was conducted by SPSS 20.0.

Results: Of the 98 patients in this study, 60 rectal patients accounted for 61.2%. Ninety-five (96.9%) patients were diagnosed as stage III or IV tumors, 76 (77.5%) patients had lymph node metastasis, and 27 (27.5%) patients had distant metastasis. The median survival time was 22.1 months (range, 1-165 months). The 1-, 3-, and 5-year OS rates of the patients were 74.5% (95%CI: 65.9%-83.1%), 44.8% (95%CI: 34.8%-54.8%), and 31.2% (95%CI: 21.4%-41.0%), respectively. Preoperative carcinoembryonic antigen (CEA), N staging, M staging, local relapse were associated with OS (χ^2=4.163, 8.320, 11.199, 15.436, P < 0.05), while tumor nodules, postoperative chemotherapy, and postoperative radiotherapy had significant influence on PFS (χ^2=10.039, 11.733, 7.116, P < 0.05). On multivariate analyses, preoperative CEA (HR = 2.514, 95%CI: 1.108-5.704) and distant metastases (HR = 2.127, 95%CI: 0.999-4.525) were independent predictors for survival. Based on the point of 30% and 80%, which was calculated by X-tile, we found that the proportion of signet ring cells in colorectal cancer had no significant influence on OS and PFS.

Conclusions: Long-term follow-up of colorectal SRCC showed that it was a rare subtype of colorectal cancer with poor outcomes. Furthermore, the dismal prognosis was related to the presence of signet ring cells, rather than the proportion of signet ring cells. Preoperative CEA and distant metastases were hopeful to predict prognosis of CRC-SRC independently.

500P Effect of lateral lymph node dissection for lower rectal cancer: An ad hoc analysis of the ACTS-RC randomized clinical trial

E. Oki[1], M. Shimokawa[2], A. Murata[3], T. Takahashi[4], K. Maeda[5], T. Kusumoto[6], Y. Munemoto[7], K. Ando[1], R. Nakanishi[1], M. Sugiyama[1], Y. Nakashima[1], H. Saeki[1], S. Saji[8], Y. Maehara[1]
[1]Surgery and Science, Kyushu University Hospital, Fukuoka, Japan, [2]Clinical Research Institute, National Kyushu Cancer Center, Fukuoka, Japan, [3]Department of Gastroenterological Surgery, Hirosaki University Graduate School of Medicine, Aomori, Japan, [4]Department of Surgical Oncology, Gifu University Graduate School of Medicine, Gifu, Japan, [5]Department of Surgical Oncology, Osaka City University, Osaka, Japan, [6]Department of Surgery, Gastrointestinal Center, National Hospital Organization Kyushu Medical Center, Fukuoka, Japan, [7]Department of Surgery, Fukui-ken Saiseikai Hospital, Fukui, Japan, [8]Japanese Foundation for Multidisciplinary Treatment of Cancer, Tokyo, Japan

Background: The phase III ACTS-RC (Adjuvant Chemotherapy for Stage II/III Rectal Cancer) trial showed benefits in relapse-free survival (RFS) in rectal cancer with tegafur, 5-chloro-2,4-dihydropyrimidine, and potassium oxonate (S-1) adjuvant chemotherapy in comparison with uracil and tegafur (UFT) therapy. Lateral lymph node dissection (LLND) has been one of the standard treatments for lower rectal cancer patients in Japan. However, it has been debated whether LLND has survival benefits. The aim of this study was to evaluate the impact of lateral LLND on the outcomes in the ACTS-RC randomized clinical trial.

Methods: In a total of 445 lower rectal cancer cases (Stage I/II/IIIA/IIIB/IIIC: 1/130/10/59/165/80) from 959 rectal cancer cases in the ACTS-RC trial, 215 underwent LLND and 230 did not. UFT and S-1 therapy was prescribed for 110 and 105 patients with LLND, respectively, and for 111 and 119 patients without LLND, respectively.

Results: There were no significant differences in patient background characteristics, except for age and pathological T stage, between the LLND and without-LLND groups. Younger patients were often selected as candidates for LLND, and LLND had no impact on RFS or overall survival (OS) in all patients with lower rectal cancer (hazard ratio [HR]=0.941, 95% confidence interval [CI]: 0.696–1.271). In Stage IIIB/C patients, LLND improved the RFS (HR = 0.762, 95% CI: 0.533–1.091). This trend was the same in both the S-1 (HR = 0.766, 95% CI: 0.449–1.306) and UFT arms (HR = 0.790, 95% CI: 0.487–1.283), despite the better RFS in the S-1 arm than in the UFT arm. LLND did not show a major impact on OS in Stage IIIB/C patients.

Conclusions: This exploratory analysis showed that LLND improves RFS in patients receiving either UFT or S-1 therapy, although the results were not significant. LLND has an additional impact on improving RFS of patients with lower rectal cancer undergoing adjuvant chemotherapy.

502P Effects of mesorectal fascia (MRF) status for locally advanced rectal cancer: Results of a multicenter, randomized, controlled, phase II trial (FDRT-002)

J. Zhu, C. Li

Department of Radiation Oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: To identity the effects of high-dose intensity modulated radiation therapy(IMRT) for locally advanced rectal cancer according to MRF status.

Methods: Eligible patients from multicenter who had histologically confirmed locally advanced rectal adenocarcinoma (cT3-T4 and/or cN+) located within 12 cm from the anal verge, were randomly assigned (1:1) to either the low intensity group (50 Gy/25Fxs concurrent with oxaliplatin 50 mg/m2 weekly and capecitabine 625 mg/m2 bid d1-5 weekly) or the high intensity group (50 Gy/25Fxs and a concomitant boost of 5 Gy to the primary tumor, followed by one cycle of XELOX two weeks after the completion of chemoradiotherapy). Surgery was scheduled eight weeks after the completion of CRT. All patients were recommended to receive postoperative XELOX chemotherapy regardless of pathological stage. The primary endpoint was pathological complete response rate (pCR). Secondary endpoints included LC, OS, DFS and toxicities.

Results: From February 2010 to December 2011, 120 locally advanced rectal cancer patients (60 in high intensity group and 60 in low intensity group) were involved. The data were analyzed by MRF status (74 in the MRF- group and 46 in the MRF+ group). Patients in the MRF- group had better pCR (21.6% vs. 13.0%, p = 0.238), LC (p = 0.012), DFS (p = 0.002) and OS (p = 0.007) than those in MRF+ group. While stratified with MRF status, high intensity group showed a better tumor response, especially in positive MRF group. But no significant interaction between MRF and intensity was found in long-term prognosis.

Conclusions: MRF is a strong prognostic factor and a predictor of tumor regression. High-dose treatment may be beneficial to MRF+ patients via improving tumor response.

503P Planned organ preservation for selected T2, T3 rectal cancer: French experience using chemo radiotherapy and contact X ray boost

J-P. Gérard[1], N. Barbet[2], K. Benezery Sanna[3], R. Coquard[4], Y. Chateau[5], J. Gal[5], J. Doyen[3]

[1]Radiothérapie, Centre Anticancer Antoine Lacassagne, Nice, France, [2]Radiothérapie, Centre de Radiothérapie, Macon, France, [3]Radiothérapie, Centre Antoine Lacassagne, Nice, France, [4]Radiothérapie, Centre Bayard, Lyon Villeurbanne, France, [5]Research Department, Centre Antoine Lacassagne, Nice, France

Background: Combining CRT (50 Gy+ capecitabine) and CXB boost provides high probability of organ preservation. We report the experience of three French institutions using CXB.

Methods: Selection used digital rectal examination, colonoscopy, MRI (and/or Endorectal-ultrasound, 18FDG Pet-CT). Inclusion was: adenocarcinoma (distal, middle rectum), T2 T3a-b, tumor diameter ≤ 4cm, N0, M0. Treatment: CXB (80-110 Gy/3-4 fr) followed by CRT (CAP 50). Tumor response assessed on week 14 after start of treatment using DRE, rigid rectoscopy and MRI. Clinical complete response (cCR) was defined as no visible tumor, supple rectal wall and TRG 1-2 MRI. In case of cCR a close surveillance or local excision was proposed.

Results: Between 2002 -2016, 84 patients were treated (Lyonvilleurbanne: 16, Mâcon: 11, Nice: 57). Median age: 75 years, Male: 59, Female: 25. T2:52; T3:32. Operable patients: 69 (83%). Median follow-up time was 53 months. A cCR was achieved in 94% of cases. Local excision was performed in 16 patients (ypT0/pT1: 14). At 4 years, the cancer specific survival was 82% [CI:96-70] and the local relapse rate 12% [CI: 2-22]. 7 local relapses were seen with 2 after 5 years with one isolated perirectal lymph node relapse at 7 years. Acute grade 3 toxicity (diarrhea, proctitis) was seen in 9 patients mainly related to CRT and did not require treatment modification. Main late toxicity (> 6 months after treatment) was rectal bleeding (due to radiation telangiectasia) which required plasma argon coagulation in 5 patients. No TME surgery was performed and organ preservation was achieved in all cases (75 patients with local control). Bowel function was good (LARS score<20) in 85% of patients with no diverting stoma for poor function.

Conclusions: After adequate selection and treatment, rectal cancer T2T3a-b N0 ≤4cm can achieve a high rate of cCR (≥85%) with organ preservation, good bowel function and low rate of local relapse (< 15%) with low toxicity. Prolonged follow-up is mandatory. As rectal adenocarcinoma is radioresistant tumor, the treatment must combine CRT and CXB boost. Like anal squamous cell cancer, planned organ preservation can be proposed to operable patients. The ongoing European OPERA trial aims at bringing evidence to this option.

504P Comparison between magnetic resonance imaging (MRI) and pathology in the assessment of tumour regression grade (TRG) in rectal cancer (RC)

F. Sclafani[1], G. Brown[2], D. Cunningham[1], A. Wotherspoon[3], L. Sena Teixeira Mendes[3], J. Evans[2], C. Peckitt[4], R. Begum[1], D. Tait[1], J. Capdevila[5], B. Glimelius[6], S. Roselló[7], J. Thomas[1], J. Oates[1], I. Chau[1]

[1]Medicine, The Royal Marsden NHS Foundation Trust, Sutton, UK, [2]Radiology, The Royal Marsden NHS Foundation Trust, Sutton, UK, [3]Histopathology, The Royal Marsden NHS Foundation Trust, Sutton, UK, [4]Clinical Research & Development, The Royal Marsden NHS Foundation Trust, Sutton, UK, [5]Gastrointestinal and Endocrine Tumor Unit, Vall d'Hebron University Hospital, Barcelona, Spain, [6]Immunology, Genetics and Pathology, University Hospital, Uppsala, Sweden, [7]Medical Oncology, Biomedical Research institute INCLIVA - University of Valencia, Valencia, Spain

Background: Based on the ability to distinguish between areas of residual cancer and treatment induced fibrosis after neoadjuvant treatment, a 5-tier MRI-based (mr)TRG system that follows the principles of the pathological (p)TRG system previously proposed by Dworak has been developed for RC. However, limited data exist regarding the correlation between mrTRG and pTRG, and the prognostic value of mrTRG in patients who are assessable for pTRG is unclear.

Methods: mrTRG, as assessed by a radiologist according to Patel et al (J Clin Oncol 2011), and pTRG, as assessed by a pathologist according to Dworak et al (Int J Colorect Dis 1997), were compared in MRI-defined, high-risk, locally-advanced RC patients from two phase II trials (EXPERT and EXPERT-C). All patients had received an intensified neoadjuvant treatment with induction chemotherapy followed by chemoradiotherapy. The agreement between radiologist and pathologist was assessed with the weighted κ test while the Kaplan-Meier method was used to estimate survival outcomes.

Results: 191 patients who had undergone neoadjuvant treatment and surgery with a curative intent were included. Median time from completion of neoadjuvant treatment to pre-operative MRI and surgery was 4.1 weeks (interquartile range [IQR]: 3.7-4.7) and 6.6 weeks (IQR: 5.9-7.6), respectively. Fair agreement was found between mrTRG and pTRG when regression was classified according to standard 5-tier systems ($\kappa = 0.24$) or modified 3-tier systems ($\kappa = 0.25$). After a median follow-up of 65.5 months (95% CI: 65.1-66.2), survival outcomes of patients with intermediate pathological regression (pTRG 2) were numerically better if good/complete regression was also observed on imaging (mrTRG 1-2) compared to poor regression (mrTRG 3-5) (5-year recurrence-free survival 76.9% versus 65.9%, p = 0.18; 5-year overall survival 80.6% versus 68.8%, p = 0.22).

Conclusions: Only fair agreement was found between mrTRG and pTRG which suggests that these parameters may represent biologically distinct phenomena. Assessing tumour regression on pre-operative MRI may provide complementary prognostic information to pTRG and help to refine stratification of RC patients after surgery.

Claude Huriez, Lille, France, [8]Medical Oncology, Polyclinique de Gentilly, Nancy, France, [9]Digestive Oncology, Hôpital Européen Georges-Pompidou, Paris, France, [10]Gastroenterolgy, CH Pasteur, Colmar, France, [11]Gastroenterology and Digestive Oncology, CH Orleans, Orleans, France, [12]Department of Oncology, CHU Charles Nicolle, Rouen, France, [13]Digestive Oncology, Clinique Armoricaine de Radiologie, St. Brieuc, France, [14]Medical Oncology, Clinique Victor Hugo, Le Mans, France, [15]Digestive Oncology, CH General Niort, Niort, France, [16]Gastroenterology, CHU Le Bocage, FFCD, Burgundy University, INSERM U866, Dijon, France, [17]Department of Gastroenterology and Digestive Oncology, Hôpital Européen Georges Pompidou, Paris, France

Background: Optimal therapeutic strategy in patients (pts) with RCSM remains discussed and many front-line options can be discussed to best treat primary tumor and metastatic disease: surgery (S), radiotherapy (RT), chemoradiotherapy (CRT) or chemotherapy (CT). The FFCD 1102 trial evaluated the efficacy of upfront FOLFIRINOX in this setting.

Methods: Chemotherapy-naïve pts with RCSM received FOLFIRINOX: oxaliplatin 85 mg/m^2 d1 + irinotecan 180 mg/m^2 D1 + leucovorin 400 mg/m^2 d1 followed by 5FU 400 mg/m^2 bolus d1 and 2,400 mg/m^2 46h continuous infusion biweekly; 8 cycles were mandatory. CT-scan and MRI at baseline, 2 and 4 months (m) were centrally reviewed. The objective responses were assessed on CT-scan for metastases (RECIST criteria) and MRI for rectal tumor (volume decrease $\geq$ 70%). The primary endpoint was disease control rate at 4 m (4m DC). With a Simon 2-stage design, a targeted (H1) 4m DC $>$ 75% was defined (unilateral alpha of 5% and statistical power of 90%).

Results: 65 pts were enrolled (07/2012 to 02/2015): male 78%; median age 61 years; PS 0-1 99%; liver metastases 92%; ^{3}2 metastatic sites 63%. All pts received at least 1 cycle of CT, and 85% the 8 planned cycles. The 4m DC was 94% (95% CI, 86.3-97.8). Percentages of patients with local symptoms (rectal bleeding, rectal syndrome, sub-occlusion) were 72%, 16% and 10% at baseline, 2 and 4 m, respectively. For evaluable pts at 4 m, response rates of metastases and primary tumor were 86% (55/64) and 62.5% (30/48). Median follow-up was 35.0 m (95% CI, 31.3-43.7). After 8 cycles of FOLFIRINOX, therapeutic strategy was investigators' choice: 60 pts (92%) received CT, 38 (58%) had a RT or CRT, 32 (49%) a rectal tumor resection (RS), and 22 (34%) a surgery and/or ablation of their metastases (MS). On ITT, median PFS and OS were 10.9 m (95% CI, 8.8-12.9) and 33.4 m (95% CI, 22.6-38.2), respectively. OS were 17.6 m (95% CI, 11.8-26.4) in 28 pts (43%) who had no surgery, 38.8 m (95% CI, 13.6-44.6) in 15 pts (23%) who had RS only, and 42.1 m [33.45-NA] in 22 pts who had MS.

Conclusions: Front-line FOLFIRINOX allows a good local and distant control of RCSM, and leaves the opportunity to decide best therapeutic strategy according to the response obtained after the induction step.

506P Neoadjuvant treatment with mFOLFOXIRI alone versus chemoradiotherapy in locally advanced rectal cancer: A propensity score analysis from two prospective trials

J. Zhang[1], Y. Cai[1], H. Hu[1], D. Chen[1], J. Xiao[1], W. Wang[1], P. Lan[2], M. Huang[2], L. Wang[2], X. Wu[2], L. Kang[2], J. Wang[2], Y. Deng[1]

[1]Medical Oncology, The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China, [2]Surgical Oncology, The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background: Neoadjuvant chemoradiotherapy (CRT) is the standard of treatment for locally advanced rectal cancer, but it delays administration of systemic chemotherapy, leading to high incidence of distant metastases. To enhance systemic chemotherapy and avoid the damage of radiation, neoadjuvant chemotherapy regimens were under investigation. Here, we aimed to compare the efficacy of preoperative chemotherapy with mFOLFOXIRI alone versus chemoradiotherapy in locally advanced rectal cancer.

Methods: Prospectively maintained databases of patients from two clinical trials (NCT01211210 and NCT02217020) underwent preoperative treatment for locally advanced rectal cancer in a single center were included. Those had received standard CRT or mFOLFOXIRI chemotherapy alone preoperatively were selected for this study. All patients had undergone total mesorectal excision. A comparative analysis was performed after the implementation of propensity score matching on the 2 main cohorts (mFOLFOXIRI and CRT).

Results: A total of 142 patients were included in the study, with median age of 51 years old. After propensity score matching, 71 patients were comparable in the two groups. Comparable pathologic complete response (pCR) rate (15.5% vs. 12.7%, P = 0.63) and tumor downstaging rate (42.3% vs. 36.6%, P = 0.49) were observed in the mFOLFOXIRI group and CRT group, respectively. The anal preservation rate was similar between the two groups (87.3% vs. 88.7%, p = 0.79). But lower incidence of anastomotic fistula (7.0% vs. 19.7%, P = 0.026) was shown in mFOLFOXIRI alone group than that of CRT group. And radiation-related dermatitis or proctitis was occurred in 41.7% of patients in the CRT group.

Conclusions: Preoperative mFOLFOXIRI alone showed similar early efficacy in terms of pCR rate and tumor downstaging rate when comparing with CRT, and led to less toxicity and fewer postoperative complications. But this finding requires further analysis from long-term survival data. The phase III study comparing FOLFOXIRI with CRT is ongoing.

Clinical trial identification: This study included two prospective clinical trials NCT01211210 (FOWARC study) and NCT02217020 (FORTUNE study).

Background: The multicenter phase II FACT trial demonstrated that modified FOLFOX6 (mFOLFOX6) was efficacious treatment for stage II/III rectal cancer patients with a T3/T4 tumor (Koike J, et al. Cancer Chemother Pharmacol 2017). We now reported the disease-free survival (DFS) and overall suravival (OS) after a median follow-up of more than 3 years.

Methods: Patients received four 2-week cycles of mFOLFOX6 therapy (oxaliplatin at 85 mg/m^2 + l-leucovorin at 200 mg/m^2 + fluorouracil as a 400 mg/m^2 bolus followed by infusion of 2,400 mg/m^2 over 46 hours, all on Day 1). They were evaluated by

computed tomography after completion of the fourth cycle. If there was no disease progression, two additional cycles were administered and then surgery was performed. Adjuvant chemotherapy was generally administered for 6 months using various regimens at the discretion of the physician.

Results: At a median follow-up of 42.8 months, median DFS from registration of clinical trials was 42.2 months, and median DFS from surgery was 38.9 months. Median survival time (MST) from registration of clinical trials was 42.8 months, and OS from surgery was 38.9 months. The safety profile was almost similar to previous analysis results.

Conclusions: Neoadjuvant chemotherapy using mFOLFOX6 for stage II/III rectal cancer patients with a T3/T4 tumor was well tolerated, as previously reported. In this trial, neoadjuvant mFOLFOX6 showed improved median DFS and MST.

CIBERONC Instituto de Salud Carlos III, Cordoba, Spain

Background: Combined modality treatment with preoperative radiation therapy (RT) + capecitabine is a standard of care for locally advanced rectal adenocarcinoma. However, new strategies to improve outcomes are necessary. We previously reported neither differences in pathologic complete response (primary objective) nor in safety results with preoperative RT + capecitabine with or without Bev. We present now the Disease-free survival (DFS), distant relapse free survival (RFS) and Overall Survival (OS) data at 3 and 5 years.

Methods: Patients (pts) were randomized in a 1:1 ratio to 5 weeks (w) of RT 45 Gy with concurrent capecitabine 825 mg/m2 bid x 5 d/w with Bevacizumab (Bev) 5 mg/kg q2w (3 doses) (arm A) or without Bev (arm B). Adjuvant systemic chemotherapy administration was upon investigatoŕs criteria.

Results: Ninety pts were included (44 in arm A and 46 in arm B). Preoperative treatment compliance was similar in both arms. Seventy-five pts received adjuvant systemic chemotherapy: 34 (77.3%) in arm A and 41 (89.1%) in arm B ($p = 0.1313$). One pt (arm B) developed local relapse. Eleven pts in arm A and 10 in arm B developed distant metastasis. With a median follow-up of 63.5 and 63.5 months for arms A and B, respectively, median DFS, median RFS and median OS have not been reached for both arms. DFS at 3 y and 5 y was 75.0% and 68.2% (arm A) vs 71.7% and 69.6% (arm B), respectively (5-y DFS, $p = 0.9820$). Distant RFS at 3 y and 5 y was 81.0% and 76.2% (arm A) vs 80.4% and 78.3% (arm B), respectively (5y-distant RFS, $p = 0.6923$). OS was 88.6% and 81.0% (arm A) vs 95.7% and 87.0% (arm B) at 3 and 5y, respectively (5-y OS, $p = 0.3350$). Five pts had a second malignancy (1 in arm A, 4 in arm B), without significant differences between arms.

Conclusions: In our study, the addition of bevacizumab to capecitabine and radiotherapy in the neoadjuvant setting for locally advanced rectal cancer does not confer benefits in DFS, RFS or OS.

509P Immunological features of resected tumor after neoadjuvant chemotherapy (NAC) and chemoradiotherapy (CRT) become the superior prediction markers for recurrence in rectal cancer

K. Imaizumi[1], T. Suzuki[2], M. Shimomura[2], Y. Tsukada[1], T. Sasaki[1], Y. Nishizawa[1], M. Kojima[3], M. Ito[1], T. Nakatsura[2]

[1]Colorectal Surgery, National Cancer Center Hospital East, Kashiwa, Japan, [2]Cancer Immunotherapy, Exploratory Oncology Research & Clinical Trial Center, National Cancer Center Hospital East, Kashiwa, Japan, [3]Pathology, National Cancer Center Hospital East, Kashiwa, Japan

Background: Although CRT is the standard neoadjuvant therapy for local advanced rectal cancer (RC), benefits of NAC have also been reported recently. In this study, we investigate whether the tumor microenvironment is related to local therapeutic effects and recurrence free survival (RFS) after neoadjuvant therapy, and explore the role of the anti-tumor immune response in cancer treatment.

Methods: 200 RC patients were enrolled and categorized into three groups according to pretreatment: CRT (n = 48, 5-Fluorouracil or Capecitabine + Radiation), NAC (n = 51, FOLFOX), Surgery alone (n = 101). The infiltration and status of immune cells were assessed by multiplex fluorescence immunohistochemically analysis.

Results: The growth of residual tumor cells after treatment was evaluated using Ki67 expression. Compared with the surgery group, CRT, but not NAC, significantly decreased the percentage of Ki67high cells in cytokeratin positive cells. However, the percentage of Ki67high tumor cells is comparable between all tumor regression grade (TRG) groups. Assessing the immunological features of tumor tissues, we found that the infiltration of T cells into tumors is significantly higher in TRG 1 patients than in patients with TRG 2, 3, and those treated with surgery alone. The percentage of tumor infiltration in Ki67high population of CD4 and CD8 T cells is more prominent, suggesting that aggressive infiltration of T cells might be involved in the treatment effect of neoadjuvant therapies. Notably, in the NAC group, patients with high accumulation of Ki67high CD8 T cells in tumor and stroma tissue experienced long term RFS, compared with patients with low accumulation of Ki67high CD8 T cells. On the other hand, after neoadjuvant therapy with CRT, patients with high accumulation of both CD8 and Ki67high CD4 T cells in tumor achieved long term RFS.

Conclusions: Our results suggested that CRT and NAC had different effects on the tumor microenvironment. The densities of Ki67high CD8 T cells in tumors could be a strong inhibitor of recurrence for RC after NAC. In the case of CRT, the densities of CD8 T cells and Ki67high CD4 T cells in tumors could inhibit recurrence.

510P The ADC value of post-RT might predict TRG after neoadjuvant radiotherapy for local advanced rectal cancer

W. Junxin, L. Jinluan, D. Kaixin

Department of Radiation Oncology, Fujian Cancer Hospital, Fuzhou, China

Background: This study evaluates the ADC value of post-RT associated with Tumor regression grade (TRG) after neoadjuvant radiotherapy for locally advanced rectal cancer.

Methods: We retrospectively analyzed 88 patients with locally advanced rectal cancer between April 2010 to September 2015. Forty-four patients underwent neoadjuvant short-course radiotherapy, and the other 44 patients underwent neoadjuvant long-course chemo-radiotherapy. The ADC value of post-RT were measured by Diffusion-weighted MRI technology. The slides of surgical specimens were reviewed and classified according to Mandard TRG. We compared patients with good response (Mandard TRG1 + 2) and patients with bad response (Mandard TRG3 + 4+5). The relationship between ADC value of post-RT and TRG was analysised.

Results: In univariate analysis, age ($P = 0.006$), adjuvant chemotherapy ($P = 0.023$), pathological type ($P = 0.024$), differentiation degree ($P = 0.001$), distance from tumor to the anal margin ($P = 0.031$) and TRG ($P = 0.007$) were significantly associated with overall survival(OS). Multivariate analysis showed that TRG ($P = 0.034$) were independently prognostic of OS. There was no significant difference in OS between the long-course chemo-radiotherapy group and short-course radiotherapy group ($P = 0.261$). The 5-year OS between TRG1 + 2 and TRG3 + 4+5 was significant (90.9% vs 67.4%, $P = 0.004$). Neoadjuvant radiotherapy ($P = 0.000$), pT ($P = 0.010$), gross type ($P = 0.020$) and the ADC value of post-RT ($P = 0.002$) were significantly associated with TRG. The best critical point of ADC value of post-RT was $1.71 \times 10^{-3}mm^2/s$ by using ROC curve in predicting TRG1 + 2. The patients with low CEA level before radiotherapy had higher ADC value of post-RT ($ADC \geq 1.71 \times 10^{-3}mm^2/s$), and the difference was statistically significant ($P = 0.024$).

Conclusions: There was no significant difference in OS between long-course chemo-radiotherapy and short-course radiotherapy group. TRG can predict the efficacy of neoadjuvant long-course or short-course radiotherapy in patients with locally advanced rectal cancer. The ADC value of post-RT might predict TRG after neoadjuvant radiotherapy for patients with locally advanced rectal cancer.

511P Polyethylene glycol embolics loaded with irinotecan for chemoembolization of refractory liver metastases from colorectal cancer

G. Fiorentini[1], D. Sarti[1], R. Carandina[2], M. Nardella[3], L. Mulazzani[4], A. Felicioli[4], D. Barnes Navarro[5], F. Mugnos Gomez[6], O. Zoras[7], C. Aliberti[2]

[1]Oncology-Hematology, Ospedale San Salvatore, Pesaro, Italy, [2]Interventional Radiology, Oncology Institute of Veneto, Institute for the Research and Treatment of Cancer (IRCC), Padua, Italy, [3]Radiology, Azienda Sanitaria Locale Matera, Madonna delle Grazie Hospital, Matera, Italy, [4]Diagnostics for Images Unit and Interventional Radiology, Ospedale San Salvatore, Pesaro, Italy, [5]Interventional Radiology, Hospital Clínic de Barcelona, Barcelona, Spain, [6]Radiology, Hospital Universitario y Politecnico La Fe, Valencia, Spain, [7]Surgical Oncology, University of Crete, Medical School, Crete, Greece

Background: Patients with liver metastases from colorectal cancer are in 80% of cases non-indicated for resection. The standard first line treatment of unresectablelivermetastases is systemic chemotherapy, however this method results in progression for 70% of patients. The indicated therapy for refractory patients is the chemoembolization. In this study we monitored tumor response, and adverse events after chemoembolization of colorectal cancer liver metastases with polyethylene glycol embolics loaded with irinotecan. Secondary objectives were to monitor quality of life, time to progression and survival of patients.

Methods: Patients were included in the study if: affected by CRC-LM, who were refractory to systemic chemotherapy, treated with chemoembolization using polythylene glycol embolics, and liver involvement >50%. Tumor response, performance status (PS), tumor marker antigens, and quality of life (QoL) were monitored at 1, 3 and 6 months after chemoembolization. Q oL was assessed with the palliative scale (PSS).

Results: We treated 50 consecutive CRC-LM patients with chemoembolization using polythylene glycol embolics, their tumor response one month after chemoembolization was 28% of complete response (CR), and 48% of partial response (PR), 8% stable disease (SD), and 16% of progression. Tumor response 3 months after chemoembolization was CR 24%, PR 38%, SD 19% and progression disease (PD) 19%. Tumor response 6 months after chemoembolization was CR 18%, PR 44%, SD 21% and progression disease (PD) 18%. QoL was 90% PPS at each time point. Median time to progression was 2,5 months (range 0,8 - 6). Median follow-up was 14 months (0,8-25 range). Chemoembolizations were performed with no complications. Observed side effects (mild or moderate intensity) were: pain in 32% of patients, increase of transaminase levels in 20% fever in 14%, whereas 30% of patients did not complain any adverse event.

Conclusions: Chemoembolization of refractory liver metastases from colorectal cancer with polyethylene glycol embolics loaded with irinotecan was effective in tumor response and resulted in mild toxicity, and good QoL.

512P Neoadjuvant systemic chemotherapy prior to cytoreductive surgery and hyperthermic intraperitoneal chemotherapy for the treatment of peritoneal carcinomatosis from colorectal cancer

N. Asher[1], G. Lahat[2], R. Geva[3]

[1]Medical Oncology, Tel Aviv Sourasky Medical Center-(Ichilov), Tel Aviv, Israel, [2]Surgical Oncology, Tel Aviv Sourasky Medical Center-(Ichilov), Tel Aviv, Israel, [3]Research Unit, Division of Oncology, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel

Background: Cytoreductive surgery (CRS) and Hyperthermic Intraperitoneal Chemotherapy (HIPEC) have become a standard treatment option for peritoneal carcinomatosis (PC) arising from colorectal carcinoma, despite the complexity and morbidity of this procedure. The timing of CRS+HIPEC in the course of the disease in unclear, and there is no consensus regarding pre-operative treatments. In this study we analyzed the effect of neoadjuvant systemic chemotherapy prior to CRS+HIPEC on patients' outcome.

Methods: Data on consecutive colorectal patients with PC, treated in the Sourasky Medical Center from Jan 2007 to Dec 2016 was collected. Demographic, pathologic and clinical data was registered for all patients. For patients treated with neoadjuvant chemotherapy, the regimen, duration and responses were recorded. Outcome measurements were postoperative complications, progression free survival (PFS) and overall survival (OS).

Results: Seventy-two (72) patients were identified, of whom 43 (59.7%) were treated with neoadjuvant chemotherapy and 29 (40.3%) were referred directly to CRS+HIPEC. No significant demographic, pathological or clinical differences between the groups were found. Median PFS was 12 months in the Neo- group and 17 months in the Neo+ group ($p = 0.015$). On multivariate Cox-PH analysis, the effect of neoadjuvant chemotherapy on PFS was maintained ($HR = 0.34$, $p = 0.002$). Median OS was 41 months in the Neo- and 47 months in the Neo+ with no statistical difference. In the Neo+ group, on univariate analysis, there was no significant effect to chemotherapy regimen, duration of treatment, nor best response. There was no difference in postoperative complication rate between the groups.

Conclusions: In patients candidate for CRS+HIPEC for the treatment of PC from colorectal cancer, the administration of systemic neoadjuvant chemotherapy significantly prolongs PFS with no additional postoperative risks. Prospective randomized trials and larger patient cohorts are needed to confirm these findings and assess the effect on OS.

513P Efficacy and tolerability of chronomodulated FOLFIRINOX (chronoIFLO) as 1st or 2nd line treatment in patients (pts) with metastatic colorectal cancer (MCC): Final results from an international trial (EORTC 05011)

C. Garufi[1], F. Levi[2], A. Karaboué[3], A. Torsello[4], C. Focan[5], P. Chollet[6], P. INNOMINATO[2]

[1]Medical Oncology, Ospedale Di Pescara, Pescara, Italy, [2]Medical School, University of Warwick, Coventry, UK, [3]Research & Therapeutic Innovation, AK-SCIENCE, Vitry-sur-Seine, France, [4]Oncology, San Giovanni Hospital, Rome, Italy, [5]Oncology, Centre Hospitalier Chrétien (CHC), Liège, Belgium, [6]Oncology, Centre Jean Perrin, Clermont-Ferrand, France

Background: FOLFIRINOX is an effective yet toxic protocol against gastro-intestinal cancers. We report final updated global results from a randomised international trial aiming to identify the least toxic time of Irinotecan (I) combined with Oxaliplatin (O), 5-Fluorouracil (F) and Leucovorin (L).

Methods: 199 MCC pts were randomised to receive chronomodulated I (180 mg/m2 over 6-h) on day 1 (d1) with peak delivery at 1:00, 5:00, 9:00, 13:00, 16:00 or 21:00, followed by 4-d fixed-time chronomodulated O (20 mg/m2/d) over 11.5 h, with peak delivery at 16:00, alternating with F (700 mg/m2/d) and L (300 mg/m2/d) over 11.5 h, with peak delivery at 4:00. ChronoIFLO was administered every 3rd week using an automatic programmable-in-time pump.

Results: 136 males (68%) and 63 females (32%) were registered at 18 centers. They had a median age of 61 years (range: 30-81), a WHO PS of 0 (73%), 1 (23%) or 2 (4%). ChronoIFLO4 was given as 1st (154 pts, 77%) or 2nd line (45 pts, 23%; 14 pts had previously received I and 20 pts, O). Pt features were similar in the 6 treatment groups. Median number of cycles was 6 (1-18), and mean relative dose intensities were 88% for I, 88% for O, 89% for F. Overall grade 3-4 toxicity occurred in 136/199 pts (68%) and 248/1158 cycles (21%). The most common severe toxicities were diarrhoea (43% of pts), nausea (19%), neutropenia (17%), fatigue (13%) and anorexia (11%). 1st line chronoIFLO achieved an objective response rate (ORR) of 61% [95% Confidence Limits: 53-69], a disease control rate (DCR) of 90% [85-95], a median progression-free survival (PFS) of 8.7 months (mo) [7.6-9.8], and a median overall survival (OS) of 19.5 mo [14.8-24.2]. Respective figures for 2nd line were: ORR, 39% [24-54]; DCR, 76% [63-89]; PFS, 7.4 mo [5.4-9.3]; OS, 16.6 mo [12.5-20.7].

Conclusions: Chronomodulated triplet showed favourable safety and activity profiles both as frontline or salvage treatment of MCC, in comparison to previous reports of conventional delivery. The therapeutic index of chronoIFLO could benefit from the personalisation of drug delivery patterns to match individual differences in internal clock phase.

514P A multicentre, randomized phase 3 study on the optimization of the combination of bevacizumab with mFOLFOX/OXXEL in patients with metastatic colorectal cancer (mCRC)

A. Avallone[1], G. Nasti[1], G. Rosati[2], C. Carlomagno[3], C. Romano[1], D. Bilancia[4], A. De Stefano[3], A. Ottaiano[1], A. Cassata[1], L. Silvestro[1], S. Tafuto[1], F. Bianco[5], P. Delrio[5], F. Izzo[5], E. Di Gennaro[6], S. Lastoria[7], C. Gallo[8], F. Perrone[9], A. Budillon[6], M.C. Piccirillo[9]

[1]Medical Oncology, Istituto Nazionale Tumori – I.R.C.C.S - Fondazione Pascale, Naples, Italy, [2]Medical Oncology, San Carlo Hospital, Potenza, Italy, [3]Oncology, AOU Policlinico Federico II, Naples, Italy, [4]Medical Oncology, Azienda Ospedaliera San Carlo, Potenza, Italy, [5]Surgical Oncology, Istituto Nazionale Tumori – I.R.C.C.S - Fondazione Pascale, Naples, Italy, [6]Experimental Pharmacology, Istituto Nazionale Tumori – I.R.C.C.S - Fondazione Pascale, Naples, Italy, [7]Nuclear Medicine, Istituto Nazionale Tumori – I.R.C.C.S - Fondazione Pascale, Naples, Italy, [8]Medical Statistics, Università degli Studi della Campania "Luigi Vanvitelli", Naples, Italy, [9]Clinical Trials Unit, Istituto Nazionale Tumori – I.R.C.C.S - Fondazione Pascale, Naples, Italy

Background: Bevacizumab is a humanized anti-vascular endothelial growth factor (VEGF) monoclonal antibody, approved in combination with chemotherapy in the treatment of mCRC. It is proposed that the schedule of administration might be critical

and that anticipating bevacizumab to chemotherapy, might improve treatment efficacy.

Methods: mCRC patients, ≤ 75 years old, ECOG PS ≤ 1, having received no more than one previous treatment, with at least one measurable lesion according to RECIST, were randomized (1:1) to receive standard administration of bevacizumab (5mg/kg d1 Q14) with chemotherapy (mFOLFOX/OXXEL regimen for 12 cycles) vs experimental bevacizumab given 4 days before chemotherapy (same dose), at each cycle. Patients could receive maintenance bevacizumab (7.5 mg/kg d1 Q21) until disease progression or unacceptable toxicity in both arms. Primary end point was the objective response rate (ORR). With 80% power and 2-tailed alpha 0.05, an expected 20% increase in response rate, 230 patients were planned. With 163 events, the study also had 80% power to detect a hazard ratio (HR) 0.64 of progression-free survival. Analyses were based on intention to treat.

Results: From May 2012 to Dec 2015, 230 patients were randomly assigned to experimental (n = 115) and standard (n = 115) arm. Median age was 62 (IQ range 53-68), 79% were PS 0, 93% were not pretreated, 53% had a single metastatic site, 54% were RAS-mutant (47% and 62% in the standard and experimental arm, respectively). ORR was 54% in both arms (p = 0.89). With a median follow-up of 32.4 months, 204 PFS events and 131 deaths were reported. Median PFS was 10.5 and 11.7 months (HR 0.79, 95% CI: 0.60-1.05; multivariate adjusted p = 0.10) and median OS was 23.7 and 29.9 months (HR 0.73, 95% CI: 0.52-1.04; multivariate adjusted p = 0.08), in the standard and experimental arm, respectively. 57.4% and 59.1% of the patient received a following treatment in the standard and experimental arm, respectively.

Conclusions: Anticipating bevacizumab to chemotherapy does not improve ORR. A not statistically significant prolongation of PFS and OS was reported in this study. Supported by the Italian Ministry of Health. CT.gov NCT01718873.

515P First-in-human Phase I study of bacterial RNA interference therapeutic CEQ508 in patients with familial adenomatous polyposis (FAP)

V. Trieu[1], L. Hwang[1], K. Ng[2], O. D'Cruz[2], S. Qazi[2], A. Fong[2]
[1]Clinical Research, Marina Biotech, City of Industry, CA, USA, [2]Clinical Research, Autotelic Inc., Costa Mesa, CA, USA

Background: FAP is an inherited gastrointestinal (GI) disorder that predisposes patients to early-onset of colorectal cancer due a mutation in the APC gene resulting in nuclear accumulation of β-catenin. CEQ508 is a live-attenuated Escherichia coli genetically engineered to produce and deliver β-catenin short-hairpin RNA into the mucosa. This first-in-human study (START-FAP) aimed to assess the safety, tolerability, and efficacy in response to CEQ508 in FAP patients.

Methods: Six patients with FAP were orally administered (3 each in Cohort 1 and 2) with CEQ-508 (10^8 and 10^9 CFU/day for 28 days). The primary objective was to establish safety profile of oral CEQ508 and to determine the MTD. The secondary objective was the extent of knockdown of the target gene β-catenin in GI tissues (duodenum, ileum, right and left colon, antrum) taken during endoscopy at baseline and at end-of-treatment (EOT). β-catenin expression levels were measured using qPCR and normalized to housekeeping genes (EIF2B1, HPRT1, GUSβ). A mixed-model nested-ANOVA was used to evaluate β-catenin knockdown.

Results: Daily oral dosing of 10^8 and 10^9 CFU of CEQ508 for 28 days was well-tolerated. Histology of polyps and normal mucosa at baseline and EOT indicated no changes in tissue morphology or inflammation in cohort 1 patients. A slight inflammation (from score of 0 to 1 at EOT) was noted in normal colon mucosa of cohort 2 patients. Daily oral dosing of 10^9 CFU of CEQ508 for 28 days was well-tolerated with targeted β-catenin knockdown in polyps. β-catenin expression was highest in duodenum and lowest in antrum with no significant treatment effects in normal mucosa. Significant reduction was observed in overall β-catenin expression in polyps at EOT (P = 0.0005). Reduction was observed primarily in the duodenum (39.3%, P < 0.0001) and ileum (28.8%, P = 0.012).

Conclusions: Bacterial delivery of RNAi in FAP patients demonstrated an acceptable safety profile at the two dose levels tested. Without hitting MTD, START-FAP achieved both the primary endpoint of safety and secondary endpoint of b-catenin knockdown. CEQ508 is now being moved into clinical development in combination with Celecoxib/Lisinopril (IT-102) against FAP.

516P A Multicentre Phase I/II Study of TAS-102 with nintedanib in patients with metastatic colorectal cancer refractory to standard therapies (N-task force: EPOC1410)

K. Yamazaki[1], Y. Kuboki[2], E. Shinozaki[3], H. Hara[4], Y. Komatsu[5], T. Nishina[6], K. Yamaguchi[3], S. Yuki[7], H. Bando[2], M. Asayama[8], T. Tsushima[1], S. Hamauchi[1], H. Nakatsumi[7], T. Kajiwara[6], M. Wakabayashi[9], S. Nomura[10], A. Sato[9], T. Doi[11], A. Ohtsu[12], T. Yoshino[2]
[1]Division of Gastrointestinal Oncology, Shizuoka Cancer Center, Shizuoka, Japan, [2]Department of Gastrointestinal Oncology, National Cancer Center Hospital East, Kashiwa, Japan, [3]Department of Gastroenterology, Cancer Institute Hospital of JFCR, Tokyo, Japan, [4]Department of Gastroenterology, Saitama Cancer Center Hospital, Saitama, Japan, [5]Department of Cancer Chemotherapy, Hokkaido University Hospital Cancer Centre, Sapporo, Japan, [6]Department of Gastrointestinal Medical Oncology, Shikoku Cancer Center, Matsuyama, Japan, [7]Department of Gastroenterology and Hepatology, Hokkaido University Hospital, Sapporo, Japan, [8]Department of Gastroenterology, Saitama Cancer Center, Ina, Japan, [9]Office of Clinical Research Support, National Cancer Center Hospital East, Chiba, Japan, [10]Office of Clinical Research Support, National Cancer Center Hospital East, Kashiwa, Japan, [11]Department of Experimental Therapeutics, National Cancer Center Hospital East, Kashiwa, Japan, [12]National Cancer Center Hospital East, Kashiwa, Japan

Background: TAS-102 demonstrated significant improvement in overall survival (OS) over placebo in patients (pts) with metastatic colorectal cancer (mCRC). Nintedanib is a triple angiokinase inhibitor of VEGFR (1, 2, 3), PDGFR (a, β), and FGFR (1, 2, 3). In preclinical models, the combination of TAS-102 plus nintedanib demonstrated enhanced activity against CRC compared with either drug alone. This study was conducted to determine the recommended phase II dose (RP2D) and evaluate the efficacy and safety in pts with mCRC refractory to standard therapies. RP2D was determined nintedanib 200mg BID every day adding to standard-dose of TAS-102 in the phase I part (Nishina T, et al. ESMO 2016). We present here on the efficacy and safety data from the ongoing study.

Methods: The key eligibility criteria were pts with mCRC refractory or intolerant to fluoropyrimidine, irinotecan, oxaliplatin, anti-angiogenesis inhibitor and anti-EGFR antibody (if wild-type RAS) and without prior regorafenib. Primary endpoint was investigator-assessed progression-free survival (PFS) rate at 16 weeks in pts treated with RP2D. Using a single stage binomial design, this study required 52 pts, with the PFS rate at 16 weeks of 40% deemed promising and 25% unacceptable (alpha=0.1; beta=0.2).

Results: From August 2015 to August 2016, 55 pts were enrolled. Among them, 52 pts received the RP2D as full analysis set. The PFS rate at 16 weeks was 38.5% (80% confidence interval: 29.3–48.3%). Four pts (7.7%) achieved a partial response, median PFS and disease control rate were 3.7 months and 69.2%, respectively. Median OS was 9.2 months. The median number of treatment cycles was 4 (range 1 - 14). The most common grade 3 or worse treatment-associated adverse events were neutropenia (59.6%), anemia (17.3%), thrombocytopenia (11.5%) and increased liver enzymes (AST: 9.6%, ALT: 7.7%; asymptomatic reversible elevation without any bilirubin elevation). Febrile neutropenia occurred in two (3.8%) pts. There was no treatment-related death.

Conclusions: Standard-dose of TAS-102 with nintedanib 200 mg BID showed promising antitumor activity with acceptable toxicity for mCRC pts.

Magrassi, University of Campania Luigi Vanvitelli, Naples, Italy, [12]Medical Oncology, Hammersmith Hospital, Imperial College London, London, UK, [13]GI Medical Oncology, Mayo Clinic, Rochester, MN, USA, [14]Biostatistics, Array BioPharma Inc., Boulder, CO, USA, [15]Clinical Sciences, Array BioPharma Inc., Boulder, CO, USA, [16]GI Medical Oncology, University of Texas MD Anderson Cancer Center, Houston, TX, USA

Background: Phase 2 data for the combination of ENCO (a selective BRAF inhibitor) + CTX (an anti-EGFR antibody) in pts with $BRAF^{V600E}$ mCRC showed the regimen was well tolerated and improved response rate, progression-free survival, and overall survival compared with historical controls. BEACON CRC (NCT02928224) is a randomized phase 3 study evaluating both the triplet combination BINI (a MEK inhibitor) + ENCO + CTX and the doublet combination ENCO + CTX compared with investigators' choice of irinotecan (IRI) + CTX or FOLFIRI (folinic acid, 5-fluorouracil, and IRI) + CTX in pts with $BRAF^{V600E}$ mCRC whose disease has progressed after 1 or 2 prior regimens in the metastatic setting. Here we describe the results of the SLI to determine the safety of the triplet combination.

Methods: Nine pts with $BRAF^{V600E}$ mCRC would receive ENCO 300 mg QD + BINI 45 mg BID + CTX 400 mg/m^2 (then 250 mg/m^2 QW) in 28-day cycles. If < 33% of pts had a dose-limiting toxicity (DLT), 16–21 additional pts would be treated at the same dose. If ≥ 33% of pts had a DLT, lower doses of BINI and/or ENCO would be assessed.

Results: Thirty pts received the initial dose level; median age was 59 years, 17 pts were female, and 17 had an ECOG PS of 0. DLTs were reported in 5 pts: infusion reaction following CTX (n = 2), inability to receive ≥75% dose intensity due to grade 2 retinopathy (n = 2), and grade 2 decreased ejection fraction (n = 1). The most common adverse events (% of pts with grade 1, 2, 3, 4) were diarrhea (38, 28, 3, 0), nausea (41, 3, 0, 0), dermatitis acneiform (38, 7, 0, 0), and fatigue (21, 14, 7, 0). Twenty-eight pts continue on treatment; 1 pt died due to rapid disease progression and 1 pt discontinued due to disease-related biliary obstruction. Preliminary efficacy data support the benefit of adding BINI to the doublet regimen; additional follow-up will provide mature safety and efficacy data from the SLI cohort and will be presented.

Conclusions: ENCO + BINI + CTX, at the full planned dose of each agent, was generally well tolerated. Safety and preliminary efficacy data support the initiation of the phase 3 portion of the BEACON trial.

Clinical trial identification: NCT02928224

Background: Although bevacizumab and monoclonal antibodies directed against epidermal growth factor receptor (EGFR) cetuximab and panitumumab are commonly used in the treatment of metastatic colorectal cancer (mCRC) without activating RAS mutations, the optimal sequencing of these agents is currently unclear.

Methods: A national registry of targeted therapies was used to analyse baseline characteristics and outcomes of patients with mCRC who received bevacizumab followed by antiEGFR agents or a reverse sequence as first- and second-line treatment. The cohort for analysis included all patients with valid data in the registry who met the following inclusion criteria: a) sequential therapy with first-line cetuximab or panitumumab and second-line bevacizumab or first-line bevacizumab and second-line cetuximab or panitumumab; b) progression documented in the database between the first and the second line; c) first-line therapy using FOLFOX or FOLFIRI regimens as chemotherapy backbone; and d) wild-type KRAS status and wild-type or unknown NRAS status.

Results: The cohort included 490 patients; 181 patients received cetuximab or panitumumab as a part of first-line treatment and bevacizumab as a part of second-line treatment, while 309 patients were treated with the reverse sequence. Median overall survival (OS) from the initiation of first-line therapy was similar for patients treated with the different sequences (Table). No statistically significant differences in OS were detected between patients treated with the different sequences for subgroups of patients defined by age, chemotherapy backbone, synchronous/metachronous metastatic disease, anatomic location of the primary tumour, RAS status, and body-mass index. Progression-free survival, calculated as the time from the initiation of first-line therapy to progression on the second-line therapy moderately favoured the bevacizumab → antiEGFR sequence (Table).

Conclusions: This retrospective analysis of data from a large patient registry does not support the hypothesis that the sequence of antiEGFR agents and bevacizumab has an impact on OS of mCRC patients.

519P Outcomes in patients receiving maintenance therapy in two panitumumab (Pmab) first-line trials for metastatic colorectal cancer (mCRC)

F. Rivera Herrero[1], J-B. Bachet[2], D.P. Modest[3], F. de Braud[4], F. Pietrantonio[5], R. Koukakis[6], G. Demonty[7], J-Y. Douillard[8]

[1]Medical Oncology, Hospital Universitario Marques de Valdecilla, Santander, Spain, [2]Department of Gastroenterology, La Pitié-Salpetrière Hospital, Assistance Publique des Hôpitaux de Paris (APHP), Paris, France, [3]Department of Medical Oncology & Comprehensive Cancer Center, University Hospital Grosshadern, Ludwig-Maximilian-University, Munich, Germany, [4]Medical Oncology/Department of Oncology and Hemato-oncology, Fondazione IRCCS Istituto Nazionale dei Tumori/Università degli Studi di Milano, Milan, Italy, [5]Medical Oncology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [6]Biostatistics, Amgen Ltd, Uxbridge, UK, [7]Medical Development, Amgen (Europe) GmbH, Zug, Switzerland, [8]Department of Medical Oncology, Institut de Cancérologie de l'Ouest (ICO) René Gauducheau, Nantes, France

Background: Maintenance therapy for mCRC is intended to prolong progression-free survival (PFS) with reduced toxicity, but little information is available concerning the value of epidermal growth factor receptor-targeted antibodies in this setting. Here we present data on outcomes of maintenance therapy from two first-line Pmab trials.

Methods: These retrospective analyses include data from patients with RAS WT (no mutations in KRAS or NRAS exons 2, 3 and 4) mCRC from two randomised trials: PRIME (Pmab + FOLFOX vs. FOLFOX) and PEAK (FOLFOX + either Pmab or bevacizumab). Maintenance therapy was defined as continuation of the other components of the patient's study treatment after discontinuation of oxaliplatin. PFS and overall survival (OS) from baseline and from start of maintenance therapy were summarised for patients without progression in each treatment arm.

Results: In PRIME and PEAK, 93 and 61 patients with RAS WT mCRC, respectively, received maintenance therapy (median [IQR] duration: PRIME, 16 [7–37] months; PEAK, 20 [13–41] months). Median PFS and OS overall and from start of maintenance therapy were longer in patients receiving Pmab maintenance vs. controls in both studies (Table).

Conclusions: Even if time to oxaliplatin discontinuation is heterogeneous and patients receiving maintenance treatment are among those with greater treatment benefit, these retrospective data suggest that deintensification of Pmab-based treatment to 5-fluorouracil/Pmab maintenance is feasible and associated with extended PFS and OS. While maintenance is not part of the licensed indication for Pmab, physicians may drop oxaliplatin in patients with good initial response, to minimize toxicity, with the hypothesis that outcome would not be impacted. Ongoing prospective trials should confirm the value of Pmab maintenance and inform the design of future trials in which treatment strategy and sequence will be studied.

520P AMALTHEA: A prospective, single-arm study of the Hellenic Cooperative Oncology Group evaluating the efficacy and safety of 1st line FOLFIRI+Aflibercept in patients with metastatic colorectal cancer

G. Pentheroudakis[1], V. Kotoula[1], G-A. Koliou[1], I. Tikas[1], V. Karavasilis[1], E. Samantas[1], G. Aravantinos[1], E. Daskalaki[1], I. Souglakos[2], G. Koumakis[1], I. Efstratiou[1], C. Petraki[1], C. Poulios[1], D. Bafaloukos[1], D. Pectasides[1], E. Vrettou[1], G. Fountzilas[1]

[1]Data Office, Hellenic Cooperative Oncology Group (HeCOG), Athens, Greece, [2]Division of Internal Medicine, University of Crete, Heraklion, Greece

Background: The efficacy and safety of the FOLFIRI regimen combined with aflibercept has not been studied in the first-line management of patients with metastatic colorectal cancer (mCRC).

Methods: In the context of a prospective single-arm trial, patients with mCRC received standard doses of Leucovorin, 5-Fluorouracil and Irinotecan (FOLFIRI) combined with aflibercept (4 mg/KBW iv) every 2 weeks until disease progression, unacceptable toxicity or completion of 12 cycles, followed by aflibercept maintenance. Endpoints were the 12-month Progression-Free Rate (PFR12), efficacy and toxicity.

Results: 73 fit patients were enrolled in the study between 2014 and 2016. Fifty-five patients had tumors in the left colon, forty-four presented with synchronous metastases. Median relative dose intensities administered were 0.85 (95% CI 0.74-0.84) for 5-FU CI, 0.80 (95% CI 0.73-0.89) for Irinotecan and 1.0 (95% CI 0.92-0.98) for Aflibercept. In total, adverse events occurred in 70 patients (95.9%), with no toxic deaths. The most common grade 3 or 4 adverse events were neutropenia (13 patients, 18%), febrile neutropenia (3 patients, 4%), diarrhoea (11 patients, 15%), hypertension (19 pts, 26%), proteinuria (8 pts, 11%), infections (8 pts, 11%), mucositis (6 pts, 8%). Among 85 adverse events of special interest (AESI) observed, 57 events ended with complete recovery. Among eight patients with severe proteinuria, improvement to grade 0/2 occurred in six at a median time of 4.8 months. The Objective Response Rate (ORR) was 46.6% in the ITT population (n = 73) and 51.5% in the evaluable population (n = 66). Among potential prognostic clinicopathological parameters (including RAS, BRAF status, primary site), the presence of synchronous metastases and a relapse-free interval <12 months were significantly associated with response (odds ratio 2.92 and 3.75 respectively), while a performance status of 0 with overall survival (hazard ratio 0.42). At a median follow-up of 20.9 months, the median OS was 24.7 months (95% CI 17.3-30.5), the median PFS 8.4 months (95% CI 7.44-9.44), while the 12-month PFS rate was 21.8%.

Conclusions: The FOLFIRI + Aflibercept regimen is active and safe, however it failed to improve historical benchmarks of efficacy in chemonaive patients with mCRC.

Background: Triweekly capecitabine plus irinotecan (XELIRI) is not completely regarded as a valid substitute for fluorouracil, leucovorin, and irinotecan (FOLFIRI) in metastatic colorectal cancer (mCRC) because of the potential for greater toxicity. Therefore, we conducted a phase II study to assess the efficacy and safety of biweekly XELIRI plus bevacizumab (BV) as second-line chemotherapy for mCRC. High dose BV (10 mg/kg) combined biweekly XELIRI as second-line chemotherapy was one of the first trial in the world.

Methods: Patients with mCRC who had received prior chemotherapy including oxaliplatin based regimen were eligible for this study. Protocol treatment administrated capecitabine 1,000 mg/m2 twice daily from the evening of day 1 to the morning of day 8, intravenous irinotecan 150mg/m2 on day 1, and BV 10 mg/kg on day 1 every 2 weeks. The primary endpoint of this study were progression-free survival (PFS) and safety. The secondary endpoint were overall survival (OS), time to treatment failure (TTF), response rate (RR) and disease control rate (DCR).

Results: Between January 2013 and July 2015, 51 patients were enrolled in this study. The patients' characteristics were as follows: median age, 66 years (range 41–82); male/female, 29/22; The median PFS was 5.7 months (95% confidence interval, 4.2–7.2 months). The median OS was 13.4 months (95%CI, 11.4–16.7 months). The median TTF was 5.2 months (95%CI, 3.9–7.2 months). The response rate was 14%, and the disease control rate was 78%. Grade 3 or higher adverse events were mainly febrile neutropenia in two patients and hypertension in 14 patients (28.6%). One patient had grade 4 intestinal pneumonia but improved by intensive treatment. There were no other severe adverse events or treatment-related deaths.

Conclusions: In mCRC patients, biweekly XELIRI + BV 10 mg/kg is effective and feasible as second-line chemotherapy. Biweekly XELIRI + BV is considered a useful substitute for FOLFIRI + BV in mCRC, and further study of this combination therapy is warranted.

522P Sex-related differences in circadian-dependent tolerance of Irinotecan (I) added to chronomodulated (chrono) 5-Fluorouracil (F), Leucovorin (L) and Oxaliplatin (O): Final results from international randomised time-finding study in patients with metastatic colorectal cancer (MCC)

F. Levi[1], C. Garufi[2], A. Karaboué[3], C. Focan[4], P. Chollet[5], X-M. Li[6], P. INNOMINATO[1]

[1]Medical School, University of Warwick, Coventry, UK, [2]Medical Oncology, Ospedale Di Pescara, Pescara, Italy, [3]Research & Therapeutic Innovation, AK-SCIENCE, Vitry-sur-Seine, France, [4]Oncology, Centre Hospitalier Chrétien (CHC), Liège, Belgium, [5]Oncology, Centre Jean Perrin, Clermont-Ferrand, France, [6]Team-3 Chronotherapy of Liver Cancers and Optimization of Liver Function, INSERM U935, Villejuif, France

Background: The least toxic time (LTT) of I varied by up to 8 hours according to sex in mice (Li et al. Cancer Res 2013). The translational relevance was investigated through a post-hoc analysis of a randomised trial, where the planned methodology did not identify the LTT of I combined with F, L and O (chronoIFLO) in the whole population.

Methods: 199 MCC patients at 18 EU centers were randomised to receive chrono I (180 mg/m2 over 6-h, with peak delivery at 1:00, 5:00, 9:00, 13:00, 17:00 or 21:00) on day (d) 1, followed by fixed-time chrono O (20 mg/m2/d over 11.5 h; peak delivery at 16:00) and F-L (700 and 300 mg/m2/d, respectively, over 11.5h, with peak delivery at 4:00), for 4 d. ChronoIFLO was administered q3 weeks as 1st or 2nd line. The main endpoints were the circadian profiles of Grade (G) 3-4 toxicity and best objective response (OR), according to sex. Rhythmic trends were determined with cosinor using smoothed data through moving average.

Results: The trial included 136 males (m; 68%) and 63 females (f; 32%), with similar characteristics among the 6 treatment groups. The rates of all G3-4 toxicities ranged from 64% to 69.6% in m, and from 50% to 93.3% in f according to I timing. The LTT was at 12:30 [95% CI, 11:30-13:30] in m ($p = 0.002$), and at 15:55 [12:40-19:08] in f ($p = 0.05$) for all G3-4 toxicities. G3-4 neutropenia varied >3-fold as a function of I timing (10 to 33.3% in m; 0 to 38.5% in f), and the least corresponded to I peak delivery at 11:00 [08:00-13:08] in m ($p = 0.045$) and 18:07 [15:07-21:08] ($p = 0.047$) in f. Similar circadian trends were found for mucosal G3-4 toxicities in both sexes. No timing effect was found for G3-4 diarrhoea. OR rates ranged from 38.9% to 80% in m, and 37.5% to 83.3% in f between groups, with most effective timing of I overlapping with LTT in m (14:50 [11:52-17:26], $p = 0.039$), but not in f (02:17, $p = 0.074$).

Conclusions: Optimal timing of I tolerability occurred 4 to 7 h earlier in m as compared to f, in agreement with prior mouse data. The relevance of sex for the determination of optimal efficacy timing is further supported here.

523P Mechanism of pelareorep (Pel)-mediated cell death in a Phase I study in combination with irinotecan/fluorouracil/leucovorin/bevacizumab (FOLFIRI/B) in patients with KRAS mutant metastatic colorectal cancer (mCRC)

S. Goel, A. Ocean[2], I. Chaudhary[1], M.H. Ghalib[1], E. Kaledzi[1], U. Shah[1], A.A. Gutierrez[3], M. Coffey[3], G. Gill[3], R. Maitra[1]

[1]Medical Oncology, Montefiore Medical Center (East campus), Medical Park at Eastchester Albert Einstein Cancer Center, Bronx, NY, USA, [2]Medical Oncology, NewYork-Presbyterian/Weill Cornell Medical Center, New York, NY, USA, [3]Clinical Development, Oncolytics Biotech Inc, Calgary, AB, Canada

Background: Pelareorep (REOLYSIN) is an immuno oncology viral agent that contains a naturally occurring, ubiquitous, non-enveloped human dearing strain reovirus. Pelareorep selectively replicates in tumor cells harboring gene mutations that downregulate the IFN-induced antiviral response (e.g., KRAS-mutations) which results in their lysis. Pel is synergistic with irinotecan (IRI) in in vitro and in vivo models.

Methods: This is a phase I dose escalation study of FOLFIRI/B + Pel. Eligible pts are adults with oxaliplatin refractory KRAS-mutant mCRC. Both, IRI (150-180 mg/m^2) and Pel ($1x10^{10}$ $TCID_{50}$ to $3x10^{10}$ $TCID_{50}$) were escalated. Pel was given IV over 1 hr days 1-5 every 4 weeks (wk). Primary objectives were to determine toxicity, recommended phase two dose (RPTD), and pharmacokinetics. Secondary objectives were response rate, progression-free and overall survival (PFS and OS). Tumor biopsies post Pel were optional and subject to electron microscopy (EM).

Results: 36 pts enrolled; FOLFIRI naïve (24) and pre-treated (12). Common (>10%) grade 3-4 toxicity include: neutropenia, anemia, and thrombocytopenia. At 180 mg/m^2 of IRI, among FOLFIRI pretreated pts, 2 had dose-limiting toxicity (DLT) in cycle 1; in FOLFIRI naïve patients, none/6 had a DLT, with a median PFS of 49 wk (range: 10-91 wk). 5 patients are currently on therapy. The RPTD is IRI 180 mg/m^2 and Pel $3x10^{10}$ $TCID_{50}$. Of 32 evaluable pts, 3 had a partial response. EM of tumor biopsies showed dying cells with degenerating endoplasmic reticulum, large nonfunctional mitochondria, heterochromatin, condensed DNA, and viral factories, both empty and active. There were discrete holes in the cytoplasm leading to dampening of cellular proliferation. Immunogold staining against viral capsid protein σ demonstrated viral "homing" in the tumor cells. Flow cytometry reveals expansion of dendritic cells with consequent activation of cytotoxic T cells.

Conclusions: The combination was safe, well tolerated, with a PFS (49 wk), superior to historic data (25-30 wk). Detailed PK and immune data will be presented.

Clinical trial identification: NCT01274624

524P Bevacizumab first line and impact on subsequent anti-EGFR activity

T.J. Price[1], J. Hardingham[1], C. Karapetis[2], E. Smith[3], R. Padbury[4], A. Roy[2], D. Roder[5], M.E. Burge[6], A. Townsend[3]

[1]Medical Oncology, Queen Elizabeth Hospital and University of Adelaide, Woodville, Australia, [2]Medical Oncology, Flinders Centre for Innovation in Cancer, Bedford Park, Australia, [3]Medical Oncology, Queen Elizabeth Hospital and University of Adelaide, Adelaide, Australia, [4]Surgery, Flinders University, Adelaide, Australia, [5]Epidemiology, University of South Australia, Adelaide, Australia, [6]Medical Oncology, Royal Brisbane and Women's Hospital, Brisbane, Australia

Background: Authors hypothesize that initial anti-VEGF therapy may induce biological changes that then increase the risk of acquired resistance to subsequent EGFR inhibitors.

Methods: A retrospective cohort study was performed to compare the characteristics and survival of patients who were treated with an anti-EGFR therapy at 2nd line and beyond. We separated two groups defined by the first line therapy; 1. chemotherapy plus bevacizumab (CB) and 2. chemo (C) alone. Two survival times were measured for this in this updated analysis; survival from the time of commencing first line chemotherapy and survival from commencement of anti-EGFR therapy. We analysed outcomes separately for the 2nd line anti-EGFR groups (2L) and the '3rd line and beyond' (3L) groups, Long rank (mantel-cox) test analysis was performed to determine whether receiving first line bev was associated with worse overall survival (OS).

Results: 450 mCRC patients who received either CB (n = 249) or C (n = 201), and then an anti-EGFR therapy were studied. Significant differences between CB and C groups for patient characteristics included; decreased median age (61.3 years (range 20.6 - 86.7) v 64.5 (24.3 - 91.8), p = 0.0006), lower use of irinotecan regimens (22% v 42%) and increased use of single agent FU (11% v 1.5%). There was no difference in gender (males 65.5% v 66.7%). There was no difference in proportion of patients receiving anti-EGFR second line (2L), CB 39% v C 43%. Where BRAF MT status was assessed 11% had MT (CB 23% v C 0). Median OS for the 2L group, as measured from the commencement of first line therapy, was 24.4 months for CB v 18.9 months for C (p = 0.0176). Median OS for the 3L group from the commencement of first line therapy was 32.8 months for CB v 29.9 months for C (p = NS). The survival from commencement of anti-EGFR therapy for CB v C respectively was; 2L 10.5 months v 11.6 months (p=NS), 3L 9.9 months v 8.3 months (p=NS).

Conclusions: Overall survival was significantly improved for CB compared to C when measured from initial treatment. This likely reflects patient selection. Overall survival however from commencement of 2L or 3L anti-EGFR was not altered significantly by prior exposure to bevacizumab in this population based registry.

525P Efficacy of anti-EGFR antibodies combined with chemotherapy for elderly patients with RAS wild-type metastatic colorectal cancer: A systematic review and metanalysis

L. Belluomini[1], I. Carandina[1], F. Bonetti[2], B. Urbini[1], F. Daniel[1], F. Lancia[1], L.R. Martella[1], I. Toma[1], A. Moretti[1], E. Bannò[1], C. Nisi[1], L. Da Ros[1], A. Frassoldati[1]

[1]Medical Oncology, Azienda Ospedaliera di Ferrara St. Anna, Ferrara, Italy, [2]Internal Medicine, Azienda Ospedaliera di Ferrara St. Anna, Ferrara, Italy

Background: The incidence of Colorectal Cancer (CRC) increases with age, reaching a peak around 70-75 years. The anti-EGFR monoclonal antibodies combined with chemotherapy represent a valid option in patients with RAS wild-type (wt) metastatic CRC (mCRC), allowing a significant improvement in survival. However, few data are available regarding the use of these agents in the elderly population. The aim of the study is to evaluate the efficacy of adding anti-EGFR monoclonal antibodies (Cetuximab or Panitumumab) to chemotherapy in the treatment of RAS wt mCRC older patients.

Methods: A systematic review of the published data using PubMed and EMBASE databases and the congress documents of the main national and international symposia was performed. The random effect model was used to combine the effect estimates, the I^2 and Cochran's Q index to quantify the between-study heterogeneity unexplained by sampling error.

Results: Four randomized trials (two regarding Cetuximab and two Panitumumab combined with 5-FU based doublet chemotherapy) have been selected among the 2765 initially identified studies. None of the studies had been specifically designed for the elderly population, so PFS and OS HR values were extracted from pre-specified subgroup analyses. In our study, 605 elderly patients were included: 289 patients received only chemotherapy and 316 patients received chemotherapy in combination with anti-EGFR antibodies. The meta-analysis showed a statistically significant benefit of the combination of chemotherapy and anti-EGFR against chemotherapy alone both in terms of PFS (HR 0.79, IC 95% 0.64-0.98, p = 0.028, Q = 2.54, df = 3, I^2 = 0%) and OS (HR 0.82, IC 95% 0.68-0.98, p = 0.032, Q = 0.57, df = 3, I^2 = 0%). The subgroup-analyses confirmed that the Panitumumab studies had a major impact than Cetuximab ones on the final metanalysis result.

Conclusions: The addition of Cetuximab or Panitumumab to chemotherapy could represent a valid therapeutic option in terms of efficacy, also in elderly patients with RAS wt mCRC. However, the available data in this subset of patient are limited. Dedicated studies are needed in order to determine the best therapeutic strategy.

526P Efficacy of panitumumab and cetuximab in elderly patients (aged ≥75) with chemotherapy-refractory wild-type KRAS exon 2 metastatic colorectal cancer (mCRC): Retrospective analysis of data from nationwide drug-reimbursement-access program

M. Swierkowski[1], A. Ptak-Chmielewska[2], A. Sliwczynski[3], T. Czeleko[3], Z. Teter[3], C. Szczylik[1]

[1]Department of Oncology, Military Insitute of Medicine, Warsaw, Poland, [2]Institute of Statistics and Demography, Warsaw School of Economics, Warsaw, Poland, [3]Warsaw, National Health Fund, Warsaw, Poland

Background: Panitumumab and cetuximab are standards of treatment for chemotherapy-refractory, wild-type KRAS exon 2 mCRC patients. There are limited data on efficacy of these drugs in elderly patients.

Methods: Data were obtained from 2425 patients enrolled into nationwide Panitumumab/Cetuximab Reimbursement-Access Program ongoing in 62 Polish cancer centres. All reported patients were included to analyses from April 2012 to December 2015. Key inclusion criteria to the program: mCRC, refractory to chemotherapy (5FU, oxaliplatin, irinotecan), aged ≥18 years, wild-type KRAS exon 2 tumour status, measurable disease, ECOG performance status 0-2. Inclusion and exclusion criteria were the same for panitumumab and cetuximab therapy in all centres. Pre-planned, uniform schedule of efficacy assessment (every 12 weeks) was applied from start of therapy in all centres. Individual patients data concerning efficacy outcome measures were entered prospectively via electronic system into databases of public, national payer - National Health Fund (NFZ). We performed retrospective analysis using Kaplan-Meier method to assess overall survival (OS) and progression-free survival (PFS). OS and PFS were compared by log-rank test between patients aged <75 and ≥75.

Results: Out of 2425 patients, 247 were aged ≥75 years (10%) (165 patients received panitumumab and 82 received cetuximab). In panitumumab group, median OS was comparable in younger and older patients, 9.9 vs 9.6 months, respectively (HR, 1.07; 95% CI: 0.87-1.31; p = 0.5121), as was median PFS, 5.5 vs 5.8 months (HR, 1.08; 95% CI: 0.85-1.38; p = 0.5206) (n = 994 vs n = 130). In cetuximab group, median OS was also comparable in younger and older patients, 10.2 vs 9.9 months, respectively (HR, 0.95; 95% CI: 0.73-1.23; p = 0.6749), as was median PFS, 5.2 vs 5.2 months (HR, 0.92; 95% CI: 0.67-1.30; p = 0.6352) (n = 559 vs n = 60).

Conclusions: Panitumumab and Cetuximab provide similar efficacy outcomes in younger and older patients in everyday practice.

527P Toxicity and efficacy of flat-dosed versus body-surface area (BSA)-dosed capecitabine

F.M. Man[1], G.D. Veerman[1], E. Oomen-De Hoop[1], E. Meerten[1], T. van Gelder[2], R.H.J. Mathijssen[1]

[1]Medical Oncology, Erasmus MC Cancer Institute, Rotterdam, Netherlands, [2]Hospital Pharmacy, Erasmus MC, Rotterdam, Netherlands

Background: Capecitabine (cape) is a pro-drug for the cytotoxic agent 5-fluorouracil and widely used in the treatment of colorectal cancer. In general, cape is dosed on body surface area (BSA), despite all drawbacks of this dosing strategy. In this study, toxicity and efficacy of flat-dosed cape (i.e. without adjustments for body size) was analysed, and compared to BSA-dosed cape.

Methods: All patients treated with cape at our center between 2003-2015 were included when they had been treated with flat-dosed cape and no prior treatment with fluoropyrimidines. Data on adverse events and survival was collected. Cape-specific toxicity (CS_{tox}) was defined as toxicity grade for diarrhea ≥ 3, hand-foot syndrome ≥ 2 and neutropenia ≥ 2. Clinical relevant toxicity (CR_{tox}) consisted of hospital admission, dose delay, reduction or discontinuation. Patients were divided per treatment in 3 groups based on BSA-quartiles: lowest 25%, middle 50% and highest 25%, corrected for sex. Toxicity was compared using the X^2-test and binary logistic regression analysis. Survival analysis was done by the Kaplan-Meier method.

Results: Among 1952 evaluated patients; 1055 patients were included (60% male). Three regimes were evaluated: cape-radiotherapy (CRT, n = 769), cape-oxaliplatin (CAPOX, n = 189) and cape monotherapy (MONO, n = 97). The mean dose of flat-dosed cape was 7.1% lower compared to BSA-dosed cape (p < 0.01). CS_{tox} and CR_{tox} occurred in 20% and 27% of patients, respectively. The X^2-test per BSA-group showed no difference in CS_{tox} and CR_{tox} in CAPOX and MONO (p > 0.05), for CRT there was

a difference in CS_{tox} ($p = 0.009$) and CR_{tox} ($p = 0.014$). Corrected for sex, age and renal function, only in the CRT group BSA predicted CS_{tox} (OR: 0.248, 95% CI: 0.072-0.857, $p = 0.028$) and CR_{tox} (OR: 0.246, 95% CI: 0.083-0.727, $p = 0.011$). Survival analyses for CAPOX and CRT showed no differences between BSA-groups and median survival was comparable to literature.

Conclusions: Flat-dosed cape is safe in CAPOX and MONO. Only in CRT, BSA is predictive for CS_{tox} and CR_{tox}. No survival differences could be identified in subgroups. Therefore, flat-dosed cape is a safe and effective dosing strategy in regimens without RT.

528P Efficacy of panitumumab and cetuximab in patients with chemotherapy-refractory wild-type KRAS exon 2 metastatic colorectal cancer (mCRC): Retrospective analysis of data from nationwide drug-reimbursement-access program

M. Swierkowski[1], A. Ptak-Chmielewska[2], A. Sliwczynski[3], T. Czeleko[3], Z. Teter[3], C. Szczylik[1]

[1]Department of Oncology, Military Insitute of Medicine, Warsaw, Poland, [2]Institute of Statistics and Demography, Warsaw School of Economics, Warsaw, Poland, [3]Warsaw, National Health Fund, Warsaw, Poland

Background: Panitumumab and cetuximab are standards of treatment for chemotherapy-refractory, wild-type KRAS exon 2 mCRC patients. There are limited data on efficacy of these drugs in everyday practice on national level.

Methods: Patients enrolled into nationwide Panitumumab/Cetuximab Reimbursement-Access Program ongoing in Polish cancer centres. All reported patients were included to analyses from April 2012 to December 2015. Key inclusion criteria to the program: mCRC, refractory to chemotherapy (5FU, oxaliplatin, irinotecan), wild-type KRAS exon 2 tumour status, measurable disease, ECOG performance status 0-2. Inclusion and exclusion criteria were the same for panitumumab and cetuximab therapy in all centres. Pre-planned, uniform schedule of efficacy assessment (every 12 weeks) was applied from start of therapy in all centres. Individual patients data concerning efficacy outcome measures were entered prospectively via electronic system into databases of public, national payer - National Health Fund (NFZ). We performed retrospective analysis using Kaplan-Meier method to assess overall survival (OS) and progression-free survival (PFS). Objective response rate (ORR) was also reported.

Results: As of April 2012, 2425 patients were enrolled into the program in 62 cancer centres (1527 patients received panitumumab and 898 received cetuximab). Median follow-up was 17.9 months for panitumumab and 25.3 months for cetuximab. Median OS was 9.9 months (95% CI 9.4-10.5) with panitumumab and 10.2 months with cetuximab (95% CI 9.5-10.9). There was no OS significant difference between groups ($p = 0.09$). Median PFS was 5.6 months (95% CI 5.5-5.7) with panitumumab ($n = 1124$) and 5.2 months (95% CI 4.9-5.4) with cetuximab ($n = 619$). There was no PFS difference between groups ($p = 0.16$). ORR was 16% in panitumumab and 13% in cetuximab group.

Conclusions: Panitumumab and Cetuximab provide similar efficacy outcomes in everyday practice in one health care system. Reimbursement, centralized drug-access programs may serve as a source of data for survival analysis on national level.

529P Multicenter randomized phase II trial (BEVATOMOX) assessing the raltitrexed, oxaliplatin and bevacizumab combination versus FOLFOX6 bevacizumab as 2nd line treatment in metastatic colorectal cancer (mCRC)

E. Samalin[1], H. Senellart[2], S. Thezenas[3], S. Jacquot[4], S. Ellis[5], F. Khemissa[6], M. Ramdani[7], F. Portales[1], E. Assenat[1], T. Mazard[1], L. Mineur[8], M. Ychou[1]

[1]Medical Oncology, ICM Regional Cancer Institute of Montpellier, Montpellier, France, [2]Medical Oncology, ICO Institut de Cancerologie de l'Ouest René Gauducheau, Saint-Herblain, France, [3]Biometrics Unit, ICM Regional Cancer Institute of Montpellier, Montpellier, France, [4]Medical Oncology, Centre de Cancérologie du Grand Montpellier, Montpellier, France, [5]Radiotherapy Department, Centre Catalan d'Oncologie, Perpignan, France, [6]Department of Hepatology Gastroenterology, CH Perpignan, Saint Jean Hospital, Perpignan, France, [7]Gastroenterology Department, CH de Béziers, Béziers, France, [8]Radiotherapy and Oncology GI and Liver, Institut Sainte Catherine, Avignon, France

Background: The FOLFOX-Bev combination as 2nd line after Irinotecan-based chemotherapy (CT) failure is efficient in mCRC treatment, independently of the tumour RAS status. The Raltitrexed-Oxaliplatin (TOMOX) combination is reported with acceptable toxicity in mesothelioma patients (pts). Our multicentre randomized phase II study assessed the 6-month progression-free survival (6-PFS) of the TOMOX-Bev combination as 2nd line treatment in mCRC pts.

Methods: Pts OMS≤2 with histologically-proven mCRC, resected/asymptomatic primary tumor, unresectable metastases, and progressive metastatic disease (RECIST) after Irinotecan-based CT, were randomized (1:2) receiving either FOLFOX6 plus Bev (C arm, Bev IV 5mg/kg, then FOLFOX6 D1=D15, 12 cycles) or TOMOX plus Bev (Exp arm, Bev IV 7.5mg/kg, Raltitrexed IV 3mg/m^2 according to creatinine clearance, then Oxaliplatin 130mg/m^2 IV, D1=D21, 8 cycles). Primary endpoint was the 6-PFS. Main secondaries were toxicity, objective response and overall survival (OS). 92 pts, 30 and 62 in the C and Exp arms, were to be recruited.

Results: Due to low accrual rate, 83 pts (63.9% men) were included between 07.2011 and 05.2016, 33 and 50 in the C and Exp arms. Median age was 66 years (48-82). Primary tumour was localized in the left (48.2%) and right colon (37.3%) or rectum (18.1%), resected in 72.3% (36% with adjuvant CT). All pts (RASmt 54.2%) were pretreated with FOLFIRI, combined with anti-EGRF (7%) or Bev (92%). Median numbers of study treatment cycles were 8 and 4 in the C and Exp arms. Major grade 3-4 toxicities (C and Exp arms) were mucositis (12.1 *vs* 12.5%), paresthesia (0 *vs* 6.3%), hand-foot syndroma (3 *vs* 0%) and neutropenia/febrile (6.1/3 *vs* 8.2/2%). The 6-PFS rates were 51.5% (95%CI: 36-67) and 38% (95%CI: 26-51) in the C and Exp arms, and median OS was 11.1 (9.5-16.4) and 9.3 (5.7-11.6) months, respectively. In the Exp arm, OS was longer in pts with left colon tumour *vs* right (11.1 vs 4.6 months).

Conclusions: The TOMOX-Bev combination is feasible as 2nd line treatment in mCRC pts with acceptable toxicity. We cannot conclude in terms of efficacy due to low accrual rate. We confirm a longer OS in pts with left colon tumour.

530P Safety analysis of phase Ib study of FOLFOXIRI plus ramucirumab as first-line therapy for patients with metastatic colorectal cancer

H. Taniguchi[1], Y. Kito[2], H. Satake[3], Y. Horie[4], T. Yamada[5], T. Esaki[6], T. Denda[7], K. Mori[8], K. Yamazaki[9]

[1]Department of Clinical Oncology, Aichi Cancer Center Hospital, Nagoya, Japan, [2]Department of Medical Oncology, Ishikawa Prefectural Central Hospital, Kanazawa, Japan, [3]Department of Medical Oncology, Kobe City Medical Center General Hospital, Kobe, Japan, [4]Department of Clinical Oncology, St. Marianna University School of Medicine, Kawasaki, Japan, [5]Division of Gastroenterology, University of Tsukuba, Tsukuba, Japan, [6]Department of Gastrointestinal and Medical Oncology, National Kyushu Cancer Center, Fukuoka, Japan, [7]Division of Gastroenterology, Chiba Cancer Center Hospital, Chiba, Japan, [8]Clinical Research Center, Shizuoka Cancer Center, Shizuoka, Japan, [9]Division of Gastrointestinal Oncology, Shizuoka Cancer Center, Shizuoka, Japan

Background: Ramucirumab (Rmab), an anti-VEGFR-2 antibody, inhibits VEGF-A, -C, -D binding and endothelial cell proliferation, although bevacizumab (Bmab) binds to and blocks circulating VEGF-A. We conducted a phase Ib study to determine the recommended phase II dose (RP2D) of FOLFOXIRI plus Rmab for metastatic colorectal cancer (mCRC) patients.

Methods: The eligibility criteria included patients with histologically confirmed unresectable colorectal adenocarcinoma, aged 20-75 years, ECOG PS 0-1 (patients > 70 years were eligible if their ECOG PS was 0), wild-type or heterozygous UGT1A1 *28 or *6, no history of prior chemotherapy, and adequate organ function. Three dose levels were planned as follows; oxaliplatin and Rmab dose was fixed at 85 mg/m^2 and 8 mg/kg, respectively. Level 1: 5-fluorouracil (5-FU) 3200 mg/m^2, irinotecan (IRI) 165 mg/m^2, Level 0 as starting dose: 5-FU 2400 mg/m^2, IRI 150 mg/m^2, and Level -1: 5-FU 2400 mg/m^2, IRI 120 mg/m^2. Patients were enrolled with a 3 + 3 design manner to evaluate the dose-limiting toxicity (DLT) in the first cycle.

Results: From September 2016 to February 2017, we enrolled a total of 10 patients (4 patients in the Level 0 and 6 patients in the Level 1). The patients' characteristics were as follows: median age (range), 64 (44-68); male/female, 6/4; ECOG PS 0/1, 8/2; RAS wild/mutant, 1/9; UGT1A1 *1*1/*1*28, 4/6. One patient was excluded for the DLT evaluation due to lack of safety evaluation on cycle 1 day 8. No DLT was observed in the 9 DLT-evaluable patients. In the first cycle, major adverse events were G 4 neutropenia ($n = 2$), G 3 neutropenia ($n = 1$), G 3 hypertension ($n = 1$), G 1/2 diarrhea ($n = 6$), G 1/2 anorexia ($n = 3$), G 2 allergic reaction ($n = 1$), G 1 fatigue ($n = 4$), G 1 peripheral neuropathy ($n = 4$), G 1 nausea ($n = 2$) and G 1 stomatitis ($n = 2$). G-CSF was administered in 2 patients during the first cycle.

Conclusions: The RP2D for FOLFOXIRI plus Rmab was determined at the Level 1. A randomized phase II study of FOLFIRI plus Rmab versus FOLFOXIRI plus Rmab for chemotherapy-naïve mCRC patients (WJOG9216G trial; UMIN000026527) is ongoing. The update results will be presented in the congress.

531P Prognostic factors and specific populations in the pharmacogenetic randomized phase II trial of FOLFIRI with high-dose (HD) of irinotecan vs standard doses in metastatic colorectal cancer (mCRC) patients (pts) according to UGT1A1 genotype

M. Tobeña[1], D. Paez[1], A. Sebio Garcia[1], J. Fernandez-Plana[2], M. Martín[1], A. Virgili[1], L. Cirera[2], P. Riera[3], I. Sullivan[1], J. Salazar[3]

[1]Medical Oncology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [2]Medical Oncology, Hospital Mutua de Terrassa, Terrassa, Spain, [3]Genetics, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background: Pts with a favourable UGT1A1 genotype (homozygous wild type *1/*1 and heterozygous *1/*28) can be treated with HD of irinotecan without significant adverse events. This randomized phase II trial aimed to evaluate the efficacy and safety of FOLFIRI regimen with HD of irinotecan (HD-FOLFIRI) in mCRC pts. Pts genetically at risk for toxicity (*28/*28) were excluded. Potential prognostic factors and specific population subgroups are presented.

Methods: Chemotherapy-naïve patients with the UGT1A1 *1/*1 or *1/*28 genotypes were randomized to receive HD-FOLFIRI vs FOLFIRI every two weeks. Irinotecan doses for UGT1A1 *1/*1 and *1/*28 pts in the experimental group were 300mg/m^2 and 260mg/m^2 respectively. The standard irinotecan dose of 180mg/m^2 was administered in the control group. Main clinical-pathological characteristics and clinical outcomes of pts included were analysed.

Results: Between Jun-12 and Oct-16 82 pts were included. The ORR was significantly higher in the experimental group (67.5% vs 43.6%; p = 0.001). There were not interactions between ORR and clinical characteristics (sex, age, ECOG, tumour location, synchronous disease) and RAS/BRAF status. However, when BRAF mutation was considered, no objective response was observed in the control group compared with 41.7% of pts treated with HD-FOLFIRI (p = 0.003). Metastatic surgical resection was performed in 15 pts (22.5% in HD-FOLFIRI and 15.4% in FOLFIRI) and was associated with ORR (29.5% vs 5.7%; p = 0.007). Median PFS and OS were 8.6 and 26 months (m) (HD-FOLFIRI) and 8.2 and 29 m (FOLFIRI). ECOG 0/1(9.9 vs 7.2 m) and metastatic resection (15.5 vs 7.8 m) were significantly associated with PFS. In terms of OS pts with metastatic surgery (not reach vs 18.4 m) achieved better outcome. Multivariate analysis showed significant association between metastatic resection with both, PFS and OS.

Conclusions: These data confirm the safety of chemotherapy with HD of irinotecan and demonstrate that such strategy improves ORR, which may, in turn, impact favourably on pts survival, especially in those with poor prognosis.

532P Analysis of efficacy and prognostic factors in second-line chemotherapy for BRAF V600E mutant metastatic colorectal cancer

S. Mitani[1], H. Taniguchi[1], K. Honda[1], T. Masuishi[1], Y. Narita[1], S. Kadowaki[1], T. Ura[1], M. Ando[1], M. Tajika[2], K. Muro[1]

[1]Department of Clinical Oncology, Aichi Cancer Center Hospital, Nagoya, Japan, [2]Department of Endoscopy, Aichi Cancer Center Hospital, Nagoya, Japan

Background: *BRAF V600E* mutant (MT) metastatic colorectal cancer (mCRC) has distinct clinicopatholigical features and extremely poor prognosis. First-line chemotherapy was studied in reports assessing cytotoxic doublets or triplets with or without antibodies, but treatment outcomes of second-line chemotherapy were still unknown. The aim of this study is to examine the efficacy of second-line chemotherapy and evaluate prognostic factors in *BRAF V600E* MT patients (pts).

Methods: We retrospectively reviewed *BRAF V600E* MT mCRC pts who underwent second-line chemotherapy between 2007 and 2016. *BRAF* status was examined by PCR-based assay.

Results: Of 71 *BRAF V600E* MT pts, 51 received second-line chemotherapy. Before second-line chemotherapy, baseline patient characteristics were as follows: median age (range), 59 (28–86) years; male/female, 20/31; Eastern Cooperative Oncology Group (ECOG) performance status (PS) 0/1/≥2, 17/28/6; histology low, intermediate/high grade or mucinous status, 34/17; primary tumor location right/left side, 29/22; metastatic site liver/peritoneum, 29/35; metastatic sites 1/≥2, 11/40; and Glasgow Prognostic Scale (GPS) 0/1/2, 23/14/12. As first-line chemotherapy, 48 pts (94%) received oxaliplatin- or irinotecan-based regimens, including 5 (10%) who received FOLFOXIRI. In second-line chemotherapy, 39 pts (76%) received oxaliplatin- or irinotecan-based regimens. Median progression-free survival (PFS) and overall survival (OS) were 2.5 and 6.2 months (M). Overall response and disease control rates were 7% and 43%. All regimens achieving partial responses were BRAF inhibitors in combination with anti-EGFR bodies. Therefore, response rate was 0% if 4 pts treated with trial drugs were excluded. Multivariate analyses for both PFS and OS showed that GPS was an independent prognostic factor. Median OS in pts with GPS 0, 1, and 2 was 10.0, 5.0, and 1.6 M, respectively.

Conclusions: We revealed the dismal results of second-line chemotherapy in *BRAF V600E* MT mCRC pts. GPS can predict the treatment outcomes and identify pts unfit for chemotherapy, indicating that GPS is useful in future clinical trials targeting *BRAF V600E* mutation.

Background: Deficient Mismatch Repair (dMMR) and/or microsatellite instability-high colorectal cancers (CRC) represent 12% of all tumors. dMMR non-metastatic CRC are associated with good prognosis but also with resistance to adjuvant 5FU. dMMR metastatic CRC (mCRC) is found in 5% and its influence on prognosis and chemosensitivity is little known.

Methods: This multicenter study included patients with dMMR mCRC treated between 2005 and 2015 in 18 French centers. The Kaplan-Meier method was used to calculate overall survival (OS) and progression-free survival (PFS). Prognostic variables were evaluated in univariate (Log rank test) and multivariate analyses (Cox regression model).

Results: 284 patients with dMMR mCRC were included. Lynch syndrome was found in 43% and *BRAF* mutation in 32%. Median OS was 25.0 months. Peritoneal carcinomatosis (p < 0.01) and surgery of metastasis (p < 0.01) were associated with OS in multivariate analysis but not *BRAF* mutation and Lynch syndrome. 37% of patients had surgery of metastasis, 79% received first-line chemotherapy (palliative or perioperative), 46% second-line, 16% third-line. First-line regimens were 5FU-based (n = 20), oxaliplatin-based (n = 106) or irinotecan-based (n = 82) without or with anti-VEGF (n = 71) or anti-EGFR (n = 34). Median PFS on first-line chemotherapy was 5.7 months and in multivariate analysis only surgery of metastasis was associated with PFS (p < 0.01). Median PFS and OS on palliative first-line chemotherapy (n = 149) were 3.9 months and 17.9 months. Median PFS (3.9, 4.4 and 3.0 months, p = 0.20) and OS (17.9, 16.8 and 23.9 months, p = 0.14) were not different according chemotherapy regimen (5FU-based, oxaliplatin-based and irinotecan-based). The addition of bevacizumab or anti-EGFR therapy were associated with a non-significant increased of PFS as compared to chemotherapy alone (4.6, 6.0 and 3.5 months, p = 0.06). In second-line, median PFS and OS were 3.5 months and 15.8 months. In third-line, median OS was 6.3 months.

Conclusions: This study suggests that dMMR mCRC are associated with poor prognosis with conventional chemotherapy with or without bevacizumab or anti-EGFR. Only surgery of metastasis was associated with better PFS.

534P Exploratory analysis of baseline microsatellite instability (MSI) status in patients with metastatic colorectal cancer (mCRC) treated with regorafenib (REG) or placebo in the phase 3 CORRECT trial

K. Köchert[1], G. Beckmann[2], M. Teufel[3]

[1]Genomics and Biomarker Statistics, Bayer AG, Berlin, Germany, [2]Bioinformatics, Bayer AG, Berlin, Germany, [3]Translational Medicine Oncology, Bayer HealthCare Pharmaceuticals, Whippany, NJ, USA

Background: A high degree of MSI (MSI-H) has been associated with a good prognosis in early-stage CRC. However, emerging evidence suggests that MSI-H patients may have a worse response to chemotherapy in the metastatic setting. Here, we evaluate

survival outcomes by baseline MSI status in patients with mCRC in the CORRECT phase 3 trial.

Methods: CORRECT was an international, multicenter, placebo-controlled trial of 760 patients with treatment-refractory mCRC. Patients were randomized 2:1 to receive oral REG 160 mg or placebo once daily for Weeks 1–3 of each 4-week cycle. Subgroup analysis included patients in the safety population (≥1 dose of study drug) who consented to genetic biomarker studies and from whom archival tissue was available. Next-generation sequencing of archival tumor was performed using the FoundationONE gene panel (Foundation Medicine, Cambridge, MA). Overall survival (OS) and progression-free survival (PFS) by MSI status and its potential interaction with treatment were assessed by a Cox proportional hazards model and Kaplan–Meier analysis.

Results: Archival tumor tissue was available for 229 of the 760 randomized patients (Table). Of the 229 patients, 42 (18%) were MSI-H and 187 (82%) were non-MSI-H, 62% were male, 57%/43% were ECOG performance status 0/1, 58% had a KRAS mutation, and 3% had a BRAF mutation. Although there was less clinical benefit in patients in the MSI-H subgroup, no significant association was detected between MSI status and treatment interaction with OS or PFS in the multivariate analysis (P = 0.15).

Table: 534P

	MSI-H (n = 42)	Non-MSI-H (n = 187)
Regorafenib, n (%)	27 (64)	114 (61)
Placebo, n (%)	15 (36)	73 (39)
Overall survival, HR (95% CI)	0.97 (0.45, 2.07)	0.78 (0.53, 1.15)
Progression-free survival, HR (95% CI)	0.78 (0.39, 1.56)	0.48 (0.35, 0.67)

CI, confidence interval; HR, hazard ratio

Conclusions: This retrospective exploratory analysis of a small subgroup of patients with mCRC from CORRECT shows a prevalence of MSI-H at ~15-20% and no interaction between MSI status and REG treatment benefit. Due to small sample sizes in the subgroups no firm conclusions can be drawn and further studies are necessary to assess the correlation of MSI status with REG clinical benefit.

535P Investigation of MSI status in acquired resistance to 5-fluorouracil treatment in colorectal cancer using a SILAC-based quantitative proteomic analysis method

M. Ortega Duran, S. Shnyder, C. Sutton, S-U. Shaheed

Institute of Cancer Therapeutics, University of Bradford, Bradford, UK

Background: Colorectal cancer (CRC) still has a 45% mortality rate, and one of the barriers to therapeutic success is the development of acquired resistance to 5-fluorouracil (5-FU), the most commonly used drug in CRC treatment. Here we establish cell culture models and use state of the art proteomics methods to increase our understanding of how CRC cells develop resistance to 5-FU.

Methods: We develop 5-FU resistant CRC sublines with different microsatellite stability (MSS) profiles, since MSS is a key genetic alteration in CRC formation, and aim to use these to identify new biomarkers of 5-FU response. 5-FU resistant sublines for 2 cell lines, DLD-1 (microsatellite instability phenotype (MSI)) and HT-29 (MSS), were developed by continuous 5-FU exposure, and resistance fold changes of 130.2 and 3.5 respectively were achieved. Once 5-FU resistant sublines were developed they were analysed proteomically using a stable isotope labelling with amino acids in cell culture SILAC-approach and Orbitrap Fusion™ Tribrid™ Mass Spectrometry analysis, to identify new biomarkers of drug resistance.

Results: A total of 3003 proteins were commonly quantified in the parent cell lines (low and high passage numbers), and in the DLD-1 5-FU and HT 29 5-FU resistant sublines. Six proteins were seen to be significantly up-regulated, and eight down-regulated, in both 5-FU resistant sublines when compared to the parent cell lines.

Conclusions: This is the first use of a proteomics approach to study protein expression changes in 5-FU resistant CRC cell lines with varying microsatellite stability status, while accounting for changes which occur in the parent lines over the duration of establishing the resistant sublines. We have identified protein changes that correlate both with acquired resistance and the MSI/MSS status, and validated these finding using immunodetection techniques. We are currently extending the CRC study to look at multiple resistance mechanisms for 5-FU with other commonly used CRC therapeutics, oxaliplatin and irinotecan.

Background: Anal Squamous Cell Carcinoma (ASCC) is a rare disease, but its incidence is markedly increasing. To date, in advanced ASCC, no standard regimen exists. We have previously published the potential role of DCF regimen. Among 8 advanced ASCC consecutive patients who relapsed after CRT, the DCF regimen induced a complete response in 4 patients, including 3 pathological complete responses. Thus, this study was designed to confirm the interest of DCF regimen in advanced ASCC patients.

Methods: A multicentre phase II trial was conducted among 25 hospitals in France. Main eligibility criteria were histologically proved unresectable locally advanced recurrent or metastatic ASCC, ECOG-PS <2, and being eligible for DCF. Patients received either 6 cycles of standard DCF or 8 cycles of modified DCF depending on age (> *vs.* < = 75 years-old) and ECOG-PS (0 *vs.* 1). The trial was set up based on a Simon's optimal two-stage design, allowing an early futility interim analysis amid the first 21 patients. The primary endpoint was the observed PFS rate at 12months from the first DCF cycle. A PFS rate above 25% was expected. With a unilateral alpha error of 5% and a statistical power of 90%, 66 evaluable patients had to be included.

Results: 66 patients were enrolled from September 2014 to January 2017. Median age was 60.05 years (range, 38-78) with female predominance (81.8%). 40 (60.6%) patients had locoregional involvement at enrolment, and the most frequent metastatic sites were liver (60.6%), distal lymph node (48.5%), and lung (36.4%). At interim analysis, 10 (47.6%) patients were progression-free at 12 months from the first DCF cycle. To date, 65 patients are assessable for response rate by investigators. The objective response rate is 87.7%, including 36.9% of complete responses. Among the first 32 patients with ≥12 months of follow-up, 15 (46.9%) patients were progression-free at 12 months.

Conclusions: This first ever conducted prospective trial in front-line advanced ASCC demonstrated a high long-lasting response rate of the DCF regimen. DCF regimen should then be considered as a standard of care in this situation.

537P P2 study of ADXS11-001 Immunotherapy in patients with persistent/recurrent, surgically unresectable locoregional, or metastatic squamous cell anal cancer

C. Eng[1], M. Fakih[2], M. Amin[3], V. Morris[1], H.S. Hochster[4], P.M. Boland[5], H. Uronis[6]

[1]Department of Gastrointestinal (GI) Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA, [2]Medical Oncology, City of Hope, Duarte, CA, USA, [3]Medical Oncology, Siteman Cancer Center, Washington University School of Medicine, St. Louis, MO, USA, [4]Yale University, Yale Cancer Center, New Haven, CT, USA, [5]Medical Oncology, Roswell Park Cancer Institute, Buffalo, NY, USA, [6]Medical Oncology, Duke Cancer Institute, Durham, NC, USA

Background: The number of new anal cancer (SCCA) cases in the US has been rising annually; 20% of patients (pts) will develop metastatic (met) disease, which presents an unmet medical need. A large population-based study showed 88% of SCCA were HPV+ and 73% had HPV-16 (Hoots et al IJC 2009). ADXS11-001 (ADXS) is an irreversibly attenuated Listeria monocytogenes immunotherapy that targets HPV-associated cancers. It is bioengineered to secrete an antigen-adjuvant protein fused to the E7 peptide of HPV-16. It allows the generation of tumor antigen specific cytotoxic T cells that infiltrate and destroy tumor cells. This is the 1st P2 trial to assess the efficacy/safety of ADXS in met SCCA.

Methods: This multicenter, open-label, 2-stage design trial (NCT02399813) includes pts ≥ 18 yrs with histologically confirmed, measurable SCCA and previous ≥ 1 line of therapy for advanced disease. Pts received IV ADXS monotherapy ($1x10^9$ colony forming units) every 3 weeks for ≤ 2 years or until a discontinuation criterion was met. Tumor assessments (RECIST 1.1) were every 9 wks. Interim analysis was planned on enrollment of 31 evaluable pts (≥ 1 post-baseline scan). An objective response rate (ORR) ≥ 10% or a 6-month progression free survival (PFS) ≥ 20% with tolerable safety would allow proceeding to Stage 2.

Results: Preliminary Stage 1 results are reported with data from 29 of the planned 31 evaluable pts. Median age 60 yrs, range 43-77; 27 F/2 M; median follow-up time 191 days. One pt (3.5%) had a durable partial response lasting > 6 months (after progression on prior anti-PD-1 therapy) and 7 pts had stable disease (24%). Disease control rate was 28%. The current KM 6-month PFS estimate is 22%. Common (≥ 30%) treatment related AEs (TRAEs) were grade 1-2 chills/rigors, fever, hypotension and vomiting. Grade 3 TRAEs of cytokine related syndrome (n = 1; SAE), infusion related reactions (n = 2; 1 SAE) and hypotension (n = 2; 1 SAE) were reported.

Conclusions: ADXS monotherapy showed promising activity and met the predefined 6-month PFS rate. Treatment was well-tolerated with mostly grade 1-2 infusion related AEs that resolved successfully with standard care. Further investigation is ongoing in this population.

538P Relationship between pretreatment levels of circulating DNA, circulating tumor cells, CEA, CA19.9 and tumor burden on CT scan in patients treated for a metastatic colorectal cancer

M. Hassine[1], C. Savoye-Collet[2], D. Sefrioui[1], L. Beaussire[3], A. Gillibert[4], A. Gangloff[1], N. Sarafan-Vasseur[3], P. Michel[1], F. Di Fiore[1]

[1]Gastroenterology, CHU Hôpitaux de Rouen-Charles Nicolle, Rouen, France, [2]Radiology, Rouen University Hospital, Rouen, France, [3]Institute for Biomedical Research and Innovation, Inserm U1245, University of Rouen, Rouen, France, [4]Biostatistics, Rouen University Hospital, Rouen, France

Background: Circulating DNA has been reported as prognostic in metastatic colorectal cancer (mCRC) but its correlation with tumor burden has never been clearly established. The aim was to evaluate the correlation between pretreatment levels of circulating tumor DNA (ctDNA), cell-free-DNA (cfDNA), circulating tumor cells (CTC), CEA, CA19.9 with tumor characteristics on CT scan.

Methods: It was a retrospective analysis from a prospective trial on circulating markers (ctDNA, cfDNA, CTC, CEA, CA19.9) at baseline in mCRC patients (NCT01212510). CT scans were centrally reviewed to assess 3 tumor parameters: the diameter using RECIST version 1.1, the total tumor length (TTL) defined as the sum of diameter of all visible lesions, and the volume (Vol) of the main lesion. Relationship between circulating markers and CT scan were analysed as well as progression-free survival (PFS) and overall survival (OS) and prognostic factors using Cox models.

Results: A total of 83 mCRC patients were included. Median baseline ctDNA, cfDNA, CEA, CA19.9 and CTC were 21 (0.12-74) %, 36 (6-2275) ng/mL, 75 (2-64051) ng/ml, 90 (4-70900) UI/mL, and 7 (1-194)/mL, respectively. For CT scan, median value was 81 (11-310) mm for RECIST, 196 (14-1906) mm for TTL and 65 (2-783) $mm^3$for Vol. There was a significant correlation between RECIST and CEA (p = 0.0005), CA19.9 (p = 0.007), cfDNA (p < 0.0001), ctDNA (p = 0.01), between TTL and CEA (p < 0.0001), CA19.9 (p = 0.0008), cfDNA (p < 0.0001), ctDNA (p < 0.0001) and between Vol and CEA (p = 0.008), CA19.9 (p = 0.02), cfDNA (p = 0.0015). The median PFS and OS were significantly increased in patients with low (< vs > to median) CA19.9 (8.8 vs 3.2 m., p = 0.03 and 16.4 vs 9 m., p = 0.01), ctDNA (8 vs 3 m., p = 0.006 and 18.3 vs 8.3 m., p = 0.0001). TTL was only associated with PFS (9 vs 3 m., p = 0.009) and RECIST and Vol with OS (15.3 vs 11.8 m., p = 0.04). In multivariate analysis, RECIST (p = 0.0004), CA19.9 (p = 0.004) and OMS performance status (p = 0.04) were prognostic for OS.

Conclusions: Circulating makers and tumor burden on CT scan were correlated and prognostic. Interventional studies are needed to evaluate the usefulness of circulating makers in decision making.

Spain, Cordoba, Spain, [14]Medical Oncology, Hospital de Lleida Arnau de Vilanova, Lérida, Spain, [15]Medical Oncology, Hospital Lucus Augusti, Lugo, Spain, [16]Medical Oncology, Hospital Universitario Marques de Valdecilla, Santander, Spain

Background: CTCs, *RAS* and *BRAF* mutations are prognostic factor in mCRC pts. The VISNÚ program was designed to explore the impact of FOLFOXIRI + bevacizumab in a high-risk mCRC group according to CTCs ≥3 (VISNÚ-1) and to compare the efficacy of bevacizumab or cetuximab associated to FOLFIRI in a low-risk group according to CTCs < 3 and RAS wild-type (VISNÚ-2).

Methods: Blood samples for CTCs enumeration by Cell Search® method (Menarini – Silicon Biosystems, Inc) were collected at baseline, and samples of tumor tissue were used to determine *KRAS-NRAS-BRAF-PIK3CA* mutations. This preliminary analysis shows the correlation among CTCs, molecular mutations and clinical characteristics by chi-square analysis.

Results: 1208 pts were screened for CTCs and RAS mutation and 590 of them were eligible for the VISNÚ program. In the screening population, CTCs ≥ 3 was found in 40.8%, RAS, BRAF and PI3K mutations were present in 51.4%, 7.5% and 11.3% of pts respectively. No correlation was found among CTCs and RAS, BRAF and PIK3CA mutations (p 0.29, 0.10 and 0.12 respectively). CTCs ≥ 3 was associated with worse ECOG, stage IV, liver, lung and bone metastases, > 2 metastatic sites and CEA levels > 5 ng/ml. RAS mutation correlated with worse ECOG, stage IV, liver, lung and bone metastases, > 2 metastatic sites and CEA levels > 5 ng/ml. BRAF mutation correlated with primary right colon location, and metastases in peritoneum, lymph nodes, bone and liver and high tendency for female (p = 0.058) (Table). PIK3CA mutation was only associated with right primary location and age > 65 years.

Table: 539P

Parameters	CTCs> 3 p value	RASmut p value	BRAFmut p value
ECOG	0.0069	0.002	–
Primary location	–	–	< 0.0001
Metastatic sites			
Liver	< 0.0001	0.01	0.02*
Lung	0.02	0.005	
Bone	0.0002	0.002	0.002
Peritoneum	–	–	0.004
Lymph nodes	–	–	0.005
N° organ involved	0.001	0.007	–
Stage at diagnosis	0.002	0.02	–
CEA levels	< 0.0001	0.02	–

*BRAF mutant less frequently associated to liver involvement

Conclusions: CTCs and RAS mutation are significantly associated with other clinical poor prognostic factors. The poor prognosis of BRAF-mutated tumors reported in the literature cannot be explained by its correlation with poor prognostic clinical characteristics.

Background: Liquid biopsy can represent an alternative to tissue biopsy for biomarker testing in cancer pts. In addition, liquid biopsy can be used to monitor the response to treatment and the molecular evolution of the disease.

Methods: In the CAPRI GOIM trial, KRAS exon 2 wild type (wt) mCRC pts received first line cetuximab plus FOLFIRI. Tumor samples were assessed by Next Generation Sequencing (NGS) with the Ion AmpliSeq™ Lung and Colon Cancer Panel (Thermofisher). Plasma samples at baseline (n = 96), at 3 weeks of treatment (n = 54), at 6 weeks (n = 14) and at progression of disease (n = 24) were collected from 96 patients and analyzed for exon 2, 3 and 4 KRAS and NRAS mutations using BEAMing Digital PCR (Sysmex Inostics).

Results: Analysis of basal plasma samples from the 96 pts included in this study showed a concordance of 79,2% with the tissue RAS status as defined by NGS. The 11 cases that were RAS mutant (mut) in tissue and wt in plasma had suboptimal plasma volume available for analysis (<3ml), and in 5 cases the only sites of recurrence were lung and/or lymph nodes. Among the 9 cases with wt tissue and RAS mut plasma, all but one had a mutant allelic frequency (MAF) <1%. Plasma samples at 3 weeks were available for 11 pts RAS mut in both tumor and plasma, 6 pts RAS wt in tumor and mut in plasma, and 30 pts with both tissue and plasma samples wt. Within pts with RAS mutations in both tumor and plasma, a significant reduction in plasma RAS MAF was observed in all cases at 3 weeks. However, an increase in RAS MAF was observed in all available samples (n = 4) at the progression of the disease. A reduction of MAF after 3 weeks of treatment was also observed in pts who had a RAS positive liquid biopsy with a negative tissue. Among pts with both tissue and plasma basal samples wt, RAS mutations were found in only 1 (3,3%) case after 3 weeks of treatment and in none of the 8 available plasma samples at 6 weeks.

Conclusions: These data suggest that liquid biopsy might better recapitulate the heterogeneity of mCRC and might be useful to monitor the response to therapy. Analysis are ongoing to evaluate the clinical significance of RAS mutations with low MAF.

541P Circulating cell-free DNA as predictor of treatment failure after neoadjuvant chemoradiotherapy before surgery in patients with locally advanced rectal cancer

J.V. Schou[1], B.S. Sørensen[2], F.O. Larsen[1], R. Abrantes[2], A. Boysen[3], J.S. Johansen[1], B. Vittrup Jensen[1], D. Nielsen[1], K-L. Spindler[3]

[1]Department of Oncology, Herlev Hospital, Herlev, Denmark, [2]Department of Experimental Clinical Oncology, Århus University Hospital, Århus, Denmark, [3]Department of Oncology, Århus University Hospital, Århus, Denmark

Background: Treatment of patients with locally advanced rectal cancer (LARC) is based on a combination of chemo-radiotherapy (CRT) and surgery. The rate of distant recurrences remains over 25% and biomarkers to detect treatment failure are urgently needed. Circulating cell-free DNA (cfDNA) in plasma is a mixture of normal and cancer specific DNA segments, and a promising biomarker in patients with colorectal cancer. Only few studies have examined the potential utility of cfDNA in LARC but suggest a correlation between cfDNA and the response to neoadjuvant CRT. The aim of our study was to investigate plasma cfDNA in patients with LARC treated with induction chemotherapy (ICT), CRT and surgery.

Methods: A total of 124 patients with LARC were prospectivily included at Herlev Hospital, Denmark, from 2010-14. Patients were treated with neoadjuvant CRT and 52 also received 1-3 cycles of ICT with CAPEOX. Total cfDNA levels were measured by direct fluorescent assay in plasma samples obtained at baseline, after ICT and after CRT. Mann-Whitney test, Kaplan-Meier plots and Cox regression analysis were used for statistical analyses. Disease free survival (DFS) was measured from start until distant recurrence or death from any cause.

Results: Median baseline level of cfDNA was 0.96 ng/μL (range 0.46-2.28). Baseline cfDNA did not differ between stage II & III disease (p = 0.15). Median follow-up was 54 months and 27.4% of the patients had distant recurrence during follow-up. When dividing patients in groups of cfDNA quartiles, increasing cfDNA levels were associated with impaired outcome. Patients with baseline cfDNA levels above the 75th quartile, had a higher risk of distant recurrence and shorter median RFS compared to those below, (HR 2.63; CI95%: 1.34-5.15; p = 0.008). The same applied to DFS (HR 1.97, CI95%: 1.09-1.97, p = 0.003). High cfDNA level after CRT was associated with an increased risk of distant recurrence (p = 0.052).

Conclusions: Our results demonstrate a strong correlation between high baseline level of cfDNA and increased risk of distant recurrence in patients with LARC treated with neo-adjuvant CRT. Consequently, cfDNA could hold potential for better pre-treatment risk assessment and as tool for individualized therapy in this setting.

CIBERONC Instituto de Salud Carlos III, Cordoba, Spain

Background: CRC cells evade EGFR blockade by several mechanisms of acquired resistance, mainly mutations in RAS, EGFR ECD, HER2 and MET. ctDNA is shed into the bloodstream by tumor cells and can be effectively used to track tumor heterogeneity and to evaluate acquired mutations at tumor progression.

Methods: We included mCRC pts treated in a phase II study of FOLFIRI + panitumumab in irinotecan-refractory mCRC. ctDNA was collected at the end of treatment, processed with the Oncomine colon ctDNA Assay, and sequenced in the PGM Ion Torrent NGS System. The detectable cutoff mutation was 0.1%. Subclonal mutations were defined as mutations with mutant allele fraction (MAF) $\leq$ 50% of the greatest somatic MAF in the sample. Baseline mutations were analyzed in tumor tissue by dPCR.

Results: ctDNA from 16 pts was analyzed. Clinical characteristics of pts were 69% male; median age 61.5 years; 75% left vs 25% right colon. At least one mutation was detected in 94% of pts (15/16); median mutations per sample was 2.5 (range 1 -13). The frequency of detected mutations was: 13 TP53, 3 APC, 1 CTNNB1, 15 KRAS, 8 NRAS, 7 EGFR, 4 BRAF, 4 PIK3CA, 4 MAP2K1, 1 GNAS, 1SMAD4. While TP53, APC, PIK3CA

and BRAF were most likely to be clonal, EGFR, MAP2K1, RAS were generally subclonal. All EGFR ECD mutations emerged in the left colon and all co-existed with RAS mutations plus at least one additional acquired mutation (median 6, range 3-11). RAS/BRAF mutations emerged in 100% and 66% of right and left colon respectively, and co-existed with other acquired mutations in 72% of cases (median 3, range 1-11) Best response was: PR 8 pts, SD 6 pts and PD 2. In both pts with PD only one acquired mutation was detected at progression (PIK3CA and KRAS respectively), and both mutations were detected in the matching pre-treatment tissue and plasma sample at low MAF. Pts follow-up is ongoing, correlation between mutational profile and response to treatment will be presented.

Conclusions: ctDNA analysis captured intrapatient heterogeneity that developed as a result of EGFR inhibition. All EGFR ECD mutations emerged in the left colon and always co-existed with several other mechanisms of acquired resistance, reflecting genomic complexity.

Background: FOLFOXIRI plus bev is a standard initial therapy for mCRC but toxic in Japanese patients (pts) due to frequent febrile neutropenia (FN). We performed a phase II trial to assess the safety and activity of 1st-line m-FOLFOXIRI plus bev for mCRC with RAS mt. In addition, pre-planned analysis of a number of genes in ctDNA during therapy that might be determinants of therapeutic efficacy was performed.

Methods: Pts with unresectable/measurable tumors received bev and m-FOLFOXIRI [irinotecan 150 mg/m^2, oxaliplatin 85 mg/m^2, levofolinate (LV) 200 mg/m^2, and fluorouracil 2400 mg/m^2 repeated biweekly]. After induction therapy for a maximum of 12 cycles, maintenance therapy with fluorouracil/LV plus bev was administered. The primary endpoint was objective response rate (ORR). Progression-free survival (PFS), overall survival, early tumor shrinkage (ETS), depth of response (DpR), and safety were secondary endpoints. Plasma samples for extraction of ctDNA were collected at 3 points (pre-, 8w, and progression) and analyzed for specific KRAS, NRAS, BRAF, and PIK3CA variants with real-time PCR assays.

Results: Sixty-two of 64 participants evaluable for efficacy had the following characteristics: median age 63, 55% male, 92% PS0, and 27% right-sided tumors. Median follow-up time was 7.9 months. ORR and disease control rate were 74.2% and 96.8%, respectively. ETS was 74%, and median DpR was 48%. Median PFS was not reached. Common grade 3 or 4 adverse events were neutropenia (49%), hypertension (22%), diarrhea (13%), and FN (4.8%). No treatment-related deaths occurred. Analysis of ctDNA from pre-treatment plasma confirmed mts in 72% (38/53) of pts. Absence of mt at 8w correlated with ORR regardless of mt status at pre-treatment [no mt; 80% (32/40), any mt; 45% (5/11), P = 0.05, t-test]; moreover, pts with PIK3CA mt at pre-treatment had a poor response (43%, 3/7).

Conclusions: m-FOLFOXIRI plus bev is active and feasible for Japanese mCRC pts with RAS mt. *KRAS*, *NRAS*, and *PIK3CA* mt in ctDNA were associated with response to the triplet plus bev and might potentially be used to predict outcomes.

544P The frequency of RAS mutation in circulating tumor DNA predicts worse survival in patients with mCRC

L. Yang[1], Y. Cai[1], J. Zhang[1], H. Hu[1], Z. Wu[1], R. Deng[1], Y. Deng[2]

[1]Medical Oncology, The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China, [2]Medical Oncology, The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background: RAS mutations predict a worse prognosis in metastatic colorectal cancer(mCRC). However, there are few findings regarding the prognostic value of RAS mutations in circulating tumor DNA (ctDNA). We aimed to compare the concordance of genomic alterations between ctDNA and tissue biopsies and assess the prognostic value of RAS mutations in ctDNA.

Methods: Gene mutational status in plasma and tissue were evaluated in mCRC patients by next-generation sequencing (NGS). Kaplan-Meier curve and Cox regression model were used to compare the progressive free survival (PFS) between different level of RAS mutations frequency.

Results: of NGS testing from tumor tissue and ctDNA from 110 sequential mCRC patients were compared. Analysis of 6 gene in baseline tissue and plasma samples showed a 67.3% overall agreement. Concordance between the two platforms for KRAS, NRAS, BRAF, PIK3CA, SMAD4 and FBXW7 mutations, were 80.0%, 98.2%,97.2%,91.8%,69.1%,93.6% and 96.4%, respectively. RAS mutation rate in tissue and ctDNA were 48.1% and 29.1%. Fifty-nine patients were detected RAS mutation in tumor tissue, only thirty-six patients with plasma RAS mutation. One patient was detected ctDNA RAS mutation without mutation in tissue. Across plasma RAS gene, sensitivity and specificity were 61.0% and 99.3%, respectively. With a 48.2% cut-off rate, we divided 59 tissue RAS mutation patients into two different ctDNA RAS mutation groups(high frequency and low frequency group. Median PFS in high frequency group was 1.9 months and in low frequency group was 4.8 months(P = 0.002). In multivariate analysis considering other clinical factors(i.e. synchronous or metachronous metastasis, solitary and multiple metastases and CEA level, high ctDNA KRAS mutation frequency was independent adverse prognostic factor (HR 4.09,95% CI 1.61-10.40,p=0.003) for PFS in tissue KRAS mutation patients.

Conclusions: Plasma and tissue NGS testing have a high concordance in genomic alterations. Higher rate of baseline KRAS mutation frequency predicts worse prognosis in mCRC. Both plasma and tissue NGS may be necessary to describe the complex biology of mCRC.Circulating tumor DNA testing could be a viable alternative for genotyping of mCRC and recommended for routine clinical practice.

545P Epidermal growth factor receptor (EGFR) copy number (CN) as a biomarker of prognosis and panitumumab (Pan) benefit in RAS-wt advanced colorectal cancer (aCRC)

J. Seligmann, H. Wood, S. Richman, F. Elliott, M. Taylor, E. Tinkler-Hundal, J. Barrett, M. Seymour, P. Quirke

Leeds Institute of Cancer and Pathology, University of Leeds, Leeds, UK

Background: Whilst RAS mutations predict which aCRC patients (pts) will not benefit from anti-EGFR agents, RAS-wt status does not reliably predict who will. Several studies report that high EGFR ligand expression (EREG/AREG) is predictive of anti-EGFR agent benefit but progression towards clinical utility is limited by lack of consensus on a clinical dichotomisation point and additional tumor material required. Here we explore EGFR copy number as a biomarker of prognosis and predictor of Pan benefit in a randomised trial in aCRC.

Methods: EGFR CN, EREG/AREG RNA expression, *RAS/RAF* mutations were assessed in tumor from 275 pts randomised to 2nd-line irinotecan (Ir) or IrPan (PICCOLO, *Lancet Onc* 14:749-59). EGFR CN status was measured by the Affymetrix OncoScan array, analysed using Biodiscovery Nexus software and defined as normal (2 copies) or gain (>2 copies). Prognostic analysis was in Ir alone pts. Predictive analysis, in the 234 *RAS*-wt pts, compared baseline values with outcomes using Cox proportional hazards models.

Results: 196 (71.3%) pts were classified as EGFR gain and 79 (28.7%) as normal. EGFR gain was significantly associated with high EREG and AREG RNA expression (both $p < 0.001$). EGFR gain was not prognostic for OS ($p = 0.97$) or PFS ($p = 0.98$). However, it was predictive of Pan benefit: in *RAS*-wt pts with EGFR gain, median PFS was 5.7 mo (IrPan) vs 3.7 mo (Ir) (HR = 0.60[0.43-0.83], $p = 0.002$), but pts with normal EGFR had no benefit: 3.4 mo (IrPan) vs 2.9 mo (Ir) (HR = 1.23[0.72-2.08], $p = 0.45$); interaction $p = 0.02$. Significant PFS biomarker/treatment interaction was also seen in all 275 pts, including *RAS* or *RAF* mutants ($p = 0.01$). In *RAS*-wt pts EGFR gain was associated with higher response rates than normal with IrPan (45.3% vs 18.7%, $p = 0.01$) but not with Ir (13.3% vs 12.9%, $p = 1.0$). Interaction was not significant ($p = 0.22$) or for OS ($p = 0.20$).

Conclusions: EGFR CN status may allow for further stratification for Pan benefit in *RAS*-wt patients. Normal EGFR CN status identified nearly 1/3 of pts without Pan benefit. This biomarker is consistent with EGFR ligand data, and is a DNA-based assay with a clearly definable dichotomised cut-point and therefore is of potential clinical utility.

Background: The CAPRI-GOIM trial consisted of two parts: FOLFIRI plus cetuximab in first line followed by cetuximab plus FOLFOX as second line treatment for molecularly selected mCRC pts. The primary endpoint was progression-free survival (PFS). Secondary endpoints included overall survival (OS), response rate and safety. This is an updated analysis providing the mature results for OS in KRAS, NRAS, BRAF, PIK3CA wt pts.

Methods: In the CAPRI-GOIM trial 340 mCRC pts with KRAS exon 2 wt tumors were treated in first line with FOLFIRI plus cetuximab until disease progression or unacceptable toxicity. After first line therapy progression, pts (157), who achieved a clinical response with first line treatment, were randomized to FOLFOX plus cetuximab (Arm A) or to FOLFOX (Arm B). Archival tissue samples from primary tumours were centrally assessed by next generation sequencing (NGS) with the Ion AmpliSeq Colon and Lung cancer panel. Here we report mature survival data at median follow-up of 69 months (m) (cut off date: April 30, 2017) for 98 out of the 124 RAS wt patients with NGS analysis, that were representative of the 340 intention to treat patient population.

Results: Median OS for these 98 pts was 34.0 m (95% CI 30.2–37.8) with PFS of 11.7 m (95% CI 10.3–13.1). Eighty six out of 98 pts had tumors that were KRAS, NRAS, BRAF, PIK3CA wt. In this cohort, OS was 35.8 m (95% CI 29.9–41.9) with PFS of 12.3 m (95% CI 10.7–14.0). PFS and OS were also evaluated according to tumour location (see Table for results).

Table: 546P

Cohort	Median OS (months)		Median PFS (months)	
	Right	Left	Right	Left
RAS wt (n = 98)	33.4 (31.7-34.9)	35.8 (29.9-41.7)	9.9 (7.9-12.0)	12.3 (11.0-13.6)
KRAS, NRAS, BRAF, PIK3CA wt (n = 86)	34.0 (22.1-46.0)	35.8 (29.5-42.3)	9.9 (5.3-14.6)	12.3 (10.7-14.0)

Conclusions: Long-term follow-up analysis of pts enrolled in the CAPRI-GOIM trial showed a median OS of approximately 36 m in KRAS, NRAS, BRAF and PIK3CA wt pts. A better prognostic outcome in terms of OS and PFS was observed in left-sided as compared to right-sided tumors.

CIBERONC Instituto de Salud Carlos III, Cordoba, Spain

Background: In metastatic colorectal cancer (mCRC) recent studies have shown the importance to accurately quantify low-abundance mutations of RAS pathway because response to anti-EGFR therapy may depend on certain mutation thresholds. We designed a clinical trial to compare clinical outcomes of patients selected with different analytical sensitivity thresholds for RAS/BRAF mutated alleles using a highly sensitive and quantitative technique of digital PCR (dPCR).

Methods: Hotspots including RAS (KRAS and NRAS exons 2/3/4) and BRAF (exon 15) were prospectively analyzed in tumour FFPE samples from 61 patients with mCRC included in the ULTRA trial. Patients had received one or two previous chemotherapy lines and were deemed resistant to irinotecan. Response rate (RR), progression-free survival (PFS) and overall survival (OS) were correlated with the mutational status based on three different cut-off points (0.1%, 1% and 5%).

Results: The overall RR was 51.7% and comparative analysis of clinical outcomes translated into a differential progression free survival (PFS), response rate (RR) and progression disease (PD) in the different cohorts defined by the 3 selected analytical sensitivity cut-off points (Table). PFS prediction was higher when we considered a threshold of 5% in RAS/BRAF scenario (HR mut vs wt = 3.85; CI95% [1.16-12.82], $p = 0.018$).

Conclusions: Optimal sensitivity RAS/BRAF mutational analysis cut-off for clinical outcome prediction lies between 1 and 5% (closer to 5%). Increasing analytical sensitivity worsens patient's selection. Further sensitivity threshold comparative analysis will define an optimal cut-off.

Table: 547P

			Highly-sensitive digital PCR		
			cut-off 0.1%	**cut-off 1**%	**cut-off 5**%
RAS + BRAF	mut/wt (n/n)		14/47	8/53	3/58
	RR % (mut/wt)		46.2/52.1	37.5/52.8	33.3/51.7
	SD % (mut/wt)		46.2/33.3	50.0/34.0	33.3/36.2
	PD % (mut/wt)		7.7/12.5	12.5/11.3	33.3/10.3
	PFS months	median (mut/wt)	9.3/7.6	7.4/7.6	4.0/8.8
		HR (mut vs wt)	0.82	0.77	3.85

548P Prognostic impact of BRAF and KRAS mutations according to the consensus molecular subtypes of colorectal cancer

J. Smeby[1], A. Sveen[1], C.H. Bergsland[1], J. Bruun[1], M. Merok[2], S.A. Danielsen[1], M. Hektoen[1], M. Eknæs[1], I.A. Eilertsen[1], M. Grønlie Guren[3], A. Nesbakken[4], R.A. Lothe[1]

[1]*Department of Molecular Oncology, Oslo University Hospital, Oslo, Norway,* [2]*Department of Gastroenterological Surgery, Akershus University Hospital, Lørenskog, Norway,* [3]*Department of Oncology, Oslo University Hospital, Oslo, Norway,* [4]*Department of Gastroenterological Surgery, Oslo University Hospital, Oslo, Norway*

Background: In the present study we report the distribution and prognostic impact of KRAS and BRAF mutations according to microsatellite instability (MSI) status and consensus molecular subtypes (CMS) in colorectal cancer (CRC).

Methods: A total of 1197 primary tumor samples from a consecutive series of patients treated surgically for stage I-IV CRC at Oslo University Hospital, Norway, were included in the study. Comprehensive clinical and pathological data were prospectively collected for all patients. Mutation analyses were performed for hotspots in KRAS (exon 2: codon 12 and 13, exon 3: codon 61) and BRAF (exon 15: codon 600) and MSI-status was determined. A subset of samples were analyzed for gene expression using exon-level microarrays and classified according to the CMS groups of CRC, with confident classification obtained in 317 samples. To increase the number of samples with CMS classification the analysis was supplemented with gene expression data for 514 patients in the publically available dataset GSE39582, including also MSI status, BRAF and KRAS mutation status, as well as clinical data. Gene expression signatures previously shown to be associated with BRAF and KRAS mutations, respectively, were used to evaluate differential impact of mutations on gene expression among CMS groups.

Results: $BRAF^{V600E}$ and KRAS mutations are shown to have inferior relapse-free survival in MSS tumors exclusively (BRAF mut vs KRAS/BRAF wt: Hazard ratio (HR) 2,35 (1,71-3,22); $p < 0,001$ and KRAS mut vs KRAS/BRAF wt: HR 1,23 (1,01-1,49); $p = 0,044$). Stratifying the survival analysis according to CMS groups reveals the negative prognostic impact of $BRAF^{V600E}$ mutations to be specific to MSS tumors in CMS1 (BRAF mut vs wt: HR 4,96 (1,74-14,12); $p = 0,003$), while KRAS mutations are associated with poor prognosis distinctively in MSS tumors in CMS2 (KRAS mut vs wt: HR 1,60 (1,11-2,30); $p = 0,011$). Further, the effects of BRAF and KRAS mutations on gene expression signatures are shown to vary according to MSI-status and CMS subtype, substantiating the subtype-specific prognostic associations.

Conclusions: *$BRAF^{V600E}$* mutations have poor prognostic value specific to MSS tumors in CMS1, while *KRAS* mutations are associated with adverse outcome in MSS tumors in CMS2.

549P Gene expression signatures in BRAF V600E mutant colorectal cancer in relation to WNT signaling cascade

K. Yasui[1], T. Nagasaka[1], A. Nyuya[1], T. Toshima[1], T. Kawai[1], K. Shigeyasu[1], S. Yano[1], Y. Mori[1], J. Haraga[2], K. Nakamura[2], Y. Umeda[1], A. Goel[3], T. Fujiwara[1]

[1]*Gastroenterological Surgery, Okayama University Hospital, Okayama, Japan,* [2]*Department of Obstetrics and Gynecology, Okayama University Hospital, Okayama, Japan,* [3]*Center for Gastrointestinal Research, Center for Translational Genomics and Oncology, Baylor Scott & White Research Institute, Charles A. Sammons Cancer Center, Baylor University Medical Center, Dallas, TX, USA*

Background: Colorectal cancers (CRC) with BRAF V600E mutations have typically shown poor outcomes in several clinical trials, but its biological role has not been fully elucidated. Classification of CRCs according to gene expression profiling and methylome analysis remains controversial with regards to their ability to stratify patients for precision therapy.

Methods: We performed mRNA microarray analysis and used pathway analyses by Gene Set Enrichment Analysis (GSEA) in the following three subsets; eight BRAF-mutant CRC tissues without MSI, six BRAF-mutant CRCs with MSI and five BRAF-wild type CRCs with MSI. Following identification of candidate biomarkers that affect poor outcomes and associate with BRAF V600E mutation, we examined epigenetic variations of these candidate biomarkers in a cohort of 1068 CRC patients who underwent surgical resection of their primary tumor and/or metastatic lesions from 1994 to 2015 at the Okayama University Hospital.

Results: Prominent signatures enriched in CRCs with BRAF V600E mutation were EMT-related processes (EMT and myogenesis), Wnt signaling and intestinal differentiation-related genes. Among the differentially expressed genes, Wnt-antagonist, Secreted frizzled-related proteins (SFRPs) were significantly upregulated in CRCs with BRAF V600E mutation especially without MSI. As SFRPs are well known to be inactivated by promoter hypermethylation, and up to 80% of CRCs are methylated in the promoter region of the SFRP2 gene, we speculated and analyzed SFRP2 promoter methylation status in 993 CRCs of our cohort by a modified highly sensitive assay for bisulfite DNA followed by fluorescence-based PCR, as we previously reported (JNCI 2009). SFRP2 methylation was observed in 647 (65.2%). Interestingly, SFRP2 unmethylated CRCs with genetic mutation in the KRAS/BRAF genes demonstrated significantly poorer outcome in RFS compared with SFRP2 methylated CRCs with genetic mutations in the KRAS/BRAF genes (5-yrs RFS: 59.0% vs 80.4%, $P < 0.001$, HR: 2.07 [95% CI, 1.19 to 3.48], $P = 0.01$).

Conclusions: Our results suggest that SFRP2 methylation status could be a potential prognostic biomarker for CRCs, especially with genetic mutations in the KRAS/BRAF genes.

550P Prognostic significance of BRAF mutation-associated gene signature in colorectal cancer

J.E. Hwang[1], W.K. Bae[1], H-J. Shim[1], S.H. Cho[1], I.J. Chung[1], K. Kim[1], E.C. Hwang[2]

[1]Medical Oncology, Chonnam National University Medical School & Chonnam National University Hwasun Hospital, Hwasun, Republic of Korea, [2]Urology, Chonnam National University Medical School & Chonnam National University Hwasun Hospital, Hwasun, Republic of Korea

Background: BRAF mutation is associated with poor survival in colorectal cancer. We aimed to generate genomic signature associated with BRAF mutation that possibly predict prognosis in colorectal cancer.

Methods: A gene expression signature reflecting BRAF mutation was generated in TCGA cohorts (n = 207). The colorectal cancer patients were stratified into two groups according to this signature: BRAF mutation type colorectal cancer or BRAF wild type colorectal cancer. Prognostic significance of BRAF mutation-associated gene signature was tested in two other cohorts (GSE 17538, GSE 14333).

Results: The BRAF mutation signature was associated with poor prognosis in two independent cohorts (total n = 522). BRAF mutation signature was associated with poor disease-free survival (median: not reached, P = 0.0303) in GSE14333, and associated with poor overall survival (BRAF mutation vs. wild, P = 0.019 median, 37.310 vs. 134.860 months), and disease-free survival in GSE 17538 (BRAF mutation vs. wild, P = 0.027, median 36.9 months vs. not reached). In a multivariate analysis, BRAF mutation signature was independent poor prognostic factor for disease-free survival (hazard ratio 2.1; 95% CI 1.43-2.62: P = 0.001). Gene network analyses suggested epithelial-mesenchymal transition is the possible explanation for poor prognosis of BRAF mutation colorectal cancer.

Conclusions: BRAF mutation signature is highly associated with poor prognosis in colorectal cancer and the molecules associated with epithelial-mesenchymal transition can be potential treatment targets in BRAF mutation colorectal cancer.

551P Comparative and multimodal analysis of the EGFR, HER2, c-MYC, and MET copy number alteration using in situ hybridization in Korean colorectal cancer patients with integration of array-based copy number data from The Cancer Genome Atlas

Y. Kwak[1], S. Yun[2], S.K. Nam[1], A.N. Seo[3], K.S. Lee[1], H-K. Oh[4], D.W. Kim[4], S.B. Kang[4], W.H. Kim[5], H.S. Lee[1]

[1]Department of Pathology, Seoul National University Bundang Hospital, Sungnamsi, Republic of Korea, [2]Department of Pathology, Samkwang Medical Laboratories, Seoul, Republic of Korea, [3]Department of Pathology, Kyungpook National University Hospital, Daegu, Republic of Korea, [4]Department of Surgery, Seoul National University Bundang Hospital, Sungnamsi, Republic of Korea, [5]Department of Pathology, Seoul National University College of Medicine, Seoul, Republic of Korea

Background: The purpose of this study was to explore gene copy number (GCN) variation of *EGFR*, *HER2*, *c-MYC*, and *MET* in patients with primary colorectal cancer (CRC).

Methods: Dual-colour silver-enhanced in situ hybridization was performed in tissue samples of 334 primary CRC patients. The amplification status (GCN ratio ≥2) and GCN gain (average GCN ≥4) data for the EGFR, HER2, c-MYC and MET genes were obtained. GCN variation was also assessed by the criterion of the 2013 ASCO/CAP guidelines for HER2 testing. The publicly available genetic data of 257 CRC cases from The Cancer Genome Atlas (TCGA) were used for comparative analysis.

Results: Amplification of *EGFR*, *HER2*, *c-MYC* and *MET* was detected in 8 (2.4%), 20 (6.0%), 29 (8.7%), and 14 (4.2%) patients, respectively. Of 66 patients with at least one amplified gene (*HER2-MET* co-amplification: two patients; *HER2-c-MYC* co-amplification: two patients; *EGFR-c-MYC* co-amplification: one patient). There were 109 patients with GCN gains of one or more genes (*EGFR*: 11/334, *HER2*: 29/334, *c-MYC*; 60/334, *MET*: 48/334) and 32.1% (35/109) had multiple GCN gains. When each GCN was assessed by the criterion of the ASCO/CAP 2013 guideline for HER2 testing, 116 people showed positive or equivocal results for one or more genes. The cumulative amplification status had no association with patients' outcome. However, the cumulative results of the GCN gain and GCN status determined according to the ASCO/CAP guideline had a significant prognostic correlation in the univariate (*P* values of 0.006 and 0.022, respectively) and multivariate analysis (*P* values of 0.010 and 0.017, respectively). In analysis of TCGA data, high-level amplification of EGFR, HER2, c-MYC, and MET was observed in 1 (0.4%), 8 (3.1%), 11 (4.3%) and 1 (0.4%) cases, respectively. Copy number alteration status had no prognostic association in TCGA cohort.

Conclusions: In this study, we evaluated GCN variation of four genes in a large sample of Korean CRC patients. The amplification status was not related to patient outcome. However, the GCN gain and GCN status according to the ASCO/CAP 2013 guideline were independent prognostic factors.

552P Mutational status and metastatic patteRn in a cohort Of ADvanced colorectal cancer (aCRC) patients (pts): The ROAD study

E. Ongaro[1], G. De Maglio[2], L. Gerratana[1], M. Bonotto[1], S.K. Garattini[1], D. Basile[1], M. Cattaneo[1], V.J. Andreotti[1], F. Cortiula[1], A. Parnofiello[1], V. Fanotto[1], S. Pizzolitto[2], G.G. Cardellino[1], M. Casagrande[1], F. Puglisi[1], G. Aprile[3], N. Pella[1], G. Fasola[1]

[1]Department of Oncology, University and General Hospital of Udine, Udine, Italy, [2]Department of Pathology, University and General Hospital of Udine, Udine, Italy, [3]Department of Oncology, San Bortolo General Hospital, Vicenza, Italy

Background: Somatic mutation status in aCRC is becoming increasingly relevant as it may predict efficacy of biological therapies but also site-specific patterns of metastatic spread and outcome.

Methods: We retrospectively analysed a cohort of 640 consecutive aCRC pts diagnosed at University Hospital of Udine, Italy, from 1st January 2000 to 15th March 2017. KRAS, NRAS, BRAF and PIK3CA status was all locally determined by pyrosequencing and/or mass-Spectrometry Assay, with commercially available kits (diatech pharmacogenetics). Pearson's X^2 test was performed with uni- and multivariate models to test association of mutational status and site-specific metastatic spread at the time of diagnosis, death or last follow-up.

Results: Overall, we detected 283 (47%) KRAS mutations, 21 (4%) NRAS mutations, 40 (7%) BRAF mutations, and 61 (14%) PIK3CA mutations. Most common mutations in KRAS gene were located in exon 2 (86%), while about 3% of mutations involved exon 3 and 5% exon 4. NRAS mutations involved equally exons 2 and 3. All BRAF mutated tumours except for one, exhibited exon 15 V600E mutations. Pts with KRAS mutations had an increased risk to develop lung metastases (odds ratio, OR 2.56, 95% CI 1.76-3.71; p < 0.001, in multivariate analyses) or central nervous system metastases (OR 2.58, 95% CI 1.15-5.76; p = 0.021, in univariate model). Instead, pts harbouring BRAF mutations had higher risk of peritoneal (OR 3.05, 95% CI 1.56-5.96, p = 0.001) and nodal (OR 2.20, 95% CI 1.21-4.66, p = 0.012) spread, in uni- and multivariate models, respectively. Liver metastases were not associated with a specific mutational status. Moreover, no associations between NRAS or PIK3CA status and metastatic sites were found.

Conclusions: Our findings suggest that molecular biology may help predicting the metastatic spread in aCRC pts. If confirmed by further studies, these observations could translate into tailored surveillance and follow-up protocols.

553P First-line panitumumab (P) plus capecitabine (C) for the treatment of elderly patients (pts) with wild-type KRAS metastatic colorectal cancer (mCRC): Preliminary results of the phase II, PANEL GITuD-2011-01 study

J.C. Méndez Méndez[1], M. Ramos[2], J.C. De la Cámara Gómez[3], M.L. Pellón[3], M. Covela[4], G.A. Quintero Aldana[5], M. Salgado Fernandez[6], A. Fernández-Montes[7], M. Reboredo[8], M. Valladares-Ayerbes[9], M. Jorge Fernandez[10], P. González Villarroel[10], C. Romero Reinoso[11]

[1]Medical Oncology, Centro Oncológico de Galicia, A Coruña, Spain, [2]Medical Oncology, Centro Oncologico de Galicia, A Coruña, Spain, [3]Medical Oncology, Complejo Hospitalario Universitario Ferrol, Ferrol, Spain, [4]Medical Oncology, Hospital Universitario Lucus Augusti, Lugo, Spain, [5]Medical Oncology, Hospital Universitario Lucus Augusti, Lugo, Spain, [6]Medical Oncology, Complejo Hospitalario De Ourense, Ourense, Spain, [7]Medical Oncology, Complejo Hospitalario Universitario de Ourense, Orense, Spain, [8]Medical Oncology Department, Hospital Universitario a Coruña, A Coruña, Spain, [9]Medical Oncology, Hospital Virgen del Rocío, Seville, Spain, [10]Medical Oncology, Complejo Universitario Hospitalario Álvaro Cunqueiro, Vigo, Spain, [11]Medical Oncology, Hospital Povisa, Vigo, Spain

Background: Despite the high prevalence of CRC in elderly pts (Siegel R et al. 2014), they have been underrepresented in clinical trials (Hutchins LF et al. 1999) and their optimal treatment is yet to be determined. Here, we present the preliminary results of PANEL, a multicenter, single arm, phase II study in elderly pts with WT KRAS mCRC treated with P+C as first-line regimen.

Methods: Pts (≥70 years; ECOG-PS ≤ 2) received P (9 mg/kg, day 1 and q3w) plus C (850 mg/m^2 BID, days 1-14 of a 3 wks cycle) until disease progression or unacceptable toxicity. Response was evaluated every 9 wks according to RECIST 1.1. The outcome measures were: objective response rate (ORR), duration of response (DoR), time to response (TTR), to progression (TTP) and to treatment failure (TTF), progression-free survival (PFS), overall survival (OS), and safety.

Results: 26 pts (11 women; median age: 78 years; ECOG PS: 0 [27%]/1 [65%]/2 [8%]; median serum carcinoembryonic antigen: 25.2 ng/ml [IQR: 93.5]; median lactate

dehydrogenase: 340 U/L [IQR: 195]) received a mean (SD) of 8.3 (5.5) P cycles and 7.7 (4.8) C cycles. 81% and 62% of pts received ≥80% of relative dose intensity of P and C, respectively. Confirmed ORR was 38%, with 69% of pts achieving at least stable disease. Median (95%CI) DoR was 8.7 (6.2-12.7) months, and median TTR was 2.2 (1.8-3.2) months. Median (95%CI) TTP was 9.9 (5.3-12.0) months, with a median TTF of 5.4 (3.1-9.1) months. The median (95%CI) PFS was 9.6 (5.3-11.5) months, and the median OS was 23.7 (12.0-27.5) months. 14 (54%) pts reported grade 3/4 adverse events (Table). There were no cases of neutropenia, trombopenia or toxic deaths.

Table: 553P Incidence of adverse events

	Grade 1-2, N (%)	Grade 3, N (%)	Grade 4, N (%)
Anemia	3 (12%)		
Paronychia	2 (8%)	2 (8%)	
Rash	3 (12%)	1 (4%)	
Mucositis	5 (19%)		
Skin toxicity	10 (39%)	4 (15%)	
Diarrhea	4 (15%)	1 (4%)	
Hand-Foot Syndrome	1 (4%)	2 (8%)	
Hypomagnesemia	4 (15%)		1 (4%)

Conclusions: These preliminary results suggest that panitumumab plus capecitabine is a safe and effective regimen in elderly patients with WT KRAS mCRC.

Clinical trial identification: The number of trial protocol: 2012-000751-13 The realase date (when it was obtained): 2012-06-18

554P Prevalence of KRAS/NRAS/BRAF mutations detected by massive parallel sequencing and differential outcomes in MCRC patients (pts) treated with first line FIr-B/FOx adding bevacizumab (BEV) to triplet chemotherapy

G. Bruera[1], F. Pepe[2], U. Malapelle[2], P. Pisapia[2], A. Dal Mas[3], G. Calvisi[3], G. Troncone[2], E. Ricevuto[1]

[1]*Oncology Territorial Care, Department of Biotechnological and Applied Clinical Sciences, S. Salvatore Hospital, ASL1 Abruzzo, University of L'Aquila, L'Aquila, Italy,* [2]*Department of Public Health, University Federico II, Naples, Italy,* [3]*Pathology, S. Salvatore Hospital, ASL1 Abruzzo, L'Aquila, Italy*

Background: KRAS/*NRAS*/*BRAF* genotypes guide tailoring of first and subsequent lines of MCRC treatment strategy. First line triplet chemotherapy/BEV regimens significantly improved progression-free survival (PFS) and overall survival (OS) in MCRC patients. OS may be significantly worse in *KRAS* c.35 G > A and *BRAF* mutant (mut) MCRC. Prevalence and differential clinical outcome according to *KRAS*/*NRAS*/*BRAF* genotype was evaluated in MCRC patients treated with FIr-B/FOx intensive regimen.

Methods: Tumoral samples of 67 MCRC pts treated with FIr-B/FOx (77% overall) were analyzed through a 50 genes panel (PGM/Colon Lung Cancer) by ION Torrent. *KRAS* exons 2-4 ($KRAS_{2-4}$), *NRAS* exons 2-4 ($NRAS_{2-4}$), and *BRAF* exon 15 ($BRAF_{15}$) were evaluated. Molecular diagnostic criteria for mutation detection: >500× sequence coverage; >1% mutant allelic fraction. Clinical outcomes (PFS and OS) were evaluated and compared by log-rank.

Results: $KRAS_{2-4}$ mut were 42 (66.7%), 4 not evaluable; $NRAS_{2-4}$mut 13 (19.4%); $BRAF_{15}$ mut 5 (7.5%). $KRAS_{2-4}$/$NRAS_{2-4}$/$BRAF_{15}$ mut MCRC patients were 49 (77.8%), wt 14 (22.2%): single gene mut 40 (63.5%), $KRAS_{2-4}$34 (54%), and $NRAS_{2-4}$ 6 (9.5%); >1 mut genes 9 (14.3%), double mut 5 and triple mut 4, specifically double *KRAS 1*, *KRAS*/*NRAS* 2, *KRAS*/*BRAF* 1, *NRAS*/*BRAF* 1, double *KRAS*/*NRAS* 1, *KRAS*/*NRAS*/*BRAF* 3. $BRAF_{15}$ mut were all atypical and concomitant with *KRAS* and/or *NRAS* mutations. Prevalence of $KRAS_{2-4}$, $NRAS_{2-4}$, $BRAF_{15}$ >1 mut samples were 19%, 53.8%, and 100% of each mut gene. At median follow-up 21 months (m), PFS and OS overall, and of $KRAS_2$ genotype were consistent with previously reported; in c.35 G > A $KRAS_2$ mut trendly worse PFS 8 m and OS 14m. Differential clinical outcome of MCRC patients wt and mut were not significantly different: $KRAS_{2-4}$, PFS 13 and 12m, OS 27m equivalently; $NRAS_{2-4}$, PFS 16 and 12m, OS 28 and 22m; $BRAF_{15}$ PFS 14 and 8 m, OS 28 and 11 m; $KRAS_{2-4}$/$NRAS_{2-4}$/$BRAF_{15}$ PFS 18 and 12m, OS 28 and 22m.

Conclusions: Clinical outcome of MCRC patients treated with FIr-B/FOx is not significantly affected by $KRAS_{2-4}$/$NRAS_{2-4}$/$BRAF_{15}$ genotype; efficacy may be increased in triple wt patients; the prevalent c.35 G > A $KRAS_2$ and $BRAF_{15}$ mut may show worse prognosis.

Background: The RAISE trial (NCT01183780) demonstrated that RAM plus FOLFIRI (leucovorin, fluorouracil, and irinotecan) significantly improved overall survival (OS) and progression-free survival (PFS) compared with placebo plus FOLFIRI (PBO) as second-line mCRC treatment. Despite multiple approved anticancer treatments targeting angiogenesis, there are currently no predictive markers to guide patient selection. The extensive RAISE biomarker program assessed the association of multiple candidate biomarkers with RAM efficacy outcomes.

Methods: Plasma and tumor tissue collection was mandatory in the RAISE trial. Analyses were performed using exploratory assays to assess the correlations of the baseline marker levels (vascular endothelial growth factor [VEGF]-C and D; soluble vascular endothelial growth factor receptor [sVEGFR]1, 2, and 3; and VEGFR2 immunohistochemistry in tumor tissue) with clinical outcomes. Cox regression analyses adjusted for stratification factors were performed for each marker.

Results: Biomarker results were available from >80% of patients. Among the candidate biomarkers analyzed, only VEGF-D levels had a consistent and statistically significant association with OS and PFS, suggesting a predictive relationship. Higher levels were associated with improved RAM efficacy (Table). This relationship was consistent across the full range of VEGF-D levels.

Conclusions: These analyses from RAISE identified VEGF-D as a potential predictive marker for RAM efficacy in mCRC. Further investigation of this relationship is being pursued.

Clinical trial identification: NCT01183780

Table: 555P Correlation of VEGF-D with Efficacy Outcomes: based on cut point from exploratory subset. Results below from combined exploratory + confirmatory groups

Background: Results of previous studies on the association of the CpG island methylator phenotype (CIMP) with colorectal cancer (CRC) prognosis were inconsistent and the variety of markers selected to define CIMP was widely blamed for the inconsistency. The current study was therefore aimed to comprehensively investigate the associations of DNA methylation at CIMP-related genes with CRC survival.

Methods: Patients with CRC diagnosed between 2003 and 2007 were followed up for a median of 5.2 years and divided into a screening cohort (n = 568) and a validation cohort (n = 308). DNA methylation was measured in tumor tissue using the Illumina Infinium HumanMethylation450 BeadChip. Cox proportional hazard regression models were used to estimate adjusted hazard ratios (HR) and 95% confidence intervals (CI) of survival after CRC, including adjustment for tumor stage, microsatellite instability, BRAF mutation status and other important factors.

Results: Of 48 genes used to define CIMP in the previous studies, 43 were also covered by the methylation array. In the screening cohort, ten CpG sites were identified to be associated with CRC survival. Seven of these ten CpG sites were also associated with CRC survival in the validation cohort and were used to construct a prognostic score. CRC patients with a prognostic score in the lowest tertile (lowest methylation levels at the CpG sites) showed poorer disease-specific survival compared with patients in the highest tertile in both the study cohort and the validation cohort (HR = 3.11; 95% CI = 1.97-4.91 and HR = 3.06; 95% CI = 1.71-5.45 respectively).

Conclusions: A CpG panel consisting of seven CpG sites was found to be strongly associated with CRC survival, independent from important clinical factors and mutations associated with CIMP.

Background: Some patients (pts) with mCRC have an early progression during induction chemotherapy (IC). Early identification of these pts is an important challenge in order to intensified front line treatment. For pts who have a tumor response or stabilization after IC a chemotherapy-free interval (CFI) could be proposed. Identification of the subgroup of pts that should not stopped chemotherapy (CT) and pts that will benefit from a long CFI is also of importance.

Methods: PRODIGE 9 pts had 12 courses of FOLFIRI + bevacizumab before an IC with or without bevacizumab monotherapy. As the pts are randomized before IC the whole strategy could be assessed. Following factors were evaluated for early progression during IC and for early (< 3 mths) or late progression (≥ 5 mths) during 1st CFI: treatment arm, sex, age, WHO PS, primary tumor resected, number of metastatic site, primary localization, leucocyte, platelets, alkaline phosphatase, CEA level, *KRAS* mutation, *BRAF* mutation and decrease of CEA at 2 months. Tumor response at the end of IC and early shrinkage at 1st evaluation were evaluated only for CFI duration. A logistic model was used to identify the prognostic factors with a . A significance level of 0.2 was required to enter into the model and to stay in the model.

Results: An early progression during IC occurred in 85 pts. Leucocytes $>10 \times 10^9$/L ($p = 0.02$), and decrease of less than 50% of CEA at 2 mths ($p = 0.01$) were associated with early progression. A first CFI was done in 344 pts. 128 pts had a short CFI, 100 an intermediate one between 3 and 5 mths and 116 a long CFI. Two factors were significantly associated with a short CFI: normal CEA at baseline ($p = 0.03$) and complete or partial response at 1st evaluation ($p = 0.08$). In the sub-group of 95 pts with *BRAF* determination, these 2 results were the same.

Conclusions: High baseline leucocytes count and the lack of decrease of CEA at 1st evaluation are associated with early progression and could be considered in favor of an early CT intensification. Two factors predict significantly CFI duration: Baseline CEA and tumor response to 1st evaluation. Surprisingly, our results suggest that a high baseline CEA and a stable disease at 1st evaluation are associated with a longer CFI.

558P High PD-L1 expression and high CD8+ T-cell infiltration identifies a new subpopulation of colorectal cancer with high risk of relapse and poor outcome

M. Fakih[1], C. Ouyang[2], C. Wang[3], T.Y. Tu[3], M. Cho[1], M. Sy[1], J. Longmate[4], P.P. Lee[3]

[1]Medical Oncology, City of Hope, Duarte, CA, USA, [2]Office of Chief Informatics, City of Hope, Duarte, CA, USA, [3]Immuno-Oncology BRI, City of Hope, Duarte, CA, USA, [4]Information Sciences - BRI, City of Hope, Duarte, CA, USA

Background: CD8+ T-cell primary tumor infiltration is associated with improved colorectal cancer (CRC) outcome. However, the interaction between CD8+ T-cell infiltration and intra-tumor PD-L1 expression has not been previously characterized. This study aims to explore the impact of PD-L1 expression and degree of CD8+ T-cell infiltration on the outcome of patients with stage II and III CRC.

Methods: CD8, PD-1, PD-L1, cytokeratin 20, and CD68 expression were quantified via multi-spectral immunohistochemistry of primary CRC tumors from 35 patients with recurrent disease (cases) and 36 patients without recurrence (controls). The TCGA (The Cancer Genome Atlas) and the NCBI-GEO (Gene Expression Omnibus) datasets of 385 and 828 stage II-III cases, respectively, were used to validate the prognostic value of the discovery set biomarkers, both for relapse free survival (RFS) and overall survival (OS).

Results: In the 71-patient discovery case-control set, densities of CD8+ and PD-L1+ cells in tumor microenvironment classified patients into three distinct populations. High CD8+ cell infiltration (above median) and high PD-L1 expression (>90 percentile) was associated with high risk of relapse: all 7/7 patients with $CD8^{Hi}$/$PD\text{-}L1^{Hi}$ experienced disease relapse, despite being enriched in mismatch repair deficiency (4 patients). Low CD8+ cell infiltration was associated with a high relapse rate irrespective of PD-L1 status: 80% of patients with $CD8^{L}$ relapsed. $CD8^{Hi}$ in the absence of high PD-L1 expression ($CD8^{Hi}$/$PD\text{-}L1^{L}$) had the lowest risk of relapse: 7% of patients relapsed. The validation data sets confirmed that the $CD8^{Hi}$/$PD\text{-}L1^{L}$ and the $CD8^{L}$ groups carried an inferior RFS (NCBI-GEO data set: HR = 1.655, p = 0.02) and OS (TCGA data set: HR = 3.556, p = 0.0095) in comparison to the $CD8^{Hi}$/$PD\text{-}L1^{L}$ group. A multivariate analysis that includes age, stage, and mismatch repair (MMR) status, confirmed the independent impact of both $CD8^{Hi}$ and $PD\text{-}L1^{Hi}$ on RFS and OS in both validation sets.

Conclusions: $CD8^{Hi}$/$PD\text{-}L1^{Hi}$ defines 10% of patients with stage II/III CRC and confers a high risk of relapse, despite enrichment with MMR deficiency. This subgroup of patients may be suitable for the investigation of PD-1 checkpoint inhibitors.

Background: Accurate evaluation of lymph node (LN) status is important for prediction of prognosis and decision of postoperative adjuvant therapy in cancer patients. Histopathological diagnosis, usually used for this evaluation, has shortcoming of lower sensitivity due to observing only small portion of whole lymph node. To overcome it we developed a new molecular diagnostic system, one-step nucleic acid amplification (OSNA^{TM}) assay which measures cytokeratin (CK) 19 mRNA expression level in whole lymph node and reported the usefulness in colorectal cancer (CRC) as well as in breast, gastric and lung cancers. According to our recent study in CRC, 17.6% of stage II (histologically node negative) patients were found to be molecularly positive in OSNA assay. In this multicenter trial, we investigated the clinical impact of OSNA positive cases.

Methods: Patients with cN0 and cN1 CRC in 11 Japanese representative medical institutes were enrolled. All LNs were examined histopathologically by using one-slice hematoxylin-eosin staining. In addition, half of the LN, which could be cut into half (average, 9.8 LN/patient), was examined by OSNA assay. Patients were classified in accordance with the UICC staging criteria and OSNA results, and the 3-year disease-free survival (DFS) of each cohort was analyzed.

Results: We enrolled 204 patients with CRC, excluded 9 patients, and analyzed 195 patients (stage I: n = 50, stage II: n = 71, stage III: n = 74). Of the patients with node-negative CRCs, only one was OSNA positive at stage I, and 11 were OSNA positive at stage II. OSNA-positive stage II cases had much lower 3-year DFS rate than OSNA negative ones (p = 0.005). Among various clinical and pathological parameters, only OSNA status was a significant prognostic factor for 3-year DFS in stage II CRC cases (p = 0.025).

Conclusions: This prospective multicenter study showed for the first time a prognostic value of OSNA positivity in stage II CRC. This assay is useful for selecting high-risk patients with stage II CRC. Further study to determine the treatment strategy for patients with OSNA-positive stage II CRC is necessary.

560P Impact of Immune response-associated gene polymorphisms on tumor response in rectal cancer patients treated with capecitabine +/- oxaliplatine and radiation in the ACCORD-12/PRODIGE-2 phase III trial

B. Valerie[1], C. Mollevi[2], N. Chaput[3], S. Gourgou[2], D. Azria[4], J.F. Seitz[5], L. Bigot[6], B. Juzyna[7], I. Miran[8], J-P. Gérard[9], P. Laurent-Puig[10]

[1]Oncologic Medicine, Gustave Roussy, Villejuif, France, [2]Biostatistics, Institut du Cancer de Montpellier, Montpellier, France, [3]Immunology, Gustave Roussy, Villejuif, France, [4]Radiotherapy, Laboratoire de Radio-Analyse du C.R.L.C., Montpellier, France, [5]Gastroenterology, CHU La Timone Adultes, Marseille, France, [6]Inserm U981, Gustave Roussy, Villejuif, France, [7]R&D UNICANCER, UNICANCER, Paris, France, [8]Translational Research, Gustave Roussy, Villejuif, France, [9]Radiothérapie, Centre Anticancer Antoine Lacassagne, Nice, France, [10]Department of Biology, Paris Descartes University, Paris, France

Background: We examined whether 133 germline polymorphisms (SNPs) in 15 candidate genes *(CSF1R, IL8RA, TLR4, IL10, IL10RA, CTLA4, IL2, IL2RA, TGFb1, ICOS, IL13, IL13RA2, IFNgR, IL15* and IL15RA) would predict clinical outcome in the ACCORD-12 phase III trial which randomly compared neoadjuvant radiotherapy (RT) plus capecitabine (CAP45) with dose-intensified RT plus capecitabine and oxaliplatin (CAPOX50) in T3-4 Nx M0 resectable rectal cancer.

Methods: A candidate-gene association study was conducted in 316 patients (n = 161 in the CAPOX50 and n = 155 in the CAP45 arm). The primary end-point was tumor response according to the Dworak score in each arm. Logistic regressions were used to assess uni/multivariate associations. The Storey and Tibshirani method based on the control of false discovery rate was used (q-value <0.10 considered as true discovery). Multivariate models adjusted on treatment arm were performed to determine prognostic and predictive values of haplotypes (R package SNSassoc and function haplo.glm were used) for tumor response.

Results: In univariate analysis, two SNPs in IL2RA (rs11256456: OR = 5.1 [2.38; 11] and rs706781: OR = 4.2 [1.98; 8.74]) were significantly associated with the Dworak score in the CAP45 arm, and one in IL2RA the CAPOX50 arm (rs2104286: OR = 0.11 [0.01; 0.90]. All were confirmed in the multivariate analysis. Patients were categorized into 3 haplotype groups after the haplotype analysis of IL2RA rs11256456 and rs706781: one had a positive prognostic effect on tumor response in the CAP-45 arm (OR = 3.85 [1.97; 7.53], p = 0.0001) and in the overall population (OR = 1.76 [1.15; 2.68], p = 0.009). Interaction was also significant, suggesting a predictive positive effect of the same haplotype for response to CAP-45 (OR = 4.12 [1.71, 9.94], p = 0.002). None of the three IL2RA SNPs were correlated with survival in the multivariate analysis.

Conclusions: This pharmacogenetic analysis shows that SNPs in IL2RA are significantly associated with response to neoadjuvant chemoRT in patients with locally advanced rectal cancer. Their predictive effect may identify patients who benefit from CAP-45.

561P Improving treatment decisions in colon cancer: The tumor-stroma ratio (TSR) additional to the TNM classification

W. Mesker[1], G. van Pelt[1], A. Huijbers[1], J. van der Laak[2], E. Dequeker[3], J-F. Fléjou[4], R. Al Dieri[5], D. Kerr[6], J. Van Krieken[2], R. Tollenaar[1]

[1]Surgery, Leiden University Medical Center, Leiden, Netherlands, [2]Pathology, Radboud UMC, Nijmegen, Netherlands, [3]Medische Diagnostiek, Kul-Uz, Leuven, Belgium, [4]Pathology, Hôpital Saint Antoine, Paris, France, [5]European Society of Pathology, Brussels, Belgium, [6]Nuffield Division of Clinical and Laboratory Sciences, University of Oxford, Oxford, UK

Background: The tumor-micro-environment is an important determinant of tumor behaviour. We developed a new, easy to apply, practice changing method to select

colon cancer patients for adjuvant therapy: the tumor-stroma ratio (TSR). This parameter is independently validated. The current proposal aims to prepare implementation of the method by training international pathologists and prospective validation of the parameter in an international setting.

Methods: 1. A reproducibility study on TSR scoring in H&E stained tumor tissues will be conducted among international pathologists. An e-learning module will be developed with a quality assessment program in the framework of the European Society of Pathology EQA program. 2. Automation of the TSR using whole slide imaging and state-of-the-art pattern recognition techniques. 3. A prospective clinical trial will be performed that evaluates the introduction of the TSR in clinical practice.

Results: A high amount of stroma within the primary tumor results in worse patient outcome. The TSR can be determined at routine pathology diagnostics and has an excellent inter-observer agreement with $K > 0.80$. The TSR has been validated by independent international groups. Moreover it has been validated for breast, oesophageal, cervical, lung and gastric cancer. For colon cancer several cohort studies resulted in significant differences in survival time between stroma-high and stroma-low patients ($p < 0.0001$, HZ 2.5). These results were validated in the VICTOR trial (stage II, III: OS $p < 0.0001$, HR = 1.96; DFS $P < 0.0001$, HR = 2.15) and the Quasar II study (stage II, III: OS $p = 0.003$, HR = 1.53; DFS $p = 0.001$, HR = 1.53).

Conclusions: Standardization and prospective validation of TSR will result in inclusion of the parameter in the TNM classification leading to more accurate decision making for adjuvant chemotherapy.

562P Development and validation of multiplex biomarker assay to stratify colorectal cancer (CRC) patient samples into subtypes

A. Sadanandam[1], K. Eason[1], E. Fontana[1], G. Nyamundanda[1], M. Del Rio[2], K. Si-Lin[3], T.W. Siew[4], P. Martineau[2], I.B. Tan[3], C. Ragulan[1]

[1]Molecular Pathology, Institute of Cancer Research (ICR), Sutton, UK, [2]INSERM, Montpellier Cancer Research Institute France, Montpellier, France, [3]Medical Oncology, National Cancer Centre Singapore, Singapore, [4]Colorectal Surgery, Singapore General Hospital, Singapore

Background: We previously classified colorectal cancer (CRC) into five distinctive subtypes (CRCAssigner) and later into four consensus molecular subtypes (CMS) based on microarray or RNAseq gene expression profiles. The goal of this study was to develop a less expensive multiplex biomarker assay to stratify patient samples into CRC subtypes using the nCounter platform (NanoString Technologies) with short turnaround time for potential clinical use.

Methods: We used three cohorts of primary untreated CRC samples (n = 51) with two microarray (Del Rio; Montpellier Cancer Research Institute, France and OriGene; OriGene, Rockville, MD, USA) and one RNAseq (SG; Singapore General Hospital, Singapore) gene expression profiles. We reduced our published 786-gene CRCAssigner signature (CRCAssigner-786) into a short gene panel (CRC-panel). Initially, we compared CMS subtypes with CRCAssigner-786 subtypes, followed by CRCAssigner-786 subtypes with that of the microarray/RNAseq-based CRC-panel. We then developed a customized nCounter CRC-panel and compared to different subtype classifications. To assess reproducibility, we generated technical replicates.

Results: There was an average of 70% concordance between CMS and CRCAssigner subtypes across different cohorts. 94% of predicted subtypes were concordant using microarray CRCAssigner-786 versus microarray CRC-panel signatures in both the Del Rio (16/17) and OriGene (16/17) cohorts. nCounter CRC-panel assay classified 82% (14/17) Del Rio and 65% (11/17) OriGene samples consistently with microarray-based CRC-panel classification. In the SG cohort, nCounter CRC-panel classified 76% (13/17) and 94% (16/17) of samples consistently with RNAseq-786 and RNAseq CRC-panel, respectively. Pearson's correlation coefficient between five pairs of technical replicates was 0.98.

Conclusions: nCounter assay stratified CRC samples into subtypes to known classifications. Given the high reproducibility and reduced costs, nCounter platform has been tested in formalin-fixed paraffin-embedded samples (ESMO-2017 Abstract-#3467). This assay may facilitate prospective validation of CRC subtypes in the clinic.

563P HER2 overexpression and amplification in patients with colorectal cancer (HOLIC): A large-scale retrospective study in Chinese population

S. Ni[1], J. Peng[2], D. Huang[1], H. Sun[1], L. Wang[1], C. Tan[1], J. Cai[2], W. Sheng[1]

[1]Pathology, Fudan University Shanghai Cancer Center, Shanghai, China, [2]Colorectal Surgery, Fudan University Shanghai Cancer Center, Shanghai, China

Background: HER2 overexpression or amplification may be a potentially predictive factor for anti-HER2 response and anti-EGFR resistance in colorectal cancer (CRC). However, the prevalence of HER2 positivity in CRC patients and its correlation with clinicopathologic features are not clear.

Methods: HER2 and MMR protein expression were tested by immunohistochemistry (IHC) in formalin-fixed, paraffin-embedded samples from 4,913 consecutive CRC patients treated with surgical resection during 2011-2014 in our institution. Dual color silver-enhanced in situ hybridization (DISH) was performed in all IHC 3+/2+ cases. The scoring criteria of HER2 status in gastric cancer was used. RAS/BRAF mutation status was assessed by Sanger DNA sequencing.

Results: HER2 positivity was found in 160/4,913 (3.3%) cases, including 68 cases (42.5%) with IHC 3+ and 92 cases (57.5%) with IHC 2+/DISH+. HER2 positivity was more common in younger patients (<60 year old), correlated with perineural invasion, vascular invasion, lymph node metastases, and higher TNM stage. HER2 positivity was not related to tumor location. Only one HER2 positive case had MMR protein deficiency. Among the 160 HER2 positive cases, 56 (35%) harbored a KRAS mutation, 17 (10.6%) harbored a NRAS mutation, and 4 (2.5%) harbored a BRAF mutation.

Conclusions: To our knowledge, this is the largest study of HER2 status in Asian patients with CRC. HER2 positivity occurred in a small number of patients with CRC, related to unfavorable prognostic factors, more common in younger patients and rare in MMR deficiency cases. Compared with previous results in western population, the RAS/BRAF mutation rate of HER2 positive Chinese CRC patients seems much higher. The further study regarding molecular information of these HER2 positive CRC patients is ongoing.

564P The inflamed immune phenotype can be induced by systemic treatment in angiogenic colorectal liver metastases in contrast to non-angiogenic liver metastases

S. Stremitzer[1], P. Vermeulen[2], M. Kockx[2], L. Dirix[3], S. Graver[4], S. Scherer[4], D. Yang[5], W. Zhang[6], J. Stift[7], F. Wrba[7], T. Gruenberger[8], H-J. Lenz[9]

[1]Department of Surgery, Medizinische Universitaet Wien, Vienna, Austria, [2]Histogenex, Antwerp, Belgium, [3]Department of Medical Oncology, St-Augustinus Ziekenhuis, Wilrijk, Belgium, [4]Biocenter Wuerzburg, University of Wuerzburg, Wuerzburg, Germany, [5]Department of Preventive Medicine, University of Southern California, Los Angeles, CA, USA, [6]Medical Oncology, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA, USA, [7]Clinical Institute of Pathology, Medical University Vienna, Vienna, Austria, [8]Department of Surgery I, KA Rudolfstiftung - Krankenanstalt der Stadt Wien, Vienna, Austria, [9]Department of Medical Oncology, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA, USA

Background: Recent data suggest that patients with colorectal cancer who present with desmoplastic (angiogenic) histopathological growth pattern (HGP) colorectal liver metastases (CLM) might derive more benefit from bevacizumab-based chemotherapy than patients who present with replacement (non-angiogenic) HGP CLM.

Methods: The immune phenotype ('inflamed', 'excluded', 'desert') was analyzed regarding the association with HGPs in a cohort of 118 patients with resectable CLM [m:f 66:52, median age 62.3 (31.0-80.4) years, median follow-up 32.2 (5.0-92.7) months] treated with 3 months of neoadjuvant and adjuvant bevacizumab-based chemotherapy and liver resection. The HGPs of CLM were assessed on H&E-stained sections according to international guidelines. The immune phenotypes were based on the distribution pattern of cytotoxic T-lymphocytes in CD8-immunostained tissue sections.

Results: In 39.8% of the lesions the predominant means of vascularization was vessel co-option, as reflected by the replacement HGP. This non-angiogenic growth was associated with worse recurrence-free and overall survival (RFS, OS) with hazard ratios (HR) of 2.03 and 2.63 ($P = 0.002$ and $P = 0.005$, respectively). The HGPs were associated with the immune phenotypes. About 60% of the desmoplastic (angiogenic) HGP CLM were 'inflamed', while this was true for only 17% of the replacement (non-angiogenic) HGP CLM. More than half of the CLM with non-angiogenic growth were characterized by an immune desert as opposed to only 6% of the angiogenic CLM ($P < 0.001$). The non-inflamed immune phenotypes were associated with worse RFS (HR 1.85; $P = 0.03$).

Conclusions: Immune regulatory and angiogenesis pathways are known to interact. Our data suggest that the inflamed immune phenotype can be induced by systemic treatment in angiogenic CLM. The HGPs therefore are a potential biomarker for treatment that includes targeting the immune contexture.

565P Whole-exome sequencing of matched germline and plasma cell-free DNA portrays the somatic mutation landscape of refractory metastatic colorectal cancer and identifies mutated KDR/VEGFR2 as new cause of therapy resistance

R.A. Toledo[1], E. Garralda[2], T. Pons[1], J. Monsech[1], E. Vega[3], R. Alvarez[3], A. Cubillo[4], C. Blanco-Aparicio[5], O. Dominguez[6], J.L. Martinez[7], M. Hidalgo[8]

[1]Clinical Research Program, CNIO- Spanish National Cancer Center, Madrid, Spain, [2]Early Clinical Drug Development Group, Vall d'Hebron Institut d'Oncologia (VHIO), Barcelona, Spain, [3]Oncology, Centro Integral Oncológico Clara Campal (CIOCC), Hospital Universitario HM Sanchinarro, Madrid, Spain, [4]Oncology, Hospital Madrid Norte San Chinarro Centro Integral Oncologico Clara Campal, Madrid, Spain, [5]Experimental Therapy, CNIO- Spanish National Cancer Center, Madrid, Spain, [6]Genomics Unit, CNIO- Spanish National Cancer Center, Madrid, Spain, [7]Proteomics Unit, CNIO- Spanish National Cancer Center, Madrid, Spain, [8]Oncology, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, USA

Background: Anti-angiogenic therapies have been broadly used in oncology as in treatment of metastatic colorectal cancer (mCRC) patients, however the causes of resistance occurring in the majority of the patients treated remain largely unknown.

Methods: Whole-exome sequencing libraries of matched leukocyte and basal cfDNA samples (WES-gcfDNA) were generated and sequenced on HiSeq4000. *KDR*/VEGFR2 mutations were cloned and stably expressing CRC cell lines used for xenograft studies. Biochemical kinase assays were carried out to assess the impact of the VEGFR2 mutants on the inhibition of VEGFR2 kinase activity by cabozantinib, lenvatinib, axitinib and dovitinib. Patient-derived Avatar model was treated with multiple anti-angiogenic drugs. Somatic mutation landscapes depicted by WES-gcfDNA and the standard tumor WES (obtained later on) were compared.

Results: We investigated a RAS/BRAF/PIK3CA wild-type mCRC patient highly refractory to (sequentially): FOLFIRI-cetuximab; FOLFOX-bevacizumab; afatinib-cetuximab (phase-1 trial); oncolytic adenovirus monotherapy (phase-1 trial); capecitabine-bevacizumab; and finally regorafenib. No radiological or clinical benefit was observed after any of these treatments and the patient died due to his progressive disease within 14 months. WES-gcfDNA enabled us to identify the KDR/VEGFR2 L840F mutation exclusively in the cancer sample. Using the methods described above we obtained comprehensive experimental data showing that L840F decreases efficiency of TKIs, promote tumor growth and confer strong in vivo resistance to numerous anti-angiogenic therapies, including bevacizumab and VEGFR2 inhibitors. Other KDR/VEGFR2 somatic mutations we retrieved from cancer sequencing projects showed similar oncogenic and resistant phenotype.

Conclusions: Our study introduces WES-gcfDNA as a robust noninvasive gene discovery platform capable of portraying the somatic mutation landscape of metastatic cancer patients from blood sample solely. Moreover, we characterize a previously unexplored oncogenic and cancer therapy modulating role of VEGFR2 mutants.

Background: We initiated the Nationwide Cancer Genome Screening Project in Japan since February 2014. From February 2015, we have introduced the Next Generation Sequencing to detect cancer genome alterations in advanced colorectal cancer (aCRC), called as the SCRUM-Japan GI-SCREEN. The objective is to evaluate the frequency of cancer genome alterations and to identify patients who are candidate for clinical trial with corresponding targeting agents.

Methods: This study is ongoing with 20 major cancer centers. Patients with aCRC who plan to or receive chemotherapy were eligible. DNA and RNA were extracted from formalin-fixed paraffin embedded (FFPE) tumor samples and were analyzed by the Oncomine Cancer Research Panel (OCP) which allows to detect mutations, copy number variant (CNV) and fusion genes in a CLIA certified CAP accredited lab. The detected genomic variant data were classified according to genetic drivers of cancer, including gain- and loss-of-function or single nucleotide variant based on the Oncomine Knowledgebase.

Results: As of October 31st in 2016, total of 1011 aCRC patients were enrolled and 981 samples were analyzed. The sequence was successfully performed in 751 tumors (76.6%). Out of 751 patients, the origin of samples included the primary site of 83.1% (Right-side 24.6%, Left-side 58.5%), metastatic site of 15.3%, and unknown of 1.6%. The frequently detected mutations in 751 samples of which results were available were TP53 (69.0%), APC (62.8%), and KRAS (43.8%), and CNVs ($\geq$ 7copies) were FLT3 (3.6%), ERBB2 (2.8%), and MYC (2.7%). BRAF V600E was identified in 48 cases (6.4%) and CCDC6-RET fusion was identified in one case (0.1%). We will show the clinical outcome based on certain key cancer genome alterations.

Conclusions: This nationwide screening system is efficient to detect rare gene alterations in aCRC. This novel knowledge provides an intriguing background to investigate new targeted approaches in these patients and represents the progress toward precision medicine.

567P Clinical utility of quasi-monomorphic variation range (QMVR) on the determination of microsatellite instability (MSI) status in patients (pts) with colorectal cancer (CRC): GI-SCREEN-CRC-MSI sub-study 01

W. Okamoto[1], H. Bando[2], T. Fukui[3], T. Yamanaka[4], K. Akagi[5], T. Yoshino[2]

[1]Biobank Translational Research Support Section, Translational Research Management Division, Clinical Research Support Office, National Cancer Center Hospital East, Kashiwa, Japan, [2]Department of Gastroenterology and Gastrointestinal Oncology, National Cancer Center Hospital East, Kashiwa, Japan, [3]Biomedical Business Department, FALCO Biosystems, Kyoto, Japan, [4]Department of Biostatistics, Yokohama City University School of Medicine, Yokohama, Japan, [5]Division of Molecular Diagnosis, Saitama Cancer Center, Saitama, Japan

Background: The current analysis for the determination of Microsatellite Instability (MSI) status in tumors requires matched normal DNA as references. Five quasi-monomorphic markers (NR-21, BAT-26, BAT-25, NR-24, and MONO-27) of the Promega panel are known to have few variant alleles in both Caucasian and Asian patients (pts). For that reason, the peak of PCR products from normal DNA are confined within the Quasi-Monomorphic Variation Range (QMVR), of which Japanese pts with metastatic colorectal cancer (mCRC) are almost the same as those of Caucasian (Patil DT, et al., 2012 and Bando H. ASCO-GI 2017).

Methods: The purposes of this clinical evaluation study are to establish the QMVR in Japanese pts with mCRC and to evaluate the clinical utility of the QMVR in the determination of MSI status without matched normal DNA. The primary endpoint is the concordance of MSI status between the standard method using DNA from tumor plus matched normal samples and testing method using DNA from only tumor samples.

The new MSI kits including the Promega MSI panel were manufactured under the Quality Management System (QMS) for *in vitro* diagnostics (IVDs). As the decision algorithm, tumors exhibiting 2 or more markers outside the QMVR were classified as MSI-H, cases with 1 marker or without any marker outside the QMVR were classified as non MSI-H (MSI-L/MSS).

Results: Totally 435 pts with mCRC were enrolled. Median age was 66 years old and 248 (57.0%) pts were male. 368 (84.6%) primary and 67 (15.4%) metastatic specimens were used. There were 11 (2.5%) MSI-H cases by the standard method and the sensitivity of the testing method was 100% while the specificity of the testing method was also 100%. Thereby the two methods was completely concordant. Among the five quasi-monomorphic markers, 3 and 2 cases were discordant in NR-21 and BAT-25, respectively. In BAT-26, NR-24, and MONO-27, all cases were completely concordant.

Conclusions: By using the QMVR, MSI status of Japanese pts with mCRC can be determined without matched normal DNA, and the QMVR might be applicable to Caucasian pts.

568P The impact of antithrombotics on immunochemical fecal occult blood testing for colorectal cancer screening

V. Van der Voort[1], L. Wauters[2], P. Dobbels[1], K. Hendrickx[1], V. Casneuf[1], J. Vandervoort[1]
[1]*Gastroenterology, OLV Aalst, Aalst, Belgium,* [2]*Gastroenterology, KU Leuven, Leuven, Belgium*

Background: The impact of antithrombotics on immunochemical fecal occult blood testing (iFOBT) for colorectal cancer (CRC) screening in the general population remains unclear.

Methods: A prospective cohort of patients undergoing endoscopy for positive iFOBT in 2015 at 3 centers in Belgium was analyzed. Medical records were reviewed for demographic and clinical variables: gastro-intestinal (GI) symptoms, family history of polyps/CRC, use of antithrombotics (including Aspirin and/or Clopidogrel, Dipyridamole, Ticagrelor, novel anticoagulants or vitamin K antagonists). Endoscopy reports were checked for colorectal pathology. Significant findings were defined as CRC or advanced adenomas. Rates of false positive iFOBT and detection of CRC or advanced adenomas were compared in patients with and without antithrombotics or Aspirin. Finally a distinction was made between patients who had a iFOBT through programmatic or opportunistic screening.

Results: A total of 510 patients (64% male, median (IQR) age 63.2 years) with positive iFOBT were included. Colorectal pathology was confirmed in 73% of the patients; more commonly in males and family history. Significant findings were present in 220/371 (59%) patients with colorectal pathology. Antithrombotics were used in 25% of the patients and associated with male gender, older age and lower GI symptoms. Aspirin alone was used in 17% and associated with male gender and older age. Rates of false positive iFOBT, detection of advanced adenoma and CRC were similar in patients with or without antithrombotics and in patients with Aspirin alone compared to no antithrombotics. iFOBT was mainly used in programmatic screening (91%), with no differences in demographic or clinical variables between these two groups.

Conclusions: Although antithrombotic drugs were mostly prescribed in male and older patients with an inherent higher cancer risk, detection rates of CRC and advanced adenoma's were similar. Despite the higher rate of lower GI symptoms, antithrombotics or Aspirin alone did not lead to more false positive iFOBT. Use of antithrombotics or Aspirin alone does not seem to impact the performance of iFOBT for screening of CRC in the general population.

569P miR-93 regulates epithelial-to-mesenchymal transition process in metastatic colorectal cancer by targeting EphA4

S. Gao
Department of Colorectal, Shanxi Cancer Hospital, Taiyuan, China

Background: Regulating epithelial-to-mesenchymal transition (EMT) in cancer cells has been widely considered as an approach to combat cancer progression and therapeutic resistance, whereas a limited number of broadly comprehensive investigations of microRNAs involved in metastatic colorectal cancer (mCRC) have been conducted. In this study, we investigated the roles and mechanisms of EMT process in mCRC.

Methods: We used in situ hybridization and quantitative reverse transcriptase polymerase chain reaction to measure expression of miR-93 in colorectal tissues, nontumor tissues and metastatic liver tissues. CRC cell lines were transduced with lentiviruses that expressed miR-93, its inhibitor sequence targeted miR-93 or a scrambled sequence (control); proliferation, metastasis, invasion and colony formation were analysed. We analysed growth of CRC cells that overexpress miR-93 or its inhibitor in severe combined immune-deficient mice. Western blot, and luciferase reporter assays were used to measure expression and activity of Eph tyrosine kinase receptor (EphA4) and related signalling molecules.

Results: In this study, we demonstrated that miR-93 regulated the epithelial-mesenchymal transition (EMT) process by targeting EphA4 in metastasis colorectal cancer (mCRC). We examined the fact that CRC tissues and metastatic liver tissues had increased levels of miR-93 compared with the nontumor tissues and cells, by which we identified miR-93 can regulate EMT process. In addition, overexpression of miR-93 increased proliferation of CRC cells, metastasis, invasion and colony formation in vitro, whereas miR-93 depletion reduced these parameters. In severe combined immune-deficient mice, overexpression of miR-93 by CRC cells increased liver metastasis and overexpression of the miR-93 inhibitor reduced it. By further study the role of miR-93 in EMT and tumor metastasis, we identified by microarray analysis that the direct and functional target genes of miR-93 was EphA4. Knockdown of EphA4 phenocopied the effect of miR-93 and ectopic expression of EphA4 restored the effect of miR-93 on proliferation, migration, invasion and liver metastasis in CRC cells.

Conclusions: Our findings for the first time revealed that miR-93 regulates the epithelial-mesenchymal transition (EMT) process by targeting EphA4 to affect liver metastasis in colorectal cancer (CRC). Mechanistically, miR-93 inhibited tumor metastasis by directly targeting EphA4 which is a crucial factor in regulating EMT. Collectively, this study provide new insights into exploring the therapeutic potential of miR-93 which is able to regulate EMT process to affect tumor metastasis, and warrant further study in clinical settings.

570P Array based profiling of emerging molecules in colorectal cancer

E. Shinozaki[1], S. Sakata[2], T. Konishi[3], H. Osumi[1], M. Ueno[3], K. Yamaguchi[1], K. Takeuchi[2]
[1]*Gastrointestinal Oncology, Cancer Institute Hospital of JFCR, Tokyo, Japan,* [2]*Pathology Project for Molecular Targets, The Cancer Institute of JFCR, Tokyo, Japan,* [3]*Gastroenterological Surgery, Cancer Institute Hospital of JFCR, Tokyo, Japan*

Background: Colorectal cancer (CRC) also has various genetic backgrounds and diversity. In addition to the RAS gene, a lot of new knowledge about molecules playing an important role in the process of carcinogenesis or drug resistance, and emerging molecules as targets for new treatments have been reported recently. In this research, we aim to clarify correlation between emerging molecules and differences through clinical stages in CRC usig tissue array.

Methods: Consecutive patients who underwent sugery in our hospital from June 2003 to March 2011 were enrolled in this study. Tissue array based profiling of emerging molecules was performed on archival samples using immunohistochemistry for MLH1/MSH2/MSH6/PMS2, CDX2, HER2 and PD-L1, and fluorescence in situ hybridization for *ERBB2*. We analyzed the correlation among molecular profile, overall survival, pathological findings and location of CRC.

Results: A total of 1122 CRC from stage 0 to IV were analyzed; details in Table. In dMMR population, the proportion of PD-L1 expression (19.2%) was increased significantly compared to those in pMMR population (2.5%). In the univariate analysis, CDX2 negative, BRAF mutation and poorly differentiated histology and in the multivariate analysis, CDX2 negative, dMMR and poorly differentiated histology were idnetified as predictive factors for OS in whole population.

Conclusions: Our data comprehensively summarized the significance of the recent emerging molecules in CRC over the clinical stages. These are considered to contribute to precision medicince in near future.

571P Multiplatform assay to classify formalin-fixed paraffin-embedded (FFPE) colorectal cancer (CRC) samples into molecular subtypes with mutational profiles

E. Fontana[1], C. Ragulan[2], D. Cunningham[3], S. Hulkki-Wilson[2], F. Sclafani[3], G. Nyamundanda[2], K. Eason[2], R. Begum[3], I. Chong[1], C. Peckitt[4], M.A. Bali[5], J. Oates[3], D. Watkins[3], S. Rao[3], M. Hubank[2], A. Wotherspoon[6], N. Valeri[1], I. Chau[3], N. Starling[3], A. Sadanandam[1]

[1]Molecular Pathology, The Institute of Cancer Research/Royal Marsden Hospital, Sutton, UK, [2]Molecular Pathology, The Institute of Cancer Research, Sutton, UK, [3]Medicine, The Royal Marsden NHS Foundation Trust, Sutton, UK, [4]Clinical Research & Development, The Royal Marsden NHS Foundation Trust, Sutton, UK, [5]Radiology, The Royal Marsden NHS Foundation Trust, Sutton, UK, [6]Histopathology, The Royal Marsden NHS Foundation Trust, Sutton, UK

Background: The implementation of CRC subtypes along with other molecular features in clinic is challenging due to lack of easy-to-use and low cost assays suitable for FFPE tissues. Based on our CRCAssigner and Consensus Molecular Subtype (CMS), we validated a small gene panel for nCounter assay (Nanostring Technologies) to classify CRC fresh-frozen samples (ESMO 2017 Abstr 4633). Here, we tested nCounter and MiSeq platforms (Illumina; targeted mutational panel) in archival FFPE samples.

Methods: Tissues from 36 chemorefractory patients treated at the Royal Marsden were collected. Tumour-enriched areas were macrodissected, RNA/DNA was extracted, and nCounter assay was performed. RNA technical (same extraction, n = 6) and biological (same block, different extractions, n = 3) replicates were generated. Hotspot *BRAF*, *KRAS*, *NRAS*, *PIK3CA*, *TP53* mutations (MT) were sequenced.

Results: Out of 26 untreated primaries, 8 were enterocyte/transit-amplifying (TA) (CMS2, 30%), 7 goblet-like (CMS3, 27%), 8 stem-like (CMS4, 30%), 0 inflammatory (CMS1), and 3 mixed subtypes. *BRAF/RAS* MT were mutually exclusive and detected in all goblet-like (CMS3) samples. Interestingly, *PIK3CA* mutation was exclusively present in differentiated (goblet-like and enterocyte) subtypes, whereas *TP53* mutation was detected in all the subtypes. Among 10 pre-treated samples, 3 were inflammatory (CMS1, 30%), 3 TA (CMS2, 30%), 3 stem-like (CMS4, 30%), and 1 mixed subtypes. Pearson correlation coefficients were 0.96 and 0.88 (high reproducibility) for technical and biological replicates, respectively.

Conclusions: With the caveat of small numbers, the subtype distribution in chemorefractory patients is different compared to early stage patients assessed within the CMS consortium. The enrichment for less differentiated subtypes in pre-treated samples suggests potential treatment-induced changes in tumours. Overall, nCounter assay along with MiSeq platform was able to classify standard archival diagnostic CRC FFPE samples into subtypes, which warrants further improvement and validation for clinical practice.

572P A robust gene signature for the detection of early relapse in stage I-III colon cancer

W. Dai, Y. Li, S. Mo, G. Cai

Department of Colorectal Surgery, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Almost 40% to 50% of colon cancer relapse emerged within the first year after initial primary resection. We hypothesized that differences in mRNA expression before treatment could identify patients at high risk of early relapse.

Methods: Public microarray datasets of stage I-III colon cancer samples were extracted from Gene Expression Omnibus database. Propensity score matching analysis was performed between patients in early relapse group and long-term survival group from GSE39582 discovery series (N = 386) and internal validation series (N = 111). Linear Models for Microarray data (LIMMA) method were then used to identify the differentially expressed genes (DEGs). We then built an eight-mRNA-signature using Cox regression model. Time-dependent ROC was used to analyze the predictive accuracy of this classifier in both the discovery and internal validation series. The prognostic value of the signature was further externally validated in GSE14333 and GSE33113 datasets.

Results: After DEGs analysis, eight mRNAs were found with more than 1.5 fold changes and P value <0.05 both in discovery and internal validation sets. With specific risk score formula, patients were further classified into high-risk group and low-risk group. Relapse free survival was significantly different between the two groups in every series including discovery, internal validation and another two external validation sets of patients. Time-dependent ROC at 1 year suggested the more prognostic accuracy of classifier (AUC=0.717) than AJCC TNM staging system (AUC=0.631) in the entire GSE39582 (N = 498) dataset.

Conclusions: We developed a robust mRNA signature consisting of both up- and down-regulated mRNAs that can effectively classify colon cancer patients into groups with low and high risks of early relapse. This mRNA signature may help select high-risk colon cancer patients who deserve more aggressive therapeutic intervention.

573P microRNA(miR) subtypes correlates with colorectal cancer(CRC) molecular subtypes: Validation of miR-30b interaction with genes up-regulated in the high-stroma subtype

B. Perez-Villamil[1], M. Paz-Cabezas[1], T. Calvo-López[1], J. Ogando-Castro[2], J. Sastre[1], S. Mañes[2], E. Díaz-Rubio[1]

[1]Genomics and Microarrays Lab, Medical Oncology Department, IdiSSC, Hospital Universitario Clinico San Carlos, CIBERONC, Madrid, Spain, [2]Immunology and Oncology Department, Centro Nacional De Biotecnología. CSIC, Madrid, Spain

Background: Colorectal Cancer (CRC) is a heterogeneous disease. Microarray molecular profiling has been used to identified tumor subtypes with different clinical behavior (1,2). Our main objective was to find out whether microRNAs (miR) were able to classify CRC tumors in the same way as mRNA and to identify miR targets in the colon tumors associated to the poor outcome High-stroma/CMS4 subtype.

Methods: mRNA and miR expression were analyzed in 88 colorectal tumors (24 Dukes A, 26 B, 19 C, 19 D) using gene expression and miR microarrays. Hierarchical clustering was used to classified tumors based on miR expression. Association or miR subtypes to mRNA subtypes and to CMS was carried out. TALASSO software (http://talasso.cnb.csic.es) was used to find miR-mRNA interactions. Candidate gene-miR interactions were scored and biologically validated in 293T cell line.

Results: Expression profiling of miRs revealed three molecular subtypes clearly associated with those obtained by mRNA expression profiling (p = 0.000 for HC subtypes

and p = 0.001 for CMS subtypes). miR subtype 1 associates with the Low-stroma/CMS2 Subtypes, miR subtype 2 correlates with the High-stroma/CMS4 subtypes and miR subtype 3 is associated with Mucinous-MSI/CMS1 subtypes. 788 genes showed significant interaction with 176 miRs ($p < 0.05$). Based on the biological relevance and the expression profile between subtypes, 88 miR-mRNA interactions were selected as candidates. SLC6A6 that is up-regulated in the high-stroma/CMS4 subtype, showed interaction with miR-30b (P = 0.035). Site-directed mutagenesis over the predicted region of interaction in SLC6A6 3'-end led to the loss of the interaction (p = 0.201).

Conclusions: 1. There is a clear correlation between mRNA classification and 3 novel miR subtypes. 2. miR subtype 1 is associated with Low-Stroma/CMS1 subtype, miR subtype 2 with High-stroma/CMS4 subtypes and miR subtype 3 with Mucinous-MSI/CMS1 subtypes. 3. High-stroma gene (SCL6A6) shows specific interaction with miR-30b.

574P Gene expression changes in the immunotherapy targets CTLA4 and LAG3 in right- and left-sided colorectal cancer tissues during preoperative oral uracil and tegafur/leucovorin chemotherapy

S. Sadahiro[1], T. Suzuki[1], A. Tanaka[1], K. Okada[1], G. Saito[1], H. miyakita[1], H. Nagase[2]

[1]Surgery, Tokai University, Isehara, Japan, [2]Applied Pharmacology Lab., Taiho Pharmaceutical Co., Ltd., Tokushima, Japan

Background: Oral uracil and tegafur (UFT)/leucovorin (LV) are widely used as a standard adjuvant chemotherapy for colorectal cancer (CRC). On the other hand, immune checkpoint inhibitors such as pembrolizumab are being developed for the treatment of patients with CRC with high microsatellite instability or a mismatch repair deficiency. However, the effects of standard chemotherapy on the expression levels of immunotherapy targets are unknown. In the present study, we examined the gene expression levels of immunotherapy targets in tumor tissues before and after UFT/LV chemotherapy in patients with CRC.

Methods: The subjects were 80 patients with CRC who were scheduled to undergo surgery. UFT (300 mg/m^2/day) and LV (75 mg/day) were administered for 2 weeks before surgery. Using an RT-PCR assay, the gene expression levels of four immunotherapy targets, CD274, CTLA4, IDO1 and LAG3, were quantitatively evaluated in paired samples of tumor-biopsy specimens obtained before chemotherapy (pre-samples) and resected-tumor specimens obtained after chemotherapy (post-samples).

Results: In the pre-samples, no differences in the gene expression levels of the four immunotherapy targets were observed between the right- and left-sided colorectal cancer biopsy specimens, but the gene expression levels of LAG3 were significantly higher in elderly patients (≥75 years) than in younger patients (<75 years) ($P = 0.0027$). When the pre- and post-samples were compared, the gene expression levels of CTLA4 and LAG3 were significantly higher after UFT/LV chemotherapy ($P = 0.0003$ and $P = 0.0111$, respectively). Interestingly, these increases in gene expression were only observed in left-sided tumors ($P < 0.0001$ and $P = 0.0056$, respectively), and not in right-sided tumors ($P = 0.3922$ and $P = 0.4085$, respectively).

Conclusions: The increases in the gene expressions of the immunotherapy targets CTLA4 and LAG3 after oral chemotherapy with UFT/LV were specific to left-sided colorectal tumors, suggesting that immunotherapy strategies for patients with CRC after standard chemotherapy should be considered separately for right- and left-sided colorectal tumors.

575P Prognostic value of microsatellite instability status in stage II/III rectal cancer patients who received upfront surgery

C.R. Oh[1], J.E. Kim[2], Y.S. Hong[2], S.Y. Kim[2], T.W. Kim[2]

[1]Department of Internal Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [2]Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea

Background: Microsatellite instability (MSI) is one of the most important prognostic factors in patients with colon cancer but the impact of MSI in rectal cancer, which is known to have a lower incidence of MSI-high (MSI-H) tumours than proximal colon cancer, has not been fully evaluated. We studied whether MSI status affects survival in stage II and III rectal cancer patients who underwent upfront curative resection.

Methods: 1138 patients who had operation between February 2008 and August 2015 in a single, tertiary care center in South Korea were included and PCR-based MSI testing was performed on tumour tissue from each patient. Study endpoints were disease free survival (DFS) and overall survival (OS).

Results: Among 1138 patients, 25 (2.2%) had MSI-H tumours. Compared with microsatellite stable (MSS) or MSI-low (MSI-L) tumours, MSI-H showed similar clinical characteristics including age at diagnosis, gender, tumour location and pathologic tumour stage but they were highly associated with histological grade of tumour (p = 0.005) and presence of family history of colorectal cancers (p = 0.003). The 5-year DFS rates for patients with MSI-H and MSS/MSI-L were 78.0% and 69.2%, respectively (p = 0.637), and the 5-year OS rate was 84.0% with MSI-H and 82.4% with MSS/MSI-L (p = 0.735). On multivariate Cox regression analysis, there was also no significant difference in either DFS (p = 0.855) or OS (p = 0.912) for the patients with rectal cancer based on MSI status.

Conclusions: Our results suggested that MSI has no definite prognostic role in patients with rectal cancer. MSI status was associated with differentiation of tumour and family history of colorectal cancer.

576P Biomarker testing practices in the SECURE (proSpective obsErvational clinical practiCe stUdy in the first-line management of metastatic colorectal cancer [mCRC] with eRbitux in combination with chemothErapy) study

G. Aravantinos[1], A. Shahrasbi[2], M. Oukkal[3], B. Larbaoui[4], P. Ronga[5], D. Messinger[6], J. Hamad[7], W. Benbrahim[8]

[1]2nd Oncology Clinic, Hospital of Agioi Anargyroi, General Oncology Hospital of Kifissia, Athens, Greece, [2]Medical Oncology, Dr. Abdolali Shahrasbi's Private Clinic, Tehran, Iran, [3]Medical Oncology, Clinique de Chimiothérapie de Beau Fraisier, Centre Hospitalier (CHU) de Beni Messous, Algiers, Algeria, [4]Medical Oncology, Centre Anti Cancer Emir Abdel Kader d'Oran, Oran, Algeria, [5]Global Medical Affairs Oncology, Merck KGaA, Darmstadt, Germany, [6]Biostatistics, Prometris GmbH, Mannheim, Germany, [7]Global Medical Affairs and Global Drug Safety, Merck Serono Middle East FZE-LLC, Dubai, United Arab Emirates, [8]Medical Oncology, Anti Cancer Center, Batna, Algeria

Background: First-line treatment decisions in patients with mCRC are influenced by biomarker testing. The purpose of the SECURE study is to obtain real-world evidence regarding the decision pathway in first-line treatment selection. Here, we report information concerning biomarker testing practices in the SECURE study.

Methods: SECURE is a 2-part, noninterventional, multicenter, multinational, open-label, prospective phase 4 study being conducted in Algeria, Egypt, Greece, Iran, and Oman. In the first part of the study, patients with previously untreated mCRC were followed to record biomarker testing practices and first-line treatment decisions; treatment decisions were entirely at the discretion of the investigators. The second phase of the study – which is ongoing – involves monitoring clinical outcomes in patients with *RAS* wild-type mCRC treated with cetuximab-based regimens.

Results: Biomarker testing was performed in 169 of the 182 (92.9%) evaluable patients in the first phase of the SECURE study. *KRAS* (91.8%), *NRAS* (74.2%), *BRAF* (25.8%), and EGFR (20.9%) were the most commonly assayed biomarkers; also, microsatellite instability, PI3KCA, p53, PTEN, and MSH6 were measured in < 10% of patients. Biomarker testing was performed in-house in only 4.9% of cases, whereas 87.9% of biomarker testing occurred in external laboratories. Of interest, the median total duration of biomarker testing was < 10 days (*KRAS*, 9 days; *NRAS*, 9 days; *BRAF*, 8 days; EGFR, 8 days), and the median duration between biomarker testing results and the initiation of cetuximab-based therapy was 14 days. In our cohort, upon *KRAS* assessment, 47.3% of patients were found to be wild-type, 39.6% mutant, 1.6% inconclusive, 2.7% not available, and 0.5% missing. Updated data will be presented at congress.

Conclusions: SECURE provides clarity regarding the decision pathway for patients presenting with mCRC. Our findings suggest that biomarker testing occurs in the overwhelming majority of cases, although opportunities may exist to further optimize biomarker testing practices and better guide treatment decisions.

577P Exosomal ECM1 protein expression in plasma from the tumor-draining vein (mesenteric vein) and time to relapse in colon cancer patients

S. Santasusagna[1], A. Navarro[1], I. Moreno[2], R. Ibeas[2], F. Martinez[2], J.J. Castellano[1], C. Muñoz[1], J. Canals[1], S. Morales[1], R. Hernandez[2], J. Moreno[2], M. Monzo[1]

[1]Molecular Oncology and Embryology Laboratory, Human Anatomy Unit, University of Barcelona, Barcelona, Spain, [2]Medical Oncology and Surgery, Hospital Municipal de Badalona, Badalona, Spain

Background: Exosomes are microvesicles that contain and transport coding and non-coding RNA, DNA, and proteins. They are secreted by several cell types, including

tumor cells, and captured by receptor cells in a target organ, where they modify the tissue microenvironment, forming a pre-metastatic niche where circulating tumor cells can anchor. It has recently been found that blood from a tumor-draining vein can provide more reliable information about biomarkers than that obtained from a peripheral vein (PV). Venous return from the colon occurs through the mesenteric veins (MV), making the MV an excellent source to analyze potential biomarkers contained in exosomes released by the tumor cells in colon cancer before they reach the target organ. We have assessed the presence of exosomal proteins in the MV and PV of surgically resected colon cancer patients and correlated our findings with time to relapse (TTR).

Methods: On the day of surgery, blood samples were obtained from the MV and PV of 31 stage I-III colon cancer patients. Exosomes were isolated by ultracentrifugation and confirmed by cryogenic transmission electron microscopy. High-throughput proteomic analysis by mass spectrometry was used to identify expression levels of exosomal proteins. Findings were confirmed by western blot in MV and PV samples, as well as in samples from healthy controls, using TSG101 as a recognized marker of exosomes.

Results: TSG101 was more highly expressed in relapsed patients than in non-relapsed patients or controls. The ECM1 protein was more highly expressed in both MV and PV exosomes from patients than in those from controls. However, ECM1 expression was 13 times higher in relapsed than in non-relapsed patients in MV – but not PV – exosomes. Among 17 patients with low exosomal ECM1 levels in MV, TTR was 40.2 months, compared to 31.3 months for 14 patients with high levels ($P = 0.04$).

Conclusions: ECM1 and TSG101 are higher expressed in relapsed patients and high expression of exosomal ECM1 released by the tumor is associated with shorter TTR. The analysis of exosomes isolated from the tumor-draining vein, the MV, is a promising method for the identification of biomarkers before reaching the target organ.

578P LAG-3 expression in tumor infiltrating immune cells is associated with poor prognosis in patients with microsatellite instability high colon cancer

I. Lee[1], S.J. Lee[1], B.W. Kang[1], Y.S. Chae[1], H.J. Kim[2], S.Y. Park[2], J.S. Park[2], G.S. Choi[2], J.G. Kim[1]

[1]Department of Oncology/Hematology, Kyungpook National University Medical Center, Daegu, Republic of Korea, [2]Department of Surgery, Kyungpook National University Medical Center, Daegu, Republic of Korea

Background: Recent findings demonstrated that microsatellite instability high (MSI-H) colon cancer contains high T-cell infiltration and highly upregulated expression of multiple immune checkpoints. There is increasing evidence on the role of LAG-3 in the downregulation of T cell responses and on its involvement in tumor-infiltrated T regulatory function. The aim of this study was to reveal the prognostic impact of MSI-H colon cancer showing immune checkpoint protein expressions, which are good candidates for immunotherapy.

Methods: From January 2011 to April 2015, we included 98 patients with MSI-H colon cancer who underwent curative surgery at Kyungpook National University Medical Center. Inhibitory receptors such as cytotoxic T-lymphocyte-associated protein 4 (CTLA-4), lymphocyte-activation gene 3 (LAG-3), programmed death-ligand 1 (PD-L1), programmed cell death 1 (PD-1) and indolamine 2'3'-dioxygenase (IDO) expression status were retrospectively analyzed using immunohistochemistry (IHC). Positivity in tumor cells (T) and immune cells (I) were separately evaluated. IHC values were determined to be positive when moderate or strong intensity of the membranous to cytoplasmic staining pattern were shown in more than 5% of the tumor cells or immune cells.

Results: Among the 93 patients, 22 patients (23.9%) and 63 (68.5%) were determined as PD-L1(T) positive and PD-L1 (I) positive, while 12 (13.2%) and 42 (45.7%) were determined as LAG-3(I) positive and PD-1 (I) positive. Twenty-seven patients (29.3%) and 66 (71.7%) were determined as CTLA-4 (T) positive and CTLA-4 (I) positive, while 66 (71.7%) and 26 (28.3%) were determined as IDO (T) and IDO (I) positive. During median follow-up duration of 39 months, 16 (17.4%) patients experienced recurrence. LAG-3 (I) positivity was significantly associated shorter relapse-free survival ($p = 0.016$). Moreover, LAG-3 expression was significantly correlated with PD-L1 (T) expression ($p = 0.003$). Co-expression of PD-L1 and LAG-3 showed worse prognosis for relapse-free survival ($p < 0.001$).

Conclusions: In conclusion, LAG-3 positivity showed worse prognosis in patients with MSI-H colon cancer.

Background: The TRIBE study showed that FOLFOXIRI plus bevacizumab (Bmab) significantly improved efficacy outcomes as first-line treatment in patients (pts) with metastatic colorectal cancer. A prospective single-arm, multicenter, phase II study investigated the efficacy and safety of Japanese pts.

Methods: Pts were treated with 12 cycles of FOLFOXIRI plus Bmab as induction therapy followed by maintenance with 5-FU plus Bmab until disease progression or unacceptable toxicities. Pts with the double heterozygous or homozygous genotype of the UGT1A1 *28 and *6 polymorphisms were excluded. Prophylactic uses of G-CSF were not permitted. The primary end point was progression-free survival (PFS) rate at 10 months by investigator, which was confirmed by central assessment.

Results: Totally, 69 pts were enrolled. The median age was 60 years, and 42 pts were male. 39 pts with the UGT1A1 single heterozygous genotype and 30 pts with wild-type were enrolled. At a median follow-up time of 19.6 months, the PFS rate at 10 months by investigator and central assessment were 75.2% (95% CI, 63.8–86.6) and 69.0% (95% CI, 56.6-81.4), respectively. The median PFS was 13.3 months (95% CI, 11.5–19.4). The response rate and the rate of early tumor shrinkage were respectively 73.9% and 71.0%, achieving R0 resection rate of 24.6%. The major grade ≥ 3 adverse events were neutropenia (74%), hypertension (35%), and febrile neutropenia (FN; 22%). One treatment-related death occurred. During the first 2 cycles of induction therapy, grade 4 neutropenia and FN in UGT1A1 single heterozygous pts were 46% and 26%, while those in wild-type pts were 13% and 10% ($P = 0.0044$ and $P = 0.127$). However, no association in terms of efficacy between UGT1A1 single heterozygous and wild-type pts was indicated.

Conclusions: The efficacy of FOLFOXIRI plus Bmab in Japanese were consistent with those of previous phase II and III studies, with manageable but different toxicity profiles in terms of grade 4 neutropenia and FN between UGT1A1 single heterozygous and wild-type pts. Prophylactic use of G-CSF in UGT1A1 single heterozygous pts was suggested considering the high incidence of grade 4 neutropenia and FN.

580P The expression of interleukin 17 receptor A is associated with poor prognosis in patients with colorectal cancer and its knockdown inhibits tumor growth and modulates tumor-infiltrating immune cells in mice tumor

C-Y. Yang[1], C-H. Lin[2], J-K. Jiang[3]

[1]Department of Education and Research, Taipei City Hospital, Taipei, Taiwan, [2]Institute of Microbiology and Immunology, National Yang-Ming University, Taipei, Taiwan, [3]Department of Surgery, Taipei Veterans General Hospital, Taipei, Taiwan

Background: Interleukin 17 receptor type A (IL17RA) is a potent mediator in the pathogenesis and progression of colorectal cancer. Our previous study has shown that IL17A is a potential therapeutic target in modulating tumorigenesis, and metastasis, and serves as a prognostic marker in colorectal cancer (CRC), but the role of IL17RA in colonic tumorigenesis is still not clear. This study aims to evaluate the potential role and function of IL17RA in CRC.

Methods: IL17RA expression was determined in colorectal cancer tissues and adjacent normal tissues of CRC patients by using quantitative RT-PCR and immunohistochemistry. To investigate the functional significance of IL17RA expression, and clinical significance of IL17RA expression in CRC patients, disease-free survival was analyzed in patients with CRC. The IL17RA knockdown stable clones were used for in vitro migration/invasion assay and were subcutaneously implanted in mice to measure tumor growth.

Results: A higher IL17RA mRNA level in tumor tissue of CRC patients than adjacent normal tissues ($p = 0.0016$) was found and it was significantly correlated with recurrence ($p = 0.008$) and poor disease-free survival ($P < 0.001$). The knockdown of IL-17RA affected the tumor microenvironment and decreased tumor volume of subcutaneous xenograft model. The scarcity of IL-17RA were found to inhibit the percentage of intratumoral tumor-infiltrating leukocytes including CD4+ CD25+ regulatory T cells and myeloid-derived suppressor cells as determined by flow cytometry analysis. Moreover, IL-17RA-knockdown cells increased apoptotic ability via upregulating PARP1, cleaved-caspase 3.

Conclusions: IL-17RA participates in mediating tumor growth and angiogenesis of CRC and plays a crucial role in the progression of CRC. It could serve as prognostic marker of CRC patients and could potentially be used as a therapeutic target in clinical application.

582P Comparison of performances of three technologies for detection of RAS mutations in cfDNA (NGS strategy, BEAMing assay and ddPCR BioRAD assay)

J. Garcia[1], J. Forestier[2], E. Dusserre[1], C. Rodriguez-Lafrasse[1], V. Cheynet[3], A.S. Wosny[1], C. Ferraro Peyret[4], K. Brengel-Pesce[3], M. Guillet[2], M. Chauvenet[2], S. Couraud[5], M. Brevet[4], T. Walter[2], L. Payen[6]

[1]Biochemistry and Molecular Biology, Hospices Civils of Lyon, Lyon, France, [2]Clinical Department, Hospices Civils of Lyon, Lyon, France, [3]BioMerieux, Hospices Civils of Lyon, Lyon, France, [4]Pathology, Hospices Civils of Lyon, Lyon, France, [5]Clinical Department, Centre Hospitalier Lyon Sud, Pierre Bénite, France, [6]Biochemistry and molecular Biology, Hospices Civiles de Lyon, Lyon, France

Background: A number of RAS mutations confer resistance to anti-EGFR treatments used in the management of colon cancer. The objective of this study was to evaluate the ability of cell-free plasma DNA (cfDNA) to reflect the mutational status of a tumor in order to use liquid biopsies instead of invasive and painful solid tumor biopsies when monitoring tumor progression.

Methods: We selected tumors from the CIRCAN_0 cohort. The molecular profiles from solid biopsies were routinely assessed with the PGM NGS technology. Plasma samples were collected at diagnosis (colon cancer) and during progression (lung cancer). KRAS and NRAS somatic alterations were quantified using three different technologies: droplet digital polymerase chain reaction (ddPCR) from BioRad and BEAMing (Oncobeam) from Sysmex Innostics, as well as next generation sequencing (NGS, NextSEQ500 by Illumina) using the library prepared with the 56G oncology panel kit from Swift Biosciences.

Results: The highly sensitive and specific assays enabled us to obtain excellent matches with solid biopsies determined in cfDNA for colon cancer at diagnosis and for lung cancer during disease progression. When examining cfDNA from patients displaying mutations in their colon biopsy for one of the KRAS and/or NRAS mutations, 100% of the mutations were confirmed using the OncoBEAM technology, whereas only 66% matched the initial PGM status using the two other technologies. The BEAMing technology enabled us to detect KRAS mutations in patients with negative biopsy, increasing the detection of the KRAS positive profiles compared to the standard solid biopsy method. cfDNA was sampled during progression and the high sensitivity and reproducibility of the BEAMing technology enabled us to identify patients with KRAS persistence and others, developing an additional mechanism of relapse.

Conclusions: The advantage of the NGS technology is the larger coverage of longer gene regions for screening purposes, while the BEAMing technology provides highly sensitive results allowing us to follow the kinetics of appearance and disappearance of somatic alterations, linked to the efficiency of therapies.

Background: mCRC is a group of heterogeneous diseases rather than a homogeneous one, resulting in clinical and molecular characteristics between right- and left-sided tumors driving to different prognosis.

Methods: Pts with KRAS Wild-Type (WT) mCRC treated in 1st-line with EGFR monoclonal antibody inhibitors (EGFRI) plus either FOLFOX or FOLFIRI from two randomized phase II trials (MACRO-2/PLANET) were included in the analysis. Pts were classified according to their primary tumor location as right-sided or left-sided. The main objective was to analyze the effect of primary tumor location on objective response rate (ORR), progression-free survival (PFS) and overall survival (OS). Differential responses in RAS WT pts according to tumor location were also evaluated.

Results: Pts with KRAS WT left-sided primary tumors (N = 209) versus right-sided primary tumors (N = 52) were analyzed. RAS was retrospectively determined in 69% of pts. Both KRAS and RAS WT left-sided had significantly superior ORR, median PFS and median OS compared with right-sided (Table).

Table: 583P

	KRAS WT		RAS WT	
	Right-sided (N = 52)	Left-sided (N = 209)	Right-sided (N = 33)	Left-sided (N = 148)
ORR (con˚rmed)				
Rate, %	25.0	46.9	33.3	52.7
OR (95% CI)	0.38 (0.19 – 0.75)		0.45 (0.20 – 0.99)	
P-value	0.004		0.044	
PFS				
Median, m	7.20	9.86	6.54	10.09
(95% CI)	(4.21 – 11.14)	(9.13 – 11.73)	(3.91 – 12.58)	(9.43 – 12.06)
HR (95% CI)	0.64 (0.44 – 0.92)		0.63 (0.40 – 0.99)	
P-value	0.016		0.044	
OS				
Median, m	13.57	27.73	13.57	32.79
(95% CI)	(8.44 – 26.02)	(24.97 – 36.17)	(8.41 – 34.23)	(26.45 – 39.85)
HR (95% CI)	0.47 (0.33 – 0.67)		0.44 (0.28 – 0.68)	
P-value	<0.0001		0.0002	

CI: confidence intervals; HR: hazard ratio; m: months; OR: odds ratio; ORR: objective response rate; OS: overall survival; PFS: progression-free survival WT: wild-type.

Conclusions: Pts with Left-sided primary tumors KRAS or RAS WT mCRC treated with first-line EGFRI plus chemotherapy have significantly improved efficacy outcomes as compared with pts with right-sided primary tumors KRAS or RAS WT mCRC

Background: WJOG6510G study compared cetuximab (Cmab) versus panitumumab (Pmab) in combination with irinotecan (IRI) for patients (pts) with KRAS exon2 wild-type (WT) metastatic colorectal cancer (mCRC) previously treated with fluoropyrimidine-, oxaliplation- and IRI- based chemotherapies. The study demonstrated that Pmab + IRI was not only non-inferior but slightly superior to Cmab + IRI in terms of PFS and OS (median PFS 4.3 months versus 5.4 months, HR 0.68, 95%CI 0.47-0.99, p = 0.040; median OS 11.5 months versus 14.9 months, HR 0.68, 95% CI 0.46-1.02, p = 0.06) (Sugimoto N, et al. ASCO-GI 2017). Here, we report predefined subgroup analyses of the study according to patient characteristics.

Methods: Pre-planned subgroup analyses investigated the homogeneity of treatment effects for PFS and OS across the following subgroups defined by age, gender, ECOG PS, histological type, prior resection of primary site, prior bevacizumab use, reason for oxaliplatin discontinuation, and primary tumor location. Cecum to transverse colon classified as right-sided CRC (RCRC), splenic flexure to rectum classified as left-sided CRC (LCRC).

Results: Totally, 120 (Cmab arm 59, Pmab arm 61) pts were eligible for the analyses. The subgroup analyses in PFS and OS revealed favorable tendency of Pmab arm for almost all factors. Among patients with LCRC (n = 104), Pmab+IRI significantly improved PFS and OS relative to Cmab+IRI (median PFS 4.2 months versus 5.6 months, HR 0.65, 95% CI 0.44-0.97, p = 0.030; median OS 11.1 months versus 15.4 months, HR 0.62, 95% CI 0.40-0.96, p = 0.030). In contrast, in RCRC tumors, comparable survival outcomes were observed between Cmab arm and Pmab arm.

Conclusions: Pmab + IRI for pretreated mCRC patients was associated with favorable PFS and OS compared to Cmab + IRI, especially with left-sided colorectal tumors.

Background: Until now, we have managed all CRC patients (pts) in the same way, However, emergent data show that location of primary tumor can have a prognostic and predictive value in metastatic setting. In this study, we analized differences in sv and cpc between right (R) and left-sided (L) CRC.

Methods: This prospective, multicentre observational study was conducted in coordination with 22 public-sector hospitals of Spain. Pts diagnosed with new CRC, stage I-IV and surgically treated, were included. We defined R-CRC as tumors originated in cecum, ascending colon, hepatic flexure or transverse colon, and L in splenic flexure, descending and sigmoid colon or rectum.

Results: Of 2694 recruited pts, 807 (30%) had R and 1887 (70%) L-CRCs. Most of cases were non-metastatic (89.9%), and males (63.5%). Mortality risk was higher for R-CRC and independent of stage (localised vs metastatic), with HR 1.69; 95% IC 1.24-2.29. Pts with R-tumors were slightly older than L, with a higher Body Mass Index (BMI), a greater predominance of women, non-smokers and regular Nonsteroidal Anti-Inflammatory Drugs (NSAIDs) users. At presentation, they stayed asymptomatic, had elevated CA 19.9 or interval CRCs (diagnosed after negative screening test), and needed urgent surgery more frequently. They also showed special histologies, high grade and vascular invasion more often than L. Although differences in N and M staging were not detected, we observed more T1-T2 in L and more T3- T4 in R-tumors.

Table: 585P Differences in sv and cpc

	R-CRC	L-CRC	p
Sv 2 years (%, 95% IC)	87.9 (85.5 - 90.3)	91.9 (90.6 - 93.2)	0.002
Age (mean, SD)	69.8 ±10.5	67.8 ±11.0	<0.001
Woman (%)	43.0	33.7	<0.001
BMI (mean, SD)	28.1 ±5.0	27.5 ±4.7	0.008
Non-Smoker	55.4	45.2	<0.001
Regular NSAIDs user (%)	6.7	4.4	0.017
Asymptomatic (%)	10.5	7.5	0.017
Interval tumor (%)	12.3	7.1	0.038
Elevated Ca 19.9 (%)	18.8	13.5	0.029
Urgent surgery (%)	6.4	3.1	<0.001
Mucinous, signet-ring and medullary (%)	16.5	7.8	<0.001
High grade (%)	20.1	10.5	<0.001
Vascular invasion (%)	18.7	11.7	<0.001
T stage			<0.001
T1-T2	19.5	29.2	
T3-T4	80.1	67.8	

Conclusions: R and L-CRCs are different, and prognosis is better for L-tumors, independently of stage.

586P The prognostic value of sidedness of the primary tumor after local treatment for oligometastatic colorectal cancer: A Danish population based study

A. Boysen[1], K-L. Spindler[1], M. Høyer[1], F.V. Mortensen[2], T.D. Christensen[3], A.G. Ording[4]
[1]Oncology, Aarhus University Hospital, Aarhus, Denmark, [2]Surgical Gastroenterology, Aarhus University Hospital, Aarhus, Denmark, [3]Thoracic Surgery, Aarhus University Hospital, Aarhus, Denmark, [4]Epidemiology, Aarhus University Hospital, Aarhus, Denmark

Background: Metastasis directed therapy of metastatic colorectal cancer (mCRC) includes resection, radiofrequency ablation (RFA) and stereotactic radiotherapy (SBRT) of liver and/or lung metastases. The location of the primary tumor may influence survival in advanced disease. The aim of this study was to analyse the prognostic value of the primary tumors sidedness after local treatment of oligometastatic CRC in a national population based study.

Methods: Data was retrieved from the Danish Cancer Registry and the Danish National Patient Registry (DNPR) from all patients who underwent surgery for CRC between 2000-2013. Additional data from the DNPR included liver and/or lung metastasectomy, RFA or SBRT. Based on the surgical codes for primary tumor resection in DNPR, patients were grouped as right or left sided (including rectal cancer). Survival was calculated from the date of last recorded local treatment until death from any cause or end of follow-up. A Cox proportional hazard model was used to compute hazard ratios (HRs) for mortality between groups adjusting for age, gender, co-morbidity, nodal stage and site of local treatment.

Results: A total of 38131 patients had surgery for a primary CRC and 2912 patients underwent a total of 3602 metastasis directed procedures. The median age was 64.9 years (range 20-92 years) and 59% were male. Local treatment modalities comprised liver surgery (n = 1616), lung surgery (n = 1075), liver RFA (n = 705), liver SBRT (n = 124) and lung SBRT (n = 82). In the locally treated cohort 590 and 2264 patients were resected for a right and left sided primary tumor, respectively, (unknown primary location n = 58). For all patients (n = 2912), the median survival was 3.8 years (95% CI 3.6-4.0). For patients with a right and left sided tumor, the median survival reached 3.2 years (95% CI 2.7-3.5) and 4.0 years (95% CI 3.8-4.2), respectively. With left sided as the reference the adjusted HR 1.20(95%CI 1.07-1.38, p = 0.003).

Conclusions: In this national population based study, we report a longer median survival for CRC patients with a left sided primary as compared to right sided primary tumor after local treatment for liver and lung metastasis.

587P Survival by sidedness of metastatic colorectal cancer (mCRC) treated with epidermal growth factor receptor antibodies (EGFR-Ab) in the refractory setting: A population-based study of 1509 patients

E. Segelov[1], C. Earle[2], A.P. Venook[3], R. Saskin[4], L. Mofid[4], S. Singh[2]
[1]Medical Oncology, Monash University and Monash Health, Melbourne, Australia, [2]Medical Oncology, Sunnybrook Odette Cancer Center, Sunnybrook HSC, Toronto, ON, Canada, [3]Medical Oncology and Translational Research, UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA, USA, [4]Epidemiology, Institute for Clinical Evaluative Sciences, Toronto, ON, Canada

Background: Sidedness of primary is an established prognostic factor in mCRC and recently has been shown to be an important predictive factor for patients (pts) treated with EGFR-Ab (always in combination with chemotherapy) in 1st and 2nd line settings. Limited data is available in 3rd line and beyond, where EGFR-Ab are used either as monotherapy or with chemotherapy. In Ontario, Canada, public funding of EGFR-Ab is restricted to chemorefractory disease. This study examines the impact of sidedness on overall survival (OS) in chemorefractory mCRC treated with EGFR-Ab monotherapy and combination.

Methods: This population-based retrospective cohort study used linked data from the Institute for Clinical Evaluative Sciences to evaluate mCRC pts treated in Ontario with EGFR-Ab from Jan 2006-Dec 2014. Over 99% of cases are captured via the Ontario Cancer Registry. The primary outcome was OS. Monotherapy v combination was compared by panitumumab (pani; funded only as monotherapy) v cetuximab (cet; funded only with chemotherapy) outcomes. Sidedness was determined by ICD-10 code as right (R; including transverse colon) or left (L).

Results: Of 67117 CRC pts,1553 received EGFR-Ab for refractory mCRC (429 R, 1080 L, 44 unknown). 71% received pani. R were more commonly female, with significantly shorter time (months, m) from diagnosis to EGFR-Ab therapy (mean ± SD: 28.7 ± 18.3 v 32.8 ± 19.2; p < 0.001). Median OS for R with any EGFR-Ab therapy was significantly worse than L: 30.5 v 39.3 m (HR 1.22; 95% CI 1.07-1.38; p = 0.0026); this was true for monotherapy (HR 1.22; 95% CI 1.05-1.42, p = 0.0089) with a near-significant trend for combination (HR 1.30; 95% CI 0.99-1.7, p = 0.055). For L, OS was identical between monotherapy and combination; for R there was a near-significant trend to longer survival with combination (HR 0.76; 95% CI 0.58-1.01, p = 0.058).

Conclusions: This large population cohort demonstrates that R sidedness is significantly predictive for survival with EGFR-Ab in refractory mCRC, consistent with findings in earlier lines of therapy. The differences are particularly seen with monotherapy. L sided cancers appear to benefit equally from monotherapy as combination.

588P Differences in prescribing attitudes and treatment patterns between right-sided and left-sided mCRC in EU5 and the US

F. Bermudez, A. Franceschetti
Global Oncology Therapy Monitor, Ipsos MORI, London, UK

Background: There is evidence to suggest that location of primary colorectal tumours has an impact on prognosis and efficacy of biological agents. Studies focus on *RAS WT* (*KRAS WT* and *NRAS WT*) mCRC, and have identified that left sided colon cancer (LSCC) is more common than right sided colon cancer (RSCC), is observed more in males and is associated with a better prognosis. RSCC on the other hand, is observed more in females and is associated with a worse prognosis. Patients with LSCC show a better response to EGFR inhibitors, whereas those with RSCC show a better response to VEGF inhibitors. This study aims to demonstrate the differences in prescribing habits by tumour location in EU5 and US and to evaluate the impact of new clinical data on real-world treatment patterns.

Methods: Between July 2016 and January 2017, a panel of oncologists in EU5 (n = 624) and US (n = 101) were asked to report on mCRC RAS WT patients and their treatments through the submission of online de-identified record forms.

Results: Out of 996 mCRC patients in EU5 and 821 in US, there are significantly more males with LSCC (57% & 56%) than RSCC (43% & 44%, p < 0.01), whereas for females the split between sides is not significantly different. Out of 2,106 1L *RAS WT* patients in EU5 and 198 in US, those with LSCC receive EGFR inhibitors more than RSCC (p < 0.01 & p < 0.05), but receive VEGF inhibitors less than RSCC patients (p < 0.01 EU5 only). There is no difference in treatment between LSCC and RSCC for 2L+ *RAS WT* patients in US, but in EU5 LSCC patients are prescribed VEGF inhibitors more than RSCC patients (p < 0.05). 'New clinical data' is a more frequent reason for using VEGF inhibitors or chemo-only on RSCC (14% & 4%) than for LSCC (7% & 2%, p < 0.01) in EU5. In US, the same is true for chemo-only patients with RSCC (18%) compared to LSCC (8%), whereas 'new clinical data' is a more significant reason for using EGFR inhibitors on LSCC (14%) than for RSCC (0%, p < 0.01).

Conclusions: 1L mCRC patients with LSCC receive EGFR inhibitors more than RSCC patients, whereas RSCC patients receive VEGF inhibitors more than LSCC patients, a trend not observed in 2L+. This supports the literature when considering that 'new clinical data' has been a significant reason for these prescribing patterns.

Background: Primary tumor location (PTL) has been shown to be not only a prognostic but also predictive factor for 1st-line cet treatment in mCRC. Molecular differences

between PTLs may contribute the sidedness-specific response to cet. We investigated genes associated with efficacy of cet treatment depending on tumor sidedness.

Methods: We enrolled 77 patients (pts) (57% males, median 63-y old, and 15% right-colon cancer) with KRAS exon 2 wild-type tumors from the JACCRO CC-05 or CC-06 trial of 1st-line therapy with cet plus FOLFOX or SOX, respectively. All pts' tissues were measured for expression levels of 2500 genes by HTG EdgeSeq Oncology Biomarker Panel using next generation sequencing for quantitative analysis of targeted RNAs. Univariate Cox regression analysis using log2 values of counts per million (CPM) was conducted for all genes that passed QC filtering in each sidedness (left [L]/right [R]) to assess the association with clinical outcomes. Further univariate Cox regression analysis was performed to define an optimal cutoff point for significant genes. Also, we performed a gene set enrichment analysis (GSEA) to identify classes of genes associated with outcomes in each side. Tumors proximal or from L flexure to rectum were defined as R-sided or L-sided, respectively.

Results: Sixty-nine of 77 pts were assessable for gene expression data. NOTCH1 high-expression (log2(CPM) $\geq$ 7.5) predicted significant longer progression-free survival (PFS) (median 14.7 vs. 11.1 m, HR 0.43, 95%CI 0.22-0.81, P = 0.01) and overall survival (OS) (median 42.8 vs. 26.5 m, HR 0.35, 95%CI 0.15-0.79, P = 0.01) in pts with L-sided tumor (n = 60) but not in R-sided tumor (n = 9).The GSEA showed that gene set of inflammatory response correlated with better PFS in both sides. The regulation of DNA replication gene set was associated with favorable OS but no gene set correlated with bad OS in L-side. Several types of gene set were identified to predict better or worse outcomes in R-side.

Conclusions: Our data suggest that gene expression signatures may explain differences in cet efficacy dependent on tumor sidedness. NOTCH1 may potentially discriminate favorable responders to cet in pts with L-sided tumors.

Background: The RECIST criteria may be limited in assessing response to biologic agents such as bevacizumab (BVZ). Computed tomography-based morphologic criteria (CTMC) might be an alternative to evaluate response in these cases. The aim of this trial was to evaluate the correlation of overall objective responses evaluated by RECIST with CTMC and the pathologic response (pR) after the resection of liver metastases from colorectal cancer.

Methods: Patients with $\leq$ 4 resectable CLM, with no prior chemotherapy for metastatic disease, received 3 cycles of capecitabine/oxaliplatin (XELOX)+BVZ. Response was evaluated using RECIST criteria and CTMC. For CTMC, metastasis was assigned to 1 of 3 groups (Table): CTMC were defined as optimal (metastasis changed from a group 3 or 2 to a 1), incomplete (group changed from 3 to 2), and none (the group had not changed or increased). Those patients without progression, received another cycle of XELOX prior to surgery. After surgery, BVZ + XELOX was given for up to 4 additional cycles. pR was scored as minor ($\geq$50% of residual tumor cells), major (1-49% residual tumor cells), and complete (no residual tumor cells detected).

Results: 83 patients were recruited. 68 were evaluated by RECIST and 67 of them by CTMC; 60 underwent surgery, 51 with metastases resection and histologically analysis. 33 of 68 pts reached partial response by RECIST (49%, 95%CI 37-60%) and 58 had optimal (26) or incomplete (32) response by CTMC (85%, 95%CI 75-92%). Complete (12) or major (30) pR was achieved in 42 of 51 pts (82%, 95%CI 70-90%). Although there was no correlation between the RECIST criteria, CTMC and pR, CTMC was more specific for predicting complete/major pR than RECIST (36 of 42, CTMC vs. 24 of 42, RECIST, p=.0038). In patients with liver resection overall survival at 48 months was 65.8%.

Table: 590P

Computed Tomographic Morphologic Groups

	Computed Tomographic Tumor Characteristics		
Morphology Group	Overall Attenuation	Tumor-Liver Interface	Peripheral Rim of enhancement
3	Heterogeneous	Ill defined	May be present
2	Mixed	Variable	If initially present, partially resolved
1	Homogeneous and hypoattenuating	Sharp	If initially present, completely resolved

Conclusions: CTMC was more specific for predicting complete/major pR than RECIST criteria. After liver metastases resection, 82% of patients had complete or major pR. CTMC seem to be a better surrogate marker of objective pR than RECIST.

591P Tumor staging with magnetic resonance imaging after neoadjuvant chemoradiation for locally advanced rectal cancer and comparison of pathologic staging

C. De la Pinta, M. Martin, F. López, E. Fernández, A. Hervás, S. Sancho

Radiation Oncology, Hospital Universitario Ramon y Cajal, Madrid, Spain

Background: This study was designed to evaluate the role of magnetic resonance imaging (MRI) on preoperative restaging locally advanced rectal cancer after neoadjuvant chemoradiotherapy (CRT), in order to facilitate individualization of surgical management.

Methods: We analyzed 106 patients who had received neoadjuvant CRT underwent a MRI before and after CRT. All patients underwent restaging MRI followed by surgery after the end of CRT. The primary endpoint of the present study was to estimate the accuracy of post-CRT MRI as compared with pathologic staging.

Results: Pathologic T classification matched the post-CRT MRI findings in 38(35.8%) of 106 patients. Sensitivity in T0, T3 and T4 was 25%, 50% and 80% respectively. Specificity in T0, T3 and T4 were 80,2%, 69,7% and 99% respectively. Sensitivity in N0 and N1 were 78,5% and 38,4% respectively. Specificity was 18,2% in N0 and 91,4% in N1. 43 (40,5%) of 106 patients were overstaged in T classification. Pathologic N classification matched the post-CRI MRI findings in 71 (66,7%) of 106 patients. 21(19.8%) of 106 patients were overstaged in N classification. 25 patients (23,6%) achieved T downstaging and 14 patients N dowstaging (13,2%) on restaging MRI after CRT. 24(22,6%) of 106 patients who had been downstaged on MRI after CRT were confirmed on the pathological staging with same stage (T and N).

Conclusions: MRI has low accuracy for restaging locally advanced rectal cancer after preoperative chemoradiation so it is currently not consistent enough for clinical application.

Background: Quality of life (QoL) in patients with colorectal cancer and liver metastases treated with selective internal radiotherapy (SIRT) using Yttrium-90 resin microspheres combined with FOLFOX (standard chemotherapy) has not been compared to FOLFOX alone. We report QoL results from a prospectively pooled analysis of 3 multicentre randomized trials: FOXFIRE, FOXFIRE-Global and SIRFLOX.

Methods: Patients were randomized to FOLFOX or FOLFOX+SIRT in 14 countries. Second-line therapy was permitted upon disease progression. EORTC QLQ-C30 and EuroQoL EQ-5D (3 level) questionnaires were given to all patients at baseline, 2-3, 6 and 12 months from starting treatment and yearly thereafter, and at disease progression. We compared QoL scores between arms at each timepoint, calculating mean differences adjusted for baseline scores, using a 5% significance level. No missing data imputation was performed.

Results: 1103 patients were randomised overall. Questionnaire response rates ranged from 92% (1010/1103) at baseline to 33% (163/493) at 24 months. Patients randomised to SIRT showed significantly ($p < 0.05$) worse scores on 3 of 6 QLQ-C30 functioning scales and 3 of 9 symptom scales (fatigue, nausea and vomiting, appetite loss) at 4-8 weeks after treatment (2-3 months from baseline). SIRT patients had significantly better functioning scores on 3 of 6 scales at disease progression, and significantly less dyspnoea or constipation. Almost no other QLQ-C30 scales showed significant differences at 6, 12 or 24 months. The EQ-5D showed a statistically significant decrement of 0.02 in patients in the SIRT group 2-3 months from baseline, but no differences at other timepoints.

Conclusions: This analysis has shown that QoL is slightly impaired in functioning and symptom domains 4-8 weeks after treatment with SIRT+FOLFOX compared with FOLFOX alone, but slightly better when measured at disease progression. These differences were consistent between the QLQ-C30 and EQ-5D instruments. The differences detected were not large enough to be considered clinically significant.
