Methods: TAILOR is a randomized phase 3 trial that includes a modified intention-to-treat population of 393 patients from China with *RAS* wt mCRC treated with FOLFOX-4 ± cetuximab. The primary endpoint of TAILOR is PFS based on independent review; secondary endpoints include OS, ORR, and QoL. QoL is investigated using the European Organisation for Research and Treatment of Cancer QoL questionnaire core-30 (EORTC QLQ-C30). QoL assessments were planned to be performed at baseline, every 8 weeks of treatment thereafter, and at the final tumor assessment. Patients with *RAS* wt tumors are considered evaluable for QoL if they provide ≥ 1 evaluable EORTC QLQ-C30 from screening to end of evaluation. Pattern-mixture modeling is used to compare QoL between treatment groups by taking into account dropout pattern and other covariates.

Results: Among 393 patients with *RAS* wt tumors, 390 were evaluable for QoL. Before adjustment for several factors (treatment, time, dropout pattern, age, sex, ECOG performance status, number of disease sites, liver-only metastases, and interaction between treatment and dropout pattern), global health status/QoL showed slightly more deterioration in the FOLFOX-4 + cetuximab arm vs FOLFOX-4 arm; however, when these factors were included in the analysis model, the difference between treatment groups was not considered clinically relevant. Similar findings were obtained upon analogous evaluation of social functioning, an individual QoL-related dimension of interest in mCRC.

Conclusions: Adding cetuximab to first-line FOLFOX-4 significantly improved PFS, OS, and ORR without negatively impacting QoL in TAILOR study patients with *RAS* wt mCRC, consistent with observations from earlier cetuximab pivotal trials. These observations confirm cetuximab in combination with FOLFOX-4 as a standard-of-care first-line treatment regimen for patients with *RAS* wt mCRC.

Clinical trial identification: NCT01228734

594P Implementation, participation and satisfaction rates of a web-based decision support tool for patients with metastatic colorectal cancer

L. Keikes[1], R. The[2], K. Karssen[2], A. Mels[3], J. De Vos-geelen[4], J.W.B. de Groot[5], M. Koopman[6], M.G.H. van Oijen[1]

[1]Medical Oncology, Academic Medical Center, Amsterdam, Netherlands, [2]Research, Zorgkeuzelab, Delft, Netherlands, [3]Research, Dutch Digestive Foundation, Amersfoort, Netherlands, [4]Medical Oncology, Maastricht University Medical Center (MUMC), Maastricht, Netherlands, [5]Medical Oncology, Isala, Zwolle, Netherlands, [6]Medical Oncology, University Medical Center Utrecht, Utrecht, Netherlands

Background: The use of decision support tools facilitates shared decision-making, but effective implementation of these tools with adequate patient and provider participation is challenging. Our study aims to effectively implement a newly developed patient-centred decision support tool for patients with metastatic colorectal cancer with sufficient patients' and providers' participation and satisfaction.

Methods: We conducted a patients' and oncologists' needs assessment and developed a decision support tool consisting of a consultation tool and web-based information about treatment options. Between July 2016 (launch) and February 2017, we measured patient participation with log in rates and time spent by online tracking and calculated participation sum scores (low, intermediate and high). Patient satisfaction was voluntarily obtained during online support. We measured oncologist participation in 11 centers by the number of oncologists that handed out at least 1 consultation tool. Satisfaction was measured by structured interviews and a survey.

Results: Implementation rates differed between 3 and 72 handed out (median 23) consultation tools per centre with a median patients' log in rate of 57% (range 39-83%). The majority of patients (68%) had an intermediate high or high participation sum score. The median time spent during online support was highest for questions about patients' perspective (5 mins) and colorectal cancer information (4 mins). Patient satisfaction was 76%. Oncologists' participation per centre ranged from 25 to 100%. The average rating of the decision support tool was 7.8 (scale 1 to 10) by participating

oncologists and 7.3 by other healthcare providers. Several thresholds for implementation were a negative attitude towards shared decision-making and oncologists' fixed treatment preferences.

Conclusions: Implementation of our decision support tool succeeded and patient and oncologist satisfaction was above average. Patients' log in rates differed considerably between participating hospitals while patient online participation was generally high. The most important faced challenge remains to overcome providers' negative attitude towards shared decision-making.

595P Quality-of-life in patients with metastatic colorectal cancer (mCRC) treated with aflibercept and FOLFIRI – Interim results of the non-interventional AIO study QoLiTrap

R. von Moos[1], G. Derigs[2], F. Scholten[3], J. Thaler[4], C. Losem[5], H. Kroening[6], C. Windemuth-Kieselbach[7], R.D. Hofheinz[8]

[1]Medical Oncology, Hospital Graubuenden, Chur, Switzerland, [2]Oncology, Hospital Frankfurt, Frankfurt, Germany, [3]Oncoogy, Klinikum Frankfurt Hoechst, Frankfurt am Main, Germany, [4]Oncology, Klinikum Wels-Grieskirchen GmbH, Wels, Austria, [5]Oncology, Facharztzentrum Neuss, Neuss, Germany, [6]Oncology, Medical Practice, Magdeburg, Germany, [7]Biostatistics, Alcedis, Gießen, Germany, [8]Oncology, University Hospital, Mannheim, Germany

Background: The anti-angiogenic fusion protein Aflibercept targets VEGF-A, VEGF-B and PlGF. Aflibercept in combination with FOLFIRI is approved in patients with mCRC that is resistant or has progressed after oxaliplatin-containing therapy.

Methods: QoLiTrap (AIO-LQ-0113) is an international (Austria, Germany, Switzerland) non-interventional study with a recruitment target of 1500 patients. Primary goal is to evaluate Quality-of-life (QoL) in mCRC patients treated with aflibercept + FOLFIRI using the EORTC-QLQ C30 questionnaire at baseline and before every cycle.

Results: For this interim analysis (data cut-off: 02 March 2017) 576 patients (mean age: 64.7 ± 10 years; 65.1% male, 50.5% with documented RAS mutation, ECOG 0-1: 85.6% of patients) who completed the baseline and at least 2 post-baseline EORTC-QLQ C30 questionnaires were evaluated. Aflibercept was administered for a median number of 6 (and up to 55) cycles. Patients had a median global health score of 58.3 which decreased moderately (mean change -4.0, $p < 0.0001$) within the first 12 weeks of therapy with no significant worsening in gastrointestinal, dyspnea, and sleep disturbance symptom scales. 202 patients receiving study therapy as 2nd line treatment were pretreated with anti-EGFR antibody and/or bevacizumab. Within this subgroup, CR and PR was documented for 26% and SD for 47% of evaluable patients as best response to aflibercept and the median PFS amounted to 8.2 months [95% CI 6.0 – 9.0]. No difference between PFS of RAS wildtype and RAS mutated patients was observed. No new safety signals were identified from the current interim analysis.

Conclusions: The current interim analysis indicates that aflibercept + FOLFIRI in mCRC patients under routine conditions was accompanied by a moderate decline in global health status. Preliminary efficacy results are encouraging, also for patients pretreated with anti-EGFR antibody and/or bevacizumab, who showed a disease control rate of 73% in second line aflibercept therapy. 596P Chemotherapy-induced thrombocytopenia (CIT) in metastatic colorectal cancer (mCRC) patients

K. Cetin[1], A. Toler[2], M. Eisen[3], G.A. Soff[4]

[1]Center for Observational Research, Amgen (Headquarters) - USA, Thousand Oaks, CA, USA, [2]Center for Observational Research, ICON/Docs Global, Inc. and Amgen (Headquarters) - USA, Thousand Oaks, CA, USA, [3]Global Development, Amgen (Headquarters) - USA, Thousand Oaks, CA, USA, [4]Hematology Service, Memorial Sloan-Kettering Cancer Center, New York City, NY, USA

Background: Thrombocytopenia is a common hematologic toxicity of myelosuppressive chemotherapy and can complicate a patient's care.

Methods: This is a descriptive secondary analysis of data from two large clinical trials of mCRC patients – 1,078 treatment-naïve patients receiving fluorouracil, leucovorin, and oxaliplatin (FOLFOX4) and 1,067 previously-treated patients receiving fluorouracil, leucovorin, and irinotecan (FOLFIRI) – to investigate the frequency and clinical consequences of CIT. Evidence of CIT was studied in two ways: 1) recorded platelet counts throughout the study (overall and by grade: $<100\text{-}75 \times 10^9$/L [grade 1]; <75-50 [grade 2]; <50-25 [grade 3]; <25 [grade 4]); and 2) the occurrence of "thrombocytopenia" as an adverse event that directly resulted in platelet transfusion, chemotherapy discontinuation, and/or chemotherapy dose change/delay. The number, duration, and timing (with respect to chemotherapy cycle) of CIT episodes and the co-occurrence of neutropenia and/or anemia (overall and by grade), were also analyzed but not reported in this abstract.

Results: Evidence of CIT based solely on platelet count was relatively common in the FOLFOX4 study (37% of patients had ≥1 platelet count $<100 \times 10^9$/L) and less frequent in the FOLFIRI study (4%), during a median follow-up of approximately one year in each study. Evidence of grades 2, 3 and 4 thrombocytopenia were observed in 15%, 2%, and 1% of FOLFOX4 patients, respectively, and in 1%, <1%, and 0%, of FOLFIRI patients, respectively. Thrombocytopenia as an adverse event resulting in one of the clinical outcomes of interest occurred a total of 433 times across the two studies (FOLFOX4: 406; FOLFIRI: 27). Most events (97%) were addressed solely through a chemotherapy dose change and/or delay, but there were 4 events that were managed exclusively by chemotherapy discontinuation and 10 instances when a platelet transfusion was required (2 of which also led to chemotherapy discontinuation).

Conclusions: In mCRC patients receiving chemotherapy, thrombocytopenia can pose a real clinical problem, commonly leading to chemotherapy delays and/or dose reductions and in some cases, necessitating platelet transfusion and cessation of chemotherapy treatment.

Clinical trial identification: This was a secondary analysis of data from two clinical trials: NCT00364013 and NCT00339183

597P Real world use of palliative systemic therapy (tx) in patients (pts) with metastatic early onset colorectal cancer (mEOCRC) within a UK specialist cancer centre

A. Georgiou, S. Khakoo, A. Minchom, K. Kouvelakis, R. Kalaitzaki, N. Nobar, V. Calamai, M. Ifijen, M. Lethby, F. Arouri, I. Chau, D. Watkins, S. Rao, D. Cunningham, N. Starling

Department of Medicine, Royal Marsden Hospital NHS Foundation Trust, London, UK

Background: The incidence of EOCRC, defined as CRC diagnosed in pts< 50 years old, is increasing. Current literature relating to the palliative systemic tx used, its efficacy, tolerability and outcomes in this group is sparse.

Methods: Retrospective analysis of pts with mEOCRC treated with systemic tx at the Royal Marsden Hospital (RMH) between Jan 2009 – Dec 2014 was conducted.

Results: 114 pts had palliative systemic tx. 93 had mEOCRC at diagnosis of whom 51% were male, median age 43 (range 21-49), 90% performance status ≤1. 72% had left (L) sided tumours. 4% had signet cells. 2 pts had known hereditary syndromes. 72% had

Table: 597P

Metastatic tx line	1	2	3	4
N	114	78	40	15
Median PFS, months	6.9	5.0	2.0	3.9
Best Response (%)	CR 4 PR 40 SD 23 PD 32 NA 1	CR 1 PR 17 SD 26 PD 51 NA 5	PR 8 SD 23 PD 69	PR 7 SD 13 PD 73 NA 7
mOS from diagnosis if last line of tx, months	9.0	14.9	18.7	31.7

liver, 20% peritoneal and 20% lung metastases (met). All 114 pts had ≥1 line of doublet cytotoxic tx. The most commonly administered regimens were: 15% FOLFIRI+ bevacizumab (Bev), 15% FOLFIRI, 11% CAPOX, 10% FOLFOX+ Bev. 12% of tx was given within trials. 38% of pts had tx delays and 38% dose reductions or one agent of a combination tx discontinued early, during their the first line tx. 19% had radiofrequency ablation to liver or lung met. Median overall survival (mOS) in pts presenting with mEOCRC: 18.5 months (95% C.I 14.3-22.6). In addition to BRAF mutant pts, the groups below also trended towards a lower mOS, months (95%C.I): -Younger age: Age 20-29=8.3 (2.6-28.6), 30-39=16.1 (9.6-22.6), 40-49=21.2 (14.9-27.7) -Right (R) sided tumour: R = 13.7 (8.3-18.7) vs L = 20.2 (14.9-27.7) -Signet cells =7.0 (NA) vs No signet cells =18.7 (14.3-22.6) -Fewer lines of systemic tx (Table) The majority of *KRAS* Wild Type (WT) pts (n = 46) had cetuximab or panitumumab. mOS was 21.7 months (95% C.I 16.0-27.7) for WT vs 15.8 months (95% C.I 9.9-21.2) in mutant pts.

Conclusions: Pts treated with sequential combination systemic tx had a better mOS. However, pts with mEOCRC appear to have lower response rates, progression free survival (PFS) and OS when compared to recently published randomised trials. This suggests a more aggressive disease phenotype that warrants further research and tx development.

598P PD-L1 expression in resected colorectal adenocarcinomas is associated with micrometastais

K.U. Park[1], I. Hwang[2], H-M. Ryoo[3], M.H. Heo[1]

[1]Department of Internal Medicine, Keimyung University Dongsan Medical Center, Daegu, Republic of Korea, [2]Department of Pathology, Keimyung University Dongsan Medical Center, Daegu, Republic of Korea, [3]Department of Internal Medicine, Catholic University of Daegu School of Medicine, Daegu, Republic of Korea

Background: Programmed cell death 1 (PD-1) and its ligand (PD-L1) are key suppressors of the cytotoxic immune response. PD-L1 expression on tumor cells may be induced by the immune microenvironment, resulting in immune escape, and an adverse prognosis in many malignancies. In colorectal carcinoma the response to PD-1/PD-L1 inhibition is correlated with microsatellite instability. However, little is known about the clinicopathologic, molecular, and prognostic characteristics of colorectal carcinoma with PD-L1 expression. In surgically resected colorectal adenocarcinoma, micrometastasis should be crucial for recurrence, and micrometastasis may be related to PD-L1. The aim of this study is to assess the PD-L1 expression and its association with clinicopathologic manifestations.

Methods: PD-L1 expression was evaluated in 176 resected colorectal adenocarcinomas using tissue microarrays. Immunohistochemical staining was performed to evaluate the expression of PD-L1. The relationship of clinicopathologic manifestations and PD-L1 expression in colorectal cancer were evaluated by chi-squared test, Kaplan-Meier survival and Cox regression test.

Results: High PD-L1 expression was present in 52.8% colorectal adenocarcinoma and was not related pathologic T or N stage. High PD-L1 expression was associated with decreased recurrence rate ($p < 0.001$), better disease-free survival ($p < 0.001$). Cox regression analysis revealed that pathologic N stage and High PD-L1 expression was an independent prognostic factors of disease-free survival ($p < 0.001$).

Conclusions: High PD-L1 expression is an independent prognostic factor, such as pathologic stage in colorectal adenocarcinoma. PD-L1 expression is independent prognostic factor, relating immune response to micrometastasis and immune suppression by PD-L1 may not be effective in micrometastasis of colorectal adenocarcinoma.

599P Real life registry data of primary localisation of a well-defined colon cancer population of western Austria (Salzburg, Tyrol and Vorarlberg), eastern Switzerland (St. Gallen and Graubünden) and Liechtenstein

B.L. Hartmann[1], W. Oberaigner[2], H. Frick[3], L. Weiss[4], T. Winder[1], K. Philipp-Abbrederis[5], C. Herrmann[3], M.Q. Huynh[6], G. Spizzo[5], C.M. Lang[7], A. Seeber[5], J. Schneider[8], E. Wöll[9], P. Mosler[10], R. Greil[4], M. Rössle[11], H. Rumpold[1], G. Gastl[5], R. von Moos[12], A.H. Lang[13]

[1]Innere Medizin II, LKH Feldkirch, Feldkirch, Austria, [2]IET, Tirol Kliniken, Innsbruck, Austria, [3]Krebsregister, Kantonsspital St.Gallen, St. Gallen, Switzerland, [4]Internal Medicine IV, Landeskrankenhaus Salzburg - Universitätsklinikum der PMU, Salzburg, Austria, [5]Haematology and Oncology, Innsbruck Medical University, Innsbruck, Austria, [6]Innere Medizin, LKH Bregenz, Bregenz, Austria, [7]Chirurgie, LKH Bregenz, Bregenz, Austria, [8]Pathologie, LKH Feldkirch, Feldkirch, Austria, [9]Innere Medizin, Krankenhaus St. Vinzenz-Zams Spital Tirol Oberland, Zams, Austria, [10]Gastroenterology, Kantonsspital Graubünden, Chur, Switzerland, [11]Pathology, Kantonsspital Graubünden, Chur, Switzerland, [12]Oncology, Kantonsspital Graubünden, Chur, Switzerland, [13]Krebsregister Vorarlberg, AKS, Bregenz, Austria

Background: Primary tumors arising from different regions of the colon are biologically distinct; thus location is associated with different features such as microbiota and molecular alterations. Recently, retrospective analysis of phase III trials have shown better prognosis and a significant benefit of anti-EGFR antibodies in left sided RAS wild-type metastatic colon cancer patients. Epidemiological analysis of colon cancer patients from the neighbouring Cancer Registries of Salzburg, Tyrol and Vorarlberg, St. Gallen, Graubünden, and Liechtenstein was to support different prognostic value of left-and right-sided colon cancer.

Methods: 7626 patients with pathologically confirmed colon cancer diagnosed between 2005 and 2015 were identified from the database of the population-based cancer registries of Western Austria, Eastern Switzerland and Liechtenstein. Patients were categorized in two groups: Right-sided colon cancer (RCC) including tumors of the colon transversum and left-sided colon cancer (LCC). Analysis was conducted separately for UICC stages III and IV. Survival curves were estimated applying the Kaplan-Meier method; for comparison of RCC and LCC cohorts the Logrank test was applied. Tumor stage and localisation are shown in the following table.

Table: 599P

Staging UICC	RCC	LCC	Total
I	626 (16.7%)	918 (23.6%)	1544 (20.2%)
II	1091 (29.2%)	979 (25.2%)	2070 (27.1%)
III	995 (26.6%)	1016 (26.1%)	2011 (26.4%)
IV	863 (23.1%)	807 (20.8%)	1670 (21.9%)
X/nos	164 (4.4%)	167 (4.3%)	331 (4.3%)
Total	**3739 (100.0%)**	**3887 (100.0%)**	**7626 (100.0%)**

Results: Tumor location per se in stage III and IV colon cancer in the current retrospectively, epidemiological study, revealed a significantly better overall survival for LCC than for RCC in stage III and IV in a univariate analysis. After stratification by age, hazard ratio was 0.91 (95% Confidence interval 0.78-1.07) in stage III and 0.75 (95% confidence interval 0.66-0.84) in stage IV, thereby confirming recent, retrospective data from large phase III clinical trials (FIRE-3, CHRYSTAL; PEAK and PRIME).

Conclusions: Real life registry data of a well- defined colon cancer population confirm retrospective clinical trial data that LCC in stage III and IV carry a more favourable outcome than RCC, even in the era of modern chemo-immunotherapy.

600P Improving visualization and adherence by converting the Dutch colorectal cancer guidelines into decision trees: The Oncoguide project

M.G. van Oijen[1], X.A. Verbeek[2], T. van Vegchel[2], I.D. Nagtegaal[3], M.J. Lahaye[4], A. Méndez Romero[5], H. Rütten[6], S. de Bruijn[7], H.M. Verheul[8], P.J. Tanis[9], C.J.A. Punt[10], L. Keikes[10]

[1]Medical Oncology, Academic Medical Center (AMC), Amsterdam, Netherlands, [2]Research, Comprehensive Cancer Center Netherlands, Utrecht, Netherlands, [3]Pathology, Radboud University Medical Centre Nijmegen, Nijmegen, Netherlands, [4]Radiology, Netherlands Cancer Institute, Amsterdam, Netherlands, [5]Radiation Oncology, Erasmus MC, Rotterdam, Netherlands, [6]Radiation Oncology, Radboud University Medical Centre Nijmegen, Nijmegen, Netherlands, [7]Gastroenterology, Reinier de Graaf Hospital, Delft, Netherlands, [8]Medical Oncology, Vrije University Medical Centre (VUMC), Amsterdam, Netherlands, [9]Surgery, Academic Medical Center (AMC), Amsterdam, Netherlands, [10]Medical Oncology, Academic Medical Center, Amsterdam, Netherlands

Background: Clinical guidelines are designed to prevent undesired practice variation where high quality evidence or expert consensus is available. However, reading and interpretation of text-based guidelines is time-consuming and might be difficult to apply in routine daily practice. Therefore, the aim of our study is to examine the feasibility of converting the Dutch multidisciplinary colorectal cancer guideline recommendations into data driven algorithms (decision trees) to facilitate guideline usage.

Methods: We converted the most recent Dutch colorectal cancer guideline (published in 2014) into decision trees modelled by decision nodes representing patient or disease characteristics ultimately branching into guideline recommendations. Where not evidence-based, decision trees were discussed with an expert panel until agreement was reached. Thereafter, the developed decision trees were published in open access decision support software.

Results: In total, we developed 34 decision trees driven by 101 decision nodes. Decision trees focused on recommendations for diagnostics (n = 1) staging (n = 10), treatment (colon: n = 1, rectum: n = 5, both: n = 9), pathology (n = 4), follow-up (n = 3) and 1 overview decision tree. We identified guideline recommendation information gaps, for example specific surgical policy related to (the number of) lung metastases, a recommendation about follow-up schemes after resection or local treatment (e.g. RFA) of metastases and the period between neo-adjuvant treatment and re-staging. It was

difficult to convert some of the guideline recommendations into decision trees (i.e. 'consider PET-CT scan to exclude extrahepatic metastases'), related to non-conclusive evidence on specific topics.

Conclusions: Converting the Dutch colorectal cancer guideline into decision trees is feasible, but presents several challenges. Using decision trees may (I) improve guideline adherence or more conscious guideline deviation; (II) improve guideline (adherence) evaluation from cancer registries; and (III) ultimately learn from clinical cases with documented motivation for guideline deviation.

601P Colon and rectal cancer incidence are rising among young Europeans: Results from the cancer registry of Crete

D. Sifaki-Pistolla[1], E. Saloustros[2], G. Pitsoulis[3], L. Vamvakas[4], D. Mavroudis[4], V. Georgoulias[5], C. Lionis[1]

[1]Social and family medicine clinic, University of Crete, School of Medicine, Heraklion, Greece, [2]Oncology Unit, General hospital of Heraklion 'Venizelio', Heraklion, Greece, [3]Region of Crete, Regional council, Heraklion, Greece, [4]Medical Oncology, University hospital of Heraklion, Heraklion, Greece, [5]Medical Oncology, University of Crete, School of Medicine, Heraklion, Greece

Background: Colorectal cancer (CRC) incidence is declining rapidly overall in most European countries. Curiously, in the United States, a worrisome increase in incidence has recently been reported among young adults. We report the first study on this specific age group in the European population.

Methods: This retrospective study was conducted in Crete, Greece using data on malignant neoplasms of the colon (ICD-10: C18), rectosigmoid junction and rectum (ICD-10: C19-20). Data were obtained from the database of the regional Cancer Registry of Crete () and coded according to the international classification system for Oncology (ICD10-O-2). Information on patient's demographic profile, personal and family medical history and lifestyle factors (smoking habits, alcohol consumption) were also available. The analysis was performed in STATA, while all tests were at $a = 0.05$.

Results: The mean age-specific incidence rates (ASpIR) of CRC patients <50 years at diagnosis were 5.1/100,000/year, while for patients≥50 years the ASpIR was 150/100,000/year. The rates were significantly higher for male patients compared to females ($p = 0.02$), especially between the ages of 30 and 70 years. Contrary to that, females aged 20-24 years presented slightly higher ASpIR comparing to males. Focusing on patients <50 years, significant percentage changes of incidence rates per year ($p < 0.05$) are observed for both colon and rectal cancer. The age group of 20-34 years presented 29.7% increase from 1992 to 2013, while the increase for the period 2014 to 2024 is expected to reach 36.9%. Similar increases were observed in the age group of 35-49 years (2003-2013: + 25.1%, 2014-2024: + 28.5%). Interestingly, and despite the fact that screening is voluntary in Greece, a decline in incidence rate by 31.4% was observed in adults ≥50 years old, more predominantly after 2008.

Conclusions: We confirmed in European population an increased incidence of CRC under the age of 50 and a worrisome prediction for the near future. Since mortality in young adults with CRC is high, efforts to promote research and awareness among patients and physicians about the unique characteristics of early-onset CRC are critical.

602P Epidemiology of colorectal cancer in Korea: Korean National Health insurance bigdata analysis

S-C. Lee[1], S.K. Baek[2], J.S. Lee[3], H.J. Ha[2], S-B. Bae[1], I.G. Hwang[4], J.G. Kim[5], T.W. Kim[6]

[1]Internal Medicine, Soonchunhyang University Hospital, Cheonan, Republic of Korea, [2]Internal Medicine, Kyung Hee University Hospital, Kyung Hee University School of Medicine, Seoul, Republic of Korea, [3]Clinical Research Center, Asan Medical Cencer, Seoul, Republic of Korea, [4]Internal Medicine, Chung-Ang University Hospital, Chung-Ang University College of Medicine, Seoul, Republic of Korea, [5]Oncology/Hematology, Kyungpook National University Medical Center, Kyungpook National University School of Medicine, Daegu, Republic of Korea, [6]Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea

Background: This study was conducted to demonstrate the epidemiology of colorectal cancer (CRC) in Korea using the by analysis of big data using the Korean National Health Insurance Service (NHIS).

Methods: We analyzed the NHIS database of patients admitted hospitals which received its quality assessment of CRC between 2011 and 2014.

Results: We included 71,513 colorectal cancer patients. Median follow-up duration was 3.2 years (range 0.003-5.5 years). Male patients were 60.1% and median age was 65 years old (interqurtile range 56-73). The stage at diagnosis was stage I in 22.0%, stage II 29.0%, stage III 35.6%, stage IV 12.9%. As primary site according to surgery code, colon is 61.7% and rectum is 38.3%. Patients with adenocarcinoma were 96.5%. Survival probability at 5 year elderly patients (^{3} 70 years old) showed worse survival rate than that of patient with age <70 [HR 2.24, 95% confidence interval (CI) 2.17 -2.32]. By stage, survival probability at 5 year is 91.9% with stage I, 82.8% with stage II, 73.8% with stage III, and 30.4% with stage IV.

Conclusions: These results show epidemiology and survival of CRC in Korea. Our study was the first to describe these data for colorectal cancer at a nationwide level.

603P Watch and wait versus surgery with pathological complete response: Single institution experience

J. Souza[1], R. Guimarães[2], M.B. Siqueira[1], R. Gil[1], R. Araujo[3], M. Valadão[3]

[1]Medical Oncology, Instituto Nacional de Cancer, Rio De Janeiro, Brazil, [2]Radiotherapy, Instituto Nacional de Cancer, Rio De Janeiro, Brazil, [3]Surgical Oncology, Instituto Nacional de Cancer, Rio De Janeiro, Brazil

Background: Neoadjuvant chemoradiation therapy improves local control, may lead to significant tumor regression and even complete pathological response. We compared patients managed by watch and wait approach and those submitted to surgery with pathological complete response.

Methods: We included patients with rectal adenocarcinoma who had received neoadjuvant long-course chemoradiation therapy (45-50.4 Gy in 25-28 daily fractions with concurrent fluoropyrimidine-based chemotherapy) between July 2003 and December 2012. After, we compared outcomes between two groups: 1) 39 patients managed with watch and wait (WW) approach after clinical complete response; 2) 68 patients submitted to surgery and had pathological complete response (pCR). The primary endpoint was relapse-free survival (RFS).

Results: The median age was 63.5years of age (43-81y) for WW and 60 (29-86y) for pCR. After median follow up of 73 months, of 39 patients managed by watch and wait, 8 (20%) patients had local relapse, 4 (10%) patients had distant relapse, and 3 (7.5%) patients had both and of 68 patients with pCR, 4 (5.8%) patients had local relapse, 5 (7.3%) patients had distant relapse, and 3 (4.4%) patients had both. Salvage surgery was possible in 5 (62.5%) patients after local relapse and 1 (33%) patient after local and distant relapse in WW group, but was not possible in any patient in pCR group. Twenty-five (62.5%) patients have sustained complete clinical response without any surgery in WW group. Local relapse was 3 times higher in WW group (OR 3 – CI:1.09-8.69) and distant relapse were equal (OR: 1.3 – CI:0.43-4.26). The 3- and 5-year RFS was 84.8% and 75.1%, respectively, and was significant better in pCR than WW (HR: 2.46 CI: 1.13-5.49 – p: 0.02). The 3- and 5-year OS was 89.3% and 79.1%, respectively, and was similar in both groups (HR: 1.43 CI: 0.64-3.27 – p: 0.36). Permanent colostomy was 2.6 higher in pCR group (CI:1.02-6.69).

Conclusions: The watch and wait approach had worse RFS without impact on overall survival. Radical rectal surgery was avoided in 62.5% of patients selected and salvage surgery was possible in 62.5% of patients who had local relapse in WW group. The odds of permanent colostomy were 2.6 higher in pCR group.

Background: The J003 trial and RECOURSE trial revealed the safety and efficacy of TAS-102 for patients with metastatic colorectal cancer (mCRC). In March 2014, TAS-102 was approved in Japan, however, there are few studies exploring the efficacy and safety of TAS-102, particularly in the daily practice use. Therefore, we performed this retrospective analysis in order to investigate the real-world clinical practice of TAS-102 for patients with mCRC.

Methods: We retrospectively analyzed the clinical data of 411 patients who received TAS-102 in the multi-institutional retrospective study (HGCSG1503). This study was analyzed by CTCAE v4.0 for adverse events (AEs), RECIST v1.1 for response rate (RR)/ disease control rate (DCR), and Kaplan-Meier method for progression free survival (PFS) and overall survival (OS).

Results: Patients characteristics were as follows; male/female 218/193, median age 66 (range 33-88), ECOG PS (0/1/2/3) 170/190/43/8, KRAS Exon2 wild/mutant 210/187 (14 patients; KRAS Exon2 was not tested). The initial starting dose was 70 mg/m^2 (n = 326, 79.3%) and reduced dose (n = 85, 20.7%). Dose reductions were required in 101 patients (24.6%). The common ≥grade 3 AEs were neutrophil count decreased (48.1%), white blood cell decreased (34.8%), and anemia (28.7%). RR and DCR were 0.5% and 37.2%, respectively. Median PFS and OS were 2.2 and 7.3 months. In analysis on the relationship between ECOG PS 0-1 and PS 2-3, DCR was 38.7% vs. 26.7% (p = 0.140), median PFS was 2.3 vs. 1.5 months (HR 2.000, p < 0.001), and MST was 8.1 vs. 3.4 months (HR 2.778, p < 0.001).

Conclusions: In this analysis, TAS-102 in the real-world clinical practice showed slightly higher anemia to the previous pivotal clinical trials. Although the efficacy in patients with PS 0–1 was similar to the previous reports, TAS-102 did not show the efficacy for patients with PS 2-3.

605P Preliminary results on germline and somatic molecular investigations in Romanian Lynch syndrome patients

L. Negura[1], A. Chicos[1], R. Avadanei[1], A.M. Negura[2]

[1]Oncogenetics, G.T. Popa University of Medicine and Pharmacy, Iasi, Romania, [2]Biology, Alexandru Ioan Cuza University of Iasi, Iasi, Romania

Background: Up to 30% of colorectal cancers (CRCs) have evidence of a familial component, and about 5% are thought to be due to inherited mutations in MMR (MisMatch Repair) genes. Lynch syndrome (LS) is characterized by a very early onset and lifetime risk estimated to 80%. The gold standard for LS diagnostic is complete Sanger sequencing, a very complex and expensive analysis. MMR mutations are detected in only 60% of criteria fulfilling families, while they are present in up to 20% of families not fulfilling these criteria and which are implicitly excluded from genetic counselling. Therefore, we propose an adapted algorithm, based on germline and tumor analysis, intended to increase molecular diagnostic efficiency and CRC casuistry coverage.

Methods: 20 LS families were selected according to Amsterdam criteria, and one index case per family agreed to participate by signing informed consent. All coding regions and exon-intron boundaries of MSH2, MLH1 and MSH6 were screened by double strand Sanger sequencing. Sequence variants were interpreted by *in-silico* analysis. MLPA was performed for large genomic rearrangements. MMR protein expression in tumors was investigated by immunohistochemistry. Somatic tumor DNA was checked for Microsatellite instability (MSI), MLH1 promoter hypermethylation (PHM), as well as for BRAF V600E mutation.

Results: Over 50% of our samples presented germline variants, the majority being benign. Four unclassified variants are altering splicing enhancers. One deleterious variant, but no recurrent MMR mutations were detected. No large genomic rearrangements were identified. IHC showed loss of MSH2 and MLH1 in several samples also presenting high MSI. No PHM was observed, but somatic BRAF V500E showed to be present in several samples. Data from germline analysis correctly correlated with somatic investigations.

Conclusions: This is the first complete molecular approach of LS in Romania. Our work has an important impact on reducing the cost and time of molecular diagnostic, include for diagnostic more patients than usually selected, perform a more efficient diagnostic with >80% mutation finding probability, provide evidence-based recommendations for oncogenetic diagnostic. 606P Clinical manifestations and prognostic factors of bone metastasis in colorectal cancer

Y.J. Chun, S.W. Lee, J.H. Kim, E-A. Choe, H.S. Park, S.H. Beom, S.J. Shin, J.B. Ahn

Medical Oncology, Yonsei Cancer Center Yonsei University, Seoul, Republic of Korea

Background: Bone metastasis from colorectal cancer (CRC) is known as poor prognostic factor. However, the clinical manifestations and outcomes of CRC with bone metastasis are uncertain.

Methods: CRC with bone metastasis were searched from January 2006 to April 2016, and bone metastasis was diagnosed by plain x-ray, computed tomography (CT), magnetic resonance image (MRI), whole body bone scan (WBBS) or positron emission tomography (PET). Clinical data including site of bone metastasis, visceral metastasis, laboratory finding at diagnosis of bone metastasis, and *K-ras* mutation were reviewed. Time to event endpoint was analyzed by Kaplan-Meier survival curves for overall survival (OS).

Results: Of 12,005 CRC patients, 321 (2.7%) had bone metastasis. Colon cancer (58.5%) is more than rectal cancer (41.5%), and pattern of metachronous bone metastasis was 166 (51.7%). Median time to bone metastasis was 28.2 months from diagnosis of CRC in metachronous patients. The most common bone metastasis site was spine (69.5%) and followed by pelvis (52.1%) and long bone (21.6%). At the time of bone metastasis, liver (58.2%), lung (51.5%) and peritoneal (23.8%) metastasis was also observed, and bone only metastasis was 28 (8.5%) patients. High neutrophil-lymphocyte ratio (NLR, ≥3.0), alkaline phosphatase (ALP, ≥123 IU/L) and carcinoembryonic antigen (CEA, ≥5 ng/mL) had significantly correlated with bone only metastasis at a low frequency. Median OS from diagnosis of bone metastasis was 8.0 months (95% CI = 6.8-9.2). Patients with bone only metastasis had longer OS (median OS, 19.1 vs. 7.6 months, P < 0.001) compared to patients with other organ combined metastasis. On multivariate analysis, age ≥61 (Hazard ratio (HR), 1.35; 95% CI = 1.04-1.74), no bone only metastasis (HR, 2.43; 95% CI = 1.38-4.27), peritoneal metastasis (HR, 1.53; 95% CI = 1.12-2.08), NLR ≥ 3 (HR, 1.49; 95% CI = 1.15-1.95) and ALP ≥ 123 (HR, 1.78; 95% CI = 1.34-2.36) were independent factors for OS. And bone only metastasis is the most significant prognostic factor for bone metastasis of CRC.

Conclusions: Bone metastasis of CRC is not a rare event and has a poor prognosis. Bone only metastasis is the most significant prognostic factor and further studies are needed.

607P Outcomes of adjuvant chemotherapy for stage II and III colorectal cancer in Korea, 2011-2014: A nationwide study based on the database of quality assessment and the health insurance

I.G. Hwang[1], J.S. Lee[2], S-C. Lee[3], S.K. Baek[4], J.G. Kim[5], T.W. Kim[6]

[1]Internal Medicine, Chung-Ang University College of Division of Hemato-Oncology Medicine, Seoul, Republic of Korea, [2]Statistics, Asan Medical Center, Seoul, Republic of Korea, [3]Internal Medicine, Soonchunhyang University Hospital Cheonan, Cheonan, Republic of Korea, [4]Internal Medicine, Kyung Hee University Hospital, Kyung Hee University School of Medicine, Seoul, Republic of Korea, [5]Department of Oncology/ Hematology, Kyungpook National University Medical Center, Daegu, Republic of Korea, [6]Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea

Background: Few population-based analyses on treatment outcomes of colorectal cancer (CRC) have been conducted in Asian countries. We conducted a nationwide study to assess the outcomes of adjuvant chemotherapy (AC) for patients with stage II and III CRC in South Korea.

Methods: Data from the Health Insurance Review and Assessment Service Database (HIRA) were analyzed for demographics, tumor characteristics, adjuvant chemotherapy, and survival of patients who underwent curative-intent surgical resection for CRC from 2011 to 2014.

Results: From the HIRA data, a total of 61315 patients were identified: 15620 (25.5%) in stage I, 20525 (33.5%) in Stage II, and 25170 (41.0%) in stage III. Chemotherapy regimens were consisted: 11332 (18.5%) in 5-fluorouraci plus leucovorin or capecitabine (FL/CAP), 13183 (21.5%) in FL/CAP with oxaliplatin (FOLFOX/CAPOX), 357 (0.6%) in uracil and tegafur/doxifluridine (UFT/D) and 36443 (59.4%) in surgery alone. For the patients with stage II colorectal cancer, the adjuvant chemotherapy was associated with a significant increase in survival rate (FL/CAP: hazard ratio [HR], 0.44; 95% CI, 0.40-0.50, and FOLFOX/CAPOX: HR, 0.48; 95% CI, 0.41-0.55, respectively), however UFT/D regimens were not statistically significant. In the patients with stage III, the adjuvant chemotherapy was significantly effective for survival rate (FL/CAP: HR, 0.43; 95% CI, 0.40-0.47, FOLFOX/CAPOX: HR, 0.38; 95% CI, 0.36-0.41, respectively), UFT/D were also not statistically effective.

Conclusions: Adjuvant chemotherapy with FL/CAP and FOLFOX/CAPOX showed a survival benefit for patients with stage II and III colorectal cancer.

608P Variations in clinicopathological features, treatment patterns, and outcomes of young adults with colorectal cancer in the United States and Egypt

A. Heeke[1], N. Rashad[2], H.M. Khaled[3], N. Ali Eldin[4], G.A. Motaal[2], H. Wang[5], B. Weinberg[1], M. Salem[1]

[1]Hematology/Oncology, Lombardi Comprehensive Cancer Center Georgetown University, Washington, DC, USA, [2]Medical Oncology, Maadi Armed Forces Hospital, Cairo, Egypt, [3]Medical Oncology, National Cancer Institute, Cairo, Egypt, [4]Biostatistics and Cancer Epidemiology, National Cancer Institute, Cairo, Egypt, [5]Biostatistics and Bioinformatics, Lombardi Comprehensive Cancer Center Georgetown University, Washington, DC, USA

Background: A recent American Cancer Society study showed that the rate of colorectal cancer (CRC) in young American adults is rising. There are limited data on young Arabian adults with CRC. Herein we explore differences between American and Egyptian young adults with CRC.

Methods: A retrospective review of young (≤46 years old) patients (pts) with CRC in the United States (US-pts) and Egypt (EGY-pts) was undertaken. T and Fisher's exact tests were used for comparative analyses. Kaplan-Meier methodology estimated survival.

Results: In total, 504 pts with CRC were studied, incorporating 62 US-pts (median age 38 yrs, range 20-46) and 442 EGY-pts (35 yrs, 15-46). US-pts were more commonly female (66% vs 41%, $p < 0.001$) and had more colon primaries (75% vs 50%, $p = 0.001$). EGY-pts had more left-sided tumors (78% vs 61%, $p = 0.008$), of which 49% were rectal primaries (vs 24% for US-pts, $p < 0.001$). US-pts had more well-differentiated tumors (25% vs 3%, $p < 0.001$), whereas EGY-pts had more mucin-producing tumors (40% vs 26%, $p = 0.042$). US-pts were more likely to have bowel obstruction (64% vs 17%, $p < 0.001$) and present with metastatic (met) disease (66% vs 28%, $p < 0.001$), particularly in the liver, lung, and peritoneum (56% vs 40%, $p = 0.04$; 35% vs 5%, $p < 0.001$; 48% vs 16%, $p < 0.001$). Comparing pts with met disease, EGY-pts tended to have rectal primaries (33% vs 22%), while US-pts had more right-sided tumors (38% vs 18%). US-pts were more likely to undergo palliative resection or metastatectomy (41% vs 26%, $p = 0.039$) and receive bevacizumab (69% vs 1%, $p < 0.001$). EGY-pts received more 5-FU alone (39% vs 2%, $p < 0.001$) or 5-FU + radiation (40% vs 0%, $p < 0.001$), whereas US-pts received more FOLFOX/FOLFIRI (64% vs 13%, $p < 0.001$). There was no statistically significant difference in median overall survival between US-pts (Not Reached) and EGY-pts (76 months (mos), $p = 0.6$), nor median progression free survival between US-pts (20 mos) and EGY-pts (13 mos, $p = 0.202$).

Conclusions: Significant differences were observed among young US-pts and EGY-pts with CRC, particularly primary tumor location, patterns of metastasis, and treatment used. Further evaluation of the environmental and ethnic impact on disease biology and treatment outcomes is warranted.

609TiP PRODIGE 50 - ASPIK French: French double blind randomised study of aspirin versus placebo in resected stage III or high risk stage II colon cancer with PIK3CA mutation

P. Michel[1], T. André[2], V. Boige[3], T. Aparicio[4], E. Maillard[5], J. Bez[6], J. Blot[7], J-B. Bachet[8], L. Dahan[9], R. Guimbaud[10], S. Manfredi[11], D. Tougeron[12], J. Taieb[13], J. Selves[14], C. Lepage[15], F. Di Fiore[1]

[1]Department of Oncology, CHU Charles Nicolle, Rouen, France, [2]Medical Oncology, Hopital Saint Antoine, Paris, France, [3]Department of Gastroenterology, Gustave Roussy, Villejuif, France, [4]Department of Gastroenterology, CHU Saint Louis AP-HP, Paris, France, [5]Biostatistics, FFCD, Dijon, France, [6]Clinical Chief Project Management, FFCD, Dijon, France, [7]Clinical Chief Project Management, CHU Charles Nicolle, Rouen, France, [8]Department of Gastroenterology, CHU Pitié Salpetriere, Paris, France, [9]Department of Gastroenterology and Oncology, CHU La Timone, Marseille, France, [10]Department of Gastroenterology and Oncology, CHU Rangueil, Toulouse, France, [11]Department of Gastroenterology, CHU Le Bocage, Dijon, France, [12]Department of Gastroenterology, CHU Poitiers Bernard Hôpital, Poitiers, France, [13]Department of Gastroenterology and Digestive Oncology, Hôpital Européen Georges Pompidou, Paris, France, [14]Department of Anatomopathologie, Purpan Hospital, Toulouse, France, [15]Department of Gastroenterology, CHU Le Bocage, FFCD, Burgundy University, INSERM U866, Dijon, France

Background: Four retrospective studies were recently published on aspirin efficacy in patients with surgically resected colorectal cancer (CRC). Two of these studies strongly suggest that low-dose aspirin (100 mg/d) after resection of CRC with *PIK3CA* mutation could act as a targeted therapy with a major protective effect in terms of cancer specific survival. The other two studies did not confirm the benefit of aspirin in this setting. These retrospective studies provide an insufficient level of evidence to demonstrate the benefit of low-dose aspirin as adjuvant therapy for CRC with *PIK3CA* mutation (approximately 12% of all CRC). Therefore, as recommended in the conclusion of these studies and meta-analyses, prospective studies addressing this issue are warranted.

Trial design: PRODIGE 50 is a double blind randomized phase III study comparing aspirin and placebo in patients with curative resection of stage III or high-risk stage II colon cancer with *PIK3CA* mutation. The primary end point is 3-year disease-free survival (DFS). Among secondary endpoints Disease-free survival at 5 years, Overall survival at 5 years, Compliance to aspirin (comptability of containers) will be evaluated. Randomization (1:1 ratio) is stratified according to center, stage (II *vs* III), *RAS* mutation and chemotherapy (oxaliplatin vs no oxaliplatin). The treatment is planned for 3 years (1 tablet 100 mg/day). Abdominal ultrasound/or CT-scan and CEA is performed every 3 to 6 months during 3 years then every 6 months during the two next years. Hypotheses (α two-sided=5%, power= 80%) are to improve 3-year DFS from placebo: 72% to aspirin: 83% (HR = 0.56). 94 events and 264 patients with *PIK3CA* mutation are required. 2200 patients will be screened. Patient blood and tumor tissues will be collected in order to establish a large biobank as a basis for translational research projects including identification and quantification of circulating tumour DNA and evaluating Cox2 expression. Inclusion start is planned on September 2017 until 2019.

Background: Regorafenib is a multikinase inhibitor with broad anti-angiogenic, anti-stroma and anti-proliferative effects that improved overall survival in patients with mCRC after failure of all approved drugs in the CORRECT phase 3 trial. The different tolerability profile of regorafenib compared with other agents normally used for the treatment of colorectal cancer, caused frequent dose-reductions and interruptions, thereby jeopardizing dose-intensity and limiting incorporation of the drug as standard of care. The CORRECT trial showed that the highest rate and intensity of treatment-related adverse events occurs during the first two cycles. The standard approved dose of regorafenib (160 mg daily three weeks on/one week off) was determined in a phase 1 study and this dose was moved directly into the phase 3 trial. The immediate sub-MTD dose level of 120mg daily 3 weeks on/1 week off did not show any DLT among 7 patients treated in the phase I. In addition, an intermittent dose approach consisting of regorafenib 160 mg daily on a 1 week on/1 week off schedule was tested in combination with chemotherapy in the CORDIAL trial and showed a favorable safety profile.

Trial design: This randomized phase 2 study will evaluate the tolerability regorafenib using different dose-escalation approaches in patients with treatment refractory mCRC. Patients will be randomized 1:1:1 to receive regorafenib at the standard approved dose (arm A), or at 120 mg daily 3 weeks on/one week off during the first cycle (arm B), or 160 mg daily one week on/one week off during the first cycle (arm C). In arms B and C, the dose will be escalated to the standard dose from cycle two onwards if no limiting toxicity appears. The primary objective is to compare the safety profile of the different treatment arms. Secondary aims include assessment of the percentage of total administered dose over the planned dose, dose intensity during the treatment period and during first two cycles, disease control rate, progression-free survival, time to treatment failure, and overall survival. The trial is in progress; 160 of 295 planned patients have been recruited at the end of March 2017 (first patient 15 July 2016).

Background: For the 4% of patients with metastatic mismatch repair deficient (dMMR) colorectal cancers, impressive responses are seen with anti-PD1 monotherapy, with response rates up to 40%. Data in patients with non-metastatic colon cancers (CCs) are lacking. Both MSS and MSI early stage CCs show a higher proportion of T-cell infiltration, when compared to metastatic disease. Also, preclinical work has shown improved responses to anti-PD1 therapy by addition of COX (2)-inhibition, suggesting this could be a useful adjuvant that might help induce responses in MSS CRCs.

Trial design: The NICHE trial is a single center, investigator-initiated study, in which patients with newly diagnosed colon cancer who have no signs of distant metastases will be treated with short-term immunotherapy ± COX2-inhibition. Treatment will be given in the window period until surgical resection of the tumor. In this exploratory study, the primary objective will be to determine the safety and feasibility of pre-operative immunotherapy in CC. Secondary objectives include exploring the immune activating capacity of immunotherapy in early stage CCs and the added effects of COX2 inhibition, changes in immune suppressive pathways and the correlation of mutational load to putative markers of response. After additional tumor biopsies are taken via endoscopy, patients with dMMR tumors will all be treated with a single dose of ipilimumab 1mg/kg on day 1 and two cycles of nivolumab 3mg/kg on day 1 and 15. Patients with MSS tumors will be randomized to receive celecoxib 200mg once daily in combination with abovementioned treatment. After 5-6 weeks, patients will undergo surgery, where tumor and normal tissue will again be harvested. When deemed advisable by the pathology report, standard adjuvant treatment with chemotherapy will be offered. A total of 30 patients with MSS tumors and 30 patients with MSI tumors will be enrolled. Recruitment for this study is ongoing and currently two patients have been enrolled.
Conclusion: This is, to our knowledge, the first study exploring pre-operative immunotherapy in patients with non-metastatic CC and will hopefully help identify mechanisms that interfere with clinical activity of immunotherapy, and to develop future strategies and combinations for CRC.

Background: HER2 amplification is identified in approximately 5% out of RAS wild-type metastatic colorectal cancer (mCRC) and likely related to the resistance to EGFR blockade. Some preclinical and clinical studies have shown the efficacy of HER2-targeted therapy against HER2-positive mCRC. To identify this orphan-fractionated mCRC, we collaborate with the nationwide cancer genome screening project (SCRUM-Japan GI-SCREEN) by means of tissue/circulating tumor DNA (ctDNA) screening.

Trial design: TRIUMPH study is a multicenter phase II study to evaluate efficacy and safety of combination therapy with trastuzumab and pertuzumab in patients with HER2-positive mCRC confirmed by either tissue or ctDNA analysis. Eligibility criteria includes histologically confirmed mCRC; ECOG PS $\leq$ 1; RAS wild-type and HER2-positive defined as IHC 3+ or FISH positive (HER2/CEP17 ratio $\geq$ 2.0) by means of tissue screening, or HER2-amplified and RAS wild-type identified from ctDNA (Guardant360); and refractory or intolerant to fluoropyrimidine, irinotecan, oxaliplatin, and anti-EGFR antibody. Enrolled patients will receive intravenous trastuzumab (8 mg/kg loading dose, followed by 6 mg/kg) and pertuzumab (840 mg loading dose, followed by 420 mg) every 3 weeks. In addition, the natural history data of patients with HER2-positive and RAS wild-type who do not meet the eligibility will be followed as a historical control. The primary endpoint is objective response rate (ORR) by investigator's assessment in patients with HER2 positive tumor confirmed by tissue analysis as well as ctDNA analysis, respectively. A sample size for each group is calculated to be 18 on the basis of a power of 80% to test the null hypothesis of ORR of less than 5% versus the alternative hypothesis of ORR of over 30%, at a one-sided alpha level of 0.025. Furthermore, ctDNA will be serially analyzed to investigate the resistance mechanisms; a key focus of current research is to provide clinically meaningful thresholds which may be used for identifying and implementing treatment changes.

Background: Developing appropriate therapy for colorectal cancer is one of the most important health issues worldwide. The CORRECT study was a Phase III, international, placebo-controlled study in which the case data was accumulated from 17 countries including Japan. The results showed the overall survival (OS), the primary endpoint, was significantly prolonged in the regorafenib group, compared with the placebo group. A total of 760 patients were enrolled in the CORRECT study, including 100 Japanese patients. On the other hand, the administration method of regorafenib does not depend on the height, weight, or race of the patients, or other parameters, and 160 mg/body/day is the standard starting dose, but some cases require dose reduction to 120 mg/day or less due to the difficulty of continuous administration of 160 mg/day because of adverse events.

Trial design: This is a multicenter, single-arm, phase II trial. Eligibility criteria include age > = 20 years, histopathologically diagnosed colorectal cancer considered as unresectable due to distant metastasis or locally advanced cancer, indicating disease progression during the standard chemotherapy or within three months after the last administration of the standard chemotherapy, with adequate bone marrow reserve and organ function. The standard chemotherapy includes fluoropyrimidine, oxaliplatin, irinotecan, and bevacizumab, and anti-EGFR (incase of patients with only RAS WT). Treatment history of TAS-102 is not allowed. Regorafenib 120 mg/body/day is orally administrated once a day, after meal for 3 weeks (Days 1 to 21), followed by a 1-week treatment-off period (Days 22 to 28). This 4-week period is considered as 1 cycle and shall be repeated until progression of disease based on RECIST v1.1. The purpose of the study is to evaluate the efficacy and safety of regorafenib when starting regorafenib treatment at 120 mg/day for the patients with metastatic colorectal cancer. Primary endpoint: disease control rate (> = 6 weeks). Secondary endpoints: OS, progression-free survival, response rate, safety, and drug adherence.

614TiP Phase II study of Ccr-based dose-control of S-1 in the first-line chemotherapy of S-1/oxaliplatin (SOX) + bevacizumab regimen for advanced colorectal cancer

D. Manaka, R. Nishitai, S. Konishi, T. Ohta, T. Hattori, H. Ann, K. Kawaguchi, Y. Nishikawa, R. Kudo, S. Hamasu*Department of Surgery, Gastrointestinal Center, Kyoto Katsura Hospital, Kyoto, Japan*

Background: In the 1st line therapy of metastatic colorectal cancer(mCRC), SOX+Bevacizumb(Bev) regimen (L-OHP: 130 mg/m2 day 1, Bev: 7.5 mg/kg day 1, S-1: 80, 100, 120 mg*/body days 1–14 repeated every 3 weeks, *According to body surface area, BSA < 1.25 m2, BSA ≥ 1.25 to < 1.5, BSA ≥ 1.5) has been prooved to be non-inferior to mFOLFOX6+Bev with respcet to PFS by the Japanese phase III study, SOFT trial (JapicCTI-090699). In the east-Asian countries, SOX regimen is now widely used in the 1st line treatment of mCRC because of the advantages of the port-free administration in the out-patient clinic. However, in SOFT trial, incidences of grade 3 or higher diarrhea was statistically higher in SOX group than in mFOLFOX6 group (9% *vs* 3%; p = 0·0040), which was thought to be responsible of S-1. Especially in SOX group, the patients whose creatinine-clearence(Ccr) below 70ml/min, grade 3 or higher diarrhea was significantly by far common than in patients with Ccr above 70ml/min (21.1% vs 5.7%; p = 0.0012). Therefore, it will be suggested that Ccr-based dose-control of S-1 will be effective to decrease severe diarrhea that will lead to the impairment of the compliance of SOX regimen.

Trial design: This trial is an open-label, multi-center, phase 2 study. Before administration of SOX regimen, Ccr is measured. The patients with Ccr >_70, the standard dose will be administered, and in the patients with Ccr 70>_60, the level 1 dose control (decrease) will be performed, and in the patients with Ccr 60>_50, the level 2 dose control will be performed (in the patients <50, no administration will be permitted). The primary endpoint is the incidence of grade 3 or higher diarrhea, and the secondary endpoints are SO, PFS, RR, TTF, R0 resectability, ETS. Thirty-five patients are going to be enrolled, and 21 patients have undergone enrollment at the time of submission of the present abstract.

616O Pertuzumab (P) + trastuzumab (H) + chemotherapy (CT) for HER2-positive metastatic gastric or gastro-oesophageal junction cancer (mGC/GEJC): Final analysis of a Phase III study (JACOB)

J. Tabernero[1], P.M. Hoff[2], L. Shen[3], A. Ohtsu[4], M.A. Shah[5], K. Cheng[6], C. Song[6], H. Wu[7], J. Eng-Wong[6], Y-K. Kang[8]

[1]Vall d'Hebron University Hospital and Institute of Oncology (VHIO), Universitat Autonomas de Barcelona, Barcelona, Spain, [2]Centro de Oncologia, Hospital Sirio Libanes, Sao Paulo, Brazil, [3]Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Gastrointestinal Oncology, Peking University Cancer Hospital and Institute, Beijing, China, [4]Exploratory Oncology Research & Clinical Trial Center, National Cancer Center Hospital, Kashiwa, Japan, [5]Meyer Cancer Center at Weill Cornell Medical College, Medical Oncology/Solid Tumor Program, New York, NY, USA, [6]Product Development Oncology, Genentech, Inc, South San Francisco, CA, USA, [7]Biostatistics, Biometrics, Roche (China) Holding Ltd, Shanghai, China, [8]Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea

Background: Targeting HER2 with H + CT significantly improves overall survival (OS) vs CT alone in patients (pts) with HER2-positive mGC/GEJC. In HER2-positive metastatic breast cancer, P + H + docetaxel significantly improves progression-free survival (PFS) and OS vs placebo (PLA) + H + docetaxel. We therefore assessed the efficacy and safety of adding P to H + CT in pts with HER2-positive mGC/GEJC.

Methods: JACOB (NCT01774786) is a double-blind, randomised, PLA-controlled, Phase III study in mGC/GEJC. Pts were randomised 1:1 to PLA + H + CT (standard cisplatin/fluoropyrimidine regimen) or P + H + CT. P and H were given every 3 weeks until disease progression or unacceptable toxicity (P at 840 mg, H: 8 mg/kg loading and 6 mg/kg maintenance doses). CT was given as per standard regimens/doses. Stratification factors were world region, prior gastrectomy and HER2 immunohistochemistry score. Primary endpoint was OS. Secondary endpoints included PFS and safety. JACOB was estimated to have 80% power to detect a significant improvement in OS (hazard ratio [HR] 0.777) at the final efficacy analysis after 502 events (overall two-sided α-level 5%).

Results: From 10 Jun 2013 to 12 Jan 2016, 388 pts were randomised to P + H + CT and 392 to PLA + H + CT. After a median OS follow-up of approx. 2 years, 504 patients had died, 242 in the P + H + CT arm (median OS 17.5 months) and 262 in the PLA + H + CT arm (median OS 14.2 months) (HR 0.84, 95% confidence interval [CI] 0.71–1.00; p = 0.0565). Median PFS was 8.5 months and 7.0 months respectively (HR 0.73, 95% CI 0.62–0.86). The safety profile was generally comparable between treatment arms except for diarrhoea (all grades: 61.6% in P + H + CT vs 35.1% in PLA + H + CT). Incidence of symptomatic and asymptomatic left ventricular systolic dysfunction was low and similar in both arms.

Conclusions: The study failed to demonstrate a statistically significant improvement in OS with the addition of P to H + CT, although a 3.3-month increase in median OS was observed. P was generally well tolerated and no new safety signals were identified. Further analyses will be presented.

Background: Nivo monotherapy demonstrated its efficacy with manageable safety for G/GEJ cancer refractory or intolerant to standard chemotherapy at the primary analysis (ATTRACTION-02[ONO-4538-12]: ASCO-GI 2017, Kang YK et al. *J Clin Oncol.* 2017; 35 [suppl 4S abstract 2]). Here, we report updated results, and the relationship between efficacy of Nivo and PD-L1 expression levels.

Methods: 493 patients(pts) aged $\geq$ 20 years with ECOG PS 0-1 and unresectable advanced or recurrent G/GEJ cancer after failure of two or more previous chemotherapy regimens were randomized in a 2:1 ratio to receive 3 mg/kg Nivo (N = 330) or placebo (N = 163) every 2 weeks until unacceptable toxicity or disease progression. The primary endpoint was overall survival (OS). The PD-L1 expression was assessed by immunohistochemistry (28-8 pharmDx assay). And updated results of the efficacy and safety were based on $\geq$ 1-year follow-up after last patient enrollment.

Results: As of the data cut-off on February 25th 2017, one year after last patient enrollment, the median OS (mOS) was 5.32 months with Nivo versus 4.14 months with placebo (hazard ratio [HR], 0.61; 95% confidence interval [CI], 0.50-0.75; p < 0.0001). The OS rates were 46.4% (95% CI, 40.8-51.8) versus 34.7% (95% CI, 27.4-42.1) at 6 months and 27.6%(95% CI, 22.8-32.6) versus 11.6% (95% CI,7.2-17.1) at 12 months. Immunohistochemistry was performed for exploratory analyses of OS by PD-L1 status on pretreatment tumor biopsies obtained from 197 pts. In pts with PD-L1-positive (expression $\geq$1%) tumors, the mOS was 5.22 months in the Nivo (16 pts) versus 3.83 months in placebo (10 pts) (HR, 0.58; 95% CI, 0.24-1.38). In pts with PD-L1 negative (<1%) tumors, mOS was 6.05 months (115 pts) versus 4.19 months (52 pts) (HR, 0.70; 95% CI, 0.49-1.00), respectively.

Conclusions: With minimum 1-year of follow-up, long-term survival benefit of nivolumab was confirmed for patients with advanced G/GEJ cancer. Although tumor samples were available only in 40% of all enrolled patients, Nivo demonstrated benefit irrespective of PD-L1 expression in the exploratory analysis.

N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation

Background: A recent phase 3, randomized, open-label, noninferiority trial compared the efficacy and safety of LEN to SOR as first-line systemic treatment in unresectable HCC (954 patients). The study included analyses to evaluate the impact of therapy for HCC on HRQOL.

Methods: HRQOL was assessed using the European Organization for Research and Treatment of Cancer Quality-of-Life Questionnaire (EORTC QLQ-C30), the HCC-specific module (EORTC QLQ-HCC18), and the European Quality of Life (EQ-5D-3L) at baseline, Day 1 of each cycle, and off-treatment visit. Changes from baseline in both treatment arms were assessed using linear-mixed models with selected covariates (baseline score, geographical region, macroscopic portal vein invasion and/or extrahepatic spread, ECOG-PS, body weight). Time to worsening for each domain was represented as months to deterioration defined by a minimally important difference (MID).

Results: A total of 954 patients (LEN treatment n = 478; SOR treatment n = 476) were randomized and included in the intent-to-treat population. Baseline HRQOL scores were similar for patients receiving LEN or SOR across all domains. Significant changes from baseline HRQOL scores were noted for Nutrition, Diarrhea, Role Function (RF), Pain, and Body Image (BI). In the QLQ-HCC18 Nutrition domain, lower adjusted mean scores in favor of LEN were reported at most time points with significant differences at Cycle 6 and Cycle 9 ($p < 0.05$). SOR was associated with worsening Diarrhea symptoms with lower adjusted mean scores in favor of LEN reported at Cycles 3, 6, 9, and 12 ($p < 0.01$). Median months to clinically meaningful worsening among each treatment group was statistically significant favoring LEN for the QLQ-C30 domains of RF (2.0 vs 1.9; $p = 0.0098$), Pain (2.0 vs 1.8; $p = 0.0060$), and Diarrhea (4.6 vs 2.7; $p < 0.0001$), and in the QLQ-HCC18 domains of BI (2.8 vs 1.9; $p = 0.0041$), and Nutrition (4.1 vs 2.8; $p = 0.0060$).

Conclusions: Most domains met the noninferiority assumption between LEN and SOR. The additional evidence of significant HRQOL benefits further support LEN in terms of functional deterioration delays.

Background: Tivantinib is a small molecule inhibitor of c-Met. A previous phase 2 study suggested a clinical benefit of tivantinib as a second-line therapy for hepatocellular carcinoma (HCC) with high expression of c-Met. This Japanese study aimed to confirm the efficacy and safety of tivantinib in this population (NCT02029157).

Methods: Main inclusion criteria were HCC patients refractory or intolerant to a prior sorafenib therapy, Child Pugh A, ECOG PS ≤ 1, at least one measurable lesion according to RECIST 1.1, and diagnosed as c-Met high (regarded as $\geq 2+$ in $\geq 50\%$ of tumor cells, by IHC). Enrolled patients were blindly randomized to either tivantinib or placebo group in 2:1 ratio. Stratification factors were vascular invasion (Y/N) and ECOG PS (0/1). Tivantinib (120 mg bid) or placebo was orally administered until discontinuation criteria was met. Primary endpoint was PFS by the independent review committee, based on CT/MRI every 6 weeks. Secondary endpoints included OS and safety. A sample size of 160 patients and 136 PFS events were calculated to detect a HR of 0.6 (improvement in median PFS from 8 to 13.3 weeks), with 10% dropout, 80% power, and log-rank test with 5% two-sided alpha.

Results: From 60 sites in Japan, 386 patients were consented, and 195 patients were randomized (tivantinib; n = 134, placebo; n = 61). As results, median PFS was 2.8 months in the tivantinib group, whereas 2.3 months in the placebo group (HR = 0.72 [95% CI 0.51-1.02], $p = 0.065$). Median OS at the time of analysis was 9.9 months in the tivantinib group, whereas 8.5 months in the placebo group (HR = 0.85 [95% CI 0.59-1.22]), but additional follow up may be needed to confirm long-term outcome. Grade ≥ 3 AE occurring $\geq 5\%$ were neutropenia (31.6%), leukopenia (24.8%), lymphopenia (7.5%), anemia (14.3%) and febrile neutropenia (6.0%) in the tivantinib group, whereas none in the placebo group. New toxic profile was not identified except for known AE in the previous study.

Conclusions: Although favorable survival were observed in the tivantinib group, this study in Japan could not show the significant clinical benefit of tivantinib as a second-line therapy for c-Met high HCC.

Background: Delta-like ligand 4 (DLL4) is a ligand that activates the Notch pathway which is important for cancer stem cell (CSC) survival. Demcizumab is a humanized, anti-DLL4 antibody that has been shown using an in vivo tumorigenicity limiting dilution assay to inhibit tumor growth and decrease CSC frequency in minimally passaged human xenograft models. In addition, inhibition of DLL4 has also been shown in preclinical studies to cause dysfunctional sprouting of new vessels resulting in an antiangiogenic effect. Encouraging data from a Phase 1b study of paclitaxel protein-bound particles for injectable suspension (Abraxane®), gemcitabine and demcizumab in patients with 1st line metastatic pancreatic cancer led to this double blind randomized 3 arm placebo-controlled Phase 2 study.

Methods: Patients with metastatic pancreatic cancer were randomized (1:1:1) to 1st-line therapy with either Arm 1 - GAP, Arm 2 - GAD with a single 70 day truncated course of demcizumab or Arm 3 - GAD with two 70 day truncated courses of demcizumab (second course starting on Day 168). GA were given at usual dose & schedule, P/D was given IV on days 1 and 15 in cycles 1-3 & 7-9. The primary endpoint was progression-free survival and secondary endpoints included response, survival, safety, immunogenicity, pharmacokinetics, and biomarkers of Notch signaling and CSCs in blood, hair follicles and tumor cells. The primary study analyses compared GAP to the two pooled GAD arms.

Results: 207 patients were randomized and 204 were treated. The median age was 63, the male/female ratio was 116/88, the ECOG 0 vs 1 distribution was 98/106, the median # metastatic sites was 2 and 74% had hepatic metastases. The response/clinical benefit rates were 41.2%/70.6% and 33.1%/74.3% in the GAP and pooled GAD arms, respectively. The median progression-free survival (PFS) (mPFS) was 5.5 months in the GAP and pooled GAD arms. The interim median overall survival (OS) for the GAP and pooled GAD arms were not reached and 13.2 months (HR = 1.02), respectively. Geographic differences in OS were observed. GAD was generally well tolerated with nausea, diarrhea, anemia, peripheral edema and fatigue being the most common reported toxicities. The incidence of the Grade 3 or greater toxicities of special interest with demcizumab therapy were hypertension (7.4% vs 16.2%), pulmonary hypertension (0% vs 0.7%), heart failure (0% vs. 3.7%), and bleeding (1.5% vs. 8.1%) in the GAP and pooled GAD arms, respectively. No cases of Grade 3 heart failure or pulmonary hypertension occurred during the 2nd 70 day course of demcizumab.

Conclusions: The addition of either 1 or 2 truncated courses of demcizumab to 1st-line gemcitabine and Abraxane did not improve the efficacy compared to GAP in patients with 1st line metastatic pancreatic cancer. GAD therapy was generally well tolerated.

Background: L-asparaginase (L-ASP) hydrolyses asparagine, an amino acid essential for the survival and proliferation of cancer cells. Asparagine synthetase (ASNS) expression is believed to play a role in determining sensitivity to asparaginase treatment. Eryaspase, L-ASP encapsulated in erythrocytes, showed encouraging activity and improved safety profile compared to L-ASP in patients (pts) with relapsed ALL. This prompted us to evaluate eryaspase in combination with chemo in pancreatic cancer (PC).

Methods: This open label, multicenter phase 2b randomized study (2:1) enrolled pts with second-line metastatic PC. Pts eligible to gemcitabine or FOLFOX regimen were randomized to chemo +/- eryaspase (100 IU/Kg D3 and D17 of 4-wk regimen) until disease progression. The endpoint of the study was improvement in PFS or OS in pts with no or low ASNS (0/1) expression as determined by IHC, with a target Hazard ratio (HR) < 0.85. Secondary endpoints included OS, PFS, ORR, safety and QoL. The primary analysis took place after around 6 mo follow-up (FUP).

Results: 140 pts were enrolled. The baseline characteristics were well balanced across the 2 treatment arms. The ASNS 0/1 (n = 65 and 32 in eryaspase & control arms, respectively), demonstrated a HR of 0.73 for PFS and 0.62 for OS; therefore the trial met its primary endpoint. In the entire patient population, eryaspase led to improvement of OS (median 26.1 wks) compared to control (median 19 wks); HR of 0.57 (P = 0.03). Similarly, eryaspase led to significant improvement in PFS. The treatment effect in favor of eryaspase was comparable across various prognostic indicators. Overall, treatment was well tolerated, with asthenia, nausea and vomiting, and myelosuppression being the most frequent events in both arms. Final results with additional FUP on efficacy and safety outcome measures will be provided at the meeting.

Conclusions: In pts with PC receiving second-line chemotherapy treatment, the addition of eryaspase provided significant improvement in OS and PFS, irrespective of ASNS expression levels. The role of the ASNS expression will be further investigated. Further investigation of eryaspase in PC in a P3 study is warranted.

Background: Treatment options for pts with LAPC are limited. In the phase 3 MPACT trial, *nab*-P + G treatment (Tx) resulted in a > 3-fold reduction in primary pancreatic tumor burden vs G in pts with metastatic PC, suggesting that the regimen may be effective in LAPC. Interim efficacy and safety results from the international, multicenter, prospective phase 2 LAPACT trial are presented.

Methods: During induction, treatment-naive pts with unresectable LAPC and ECOG PS ≤ 1 received 6 cycles of *nab*-P 125 mg/m^2 + G 1000 mg/m^2 on D 1, 8, and 15 of each 28-day cycle. After induction, pts without PD or unacceptable AEs were eligible for the investigator's choice (IC) of continued Tx with *nab*-P + G, chemoradiation (CRT), or surgery. Surgery could occur prior to completing 6 cycles if the investigator deemed a sufficient tumor response. The primary endpoint was TTF. A secondary endpoint was disease control rate (DCR = CR, PR, and SD [≥ 16 weeks]) in pts who completed induction and had ≥ 1 postbaseline assessment. Data for pts who received their first dose of Tx by Oct 1, 2016 are reported.

Results: A total of 101 pts with LAPC received *nab*-P + G induction. Median age was 65 years (range, 42-85), and median time from primary diagnosis to first dose was 27 days. Pts received a median of 5 Tx cycles (range, 1-6). A total of 60 patients (59%) completed induction. Among 93 evaluable patients, the DCR was 82% (76/93; PR, n = 33; SD ≥ 16 wks, n = 43); 12 pts had SD < 16 wks, and 5 pts (5%) had PD. The most frequent reasons for discontinuation during induction (n = 101 evaluable) were AEs (18%), PD (7%), and physician decision (5%). The 2 most common grade ≥ 3 AEs were neutropenia (37%) and anemia (9%). Grade ≥ 3 peripheral sensory neuropathy was reported in 4% of pts. After completion of induction, 42 patients received protocol-specific IC therapy: 13 continued *nab*-P + G, 15 received CRT, and 14 underwent surgery (R0, n = 4; R1, n = 6; R2, n = 1; 3 missing; resection conversion rate = 33%).

Conclusions: The reported DCR of 82% and PR rate of 35% for *nab*-P + G are promising, and there were no new safety signals compared with previous studies. These interim results suggest that *nab*-P + G is an appropriate LAPC Tx. NCT02301143.

Background: Nab-P+G significantly improved overall survival versus G in Patients (P) with Karnofsky index ≥70% metastatic PDAC (Von Hoff et al, 2013). The aim of this study was to select a tolerable dose -schedule of nab-P+G (Ph I), and to evaluate the efficacy of the selected regimen (Ph II) in patients with previously untreated ECOG-2 advanced PDAC.

Methods: In the phase1 portion of the study patients were randomized to one of 4 treatment regimens including G 1000 mg/m^2 and nab-P 150 mg/m^2 (arm B) or 125 mg/m^2 (arm D) days 1 and 15 every 28 days or same dose of G and nab-P 100 mg/m^2 (arm C) or 125 mg/m^2 (arm E) days 1, 8, and 15 every 28 days. The two safest regimens determined by analyzing hematological and non-hematological grade 3-4 toxicity, 30 and 60 days mortality, treatment discontinuation due to toxicity and dose intensity were selected for evaluation in the phase 2 portion of the study with 6 months overall survival (OS) as the primary endpoint.

Results: Regimens arm C and arm E (days 1, 8, 15 every 28 days schedule) were selected for the phase 2 portion of the study. A total of 221 patients (111 in arm C/110 in arm E) were enrolled. Median age was 71/68 y, 51/55% were male and 91/83% had metastatic disease (liver 63/62%). Most frequent grade 3-4 toxicity per arm were anemia (12/7%), neutropenia (32/30%), thrombocytopenia (7/11%), febrile neutropenia (3/4%), asthenia (14/16%) and neurotoxicity (11/16%). There were no significant differences in 6 months OS 63/69%, response rate (RR) 24/28% and median progression free survival (PFS) 5.7/6.7 months respectively in each arm.

Conclusions: Nab-P in combination with G, both at 100 and 125 mg/m^2 dose administered on a standard schedule of days 1, 8 and 15 is well tolerated and results in acceptable OS, RR and PFS in this fragile patient population.

Background: Muparfostat is an investigational new drug which deters tumor growth by blocking tumor angiogenesis and prevents tumor cells from spreading via heparanase inhibition. Previous phase II trial of muparfostat demonstrated good tolerability and favorable clinical response.

Methods: This international multicenter clinical trial was conducted in Asia-Pacific region (Taiwan, Korea, China, and Hong-Kong) from 2011. A total of 520 HV-HCC patients after surgical resection were randomized (1:1) to receive injection of either muparfostat (160 mg/day, 4-days-on/3-days-off, 3-weeks-on/1-week-off) or placebo for 52 weeks and followed up for 96 weeks. The primary endpoint was centrally assessed disease-free survival (DFS). Secondary endpoints included overall survival (OS), time to recurrence, and safety.

Results: Baseline patient demographics and characteristics were balanced between the treatment and placebo arms. All subjects completed the 52-week treatment. After interim analysis in 2014, the trial was concluded in 2015. The final intention-to-treat analysis ($N = 519$) yielded a non-significant result ($p > 0.05$) on DFS, not reaching the primary end point. Nevertheless, per-protocol analysis ($N = 423$) revealed a possible positive protective effect in subgroup patients with microvascular invasion. Muparfostat showed a significant prolongation in the disease-free time after completion of the 1-year treatment (hazard ratio: 0.13, 95% CI: 0.017 - 0.991, $p = 0.049$). Muparfostat had a good safety profile. There were five clinically suspected cases of heparin-induced thrombocytopenia but only one was confirmed.

Conclusions: Despite the DFS was not improved in the overall treatment group, muparfostat could significantly prolong the DFS in the microvascular-invasion subgroup, comprising 40% of the trial population. The finding potentiated muparfostat as single therapy or in combination with other anti-cancer agents for future HCC adjuvant therapy trials.

Clinical trial identification: PATRON/NCT01402908

625PD Protein biomarkers as predictors of outcome with regorafenib (REG) in patients (pts) with hepatocellular carcinoma (HCC) in the RESORCE trial

M. Teufel[1], K. Köchert[2], G. Meinhardt[3], R.S. Finn[4], J.M. Llovet[5,6,7], J. Bruix[5]

[1]Translational Medicine Oncology, Bayer HealthCare Pharmaceuticals, Whippany, NJ, USA, [2]Genomics and Biomarker Statistics, Bayer AG, Berlin, Germany, [3]Clinical Development Oncology, Bayer HealthCare Pharmaceuticals, Whippany, NJ, USA, [4]Division of Hematology/Oncology, David Geffen School of Medicine at UCLA, Los Angeles, CA, USA, [5]BCLC Group, Liver Unit, Hospital Clinic, University of Barcelona, IDIBAPS, CIBEREHD, Barcelona, Spain, [6]Liver Cancer Program, Division of Liver Diseases, Icahn School of Medicine at Mount Sinai, New York, NY, USA, [7]Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Spain

Background: REG improved overall survival (OS) and time to progression (TTP) versus placebo in pts with HCC who progressed during prior sorafenib in the phase 3 RESORCE trial. This exploratory analysis evaluated potential correlations between baseline plasma protein levels and REG clinical benefit (OS and TTP) in RESORCE.

Methods: Baseline plasma samples were available from 499/573 pts. A total of 266 circulating proteins valid for analysis were quantified by a Luminex assay (Myriad RBM). The predictive and prognostic effects (HR and 95% CI) were evaluated using a Cox proportional hazards model with protein levels measured as a continuous variable. The predictive effect was modeled as a protein–treatment interaction effect and subjected to Akaike information criterion (AIC)-based selection to assess its association with OS and TTP. Subgroup analysis was done on proteins identified as significant for OS and TTP to generate a patient-wise protein composite score.

Results: The overall and biomarker cohorts were similar for demographic variables and outcomes. Five proteins were predictive for OS (Table), but were not prognostic; 47 were predictive for TTP (6 were prognostic) and included the 5 proteins predictive for OS. In general, the REG treatment benefit for OS was maintained in dichotomized, quartile, and STEPP subgroup analyses, with lower protein levels correlating with improved treatment benefit. However, composite scores integrating information across predictive proteins indicated that in a small group of pts ($n = 20$ OS; $n = 8$ TTP) a high protein concentration was associated with a reduced treatment effect.

Conclusions: Although this exploratory analysis suggests that most pts with HCC derive benefit from REG treatment, multiple proteins were identified as potentially predictive for OS and TTP treatment benefit with REG. Further analyses including biochemical and clinical factors are warranted.

Clinical trial identification: NCT01774344

Background: Postoperative S-1 for 1 year (corresponding to 8 courses) is a standard adjuvant chemotherapy for p-stage II gastric cancer based on ACTS-GC phase III study comparing surgery alone and S-1. Duration of adjuvant chemotherapy for 1 year selected in ACTS-GC was not based on solid evidence while 6 months are established for colon cancer based on several phase III studies to compare duration. It remains unclear whether S-1 for 1 year could be shortened to 6 months (corresponding to 4 courses) without worsening the survival.

Methods: We conducted a multi-center phase III trial to confirm non-inferiority in relapse-free survival (RFS) of 4 courses S-1 to 8 courses S-1 in p-stage II gastric cancer. Key eligibility criteria were p-stage II except T1 and T3N0 (7th edition of TNM), performance status 0-1, R0 resection with D2 lymph node dissection for $\geq$c-stage II or D1+ lymph node dissection for c-stage I, within 7 weeks after surgery, and age between 20 and 80 years. Primary endpoint was RFS and secondary endpoints included overall survival (OS), time to treatment failure (TTF), and adverse events. Patients were randomized into 4 course S-1 or 8 courses S-1. 80 mg/m^2 of S-1 was administered for 4 weeks with a rest for 2 weeks as one course. Total sample size was determined to be 1,000 with 3-year RFS of 85% in both arms and non-inferiority margin of hazard ratio (HR) of 1.37, one-sided alpha of 5% and 80% power.

Results: Between Feb 2012 and Mar 2017, 590 patients were enrolled in this study. Among them, 528 patients were analyzed at the first planned interim analysis at Mar 2017. JCOG Data and Safety Monitoring Committee recommended early termination of the trial because the point estimate of HR was greater than non-inferiority margin of HR, which met the prespecified criteria for early stopping. The study was closed on the basis of futility. RFS at 3 years was 88.9% for 4-courses arm and 95.3% for 8-courses arm (HR 2.52, 95% CI 1.11-5.77). OS at 3 years was 91.7% for 4-courses arm and 97.7% for the 8-courses arm (HR 5.18, 95% CI 1.50-17.89).

Conclusions: Postoperative S-1 adjuvant chemotherapy for p-stage II gastric cancer should be continued until 1 year so far as feasible.

627PD Comparison of the eighth and seventh editions of the American Joint Committee on Cancer TNM staging systems for gastric cancer: Proposal for a simplified and improved TNM staging system

J. Lin, H. Chang-Ming, J. Lin, C. Zheng, P. Li

Department of Gastric Surgery, Fujian Medical University Union Hospital, Fuzhou, China

Background: To evaluate the prognostic significance of the eighth edition of American Joint Committee on Cancer (AJCC) TNM staging classification for gastric cancer.

Methods: Data from 4,957 consecutive patients who underwent radical gastrectomy between 1997 and 2014 were retrieved from our database. The prognostic value of the eighth edition was compared with that of the seventh edition of the AJCC TNM classification. The analysis was repeated in an external validation set.

Results: Significant differences in 5-year overall survival (OS) rates were observed for each TNM stage when using the eighth edition system, and smaller AIC values and a higher c-statistic were observed relative to those of the seventh edition. However, the OS rates in each subgroup of stage III patients in the eighth edition were significantly different. Additionally, patients with the same pN stage, namely the pT4a and pT4b groups, showed similar 5-year OS. Based on the survival data, we propose a simplified staging system. In the improved TNM (iTNM) staging system, the subgroups of a given TNM stage do not have statistically significant OS differences. The iTNM staging exhibits superior prognostic stratification, with lower AIC values and a higher c-statistic than the eighth edition TNM classification. Similar results were obtained with the external validation dataset.

Conclusions: The eighth edition of the AJCC TNM classification provides superior prognosis to that of the seventh edition. However, it remains associated with some stage migration. The iTNM staging system permits simplification and slightly better prognostic prediction.

628P Treatment outcome of gastric cancer associated with esophageal cancer

N. Mori, T. Tanaka, S. Matono, Y. Akagi

Surgery, Kurume University School of Medicine, Kurume, Japan

Background: The incidence of synchronous and metachronous gastric cancer is high in esophageal cancer patients.

Methods: 113 esophageal cancer (EC) patients with synchronous and metachronous gastric cancer (GC) were analyzed between 1997 and 2016 retrospectively. There were 110 men and 3 women, with a median age of 67 years. 58 had a synchronous gastric cancer (S group) and 55 had a metachronous (M group). In the M group, there were 36 patients with a subsequent esophageal cancer (SEC) and 19 with an antecedent esophageal cancer (AEC).

Results: 1) S group: T stage of EC was 1 in 14 patients, 2 in 4, 3 in 25, and 4 in 15. Stage was 0 in 4 patients, I in 6, II in 9, and III in 39. T stage of GC was 1 in 46 patients, 2 in 6, 3 in 4, and 4 in 2. Stage was I in 49 patients, II in 5, and III in 4. 35 underwent esophagectomy (31 gastrectomy and 4 endoscopic treatments) and 23 received definitive chemoradiotherapy for EC (4 gastrectomy, 3 endoscopic treatments, and 16 observations for gastric cancer). 2) SEC group: The median range between gastrectomy and esophageal treatment was 8.4 years. T stage of EC was 1 in 13 patients, 2 in 6, 3 in 11, and 4 in 6. Stage was I in 3 patients, II in 8, and III in 25. Of the 36 pts, 16 underwent esophagectomy, 18 received definitive (chemo-) radiotherapy, and 2 underwent endoscopic treatment. 3) AEC group: The median range between esophagectomy and gastric treatment was 6.5 years. T stage of EC was 1 in 6 patients, 2 in 1, and 3 in 8, and 4 in 4. Stage was I in 6, II in 6, and III in 7. T stage of GC was 1 in 11 patients, 2 in 4, and 3 in 4. Of 19, 10 underwent endoscopic treatment, 5 underwent gastrectomy, 1 received chemotherapy, and 1 did not receive any anti-cancer treatment. The overall survival rates at 5 years in S group, SEC group, and AEC group were 50%, 45%, and 51%, respectively. There was a significant difference in the overall survival rates between the surgery group (45%) and non-surgery group (36%) in the S group ($p = 0.0006$). In the SEC group, there was a tendency of long survival in those who underwent surgery (56%), compared to those who did not have surgery (37%) ($p = 0.06$). Prognosis of patients with gastric tube cancer was 10 years after EC treatment and 4 years after gastric tube cancer treatment.

Conclusions: Patients in the S group who underwent surgery had a good prognosis. Periodic endoscopic examination is necessary for early diagnosis of gastric tube cancer.

629P Sarcopenia, myosteatosis, and weight loss as determinants of survival and toxicity in patients with resectable esophageal and gastroesophageal junction (GEJ) cancer receiving preoperative chemoradiotherapy (CRT)

A.G. Lui, A. Gallivan, M. Iafolla, Z. Abdelaziz, D. Yusuf, S. Ghosh, J. Spratlin, K. Mulder, M. Sawyer

Medical Oncology, Cross Cancer Institute, University of Alberta, Edmonton, AB, Canada

Background: Abnormal body composition (sarcopenia, myosteatosis, and significant weight loss of $\geq$ 8% (SWL)) has been associated with poor outcomes. This study evaluated sarcopenia, low skeletal muscle attenuation (SMA), and SWL as factors associated with toxicity, recurrence free survival (RFS), and overall survival (OS) with neoadjuvant CRT, in patients with resectable esophageal/GEJ cancer.

Methods: We retrospectively reviewed all pts with resectable esophageal/GEJ cancer treated with curative intent preoperative CRT (paclitaxel/carboplatin) from 2010-2013. Pretreatment CT scans were used to measure skeletal muscle index (SMI) and SMA to determine sarcopenia and myosteatosis, respectively. SWL was determined from the first dietitian recorded body weight and pre-morbid body weight. Treatment delays/modifications (TDM) were used as surrogates for toxicity.

Table: 629P Body composition analysis, toxicities, and OS

		SMI		SMA		Weight Loss	
	All Patients	Sarcopenia n = 35 (40%)	No Sarcopenia n = 53 (60%)	Myosteatosis n = 46 (52%)	No Myosteatosis n = 42 (48%)	SWL n = 40 (45%)	Non-SWL n = 48 (55%)
Mean SMI (cm^2/m^2)	51.2	44.1	55.9	49.3	53.4	47.9	54.0
Mean MA (HU)	34.2	33.6	34.6	27.9	41.0	33.1	35.0
Mean Weight Loss (%)	9.0	10.2	8.2	10.5	7.4	16.2	3.1
Treatment delays/modifications							
YES	36 (40.9%)	13 (37.1%)	23 (43.4%)	26 (56.5%)	10 (23.8%)	21 (52.5%)	15 (31.3%)
NO	52 (59.1%)	22 (62.9%)	30 (56.6%)	20 (43.5%)	32 (76.2%)	19 (47.5%)	33 (68.8%)
Median OS (months)	23.4	19.8	28.3	20.3	28.3	16.7	49.4

Results: Of 88 evaluable patients, 76 (86%) were males with a median age of 62. Histology includes: 72 (82%) adenocarcinoma; 13 (15%) squamous cell carcinoma, 3 (3%) other. Sarcopenia, myosteatosis, and SWL were present in 35 (40%), 46 (52%) and 40 (45%) patients, respectively. By univariate analysis, sarcopenia and SWL were associated with shorter OS and RFS (Sarcopenia $p = 0.009$ and $p = 0.042$, respectively, SWL $p = 0.012$ and $p = 0.061$, respectively). Myosteatosis was associated with TDM ($p = 0.001$). On multivariate analysis, sarcopenia and SWL were associated with shorter OS and RFS, independent of stage and performance status (PS).

Conclusions: Sarcopenia and SWL are associated with shorter OS and RFS independent of stage and PS. Myosteatosis is associated with treatment-related toxicities. These results highlight the prognostic and predictive utility of body composition analysis in survival and treatment related toxicities in esophageal/GEJ cancer patients treated with curative intent preoperative CRT.

630P Optimal extent of abdominal lymph node dissection for advanced Siewert type II and III esophagogastric junction carcinoma

J. Lin, H. Chang-Ming, C. Zheng, P. Li, J. Xie
Department of Gastric Surgery, Fujian Medical University Union Hospital, Fuzhou, China

Background: The aim of this study was to clarify the optimal abdominal lymphadenectomy for advanced in Siewert types II and III adenocarcinoma of the esophagogastric junction (AEG).

Methods: From June 2007 to June 2014, the data of 573 patients who underwent radical total gastrectomy due to advanced Siewert types II and III was collected and retrospectively analyzed. The incidence of abdominal lymph node metastasis (LNM) of each station were compared between patients with Siewert type II and III AEG. And we used the therapeutic index to assess the efficacy of abdominal lymph node dissection of each station.

Results: Of the 573 patients, 247 (44.0%) had Siewert type II AEG and 326 (56.0%) had type III AEG. Among them, 252 patients carried out abdominal D2 lymphadenectomy and 321 patients underwent D2 lymphadenectomy without No. 10 lymphadenectomy (D2-). The mean number of dissected LNs was 34.6 ± 13.0, and the numbers of dissected lymph nodes at each lymph node station did not significantly differ between patients with type II and III AEG ($P > 0.05$). The therapeutic index of No.1-3, 7, 9 and 11 LNs was over 4.0 in advanced type II AEG cases, while the index was higher than 4.0 in No.1-4 and 7-11 LNs in patients with type III AEG. The index of No.10 LNs was more than 10 in type III AEG subgroups with primary tumors invading the serosa layer (15.6), undifferentiated cancers (10.9) and tumor size ≥50mm (10.5).

Conclusions: Dissection of No. 1-3, 7, 9 and 11 LNs would obtain highest survival benefits regardless of the Siewert subtype. Patients with type AEG, especially those with primary tumors invading the serosa layer, undifferentiated cancers and tumor size ≥50mm might obtain relatively higher survival benefits from No. 10 lymphadenectomy.

631P Prognostic stratification of pathologic stage in patients with preoperative chemoradiotherapy followed by curative esophagectomy for localized esophageal squamous cell carcinoma

J. Kang[1], S.R. Park[1], Y-H. Kim[2], H.R. Kim[2], J.H. Kim[3], H-Y. Jung[4], G-H. Lee[4], H.J. Song[4], D.H. Kim[4], K.D. Choi[4], J-S. Ryu[5], K-J. Cho[6], S-B. Kim[1]

[1]Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [2]Thoracic Surgery, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [3]Radiation Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [4]Gastroenterology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [5]Nuclear Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [6]Pathology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea

Background: While the majority of advanced-stage esophageal cancers are treated with surgery after neoadjuvant chemoradiotherapy (NCRT), the utility of prognostication of pathologic TNM stage (pTNM) after NCRT (ypTNM) remains elucidated. Since ypTNM stage could be influenced by pretreatment tumor burden or treatment efficacy of NCRT, ypTNM stage-specific groups might be heterogeneous in terms of prognosis. Identifying prognostic factors in ypTNM stage-specific groups would guide more detailed prognostication.

Methods: From 2007 to 2014, 569 patients with squamous cell carcinoma who underwent R0 surgery with NCRT (n = 222) or who underwent R0 surgery alone (n = 347) were included. We performed uni- and multivariate analysis to identify prognostic factors for overall survival (OS) in patients with surgery after NCRT based on pTNM stages (AJCC 7^{th}).

Results: The 5-year OS rates for patients with ypTNM stage 0, 1 (including pT0N+M0), 2 and 3 in surgery after NCRT group were 74.1%, 51.6%, 29.4%, and 17.5% ($P < 0.001$), while those for patients with pTNM stage 0, 1, 2 and 3 in upfront surgery group were 92.9%, 81.3%, 61.7%, and 26.4%, respectively ($P < 0.001$). The 5-year survival rates of NCRT and upfront surgery groups in stage 1 and 2 showed distinct differences. In univariate analysis, age and clinical stage were associated with OS for ypTNM stage 0; clinical complete response (cCR) was for ypTNM stage 1; cCR, lymphovascular invasion (LVI), and perineural invasion (PNI) were for ypTNM stage 2; and LVI and PNI were for ypTNM stage 3, respectively. Subgroup analyses for each ypTNM stage are summarized in the Table.

Table: 631P Subgroup analysis of 5-year OS according to ypTNM stage

ypTNM Stage		5-year OS rate	p-value
0	Age <65, clinical stage 1–2	85.8%	0.005
	Age <65, clinical stage 3–4	76.9%	
	Age >65, clinical stage 1–2	71.5%	
	Age >65, clinical stage 3–4	44.7%	
1(including ypT0N+M0)	cCR	87.5%	0.008
	non-cCR	41.2%	
2	LVI (-), PNI (-), cCR	66.7%	0.089
	LVI (-), PNI (-), non-cCR	39.1%	
	LVI(+) and/or PNI (+)	0.0%	
3	LVI (-), PNI (-)	30.3%	0.029
	LVI (+) and/or PNI (+)	7.1%	

Conclusions: In patients with surgery after NCRT, pathologic prognostic factors (LVI and PNI) were significantly associated with the prognosis of advanced stages, whereas clinical prognostic factors (cCR, clinical stages and age) were of early stages. Although further studies are needed to validate the results of this study, we carefully suggest that clinical and pathological factors have a role in predicting survival outcome in detail based on ypTNM stage by stratifying each ypTNM stage into groups showing distinct survival profiles.

632P Thromboembolic complications in patients with oesophagogastric adenocarcinoma undergoing preoperative chemotherapy

T. Germetaki[1], K. Kamposioras[2], G. Papaxoinis[1], J. Weaver[1], S. Galloway[3], S. Stamatopoulou[1], M. Nasralla[1], Z. Kordatou[1], A. Anthoney[4], W. Mansoor[1]

[1]Medical Oncology, The Christie NHS Foundation Trust, Manchester, UK, [2]Medical Oncology, The Mid Yorkshire Hospitals NHS Trust-Pinderfields General Hospital, Wakefield, UK, [3]Oesophago-gastric Surgery, University Hospital of South Manchester, Manchester, UK, [4]Medical Oncology, The Leeds Teaching Hospitals NHS Trust, Leeds, UK

Background: The scope of the present study was: to describe the incidence of thromboembolic events (TE) in patients (pts) with resectable oesophagogastric (OG) adenocarcinoma receiving preoperative chemotherapy (CT) with curative intent; to assess risk factors of developing TE; to determine their impact on patient outcome.

Methods: Data from 590 pts with OG adenocarcinoma, who received epirubicin, cisplatin and capecitabine (ECX) or 5-fluorouracil (ECF) preoperatively in 3 UK hospitals, between 2009 & 2016, were collected retrospectively.

Results: Median age was 66 years (range 28-85), 81% were males, 21% had gastric primaries, 98% received ECX chemotherapy, and 87% completed all 3 cycles of preoperative CT. In total, 52 pts (9%) had a venous and 22 (4%) an arterial event. Of patients with venous TE, 39 had pulmonary embolism and 13 deep vein thrombosis. Of patients with arterial TE, 7 developed cardiac infarct, 8 limb ischemia, 4 cerebrovascular accident and 3 superior mesenteric artery thrombosis. Arterial TE was associated with much higher inoperability rate compared to cases with venous TE or without TE (77% vs. 31% vs. 20% respectively, $p < 0.001$). Primary tumour location in the stomach (Odds ratio [OR] 3.24, 95%CI 1.72-6.12, $p < 0.001$), overweight (OR 3.11, 95%CI 1.33-7.26, $p = 0.009$) or obese status (OR 4.52, 95%CI 1.85-11.09, $p = 0.001$) and the presence of central venous access (OR 3.40, 95%CI 1.00-11.55, $p = 0.050$) were independent risk factors for venous TE development, while anticoagulant treatment was independently associated with a lower risk of venous TE (OR 0.22, 95%CI 0.06-0.83, $p = 0.026$). A very high Khorana score (of 4-5) was the only independent risk factor for arterial TE (OR 6.38, 95%CI 1.85-22.04, $p = 0.003$). Furthermore, arterial TE was an independent poor prognostic factor for OS when adjusted for baseline patient, tumour and treatment characteristics (Hazard ratio [HR] 3.02, 95%CI 1.85-4.95, $p < 0.001$).

Conclusions: Preoperative ECX/ECF chemotherapy for patients with resectable OG adenocarcinoma was associated with relatively high incidence of TE. However, only arterial TE affected patient outcome

633P Endoscopic resection for Barrett's esophagus: Uzbekistan experience

S. Rasul

Surgery department, Tashkent Medical Academy, Tashkent, Uzbekistan

Background: In the treatment of esophageal dysplasia, particularly Barrett's esophagus, radical endoscopic resection (SRER) has shown its effectiveness. The purpose of this study was to evaluate the long-term results of treatment of Barrett's esophagus dysplasia after a successful SRER.

Methods: Patients who received SRER for BE $\leq$ 5 cm with high-grade dysplasia (HGD) or early cancer (EC) achieved complete elimination of intestinal metaplasia (CE-IM) and neoplasia (CE-neo). Primary outcomes: relapse of neoplasia (HGD/EC), recurrence of dysplasia (including indefinite dysplasia) and recurrence of endoscopically visible BE. METHODS: Patients who received SRER for BE $\leq$ 5 cm with high-grade dysplasia (HGD) or early cancer (EC) achieved complete elimination of intestinal metaplasia (CE-IM) and neoplasia (CE-neo). Primary outcomes: relapse of neoplasia (HGD/EC), recurrence of dysplasia (including indefinite dysplasia) and recurrence of endoscopically visible BE.

Results: Hidden Barrett's glands, IM in biopsy specimens obtained distal to the normal emerging neo-squamocolumnar compound, the need for re-treatment, and sustained by CE-IM and CE-neo at the last follow-up endoscopy. RESULTS: 76 patients were included (65 men, mean age 66 years, median BE C2M3). The median follow-up was 76 months. A repetition of neoplasia was observed in 1 patient (T1bN0M0) after 130 months of observation and was treated with medical surgery (annual frequency 0.22% per year of the patient's observation). Four patients had recurrent dysplasia (0.87% per patient-year of follow-up). Twelve patients had recurrent endoscopically visible BE after median follow-up for 22 months (2.6% for each subsequent patient-year of observation), mostly small islands or languages. Five patients were found to have one Barrett burial gland finding (1.1% per year of the patient's observation), and 27 patients (5.9% per year of the patient's observation) showed MI in biopsies only distal to the neo-squamocolumnar junction was not reproduced in 56%. Repeated treatment was performed in 9 patients. CE-IM and CE-neo (excluding IM in the neon-squamolecular compound) in the last endoscopic endoscopy were seen in 95% and 97% of patients, respectively.

Conclusions: This study presents the longest published data on SRER to date. 6-year results show that a successful SRER is a long-term therapy for BE $\leq$ 5 cm with HGD/EC.

634P Risk of second malignancies after definitive therapy for esophageal cancer: A competing risk analysis

S. Mitani[1], I. Oze[2], S. Kadowaki[1], T. Masuishi[1], Y. Narita[1], H. Taniguchi[1], T. Ura[1], M. Ando[1], M. Tajika[3], C. Makita[4], T. Kodaira[4], N. Uemura[5], T. Abe[5], K. Muro[1]

[1]Department of Clinical Oncology, Aichi Cancer Center Hospital, Nagoya, Japan, [2]Division of Molecular and Clinical Epidemiology, Aichi Cancer Center Research Institute, Nagoya, Japan, [3]Department of Endoscopy, Aichi Cancer Center Hospital, Nagoya, Japan, [4]Department of Radiation Oncology, Aichi Cancer Center Hospital, Nagoya, Japan, [5]Department of Gastroenterological Surgery, Aichi Cancer Center Hospital, Nagoya, Japan

Background: Esophageal cancer (EC) is associated with synchronous or metachronous cancer at other primary sites. However, few studies have evaluated second malignancies after treatment. We aimed to clarify the frequencies and risk factors of second malignancies after definitive therapy for EC.

Methods: EC patients (pts) who received definitive therapy at Aichi Cancer Center Hospital between 2000 and 2010 were retrospectively analyzed. Exclusion criteria were synchronous cancer or a past cancer history. We used competing risks regression model, which defined death and the development of second malignancies as competing risk, to conduct risk analyses. Standardized incidence rate (SIR) was calculated using population-based cancer registry.

Results: A total of 758 pts were included. Patient characteristics were as follows: male, 84%; median age, 64 (range, 32–84) years; squamous cell carcinoma, 94%; upper-third/middle-third/lower-third, 19/49/31%; clinical stage 0–I/II/III/IV, 28/24/45/3%; alcohol consumption history, 87%; smoking history, 86%. Chemotherapy, surgery, radiotherapy and endoscopic therapy were performed in 579 (76%), 374 (49%), 349 (46%), and 107 (14%) pts, respectively. With a median follow-up of 3.7 years, a total of 131 second malignancies were observed in 106 patients (14%). Cumulative incidences of second malignancies after 5 years were 7.6%. SIR of the patients was 1.83 [95% confidence interval (CI): 1.50–2.22]. Most common primary tumor sites were head and neck (20%), followed by lung (17%), stomach (16%), and colon and rectum (11%). Risk analyses revealed that age $\geq$ 65 [subdistribution hazard ratio (sHR): 1.51, 95% CI: 1.01–2.24, vs. <65] and clinical stage 0–I (sHR: 2.48, 95% CI: 1.46–4.22, vs. stage III and IV) and II (sHR: 2.10, 95% CI: 1.23–3.58, vs. stage III and IV) were associated with second malignancies. There was no significant association between second malignancies and treatment modalities.

Conclusions: EC pts are at a high risk of second malignancies after definitive treatment. Careful follow-up is required, especially in elderly pts or pts with early-stage.

635P Prognostic significance of local immunity factors in esophageal cancer

E.N. Kolesnikov[1], O.I. Kit[1], E.Y. Zlatnik[2], A.L. Bazaev[1], A.Y. Maksimov[1], I.A. Novikova[2], O.N. Selyutina[2], E.S. Bondarenko[2], V.S. Trifanov[1], L.V. Kharin[1], P.N. Gabrichidze[1], M.A. Kozhushko[1], S.S. Mezentsev[1], L.Y. Vladimirova[3]

[1]Department of Abdominal Oncology, Rostov Research Institute of Oncology, Rostov-on-Don, Russian Federation, [2]Laboratory of Immunophenotyping of Tumors, Rostov Research Institute of Oncology, Rostov-on-Don, Russian Federation, [3]Drug Therapy Department, Rostov Research Institute of Oncology, Rostov-on-Don, Russian Federation

Background: The purpose of the study was to assess possible prognostic significance of local immunity parameters in patients with esophageal cancer.

Methods: We studied tissues of tumor, peritumoral zone (PZ) and resection line (RL) obtained from 37 patients (11 women, 24 men aged 46–78 years) during surgical treatment of esophageal cancer with tumors located in the upper (1), mid (16), lower (19) thoracic esophagus and its abdominal part (1 patient). Histological study showed squamous cell carcinoma, keratinizing in 27 and non-keratinizing in 10 patients. Differentiation of tumors was G3, G2 and G1 in 7, 19 and 11 patients, respectively. The follow-up period lasted from 11 to 22 months. 10 patients received postoperative multi-course CF polychemotherapy. Metastases to distant lymph nodes developed in 13 patients, metastases to parenchymal organs in 6 patients; 7 patients died. 16 patients did not show signs of progression during the follow-up period. Subsets of T, B and NK-lymphocytes were determined in homogenates of tissues obtained during surgery using the FACSCantoII flow cytometer (BD) with a panel of antibodies CD45, CD3, CD4, CD8, CD19, CD16/56; levels of T-regs (CD4+CD25+CD127dim) were also assessed. Percentages of lymphocytes were calculated from the total lymphocyte number, T-regs – from the number of CD3+CD4+ cells.

Results: The ratios of percentages of different lymphocyte subsets were compared in presence or absence of the disease progression during a follow-up period. The ratio of T-regs in PZ to the level in tumor in patients with further progression was 0.643 ± 0.3, while in patients without progression it was significantly lower -0.15 ± 0.033 ($p < 0.05$). The ratio of T-regs in PZ to the level in RL during a follow-up period in patients with progression was -2.8 ± 0.43, without progression -0.57 ± 0.126 ($p < 0.05$). On the contrary, the coefficient of CD3+CD8+ cells in RL to their level in tumor was lower in patients with progression (0.91 ± 0.153) than in patients without it (1.33 ± 0.32) ($p < 0.05$).

Conclusions: The ratios characterizing local immunity (PZ/tumor and PZ/RL for T-regs and RL/tumor for CD3+CD8+ lymphocytes) in patients with esophageal cancer proved to have prognostic significance for progression.

636P Recent advance in enhanced recovery after esophagectomy: A systematic review and meta-analysis

Y. Wang

Thoracic Surgery, 4th Hospital Hebei Medical University, Shijiazhuang, China

Background: Many studies have shown that enhanced rehabilitation after surgery (ERAS) protocol can be closely linked to the reduced hospital stay and better outcomes of cancer patients, including those with esophageal carcinoma. However, not all studies have generated encouraging results. Therefore, a systematic review and meta-analysis of recent advance evidence to evaluate the significance of ERAS following esophagectomy was conducted.

Methods: A literature search was performed in Medline, Embase, Pubmed, CINAHL, and the Cochrane library for articles describing an enhanced rehabilitation after surgery protocol in esophagectomy for esophageal cancer published between January 2010 and December 2016. The primary outcome measure was postoperative cardiac or pulmonary complication rates. Secondary outcome measures were postoperative length of stay, readmissions, and mortality. Statistical analysis was carried out using Comprehensive Meta Analysis 2.0.

Results: The literature search identified 118 potentially relevant papers. 12 papers met the inclusion criteria for the review: 7 case-control studies, 3 retrospective studies, and 2 prospective randomized controlled study, describing a total of 1,895 patients. Meta-analysis of six studies focusing on pulmonary complications showed that there was a significant difference in favor of the ERAS group (OR = 0.625, 95% confidence interval (CI) 0.479–0.815, p = 0.001; I^2=0%). Implementation of an ERAS protocol led to a significant decrease in cardiac complications (OR = 0.656, 95% confidence interval (CI) 0.474–0.907, p = 0.011; I^2=12.905%). Postoperative length of hospital stay was significantly shorter in ERAS group [standard mean difference = −2.058d, 95%confidence interval (CI) −3.202 to − 0.913, P = 0.000; P for heterogeneity =0.000, I^2=96.109%]. Introduction of an ERAS protocol did not result in an increase in anastomotic leak, chyle leak, mortality or readmissions. There was no significant difference in ICU stay and hospital cost.

Conclusions: ERAS protocol as compared with conventional procesure may reduce postoperative hospital stay and cardiac or pulmonary complication rates in patients undergoing esophagectomy for esophageal cancer.

Background: High rates of venous thromboembolic events (VTE) are reported for patients (pts) with upper GI-cancers (stomach, pancreas) and treatment with Cisplatin (Cis), but mainly in retrospective analyses and in advanced disease. A prospective analysis of VTE in pts with resectable esophageal cancer is warranted.

Methods: Pre-planned analysis of VTE in a multicenter phase III trial according to reported AEs and SAEs from start of preoperative treatment until 6 months postoperatively. Pts with resectable esophageal cancer (T2N1-3; T3-4aNx) received 2 cycles of induction chemotherapy (CT) with Docetaxel (Doc) 75mg/m^2, Cis 75 mg/m^2 followed by chemoradiation (CRT) with 45 Gy, Doc 20 mg/m^2 and Cis 25 mg/m^2 weekly and then surgery or were randomly assigned to the same treatment with addition of neoadjuvant and adjuvant cetuximab.

Results: Of 300 pts 29 VTE were reported in 26 pts with an incidence rate (IR) of 8.7%. 3 pts had 2 VTE. 72% (21/29) of all VTE occurred preoperatively. No significant difference between treatment arms was found, odds ratio (OR) 0.8 [95%CI 0.4-1.9], p = 0.7. Grades (G) of VTE according to CTCAE v4.0: 3% (1/29) G1, 41% (12/29) G2, 45% (13/29) G3 and 10% (3/29) G5. In a multivariable logistic regression including baseline hemoglobin, platelets, neutrophils, BMI, treatment arm and histology, only adenocarcinoma (IR 11.1%, 21/189) compared to squamous cell cancer (IR 4.5%, 5/111) was significantly associated with VTE-risk during treatment, OR 2.9 [95%CI 1.02;8.4], p = 0.046. Baseline Khorana risk score (KRS) for VTE was 0 in 73% (19/26), 1-2 in 23% (6/26) of pts and 3 in one patient with VTE ($\geq$ 3 equal to high-risk and recommendation for prophylaxis). Median PFS in pts with VTE was 2.1 yrs vs. 2.5 yrs for pts without VTE.

Conclusions: This first prospective analysis of VTE in resectable esophageal cancer pts reveals a high IR during perioperative therapy of almost 9% comparable to high-risk pts according to KRS. Only one of these pts would have been identified by KRS as high-risk. Prophylactic anticoagulation balanced against individual bleeding risks could be considered in esophageal cancer pts treated with neoadjuvant Cis-based CT and RCT, especially in adenocarcinoma.

Background: Nivolumab (Nivo) monotherapy has demonstrated clinical activity and safety for esophageal cancer refractory or intolerant to standard chemotherapy (Lancet oncology, online March 14, 2017, http://doi.org/10.1016/S1470-2045(17)30181-X). We report updated results base on a minimum follow-up of 2-years.

Methods: Patients aged ≥ 20 years with ECOG PS 0-1 were enrolled and treated with Nivo (3 mg/kg, IV, Q2W) until progression or unacceptable toxicity. The primary endpoint was objective response rate (ORR) evaluated by independent review committee according to RECIST 1.1. Other endpoints included safety, overall survival (OS), progression-free survival (PFS) and duration of response (DOR).

Results: Between February 25, 2014 and November 14, 2014, 65 patients with esophageal squamous-cell carcinoma were enrolled; median age of 62 years (range 49-80); male/female, 54/11; ECOG PS 0/1, 29/36; median number of 3.0 (range 1-8) prior regimens. The primary endpoint of ORR was 17.2% (11/64 patients, CR/PR: 1/10, 95% confidence interval [CI] 9.9, 28.2) as of May 17, 2015. Median OS and PFS were 10.8 and 1.5 months. With a minimum follow-up of 2-years (cutoff date November 17, 2016), 6 patients remained on treatment with Nivo. The ORR was 17.2% (CR/PR: 3/8) and median DOR was 11.17 months (95% CI 3.02, -). The Kaplan-Meier estimated 1-, 1.5- and 2-years OS rate were 45.3% (95% CI 32.9, 56.9), 25.0% (15.2, 36.0) and 17.2% (9.2, 27.3). One, 1.5- and 2-years PFS rate were 10.3% (95% CI: 4.2, 19.4), 8.6% (3.2, 17.3) and 8.6% (3.2, 17.3). Adverse events (AEs) were reported in 56 (86.2%) of 65 patients including grade 3 − 4 AEs reported in 19 patients (29.2%). The most common AEs were diarrhea (21.5%), decreased appetite (18.5%), lung infection (13.8%) and cough (12.3%). Seven patients (10.8%) discontinued the study treatment due to drug-related AEs, while no treatment-related death was reported.

Conclusions: Nivo suggest a durable, long-term survival benefit with 17.2% of patients alive at 2-years. These data support ongoing phase III study (NCT 02569242) assessing Nivo monotherapy compared with docetaxel or paclitaxel.

639P A phase II study of TAS-102 for advanced/recurrent esophageal cancer refractory/intolerable to standard therapies

T. Kojima[1], H. Kasai[2], T. Tsushima[3], H. Hara[4], Y. Mori[5], R. Ishihara[6], K. Kato[7], S. Hironaka[8], K. Mukai[2], O. Kikuchi[5], K. Enomoto[2], H. Tada[2], R. Uozumi[2], A. Kawaguchi[9], M. Muto[5]

[1]Department of Gastroenterology and Gastrointestinal Oncology, National Cancer Center Hospital East, Chiba, Japan, [2]Institute for Advancement of Clinical and Translational Science (iACT), Kyoto University Hospital, Kyoto, Japan, [3]Division of Gastrointestinal Oncology, Shizuoka Cancer Center, Shizuoka, Japan, [4]Department of Gastroenterology, Saitama Cancer Center, Saitama, Japan, [5]Department of Therapeutic Oncology, Kyoto University Hospital, Kyoto, Japan, [6]Department of Gastrointestinal Oncology, Osaka Medical Center for Cancer and Cardiovascular Diseases, Osaka, Japan, [7]Gastrointestinal Medical Oncology Division, National Cancer Center Hospital, Tokyo, Japan, [8]Clinical Trial Promotion, Chiba Cancer Center Hospital, Chiba, Japan, [9]Center for Comprehensive Community Medicine, Faculty of Medicine, Saga University, Saga, Japan

Background: There is no effective chemotherapy for patients with esophageal squamous cell carcinoma (ESCC) refractory or intolerant to 5-FU, platinum, and taxanes. TAS-102 is an oral combination drug of trifluridine and tipiracil hydrochloride. Our preclinical study showed that TAS-102 has antitumor activity against 5-FU resistant esophageal cancer cells. We conducted this study to evaluate the safety and efficacy of TAS-102 in ESCC patients who were refractory or intolerant to standard treatment (UMIN000019268).

Methods: Patients with histologically proven advanced or recurrent ESCC, which had been refractory or intolerable to 5-FU, platinum, and taxanes, were eligible. Patients also had to satisfy following criteria: >20 years of age; ECOG performance status 0 or 1; adequate organ functions. TAS-102, 35 mg/m2 bid, was administered on days 1-5 and 8-12 for the first 2 weeks followed by 2-week rest. The regimen was repeated every 4 weeks until disease progression, serious adverse event, or refusal. Primary endpoint was progression-free survival rate at 3 months (PFS3). With expected PFS3 of 25% to 30% and the null hypothesis of 10% under 80% power and a one-sided significance level of 5%, 35 patients was needed.

Results: A total of 42 patients were enrolled. 90% of the patients were male, 95% had distant metastasis, and 98% had target lesion (s). As of data cutoff, 34 events were observed. PFS3 was 15.4% (90% CI: 7.4%, 26.0%), which did not reject the null hypothesis. Median PFS and OS were 1.3 months and 4.5 months, respectively. Response rate was 0%, although 24% (10/42) of patients achieved stable disease. There were 3 patients not evaluable for response. Major treatment related adverse events of grade ≧3 were: neutrophil count decreased (48%), febrile neutropenia (7%), and appetite decreased (5%). No treatment related death was observed.

Conclusions: TAS-102 was feasible and showed modest efficacy in patients with refractory ESCC.

640P Dual CDK 4/6 inhibitor demonstrates potent antitumor efficacy in vitro and in vivo against esophageal adenocarcinoma

A.N. Omstead[1], J.E. Kosovec[1], M.J. Biedka[1], R.W.W. Biederman[2], R.J. Kelly[3], A.H. Zaidi[1], B.A. Jobe[1]

[1]Esophageal and Lung Institute, Allegheny Health Network, Pittsburgh, PA, USA, [2]McGinnis Cardiovascular Institute, Allegheny Health Network, Pittsburgh, PA, USA, [3]Department of Oncology, Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins Hospital, Baltimore, MD, USA

Background: Esophageal adenocarcinoma (EAC) is a leading cause of cancer deaths, and current treatment options are limited. Cell cycle regulators CDK4 and CDK6 are progressively upregulated in EAC carcinogenesis and associated with poor prognosis. The modified Levrat model of esophagojejunostomy (EJ) in a rat has demonstrated well-documented utility for *in vivo* efficacy testing against *de novo* EAC. In the present study, we evaluate a dual CDK4/6 inhibitor, abemaciclib, for the treatment of EAC.

Methods: Human EAC cell lines, OE33 and FLO1, were used to evaluated proliferation and apoptosis using BrdU and flow cytometry, respectively. EJ was performed on 38 Sprague-Dawley rats to induce gastroduodenoesophageal reflux and the subsequent development of EAC. At 36 weeks post-operatively, rats were randomized to receive IP abemaciclib at 26 mg/kg per day or placebo (acetate buffer) for 4 weeks. Drug efficacy was evaluated with MRI, endoscopic biopsy, gross histological evaluation, and CDK4/6 pathway expression by RT-PCR.

Results: With an established ED50 of 6μM in OE33 and 14μM in FLO1, proliferation decreased with treatment by 89.5% and 87.5%, respectively. Flow cytometry

demonstrated an increase of apoptosis by 45.6% and 38.9%, respectively. Twenty of 23 (87.0%) treated animals and all of 18 (100%) control animals reached study endpoint. Treatment group mortality consisted of rats afflicted with moderate peritonitis, diarrhea, and weight loss. Mean MRI tumor volume decreased by 151.0% in treatment animals and increased by 108.3% in control animals ($p < 0.01$). Treatment with abemaciclib demonstrated tumor volume increase in 0% (control = 66.7%) ($p < 0.01$), decrease in 79% (control = 0%) ($p < 0.01$), and stable volume in 21.1% (control = 33.3%) ($p = 0.41$). EAC prevalence in treatment animals decreased by 48.2%; whereas, prevalence in control animals increased by 5.5% ($p < 0.01$). mRNA expression, pre- and post-treatment, demonstrated significant downregulation of CDK4, CDK6, RB1, pRB1 and Cyclin-D ($p < 0.05$).

Conclusions: Abemaciclib exhibits potent in vitro and in vivo antitumor efficacy in EAC models, providing the rationale for future clinical testing.

641P The influence of body composition on the systemic exposure of paclitaxel in esophageal cancer patients

L. Van Doorn[1], H.N. Rier[2], J.L.A. van Vught[3], C. van Kesteren[4], S. Bins[1], R.H.J. Mathijssen[1], M-D. Levin[2], S.L.W. Koolen[1]

[1]Medical Oncology, Erasmus MC Cancer Institute, Rotterdam, Netherlands, [2]Department of Internal Medicine, Albert Schweitzer Hospital, Dordrecht, Netherlands, [3]Department of Surgery, Erasmus MC, University Medical Center, Rotterdam, Netherlands, [4]Department of Pharmacy, Albert Schweitzer Hospital, Dordrecht, Netherlands

Background: Weight loss and malnutrition are common symptoms of esophageal cancer, which can lead to skeletal muscle wasting and loss of adipose tissue. It was hypothesized before that the pharmacokinetics (PK) of chemotherapy may depend on body composition (Prado et al, 2013). In addition, we earlier showed that the clearance (CL; L/h) of unbound paclitaxel (pac) is related to body-surface area (BSA; m^2) and gender (Bins et al, 2014). Therefore, now we aimed to assess the relationship between pac CL and body composition.

Methods: We analyzed 197 patients with stage III esophageal cancer who were treated with pac and carboplatin in a prospective study between 2008 and 2013. CL of pac, which was estimated using nonlinear mixed effects modeling (NONMEM) was used as a measure of systemic pac exposure (de Graan et al, 2012). Skeletal muscle index (SMI, cm^2/m^2), muscle attenuation (MA) and visceral adipose tissue (VAT; cm^2) were measured at the level of the 3rd lumbar vertebra on computed tomography (CT) scans performed before treatment. Gender-specific differences in pac CL, based on the 1st quartile and the 4th quartile of the SMI and VAT measurement were analyzed with a Mann-Whitney test. A Spearman rank correlation (r) was calculated to explore the relationship between pac CL and SMI, VAT and MA, respectively.

Results: CT images and pac PK data were available for 183 patients (78% was men). Pac CL was correlated with SMI ($r = .27$, $p = .001$) and VAT ($r = .28$, $p = .001$), while no correlation was found with MA ($r < .01$, $p = .91$). Interestingly, while in male patients with the highest SMI a higher pac CL was found compared to the lowest SMI ($p = .024$), and also for the 1st and 4th quartile of VAT ($p = .003$), in female patients no effect of SMI and VAT on pac CL was seen.

Conclusions: Skeletal muscle mass and visceral adipose tissue are positively correlated with pac CL in male patients with esophageal cancer. Differences in body composition between men and women may potentially explain the difference in the outcome of this analysis, and may also partly explain the difference in pac CL between both genders. Although the effect sizes are too small to support dose adaptions based on VAT or SMI, these parameters partly explain the large interpatient variability in pac PK.

642P Survival in advanced oesophagogastric adenocarcinoma (OGA) improves with the use of multiple lines of therapy: Results from an analysis of over 500 patients (pts)

C. Cafferkey[1], M. Davidson[1], E. Goode[1], D. Hughes[1], P. Reguera[1], R. Kalaitzaki[1], K. Kouvelakis[1], C. Peckitt[2], I. Chau[3], D. Watkins[2], S. Rao[3], D. Cunningham[4], N. Starling[1]

[1]Medical Oncology, Royal Marsden Hospital NHS Foundation Trust, London, UK, [2]Department of Medicine, Royal Marsden Hospital, Sutton, UK, [3]Deaprtment of Medicine, Royal Marsden Hospital, Sutton, UK, [4]GI and Lymphoma Research Unit, Royal Marsden Hospital NHS Foundation Trust, London, UK

Background: Palliative chemotherapy (CT) remains the primary mode of treatment for advanced OGA and is shown to improve survival in the 1st and 2nd line setting. We sought to evaluate the use of systemic therapy and assess survival outcomes for pts with advanced OGA treated at the Royal Marsden Hospital (RMH).

Methods: Retrospective analysis of consecutively treated pts receiving at least 1 cycle of CT for advanced OGA at RMH between April 2009 - Nov 2015.

Results: 511 pts were identified; 75% male, 25% female; median age at diagnosis 66 yrs (range 24-90). Treatment intent at initial diagnosis was radical in 21% (with subsequent relapse) and palliative in 79%. There was no significant difference in median overall survival (OS) in the advanced setting between pts with relapsed disease after initial radical treatment and pts with metastatic disease at diagnosis (12.6 vs 11.3m; $p = 0.10$). OS was significantly improved for confirmed HER2+ve pts compared to HER2-ve (15.0 vs 11.9m; $p = 0.02$). OS was significantly improved in pts treated within a therapeutic clinical trial at any line of treatment compared with those who were not (13.5 vs 10.1m; $p = 0.02$). Survival was significantly correlated with number of treatment lines received ($p < 0.001$).

Conclusions: We have demonstrated the pattern of usage of systemic therapy for over 500 patients treated within a single UK oncology centre. Survival outcome remains poor for the majority of pts who have 1st line CT only. Pts suitable for sequential CT have better outcomes and entry into clinical trials is associated with improved survival. There remains a need to define evidence-based therapies for the small but increasing proportion of pts suitable for treatment in the 3rd line and beyond.

643P The research progress in randomized, multicenter, controlled evaluation of S-1 and oxaliplatin as neoadjuvant chemotherapy for advanced gastric cancer patients

X. Wang, L. Chen

General Surgery, Military General Hospital of Beijing (PLA), Beijing, China

Background: There is differrence beteween the perioperative and adjuvant chemotherapy in east and west country, but there is no study to compare the effect between the perioperative and adjuvant chemotherapy based on the D2 gastrectomy in advanced gastric cancer till now. Our study wants to evaluate the efficacy and safety of S-1 and oxaliplatin as neoadjuvant chemotherapy for advanced gastric cancer.

Table: 642P

	1st line	2nd line	3rd line	>3 lines
N	511 (100%)	200 (39%)	70 (14%)	15 (3%)
Treatments	Triplet 63% Doublet 33% Single 4%	Triplet 12% Doublet 34% Single 54%	Triplet 3% Doublet 37% Single 60%	
Clinical trial	103 (20%)	57 (29%)	25 (36%)	5 (33%)
Median no. cycles	6	3	3	
ORR	CR 2% PR 47% SD 29%	CR 0% PR 20%, SD 34%	CR 0% PR 19% SD 24%	
PFS (m)	5.5	3.0	1.8	
OS (m)	11.5 (whole cohort)			
OS (m)	8.3 (1st line only received)	14.0 (1st + 2nd line received)	20.1 (1st, 2nd + 3rd line received)	33.0 (>3 lines received)

Methods: Between September 2012 and December 2016, 420 patients with clinical stage IIA-IIIC gastric cancer were eligible for inclusion. They were randomly assigned to either the neoadjuvant chemotherapy group (n = 210) or the adjuvant chemotherapy group (n = 210). The reaction rate, effective rate, T-stage, incidences of adverse reaction, surgical R0 resection rate, CY1 rate and pCR rate in the two groups were compared.

Results: In neoadjuvant chemotherapy group, the reaction rate, effective rate, and pCR rate were 80%, 40% and 20% respectively. The surgical R0 resection rate (80% vs 70%) were much higher in neoadjuvant chemotherapy group. There was no significant difference in incidences of adverse reaction between the two groups. However, the CY1 rate (5% vs 8%) was lower and T-stage was earlier in neoadjuvant chemotherapy group.

Conclusions: S-1 and oxaliplatin as neoadjuvant chemotherapy is effective for advanced gastric cancer, and there was no increase of adverse reaction.

644P The N stages for early gastric cancer should differ from those of advanced gastric cancer: Results based on the SEER database

J-X. Lin, H. Chang-Ming, C. Zheng, P. Li, J. Wang

Department of Gastric Surgery, Fujian Medical University Union Hospital, Fuzhou, China

Background: The aim of this study was to establish an appropriate N staging system for early gastric cancer (EGC).

Methods: Data from 24,223 patients who underwent radical gastrectomy between 1988 and 2011 were retrieved from the National Cancer Institute's Surveillance, Epidemiology, and End Result (SEER) database. The optimal cutoff value for the number of LNs was determined by the X-tile program. The overall survival (OS) based on eighth edition and new TNM staging systems were compared, and the analysis was repeated in an external validation set.

Results: In the same T category, the OS rates were significantly different in each N category for advanced gastric cancer (AGC). However, no significant differences were observed in OS between N1 and N2 cancers or between N3a and N3b cancers in cases of EGC. The X-tile program identified that the difference in survival was most significant when 6 metastatic LNs were present. The new staging system for EGC consisted of T1N0, T1N1' (1-6 metastatic LNs) and T1N2' (≥7 metastatic LNs). Compared with the eighth edition of the TNM staging system, the OS of patients in the T1N1' stage was similar to that of patients with stage IIA disease, whereas the OS of patients in the T1N2' stages was similar to that of patients with stage IIB disease ($P < 0.05$). The new TNM staging system exhibited slightly superior prognostic stratification with lower AIC values and higher $\chi 2$ and c-statistic compared with the eighth edition of the TNM classification system. Similar results were found in the external validation dataset from the Fujian Medical University Union Hospital (FMUUH) database.

Conclusions: The N category of the eighth edition of the AJCC TNM classification exhibits variation in the survival of patients with AGC. However, this classification remains associated with some stage migration in EGC and the proposed N category permits better prognostic prediction.

645P Young-onset gastric cancer: The role of microbial factors

I. Ben-Aharon[1], A. Moore[1], E. Hikri[2], T. Goshen-Lago[1], T. Lazar[2], H. Kashtan[3], B. Brenner[1]

[1]Oncology, Rabin Medical Center, Petah Tikva, Israel, [2]Cell Biology, Tel-Aviv University, Tel-Aviv, Israel, [3]Surgery, Rabin Medical Center, Petach Tikva, Israel

Background: Gastric cancer (GC) is a leading cause of cancer death, associated with environmental and genetic factors, with increasing incidence in young patients. Recently, as part of the Cancer Genome Atlas (TCGA) project, a comprehensive molecular characterization of gastric adenocarcinoma revealed unique molecular and genetic patterns that were classified GC into four subtypes among which is the Epstein-Barr Virus (EBV)-associated subtype. The EBV-associated subtype is positive for the virus, displays unique genomic landscape and represents 8.7% of the cohort of the TCGA. Since most of the young-onset GC is sporadic and non-hereditary upon former studies, environmental factors may play a role in the pathogenesis of GC among young patients. We hypothesized that the prevalence of EBV-subtype may be higher in young-onset GC than in the average-onset.

Methods: Tissue tumor samples of matched cohorts of young-onset (<45y) and average-onset (>60y) were retrospectively retrieved, DNA was extracted and analyzed by quantitative PCR (qPCR) for EBV using two different EBNA primers to validate the detection of the virus. Clinical data among which patient demographics, tumor location and family history were extracted from medical records and correlated to age.

Results: Twenty-nine young-onset GC patients and 34 average-onset GC patients were enrolled into the study. Median age for the young-onset was 34y (range 21-45) and for the average-onset 69y (60-90). Thirty-six percent of the young-onset were male, compared with 57% in the average-onset. Family history was more prevalent in the average-onset cohort (37% vs. 29%). The distribution of the tumor location differed between the two groups – whereas in the young-onset 36% of the tumors were in the body of the stomach compared with 46% of the average-onset that were in the antrum. EBV was significantly more prevalent in the young-onset cohort (32.1% compared with 11.4% in the average-onset).

Conclusions: Our study indicate that EBV may play a key role in the pathogenesis of young-onset GC. Since young-onset GC is not predominated by hereditary factors, environmental and microbial factors should be further studied as essential contributors, what may potentially govern early detection in high risk populations.

646P Comprehensive complication index (CCI) predicts cancer-specific survival of patients with postoperative complications after curative resection of gastric cancer

R. Tu, H. Chang-Ming, J. Lin, P. Li, C. Zheng

Department of Gastric Surgery, Fujian Medical University Union Hospital, Fuzhou, China

Background: To investigate prognostic impact of postoperative complications for patients with gastric cancer.

Methods: Postoperative complications of patients undergoing radical gastrectomy for gastric cancer were reviewed. The severity of complications was graded by the CCI and C-D classification.

Results: A total of 5327 patients were included in the study. Complications were observed in 767 patients. When the C-D classification system was applied, for patients with grade I-II complications, the length of stay (LOS) of those with high CCI (CCI ≥ 26.2) was significantly longer than that of patients with low CCI (CCI<26.2) ($p < 0.001$). The 5-year cancer-specific survival rate of the patients with complications (52%) was lower than that of patients without complications (61%) ($p < 0.001$). Analysis of the factors associated with prognosis in patients with gastric cancer revealed that complications were independent risk factors for specific survival. When CCI was used to classify complication severity, the 5-year cancer-specific survival rate of the high CCI group was 46.3%, which was lower than that of the low CCI group (54.9%, $p = 0.009$).

Conclusions: Complication after radical gastrectomy is an independent prognostic factor, and the complication severity as graded by CCI reflects the difference of cancer-specific survival in gastric cancer patients with postoperative complications.

647P ATM loss, MSI and survival in the MAGIC trial

E. Smyth[1], M. Fassan[2], K. Kouvelakis[3], M. Nankivell[4], C. Peckitt[3], A. Wotherspoon[5], N. Valeri[6], M. Rugge[2], W. Allum[7], R. Langley[4], D. Cunningham[1]

[1]Gastrointestinal Oncology, Royal Marsden Hospital, London, UK, [2]Department of Medicine, University of Padua, Padua, Italy, [3]Clinical Research and Development, Royal Marsden Hospital, Sutton, UK, [4]Clinical Trials Unit, Medical Research Council at University College London, London, UK, [5]Pathology, Royal Marsden Hospital, London, UK, [6]Molecular Pathology, The Institute of Cancer Research/Royal Marsden Hospital, Sutton, UK, [7]Surgery, Royal Marsden Hospital, London, UK

Background: Loss of ataxia-telangiectasia mutated (ATM) protein has been associated with worse prognosis in resected gastric cancer (GC), and may predict sensitivity to drugs targeting DNA damage pathways. Microsatellite instability (MSI) is prognostic in surgically treated GC patients (pts) and may be negatively prognostic in perioperative chemotherapy (chemo) treated GC. We examined the effect of ATM and MSI on overall survival (OS) for pts randomised to surgery alone or perioperative ECF chemo in the MRC MAGIC trial.

Methods: ATM was assessed using anti-ATM antibody (clone Y170) on 4 μm TMA sections. ATM negative (neg) tumours had >90% cells neg for nuclear ATM. MSI was assessed using Promega MSI System. MSS tumours had all markers stable; MSI-L had only 1 unstable marker; MSI-H had at least 2 unstable markers. Trial arms were analysed independently.

Results: 39 of 225 evaluated pts (17%) were ATM-neg. Pts with/without ATM data had similar OS. Clinicopathological characteristics were similar between ATM-neg and positive (pos) pts. 217 pts had MSI and ATM status available: MSI and ATM status were highly correlated (ATM-neg/MSS n = 27, ATM neg/MSI-H n = 10, ATM-pos/MSS n = 175, ATM-pos/MSI-H n = 5, $p < 0.001$). Median OS for all biomarker groups is detailed in the table.

Table: 647P Overall survival (OS) by ATM, MSI and treatment arm

	subjects	Events	Median OS	95% CI for Median OS		HR	95% CI for HR		Cox PH test
Surgery alone arm: OS from surgery by ATM status									
ATM neg	22	10	48.3	8.5	NE	1.3	0.7	2.6	0.41
ATM pos	105	74	23.4	18.9	31.2				
Surgery alone arm: OS from surgery, by ATM and MSI status									
ATM neg MSS	14	10	15.4	3.4	48.3				
ATM pos MSS	102	73	23.4	18.9	31.2	0.80	0.4	1.6	0.51
ATM neg MSI-H	5	0	NE	NE	NE				
ATM pos/MSI-H									
Chemotherapy + surgery arm: OS from surgery by ATM status									
ATM neg	17	8	na	5.8	na	1.5	0.7	3.1	0.32
ATM pos	81	55	19.6	13.4	35.2				
Chemotherapy+ surgery arm: OS from surgery by ATM and MSI status									
ATM neg MSS	11	5	NE	NE	NE				
ATM pos MSS	73	50	19.6	13.4	35.2	1.7	0.7	4.3	0.24
ATM neg MSI-H	4	3	5.8	NE	NE				
ATM pos MSI-H	5	4	9.7	NE	NE	0.8	0.8	3.8	0.78

Conclusions: In MAGIC, ATM status was not prognostic for OS in either treatment arm. ATM loss was much more common in MSI-H pts. In this relatively underpowered analysis, chemo treated MSS-ATM-neg pts had encouraging OS. In chemo treated pts, prognosis was poor for MSI-H patients independent of ATM status. Further evaluation of ATM, MSI and chemo outcomes may be justified.

648P Negative lymph node count is a significant prognostic factor in patient with stage IV gastric cancer after palliative gastrectomy

C. Zhuo, M. Ying, R. Lin, X. Wu, S. Guan, C. Yang

Gastrointestinal Surgical Oncology, Fujian Cancer Hospital & Fujian Medical University Cancer Hospital, Fuzhou, China

Background: Negative lymph node (NLN) count has been validated as a protective predictor in various cancers after radical resection. However, the prognostic value of NLN count in the setting of gastric cancer patients who have received palliative resection has not been investigated. The aim of the present study was to explore the effect of NLN counts on the survival outcomes in patients with stage IV gastric cancer after palliative resection.

Methods: Surveillance, Epidemiology, and End Results Program (SEER)-registered gastric cancer patients were used for analysis in this study. Kaplan-Meier survival curves and multivariate Cox proportional hazards model were used to assess the risk factors for survival.

Results: A total of 1,495 patients with stage IV gastric cancer underwent palliative resection were identified from SEER database between 2004 and 2011. It showed that NLN count ($P < 0.001$) and N stage ($P < 0.001$) were independently prognostic factors in patients with stage IV gastric cancer after palliative surgery. X-tile plots identified 2 and 11 as the optimal cutoff values to divide the patients into high, middle and low risk subsets in term of cause-specific survival (CSS). And NLN count was proved to be an independently prognostic factor in multivariate Cox analysis (2-10, HR = 0.762, 95% CI: 0.660-0.880, ≥11, HR = 0.525, 95% CI: 0.437- 0.632, $P<0.001$, 0-1 as reference). The risk score of NLN counts demonstrated that the plot of hazard ratios (HRs) for NLN counts sharply increased when the number of NLN counts decreased.

Conclusions: Our present study revealed that NLN count was an independent prognostic predictor in stage IV gastric cancer after palliative resection. Standard lymph node dissection, such as D2 lymphadectomy maybe still necessary during palliative resection for patients with metastatic gastric cancer.

649P PD-L1 expression in primary tumours and paired lymph node metastases in chemoradiotherapy-naïve esophageal and gastric adenocarcinoma: Relationship with MSI status and prognosis

M. Svensson[1], D. Borg[1], C. Hedner[1], J. Eberhard[1], B. Nodin[1], K. Leandersson[2], K. Jirström[1]

[1]Department of Clinical Sciences Lund, Oncology and Pathology, Lund University, Lund, Sweden, [2]Cancer Immunology, Department of Translational Medicine, Lund University, Lund, Sweden,

Background: Although neoadjuvant and/or adjuvant treatment enhances survival in patients with resectable esophageal and gastric (EG) cancer, the prognosis remains poor and there is a great need to identify novel treatment strategies and suitable biomarkers. The efficacy of immune-modulating therapies in EG cancer remains to be confirmed. Expression of programmed death ligand 1 (PD-L1) is, together with microsatellite instability (MSI) status, a putative biomarker of response to such therapies, but their prognostic value in EG cancer remains unclear. Therefore, the aim of this study was to examine the expression of PD-L1 in tumour cells (TC) and tumour-infiltrating immune cells (IC) in chemoradiotherapy-naïve primary EG tumours and paired lymph node metastases. Particular attention was given to the relationship with MSI status and prognosis.

Methods: PD-L1 expression in TC and IC was assessed by immunohistochemistry (IHC) on tissue microarrays with all primary tumours (n = 165) and paired lymph node metastases (n = 61) from a retrospective consecutive cohort of patients with chemoradiotherapy-naïve resected EG cancers. MSI was defined as loss of IHC expression of MLH1, MSH2, MSH2 or MSH6. Univariable and multivariable Cox regression analysis was used to calculate overall survival (OS).

Results: There was a significant correlation between TC and IC PD-L1 expression in primary tumours ($p < 0.001$) but not in metastases. There was no significant association between TC PD-L1 expression in primary tumours and metastases, but IC PD-L1 expression was significantly higher in metastases ($p = 0.027$).There were strong significant associations between PD-L1 expression in TC and IC, respectively, and MSI ($p < 0.001$ for both). Neither TC PD-L1 expression nor MSI status was prognostic. However, high IC PD-L1 expression (>50%) was significantly associated with a prolonged OS, independent of conventional prognostic factors and MSI status (HR = 0.39, 95% CI 0.15-0.99).

Conclusions: PD-L1 expression in TC does not differ significantly between primary tumours and lymph node metastases, PD-L1 expression in IC but not in TC is an independent favourable prognostic factor.

650P Effects of preoperative malnutrition on short- and long-term outcomes of patients with gastric cancer: Can we do better?

J. Lu, H. Chang-Ming, H. Huang, C. Zheng, P. Li

Department of Gastric Surgery, Fujian Medical University Union Hospital, Fuzhou, China

Background: This study aimed to examine the effect of preoperative nutritional status on short- and long-term outcomes in patients who underwent radical gastrectomy. It also explored the role of preoperative correction of hypoalbuminemia (PCH) in malnourished patients with gastric cancer.

Methods: We prospectively reviewed data from patients with gastric cancer who were treated in our department between January 2009 and December 2014. The effect of preoperative nutritional status on short- and long-term outcomes in patients who underwent radical gastrectomy was investigated. We explored whether PCH could improve the short- and long-term outcomes of these patients.

Results: A total of 1,976 patients were analyzed, including 412 in the malnourished group and 1,564 in the well-nourished group. The overall incidence of complications in the malnourished group was significantly higher than that of the well-nourished group (21.4% vs 15.5%, $p = 0.005$). Except for incision infection (3.2% vs 1.6%, $p = 0.041$), there were no significant differences for other complications. In the malnourished group, 98 cases of preoperative hypoproteinemia were corrected (PCH group), whereas 314 cases were not (NPCH group). The incidence of incision infection in the PCH group was significantly lower than that in the NPCH group (0% vs 4.1%, $p = 0.041$). The median follow-up time was 39 months (1.0–88.0 months). The 3-year overall survival (OS; 59.1% vs 75%, $p < 0.001$) and disease free survival (DFS; 54.8% vs 72.5%, $p < 0.001$) were significantly lower in the malnourished group than in the well-nourished group. A multivariate Cox regression analysis showed that malnutrition was an independent prognostic factor for 3-year OS (HR = 1.255 (1.008-1.490), $p = 0.041$) and DFS (HR = 1.179 (1.012-1.411), $p = 0.046$). For the malnourished group with stage I gastric cancer, the PCH group and the NPCH group showed no significant differences in 3-year OS (90.0% vs 89.0%, $p = 0.227$) or DFS (90.0% vs 87.3%, $p = 0.363$). However, for the malnourished group with stage II/III gastric cancer, the 3-year OS (69.9% vs 47.6%, $p = 0.013$) and DFS (55.4% vs 43.6%, $p = 0.046$) were significantly higher in the PCH group than in the NPCH group.

Conclusions: The incidence of incision infection was significantly higher in patients with malnutrition than in well-nourished patients. The 3-year OS and RFS were significantly lower in malnourished patients than in well-nourished patients. PCH can both reduce the incidence of incisional infection in patients with malnutrition and significantly improve the 3-year OS and RFS for malnourished patients with stage II/III gastric cancer.

651P Is there any relationship between Helicobacter pylori infection and HER2 expression in gastric cancer?

E. Algin[1], M. Baykara[2], G. Yilmaz[3], B. Cetin[4], O. Ekinci[3], A. Uner[5], A. Ozet[5]

[1]Medical Oncology, Ankara Numune Education and Research Hospital, Ankara, Turkey, [2]Medical Oncology, Department of Medical Oncology, Sakarya Education and Research Hospital, Sakarya, Turkey, [3]Pathology, Department of Pathology, Gazi University Faculty of Medicine, Ankara, Turkey, [4]Medical Oncology, Department of Medical Oncology, Cumhuriyet University Faculty of Medicine, Sivas, Turkey, [5]Medical Oncology, Department of Internal Medicine, Division of Medical Oncology, Gazi University Faculty of Medicine, Ankara, Turkey

Background: Helicobacter pylori (HP) is a significant causative agent of gastric cancer (GC). However, the underlying mechanisms involved in its pathogenesis and association with oncoproteins are unclear. The aim of the present study was to evaluate the relationship between HP infection and human epidermal growth factor receptor 2 (HER2) expression in gastric cancer patients.

Methods: Surgery (173) or endoscopic biopsy (35) specimen of 208 patients diagnosed with GC was evaluated for the presence of HER2 and HP. HER2 expression was assessed by fluorescence in situ hybridization (FISH) method, whereas HP status was evaluated histologically. Giemsa stain was used to identify HP status, in case HP could not be recognised in routine hematoxylin eosin stained sections despite careful examination.

Results: The median age was 63 years (27-91) and most patients were male (male/female: 149/59). Histopathologic diagnosis was adenocarcinoma in 117 (56.2%), signet ring cell adenocarcinoma in 51 (24.6%), and mixed adenocarcinoma-signet ring cell adenocarcinoma in 40 patients (19.2%). Of all 208 patients, HP was positive in 87 (41.8%) and negative in 121 (58.2%) patients. FISH positivity for HER2 was observed in 41 (19.7%), whereas FISH negativity was observed in 167 (80.3%) patients. According to the Chi-square test, patient distribution were 21 in HER2 positive HP negative group, 20 in HER2 positive HP positive group, 100 in HER2 negative HP negative group and 67 in HER2 negative HP positive group. No correlation was found between HP and HER2 status ($p = 0.314$). In addition, there was no relationship between HP status and the age, gender, histopathologic diagnosis, tumor location, TNM stage, ECOG performance status, grade, lymphovascular invasion, perineural invasion, and Lauren classification. Median OS of the entire population was 14.8 months (0.07-82.5). Median OS was 12.9 months (95% CI 7.7-18.0) in HP negative group and 27.4 months (95% CI 16.4-38.4) in HP positive group and the difference was statistically significant ($p = 0.046$).

Conclusions: Our results suggest that there is no relationship between HP infection and HER2 status in patients with GC. However, debate on this topic continues. Comprehensive prospective studies with larger series are required to clarify this relationship.

652P Iron deficiency anemia in gastric cancer: A Canadian single site retrospective cohort study

C. Brezden-Masley, G. Tang, R. Hart, M. Sholzberg

Hematology/Oncology, St. Michael's Hospital, Toronto, ON, Canada

Background: Globally, gastric cancer is highly prevalent amongst men and women. While many studies have identified the prevalence and association of iron deficiency anemia (IDA) in all cancer patients, few have focused on the gastric population. We aimed to determine the proportion of patients with gastric cancer who developed IDA, chemotherapy induced anemia (CIA), and to identify types and frequencies of IDA therapies.

Methods: A retrospective study was carried out in 127 consecutive gastric cancer patients from 2006 to 2016 at St. Michael's Hospital, Toronto, Canada. Patient demographics, previous history of IDA, and IDA-based therapies were reviewed. IDA was defined as hemoglobin (Hb) <130 g/L in men and <120g/L in women and iron deficiency was defined as a transferrin saturation <20%. Pairwise deletion method was used for missing data. SAS 9.3 was used for data analysis.

Results: Of the 127 patients (median age 70 [interquartile range (IQR): 59-77]), 64.6% (82/127) were male. Most patients were diagnosed as stage III with a mean Hb of 119 g/L (standard deviation (SD): 20.2 g/L). Only 18.1% (23/127) patients had a history of IDA, 44.4% (20/45) had IDA at the time of gastric cancer diagnosis, and 59.1% (75/127) were anemic. Of the 127 patients, 16.5% had open surgery, while 45.7% had laparoscopic surgery. A total of 78 patients received chemotherapy, and of these 61 (78.2%) developed CIA. At last follow-up, 38.7% (24/62) patients developed IDA, and 79.5% (101/127) were anemic. Red blood cell (RBC) transfusions were most frequently prescribed (49.1%; median 4 units, IQR: 2-6.5), compared to oral (31.5%) or IV iron (16.5%) therapy.

Conclusions: There was a high proportion of IDA (38.7%) in our gastric cancer population despite inconsistent screening for ID. The incidence of anemia increased by 20% from the time of gastric cancer diagnosis to last follow-up. Approximately half of the patients received a RBC transfusion during their care. Our findings highlight the need for targeted therapy for ID to reduce RBC transfusion risk and to improve health-related quality of life. In response to our findings, we have implemented a quality improvement initiative that involves screening of iron status and provision of IV iron given limited oral absorption of iron in gastric cancer patients.

653P Is surgical resection beneficial in recurrent or metastatic gastric cancer?

Y. Choi, M.S. Ahn, H.W. Lee, S.Y. Kang, J-H. Choi

Department of Hematology-Oncology, Ajou University School of Medicine, Suwon, Republic of Korea

Background: Although chemotherapy is currently established as a standard treatment in recurrent or metastatic gastric cancer, the role of palliative surgical resection is still controversial. We investigated the survival benefit of surgical resection in patients (pts) with recurrent or metastatic gastric cancer who received systemic chemotherapy.

Methods: A retrospective review was conducted on 696 pts who received palliative chemotherapy for recurrent (n = 307) or primary metastatic (n = 389) gastric cancer. Overall survival (OS) of pts who underwent surgical resection followed by chemotherapy was compared to that of pts who received chemotherapy alone.

Results: Among 138 pts (primary metastatic: 96, recurrent: 42) with surgical resection, gastrectomy, metastasectomy, and gastrectomy with metastasectomy were performed in 83 (primary metastatic: 81), 42, and 13 pts, respectively. Higher surgical resection rate was observed in pts with young age (<70) ($p = 0.005$), ECOG PS 0 or 1 ($p = 0.010$), primary metastatic ($p < 0.0001$), absence of liver metastasis ($p = 0.003$), and signet ring cell histology ($p = 0.002$). The median OS of pts who underwent surgical resection before chemotherapy was significantly longer than that of pts who received chemotherapy alone (19 vs. 9 months, $p < 0.0001$). The OS benefit of surgical resection was consistent across subgroups in terms of baseline characteristics. In multivariate analysis, surgical resection was independently associated with favorable OS (hazard ratio=0.41, $p < 0.0001$) along with ≥second-line chemotherapy ($p < 0.0001$), while

ECOG PS 2 or 3 ($p = 0.015$), signet ring cell histology ($p < 0.0001$), and peritoneal metastasis ($p = 0.038$) were independent prognostic factors of poor OS. In addition, the median OS of pts who underwent complete resection ($n = 61$) was significantly longer than that of pts who underwent incomplete resection ($n = 77$) (29 vs. 15 months, $p = 0.005$).

Conclusions: The present study suggests that judicious use of surgical resection before chemotherapy in recurrent or metastatic gastric cancer pts may result in favorable outcome, although large scale phase III trials are essential to establish this treatment approach as a standard practice.

654P Nomograms for pre- and post- operative prediction of long-term survival for patients of proximal gastric cancer: A large-scale, single-centre retrospective study

Q. Chen, H. Chang-Ming, C. Zheng, P. Li, J. Xie
Department of Gastric Surgery, Fujian Medical University Union Hospital, Fuzhou, China

Background: The prognostic prediction for long-term survival for patients of proximal gastric cancer has not been well established.

Methods: Between December 2006 and June 2013, we prospectively collected and retrospectively analyzed the medical records of 746 patients with upper-third gastric cancer (GC). The data were split 75/25, with one group used for model development and the other group used for validation testing. COX regression was used to identify preoperative and postoperative risk factors associated with OS.

Results: Among the 746 patients examined, the 1-, 3- year overall survival rate is respectively: 89.4%, 66.1%. The preoperative T staging (cT), preoperative N staging (cN), ASA score, preoperative CA199, preoperative tumor size and the weight loss of 3-6 months were incorporated into the preoperative nomogram for overall survival (OS) prediction for the training set. In addition to these variables, LVI, postoperative tumor size, postoperative T stage, postoperative N stage, postoperative blood transfusion and postoperative complications were incorporated into the postoperative nomogram. All calibration curves for probability of OS fitted well. In the training cohort, the preoperative nomogram achieved a C-index of 0.751[95% confidence interval (CI) 0.732-0.770] in predicting OS and accurately stratified patients into 4 prognostic subgroups (5-year OS rates: 86.8%, 73.0%, 43.72% and 20.9%, $P < 0.001$). The postoperative nomogram had a C-index of 0.758 in predicting OS and accurately stratified patients into 4 prognostic subgroups (5-year OS rates: 82.6%, 74.3%, 45.9% and 18.9%, $P < 0.001$).

Conclusions: The 2 nomograms showed accurate pre- and postoperative prediction for long-term survival for patients of proximal gastric cancer.

655P Safety of neoadjuvant/adjuvant chemotherapy for gastroesophageal cancers: A single cancer centre experience

A. Madi[1], M. Gore[2], M. McKay[2], H. Wong[2], G. Cave[3], R. Rao[4], J. Nicholson[4], H. Smart[5], N. Howes[4], J. Wood[6]

[1]Medical Oncology, Clatterbridge Cancer Centre, Wirral, UK, [2]Clinical Effectiveness, Clatterbridge Cancer Centre, Wirral, UK, [3]Gastroenterology, Whiston Hospital, Prescot, UK, [4]Surgery, Royal Liverpool University Hospital, Liverpool, UK, [5]Gastroenterology, Royal Liverpool University Hospital, Liverpool, UK, [6]Pharmacy, Clatterbridge Cancer Centre, Wirral, UK

Background: Neoadjuvant/adjuvant chemotherapy for gastroesophageal cancers leads to improvement in overall survival and is currently a standard practice. We performed a retrospective study at the Clatterbridge Cancer Centre to examine its safety and identify risk factors.

Methods: Patients with gastroesophageal cancers who received cisplatin/5-FU based neoadjuvant and/or adjuvant chemotherapy were identified from electronic records. We looked at the number of emergency hospital admissions and death events within 30 days from receiving chemotherapy. Information was collected from hospital registry data and medical notes. We also looked at performance status (PS) (0/1 versus ≥ 2) and age (continuous variable) as potential factors for predicting the risk of death.

Results: We identified 1121 patients May 2002- Feb 2015. 73% were male; PS 0-1 in 91%, 2 in 6% and unknown in 3%; median age 64 years (16-81). 62% received cisplatin/5FU or cisplatin/capecitabine (as in the OEO2 Trial) and 38% received epirubicin/cisplatin/capecitabine (as in the MAGIC Trial). Mortality data was available for all patients whereas admission data was available for only 360 patients. There were 98 30-day admissions and these affected 83 patients (23%). The 3 most common causes for admissions were: Gastrointestinal toxicities 45%, infection 15% and vascular events 10%. There were 31 30-day death events (2.8%). There was no difference in mortality rates according to PS but older age was associated with a higher incidence of death (Mann-Whitney test: $P = 0.002$). The median age for patients who died within 30 days from chemotherapy was 69 years. The group of patients ≥ 70 years (26% of the study population) had an odds ratio of 2.37 for dying compared with patients < 70 years.

Conclusions: In our experience, mortality rate after neoadjuvant/adjuvant chemotherapy for gastroesophageal cancers was similar to that reported in landmark studies: In OEO2 3% of patients died before surgery and in MAGIC 1.6% died within 60 days from chemotherapy. PS did not seem to predict risk of death but this can be attributed to the good selection of patients as only 6% had a PS of 2. Patients ≥ 70 years had a higher risk of death and this should be taken into consideration when assessing patients for chemotherapy.

656P Peritoneal lavage CEA mRNA levels predict conversion gastrectomy outcomes after induction chemotherapy in gastric cancer patients with peritoneal metastasis

H. Yamaguchi[1], Y. Sato[2], H. Ishigami[3], H. Oozawa[4], M. Kurihara[2], Y. Yatomi[2], J. Kitayama[4]

[1]Department of Clinical Oncology, Jichi Medical University, Tochigi, Japan, [2]Department of Clinical Laboratory, The University of Tokyo, Tokyo, Japan, [3]Department of Chemotherapy, The University of Tokyo, Tokyo, Japan, [4]Department of Surgery, Jichi Medical University, Tochigi, Japan

Background: The outcome of gastric cancer patients with peritoneal metastasis remains poor. We treated these patients with intraperitoneal and intravenous administration of paclitaxel plus oral tegafur/gimeracil/oteracil (S-1), followed by gastrectomy in responders. However, it remains to be determined whether gastrectomy contributes significantly to the survival benefit in good responders. It is also unclear how and when gastrectomy should be performed. Therefore, reliable biomarkers are urgently needed to predict the outcome of gastrectomy. Herein, we evaluated the clinical significance of carcinoembryonic antigen (CEA) mRNA levels in peritoneal lavage as a biomarker for the indication of conversion gastrectomy.

Methods: The peritoneal lavage of 68 patients who received the above regimen as induction chemotherapy was repeatedly collected via intraperitoneal access ports. Gastrectomy was considered when improvement of peritoneal metastasis was confirmed by a second laparoscopic examination with negative peritoneal cytolog. CEA and porphobilinogen deaminase (PBGD) mRNAs were chronologically quantified using the transcription reverse-transcription concerted reaction method. The CEA-mRNA Index (CmRI) was calculated as CEA mRNA/PBGD mRNA x 10,000.

Results: Thirty-nine patients received gastrectomy and 29 patients did not (median survival time (MST): 27.8 vs. 10.7 months, $P < 0.001$). In the gastrectomy-positive group, the outcome largely differed according the CmRI immediately prior to surgery. Patients ($n = 20$) who had a preoperative CmRI value of < 100 were associated with a significantly longer MST compared to patients ($n = 19$) who had a preoperative CmRI value of > 100 (41.8 vs. 20.8 months, $P < 0.001$). A preoperative CmRI value of < 100 was an independent predictor of survival for gastrectomy-positive patients in the multivariate analysis.

Conclusions: The CmRI reflects the response of peritoneal metastases to induction intraperitoneal chemotherapy. It may be a useful biomarker to determine gastrectomy in gastric cancer patients with peritoneal metastasis.

657P Nutritional recovery after open and laparoscopic distal gastrectomy for early gastric cancer: A prospective multicenter comparative trial (CCOG1204)

C. Tanaka[1], M. Kanda[1], K. Misawa[2], S. Ito[3], Y. Ito[3], Y. Mochizuki[4], K. Ishigure[5], T. Yaguchi[6], J. Teramoto[7], H. Nakayama[8], Y. Kawase[9], M. Fujiwara[1], Y. Kodera[1]

[1]Gastroenterological Surgery, Nagoya University, Graduate School of Medicine, Nagoya, Japan, [2]Department of Gastroenterological Surgery, Aichi Cancer Center Chuo Hospital, Nagoya, Japan, [3]Department of Gastroenterological Surgery, Aichi Cancer Center Hospital, Nagoya, Japan, [4]Department of Surgery, Komaki Municipal Hospital, Komaki, Japan, [5]Department of Surgery, Konan Kosei Hospital, Konan, Japan, [6]Department of Surgery, Kainan Hospital, Yatomi, Japan, [7]Department of Surgery, Yokkaichi Municipal Hospital, Yokkaichi, Japan, [8]Department of Surgery, National Hospital Organization Nagoya Medical Center, Nagoya, Japan, [9]Department of Surgery, Tosei General Hospital, Seto, Japan

Background: Little information from prospective clinical trials is available on the influences of surgical approaches on postoperative body compositions and nutritional status. We designed a prospective non-randomized trial to compare postoperative

chronological changes in body composition and nutritional status between laparoscopic and open distal gastrectomy for stage I gastric cancer (GC).

Methods: Body compositions and nutritional indicators in blood tests were measured at the baseline and at the 1st, 3rd, 6th and 12th postoperative months (POM). The primary endpoint was the decrease relative to the baseline in the body muscle mass at POM6.

Results: Ninety-six patients for the laparoscopic group and 52 for the open group were eligible for data analysis. No significant differences were found in any baseline demographics, body compositions and nutritional indicators between the groups. The changes of body muscle mass at POM 6 were similar in both groups. Overall, no significant differences between the groups were observed in any of the body composition and nutritional indicators during the first year after surgery.

Conclusions: Postoperative body compositions and nutritional status was not affected by surgical approaches during the first 12 months after surgery in patients who underwent distal gastrectomy for stage I GC.

658P Randomized, controlled Phase III trial comparing 3D and 2D laparoscopic gastrcetomy for gastric cancer

J. Lu, H. Chang-Ming, C. Zheng, P. Li, J. Xie, J. Lin

Department of Gastric Surgery, Fujian Medical University Union Hospital, Fuzhou, China

Background: To determine the safety and superiority of three-dimensional (3D) laparoscopic gastrectomy (LG) compared with two-dimensional (2D) laparoscopic in patients with gastric cancer.

Methods: A large-scale, phase 3, prospective randomized controlled trial was conducted. The primary end point was operation time. Morbidity within 30 postoperative days and surgical outcomes were compared to evaluate the safety and efficacy of 3D LG as a secondary end point.

Results: A total of 438 patients were randomized (3D group 219 cases; 2D group 219 cases) between January 1, 2015 and April 1, 2016. Nineteen patients were excluded. Finally, a total of 419 patients were analyzed (3D group 211 cases, 2D group 208 cases). There were no significant differences between the two groups regarding the operation time (3D vs 2D, 175.52±35.53 min vs 173.63±37.00 min, $p = 0.596$). The operation time was further stratified analysis by BMI and operative region which showed that when BMI is larger than 25kg/m2 the 3D group in the Splenic Hilar regional lymph node cleaning time was significantly lower than the 2D group (29.4±7.8 min vs 23.3±6.4 min, $p = 0.024$). The intra-operative blood loss in the 3D group was significantly lower than the 2D group (61.37±82.99 ml vs 81.54±119.44 ml, $P = 0.045$). Furthermore analysis suggested that 3D laparoscopic was a protect factor for excessive blood loss (≥200ml). The postoperative complication rates of the 3D and 2D groups were 17.1% (36/211) and 13.9% (29/208), respectively, $p = 0.378$. No patients died during the postoperative hospital stay. Postoperative questionnaire survey showed that the surgeon experienced better depth perception with the 3D system and there was no significant difference in postoperative strain between the two groups.

Conclusions: 3D LG not only can significantly reduce the lymph node dissection time at complicated regional, but also has a benefit of less intra-operative blood loss and lower occurrence of excessive bleeding incidence compared with conventional 2D surgery. (Number NCT02327481)

Background: Although anthracycline-based triplets are one of the most widely used regimens for the treatment of advanced gastric cancer (AGC), the incremental benefit associated with the inclusion of anthracyclines in therapeutic combinations is unknown. The aim of this study is to evaluate the efficacy and tolerance of epirubicin triplets vs platinum-fluoropyrimidine doublets in a national AGC registry.

Methods: We recruited patients with AGC treated at 28 Spanish centers with polychemotherapy, without trastuzumab, from 2008 to 2016. The effect of anthracycline-based triplets was assessed by propensity score matching (PSM) and Cox proportional hazards (PH) regression.

Results: 1002 patients (doublets, $n = 653$, triplets with anthracyclines, $n = 349$) were included. In the multivariate Cox PH regression model, there was no significant increase in OS in favor of anthracycline-based triplets: HR 0.90 (95% CI, 0.78-1.05), $p = 0.20035$. After PSM, the sample contains 325 pairs with similar baseline characteristics. There was also no increase of OS with this method: 10.5 (95% CI, 9.7-12.3) vs. 9.9 (95% CI, 9.2-11.4) months, HR 0.91 (CI 95%, 0.76-1.083), (stratified log-rank test, $p = 0.226$), for doublets without anthracyclines vs anthracycline-based triplets. Objective responses were higher with triplets: 32.9% vs. 24.0% ($p = 0.014$) without significant differences in PFS: HR 0.95 (CI 95%, 0.80-1.13), stratified log-rank test, $p = 0.873$. Triplets were associated with higher hematological toxicity, and increased toxicity-related admissions by 86%. The addition of epirubicin is viable, but 23.7% discontinued treatment because of adverse effects or patient decision.

Conclusions: Anthracycline triplets increased the antitumor effect (objective responses) of the treatment. However, they were not associated with an incremental benefit in PFS or OS and instead had a higher toxicity.

660P First-in-human study of IMAB362, an anti-claudin 18.2 monoclonal antibody, in patients with advanced gastroesophageal cancer

U. Sahin[1], M. Schuler[2], S. Bauer[3], A. Krilova[4], M. Utsch[5], C. Huber[1], Ö. Türeci[5]

[1]Translational Oncology, University Medical Center of the Johannes Gutenberg University Mainz, Mainz, Germany, [2]Department of Medical Oncology, West German Cancer Center, University Hospital Essen, Essen, Germany, [3]Onkologisches Zentrum Lebach, Gemeinschaftspraxis Hematology and Oncology, Lebach, Germany, [4]Oncology Clinic, Liepaja Piejuras Hospital, Liepaja, Latvia, [5]Ganymed Pharmaceuticals, AG, Mainz, Germany

Background: Claudin 18.2 (CLDN18.2), a gastric mucosa tight junction protein, is aberrantly expressed in various cancers. IMAB362, an anti-CLDN18.2 monoclonal antibody, specifically binds to CLDN18.2-positive cancer cells. This first-in-human (FIH), dose-escalation study evaluated the clinical effects of IMAB362 in patients with advanced gastroesophageal cancer (GEC) after a single IV infusion.

Methods: This phase 1 study (NCT00909025), conducted at 6 centers in Germany and Latvia, enrolled patients (≥18 yrs) with advanced GEC into 5 sequential dose-escalations cohorts (33, 100, 300, 600, 1000 mg/m^2) that followed a 3 + 3 design. Safety/tolerability, including determination of maximum tolerated dose (MTD) based on emergence of dose-limiting toxicities (DLTs), was the primary objective; secondary objectives included assessment of the IMAB362 pharmacokinetic (PK) profile, immunogenicity, and antitumor activity (assessed by RECIST v1.0).

Results: All 15 enrolled patients (median age 61.3 years [range: 46–76]) had received ≥1 prior chemotherapy with nearly half ($n = 7/15$; 47%) having undergone previous radiotherapy. All IMAB362 doses tested were generally well tolerated; as no DLT was

observed within 4 weeks of treatment the MTD was not established. Mild-to-moderate gastrointestinal disorders (eg, nausea, vomiting) were the most common treatment-related adverse events (AEs); however, no clear dose dependency was observed. Neither of the 2 serious AEs (grade 2 odynophagia [300 mg/m^2]; grade 3 urinary retention [600 mg/m^2]) was considered treatment related. No antibodies against IMAB362 were detected. Most patients (n = 12/15; 80%) showed progressive disease at Weeks 4–5 after a single IMAB362 IV infusion; however, 1 patient in the 600 mg/m^2 dose group had stable disease for ~2 months postinfusion. The linear, dose-proportional PK profile supports IMAB362 dosing at 300–600 mg/m^2 every 2 weeks.

Conclusions: Single-dose administration of IMAB362 was well tolerated up to 1000 mg/m^2 in this FIH dose-escalation study. These results encourage further clinical testing of IMAB362 in patients with CLDN18.2-positive GEC.

661P Bidirectional chemotherapy in gastric cancer (GC) with peritoneal carcinomatosis (PC) combining intravenous chemotherapy with pressurized intraperitoneal aerosol chemotherapy (PIPAC): Results of 103 procedures in 52 patients

V. Khomyakov[1], A. Ryabov[1], L. Bolotina[2], A. Utkina[1], A. Ivanov[1], O. Kuznetsova[3]

[1]Thoracoabdominal, P.A. Herzen Moscow Research Oncological Institute – branch of the National Medical Research Radiological Center, Moscow, Russian Federation, [2]Chemotherapy, P.A. Herzen Moscow Research Oncological Institute - National Medical Research Radiological Center, Moscow, Russian Federation, [3]Pathology, P.A. Herzen Moscow Research Oncological Institute - National Medical Research Radiological Center, Moscow, Russian Federation

Background: Up to 43% of GC patients show synchronous PC at time of diagnosis and peritoneal relapse develops in 10–46% of cases after radical surgery. Systemic chemotherapy shows low response rate (14-25%) and median survival of 8-10 months. Innovative therapeutic approaches are needed to improve survival.

Methods: Treatment protocol for untreated patients included initial staging laparoscopy/laparotomy, 3–4 courses of systemic chemotherapy (XELOX) followed by Pressurized IntraPeritoneal Aerosol Chemotherapy (PIPAC) with low-dose Cisplatin and Doxorubicin every 6 weeks until progression of disease or death. Criteria of progression were 50% and more PCI increase or distant metastases. Patients with primary or recurrent GC, who received earlier one or two lines of systemic chemotherapy, didn't receive 4 XELOX courses before PIPAC. Primary endpoints were overall survival and pathologic response after peritoneal rebiopsy.

Results: 52 patients were included (15 men, 37 women, mean age 53.5 years), 38 patients had primary GC with PM and 14 had peritoneal relapse after surgery (with or without adjuvant therapy). 19 patients had systemic chemotherapy before inclusion to the program. Mean PCI was 12.6 (min-max 3-34). Altogether, 103 PIPAC procedures were performed in the 52 patients. The main reason for not undergoing more than one PIPAC was PC progression (16). Pathological response was estimated in 30 pts underwent more than 1 PIPAC. 33% of patients showed complete pathologic response (CR), 50% - PR and 17% of cases had weak or no response. PCI score has decreased in 37% of patients, remained stable in 10% and has increased in 53% of cases. Thus PCI change isn't equal to the pathologic response. Median survival was 14.6 months and one-year overall survival was 62%. The median survival was better in patients with low PCI and in those who responded to systemic chemotherapy, but the difference was not significant.

Conclusions: Bidirectional chemotherapy combining intravenous chemotherapy and PIPAC can induce objective tumor regression and is associated with a promising survival in GC with PC.

662P Gastrectomy after response to intraperitoneal and systemic chemotherapy for gastric cancer with peritoneal metastasis or positive peritoneal cytology

H. Ishigami[1], H. Yamaguchi[2], H. Yamashita[3], M. Asakage[4], J. Kitayama[5]

[1]Department of Chemotherapy, The University of Tokyo, Tokyo, Japan, [2]Department of Clinical Oncology, Jichi Medical University, Tochigi, Japan, [3]Department of Gastrointestinal Surgery, The University of Tokyo, Tokyo, Japan, [4]Department of Surgery, Hitotsubashi Hospital, Tokyo, Japan, [5]Support Center for Clinical Investigation, Jichi Medical University, Tochigi, Japan

Background: The prognosis of gastric cancer patients with peritoneal metastasis (P1) or positive peritoneal cytology (CY1) remains poor in spite of recent progress in systemic chemotherapy. We developed several regimens combining intraperitoneal (IP) and systemic chemotherapy, and evaluated the safety and efficacy in clinical trials. Gastrectomy after response to combination chemotherapy is a promising option for P1 or CY1 gastric cancer. A retrospective study was performed to evaluate this multidisciplinary treatment strategy.

Methods: This study enrolled 158 primary P1 or CY1 gastric cancer patients treated with IP paclitaxel or docetaxel with systemic chemotherapy at the University of Tokyo Hospital between 2005 and 2015. Gastrectomy was performed when peritoneal cytology turned negative, and the disappearance or obvious shrinkage of peritoneal metastasis was confirmed by laparoscopy. Combination chemotherapy was restarted after surgery and repeated with appropriate dose reduction.

Results: Ninety-one patients were chemo-naïve, and 67 patients had received standard systemic chemotherapy at the previous hospitals before the initiation of IP chemotherapy. Gastrectomy was performed in 94 (P1 85, P0CY1 9) of 158 (P1 147, P0CY1 11) patients after response to chemotherapy. R0 resection was achieved in 61 of 94 patients (65%). Postoperative complications included anastomotic leakage in 3 patients and pancreatic fistula in 2 patients, which were cured conservatively. The median survival time (MST) of 94 patients with gastrectomy was 31.3 months (95% confidence interval [CI] 26.1-39.3 months) from the initiation of IP chemotherapy and 35.8 months (95% CI 28.5-40.1 months) from the diagnosis of gastric cancer. Relapse or progression was observed in 78 of 94 patients with a median time of 17.9 months (95% CI 15.0-24.2 months). The first site of recurrence or progression was the peritoneum in 61 patients and the other site in 28 patients (both in 11 patients). The MST of 64 patients without gastrectomy was 12.3 months (95% CI 10.0-13.9 months).

Conclusions: Gastrectomy after response to intraperitoneal and systemic chemotherapy is safe and may prolong the survival of P1 and CY1 gastric cancer patients.

663P Change in the molecular profile of tumor tissues during treatment with trastuzumab, as analyzed by next-generation sequencing and immunohistochemistry: A multicenter prospective biomarker study on HER2-positive gastric cancer

N. Takahashi[1], S. Iwasa[2], T. Sawada[3], Y. Sasaki[4], H. Taniguchi[5], I. Oda[6], T. Honda[7], Y. Kojima[8], H. Hara[9], Y. Honma[2], A. Takashima[2], K. Kato[2], T. Hamaguchi[10], Y. Yamada[11]

[1]Department of Gastroenterology, Saitama Cancer Center, Ina-machi, Kita-Adachi-gun, Japan, [2]Gastrointestinal Medical Oncology Division, National Cancer Center Hospital, Tokyo, Japan, [3]Department of Advanced Research in Community Medicine, Kanazawa University, Kanazawa, Japan, [4]Department of Medical Genome Sciences, Research Institute for Frontier Medicine, Sapporo Medical University, Hokkaido, Japan, [5]Pathology and Clinical Laboratory Division, National Cancer Center Hospital, Tokyo, Japan, [6]Endoscopy Division, National Cancer Center Hospital, Tokyo, Japan, [7]Gastroenterology and Hepatology, Nagaski University Hospital, Nagasaki, Japan, [8]Department of Gastroenterology, National Center for Global Health and Medicine, Tokyo, Japan, [9]Department of Gastroenterology, Saitama Cancer Center Hospital, Saitama, Japan, [10]Gastrointestinal Medical Oncology, National Cancer Center Hospital, Tokyo, Japan, [11]Department of Clinical Oncology, Hamamatsu University, Shizuoka, Japan

Background: Trastuzumab (Tmab) is an active molecular-targeted drug for HER2-positive gastric cancer (GC) patients. However, continued use of Tmab beyond progression is not established in HER2-positive GC, unlike that of breast cancer. Therefore, we conducted this study to evaluate the resistance mechanism of anti-HER2 drugs in metastatic GC patients.

Methods: Metastatic HER2-positive GC patients treated with Tmab were registered prospectively, and tumor tissues were obtained by biopsy from primary lesions at the following points: (1) pre-treatment, (2) post-treatment, and (3) disease progression during chemotherapy with Tmab. Formalin-fixed paraffin-embedded tissue slides were prepared, and the expression of receptor tyrosine kinases (RTKs) such as EGFR, HER2, HER3, c-MET, FGFR2 and IGF-1R was evaluated by immunohistochemistry (IHC). Hot spot mutations and copy number variations (CNVs) were analyzed by next-generation sequencing (NGS) using Ion AmpliSeq Cancer Hotspot Panel v2.

Results: Twenty patients were enrolled and evaluated by IHC, and 15 of 20 patients were evaluated by NGS. One patient was excluded because HER2 status was revealed as negative after registration. HER2 expression (≥2+) by IHC have disappeared after treatment in 8 patients (42%). FGFR2 expression (≥2+) by IHC was most frequently

observed after treatment. Cases with IGF-1R expression (≥2+) were significantly increased after treatment ($p < 0.05$). Somatic mutations of *TP53* (n = 9), *KRAS* (n = 2), *BRAF* (n = 2), *SMAD4* (n = 1), *CDH1* (n = 1), and *CDKN2A* (n = 1) were observed before treatment. Mutations of *TP53* (n = 2), *KRAS* (n = 2), *PIK3CA* (n = 2), *CDH1* (n = 2), *PDGFRA* (n = 1), and *PTEN* (n = 1) were newly observed during the treatment. CNV analyses revealed that the cases with gain of *KRAS* and loss of *STK11* were likely to increase during treatment with Tmab.

Conclusions: Our study indicated that molecular changes in RTK expression and genomic alternation frequently occur during treatment with Tmab. These findings will contribute to the development of individualized treatment for HER2-positive GC patients.

664P Phase 1 Study of IMAB362 with immunomodulation in patients with advanced gastric cancer

S-E. Al-Batran[1], Z. Zvirbule[2], F. Lordick[3], P. Thuss-Patience[4], M. Just[5], M. Bitzer[6], V. Brass[7], A. Krilova[8], D. Maurus[9], Ö. Türeci[9]U. Sahin[10]

[1]Institute of Clinical Cancer Trials (ICCT), Krankenhaus Nordwest, Frankfurt am Main, Germany, [2]Latvian Oncology Center, Riga East University, Riga, Latvia, [3]University Cancer Center Leipzig, University Hospital Leipzig, Leipzig, Germany, [4]Medical Clinic of Hematology, Oncology and Tumor Immunology, Charite University Medicine Berlin, Berlin, Germany, [5]Oncology, Practice for Oncology Bielefeld, Bielefeld, Germany, [6]Department of Internal Medicine I Gastroenterology, Hepatology, Infectious Diseases, University Hospital Tuebingen, Tübingen, Germany, [7]Clinic of Internal Medicine II, Gastroenterology and Hepatology, University Hospital Freiburg, Freiburg, Germany, [8]Oncology Clinic, Piejuras Hospital, Liepaja, Latvia, [9]Ganymed Pharmaceuticals, AG, Mainz, Germany, [10]Translational Oncology, University Medical Center of the Johannes Gutenberg University Mainz, Mainz, Germany

Background: IMAB362, a monoclonal antibody to Claudin 18.2 (CLDN18.2), has demonstrated strong tumor cell killing activity via antibody-dependent cell-mediated cytotoxicity (ADCC) and complement-dependent cytotoxicity (CDC) in preclinical gastric cancer models. Safety/tolerability, pharmacodynamics (PD), and clinical response of IMAB362 in combination with zoledronic acid (ZA) and interleukin-2 (IL-2), which expand and activate ADCC-mediating gamma9delta2 T cell effector populations, was assessed in patients with advanced upper GI adenocarcinomas.

Methods: This open-label phase 1 exploratory study (NCT01671774) enrolled heavily pretreated patients (age ≥18 yrs) whose tumor cells had CLDN18.2 staining intensity either 2+ in ≥ 40% cells or any 3+ by IHC. Patients were enrolled into 1 of 4 treatment arms: Arm 1, IMAB362 + ZA; Arm 2, IMAB362 + ZA + 1 million IU (mIU) IL-2; Arm 3, IMAB362 + ZA + 3 mIU IL-2; Arm 4, IMAB362 alone. Patients received: IV IMAB362 Q3W, 800 mg/m^2 on Cycle 1, Day 1 and 600 mg/m^2 on Day 1 of every subsequent cycle; IV ZA 4 mg, Day 1 of Cycles 1 and 3; subcutaneous IL-2, Days 1–3 of Cycles 1 and 3. Safety/tolerability of IMAB362, immune cell phenotyping by flow cytometry and IMAB362-induced ADCC in a cytotoxicity assay were primary endpoints; clinical response (per RECIST v1.1) was a secondary endpoint.

Results: Of the 29 enrolled patients, 28 received treatment (Arm 1, n = 7; Arm 2, n = 9; Arm 3, n = 7; Arm 4, n = 5), 21 were in the PD analyses, and 19 in response analyses. IMAB362 had acceptable safety/tolerability unaltered by immunomodulation; grade 1–4 nausea and vomiting (both n = 15/28; 54%) were the most common adverse events. Expansion and activation of gamma9delta2 T cells and activation of NK cells were initiated by all treatment arms; however, these effects were more extensive in pts treated with IMAB362 + ZA/IL-2 (n = 10 [5 each in Arms 2 and 3]). A strong ADCC in response to IMAB362 was observed in most patients; however, ADCC kinetics over time and dependency on ZA/IL-2 were not conclusive. No patient achieved confirmed response; 11 (58%) had confirmed stable disease.

Conclusions: This study provided encouraging data on safety/tolerability and cytotoxicity of IMAB362 in combination with ZA/IL-2. Objective responses were not observed.

665P Modified Glasgow prognostic score, prognostic nutritional index and ECOG score could be new prognostic factors for survival in metastatic gastric cancer

B. Demirelli[1], N. Babacan[2], S. Koca[2], B.N. Uzun[3], Ö. Ercelep[2], M.A. Ozturk[2], S. Kaya[2], E.T. Simsek[2], S. Khalil[2], R. Hasanov[2], O. Alan[2], T.A. Telli[2], M.E. Arıbal[3], F. Dane[2], F. Yumuk[2]

[1]Internal Medicine, Marmara University Hospital, Istanbul, Turkey, [2]Medical Oncology, Marmara University Hospital, Istanbul, Turkey, [3]Radiology, Marmara University Hospital, Istanbul, Turkey

Background: Metastatic gastric carcinoma (MGC) patients usually present with cachexia and sarcopenia. We aimed to analyze the prognostic values of the sarcopenia index (SI), cachexia index (CI) and inflammatory indexes (advanced lung cancer inflammation index [ALI], modified Glasgow Prognostic Score [mGPS], prognostic index [PI], prognostic nutritional index [PNI] and neutrophil-to-lymphocyte ratio [NLR]) on MGC at presentation.

Methods: A retrospective study was performed in 87 patients with MGC. SI, CI, PI, PNI, ALI, mGPS and NLR was measured and calculated appropriately. Due to lack of studies from our country, SI cutoff value has been obtained by using both western (EGWSOP) and eastern (Harada Y, et al) sources separately. Statistical analysis has been done by SPSS.

Results: Median follow-up time was 9 months (range 1-64) and 78 patients died during follow-up. Fiftynine patients were male (63%) and median age was 62 (23-88). According to univariate analysis these factors had significant negative impact on general survival (GS): increased leukocyte ($p = 0{,}003$) and neutrophile ($p < 0{,}001$), decreased lymphocyte count ($p = 0{,}048$), increased CRP ($p < 0{,}001$) and decreased serum albumin ($p < 0{,}001$), high mGPS ($p < 0{,}001$) and PI score ($p < 0{,}001$), PNI level <45 ($p < 0{,}001$), NLR level ≥ 3,41 ($p < 0{,}001$), ALI level <18 ($p < 0{,}001$), CI level under 35 ($p < 0{,}001$), SI (Harada Y, et al) ≤44,5 for males and ≤36,5 for females ($p = 0{,}003$), ECOG score ≥ 2 ($p < 0{,}001$), weight loss more than 10% during last 6 months ($p = 0{,}002$), BMI under 24 ($p = 0{,}009$). According to multivariable analysis mGPS (HR 2,494, 95% CI 1,25–4,94 $p = 0{,}02$), PNI (HR 4,2, 95% CI 1,73–10,1 $p < 0.001$) and ECOG score (HR 1,541, 95% CI 1,089-4,214, $p = 0.004$) were independent prognostic factors on GS. mGPS was found to be more valuable than other indexes for predicting mortality. The time consumed during these tests were: m GPS 10 sec, PNI 20 sec, PI 15 sec, NLR 15 sec, ALI 40 sec, CI 17 min, SI 15 min.

Conclusions: On our study; mGPS, PNI and ECOG score were independent indicators for shorter survival. mGPS and PNI, which can be calculated by using only CRP, albumin levels and complete blood counts, might be inexpensive, practical and beneficial in routine clinical practice.

666P Accuracy and prognostic significance of oncologists' estimates and scenarios for survival time in a randomised Phase 2 trial of regorafenib in advanced gastric cancer

A. Vasista[1], A. Martin[1], N. Pavlakis[2], K. Sjoquist[1], S. Snow[3], D. Jonker[4], Y.J. Chua[5], R. Epstein[6], A. Bonaventura[7], M. Khasraw[8], S.C. Varma[9], N. Singhal[10], D.T. Ransom[11], F. Aubin[12], R. Burkes[13], H. Lim[14], F. Lemay[15], S. Begbie[16], M.R. Stockler[1], B. Kiely[1]

[1]Medical Oncology, NHMRC Clinical Trials Centre, Camperdown, Australia, [2]Medical Oncology, Royal North Shore Hospital, St Leonards, Australia, [3]Medical Oncology, Queen Elizabeth II Health Sciences Centre, Halifax, NS, Canada, [4]Medical Oncology, Ottawa Health Research Institute, Ottawa, ON, Canada, [5]Medical Oncology, Canberra Hospital, Garran, Australia, [6]Medical Oncology, St Vincents Hospital, Darlinghurst, Australia, [7]Medical Oncology, Newcastle Private Hospital, Newcastle, Australia, [8]Medical Oncology, Geelong Hospital, Geelong, Australia, [9]Medical Oncology, Townsville Hospital, Douglas, Australia, [10]Medical Oncology, Royal Adelaide Hospital, Adelaide, Australia, [11]Medical Oncology, St John of God, Subiaco, Australia, [12]Medical Oncology, Hospital Notre Dame, Montreal, QC, Canada, [13]Medical Oncology, Mount Sinai Hospital, Toronto, ON, Canada, [14]Medical Oncology, BCCA Vancouver Cancer Centre, Vancouver, BC, Canada, [15]Medical Oncology, Centre Hospitalier Universitaire de Sherbrooke, Sherbrooke, QC, Canada, [16]Medical Oncology, North Coast Cancer Centre, Port Macquarie, Australia

Background: We have proposed that best, worst and typical scenarios for survival, based on simple multiples of an individual's expected survival time (EST) estimated by their oncologist, are a useful way of formulating and explaining prognosis in advanced cancer. We aimed to determine the accuracy and prognostic significance of such estimates in a multicentre, randomized trial.

Methods: 66 oncologists estimated the EST at baseline for each of 152 participants in the INTEGRATE trial. We expected oncologists' estimates of EST to be well calibrated

(∼50% of patients living longer or shorter than their EST) and imprecise (<33% living within 0.67 to 1.33 times their EST), but to provide accurate scenarios for survival time (∼10% dying within a quarter of their EST, ∼10% living longer than 3 times their EST and ∼50% living for half to double their EST). We also hypothesized that oncologists' estimates of EST would be independently predictive of overall survival in a multivariable Cox model including conventional prognostic factors and health related quality of life.

Results: Oncologists' estimates of EST were well calibrated (45% shorter than observed), imprecise (29% lived within 0.67 to 1.33 times observed), and moderately discriminative (Harrell C-statistic 0.62, P = 0.001). Scenarios derived from oncologists' estimates were remarkably accurate: 9% of patients died within a quarter of their EST, 12% lived longer than three times their EST and 57% lived within half to double their EST. Oncologists estimates of EST (in months) were independently significant predictors of overall survival (HR = 0.89, 95% CI 0.83 to 0.95, P = 0.001) in a Cox model including ECOG performance status, primary site, number of metastatic sites, neutrophil to lymphocyte ratio≥ 3, treatment group, age, and the EORTC QLQC30 physical function score.

Conclusions: Oncologists' estimates of survival time were well calibrated, moderately discriminative, and independently significant predictors of overall survival. Best, worst and typical scenarios for survival based on simple multiples of the EST were remarkably accurate and would provide a useful method for estimating and explaining prognosis in this setting.

667P ERBB3 mutations in advanced gastric signet-ring cell carcinoma (SRCC) and the implications for targeted therapy

J. Wei, B. XU, S. Jin, L. Yu, B. Liu

The Comprehensive Cancer Centre of Drum Tower Hospital, Medical School of Nanjing University & Clinical Cancer Institute of Nanjing University, Nanjing 210008, China, Nanjing, China

Background: Studies have shown that ERBB3 mutations are associated with poor clinical prognosis by increasing the rate of metastasis and recurrence in many cancers. ERBB3 targeted therapeutics can be effective against ERBB3 mutant-driven tumors. ERBB signal pathway plays a very important role in the initiation and progression of gastric cancer, however the ERBB2 expression and mutation rate is relative low especially in gastric SRCC. Thus, ERBB3 might be a promising target for the treatment in SRCC patients. The aim of this study is to speculate the prognostic and targeted therapy value in gastric SRCC by evaluating the mutation rate and type of ERBB3.

Methods: 92 patients with histological diagnosis of advanced gastric SRCC were retrospectively selected for this study. ERBB3 mutation was evaluated by next generation sequencing from formalin-fixed paraffin-embedded (FFPE) samples. ERBB2 expression was tested by immunohistochemistry. Correlations between ERBB2/3 status and clinical pathologic characteristics and overall survival (OS) were performed.

Results: All of the 92 patients were diagnosed as local advanced or metastatic gastric SRCC (92.4% were stage III, 7.6% were stage IV). All the patients received 5-FU-based first-line chemotherapy. 14 out of all 92 patients were ERBB3 mutated SRCC, 12 of all the 14 mutations were in the extracellular domain, 2 were in the transmembrane region. There was no correlation between ERBB3 mutation and serosa invasion (P = 0.389) or lymph node metastasis (P = 1.000). The median OS was 20.5 months (95% CI = 10.05to 30.95 months) for patients with ERBB3 mutation, and 19.0 months (95% CI = 15.54 to 22.46 months) for patients without ERBB3 mutation (P = 0.567). There was no difference in OS according to HER2 positive or negative in ERBB3 mutated patients (14.8 months vs 20.5 month, P = 0.374).

Conclusions: Our study demonstrated 15.2% of gastric SRCC patients harboring ERBB3 mutation, providing a potential subgroup of gastric SRCC for targeted treatment on ERBB pathway. No difference of OS was observed, probably due to the relative small sample size and low ERBB2 positive rate in SRCC patients. Further investigation on ERBB3 is warranted to clarify mechanisms of ERBB pathway in gastric SRCC.

Magrassi, Università degli Studi della Campania Luigi Vanvitelli, Naples, Italy, [17]Department of Oncology, San Bortolo General Hospital, Vicenza, Italy

Background: The estimation of life expectancy of mGC pts in the second-line setting may be biased by the absence of objective prognostic tools to be used for enrollment in clinical trials and for decision making in the daily practice. The availability of evidence-based second-line treatment options highlights the need of nomograms/prognostic scores which may assist clinicians in refining pts' clinical selection in the salvage setting. The aim of this study was to build a nomogram for predicting the individual 12-weeks overall survival (OS) of mGC pts starting a second-line treatment.

Methods: At 26 Italian Institutions, 320 mGC patients receiving second-line chemotherapy, ramucirumab or paclitaxel-ramucirumab were used as developing set. Putative prognostic variables (age, gender, ECOG PS, T resection, Lauren's histotype, primary anatomic site, synchronous presentation, number and location of metastatic sites, PFS and response to 1-line, LDH, neutrophils/lymphocytes ratio) were selected using a random forest model and included in a Cox multivariable model from which the nomogram was derived. The nomogram performance was evaluated by means of calibration plot and discriminative ability (Harrell's C index).

Results: Three variables were selected and included in the nomogram: ECOG PS (P < 0.0001), neutrophils/lymphocytes ratio (P < 0.0001) and peritoneal involvement (P = 0.0005). The model discriminative ability index was 0.858. The internal calibration plot did not show significant differences between observed and predicted 12-weeks OS probabilities. External validation analysis is currently ongoing.

Conclusions: Our nomogram may be a useful tool to predict 12-weeks life expectancy in mGC pts candidates for second-line therapy. Based on 3 easy-to-collect variables, the" Gastric Life" nomogram may improve second-line pts' selection and assist researchers for the enrollment in clinical trials.

669P TG01/GM-CSF and adjuvant gemcitabine in patients with resected RAS-mutant adenocarcinoma of the pancreas

S. Dueland[1], J.W. Valle[2], K. Bell[1], O. Faluyi[3], H. Staiger[2], T.J. Gjertsen[4], A-S. Møller[4], A-K. Aksnes[4], D. Palmer[3]

[1]Department of Clinical Cancer Research, Oslo University Hospital and Norwegian Radium Hospital, Oslo, Norway, [2]Clinical Oncology, The Christie NHS Foundation Trust, Manchester, UK, [3]Department of Molecular and Clinical Cancer Medicine, University of Liverpool, Liverpool, UK, [4]Clinical, Targovax ASA, Oslo, Norway

Background: The study evaluated the immune response, safety and clinical efficacy of the TG01/GM-CSF vaccine, an antigen-specific cancer immunotherapy consisting of 7 RAS peptides targeted to KRAS mutated pancreatic adenocarcinoma (PAC). The efficacy of adjuvant chemotherapy in resected disease is limited with 1- and 2-year published overall survival (OS) rates ranging from 56-80% and 30-54% respectively. TG01 induces RAS mutant-specific T-cell responses which are enhanced by co-administration of GM-CSF.

Methods: Patients (pts) were eligible after R0 or R1 PAC resection. As soon as possible after surgery, TG01 (0.7 mg intradermal injection (id)) together with GM-CSF (0.03 mg id) was given on days 1, 3, 5, 8, 15, 22 and 2-weekly thereafter until the end of gemcitabine (starting within 12 weeks of surgery and given for 6 cycles). Thereafter TG01/GM-CSF was given 4-weekly up to 1 yr and 12-weekly up to 2 yrs. Immune response was assessed using antigen-specific (TG01) Delayed-Type Hypersensitivity and T-cell proliferation. OS and disease free survival (DFS) was assessed from surgery; ∼8 weeks before first TG01 injection.

Results: To date, 19 pts (68% R1) have been followed for 2 1/2 yrs. Median CA19-9 was 15 (5, 240) U/ml at baseline. 8 SARs in 5 pts have occurred; 4 related to gemcitabine (anemia, pulmonary infection and 2 fever); 3 related to TG01/GM-CSF (2 anaphylaxes and 1 hypersensitivity); and 1 possibly related to all products (dyspnea). The allergic reactions only occurred after several cycles of gemcitabine and resolved within 1-2 hrs. There were no treatment related deaths. TG01 induce an immune response in 17/19 patients by week 11, which demonstrate that TG01 vaccination activate TG01 specific T-cells. OS rate at 2 yrs was 68.4 (95% CI 47.5, 89.3). OS rate at 2 1/2 yrs will be presented. Median OS was 33.1 months (95% CI 16.8, 40.1). Median DFS was 13.9 months (95% CI 5.4-21.0).

Conclusions: The regimen was generally well tolerated although some late, manageable allergic reactions were seen. OS and DFS was encouraging in view of published reports. TG01/GM-CSF generated early immune responses in 89% of patients with R0/R1 resected pancreatic cancer. 13 pts have been recruited in a modified dose cohort with 2 yrs data in 2Q 2018.

Clinical trial identification: NCT02261714.

Background: There is a need for effective treatments in the second- or further line setting in advanced gastric cancer, especially for new agents. In the current trial we evaluated paclitaxel with RAD001 (everolimus) in patients with gastric carcinoma who have progressed after therapy with a fluoropyrimidine/platinum-containing regimen.

Methods: This is a randomized, double-blind, multi-center phase III study. Patients with gastric carcinoma or adenocarcinoma of the esophagogastric junction (EGJ) who have progressed after treatment with a fluoropyrimidine/platinum-containing regimen were randomly assigned to receive Paclitaxel (80 mg/m2) on day 1, 8 and 15 plus placebo (arm A) or RAD001 (10mg daily, arm B) d1-d28, repeated every 28 days as 2nd, 3rd or 4th line therapy. Primary end point was overall survival (OS), secondary endpoints were best overall response, disease control rate, progression free survival (PFS) and toxicity.

Results: 300 patients (median age: 62 years; median lines prior therapy: 2; 47.7% of patients had prior taxane therapy) were randomly assigned (Arm A, 150, Arm B, 150). In the intention to treat population, there was no significant difference in median PFS (placebo, 2.07 vs. RAD001, 2.2 months, HR 0.88, $p = 0.3$) or median OS (placebo, 5.0 vs. RAD001, 6.1 months, HR 0.93, $p = 0.54$). For patients with prior taxane use, RAD001 improved PFS (placebo 1.8 vs. RAD001, 2.7 months, HR 0.69, $p = 0.03$) and OS (placebo 3.9 vs. RAD001, 5.8 months, HR 0.73, $p = 0.07$). Combination of paclitaxel and RAD001 was tolerable, but the RAD001 arm was associated with significantly more grade 3-5 mucositis (13.3% vs. 0.7%; $p < 0.001$).

Conclusions: The addition of RAD001 to paclitaxel/RAD001 did not improve outcomes in pretreated metastatic gastric/EGJ cancer. Of note, activity was seen in the taxane pretreated group. Additional biomarker studies are planned to look for subgroups that may have a benefit.

Background: Nivo monotherapy demonstrated its efficacy with manageable safety for G/GEJ cancer refractory or intolerant to standard chemotherapy at the primary analysis (ATTRACTION-02[ONO-4538-12]: ASCO-GI 2017, Kang YK et al. J Clin Oncol. 2017; 35 [suppl 4S abstract 2]). This randomized phase 2/3 trial is to evaluate the efficacy and safety of Nivo in combination with 1st line chemotherapy in unresectable advanced or recurrent G/GEJ cancer (NCT02746796).

Methods: This trial includes previously untreated pts aged $\geq$ 20 years with ECOG PS 0-1 and had measurable, unresectable advanced or recurrent HER2 (-) G/GEJ cancer. It consists of 2 parts. Part 1 is a randomized, open-label trial to evaluate the feasibility of Nivo (360 mg, Q3W) in combination with oxaliplatin (130 mg/m^2, Q3W) plus either S-1 (40 mg/m^2 twice daily, day 1-14, SOX) or capecitabine (1000 mg/m^2 twice daily, day 1-14, CapeOX) in terms of activity and safety. Part 2 is a randomized, double-blind, placebo-controlled trial comparing Nivo to placebo in combination with SOX/CapeOX in terms of overall survival and progression free survival (PFS).

Results: A total of 40 pts were included into part 1, 21 pts were randomized to Nivo+SOX and 19 to Nivo+CapeOX. The median age was 62.5 years, 27 pts (67.5%) were male, 20 pts (50.0%) had ECOG PS 1. Median duration of treatment was 7.03 months (range 0.1-9.9) as of 24 Feb 2017. Both treatments were well tolerated. Grade 3-4 treatment-related adverse events (AEs) were reported 23 pts (57.5%). No Nivo-related AEs leading to discontinuation were reported. Overall response rate was 68.4% (26/38, CR10, PR16) and disease control rate was 86.8%. Median PFS was not reached. 18 pts (46.2%) remain on treatment at the time of the data cut off. There were no significant differences in activity and safety between the 2 treatments.

Conclusions: Nivo+SOX/CapeOX were feasible with promising activity as the 1st-line chemotherapy in pts with previously untreated unresectable advanced or recurrent G/GEJ cancer. Part 2 of the study is ongoing.

Medizinische Klinik, Städtisches Krankenhaus Dresden, Dresden, Germany

Background: This is a single-arm study (NCT01956149) to determine prolonged (> =4 months) disease control rate with cabazitaxel administered in second- (or later) setting for patients with advanced or metastatic adenocarcinoma of the esophagogastric junction (EGJ) and stomach.

Methods: 65 patients with advanced EGJ and stomach cancer were treated with 20mg/m2 Cabazitaxel every 3 weeks for a maximum of 6 cycles. Main objective of the study was a prolonged Disease Control Rate (pDCR: CR, PR or SD lasting at least 4 months). Secondary Outcome Measures were overall survival (OS), progression-free survival (PFS), response rate by subgroup (with vs without previous treatment with a taxane) and toxicity. Patients were assessed for tumor response every 6 weeks during therapy and during follow-up (up to 12 months).

Results: 65 patients (median age: 63, range 31-86 years) were assigned to treatment. Median no. of prior therapies was 2. 80% had received prior taxane therapy. Patients received a median of 2 cycles of cabazitaxel. Efficacy results are for the per protocol (PP) population. pDCR was 12.7%, (95%CI: 5.3%- 24.5%). pDCR was 20.0% in 2nd line patients (95%CI: 6.8%-40.7%) and 30.0% (95%CI: 6.7%-65.2%) in all lines in patients without prior taxane use. Response rate was 5.5% (95%CI: 1.1%-15.1%) in total PP and 20.0% in the population without prior taxane use. Median OS was 4.6 months (7.4 months without prior taxane vs 3.8 months with prior taxane). Median PFS was 1.38 months (95%CI: 1.28- 1.87) with and 2.01 months (95%CI: 0.20- 4.67) without prior taxane use. Most common grade 3/4 toxicities were neutropenia in 13% of the patients, pain (12%), leucopenia (10%), anemia (10%), fatigue (10%) and nausea (10%).

Conclusions: Cabazitaxel is active in heavily pretreated patients with metastatic and advanced esophagogastric junction and gastric adenocarcinoma. Toxicity is moderate. Patients without prior taxane use derived more benefit from Cabazitaxel.

673P Comparison of cytotoxic backbones for first line trastuzumab-containing regimens in HER2-positive advanced esophagogastric cancer: A meta-analysis

E. ter Veer, A. Creemers, L. de Waal, M.G.H. van Oijen, H.W.M. van Laarhoven

Department of Medical Oncology, Academic Medical Center (AMC), Amsterdam, Netherlands

Background: According to the ToGA study, trastuzumab plus cisplatin and capecitabine/5-fluorouracil (5-FU) is standard first-line treatment for HER2+ advanced esophagogastric cancer. However, optimality of this cytotoxic backbone is questioned. We examined the relative efficacy and safety of alternative trastuzumab-based cytotoxic backbone regimens compared to standard ToGA using meta-analysis.

Methods: Medline, EMBASE, CENTRAL and ASCO and ESMO were searched up to March 2017 for studies investigating alternative first-line trastuzumab-based regimens for patients with HER2+ esophagogastric cancer, with protein expression IHC3+ or IHC2+ and gene amplification by in situ hybridisation (ISH+). We compared overall survival (OS) of alternative trastuzumab-based regimens to trastuzumab plus cisplatin and capecitabine/5-FU of the ToGA trial IHC3+ or IHC2+/ISH+ subgroup. Hazard ratios (HR) and 95% confidence intervals (95%CI) were calculated by extraction of published Kaplan-Meier curves. Incidence counts and toxicity sample sizes were extracted for grade 1-2 and grade 3-4 adverse events and compared using single arm proportion meta-analysis.

Results: We included 15 studies (557 patients). For doublet backbone regimens, OS was significantly longer with trastuzumab plus oxaliplatin and capecitabine/5-FU compared to the ToGA regimen (median OS 20.7 vs 16.0 months, HR 0.75, 95%CI 0.59-0.99) and showed a more convenient toxicity profile. The doublet backbone trastuzumab plus cisplatin and S-1 showed no significant difference in OS compared to the ToGA regimen, but had a different toxicity profile, including less grade 1-2 hand-foot syndrome. Trastuzumab plus singlet backbone cisplatin or capecitabine had a significantly worse survival compared to the ToGA regimen and were more toxic. Trastuzumab with triplet cytotoxic backbones or with bevacizumab and doublet cytotoxic backbone had no survival benefit and were generally more toxic compared to ToGA.

Conclusions: Trastuzumab plus a doublet cytotoxic backbone containing oxaliplatin is preferable compared to the conventional ToGA regimen with cisplatin. S-1 can substitute capecitabine or 5-FU when specific toxicities are encountered.

Background: NIVO improved OS vs placebo in Asian pts with gastric/gastroesophageal junction cancer in the phase 3 ATTRACTION-2 study (Kang YK, et al. ASCO GI 2017 [abstract 2]). In CheckMate 032, NIVO ± ipilimumab (IPI) demonstrated ORRs of 14% (NIVO monotherapy) and 26% (NIVO 1 mg/kg + IPI 3 mg/kg) in CT-Rx EG cancer (NCT01928394; Janjigian YY, et al. ASCO 2017 [abstract 4014]). The Cancer Genome Atlas identified MSI-high (MSI-H) EG tumors as having therapeutic targets that may make them responsive to immune checkpoint inhibitors. This exploratory analysis evaluated ORR and OS by MSI status in pts with EG cancer treated with NIVO monotherapy in CheckMate 032.

Methods: Pts with adv CT-Rx EG (including gastric, esophageal, and gastroesophageal junction) cancer were treated with NIVO 3 mg/kg every 2 weeks (n = 59). MSI status was centrally assessed using a PCR-based assay. Best objective response (BOR), ORR, and DCR (BOR of CR, PR, or SD) per investigator (INV) were assessed per RECIST v1.1.

Results: MSI status was determined in 25 pts; 7 (28%) were MSI-H, and 18 (72%) were non–MSI-H. ORR per INV was 29% in MSI-H pts, 11% in non–MSI-H pts, and 9% in pts with unknown MSI (MSI-U). DCR was 71%, 28%, and 26%, respectively. Of the 7 responders, 3 were PD-L1^{+} ($\geq$1% tumor expression; 1 per MSI category), 3 were PD-L1^{-} (MSI-U, n = 2; non–MSI-H, n = 1), and 1 was not evaluable for PD-L1 assessment (MSI-H). BOR is shown in the Table. Median OS (95% CI) was 14.75 mo (1.51, NA) in MSI-H pts, 6.49 mo (2.96, 12.42) in non–MSI-H pts, and 5.03 mo (2.76, 16.16) in MSI-U pts. Safety for the full EG cohort was previously reported (Janjigian YY, et al. ASCO 2016 [abstract 4010]).

Table: 674P ORR and BOR per INV according to MSI status

	MSI-H n = 7	Non–MSI-H n = 18	MSI-U n = 34
ORR, n (%) [95% CI]	2 (29) [4, 71]	2 (11) [1, 35]	3 (9) [2, 24]
BOR, n (%)			
CR	1 (14)	0	0
PR	1 (14)	2 (11)	3 (9)
SD	3 (43)	3 (17)	6 (18)
PD	2 (29)	11 (61)	21 (62)
Not evaluable	0	2 (11)	4 (12)

Conclusions: In this subgroup analysis, 7 pts (28%) were MSI-H, representing a biologically unique subset of EG tumors. NIVO monotherapy led to survival benefit and responses in both MSI-H and non–MSI-H pts.

675P Involvement of the immunoregulator MZB1 in progression of gastric cancer

Y. Tanaka, M. Kanda, C. Tanaka, D. Kobayashi, H. Tanaka, H. Takami, M. Hayashi, N. Iwata, Y. Niwa, S. Yamada, G. Nakayama, H. Sugimoto, M. Koike, M. Fujiwara, Y. Kodera

Gastroenterological Surgery, Nagoya University Hospital, Nagoya, Japan

Background: The initiation and progression of gastric cancer are associated with inappropriate immune responses caused by chronic inflammation of the gastric mucosa.

Methods: To identify immunoregulatory molecules involved in gastric cancer progression, transcriptome analysis was conducted using tissues from patients with metastatic gastric cancer. Gastric cancer cells lines and 200 pairs (cancerous and non-cancerous) of gastric tissues from patients with gastric cancer were analyzed for gene expression, amplification, DNA hypermethylation and functions of the candidate molecule.

Results: The transcriptome analysis revealed that marginal zone B and B1 cell specific protein (MZB1) was expressed at significantly decreased levels in primary gastric cancer tissues when compared with the corresponding normal gastric mucosae. PCR array analysis exploring genes expressed cooperatively with MZB1 revealed that differential expression of MZB1 mRNA in gastric cancer cell lines correlated positively with the levels of the mRNAs encoding estrogen receptor 1 and desumoylating isopeptidase 1. Hypermethylation of the MZB1 promoter was frequent in cell lines with decreased levels of MZB1 mRNA. siRNA-mediated knockdown of MZB1 significantly increased proliferation, invasion and migration of gastric cancer cell lines. Low MZB1 expression was an independent prognostic factor for recurrence after curative gastrectomy and was associated significantly with increased haematogenous recurrence.

Conclusions: The immunoregulator MZB1 acts as a suppressor and serves as a predictor for recurrence after curative resection in gastric cancer.

[1]Department of Clinical Oncology, Aichi Cancer Center Hospital, Nagoya, Japan, [2]Department of Pathology and Molecular Diagnostics, Aichi Cancer Center Hospital, Nagoya, Japan, [3]Department of Endoscopy, Aichi Cancer Center Hospital, Nagoya, Japan, [4]Department of Gastroenterological Surgery, Aichi Cancer Center Hospital, Nagoya, Japan

Background: Recent genomic and molecular characterization of gastric adenocarcinoma (GAC), such as Cancer Genome Atlas (TCGA), have shed light on the PD-L1 positivity and four different subtypes. Several PD-L1 IHC assays of scoring-criteria are developed in parallel. This study aimed to evaluate PD-L1 staining patterns and molecular profiling by TMA in GAC.

Methods: In total, 331 consecutive patients (pts) with GAC underwent curative surgery at Aichi Cancer Center Hospital between Jan 2009 and Dec 2010. Pts with no systemic chemotherapy before surgery and sufficient tumor content on the formalin-fixed and paraffin-embedded (FFPE) slides were eligible. EBV-encoded RNA in situ hybridization, IHC for deficient mismatch repair proteins (dMMR, MLH1/MSH2/MSH6/PMS2), HER2 and PD-L1 (22C3, 28-8, E1L3), and HER2 DISH were evaluated in TMA. Four cores of tumor tissue were punched out from individual FFPE tumor blocks and arrayed in a new TMA block. PD-L1 tumor positivity was categorized to $\geq$1%/$\geq$25%/$\geq$50% tumor cell membrane staining. Disease free survival (DFS) and overall survival (OS) were estimated by the Kaplan-Meier method.

Results: Among the cases, 226 pts were included in this study, excluding pts with prior chemotherapy (n = 26) and insufficient tumor samples (n = 79). Patient characteristics were as follows: male/female, 162/64; pStage (AJCC 7th ed.) I/II/III/IV, 100/39/58/29; EBV +/-, 13/213; proficient MMR/dMMR, 197/29, HER2 +/-, 24/202, and PD-L1 $\geq$1%/$\geq$25%/$\geq$50% (22C3 vs. 28-8 vs. E1L3), 11/4/2 vs. 7/6/6 vs. 12/10/8. Among 22C3, 28-8, and E1L3 assays, 94–97% of the pairs were concordant. PD-L1 positivity by all three assays was associated with EBV + ($p < 0.05$), whereas only 28-8 staining positivity was correlated with dMMR ($p = 0.04$). EBV+, dMMR, and HER2+ were mutual except three pts who had both dMMR and HER2+. There was no significant difference in DFS and OS among EBV, MMR, HER2 and PD-L1 status.

Conclusions: The three tested PD-L1 assays did not show comparable staining patterns in all cases. Studies that correlate not only PD-L1 staining patterns but also EBV+/dMMR/HER2+ and response to immunotherapy are required to evaluate.

Background: The choice of first-line chemotherapy in advanced HER2-negative gastric cancer (AGC) is based on the center's preferences and adverse effects profile. There is neither a standard accepted regimen nor predictive factors for drug response in clinical practice other than HER2 status. The objective is to evaluate whether Lauren's classification influences the efficacy of different chemotherapies and the survival of patients.

Methods: The data come from a national registry of AGC in which 31 Spanish centers participate. Eligibility criteria include the diagnosis of a stomach or gastroesophageal junction adenocarcinoma, HER2 negativity, and the use of two or three drug chemotherapy combinations. We used Cox proportional hazards (PH) regression with treatment-by-histology interaction tests to estimate the therapeutic effects.

Results: The registry contains 1215 HER2-negative tumors that could be analyzed for survival endpoints and 675 evaluable for overall response rate (ORR). Overall, the study failed to confirm a decrease in the ORR in the presence of diffuse component (Mantel-Haenszel, common odds ratio of 0.744 (CI 95%, 0.538-1.030), P = 0.088, nor heterogeneity of response according to histology. However, in the intestinal type, docetaxel-based or anthracycline-based regimens were more active than oxaliplatin-fluoropyrimidine regimens (ORR 62% and 60% vs. 45%, P < 0.05) and the latter had a higher ORR (within this histological group) compared to cisplatin-fluoropyrimidine (45% vs 28%, P = 0.0292). The diffuse type showed an increase in mortality with a hazard ratio HR of 1.231 (CI 95%, 1,070-1,417), P = 0.0036. In subgroup analyses, docetaxel-based regimens were associated with increased survival only in the subgroup with intestinal tumors: HR 0.74 (95% CI, 0.55-0.99), P = 0.037. Subgroup analyses for progression-free survival showed consistent effects in each subgroup.

Conclusions: In this registry, tumor subtypes based on Lauren's classification predicted survival, and responded differently to chemotherapy. Future clinical trials should stratify estimates of effects based on histology.

678P Comparison of oxaliplatin-related spleen enlargement in patient with gastric cancer who received S-1 versus capecitabine as a combination partner of oxaliplatin

S. Seo[1], M. Kim[1], M.J. Kim[2], M-J. Kim[3], Y.I. Park[3], S.R. Park[1]

[1]Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [2]Center for Colorectal Cancer, Research Institute and Hospital, National Cancer Center, Goyang, Republic of Korea, [3]Center for Gastric Cancer, Research Institute and Hospital, National Cancer Center, Goyang, Republic of Korea

Background: Oxaliplatin (OX)-based chemotherapy is known to cause hepatic sinusoidal injury, resulting portal hypertension with splenomegaly (SM). We compared this OX-induced hepatopathy, SM, and their clinical significance according to combined oral fluoropyrimidines, S-1 vs. capecitabine (X) in gastric cancer (GC).

Methods: We analyzed pts from two prospective trials for GC, adjuvant XELOX (X 1000 mg/m^2 bid on D1-14 + OX 130 mg/m^2 on D1 q3w, 8 cycles; n = 52) and palliative SOX (S-1 40 mg/m^2 bid on D1-14 + OX 130 mg/m^2 on D1 q3w, continuous [SOX-c, n = 52] vs. intermittent [SOX-i, discontinuing after 6th and restarting on progression, n = 53]) Spleen volume (vol) was retrospectively measured by *Rapidia software*.

Results: Baseline sex, age, ECOG PS, BSA, spleen vol, levels of platelet (plt)/liver enzyme/bilirubin (bil) and OX cumulative dose during 8 cycles did not differ in XELOX and SOX-c. After 8 cycles, the SOX-c had more SM, hepatic enhancing heterogeneity, hyper-bil, and thrombocytopenia than the XELOX (Table). The SOX-c was a risk factor for developing SM (adjusted odds ratio, 4.7; 95% CI, 2.0-10.8; p<.001) When tracking serial spleen vol and plt at baseline, 2nd, 4th and 6th cycles in SOX-c and SOX-i, spleen vol significantly increased over time (mean, 160, 182, 216, 247 cm^3; p<.001), whereas plt were decreased (mean, 290, 168, 132, 116 x10^3/uL; p<.001). In SOX-i group, spleen vol decreased at 6th cycles, 6, 12, 18 and 24w after stopping SOX (mean, 194, 181, 167, 158, 150 cm^3; p=.016).

Conclusions: S-1 seems to enhance OX-induced hepatic sinusoidal injuries than capecitabine in pts with GC with clinical significance of higher incidences of splenomegaly, thrombocytopenia, and hyperbilirubinemia.

of chemotherapy in elderly patients with gastric cancer. Safety and efficacy of S-1 treatment in elderly versus younger patients were evaluated in the phase III JFMC36-0701 trial.

Methods: Between February 2007 and June 2010, 309 patients with advanced or recurrent gastric cancer were randomly assigned to S-1alone or S-1plus lentinan treatment; 134 patients (43.4%) enrolled were ≥75 years of age (range, 75-94) and 175 (56.6%) were <75 years of age (range, 30-74). S-1 was given orally in the dose of 40 mg/m2 twice daily for the first 4 weeks of a 6-week cycle. Lentinan was given as an intravenous infusion of 2 mg/body every week. Overall survival (OS), overall response rate (ORR) and safety were compared between patients aged ≥75 and <75 years.

Results: Patient characteristics were comparable between the two cohorts. OS was 12.8 (95% CI 10.7-14.9) and 11.5 (95% CI 9.5-13.4) months for patients aged ≥75 and <75 years, respectively with no statistical difference. The ORR was evaluable in the 190 patients with measurable disease at baseline. The ORR was 23.4% and 18.6% in patients aged ≥75 and <75 years, respectively. Disease control rates were also similar: 44.2% versus 48.7% for elderly versus younger patients. Rates of neutropenia (≥grade3) were comparable for elderly and younger patients (12.7% versus 10.4%), and the incidences of non-hematologic adverse events (≥grade3) such as anorexia, vomiting and fatigue were also similar in both elderly and younger patients (12.7% versus 10.4%, 0% versus 1.8% and 7.9% versus 4.9%, respectively).

Conclusions: This subgroup analysis suggests that elderly patients with advanced or recurrent gastric cancer derive similar benefit from S-1 treatment to younger patients, with acceptable toxicity.

680P Phase II study of modified docetaxel, cisplatin and S-1 (mDCS) combination chemotherapy in patients with unresectable metastatic gastric cancer

Y. Sato[1], H. Ohnuma[2], K. Okamoto[3], H. Miyamoto[3], M. Hirakawa[2], N. Uemura[4], S. Kikuchi[2], T. Sagawa[4], K. Fujikawa[4], Y. Takahashi[4], S. Minami[5], T. Okuda[5], M. Takahashi[6], J. Kato[2], T. Takayama[3]

[1]Department of Community Medicine for Gastroenterology and Oncology, Tokushima University Graduate School of Biomedical Sciences, Tokushima, Japan, [2]Medical Oncology and Hematology, Sapporo Medical University, Sapporo, Japan, [3]Department of Gastroenterology and Oncology, Tokushima University Graduate School of Biomedical Sciences, Tokushima, Japan, [4]Department of Gastroenterology, Hokkaido Cancer Center, Sapporo, Japan, [5]Gastroenterology, Oji General Hospital, Tomakomai, Japan, [6]Department of Gastroenterology, Sapporo Kyoritsu-Gorinbashi Hospital, Sapporo, Japan

Background: We have previously conducted phase II studies to evaluate the effect of adding docetaxel to base treatment with S-1 plus cisplatin (DCS) to further improve the therapeutic response; both a very high response rate (87.1%) and a promising median survival time (687 days) in patients with unresectable advanced gastric cancer were noted (Y. Sato et al. Cancer Chemother Pharmacol. 2009); however, it also showed a high incidence of grade 3/4 toxicity. With the aim of reducing toxicities, we conducted a phase II study of modified DCS (mDCS), using a reduced dose of docetaxel, and evaluated the clinical efficacy and adverse events of this regimen.

Methods: Patients with unresectable gastric cancer received chemotherapy with S-1 (40 mg/m^2 b.i.d) on days 1–14, and docetaxel (50 mg/m^2) plus cisplatin (60 mg/m^2) on day 8 every 3 weeks. The primary endpoint was the response rate (RR). Overall (OS) and progression-free survival (PFS), and toxicities were also evaluated.

Results: Forty-nine patients were enrolled from November 2011 to April 2014, and 47 were eligible. The overall RR was 78.8%, including two cases of a complete response (4.3%), and 35 cases of a partial response (74.5%). Ten cases had stable disease (21.3%) but none showed progressive disease. Of the 47 cases, 16 cases (34.0%) underwent curative conversion surgery. The median PFS was 350 days (95% CI; 238–406 days) and median OS was 561 days (95% CI; 401–783 days). Grade 3/4 neutropenia developed in 76.6%, and febrile neutropenia in 31.9%, of patients. Non-hematological grade 3/4 adverse events were anorexia (23.4%), nausea (4.3%), and diarrhea (8.5%).

Conclusions: mDCS therapy showed high clinical efficacy and fewer toxicities, but careful management of these is still essential.

681P Clinical impact of programmed death ligand-1 and -2 expression after platinum based chemotherapy in metastatic gastric cancer

J.H. Yang, S. Park, E.K. Joung, M.A. Lee, S.Y. Roh, I-H. Kim

Department of Internal Medicine, Division of Medical Oncology, Seoul St. Mary's Hospital, Seoul, Republic of Korea

Background: The effect of chemotherapy on programmed death ligand-1 (PD-L1) and PD-L2 expression is not well known. Therefore we aimed to investigate the effect of chemotherapy to PD-L1/2 expression in metastatic gastric cancer (mGC).

Methods: We evaluated the PD-L1 and 2 expression of 63 patients with paired tumor tissue before and after 3 to 4 cycles of palliative first line platinum-based chemotherapy. PD-L1/2 expression was detected by immunohistochemistry(IHC) method in paired tumor specimens.

Results: There were no significant differences in PD-L1 and PD-L2 expression across various clinicopathological parameters. The detection of PD-L1 on tumor cells decreased from 58% to 38% after chemotherapy ($p = 0.028$), but not with PD-L2 (from 43% to 36%). Among patients with objective response (CR and PR), PD-L1 expression decreased with statistical significance ($p = 0.033$), but not among patients with SD and PD ($p = 0.275$). In univariate and multivariate analysis, patients with positive PD-L1 at the pre-chemotherapy showed better progression free survival (PFS, hazard ratio [HR]=0.42, $p = 0.014$). In contrary, after chemotherapy, patients with positive PD-L1 showed decreased PFS (HR = 1.97, $p = 0.023$). And pre-chemotherapy PD-L1 statuses didn't have any correlation with OS difference, however, post-chemotherapy negative PD-L1 prolonged OS (HR = 1.92, $p = 0.047$). PD-L2 statuses had no difference of PFS and OS before and after chemotherapy. Univariate and Multivariate analysis showed that negative to positive change and positive to negative change of PD-L1 expression was associated with poorer PFS (HR = 0.030, $p = 0.03$) and better PFS (HR = 0.02, $p = 0.024$), respectively.

Conclusions: Our data suggests that chemotherapy may have an effect on the status of PD-L1/L2 expression. PD-L1/L2 expression may change during chemotherapy, so we suggest monitoring the pattern of change through serial tumor samples to reflect the correct status of PD-L1 expression.

682P Clinical practice observation of trastuzumab (TRA) in patients (pts) with HER2-positive metastatic adenocarcinoma of the stomach (mGC) or the gastro-oesophageal junction (GEJ): Final analysis from the German non-interventional study HerMES

S-E. Al-Batran[1], E. Moorahrend[2], C. Maintz[3], D. Hempel[4], P. Thuss-Patience[5], V. Gaillard[6], S. Hegewisch Becker[7]

[1]Institute of Clinical Cancer Trials (ICCT), Krankenhaus Nordwest, Frankfurt am Main, Germany, [2]Department of Hematology and Oncology, Outpatient Clinic, Porta Westfalica, Germany, [3]Hematology and Oncology, Practice for Hematology and Oncology, Wuerselen, Germany, [4]Department Hematology - Oncology, Oncology Donauwoerth, Donauwoerth, Germany, [5]Department of Hematology, Oncology, and Tumor Immunology, Charité University Medicine Berlin, Campus Virchow-Klinikum, Berlin, Germany, [6]Medical Affairs, Roche Pharma AG, Grenzach Wyhlen, Germany, [7]Haematologisch-Onkologische Praxis Eppendorf, Hope - Facharztzentrum Eppendorf, Hamburg, Germany

Background: HER2-pos metastatic cancer of GEJ or stomach are indications with a high medical need. TRA plus standard chemotherapy (CT) has been approved as 1L therapy in HER2-pos mGC or mGEJ-C pts according to ToGA-study. HerMES (NCT01220934) was designed to collect data on clinical routine practice in 171 specialist centers in Germany.

Methods: Between January 2010 and July 2016, 434 pts were identified. 364 pts matched criteria for TRA-therapy and were treated accordingly (population of the present analysis). Another 39 pts did not match criteria for HER2-positivity with TRA-therapy and will be evaluated separately. Main parameters of interest were overall response rate (ORR), progression free survival (PFS), safety and overall survival (OS). QoL and patient reported outcomes will be presented later.

Results: Mean age was 65 years, 75% were male, and 51% had mGEJ-C. TRA was given at an average dose of 5.73 mg/kg. Mean treatment duration for TRA was 7 months (mos) and 61 pts (17%) received TRA-therapy for more than 1 year. CT regimen frequently used were cisplatin/5-FU (21%), oxaliplatin/5-FU/docetaxel (10%), and cisplatin/capecitabine (8%). ORR was 43% [95%CI 0.38;0.49], median PFS was 7 mos [6.3;7.6], and median OS was 10 mos [8.8;11.1]. Most frequent related AEs (reported in > 5% of pts) were diarrhea in 29 (8%), nausea in 24 (6.6%) and fatigue in 22 cases (6%). TRA-rel cardiac AEs occurred in 21 pts (6%).

Conclusions: To our knowledge this is the largest prospective observational trial on TRA in the daily clinical routine care of metastatic GC/GEJ-C. Chemotherapy backbones were diverse. The outcome was similar to ToGA, taking into account the unselected patient population.

683P Intratumoral PD-L1 expression is associated with worse survival of patients with Epstein-Barr virus-associated gastric cancer

B.W. Kang, A.N. Seo, I. Lee, S.J. Lee, Y.S. Chae, J.G. Kim
Oncology, Kyungpook National University Hospital, Daegu, Republic of Korea

Background: This study investigated the clinical relevance and prognostic impact of the overall expression of programmed cell death protein ligand-1 (PD-L1) and programmed cell death protein ligand-2 (PD-L2), in patients with Epstein-Barr virus-associated gastric cancer (EBVaGC).

Methods: After reviewing 1318 consecutive cases of surgically resected or endoscopic submucosal dissected gastric cancers, the expression status of PD-L1 and PD-L2 in 120 patients with EBVaGC identified by EBV-encoded RNA *in situ* hybridization was retrospectively analyzed using immunohistochemistry (IHC). For each IHC marker, positivity was separately in intraepithelial tumor cells (iTu-) and immune cells in the tumor stroma area (str-).

Results: Among 116 eligible patients, 57 (49.1%) and 66 patients (56.9%) were determined as iTu-PD-L1-positive and str-PD-L1-positive, respectively, while 23 (21.6%) and 45 patients (38.8%) were determined as iTu-PD-L2-positive and str-PD-L2-positive, respectively. iTu-PD-L1-positivity was found to be significantly associated with lymph node (LN) metastasis (p=0.012) and a poor disease-free survival (DFS)(P=0.032), yet not overall survival (p=0.482). Meanwhile, str-PD-L1-positivity was correlated with the density of iTu- and str-tumor-infiltrating lymphocytes (TILs)(P=0.003, P=0.004, respectively), yet not the patient outcomes. In contrast, str-PD-L2-positivity was related to a lower T category (P=0.003), absence of LN metastasis (P=0.032) and perineural invasion (P=0.028), and iTu- and str-TILs (P<0.001, P<0.001, respectively). iTu- and str-PD-L2-positivity showed a trend towards an improved DFS, although not significant (P=0.060, P=0.073, respectively). In a multivariate analysis, iTu-PD-L1-positivity was independently associated with a poor DFS (P=0.006, Hazard ratio=12.085).

Conclusions: iTu-PD-L1 expression can be used to predict a poor outcome in patients with EBVaGC, and can represent a rational approach for PD-1/PD-L pathway-targeted immunotherapy.

684P Targeting c-met and DNA double-strand break (DSB) repair pathways for BRCA-mutated gastric carcinomas

M.V. Karamouzis[1], C. Mihailidou[1], P. Papakotoulas[2], A. Anestis[1], E. Koustas[1], A.G. Papavassiliou[3]
[1]*Molecular Oncology Unit, Department of Biological Chemistry, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece,* [2]*Medical Oncology Clinic, Theagenion Cancer Hospital, Thessaloniki, Greece,* [3]*Department of Biological Chemistry, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece*

Background: In the present study, we underline the importance of combining c-Met Inhibitor (Inh.) and DSB repair Inhibitor (PARP Inh.) with the goal of accomplishing a synergistic therapeutic strategy in BRCA-mutated gastric carcinomas.

Methods: Firstly, to verify whether c-Met affects tumor response to PARP Inh., AGS (low c-Met expression) and Hs746T (high c-Met expression) cell lines, were subjected to knockdown c-Met expression, in the presence of PARP Inh. (NU1025). Subsequently, we examined the correlation between BRCA1/2 and c-Met. We knocked down BRCA1/2 expression in AGS and Hs746T cells and treated them with PARP Inh. Next, we examined the effects of combining c-Met Inh. (SU11274) and PARP Inh. (NU1025), measured by MTT, clonogenic cell survival and Annexin, assays. We also evaluated the effect of combining PARP Inh. and c-Met Inh. in AGS/Hs746T xenograft tumor models. AGS/Hs746T -pcDNA3 and AGS/Hs746T -si*BRCA* cells were injected into SCID mice. Tumor sizes were measured every 3 days. DNA damage was assessed by γ-H2AX staining.

Results: Silence of Met expression promoted Hs746T cells more sensitive to PARP Inh. to similar levels as the AGS cells, as indicated by decreased cell viability. Silence of BRCA1/2 expression sensitized only AGS cells, signifying that increased expression of c-Met renders cells resistant to PARP Inh. in the context of inactivating BRCA1/2. Combining c-Met Inh. and PARP Inh. suppressed cell growth and clonogenicity and enhanced apoptosis in both AGS and Hs746T cells. The dual inhibition was demonstrated to be even more successful when cells were knockdown for BRCA1/2. Also, co-inhibition treatment substantially reduced tumor growth to AGS/Hs746T -pcDNA3 and more even effectively to AGS/Hs746T –si*BRCA1/2* xenograft models, compared to either Inh. alone. DNA damage was higher in AGS/Hs746T –si*BRCA1/2* compare to AGS/Hs746T -pcDNA3 xenograft models.

Conclusions: BRCA deficiency renders gastric tumor cells sensitive to PARP inhibition. In addition, treatment with c-Met Inh. enhanced Hs746T sensitivity to the PARP Inh. Our data demonstrate that dual Met/PARP inhibition is synergistic providing an effective therapeutic strategy in BRCA-mutated gastric carcinomas.

685P Clinical efficacy observation for endostar combined with chemotherapy treating gastric cancer peritoneal carcinomatosis

H. Ma, A. Huang, J. Yao, T. Zhang
Cancer Center, Wuhan Union Hospital (of Tongji Medical College of HUST), Wuhan, China

Background: The peritoneal carcinomatosis of gastric cancer is a current therapeutic difficulty and the related clinical data are still limited so far. In this study, we evaluated efficacy and safety of the recombinant human endostatin (Endostar) characterized by broad-spectrum anti-angiogenesis combined with chemotherapy on gastric cancer peritoneal carcinomatosis.

Methods: From Jan. 2014 to Dec. 2016, 33 advanced stage gastric cancer patients associated with peritoneal carcinomatosis were enrolled. Their pathological information, imaging as well as therapy information were retrospectively analyzed. Twenty-one patients only received systemic chemotherapy as control group, and twelve patients received Endostar combined with chemotherapy as combination therapy group. All the 33 patients were evaluated on phase-efficacy and followed-up to record survival time. The tumor time to progression (TTP), overall survival (OS), Objective Response Rate (ORR), disease control rate (DCR) and therapy-related adverse reactions were evaluated to confirm effect of Endostar therapy.

Results: All the patients were evaluable. The evaluation on efficacy indicated that Endostar combined with chemotherapy increased ORR (41.6% vs. 23.81%) and DCR (83.3% vs. 61.91%) compared with control group, although there was no statistical difference between them. The survival analysis indicated that Endostar combined with chemotherapy effectively extended time to disease progression (4.60 ± 0.32 months vs. 3.50 ± 0.34 months, P = 0.03), and the median OS (15.80 ± 3.4 months vs. 9.80 ± 0.7 months, P = 0.01) compared with single chemotherapy. Furthermore, the evaluation on adverse reactions indicated that combination therapy did not have more adverse reactions.

Conclusions: The recombinant endostatin with broad-spectrum anti-angiogenesis could effectively control the development of peritoneal carcinomatosis disease and extend survival with high safety and tolerance. However, further prospective study needs to be performed to confirm the clinical application value.

Clinical trial identification: This retrospective study was approved by hospital ethical committee and all informed consent were obtained.

686P Modified epirubicin and oxaliplatin plus capecitabine (EOX) Regimen as second-line therapy after failure of modified docetaxel and cisplatin plus fuorouracil (DCF) regimen in advanced gastric cancer

Y. Bozkaya, O. Yazici, N. Ozdemir, G.U. Erdem, N.S. Demirci, N. Zengin
Medical Oncology, Ankara Numune Training and Research Hospital, Ankara, Turkey

Background: In advanced gastric cancer, we aimed to evaluate the effectiveness of mEOX regimen as second line therapy after failure of mDCF regimen.

Methods: In between 2009 and 2016, the patients who were progressed after mDCF (docetaxel 60 mg/m^2 on day 1, cisplatin 60 mg/m^2 on day 1, Fluorouracil 600 mg/m^2/day for 5 days) and received mEOX (epirubicin 50 mg/m^2 on day 1, oxaliplatin 85 mg/m^2 day 1 and capecitabine twice-daily dose of 625 mg/m^2, p.o. for 2 weeks) every 3 weeks until progression or unacceptable toxicity, were retrospectively analyzed. Progression-free survival (PFS) was defined as the time interval from the day of progression on mDCF therapy to the date of disease progression or death after first cycle of EOX therapy.

Results: Total 129 patients were included to study population. Median age was 55 years (range= 27-78 years). Most of the patients were male (76%). Undifferentiated signet ring cell carcinoma was the most frequent histological subtype (72.1%). The most of the patients had eastern cooperative oncology group (ECOG) performance status 0-1 (72.9%). The most frequent regions of metastasis were; non-regional lymp nodes (55.8%), liver (45.7%), peritoneum (39.5%). Most of the patients (75.2%) had ≥ 2 regions of metastasis. The median number of chemotherapy courses was five (range= 2–

9). Forty-nine patient achieved a partial response and 33 patients showed stable disease, resulting in a ORR (overall response rate) of 38% and a DCR (disease control rate) of 63.6%. Most frequent grade 3-4 hematological and non-hematological toxicity was neutropenia (8.5%) and nausea/vomiting (5.4%). None of the patients had toxic death. The median PFS was 4.7 months (95% confidence interval [CI], 4.1–5.3), and OS was 7.4 months (95% CI, 6.3–8.5). In multivariate analysis age $\geq$ 60 years and ECOG performance status (0-1) were independent prognostic factors that affect PFS and OS.

Conclusions: In advanced gastric cancer patients, who were progressed after first line chemotherapy and having ECOG performance status 0-1, mEOX was well tolerated triple regimen with promising OS and PFS.

687P Phase II clinical trial of second-line weekly paclitaxel plus trastuzumab for patients with HER2-positive metastatic gastric cancer

Y. Horita, M. Nishino, S. Sugimoto, A. Kida, A. Mizukami, M. Yano, F. Arihara, K. Matsuda, M. Matsuda, A. Sakai

Internal Medicine, Toyama Prefectural Central Hospital, Toyama, Japan

Background: Combination therapy with fluorouracil, platinum, and trastuzumab (Tmab) has been established as the first-line chemotherapy for HER2-positive gastric cancer, but there is no established therapy in the second-line setting. This study aimed to evaluate the efficacy and safety of weekly paclitaxel plus Tmab as second-line chemotherapy for HER2-positive gastric cancer patients.

Methods: Eligible patients were $\geq$ 20 years old, histologically confirmed gastric adenocarcinoma with HER2-positive (IHC3+ or IHC2+ and FISH (or DISH)-positive), previously treated chemotherapy (not except pretreated-Tmab), ECOG PS of 0, 1 or 2, and adequate organ function. Eligible patients received weekly paclitaxel plus Tmab (paclitaxel: 80 mg/m^2 IV on day1, 8, 15, repeated every 4weeks, Tmab: 8mg/kg (1st time) IV on day1, after 2nd time, 6mg/kg IV, repeated every 3weeks). All therapy was administered until disease progression. The primary endpoint was response rate, the secondary endpoint were Progression-free survival (PFS), Overall survival (OS) and Toxicity.

Results: Twenty-eight patients were enrolled between 08/2011 and 03/2017. Patients characteristics were; median age, 69.5 years; male, 22(79%); ECOG-PS0/1/2, 5(18%)/17(61%)/6(21%); Tmab pretreated/untreated, 20(71%)/8(29%). The overall response rate was 22% with 6 partial responses, 8 stable diseases, 13 progression and 1 not evaluable yet. Median PFS was 4.6 months (95% CI: 2.2-7.0). Median OS was 9.6 months (95% CI: 2.3-16.9). Grade 3/4 toxicities included neutropenia in 36%, leukopenia in 21%, anemia in 11%, anorexia in 7%, febrile neutropenia in 7%, respectively. Tmab beyond progression (TBP) group (n = 20) did not differ from non-TBP group (n = 8) in PFS and OS (PFS; 5.0:2.8 (months), p = 0.369, OS; 12.4:6.1 (months), p = 0.363, log-rank test). And, in TBP group, therapeutic effect was associated with duration of PFS of 1st line Tmab combined chemotherapy ($\geq$ 6 months (n = 10): < 6 months (n = 10), PFS; 6.4:2.8 (months), p = 0.016, OS; Not reached:6.5 (months), p = 0.002, log-rank test).

Conclusions: Weekly paclitaxel plus trastuzumab appeared favorable and well tolerated as second-line chemotherapy for HER2-positive gastric cancer patients in this single arm study.

688P Beyond first line treatment for advanced esophagogastric adenocarcinoma (EGAC): A phase 1 dose escalation study of regorafenib (Reg) combined with paclitaxel (PTX) (REPEAT study)

S. Schokker[1], S.O. Van der Woude[1], R.A.A. Mathot[2], M.F. Bijlsma[3], M.G.H. Van Oijen[4], C.J.A. Punt[5], H.W.M. Van Laarhoven[1]

[1]Cancer Center Amsterdam, Laboratory of Experimental Oncology and Radiobiology, Department of Medical Oncology, Academic Medical Center Amsterdam, Amsterdam, Netherlands, [2] Department of Clinical Pharmacology, Academic Medical Center Amsterdam, Amsterdam, Netherlands, [3]Cancer Center Amsterdam, Laboratory of Experimental Oncology and Radiobiology, Academic Medical Center Amsterdam, Amsterdam, Netherlands, [4]Department of Medical Oncology, Academic Medical Center Amsterdam, Amsterdam, Netherlands, [5]Cancer Center Amsterdam, Department of Medical Oncology, Academic Medical Center Amsterdam, Amsterdam, Netherlands

Background: Second line treatment with Ramucirumab inhibiting angiogenesis is effective as monotherapy and combined with PTX. Reg, a multikinase inhibitor of angiogenic, stromal, and oncogenic receptor tyrosine kinases is effective as monotherapy. Since survival remains poor new treatment strategies are needed. Therefore, we conducted a phase I dose escalation trial to determine the recommended dose for phase 2 testing (RP2D) of Reg with PTX.

Methods: Adult patients (pts) with metastatic EGAC who failed at least one prior treatment line, including a fluoropyrimidine and a platinum compound, received PTX 80 mg/m2 i.v. on day 1, 8 and 15 of a 28 day cycle, with Reg on day 1-21 in one of 3 dose levels (DL-1: 80, DL-2: 120, DL-3: 160 mg QD) in a standard 3 + 3 design. Tumor response was assessed every 2 cycles (RECIST v1.1). Pts were treated until progressive disease (PD) or unacceptable adverse events.

Results: We enrolled 14 pts (median age 63), 8 with esophageal and 6 with gastric cancer. Pts had received 1 (n = 7) or 2 (n = 7) prior lines of palliative chemotherapy and 13 pts were evaluable for dose limiting toxicity (DLT). No DLT occurred at DL-1, 1 DLT occurred at DL-2 (grade 3 hand-foot-syndrome), and 3 DLT's occurred in 2 pts at DL-3 (grade 3 mucositis, diarrhea and GGT elevation). RP2D of Reg was established at 120 mg. Other grade 3/4 toxicities were hypertension (29%), mucositis (21%) and non-febrile neutropenia (14%). Grade 1/2 toxicities included neuropathy (64%), hoarseness (57%), infections (50%), nausea/vomiting (43%), toxicodermia (43%), mucositis (36%), diarrhea (29%) and epistaxis (29%). Median follow up is 8.3 months with 2 pts still on treatment. Median number of cycles is 4. Reasons for stopping were PD (n = 9) or toxicity (n = 3). Best responses were PR (n = 1), SD (n = 12) and PD (n = 1). Median PFS is 4.2 and median OS 8.5 months.

Conclusions: RP2D of Reg combined with PTX is 120 mg QD. This combination is well tolerated and shows promising effects on survival in heavily pretreated patients. An expansion cohort to further study efficacy as well as the effect of Reg on PTX uptake and expression of downstream Reg targets in metastases is being accrued.

689P Phase I dose escalation study with expansion cohort of the addition of nab-paclitaxel (nab-P) to capecitabine and oxaliplatin (CAPOX) as first line treatment of advanced esophagogastric adenocarcinoma (EGAC) (ACTION study)

S. Schokker[1], D.J. Van Zoen[2], S.O. Van der Woude[1], S.L. Meijer[3], R.A.A. Mathot[4], M.F. Bijlsma[5], M.G.H. Van Oijen[6], C.J.A. Punt[7], H.W.M. Van Laarhoven[1]

[1]Cancer Center Amsterdam, Laboratory of Experimental Oncology and Radiobiology, Department of Medical Oncology, Academic Medical Center Amsterdam, Amsterdam, Netherlands, [2]Department of Medical Oncology, Academic Medical Center Amsterdam, Amsterdam, Netherlands, [3]Department of Pathology, Academic Medical Center Amsterdam, Amsterdam, Netherlands, [4]Department of Clinical Pharmacology, Academic Medical Center Amsterdam, Amsterdam, Netherlands, [5]Cancer Center Amsterdam, Laboratory of Experimental Oncology and Radiobiology, Academic Medical Center Amsterdam, Amsterdam, Netherlands, [6]Department of Medical Oncology, Academic Medical Center Amsterdam, Amsterdam, Netherlands, [7]Cancer Center Amsterdam, Department of Medical Oncology, Academic Medical Center Amsterdam, Amsterdam, Netherlands

Background: The prognosis of advanced EGAC remains poor. Triplets containing taxanes show a survival benefit but at the cost of increased toxicity. Given the favorable toxicity profile of nab-P compared to conventional taxanes we conducted a phase 1 dose escalation study to find the maximum tolerated and recommended phase 2 dose (MTD/RP2D) of the addition of nab-P to CAPOX.

Methods: Patients (pts) with metastatic or non-resectable EGAC received oxaliplatin 65 mg/m2 day 1 and 8 and capecitabine 1000 mg/m2 bid day 1-14 in a 21 day cycle, with nab-P day 1 and 8 at 4 dose levels (DL1 60, DL2 80, DL3 100 and DL4 120 mg/m2, respectively) in a standard 3 + 3 design, followed by an expansion cohort of 20 pts. Tumor response was assessed every 3 cycles (RECIST 1.1). Pts were treated until progressive disease (PD), unacceptable toxicity or a maximum of 6 cycles after which capecitabine monotherapy was continued. Ox and nab-P were reintroduced if PD occurred after more than 3 months.

Results: We enrolled 26 pts (median age 63; 18 had esophageal cancer and 8 gastric cancer). Ten pts had received prior curative treatment. At DL1 and DL2 no dose limiting toxicity (DLT) occurred. At DL3 2 DLT's occurred (diarrhea and dehydration due to vomiting/diarrhea). MTD was established at 80 mg/m2 and chosen for evaluation in the expansion cohort. However, because of diarrhea grade 3 in 5/12 pts (42%) in the course of treatment the nab-P dose was reduced to 60 mg/m2. Grade 3/4 toxicity of all pts treated at this DL was nausea (18%), diarrhea, vomiting, anorexia and elevated GGT (all 9%). Notable grade 1/2 toxicities were neuropathy (82%), dysgeusia, diarrhea (both 64%), nausea (55%) and vomiting (45%). Best responses were PR (13 pts), SD (9 pts) and PD (2 pts). Median follow up is 9.1 months, 22 pts completed 6 cycles and 5

pts are still on treatment of whom 4 on capecitabine monotherapy. Median PFS is 8.0 months.

Conclusions: MTD of nab-P in combination with CAPOX is 80 mg/m2 and RP2D 60 mg/m2 in a 3-weekly schedule. Given the manageable toxicity at RP2D and promising efficacy, further evaluation of this regimen is warranted. Biomarker research is currently ongoing.

690P KRAS status and HER2 targeted treatment in advanced gastric cancer

E. Shinozaki[1], H. Osumi[1], K. Chin[1], M. Ogura[1], D. Takahari[1], T. Ichimura[1], T. Matsushima[1], T. Wakatsuki[1], I. Nakayama[1], Y. Imamura[2], M. Watanabe[2], K. Yamaguchi[1]

[1]Gastrointestinal Oncology, Cancer Institute Hospital of JFCR, Tokyo, Japan, [2]Gastroenterological Surgery, Cancer Institute Hospital of JFCR, Tokyo, Japan

Background: Trastuzumab targeted on HER2 has been shown to confer overall survival benefit adding to fluoropyrimidine (Fp) plus CDDP in HER2-positive advanced gastric cancer (AGC). HER2 is known to make the formation of heterodimer with EGFR, HER3 and HER4. HER2 containing heterodimer activates the common downstream of HER family such as MAPK pathway via RAS and PI3K pathway. *RAS* and *PIK3CA* mutations has been well known as predictive biomarkers for anti EGFR treatment in colorectal cancer and anti HER2 treatment in breast cancer. However it remains unclear that the implications for these status and HER2 targeted treatment in AGC. In this study we attempted to assess the relationship with the efficacy of trastuzumab including treatments and mutational status of molecules in HER family signaling pathway.

Methods: Out of over 500 AGC between March 2011 and November 2015 we chose 100 patients (pts) received Fp plus CDDP with trastuzumab as 1st-line, finally total 77 pts with sufficient specimen for DNA extraction were enrolled in this analysis. Multiplex genotyping of common downstream in HER family was performed on archival samples using Luminex Assay (MEBGEN and GENOSEARCH Mu-PACK, MBL) for *KRAS* and *NRAS* including exon 2, 3 and 4, *PIK3CA* and *BRAF*. *KRAS* amplification was measured by quantitative real-time reverse transcription- polymerase chain reaction. The relative level of *KRAS* mRNA was normalized by *HPRT-1* mRNA. We assessed the relationship between gene or mRNA status and clinical outcomes. Tumor response was re-assessed by the investigator retrospectively by RECIST1.1.

Results: *KRAS* mutation of exon2 was detected in only 6 patients of 77 pts (7.8%). No mutations were found in *NRAS*, *PIK3CA* and *BRAF* in this HER2 positive AGC series. *KARS* amplification was detected in 16 pts (20.1%) (cut-off > 3.0). An overall RR and the disease control rate (DCR) in *KRAS* wild type (WT) vs. mutant type (MT) were following, RR; 66.2% vs. 16.7%, DCR; 87.3% vs. 66.7%, respectively (CR2/0, PR 45/1, SD 15/3, PD 9/2). The median PFS and OS in *KRAS* WT vs. MT were as followed, 8.9 months (m) vs. 3.6 m and 20.8 m vs. 10.3 m, respectively. *KRAS* MT showed low response rate and extremely shorter PFS and OS compared with *KRAS* WT. On the other hands, *KRAS* amplification did not affect the clinical outcomes.

Conclusions: Our data suggested HER2-positive AGC harbored *KRAS* mutation at the low frequency. *KRAS* mutation was strong prognostic and might predict the lack of benefit as receiving HER2 targeted treatment. Further investigation was warranted to confirm the predictive value of *KRAS* status in HER2-positive AGC receiving trastuzumab to fluoropyrimidine plus CDDP.

691P Inter-patient and intra-tumoral heterogeneity of oncogenic copy number alterations (CNAs) in gastric and gastroesophageal junction (GEJ) adenocarcinomas

J. Chao[1], V. Bedell[2], M.S. Li[3], P. Chu[4], Y-C. Yuan[5], S.J. Klempner[6], R-J. Lin[7]

[1]Medical Oncology and Therapeutics Research, City of Hope Comprehensive Cancer Center, Duarte, CA, USA, [2]Cytogenetics Core, City of Hope Comprehensive Cancer Center, Duarte, CA, USA, [3]Biostatistics, City of Hope Comprehensive Cancer Center, Duarte, CA, USA, [4]Pathology, City of Hope Comprehensive Cancer Center, Duarte, CA, USA, [5]Bioinformatics Core, City of Hope Comprehensive Cancer Center, Duarte, CA, USA, [6]Medical Oncology, The Angeles Clinic and Research Institute, Los Angeles, CA, USA, [7]Molecular and Cellular Biology, City of Hope Comprehensive Cancer Center, Duarte, CA, USA

Background: Intra-tumoral heterogeneity is well recognized to be inherent in biomarker discovery for gastric cancer since the initial reporting of HER2 overexpression. The Cancer Genome Atlas (TCGA) has laid the groundwork for CNAs comprising the mutational landscape of gastric cancer. We aimed to investigate through a genomic single nucleotide polymorphism (SNP) array panel and fluorescence in-situ hybridization (FISH) inter-patient and intra-tumoral spatial heterogeneity of CNAs.

Methods: 41 gastric adenocarcinoma patient samples treated with upfront surgical resection were retrospectively identified from the City of Hope Biospecimen Repository. CNAs of 891 cancer-related genes at 50-100 Kb resolution and detection of 74 frequent somatic mutations in 9 genes of interest (*BRAF, KRAS, EGFR, IDH1, IDH2, PTEN, PIK3CA, NRAS, TP53*) were assayed using the Affymetrix OncoScan™ platform. Genome wide coverage outside of the 891 cancer genes were provided at 300 Kb resolution along with genome wide LOH provided at 3-10 Mb resolution. For samples with multiple CNAs detected, FISH was pursued to define down to a single-cell level the spatial distribution of CNAs.

Results: Detectable percentage (%) genomic changes ranged from 0.03 to 73.90%. Lauren intestinal subtype histology correlated strongly with higher % genomic changes compared to diffuse subtype histology ($p = 0.0012$). Tumors located in the GEJ/cardia/proximal stomach also correlated with higher % genomic changes compared to gastric body/antrum tumors ($p = 0.0028$). A variety of oncogenic CNAs were observed across patients including high copy gains in EGFR, JAK2, FGFR2, MET, VEGFA, KRAS, NRAS, and PIK3CA. One sample exhibited co-amplification of CD274 and PDCD1LG2 (encoding PD-L1 and PD-L2), in addition to concurrent amplification of ERBB2, JAK2, FGFR2, MET, KRAS, and PIK3CA. FISH images of the spatial distribution of CNAs will be presented.

Conclusions: The inherent spatial intra-tumoral heterogeneity of oncogenic CNAs with de novo disease presentation illustrates the challenges in gastric cancer therapy. Further study will offer insight into strategies on combinatorial and/or sequential targeted and immunotherapeutic approaches.

692P Identification of an RNF43 mutated gastric cancer patient population with potential sensitivity to porcupine inhibitor RXC004 and development of a complimentary ctDNA liquid biopsy assay for patient screening

M. Bingham[1], I. Bhamra[1], R. Armer[1], B. Thompson[1], S. Woodcock[1], A. Thomason[1], C. Phillips[1], H. McKeever[1], J. Bradford[2], B. Chaffey[3], L. Little[3], G. Clack[4]

[1]Oncology and Immunology, Redx Pharma Plc, Manchester, UK, [2]Department of Oncology and Metabolism, University of Sheffield, Sheffield, UK, [3]Bioscience Building, NewGene Ltd, Newcastle-Upon-Tyne, UK, [4]Faculty of Medicine, University of Sheffield, Sheffield, UK

Background: RXC004 is a small molecule PORCN inhibitor, entering first-in-human trials in 2017. PORCN inhibition has been shown to have potential for the treatment of molecularly selected pancreatic and colorectal cancers, as well as the ability to synergise with anti-PD1 checkpoint inhibition. The aim of this study was to identify additional patient segments predicted to benefit from treatment with a PORCN inhibitor.

Methods: Mutation incidence for the WNT pathway gene RNF43 was analysed in 674 gastric cancer samples. RXC004 was profiled in gastric, pancreatic and biliary PDX models carrying the RNF43 mutations and growth inhibition was correlated with WNT pathway inhibition. To support the clinical trial a patient selection strategy, based on detection of RNF43 mutations from a liquid biopsy, using MassArray mass spectrometry technology is described.

Results: Bioinformatics data-mining of TCGA identified that the prevalence of RNF43 mutation in gastric cancer is 14-16%. A specific hot spot mutation (G659Vfs*41) has been identified, which accounts for ~70% of the RNF43 mutations. Profiling of RXC004 in RNF43 mouse models of gastric and pancreatic cancer shows the potential for monotherapy efficacy. In order to translate our findings to the clinic, we developed an assay suitable for detection of RNF43 mutations in circulating tumour DNA (ctDNA) from patient plasma. Multiplexed assays for RNF43 mutations, including the G659Vfs*41 hotspot, have been developed using MassArray technology. By converting to UltraSeek MassArray methodology we are targetting a sensitivity of 0.1% allelic frequency and specificity >99% in patient ctDNA.

Conclusions: RXC004 is entering first-in-human trials in 2017 with a modular phase I/IIa clinical protocol design which allows for phase IIa expansion arms in molecularly selected patient segments including gastric cancer. We demonstrate that there is an RNF43 mutated patient segment which may benefit from therapy with RXC004, and that these patients have the potential to be identified by a ctDNA screening approach.

Background: The aim of this analysis was to evaluate the prognostic effect of surgery of metastases in patients from a national registry of advanced gastric cancer.

Methods: The effect of surgery of metastases was assessed by multivariable Cox proportional hazards regression adjusted by confounding factors. To avoid immortal time bias in variables that occur after the initial period of observation, surgery of metastases, primary tumor resection, and the assessment of tumor response by RECIST were considered as time-dependent variables. All P values are two-sided. Statistical analyses were performed using RStudio, including the survival package.

Results: The registry contains 1531 evaluable patients. Of these, 5.3% (n = 82) patients underwent surgery for metastases (liver metasectomies were performed in 23 patients, peritoneal surgeries in 39, a pulmonary metastasis excision in 1 patient, and 19 surgeries in other locations). The majority of the cases (53.6%) had a single metastatic location. The median overall survival in non-operated patients was 10.4 months (confidence interval [CI] 95%, 9.9-10.9) versus 19.8 months (CI 95%, 17.4-28.8) in patients with resection of metastases. In the multivariable Cox proportional hazards regression, the resection of metastases was associated with a reduction in mortality with a hazard ratio (HR) of 0.57 (95% CI, 0.43-0.76) (see Table 1). Table 1. Cox proportional hazards regression

Conclusions: In this registry of patients with advanced gastric tumors, surgery of metastases appears to confer a favorable survival benefit when performed on carefully selected patients.

694P Comparison of HER2 related molecular expression and its significance for clinical outcomes between the primary and paired liver metastasis in advanced gastric cancer

H. Osumi[1], E. Shinozaki[1], N. Yamamoto[2], K. Chin[1], M. Ogura[1], D. Takahari[1], T. Wakatsuki[1], T. Ichimura[1], I. Nakayama[1], T. Matsushima[1], A. Saiura[3], T. Yamaguchi[3], K. Yamaguchi[1]

[1]Department of Gastroenterology, Cancer Institute Hospital of JFCR, Tokyo, Japan, [2]Department of Pathology, Cancer Institute Hospital of JFCR, Tokyo, Japan, [3]Department of Sugery, Cancer Institute Hospital of JFCR, Tokyo, Japan

Background: Although clinical outcomes are improved with anti HER2 therapy for HER2 positive advanced gastric cancer (AGC), the relationship with HER2 related molecules and their significance for clinical outcomes are still unclear including the difference between the primary and paired liver metastasis in AGC.

Methods: A total of 58 AGC with liver metastasis were enrolled in this study from November 1995 to March 2009. We investigated HER2 protein expression by immunohistochemistry (IHC) using HercepTest (DAKO) in standard procedure and assessed according to Gastric Cancer Scoring System. HER2 positivity (3+) defined complete, basolateral or lateral membranous reactivity in > 10% of the cells. About the other molecular expressions (EGFR, c-MET, IGFR), positive expression was defined as 25% or more staining with intensity 2 or 3+. We also investigated the relationship between recurrence free survival (RFS), overall survival (OS) and HER2 related molecular expression in both primary and liver metastasis.

Results: The HER2 positivity (3+) rate of primary and liver metastasis were 11.5 (6/52) and 9.4% (5/53), respectively, and concordance rate between the primary and liver metastasis was 91.4% (53/58). The EGFR positivity rate of primary and liver metastasis were 1.7% (1/57) and 5.4% (3/55), respectively, and concordance rate between the primary and liver metastasis was 93.1% (54/58). The c-MET positivity rate of primary and liver metastasis were 44.8 (26/32) and 45% (18/40), respectively, and concordance rate between the primary and liver metastasis was 75.8% (44/58). The IGFR1 positivity rate of primary and liver metastasis were 45 (18/40) and 41.4% (17/41), respectively, and concordance rate between the primary and liver metastasis was 70.6% (41/58). Median RFS and OS were 7.3 months (6.2-11.8) and 34 months (16.2-41.7), respectively. There were no relationships between any HER2 related molecular expressions and RFS, OS in both primary and liver metastasis.

Conclusions: EGFR and HER2 were high concordance rate between the primary site and liver metastasis, respectively. There were no relationships between any HER2 related molecular expressions and clinical outcomes in this cohort.

Background: Observation study is difference with randomized controlled trial and reflects the real world data in clinical practice with larger sample size, wider inclusion criteria, various interventions and long-term follow-up. We analyzed the real world data achieve real world evidence, which was applied to analyze discuses, patients, treatment patterns, resource utilization and outcome. The aim of this study was to evaluate the efficacy and safety of apatinib in real world, and provide a decision reference for Clinical practice.

Methods: This was a prospective, multicenter, non-intervention registered study. The patients (pts), were ≥18 years old, with histologically confirmed advanced gastric cancer (GC) or adenocarcinoma of esophagogastric junction (AEG), two or more lines of prior chemotherapy. All the pts were orally given apatinib at an initial dose of 500 mg until disease progression or death. Dose adjustment was allowed.

Results: The 230 pts, included 164 males and 66 female were eligible, the average age of pts was 62 years old, stage IV was the mainly clinical stage, the main ECOG performance status was 1, 54.78% pts were given apatinib 500 mg qd. 63.91% pts were received chemotherapy along with apatinib. In the 230 pts, there were 125 received efficacy evaluation. 8 pts achieved partial response (PR), 64 had stable disease (SD), and 53 had progressive disease (PD). The objective response rate (ORR) was 6.4% and the disease control rate (DCR) was 57.6%. The middle progression free survival (mPFS) and middle overall survival (mOS) were 3.3 months and 6.3 months, respectively. Compared with the non chemotherapy, chemotherapy achieved a longer mPFS (3.8months VS 2.9 months) and mOS (8.3months VS 5.0 months). 211 pts were included for safety analysis. The incidence of adverse events (AEs) was 91.2%, The grade 3 and 4 was 62.3%. The incidence of serious adverse events (SAE) was 17.2%. Main AEs were hypertension, Hand-foot syndrome, proteinuria and fatigue. Pts received chemotherapy achieved a better tolerance.

Conclusions: The real world data show that apatinib treatment significantly improved OS and PFS with an acceptable safety profile in patients with advanced gastric cancer.

696P Correlation between SPARC expression and efficacy of nab-paclitaxel for advanced gastric cancer refractory to fluoropyrimidine: An exploratory analysis of a phase II trial, CCOG1303

D. Kobayashi[1], A. Enomoto[2], Y. Mochizuki[3], T. Matsui[4], H. Nakayama[5], Y. Kawase[6], K. Ishigure[7], T. Shikano[8], K. Torii[9], Y. Kodera[1]

[1]Gastroenterological Surgery, Nagoya University, Graduate School of Medicine, Nagoya, Japan, [2]Pathology, Nagoya University, Graduate School of Medicine, Nagoya, Japan, [3]Department of Surgery, Komaki Municipal Hospital, Komaki, Japan, [4]Department of Surgery, Aichi Cancer Center Hospital, Okazaki, Japan, [5]Department of Surgery, National Hospital Organization Nagoya Medical Center, Nagoya, Japan, [6]Department of Surgery, Tosei General Hospital, Seto, Japan, [7]Department of Surgery, Konan Kosei Hospital, Konan, Japan, [8]Department of Surgery, Yokkaichi Municipal Hospital, Yokkaichi, Japan, [9]Department of Surgery, Nakatsugawa Municipal General Hospital, Nakatsugawa, Japan

Background: Secreted protein acidic and rich in cysteine (SPARC) reportedly influences the response to albumin-bound paclitaxel due to its characteristics of albumin-binding matrix-associated protein that may enhance the drug accumulation in the tumor tissue. However, its role in gastric cancer (GC) has been controversial. In this study, correlation between SPARC expression and the efficacy of nab-paclitaxel (nab-PTX) for GC was evaluated to explore its potential as a predictor of sensitivity.

Methods: In a multi-institutional prospective phase II trial (CCOG1303), efficacy of nab-PTX under a modified dose reduction criteria was evaluated in 47 advanced GC patients refractory to fluoropyrimidine. Correlation between SPARC expression on immunohistochemistry and efficacy endpoints was evaluated as a predetermined exploratory analysis in the CCOG1303 trial. SPARC staining was scored in two compartments: cancer associated fibroblasts (CAF) in the tumor stroma and tumor epithelial cells.

Results: The SPARC expression in the tumor epithelia was higher than that in the non-tumorous epithelia in only 5 patients (11%), while negative or weaker SPARC staining in the tumor epithelia was observed in the remaining specimens. SPARC expression level in the CAF was classified into the following 3 categories: 1/3 or less (score 0), 1/3∼2/3 (score 1+), and 2/3 or more (score 2+) of CAF were positive for SPARC [18 patients (38%), 11 (23%), and 18 (38%), respectively]. There was no difference according to clinicopathological characteristics between CAF SPARC level [low (score 0) vs. high (score 1+/2+)]. CAF SPARC level (low vs. high) was not associated with the progression free survival (median, 4.8 vs. 3.0 months; $P = 0.259$), overall survival (median, 10.2 vs. 8.0 months; $P = 0.419$), time to treatment failure (median, 4.7 vs. 3.0 months; $P = 0.291$), and overall response rate (0 vs. 25%; $P = 0.850$).

Conclusions: SPARC level was not correlated with efficacy of nab-PTX for GC. The results of this exploratory analysis do not support the possibility of SPARC expression level for clinical biomarker regarding nab-PTX in GC.

697P Detection of microsatellite instability (MSI) with a novel panel of biomarkers in gastric cancer samples

B. De Craene[1], Z. Feng[2], E. Rondelez[1], L. Vandenbroeck[1], K. Peeters[1], G. Maertens[1], E. Sablon[1], T. Cai[2]

[1]CREATE, Biocartis NV, Mechelen, Belgium, [2]Research & Development, EMD Serono Research and Development Institute, Inc., Billerica, MA, USA

Background: Detection of microsatellite instability (MSI) is recommended to identify colorectal cancer (CRC) patients with Lynch syndrome, but MSI is present in several other tumor types such as ovarian and gastric cancer. Current clinical reference methods to detect MSI stain for mismatch repair proteins or analyze frequently mutated DNA repeat regions. The Idylla™ MSI Test is being developed for a unique set of novel biomarkers (Zhao et al. 2014; eLife) capable of faster detection with greater specificity and selectivity compared to current methods.

Methods: To assess the suitability of the novel marker set to detect MSI status in gastric cancer, we performed a small-scale evaluation study: 10 novel MSI biomarkers with proven efficacy in CRC were tested in 150 gastric cancer samples. Repeat length was determined on FFPE DNA by PCR followed by melting curve analysis. Eighty-five samples were screened with a reference methodology for MSI detection (Promega MSI analysis system).

Results: Fifteen out of 150 samples (10%) were classified as MSI-H with the novel set of biomarkers. At least 5/10 (50%) of the markers scored mutant in each of these 15 samples. All of the 10 markers scored wild type in 131/150 samples. All samples with at least one mutant marker ($n = 19$) and 66 randomly selected samples with no mutant markers were screened with the Promega MSI analysis system. 9/85 samples failed with the reference method, even after repeat testing, while the Idylla™ methodology did not generate any failures (0/150). For 76 samples with results available for both methods, the overall percent agreement was 100% (76/76).

Conclusions: Fifteen out of 150 samples (10%) were classified as MSI-H with the novel set of biomarkers. At least 5/10 (50%) of the markers scored mutant in each of these 15 samples. All of the 10 markers scored wild type in 131/150 samples. All samples with at least one mutant marker ($n = 19$) and 66 randomly selected samples with no mutant markers were screened with the Promega MSI analysis system. 9/85 samples failed with the reference method, even after repeat testing, while the Idylla™ methodology did not generate any failures (0/150). For 76 samples with results available for both methods, the overall percent agreement was 100% (76/76).

Background: Ramucirumab (RAM) is approved for the treatment of advanced gastric cancer or gastroesophageal junction adenocarcinoma with disease progression after prior platinum and/or fluoropyrimidine chemotherapy at 8 mg/kg every 2 weeks (Q2W) based on results of 2 phase 3 trials. Exposure-response analyses from these trials indicated efficacy of RAM correlated with exposure. JVDB is an open-label RAM monotherapy study that examined pharmacokinetics (PK) and safety of the standard and 3 higher exposure regimens.

Methods: Patients (n = 164) were randomized 1:1:1:1 to 4 treatment arms: 8 mg/kg Q2W (Arm 1), 12 mg/kg Q2W (Arm 2), 6 mg/kg every week (Arm 3), and 8 mg/kg Days 1 and 8 (D1D8) every 3 weeks (Q3W) (Arm 4). PK was collected from all groups. Treatment-emergent adverse events (TEAEs) were graded by NCI CTCAE v4.0. Tumor response was assessed by RECIST 1.1.

Results: Mean RAM trough and peak concentrations are shown (Table). Median (months) progression-free survival (PFS) was similar across all arms (Arm 1=1.45; Arm 3=1.54; Arm 4=1.51), with the exception of Arm 2=2.50. PFS hazard ratio (HR) for Arm 2 vs 1=0.82; Arm 3 vs 1=0.88; Arm 4 vs 1=0.77. Overall survival (OS) HR for Arm 2 vs 1=0.70; Arm 3 vs 1=0.95; Arm 4 vs 1=0.90. The most common TEAEs were fatigue (22.4%), decreased appetite (21.1%), abdominal pain (18%), and vomiting (18%), consistent with the REGARD trial.

Table: 698P

		Trough (µg/ml)		Peak (µg/ml)	
Arm	**Regimen**	**Week 6**	**Week 12**	**Week 6**	**Week 12**
1	8 mg/kg Q2W (standard)	47.6	64.3	189	195
2	12 mg/kg Q2W	71.0	79.4	303	309
3	6 mg/kg QW	83.0	125	187	226
4	8 mg/kg D1D8 Q3W	57.4	81.6	180	210

Conclusions: Trough concentrations of the 3 experimental regimens were greater than the standard regimen. Arm 2 displayed the highest peak RAM concentration. Though efficacy findings were not significant, some trends toward improved PFS and OS versus the standard regimen were observed. Despite higher RAM exposures observed with the alternative regimens, safety profiles were comparable to the standard regimen.

699P The effectiveness of the 8th American Joint Committee on Cancer TNM classification in the prognosis evaluation of stage III gastric cancer patients: A comparative study between the 7th and 8th editions

J. Lu, H. Chang-Ming, C. Zheng, Q. Chen, R. Tu

Department of Gastric Surgery, Fujian Medical University Union Hospital, Fuzhou, China

Background: The 8th edition of the AJCC TNM staging system for gastric cancer was released in 2016 and included major revisions, especially of stage III. We aimed to compare the prognostic value of the seventh and eighth editions of the AJCC TNM classification for stage III gastric cancer.

Methods: Clinical data on 1,579 patients operated on for stage III gastric cancer according to the seventh edition between December 2006 and November 2014 were analyzed and the 7th and 8th TNM classifications were compared in terms of prognostic performance.

Results: According to the 8th AJCC TNM classification, the 5-year overall survival rates of IIIA, IIIB and IIIC were 49.4%, 29.6% and 15.2%, respectively (P<0.001). The median number of lymph nodes (LNs) resected was 33 (range 5-112), and the optimal cut-off value for the number of LNs resected was 30. Cox regression multivariate analysis showed the 8th AJCC N classification, 8th AJCC T classification, tumor size, lymphatic vessel invasion, and number of LNs removed were independent prognostic factors. However, the 7th edition classification had higher c-index, linear trend and likelihood ratioχ2 scores, and smaller AIC values compared with those for the 8th edition, which represented the optimum prognostic stratification. Further subgroup analysis found that the 8th staging system generated the best prognostic stratification only when LNs removed≥30.

Conclusions: The 8th TNM classification provide better accuracy than 7th edition in predicting the prognosis of stage III gastric cancer with LNs harvested≥30.

700P Comparison of prognostic models for hepatocellular carcinoma (HCC) in patients treated with the sorafenib: Results from a Canadian multi-center HCC database

H.H. Samawi[1], S. Hao-Wen[2], K. Chan[3], M.A. Alghamdi[4], R.M. Lee-Ying[4], J. Knox[2], P. Gill[1], A. Romagnino[3], E. Batuyong[4], Y-J. Ko[3], W.Y. Cheung[4], V.C. Tam[4]

[1]Medical Oncology, British Columbia Cancer Agency, Vancouver, BC, Canada, [2]Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada, [3]Medical Oncology, Sunnybrook Odette Cancer Centre, Toronto, ON, Canada, [4]Medical Oncology, Tom Baker Cancer Centre, Calgary, AB, Canada

Background: Several staging systems and models (TNM, BCLC, Okuda, CLIP and ALBI) have been developed to estimate the prognosis of patients with HCC. Most of these were developed prior to the prevalent use of sorafenib. The purpose of this study was to compare the prognostic and discriminatory power of these models in predicting survival for HCC patients treated with sorafenib.

Methods: Patients who received sorafenib for the treatment of HCC between January 1, 2008 and June 30, 2015 in the provinces of British Columbia and Alberta, as well as Princess Margaret Cancer Centre and Sunnybrook Odette Cancer Centre in Toronto, Ontario were included. Survival outcomes for each model were assessed with Kaplan-Meier (KM) curves and compared with the log-rank test. Time dependent area under the curve (t-AUC) was used to test the discriminatory power of each model (higher t-AUC = more discriminatory power). Akaike information criterion (AIC), a measure of goodness-of fit of models while penalizing overly complex models, was used to compare the models (lower AIC = better model).

Results: A total of 681 patients were included in this analysis. Median age was 64 years (range 8-91). Majority were males (80%), had a Child-Pugh score A (86%), ECOG performance status 0 (30%) and 1 (60%). 37% of patients were of East Asian ethnicity. Most common etiology for liver disease was hepatitis B (33%) and C (29%). At start of sorafenib, most patients were BCLC stage C (92%) and TNM stage IV (61%). The median overall survival for the entire cohort was 9.2 months (95% CI 8-10.4). CLIP had the highest t-AUC and the lowest AIC. See table below for t-AUC and AIC results.

Table: 700P

Prognostic model	AIC	t-AUC (95% CI)
CLIP	5725.76	0.659 (0.601 – 0.718)
Okuda	5730.38	0.645 (0.597 – 0.694)
ALBI	5756.73	0.558 (0.510 – 0.599)
BCLC	5759.25	0.558 (0.518 – 0.599)
TNM stage	5771.51	0.561 (0.499 – 0.623)

Conclusions: According to our large multi-center study, CLIP appears to be the most informative in predicting survival in HCC patients treated with sorafenib. Prospective studies are needed to determine its role in patient selection for clinical trials and in guiding treatment decisions. The TNM and BCLC staging systems were the least useful in predicting survival in this population.

Background: Therapeutic outcomes for patients (pts) with advanced hepatocellular carcinoma (HCC) are currently poor, despite the introduction of new therapies. c-Met is a potential therapeutic target in HCC, and c-Met inhibitors have demonstrated activity in preclinical HCC models. Tepotinib (MSC2156119J) is a highly selective c-Met inhibitor that has favorable safety and promising clinical activity, particularly against c-Met+ solid tumors. We report the final results of a phase Ib trial of tepotinib in pts with advanced HCC.

Methods: Enrolled pts were Asian adults with confirmed HCC of BCLC Stage C, Child-Pugh Class A liver function without encephalopathy, and ECOG PS 0–2. Pts received tepotinib 300, 500 (the RP2D), or 1,000 mg/day on a 21-day cycle. c-Met expression was retrospectively determined by IHC (c-Met+ defined as $\geq$ 50% tumor IHC2+/3+). The primary objective was to confirm the recommended phase II dose (RP2D) of tepotinib.

Results: No dose-limiting toxicities were observed in the 27 pts enrolled (median age 57 [38-69]; male 23; ECOG PS 0/1 11/16), who received tepotinib 300 mg/day (n = 7), 500 mg/day (n = 14), or 1,000 mg/day (n = 6, 3 with dose reduction). 22 pts had treatment-related treatment-emergent adverse events (TRTEAEs), most commonly diarrhea (n = 10), nausea (n = 8), elevated AST (n = 7), and elevated ALT (n = 6). The most common grade $\geq$3 TRTEAEs were elevated AST (n = 3), elevated ALT (n = 3), and elevated lipase (n = 3). Best overall response (BOR) was partial response (PR) in 2 pts, of duration 19.0 months (500 mg) and 4.4 months (1,000 mg). 8 pts had a BOR of stable disease (SD), 14 pts had PD, 1pt had Non-CR/Non-PD, 2pts were not evaluable. 5 pts had progression-free survival >8 months. Tumor c-Met status was available for 26 pts; of 7 pts with c-Met+ tumors, 2 had a PR and 2 had SD. PK and exploratory biomarkers were investigated.

Conclusions: Tepotinib had antitumor activity in Asian pts with advanced HCC, particularly those with c-Met+ tumors, and was well tolerated at doses up to 1,000 mg/day. A maximum tolerated dose was not defined. The efficacy and safety of first-line tepotinib in pts with c-Met+ HCC are being compared with those of sorafenib in the phase II part of this study.

702P Correlation between overall survival (OS) and time to progression (TTP) and between OS and response rate (RR) by RECIST in advanced hepatocellular carcinoma (HCC)

L. Huang[1], Y. De Sanctis[1], M. Shan[1], J. Bruix[2], J.M. Llovet[2,3,4], A-L. Cheng[5], G. Meinhardt[6], K. Nakajima[7]
[1]Medical Writing and Statistics, Oncology SBU, Bayer HealthCare Pharmaceuticals, Whippany, NJ, USA, [2]BCLC Group, Liver Unit, Hospital Clinic, University of Barcelona, IDIBAPS, CIBEREHD, Barcelona, Spain, [3]Liver Cancer Program, Division of Liver Diseases, Icahn School of Medicine at Mount Sinai, New York, NY, USA, [4]Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Spain[5]Department of Oncology, National Taiwan University Hospital, Taipei, Taiwan, [6]Clinical Development Oncology, Bayer HealthCare Pharmaceuticals, Whippany, NJ, USA,[7]Global Medical Affairs, Bayer HealthCare Pharmaceuticals, Whippany, NJ, USA

Background: TTP and RR have been suggested as potential surrogate endpoints for OS in advanced HCC. Here, we report correlation between OS and TTP/RR using simulated trials based on patient-level data from the phase 3 SHARP and AP trials in patients with advanced HCC randomized to sorafenib (SOR) or placebo (PBO).

Methods: A bootstrap approach was applied to simulate 10,000 trials of patients with advanced HCC from SHARP (N = 602; NCT00105443) and AP (N = 226; NCT00492752). RR was measured by investigator assessment per RECIST with SHARP–BCLC amendments (Reig et al. Semin Liver Dis 2014) prior to crossover of PBO subjects to SOR treatment. Pearson correlation was calculated between estimated median OS (mOS) and estimated median TTP (mTTP)/estimated RR for the SOR and PBO arms separately. Pearson correlation of log-rank test statistics comparing SOR and PBO were calculated for OS and TTP; Cochran–Mantel–Haenszel test statistic comparing the 2 arms for RR was also evaluated.

Results: The mean of mOS, mTTP, and RR from simulated trials was similar to that reported in SHARP and AP (Table). The correlation between mOS and mTTP was 0.270 for SOR and 0.218 for PBO in SHARP, and 0.315 for SOR and 0.258 for PBO in AP; the correlation of log-rank test statistics comparing SOR and PBO was 0.387 in SHARP and 0.581 in AP. In SHARP, the correlation between mOS and RR was 0.174 for SOR and 0.051 for PBO; the correlation of test statistics comparing SOR and PBO was 0.156. In AP, the correlation between mOS and RR was 0.138 for SOR and 0.099 for PBO; the correlation of test statistics comparing SOR and PBO was 0.211.

Conclusions: The simulated data were representative of patient population data in the SHARP and AP trials for mOS, mTTP, and RR. Our analysis showed a weak correlation between OS and TTP/RR in these trials, suggesting that TTP and RR by RECIST are not reliable surrogate endpoints for OS in patient with advanced HCC.

703P Cost effectiveness of selective internal radiation therapy (SIRT) with Y-90 resin microspheres versus sorafenib in Barcelona Clinic Liver Cancer (BCLC) stage C hepatocellular carcinoma patients in the UK

D. Palmer[1], P. Ross[2], T. Shah[3], D. Yu[4], S. Shergill[5], K. Patterson[6], N. Brereton[6], D. Lee[6]
[1]Department of Molecular and Clinical Cancer Medicine, University of Liverpool, Liverpool, UK, [2]Department of Oncology, Guy's & St Thomas' NHS Foundation Trust and King's College Hospital NHS Foundation Trust, London, UK, [3]Neuroendocrine Tumour Centre, Queen Elizabeth Hospital Birmingham, Birmingham, UK, [4]Department of Radiology, Royal Free Hospital, London, UK, [5]Global Pricing, Reimbursement & Market Access, SIRTEX, London, UK, [6]Health Economics Analysis Team, BresMed, Sheffield, UK

Background: Recently presented pivotal trial data (Vilgrain *et al. International Liver Congress 2017*) has shown that there is no significant difference in overall survival between selective internal radiation therapy (SIRT) with Y-90 resin microspheres (SIR-Spheres®; Sirtex Medical, North Sydney, Australia) and sorafenib for patients with Barcelona Clinic Liver Cancer (BCLC) stage C liver-limited or liver-predominant hepatocellular carcinoma. Y-90 resin microspheres are, however, safer and better tolerated by patients than sorafenib, as well as reducing costs, due to single administration and less frequent and severe side effects. Our aim was to evaluate the cost effectiveness of SIRT using Y-90 resin microspheres versus sorafenib for the treatment of patients with BCLC stage C hepatocellular carcinoma in the UK.

Methods: A cost-minimisation model was built, with equal efficacy assumed between Y-90 resin microspheres and sorafenib. Adverse events data were collected from the Phase III SHARP trial for sorafenib (Llovet *et al. N Engl J Med* 2008;359:378–90) and from the ENRY study for Y-90 resin microspheres (Sangro *et al. Hepatology* 2011;54:868–78). Treatment costs were taken from standard UK sources and real-world data from a UK hospital; treatment and adverse events disutilities were taken

Table: 702P

Trial	Treatment	mOS, days	Simulated data Mean (SD) of mOS, days	mTTP, days	Simulated data Mean (SD) of mTTP, days	RR	Simulated data Mean (SD) of RR
SHARP	Sorafenib	327	329 (26.5)	119	118 (10.1)	0.057	0.057 (0.013)
	Placebo	243	245 (21.7)	82	83 (2.4)	0.023	0.023 (0.009)
AP	Sorafenib	198	198 (18.8)	84	85 (6.4)	0.033	0.033 (0.014)
	Placebo	127	129 (14.5)	42	42 (2.5)	0.013	0.013 (0.013)

m, median; SD, standard deviation

from published literature. Inputs were validated by UK clinicians and one-way and probabilistic sensitivity analyses were performed.

Results: SIRT using Y-90 resin microspheres is dominant versus sorafenib, providing greater quality-adjusted life years (QALYs) at a lower cost. Y-90 resin microspheres provide 0.0079 (95% confidence interval [CI] 0.0046–0.0111) more QALYs than sorafenib, while saving £8,909 (95% CI £3,257–£14,570). One-way sensitivity analysis showed time on treatment for sorafenib and the work-up and administration costs of Y-90 resin microspheres to be the parameters with the largest influence on results.

Conclusions: In the case of equal efficacy between Y-90 resin microspheres and sorafenib, SIRT using Y-90 resin microspheres is a cost-effective therapy for BCLC stage C hepatocellular carcinoma patients in the UK.

704P Ang-2 polymorphisms in relation to outcome in advanced HCC patients receiving sorafenib

A. Casadei Gardini[1], G. Marisi[1], F.G. Foschi[2], M. Scartozzi[3], G.L. Frassineti[1]

[1]Medical Oncology, Istituto Tumori della Romagna I.R.S.T., Meldola, Italy, [2]Medical Oncology, IRST-IRCCS, Meldola, Italy, [3]Medical Oncology, Università of Cagliari, Cagliari, Italy

Background: Sorafenib, an oral multikinase inhibitor, represents the standard care for advanced hepatocellular carcinoma. Angiopoietin-2 (Ang-2) is a crucial angiogenic factor. By binding to its receptor Tie2, Ang-2 cooperates with the VEGF pathway to maintain normal physiological functions. In the presence of VEGF, Ang-2 destabilizes blood vessels and promotes vascular sprouting. In cancers, Ang-2 is linked to not only angiogenesis but also invasive and metastatic phenotypes. Although sorafenib exerts no significant activity against Tie2, the predictive value of Ang-2 has been explored in 2 studies. The actual role of Ang-2 in predicting sorafenib efficacy warrants further investigations. Polymorphism analysis seems to have more advantages than protein or gene expression analysis. In our study we analysed the role of ANG-2 polymorphisms in relation to clinical outcome in patients with hepatocellular carcinoma treated with sorafenib.

Methods: We analyzed 135 patients with hepatocellular carcinoma treated with sorafenib. Peripheral blood samples or FFPE tumor tissues were available for DNA extraction and genotyping analysis. Nine Ang-2 polymorphisms were analyzed by direct sequencing or Real Time PCR method.

Results: With regard to Ang4 rs55633437 was observed that patients carrying the allele GG were associated with a better PFS and OS. The variants GG were associated with a median OS of 16.9 months vs 6.5 months of variants GT and TT ($p = 0.016$). The variants GT and TT were associated with a median PFS of 2.94 months vs 4.67 months of variants GG ($p = 0.03$). These data were confirmed by multivariate analysis.

Conclusions: Ang4 rs55633437 could represent prognostic markers in patients with advanced hepatocellular carcinoma treated with sorafenib.

705P Circulating miRNA biomarkers predicting regorafenib (REG) clinical benefit in patients with hepatocellular carcinoma (HCC) in the RESORCE trial

M. Teufel[1], H. Seidel[2], K. Köchert[3], G. Meinhardt[4], R.S. Finn[5], J.M. Llovet[6,7,8], J. Bruix[6]

[1]Translational Medicine Oncology, Bayer HealthCare Pharmaceuticals, Whippany, NJ, USA, [2]Bioinformatics, Bayer AG, Berlin, Germany, [3]Genomics and Biomarker Statistics, Bayer AG, Berlin, Germany, [4]Clinical Development Oncology, Bayer HealthCare Pharmaceuticals, Whippany, NJ, USA, [5]Division of Hematology/Oncology, David Geffen School of Medicine at UCLA, Los Angeles, CA, USA, [6]BCLC Group, Liver Unit, Hospital Clinic, University of Barcelona, IDIBAPS, CIBEREHD, Barcelona, Spain, [7]Liver Cancer Program, Division of Liver Diseases, Icahn School of Medicine at Mount Sinai, New York, NY, USA, [8]Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Spain

Background: REG improved overall survival (OS) and time to progression (TTP) versus placebo in patients with HCC who progressed during prior sorafenib in the phase 3 RESORCE trial (Bruix et al, *Lancet* 2017). This exploratory analysis evaluated the potential of circulating miRNA plasma biomarkers to predict the OS and TTP benefit with REG in RESORCE.

Methods: Valid biomarker data were available for 343/573 patients. Expression levels of 750 plasma miRNAs collected at baseline were quantified by qPCR. To be eligible, miRNAs had to be measurable on a continuous scale or dichotomized by pre-processing (present vs absent), and present in $\geq 5\%$ of patients (i.e. $n \geq 18$). The predictive and prognostic effects (HR and 95% CI) were evaluated using a Cox proportional hazards model with miRNAs as continuous or dichotomized variables. A predictive effect was modeled as an miRNA–treatment interaction effect and subjected to Akaike information criterion (AIC)-based selection to assess its association with OS and TTP.

Results: Demographic covariates were generally similar in the overall RESORCE and miRNA biomarker cohorts, except the latter had a smaller proportion of Asian patients. Of the 750 miRNAs analyzed, 25 showed a multiplicity-adjusted prognostic effect ($P \leq 0.05$) for OS. Nine miRNAs showed a multiplicity-adjusted predictive effect ($P \leq 0.05$) for OS; 3 of the 9 predictive markers were also prognostic (Table). No miRNA was found to be predictive for TTP.

Table: 705P

miRNA	miRNA predictive for OS		miRNA prognostic for OS
	HR (95% CI)	P-value	P-value
hsa-miR-15b-3p	0.37 (0.20, 0.70)	≤0.05	0.01
hsa-miR-107	0.54 (0.37, 0.81)	≤0.05	0.06
hsa-miR-320b	0.57 (0.41, 0.81)	≤0.05	0.01
hsa-miR-122-5p	1.35 (1.14, 1.60)	≤0.05	0.39
hsa-miR-374b-3p	1.36 (1.11, 1.65)	≤0.05	0.06
hsa-miR-200a-3p	1.39 (1.15, 1.68)	≤0.05	0.03
hsa-miR-30a-5p	1.47 (1.14, 1.88)	≤0.05	0.34
hsa-miR-125b-5p	1.54 (1.19, 1.99)	≤0.05	0.32
hsa-miR-645	3.16 (1.52, 6.55)	≤0.05	0.06

Conclusions: This exploratory analysis suggests that multiple miRNAs may be potentially predictive for OS in patients treated with REG. The biological role of the miRNAs in HCC as well as their potential functional correlation to treatment benefit needs to be analyzed further.

706P Overall survival (OS) by platelet count at baseline in patients with hepatocellular carcinoma (HCC) treated with sorafenib (SOR) in the SHARP and AP trials and regorafenib (REG) in the RESORCE trial

G. Meinhardt[1], Y. De Sanctis[2], M-A. LeBerre[3], K. Nakajima[4]

[1]Clinical Development Oncology, Bayer HealthCare Pharmaceuticals, Whippany, NJ, USA, [2]Medical Writing and Statistics, Oncology SBU, Bayer HealthCare Pharmaceuticals, Whippany, NJ, USA, [3]Pharmaceuticals Division, Bayer HealthCare SAS, Loos, France, [4]Global Medical Affairs, Bayer HealthCare Pharmaceuticals, Whippany, NJ, USA

Background: SOR and REG significantly improved OS versus placebo (PBO) in patients with unresectable HCC: SOR in the first-line setting in both the SHARP (median OS: 10.7 SOR vs 7.9 months PBO, HR 0.69; $P < 0.001$) and AP trials (median OS: 6.5 SOR vs 4.2 months PBO, HR 0.68; $P = 0.014$); and REG in patients who progressed during prior SOR in the RESORCE trial (median OS: 10.6 REG vs 7.8 months PBO, HR 0.63; $P < 0.0001$). This exploratory analysis evaluated OS by baseline platelet count in HCC in the SHARP, AP, and RESORCE trials.

Methods: Patients with advanced HCC who received treatment in SHARP (SOR $n = 299$, PBO $n = 303$; NCT00105443), AP (SOR $n = 150$, PBO $n = 76$; NCT00492752), and RESORCE (REG $n = 374$, PBO $n = 193$; NCT01774344) were included in the analysis. Patients were subgrouped according to a baseline platelet count of $> 150 \times 10^9$/L and $\leq 150 \times 10^9$/L. OS (HR and its 95% CI) was evaluated using a Cox proportional hazards model.

Table: 706P

Trial (active drug)	Platelet count	n	Median OS for active drug, days	Median OS PBO, days	HR* (95% CI)
SHARP (SOR)	$>150 \times 10^9$/L	379	290	218	0.81 (0.63, 1.04)
	$\leq 150 \times 10^9$/L	221	442	297	0.60 (0.42, 0.85)
AP (SOR)	$>150 \times 10^9$/L	130	186	119	0.62 (0.42, 0.93)
	$\leq 150 \times 10^9$/L	95	227	166	0.78 (0.47, 1.31)
RESORCE (REG)	$>150 \times 10^9$/L	254	326	230	0.57 (0.41, 0.78)
	$\leq 150 \times 10^9$/L	318	313	241	0.78 (0.58, 1.04)

*HR < 1 indicates superiority of SOR/REG over PBO.

Results: In SHARP, 180 patients (60%) treated with SOR and 199 (66%) receiving PBO had a baseline platelet count of $> 150 \times 10^9$/L; 84 (56%) with SOR and 46 (61%) with PBO in AP; 163 (44%) with REG and 91 (47%) with PBO in RESORCE. Baseline variables were generally similar between subgroups for AP; in RESORCE, more patients had hepatitis C in the $>150 \times 10^9$/L platelet count group; in SHARP, the lower platelet count group had more patients with ECOG PS 0 and BCLC B, fewer patients with macrovascular invasion and extrahepatic spread, less tumor burden, and more cases of hepatitis C. In SHARP and AP, a lower platelet count at baseline was associated with improved OS, but this was not observed in RESORCE. Both SOR and REG improved OS over PBO in both subgroups.

Conclusions: The analysis indicates that platelet count may be a prognostic factor for first-line HCC but not for second-line HCC patients. SOR and REG are effective treatment options in HCC regardless of platelet count at baseline.

707P Network meta-analysis (NMA) of treatments for unresectable hepatocellular carcinoma (uHCC)

G. Tremblay[1], G. Meier[2], D. Misurski[2], M. Baig[2], T. Tamai[2], S. Kraljevic[3], A. Shor[1], A. Forsythe[1]

[1]Purple Squirrel, Economics, New York, NY, USA, [2]Eisai, Inc, WoodCliff Lake, NJ, USA, [3]Eisai Co., Ltd, Hatfield, UK

Background: In a phase 3 randomized controlled study (RCT) lenvatinib (LEN) demonstrated significantly better progression-free survival (PFS) vs sorafenib (SOR) in treatment-naive (1L) uHCC patients. Prior SOR RCTs had been conducted vs placebo (PBO). Our aim was to synthesize all efficacy evidence enabling a comparison of both LEN and SOR to PBO.

Methods: EMBASE®, MEDLINE®, MEDLINE® in-process, and Cochrane databases were systematically searched through February 2017 for relevant RCTs in 1L uHCC. Data from the recently completed LEN RCT were added to the review. A conventional NMA based on PFS and overall survival (OS) was performed using a frequentist random effect NMA programmed in R-3.3.1. PBO was used as the reference treatment.

Results: 3 Studies met inclusion criteria: 1 recently completed LEN vs SOR study (N = 954) and 2 RCTs comparing SOR to PBO: (1) Llovet 2008 (N = 602) and (2) Cheng 2009 (N = 226). The 3 RCTs were generally comparable with some variability in patient baseline characteristics: mean age, years (63, 66, 61), % male (84, 87, 85), % ECOG score 0-1 (100, 93, 95), % Child–Pugh class A (99, 97, 97), and % prior hepatitis B/C (50/23, 19/28, 73/8) in LEN vs SOR, SOR vs PBO (1), and SOR vs PBO (2), respectively. In the NMA vs PBO, LEN and SOR yielded indirect hazard ratios (HRs) of 0.38 and 0.58 for PFS and 0.63 and 0.69 for OS, respectively. Using LEN as a common comparator, SOR and PBO yielded indirect HRs of 1.52 and 2.63 for PFS and 1.09 and 1.58 for OS, respectively (Table).

Table: 707P

Intervention	PFS HR (95% CI)	OS HR (95% CI)
PBO – Comparator		
LEN	0.38 (0.30; 0.49)	0.63 (0.50; 0.80)
SOR	0.58 (0.47; 0.70)	0.69 (0.57; 0.83)
LEN – Comparator		
SOR	1.52 (1.30; 1.76)	1.09 (0.94; 1.26)
PBO	2.63 (2.06; 3.36)	1.58 (1.25; 2.00)

Conclusions: This NMA demonstrated that for 1L uHCC patients, both LEN and SOR demonstrated significantly better PFS vs PBO: 62% progression risk reduction for LEN vs 42% for SOR.

708P Epidemiological study of histologically proven advanced hepatocholangiocarcinoma: An AGEO multicenter retrospective study

Y. Touchefeu[1], C. Prieux-Klotz[2], D. Tougeron[3], T. Lecomte[4], M. Caulet[4], T. Matysiak Budnik[1], V. Hautefeuille[5], M. Tiako-Meyo[6], A. Zaanan[7], M. Salimon[1]

[1]IMAD, Department of Gastroenterology, Nantes University Hospital, Nantes, France, [2]Department of Gastroenterology, Cochin University Hospital, Paris, France, [3]Department of Gastroenterology, CHU Poitiers, Jean Bernard Hôpital, Poitiers, France, [4]Department of Gastroenterology, CHU de Tours, Hôpital Trousseau, Chambray-lès-Tours, France, [5]Department of Gastroenterology, CHU Amiens-Picardie Site Nord, Amiens, France, [6]Department of Gastroenterology, Hôpital Européen Georges Pompidou, Paris, France, [7]Department of Gastroenterology, Hopital European Georges Pompidou, Paris, France

Background: Hepatocholangiocarcinoma (cHCC-ICC) is a rare primary hepatic tumor combining the features of cholangiocarcinoma and hepatocellular carcinoma. Few data about the epidemiology of cHCC-ICC have been reported, mainly from surgical series in Asian and American populations. The aim of this study was to evaluate epidemiological features and overall survival (OS) of histologically proven advanced cHCC-ICC patients.

Methods: Data from patients treated for histologically proven cHCC-ICC in six French university hospitals between 2008 and February 2017, were retrospectively collected. The main clinical, biological, treatment and follow up data were reported. Statistical analysis was performed using Graph Pad Prism 6.

Results: Thirty patients were included (76.6% of men, median age 64 years [extreme 37-88]). Cirrhosis was associated in 33.3% of cases (Child-Pugh score A: 70%). Positive serology for hepatitis B virus and C was found in respectively, 5 (16.6%) and 2 (6.6%) patients; with 1 co-infection. Chronic alcoholism was noted in 33.3%, diabetes and obesity were both present in 26.6% of cases. Alpha-fetoprotein, carbohydrate antigen 19-9 and carcinoembryonnic antigen serum levels were above normal in respectively 39% (median = 5.3 µg/L [2 – 21 479]), 50% (median = 21.8 IU/mL [4.5-20 000]) and 14% (median = 2.4 µg/L [2-88]) of cases. Six patients (20%) were initially treated by surgical resection. At the diagnosis of advanced disease, 66.6% of patients had multifocal hepatic lesions, 50% distant metastases (bone (23.3%), lung (20%), peritoneal metastases (13.3%)). Twenty-seven patients (90%) received first line of systemic treatment. Twenty-four patients were treated by chemotherapy: Gemcitabine (Gem) alone (n = 1), Gem+oxaliplatin (Gemox) (n = 12), Gemox + bevacizumab (n = 9), Gem+cisplatin (n = 2). Two patients received chemoembolization, 1 patient received sorafenib. Twenty-one (70%) and 4 (13.3%) patients had a second and third line of treatment, respectively. Median OS was 14.5 months.

Conclusions: Advanced cHCC-ICC appear to be aggressive tumors with a poor prognosis. Cirrhosis was associated in one third of cases. Systemic treatments are not standardized and must be evaluated in a dedicated study.

709P A Phase II study of sorafenib and yttrium-90 glass microspheres for advanced hepatocellular carcinoma, BCLC stage C

A.O. Kaseb[1], R. Abdel-Wahab[1], R. Murthy[2], M. Hassan[3], K. Raghav[1], L. Xiao[4], J. Morris[4], R. Avritscher[2], B.C. Odisio[2], C. Ohaji[1], R.A. Wolff[1], J.C. Yao[1], A. Mahvash[2]

[1]GI Medical Oncology Department, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [2]Interventional Radiology Department, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [3]Epidemiology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [4]Biostatistics, The University of Texas MD Anderson Cancer Center, Houston, TX, USA

Background: Combined use of sorafenib and local therapy for treating unresectable hepatocellular carcinoma (HCC) is not well established. Notably, most common cause of death in HCC is liver failure, therefore we tested the promise of controlling the local tumors even in the setting of advanced/metastatic disease to improve survival. Our study aimed to assess the efficacy and safety of combined use of sorafenib and yttrium-90 resin microspheres (Y90 RMS) in unresectable HCC defined as Barcelona Clinic Liver Cancer class C.

Methods: Between October 2013 and August 2016 we enrolled 40 advanced stage HCC patients, 38 patients were treated with sorafenib followed (after 4 weeks) with Y90 RMS at MD Anderson Cancer Center. Survival analysis was done to evaluate median overall survival (OS) and progression-free survival (PFS). We used modified Response Evaluation Criteria in Solid Tumors (RECIST) to assess response to treatment and the Common Terminology Criteria for Adverse Events (CTCAE) v4.0 to evaluate the grading of treatment related toxicity.

Results: The majority of our patients were males (74%), white (47%), 66% of patients had underlying liver cirrhosis, 26% had vascular invasion, and 26% had extrahepatic disease. The estimated median OS and 95% confidence interval (CI) in months was 18.46 (12.29 – NA) and the estimated PFS was 12.29 months (5.72 – 18.79). Stable disease (SD) was observed in 44.74% of patients, while 28.95% achieved partial response (PR). Grade III-IV adverse events included fatigue (n = 3), hyperbilirubinemia (n = 2), thrombocytopenia (n = 1), proteinuria (n = 1), hyponatremia (n = 1), elevated liver enzymes (n = 4), hypertension (n = 4), diarrhea (n = 1), nausea (n = 1) and vomiting (n = 2).

Conclusions: This is the first prospective study to evaluate sorafenib followed by Y90 in HCC. Our study included patients with metastatic HCC and showed that combined use of sorafenib and Y90 was tolerable and was associated with longer OS and PFS compared to previous studies which evaluated sorafenib alone. However, future randomized phase III studies are warranted to assess sorafenib+/-Y90 in metastatc disease setting.

710P Assessing cancer risk in patients with HFE gene variants and type 1 hereditary hemochromatosis

K. Youkhana[1], V. Tutaeva[1], H. Williams[1], O. Corbali[2], S. Krishnamurthy[3], R. Metpally[3], N. Kip[1]

[1]Medical Oncology, Geisinger Medical Center, Danville, CA, USA, [2]Faculty of Medicine, Istanbul University, Istanbul, Turkey, [3]Bioinformatics, Geisinger Medical Center, Danville, CA, USA

Background: Patients with type 1 hereditary hemochromatosis are reported to have a 20-200-fold increased risk of hepatocellular carcinoma. However, not much is known about the risk of developing non-hepatobiliary cancers in these patients or those heterozygous for HFE variants. The purpose of this study is to assess the risk of non-hepatobiliary cancers in a large cohort.

Methods: Using the Geisinger-Regeneron DiscovEHR cohort, we sequenced whole exomes of 51,289 study participants to further analyze the HFE gene variations (C2892Y, H63D or S65C) for risk of cancer development. The cancer prevalence and statistical significance was assessed in both genders from multiple HFE genotypes.

Results: There were 51, 270 participants in this study: 30, 280 (59%) women and 20, 990 (41%) men. There was an increased risk of cancer overall among patients who harbored one or more HFE gene mutation (Kruskal-Wallis; $p < 0.00001$). While most cancers occurred in patients who had no known HFE mutations (20.5%), cancers were found in patients heterozygous for H63D/WT (6.14%) and C282/WT (2.31%). When the probability of cancer among men without HFE mutations were compared to other men with varying mutant genotypes, men with one or more HFE mutations had an increased probability of cancer if: homozygous C282Y ($p < 0.0001$), compound heterozygous for C282Y/H63D ($p < 0.0001$), homozygous H63D ($p < 0.0001$), S65C/WT ($p < 0.0001$), C282Y/S65C ($p < 0.0001$), WT/C282Y ($p < 0.0053$) and not H63D/WT mutation ($p < 0.10$). Among women, only H63D/S65C and H63D/H63D mutation(s) was/were associated with an increased risk of cancer ($p < 0.0001$).

Conclusions: To our knowledge, this is the first whole exome sequencing study analyzing the HFE gene variants for cancer risk in over 50 thousand individuals. This study showed that cancer risk is increased in both HFE variants and non-HFE variants carriers and that cancer screening should be considered in this cohort.

711P Selective Internal Radiation Therapy (SIRT) with Yttrium-90-glass-microspheres plus chemotherapy in first-line treatment of advanced cholangiocarcinoma (MISPHEC study)

J. Edeline[1], Y. Touchefeu[2], B. Guiu[3], O. Farges[4], D. Tougeron[5], P. Compagnon[6], L. Chone[7], B. Campillo-Gimenez[8], M. Pracht[1], A. Lievre[9], S. Le Sourd[1], K. Boudjema[10], E. Garin[11], E. Boucher[1]

[1]Medical Oncology, Centre Eugene Marquis, Rennes, France, [2]IMAD, Department of Gastroenterology, Nantes University Hospital, Nantes, France, [3]Interventional Radiology, CHU Montpellier, Montpellier, France, [4]Hepatobiliary Surgery, AP-HP Hôpital Beaujon, Clichy, France, [5]Department of Gastroenterology, CHU Poitiers, Jean Bernard Hôpital, Poitiers, France, [6]Hepatobiliary surgery and transplantation, CHU Henri Mondor, Creteil, France, [7]Hepatology, CHU Nancy, Nancy, France, [8]Clinical Research, Centre Eugene Marquis, Rennes, France, [9]Gastroenterology, CHU Pontchaillou, Rennes, France, [10]Hepatobiliary Surgery, CHU Pontchaillou, Rennes, France, [11]Nuclear Medicine, Centre Eugene Marquis, Rennes, France

Background: Patients with non-resectable intra-hepatic cholangiocarcinoma (ICC) have a bad prognosis, and the efficacy of chemotherapy is limited. SIRT is a promising treatment option in hepatic tumors. In ICC there is no prospective studies of combination SIRT with chemotherapy.

Methods: This phase II single-arm study prospectively included patients with non-resectable ICC (liver-only or limited extra-hepatic disease) in 7 centers. Patients received Cisplatin 25mg/m^2 and Gemcitabine 1000mg/m^2 (reduced to 300mg/m^2 the cycles just before and following SIRT) day 1 and 8 of a 21-days cycles. SIRT was delivered during cycle 1 (unilobar disease), or cycles 1 and 3 (bilobar disease). Primary objective was response rate (RR) at 3 months according to RECIST 1.1, with the objective to show a RR > 22%. Secondary objectives were toxicity, Progression-Free Survival (PFS), Overall Survival (OS), disease control rate (DCR) and RR according to Choi criteria.

Results: 45 patients met clinical inclusion criteria, and 41 were deemed treatable with SIRT after pretreatment angiography and included in the study. 34% of patients had abdominal extrahepatic lesions, 17% had thoracic lesions, tumor was unilobar in 66%, and median CA19.9 was 1499 UI/L. Grade 3 or more hematological toxicities were seen in 27 (66%) patients, and grade 3 or more non-hematological toxicities in 21 (49%). Median number of chemotherapy cycles were 6 (range 1-15). RECIST RR was 39% [90% CI: 26-53], and DCR was 98% (all 40 evaluable patients had disease control). In the 29 patients evaluated with Choi criteria, RR was 86%. 9 patients (22%) were downstaged to surgery, with 8 (20%) achieving R0 resection. Median PFS was 13 months [95% CI: 7-NR], with 12- and 24-months PFS rates of 51% and 37%, respectively. Median OS was 21 months [95% CI: 14-NR], with 12- and 24-months OS rates of 73% and 36%, respectively.

Conclusions: Combination of chemotherapy and SIRT achieved promising activity in first-line treatment of inoperable ICC, with median PFS and OS comparing favorably with chemotherapy-only historical data, and a significant proportion of patients downstaged to surgery. Toxicity was manageable. Further studies of SIRT in ICC are warranted.

712P Effect of adjuvant chemotherapy and chemoradiotherapy in patients with ampullary carcinoma: A NCDB analysis

G. Westin[1], B. Huffman[2], S. Alsidawi[3], A. Mahipal[3]

[1]Oncology, Mayo Clinic, Rochester, MN, USA, [2]Internal Medicine, Mayo Clinic, Rochester, MN, USA, [3]Medical Oncology, Mayo Clinic, Rochester, MN, USA

Background: Ampullary carcinoma is a rare gastrointestinal cancer and the benefit of adjuvant chemotherapy is debatable. We used the National Cancer Data Base (NCDB) to evaluate if adjuvant chemotherapy (AC) or adjuvant chemo-radiation (ACR) provides a survival benefit in patients undergoing resection.

Methods: Utilizing the NCDB from 2004-2012, 5949 patients who underwent ampullary tumor resection were identified. All patients had confirmed histological diagnosis, and follow up. Patients not considered candidates for AC or ACR were excluded. 2194 patients underwent surgical resection alone (S). This cohort was compared with 874 patients who received AC, and 1128 patients ACR. Patients were stratified into node negative (NN) or node positive (NP) disease. Overall survival (OS) was performed utilizing Kaplan-Meier method, and log-rank tests were used for statistical comparisons. Cox proportional hazards were performed to control for age, gender, race, type of facility (academic versus non-academic), income, education, Charlson-Deyo score (CDS), T size, and histologic grade. All tests were two sided and a P value of < 0.05 was considered significant.

Results: The median age at diagnosis was 65 years (range 20-90). In the NN group, median OS was not reached (NR) for AC, NR for ACR and 101 months (mo) for S ($p = 0.21$). In contrast in the NP group, median OS was 33 mo for AC, 35 mo for ACR

and 27 mo for S ($p < 0.0001$). In a multi-variate analysis of NP patients, AC or ACR were independent positive prognostic factors with Hazard Ratio 0.79 for AC (95% CI 0.68-0.9; $p = 0.0005$) and 0.76 for ACR (95% CI 0.67-0.8; $p < 0.0001$) when compared to S. No differences were seen when AC was directly compared to ACR. Older age, tumor size larger than 2 cm, poor histologic grade, high CDS, low income and black race were independent negative prognostic factors.

Conclusions: Adjuvant chemotherapy or chemoradiotherapy are associated with a significant survival benefit in patients with resected node positive ampullary carcinoma when compared to surgery alone. The addition of radiation, however, does not confer additional benefit over adjuvant chemotherapy. Patients with node negative disease do not seem to benefit from adjuvant therapy regardless of primary tumor size.

713P The mutational landscape of periampullary adenocarcinomas in relation to morphological subtype and patient survival

S. Lundgren[1], E. Karnevi[1], J. Elebro[1], B. Nodin[1], J. Eberhard[1], K. Leandersson[2], G.B. Jönsson[1], K. Jirström[1]

[1]Department of Clinical Sciences, Lund University, Lund, Sweden, [2]Cancer Immunology, Department of Translational Medicine, Lund University, Lund, Sweden

Background: Periampullary adenocarcinomas, including pancreatic cancer, are a heterogenous group of tumours. Despite improvements in oncological treatments in recent years, these patients still suffer from a poor prognosis. Emerging evidence shows that tumour morphology, intestinal type (I-type) and pancreatobililary type (PB-type), is a more relevant prognostic factor than anatomical tumour origin. The aim of this study was to map the mutational landscape in periampullary adenocarcinomas with particular reference to tumour morphology and prognosis.

Methods: The mutational status of 70 selected genes was mapped using next generation sequencing (NGS) in primary tumours from 103 patients with periampullary adenocarcinoma from a well-characterised consecutive cohort treated with pancreaticoduodenectomy at the University hospitals in Lund and Malmö, Sweden. Microsatellite instability (MSI) status was assessed by immunohistochemistry.

Results: The 5 most common mutations were TP53 ($n = 55$, 54.5%) followed by KRAS ($n = 27$, 46.5%), NF1 ($n = 45$, 44.6%), MAP3K1 ($n = 40$, 39,6%) and FGR1 ($n = 22$, 21.8%). Morphology or MSI status did not impact the burden of mutations. High tumour burden was not associated with patient survival. In the whole cohort, 9 mutations were prognostic (CDH1, CTNNB1, ERBB3, ERBB4, FGFR1, H6PD, KRAS, SH3BP4 and STK11). In I-type tumours, 6 mutations were prognostic (CDH1, CTNNB1, GATA3, KRAS, MYC and SH3BP4) while 5 mutations were prognostic in PB-type tumours (ERBB4, H6PD, NRAS, PARP1 and STK11). Notably, PARP1 and ERBB3 mutations were associated with improved prognosis. Adjusting for clinical parameters, two mutations remained significant in PB-type tumorus; STK11 (HR = 6.25; 95% CI 1.12-35.04) and PARP1 (HR = 0.86; 95% CI 0.10-0.71). In I-type tumorus, three mutations remained significant; KRAS (HR = 4.78; 95% CI 1.33-17.15), GATA3 (HR = 15.65; 95% CI 2.72-90.26) and CTNNB1 (HR = 9.03; 95% CI 1.18-69.05).

Conclusions: The results from this study demonstrate that the prognostic impact of different mutations, e.g. KRAS, in periampullary adenocarcinoma differs by morphological subtype. Thus, morphology is an important factor to consider in the development of novel targeted therapies and in biomarker studies.

714P Gemcitabine and platinum- based chemotherapy in first line treatment of hepatocholangiocarcinoma: An AGEO multicenter retrospective study

M. Salimon[1], C. Prieux-Klotz[2], D. Tougeron[3], T. Lecomte[4], M. Caulet[4], T. Matysiak Budnik[1], V. Hautefeuille[5], M. Tiako-Meyo[6], A. Zaanan[7], Y. Touchefeu[1]

[1]IMAD, Department of Gastroenterology, Nantes University Hospital, Nantes, France, [2]Department of Gastroenterology, Cochin University Hospital, Paris, France, [3]Department of Gastroenterology, CHU Poitiers, Jean Bernard Hôpital, Poitiers, France, [4]Department of Gastroenterology, CHU de Tours, Hôpital Trousseau, Chambray-lès-Tours, France, [5]Department of Gastroenterology, CHU Amiens-Picardie Site Nord, Amiens, France, [6]Department of Gastroenterology, Hôpital Européen Georges Pompidou, Paris, France, [7]Department of Gastroenterology, Hopital European Georges Pompidou, Paris, France

Background: Hepatocholangiocarcinoma (cHCC-ICC) is a rare primary hepatic tumor combining features of cholangiocarcinoma (ICC) and hepatocellular carcinoma (HCC). The aim was to evaluate the overall survival (OS), progression free survival (PFS) and prognostic factors in unresectable cHCC-ICC treated by gemcitabine (gem) and platinum- based chemotherapy in first line systemic treatment.

Methods: Data from patients treated for advanced cHCC-ICC by gem and platinum-based chemotherapy in six French university hospitals between 2008 and 2016, were retrospectively collected. The diagnosis of cHCC-ICC was based on histological analysis or, in case of typical histology of ICC or HCC, on discordant CT-Scan findings and/or tumor marker (alpha-fetoprotein, carbohydrate antigen 19-9, carcinoembryonic antigen) serum levels suggesting the alternative histology. OS and PFS were estimated by Kaplan-Meier method. Prognostic factors were analyzed by Log-rank test in univariate analysis and by Cox model in multivariate analysis. Statistical analysis was performed using Graph Pad Prism 6.

Results: Forty patients were included (70% men, median age 66 years [extremes 32-88]). cHCC-ICC was histologically proven in 55% of cases. At diagnosis, twenty-three patients (57.5%) had metastatic synchronous lesion. Twenty-nine patients (72.5%) were treated by gem + oxaliplatine (GEMOX), 9(22.5%) by GEMOX + bevacizumab, 2(5%) by gem + cisplatine. Eighteen patients (45%) received second line of treatment. In the first line, patients received a median of 10 cycles of chemotherapy (extremes 1-28). RECIST1.1 criteria were reported in 35 cases: 9 patients (25.7%) had partial response, 18 (51.4%) had stable disease, 8 (22.8%) had tumor progression at first evaluation. Median PFS and OS were 9 and 15.4 months, respectively. In multivariate analysis, significant prognostic factors of poor OS were: positive serology for hepatitis B virus and/or C (HR = 1.35 IC95% [1.13-13.24] $p = 0.031$), serum bilirubin level > 30µmol/L (HR = 1.66 IC95% [1.57-17.54] $p = 0.007$), ECOG score ≥ 2 (HR = 2.46 IC95% [2.23-61.75] $p = 0.004$).

Conclusions: These data suggest a chemosensitivity of cHCC-ICC to gemcitabine and platinum based chemotherapy.

715P Jab1 silencing inhibits proliferation and sensitizes to cisplatin in biliary tract cancer

J-W. Kim[1], A-R. Nam[2], J.E. Park[2], J-H. Bang[2], M.H. Jin[2], D-Y. Oh[3], Y-J. Bang[3]

[1]Department of Internal Medicine, Seoul National University Bundang Hospital, Seongnam, Republic of Korea, [2]Cancer Research Institute, Seoul National University College of Medicine, Seoul, Republic of Korea, [3]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea

Background: Jab1 is a coactivator of c-Jun that enhances the transcriptional function of c-Jun. Jab1 is frequently overexpressed in various cancers and is associated with poor prognosis of cancer patients. Thus, Jab1 could be a potential therapeutic target in cancer. However, the role of Jab1 in biliary tract cancer (BTC) has not been studied.

Methods: We evaluated the therapeutic potential of Jab1 inhibition in BTC. In vitro studies included western blot, cell growth inhibition assays, cell cycle analysis, wound healing assays, comet assays, real-time PCR, and cycloheximide chase assays. Female Balb/c athymic nude mice were used for in vivo studies.

Results: Among eight BTC cell lines tested (SNU245, SNU308, SNU478, SNU869, SNU1079, SNU1196, HuCCT-1, and TFK-1), many showed higher Jab1 expression levels. In addition, Jab1 silencing by siRNA increased p27 expression levels. Notably, SNU478 and HuCCT-1 cells exhibited profound Jab1 knockdown and increased p27 expression by Jab1-specific siRNA transfection. Jab1 silencing induced anti-proliferative and anti-migratory effects and resulted in G1 cell cycle arrest in SNU478 and HuCCT-1 cells. Jab1 knockdown alone induced spontaneous DNA damage, resulting in anti-proliferative and anti-migratory effects. Moreover, Jab1 knockdown potentiated the anti-proliferative and anti-migratory effects of cisplatin by increasing DNA damage. Interestingly, Jab1 silencing increased PTEN protein half-life without significant increase of PTEN mRNA expression levels, resulting in increased PTEN expression and decreased AKT and Src phosphorylation. In the HuCCT-1 mouse xenograft model, stable knockdown of Jab1 by shRNA also showed anti-proliferative effects in vivo, with decreased Ki-67 expression and AKT phosphorylation and increased TUNEL and p27 expression.

Conclusions: Jab1 knockdown demonstrated anti-proliferative and anti-migratory effects in BTC cells by increasing DNA damage and stabilizing PTEN, resulting in G1 cell cycle arrest and apoptosis. In addition, Jab1 silencing potentiated the anti-proliferative effects of cisplatin by enhancing DNA damage. Our data suggest that Jab1 may be a potential therapeutic target in BTC that is worthy of further investigations.

Background: We have conducted the Nationwide Cancer Genome Screening Project in Japan since April 2015 using Next Generation Sequencing in cancers of digestive system, called as the SCRUM-Japan GI-SCREEN. We evaluated the frequency of cancer genome alterations. We show the result of advanced biliary tract cancer cohort (aBC; intra hepatic bile duct (IHBD), extrahepatic bile duct (EHBD), gallbladder (GB), and ampulla of Vater (AV)).

Methods: This study is ongoing with the participation of 20 major cancer centers. Patients who plan to or receive systemic chemotherapy were eligible. DNA and RNA were extracted from FFPE tumor samples and were analyzed by the Oncomine Cancer Research Panel (OCP) which allows to detect gene mutation, copy number variant (CNV) and fusions across 143 genes in a CLIA certified CAP accredited laboratory. The detected genomic variant data were classified according to genetic drivers of cancer including gain- and loss-of-function or single nucleotide variant based on the Oncomine Knowledgebase.

Results: As of October 31st in 2016, a total of 108 aBC samples were analyzed and the sequence with the OCP was successfully performed in 73 (67.6%). The frequent/important mutations in 73 samples of which results were available were shown in table. The druggable CNVs (≥ 7 copies) were *CDK4/6* (n = 4), *EGFR* (2), *FGFR3* (2), and *ERBB2* (1). No gene fusion was detected. Proportion of gene mutations: n (%)

Table: 716P

	IHBD n = 31	EHBD n = 27	GB n = 10	AV n = 5
KRAS	10(32)	8(26)	2(20)	2(40)
TP53	5(16)	6(19)	6(60)	2(40)
BRAF	0	1(3)	0	1(20)
PIK3CA	0	0	4(40)	0
BRCA2	0	2(6)	0	0
ATM	1(3)	2(6)	1(10)	0
IDH1	3(10)	1(3)	0	0
FGFR2/3	2(6)	0	0	1(20)
ERBB3	1(3)	3(10)	0	0

Conclusions: This nationwide screening system is efficient to detect rare gene alterations in aBC. This novel knowledge provides an intriguing background to investigate new target approaches and represents a progress toward more precision medicine.

717P Prognostic implication of inflammation-based prognostic scores in patients with intrahepatic cholangiocarcinoma (iCCA) treated with first-line Gemcitabine plus Cisplatin (GEMCIS)

H. Cho, C. Yoo, K-P. Kim, H-M. Chang, B-Y. Ryoo

Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea

Background: There is increasing evidence that inflammation-based prognostic scores have prognostic value in several cancer types, including iCCA. However, most of the studies are focused on evaluating their value in patients with resectable disease. We retrospectively evaluated the prognostic implication of inflammation-based prognostic scores including modified Glasgow Prognostic Score (mGPS) based on serum albumin and C-reactive protein, neutrophil-lymphocyte ratio (NLR), and platelet-lymphocyte ratio (PLR) in patients with unresectable or metastatic iCCA.

Methods: Between April 2010 and May 2015, a total of 296 patients with histologically documented advanced iCCA were treated with first-line GEMCIS in Asan Medical Center, Seoul, Korea. Of these, 257 patients had complete data for inflammation-based prognostic scores and were included in this study. Primary endpoint was overall survival (OS).

Results: Median age was 59 years (range, 27-78) and 158 patients (61.5%) were male. Initially metastatic disease was the most common disease status at GEMCIS (n = 170, 66.1%) followed by recurrence after surgery (n = 44, 17.1%) and locally advanced unresectable disease (n = 43, 16.7%). With a median follow up duration of 25.0 months (95% CI, 19.6-30.4), median OS was 9.1 months (95% CI, 8.0-10.2). In univariate analyses, high mGPS and NLR scores were associated with poorer OS (mGPS 1-2 vs 0: median 6.9 vs 14.1 months, $p < 0.01$, and NLR 1-2 vs 0: 6.9 vs 11.8 months, $p < 0.01$). PLR was not associated with OS ($p = 0.39$). In the multivariate analysis including potential prognostic factors such as disease extent, number of metastatic sites, performance status and liver cirrhosis, only mGPS remained significant (1-2 vs 0; HR = 1.59, $p < 0.01$).

Conclusions: The current study suggests that mGPS might be the relevant prognostic index which can stratify the survival outcomes of patients with unresectable or metastatic iCCA who received first-line GEMCIS.

718P Phase 2 study of triplet chemotherapy with oxaliplatin, irinotecan and S-1 (OIS) as first-line treatment in patients with advanced biliary tract cancer (BTC)

C. Yoo[1], B. Han[2], K-P. Kim[1], H.S. Kim[2], J.H. Kim[3], H-M. Chang[1], B-Y. Ryoo[1], D.Y. Zang[2]

[1]Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [2]Internal Medicine, Hallym University Medical Center, Anyang, Republic of Korea, [3]Medical Oncology, Hallym University Medical Center, Seoul, Republic of Korea

Background: Although gemcitabine plus cisplatin has been established as the standard first-line chemotherapy for patients with advanced BTC based on the success of the ABC-02 trial, the overall prognosis is still poor as median survival of less than 1 year. Therefore, we investigated novel combination of three drugs including oxaliplatin, irinotecan and S-1, oral fluoropyrimidine, (OIS) for advanced BTC.

Methods: Chemotherapy-naïve patients with histologically documented unresectable or metastatic BTC were eligible for this study. Patients received oxaliplatin 65 mg/m2 Day 1, irinotecan 135 mg/m2 Day 1, and S-1 40 mg/m2 BID Day 1-7, every 2 weeks, until the disease progression or intolerable toxicities. Primary endpoint was objective response rate (ORR) defined by RECIST v1.1 and secondary endpoints include progression-free survival (PFS), overall survival (OS) and safety profile. According to the Simon's optimal two-stage design with type 1 error of 0.05 and a power of 80%, 31 patients were needed with a hypothesis of improving ORR from 20% to 35%.

Results: Between October 2015 and June 2016, a total of 32 patients were enrolled in two referral institutes in Korea. Median age was 64 years (range 40-76) and 24 (75%) patients were male. All but one patient (97%) had metastatic or recurrent disease. Intrahepatic lesion is the most common primary tumor site (n = 13, 41%) and followed by gallbladder (n = 11, 34%) and extrahepatic lesion (n = 8, 25%). With median follow-up duration of 10.1 months, patients received median 12 cycles (range, 1-21) of study treatment. ORR was 50% as partial response was achieved in 16 patients. Median PFS was 7.1 months (95% CI, 5.3-8.8) and median OS was not reached. The 1-year PFS and OS rates were 25% and 59%, respectively. Most common grade 3-4 adverse events were neutropenia (n = 10, 32%), followed by diarrhea (n = 2, 6%) and peripheral neuropathy (n = 2, 6%).

Conclusions: OIS triplet combination chemotherapy was feasible and showed promising efficacy outcomes as first-line treatment in patients with advanced BTC. Randomized trial is needed to validate the efficacy of this triplet regimen.

719P Prognostic impact of hepatitis B virus (HBV) infection in advanced intrahepatic cholangiocarcinoma (iCCA) patients (pts) treated with first-line gemcitabine plus cisplatin (GEMCIS)

E.J. Kim, H. Cho, C. Yoo, K-P. Kim, H-M. Chang, B-Y. Ryoo

Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea

Background: HBV infection is a well-known risk factor of iCCA. However, its prognostic impact has rarely been investigated in pts with advanced iCCA who received chemotherapy.

Methods: Between April 2010 and May 2015, a total of 296 pts with histologically documented advanced iCCA received first-line GEMCIS in Asan Medical Center, Seoul, Korea, and were included in this retrospective analysis. Primary endpoint was overall survival (OS). In the multivariate analysis, variables which showed potential association with survival ($p < 0.15$) in the univariate analysis were included.

Results: Median age was 59 years (range, 27-78), and 62 (20.9%) pts with hepatitis B surface antigen positive formed the HBV group. Initially metastatic disease was the most common disease status at the time of GEMCIS (n = 184, 62.2%) followed by recurrence after curative surgery (n = 69, 23.3%) and locally advanced unresectable disease (n = 43, 14.5%). In comparison with the non-HBV group, HBV group were related with young age (mean age 56.4 vs 60.0), male predominance (74.2% vs 57.3%), lower rates of elevated CA 19-9 (42.0% vs 68.5%) and alkaline phosphatase (42.6% vs 60.5%) ($p < 0.05$ for all). In univariate analysis, HBV infection showed marginal relationship with poor OS (vs non-HBV infection; median 8.3 vs 10.0 months; HR = 1.27, p = 0.13). In multivariate analysis including potential prognostic factors, however, HBV group was significantly associated with poorer OS (HR = 1.52, p = 0.02). In addition, initially metastatic disease (vs locally advanced/recurrent disease; HR = 1.49), number of metastatic sites ≥2 (vs 0-1; HR = 1.50), poor ECOG performance status (2 vs 0-1; HR = 1.94), elevated total bilirubin (vs normal; HR = 1.83), and albumin <3.5 g/dL (vs ≥ 3.5 g/dL; HR = 1.53) were significantly associated with poorer OS ($p < 0.05$ for all).

Conclusions: Our results suggest that HBV infection might be an independent poor prognostic factor in pts with advanced iCCA treated with first-line GEMCIS. Further translational research is needed to define the differences in the molecular phenotypes between HBV- and non-HBV-associated iCCA.

720P Inoperable carcinoma gallbladder: Comparison of two palliative chemotherapy regimens (gemcitabine-platinum versus CAPEOX)

H. Malhotra[1], A. Daga[2], D. Gangopadhayay[2], A. Yadav[1], A. Mathur[2], B. Malhotra[3]

[1]Medicine & Medical Oncology, SMS Medical College & attached Hospital, Jaipur, India, [2]Medicine, SMS Medical College & attached Hospital, Jaipur, India, [3]Microbiology, SMS Medical College & attached Hospital, Jaipur, India

Background: Cancer of the gall bladder (CaGB) constitutes one of the ten commonest cancers in women in north India. Palliative chemotherapy is indicated for the advanced stage, inoperable patient in good performance status (PS). There is no standard-of-care regimen for this disease. We prospectively evaluated the efficacy & safety of GEMPLAT v/s CAPEOX chemotherapy in this cohort of patients.

Methods: Fifty chemo-naive, newly diagnosed patients (25 in each arm) of inoperable CA GB, in good PS (0, I, II) were included. Patients were randomised to receive either GEMPLAT or CAPOX. Primary end point was response rates (RR) & progression free survival (PFS); secondary end point: Overall survival (OS), toxicity & quality of life (QOL). Response assessment was done after every two cycles using by the RECIST 1.1 criteria. QOL was assessed every two cycles.

Results: Thirty one females & 19 males, mean age of 45.7 years (range 32 to 69) were included. There were no CRs in either arm. Partial response (PR) & stable disease (SD) was seen in 6 (24%) & 8 (32%) patients, respectively, in GEMPLAT arm; and 2 (8%) and 5 (20%) achieved PR and SD, respectively in CAPEOX group. Overall response rate (ORR) was 24% & 8%, respectively, for GEMPLAT & CAPOX. The median OS in GEMPLAT arm was 9.9 months versus 2.6 moths in CAPOX. The median PFS was higher in GEMPLAT group (7.6 months) as compared to CAPOX group (1.5 months). Grade 3/4 anemia & neutropenia occurred in 3 (12%) & 2 (8%) patients in the GEMPLAT arm, respectively with no grade 3/4 hematological toxicities in CAPOX arm. Five (20%) patients developed grade 3/4 transaminitis on GEMPLAT. One (4%) patients in CAPOX arm developed sensory neuropathy and 3 (12%) have grade 3/4 skin toxicity.

Conclusions: In our study, the GEMPLAT regimen showed higher RR, OS and PFS as compared to CAPOX. QOL was better in the GEMPLAT arm. CAPOX regimen was better tolerated and less toxic. The main toxicity of GEMPLAT was haematological & hepatic while that of CAPEOX was dermatological. We conclude that GEMPLAT should be the standard-of-care first line palliative chemotherapy regimen for inoperable CaGB patients in good PS. Larger, multi-centre studies are needed to confirm our findings and to compare CAPOX/other regimens with GEMPLAT.

721P Surgical indication for advanced intrahepatic cholangiocarcinoma according to the optimal preoperative carbohydrate antigen 19-9 cut-off value

Y. Yamamoto, T. Sugiura, Y. Okamura, T. Ito, R. Ashida, K. Uesaka

Division of Hepato-Biliary-Pancreatic Surgery, Shizuoka Cancer Center, Shizuoka, Japan

Background: The EASL guidelines for intrahepatic cholangiocarcinoma (ICC) discouraged resection for ICC patients with lymph node metastasis (LNM), intrahepatic metastasis (IM), or vascular invasion (VI). The clinical impact of hepatectomy in ICC patients with IM, periductal infiltration (MF+PI), LNM, and VI remains unclear.

Methods: Patients ICC who underwent hepatectomy for MF dominant ICC and unresected patients due to IM, LNM, or locally advanced tumors (unresectable group) were enrolled. The clinical impact of CA19-9 and hepatectomy were evaluated in ICC. The best CA19-9 cut-off value for ICC was examined based on the overall survival (OS). The surgical outcomes of patients who underwent hepatectomy for ICC with LNM, IM, VI, or PI were investigated, and survival of those patients was compared with that of patients with unresectable ICC based on their prognostic factors.

Results: A total of 73 resected patients and 20 unresectable patients were enrolled. The optimal CA19-9 cut-off value (based on the greatest difference in overall survival [OS]), was 300 U/mL. The OS at CA19-9<37 U/mL (n = 26; MST, 49.6 months) and 37-300 U/mL (n = 28; MST, 45.1 months) was comparable (P=0.842); however, the OS at CA19-9=37-300 U/mL was significantly better than that at CA19-9≥300 U/mL (n = 19; MST, 15.3 months; P<0.001). CA19-9≥300 U/mL, IM, and MF+PI were independent prognostic factors. Patients with CA19-9<300 U/mL who developed IM (MST, 35.2 months), MF+PI (MST, 32.9 months), LNM (MST, 34.0 months), VI (MST, 32.9 months) or who required major vascular resection (MST, 45.1 months) had a better prognosis than those with CA19-9≥300 U/mL who developed IM (MST, 8.7 months; P=0.001), MF+PI (MST, 7.5 months; P=0.040), LNM (MST, 8.7 months; P=0.005), or VI (MST, 8.7 months; P = 0.007), or who required major vascular resection (MST, 14.8 months; P=0.015); their prognosis was comparable to the unresectable group. (P=0.750, 0.767, 0.391, 0.224, 0.188)

Conclusions: Even if ICC patients develop IM, PI, LNM, or VI, or require major vascular resection, hepatectomy can be considered for selected patients with CA19-9<300 U/mL. However, surgeons should carefully determine the indications for resection in the patients with CA19-9≥300 U/mL.

722P A phase 2 study of lenvatinib monotherapy as second-line treatment in unresectable biliary tract cancer: Primary analysis results

M. Ikeda[1], T. Sasaki[2], C. Morizane[3], N. Mizuno[4], F. Nagashima[5], S. Shimizu[6], N. Hayata[7], H. Ikezawa[7], T. Suzuki[7], R. Nakajima[7], C. Dutcus[8], M. Ueno[9]

[1]Department of Hepatobiliary and Pancreatic Oncology, National Cancer Center Hospital East, Kashiwa, Japan, [2]Hepato-Biliary-Pancreatic Medicine Department, The Cancer Institute of JFCR, Tokyo, Japan, [3]Hepatobiliary and Pancreatic Oncology Division, National Cancer Center Hospital, Tokyo, Japan, [4]Department of Gastroenterology, Aichi Cancer Center Hospital, Nagoya, Japan, [5]Department of Internal Medicine, Medical Oncology, School of Medicine, Kyorin University Hospital, Tokyo, Japan, [6]Department of Gastroenterology, Saitama Cancer Center, Saitama, Japan, [7]Eisai Co., Ltd., Tokyo, Japan, [8]Clinical Development, Eisai Inc., Woodcliff Lake, NJ, USA, [9]Hepatobiliary and Pancreatic Oncology, Kanagawa Cancer Center Hospital, Yokohama, Japan

Background: Lenvatinib (LEN) inhibits vascular endothelial growth factor receptors, fibroblast growth factor receptors, and platelet-derived growth factor receptor-α. These targets have been shown to be expressed in patients (pts) with biliary tract cancer (BTC). A planned interim analysis of this phase 2 study demonstrated preliminary efficacy of LEN 24 mg/d in pts with BTC.

Methods: This open-label phase 2 study conducted in Japan enrolled pts aged ≥ 20 years with a confirmed unresectable BTC, measurable disease per Response Evaluation Criteria in Solid Tumors v1.1, and 1 prior gemcitabine (GEM)-based doublet chemotherapy to receive LEN 24 mg/d. The primary endpoint was objective response rate (ORR). Secondary objectives included disease control rate (DCR), overall survival (OS), progression-free survival (PFS), safety, and pharmacokinetics.

Results: The primary analysis was performed with data on 26 pts. Median age was 64 years and 15 pts (58%) were men. Eastern Cooperative Oncology Group performance status was 0 for 19 pts (73%) and 1 for 7 pts (27%). Six pts (23%) had prior surgery, 20 pts (77%) received prior GEM + cisplatin therapy, and 6 pts (23%) received prior GEM + TS-1. There were 6 pts (23%) with intrahepatic bile duct, 8 (31%) with extrahepatic bile duct, 10 (39%) with gallbladder, and 2 (8%) with ampulla of Vater primary tumor locations. ORR was 12% (90% CI: 3.2–27.2) by both independent and investigator review. DCR was 85% (90% CI, 68.2–94.6) by investigator, and 46% (90% CI, 29.2–63.8) by independent, review. Median PFS was 3.2 months (95% CI, 2.8–7.2) and 1.6 months (95% CI, 1.4–3.2) by investigator and independent review, respectively. Median OS was 7.4 months (95% CI, 4.5–11.3). All pts had treatment-emergent adverse events (TEAEs). Common TEAEs included hypertension, dysphonia, proteinuria, palmar-plantar erythrodysesthesia, decreased appetite, thrombocytopenia, and fatigue. TEAEs led to dose reduction in 20 pts (77%) and discontinuation in 2 pts (8%).

Conclusions: LEN 24 mg/d showed anti-tumor activity in pts with unresectable BTC who had failed GEM-based combination therapy. Toxicities were manageable with dose modifications, reductions, or discontinuations.

723P Genotyping and mRNA profiling reveal actionable targets in biliary tract cancers

K. Papadopoulou[1], S. Murray[2], K. Manousou[1], I. Tikas[1], C. Dervenis[1], J. Sgouros[1], D. Rontogianni[1], S. Lakis[1], C. Poulios[1], S. Pervana[1], G. Lazaridis[1], G. Fountzilas[1], V. Kotoula[1]

[1]Data Office, Hellenic Cooperative Oncology Group (HeCOG), Athens, Greece, [2]N/A, BioPath Innovations SA, Athens, Greece

Background: Biliary tract cancer (BTC) is a heterogeneous disease of poor prognosis and variable pathogenesis, prompting for the identification of tumor features that may aid in the design of personalized treatments. Herein, we examined genotype and angiogenesis-related features in BTC.

Methods: We applied genotyping (Sanger, qPCR, 101-gene panel NGS) and mRNA relative quantification methods in 84 FFPE BTC (55 gallbladder [GBC], 14 intrahepatic [ICC], 15 extrahepatic [ECC] carcinomas), along with b-catenin immunohistochemistry (IHC).

Results: We identified 541 mutations in 68 (81%) tumors. Six GBC had 17 – 160 mutations, multiple per gene (hypermutated [hm]); non-hm tumors had <14 mutations. Top mutated genes were CTNNB1 (36%); PTEN (33%); TP53 (31%); PIK3R1 (29%); PIK3CA (13%); BRCA2 and KRAS (12%); BRCA1 (11%). In comparison to non-hm GBC, all hmGBC carried mutations in BRCA2 and other homologous recombination repair (HRR) genes, and also in PD1, but not in CTNNB1 and KRAS. None of the known pathogenic BRCA2 p.D2723G and BRCA1 p.Q563* and c.5266dupC was present at frequencies expected for germline mutations. We observed copy gains in EGFR (35% of tumors) and less frequently in PRKAR1A, PIK3CA, PIK3R1, MET and ERBB2. TP53 mutations were prevalent in GBC ($p < 0.001$) and PRKAR1A copy gains in ICC ($p = 0.007$). PTEN was co-mutated with CTNNB1 ($p < 0.001$). Unrelated to CTNNB1 mutations, nuclear b-catenin was detected in 45% of tumors, among them in 5/6 hmGBC. We observed strong mRNA expression correlation of the two neuropilins (NRP1 and NRP2) with each other (Spearman's rho 0.59) and with the endothelin receptor (EDNRA; NRP2 rho 0.66; NRP2 rho 0.51), as well as between VEGFA and its receptors (FLT1 rho 0.49; KDR rho 0.45). All PIK3CA mutated tumors expressed endothelin1 mRNA ($p = 0.010$). Most tumors expressing nuclear b-catenin were negative for VEGFC ($p = 0.009$) and FLT4 ($p = 0.002$) mRNA expression.

Conclusions: We confirmed the presence of different genotypes among GBC, ICC and ECC. Novel findings are the coexistence of PI3K and WNT pathway gene alterations in BTC, their association with angiogenesis, and the hmGBC subtype with HRR gene mutations, which may be considered for new treatment options in this difficult to treat disease.

724P HER-2/HER-3 pathway as a potentially-actionable target in biliary tract cancers (BTCs): A retrospective analysis

A. Lamarca[1], S. Galdy[1], S. Moghadam[2], J. Rogan[2], M.G. McNamara[3], R.A. Hubner[1], A. Cramer[4], J.W. Valle[3]

[1]Medical Oncology, The Christie NHS Foundation Trust, Manchester, UK, [2]Biobank, Manchester Cancer Reseacrh Centre, University of Manchester, Manchester, UK, [3]Medical Oncology, The University of Manchester/The Christie, Manchester, UK, [4]Pathology Partnership, The Christie NHS Foundation Trust, Manchester, UK

Background: Cholangiocarcinoma (CC), gallbladder cancer (GBC) and ampullary cancer (AC) (collectively BTCs) are poor-prognosis cancers. Cisplatin-gemcitabine chemotherapy is the standard treatment for patients (pts) with advanced BTC. New treatment targets are warranted; the human epidermal growth factor receptor (HER)-2 and HER-3 pathways may be potential candidates. High-quality data regarding expression and/or amplification rates in BTC are lacking.

Methods: Pts diagnosed with BTC and with available paraffin-embedded archival tissue were eligible. Seventy consecutive pts were required (power 0.91; assumptions: 5% (no expression) vs. 15% (expression of interest); α-error 0.1). All pts had been previously consented for tissue storage for research purposes. The study was approved by the local BioBank Ethics Committee. Overexpression of HER-2 and HER-3 was analysed by immunohistochemistry (IHC) following standard guidelines (gastric criteria were followed for HER-2); samples with "2+; borderline" IHC expression underwent additional fluorescence in-situ hybridisation (FISH). Kaplan Meier and Cox Regression analyses were employed for survival. Logistic regression was used to identify factors associated with HER overexpression.

Results: Of 167 screened pts between Jan-13 and Jul-15, 76 samples were retrieved for quality assessment; 67 were eligible with a median age of 65.6 years (range 32.9-79.3); 51.2% were female; 85.1% had ECOG performance status 0-1; all were adenocarcinomas. Primary site was GBC (n = 10, 14.9%), CC (n = 44, 65.7%; n = 26 intra-hepatic (ICC), n = 18 extra-hepatic (ECC)) and AC (n = 13, 19.4%). Stage at diagnosis: I/II (n = 21, 31.3%) or III/IV (n = 46, 68.7%). Estimated median overall survival (OS) for all pts was 15.9 months (95% CI 11.1-20.3). HER-2 overexpression was identified in 1 pt (1.5%). HER-3 overexpression was identified in 16 (23.9%): 1 pt was classified as "3+; positive" by IHC and 15 were confirmed by FISH following a "2+" expression in IHC. Neither HER-2 ($p = 0.103$) nor HER-3 ($p = 0.087$) impacted on OS. No factors related to HER-3 overexpression were identified.

Conclusions: HER-3 is overexpressed in a significant subset of pts diagnosed with BTC; treatment targeting this pathway may warrant evaluation.

725P Actionable molecular alterations in advanced biliary tract carcinomas: Preliminary data from the ProfiLER program (NCT01774409)

P. Cassier[1], C. de la Fouchardiere[1], P. Guibert[1], D. Pissaloux[2], C. Pacaux[1], C. Terret[1], L. Eberst[1], M. Sarabi[1], V. Attignon[2], Q. Wang[3], V. Corset[4], D. Perol[4], J-Y. Blay[1], F. Desseigne[1]

[1]Department of Medical Oncology, Centre Léon Bérard, Lyon, France, [2]Département de Recherche Translationnelle, Centre Léon Bérard, Lyon, France, [3]Recherche Translationnelle, Centre Léon Bérard, Lyon, France, [4]Département de Recherche Clinique, Centre Léon Bérard, Lyon, France

Background: Patients (pts) with advanced biliary tract cancers (BTC) have poor prognosis and limited therapeutic option. The objectives were to characterize tumor genomic alterations for patients diagnosed with BTC enrolled in the ProfiLER program and identify actionable targets.

Methods: The ProfiLER program is a multicentric prospective molecular profiling trial in patients with advanced cancers. DNA extracted from either archival or freshly collected tumor samples was analyzed by targeted exon sequencing (NGS) of 59 cancer related genes and whole genome array comparative genomic hybridization (CGH). Genomic profiles were discussed at a dedicated molecular tumor board (MTB) for recommendation of molecularly targeted agents (MTA) when applicable.

Results: Of 2184 included pts in the ProfiLER program, 45 pts diagnosed with advanced BTC (intrahepatic cholangiocarcinoma – ICC, n = 32; vesicular carcinoma, n = 7; main biliary duct, n = 5; primary was unknown for one pt) were included between March 2013 to April 2017. Median age was 61 (range 35-78) years, and 21 pts (47%) were women. The median time from inclusion to MTB discussion was 12 (range 3-99) weeks. NGS was feasible for 31 pts (69%) and CGH for 24 (53%), both analyses were available for 22 (49%) and at least one analysis was available for 34 (75%) pts. 19 pts (56% of 34 analyzed pts) had at least one actionable alteration: *CDKN2A* homozygous deletion (n = 8), *MDM2* amplification (n = 3) and *PDGFRA* amplification (n = 5) were the only recurrent alterations. Among 31 pts with NGS data, 7 had TP53 mutations, 4 had KRAS mutations while none had BRAF mutations. Four pts received MTA based on the alteration identified (CDK4/6 inhibitor for CDK4 amplification, ERBB2 inhibitor for a ERBB2 mutation, EGFR inhibitor for EGFR mutation and mTOR inhibitor for homozygous TSC2 deletion), progressive disease was the best response in all pts.

Conclusions: CGH and NGS identified actionable alterations in 56% of pts with BTC for whom analyses could be performed. However, the analyses were both feasible in only 49% of patients due to the use of archival biopsy samples in most cases.

Background: Advanced biliary tract cancers (aBTCs) are heterogeneous diseases with a median overall survival (OS) < 1year. Platinum-based chemotherapy doublets are the frontline standard-of-care. Increasing evidence points out the strong addiction of aBTCs to druggable oncogenic alterations. We assessed the success rate and the clinical benefit of administering molecular targeted agents (MTAs) based on the molecular alterations found in patients with aBTCs.

Methods: Patients with aBTCs were prospectively enrolled in our prospective molecular screening program (MOSCATO 01). An on-purpose tumor biopsy was performed for each patient, followed by high-throughput molecular analysis. Patients were then guided to MTAs matching the molecular alterations. The primary endpoint was progression-free survival (PFS), with clinical benefit defined by a PFS ratio (PFS [MTA]/PFS [prior line]) >1.3.

Results: From November 2011 to March 2016, among 1036 adult patients included in the MOSCATO-01 trial, 48 biopsy procedures were performed in 43 patients (4%) with aBTC (4 patients re-included, one 3 times).Thirty three patients (77%) had intrahepatic cholangiocarcinoma. Patients had failed a median of 2 previous lines (range, 1-5). Successful biopsy procedures and DNA extractions enabled molecular analysis in 38 samples (79%), and at least one molecular alteration was detected in 35 samples (71%). Following analysis, 25 patients could be orientated to an appropriate early clinical trial or accessible MTA (25/38, 66%), and 19 patients could be treated on the basis of molecular alterations (19/38, 50%). For the biology-driven treatment group, The PFS ratio was 1.52 [0.08, 7.1]. Six patients (32%) had an objective response (complete [CR] or partial [PR] response), 16 (84%) had a clinical benefit (stable disease+PR+CR), and 7 (37%) had a PFS≥6 months. This strategy led to a significant overall survival improvement compared to patients who were not treated according to their tumor molecular characterization (HR = 0.26 [95%CI, 0.10 − 0.67], p = 0.003).

Conclusions: With 25 patients out of 48 inclusions (52%) driven to a MTA, patients with aBTCs are ideal candidates for molecular profiling.

Background: Previous studies have shown increased survivals in patients (pts) with borderline (BR) or locally advanced (LA) pancreatic adenocarcinoma (PAC) resected after induction FOLFIRINOX (i-FLX). Two-thirds of pts received also chemoradiotherapy (CRT) in most series. The aim of this study was to evaluate the impact of preoperative CRT after i-FLX in pts resected for BR or LA PAC.

Methods: Data of pts who underwent a curative intent resection after i-FLX with or without concomitant fluoropyrimidine- or gemcitabine-based CRT in 23 French centers from AGEO/FRENCH groups were reviewed in this retrospective study.

Results: From November 2010 to December 2015, 203 pts (119 men, median age of 61.7 years, 106 BR and 97 LA) underwent a pancreatic resection after a median number of 6 cycles (1-30) of i-FLX. CRT was administered in 102 pts (50%), 49 (46%) BR and 53 (54%) LA, with 54 Gy (45-59) median of radiation dose. Initial median tumour size was 31.5 mm (10-110), 82.3% located in the pancreatic head. 40% (n = 80) of tumours required vascular resection. Post-operative mortality (D-60) and morbidities (grade 3-4) were 3.4% and 19.7%, respectively. R0 resection was achieved in 83.3% (n = 169) of pts, higher in those receiving CRT (89.2% vs. 76.2%; p = 0.01). The histological complete response (ypT0N0) and major response (ypT0-1N0) rates were 11% (n = 22) and 23% (n = 47) respectively, significantly higher in pts with CRT (16.0% vs. 5.1%;

p = 0.009 and 32.0% vs. 13.4%; p = 0.001). After a median follow-up of 34.4 months, recurrence occurred in 118 pts (58.1%) and 76 (37.4%) died. Median DFS and OS were 16.7 [95% CI: 12.7-20.7] and 46.7 months [95% CI: 37.7-55.7] respectively. Pts receiving additional CRT had longer disease free survival (19.0 vs. 13.3 months; p = 0.17) and significantly longer overall survival than those receiving i-FLX alone (62.9 vs. 35.0 months; p = 0.028).

Conclusions: In this retrospective study, preoperative CRT after i-FLX seems to improve R0 resection rates and histological responses in pts resected for BR or LA PAC. Surgery after i-FLX seems to be safe even when combined with CRT. This strategy should be further evaluated in a prospective manner.

728P Intratumoral heterogeneity of SMAD4 immunohistochemical (IHC) expression and its role in prediction of recurrence patterns in patients with resectable pancreatic cancer (PC)

I. Pokataev[1], A. Kudaibergenova[2], A. Artemyeva[3], D. Podluzhnyi[4], N. Kudashkin[4], Y. Patyutko[4], E. Moroz[5], E. Kharchenko[3], A. Popova[1], M. Fedyanin[1], A. Rumyantsev[1], I. Bazin[1], A. Tryakin[1], E. Glukhov[4], O. Sekhina[1], D. Chekini[1], S. Tjulandin[1]

[1]Department of Clinical Pharmacology and Chemotherapy, N. N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation, [2]Department of Cytology, N. N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation, [3]Department of Morphology, Petrov Institute of Oncology, Saint Petersburg, Russian Federation, [4]Department of Surgery, N. N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation, [5]Department of Morphology, N. N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation

Background: Up to 30% of patients with resectable PC have only locoregional recurrences and never experience metastatic disease. Several authors reported SMAD4 expression can predict locoregional pattern of PC progression. The aim of our study was to evaluate consistency of SMAD4 expression in different tumor areas and its correlation with patterns of PC recurrence.

Methods: Records of PC patients treated in N.N. Blokhin Russian Cancer Research Center since 2002 to 2015 were analyzed. Inclusion criteria for this retrospective analysis were: nonmetastatic morphologically confirmed PC, R0-R1 resection and archive tumor samples availability. Formalin-fixed, paraffin-embedded tissue sections of different areas of the primary tumor (central area and zones of invasion) and of lymph node metastases were analyzed via IHC for SMAD4 expression using TMA technology.

Results: A total of 356 tissue sections obtained from 91 patients were assessed for SMAD4 expression. Positive SMAD4 expression was revealed in tumor blocks of 26 patients. There was high intratumoral heterogeneity of SMAD4 expression: only in 4 of 26 patients (15.4%) SMAD4 expression was positive in all assessed tumor slides. There were 54 recurrences (9 locoregional, 41 distant and 4 both local and distant) with median follow-up 21.7 months. There were no correlation between SMAD4 expression and locoregional recurrence pattern (Goodman & Kruskal's tau coefficient 0.08 ± 0.03, p = 0,13). There was no difference in distant recurrence-free survival by SMAD4 IHC expression status: medians were 11.8, 19.5 and 7.1 months for patients with SMAD4 negative, heterogeneous or positive tumors, respectively (p = 0.987). SAMD4 status also showed no prognostic significance: medians overall survival were 20.5, 32.6 and 15.2 months for patients with SMAD4-positive, heterogeneous and negative tumors, respectively (p = 0.131).

Conclusions: Different areas inside the primary tumor and lymph node metastases heterogeneously express SMAD4. SMAD4 IHC expression is not a biomarker of a recurrence pattern following surgical resection for PC.

729P Outcome of patients with pancreatic adenocarcinoma with complete pathological response following neo-adjuvant therapy

H.R. Kourie[1], A. Sa Cunha[2], S. Pernot[1], R. Coriat[3], A. Sauvanet[4], N. Regenet[5], S. Louafi[6], J-B. Bachet[7], D. Pietrasz[7], J. Taieb[1]

[1]Gastroenterology and Digestive Oncology, Hôpital Européen Georges-Pompidou, Sorbonne Paris Cité Université Paris Descartes, Paris, France, [2]Centre Hépato-Biliaire, Hôpital Paul Brousse, Unité d'Hospitalisation Chirurgie Hépatique, Biliaire et Pancréatique, Villejuif, France, [3]Gastroenterology and Digestive Oncology, Hôpital Cochin, Paris, France, [4]Hôpital Beaujon - Université Paris VII, Service de Chirurgie Hépatobiliaire et Pancréatique - Department of HBP Surgery Pôle des Maladies de l'Appareil Digestif (PMAD), Clichy, France, [5]Service de Chirurgie Digestive et Endocrinienne, CHU Nantes, Nantes, France, [6]Oncology, Centre Hospitalier de Longjumeau, Longjumeau, France, [7]Department of Gastroenterology, CHU Pitié Salpetriere, Paris, France

Background: Recently, the natural history of metastatic pancreatic adenocarcinoma (PC) has changed after the introduction of new chemotherapeutical regimens FOLFIRINOX and gemcitabine/nab-paclitaxel, with median overall survival exceeding the year. These regimens were also largely prescribed in the neo-adjuvant setting for locally advanced (LAPC) and borderline (BPC) PC leading sometimes to a complete pathological response (CPR) rarely seen with previous neoadjuvant regimens. The aim of this study was to assess outcomes of patients (pts) who presented CPR after induction therapy for PC.

Methods: We retrospectively identified pts with PC presenting CPR after neo-adjuvant therapy in 7 participating French centers from the AGEO group between November 2010 and March 2017.

Results: 26 pts were enrolled, 12 had LAPC, 13 BPC and 1 oligo-metastatic PC; M/F ratio was 1.6 and mean age was 61 years. All pts were treated with neo-adjuvant FOLFIRINOX (n = 26), de-escalated to gemcitabine (n = 1) and FOLFIRI (n = 2). The median number of cycles was 6 [4-24] and 85% of pts received neo-adjuvant radiation therapy after chemotherapy. Response to neo-adjuvant chemotherapy (RECIST V1.1), was as follow: CR 8% PR 57%, SD 27% and 8% were not evaluated. 30% of pts received adjuvant chemotherapy mainly with gemcitabine and 9 (35%) relapsed (distant metastases, n = 8). Median time to recurrence in pts that replapsed was 12.9 months. After a median follow-up of 29.5 months, the median overall survival (OS) from surgery was not reached and the median disease free survival was 38.8 months. The 1-year and 2-year OS rates were respectively 100% and 94%. The 1-year and 2-year DFS rates were 86% and 70%.

Conclusions: CPR seem to be an important prognostic marker in pts resected of a PC after neo-adjuvant therapy. The limited recurrences rate and the 1 and 2-year OS and DFS rates are very promising. A longer follow-up and prospective series are now necessary to confirm the favorable outcomes of these PC with CPR.

Background: Disease burden and cumulative toxicity due to chemotherapy may negatively impact QoL of pts with cancer. Early results from the LAPACT trial suggest promising efficacy of *nab*-P + G in LAPC. An evaluation of the potential impact of *nab*-P + G on health-related QoL is warranted.

Methods: During induction, treatment-naive pts with unresectable LAPC and ECOG PS ≤ 1 received 6 cycles (C) of *nab*-P 125 mg/m^2 + G 1000 mg/m^2 D 1, 8, and 15 of each 28-day C. After induction, pts without PD or unacceptable AEs were eligible for the investigator's choice (IC) of continued treatment (Tx) with *nab*-P + G, chemoradiation, or surgery. Surgery could occur prior to completing 6 C if the investigator deemed a sufficient tumor response. Pt-reported QoL, a secondary endpoint, was assessed via EORTC QLQ-C30 and QLQ-PAN26 at initial screening, during the induction and IC phases on D 1 of each C, and at follow-up after the last dose. Results presented here are from the induction phase. Data for pts receiving their first Tx dose by Oct 1, 2016 are reported.

Results: A total of 101 pts received Tx, and 75% (76/101) pts had a baseline and ≥ 1 postbaseline QoL assessment. The median age was 65 years (range, 42-85); 53% had an ECOG PS 1. All QoL dimensions were improved/stable in ≥ 67% of pts (Table). In general, median time to improvement was ≤ 1 week of completing the first Tx C (28 days/C). A majority (> 60%) of pts had ≥ 1 complete resolution of anxiety (tense), constipation, depression, nausea, or pain during induction. Forty-two percent of pts received additional Tx during the IC phase.

Conclusions: QoL was generally improved/stable during induction, with some dimensions improving within 1 week of completing the first C. This suggests that QoL is

731P Prognosis of familial pancreatic cancer (FPC): A matched case analysis

G.M. O'Kane[1], A. Borgida[2], A. Dodd[1], K.L. Aung[1], S. Holter[2], J. Knox[3], S. Gallinger[1]
[1]*McCain Pancreatic Centre, University Health Network, Princess Margaret Cancer Centre, Toronto, ON, Canada,* [2]*Zane Cohen Centre, Lunenfeld-Tanenbaum Research Institute, Toronto, ON, Canada,* [3]*Department of Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: FPC is a putative genetically heterogeneous syndrome defined as kindreds with multiple blood relatives with pancreatic adenocarcioma (PDAC). It has been hypothesized that germline mutations in DNA repair genes contribute to FPC, resulting in variable outcomes and response. We evaluated survival in FPC patients (pts) with resectable and unresectable PDAC.

Methods: Pts were identified from the Ontario Pancreatic Cancer Study database, recruited from January 1998-July 2016. All pts were seen by genetic services. FPC pts were age and stage matched with cases without a family history of PDAC and who tested germline BRCA mutation negative (non-FPC). Stage was classified as early operable (I/II) or late inoperable (III/IV). Pts were matched within 5 years of the treatment period. Only those who had either received surgery or at least 1 cycle of chemotherapy were included. The Kaplan-Meier method was used to assess survival.

Results: 144 pts were evaluated, 72 in each cohort. In the FPC group, 65 pts had at least 1 FDR with PDAC and 7 pts, at least 2 relatives (1^{st}-3^{rd} degree) with PDAC. Median age was 66 years; there were more females in the FPC group (54% vs 49%). 33 pts (46%) in each group had early stage disease and received surgery. Adjuvant therapy was given in 70% and 73% of the FPC and non-FPC cohorts respectively. 1 FPC pt, received adjuvant gemcitabine/erlotinib. 6 non-FPC pts received FOLFIRINOX, 3 as neo-adjuvant and 3 as adjuvant treatment. Of those with late stage disease, (n = 39 each), combination chemotherapy was given in 23 (59%) and 28 (72%) pts in FPC *vs* non-FPC groups respectively. The median overall survival (OS) was 16 months (mths) in the FPC group *vs* 13mths in the non-FPC group (p = 0.46). Stratifying by stage, in FPC vs non-FPC pts, median OS in early disease was 31 *vs* 27 mths (p = 0.73) and in late disease 13 vs 9 mths (p = 0.12). Platinum was used in 18 (46%) FPC and 17 (44%) non-FPC pts with late disease. Platinum regimens improved median OS overall compared to no platinum (12mths vs 9mths, p = 0.04) but was not associated with FPC status.

Conclusions: FPC is poorly understood but trends towards a better prognosis and response to therapy. The use of platinum based chemotherapy in these pts could be considered; however further research is warranted.

732P Should pancreatic cancer be included in BRCA1/2 testing criteria?

M. Venturelli[1], A. Toss[1], S. Pipitone[1], I. Marchi[1], E. Tenedini[2], V. Medici[2], E. Tagliafico[2], E. Razzaboni[1], F. Spaggiari[1], E. De Matteis[3], S. Cascinu[1], L. Cortesi[1]

[1]Department of Oncology and Hematology, University of Modena and Reggio Emilia, Modena, Italy, [2]Center for Genome Research, University of Modena and Reggio Emilia, Modena, Italy, [3]Department of Oncology and Hematology, Vito Fazzi Hospital, Lecce, Italy

Background: BRCA1/2 mutation carriers have an increased risk for breast cancer (BC), ovarian cancer (OC), prostate cancer and pancreatic cancer (PC). On this basis, the NCCN Guidelines include prostate and PC among the BRCA testing criteria. In our Institution, BRCA diagnostic test is exclusively offered to patients affected by BC or OC, according to the Modena criteria, or to healthy women with BRCAPro> 40%. The aim of this study was to compare the rate of positive BRCA test in families with PC, classified according to NCCN guidelines or Modena criteria.

Methods: We retrospectively analyzed families with family history of PC registered in the archive of our Family Cancer Clinic. Analysis of BRCA1/2 mutation was evaluated in these families and the BRCA mutation detection rate was calculated according to both selection criteria. We also evaluated age at diagnosis and overall survival of patients affected by PC.

Results: 435 families with at least one diagnosis of PC have been identified. 393 families had PC and BC and/or OC cases and were included in our analysis. 55.5% of these families were candidate to BRCA testing according to the Modena Criteria, whereas 90.8% of families were candidate according to the NCCN Guidelines. 65.6% of families selected according with the Modena Criteria underwent BRCA test, identifying 19 BRCA1 mutations and 16 BRCA2 mutations (detection rate 24.5%). 45.9% of families with the NCCN Criteria underwent the test with the identification of the same mutations (detection rate 21.3%). Mean age at PC diagnosis was lower in patients with family history of BC and/or OC (65.8 years) and in BRCA mutated families (65.7 years) than in general population (72 years). One-year OS rate was higher in patients with family history of BC and/or OC (41.3%) and in BRCA mutated families (50%) than in general population (23%). 5-year OS was around 5% for patients with family history or BRCA mutation in the family and general population.

Conclusions: Our retrospective study confirms the high rate of positive BRCA1/2 test in families with PC associated to BC and/or OC. The NCCN Guidelines compared to the Modena Criteria did not increase the BRCA mutation detection rate. Notably, PC diagnosed in families with history of BC and/or OC or BRCA mutation showed younger age at diagnosis and better 1-year OS. We are planning to test all the remaining families selected by NCCN guidelines.

733P Sequential chemo-chemoradiation (CCRT) in locally advanced pancreas cancer in an irish high volume centre

R. Abdul Rahman[1], M.Y. Teo[2], M. Moriarty[3], R. McDermott[1], G. McVey[3]

[1]Medical Oncology, St Vincents University Hospital, Dublin, Ireland, [2]Oncology, Memorial Sloan-Kettering Cancer Center, New York, NY, USA, [3]Radiaiton Oncology, St. Lukes Hospital, Rathgar, Ireland

Background: We adopted the sequential CCRT approach for management of patients (pts) with LAPC in July 2008. Pancreas cancer care was centralised to 2 high volume cancer centres in Ireland since 2011. The objective of this study is to examine the efficacy of CCRT and its differences pre- and post-July 2008, and to compare the efficacy of newer chemo-regimens FOLFIRINOX (FFX) and Gemcitabine/nab-Paclitaxel (GA) with other regimens.

Methods: Pts were identified from the medical oncology and pancreatobiliary surgery databases. Eligible pts had pathological diagnosis of pancreatic adenocarcinoma, and radiologically and/or laparoscopically-confirmed LAPC disease with no distant metastases. Only those who commenced induction chemo were included in the final analysis. OS was calculated from date of pathological diagnosis to death.

Results: Between Mar 05 - Apr 17, 102 pts were identified. 56, 55% were male with a median age of 67 yrs (range: 42 – 87). 86 pts commenced induction chemo, with FFX+GA (15 + 5), gemcitabine (30), gemcitabine-based (24) and fluorouracil-based regimen (12). All pre-July 08 pts were treated with chemo only. Post-July 08, 70 pts commenced induction chemo, and 38, 54% went on to have sequential CRT (s-CRT). Those who received combination chemo were more likely to proceed with s-CRT, 84% vs 59% respectively, p = 0.023. 5FU was the most common radiosensitiser used (20), followed by gemcitabine (5). Median follow-up was 12.5 mos (95% CI: 11.60 -15.34). OS for all 86 pts were 13.4 mos (95% CI: 11.8- 15.0) and for post-July 08 cohort was significantly longer (14.1 mos vs 8.9 mos, HR: 0.47, 95% CI 0.26 – 0.83, p = 0.01). Amongst the post-July 08 pts, OS for patients who received s-CRT was significantly superior when compared to patients who did not (18.1 vs 10.0 mos, HR 0.35, 95% CI 0.21 – 0.58, p < 0.001). Induction chemo with FFX/GA showed numerical improvement in OS, 16.9 vs 13.3 mos, HR 0.83, 95% CI 0.48 – 1.43, p = 0.5). 6 pts went on to have resection and all were post-July 08 cohort (OS: 18.1 vs 13.3 mos, p = 0.4).

Conclusions: Our results showed superior OS for pts who received CCRT since the implementation of CCRT and centralisation of pancreas cancer care. Treatment with newer regimen appear to improve OS.

735P The prognostic significance of infiltrating lymphocytes in resectable pancreatic ductal adenocarcinoma in untreated versus neoadjuvant treated patients

J.B. Goldstein[1], D. Chatterjee[2], M. Zaid[3], B. Chaudhury[3], D. Elganainy[2], D.M. Halperin[1], R. Nejati[2], H. Wang[1], M.H. Katz[4], J.E. Lee[4], J. Fleming[4], J. Rodriguez Canales[5], J. Blando[5], I.I. Wistuba[5], A. Maitra[2], R.A. Wolff[1], H. Wang[2], G.R. Varadhachary[1], E. Koay[3]

[1]Gastrointestinal Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA, [2]Pathology, MD Anderson Cancer Center, Houston, TX, USA, [3]Radiation Oncology, MD Anderson Cancer Center, Houston, TX, USA, [4]Surgical Oncology, MD Anderson Cancer Center, Houston, TX, USA, [5]Translational Molecular Pathology, MD Anderson Cancer Center, Houston, TX, USA

Background: Tumor microenvironment plays an important role in chemoresistance and tumor progression of PDAC. The role of tumor infiltrating lymphocytes in treated PDAC remains unclear. This study examines the distribution of intratumoral lymphocytes and their correlation with survival and clinicopathologic factors in patients with resected PDAC.

Methods: We studied 75 patients who completed pancreaticoduodenectomy (PD) plus neoadjuvant therapies between 1999 and 2007. Neoadjuvant therapies included Gemcitabine + nab-paclitaxel and FOLFIRINOX or chemoradiation. Immunohistochemistry (IHC) for CD4, CD8, and FOXP3 were performed on resection specimens, which contained two representative slides from each patient. Digital images of IHC-stained slides were obtained at 20 x magnifications using a whole slide scanner (ScanScope, Aperio AT Turbo). Tumor regions were hand-annotated on whole slide images and computer assisted quantitative analysis was performed using Aperio's ImageScope software. The tumor infiltrating lymphocytes were calculated as the percentage of positive staining area vs the total tumor area. Cox Regression analysis was performed for univariate and multivariate analysis.

Results: The average percentage for CD4, CD8 positive cells were 6.08 ± 7.76, 2.84± 3.64, respectively in the treated cohort. Using the 50 percentile value as a cutoff, patients with high CD4+ lymphocytes had better disease free survival vs low CD4 positive lymphocytes (HR 0.234, P = 0.0031). There were no significant correlations between CD 4+, CD8+, CD68+, Granzyme B+, KP-1+, FOXP3+ lymphocytes and overall survival (p > 0.05). In multivariate analysis, neither CD4+ lymphocytes (HR: 0.49, P = 0.004), CD 8+ or CD 4/CD 8 ratio were independent prognostic factors for overall survival (See table).

Conclusions: Our study showed that the presence of high CD4+ and CD8+ lymphocytes is an independent prognostic factor for disease free survival in resectable neoadjuvant treated PDAC patients. We believe that neoadjuvant chemotherapy induces an enhanced immune response that may contribute to improved survival outcomes. Results are currently being analyzed looking at tumor infiltrating lymphocytes in resectable PDAC patients receiving receiving surgery alone.

Table: 735P

Variable	Univariate Analysis (DFS)		Mulitivariate Analysis (DFS)	
	P-value	HR (95% CI)	*P*-value	HR (95% CI)
CD 4 High vs. Low (Reference)	0.003	0.234 (0.073-0.627)	0.510	0.553 (0.094-3.220)
CD 8 High vs. Low (Reference)	0.021	0.366 (0.146-0.858)	0.695	0.752 (0.170-2.919)
CD 4/CD 8 ratio High vs. Low (Reference)	0.046	0.393 (0.141-0.983)	0.112	0.344 (0.084-1.281)

736P Randomized phase 2 trial of peri- or post-operative chemotherapy in resectable pancreatic adenocarcinoma

M. Reni[1], S. Zanon[1], G. Balzano[2], R. Castoldi[2], A. Zerbi[3], M.C. Tronconi[4], D. Pinelli[5], S. Mosconi[6], C. Doglioni[7], M. Falconi[2], L. Gianni[1]

[1]Medical Oncology, IRCCS San Raffaele Scientific Institute, Milan, Italy, [2]Surgery, IRCCS San Raffaele Scientific Institute, Milan, Italy, [3]Pancreatic Surgery, Humanitas Clinical and Research Center, Rozzano, Italy, [4]Cancer Center, Humanitas Clinical and Research Center, Rozzano, Italy, [5]Surgery, "Papa Giovanni XXIII" Hospital, Bergamo, Italy, [6]Oncology, Papa Giovanni XXIII Hospital, Bergamo, Italy, [7]Pathology, IRCCS San Raffaele Scientific Institute, Milan, Italy

Background: Pancreatic ductal adenocarcinoma (PDAC) has a remarkable trend to metastasize early. Accordingly, there is a strong rational to investigate preoperative chemotherapy in patients with resectable disease. We conducted a multicenter randomized phase 2 trial (PACT-15; NCT01150630) to assess the role of combination chemotherapy in perioperative setting.

Methods: Treatment-naïve patients with 18-75 yr, KPS>60 and pathologically confirmed stage 1-2 resectable PDAC were randomized to surgery followed by 6 cycles of adjuvant gemcitabine 1000 mg/m^{2}1,8,15q4w (arm A), or PEXG (cisplatin 30 mg/m^2, epirubicin 30 mg/m^2, and gemcitabine 800 mg/m^2 1,15q4w and capecitabine 1250 mg/m^2/day 1-28) (arm B), or to 3 cycles of PEXG before and 3 after surgery (arm C). The primary endpoint was 1-year event-free survival (EFS); the secondary endpoints were EFS, overall survival (OS), and the difference in pathological findings between arm A+B and arm C. With 24 eligible patients in each group (H0 20%, H1 40%, α 10%, β 20%), $\leq$16 events of 24 would support further evaluation of experimental therapy.

Results: Between September 2010 and April 2015, 88 eligible patients were randomized in 9 Italian centers (arm A: 26, B: 30, C: 32). Basal patients and tumor characteristics were well balanced across arms. One-year EFS (A, B, C) was 6/26 (23%), 15/30 (50%), 23/32 (72%). Median EFS was 4.8, 12.4, 18.9 months (A vs C p=0.002). Three-year OS (A,B,C) was 35%, 42%, 55%. Median OS (A,B,C) was 20.4, 25.1, not reached at 33 months (A vs C p = 0.022). Pathological results are summarized in the table. Treatment safety profile was good.

Table: 736P Pathological findings

	A+B	C
Enrolled	56	32
T resection	49 (88%)	27 (84%)
Intraoperative metasteses	7/56 (13%)	2/32 (6%)
Postoperative metastases	10/56 (18%)	3/32 (9%)
Grade 3	29/49 (59%)	6/27 (22%)
T1	2/49 (4%)	4/27 (15%)
No	13/49 (27%)	13/27 (48%)
Ro	16/49 (33%)	15/27 (56%)
Median size	2.5 cm	2.0 cm

Conclusions: Patients receiving perioperative chemotherapy had significant improvement of EFS and OS as compared to those receiving adjuvant treatment. This trial provides the strongest piece of evidence currently available in favor of preoperative chemotherapy in resectable PDAC.

737P TP53 mutation predicts sensitivity to adjuvant gemcitabine in pancreatic cancer: Results from the CONKO-001 study

M. Sinn[1], J. Budczies[2], F. Damm[1], P. Lohneis[2], R. Schmuck[3], D. Treue[2], J.K. Striefler[1], M. Bahra[3], U. Pelzer[1], A. Jühling[1], H. Bläker[2], S. Bischoff[1], H. Oettle[4], C. Denkert[5], H. Riess[1], B. Sinn[2]

[1]Medical Oncology, Charite Universitätsmedizin Berlin, Berlin, Germany, [2]Institute of Pathology, Charite Universitätsmedizin Berlin, Berlin, Germany, [3]Surgery, Charite Universitätsmedizin Berlin, Berlin, Germany, [4]Hematology/Oncology, Medical Practice-Helmut Oettle, Friedrichshafen, Germany, [5]Institut of Pathology, Charite Universitätsmedizin Berlin, German Cancer Consortium (DKTK) Partner Site Berlin, Berlin, Germany

Background: Pancreatic adenocarcinoma (PDAC) is a molecular heterogeneous disease, but clinically relevant genetic biomarkers are still missing. There are no data from prospective studies after curatively intended surgery and adjuvant chemotherapy so far.

Methods: CONKO-001, was a prospective randomized phase III study and investigated the role of adjuvant gemcitabine (Gem) as compared to observation (Obs). Formaline-fixed paraffin-embedded tissue samples of 187 patients (pts) could be collected, of which 97 could be analysed after DNA-extraction by targeted next generation sequencing (NGS), using a predefined sequencing panel including mutation hotspot regions of 36 genes (ACTN4, ACVR1B, APC, ARID1A, ARID1B, ARID2, ATM, BRAF, CDK6, CDKN2A, CNDP2, CREBBP, CTNNB1, ERBB2, FGFR1, GATA6, KDM6A, KMT2C, KMT2D, KRAS, MAP2K4, MET, MYC. PBRM1, PIK3CA, PREX2, RNF43, RPA1, SF3B1, SMAD4, SMARCA2, SMARCA4, SOX9, STK11, TGFBR2, TP53). Mutational status was correlated with survival by fitting a cox proportional hazard model.

Results: Patient's characteristics were balanced between Gem (n = 49) and Obs (n = 48) group. KRAS, TP53, SMAD4 mutation was found in 73% (Gem/Obs n = 33/38), 59% (n = 28/29), 8% (n = 4/4) of patients. KRAS/SMAD4 mutation status was not associated with (treatment-related) survival. TP53 mutation was identified as a negative prognostic factor for untreated patients: hazard ratio (HR) for disease free-survival (DFS) TP53 mutant vs TP53 wildtype 2.90 (95% CI 1.55 -5.41). Furthermore, TP53 mutation was found to be a positive predictive factor for Gem: HR for DFS Gem vs Obs in TP53 wildtype patients was 0.87 (95% CI 0.46-1.66) in comparison to TP53 mutated patients with a HR of 0.22 (95% CI 0.12-0.39). Test of TP53-by-treatment-interaction was statistically significant; p = 0.002.

Conclusions: To the best of our knowledge, we present the first NGS data from a prospective clinical study in PDAC. In contrast to previous data, we could not identify KRAS or SMAD4 mutation as clinically relevant factors in primarily resectable PDAC. In CONKO-001, TP53 mutated patients had an unfavorable prognosis when randomized to Obs and profited strongly from adjuvant Gem, while adjuvant treatment did not significantly prolong DFS in TP53 wildtype patients.

738P Strong tumour cytidine deaminase (CDA) staining predicts for improved survival associated with sequential nab-Paclitaxel (nabP) and gemcitabine (GEM) chemotherapy as first line treatment of patients (pts) with metastatic pancreatic adenocarcinoma (mPDAC)

P. Corrie[1], W. Qian[1], A. Gopinathan[2], M. Williams[2], R. Brais[1], J.W. Valle[3], B. Basu[1], S. Falk[4], C. Iwuji[5], H. Wasan[6], D. Palmer[7], M. Scott-Brown[8], J. Wadsley[9], S. Arif[10], L. Bax[1], P. Bundi[1], R. Skells[1], A. Neesse[11], D. Tuveson[12], D. Jodrell[1]

[1]Addenbrookes Hospital, Cambridge University Hospitals NHS Foundation Trust, Cambridge, UK, [2]Cambridge Institute, Cancer Research UK, Cambridge, UK, [3]Medical Oncology, The Christie NHS Foundation Trust, Manchester, UK, [4]Oncology, Bristol Haematology and Oncology Centre, Bristol, UK, [5]Medical Oncology, Leicester Royal Infirmary, Leicester, UK, [6]Medical Oncology, Hammersmith Hospital, London, UK, [7]Medical Oncology, Clatterbridge Cancer Centre, Wirral, UK, [8]Medical Oncology, University Hospital Coventry and Warwickshire, Coventry, UK, [9]Medical Oncology, Weston Park Hospital Cancer Research Centre, Sheffield, UK, [10]Medical Oncology, Velindre Cancer Centre, Cardiff, UK, [11]Department of Gastroenterology, Universitätsmedizin Göttingen - Vorstand, Göttingen, Germany, [12]CSHL Cancer Center, Cold Spring Harbor Laboratory, Cold Spring Harbor, NY, USA

Background: *Nab*P+GEM chemotherapy improves survival as treatment for mPDAC, compared with GEM alone. The UK randomised phase 2 SIEGE trial showed that sequential (SEQ) delivery of *nab*P+GEM (with *nab*P given 24 hours before GEM) trended towards improved efficacy compared with standard concomitant (CON) delivery. Preclinical models suggest that *nab*P potentiates GEM activity by either impacting on stroma or reducing CDA levels.

Methods: 146 pts were randomised to receive CON or SEQ *nab*P+GEM. Baseline whole blood (wb) CDA activity was measured using an endpoint read, spectrometric, plate based assay. Baseline tumour IHC assessed stromal content (H&E), CDA (ab137605) and nucleoside transporter protein, hENT1 (Ventana SP120) expression.

Results: 6-month (m) progression-free survival (PFS, primary end point) by SEQ and CON arms was 47% and 33%; median PFS was 5.8 and 4.1m (HR 0.68, 95%CI 0.48-0.97); median overall survival (OS) was 10.1 and 7.9m, respectively. Baseline wb CDA activity correlated only with ANC (R^2 0.70, p<.0001) after adjustment for other baseline factors

including KPS, disease burden, CRP and did not predict for PFS, OS or toxicity. Of 105 tumours evaluable by IHC, 34 had diffuse strong (ds) CDA staining which predicted for improved PFS with SEQ therapy (HR 0.43, 95%CI 0.20-0.91); this was not evident for other staining patterns or ds-CDA staining for pts on CON therapy. Ds-CDA staining trended towards improved OS with SEQ compared with CON therapy (HR 0.73, 95%CI 0.35-1.52). On disease progression, 34 pts (13 SEQ, 21 CON) received further anti-cancer treatment. Stroma or hENT1 expression did not predict for PFS or OS with SEQ or CON therapy. Tumour stroma staining, but not CDA or hENT1, was an independent prognostic factor for improved OS (moderate/extensive vs none/little, HR 0.55, 95%CI 0.37-0.84).

Conclusions: Whole blood CDA activity was not a useful predictive biomarker, due to the dominant neutrophil effect. Instead, strong tumour CDA expression predicted for pts most likely to have a survival benefit from SEQ therapy and warrants further exploration.

739P Randomized phase 2 trial of nab-paclitaxel plus gemcitabine, ± capecitabine, cisplatin (PAXG regimen) in metastatic pancreatic adenocarcinoma

M. Reni[1], S. Zanon[1], C. Pircher[1], M. Chiaravalli[1], M. Macchini[1], U. Peretti[1], E. Mazza[1], G. Balzano[2], P. Passoni[3], R. Nicoletti[4], P.G. Arcidiacono[5], G. Pepe[6], C. Doglioni[7], S. Romi[1], D. Ceraulo[1], M. Falconi[2], L. Gianni[1]

[1]Medical Oncology, IRCCS San Raffaele Scientific Institute, Milan, Italy, [2]Surgery, IRCCS San Raffaele Scientific Institute, Milan, Italy, [3]Radiotherapy, IRCCS San Raffaele Scientific Institute, Milan, Italy, [4]Radiology, IRCCS San Raffaele Scientific Institute, Milan, Italy, [5]Gastroenterology, IRCCS San Raffaele Scientific Institute, Milan, Italy, [6]Nuclear Medicine, IRCCS San Raffaele Scientific Institute, Milan, Italy, [7]Pathology, IRCCS San Raffaele Scientific Institute, Milan, Italy

Background: The recommended phase 2 dose of *nab*-paclitaxel (150 mg/m^2) in combination with cisplatin, capecitabine, and gemcitabine (800, 30, and 1250 mg/m^2 every 2 weeks, respectively; PAXG regimen) were determined in a phase Ib trial. We now report the final results of a randomized phase 2 trial of PAXG or nab-paclitaxel-gemcitabine (AG) in metastatic pancreatic adenocarcinoma (NCT01730222).

Methods: Previously untreated patients with pathologic diagnosis of metastatic pancreatic adenocarcinoma, 18-75 years, Karnofsky Performance Status $\geq$ 70 were eligible. Primary endpoint was the progression-free survival rate at 6 months (PFS6). With 42 eligible patients in each group, a PFS6 in $\geq$ 25 of 42 would support further evaluation of the PAXG regimen.

Results: Between Apr 2014 and June 2016, 83 patients (table 1) were randomized at a single Institution to receive PAXG (arm A; N = 42) or AG (arm B; N = 41). PFS6 was 31/42 (74%), and 24/41 (59%), respectively. PFS at 1 year and median PFS was 26% and 8.1 for arm A and 7% and 6.8 months for arm B. One-year survival was 62% and 41%, respectively. Median survival was not reached at 13.5 months for arm A and was 11.2 for arm B. PAXG regimen did not increase grade 3-4 extra-hematological toxicity as compared to AG.

Table: 739P Baseline Characteristic

		PAXG	AG
Number		42	41
Male/female		20/22	23/18
KPS	90-100	34 (81%)	26 (63%)
	70-80	8 (19%)	15 (37%)
Age	median	66	63
	range	44-75	29-75
Biliary stent		9 (22%)	8 (19%)
CA19.9	>ULN	32 (76%)	31 (76%)
	median	1413	1546
Neutrophil/Lymphocyte >5		15%	21%

Conclusions: The results show that addition of cisplatin and capecitabine to the AG backbone is feasible and linked with improved disease control. The PAXG regimen warrants further exploration in this setting of patients.

Background: UGT1A1*6 and UGT1A1*28 polymorphisms were reported to be associated with increased irinotecan-induced neutropenia. The aim of this subset analysis is to investigate the association between these polymorphisms and toxicities in patients (pts) treated with FOLFIRINOX in the JASPAC 06 study.

Methods: JASPAC 06 study was a nationwide multicenter observational study of FOLFIRINOX for unresectable and recurrent pancreatic cancer. Pts who were screened for UGT1A1*6 and UGT1A1*28, and treated with either original FOLFIRINOX regimen (Oxaliplatin 85 mg/m^2, Irinotecan 180 mg/m^2, Levofolinate calcium [*l*-LV] 200 mg/m^2, bolus 5-FU 400 mg/m^2, and continuous 5-FU 2,400 mg/m^2, every two weeks) or modified regimen (Oxaliplatin 85 mg/m^2, Irinotecan 150 mg/m^2, *l*-LV 200 mg/m^2, and continuous 5-FU 2,400 mg/m^2, every two weeks) as first-line chemotherapy, were analyzed in this analysis.

Results: Of 399 eligible pts enrolled in JASPAC 06 study, 203 pts were eligible in this analysis. UGT1A1 was reported as wild (W) type (-/-) in 118 pts and heterozygous (H) type (-/*6, -/*28) in 81 pts. Remaining four pts with homozygote (*6/*6, *28/*28) or compound heterozygote (*6/*28) were excluded because of small population. Among 199 pts, 79 pts were treated with original regimen and 120 pts with modified regimen. In the original FOLFIRINOX group, 54/25 pts were W/H type. The median age was 60.5/60 years and PS0 was 57/52%. Incidences of grade 3/4 leukopenia, neutropenia, febrile neutropenia, diarrhea, anorexia and grade 4 neutropenia in pts with W/H type were 28/44%, 59/68%, 24/40%, 4/20%, 9/24% and 24/40%, respectively. In the modified FOLFIRINOX group, 64/56 pts were W/H type. The median age was 62.5/62 years and PS0 was 70/70%. The same toxicities as above were 22/27%, 44/50%, 5/7%, 16/7%, 14/9% and 16/20%, respectively.

Conclusions: Treated with original FOLFIRINOX regimen, pts with UGT1A1 heterozygous type experienced severe toxicities more frequently than those with wild type. In such cases, careful management of not only hematologic but gastrointestinal toxicities seems to be needed.

741P Prognostic value of baseline neutrophil-to-lymphocyte ratio for predicting clinical outcome in metastatic pancreatic ductal adenocarcinoma (mPDAC) patients treated with liposomal irinotecan (nal-IRI) + 5-fluorouracil and leucovorin (5-FU/LV) vs 5-FU/LV alone

R.A. Hubner[1], L-T. Chen[2], C-P. Li[3], G. Bodoky[4], A. Dean[5], K-H. Lee[6], D. Cunningham[7], J.T. Siveke[8], F.S. Braiteh[9], F.A. de Jong[10], B. Belanger[11], R. Walls[11], P.D. Mody[11], D.D. von Hoff[12], A. Wang-Gillam[13]

Background: Elevated baseline neutrophil-to-lymphocyte ratio (NLR), a marker of subclinical inflammation, is associated with poor survival in several malignancies including mPDAC. Here we report the association of NLR with overall survival (OS) and progression-free survival (PFS) in a post-hoc analysis of the NAPOLI-1 trial (NCT01494506), that demonstrated improved survival with nal-IRI+5-FU/LV vs 5-FU/LV for treatment of mPDAC patients (pts) after disease progression following gemcitabine-based therapy.

Methods: Pts treated with nal-IRI+5-FU/LV or 5-FU/LV and available baseline NLR data were included (data cutoff: Nov 16, 2015). OS and PFS were assessed in pts with high (>5) or low (≤5) baseline NLR in individual and pooled treatment arms.

Results: Baseline NLR was available for 221 pts: 116/117 nal-IRI+ 5-FU/LV pts and 105/105 5-FU/LV pts. In the pooled treatment arms, pts with NLR≤5 had significantly better OS compared to pts with NLR >5 (6.2 vs 3.7 months, HR = 0.7, p = 0.02). Interestingly, this improvement in OS in pts with low vs high NLR was significant in the nal-IRI+5-FU/LV arm (8.4 vs 4.3 months, HR = 0.5, p=0.001); but not in the 5-FU/LV arm (4.8 vs 3.1 months, HR = 0.9, p=0.6). Similarly, PFS was significantly higher in pts with NLR≤5 vs NLR >5 in the pooled treatment arms (2.7 vs 1.4 months, HR = 0.7, p=0.05), and the nal-IRI+5-FU/LV arm (4.2 vs 1.4 months, HR = 0.5, p=0.002), but not the 5-FU/LV arm (1.5 vs 1.4 months, HR = 1.1, p=0.6).

Conclusions: Data from these exploratory analyses are consistent with previous reports on the prognostic value of baseline NLR in mPDAC, and extend it to the post-gemcitabine setting. Median OS and PFS were improved in pts with low vs high baseline NLR in the nal-IRI+5-FU/LV arm but not in the 5-FU/LV arm. Clinical implications of these data remain to be determined.

Background: PEGPH20 (P) degrades HA in the tumor microenvironment to increase access and therapeutic index of anticancer agents. In Stage 1 of this study, Halozyme Therapeutics, Inc. and Ventana Medical Systems, Inc., co-developed a novel HA assay, scoring algorithm, and cut-point, and showed improved progression-free survival (PFS) and objective response rate (ORR) in HA-High patients (pts) with PAG vs AG.

Table: 741P

	Pooled treatment arms		nal-IRI + 5FU/LV		5FU/LV	
Baseline NLR	≤5 (n = 155)	>5 (n = 66)	≤5 (n = 82)	>5 (n = 34)	≤5 (n = 73)	>5 (n = 32)
Median[1] OS, months (95% CI)	6.2 (5.2 - 7.6)	3.7 (3.1 - 4.4)	8.4 (6.1 - 10.2)	4.3 (3.4 - 4.7)	4.8 (3.6 - 6.1)	3.1 (1.9 - 4.2)
HR[2]	0.7		0.5		0.9	
95% CI	0.5 - 0.9		0.3 - 0.8		0.6 - 1.4	
P[3]	0.02		0.001		0.6	
Median[1] PFS, months (95% CI)	2.7 (2.4 - 3.3)	1.4 (1.4 - 1.6)	4.2 (3.1 - 5.6)	1.4 (1.4 - 2.8)	1.5 (1.4 - 2.6)	1.4 (1.3 - 1.9)
HR[2]	0.7		0.5		1.1	
95% CI	0.5 - 1.0		0.3 - 0.8		0.8 - 1.8	
P[3]	0.05		0.002		0.6	

[1]Medians reflect Kaplan-Meier estimates

[2]Hazard ratios (HRs) reflect Cox regression analysis.

[3]Two-sided p-value < 0.05 considered statistically significant in these exploratory analyses

Due to an imbalance in thromboembolic (TE) events in the PAG arm, the protocol was amended to add enoxaparin and exclude pts at high risk for TE events in Stage 2, which prospectively validated the algorithm and cut-point for the VENTANA HA RxDx assay.

Methods: In Stage 2, pts with mPDA were randomized 2:1 to PAG (P 3 μg/kg IV 2x/wk x 3 wk [C1], then 1x/wk x 3 wk [C2+] + AG) vs AG every 28 days. Endpoints were: primary—PFS and TE events; secondary—PFS by HA level, ORR; OS by HA level was exploratory. Tumor HA was evaluated using the VENTANA HA RxDx assay and algorithm; HA-High was defined by HA staining in the extracellular matrix ≥50% of the entire tumor surface at any intensity.

Results: 133 pts were enrolled; 125 pts were treated. As of December 16, 2016, an improvement in median PFS (91%) and median OS (50%) was observed in HA-High pts treated with PAG vs AG (Table), supporting tumor HA as a predictive marker for PEGPH20 efficacy. Among AG-treated pts, those with HA-High tumors showed poorer median PFS and median OS outcomes, suggesting that targeting tumor HA with PEGPH20 may improve the standard of care in mPDA.

Table: 743P

	PAG	AG	HR (95% CI)
HA-High	n = 24	n = 11	
PFS, months	8.6	4.5	0.63 (0.21-1.93)
OS, months	11.7	7.8	0.52 (0.22-1.23)
HA-Low	n = 53	n = 23	
PFS, months	6.0	7.2	1.21 (0.63-2.30)
OS, months	11.9	10.2	0.69 (0.38-1.23)

Conclusions: This is the first randomized Phase 2 study evaluating and supporting tumor HA as a potential predictive biomarker informing patient selection for PEGPH20 treatment, based on improvement in both PFS and OS in HA-High pts. The results provide support for the ongoing phase 3 HALO 109-301 study with co-primary endpoints of PFS and OS. NCT01839487.

Background: Median overall survival on 2nd line therapy of PDAC with 5-FU/LV plus oxaliplatin or nal-irinotecan is ~ 5-6 m. PDAC is refractory to immune therapies and mutational burden is relatively low and tumor infiltrating CD8+ T cells are rare. AM0010 stimulates survival, expansion and cytotoxicity of intratumoral CD8+ T cells and induced immune activation, durable stable disease and a 1yr survival of 22.5% in salvage PDAC pts. AM0010 has synergistic immune and anti-tumor activity with platinums and 5-FU in preclinical cancer models.

Methods: This phase 1b clinical study studied the safety and efficacy of AM0010 +FOLFOX as ≥ 2nd line treatment of PDAC. Pts who progressed on a median of 2 prior therapies (range 1-3) were treated with AM0010 (5ug/kg SQ, qd) + FOLFOX (n = 21). The safety population (n = 25) included four additional pts with prior FOLFOX. Tumor responses were assessed using irRC. Serum cytokines, activation of blood derived T cells and peripheral T cell clonality were analyzed. Pre-existing tumor infiltrating CD8 T cells were quantified by IHC.

Results: AM0010 + FOLFOX was generally well tolerated. G3/4 TrAEs included thrombocytopenia (52%), anemia (40%) and neutropenia (36%). Most cytopenias were transient and met retreatment criteria within 2-5 days. A modified AM0010 dose schedule of 5 days on, 2 days off avoided G3/4 cytopenias while retaining the immune stimulation. As of 05/1/2017, 2 pts have remained on treatment for > 72 weeks. 19 pts had tumor assessment following irRC (2 CR, 1 PR, 11 SD). The ORR and DCR were 15.8% and 74%. With a median follow-up of 14.2 m (range 6.8-18.9), 10 patients were alive (48%), mPFS and mOS were 3.5 and 10.2 m. Treatment induced a sustained cytokine increase in the serum and an expansion of novel T cell clones in the blood. This and a higher number of intra-tumoral CD8 T cells correlated with increased OS.

Conclusions: The combination of AM0010 with FOLFOX is well tolerated in patients with metastatic PDAC. This regimen induced sustained immune activation including the expansion of oligoclonal T cells. The prolonged tumor responses and OS are encouraging in this advanced population. This regimen is being studied in a phase 3 trial.

Clinical trial identification: NCT02009449

745P Circulating levels of ADAM12, a stromal activation biomarker, are predictive of survival in pancreatic ductal adenocarcinoma (PDAC)

H.W. van Laarhoven[1], H. Damhofer[2], V.L. Veenstra[2], C. Waasdorp[2], L.B. van Rijssen[3], F. Dijk[4], J.W. Wilmink[1], M.G. Besselink[3], O.R. Busch[3], J.P. Medema[2], J. Shiansong Li[5], R. Jiang[5], D.W. Pierce[6], M.F. Bijlsma[2]

[1]Department of Medical Oncology, Academic Medical Center (AMC), Amsterdam, Netherlands, [2]Laboratory for Experimental Oncology and Radiobiology, Center of Experimental and Molecular Medicine, Academic Medical Center, Amsterdam, the Netherlands; Biotech Research and Innovation Centre, University of Copenhagen, Copenhagen, Denmark, [3]Department of Surgery, Academic Medical Center (AMC), Amsterdam, Netherlands, [4]Department of Pathology, Academic Medical Center (AMC), Amsterdam, Netherlands, [5]Biostatistics, Celgene Corporation, Summit, NJ, USA, [6]Translational Medicine, Celgene Corporation, Summit, NJ, USA

Background: The dense stroma of PDAC promotes tumor growth and impedes delivery of cytotoxic drugs. We assessed the utility of ADAM12, a circulating biomarker of PDAC stroma identified in our preclinical models, to non-invasively measure stromal activation in patients (pts) and predict outcomes.

Methods: The prognostic and predictive value of ADAM12 was determined in an institutional cohort from the Academic Medical Center (AMC), which included 144 pts with PDAC (58 resected and 86 non-resected pts) and 38 non-age–matched healthy controls, and in a cohort of 372 pts with metastatic PDAC treated with *nab*-paclitaxel plus gemcitabine (*nab*-P/Gem) or Gem alone in the MPACT trial.

Table: 745P

	Overall Population		*nab*-P/Gem Arm		Gem Arm	
	Deaths, n/N (%)	Median OS (95% CI), mo	Deaths, n/N (%)	Median OS (95% CI), mo	Deaths, n/N (%)	Median OS (95% CI), mo
FC < 1	98/112 (88)	9.7 (8.7 - 11.6)	52/59 (88)	11.2 (9.6 - 14.0)	46/53 (87)	8.7 (6.9 - 9.5)
FC > 1	54/58 (93)	8.1 (6.5 - 9.9)	25/27 (93)	8.3 (6.5 - 11.3)	29/31 (94)	6.9 (5.5 - 9.3)
ND	30/38 (79)	13.2 (9.3 - 16.4)	17/22 (77)	14.4 (8.5 - 19.2)	13/16 (81)	12.0 (6.8 - 14.9)
HR (95% CI); *P* value						
FC < 1 vs ND FC > 1 vs ND FC < 1 vs FC > 1	1.5 (1.0 - 2.3); < .05 2.3 (1.4 - 3.6); < .01 0.7 (0.5 - 0.9); .02		1.8 (1.0 - 3.2); .04 2.8 (1.5 - 5.4); < .01 0.6 (0.4 - 1.0); .07		1.3 (0.7 - 2.3); .48 1.7 (0.9 - 3.3); .11 0.7 (0.5 - 1.2); .19	

BL, baseline; FC, fold change; HR, hazard ratio; *nab*-P/Gem, *nab*-paclitaxel plus gemcitabine; ND, no detectable; OS, overall survival; pt, patient.

Results: For the AMC cohort, higher serum ADAM12 levels (median, 372 pg/mL; $P < .01$) were found in pts with PDAC vs healthy controls (median, 154 pg/mL). High ADAM12 levels (> median) were significantly associated with poor survival ($P = .04$) in resected pts but not in non-resected pts ($P = .67$). In the pooled MPACT analysis, median overall survival (OS) was significantly longer (9.3 vs 6.9 months; log-rank $P = .01$) in pts with no detectable (ND; n = 95) vs detectable (n = 277) serum ADAM12 levels at baseline (BL). Median OS was longer in pts with ADAM12 decrease (fold change [FC] < 1) vs increase (FC > 1) from BL to cycle 2, but both OS values were significantly shorter than that in pts with ND ADAM12 levels at either time point (Table).
In a multivariate analysis, baseline ADAM12 levels (0 vs > 0; $P = .02$), treatment (*nab*-P/Gem vs Gem; $P = .02$), and Karnofsky performance status (90-100 vs 70-80; $P < .01$) were significant predictors of OS. Table. OS in pts with ADAM12 measured at both BL and cycle 2 in the MPACT study

Conclusions: Low serum levels of ADAM12 at baseline were associated with longer OS in pts with PDAC, as were decreases in ADAM12 during treatment. ADAM12 may be a valuable biomarker to predict long-term outcomes in pts treated with *nab*-P/Gem.

Background: Variations in the reporting of potentially confounding variables in studies investigating systemic treatments of unresectable pancreatic cancer challenge adequate comparisons. We establish the first international consensus on mandatory baseline- and prognostic characteristics to be taken into account in future pancreatic cancer trials for patients with unresectable disease.

Methods: A systematic review was performed for phase III trials investigating first-line systemic therapy for unresectable pancreatic cancer that were published between January 2000 and January 2016 to identify baseline characteristics and prognostic variables. The electronic databases Medline, EMBASE and the Cochrane Central Register of Controlled Trials (CENTRAL) were used. A structured overview was created demonstrating the reporting frequencies of baseline characteristics and prognostic relevance of identified variables. A modified Delphi panel of two rounds involving 23 leading medical-oncologists in the field of pancreatic cancer was used to develop the consensus.

Results: A total of 624 studies were identified. After screening, 39 randomized controlled trials (RCTs) with 15,863 patients were included. Thirty-two baseline characteristics and 26 prognostic characteristics were identified. After two consensus rounds, 24 baseline characteristics and twelve prognostic characteristics were designated as a mandatory reporting set for future trials. Table 1. Mandatory set

Table: 746P

Baseline characteristics	Prognostic characteristics
Age	Age
Albumin	Albumin
Biliary stent	Bilirubin
Bilirubin	CA 19.9
CA19.9	CRP
C-Reactive Protein (CRP)	Disease status
Disease status	LDH
Gender	Liver metastasis
Histology	NLR
LDH	Number of metastatic sites
Liver metastasis	Pain at baseline
Loss of weight > 10%	Performance status
Neutrophil lymphocyte ratio (NLR)	
Number of metastatic sites	
Pain at baseline	
Performance status	
Peritoneal metastasis	
Primary tumor location	
Prior chemotherapy/radiotherapy	
Prior surgery	
Pulmonary metastasis	
Time from diagnosis	
Tumor differentiation	
Weight/BMI	

Conclusions: The COnsensus statement on Mandatory Measurements identifies a set of baseline- and prognostic characteristics in unresectable PAncreatic Cancer Trials (COMM-PACT) that allows for adequate comparison of outcomes between studies.

747P Phase I study of resminostat/S-1 combination in patients with pre-treated biliary tract or pancreatic cancer

C. Morizane[1], I. Ohno[2], H. Ueno[1], S. Mitsunaga[2], Y. Hashimoto[2], T. Okusaka[1], S. Kondo[1], M. Sasaki[2], Y. Sakamoto[1], H. Takahashi[2], R. Hara[3], S. Kobayashi[3], O. Nakamura[3], M. Ikeda[2]

[1]Department of Hepatobiliary and Pancreatic Oncology, National Cancer Center Hospital, Tokyo, Japan, [2]Department of Hepatobiliary and Pancreatic Oncology, National Cancer Center Hospital East, Kashiwa, Japan, [3]Pharmaceutical Research & Development Department, Yakult Honsha Co., Ltd., Tokyo, Japan

Background: Resminostat is an oral hydroxamate-type inhibitor of class I, IIb, and IV histone deacetylases. S-1 is preferably used in biliary tract (BTC) and pancreatic cancer (PC) in Japan. However, patients (pts) with high thymidylate synthase (TS) expression are known to show resistance to S-1. Resminostat down-regulates TS expression and has shown additive effects to S-1 in preclinical studies. Thus, resminostat besides its antitumor activity, may overcome S-1 resistance by down-regulating TS. We report a Japanese phase I study of resminostat + S-1 combination therapy in a 2nd-line or later setting for BTC/PC.

Methods: In the first stage, we determined the optimal dosing schedule for resminostat + S-1 combination therapy, investigating its safety and efficacy in the second stage. In the former, pts were treated with one of the following 3 regimens (R): R1, resminostat 200 mg/day on Day 1 to 14 every 21 days; R2, resminostat 200 mg/day + S-1 80 to 120 mg/day according to BSA on Day 1 to 14 every 21 days; or R3, resminostat 200 mg/day on Day 1 to 5 and Day 8 to 12 ("5 + 2" dosing schedule) + S-1 80 to 120 mg/day according to BSA on Day 1 to 14 every 21 days. In the latter, additional 10 pts were treated with the regimen selected in the first stage. Dose-limiting toxicities (DLTs) were evaluated according to adverse drug reactions observed during the first cycle in the first stage.

Results: A total of 27 pts were enrolled (first stage: R1, 6 pts; R2, 5 pts; R3, 6 pts; second stage: 10 pts). Two DLTs were observed: one (Grade 2 anorexia) in a patient treated with R2 and one (Grade 3 stomatitis) in another patient treated with R3. Dose modification due to gastrointestinal toxicities was implemented frequently in pts treated with R2. Therefore, R3 was selected as the regimen for the second stage. A total of 16 pts (BTC 13 pts; PC 3 pts) were treated with R3 and it was well tolerable. Disease control rate was 81.3% (BTC 84.6%; PC 66.7%). The median progression-free survival was 3.1 months (BTC 5.5 months; PC 2.3 months).

Conclusions: The data revealed that R3 ("5 + 2" dosing schedule of resminostat in combination with S-1) was well tolerated in advanced BTC/PC pts. Further investigations are warranted for its efficacy especially in advanced BTC pts.

748P Comparisons of outcomes of patients with advanced pancreatic cancer (APC) treated with FOLFIRINOX (FX) versus gemcitabine and nab-paclitaxel (GN): A population-based cohort study

N. Papneja[1], C. Olson[2], H. Chalchal[3], M. Moser[4], N. Iqbal[5], K. Haider[5], A. Zaidi[5], J. Shaw[4], B. Brunet[5], D-A. Dueck[5], T. Abbas[5], S. Ahmed[5]

[1]Medicine, University of Saskatchewan, Saskatoon, SK, Canada, [2]Pharmacy, Saskatchewan Cancer Agency, Saskatoon Cancer Center, University of Saskatchewan, Saskatoon, SK, Canada, [3]Oncology, Saskatchewan Cancer Agency, Allan Blair Cancer Center, University of Saskatchewan, Regina, SK, Canada, [4]Surgery, University of Saskatchewan, Saskatoon, SK, Canada, [5]Oncology, Saskatchewan Cancer Agency, Saskatoon Cancer Center, University of Saskatchewan, Saskatoon, SK, Canada

Background: FX and GN are more active than gemcitabine in patients with APC. However, it is not known if FX is superior to GN in APC. In the absence of a randomized controlled trial this population-based cohort study is undertaken to compare efficacy and safety of the two standard regimens in APC.

Methods: All patients with newly diagnosed locally APC in the province of Saskatchewan, Canada, during 2011-2016 who received FX or GN, were assessed. A Cox proportional multivariate analysis was done to evaluate correlation of chemotherapy regimen and survival.

Results: 119 eligible patients with median age of 61 yrs (IQR:56-67) & M:F of 70:49 were identified. 93% had WHO performance status (PS) of 0 or 1, and 77% had metastatic PC. 15% received adjuvant therapy and 33% had ≥2 metastatic sites. Of 119 patients, 86 (72%) received FX and 33 (28%) treated with GN. There were significant differences between the two groups with respect to age (59 vs. 64 yrs), WHO PS of 2 (2% vs. 15%) and metastatic disease (81% vs. 64%), in FX and GN groups, respectively. Median progression-free survival of FX group was 6 months (95%CI: 4.5-7.5) vs. 4 months (2.9-5.1) with GN ($p = 0.39$). Median overall survival (OS) with FX was 9 months (7-11) vs. 9 months (4.2-13.8) with GN ($p = 0.88$). At 12 months 26% & 27% patients were alive in FX and GN groups, respectively. Median OS of patients who received 2nd line therapy was 15 months (10.5-19.5) vs. 8 months (6.3-9.7) with no 2nd line therapy (0.009). Patients in FX had higher incidences of any grade diarrhea (52% vs.18%), mucositis (21 vs. 3), neuropathy (63 vs.36) and thromboembolism (34 vs. 9) whereas patients in GN group had more often fatigue (66 vs.79) and thrombocytopenia (48 vs. 57). On multivariate analysis normal albumin, HR:0.63 (0.41-0.97), male sex, HR:0.65 (0.43-0.97) and 2nd line therapy, HR:0.50 (0.28-0.86) were correlated with better survival but no correlation between FX or GN and survival was noted.

Conclusions: Our results showed that real world patients with APC treated with FX or GN had comparable survival with different safety profiles. In this selected patients who received combination therapy, male gender and subsequent treatment were correlated with better survival.

749P Musculoskeletal Events (MSEs) with PEGPH20 treatment and management in patients with previously untreated metastatic pancreatic ductal adenocarcinoma (mPDA)

A. Bullock[1], P. Vervaet[2], W. Wu[3], D. Chondros[2], S.R. Hingorani[4], A. Hendifar[5]

[1]Hematol/Oncol, Beth Israel Deaconess Medical Center, Boston, MA, USA, [2]Clinical, Halozyme Therapeutics, San Diego, CA, USA, [3]Biostats, Halozyme Therapeutics, San Diego, CA, USA, [4]Oncology, Fred Hutchinson Cancer Research Center, Seattle, WA, USA, [5]Cedars-Sinai Medical Center, Samuel Oschin Cancer Center, Los Angeles, CA, USA

Background: Hyaluronan (HA) accumulation in the tumor microenvironment is associated with poor outcomes. PEGylated recombinant human hyaluronidase PH20 (PEGPH20) degrades HA, facilitating access of cancer therapies. MSEs (e.g., muscle spasms, arthralgia, and myalgia) occur frequently with PEGPH20, and were dose-limiting in Phase 1 studies. Here we describe MSEs observed in a phase 2 study of PEGPH20 (P) plus gemcitabine/nab-paclitaxel (AG) vs AG in patients with previously untreated mPDA.

Methods: In Stage 1 of the study, patients were randomized 1:1 to PAG or AG (P 3 μg/kg IV 2x/wk x 3 wks in Cycle 1, then once weekly x 3 wks in Cycle 2+) every 28 days. A clinical hold due to an imbalance in thromboembolic events resulted in ~40% of patients discontinuing PEGPH20. After the clinical hold, patients were randomized 2:1 to PAG vs AG (Stage 2). Dexamethasone 8 mg was administered orally within 2 hours before and 8-12 hours after PEGPH20 to lessen the severity of MSEs. We analyzed adverse event frequency, severity, timing, and management.

Results: 279 patients were enrolled; 260 patients comprise the safety population. All patients received a median of 3.3 months of study treatment. The proportion of patients with treatment-emergent MSEs was higher in the PAG arm vs AG arm (all grade, 86% vs 46%; grade 3, 19% vs 6%). Grade 4/5 MSEs were not observed. The most common MSEs (all grade/grade 3, PAG vs AG) were muscle spasms in lower and upper extremities (58%/13% vs. 6%/1%), arthralgia (28%/2% vs.14%/1%) and myalgia (27%/5% vs.12%/0). Median (range) time to MSE onset was 2 (0-287) days for PAG and 8 (0-196) days for AG. Median duration of Grade 3 MSEs was 9 (5-14) days for PAG vs 8.5 (2-22) days for AG. Five (4%) patients experienced MSEs that led to PAG discontinuation: muscle spasms ($n = 4$) and myalgia ($n = 1$). Medications were administered in 57% (PAG) vs. 20% (AG) of MSE episodes, predominantly to manage Grade 3 MSEs.

Conclusions: MSEs are commonly observed with AG treatment, and even more frequently with PAG. MSEs are primarily mild (Grade 1/2) and infrequently lead to treatment discontinuation. The time course, associated dose modifications, and management of MSEs will be presented.

Background: CCL2/CCR2 plays a key role in immunosuppressive properties of the pancreatic adenocarcinoma tumor microenvironment (TME), patients' (pts) prognosis and chemoresistance. PF-04136309 (oral CCR2 inhibitor) blocks recruitment and migration of inflammatory monocytes (IM) from bone marrow (BM) to TME.

Methods: This ongoing multicentre phase Ib study is investigating PF-04136309 in combination with nab-paclitaxel and gemcitabine (nab-P+Gem) in pts with previously untreated metastatic pancreatic ductal adenocarcinoma (mPDAC). Objectives; primary: safety, tolerability, maximum tolerated dose, recommended dose; secondary: pharmacokinetics (PK), pharmacodynamics of PF-04136309; exploratory: efficacy, proof of mechanism (POM), as CCR2 inhibition trapped IMs in BM and decreased IMs in peripheral blood and metastatic tumor tissue with paired tumor biopsies and bone marrow aspirates at baseline and after 1 or 2 cycles.

Results: From May 1, 2016–March 17, 2017, 21 pts (ECOG PS 0-1; mean age 61.8 yrs; range 46-79) received PF-04136309. Cohort 1, starting dose level: 1 grade 3 drug-related DLT (cognitive disorder), 1 grade 2 and 2 grade 1 rashes. Cohort 2 (1 dose level reduction): 4 (23.5%) grade 3 drug-related DLT (1 scalp dysesthesia, 1 ALT-AST, 1 pneumonia, 1 pneumonitis). Recommended total daily dose 1000mg. With median duration of treatment of 4 mo (1–9), grade $\geq$3 drug-related AEs: neutropenia 3 (17.6%), fatigue 4 (23.5%), diarrhea 1 (5.9%), lung toxicities 3 (17.6%); % pts with dose-reduction: nab-P 47%, Gem 53%, PF-04136309 41%; median relative dose intensity: nab-P 84%, Gem 67%, PF-04136309 80%. Early objective response in 10 evaluable pts: PR 6 (60%), SD 1 (10%), PD 3 (30%). Disease control rate at 4 mo: 70%. Median PFS not reached (8 pts on treatment). PF-04136309 PK was consistent with previous single agent studies. Almost all had a drop in peripheral blood CD14+CCR2+ monocytes (baseline-Day 15). IMs decreased and CD4+ and CD8+ T cells increased (5–8 fold) in paired biopsy samples. One of 2 pts had increased tumor associated PD1+CD4+ and PD-1+CD8+ T cells.

Conclusions: Encouraging safety, favorable PK, clinical responses and POM with CCR2 inhibition plus nab-P+Gem in mPDAC pts.

Clinical trial identification: NCT02732938.

Background: Recently, nab-paclitaxel/gemcitabine (NPG) became new standard first-line therapy for metastatic pancreatic cancer. Based on this, our study group has established QoliXane for metastatic pancreatic cancer patients receiving 1st line NPG, to deliver real life and Quality of life (QoL) data and build a platform for translational research (TR). This is an interim analysis of our data focused on efficacy outcome.

Methods: In this a non-interventional registry study, eligible patients were recruited after written informed consent from 95 German cancer centers. The course of therapy, efficacy-, QoL- data (prior to and during therapy) and archival tumor material were prospectively collected. In the present analysis, efficacy endpoints were analyzed in the intention-to-treat population (ITT), defined as all patients who were enrolled.

Results: 539 patients fulfilled the criteria of the ITT. Median age was 70 y (39-86). At the time of analysis, 301 (56%) pts of the ITT were alive. Mean no. of metastatic sites involved was 2. Median no. of cycles administered was 3 (range 0-6). 231 (43%) pts needed any dose modification and 209 (39%) received further therapies beyond progression. 70 (13%) pts had increased bilirubin at baseline, 18 (26%) of them had an intervention e.g. ERCP. Subjects with increased bilirubin without intervention received a median of 3 cycles, with decreasing values under therapy. 135 (25%) pts developed polyneuropathy of any grade. Median progression-free survival was 6 months (95% CI; [5- 6]). Median overall survival (OS) was 10 months (95% CI [8- 10]). 1-year OS was 40%. Median survivals by ECOG PS of 0, 1, 2, and 3 were 12 months, 9 months, 5 months, and 2 months, respectively ($p<.001$).

Conclusions: The "QoliXane" shows excellent real life efficacy data for 1st line therapy with NPG in Germany. In the expansion phase, QoliXane will transform into a permanent, high quality, prospective registry, covering all therapy lines. QoL and translational research data will follow.

Background: The data of FOLFIRINOX as second-line chemotherapy in advanced pancreatic cancer are very limited. The JASPAC06 study, a nation-wide multicenter observational study of FOLFIRINOX for the patients with unresectable or recurrent pancreatic cancer as any line treatment, showed the favorable efficacy and safety in Japanese clinical practice.

Methods: The subjects were the patients with unresectable/recurrent pancreatic cancer who received FOLFIRINOX as second-line chemotherapy.

Results: Of the 399 evaluable patients in the JASPAC06 study, 44 patients were eligible. Patients characteristics were; median age, 62 years; male, 26(59%); ECOG-PS0/1, 30(68%)/14(32%); disease status recurrent/locally/metastatic, 4(9%)/8(18%)/32(73%); biliary drainage, 11(25%); UGT1A1 status *28 and *6 wild/single heterozygous/homozygous or double heterozygous/unknown, 25(57%)/16(36%)/2(5%)/1(2%). The initial dose was reduced in 28(64%) patients. The median time to treatment failure and the number of cycles were 4.5 (range, 6-573 days) months and 6 cycles (range, 1-13 or more). The major grade 3/4 adverse events were neutropenia in 29(66%) patients, leucopenia in 17(39%), anorexia in 7(16%), febrile neutropenia in 5(11%) and anemia in 5(11%). Fatal adverse event occurred in 1 patient, which was a sudden death. The median overall survival, progression free survival and 1-year survival rate were 10.1 (95%CI, 7.1-13.1), 4.1 (95%CI, 1.5-6.8) months and 41.0%, respectively. The overall response rate and disease control rate were 28% and 65%. The reasons for discontinuation of FOLFIRINOX, excluding 2 patients ongoing treatment, were tumor progression in 38(86%) and toxicity in 4(9%).

Conclusions: It was suggested that FOLFIRINOX as second-line chemotherapy in advanced pancreatic cancer was effective for the patients with good PS and toxicity was similar to that as the first-line treatment.

Background: Considering the physical decline of mPAC pts, the assessment of QoL becomes a matter of major concern. We aimed to assess the QoL of mPAC pts treated with first-line CT in routine practice.

Methods: Observational, prospective, multicenter study including mPAC pts who started first-line CT between 2014 and 2015 in 12 Spanish centers. Treatment and clinical characteristics were recorded at CT start (baseline [BL]). The patients' QoL, ECOG, and Karnofsky index (KI) were measured at BL, at days 15 and 30, and every 4 weeks up to 6 mo of CT. QoL was measured using the EORTC QLQ-C30 global health status questionnaire (QLQ). Other variables included treatment response, overall survival (OS), and progression-free survival (PFS).

Results: The study sample included 117 pts with a median age of 65 years (range 37-84). Metastases were mostly hepatic (75%). At BL, median weight loss (last 3 mo) was 9.2%, ECOG was 0-1 and 2 in 82% and 18% of pts, respectively, and KI was 70-80 and 90-100 in 48% and 52% of pts, respectively. Main first-line CT was gemcitabine in monotherapy (19%) or combined with nab-paclitaxel (65%). Overall, median OS and PFS were 9.0 mo (95% CI 6.4-10.6) and 6.0 mo (4.6-7.8), respectively; 3% and 28% of pts achieved a complete and partial response, respectively, with stable disease in 39% of pts. During the follow-up, 64% of pts improved their QoL; the KI showed no significant changes. Of 19 pts with BL ECOG 2, between 67% and 100% had improved their QLQ score at visits at the 1st mo and following. At BL, pts with KI 70-80 had poorer QoL, but experienced a greater improvement than those with KI 90-100 ($p = 0.015$), reaching similar QLQ scores after 2 mo of CT. A similar trend was observed in pts with ECOG 0-1 vs. 2 ($p < 0.001$). Pts improved their QoL irrespective of their weight loss, but those with weight loss $\leq$10% had greater QLQ scores throughout the follow-up ($p = 0.028$). Median OS was higher in pts with BL QLQ $\geq$50 ($p = 0.015$), KI 90-100 ($p = 0.047$), and weight loss $\leq$10% ($p = 0.048$).

Conclusions: The EORTC QLQ-C30 questionnaire is suitable for measuring the QoL of mPAC pts undergoing CT. BL QLQ-C30 $\geq$50, KI 90-100, and weight loss $\leq$10% were associated with a greater OS. Most pts improved their QoL during CT, including those with poorer ECOG and KI at BL.

754P Impact of the duration of diabetes mellitus (DM) on the outcomes of metastatic pancreatic cancer (mPC) treated with gemcitabine (G): A retrospective study

K. Ohashi[1], S. Iizumi[2], A. Kuchiba[3], M. Ikeda[4], Y. Sakamoto[2], S. Kondo[2], C. Morizane[2], H. Ueno[2], K. Osame[1], S. Mitsunaga[4], I. Ohno[4], H. Imaoka[4], Y. Hashimoto[4], H. Takahashi[4], M. Sasaki[4], T. Okusaka[2]

[1]Department of General Internal Medicine, National Cancer Center Hospital, Tokyo, Japan, [2]Department of Hepatobiliary and Pancreatic Oncology, National Cancer Center Hospital, Tokyo, Japan, [3]Biostatistics Division, Center for Research Administration and Support, National Cancer Center, Tokyo, Japan, [4]Department of Hepatobiliary and Pancreatic Oncology, National Cancer Center Hospital East, Kashiwa, Japan

Background: While previous studies showed that patients (pts) with PC and long-standing DM had worse survival than pts without DM, the impact of the duration of DM on therapeutic outcomes has not been sufficiently studied in pts receiving chemotherapy for mPC.

Methods: We retrospectively analyzed the therapeutic results for pts with mPC who received G as standard therapy before the introduction of combination regimens at two sites of the National Cancer Center ("Tokyo" and "Kashiwa"). The efficacies and toxicities of G were compared among three groups classified by the DM duration: no DM, short-term DM (< 4 years), and long-term DM (≥ 4 years). To examine the associations of the DM duration with overall survival (OS) and progression free survival (PFS), Cox proportional hazards model was used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) adjusted for the baseline characteristics.

Results: Overall, 350 pts ("Tokyo": n = 202, 2008-2013; "Kashiwa": n = 148, 2008-2011), were included: 218, 87, and 45 in the no DM, short-term DM, and long-term DM groups, respectively. No statistically significant differences in baseline characteristics were observed among the three groups except for BMI (median [kg/m^2]: 20.7, 21.4, and 22.5; $p = 0.015$, Kruskal–Wallis test). Compared with the no DM group, multivariable-adjusted HRs for PFS were 1.33 (95% CI, 0.94-1.89; $p = 0.103$) for the long-term DM group and 1.12 (95% CI, 0.85-1.47; $p = 0.410$) for the short-term DM group; and those for OS were 1.37 (95% CI, 0.95-1.98; $p = 0.096$) and 1.10 (95% CI, 0.82-1.46; $p = 0.533$), respectively. There were no substantial differences in HRs between "Tokyo" and "Kashiwa" (e.g., HRs of long-term DM for PFS were 1.54 [95% CI, 0.98-2.44] and 1.33 [95% CI, 0.80-2.21], respectively; HRs of long-term DM for OS were 1.32 [95% CI, 0.82-2.14] and 1.34 [95% CI, 0.80-2.26], respectively). Also, HRs for PFS and OS did not substantially change with different cutoff years of DM duration (ranges of HRs of long-term DM with cutoff at 3-5 years: PFS, 1.36-1.55; OS, 1.21-1.33). No significant differences in tumor response and toxicity were observed.

Conclusions: A long pretreatment history of DM may be associated with a shorter PFS and OS among pts with mPC.

755P Prognostic value of neutrophil-lymphocyte ratio in first line treatment for metastatic pancreatic adenocarcinoma

Y.S. Rho[1], J. Ranger[2], S. Hamalova[2], I. Barrera[2], A. Mamo[2], G. Batist[2], P. Kavan[2]

[1]Internal Medicine, University of Hawaii, Honolulu, HI, USA, [2]Department of Oncology, McGill University, Segal Cancer Centre - Jewish General Hospital, Montreal, QC, Canada

Background: Tumor location and pro-inflammatory microenvironment are both implicated in cancer progression and thus measures of these are thought to have important prognostic value. In this study, these readily available factors were examined in patients diagnosed with metastatic pancreatic adenocarcinoma (mPC) being treated in first line with FOLFIRINOX (FFX) or Gemcitabine with nab-Paclitaxol (GNP).

Methods: A cohort of 75 patients diagnosed with mPC between 2010 – 2016 and treated either with FFX or GNP first line were analyzed. The NLR was calculated based on the complete blood count obtained on the day of the first treatment. Cox proportional hazard models were used to estimate hazard ratios (HRs) with 95% confidence intervals (CIs) associating progression free survival to the patients' demographics, treatment, clinical and pathological factors. NLR was treated as a continuous covariate.

Results: Of the total patients (60% male, median age 69), 44 (58.7%) were treated with FFX. At the time of diagnosis, 20 (26.6%) presented with ECOG 0, 43 (57.3%) with primary disease at the head of the pancreas and 25 (33.3%) with liver metastasis. Median NLR at the diagnosis was 5.35 (range 0.9 – 28.3). Increasing NLR was a significant prognostic factor for shorter PFS using a univariate model (HR 1.08, CI: 1.009 – 1.15, P = 0.026). In a multivariate model, significant prognostic factors associated with shorter PFS included primary disease location at the pancreatic tail/body (HR 1.92, CI: 1.009 – 3.664, p = 0.047) and higher NLR (HR 1.11, CI: 1.038-1.189, P = 0.002).

Conclusions: Understanding the prognostic value of pro-inflammatory status and tumor location can allow clinicians to better manage the trajectory of patients with mPC.

Background: Combined treatment of nab-P plus GEM increases survival in patients with MPC. However, treatment efficacy and safety need to be assessed in real-life practice, including pts irrespective of their clinical characteristics and number of dose administrated and treatment duration.

Methods: Retrospective, multicenter study including pts with MPC who started first-line treatment with nab-P plus GEM between December 2013 and June 2015 according to routine clinical practice. Overall survival (OS) and progression-free survival (PFS) were assessed for the total sample and the exploratory subgroups based on treatment and clinical characteristics of pts.

Results: 210 pts (60% males) were enrolled with a median age of 65 years (range 37 – 81); 25% were $\geq$ 70 years. MPC was de novo and recurrent in 78% and 22% of pts, respectively; 18% had a biliary stent. At baseline, 53% of pts had Neutrophil lymphocyte rate (NLR)$>$ 3, 82% CA 19.9 $>$ 35 U/mL, and 18% ECOG $\geq$ 2. Pts received a median of 4 cycles (1 – 21); 32% started treatment with a dose reduction and 17% received $\leq$ 30 days of treatment, mainly due to toxicity (33%) or progression (30%); 25% of pts achieved objective response, and median OS and PFS were 7.2 (95%CI 6.0 – 8.5) and 5.0 (4.3 – 5.9) months (mo), respectively. Compared with pts treated during $>$ 30 days, those with $\leq$ 30 treatment had lower OS (8.6 [7.2 – 10.2] vs. 1.9 [0.8 – 2.3] mo; $p < 0.001$). OS was not influenced by age $\geq$ vs $<$ 70 years ($p = 0.205$) and the presence of a biliary stent ($p = 0.195$), but it was significantly lower in pts with baseline NLR $>$ 3 ($p = 0.002$), CA 19.9 $>$ 35 U/mL ($p = 0.002$), and ECOG $\geq$ 2 ($p = 0.018$); 29% pts experienced at least one grade 3-4 adverse event, mostly neutropenia (14%).

Conclusions: Our results revealed that real-life MPC pts tend to be older and have worse performance status (ECOG) than those included in clinical trials with restrictive selection criteria. In fact, many pts either did not complete 1 month of treatment or started treatment with a dose reduction. Despite these limitations, nab-P plus GEM remains effective in this clinical setting. ECOG $\geq$ 2, NLR $>$ 3, and CA 19.9 $>$ 35 U/mL are associated with lower OS.

757P Safety and efficacy of gemcitabine/nabpaclitaxel in elderly patients with metastatic or locally advanced pancreatic adenocarcinoma: a retrospective analysis

J. Ventriglia, M.M. Laterza, B. Savastano, A. Petrillo, G. Tirino, L. Pompella, A. Pappalardo, M. Orditura, F. Ciardiello, F. De Vita

Clinical and Experimental Medicine, University of Campania Luigi Vanvitelli, Naples, Italy

Background: Gemcitabine/nabpaclitaxel is a polychemotherapy regimen currently used to treat metastatic pancreatic cancer patients with a good performance status (PS). Gemcitabine/nabpaclitaxel significantly improves overall survival (OS) and progression free survival (PFS), but few data are available in elderly patients. Therefore, we carried out a retrospective analysis to evaluate efficacy and safety profile of this combination in a cohort of elderly patients.

Methods: All cases of metastatic pancreatic adenocarcinoma in patients over 70 years old treated at our Department between 2014 and 2016 with gemcitabine/nab-paclitaxel were retrospectively reviewed. The primary objective was to evaluate the safety and efficacy of this regimen in the elderly population.

Results: Forty-six patients with a median age of 73 years (range: 70-79) were included in this analysis: males: 19 (41%); PS2: 6 (13%); primary location: head 26 (57%); biliary stent:14 (30%); previous surgery: 5 (11%); adjuvant CT 5 (11%). Overall response rate (ORR) was 33.3%; median progression-free survival (PFS) was 7 mo (95% CI 5.89-9.10) and median overall survival (OS) was 12 mo (95% CI 10.7-16.13). Treatment was well tolerated. No grade 4 toxicity was reported. Grade 3 toxicity included neutropenia in 5 pts (10%), peripheral neuropathy in 2 pts (4.3%), thrombocytopenia in 2 pts (4%), diarrhea in 3 pts (6.5%), nausea and vomiting in 1 pt (2.1%), and fatigue in 2 pts (4.3%). No significant difference in terms of efficacy and safety was recorded with a cohort of 50 pts under 70 years of age: ORR: 36.6%; median PFS 6.7 mo (95% CI 5.966-8.034), and median OS 10.5 mo (95% CI 7.864-12.136). Finally, pain control was achieved in 15 of 24 patients (62.5%) with a performance status improvement of 10% according to the Karnofsky scale.

Conclusions: Although pancreatic cancer mostly affects elderly people, clinical trials often include few elderly pts. These data suggest that combination of gemcitabine plus nab-paclitaxel is effective and safe in an unselected population of elderly pts showing no differences in outcome between older patients and younger patients treated with this combination.

758P Updated results of a phase II study of gemcitabine, erlotinib, and S-1 in patients with advanced pancreatic cancer

B. Han[1], H.S. Kim[1], D.R. Choi[1], B.Y. Shim[2], K.H. Lee[3], J.W. Kim[4], J.H. Kim[1], H.Y. Kim[1], H. Song[1], D.Y. Zang[1]

[1]Department of Internal Medicine, Hallym University Medical Center Hallym University College of Medicine, Anyang, Republic of Korea, [2]Department of Internal Medicine, St. Vincent's Hospital, College of Medicine, The Catholic University of Korea, Suwon, Republic of Korea, [3]Department of Internal Medicine, Yeungnam University Medical Center, Yeungnam University College of Medicine, Daegu, Republic of Korea, [4]Department of Internal Medicine, Seoul National University Bundang Hospital, Seoul National University College of Medicine, Seongnam, Republic of Korea

Background: Gemcitabine-based chemotherapy is considered as a standard front-line treatment for patients with advanced pancreatic cancer. Although addition of erlotinib or S-1 to gemcitabine has yielded better outcomes, it has showed just modest improvement in survival. To overcome this limitation, we evaluated the efficacy and safety of the combination of gemcitabine, erlotinib, and S-1 for the treatment of advanced pancreatic cancer.

Methods: Chemotherapy-naïve patients with pathologically proven locally advanced, recurrent or metastatic pancreatic adenocarcinoma were assessed for eligibility. Gemcitabine at 1,000 mg/m^2 was administered intravenously on day 1, and 8, erlotinib at 100 mg/day was administered on days 1-21, and S-1 at 60 mg/m^2 was administered on days 1-14 every 21 days and continued to maximum of 8 cycles of treatment. Dose escalation of S-1 to 80 mg/m^2 was permitted from second cycle for pre-defined tolerable patients.

Results: Thirty-seven patients (median age 61.5 years) were enrolled. A total of 140 cycles of chemotherapy were administered (median of 3.8; range 1–8 cycles). Toxicities were evaluated in 36 patients, and the responses were evaluated in 32 patients. Major grade 3/4 toxicities included neutropenia (25%), febrile neutropenia (2.8%), fatigue (22.2%), infection (8.3%), vomiting (5.6%), and mucositis (5.6%). The overall response rate was 12.5% [95% confidence interval (CI), 5.1-28.9%] and disease control rate was 71.9% (95% CI, 56.8-86.3%). The median progression-free survival and overall survival were 3.7 months (95% CI, 2.8-4.6 months) and 6.7 months (95% CI, 3.4-9.9 months), respectively.

Conclusions: The combination of gemcitabine, erlotinib, and S-1 provided an acceptable toxicity profile and modest clinical benefits in patients with advanced pancreatic cancer.

759P PANOVA: a phase II study of TTFields (150 kHz) with concomitant standard chemotherapy for front-line advanced pancreatic adenocarcinoma: Updated efficacy results

M. Kueng[1], C. Guillen-Ponce[2], F. Rivera Herrero[3], J. Gallego Plazas[4], J.A. Lopez-Martin[5], M. Benavides[6]

[1]Oncology-Haematology, HFR Fribourg - Hopital Cantonal, Fribourg, Switzerland, [2]Medical Oncology, Hospital Universitario Ramon y Cajal, Madrid, Spain, [3]Medical Oncology, Hospital Universitario Marques de Valdecilla, Santander, Spain, [4]Medical oncology, Hospital General Universitario de Elche, Elche, Spain, [5]Oncology, Hospital Universitario 12 de Octubre, Madrid, Spain, [6]Medical Oncology, Hospital Universitario Regional y Virgen de la Victoria, Malaga, Spain

Background: TTFields are a non-invasive, regional antimitotic treatment modality approved for the treatment of glioblastoma. TTFields act by disrupting mitotic spindle

formation during metaphase. TTFields were effective in preclinical models of pancreatic cancer. PANOVA was the first trial testing TTFields in pancreatic cancer. Results from the first arm of the study, testing TTFields in combination with gemcitabine, have demonstrated superiority in efficacy versus historical controls (J Clin Oncol 34, 2016 (suppl 4S; abstr 269).

Methods: Twenty advanced pancreatic cancer patients were enrolled in the second arm of PANOVA and treated with TTFields in combination with gemcitabine concomitant to nab-paclitaxel. All patients had unresectable tumors, ECOG score of 0-1 and no prior therapy. The primary endpoint was the incidence and severity of adverse events.

Results: The median age was 68.2 (range – 58-81) and most patients (65%) had an ECOG score of 1. Twelve patients (60%) had distant metastases. Ten patients (50%) had serious AEs during the study period. Eleven patients (55%) had treatment-related skin toxicity, of which 5 had grade 3 toxicity. No TTFields-related serious AEs were reported. The median PFS was 12.7 months (95% CI 5.4, NA): 9.3 months in patients with metastatic disease, and not reached in locally-advanced patients. PFS rate at 6 months was 65%: 50% in metastatic disease and 87.5% in locally advanced patients. Of the evaluable tumors, 40% had partial response and another 47% stable disease. The median OS was not reached, and the 1-year survival rate was 72% (62.5% in metastatic disease and 87.5% in locally advanced disease). None of the patients who had a minimal average compliance of 75% died during the follow up period. 87% of the evaluable patients (including all metastatic patients) had a decrease in CA-19-9 levels.

Conclusions: TTFields concomitant to gemcitabine and nab-paclitaxel are safe for advanced pancreatic cancer patients, with promising clinical outcome which doubled historical data. A phase III trial is planned, testing the efficacy of TTFields combined with gemcitabine and nab-paclitaxel in locally-advanced pancreatic cancer patients.

Background: FFX is considered one of the standard chemotherapy regimens for chemo-naïve unresectable/recurrent PC pts with good performance status (PS), but can be associated with significant toxicity. A high incidence of FN (22%) was reported from a Japanese phase II trial of FFX. The aim of this study was to clarify the risk factors for FN in these pts.

Methods: We used data obtained from the JASPAC06 study. The subjects were pts with unresectable/recurrent PC who received FFX during one year from Dec. 20, 2013. All the subjects were registered and their clinical data were sent to the data center. The logistic regression model was used to estimate odds ratios (ORs) of the potential risk factors for the development of FN.

Results: A total of 399 pts were included in this analysis. Pts characteristics were: median age 63 years; ECOG-PS 0/1/2, 70/29/1%; disease status locally advanced/metastatic/recurrent, 20/60/20%; prior chemotherapy yes/no, 37/63%; biliary stent before FFX 23%; UGT1A1 polymorphism *28 and *6 wild/single heterozygous/homozygous or double heterozygous, 55/38/4%; Dose reduction at initial treatment yes/no, 68/32%. The median number of treatment cycles was 6. FN occurred in 13% of the pts. A multivariate logistic regression analysis showed that the pretreatment white blood cell count(WBC) $< 4000/\mu L$(OR: 4.29, 95%CI: 1.08 to 15.1, $p = 0.028$), platelet count(Plt) $< 15*10^4/\mu L$ (OR: 2.41, 95% CI: 1 to 5.7, $p = 0.046$), serum total bilirubin(T-Bil) $>$ 1.0mg/dL (OR: 5.83, 95% CI: 2.28 to 14.9, $p = 0.0002$), tumor location in pancreatic head (OR: 2.53, 95%CI: 1.17 to 5.76, $p = 0.022$) and no initial dose reduction (OR: 6.13, 95% CI: 2.81 to 14.4, $p < 0.0001$) were significantly associated with higher risk of FN.

Conclusions: Pretreatment WBC $< 4000/\mu L$, Plt $< 15*10^4/\mu L$, T-Bil > 1.0mg/dL, tumor location and no initial dose reduction might be risk factors for the development of FN in unresectable/recurrent PC pts receiving FFX. The predictive factors proposed in our study could be utilized to select the pts at a high risk for the development of FN who may benefit from dose reduction or G-CSF prophylaxis.

761P A Phase I study of LDE225 in combination with gemcitabine and nab-paclitaxel in patients with metastasized pancreatic cancer

K. Lee[1], R.J. Molenaar[1], R. Klaassen[1], M.F. Bijlsma[2], M.J. Weterman[1], D.J. Richel[1], M. Wymenga[3], H.W.M. van Laarhoven[1], J.W. Wilmink[4]

[1]Medical Oncology, Cancer Center Amsterdam, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [2]Laboratory for Experimental Oncology and Radiobiology, Academic Medical Center (AMC), Amsterdam, Netherlands, [3]Medical Oncology, Medisch Spectrum Twente (MST), Enschede, Netherlands, [4]Medical Oncology, Academic Medical Center (AMC), Amsterdam, Netherlands

Background: Metastasized pancreatic cancer has a dismal survival due to poor responses to chemotherapy. Preclinical research suggests that targeting pancreatic tumor stroma with the Sonic Hedgehog inhibitor LDE225 may improve chemotherapy delivery to the tumor.

Methods: We performed a phase IB dose-escalation clinical trial. The primary objectives were to determine the dose-limiting toxicities (DLT), maximum tolerated dose (MTD), and the anti-tumor efficacy of LDE225 in combination with 1000 mg/m^2 gemcitabine and 125 mg/m^2 nab-paclitaxel in patients with metastasized pancreatic cancer. The LDE225 dose was to be escalated, gemcitabine and nab-paclitaxel doses were fixed. Treatment evaluation was performed by CT after 2 cycles of therapy according to RECIST 1.1 criteria. Additional diffusion-weighted MRI scans were performed before and after 2 cycles of treatment.

Results: 26 patients received study treatment for a median duration of 109 days (IQR 54-245) during a median of 4 (IQR 2-8.5) chemotherapeutic cycles. 6 patients discontinued due to toxicity and 20 patients because of progressive disease. At the starting dose level (400 mg LDE225), 1 out of 6 patients experienced a DLT. Because the DLT and most adverse events occurred in patients who received prior chemotherapeutic treatment we divided the cohort in a chemo-naïve ($n = 17$) and a prior-chemo group ($n = 9$). Within the chemo-naive group, the MTD was 800 mg LDE225. In the prior-chemo group, the MTD was 200 mg LDE225. No therapy-related grade 4 adverse events were reported. The most frequent grade 3 reported adverse events were: fatigue (27%), neutropenia (15%) and diarrhea (12%). Of 23 evaluable patients, 6 patients had progressive disease (26%), 8 had stable disease (35%), 8 had a partial response (35%) and 1 patient had a complete response (4%). 12 patients with SD/PR underwent both MRI scans. These patients showed a significant increase in diffusion coefficient after treatment ($1.39 \pm 0.24 \times 10^{-3}$ *vs.* $1.62 \pm 0.25 \times 10^{-3}$ mm^2/s, $P < 0.001$).

Conclusions: The addition of LDE225 to gemcitabine and nab-paclitaxel was well tolerated and showed promising anti-tumor activity, regardless of whether or not patients had received prior chemotherapy for metastatic pancreatic cancer.

762P Impact of advances in systemic chemotherapy for unresectable pancreatic ductal adenocarcinoma (PDAC) in Alberta, Canada

R. Lee-Ying[1], J. Loree[2], W.Y. Cheung[1], P. Tang[1]

[1]Medical Oncology, Tom Baker Cancer Centre, Calgary, AB, Canada, [2]Medical Oncology, British Columbia Cancer Agency, Vancouver, BC, Canada,

Background: Since 2011, new systemic therapy combinations, FOLFIRINOX and nab-paclitaxel with gemcitabine, have demonstrated improvements in survival for PDAC. It is unclear if the availability of these therapies have changed referral patterns or the uptake of systemic treatment in the Canadian context, or improved real world outcomes.

Methods: We performed a population-based analysis of patients with a biopsy-proven unresectable/metastatic PDAC from 2009-2016 in Alberta, Canada. The primary outcome was overall survival (OS) of patients who received chemotherapy, pre and post 2011, while controlling for relevant patient and disease characteristics. Secondary outcomes include the proportion of patients referred to a cancer centre, and receipt of systemic treatment in a universal health care system.

Results: A total of 1764 patients with PDAC were identified, with a median age of 70, 51% male, 86% metastatic disease and 59% occurring in the head or neck. 485 patients were diagnosed prior to 2011 while 1279 were diagnosed after. Rates of cancer centre referrals after 2011 increased from 44 to 50% ($p = 0.03$), but there was no difference in the use of initial chemotherapy (26 vs 28%, $p = 0.44$). Use of single agent regimens decreased (81% to 53%) in favour of combination therapy ($p < 0.01$). Specifically FOLFIRNOX changed from (12 to 21%) and nab-paclitaxel (3 to 21%).The median OS of patients pre-2011 who received chemotherapy compared to best supportive care (BSC) was 8.4 vs 1.8 months, and post-2011 7.3 vs 1.6 months, $p < 0.01$. After controlling for age, sex, primary location, stage, chemotherapy use and era, there was no difference in outcomes pre and post 2011, HR 1.057, 95% CI 0.95-1.18, $p = 0.31$, but chemotherapy improved survival compared to BSC, HR 0.32, 95% CI0.28-0.36, $p < 0.01$.

Conclusions: The natural history of PDAC remains very poor, despite advances in systemic therapy. The majority of patients are not receiving systemic chemotherapy, highlighting the need for improvements in diagnosis and referral, even in a universal health care system. There are no modern trials comparing best supportive care to modern chemotherapy, and this population-based study demonstrates a real-world benchmark for improving patient outcomes.

Background: Hyaluronan (HA) accumulation in the tumor microenvironment produces elevated tumor pressure, vascular compression, and reduced drug delivery. PEGPH20 degrades HA, increasing the access and therapeutic index of anticancer agents.

Methods: In Stage 1 of this phase 2 study, pts with untreated mPDA were randomized 1:1 to PAG (P; 3 µg/kg IV 2x/wk x 3 wks in C1, then 1x/wk x 3 wks in C2+, plus AG) vs AG every 28 days. An imbalance in thromboembolic (TE) events in the PAG arm led to a clinical hold (~40% of pts discontinued PEGPH20), exclusion of pts at high risk for TE events and enoxaparin prophylaxis for all pts. In Stage 2, randomization was 2:1 to PAG vs AG. Tumor HA was tested using a novel assay (VENTANA HA RxDx). Primary endpoints were PFS (evaluable pts) and TE event rate (Stage 2). Secondary endpoints were PFS by HA level and ORR.

Results: 279 pts were randomized; 231 are efficacy evaluable. Of 246 pts with HA data, 84 (34%) were HA-High. As of December 16, 2016, the primary PFS endpoint was statistically significant for PAG vs AG (HR 0.73, 95% CI 0.53-1.00; $p = 0.048$) (Table). PFS in HA-High pts was also statistically significant for PAG vs AG (HR 0.51; 95% CI 0.26-1.00; $p = 0.048$). ORR in HA-High pts was 46% (PAG) vs 34% (AG). Overall survival in HA-High pts (exploratory) was 11.5 months (mo) (PAG) and 8.5 mo (AG) (HR 0.96, 95% CI 0.57-1.61). TE events were similar (PAG 14% vs AG 10%) with enoxaparin initiation.

Table: 763P

Population	Events/Total, n Median PFS, months		HR (95% CI)	P value
	PAG	AG		
Efficacy Evaluable (n = 231)	100/139; 6.0	65/92; 5.3	0.73 (0.53, 1.00)	0.048
HA-High (n = 84)	24/49; 9.2	19/35; 5.2	0.51 (0.26-1.00)	0.048

All grade treatment-related AE included peripheral edema (PAG 63% vs AG 26%), muscle spasms (56% vs 3%), neutropenia (34% vs 19%), and myalgia (26% vs 7%).

Conclusions: Randomized Phase 2 study met both primary endpoints (PFS and TE event rate), with the largest improvement in the secondary endpoint of PFS in HA-High pts. These data support HA as a potential predictive biomarker for pt selection of PEGPH20, currently investigated in the global Phase 3 HALO 301 study with PFS and OS as co-primary endpoints. 764P Crucial relationship of neural wiskott aldrich syndrome protein(N-WASP) and lysyl oxidase-like 2(LOXL2) in the promotion of pancreatic cancer metastasis

H. Kim, J.S. Park

Department of Surgery, Gangnam Severance Hospital, Seoul, Republic of Korea

Background: Pancreatic cancer is known to have aggressive malignancy and poor prognosis. N-WASP is part of the WASP family that regulate actin polymerization. FAK (Focal adhesion kinase) promotes N-WASP and epithelial mesenchymal transition(EMT) in cancer metastasis. Previous studies reported the overexpression of LOXL2 activates FAK and Snail and promotes distant metastasis in pancreatic cancer. However, there are few evidence of the relation between LOXL2 and N-WASP. In this study, we aimed to confirm the expression of N-WASP and relationship of N-WASP and LOXL2 in pancreatic cancer.

Methods: Between June 2002 and December 2012, 80 patients underwent curative resection for pancreatic cancer at Gangnam Severance Hospital, Korea. Pancreatic cancer cell lines MIA PaCa-2, PANC-1 were used for in vitro study. We purified the whole RNA and protein to perform the RT-PCR and Western blot. We performed Chromatin immunoprecipitation(ChIP) assay to probe the interaction between Snail and promoter of N-WASP. And we confirmed the motility and invasiveness of MIA PaCa-2 and PANC-1.

Results: Among the 80 patients, 81.2% were positive for LOXL2. On univariate and multivariate analyses, poor differentiation and LOXL2 were identified as prognostic factors for DFS. High expression of LOXL2 and N-WASP were observed and correlated with the expression of mesenchymal markers (Snail, L1CAM, Vimentin). We generated stably LOXL2 silenced pancreatic cancer cell which exhibited significant changes of factors related to invasiveness and N-WASP expression. There were poorly expressions of N-WASP in Snail silencing of same cell lines. In ChIP assay, we obtained the results of the association of Snail proteins with promoter of N-WASP. Silencing of N-WASP decreased motility and invasiveness of MIA PaCa-2 and PANC-1 as determined from wound healing assay.

Conclusions: Our results demonstrated that N-WASP is a regulator of EMT in pancreatic cancer. By identifying of N-WASP expression promoted by Snail, LOXL2 and N-WASP have a powerful relationship for activating the promotion of EMT in pancreatic cancer metastasis. These findings suggest that N-WASP can be a target for the determining of distant metastasis in pancreatic cancer.

Background: We have conducted the Nationwide Cancer Genome Screening Project in Japan since April 2015 using Next Generation Sequencing in advanced non-colorectal gastrointestinal (GI) cancer (aNon-CRC), called as the SCRUM-Japan GI-SCREEN.

Methods: This study is ongoing with 20 major cancer centers. Patients with aNon-CRC, including who plan to or receive chemotherapy were eligible. DNA and RNA were extracted from FFPE tumor samples and were analyzed by the Oncomine Cancer Research Panel (OCP) which allows to detect gene mutations, copy number variants (CNVs) and gene fusions across 143 genes in a CLIA certified CAP accredited laboratory. The detected genomic variant data were classified according to genetic drivers of cancer including gain- and loss-of-function or single nucleotide variant based on the Oncomine Knowledgebase. In this presentation, we show the results of advanced small intestine cancer cohort.

Results: As of October 31st in 2016, a total of 36 advanced small intestine cancer samples were analyzed. The sequence was successfully performed in 26 tumors (72.2%). Out of 26 patients, the primary tumors are located in duodenum ($n = 15$), jejunum ($n = 7$), and ileum ($n = 2$), and unknown ($n = 2$). The frequently detected mutations in 26 samples of which results were available were *KRAS* (50.0%), *TP53* (42.3%), and *APC* (23.1%). The frequently detected CNVs ($\geq$ 7copies) were *MDM2* (7.7%) and *CDK6* (3.8%). *PIK3CA* mutations were identified in 4 cases (15.4%) and *BRAF* mutations were identified in 2 cases (7.7%). No gene fusion was detected.

Conclusions: This nationwide screening system is efficient to detect rare gene alterations in advanced small intestine cancer. This novel knowledge provides an intriguing background to investigate new target approaches and represents a progress toward more precision medicine.

766P Frequent ERBB3 (HER3) activating mutations in small bowel adenocarcinomas

L. Cabel[1], I. Bieche[1], T. Aparicio[2], M. Svrcek[3], A. Zaanan[4], P. Afchain[5], F. Di Fiore[6], J-M. Gornet[7], D. Le Corre[8], S. Vacher[1], C. Callens[1], V. Bernard[9], P. Laurent-Puig[8], F-C. Bidard[10]

[1]Department of Genetics, Institut Curie, Paris, France, [2]Oncology, Hôpital Avicenne, Bobigny, France, [3]Pathology, Hopital Saint Antoine, Paris, France, [4]Department of Gastroenterology, Hopital European Georges Pompidou, Paris, France, [5]Oncology, Hopital Saint Antoine, Paris, France, [6]Oncology, CHU Charles Nicolle, Rouen, France, [7]Department of Gastroenterology and Digestive Oncology, Hôpital St. Louis, Paris, France, [8]Department of Biology, Paris Descartes University, Paris, France, [9]NGS platform, Institut Curie, Paris, France, [10]Oncology, Institut Curie, Paris, France

Background: Functional studies have demonstrated that mutations of the ERBB3 oncogene, which encodes the HER3 receptor, are oncogenic through the activation of the HER2 signalling pathway (Jaiswal et al, Cancer Cell 2013). We and other have reported a significant clinical activity of anti-HER2 therapy in patients with ERBB3-mutated cancers (trastuzumab/lapatinib combination: Bidard et al, Ann Oncol 2015; afatinib: Choudury et al, JCO 2016). This study aimed at reporting the rate of activating ERBB3 mutations in small bowel adenocarcinoma (SBC), a rare tumor type in which we previously reported a high rate (12%) of activating ERBB2 mutations (Laforest et al, Eur J Cancer 2014).

Methods: DNA from 74 SBC, which have been previously characterized for ERBB2 mutations and MSI status, were subjected to HRM analysis followed by Sanger sequencing of ERBB3 exons 3, 6, 7, 8 and 23. Orthogonal validation by targeted NGS was performed for two patients (HiSeq, 50 genes, mean depth 10000x)

Results: 4 of the 74 SBC (5.4%) displayed activating *ERBB3* mutations, including 3 p.V104M mutations (c.310 G>A) in exon 3 and 1 p.E928G mutation (c.2783 A>G) in exon 23. No mutation was detected in exon 6, 7 and 8. Activating *ERBB3* mutations were associated with microsatellite instability ($p = 0.002$) and with the presence of activating *ERBB2* mutations ($p = 0.002$). 2 SBC cases with a co-occurrence of *ERBB2* and *ERBB3* mutations were further analyzed by targeted NGS: in addition to confirming the co-occurence of these activating mutations, mutant allelic frequencies did not suggest a subclonal distribution: 24.3% (*ERBB3* p.V104M) vs 25.9% (*ERBB2* p.L755S) and 18.5% (*ERBB3* p.V104M) vs 24.5% (*ERBB2* p.L755S) vs 20.6% (*BRCA2* p.Q1782fs) in the first and second case, respectively.

Conclusions: SBC display a high rate of *ERBB3* activating mutations, which have been shown to be targetable by anti-HER2 therapies. Strikingly, in most cases, *ERBB3* was co-mutated with *ERBB2*, suggesting a strong oncogenic addiction of these SBC to the HER2 pathway.

Background: Peritoneal metastasis (PM) is detected synchronously in ~30% of patients with advanced gastric cancer (AGC), which has been considered as late stage of the disease with a poor prognosis and were generally treated with systemic chemotherapy or best supportive care. Two new surgical modalities that have evolved to manage PM are cytoreductive surgery (CRS) and hyperthermic intraperitoneal chemotherapy (HIPEC). Our and other published retrospective data suggested that CRS plus HIPEC may prolong overall survival of the patients with limited PM. Still, the solid evidences based on large randomized clinical trials (RCT) are lacking. Accordingly, the present trial was initiated to define a comprehensive treatment.

Trial design: The investigator-initiated, multicenter, prospective two-arm RCT is comparing efficacy of CRS followed by HIPEC (CRS+HIPEC) versus chemotherapy (5-Fu based regimen, Chemo) alone for the treatment of AGC with limited PM. Eligibility for the trial is given in cT3-4NxM1 (M1 limited to peritoneum, PCI score < 20 evaluated by diagnostic laparoscopy)AGC. The trial will recruit 220 participants who are 1:1 randomized to one of two arms after diagnostic laparoscopy. Participants enrolled in the Chemo study arm will receive standard chemotherapy according to the NCCN guideline. The CRS+HIPEC study arm will receive D2 gastrectomy plus peritonectomy plus HIPEC followed by systemic chemotherapy. The primary endpoint of the trial is overall survival. The secondary endpoints include progression-free survival, morbidity and mortality and quality of life. Biological substudies on biomarkers are included. Current status: The trial was approved by the Ethical Committee of Nanfang hospital, Southern Medical University, Guangzhou, China. Patient recruitment has begun in January 2017. Overall 12 Chinese sites will commence recruitment in 2017.

768TiP A prospective multicenter, phase II trial (NAC-GA trial) to evaluate the effect of neoadjuvant nab-paclitaxel plus gemcitabine therapy on overall survival in patients with borderline resectable pancreatic cancer

K-I. Okada[1], T. Shimokawa[2], S. Hirono[1], M. Kawai[1], M. Miyazawa[1], Y. Kitahata[1], H. Yamaue[1]

[1]Second Department of Surgery, Wakayama Medical University, Wakayama, Japan, [2]Clinical Study Support Center, Wakayama Medical University, Wakayama, Japan

Background: Overall survival after neoadjuvant therapy and surgery for Borderline resectable pancreatic carcinoma (BRPC) is recognized as a goal for a multidisciplinary approach.

Trial design: Objective: The NAC-GA trial was a prospective multicenter phase II trial and its implementation was planned for patients with BRPC defined as borderline by the National Comprehensive Cancer Network (Version 2.2016) to investigate improvement of overall survival after the first day of initial therapy. Endpoints: This clinical trial primarily evaluated the primary endpoint of overall survival time from the first day of protocol therapy. The secondary endpoints were recurrence-free survival from the first day of protocol therapy, safety of the protocol therapy (adverse effects), morbidity, response rate, disease control rate, preoperative/postoperative tumor marker (CA19-9, CEA), rate of normalization, reduction rate of SUVmax value on PET-CT, chemotherapeutic effect, resection rate, R0 resection rate, surgical data, overall morbidity rates, rate of patient undergo postoperative adjuvant therapy, dose intensity, quality of life regarding fatigue and malaise assessed by the questionnaire of FACIT-F, and peripheral sensory neuropathy (PSN) assessed by the questionnaire of FACT/GOG-NTX subscale (Version 4) and Patient Neurotoxicity Questionnaire (PNQ). Sixty patients were included in the study. Treatment Methods: Enrolled patients were administered a 30-min intravenous infusion of nab-paclitaxel at a dose of 125 mg/m^2, followed by a 30-min intravenous infusion of gemcitabine at a dose of 1000 mg/m^2, on days 1, 8 and 15 over a four-week period as one cycle of regimen. Even if the dose on day 8 was missed, the next dose was still administered on day 8 of the same cycle as originally scheduled. All patients were given one week of rest between two cycles. This regimen was repeated twice. In the absence of disease progression, patients would undergo planned pancreatectomy within eight weeks. Postoperative adjuvant therapy was unregulated in this study.

Background: Gemcitabine (GEM) is a standard treatment for locally advanced pancreatic cancer (LAPC), but the prognosis is still poor. FOLFIRINOX and GEM plus nab-paclitaxel (GnP) have recently shown superior efficacy over GEM in patients (pts) with metastatic disease, and may also benefit LAPC pts. In addition, phase II study of modified FOLFIRINOX (mFOLFIRINOX), in which dose of irinotecan was reduced and bolus 5-FU was omitted, conducted in Japan showed comparable efficacy with original regimen and tolerable toxicity. The aim of this study is to evaluate the efficacy and safety of mFOLFIRINOX and GnP to determine which is more promising regimen for LAPC. Another aim of this study is to compare the selected regimen with historical control of GEM to determine which should be a standard therapy for LAPC.

Trial design: Chemotherapy-naïve pts with LAPC, an ECOG PS of 0–1, aged 20-75, and adequate organ function are randomized to mFOLFIRINOX or GnP. In the mFOLFIRINOX arm, 85 mg/m^2 of oxaliplatin, 200 mg/m^2 of l-leucovorin, 150 mg/m^2 of irinotecan, followed by 2,400 mg/m^2 of continuous 5-FU over 46 hours are infused every 2 weeks. In the GnP arm, 125 mg/m^2 of nab-paclitaxel followed by 1,000 mg/m^2 of gemcitabine are infused on days 1, 8, and 15 every 4 weeks. Both treatments are continued until disease progression or unacceptable toxicity. The primary endpoint is 1-year overall survival (OS). To select the more effective regimen in 1-year OS (53% vs $\geq$ 63%), 106 pts are needed with a probability of at least 0.85. After selecting the more promising regimen, to judge that regimen replaces GEM as a standard chemotherapy for LAPC, 120 pts are needed to maintain 80% power under the hypothesis of 1-year OS as the expected value of 70% and threshold value of 53% with one-sided alpha of 5%. The planned total sample size is 124 pts considering for a few ineligible pts and lost to follow-up. The planned accrual period is 2.5 years, and the follow-up period is 1 year for primary analysis. Thirty-six institutions are participating in this study. This study was activated in July 2016 and 24 pts were enrolled as of Apr 30, 2017.

770TiP NIFE-trial: Liposomal irinotecan (nal-IRI) plus 5-fluorouracil (5-FU) and leucovorin (LV) or gemcitabine plus cisplatin in advanced biliary-tract cancer: An open label, randomized, multicenter phase II trial of the AIO

T.J. Ettrich, L. Perkhofer, A.W. Berger, T. Seufferlein
Internal Medicine I, Ulm University, Ulm, Germany

Background: Biliary tract cancer (CCC) is associated with a poor prognosis due to mostly advanced stages at diagnosis. Overall survival does not exceed 6 months and the 5-year overall survival rate is less than 5% for patients with advanced or metastatic disease. Advanced CCC shows response to chemotherapy resulting in an improved disease control, improved survival and quality of life (QoL). In the ABC-02 phase III trial, gemcitabine combined with cisplatin compared with gemcitabine alone prolonged PFS (8.0 vs. 5.0 mo) and OS (11.7 vs. 8.1 mo) and is considered as standard of care. So far this regimen has not been compared with other active combination regimen. Irinotecan in combination with 5-FU showed promising results in 1st- and 2nd-line therapy in many GI cancers. In pancreatic adenocarcinomas, the combination of liposomal irinotecan (nal-IRI) plus 5-FU/LV improves survival in a post gemcitabine-based treatment setting. Our research hypothesis is that this regimen compares well with respect to clinical endpoints with the standard of care gemcitabine plus cisplatin in patients with advanced CCC.

Trial design: NIFE is a randomized study for patients (to be enrolled: n = 92) with locally advanced or metastatic, non-resectable, adenocarcinoma of the biliary tract: Arm A (experimental): Nal-IRI 80 mg/m2, leucovorin 400 mg/m2, 5-FU 2400 mg/m2, on day 1, cycle q2w), Arm B (standard): Cisplatin 25 mg/m2 and Gemcitabine 1000 mg/m2 on day 1 and 8, cycle q3w. NIFE is an open label, non-comparative, multicenter, two-sided phase II study with an unconnected analysis of the results in both arms against a fixed PFS rate (< 40% at 6 months). The randomization (1:1) is eminent to achieve two comparable patient groups. Primary objective is PFS at 6 months. Key secondary objectives are 3-year OS, PFS, ORR, DCR and QoL/TUDD. There will be a retrospective central surgical and radiological review. Tissue and blood sample collection will be mandatory for biomarker analyses (microdissection and exome sequencing of tumor tissue, ctDNA exome sequencing, transcriptome, miRNA-arrays). Start was in II/2017 in 25 centers in Germany.

771TiP A feasibility study of TAS-118 plus oxaliplatin as perioperative chemotherapy for locally advanced gastric cancer

A. Takashima[1], D. Takahari[2], N. Ishizuka[3], H. Katai[4], T.E. Nakajima[5], M. Ohashi[6], S. Mikami[7], S. Takahashi[8], T. Sano[6], N. Boku[1], K. Yamaguchi[2]
[1]Gastrointestinal Medical Oncology, National Cancer Center Hospital, Tokyo, Japan, [2]Gastroenterology, Cancer Institute Hospital of JFCR, Tokyo, Japan, [3]Clinical Trial Planning and Management, Cancer Institute Hospital of JFCR, Tokyo, Japan, [4]Gastric Surgery, National Cancer Center Hospital, Tokyo, Japan, [5]Clinical Oncology, St. Marianna University School of Medicine, Kanagawa, Japan, [6]Gastroenterological Surgery, Cancer Institute Hospital of JFCR, Tokyo, Japan, [7]Gastrointestinal and General Surgery, St. Marianna University School of Medicine, Kanagawa, Japan, [8]Medical Oncology, Cancer Institute Hospital of JFCR, Tokyo, Japan

Background: TAS-118 is a novel combination antitumor agent, which the components of S-1, i.e. tegafur (FT), gimeracil (CDHP), and oteracil potassium (Oxo), are combined with calcium folinate (LV) into one granular form. In a phase II study, S-1 plus LV and oxaliplatin was more active than S-1 plus LV or S-1 plus cisplatin with acceptable toxicities for patients with advanced gastric cancer. A phase 3 study comparing TAS-118 plus oxaliplatin with S-1 plus cisplatin in advanced gastric cancer is in progress in Japan and Korea (NCT02322593). This study is designed to assess feasibility of preoperative adjuvant chemotherapy with TAS-118 plus Oxaliplatin, and postoperative adjuvant therapy with TAS-118 alone or TAS-118 plus Oxaliplatin, in patients with resectable locally advanced gastric cancer with lymph node metastasis.

Trial design: Histopathologically confirmed locally advanced gastric cancer pts with cT3-4N1-3M0 on image findings (Japanese Classification of Gastric Carcinoma, 14th Edition) with no distant matastasis, aged 20 to 79 years, are enrolled in this study. Eligible pts will receive the regimen consists of 3 parts: i) preoperative 4 courses of TAS-118(80-120mg/body; day1-7) plus Oxaliplatin (85mg/m^2; day1) every two weeks ii) gastrectomy with D2 lymphadenectomy iii) postoperative 12 courses of TAS-118 alone(80-120mg/body;day1-7) (step1) or 8 cycles of TAS-118 plus Oxaliplatin(step2); every two weeks . The primary endpoints are feasibility of i) preoperative adjuvant chemotherapy with TAS-118 plus Oxaliplatin and gastrectomy, ii) postoperative adjuvant chemotherapy with TAS-118 alone(step1) and TAS-118 plus Oxaliplatin(step2). The target sample size is 45. Secondary endpoints include the treatment completion rate of chemotherapy and surgery, relative dose intensity, clinical and pathological response rates for preoperative chemotherapy, R0 resection rate, down staging rate, relapse free and overall survival, and safety. This IIT study is conducted in 3 sites in Japan and has initiated from November 2016.

772TiP A phase 1/2 study of ramucirumab plus nivolumab in patients with previously treated advanced gastric adenocarcinoma

H. Shoji[1], H. Miyamoto[2], H. Hara[3], D. Takahari[4], N. Machida[5], T. Esaki[6], K. Nagashima[7], K. Aoki[8], K. Honda[9], Y. Nagata[1], T. Miyamoto[1], N. Boku[1], K. Kato[1]
[1]Gastrointestinal Medical Oncology Division, National Cancer Center Hospital, Tokyo, Japan, [2]FIVERINGS CO., LTD., Osaka, Japan, [3]Department of Gastroenterology, Saitama Cancer Center Hospital, Saitama, Japan, [4]Department of Gastroenterology, Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, Japan, [5]Division of Gastrointestinal Oncology, Shizuoka Cancer Center, Shizuoka, Japan, [6]Department of Gastrointestinal and Medical Oncology, National Kyushu Cancer Center, Fukuoka, Japan, [7]Department of Global Clinical Research, Graduate School of Medicine, Chiba University, Chiba, Japan, [8]Division of Molecular and Cellular Medicine, National Cancer Center Reseach Institute, Tokyo, Japan, [9]Division of Chemotherapy and Clinical Research, National Cancer Center Reseach Institute, Tokyo, Japan

Background: Nivolumab (Nivo) is a human IgG4 programmed death receptor-1 (PD-1) monoclonal antibody that blocks the interaction between PD-1 and its ligands, releasing PD-1 pathway-mediated inhibition of the anti-tumor immune response. Nivo has demonstrated significant improvement in overall survival (OS) in the phase III trial (ONO4538-12) for patients (pts) in salvage line treatment of advanced gastric cancer (AGC). Ramucirumab (Ram) is a human IgG1 monoclonal VEGFR-2 antagonist antibody. Ram as monotherapy or in combination with paclitaxel, prolonged survival in AGC. Blocking VEGFR-2 relieves T cell exhaustion by reverting the expression of inhibitory molecules, and improves T cell infiltration into tumors. Based on synergistic anti-tumor effect induced by simultaneous blockades of PD-1 and VEGFR-2 in preclinical studies, this phase I/II study is designed to investigate the safety and tolerability of Nivo plus Ram in the 2nd line chemotherapy for with AGC. This study is conducted at 5 sites in Japan and started in January 2017.

Trial design: AGC pts with measurable lesions, aged $\geq$ 20 years, after disease progression on 1st line chemotherapy (platinum plus fluoropryimidine) will be enrolled in this study. Eligible pts will receive Ram and Nivo every two weeks until unacceptable toxicity or disease progression. In the phase I part, the doses of Ram/Nivo will set at 8/3 mg/kg (level 1) and 8/1 (level 0), and the recommended dose (RD) of Ram and Nivo will be determined based on the safety of 6 patients. In the phase II part, the primary endpoint is a 6-months progression-free survival (PFS) rate. The planned sample size is 44 with one-sided alpha of 0.05 and power of 80% based on the expected and threshold 6-months PFS ratios as 36% and 18% (using the Kaplan–Meier estimator). Secondary endpoints include overall response rate, disease control rate, overall survival, and safety. Exploratory endpoints include anti-tumor immune response using immune gene expression, PD-L1 and mismatch repair protein expression in tumor tissue, immune cell subset in peripheral blood, serum drug concentration measurements, serum microRNA expression, and genomic profiling of CTCs using next-generation sequencing, etc. Clinical trial information: NCT02999295

Background: In advanced gastric cancer, doublet regimen with cisplatin and fluoropyrimidine is considered as a 1st-line standard treatment (trt). Taxane is also effective in 2nd line. The addition of docetaxel (75 mg/m^2) to cisplatin (75 mg/m^2) and 5-fluorouracil ("DCF regimen") every 3 weeks has been shown to improve efficacy of 1st-line trt in a phase III trial. However, this regimen was associated with more frequent grade 3-4 toxicities, such as diarrhea, neutropenia and complicated neutropenia (febrile neutropenia or neutropenic infection). Oxaliplatin has been shown to be more tolerable than cisplatin with the same efficacy. The addition of docetaxel at 50 mg/m^2 every 2 weeks to the FOLFOX (TFOX regimen) showed to be active and tolerable in phase II studies and less toxic as compared DCF regimen. The aim of this current phase III study is to compare FOLFOX to TFOX in 1st line trt of advanced gastric cancer.

Trial design: The major eligibility criteria are: Patient $\geq$ 18 years, WHO PS $\leq$ 1, with histological proven gastric or gastro-oesophageal junction HER2 negative adenocarcinoma, metastatic or locally advanced measurable disease (RECIST v1.1 criteria). Trt is administered every 14 days.

Table: 773TiP

	FOLFOX (BRAS A)	TFOX (BRAS B)
Folinic acid (D1)	400 mg/m^2	400 mg/m^2
Oxaliplatin (D1)	85 mg/m^2	85 mg/m^2
5FU bolus (D1)	400 mg/m^2	
5FU continu (D1-2)	2400 mg/m^2	2400 mg/m^2
Docétaxel (D1)		50 mg/m^2

Trt has to be administrated until disease progression or unacceptable toxicity. The primary criterion is radiological/clinical progression-free survival (PFS). A difference of 2 months for the median PFS in favor of TFOX is expected (5.5 months in FOLFOX arm vs 7.5 months in TFOX arm), HR = 0.73. (α = 5%, power of 90%, O'Brien – Fleming function). An interim analysis is planned at 227 events (progression or death) for early efficacy or futility search. Secondary criteria are: overall survival, objective response rate, therapeutic index, toxicity, time to final deterioration in quality of life. Stratification factors are: centre, WHO PS, adjuvant chemotherapy or radio-chemotherapy, tumour stage, primary tumour location and pathological subtype. 17 patients have been randomized over the 506 planned since 19/12/2016.

774TiP Global phase 3, randomized, double-blind, placebo-controlled study evaluating PEGylated recombinant human hyaluronidase PH20 (PEGPH20) plus nab-paclitaxel and gemcitabine in patients with previously untreated, hyaluronan (HA)-high, stage IV pancreatic ductal adenocarcinoma (PDA)

E. Van Cutsem[1], A. Hendifar[2], M. Reni[3], L. Zheng[4], M. Ducreaux[5], W. Harris[6], P. Corrie[7], T. Seery[8], D. Chondros[9], A. Bullock[10]

[1]Digestive Oncology, University Hospitals Gasthuisberg Leuven and KU Leuven, Leuven, Belgium, [2]Cedars-Sinai Medical Center, Samuel Oschin Cancer Center, Los Angeles, CA, USA, [3]Oncology, Ospedale San Raffaele, Milan, Italy, [4]Oncology, The Johns Hopkins University Hospital, Baltimore, MD, USA, [5]GI Unit, Gustave Roussy, Paris, France, [6]Oncology, University of Washington School of Medicine, Seattle, WA, USA, [7]Medical Oncology, Cambridge University Hospitals NHS Foundation Trust - Addenbrooke's Hospital, Cambridge, UK, [8]Infusion Center, University of California, Irvine, CA, USA, [9]Clinical, Halozyme Therapeutics, San Diego, CA, USA, [10]Division of Hematology-Oncology, Beth Israel Deaconess Medical Center, Boston, MA, USA

Background: Poor outcome in PDA is associated with stromal hyaluronan (HA) accumulation, which may compromise treatment access. In animal models, PEGPH20 degrades tumor HA. Key data from a Phase 2 study showed that PEGPH20 plus chemotherapy improved efficacy over chemotherapy alone in tumors retrospectively identified to accumulate HA ("HA-High"). The objectives of this Phase 3 study are to compare efficacy and safety of standard-dose nab-paclitaxel (NAB) and gemcitabine (GEM) combined with PEGPH20 or placebo in patients with HA-High, previously untreated, Stage IV PDA. Primary endpoints are progression-free survival (PFS) and overall survival (OS). Secondary endpoints are objective response rate, duration of response, and safety.

Trial design: 420 patients $\geq$18 years with untreated HA-High metastatic PDA, ECOG PS 0-1 are randomized (stratified by North America/Europe/Other) 2:1 to NAB 125 mg/m^2 + GEM 1000 mg/m^2 + PEGPH20 3.0 µg/kg or to NAB + GEM + placebo, respectively. Patients with HA-High tumors are prospectively identified by the co-developed VENTANA HA RxDx Assay, which identifies HA in the extracellular matrix. HA-High status (indicating patients who may achieve clinical benefit) was determined by Halozyme to be $\geq$ 50% HA staining based on clinical outcome data from a Phase 2 study. Treatment is provided in 4-week cycles (Wk 1-3, Wk 4 rest) until disease progression, unacceptable toxicity, death, or consent withdrawal. PEGPH20 or placebo is given twice weekly (Cycle 1) then weekly (Cycles 2+), NAB + GEM once weekly for all cycles. Dexamethasone is given before and after PEGPH20 to reduce treatment-related musculoskeletal symptoms and enoxaparin is given to minimize thromboembolic events. Tumor response will be assessed by an independent central imaging vendor using RECIST v1.1. Adverse events will be graded per NCI CTCAE v4.03. An independent Data Monitoring Committee will evaluate safety and efficacy (PFS and OS) data. Trial initiated Q12016 (EudraCT 2015-004068-13; NCT02715804).

775TiP KEYNOTE-240: Phase 3, randomized study of pembrolizumab (pembro) vs best supportive care (BSC) for second-line advanced hepatocellular carcinoma (HCC)

R.S. Finn[1], S.L. Chan[2], A.X. Zhu[3], J. Knox[4], A-L. Cheng[5], A.B. Siegel[6], O. Bautista[6], M. Kudo[7]

[1]Medical Oncology, University of California, Los Angeles, Los Angeles, CA, USA, [2]Clinical Oncology, The Chinese University of Hong Kong, Prince of Wales Hospital, Shatin, Hong Kong, China, [3]Oncology, Massachusetts General Hospital, Boston, MA, USA, [4]Oncology, Princess Margaret Cancer Centre and University of Toronto, Toronto, ON, Canada, [5]Oncology, National Taiwan University Hospital, Taipei, Taiwan, [6]Oncology, Merck & Co., Inc., Kenilworth, NJ, USA, [7]Oncology, Kindai University Faculty of Medicine, Osaka, Japan

Background: Sorafenib is the standard of care (SOC) for first-line HCC; however, there is no clear SOC after disease progression on or intolerance to sorafenib. Because most HCC is driven by inflammation, the rationale to evaluate immunotherapy in patients (pts) with this type of cancer is strong. The randomized, double-blind, placebo-controlled phase 3 KEYNOTE-240 study (ClinicalTrials.gov, NCT02702401) was designed to compare efficacy and safety of the anti–PD-1 antibody pembro + BSC vs placebo + BSC in pts with previously treated advanced HCC.

Trial design: Pts aged ≥18 years with histologically or cytologically confirmed HCC (fibrolamellar and mixed hepatocellular/cholangiocarcinoma subtypes excluded), documented progression after stopping treatment with sorafenib or intolerance to sorafenib, no previous systemic therapy for HCC other than sorafenib, disease not amenable to a curative treatment approach (eg, transplantation, surgery, or ablation), measurable disease confirmed by central imaging vendor review per RECIST v1.1, Child-Pugh liver score A, ECOG performance status 0-1, adequate organ function, and predicted life expectancy >3 months are eligible. Pts will be randomly assigned 2:1 to receive pembro 200 mg IV Q3W + BSC or placebo Q3W + BSC for up to 35 cycles (~2 years) or until disease progression, unacceptable toxicity, or investigator decision. Randomization will be stratified by geographic region, presence of macrovascular invasion, and α-fetoprotein level. BSC will be provided by the investigator per local treatment practices. Response will be assessed Q6W per RECIST v1.1 by central imaging vendor review. Adverse events (AEs) will be assessed throughout treatment and for 30 days thereafter (90 days for serious AEs) and graded per NCI CTCAE v4.0. Primary objectives are comparison of PFS per RECIST v1.1 by central imaging vendor review and OS between treatment arms. Secondary objectives are comparison of ORR, DOR, DCR, and TTP per RECIST v1.1 by central imaging vendor review, and evaluation of safety and tolerability. Planned enrollment in KEYNOTE-240 is 408 pts across 26 countries.

Clinical trial identification: NCT0270240, March 3, 2016

776TiP PACTO: A single center, randomized, phase II study of the combination of nab-paclitaxel and gemcitabine with or without tocilizumab, an IL-6R inhibitor, as first-line treatment in patients with locally advanced or metastatic pancreatic cancer

I. Chen[1], J.S. Johansen[2], T.A. Zimmers[3], C. Dehlendorff[4], V. Kirk Parner[1], B. Vittrup Jensen[1], D. Nielsen[1]

[1]Oncology, Herlev and Gentofte Hospital, Herlev, Denmark, [2]Medical Oncology, Herlev and Gentofte Hospital, Herlev, Denmark, [3]Surgery, Indiana University School of Medicine, Indianapolis, IN, USA, [4]Statistics and Pharmacoepidemiology, Danish Cancer Society Research Center, Danish Cancer Society, Copenhagen, Denmark

Background: High plasma levels of interleukin-6 (IL-6) are found in patients with pancreatic cancer (PC) and in part facilitate systemic inflammation cascade and cachexia. The current phase 2 trial (PACTO) will evaluate the efficacy and safety of *nab*-paclitaxel and gemcitabine with or without tocilizumab, an IL-6R inhibitor, as first-line treatment in patients with advanced PC.

Trial design: Eligible patients with chemotherapy-naïve locally advanced or metastatic PC (n = 140), ECOG performance status (PS) of 0–1, and presence of a systemic inflammatory response (elevated C-reactive protein [CRP] levels or a modified Glasgow Prognostic Score [mGPS] of 1 or 2) will be randomized 1:1 (stratified by PS [PS 0 vs PS 1] and stage [locally advanced vs metastatic disease]) to receive tocilizumab 8 mg/kg on day 1 in combination with nab-paclitaxel 125 mg/m2 plus gemcitabine 1000 mg/m2 or nab-paclitaxel 125 mg/m2 plus gemcitabine 1000 mg/m2 on days 1, 8, and 15 of a 28-day cycle. Before randomization begins, the first six patients enrolled will be treated in the investigational arm for safety assessment and will not be included in the final analysis. The primary endpoint is overall survival (OS) rate at 6 months. Assuming a 6 month OS rate of 67% in the reference arm and an improvement by at least 20% by the intervention (corresponding to a 6 month OS of 80%), a total of 140 patients are needed (1:1 allocation) to obtain a statistical power of 80% with a significance level of 5%. Secondary endpoints include change from baseline PS, assessed by both investigator and patient, progression-free survival, OS, tumor response per RECIST 1.1, safety and assessment of quality of life by EORTC QLQ-C30. Patients will be assessed by CT scan every 8 weeks. Exploratory endpoints include circulating tumor DNA KRAS, body composition changes, plasma biomarkers of cachexia and inflammation. Treatment will continue as long as it is tolerated until disease progression. Enrollment was initiated in January 2017 and is ongoing.

777TiP ATTRACTION-04 (ONO-4538-37): A randomized, multicenter, phase 2/3 study of nivolumab (Nivo) plus chemotherapy in patients (Pts) with previously untreated advanced or recurrent gastric (G) or gastroesophageal junction (GEJ) cancer

L-T. Chen[1], Y-K. Kang[2], M. Tanimoto[3], N. Boku[4]

[1]National Institute of Cancer Research, National Health Research Institutes, and National Cheng Kung University Hospital, Tainan, Taiwan, [2]Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [3]Oncology Clinical Development Planning, Ono Pharmaceutical Co.,Ltd., Osaka, Japan, [4]Gastrointestinal Medical Oncology, National Cancer Center Hospital, Tokyo, Japan

Background: Nivo, a fully human IgG4 programmed death 1 (PD-1) immune checkpoint inhibitor, has demonstrated survival benefits across a number of tumor types. In ATTRACTION-02 (ONO-4538-12), a double-blind, placebo-controlled, Phase 3 study in pts with unresectable advanced or recurrent G/GEJ cancer refractory to or intolerant of standard therapy, Nivo monotherapy (3 mg/kg Q2W) demonstrated survival benefits (overall survival [OS] and progression free survival [PFS]) vs. placebo and a manageable safety profile (Yoon-Koo Kang, et al. 2017 ASCO Gastrointestinal Cancers Symposium). The combination fluoropyrimidine and platinum is the current standard-of-care (SOC) in the first-line treatment of pts with metastatic G/GEJ cancer that generally achieves a median survival ranging between 11 and 13 months. Therefore, new treatment options are needed to further improve the clinical outcomes of this particular pts population. This multinational, randomized, Phase 2/3 trial will evaluate the efficacy and safety of Nivo plus chemotherapy (S-1 + oxaliplatin [SOX] or capecitabine + oxaliplatin [CapeOX]) as first-line therapy for pts with unresectable advanced or recurrent G/GEJ cancer (ATTRACTION-04; NCT02746796).

Trial design: This trial consists of two parts. The part 1 is a randomized, open-label study to assess the feasibility of Nivo in combination with the first-line chemotherapy, either SOX or CapeOX. In part 2, approximately 650 chemo-naïve pts aged ≥ 20 years with ECOG PS 0-1, and HER2 negative unresectable or recurrent G/GEJ cancer will be randomized to receive chemotherapy (SOX or CapeOX, investigator's choice) plus either Nivo or Placebo. Randomization will be stratified by intensity of PD-L1 expression, ECOG PS score, disease status and geographical region. Primary endpoints are PFS assessed by independent radiological review committee (IRRC) and OS. Secondary endpoints include objective response rate and disease control rate assessed by IRRC and the site investigator, and duration of response and time to response assessed by IRRC. The part 2 study was started in February 2017.

778TiP ATTRACTION-05 (ONO-4538-38/BMS CA209844): a randomized, multicenter, double-blind, placebo- controlled Phase 3 study of Nivolumab (Nivo) in combination with adjuvant chemotherapy in pStage III gastric and esophagogastric junction (G/EGJ) cancer

M. Terashima[1], Y-W. Kim[2], T-S. Yeh[3], H.C. Chung[4], J-S. Chen[5], N. Boku[6], Y-K. Kang[7], L-T. Chen[8], M. Sasako[9]

[1]Division of Gastric Surgery, Shizuoka Cancer Center, Shizuoka, Japan, [2]Department of Cancer Control and Population Health, Graduate School of Cancer Science and policy, National Cancer Center, Goyang, Republic of Korea, [3]Department of General Surgery, Chang Gung Memorial Hospital at Linkou, Chang Gung University, Taoyuan, Taiwan, [4]Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Song Dang Institute for Cancer Research, Yonsei University College of Medicine, Yonsei University Health System, Seoul, Republic of Korea, [5]Division of Hematology/Oncology, Department of Internal Medicine, Linkou Chang Gung Memorial Hospital and Chang Gung University, Taoyuan, Taiwan, [6]Gastrointestinal Medical Oncology, National Cancer Center Hospital, Tokyo, Japan, [7]Department of Oncology, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Republic of Korea, [8]National Institute of Cancer Research, National Health Research Institutes and National Cheng Kung University Hospital, Tainan, Taiwan, [9]Department of Multidisciplinary Surgical Oncology, Hyogo College of Medicine, Nishinomiya, Japan

Background: Nivo, a fully human IgG4 programmed death 1 (PD-1) immune checkpoint inhibitor antibody, has demonstrated survival benefits across various tumor types. In ATTRACTION-02 (ONO-4538-12), a double-blind, placebo-controlled Phase 3 study in patients (pts) with unresectable advanced or recurrent G/EGJ cancer refractory to or intolerant of standard therapy, Nivo alone (3 mg/kg Q2W) achieved significant survival benefits (overall survival [OS] and progression free survival) vs. placebo with a manageable safety profile (Yoon-Koo Kang, et al. 2017 ASCO GI Cancers Symposium). In pStage II/III G/EGJ cancer, postoperative adjuvant chemotherapy with tegafur-gimeracil-oteracil potassium (S-1) or oxaliplatin/capecitabine (CapeOX) is indicated standard of care in Asian countries. However, the efficacy of these treatments is still unsatisfactory in pts with pStage III G/EGJ cancer, and thus a new treatment strategy is required. This multinational trial will evaluate the efficacy and safety of Nivo in combination with standard adjuvant chemotherapy in pts with pStage III G/EGJ cancer (ClinicalTrials.gov Identifier: NCT03006705).

Trial design: In this study, approximately 700 pts between 20 to 80 years of age with pStage III G/EGJ cancer after D2 or more extended lymph node dissection will be randomized to receive adjuvant chemotherapy (S-1 or CapeOX by investigator's choice) + either Nivo or placebo. Treatment with Nivo, placebo, and S-1 therapy will be continued for up to 1 year, and CapeOX therapy will be administered for up to 6 months. Pts will be followed up for 5 years at maximum until consent withdrawal or the start of post-study treatment due to disease relapse. Primary endpoint is relapse free survival (RFS) by central assessment. Secondary endpoints are RFS by site investigator assessments, 3- and 5-year RFS rates by central and site investigator assessments, OS and 3- and 5-year OS rates. Japan, Korea, Taiwan and China will participate into the trial. This study has already started patient enrollment.

Background: The role of adjuvant radiotherapy in patients with radical ressected gastric cancer with D2 lymph node dissection is controversial. Patients with high risk factors including late T stage (T4) and positive lymph nodes (N+) were likely to be benefit from adjuvant concurrent chemoradiotherapy. This trial was designed to compare adjuvant chemoradiotherapy, oxaliplatin plus S-1(SOX) and concurrent radiotherapy, with SOX alone in gastric cancer patients with D2 lymph node dissection and high risk factors.

Trial design: This study is a multiple center randomized phased III controlled trial undertaken by The Western Cooperative Gastrointestinal Oncology Group of China (WCGOG). Patients underwent R0 and D2 gastrectomy and pathologic diagnosed $\geq$ T4a or positive lymph node (N+) disease per AJCC 7th edition were enrolled in this study. Eligible patients were randomly assigned to receive adjuvant chemotherapy of SOX regimen and concurrent 3D-CRT/IMRT (50.4Gy/28f) or six cycles of SOX alone. Block randomization was done and stratified by disease stage. Primary endpoints are disease-free survival (DFS). Secondary endpoints are overall survival (OS), local control rate (LCR) and toxicity.

780TiP Impact of early palliative care on overall survival of patients with metastatic upper gastrointestinal cancers treated with first-line chemotherapy: Phase III EPIC trial

E. Hutt[1], A. Da silva[2], D. Pannier[1], E. Bogart[3], F. El-Hajbi[1], S. Villet[2], S. Clisant[4], M-C. Le Deley[3], A. Adenis[5]

[1]Medical Oncology, Centre Oscar Lambret, Lille, France, [2]Palliative Care, Centre Oscar Lambret, Lille, France, [3]Biostatistics, Centre Oscar Lambret, Lille, France, [4]Clinical Research Unit, Centre Oscar Lambret, Lille, France, [5]Medical oncology, Centre Oscar Lambret, Lille, France

Background: Palliative care (PC) has usually been offered at end-life stage, although the World Health Organization recommends providing PC as early as possible in the course of malignancies. Temel et al. (N Engl J Med 2010) have shown that early PC (EPC) provides a favorable effect on quality of life, as well as a surprising benefit on overall survival (OS) (secondary endpoint of this trial) over standard treatment to patients (pts) with metastatic lung cancer. Median OS of pts with metastatic upper gastrointestinal (upGI) cancers does not exceed 10-11 months, which is as poor as that reported with metastatic lung cancers. Whether or not OS benefit with EPC also applies to pts with metastatic upGI cancers is unknown. Demonstration of such benefit in these pts would lead to an earlier integration of PC in oncologic care.

Trial design: EPIC is a randomized phase III trial. It is aimed to estimate the OS benefit of EPC combined with standard oncologic care over standard oncology care only, in pts with metastatic upGI cancers who start 1st-line chemotherapy. Eligibility criteria also include ECOG PS $\leq$ 2, and life expectancy $>$ 4 weeks. Main exclusion criteria include: locally advanced tumors, esogastric cancers with unknown or positive HER2 status, dysphagia, and jaundice. Treatments will be randomized in a 1:1 ratio; a minimization procedure will be used to balance pts according to center, PS (0-1 *vs* 2) and tumor location (esogastric/gastric, pancreas, and biliary tract). Pts will be recruited nationwide, in 17 university hospitals or cancer centers. OS will be used as a primary endpoint. The content of PC visits will be studied through a specific checklist. Patient-reported outcomes (quality of life, depression and anxiety) will be also investigated. Assuming an exponential distribution of survival time, 381 deaths are required to ensure an 80%-power for an absolute difference of 10% in one-year OS (40% vs 50.3%, HR = 0.75; logrank test two-sided alpha=5%), leading to a planned sample size of 480 pts enrolled over 3 years. The main analysis will be performed on the intention-to-treat dataset. Enrollment began on September 2016.

Clinical trial identification: NCT02853474

Legal entity responsible for the study: Centre Oscar Lambret

781TiP Apatinib and irinotecan combination treatment in first-line chemotherapy refractory esophageal squamous cell carcinoma: A phase I dose escalation study

J. Jia, J. Yu, Z. Sun, Y. Yang, C. Liu, Y. Xiao, X. Zhang

VIP-2 GI Division of Medical Department, Peking University Cancer Hospital-Beijing Cancer Hospital, Beijing, China

Background: Esophageal cancer is one of the common malignant tumors. Different from that in western countries, esophageal squamous cell carcinoma (ESCC) is still the dominant pathological type in China and account for more than 95% of cases in clinic. The annual incidence of esophageal squamous cell carcinoma is 260,000 with the mortality of 210,000 in China. For patients with recurrent or metastatic disease, chemotherapy is one of important treatment alone or with radiotherapy. Taxane, platinum, and fluoropyimidine have been reported effective in ESCC and are popularly used in first-line treatment of ESCC. However, there is still no standard 2nd-line treatment for ESCC patients. Apatinib, also known as YN968D1, is an oral tyrosine kinase inhibitor to vascular endothelial growth factor (VEGFR) receptor, by which blocks the VEGF signaling pathway and results in anti-angiogenesis of tumors. Preclinical data has shown that it is effective in the treatment of a variety of solid tumors including esophageal cancer. And it was approved and launched in China in 2015 as a 3rd-line treatment for patients with advanced gastric cancer. However, the role of anti-angiogenses targeting treatment including apatinib is unknown. Here, we initialize a dose escalation phase I study to identify the dosage of apatinib when combined with irinotecan to treat ESCC patients who were with recurrent disease after esophagectomy and refractory to 1st-line chemotherapy.

Trial design: Patients, age 18-70, with measurable tumor lesion, failed in or progression after 1st line chemotherapy, were enrolled in this 3 + 3 design study. Apatinib dosage escalated from 250 mg, 500mg, to 750mg daily in 3 different cohorts while the dosage of irinotecan was maintained 150mg/m^2 very 2 weeks for 3 cycles (6 weeks). The dose-limiting toxicity (DLT) was identified as grade 4 hematologic toxicity and grade 3 to 4 non-hematologic toxicity according to NCI CTC AE 4.0 criteria. The primary endpoint is the maximum toxic dosage (MTD) and the secondary end points include the objective response rate (ORR), progression-free survival (PFS) and overall survival (OS).

782TiP PANOVA-3: A phase 3 study of TTFields with gemcitabine and nab-paclitaxel for front-line treatment of locally-advanced pancreatic adenocarcinoma (LAPC)

O. Farber[1], U. Weinberg[1], Z. Bomzon[2], M. Giladi[3], E.D. Kirson[4]

[1]Clincal Development, Novocure, Luzern, Switzerland, [2]Scientific Affairs, Novocure, Haifa, Israel, [3]Preclinical, Novocure, Haifa, Israel, [4]R&D, Novocure, Haifa, Israel

Background: TTFields are a non-invasive, regional antimitotic treatment modality, which has been approved for the treatment of glioblastoma by the FDA. TTFields predominantly act by disrupting the formation of the mitotic spindle during metaphase. TTFields were effective in multiple preclinical models of pancreatic cancer. PANOVA was the first trial testing TTFields in pancreatic cancer patients, demonstrating their safety when combined with gemcitabine and nab-paclitaxel, and preliminary promising efficacy in LAPC. PANOVA-3 is designed to test the efficacy of adding TTFields to the same chemotherapy combination in this disease stage.

Trial design: Approximately 600 patients with unresectable, LAPC (per NCCN guidelines) will be enrolled in this prospective, randomized trial. Patients should have an ECOG score of 0-2 and no prior progression or treatment. Patients will be stratified based on their performance status and geographical region. Gemcitabine and nab-paclitaxel will be administered at standard dose. The NovoTTF-100L (150kHz) system will be used by experimental arm patients for at least 18 hours/day until local disease progression per RECIST Criteria V1.1. Follow up will be performed q8w, including a CT scan of the chest and abdomen. Following local disease progression, patients will be followed monthly for survival. Overall survival will be the primary endpoint and progression-free survival, objective response rate, rate of resectability, quality of life and toxicity will all be secondary endpoints.

1733PD New promising combination therapy of a mitochondrial metabolism inhibitor with mFOLFIRINOX in pancreatic cancer

A.T. Alistar[1], B. Pasche[2], R. D'Agostino[3], T. Pardee[4], S. Luther[5], R. Desnoyer[6]

[1]Hematology oncology, Atlantic Health System, Morristown, NJ, USA, [2]Hematology Oncology, Wake Forest University, Winston Salem, NC, USA, [3]Director of Biostatistic Core, Wake Forest University, Winston Salem, NC, USA, [4]CMO, Rafael Pharmaceuticals, Cranbury, USA, [5]Clinical Operations, Rafael Pharmaceuticals, Cranbury, USA, [6]Hematology Oncology, Wake Forest University, Winston Salem, NC, USA

Background: Stage IV pancreatic cancer is a lethal disease. Current standard practice is combination chemotherapy such as FOLFIRINOX or Gemcitabine and Abraxane. The glycolic and mitochondrial metabolism are aberrant in pancreatic cancer and translate into chemoresistance. Inhibition of glutamine metabolism can potentially synergize with therapies that increase intracellular reactive oxygen species such as FOLFIRINOX components. CPI- 613 is a novel antimitocondrial developed by Rafael Pharmaceuticals that showed preclinical activity in pancreatic cancer.

Methods: We designed a phase 1 study to evaluate for synergy between CPI -613 and FOLFIRINOX for patients with stage IV pancreatic cancer. Aims: To determine the maximum tolerated dose (MTD) of CPI- 613 when used in combination with modified FOLFIRINOX. To assess the safety of CPI-613 + modified FOLFIRINOX To obtain preliminary data on efficacy of treatment.

Results: Updated Results as of July, 2017 Toxicity: No deaths due to adverse events were reported. The MTD was identified at 500 mg/m^2 and a total of 18 patients were treated at the MTD. The most common grade 3–4 non-hematological adverse events: hyperglycemia, hypokalemia, peripheral sensory neuropathy, diarrhea, and abdominal pain. The most common grade 3–4 hematological adverse events: neutropenia, lymphopenia, anemia and thrombocytopenia Preliminary efficacy: Of the 18 patients treated at MTD– 8 patients are alive and 3 patients are still on treatment. The median PFS is 10.4 months, 95% CI (119 to 560 days) – 3 patients are still alive and on treatment who have not progressed. Median overall survival is 20.1 months, data still maturing. The 95% CI cannot be accurately estimated yet. Three patients achieved a complete response.

Conclusions: CPI-613 is a first in class non-redox active lipoate derivative being tested in phase I clinical trial in combination with FOLFIRINOX. The MTD for CPI-613 was identified at 500mg/m^2. The treatment combination is feasible and well-tolerated. The response rate was 61%, which is higher than FOLFIRINOX alone (31.6%). The median PFS is 10.4months and the median OS is 20.1 months, data still maturing. A randomized, international phase 3 study of FOLFIRINOX vs. m FOLFIRINOX+ CPI613 will open in 2018.

Clinical trial identification: NCT01835041, First received: April 16, 2013 Last updated: May 30, 2017 Last verified: May 2017

1734PD Anti-CTGF human recombinant monoclonal antibody pamrevlumab increases resectability and resection rate when combined with gemcitabine/Nab-paclitaxel in the treatment of locally advanced pancreatic cancer patients

E. Carrier[1], V. Picozzi[2], M.J. Pishvaian[3], K. Mody[4], J. Winter[5], J. Glaspy[6], T. Larson[7], W.C. Conway[8], K. Lipson[1], S. Porter[1], E. Kouchakji[1]

[1]Clinical Development, FibroGen, San Francisco, CA, USA, [2]Hematology Oncology, Virgina Mason Medical Center, Seattle, WA, USA, [3]Lombardi Comprehensive Cancer Center, Georgetown University, Washington, DC, USA, [4]Department of Medicine, Mayo Clinic, Jacksonville, FL, USA, [5]Department of Surgery, Thomas Jefferson University, Philadelphia, PA, USA, [6]Ronald Reagan Medical Center, UCLA, Los Angeles, CA, USA, [7]Oncology, Virginia Piper Cancer Institute, Minnesota, MN, USA, [8]Oncology, Ochsner Clinic Foundation, New Orleans, LA, USA

Background: Pancreatic ductal adenocarcinomas (PDAC) exhibit a high degree of desmoplasia, with extensive connective tissue growth factor (CTGF) expression and extracellular matrix production[1, 2]. Pamrevlumab (FG-3019), anti-CTGF antibody, is evaluated in fibrotic disease and cancer. Studies in the LSL-Kras$^{G12D/+}$; LSL-Trp53$^{R172H/+}$; Pdx-1-Cre (KPC) transgenic mouse model of PDAC demonstrated that pamrevlumab, in combination with gemcitabine, prolonged survival and increased tumor cell apoptosis associated with the down-regulation of the anti-apoptotic protein XIAP[3].

Methods: In Phase 2 randomized study, gemcitabine/Nab-paclitaxel (G/N) +/- pamrevlumab was given to treatment-naïve locally advanced pancreatic cancer (LAPC) patients to improve resection outcomes and overall survival (OS). 33 LAPC patients were randomized 2:1 to G/N with (Arm A) (n = 22) or without (Arm B) (n = 11) pamrevlumab. Patients who completed 6 cycles of chemotherapy underwent resectability assessment by NCCN and other (CA 19-9, PET, RECIST) criteria, and, if eligible, resection with no further treatment. Patients who progressed received second-line treatment as per physician choice.

Results: No increases in SAEs or surgical complications were observed in Arm A vs Arm B. No significant difference was seen in RECIST, PET or CA 19-9 between the arms. More patients in Arm B (45%, n = 5) than in Arm A (25%, n = 3) discontinued treatment early, mainly due to progression of disease, SAE or physician choice. Of all of the patients who completed 6 cycles of treatment, 78% of patients in Arm A, and 17% of patients in Arm B were deemed resectable; and 44% in Arm A vs 17% in Arm B underwent resection. The primary reasons in patients, who scored as eligible but resected were: metastatic disease, SAE, and physician decision. An improved resection rate was associated with a trend towards improved OS in Arm A.

Conclusions: Improved resection rate combined with increased median OS in Arm A suggests that pamrevlumab is a valuable addition to neoadjuvant therapy in LAPC patients without added toxicity, and that this combination therapy may have a positive impact on OS in LAPC patients.

Background: In the LATITUDE study, treatment with ADT+AA+P significantly improved overall survival and delayed disease progression in pts with newly diagnosed, high-risk, metastatic castration-naïve prostate cancer (mCNPC). In this analysis we evaluated the impact of ADT+AA+P on PROs, including symptom and health-related quality of life (HRQoL) measures.

Methods: 1199 mCNPC pts were randomized 1:1 to ADT + AA+P or ADT + placebos (PBOs). Brief Pain Inventory-Short Form (BPI-SF), Brief Fatigue Inventory (BFI), Functional Assessment of Cancer Therapy-Prostate (FACT-P), and EQ-5D-5L questionnaires were administered at baseline (BL), Day 1 of Cycles (C) 2-13, then every 2 months until treatment discontinuation (TD). EQ-5D-5L were performed every 4 months until 12 months after TD. Time to event and repeated measures analyses on changes from baseline were conducted.

Results: Questionnaire compliance rate was high at ≥ 90%. Compared to ADT+PBOs, the ADT+AA+P arm had significant delayed time to pain and fatigue intensity and interference progression (Table). FACT-P assessments demonstrated significant delay in degradation for the total score and symptom subscales for the ADT+AA+P arm (Table). Repeated measures analyses showed maintenance or improvement from BL for the ADT+AA+P arm compared to the ADT+PBOs arm, with significant differences emerging as early as C2. Significant improvement from BL in EQ-5D VAS for general health status and health utility scores occurred as early as C5 and was maintained throughout the study.

Conclusions: Compared with ADT+PBOs, treatment with ADT+AA+P consistently demonstrated improvement across multiple PRO measures, with statistically significant improvement in HRQoL and delays in progression of pain fatigue intensity and interference, and functional decline. Results for PROs were consistent with improvements in clinical outcomes.

Background: HrPC pts with PSA relapse after local therapy may have a poor prognosis and AS may be a therapeutic option. D+AS is standard of care in hormone-naive metastatic PC. We evaluated the benefit of D+AS in HrPC pts with PSA relapse after RP and/or RT.

Methods: Multicenter, randomized phase 3 study (NCT00764166) comparing AS (triptorelin, every 3 months for 1 year) versus AS+D (70 mg/m^2 Q3W, 6 cycles). To be enrolled, pts needed ≥ 3 rising PSA values >0.2ng/mL (after RP) or > 1ng/mL above

Table 783O Time to Progression and Relative Risk for HRQoL End Points

Measure	ADT+AA+P (months)	ADT+PBOs (months)	HR (95% CI)	p Value
Median time to worst pain intensity progression (BPI-SF)	NR	16.6	0.695 (0.583-0.829)	<0.001
Median time to pain interference progression (BPI-SF)	NR	18.4	0.671 (0.561-0.803)	<0.001
Median time to fatigue intensity progression (BFI)	NR	NR	0.652 (0.527-0.805)	<0.001
Median time to fatigue interference progression (BFI)	NR	NR	0.594 (0.470-0.750)	<0.001
Median time to FACT-P degradation				
Total Score	12.9	8.3	0.853 (0.736-0.989)	0.032
Pain-related Subscale	10.2	6.5	0.760 (0.659-0.876)	<0.001
Prostate Cancer Subscale	8.3	5.6	0.808 (0.701-0.930)	0.003

HR, hazard ratio; CI, confidence interval.

Table: 7840

	AS + D (n = 125)	AS alone (n = 125)	HR (95%)	p-value
PSA-PFS (months)	20.7 [19.2-21.5]	18.6 [17.6-20.2]	0.85 (0.62-1.16)	0.31
rPFS (years)	8.8 [7.7-10.2]	9.7 [6.9-10.9]	1.01 (0.72-1.40)	0.95
25eme percentile (OS, years)	8.3	8.1	1.16 (0.76-1.77)	0.49

nadir (after RT) modified by nadir + 2ng/ml (RTOG-ASTRO Phoenix, 2006) and ≥ 1 of the following criteria: Gleason ≥8, PSA doubling time (PSADT) ≤6 mths, PSA velocity >0.75 ng/mL/year, positive surgical margins (SM), pN1, time from curative therapy to PSA relapse ≤12 months. Pts were stratified on type of local treatment (RP or RT) and PSADT (≤ or > 6 mths). Primary endpoint was PSA-PFS defined by a PSA above 0.2ng/ml and rise ≥ 50% from baseline confirmed by 2 subsequent values. Secondary endpoints were PSA response (decrease ≥50%), radiological progression (rPFS), overall survival (OS) and safety.

Results: between 2003-2007, 250 pts (median age 65 years), were randomized to AS+D (arm A, n = 125) or AS (arm B, n = 125). Local treatment: RP (95 pts, 38%), RT (69 pts, 28%) or RP+RT (86 pts, 34%). Risk factors were as follows: Gleason ≥8: 29%, PSADT≤ 6 mths 54%, PSA velocity >0.75 ng/mL/yr 84%, positive SM 37%, pN1 4%, PSA relapse ≤12 mths 45%. 58% of pts had ≥3 risk factors. Six pts had a PSA >20 ng/ml at baseline. There was no significant difference in PSA response (94% vs 98%), PSA-PFS and rPFS between 2 arms (table). Median OS was not mature. Most common grade ≥3 toxicities in arm A were neutropenia (58%), febrile neutropenia (8%) and hair loss (4%). AS toxicities were mainly grade 2 hot flushes (47%) and depression (11%).

Conclusions: AS+D failed to improve PSA-PFS, rPFS in HrPC pts relapsing PSA after local therapy.

785O Lutetium-177 PSMA (LuPSMA) theranostics phase II trial: Efficacy, safety and QoL in patients with castrate-resistant prostate cancer treated with LuPSMA

M.S. Hofman[1], S. Sandhu[1], P. Eu[1], J. Price[2], T. Akhurst[2], A. Iravani[2], G. Kong[2], A. Ravi-Kumar[2], S. Williams[1], S-P. Thang[2], D. Murphy[1], M. Scalzo[2], R.J. Hicks[2], J. Violet[2]

[1]Sir Peter MacCallum Department of Oncology, University of Melbourne, Peter MacCallum Cancer Centre, Melbourne, Australia, [2]Centre for Molecular Imaging, Peter MacCallum Cancer Centre, Melbourne, Australia

Background: Progressive metastatic castrate-resistant prostate carcinoma (mCRPC) is a highly lethal condition. Lutetium-177 (^{177}Lu)-PSMA617, a radiolabelled small molecule, binds with high affinity to prostate specific membrane antigen (PSMA) enabling beta particle therapy targeted to mCRPC.

Methods: In this phase II prospective trial, 30 pts with PSMA-avid mCRPC who had failed standard therapies received up to 4 cycles of ^{177}Lu-PSMA617 every 6 weeks. The primary endpoints were PSA and imaging response (PCWG2) and toxicity (CTCAE v4). Other endpoints were quality of life (EORTC QLQ-C30/BM22, BPI), dosimetry, PFS and OS.

Results: All patients were enrolled between 10/2015 and 12/2016 (median age 69 yr, ECOG 1; PSA doubling time 2.2 months) with 3 pts awaiting a final treatment cycle. 87% received prior chemotherapy, 47% cabazitaxel and 83% prior abiraterone and/or enzalutamide. Mean dose was 7.5 GBq (range 4.4 – 8.7 GBq) prospectively adjusted according tumour burden, renal function and weight. At this interim analysis, 17/30 pt (57%) achieved PSA decline >50%, including 11/30 (37%) with decline >80%. In 17 pt with soft tissue disease, objective response (RECIST PR+CR) occurred in 12 pt (71%). Most common adverse events were grade 1 xerostomia (19 pt, 63%) and nausea (15 pt, 50%). Grade 3 or higher hematoxicity occurred in 5 pt (17%); all had baseline thrombocytopenia and were reversible. Following the first cycle of LuPSMA, global health score improved significantly (≥10 points) in 11/30 pt (37%), while in those with bone pain, mean severity score improved significantly (≥ 10 points) in 9/21 pt (43%).

Conclusions: The LuPSMA Phase II trial provides evidence of high response rates and low toxicity with improved QoL and pain reduction in men with mCRPC who have failed conventional therapies.

786PD DNA repair gene panel mutations in young onset and aggressive vs non aggressive prostate cancer cases in the UK

R. Eeles[1], E. Saunders[1], S. Wakerell[1], I. Whitmore[1], C. Cieza-Borrella[1], K. Govindasami[1], T. Dadaev[1], Z. Kote-Jarai[1], D. Leongamornlert[2]

[1]Genetics & Epidemiology, The Institute of Cancer Research, Sutton, UK, [2]Cancer, Ageing & Somatic Mutations Programme, Wellcome Trust Sanger Institute, Cambridge, UK

Background: Prostate cancer (PrCa) is the most common solid tumour in men in the Western world. There is evidence that PrCa predisposition is due to germline common and rare variation.

Methods: We sequenced 175 genes in the DNA damage response and repair pathways using an Agilent custom capture kit and Illumina technology in PrCa cases diagnosed at < 65 years compared with controls in the UK (mean coverage 76X). Data were analysed from 1346 PrCa cases and 1186 controls using a GATK 2.8 analysis pipeline.

Results: We identified 5,118 single nucleotide variants (SNVs) and 172 indels; 216 unique protein truncating variants (PTVs) were in 96 genes of the 175 gene panel. The total number of PTVs in cases was significantly higher (181) than in controls (122); in particular, in the BROCA gene set of 22 tumour suppressor genes (P = 0.002). Mutations in *BRCA1, BRCA2, ATM, MSH5* and *CHEK2* were 3 times more common in cases compared with controls (P = 0.0018). To investigate if aggressive cases had a different mutation burden we compared 204 aggressive (Gleason score>8) versus 1049 non-aggressive (Gleason score ≤7) cases. In the single variant analysis, one variant in *BRCA2*, rs28897754 (K2950N) showed association with a more aggressive phenotype (P = 0.0016). Gene burden testing showed *BRCA2, MSH2, PALB2* and *CHEK2* had an OR > 3 in aggressive v non aggressive cases (14% v 4% respectively). Men who died of PrCa had a 17% incidence of mutation in a subset of the 175 gene panel.

Conclusions: We have shown that there is a higher percentage of DNA damage response and repair gene germline mutations in PrCa cases occurring at < 65 years, in those with aggressive and lethal disease and this result will enable us to develop a testing panel for use in clinical care in the near future.

787PD Prognostic associations of prostate-specific antigen (PSA) decline with survival, radiographic response and progression in chemotherapy-naïve men with metastatic castration-resistant prostate cancer (mCRPC) treated with enzalutamide

A.J. Armstrong[1], P. Lin[2], C.S. Higano[3], P. Iversen[4], C.N. Sternberg[5], B. Tombal[6], D. Phung[7], T. Parli[8], A. Krivoshik[9], T.M. Beer[10]

[1]Divisions of Medical Oncology and Urology, Duke Cancer Institute, Durham, NC, USA, [2]Biometrics, Medivation, Inc., San Francisco, CA, USA, [3]Medicine and Urology, University of Washington Seattle Cancer Care Alliance, Seattle, WA, USA, [4]Urology, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark, [5]Department of Oncology, San Camillo and Forlanini Hospitals, Rome, Italy, [6]Urology, Cliniques Universitaires St. Luc, Brussels, Belgium, [7]Biostatistics, Astellas Pharma Europe B.V., Leiden, Netherlands, [8]Clinical Development, Medivation, Inc., San Francisco, CA, USA, [9]Medical Sciences - Oncology, Astella Pharma, Inc., Northbrook, IL, USA, [10]Oregon Health & Science University, OHSU Knight Cancer Institute, Portland, OR, USA

Background: In the PREVAIL clinical trial, enzalutamide provided significant improvements vs placebo in radiographic progression-free survival (rPFS) and overall survival (OS) in chemotherapy-naïve men with mCRPC. This post hoc analysis aimed to evaluate the prognostic association between the magnitude of PSA decline from baseline and clinical outcomes in PREVAIL.

Methods: Men from the enzalutamide and placebo arms of PREVAIL were grouped into categories of confirmed maximal PSA decline from baseline at month 3 of

Table: 787PD

Outcome	Maximal PSA Decline From Baseline at Month 3 in the Enzalutamide Arm (N = 872)			
	No Decline/ Decline < 30% (n = 94/872)	≥ 30% Decline (n = 701/872)	≥ 50% Decline (n = 639/872)	≥ 90% Decline (n = 307/872)
Best objective soft-tissue response (CR or PR), % (95% CI)	12.0 (4.5-24.3)	70.6 (65.1-75.6)	74.8 (69.2-79.9)	89.7 (82.8-95.0)
Median (95% CI) time to PSA progression, mo	3.7 (3.7-4.6)	13.8 (11.3-14.0)	13.9 (13.8-16.6)	22.5 (16.8-NYR)
Median (95% CI) rPFS, mo	7.9 (3.7-NYR)	NYR (13.8-NYR)	NYR (13.8-NYR)	NYR (13.8-NYR)
HR (95% CI) for rPFS	1.0 (ref)	0.20 (0.13-0.31)	0.17 (0.11-0.27)	0.10 (0.05-0.19)
Median (95% CI) OS, mo	23.1 (17.8-28.0)	32.4 (31.5-NYR)	NYR (31.5-NYR)	NYR (NYR-NYR)
HR (95% CI) for OS	1.0 (ref)	0.31 (0.22-0.42)	0.28 (0.20-0.39)	0.19 (0.12-0.28)

Abbreviations: CI, confidence interval; CR, complete response; HR, hazard ratio; mo, months; NYR, not yet reached; OS, overall survival; PR, partial response; PSA, prostate-specific antigen; ref, reference, rPFS, radiographic progression-free survival.

treatment: no decline/decline < 30% and ≥ 30%, ≥ 50% or ≥ 90% decline. Confirmation required PSA decline on ≥ 1 consecutive visit after month 3. Best overall soft-tissue response (per RECIST v1.1) was determined for patients with measurable disease at baseline (data cutoff: 16 Sep 2013). Time to PSA progression (data cutoff: 16 Sep 2013), rPFS (per PCWG2; data cutoff: 6 May 2012) and OS (data cutoff: 16 Sep 2013) were estimated using the Kaplan-Meier method.

Results: In PREVAIL, men were randomized to enzalutamide (n = 872) or placebo (n = 845). Most men in the placebo arm (66%, 558/845) had no PSA decline/decline < 30%, in contrast to 11% (94/872) in the enzalutamide arm. In the enzalutamide arm, 81% (701/872) of men had a PSA decline of ≥ 30% from baseline at week 13, 73% (639/872) had a PSA decline of ≥ 50% and 35% (307/872) had a PSA decline of ≥ 90%. Key outcomes for the enzalutamide arm are provided by PSA decline category in the Table. PSA flare (rise followed by a fall) after 3 months was rare with enzalutamide (< 1%).

Conclusions: PSA declines after 3 months of enzalutamide therapy are strongly associated with soft-tissue response and improvements in rPFS and OS. Providing updated prognostic information to chemotherapy-naïve men with mCRPC can be of clinical value given the heterogeneity of long-term outcomes.

Background: A standard therapy has not been established on PSA failure after radical prostatectomy for localized prostate cancer. Therefore, the randomized controlled trial was designed to confirm the superiority of radiotherapy ± endocrine therapy over endocrine therapy alone for PSA failure after radical prostatectomy.

Methods: Patients were randomly assigned to arm A [endocrine therapy only: bicalutamide (BCL) monotherapy followed by LH-RH agonist in case of BCL failure], or arm B [64.8 Gy of salvage radiotherapy (SRT) followed by same regimen of arm A in case of treatment failure of SRT]. The primary endpoint is time to treatment failure (TTF) of BCL, and secondary endpoints are TTF of protocol treatment, clinical relapse-free survival (RFS), overall survival (OS), adverse events. The planned sample size was 210 to detect improvement of median TTF of BCL from 5 years to 8.3 years with one-sided alpha of 5% and power of 80%. This trial is registered with UMIN-CTR (C000000026).

Results: A total of 210 patients (105 patients in each arm) were registered from May 2004 to May 2011. The TTF of BCL was significantly better in arm B as shown in Table 1 (Hazard ratio 0.56 90% CI (0.40–0.77); one-sided p = 0.001). The 33 patients (32%) of 102 patients with SRT of arm B had no treatment failure of SRT, resulting in being free from hormonal therapy. In addition, TTF of protocol treatment was also significantly better in arm B. However, clinical RFS and OS were similar between the arms. Grade 4 adverse event was reported in one patient in arm B.

Conclusions: The first SRT had advantage in both TTF of BCL and protocol treatment. Although the clinical outcomes of both arms of salvage therapy were similar with each other in terms of clinical PFS and OS, the SRT was effective in 32% of the patients, which contributed to avoiding the salvage endocrine therapy.

789PD Abiraterone acetate (AA) + prednisolone (P) for metastatic castration-resistant prostate cancer (mCRPC) with early progression or non-response to androgen deprivation therapy (ADT)

G. Arai[1], M. Ogi[2], K. Kobayashi[3], N. Okuno[4], T. Takahara[2], K. Fukushima[2], K. Yoshizawa[2]

[1]Department of Urology, Dokkyo Medical University Koshigaya Hospital, Saitama, Japan, [2]Medical Affairs Division, Janssen Pharmaceutical K.K., Tokyo, Japan, [3]Urology department, Yokosuka Kyosai Hospital, Kanagawa, Japan, [4]Department of Urology, Sagamihara Hospital, Kanagawa, Japan

Background: mCRPC with early progression (≤1year) or non-response to initial ADT carries a poor prognosis, and there is no consensus regarding second-line therapy for these patients (pts) [ADT poor responders]. Although AA+P is effective for chemo-naïve mCRPC, limited data is available for ADT poor responders; thus, we conducted this study to evaluate the efficacy and safety of AA+P as secondary treatment for this population.

Methods: This was a multicenter, open-label, single arm, 2-stage trial according to Simon's minimax design [hypothesis: p_0=0.150, p_1=0.350, $\alpha = 0.025$, $\beta = 0.100$], and 48 pts were required to efficacy analysis. Key eligibility: Chemo-naïve mCRPC (testosterone level <50 ng/dL under medical/surgical castration), age ≥20, and evidence of prostate specific antigen (PSA) progression by PCWG2 criteria ≤1 year or without achieving a normal PSA level (<4 ng/mL) during initial ADT. For eligible pts, 1000 mg AA with 10 mg P was administered until disease progression. The primary endpoint was the proportion of patients achieving a PSA decline of ≥ 50% from baseline after 12 weeks of treatment in accordance with PCWG2 criteria (PSA response rate).

Results: Fifty pts were enrolled and 49 were evaluable for efficacy analysis. At baseline, the median age was 73 (range 55–86), the median PSA level was 28.34ng/mL (2.28-294.25), and the median duration of initial ADT was 6.4 months (1.4 –18.8). Among the patients, 90.0% had a total Gleason score ≥8, and all had a treatment history of bicalutamide. Most patients showed high treatment compliance (>95% with AA [n = 47/50, 94.0%] and P [n = 46/50, 92.0%]). PSA response rate was 55.1% (n = 27/49; 95%CI 41.3-68.1), and the PSA decline began after 4 or 8 weeks from baseline. The treatment was well tolerated with <25% of grade ≥3 adverse events.

Conclusions: This is the first study to investigate the efficacy of AA+P for ADT poor responders. The study demonstrated similar efficacy to the Phase 3 study COU-AA-302, which further supports the efficacy of AA+P for ADT poor responders. AA + P appears to be a promising treatment for initial ADT poor responders with an acceptable safety profile. This study is ongoing as follow up on time to PSA progression.

Clinical trial identification: NCT02405858 (March 27, 2015).

790PD Safety and immunogenicity of a DNA-vaccine immunotherapy in men with biochemically (PSA) relapsed prostate cancer

N.D. Shore[1], E. Heath[2], L. Nordquist[3], H. Cheng[4], K. Bhatt[5], M. Morrow[6], T. McMullan[7], K. Kraynyak[6], J. Lee[5], B. Sacchetta[5], L. Liu[6], S. Rosencranz[5], S.T. Tagawa[8], R.A. Parikh[9], R. Tutrone[10], J. Garcia[11], Y. Whang[12], W. Kelly[13], I. Csiki[5], M. Bagarazzi[5]

[1]Urology, Atlantic Urology Clinics, Myrtle Beach, SC, USA, [2]Karmanos Cancer Institute, Detroit, MI, USA, [3]GU Research Network LLC/Urologoy Cancer Center, Omaha, NE, USA, [4]University of Washington School of Medicine, Seattle, WA, USA, [5]Clinical Development, Inovio Pharmaceuticals, Plymouth Meeting, PA, USA, [6]R&D, Inovio Pharmaceuticals, Plymouth Meeting, PA, USA, [7]Biostatistics, Inovio Pharmaceuticals, Plymouth Meeting, PA, USA, [8]Hematology and Medical Oncology, Weill Cornell Medical College, New York, NY, USA, [9]University of Pittsburgh Medical Center, Pittsburgh, PA, USA, [10]Greater Baltimore Medical Center - Chesapeake Urology Associates, Towson, MD, USA, [11]Cleveland Clinic, Cleveland, OH, USA, [12]Medical Oncology/Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA, [13]Sidney Kimmel Cancer Center - Thomas Jefferson University, Philadelphia, PA, USA

Background: DNA vaccines INO-5150 (PSA and PSMA) +/- INO-9012 (IL-12) were administered to biochemically recurrent prostate cancer patients (pts) to demonstrate breaking tolerance, assessing antigen-specific humoral and cellular immune responses with the potential for stabilization of disease progression.

Methods: Phase I, open-label, multi-center study in pts post-definitive therapy with a rising PSA after surgery and/or RT and PSA doubling time (DT)> 3 months (mos), testosterone > 150 ng/dL, no concomitant ADT and no evidence of metastases. Safety, immunogenicity and efficacy were evaluated in 4 treatment arms in 60 planned pts (A: 16, 2mg INO-5150; B: 15, 8.5 mg INO-5150; C: 15, 2mg INO-5150 + 1mg INO-9012; D: 16, 8.5mg INO-5150 + 1mg INO-9012) treated with 4 IM doses followed by electroporation on day 0, wks 3, 12 and 24 who were followed for a total of 72 Wks.

Results: Median age, Gleason score and time since diagnosis were 69.5 yrs (range: 55.4-87.7), 7 (5-10) and 8.4 yrs (0.4-23.8) respectively. Of 61 evaluable pts, 38 (62%) had PSADT ≤ 12 mos and 23 (38%) had DT > 12 mos at Day 0. For pts with DT ≤ 12 mos, Day 0 and week 27 median DT were 6.0 (1.5, 11.6) mos and 8.1 (2.2, 100.0) mos respectively. Flow cytometry analysis revealed antigen specific upregulation of CD38 and Perforin on CD8+ T cells in 19/50 (38%) pts across the trial, with the greatest proportion in arm A, 8/14 (57%). Additional analysis for this cell subset showed a high PD-1 expression of 68.6% in this arm at week 27. Of note, in 8/15 (53%) arm A pts with DT ≤ 12 mos, their median DT at Day 0 was 6.2 (2.9, 10.2) mos and 19.2 (6.6, 100.0) mos at Wk 27. Safety: 7 Grade (Gr) 3 SAEs in 5 pts and 0 Gr 4-5 SAEs reported. Most AEs were Gr 1-3 in 51/62 (82%) pts and majority of those were associated with injection site reactions.

Conclusions: INO-5150 +/- INO-9012 was safe at dosages examined. Data demonstrated both PSA and PSMA are immunogenic and INO-5150 induced cellular immune responses. Higher proportion of arm A pts showed immunological responses as well as improvements in PSA DT, specifically pts with DT ≤ 12 mos suggesting correlation of immunological efficacy and clinical benefit. Continued analyses are planned as patient follow-up is ongoing. (NCT02514213)

791PD Re-education of tumor-associated macrophages by CXCR2 blockade drives senescence enhancement and tumor inhibition in advanced prostate cancer

D. Di Mitri[1], J. Vasilevska[1], A. Calcinotto[1], V. Gil[2], G. Boysen[2], A. Revandkar[1], D. Waugh[3], S. Barry[4], J. de Bono[5], A. Alimonti[6]

[1]Molecular Oncology, IOR, Bellinzona, Switzerland, [2]Cancer Biomarkers Team, Royal Marsden NHS Foundation Trust, Sutton, UK, [3]Centre for Cancer Research and Cell Biology, Queen's University Belfast - Centre for Cancer Research and Cell Biology, Belfast, UK, [4]Li Ka Shing Centre, IMED Oncology AstraZeneca, Cambridge, UK, [5]Division of Clinical Studies, Prostate Cancer Targeted Therapy Group, Institute of Cancer Research Royal Marsden Hospital, Sutton, UK, [6]Molecular Oncology, IOR/IOSI, Bellinzona, Switzerland

Background: Tumor-associated macrophages (TAMs) represent a major component of the tumor microenvironment that supports tumorigenesis. TAMs re-education instead that eradication has been recently proposed as a strategy to promote tumor inhibition.

Methods: We performed an immunophenotyping of Pten null prostate murine models by flow cytometry and gene expression analysis. Immunoistochemistry and immunofluorescence sainings were utilized to detect macrophages infiltration in the tumor and marker of proliferation and senescence in the tissue.

Results: We have found that aggressive prostate tumors are strongly infiltrated by TAMs that express alternatively activated M2 markers. Unexpectedly chemokines binding to the C-X-C chemokine receptor type 2 (CXCR2) were among the most upregulated factors secreted by *Pten* null tumors and controlled the functional polarization of TAMs toward an "M2-like" functional status. Pharmacological blockade of the CXCR2 receptor in different tumor models in vivo promoted the re-education of TAMs toward a pro-inflammatory phenotype, which resulted in induction of senescence and tumor inhibition. Strikingly, infusions of CXCR2 knockout monocytes in $Pten^{pc-/-}$; $Trp53^{pc-/-}$ mice demonstrated that inhibition of CXCR2 does not interfere with the tumor recruitment of monocytes but prevented the polarization of TAMs in M2-like resulting in an increased percentage of TNFα-releasing M1-like macrophages in the tumor microenvironment. Moreover, tumor cells harboring *PTEN* deletion were more sensitive to TNFα-induced senescence when compared to *PTEN* WT tumors due to increased levels of *TNFR1*.

Conclusions: Taken together our results identify TAMs as a target for prostate cancer therapy and describe new therapeutic strategies to harness the anti-tumorigenic potential of macrophages in cancer.

Background: GSK2636771 is a potent, adenosine triphosphate (ATP) competitive, selective, oral inhibitor of the PI3Kβ isoform that inhibits the growth of phosphatase and tensin homolog (PTEN) deficient tumor cells in preclinical models. Resistance to the androgen receptor (AR) inhibitor enzalutamide (Xtandi®) may be mediated through upregulation of the PI3K pathway. Thus, GSK2636771 may enhance PTEN deleted prostate cancer cell kill.

Methods: Within 30-days of documented progression on enzalutamide, subjects with PTEN deficient mCRPC are enrolled and treated with enzalutamide plus GSK2636771 in either dose escalation (DE) or dose expansion (DX) phases. Treatment continues until progressive disease (PD), unacceptable toxicities, consent withdrawal, or death. The primary objective is to assess safety, tolerability and determine the recommended phase 2 dose of this treatment combination. Secondary objectives include evaluation of pharmacokinetics, pharmacodynamics, biomarkers, and clinical activity per PCWG2/RECIST 1.1. All subjects receive 160 mg enzalutamide once daily (QD) + GSK2636771 starting at 300mg QD using a standard 3 + 3 DE design with planned 100 mg incremental escalations or de-escalation.

Results: In this ongoing study, 23 subjects received this treatment combination; 7 at 300 mg, 16 at 200 mg. Most AEs were Grade 1 or 2, with diarrhea the most common treatment-related AE (9/23; [39%]). Dose-limiting toxicities (DLTs) included Grade 3 hypocalcemia and reversible Grade 3 acute renal failure at 300mg and Grade 3 rash at 200mg. PK parameters suggested no drug-drug interaction between enzalutamide and GSK2636771. Among 13 evaluable patients at 200mg, 1 had a radiological partial response, and 2 had maximum PSA reductions of $>50\%$. Five subjects have been treated for $\geq$6 months. DE of 300 mg and DX of 200 mg cohorts are ongoing.

Conclusions: Our preliminary data indicate that GSK2636771 in combination with enzalutamide is largely well tolerated and confirm the clinical relevance of PI3Kb inhibition in PTEN-deficient mCRPC. GSK funds this study.

793PD Phase 1 study of the PSMA-targeted small-molecule drug conjugate EC1169 in patients with metastatic castrate-resistant prostate cancer (mCRPC)

M. Morris[1], N.J. Vogelzang[2], O. Sartor[3], A. Armour[4], M. Groaning[5], R. Messmann[6], A. Robarts[7], D.P. Petrylak[8], A. Tolcher[9], M.S. Gordon[10], H. Babiker[11]

[1]Genitourinary Oncology Service, Memorial Sloan-Kettering Cancer Center, New York, NY, USA, [2]Medical Oncology, Comprehensive Cancer Centers of Nevada, Las Vegas, NV, USA, [3]Oncology, Tulane University, New Orleans, LA, USA, [4]Medical, Endocyte, Inc., Indianapolis, IN, USA, [5]Clinical, Endocyte, Indianapolis, USA, [6]Medical Oncology, Endocyte, West Lafayette, IN, USA, [7]Genitourinary Oncology Service, Memorial Sloan Kettering Cancer Center, New York, NY, USA, [8]Medical Oncology, Yale University School of Medicine Medical Oncology, New Haven, CT, USA, [9]Medical Oncology, South Texas Accelerated Research Therapeutics (START), San Antonio, TX, USA, [10]Medical Oncology, HonorHealth Research Institute, Scottsdale, AZ, USA, [11]Medical Oncology, University of Arizona Comprehensive Cancer Center, Tucson, AZ, USA

Background: Prostate-specific membrane antigen (PSMA) is highly expressed in prostate cancers, but not in most non-prostate normal tissues, making it a potential therapeutic target. EC1169, a PSMA-targeted conjugate of the microtubule inhibitor tubulysin B hydrazide is being studied in a two-part phase 1 dose escalation (A)/expansion (B) study in mCRPC. The utility of the PSMA-targeted companion imaging agent ^{99m}Tc-EC0652 is also being evaluated as a patient selection tool. Part A has been completed. We now report the part B data on pts treated to date.

Methods: EC1169 is administered as an IV bolus on days 1, 8 every 21 days. The RP2 dose of 6.5 mg/m^2 was determined in Part A. Part B pts are treated at the RP2 dose and enrolled in 1 of 2 cohorts: mCRPC taxane naïve (cohort 1, 45 pts) or taxane exposed (cohort 2, 40 pts). Prior to treatment, pts undergo a ^{99m}Tc-EC0652 SPECT/CT scan. The primary endpoint of Part B is median radiographic progression-free survival (rPFS). Other study evaluations are OS, PSA, and CTC-based biomarkers.

Results: Thirty-four of a planned 85 pts in Part B have been treated (14 taxane naïve, 20 taxane exposed). Median age is 70 (range: 49-84). Median number of cycles is 3 (range: 1-7). Twenty-six pts (76.5%) reported at least 1 treatment related AE. Most treatment related AEs (TRAEs) are Gr1 and 2; G3 treatment-related constipation occurred in 1 pt. No Grade 4 TRAEs have been reported. No dose reductions due to AEs have occurred. Six of twelve evaluable taxane-exposed pts in Part B had stable disease or better at their first post-baseline scan (9 wks). One pt currently beyond the 18-week scan has achieved durable resolution of his soft tissue disease. Imaging with ^{99m}Tc-EC0652 suggests excellent disease localization.

Conclusions: The RP2 dose of EC1169 is 6.5 mg/m^2 (D1, 8 every 21 days). EC1169 has been well tolerated in 34 Part B pts at the RP2 dose A PSMA-targeted therapeutic strategy appears viable. There is evidence of anti-tumor activity in both the taxane naïve and taxane exposed pts.

794P EPI-506 (ralaniten acetate), a novel androgen receptor (AR) N-terminal domain (NTD) inhibitor, in men with metastatic castration-resistant prostate cancer (mCRPC): Phase 1 update on safety, tolerability, pharmacokinetics and efficacy

U. Vaishampayan[1], R.B. Montgomery[2], M.S. Gordon[3], D.C. Smith[4], K. Barber[5], A. de Haas-Amatsaleh[6], N. Thapar[7], C. Chandhasin[8], F. Perabo[9], K.N. Chi[10]

[1]Oncology, Karmanos Cancer Institute, Detroit, MI, USA, [2]Genitourinary Medical Oncology, University of Washington, Seattle, USA, [3]Medical Oncology, HonorHealth Research Institute, Scottsdale, AZ, USA, [4]Medical Oncology, University of Michigan, Ann Arbor, MI, USA, [5]Clinical Operations, ESSA Pharmaceuticals Corp., Houston, TX, USA, [6]Medical, ESSA Pharmaceuticals Corp., Houston, TX, USA, [7]Clinical Pharmacology, ESSA Pharmaceuticals Corp., Houston, TX, USA, [8]Medical & Scientific Affairs, ESSA Pharmaceuticals Corp., Houston, TX, USA, [9]Medical, ESSA Pharmaceuticals Corp., Houston, TX, USA, [10]Experimental Therapeutics, BC Cancer Agency, Vancouver, BC, Canada

Background: EPI-506 (ralaniten acetate) is being studied in a Phase 1/2 study as a first-in-class transcription inhibitor of the AR NTD.

Methods: Open-label, single-arm, Phase 1/2 study evaluating EPI-506 administered orally. The Phase 1 is a modified 3 + 3 design to establish safety, tolerability, pharmacokinetics (PK), maximum-tolerated-dose (MTD) and the recommended phase 2 dose (RP2D) of EPI-506. Anti-tumor activity is evaluated by PSA and imaging. Inclusion criteria include: mCRPC with progression after > =1 line of hormonal therapy or chemotherapy, failure to treatment with enzalutamide and/or abiraterone.

Results: Twenty-one patients (pts) have been enrolled in the dose escalation phase over 6 dose levels (80 - 2,400 mg). Median age was 72 (range 58-87). Prior treatments included enzalutamide only (N = 9), abiraterone only (N = 3) or both (N = 9). Eight pts also had prior chemotherapy. Twelve pts discontinued due to disease progression and 2 pts due to adverse events (AEs): Grade 4 elevated amylase (probably related; at 640mg) and Grade 4 gastrointestinal bleeding (unrelated). Median exposure was 87 days at cut-off (range 21-418). Most frequently reported treatment emergent AEs were diarrhea (N = 8), nausea (N = 6), and pain in extremities (N = 5). One possibly related Grade 3 AE (AST elevation) was observed at 1280 mg. PK data demonstrate a dose-proportional profile for C_{max} and AUC together with a positive food effect above 640 mg. Three of 21 evaluable pts demonstrated PSA declines ranging from 4 – 29%, and one pt with unchanged PSA at doses >1,280 mg. Three pts have had prolonged treatment (median of 286 days; range 219 – not reached), after intrapatient dose escalation. The study is currently enrolling pts with a total dose of 3,600 mg in both a QD and a BID dosing schedule.

Conclusions: EPI-506 is well-tolerated with an acceptable safety profile. PK indicates dose-proportionality. PSA declines and stable disease have been observed at higher dose cohorts in this ongoing study. This study is the first to evaluate targeting the AR NTD, a region critical for transcriptional function of all known AR species.

796P Phase I expansion cohort of TAS-115, a novel oral MET/VEGFR/FMS inhibitor, for castration-resistant prostate cancer patients (CRPC pts) with bone metastases

N. Matsubara[1], Y. Naito[1], M. Sasaki[2], N. Yamamoto[3], S. Takahashi[4], H. Uemura[5], T. Doi[6]

[1]Department of Breast and Medical Oncology, National Cancer Center Hospital East, Kashiwa, Japan, [2]Department of Medical Oncology, Kyoundo Hospital, Tokyo, Japan, [3]Department of Thoracic Oncology, National Cancer Center Hospital, Tokyo, Japan, [4]Department of Medical Oncology, Cancer Institute Hospital of JFCR, Tokyo, Japan, [5]Department of Urology/Renal Transplantation, Yokohama City University Medical Center, Yokohama, Japan, [6]Department of Experimental Therapeutics, National Cancer Center Hospital East, Kashiwa, Japan

Background: TAS-115 is a novel small-molecule inhibitor of hepatocyte growth factor receptor (MET) and vascular endothelial growth factor receptor (VEGFR) with antitumor activity in preclinical models. It has also been shown that TAS-115 inhibits Feline McDonough Sarcoma oncogene (FMS) kinase, essential for the differentiation of osteoclasts, and is expected to be effective against bone metastases. In this expansion cohort of phase I trial, the safety and efficacy of TAS-115 were evaluated in CRPC pts with bone metastases.

Methods: Eligible CRPC pts with bone metastases who were refractory to standard treatment including docetaxel, abiraterone and/or enzalutamide were enrolled. Two dose levels of TAS-115 (450 and 650 mg/body/day) were administered orally with a 5-days-on/2-days-off schedule for up to 21 days per cycle in this expansion cohort. Efficacy was evaluated based on the RECIST ver 1.1 and bone scan response, defined as 30% decrease in bone scan index (BSI) calculated by quantitative software of BONENAVI®(FUJIFILM RI Pharma, Japan; EXINI bone®, Exini Diagnostics, Sweden). Toxicities were evaluated based on the CTCAE ver 4.03.

Results: As of Apr 2017, a total of 15 pts received TAS-115 (9 pts with 450 mg, and 6 pts with 650 mg). Bone scan response was reported in 4 of 9 pts (44.4%) who had baseline BSI ≥0.5%, which is equivalent to grade≥1 extent of disease. The best overall response per RECIST was stable disease in 7 of 15 pts (46.7%). These efficacies were observed regardless to dose levels. One patient had a long administration period exceeded to 15 months without disease progression, and another one patient experienced remarkable pain relief induced by bone metastases. TAS-115 had no effect on the PSA and ALP. The major (≥30%) adverse drug reactions (ADRs) were anorexia, fatigue, nausea, thrombocytopenia, rash, AST increased, anemia, vomiting and edema. The rate of grade ≥3 to all ADRs was 18.8%. These AEs were recovering by interruption of TAS-115.

Conclusions: Toxicities of TAS-115 were acceptable and manageable in CRPC pts, and preliminary anti-tumor activity, especially against bone metastases was recognized. A phase II trial for CRPC pts with bone metastases is ongoing.

797P Phase II trial of SM88 in non-metastatic biochemical recurrent prostate cancer

G. Del Priore[1], W-T. Chen[2], H. Dong[2], S. Hoffman[3], G. Sokol[4]

[1]Tyme Inc, New York, NY, USA, [2]School of Medicine, Stony Brook University, Stony Brook, NY, USA, [3]Tyme Inc, New York, NY, USA, [4]Tyme Inc, Uniformed Services University of the Health Sciences, Bethesda, MD, USA

Background: Despite toxicity and no clear clinical benefit, non-metastatic recurrent prostate cancer (nmPC) is typically treated with medical castration in North America. SM88 is a non-toxic novel combination therapy based on the Warburg effect, with activity in a variety of cancers including prostate (JCO 2017 e Abstract1). End of phase 1 results demonstrated stable or rising testosterone levels while achieving CTC (circulating tumor cells) benefit and no radiographic progression events (JCO 2017e Abstract2). We now report phase II data.

Methods: Starting in Sept 2016, a prospective Phase Ib/II of SM88 (230mg po bid) enrolled recurrent nmPC with rising PSA (PCWG3 definition) and detectable CTCs, but no radiographically identified lesions.

Results: 8 (of 34 planned) subjects have completed at least 1 cycle (median 5, range 1-7). Mean age was 69.7 (62-80); all had prior ADT after curative intent RT (50%) or surgery (50%); no patient is currently on ADT. Mean testosterone level (T) was 581.4 ng/

dL and rose or remained stable in the subjects except for one patient who entered the trial castrate (<2.5) from prior RT. Overall 62.5% had some grade 1-2 adverse event (AE) but there were no drug related serious AE. EORTC-QOL-P30 relating to intimacy (Q50-54) improved or remained stable. In subjects with more than 1 cycle (n = 5), CTCs fell to undetectable (n = 1) or decreased by >30% (n = 4); at up to 6 cycles, no PSA progression (PCWG3) and no radiographic progression was reported (n = 8). No subject required other toxic therapy (100% subsequent treatment free survival). Available preliminary neutrophile:lymphocyte ratio (N::L)(n = 6) improved while urinary NTx, bone specific AlkPhos and LDH trends were essentially unchanged.

Table: 797P

subject #	cycles completed	T ng/dL	CTCs baseline	Max Decrease	N:L Max Decrease
1	6	635.7	26.75	100%	78%
2	6	<2.5	44.75	77%	37%
3	6	340.7	16.75	39%	35%
4	4	154.7	30.75	84%	29%
5	3	162.5	12.5	32%	8%
6	1	557.8	na	na	13%

Conclusions: We propose that hormonal castration is not necessary for nmPC disease control based on a preliminary assessment of both Phase Ib and II data of SM88. CTCs and N::L were improved while maintaining normal T. These early biomarker indicators are consistent with the observed 100% radiographic progression free survival and avoidance of additional toxic therapy. A phase III RCT is planned for confirmation of these results.

798P Impact of the addition of metformin (Met) to abiraterone (Abi) in metastatic castration-resistant prostate cancer (mCRPC) patients (pts) progressing on Abi treatment: A phase II pilot study

M. Mark[1], D. Klingbiel[2], U. Mey[1], R. Winterhalder[3], C. Rothermundt[4], S. Gillessen[4], R. von Moos[1], G. Manetsch[1], R. Cathomas[1]

[1]Hämatologie/Onkologie, Kantonsspital Graubünden, Chur, Switzerland, [2]Coordinating Center, SAKK, Berne, Switzerland, [3]Onkologie, Luzerner Kantonsspital, Luzern, Switzerland, [4]Onkologie, Kantonsspital St. Gallen, St. Gallen, Switzerland

Background: Abi has become one of the standard 1st line treatments in mCRPC. Cross-talk signalling pathways such as PI3K/Akt/mTOR represent a possible resistance mechanism against Abi. The oral antidiabetic agent Met has been shown to have antiproliferative effects via inhibiting mTOR. We hypothesized that the addition of Met to pts with PSA progression on Abi could influence resistance to Abi and thus delaying start of second line therapy.

Methods: Men with mCRPC experiencing PSA progression on first line Abi were enrolled in this prospective single-arm open-label multicentre Phase II trial. Pts with visceral metastases were excluded. Abi (1000mg qd)/Prednisone (5mg bd) treatment was continued and pts received Met 1000mg bd in addition. Primary endpoint was progression-free survival (PFS) at 12 weeks according to RECIST 1.1 or PCWG2 criteria. Secondary endpoints included PFS, PSA response rate, OS, toxicity and safety. 25 pts were planned to consider the trial uninteresting (H0: PFS at 12 weeks $\leq$ 15%) or promising (H1: $\geq$ 35%) using a 5% significance level and a 80% power.

Results: 25 pts with a median age of 76 years (IQR 72-82), were included between November 2013-September 2016 in 3 Swiss cancer centres. Median time to development of castration resistance was 19.5 months (mts) (IQR 11-24), and median duration on Abi before study entry was 12.1 mts (IQR 8-19). PFS rate at 12 weeks was 12% (3 of 25 pts), median PFS was 9 weeks (IQR 7-11) and median OS 20.7 mts (IQR 14-23). One patient had PSA decline of 30% and another one of 26%, all other had PSA progression. 4 pts (16%) had radiographic progression at week 12. 11 pts (44%) had grade 1 and two pts each grade 2 (8%) or grade 3 (8%) gastrointestinal toxicity (nausea, diarrhoea).

Conclusions: The addition of Met to Abi in pts with mCRPC after PSA progression on Abi did not have a substantial impact on PFS or PSA response. Toxicity of Met in combination with Abi was higher than expected.

Clinical trial identification: NCT01677897

799P Steroid switch: Reversal of resistance to abirateron acetate (AA) and prednisolone (P) combination in metastatic castration-resistant prostate cancer (mCRPC) patients

F. Gyergyay[1], B. Budai[2], K. Biro[1], Z. Küronya[1], K. Nagyivanyi[1], L. Geczi[1]

[1]Chemotherapy, National Institute of Oncology, Budapest, Hungary, [2]Department of Molecular Genetics, National Institute of Oncology, Budapest, Hungary

Background: AA+P has shown to improve overall survival (OS) in large, randomized trial in the treatment of mCRPC both in pre and post-docetaxel setting. AA is a steroidal CYP17A1 inhibitor, which suppresses androgen synthesis. Because of secondary mineralocorticoid excess it is licensed in combination with P.

Methods: Based on previous data reporting responses following steroid switch upon progression during AA+P a prospective study in mCRPC pts was started. (Lorente at al BJC (2014) 111, 2248–2253).

Results: 23 mCRPC pts were treated with AA (1000 mg q.d.) and P (5 mg b.i.d). Pts characteristics were as follows: median age 73 (95% CI 69-77) years, median Gleason score 8 (7-9), time-span since diagnosis was median 5.6 (3.6-7.8) yrs and all pts. had previous docetaxel treatment and received concomitant androgen deprivation treatment. Pts were on AA+P therapy for median 11.4 (6.4-19.8) mos. In case of PSA progression steroid switch has been applied to dexamethasone (D) (0.5 mg q.d). The PSA progression-free survival on AA+D combination was 5 (3.7-5) mos. 13 (57%) pts are still on AA+D treatment. The OS for AA was 53 (39-53) mos.

Table: 799P

Schedule		PSA progression-free survival (mos)	PSA (ng/ml) at start	PSA (ng/ml) nadir
AA+P	Median	11.4	99	32.5
	95% CI	6.4 -19.8	30-129	13-98
AA+D	Median	5	52	41.5
	95% CI	3.7 - 5	27-133	20-100

During AA+P therapy >25% decrease in PSA occurred in 65% of pts and further decrease (>25%, compared to the nadir during AA+P treatment) has been seen in 26% pts during AA+D treatment.

Conclusions: D can induce further response during AA therapy by reversing glucocorticoid receptor activation or by superior activity of D administered even as a single agent. Our data supports that steroid switch may induce further PSA regression.

Background: Abiraterone Acetate (AA) improves overall survival in mCRPC patients. It is administered with prednisone (P) to decrease the adverse events derived from CYP171A supression. In phase I/II of AA without steroids, dexamethasone (D) 0.5mg/day was added after biochemical progression reaching a 25% of PSA decline. In a retrospective post-docetaxel cohort, Lorente et al (BJC,2014) reported that the switch induced durable biochemical responses in 40% of cases.

Methods: This is a multicentre-prospective phase II study. Its primary aim was to evaluate the antitumour activity of the change of concomitant P 5mg/12h to D 0.5mg/24h daily in mCRPC patients with biochemical and/or limited radiological progression after ≥12 weeks of AA+P treatment. Biochemical response and progression free survival (bPFS) were evaluated by PCWG2 criteria. Radiological response and PFS (rPFS) were evaluated after 12 weeks by RECIST and PCWG2 criteria. Using a single-stage ÁHern Phase II design a minimum of 6 PSA responses >30% in 25 enrolled patients were required to accept the alternative hypothesis (α:5%, 1-β:80%). PTEN and TMPRSS2-ERG in archival tumour-biopsies, AR aberrations in ctDNA and AR-V7 in exosomal RNA were evaluated. The Kaplan-Meier curves were used to calculate survival outcomes.

Results: 26 patients were included. Their clinical characteristics are shown in Table 1. No new safety concerns were observed with AA+D. A decline in PSA≥30% and ≥50% were observed in 12 (46%) and 8 (35%) patients, respectively; two radiological responses were observed; bPFS and rPFS after P to D switch were 4.2 months (CI 95% 2.2-6.2) and 11.8 months (CI 95% 6.9-16.8), respectively.

Table: 800P

Characteristics	AA+D pre-CT (n = 14) N %	AA+D post-CT N %
Age Median (range)	72.9 60-85	72.9 66-78
Baseline PSA Median (range)	26.6 4.5-367	39.9 6.9-1880
Gleason 6-7 8-10 UK	5 36 8 57 1 7	6 50 6 50
ECOG 0-1 2	13 80 1 7	12 100
Metastases Bone Nodes Visceral	12 86 8 57 1 7	12 100 4 33 3 25

Conclusions: In selected clinically stable mCRPC patients the P to D switch as adjuvant of AA could be an acceptable and active therapeutic option. Biomarkers correlation with P to D switch benefit will be reported.

801P Effect of sequence on outcome of prostate cancer patients: retrospective study of a French cohort

R. Elaidi[1], Y. Belhadj[1], S. Oudard[2]

[1]Medical Oncology - Hôpital Européen Georges Pompidou, ARTIC, Paris, France, [2]Immunothérapie et Traitement Antiangiogénique en Pathologie Cancérologique, Hopital European George Pompidou, Paris, France

Background: several drugs are approved in prostate cancer (PC), both in localized and metastatic setting. Challenge of daily practice is the sequencing of available agents for optimal disease management. Trying to extract actionable information from the overall history of disease for each patient remains a difficult task but could provide new insights for better sequencing. This retrospective analysis aimed to follow-up patients included in the Rising-PSA phase 3 clinical trial (R-PSA-CP-03) until death or last contact.

Methods: we retrospectively analyzed therapies received by pts included in R-PSA at the HEGP hospital (Paris, France). Drugs were coded in 8 categories: LH: LHRH modulators, AA: anti-androgens, AA2: new generation AA, DC: docetaxel, CZ: cabazitaxel, EX: blinded experimental drugs, P: therapeutic pause, PCB: placebo(experimental). Sequence rank, therapy duration and their interaction was estimated using both a conditional repeated events model (CREM) and a multi-state model (MSM) based on Markov process stratified on disease setting. Covariables included in the models were: age and Gleason score at inclusion time.

Results: 152 pts included between 01/2003 and 09/2007 were followed > 10years. Metastatic progression: 70(46%). Death: 31(20%). Median age(y): 64(51-80)), Gleason ≥8: 47(31%). Median (range) number of sequences received: M0=8(1-15) & M1=6(1-19) including pauses. Number of times each therapy was used whatever the sequence (%M0/%M1): LH(48/10), AA(6/6), AA2(0/22), DC(10/10), CZ (0/10), EX(1/6), PCB(0/2), P(35/34). Upon CREM, the overall model fitted perfectly well the time on therapies and their sequence (robust estimation: $p < 0{,}00001$). Main effects were mostly related to docetaxel, cabazitaxel and experimental drugs in the metastatic setting. Effect of sequence was significant but no therapy x sequence interaction proved to be significant. Comparable results were obtained upon MSM and will be presented.

Conclusions: to our knowledge, this is the first attempt to model the entire course of PC taking into account both therapies and sequence. Given the complexity of our model, these results should be validated with further studies and methods.

Clinical trial identification: R-PSA-CP-03

Strasbourg-Nouvel Hopital Civil, Strasbourg, France, [13]Medical Oncology, Hôpital St. Louis, Paris, France, [14]Medical Oncology, Hopital privé Hyeres, Hyeres, France, [15]Medical Oncology, Institut de Cancérologie de Lorraine - Alexis Vautrin, Vandoeuvre Les Nancy, France, [16]Medical Oncology, Institut Curie, Paris, France, [17]Oncology, Centre Léon Bérard, Lyon, France, [18]Medical Oncology, CH Sud Bretagne, Lorient, France, [19]Clinical reasearch, Gustave Roussy, Villejuif, France, [20]Statistics, Institut Gustave Roussy, Villejuif, France

Background: Docetaxel and cabazitaxel are taxane chemotherapy approved in men with mCRPC after they demonstrated improved overall survival in first- and second-line, respectively. Recent data suggested similar efficacy when used in the first-line setting (Sartor O, ASCO 2016). These two taxanes have different safety profiles. Assessing patient preference between docetaxel and cabazitaxel would contribute to further differentiate between these two agents.

Methods: The CABADOC study is a randomized trial with a cross-over design. Patients with mCRPC were randomized in a 1:1 ratio to receive either docetaxel 75mg/m2/q3w x 4 followed by cabazitaxel 25mg/m2/q3w x 4, or the reverse sequence. Randomisation was stratified based on prior abiraterone or enzalutamide. The primary endpoint was patient preference between taxanes, assessed in patients who had received at least one cycle of each taxane and who had not experienced a progression after the first taxane. Prescott's test was used to analyze the primary endpoint taking into consideration the period effects.

Results: From June 2014 to October 2016, 195 patients were randomized in 17 centers. The median age was 70 years and the median PSA was 49 ng/mL. Patients received 3.8 ± 0.7 and 3.2 ± 1.5 cycles of chemotherapy during the first and the second period, respectively. The eligible population for the primary endpoint comprised 150 patients (45 patients were ineligible for the primary endpoint as per protocol). Among them, 66 preferred cabazitaxel (44% $IC_{95\%}$ = [36-52]), 40 preferred docetaxel (27% $IC_{95\%}$ = [20-34]), and 44 expressed no preference between taxanes (29% $IC_{95\%}$ = [22-37]) ($p = 0.009$). A greater proportion of patients preferred the first received taxane

(44%, $IC_{95\%}$ = [36-52]) versus the second taxane (27%, $IC_{95\%}$ = [20-34]), or had no preference (29% $IC_{95\%}$ = [22-37]). Less fatigue and improved quality of life were the two main reasons provided by patients for their choice. There were 3 toxicity-related deaths (1.5%). Pharmaco-economic analysis, toxicity, and quality of life data will be presented.

Conclusions: A higher proportion of men with mCRPC who are candidates to receive a taxane prefer cabazitaxel over docetaxel.

803P Indirect comparison of abiraterone acetate and docetaxel for treatment of metastatic "hormone-sensitive" prostate cancer

S. Feyerabend[1], F. Saad[2], T. Li[3], T. Ito[4], J. Diels[5], S. Van Sanden[5], P. De Porre[6], J. Roïz[7], S. Abogunrin[8], K. Fizazi[9]

[1]Urologic Oncology, Studienpraxis Urologie, Nürtingen, Germany, [2]Surgery, Centre Hospitalier de l'Université de Montréal/CRCHUM, Montréal, QC, Canada, [3]Global Market Access Oncology, Janssen Global Services, Raritan, NJ, USA, [4]Health Economics & Market Access EMEA, Janssen, High Wycombe, UK, [5]Health Economics & Market Access EMEA, Janssen, Beerse, Belgium, [6]Clinical Oncology, Janssen Research & Development BE, Beerse, Belgium, [7]Modeling & Simulation, Evidera, London, UK, [8]Outcomes Research, Evidera, London, UK, [9]Cancer Medicine, Institut Gustave Roussy, University of Paris Sud, Villejuif, France

Background: Androgen deprivation therapy (ADT) with or without chemotherapy (docetaxel [DOC]) is recommended in the clinical guidelines as the mainstay of management for metastatic "hormone-sensitive" prostate cancer (mHSPC). The LATITUDE trial demonstrated the efficacy of abiraterone acetate in combination with prednisone and ADT (ADT+AA+P) vs ADT in newly diagnosed mHSPC pts with high-risk disease (NDx HRD). We performed an indirect comparison to determine the relative efficacy of AA vs DOC in mHSPC.

Methods: We conducted a systematic literature review of randomized controlled trials (RCTs) of treatments for mHSPC. To increase comparability of results across studies, the population of interest from LATITUDE and DOC studies was restricted to men with NDx HRD and/or high volume disease (NDx HVD). Two RCTs (CHAARTED, GETUG-AFU 15), both evaluating ADT vs DOC+ADT, met the inclusion criteria. Fixed effects Bayesian network meta-analyses (NMAs) were performed to estimate the relative treatment effects for ADT+AA+P vs DOC+ADT on overall survival (OS) and radiographic progression-free survival (rPFS). The HVD subgroup of LATITUDE was used in the main analysis. The LATITUDE ITT population (NDx HRD) was included as a sensitivity analysis. As STAMPEDE did not report an NDx HVD/HRD subgroup, its M1 population was included in a sensitivity analysis.

Results: The results for HRD/HVD suggested improvement with ADT+AA+P vs DOC+ADT in OS (HR 0.84) and in rPFS (HR 0.73), with Bayesian probabilities (P) for ADT+AA+P 86.8% (OS) and 99.2% (rPFS) more effective. Main results were consistent with all sensitivity analysis results (Table).

Conclusions: Our analyses suggest that ADT+AA+P has greater reduction in risk of progression and death vs ADT+DOC. In absence of head-to-head trials, indirect comparisons based on Bayesian NMA can provide useful insights to clinicians and reimbursement decision makers on the relative efficacy of treatment options for men with mHSPC.

804P Practice patterns in metastatic castration-resistant prostate cancer (mCRPC): Evidence from the veterans health administration

A. Halwani[1], Z. Burningham[2], K.M. Rasmussen[2], V. Patil[2], S. Narayanan[3], S-W. Lin[3], S. Carroll[3], L-I. Hsu[3], J. Graff[4], R. Dreicer[5], S. Gupta[1], C. Low[1], B.C. Sauer[2]

[1]Division of Hematology, Huntsman Cancer Institute, Salt Lake City, UT, USA, [2]Division of Epidemiology, University of Utah, Salt Lake City, UT, USA, [3]Oncology, Genentech, Inc., South San Francisco, CA, USA, [4]Division of Oncology, Oregon Health & Science University- Knight Cancer Center, Portland, OR, USA, [5]Division of Hematology/Oncology, University of Virginia, Charlottesville, VA, USA

Background: Practice patterns for metastatic castration-resistant prostate cancer (mCRPC) have evolved over the last decade due to introduction of agents such as abiraterone and enzalutamide. This study examines mCRPC treatment practices over a 10-year period (which includes the time periods before and after the introduction of novel oral anti-androgens) for the first 3 lines of therapy in the largest nationwide integrated health system in the United States, the Veterans Health Administration.

Methods: By linking patient information from the Veterans Affairs (VA) Clinical Cancer Registry to clinical notes, laboratory, procedure and imaging data from the VA Corporate Data Warehouse (CDW), we identified patients who were diagnosed with prostate cancer at the VA and ultimately developed mCRPC, defined as radiological evidence of metastasis and evidence of rising PSA levels concomitant with surgical (bilateral orchiectomy) or medical castrate testosterone levels ($\leq$ 50 ng/dL within the last 3 months or ongoing treatment with androgen deprivation). Therapies used to treat mCRPC were extracted from CDW pharmacy dispensation records (docetaxel, abiraterone, enzalutamide, cabazitaxel, and others).

Results: From 2006 to 2015, 120,374 patients were diagnosed with prostate cancer, of whom 3,637 developed mCRPC. Median age at initial prostate diagnosis was 68 years (range, 41-94), average BMI was 26.5 (range, 9-59), average CCI score was 1.5 (range, 0-12) and average PSA was 45.5 ng/mL. Practices for the first 3 lines of treatment from 2006 to 2010 and 2011 to 2016 are summarized in Table 1. Patients diagnosed with mCRPC between 2006 and 2010 were more likely to receive cytotoxic therapy than patients diagnosed between 2011 and 2016 (37% vs 22%). Compared with the cohort diagnosed between 2006 and 2010, the later cohort was more likely to receive treatment

AA, abiraterone acetate; CAB, cabazitaxel; DOC, docetaxel; ENZ, enzalutamide; MIT, mitoxantrone [a]<15 patients were treated with radium-223 dichloride or sipuleucel-T

(44% vs 62%) and was also more likely to receive > 1 line of therapy (20% vs 37%). For patients diagnosed between 2011 and 2016, the most common therapies were as follows: 1L, abiraterone (29%); 2L, abiraterone (15%) and enzalutamide (14%); and 3L, enzalutamide (8%).

Conclusions: Our study is the first to describe adoption of non-chemotherapeutic treatments in a nationwide cohort of patients with mCRPC treated in the largest integrated healthcare system in the United States. Further research will focus on understanding clinical outcomes associated with this shift in practice patterns.

805P Efficacy and safety of first-line combined androgen blockade in advanced prostate cancer: A meta-analysis

Y. Sun, Y. Yang, R. Chen, L. Zhao, F. Liu, S. Ren, H. Wang, X. Lu, X. Gao, C. Xu

Department of Urology, Shanghai Changhai Hospital, Shanghai, China

Background: Combined androgen blockade (CAB) is one of the therapies for advanced prostate cancer. In this analysis, we compared the efficacy and safety of first-line CAB with castration monotherapy in advanced prostate cancer patients.

Methods: The meta-analysis was PRISMA compliant and was registered in PROSPERO (CRD42016054301). We searched PubMed, EMBASE, Cochrane and Scholar for randomized controlled trials (RCTs) published through 12th December 2016 and compared efficacy and safety of first line CAB vs. luteinizing hormone releasing hormone agonists (LHRHa) monotherapy/orchiectomy in advanced prostate cancer. Overall survival (OS) and progression free survival (PFS) were the primary outcomes (fixed/random effects model). Safety was the secondary outcome. Sub-group analyses included: i) Eastern vs. Western patients; ii) non-steroidal anti-androgen (NSAA) vs. steroidal anti-androgen (SAA). Studies with reported HR/presenting median survival and JADAD score >2 were included.

Results: We identified 16 studies (6084 patients; West-12; East-4) for inclusion. CAB treatment significantly improved the OS (14 RCTS; HR 0.90; 95% CI 0.84 to 0.97, P = 0.003) and PFS (13 RCTs; HR 0.89; 95% CI 0.80 to 1.00, P = 0.04) in advanced prostate cancer patients, compared with monotherapy. No significant difference in OS (P = 0.71) and PFS (P = 0.49) was observed between Western vs. Eastern patients. CAB with NSAA significantly improved OS (HR 0.88; 95% CI 0.82 to 0.95, P = 0.0009) and PFS (HR 0.85; 95% CI 0.73 to 0.98, P = 0.007); whereas, CAB with SAA reported similar OS (HR 1.03; 95% CI 0.86 to 1.25, P = 0.74) or PFS (HR 1.01; 95% CI 0.87 to 1.17, P = 0.74) compared with castration monotherapy. Incidence of grade 3 or 4 AEs was not significantly different between CAB and castration monotherapy (P = 0.1083).

Conclusions: First-line CAB therapy significantly improved OS and PFS in advanced prostate cancer patients, with no significant difference in grade 3 or 4 AEs compared with castration monotherapy.

806P Outcomes of prechemotherapy (pCRx) abiraterone acetate (AA) or enzalutamide (E) for metastatic castration-resistant prostate cancer (mCRPC) after ADT + Docetaxel (D) or ADT alone for metastatic hormone sensitive prostate cancer (mHSPC) in a multi-institution hospital-based registry

E. Francini[1], S. Yip[2], N.S. Ahmed[2], H. Li[3], L. Ardolino[4], C.P. Evan[1], M. Kaymakcalan[1], G.K. Shaw[1], P. Kantoff[5], M.E. Taplin[1], N. Alimohamed[2], A.M. Joshua[4], D.Y.C. Heng[2], C.J. Sweeney[1]

[1]Lank Center for Genitourinary Oncology, Dana-Farber Cancer Institute, Boston, MA, USA, [2]Genitourinary Oncology, Tom Baker Cancer Centre, Calgary, AB, Canada, [3]Departments Oncology and Community Health Sciences, University of Calgary, Calgary, AB, Canada, [4]Medical Oncology, Saint Vincent's Hospital, Sydney, Australia, [5]Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY, USA

Background: The E3805: CHAARTED trial noted that the addition of D to ADT was associated with a hazard ratio (HR) of 0.56 (95% confidence interval [CI], 0.44 to 0.70; P < 0.001) for time to CRPC and resulted in a prolongation of overall survival (OS). Therefore, we postulated that pCRx AA or E had greater activity after ADT+D compared to after ADT alone.

Methods: A cohort of mCRPC patients (pts) treated with pCRx AA or E for mCRPC between 2014 and 2017 was identified from three hospitals' IRB approved databases. Patients were grouped by use of D for mHSPC. This time frame was chosen as ADT+D became a valid therapeutic option for mHSPC in 2014 and thus time to pCRx and follow-up were short. The endpoints included OS (time to death from all causes) from ADT start, time to AA/E start from ADT start, and OS from AA/E start. Survival outcomes were analyzed by Kaplan-Meier method.

Results: Of the 102 identified, 50 (49%) had previously received ADT alone, while 52 (51%) had ADT+D. No statistically significant difference in OS from ADT start or from AA/E start was observed between the 2 cohorts (Table 1). Notably, survival in both groups from ADT start was shorter than commonly reported. Yet, deaths in the ADT+D group were 12 vs. 21 in the ADT alone, after a median follow-up of 24.4 and 29.8 months, respectively.

Table: 806P

pCRx AA/E	N (%)	N Deaths (median follow-up mo)	Median OS from ADT start (95% CI mo)	P-value	Time to AA/E start (95% CI mo)	P-value	Median OS from AA/E start (95% CI mo)	P-value
ADT	50 (49%)	21 (29.8)	33.5 (22.4 – NR)	0.2047	11.0 (8.5 – 13.7)	0.7265	17.3 (13.7 – NR)	0.6514
ADT+D	52 (51%)	12 (24.4)	NR (NR-NR)		12.8 (11.1 – 15.7)		NR (13.1 – NR)	

Conclusions: In a cohort of ADT/ADT+D treated mCRPC pts with short times to pCRx AA/E and follow-up, the efficacy of AA/E is similar regardless of previous use of D. It is possible that the pts selected for ADT+D had poorer prognostic factors and yet still did at least as well with AA/E and deaths were lesser. Larger sample sizes, longer follow-up, and better characterization of patient and tumor factors are needed to assess the efficacy of different sequences.

Background: Ra-223 prolongs survival with a favorable safety profile in metastatic castration-resistant prostate cancer (mCRPC). The pivotal phase 3 ALSYMPCA trial had a relatively short 3-year follow-up and was conducted before availability of 2nd generation hormonal agents. The REASSURE study was designed to assess long-term safety (7 years follow-up) and conducted in an era when pts had access to other effective 1st line agents such as abi/enza.

Methods: REASSURE is a global, prospective, single-arm, observational study that enrolled pts with mCRPC with bone metastases planned to start Ra-223. Treatment decision was made independently before enrollment. We undertook a planned interim descriptive analysis of safety and drug completion based on prior or concomitant abi/enza use.

Results: REASSURE enrolled 1106 pts in N. America and Europe from Sep 2014 to Sep 2016. The interim analysis included 583 pts who received ≥1 Ra-223 dose (Table; median 7 months observation). Prior abi/enza use was reported in 168 (29%) and concomitant in 153 (26%) pts. Treatment-related adverse events (TRAEs) occurred in 37%: prior abi/enza 45%, no prior abi/enza 34%; concomitant abi/enza 29%, no concomitant abi/enza 40%. TRAEs were most often gastrointestinal or hematological, with permanent discontinuation of Ra-223 in 6%: prior abi/enza 8%, no prior abi/enza 5%; concomitant abi/enza 5%, no concomitant abi/enza 7%. Serious TRAEs (mostly hematologic) occurred in 4.5% leading to permanent Ra-223 discontinuation in 1.5%.

Table: 807P Baseline characteristics and treatment completion by prior or concomitant* abi/enza

	Prior Yes (n = 168)	Prior No (n = 415)	Concomitant Yes (n = 153)	Concomitant No (n = 430)
ECOG 0–1, n (%)	122 (73)	329 (79)	121 (79)	330 (77)
No. of metastases**, n (%)				
<6	42 (26)	123 (32)	53 (37)	112 (28)
6–20	81 (51)	221 (58)	86 (60)	216 (54)
>20	39 (24)	67 (17)	27 (19)	79 (20)
Superscan	14 (9)	21 (5)	5 (3)	30 (8)
ALP (U/L), median	155	115	114	134
<140 U/L, n (%)	58 (35)	153 (37)	54 (35)	157 (37)
≥140 U/L, n (%)	73 (43)	126 (30)	51 (33)	148 (34)
PSA (ng/mL), median	136	43	43	76
LDH (U/L)***, median	327	260	291	264
Prior docetaxel or cabazitaxel, n (%)	96 (57)	100 (24)	46 (30)	150 (35)
Completed 5 or 6 Ra-223 doses, n (%)	87 (52)	282 (68)	106 (69)	263 (61)

*Prior = abi/enza stopped before starting Ra-223. Concomitant = any overlap with Ra-223.
**Pts undergoing more than one imaging modality may be reported in multiple categories.
***LDH was available for 209/583 patients.

Conclusions: Ra-223 has a good short-term safety profile when used in the routine clinical practice setting. Prior or concomitant abi/enza does not appear to increase TRAE incidence. Pts who had prior abi/enza had a lower rate of completing full Ra-223 dosing, perhaps reflecting poorer prognosis or more advanced disease as suggested by higher median PSA and LDH levels.

808P A phase II study of enzalutamide (Enz) with dutasteride (Dut) or finasteride (Fin) in men ≥ 65 years with hormone-naive systemic prostate cancer (HNSPCa)

D. Kilari[1], E. Guancial[2], D. Sahasrabudhe[2], K. Bylow[3], L. Sievert[2], K. Schaffer[2], M. Riese[3], J. Burfeind[3], K. Musto[1], C. Feng[4], E. Messing[5], S. Mohile[2], C. Fung[2]

[1]Medicine, Froedtert Hospital-Medical College of Wisconsin, Milwaukee, WI, USA, [2]Medicine, University of Rochester, Rochester, NY, USA, [3]Medicine, Froedtert Hospital-Medical College of Wisconsin, Milwaukee, WI, USA, [4]Biostatistics, University of Rochester, Rochester, NY, USA, [5]Urology, University of Rochester, Rochester, NY, USA

Background: Older men are at risk for adverse events (AEs) from androgen deprivation therapy (ADT). In prior studies, peripheral androgen blockade with bicalutamide and Fin was better tolerated but less efficacious than ADT in HNSPCa. The potential synergism of Enz and Dut/Fin provided the rationale for this Phase II study.

Methods: Eligible subjects were ≥ 65 yrs; at risk of AEs from ADT as determined by treating physicians; had metastatic (M1) or non-metastatic (M0) HNSPCa with a PSA doubling time <9 months; and had testosterone >50 ng/dl. Enz (160mg daily) with Dut (0.5mg daily) or Fin (5mg daily) was given until progression per the Prostate Cancer Working Group 2 guidelines or unacceptable AEs. Comprehensive geriatric assessment (CGA) was done at baseline and every 4 months. The primary endpoint is time to PSA progression. The secondary endpoints are time to PSA nadir, AEs, and effects on CGA domains.

Results: As of 4/15/17, we completed study enrollment of 40 subjects. Herein, we report outcomes of the first 31 subjects with a median follow-up of 43 weeks. Median age at enrollment was 80 yrs. 29%, 61%, and 10% had ECOG performance status of 0, 1, and 2, respectively. 45% had M0 and 55% had M1 HNSPCa. Gleason's sum was 6, 7, >8, and unknown in 19%, 49%, 23%, and 9%, respectively. At enrollment; the median PSA was 12.71 ng/ml. CGA showed cognitive impairment in 61%, physical impairment in 54%, depression in 16% and impairment of instrumental activities of daily living in 13%. The median time to 90% PSA decline was 7 weeks. 79% of patients had 80% DHT decline by 9 months. At the time of analysis, all patients had PSA decline of > 90% without radiographic evidence of disease progression. Baseline CGA did not correlate with efficacy (P-values >0.1). Common Grade 1 AEs included gynecomastia (26%), fatigue (35%), hot flashes (22%) and paresthesia (13%). None had Grade 3 or 4 AEs. Three men withdrew from the study due to treatment-related AEs (Grade 2 fatigue and paresthesia). Another three patients withdrew due to unrelated issues.

Conclusions: Enz with Dut/Fin appears to be safe and efficacious for older patients with M0 and M1 HNSPCa. Future research will report effects of treatment on CGA domains.

809P Cabazitaxel plus prednisone and prophylaxis of neutropenia complications in the treatment of metastatic castration-resistant prostate cancer after failure to docetaxel: A multicenter, non-comparative, open-label, phase IV study

F.C. Maluf[1], D. Cubero[2], F.A.M. de Oliveira[3], P.E.R. Liedke[4], L. Brust[5], C.G. Inocêncio[6], F.S.M. Monteiro[7]

[1]Clinical Oncology Department, Hospital Beneficencia Portuguesa of Sao Paulo, Sao Paulo, Brazil, [2]Hematology and Oncology, Faculty of Medicine of ABC, Santo André, Brazil, [3]Clinical Oncology Department, Hospital Erasto Gaertner, Curitiba, Brazil, [4]Oncology Clinical Search Unit, Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil, [5]Oncology Department, Hospital Bruno Born, Lageado, Brazil, [6]Oncology and Hematology, "Dr. Ademar Lopes" Search Center, Cuiaba, Brazil, [7]Clinical Oncology, Hospital Santa Lucia, Brasilia, Brazil

Background: This study aimed to evaluate the effectiveness of granulocyte colony-stimulating factor (G-CSF) and ciprofloxacin in the prophylaxis of hematological complications in mCRPC patients treated with cabazitaxel after docetaxel failure and at risk for neutropenia.

Methods: Phase IV, non-randomized, open-label, single-arm interventional study, with men aged ≥65 years (or < 65 years and 25% irradiated bone marrow), presenting mCPRC after docetaxel failure, ECOG status ≤1, life expectancy >12 weeks, that provided informed consent. Cabazitaxel 25 mg/m^2 was given with prednisone on day1 every 21 days. G-CSF was administered on days 2 to 8 of each cycle or until ANC >2,000/mm^3 and ciprofloxacin 1000mg on days 5 to 12. Primary endpoint was the rate of neutropenia grade ≥3 during the first cycle; secondary endpoints were the rate of neutropenia grade ≥3, febrile neutropenia, diarrhea grade ≥3, PSA response and quality of life (FACT-P) during treatment. Statistical significance was set at 0.05 and 95% confidence intervals were determined.

Results: 46 patients with median age 71.5 years (mean: 71.8 years) and 69.0 months on median since diagnosis (mean: 75.2 months) of prostatic cancer were included. Among the 45 treated patients, exposed to a median of 9.0 cycles (mean: 9.5 cycles) during 210 days, 40.0% (95% CI, 25.7%-54.3%) presented one episode of neutropenia grade ≥3 during the first cycle. During treatment, 42.2% patients presented at least one neutropenia grade ≥3; febrile neutropenia occurred in one patient (2.2%) as well as diarrhea grade ≥3. Twenty-nine patients (64.4%) achieved PSA response and 77.2% improved FACT-P score in at least one visit. Three patients (6.7%) had a serious TEAEs leading to death (none related to treatment), and 13.3% had 7 TEAEs leading to treatment discontinuation (3 related to treatment).

Conclusions: Prophylactic G-CSF and ciprofloxacin was effective in the prevention of neutropenia grade ≥3 and other hematological complications during the mCRPC treatment with cabazitaxel 25 mg/m^2 in patients who were at risk for neutropenia.

Clinical trial identification: NCT01649635 - Global Statitic Report: January 26th 2017.

Background: PROSELICA (NCT01308580) assessed effect of C20 vs C25 on overall survival in a non-inferiority study of pts with mCRPC. Primary analyses included assessment of HRQL in the overall population. Post-hoc subgroup analyses investigated changes in HRQL in pts receiving C20 vs C25 according to median treatment cycles received (6).

Methods: Functional Assessment of Cancer Therapy Prostate (FACT-P) was used to assess HRQL. The least square means of change in FACT-P total score (TS) from baseline (BL) was assessed via a mixed-effect model for repeated measurements and differences were compared for C20 vs C25 in pts receiving > 6 or ≤ 6 treatment cycles.

Results: Overall change in FACT-P TS from BL to Cycle 10 was not significantly different for C20 vs C25 (C20 n = 137: 0.02 [95% confidence interval [CI] -2.57, 2.61]; C25 n = 141: 1.33 [95% CI -1.26, 3.93]; p = 0.369). For evaluable pts who received > 6

cycles, change in FACT-P TS from BL to Cycle 10 favored C25 but not C20 (C25 n = 140: 3.06 [95% CI 0.25, 5.86], p = 0.033; C20 n = 137: 2.67 [95% CI -0.17, 5.51], p = 0.065). Difference in change was not significant for C20 vs C25 (-0.39 [95% CI: -3.66, 2.88], p = 0.816). For evaluable pts who received ≤ 6 cycles, change in FACT-P TS from BL to Cycle 6 favored pts receiving C25 (C25 n = 49: -4.61 [95% CI: -8.27, -0.95], p = 0.014; C20 n = 39: -6.58 [95% CI: -10.46, -2.69], p < 0.001) but the difference between the treatment arms was not significant (-1.96 [95% CI: -6.8, 2.87], p = 0.426). Increasing cycles, BL ECOG performance score (0–1 vs ≥ 2) and receiving > 6 cycles significantly improved FACT-P TS change from BL (p < 0.001). Difference in treatment dose (C20 vs C25) did not have a significant effect on FACT-P TS change from BL (p = 0.354).

Conclusions: In the overall population, HRQL did not differ significantly from BL to Cycle 10 for C20 vs C25. Additionally, there were no significant differences between the two treatment arms (C20 vs C25) in either subgroup (> 6 or ≤ 6 cycles). A significant change in HRQL from BL to Cycle 10 was observed in patients who received > 6 cycles of C25. Funding: Sanofi.

811P Cabazitaxel followed by androgen deprivation therapy (ADT) significantly improves time to progression in patients with newly diagnosed metastatic hormone sensitive prostate cancer (mHSPC): A randomized, open label, phase III, multicenter trial

O. Andrén[1], A. Widmark[2], A. Falt[3], E. Ulvskog[4], S. Davidsson[1], C. Thellenberg Karlsson[2], M. Hjalm-Eriksson[5]

[1]Department of Urology, Faculty of Medicine and Health, Orebro University, Orebro, Sweden, [2]Department of Radiation Sciences, Oncology, Umea University, Umea, Sweden, [3]Department of Epidemiology and Biostatistics, Faculty of Medicin and Health, Orebro University, Orebro, Sweden, [4]Department od Oncology, Orebro University, Orebro, Sweden, [5]Department of Oncology, Karolinsk Institutet, Stockholm, Sweden

Background: Patients with newly diagnosed mHSPC have a poor prognosis with a 3-year overall survival (OS) rate of 50%. Recently, combination of docetaxel (75mg/m2 every 6 weeks for 6 cycles) with ADT has become a new standard for such patients, based on results of 2 large phase 3 trials showing a significant OS benefit. In these trials, docetaxel was initiated within 3 months after ADT start. Timing of ADT and chemotherapy (CT) is controversial. In breast cancer, endocrine therapy is always started after CT, the rational being that ADT will turn clones of tumor cells in to a stage of dormancy where CT is less effective.

Methods: This phase 3 trial randomized newly diagnosed mHSPC patients to receive cabazitaxel (CABA), 25 mg/m2 every 3 weeks for 10 cycles, followed by ADT (immediately after last CABA cycle) versus ADT alone. Primary end-point was OS. Secondary end-point was progression free survival. The study planned to include 400 patients but was closed prematurely due to low inclusion rate. A total 31 patients with newly diagnosed mHSPC were included and here we present the results.

Results: Median follow up was 31 month. Of the CABA treated patients, 66.8% got six cycles or more and 46.7% completed all 10 courses. Median OS was 32,5 months with CABA followed by ADT and 29,5 months with ADT alone (HR 1.43, 95% CI 0.38-5.38). Median progression free survival was significantly longer in CABA treated patients (29 vs 12 months, HR 3.96 (95% CI 1.49-10.49). Main grade ≥ 3 toxicities were neutropenia (66%).

Conclusions: In conclusion, results from this prematurely terminated trial suggest that CABA followed by ADT is effective in newly diagnosed mHSPC and shows a manageable toxicity. These results have to be validated in larger randomized trials.

Clinical trial identification: NCT01978873

812P Health-related quality of life (HRQL) in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC) treated with cabazitaxel (CBZ) in a prospective observational study (CAPRISTANA)

A. Pichler[1], G. Barnes[2], J. Katolicka[3], H. Korunkova[4], A. Tomova[5], M. Ghosn[6], F. El Karak[6], I. Koroleva[7], J. Makdessi[8], A. Ozatilgan[9], S. Hitier[10], J. Carles[11]

[1]Department of Hematology and Oncology, Landeskrankenhaus LKH Leoben, Leoben, Austria, [2]Department of Biostatistics, Sanofi, Cambridge, MA, USA, [3]Department of Oncology, St. Ann's University Hospital, Brno, Czech Republic, [4]Department of Oncology and Radiotherapy, University Hospital, Plzen, Czech Republic, [5]Department of Oncology, Complex Oncology Center, Plovdiv, Bulgaria, [6]Department of Hematology and Oncology, Hotel Dieu de France Hospital, Beirut, Lebanon, [7]Department of Medicine, Medical University "Reaviz", Samara, Russian Federation, [8]Department of Medicine, St. George Hospital, Beirut, Lebanon, [9]Global Medical Affairs Oncology, Sanofi, Boston, USA, [10]Department of Biostatistics, Sanofi, Chilly-Mazarin, France, [11]Vall d'Hebron University Hospital, Vall d'Hebron Institute of Oncology, Barcelona, Spain

Background: Cabazitaxel (CBZ) is a taxane approved for mCRPC treatment post docetaxel based on Phase 3 clinical trial data. Observational studies are in progress to gather information on real-world treatment patterns, safety, efficacy and HRQL effect of CBZ outside of clinical trials.

Methods: The prospective, observational study CAPRISTANA evaluated the routine clinical use of CBZ (25 mg/m^2 every 3 weeks plus prednisone 10 mg/day) in pts with mCRPC previously treated with docetaxel. HRQL was assessed using Functional Assessment of Cancer Therapy - Prostate (FACT-P) version 4 and EQ-5D-3L (including VAS - visual analogue scale) questionnaires at baseline and every two cycles until CBZ discontinuation.

Results: A total of 192 pts were treated in 55 centers across 6 countries (Apr 2012–Jun 2016); 161 and 157 pts were evaluable for FACT-P and EQ-5D, respectively. Pts received 6 (median) cycles of CBZ (range 1–24); 53.6% achieved disease control with CBZ. The main reason for CBZ treatment discontinuation was disease progression (58.3%). No new safety signals were identified. In the overall FACT-P score analysis, HRQL improvement during CBZ treatment was recorded in 31.8%, no change in HRQL in 40.4%, and deterioration was recorded in 27.8% of pts. The highest rate of improvement was observed for the Prostate-Specific Concerns subscale (49.3%) and Pain Control subscale (54.2%). The highest rate of deterioration was recorded for the Functional Well-Being subscale (40.9%). Mean FACT-P score and EQ-5D health utility index and VAS scores did not show statistically significant changes during CBZ treatment.

Conclusions: In this real-world study investigating HRQL associated with the use of CBZ in pts with mCRPC, no significant changes were observed in mean on-treatment FACT-P score and EQ-5D scores. However, in contrast to observations in prospective clinical studies, pts had improvement in the Pain Control FACT-P subscale. These results suggest that, in addition to the previously demonstrated effectiveness, CBZ treatment may help pts to achieve better pain control.

Background: This study investigated real-world patterns of docetaxel use for metastatic castration-resistant prostate cancer (mCRPC) in China.

Table: 813P

Pattern of use of docetaxel in Chinese patients with mCRPC	n (%)	Median overall survival, months (95% CI)	PSA response rate, % (n/n[a])
All patients	403 (100)	22.4 (20.4, 25.8)	70.9 (168/237)
After failure of 1st-line hormonal therapy	170 (42.2)	22.5 (19.2, 29.5)[b]	73.6 (64/87)
After failure of 2nd-line hormonal therapy	125 (31.0)	23.3 (18.1, 26.5)[b]	67.1 (55/82)
After failure of ≥ 3rd-line hormonal therapy	51 (12.7)	22.4 (19.0, 36.5)	65.4 (17/26)
After failure of estramustine therapy	46 (11.4)	20.2 (16.6, 27.7)	69.7 (23/33)
Other	11 (2.7)	28.6 (17.5, not evaluable)	100.0 (9/9)

[a]Denominator is the number of patients in each category who had PSA ≥20 ng/ml at baseline;
[b]p = 0.781 for median overall survival with initiation of docetaxel following failure of 1st- and 2nd-line hormonal therapy. mCRPC, metastatic castration-resistant prostate cancer; PSA, prostate specific antigen.

Methods: A prospective, multi-centre, observational study of Chinese adults (≥18 years) with histologically confirmed metastatic prostate adenocarcinoma who received ≥1 dose of docetaxel following hormonal therapy failure (disease progression and serum testosterone <50 ng/dL). The primary endpoint was patterns of docetaxel use. Secondary endpoints included median overall survival (mOS), prostate-specific antigen (PSA) response rate (RR) and reasons for docetaxel discontinuation. Variables are summarised as mean (SD) unless specified. All patients provided written informed consent.

Results: From August 2011 to June 2016, 403 patients were enrolled at 32 centres and 315 (78.2%) completed the study. The mean number of docetaxel cycles and dose were 4.4 (2.86) and 66.9 mg/m2 (9.12), and treatment compliance was 94.0% (10.94%). mOS was similar for docetaxel after 1st- or 2nd-line hormonal therapy (Table), and was longer in patients without visceral metastases versus those with visceral metastases (23.3 months vs. 17.4 months, P = 0.019). Planned docetaxel treatment was completed by 30.8% (124) of patients; the most common reasons for discontinuation were 'other reasons' (23.3% [94]), cost of medical expenses (22.6% [91]), and tumor progression (14.1% [57]). Treatment-emergent AEs (TEAEs) occurred in 20.8% (84), and serious TEAEs in 4% (16), of patients.

Conclusions: Around three-quarters of Chinese mCRPC patients treated with docetaxel initiate treatment after failure of 1st- or 2nd-line hormonal therapy and mOS and PSA RR are similar in both settings. Docetaxel was relatively well tolerated.

Background: Addition of 6 cycles of docetaxel to ADT prolongs survival and is the standard treatment for mHSPC based on results of Chaarted and Stampede trials. Prognostic factors have not been clearly described for these patients. A retrospective analysis of clinical and pathological prognostic factors was performed in 76 patients from 5 academic institutions.

Methods: Retrospective analysis of all (n = 76) mHSPC from 5 Spanish Oncology Centres was performed. All patients had been treated with docetaxel + ADT as first line. Clinical and pathological variables were analyzed: age, Gleason (6-7 vs 8-10), presence of visceral metastases, number of bone metastases (0,1-4,5-20,>20), PSA value at diagnosis and previous to CT, PSA response previous to CT (>25%, 25-50%, 50-100% or no response), time from diagnosis to first docetaxel treatment (>or< 50days). Progression free (PFS) and overall survival (OS) were the endpoints analyzed by log-rank test.

Results: Median PFS was 17m and median OS has not been reached (80% of patients alive at 20 months). Median follow-up: 16.6m. Median age 64,3y (range: 46-80), median PSA at diagnosis 691ng/mL (range:15235-1), median PSA previous to CT 214ng/mL (range:5060-0), PSA responses to ADT previous to CT was 25% in 35 pts (46%), 25-50% in 14 pts (18.4%), less than 50% in 13 (17.2%), no response in 14 (18.4%), Gleason 6-7: 19 (25%), 8-10: 53 (69,7%), UK 3 (5.3%). Median time from diagnosis to docetaxel 45.3 d (range 0-167). PFS nor OS was related to age, PSA at diagnosis, PSA response prior to docetaxel or Gleason. Time from diagnosis to docetaxel (p = 0.04) (median 21 vs 15m; HR:2.2)) and Gleason (median not reached vs 15m; HR: 3.3) were statistically significant factors for PFS. Presence of visceral metastasis (p = 0.08) (20m vs median not reached;HR: 3.8) and time from diagnosis to docetaxel (p = 0.02) (median not reached vs 24m; HR:4.1) were significative factors for OS.

Conclusions: A time from diagnosis to docetaxel start longer than 50 days is associated with lower PFS and OS in m+HSPC patients treated with ADT + docetaxel. Gleason ≥ 8 score correlates with shorter PFS and the presence of visceral metastases with a lower OS.

815P Prognostic value of systemic inflammatory biomarkers in patients with mCRPC treated with abiraterone in pre-docetaxel setting

R. Ratta[1], E. Verzoni[1], F. Pantano[2], P. Grassi[1], D. De Lisi[2], A. Onorato[2], M. Prisciandaro[1], R. Montone[3], F. de Braud[1], D. Santini[2], G. Procopio[1]

[1]Medical Oncology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [2]Medical Oncology, Campus Bio-Medico University, Rome, Italy, [3]Trial Center, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

Background: Systemic inflammatory biomarkers have shown a prognostic impact in several solid tumors. The aim of this study was to examine the prognostic role of baseline neutrophil-to-lymphocyte-ratio (NLR), platelet-to-lymphocyte-ratio (PLR) and lymphocyte-to-monocyte-ratio (LMR) and NLR, PLR and LMR changes at 1, 2 and 3 months in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC) treated with Abiraterone Acetate (AA) in pre-docetaxel setting.

Methods: We retrospectively included mCRPC pts treated with AA at two Italian hospitals from November 2012 to April 2017. NLR, PLR and LMR were evaluated at baseline and after 1, 2 and 3 months of treatment. The impact of NLR, PLR and LMR on progression-free survival (PFS) was evaluated by Cox regression analyses both in univariate and multivariate fashion. Other clinico-pathological factors, such as PSA baseline level, Time to CRPC, Gleason Score, Presence of Visceral Metastases and Bone Metastases Burden were included.

Results: Fifty mCRPC pts treated with AA were evaluated. At univariate analysis, elevated baseline NLR and PLR were significantly associated with shorter median PFS (p = 0.01, hazard ratio [HR]=1.224 and p = 0.0001, HR = 1.013 respectively); after 1

month of treatment, NLR and PLR were significantly predictors of worst PFS (p = 0.03, HR = 1.320 and p = 0.02, HR = 1.012 respectively). After 2 and 3 months of treatment, only high PLR was associated with poor prognosis (p = 0.01, HR = 1.012 at month 2; p = 0.009, HR = 1.009 at month 3 respectively). LMR didn't show any prognostic relevance. At multivariate analysis, only baseline PLR was independently associated with PFS (p = 0.006, HR = 1.013).

Conclusions: High baseline and early-assessed NLR and PLR during treatment with AA are associated with shorter PFS in mCRPC pts. PLR more than NLR may be considered as an early and easy-to-perform prognostic marker in this setting.

816P 68Ga-PSMA-PET/CT as a changing practice tool in biochemically recurrent prostate cancer

P.M. Dominques[1], T. Abreu[2], M.B. Siqueira[3], G. Marinho[1], D. Rosa[1], H. Cottas[1], L.H. Araujo[1], D. Herchenhorn[2], F.A. Peixoto[1]

[1]Medical Oncology, Instituto COI - Clinicas Oncologicas Integradas, Rio De Janeiro, Brazil, [2]Medical Oncology, Oncologia DOR, Rio De Janeiro, Brazil, [3]Medical Oncology, Oncoclinica, Rio De Janeiro, Brazil

Background: PSMA-PET/CT have demonstrated interesting results in the detection of loco-regional and distant disease in prostate cancer patients with biochemical relapse. Even with low levels of PSA, PSMA imaging is able to identify metastatic lesions, being a possible tool for tailoring treatment decisions. This study aims to describe the use of PSMA-PET/CT in the daily practice and its clinical impact in the management of prostate cancer patients who have rising PSA after curative treatment.

Methods: We performed a retrospective analysis in 29 localized prostate cancer patients of three private Brazilian cancer institutions who underwent PSMA-PET/CT for rising PSA after treatment with curative intent. The clinical impact of PSMA-PET/CT was evaluated by whether the assistant physician changed or not the treatment strategy based solely on PSMA results. In addition, modifications related to local (salvage radiotherapy [SRT], salvage lymphadenectomy [SL]) and systemic (antiandrogen deprivation therapy [ADT], chemotherapy [chemo]) treatment were described.

Results: In total, 29 patients were enrolled. Twenty-seven (93%) had undergone radical prostatectomy, and 2 (7%) radiotherapy as the local curative treatment. Sixteen cases (55%) had not received any radiotherapy previously. The mean Gleason score, PSA level and PSADT at time of the examination were 8, 4.2 (0,05-41) ng/ml and 4.4 (0.4-27) months, respectively. PSMA-PET/CT detected at least one suspicious lesion for prostate cancer in 21/29 (58%) patients. Overall, 15/29 (51%) patients had their treatment strategy changed due to results in PSMA imaging. In only 3/29 (10%) the modifications were related exclusively to systemic protocols (1 avoided ADT, 1 added ADT and, 1 added chemo). Whereas in the 12/29 (41%) remaining cases, treatment strategy change involved local treatment. Of these 12 with a local treatment change, 7 added (6 SL, 1 SRT) and 5 avoided (5 SRT) local therapies.

Conclusions: Half of the patients with biochemical relapse that underwent PSMA-PET/CT had their treatment protocol changed, most changes related to local treatment. Although the role of PSMA imaging is not clearly defined, PSMA-PET/CT has been used as a practice changing tool in the daily practice.

817P Prostascore: A simplified tool for predicting outcomes among patients with treatment-naïve advanced prostate cancer

O. Abdel-Rahman

Clinical Oncology, Ain Shams University Faculty of Medicine, Cairo, Egypt

Background: The objective of this study is to propose and validate a new simplified model "prostascore" to help predict the outcomes of treatment-naïve patients with advanced prostate cancer.

Methods: Through SEER*Stat program, surveillance, epidemiology and end results (SEER) database was queried for eligible records spanning the period from 2010 to 2013. Multivariate analysis for the candidate prognostic factors (extent of extra-prostatic disease, PSA level and grade) was conducted through a Cox proportional model. Prostascore was then calculated for each patient. Cancer-specific and overall survival analyses according to prostascore were conducted through Kaplan-Meier analysis/log-rank testing.

Results: A total of 8727 patients with treatment-naïve advanced prostate cancer and complete baseline data were identified in the period from 2010-2013. The following factors were associated with better cancer-specific survival (isolated regional nodal disease, lower PSA level and lower grade group) ($P < 0.0001$). Based on the results of the multivariate analysis, the prostascore was described. A prostascore point was given for each of: PSA level $\geq$ 60 and grade group 4 or 5. The site/distribution of extra-prostatic disease were given the following points: 0 for isolated regional lymph nodes (N1), 1 for non regional lymph deposits (M1a), 2 for bone deposits (M1b) and 3 for other sites (M1c). A total prostascore was then calculated for each case in the cohort (which may range from 0 to 5). After assignment of a prostascore for each patient, cancer-specific and overall survivals were compared according to the score. Pair wise comparisons between all different scores were conducted. For both cancer-specific and overall survival assessment according to the prostascore model, *P* values for pair wise comparisons among different score points were significant ($P<0.0001$). Table-1 shows number of patients and three year cancer-specific survival years according to prostascore.

Table: 817P Distribution and 3-year cancer-specific survival rates for different scores in the evaluated cohort

Score	N(%)	3-year cancer-specific survival rates
0	1024 (11.7%)	98%
1	1639 (18.8%)	97%
2	898 (10.3%)	91%
3	2161 (24.8%)	88%
4	2537 (29.1%)	79%
5	466 (5.4%)	76%

Conclusions: Prostascore is an easy and reliable tool for predicting the outcomes of patients with treatment-naïve advanced prostate cancer. Further validation within the context of other treatment settings and population-based cohorts is recommended.

818P PSA doubling time (PSADT) and proximal PSA predict metastasis-free survival (MFS) in men with biochemically recurrent prostate cancer (BRPC) after radical prostatectomy (RP): Implications for patient counseling and clinical trial design

M. Markowski[1], Y. Chen[2], Z. Feng[3], B. Trock[3], J. Cullen[4], D. Suzman[1], E. Antonarakis[1], C. Paller[5], M. Han[3], A. Partin[3], M. Eisenberger[6]

[1]Oncology, Johns Hopkins University, Baltimore, MD, USA, [2]Surgery, Center for Prostate Disease Research, Rockville, MD, USA, [3]Urology, Johns Hopkins University, Baltimore, MD, USA, [4]Surgery, Center for Prostate Disease Center, Rockville, MD, USA, [5]Department of Medical Oncology, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD, USA, [6]Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins School of Medicine, Baltimore, MD, USA

Background: We previously reported a relationship between PSADT and MFS in BRPC post RP (Pound 1999; Freedland 2007; Antonarakis 2012). In men with PSADT<12 months, who are at high risk of lethal prostate cancer (PCa), we sought to identify a PSA cutpoint (proximal PSA; PP) that indicates the imminent emergence of metastasis (M+). In this report we combined Center for Prostate Disease Research and Johns Hopkins (CPDR/JHU) databases to investigate the association of the PP value on MFS in men with BRPC and PSADT <12 mths.

Methods: In the CPDR/JHU RP database (31,296), 513 men with BCR (>0.2ng/ml) with PSADT <12 mths who received no adjuvant/salvage ADT/RT were prospectively followed until radiological evidence of M+ are included in this analysis. All patients were evaluated yearly with $\geq$1 PSA and scans at regular intervals until M+. Associations with MFS were compared using logrank test and Cox regression. The PP is the most recent value $\geq$6 months prior to M+/censor.

Results: M+ occurred in 218 of 513 patients with BRPC (median follow up 9 years). Risk of M+ increased for PSADT 6.0-7.5, 4.5-6, 3.0-4.5, and $\leq$3.0 months, adjusted for pT stage and Gleason score. PP $\geq$ 10 ng/ml significantly increased risk of M+ in pts with PSADT <12 mths, regardless of PSADT subgroup, hazard ratio=2.736, p<.0001. Table 1 shows median MFS by PP in subgroups with PSADT $\leq$3 mths, 3.01-6 mths, and 6.01-12 mths.

Table: 818P

PSADT	Median metastasis-free survival (year)		
	Proximal PSA<10 ng/mL	Proximal PSA ≥10 ng/mL	P value
6.01-12 mths	20 (n = 277)	5 (n = 64)	<.0001
3.01-6 mths	7 (n = 106)	3 (n = 47)	0.0009
< =3 mths	3 (n = 48)	1 (n = 21)	0.058

*Based on logrank analysis

Conclusions: In men with PSADT<12 months, PSADT subgroups ≤7.5 months and PP ≥ 10ng/ml are independent predictors of MFS, adjusted for pT stage and Gleason score. PP ≥ 10ng/ml further define risk of M+ in BRPC with PSADT<12 months. These data can assist physicians during discussions with patients regarding the risk of developing M1 disease and facilitate clinical trial design in this prevalent group of patients.

819P PSA kinetics impact on CT-PET PSMA uptake in prostate cancer

A. Sella[1], S. Kovel[2], T. Sella[3]

[1]Zerifin, Asaf Harofe Medial center, Beer Jacob, Israel, [2]Oncology, Asaf Harofe Medial center, Beer Jacob, Israel, [3]Oncology, Cheba Medical Center, Ramat Gan, Israel

Background: CT-PET PSMA has recently been approved to more accurately detect the extent of prostate cancer. Here we examined PSA level and kinetics (PSA doubling time-PSADT) as a predictor of positive up-take in patients evaluated for suspected recurrent disease.

Methods: We retrospectively collected data on 99 patients evaluated by CT-PET PSMA. Mann-Whitney U test and student's T Test (SPSS 20) were applied to test for differences in median in PSA and PSADT level, Pearson test was used for correlation analysis. PSADT was calculated by Memorial Sloan Kettering Cancer Center calculator of 3 recent levels.

Results: Ninety nine patients underwent CT-PET PSMA. Their median age was 71 (52-94) years. Uptake was detected in 84 (84.8%) patients; 51 (51.5%) patients with metastatic disease (lymph nodes, bones, visceral) and 33 (33.3%) patients with only localized disease (prostate, prostatic bed after prostatectomy). Median Gleason 8 (6-10), median PSA 4.66 (0.12-272) ng/ml. CT-PET was positive in 57.1%, 88.9% and 96.8% of patients with PSA levels of ≤ 1, >1-2 and >2 ng/ml, respectively, and 91.7%, 90.5% and 81.8% of patients with PSADT ≤2, >2-6 and > 6 months, respectively. Only median PSA levels were significantly associated with any uptake: 5.90 ± 35.71 vs. 0.35 ± 4.18 ng/ml, p < 0.001. Median PSADT, but not PSA, was statistically associated with metastatic disease compared to only local disease: 6.2 ± 13.64 vs. 20.3 ± 130.52 months, p < 0.001. Similar results outcome were obtained using student's t-test (data not shown). Gleason score predicted for CT-PET PSMA metastatic uptake (median 8 vs. 7, p = 0.02). There was no correlation between Gleason score and PSADT (r= -0.197, p = 0.058).

Conclusions: The decision to perform CT-PET PSMA in prostate cancer patients suspected to have recurrent or metastatic disease should be based on PSA levels. PSADT is a significant marker for positive metastatic CT-PET PSMA uptake.

820P Combining functional imaging with circulating biomarker analysis to improve prognostication of metastatic castration-resistant prostate cancer (mCRPC)

V. Conteduca[1], S. Salvi[2], P. Caroli[3], E. Scarpi[4], G. Schepisi[1], C. Lolli[1], D. Wetterskog[5], S.L. Burgio[1], C. Menna[1], V. Casadio[2], F. Matteucci[3], G. Paganelli[3], G. Attard[6], U. De Giorgi[1]

[1]Department of Oncology, Istituto Tumori della Romagna I.R.S.T., Meldola, Italy, [2]Biosciences Laboratory, Istituto Tumori della Romagna I.R.S.T., Meldola, Italy, [3]Nuclear Medicine Operative Unit, Istituto Tumori della Romagna I.R.S.T., Meldola, Italy, [4]Unit of Biostatistic and Clinical Trial, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola, Italy, [5]Treatment Resistance, Division of Molecular Pathology, The Institute of Cancer Research, Sutton, UK, [6]Treatment Resistance, Division of Molecular Pathology, The Institute of Cancer Research (Sutton Site), Sutton, UK

Background: Biomarkers for treatment personalization in mCRPC could improve patient outcomes. Multiple tests on blood have reported associations with worse outcome, including serum lactate dehydrogenase (LDH), chromogranin A (CgA), neutrophil-lymphocyte ratio (NLR) and more recently *AR* copy number (CN) in plasma DNA (Conteduca, Ann Oncol 2017). Biological data suggest an association between choline uptake and androgen receptor (*AR*) expression. We here aimed to integrate 18^{F}-fluorocholine (FCH) uptake on PET/CT with plasma *AR* CN and other routinely obtained circulating biomarkers and evaluate associations with outcome.

*cut-off determined by ROC curve *Abbreviations:* ALP, alkaline phosphatase; AR, androgen receptor; CgA, chromogranin A; CI, confidence interval; dsDNA, double-strandend DNA, ECOG, Eastern Cooperative Oncology Group; FCH PET/CT, 18F-fluorocholine positron emission tomography/computed tomography; HR, hazard ratio; LDH, lactate dehydrogenase; MTV, metabolic tumor volume; NLR, neutrophil-lymphocyte ratio; PS, performance status; PSA, prostate-specific antigen; SUV, standardized uptake value; TLA, total lesion activity.

Methods: We determined plasma *AR* DNA by digital PCR and Taqman from 105 CRPC samples collected before abiraterone (n = 65) or enzalutamide (n = 40). Pre-treatment serum LDH, CgA, NLR were also measured. FCH-PET/CT scan was performed at baseline and SUVmax, total lesion activity (TLA) and metabolic tumor volume (MTV) were calculated. Patients (pts) were dichotomized in high and low according to receiver-operating characteristic (ROC) curves. Main endpoints were the correlation of FCH-PET/CT parameters with circulating biomarkers and their impact on progression-free/overall survival (PFS/OS).

Results: Plasma *AR* CN gain was observed in 27 pts (25.7%) and correlated significantly with high SUVmax ($p < 0.0001$), TLA ($p < 0.0001$), MTV ($p = 0.0006$) and greater number of lesions on FCH-PET/CT ($p < 0.0001$). On multivariable analysis, SUVmax, plasma *AR*, CgA, NLR and LDH were significantly associated with outcome (Table 1).

Conclusions: Choline uptake was significantly related to plasma *AR* CN gain as well as elevated NLR, CgA, and LDH values. This analysis identified independent predictors of survival in mCRPC and more accurate prognostic distinct groups using molecular, laboratory and imaging features. The potential integration of these non-invasive biomarkers could be as a tool for a better treatment selection of CRPC. A larger prospective evaluation is warranted.

821P A polymorphism in the promoter of the FRAS1 gene is associated with metastatic prostate cancer

C.J. Sweeney[1], M. Geybels[2], S. Coseo-Markt[3], V. Wang[4], K. Penney[5], T. Gerke[6], M.M. Pomerantz[1], G-S.M. Lee[1], D. Nitsch[7], C. Huttenhower[8], L. Mucci[3]

[1]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, USA, [2]Division of Public Health Sciences, Fred Hutchinson Cancer Research Center, Seattle, WA, USA, [3]Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA, USA, [4]Biostastatics, Dana Farber Cancer Institute, Boston, MA, USA, [5]Channing Division of Network Medicine, Brigham Womens Hospital, Boston, MA, USA, [6]Epidemiology, Moffitt Cancer Center, Tampa, FL, USA, [7]Department of General and Interventional Cardiology, University Heart Center Hamburg-Eppendorf, Hamburg, Germany, [8]Department of Biostatistics, Harvard T.H. Chan School of Public Health, Boston, MA, USA

Background: Inflammation and one of its mediating transcription factors, NF-kappa B signaling (NFκB) have been implicated in prostate cancer (PrCa) carcinogenesis. We sought to define whether germline gene polymorphisms that interact with NFκB are associated with metastatic disease after prostatectomy (RP) or radiation (XRT) for localized disease.

Methods: Using a bioinformatics approach interrogating publicly available datasets, we defined a genome-wide functional association network specific to lethal PrCa consisting of 351 genes and 8,154,133 high-confidence functional associations related to the NFκB pathway. The dense module searching (DMS) method was used to analyze 419,461 SNPs from a previously conducted genome wide association study (GWAS) case-only study of 196 lethal PrCa cases compared to 368 indolent controls in the Harvard School of Public Heath (HSPH) Cohorts. Top hits from DMS were then tested in two independent PrCa cohorts: (i) ECOG/DFCI (n = 254 cases, 256 controls) and (ii) Fred Hutchinson Cancer Research Center (FH, n = 570 cases, 103 controls). In all 3 studies, "controls" were men with PrCa who are alive with no evidence of metastasis at least 8-years after RP or XRT and "cases" were men who developed metastatic disease after RP or XRT (FH, HSPH, ECOG) or with *de novo* presentation (ECOG).

Results: From the DMS, 40 SNPs with a minor allele frequency > 0.1 were associated with lethal PrCa. Of these, rs1910301 in the promoter region of FRAS1 was nominally associated with lethal disease in all 3 studies with similar size effects: the odds ratio (OR) for the A allele was 1.40 ($p = 0.02$) in HSPH, 1.35 in ECOG/Gelb ($p = 0.04$), and borderline significant in FH [OR 1.3, $p = 0.07$]. Fixed effects meta-analysis of all three cohorts found a significant association: OR = 1.38 95% CI: 1.15-1.66; p-value 0.005.

Conclusions: A SNP in the promoter region of FRAS1, which forms a gene unit with FREM2 and together regulate epidermal-basement membrane adhesion and cell migration, is associated with metastatic PrCa. FREM2 is an NFκB regulated gene and mutations in FREM2 and FRAS1 are associated with the Fraser syndrome. Further work is needed to determine the effect of rs1910301 on FRAS1 function and cellular adhesion and the metastatic process.

822P Phenotypic circulating tumor cell (CTC) classifier of genomic instability (GI) associates with improved overall survival (OS) for metastatic castration-resistant prostate cancer (mCRPC) patients (pts) receiving platinum agents in addition to taxanes

H. Scher[1], R.P. Graf[2], A. Jendrisak[2], B. McLaughlin[1], E. Barnett[1], N.A. Schreiber[1], J. Lee[2], J. Kelvin[2], Y. Wang[2], M. Landers[2], R. Dittamore[2]

[1]Genitourinary Oncology, Memorial Sloan Kettering Cancer Center, New York, NY, USA, [2]Translational Research, Epic Sciences Inc., San Diego, CA, USA

Background: The presence of GI has been associated with DNA Damage Response (DDR) genomics. mCRPC pts with DDR(-) can have treatment (Tx) efficacy with poly ADP ribose polymerase inhibitors (PARPi). Similar Tx benefit for DDR(-) pts has been observed with alkylating agents such as platinum Tx in small cohorts. However, obtaining and sequencing metastatic biopsies is currently not scalable for routine use in the clinic due to accessibility, cost and time to result. We previously developed an imaging-based phenotypic classifier to predict presence of GI from individual CTC morphology and demonstrated that these pts had statistically worse OS when receiving androgen receptor signaling inhibitors (ARSi) or Taxanes. In a separate cohort, the same classifier predicted improved PSA response when pts were treated with a PARPi + ARSi vs. ARSi alone. Here, we examined if GI(+) mCRPC pts can have improved OS when receiving a commonly available and inexpensive platinum chemotherapy.

Methods: 89 blood samples were collected from mCRPC pts prior to taxane Tx (n = 62) or a combination of taxane + platinum (T+P) (n = 27), and processed utilizing the Epic Sciences platform. Choice of therapy was at the discretion of attending physician without knowledge of CTC results. The percent of predicted GI cells per pt sample (%pGI) was calculated after single-cell characterization. Pts were followed for OS.

Results: Pts receiving a T+P combination had higher CTC burdens and lower PSA levels but otherwise showed similar pre-Tx characteristics to taxane-only pts. In a multivariate model containing %pGI, therapy class, and total CTC burden (to help correct for disease burden and severity), a significant interaction between the T+P combination and increasing %pGI, and increased OS (HR: 0.14, CI: 0.026 to 0.72, $p = 0.018$) was observed.

Conclusions: The results of this study suggest that in a prospective setting with a balanced cohort, pts with high %pGI might have improved OS on taxanes with the addition of platinum agents. Propspective validation of the signature is planned.

823P Expression of steroid hormone transporter, SLCO1B3, is mediated by a CBP/p300 regulatory mechanism in prostate cancer

E.M. McCrea[1], P.A. Huang[2], E.M. Harris[2], J.D. Strope[2], T.M. Sissung[2], D.K. Price[1], C.H. Chau[1], W.D. Figg[2]

[1]Genitorurinary Malignancies Branch, Center for Cancer Research, National Cancer Institute, Bethesda, MD, USA, [2]Clinical Pharmacology Program, Center for Cancer Research, National Cancer Institute, Bethesda, MD, USA

Background: Recent studies support the role of steroid hormone transporters in modulating intratumoral androgen concentrations, thereby promoting castration-resistant prostate cancer (CRPC) progression. The organic anion polypeptide 1B3 (OATP1B3) transporter is expressed de novo in prostate tumors and contributes to the transport of androgen into these cells. Polymorphic variations in the SLCO1B3 gene encoding OATP1B3 are related to clinical outcome in men with prostate cancer receiving androgen deprivation therapy (ADT) or those with CRPC. The current study elucidates the mechanism of de novo SLCO1B3 expression in prostate cancer. We discovered that chetomin, a known inhibitor of HIF-1α- and CBP/p300 binding, was a potent inducer of SLCO1B3 transcripts.

Methods: We investigated the transcriptional regulation of SLCO1B3 expression by CBP/p300 using siRNA-mediated gene silencing or treatment with various CBP/p300 inhibitors (C646, HATi II) to determine the effects on gene transcription, downstream pathways, and transporter-dependent uptake studies.

Results: Treatment with various CBP/p300 inhibitors (CH1 or HAT binding domains) significantly increased the expression of SLCO1B3 and subsequent transporter-mediated androgen uptake in tumor cells. Specific downregulation of p300 or CBP by siRNA reduced SLCO1B3 expression in prostate cancer cells (22Rv1, LNCaP, and PC3), suggesting that CBP/p300 interacts with specific transcription factors essential for driving SLCO1B3 expression. Cells treated with ADT elicited differential effects on transporter expression in AR-positive vs AR-null cells. Studies are currently underway to identify cofactors involved in forming the CBP/p300 transcriptional complex regulating SLCO1B3 expression.

Conclusions: *De novo* OATP1B3 expression in prostate cancer is a mechanism of tumoral resistance to ADT resulting in greater androgen uptake. Taken together, the data suggest that ADT resistance and transporter-dependent increased uptake of residual androgens result from CBP/p300-mediated *SLCO1B3* expression. OATP1B3 should be considered a viable biological target for therapeutic intervention in prostate cancer.

824P ARV7 status and CTC count: A combined biomarker for the baseline therapeutic decision in each line of mCRPC treatment

E. Bournakis[1], E. Lianidou[2], A. Strati[2], M. Zavridou[2], A. Sfika[1], A. Bournakis[1], C. Papadimitriou[1]

[1]Oncology Department, ARETEION University Hospital of Athens, Athens, Greece, [2]Chemistry, Laboratory of Analytical Chemistry, University of Athens, Athens, Greece

Background: Metastatic Castration Resistant Prostate Cancer (mCRPC) is an entity for which we have more than one therapeutic option. Chemotherapy and novel hormonal agents (NHAs) are the main choices. Despite clinical, biochemical, radiological and histologic parameters, we have not yet confirmed the ideal sequence of regimens. Since PSA is not enough to guide treatment selection in mCRPC, there is a need for a biomarker that would lead us to the ideal regimen choice in each line of therapy for each patient (pt) in order to transform mCRPC into a chronic disease. ARV7 status and circulating tumor cells (CTCs) have shown some potential as biomarkers the last 2 years. The aim of this study was to combine these two biomarkers as a parameter for selecting the optimal treatment strategy. We aimed to categorize mCRPC pts by combining ARV7 status and CTC count and correlating this with response to therapy and, consequently, regimen choice.

Methods: CellSearch was used for CTC counts. We developed a highly sensitive and specific multiplex RT-qPCR assay in the LightCycler platform for the simultaneous quantification of AR splice variants (AR-FL, AR-V7, AR-567, AR-total) in CTCs. 41 pts and 57 samples were categorized in four groups: 1. CTChigh(h) (CTC count >10) ARV7 + (14 samples) 2. CTClow(l) (CTCcount < =10) ARV7- (20 samples) 3. CTClARV7 + (14 samples) 4. CTCh ARV7- (9 samples). Treatment choice at this point was independent of ARV7 status and CTC testing and was selected upon treating oncologist's decision.

Results: PSA response to chemotherapy or NHAs was studied for each group, as well as duration of treatment and change of pt classification in groups. In each group, pts were categorized according to treatment type (chemotherapy, NHAs) and PSA responses were categorized as PSA decline or not. Group 1 pts did not appear to respond to NHAs but only to chemotherapy and had a worse prognosis compared to all other groups; pts in group 2 appeared to have an excellent and long term response to NHAs, though if chemo was received they also responded equally to both treatment options and had a better prognosis compared to all other groups; pts in group 3 responded better to chemotherapy than NHAs (though not excluding NHAs as a treatment choice); pts in group 4 responded to chemo and not NHAs.

Conclusions: Pts CTCl and ARV7- could safely be treated with NHAs while CTCl and ARV7+ pts could be treated with either chemotherapy or NHAs, with chemotherapy probably being a "safer" choice (less PSA non responses 1/8 vs 3/6). ARV7+ status does not seem to be an exclusion criteria alone for NHAs use in this category. For CTCh pts, chemotherapy is the best choice especially when pts are ARV7+. Since CTC and ARV7 status can change, these could be used as the baseline biomarker for regimen choice.

Background: Germline BRCA1 and BRCA2 mutations have been associated to poor prostate cancer (PrCa) outcomes and may have implications for cancer treatment. Identification of these carriers would also serve for the early identification of other family members at increased risk of breast and ovarian cancer. Several tools have been developed to estimate the probability of a gBRCA mutations in the context of a family history of breast and/or ovarian cancer but its performance has not been evaluated in PrCa patients.

Methods: This is single-centre study aimed to: 1) compare the contribution of PrCa to identify families known to harbour a germline BRCA1 or BRCA2 mutation; and 2) estimate the ability of predicting a BRCA mutation in these families based on the cancer history at the time of PrCa diagnosis. A comprehensive reassessment of families attending our Familial Cancer screening program at Málaga Univ. Hospitals between 2012-16 identified 104 families known to harbour a gBRCA mutations. gBRCA mutation risk estimations were calculated with 2 commonly used risk assessment models: BRCAPRO 6.0 and Manchester Score (MS).

Results: Finally, a total of 98 families (42 BRCA1, 56 BRCA2) were included in the study, after exclusion for further analyses of families with PrCa cases in non-carriers (phenocopies). As expected, PrCa was more common in BRCA2 carriers (2 vs 19, $p = 0.002$). Median age of PrCa diagnosis was 70 yrs (48-83). Male breast cancer was more common in families with PrCa (24% vs 4% $p = 0.003$), particularly in BRCA2 families (26.3% vs 5.4%, $p = 0.023$), but no other differences in family history of cancer were observed between families with or without PrCa cases and therefore their scores using BRACAPRO and MS did not differ. A $\geq$ 10% probability of finding a BRCA2 mutation was identified in 47% of families using BRCAPRO, decreasing to 21% when the proband was the PrCa patient ($p = 0.002$). Similar results were observed when the probability was calculated using MS (42% vs 21%, $p = 0.011$)

Conclusions: The currently available predictive tools underestimate the probability of a BRCA mutation when the proband is a prostate cancer patient and should not be used as unique tools to decide which PrCa patients should undergo genetic testing.

Background: DNA repair has been reported as a frequent altered pathway in mCRPC. The prevalence of gmDDR has been recently estimated in a retrospective pooled analysis of 7 UK-US institutions as 11.8% in mCRPC (Pritchard, NEJM 2016). However, geographic differences are expected and its association with the phenotype of mCPRC in other populations remains unknown.

Methods: PROREPAIR-B study is a prospective multicenter observational cohort study. Blood samples and clinical data have been collected prospectively in 38 centres across Spain. Germline DNA was extracted from EDTA blood samples using Flexigene®. Sequencing libraries were generated from 250ng of gDNA using a custom panel of 124 genes related to DNA repair and familial cancer, with the NimbleGen SeqCap XL Target Enrichment (Roche®) tecnhology. Validation of pathogenic mutations by Sanger, MLPA or additional NGS has been performed only for 24 genes included in the BROCA panel. Preliminary statistical analyses have been conducted comparing clinico-pathological characteristics at diagnosis and at mCRPC between carriers and non-carriers.

Results: 38 validated gmDDR were detected in 419 patients (9.1%), with 5 additional cases undergoing further validation studies. BRCA2 was the most frequently mutated gene (n = 14) followed by ATM (n = 8), BRCA1 (n = 4) and CHEK2 (n = 4). Characteristics at prostate cancer diagnosis (dx): 99% caucasian; median age 66y (41-92); Gleason <7 41% vs ≥ 8 59%; localized stage 35% vs stage IV 65%. Characteristics at mCPRC dx: median age 73y (43-94); ECOG 0-1 91% vs 2 9%; presence of visceral 8%, bone 87% and lymph node metastasis 46%; median baseline PSA 26.95ng/ul (<0.02-5198). Bone metastases were significantly more common at mCRPC dx in carriers (95% vs 80%, p = 0.04), as well as ALP>2*UNL (37% vs 19%, p = 0.03) and Albumine < 4g/dl (45% vs 21%, p = 0.02). No significant differences were observed between carriers and non-carriers in age at dx or mCRPC, Gleason, stage at dx, PSA, LDH, Hemoglobin, visceral or nodal metastases at mCRPC dx (p > 0.05).

Conclusions: This is the first study that reports the prevalence of gmDDR in a cohort of mediterranean mCRPC patients.

827P Comprehensive characterization of BRCA1 and BRCA2 alterations in circulating tumor DNA and tumor tissue in men with prostate cancer: Implications for clinical care

P. Lara[1], J. McPherson[2], W. Heyer[3], R. Hartmaier[4], R. Devere White[5], J. Chung[6], S.M. Ali[7], M. Dall'Era[5]

[1]Internal Medicine/Hematology-Oncology, University of California Davis Comprehensive Cancer Center, Sacramento, CA, USA, [2]Biochemistry/Molecular Medicine, University of California Davis Comprehensive Cancer Center, Sacramento, CA, USA, [3]College of Biological Sciences, University of California Davis Comprehensive Cancer Center, Sacramento, CA, USA, [4]Foundation One, Foundation Medicine, Cambridge, MA, USA, [5]Urology, University of California Davis Comprehensive Cancer Center, Sacramento, CA, USA, [6]Pathology, Foundation Medicine, Cambridge, MA, USA, [7]R & D, Foundation Medicine, Cambridge, MA, USA

Background: Alterations in genes encoding for DNA damage repair (DDR) such as BRCA1 or 2 – as detected by next generation sequencing (NGS) – can predict for sensitivity to PARP inhibitors or platinum-based chemotherapy in advanced prostate cancer (PC). Detection of these alterations either in tumor tissue or in circulating tumor DNA (ctDNA) in men with advanced PC is clinically actionable in certain clinical contexts. Previously, we reported the comprehensive molecular characterization of DNA DDR genes in 936 unique primary & metastatic PC specimens (Dall'era, ASCO GU 2017) where 24.4% had at least 1 mutation in a DNA repair gene. We also reported that DNA DDR alterations were more common in metastatic vs. localized disease. We sought to expand this work by employing NGS in ctDNA as part of clinical care to ascertain the mutational status of BRCA1 and 2 in men with PC.

Methods: The nature and prevalence of BRCA1 and 2 alterations in ctDNA were determined from 207 men with PC through the Foundation ACT NGS assay. Mean depth of coverage was 6963x. Similarly, BRCA1/2 alterations in 936 unique PC specimens were assessed as part of the Foundation One NGS assay. Mean depth of coverage was >500X.

Results: In ctDNA specimens from 207 patients, 15 (7.2%) arboured known or likely deleterious BRCA1 (n = 4) and/or BRCA2 (n = 12) alterations consisting of 19 short variants and 2 rearrangements. One case had 4 variants in BRCA2 while 3 cases had 3 variants, of which 1 case had both BRCA1 and 2 variants. An additional 17 ctDNA cases (8.2%) arboured BRCA1/2 alterations categorized as variants of unknown significance (VUS). In the 936 tumor specimens, 118 (12%) had known or likely deleterious BRCA1 (n = 11) or BRCA2 (n = 107) alterations consisting of 4 rearrangements, 89 short variants, and 30 copy number variants. VUS were not available for tumor specimens.

Conclusions: Potentially actionable BRCA1 and/or BRCA2 alterations are detectable in ctDNA or tumor tissue in up to 15% of men with PC in this large dataset of specimens obtained in the course of clinical care. Employing plasma-based ctDNA NGS provides a clinically convenient means for assessing the status of DNA gene repair alterations comparable to that of tumor tissue.

828P Durable prostate cancer control in a randomized trial of optimal timing of dose escalated (76 Gy) radiation and 6 months ADT in prostate cancer

S. Malone[1], L. Eapen[1], C. E [1], W. Kendal[1], J. Craig[2], R. Macrae[1], G. Perry[1], J. Bowen[3], S. Morgan[1], O. Holmes[1], S. Grimes[2]

[1]Radiation Oncology, The Ottawa Hospital Cancer Centre, Ottawa, ON, Canada, [2]Clinical Trials, The Ottawa Hospital Cancer Centre, Ottawa, ON, Canada, [3]Radiation Oncology, N E Ontario Regional Cancer Centre, Sudbury, ON, Canada

Background: A pooled analysis of trials using conventional dose radiation (XRT) indicates 6 months androgen deprivation therapy (ADT) improves prostate cancer survival in Gleason 7 disease (D'Amico, JCO 2011). The benefit of ADT when used in combination with dose escalated XRT remains controversial. In EORTC 22991 trial 6 months ADT improved disease free survival at all XRT dose levels (Bolla, JCO 2016). We present long-term results of dose escalated XRT (76 Gy) in combination with 6 months ADT in the context of a Phase 3 Trial evaluating the optimal timing of ADT in combination with XRT.

Methods: 438 pts were entered on the trial. Inclusion criteria were cT1-T3, Gleason < 8, PSA < 30. Low risk pts were excluded. ADT consisted of 6 mo Total Androgen Blockade (TAB) with Goserelin and Biclutamide. Pts were randomized to upfront XRT (day 1 of ADT) or XRT after 4 months ADT. Median follow-up is 12 yrs. 10 yr overall Survival (OS), Cause Specific Survival (CSS) PSA Disease Free Survival (DFS) and Local DFS were estimated using Kaplan-Meier (KM) method.

Results: Clinical characteristics are as follows: mean age 69; 69% cT1-T2A, 31% cT2B-T3; 75% Gleason 7; mean PSA = 10. Protocol compliance: 96% of pts completed 6 mo TAB and 99% completed 6 mo Goserelin. 4% of patients stopped Biclutamide early (3% due to Grade 1-3 reversible liver toxicity). 4% of patients developed late Gr 3 proctitis. 10 yr results: PSA DFS 83%, CSS 98%, OS 76%, and local DFS 95%. The results by treatment arm will be presented in the near future.

Conclusions: The durable DFS, local control and CSS support the benefit of 6 mo ADT in combination with Dose Escalated (76 Gy) XRT. The favourable compliance, tolerance and toxicity data support this treatment approach. Potential survival benefits of ADT in intermediate risk prostate cancer will be evaluated by mature results from EORTC 22991 and RTOG 0815 trials.

Background: AQUARiUS is an ongoing study evaluating PROs and medical resource use in 2 cohorts of chemotherapy naïve mCRPC pts newly initiated on AAP or ENZ in the real-world setting.

Methods: The study prospectively collects PROs on quality of life, cognition, fatigue and pain using EORTC QLQ-C30, FACT-Cog, BFI-SF and BPI-SF questionnaires, respectively, for 12 months (mo) in 211 pts. This analysis describes PRO data for pts with 3-mo follow-up (N = 105). Multivariate repeated measures linear and logistic

Table: 829P Mean change in score from baseline for AAP (N = 46) vs ENZ (N = 59) Interpretation of the PRO items: for FACT-Cog and QLQ-C30 higher scores are favourable, for BFI-SF lower scores are favourable

*Evaluable pts

†Regression model estimates Note: 7 pts (2 AAP, 5 ENZ) included in this intention-to-treat analysis switched treatment within the first 3 months; results were consistent in the per protocol analysis and censoring analysis.

regression models were used to analyse change from baseline scores and risk for clinically meaningful worsening, respectively, adjusting for baseline characteristics.

Results: Baseline characteristics were well balanced between the ENZ (N = 59) and AAP (N = 46) cohorts. PRO items with significant differences ($p < 0.05$) between the 2 cohorts consistent across time points on continuous and/or binary endpoints are reported in the table. Change from baseline comparisons favour AAP over ENZ for mo 1, 2 and 3 for perceived cognitive impairments (e.g., 1.1 vs -5.9 at mo 3) and cognitive functioning (e.g., -0.6 vs -14.9 at mo 3) and for mo 2 and 3 for usual level and interference of fatigue (e.g., -0.7 vs 1.0 and -0.2 vs 0.7 at mo 3). Within the first 3 mo ENZ-treated pts had a significantly higher risk of experiencing clinically meaningful worsening in perceived cognitive impairments vs AAP-treated pts.

Conclusions: Initial results suggest favourable outcomes for perceived cognitive impairments and functioning, and fatigue for AAP vs ENZ within the first 3 months after treatment initiation.

830P Assessment of association between clinical characteristics and prostate specific antigen (PSA) progression in men with prostate cancer (PCa) receiving a leuprorelin acetate implant: Results from the non-interventional German cohort LEAN study

B. Schmitz-Dräger[1], S. Mühlich[2], B. Ottillinger[3], M. Studen[3]

[1]*Urology, Urologie24 and Urology, Schön Klinik Nürnberg Fürth, Fürth, Germany,* [2]*Urology, Urological Practice, Bamberg, Germany,* [3]*Medical, Hexal AG, Holzkirchen, Germany*

Background: The impact of GnRH (gonadotropin-releasing hormone) therapy on comorbidities and lifestyle is complex but important to consider in men with PCa. The LEAN study aims to analyse associations between various anamnestic factors and PSA dynamics in men with advanced, hormone-dependent PCa receiving a leuprorelin acetate solid implant (Leuprorelin Sandoz®/Leuprone® HEXAL®).

Methods: Patients were enrolled at 190 German centres from January 2014. Metabolic data, body measures, PSA and testosterone were assessed at baseline and during 1-year follow-up. Cox model analyses assessed associations between anamnestic factors and PSA progression. Data are presented as mean±standard deviations.

Results: A total of 959 patients have been recruited. Median patient age was 75 years (range 50–93; ≥65: 90%) and median body mass index (BMI) was 28 kg/m^2 (range: 18–49; >30: 22%). Primary diagnosis of PCa was 26±47 months before inclusion, with PSA levels of 32±53 ng/mL [median: 11] and serum testosterone of 3.6±2.16 ng/mL [median: 3.5]. Six of the 12 (median) core biopsies were positive at primary diagnosis, with a Gleason Score of 7.5±1.2 (median: 7). A total of 189 patients (27%) had previous radical prostatectomy 29±50 days (median: 7) before inclusion. Over 50% of patients had concomitant cardiovascular disease and 16% had disorders of glucose or lipid metabolism. At 3, 6, 9 and 12 months after the start of leuprorelin therapy, median PSA values decreased to 0.6, 0.3, 0.2 and 0.2 ng/mL, respectively, and median testosterone levels were 0.2, 0.2, 0.2 and 0.2 ng/mL. PSA progression occurred in 168 patients: in

28% of patients with BMI ≤30 and in 26% with BMI >30, indicating no clear association with BMI (p = 0.7427). Cox model analyses also showed no clear influence on PSA progression of other anamnestic factors.

Conclusions: Patients in the LEAN study represent a real-life population receiving therapy with a GnRH agonist. Results show no clear influence of anamnestic factors on PSA progression.

831P Neuropsychiatric adverse events of enzalutamide and abiraterone acetate plus prednisone treatment: Contrasting a meta-analysis of randomized clinical trials with real world reporting patterns from EUDRA

M. Sanchez Iznaola[1], R. Parra[1], G. Angela[2], J. Casariego[2], J. MuÑoz Del Toro[2], P. Robinson[3]

[1]Hemar, Janssen Cilag Spain, Madrid, Spain, [2]Medical Affairs, Janssen Cilag Spain, Madrid, Spain, [3]Hemar, Janssen Cilag, High Wycombe, UK

Background: Enzalutamide (ENZ) and abiraterone acetate plus prednisone (AAP) are oral antiandrogens indicated in Europe [1] for the treatment of metastatic castration resistant prostate cancer (mCPRC). A comparative preliminary analysis of cognitive decline and mood changes in mCRPC patients receiving ENZ and AAP has been reported[2]. However, a meta-analysis for these adverse effects (AEs) has not been available in the literature.

Methods: Following on from the methodology presented by Ruiz et al.[3] a further meta-analysis was performed to estimate the pooled Relative Risk (RR) of neuropsychiatric AEs for AAP and ENZ. A complementary analysis of the EUDRA database was performed to explore the consistency of the real world adverse drug reactions (ADR) reporting pattern with the meta-analysis.Calculation of Proportional Reporting Ratios was performed following EUDRA guidelines.

Results: The meta-analysis results indicate that patients treated with ENZ had a statistically significant higher risk of restless leg syndrome, anxiety, headache and insomnia vs control (Table). Both ENZ and AAP showed increased significant risk for falls vs control. The Proportional Reporting Ratio (PRR)[4] of suspected ADRs reported in EUDRA is higher with ENZ than with AAP for all the variables analyzed.

Conclusions: The analysis suggests that some neuropsychiatric AEs are more prevalent with ENZ vs placebo than AAP vs prednisone. The reporting trend in EUDRA is consistent with this result.

832P Influence of an international consensus conference on practice patterns in advanced prostate cancer (APC)

J. Gong[1], S.K. Pal[1], J. Hsu[1], B. Tombal[2], M.R. Sydes[3], A. Omlin[4], S. Gillessen[5]

[1]Medical Oncology, City of Hope, Duarte, CA, USA, [2]Urology, Cancer Centre, Catholic University of Louvain (UCL), Brussels, Belgium, [3]MCR Clinical Trials Unit, Institute of Clinical Trials and Methodology-UCL, London, UK, [4]Oncology and Haematology, Cantonal Hospital St.Gallen, St. Gallen, Switzerland, [5]Oncology/Hematology, Kantonsspital St. Gallen, St. Gallen, Switzerland

Background: Development of several agents and combinations in metastatic castrate-naïve (mCN) and castration-resistant (mCR) PC has led to uncertainty in best management approaches. The Advanced Prostate Cancer Consensus Conference (APCCC) 2017 convened to provide expert opinions on open questions.

Methods: 57 questions (Qs) selected from a sample of consensus Qs to be voted on at APCCC 2017 were administered as a pre- and post-conference survey to attendees. Matched responses before and after APCCC 2017 were compared to identify changes in attendees' treatment preferences in APC.

Results: From 2/2017-4/2017, pre- and post-conference surveys from 120 attendees were collected mostly from medical oncologists (41.7%) and urologists (40.8%). Attendees reached a consensus ≥75% vote in the same pre- and post-meeting question in 10/57 Qs (15.7%). A < 75% consensus vote to ≥ 75% vote (or vice-versa) change was seen in 3 key areas: abiraterone or enzalumatide was more favored as first-line option in patients (pts) who progressed on docetaxel ≤6 months in CNPC (60.0% pre- to 75.9% post-meeting), 2 years was the favored duration of osteoclast-targeted therapy in mCRPC (53.3% to 75.0%), and more next-generation imaging (MRI or PET/CT) was favored in mCRPC (12.7% to 24.1%) while CT and bone scan changed from 79.7% to 70.7% of votes. Consensus ≥75% votes was not reached in the majority of Qs, but notably there were more post-conference votes for: using a lower dose of cabazitaxel 20 mg/m^2 vs 25 mg/m^2 (24.2% to 32.8%), carboplatin in refractory mCRPC with DNA repair defects (27.5% to 42.2%), adding ADT to salvage XRT (29.1% to 49.1%), ≤3 metastases as a definition for oligometastatic PC (48.7% to 70.8%), recognition of ADT causing bone loss/fractures (57.4% to 66.4%), vitamin D + calcium in pts on ADT (62.6% to 71.7%), and osteoclast-targeted therapy in pts on ADT with osteopenia/osteoporosis (42.6% to 59.3%).

Conclusions: To the best of our knowledge, we are among the first to compare pre- and post-meeting responses that highlight interesting changes in provider preferences in APC management. Consensus conferences such as APCCC where expert opinions are discussed provide a unique learning experience and delineate key areas of controversy in APC where further study is needed.

833P Postoperative radiation therapy after radical prostatectomy

A. Hervás, C. Vallejo, J. Domínguez, F. López, M. Martin, D. Candini, E. Carrasco, S. Sancho

Radiation Oncology, Hospital Universitario Ramon y Cajal, Madrid, Spain

Background: To analize the results of adjuvant and salvage radiotherapy after radical prostatectomy and to determine prognostic factors of biochemical relapse free survival (BRFS).

Methods: 302 patients were treated at our institution over a 12-year period. Overall survival and biochemical-relapse free survival were calculated using Kaplan-Meier and multivariate Cox regression analysis was used to assess differences between groups.

Results: Mean age at diagnosis was 65 years (42-80). All patients underwent radical prostatectomy combined with pelvic lymphadenectomy in 47.1% of cases. Adjuvant RT was performed in 113 patients and salvage RT in 183 (9 for local recurrence). The distribution of patients by pT stage was pT2a-b(30.3%), pT2c (35%), pT3(29%) and pT4(2.3%). Upgrade in Gleason score between biopsy and prostatectomy was experienced by 46.7% of patients. Positive surgical margins were reported in 56.5% of cases. Neoadjuvant androgen ablation before surgery was given to 36.5%. Mean pre-RT PSA of 0.46ng/ml (0-12.8) and mean dosis to surgical bed was of 70Gy (60-76Gy). Mean follow-up was 58.85 months (1-153 months). Overall survival at 5 and 10 years was 98.1% and 94.3%, respectively and BRFS at 5 and 10 years was 76.5% vs. 61.8%, respectively. The timing of RT (ART vs. SRT) and pre-RT PSA <0.5 ng/ml were significant predictors of longer BRFS.

Conclusions: Postoperative radiation therapy provides excellent long-term overall survival with an aceptable BRFS. Pre-RT PSA <0.5ng/ml and adjuvant RT were predictors of better outcomes.

Background: In a Phase Ib/II study, the small-molecule AKT inhibitor ipatasertib in combination with abiraterone and prednisone/prednisolone demonstrated an improved radiographic progression-free survival (rPFS) vs abiraterone and prednisone/prednisolone alone, with greater benefit in patients with phosphatase and tensin homolog (PTEN)–loss tumors. This randomized Phase III trial will evaluate the efficacy, safety and pharmacokinetics (PK) of ipatasertib vs placebo (both combined with abiraterone and prednisone/prednisolone) in patients with previously untreated mCRPC.

Trial design: Eligible patients must have untreated asymptomatic or mildly symptomatic mCRPC with progressive disease by Prostate Cancer Clinical Trials Working Group 3 criteria, ongoing androgen deprivation therapy or castrated state and ECOG PS 0 or 1. Treatments with second-generation CYP450 inhibitors or androgen-receptor blockers and untreated or active central nervous system metastases are not allowed; however, prior chemotherapy for hormone-sensitive disease is permitted. Eligible cases will be randomized 1:1 to abiraterone 1000 mg QD + prednisone/prednisolone 5 mg BID plus ipatasertib 400 mg QD or placebo. Crossover between treatment arms is not allowed. Stratification factors are prior taxane-based therapy in the hormone-sensitive setting, progression factor (prostate-specific antigen [PSA] only vs other), presence of liver or lung metastasis, tumor PTEN status by immunohistochemistry (loss vs non-loss) and geographic region. The primary efficacy endpoint is investigator-assessed rPFS (intent-to-treat population and patients with PTEN-loss tumors). Additional endpoints include time to pain progression, time to next cytotoxic chemotherapy, overall survival, additional patient-reported outcomes, time to first opioid use, time to PSA progression, safety and PK. Approximately 850 patients will be enrolled at ~200 centers worldwide.

Clinical trial identification: NCT03072238.

835TiP A phase 2 trial of ODM-201 maintenance therapy in patients with metastatic castration resistant prostate cancer (mCRPC) previously treated with a AR targeting agent and non-progressive on a second line taxane (SAKK 08/16)

S. Gillessen[1], S. Hayoz[2], A. Fuhrer[2], C. Biaggi Rudolf[2], A. Pedrazzini[3], G. Procopio[4], R. Cathomas[5]

[1]Oncology/Hematology, Kantonsspital St. Gallen, St. Gallen, Switzerland, [2]Coordinating Center, Swiss Group for Clinical Cancer Research (SAKK), Bern, Switzerland, [3]Medical Oncology, Fondazione Oncologia Lago Maggiore, Locarno, Switzerland, [4]Medical Oncology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [5]Hämatologie/Onkologie, Kantonsspital Graubünden, Chur, Switzerland

Background: Treatment with the AR targeting agents abiraterone or enzalutamide followed by a taxane is currently the most used treatment for men with mCRPC. Further treatment after response to chemotherapy is only indicated in case of disease progression, with limited treatment options available. ODM-201 (Darolutamide) is a second-generation oral androgen receptor antagonist which has demonstrated a good safety profile and antitumor activity in mCRPC. This trial evaluates whether the immediate use of darolutamide after successful chemotherapy can prolong radiographic progression-free survival (rPFS) compared with watchful waiting in patients with mCRPC.

Trial design: This is a multicenter, randomized, double-blind, placebo-controlled phase 2 trial (NCT02933801) conducted in approximately 19 sites in Switzerland and Italy. Patients with mCRPC are required to have been previously treated with abiraterone or enzalutamide and have no evidence of disease progression on docetaxel or cabazitaxel. Patients (N = 88) will be randomized 1:1 to receive 600 mg darolutamide BID or placebo BID, both with best supportive care, until disease progression. Patients will be stratified by country, WHO performance status (0, 1 vs 2), presence/absence of visceral metastases, enzalutamide vs abiraterone prior to chemotherapy, and planned start of trial treatment after last taxane dose (<35 days vs ≥ 35 days). The primary endpoint is rPFS at 12 weeks after treatment initiation. The secondary endpoints are rPFS, time to PSA progression, time to symptomatic/clinical progression, event-free survival, overall survival, PSA response (30%, 50%, 90%, and best), duration of PSA response (50%), adverse events, and fatigue. The rPFS rate at 12 weeks after treatment initiation will be compared between the two treatment arms using a one-sided test statistic using the Kaplan–Meier method. Recruitment is ongoing, with the first patient randomized on 20.04.2017.

Background: Recent data show that ≈20% of pts with mCRPC have a germline or somatic alteration in either *BRCA1*, *BRCA2* or *ATM* (homologous recombination [HR] genes) (Robinson et al. *Cell.* 2015;161:1215-28), suggesting these molecular markers may be used to select pts with mCRPC for targeted treatment with a poly(ADP-ribose) polymerase inhibitor (PARPi). PARPis have demonstrated preliminary evidence of antitumour activity in pts with sporadic mCRPC and an HR gene mutation (Mateo et al. *N Engl J Med.* 2015;373:1697-708). These results provide a strong rationale for investigating rucaparib in pts with mCRPC associated with HRD.

Trial design: TRITON2 is a phase 2 study evaluating rucaparib 600 mg BID in pts (n≈160) with mCRPC who have a deleterious germline or somatic *BRCA1*, *BRCA2* or *ATM* mutation (per local and/or central testing). Pts with tumours with an alteration in any of 12 additional prespecified HR genes (eg, *RAD51C*, *RAD51D* or *PALB2*) may enrol in an exploratory cohort. Pts must have progressed on androgen receptor (AR)-targeted therapy and on 1 prior taxane-based chemotherapy for mCRPC. The primary endpoint of TRITON2 is response rate (modified RECIST v1.1/PCWG3 in soft-tissue disease and PSA response with nonmeasurable disease). TRITON3 is a randomised phase 3 study evaluating rucaparib 600 mg BID vs physician's choice of treatment (abiraterone, enzalutamide or docetaxel) in pts (n≈400) with mCRPC with a deleterious germline or somatic *BRCA1*, *BRCA2* or *ATM* mutation (per local and/or central testing). Pts must have progressed on AR-targeted therapy for mCRPC; pts who received prior chemotherapy for mCRPC or PARPi treatment are excluded. Pts will be randomised 2:1 to rucaparib or physician's choice; the latter group may cross over to rucaparib after radiographic progression confirmed by independent radiology review (IRR). The primary endpoint of TRITON3 is IRR-confirmed radiographic progression-free survival (modified RECIST v1.1/PCWG3 criteria). Pretreatment blood samples will be collected from all pts in both trials to enable development of a plasma-based companion diagnostic that predicts rucaparib sensitivity.

Clinical trial identification: TRITON2 – EudraCT 2016-003162-13, NCT02952534; TRITON3 – NCT02975934

837TiP Phase I study of apalutamide (ARN) plus abiraterone acetate (AA), docetaxel (D) in patients (pts) with metastatic castrate-resistant prostate cancer (mCRPC)

A.M. Molina[1], P.J. Christos[2], Y. Whang[3], L. Nordquist[4], A.L. Hackett[1], H. Beltran[1], B. Faltas[1], D. Nanus[1], P. Giannakakou[1], S.T. Tagawa[1]

[1]Hematology and Medical Oncology, Weill Cornell Medical College, New York, NY, USA, [2]Biostatistics and Epidemiology, Weill Cornell Medical College, New York, NY, USA, [3]Medical Oncology/Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA, [4]Medical Oncology, Urology Cancer Center and GU Research Network, Omaha, NE, USA

Background: Androgen receptor (AR) targeted therapy is the mainstay of treatment for PC, with potent AR signaling inhibitors and CYP17 inhibitors leading to improved survival. Taxanes are the only chemotherapy class to demonstrate a survival benefit in prospective randomized studies. Docetaxel (D), inhibits AR trafficking from the cytoplasm to the nucleus via stabilizing microtubules, suggesting D may complement AR-pathway targeted therapies. Recent randomized studies showing a > 1 year median survival benefit in men treated with the combination of effective direct AR-targeted therapy combined with D, suggesting that "vertical pathway blockade" in which combinations of AR-directed therapies with complementary mechanisms of action are more effective than sequential use (Sweeney NEJM 2015, James Lancet 2016). Two phase 3 trials are testing the combination of AR signaling inhibitors and CYP17 inhibitors. The safety of combining D with AA is pts with mCRPC was demonstrated in the COU-AA-206 (Tagawa Eur Urol 2016). Combinations of therapies targeting different pathways have the potential to improve efficacy.

Trial design: A multicenter phase 1 dose-escalation study will be conducted to determine the maximum tolerated dose (MTD) of ARN (novel AR signaling inhibitor) combined with AA (CYP17 inhibitor) and D (taxane) in chemotherapy-naïve mCRPC pts with ECOG performance status 0-2. Following determination of MTD, a cohort expansion at the recommended Phase 2 dose will occur. Starting doses are 120 mg/day ARN with 1000 mg/day AA, D 75 mg/m^2 every 3 weeks, and prednisone 5 mg BID. Upon completion of D, pts may continue ARN and AA. The primary endpoint is the safety and tolerability of ARN when dosed with AA and D. Tumor tissue will be collected prospectively to evaluate exploratory biomarkers predictive of response and resistance. In addition, pre- and post-treatment circulating tumor cells will be interrogated for AR localization and AR splice variants. Circulating tumor DNA will also be collected pre- and post-therapy to explore resistance mechanisms.

838TiP ARASENS: A phase 3 trial of darolutamide in males with metastatic hormone-sensitive prostate cancer (mHSPC)

B. Tombal[1], F. Saad[2], M. Hussain[3], C.N. Sternberg[4], K. Fizazi[5], E.D. Crawford[6], K. Yamada[7], C. Kappeler[8], I. Kuss[9], M.R. Smith[10]

[1]Urology, Cancer Centre, Catholic University of Louvain (UCL), Brussels, Belgium, [2]Department of Surgery, University of Montreal Hospital Center/CRCHUM, University of Montreal, QC, Canada, [3]Hematology/Oncology, Northwestern University Feinberg School of Medicine, Chicago, IL, USA, [4]Medical Oncology, San Camillo and Forlanini Hospitals, Rome, Italy, [5]Cancer Medicine, Gustave Roussy, University of Paris Sud, Villejuif, France, [6]Urologic Oncology, University of Colorado, School of Medicine, Aurora, CO, USA, [7]Oncology, Bayer Healthcare Pharmaceuticals Inc., Whippany, NJ, USA, [8]Clinical Statistics, Bayer AG, Berlin, Germany, [9]CD Oncology AR Inhib, Bayer AG, Berlin, Germany, [10]Urologic Oncology, Massachusetts General Hospital Cancer Center and Harvard Medical School, Boston, MA, USA

Background: While androgen-deprivation therapy (ADT) demonstrates antitumor activity in mHSPC with prolonged disease control, resistance ultimately occurs and patients die of castration-resistant PC (CRPC). Approximately 10-50% of PC subjects develop CRPC in < 5 yr. Chemohormonal therapy per ESMO guidelines is recommended as first-line treatment of metastatic, castration-naïve disease in men fit enough for chemotherapy. Darolutamide (ODM-201) is a unique investigational oral androgen

receptor (AR) antagonist that binds the AR and AR mutants (eg, W742L and F877L) with high affinity and selectivity, thus, inhibiting receptor function and dihydrotestosterone binding with negligible blood-brain barrier penetration. In the phase 1/2 ARADES and ARAFOR trials, darolutamide had antitumor activity and was well tolerated in men with mCRPC (Fizazi et al. Lancet Oncol 2014; Massard et al. Eur Urol 2016). As a result of this encouraging activity in mCRPC, the ARASENS trial is evaluating darolutamide plus standard ADT + docetaxel in men with mHSPC.

Trial design: This international, randomized, double-blind, placebo-controlled, phase 3 trial (NCT02799602) is being conducted in 23 countries. 1300 men with newly diagnosed mHSPC will be randomized 1:1 to either 600 mg (2 × 300 mg) darolutamide BID with food, equivalent to a total daily dose of 1200 mg or placebo, both with ADT + docetaxel (6 cycles after randomization), and stratified by extent of disease and alkaline phosphatase levels. Key inclusion criteria are confirmed PC with documented metastases, started ADT ± first-generation androgen inhibition therapy ≤12 wk before randomization, and Eastern Cooperative Oncology Group performance status 0 or 1. The primary objective is to show superior overall survival with darolutamide vs placebo, both with ADT + docetaxel. Secondary end points include time to CRPC, initiation of subsequent anticancer therapy, symptomatic skeletal event-free survival (SSE-FS), time to first SSE, initiation of opioid use, pain progression, and worsening of physical symptoms, all measured at 12-wk intervals. Safety will be assessed. The trial is open for enrollment, FPFV was in November 2016, and >110 sites in 16 countries are enrolling.

Clinical trial identification: NCT02799602

Legal entity responsible for the study: Bayer

Funding: Funded by Bayer. Darolutamide was discovered at Orion Corporation and is being jointly developed with Bayer.

839TiP A phase II clinical trial of radium-223 activity in patients (pts) with metastatic castration-resistant prostate cancer (mcrpc) with asymptomatic progression while on abiraterone acetate or enzalutamide besides AR-V7 mutational status (EXCAAPE)

J. Carles Galceran[1,2], T. Bonfill Abella[3], P. Borrega[4], R. Collado[4], J. Garde[2], M.A. Gonzalez del Alba Baamonde[5], E. Grande Pulido[6], B. Mellado[7], M.J. Mendez Vidal[8], J.M. Piulats Rodriguez[9], R. Morales Barrera[2], E. Gallardo Diaz[3], P. Paredes[7], C. Suarez Rodriguez[1], O. Reig[7], S. Vazquez Estevez[10]

[1]Vall d'Hebrón University Hospital, Barcelona, Spain, [2]Medica Scientia Innovation Research-MEDSIR, Barcelona, Spain, [3]Parc Taulí University Hospital, Parc Taulí Institute of Research and Innovation I3PT, Barcelona Autonomous University, Sabadell, Spain, [4]San Pedro de Alcántara Hospital, Cáceres, Spain, [5]Son Espases University Hospital, Palma de Mallorca, Spain, [6]Ramon y Cajal University Hospital, Madrid, Spain, [7]Clinic and Provincial University Hospital, Barcelona, Spain, [8]Reina Sofía University Hospital, Cordoba, Spain, [9]Catalan Institute of Oncology, Barcelona, Spain, [10]Lucus Augusti University Hospital, Lugo, Spain

Background: Radium-223 is indicated for pts with mCRPC with symptomatic bone metastases. Biomarkers for radium-223 treatment and its correlation with AR-V7 splice variant, are both under research. The aim of this study is to assess the activity and safety of radium-223 stratified by AR-V7 status in asymptomatic pts who have progressed while on abiraterone acetate or enzalutamide treatment.

Trial design: This is a single-arm, multicenter, phase IIA clinical trial. Pts will receive radium-223 at a dose of 55 kBq per kilogram, given at 4-weeks intervals for 6 intravenous injections, until progression or unacceptable toxicity. We will screen for AR-V7 splice variant and CTCs number after inclusion, at the end of treatment and at progression. We predict that the number of AR-V7[+] pts will be 25% at inclusion. Major inclusion criteria are: (1) mCRPC according to standard Prostate Cancer Working Group (PCWG2)-2 criteria, (2) asymptomatic according to Brief Pain Inventory short form, (3) ≥24 weeks of prior treatment with abiraterone acetate or enzalutamide, (4) adequate organ function and performance status. The primary endpoint is the radiographic progression-free survival (rPFS) according to the PCWG-2 criteria. A total of 52 pts were predefined for the primary analysis using the one arm log-rank test. In both cohorts, we test the null hypothesis that true median rPFS is ≤ 3 months versus the alternative hypothesis that is ≥ 6.3 months. The one-sided type I error was 0.025 in both AR-V7 subgroups. A sample size of 13 pts is needed in the AR-V7[+] subgroup to attain 80% power. In accordance with the expected ratio between cohorts, we will include 39 pts in AR-V7[-] subgroup. The secondary objectives are to investigate the safety of the treatment, to determine the association between AR-V7 status and tumor response and to establish the relationship between circulating tumor cells number with radium-223 activity. Trial registration number is NCT03002220. Date of registration was 20/10/2016. First patient included on 20/12/2016.

Clinical trial identification: NCT03002220, Initial Release Date: 20/Oct/2016

840TiP Stereotactic ablative radiotherapy (SABR) for oligoprogressive metastatic castration-resistant prostate cancer (mCRPC) during abiraterone therapy: A phase I study

U. Emmenegger[1], S. Cheng[1], K. Zukotynski[2], P. Cheung[3]

[1]Medical Oncology, Odette Cancer Centre, Sunnybrook Health Sciences Centre, University of Toronto, Toronto, ON, Canada, [2]Medicine and Radiology, McMaster University, Hamilton, ON, Canada, [3]Radiation Oncology, Odette Cancer Centre, Sunnybrook Health Sciences Centre, University of Toronto, Toronto, ON, Canada

Background: Despite recent therapeutic advances, there is a continuing need for novel prostate cancer treatment strategies. Some men with mCRPC may present at some point with oligometastases, a state between loco-regional and widespread metastatic disease with metastases being limited both in number and location. This oligometastatic state exists de novo, can be induced by effective systemic therapies, or may present under the picture of oligoprogression. The latter is a situation where ≤ 3-5 metastatic tumor sites progress, while all other metastases are controlled by ongoing systemic therapy. The typical practice would be to change systemic therapy at this point. SABR is an emerging treatment option for oligometastatic or oligoprogressive malignancies. Used for this indication SABR may improve survival and delay the need to change systemic therapy. However, some patients may derive limited benefit only because of early and widespread metastatic progression following SABR. While there are no validated biomarkers to predict these two scenarios to date, circulating tumor DNA (ctDNA) is a minimally invasive and highly informative biomarker platform for identifying molecular changes associated with treatment outcome.

Trial design: In the absence of published evidence on the use of SABR for oligoprogressive mCRPC in men undergoing abiraterone therapy, we are conducting a phase I study to determine the incidence of acute and late toxicities (primary endpoint) associated with delivering SABR to all oligoprogressive metastatic sites in 30 men with mCRPC on abiraterone. We also aim to collect preliminary efficacy data of such an approach as secondary endpoints (eg time to biochemical, radiological and/or symptomatic progression following SABR). Using conventional imaging, eligible mCRPC candidates will be identified based on ≤ 5 SABR amenable progressive metastatic lesions (≤ 3 in any one organ system) while all other metastases remain stable or are responding to abiraterone therapy. Before SABR, we will collect ctDNA to perform gene copy number and mutational analyses of prostate cancer relevant genes as a means to predict sustained responses to SABR.

Legal entity responsible for the study: Sunnybrook Research Institute, Toronto, ON, Canada

Funding: Janssen Inc., Canada

Disclosure: U. Emmenegger: Research support for this study and paid advisory board meetings of the manufacturer of abiraterone. All other authors have declared no conflicts of interest.

841TiP A randomized phase II study comparing cabazitaxel/prednisone to cabazitaxel alone for second-line chemotherapy in men with metastatic castrate resistant prostate cancer (mCRPC): CABACARE

C. Buonerba[1], D. Bosso[2], S. De Placido[1], G. Di Lorenzo[1]

[1]Medical Oncology Unit, Federico II Hospital, Naples, Italy, [2]Department of Clinical Medicine and Surgery, University Federico II, Naples, Italy

Background: In theTROPIC study, cabazitaxel (CAB), administered with prednisone (PDN) 10 mg daily, showed significant advantage in OS and PFS in patients (pts) progressing during or after docetaxel (DOC) treatment. Similar to DOC, CAB has been approved in combination with daily PDN, although the contributing role of PDN to

efficacy and safety has been poorly investigated. Corticosteroids have a variety of effects, which may be either favourable, mediated by adrenal androgen and cytokine suppression, or detrimental, because of adverse events associated with long-term use, promiscuous activation of AR, immunosuppression, activation of AR variants highly sensitive to PDN even at low concentrations. Moreover PDN acts as a CYP3A4 inducer, affecting clearance of taxanes. It has been shown that AR point mutations are rare in therapy-naive pts but occur in 15-45% of CRPC pts and can increase AR affinity for a wide range of steroids. Over 100 mutations have been described. In the CHAARTED trial DOC was safely administered without daily PDN showing important clinical benefits in OS, PFS, and time to CRPC.; Safety data for CAB without PDN are lacking. AR-V7 positivity and RB loss/inactivation have been identified as potentially implicated in progression with next-generation targeted agents. We also would like to prospectively assess their role as predictive biomarkers of CAB activity.

Trial design: CABACARE is a randomized, phase II, open label, multicenter study comparing CAB at 25 mg/m2 q21 plus daily PDN (10 mg) vs CAB at 25 mg/m2 q21 alone in mCRPC pts progressed during or after DOC treatment. The study is designed to test non-inferiority in terms of PFS, according to PCWG-2, of CAB alone vs CAB plus PDN, assuming that the two arms are equally effective. Each arm will enroll 110 pts. Main secondary objectives are: safety, QoL, pain assessment, overall response rate (ORR), PSA response, time to PSA progression, time to radiological progression; OS; and time to skeletal related events (SRE). The influence of Arv7 and RB status on CAB activity will also be evaluated

Background: The evolution of CRPC is heterogeneous, and despite progress in its management, with several new agents approved for CRPC, we are still so far from being able to predict which group of patients might benefit from a particular strategy. Therefore, the identification of new predictive and prognostic biomarkers is urgently needed.

Trial design: PROSABI is a prospective multicentre observational study in metastatic CRPC designed to explore biomarkers in patients treated with AA. Key inclusion criteria: a) histological confirmation of prostate cancer; b) documented criteria (PCWG2) for CRPC; c) availability of tumour tissue; d) candidate for standard treatment with AA. Primary end point: to validate the prognostic value for overall survival (OS) of the expression signature (ES) in peripheral blood of 9 genes described by Olmos et al (Lancet Oncol 2012). Secondary end points: a) to study the prognostic role for progression-free survival of the ES; b) to analyse the prognostic role for OS of early changes in the ES; c) to compare the prognostic and predictive utility of the ES with other ES (Ross et al, Lancet Oncol 2012); d) to validate in this patient cohort prognostic nomograms described for CRPC. Exploratory outcomes: a) to establish prognostic value for TMPRSS-ERG and PTEN; b) to determine the prognostic value for serum testosterone levels; c) to analyse the role of serum chromogranine; d) to study the prognostic role of AR splicing variants; e) to explore new somatic and germinal variants in peripheral blood and tissue associated to dissemination, response and resistance to AA. PROSABI is part of the PROCURE Biomarkers network, a multicentric spanish platform for biomarkers discovery in CRPC patients. 220 patients will be accrued to provide appropriate statistical power to detect at least 91 events (deaths) to analyse the main outcome. Currently, 48 centres are active for recruitment and 184 patients have been included. Blood samples are collected before, during (pre-cycle 3) and after progression to AA. Prospective data collection will be linked. This study may help to incorporate new biomarkers in clinical practice and improve the selection of therapy in mCRPC.

Background: Several new agents have been approved for CRPC, but we are still so far from being able to predict which group of patients might benefit from a particular strategy. Therefore, the identification of new predictive and prognostic biomarkers is urgently needed. In this setting, bone metabolism markers (BMM) assume particular importance regarding to R223.

Trial design: PRORADIUM is a prospective multicentre observational study in metastatic CRPC designed to explore biomarkers in patients treated with R223. Key inclusion criteria: a) histological confirmation of prostate cancer; b) documented criteria (PCWG2) for CRPC; c) availability of tumour tissue; d) candidate for standard treatment with R223. Primary end point: to validate the prognostic value for overall survival (OS) of serum BMM expression described by Primo N Lara et al (JNCI 2014). Secondary end points: a) to analyse the prognostic role for PSA response regarding to BMM expression; b) to correlate radiological response with BMM; c) to investigate the association of skeletal related events with BMM; d) to analyse the prognostic role of

alkaline phosphatase before and during R223; e) to analyse the prognostic value of "Bone Scan Index" in response evaluation; f) to analyse the prognostic role for OS of AR-V7 and AR amplification; g) to validate the prognostic role of the expression signature described by Olmos et al (Lancet Oncol 2012) in peripheral blood. Exploratory outcomes: a) to validate prognostic nomograms described for CRPC; b) to explore new somatic and germinal variants in peripheral blood and tissue associated to response and resistance to R223. PRORADIUM is part of the PROCURE Biomarkers network, a multicentric spanish platform for biomarkers discovery in CRPC patients. 161 patients will be accrued to provide appropriate statistical power to detect at least 85 events (deaths) to analyse the main outcome. Currently, 48 centres are active for recruitment and 54 patients have been included. Blood samples are collected before, during and after progression to R223. Prospective data collection will be linked. This study may help to incorporate new biomarkers in clinical practice and improve the selection of therapy in mCRPC.

Background: CRPC is a heterogeneous disease, and despite new agents approved, the optimal sequence of treatment remains unclear, far from personalised medicine that may offer the maximal benefit for the patient. For that reason, our aim is the identification of new biomarkers in CRPC patients treated with conventional therapy.

Trial design: PROSENZA is a prospective multicentre observational study in metastatic CRPC designed to explore biomarkers in patients treated with ENZ. Key inclusion criteria: a) histological confirmation of prostate cancer; b) documented criteria (PCWG2) for CRPC; c) availability of tumour tissue; d) candidate for standard treatment with ENZ. Primary end point: to study the prognostic value for overall survival (OS) of the detection of androgen receptor splicing variant 7 (AR-V7) and/or amplification of AR (AR+) in peripheral blood in this cohort. Secondary end points: a) to analyse the correlation between PSA response and AR-V7 and/or AR+; b) to evaluate the correlation between radiological response and AR-V7 and/or AR+; c) to study changes in AR-V7 frequency and/or AR+ pre and post ENZ; d) to analyse and correlate the prognostic role of AR-V7 and AR+ with other biomarkers as testosterone serum levels, PTENloss or TMPRSS-ERG fusions. Exploratory outcomes: a) to validate in this cohort prognostic nomograms described for CRPC; b) to validate the prognostic role of the expression signature described by Olmos et al (Lancet Oncol 2012) in peripheral blood; c)to explore new somatic and germinal variants in peripheral blood and tissue associated to dissemination, response and resistance to ENZ. PROSENZA is part of the PROCURE Biomarkers network, a multicentric spanish platform for biomarkers discovery in CRPC. 187 patients will be accrued to provide appropriate statistical power to detect at least 71 events (deaths) to analyse the main outcome. Currently, 48 centres are active for recruitment and 54 patients have been included. Blood samples are collected before, during and after progression to ENZ Prospective data collection will be linked. This study may help to incorporate new biomarkers in clinical practice and improve the selection of therapy in mCRPC.

Background: The previous SWITCH-I study explored the two possible sequences of Sunitinib and Sorafenib for the treatment of advanced/metastatic renal cell carcinoma (mRCC) and showed similar total progression-free-survival (tPFS) and overall survival (OS) times. This trial compared the sequential therapy with the multikinase inhibitors Sorafenib (So) followed by Pazopanib (Pa) or vice versa in mRCC patients (pts).

Methods: This multicentre, randomised phase 3 study assessed the sequential use of So-Pa versus Pa-So in pts with mRCC without prior systemic therapy. Pts were randomised to So 400 mg twice daily followed by Pa 800 mg once daily (So-Pa) in case of progression or intolerable toxicity or vice versa (Pa-So). The primary endpoint was non-inferiority of tPFS with So−Pa compared to Pa−So, assessed from randomisation to progression or death during second-line therapy defined as hazard ratio (HR) <1.225 as a one-sided 95% confidence interval (CI). Main secondary endpoints included OS, total time to progression (TTP), disease control rate (DCR), 1st-line and 2nd-line PFS as well as safety and tolerability.

Results: 377 pts were randomised (So-Pa, n = 189; Pa-So, n = 188). Median tPFS was 8.6 mo (95% CI 7.7-10.2) for So-Pa and 12.9 mo (95% CI 10.8-15.2) for Pa-So with a HR of 1.36 (upper limit of one-sided 95% CI 1.68). Therefore, non-inferiority of So-Pa in regard to tPFS was not met. However, marked statistical differences were noted in favour of Pa-So in total TTP, 1st-line PFS and DCR but not for OS and 2nd-line PFS. In the So-Pa arm 106/189 (56%) received Pa as 2nd line and for the Pa-So arm 87/188 (46%) received So as 2nd line. The most frequent any-grade treatment-emergent first-line adverse events for So were diarrhoea (56%), fatigue (37%) and hand-foot skin reaction (35%) and for Pa diarrhoea (60%), hypertension (48%) and fatigue (45%).

Conclusions: Non-inferiority of the sequence So-Pa compared to Pa–So in terms of the primary endpoint tPFS was not met. However, superiority of the sequence Pa-So over So-Pa for tPFS was not proven either, since the study design was computed with a HR of < 1.225 as a one-sided 95% CI.

Clinical trial identification: NCT01613846, first received May 4, 2012

Background: We report the updated safety and efficacy of CaboNivo and CaboNivoIpi in pts with mUC and other GU tumors (NCT02496208).

Methods: Primary objective was to determine the dose limiting toxicity (DLT) and recommended phase 2 dose (RP2D). We tested 7 dose levels (DL); 4 in part 1 (CaboNivo); 3 in part 2 (CaboNivoIpi). **Part 1** pts received cabo PO daily/Nivo IV q2wks: **DL1** Cabo 40mg/Nivo 1mg/kg, **DL2** Cabo 40mg/Nivo 3mg/kg, **DL3** Cabo 60mg/Nivo1mg/kg, **DL4** Cabo 60mg/Nivo 3mg/kg. **Part 2** pts received Cabo PO daily/Nivo/Ipi IV q3wks x4 cycles → Nivo IV q2wks: **DL5** Cabo 40mg/Nivo1&Ipi 1mg/kg, **DL6** Cabo 40mg/Nivo 3&Ipi 1mg/kg, **DL7** Cabo 60mg/Nivo3&Ipi 1mg/kg. Adverse events (AEs) were graded by CTCAE v4.0. Other objectives: overall response rate (ORR), duration of response (DOR), progression-free survival (PFS) and overall survival (OS).

Results: From 07/15/2015-04/25/2017, median(m) potential follow-up: 13.4 month-s(mo). 42 pts enrolled: 24 pts in **part 1** (mUC n = 7; urachal (Ur) n = 4; germ cell tumor n = 4; prostate cancer (PC) n = 4; bladder squamous cell carcinoma (bSCC) n = 2; penile n = 1; sarcomatoid renal cell carcinoma (sRCC) n = 1; and trophoblastic n = 1); 18 pts in **part 2** (mUC n = 8; penile n = 3; CRPC n = 5; sertoli n = 1; sRCC n = 1). Median age: 56 years (range 31-77), 90.5% male. Grade 3–4 AEs occurred in 67% of pts, mostly in **part 1:** hypophosphatemia (21%), neutropenia (21%), fatigue (12%), elevated lipase (12%); diarrhea, hypertension (HTN), dehydration, thrombocytopenia, proteinuria, and leukopenia (8% each); in **part 2:** hypophosphatemia (22%) HTN (17%); fatigue, nausea, lymphopenia, and elevated lipase (11% each). G3 immune-related AEs: aseptic meningitis (n = 1, DL1) and colitis (n = 1, DL5). No G5 toxicities or DLTs. RP2D for **part 1**: Cabo40mg/Nivo3mg/kg; for **part 2**: Cabo40mg/Nivo3&Ipi1mg/Kg. ORR=35%, 3CR (2mUC, 1SCC) & 11PR (3mUC, 2SCC, 2sRCC, 2Penile, 1Ur, 1PC). mDOR (CR+PR+SD): 7.1 mo [95% CI: 5.1-not reached], mPFS: 5.5 mo [95%CI: 4.5-12.8] and mOS was not reached. OS at 6&12 mo was 83.3%&64.3%.

Conclusions: CaboNivo and CaboNivoIpi showed durable clinical activity in mUC and rare GU malignancies with manageable toxicity.

847O A phase 1b/2 trial of lenvatinib plus pembrolizumab in patients with renal cell carcinoma

C-H. Lee[1], V. Makker[1], D. Rasco[2], M. Taylor[3], C. Dutcus[4], R. Shumaker[4], E.V. Schmidt[5], D. Stepan[4], D. Li[4], R.J. Motzer[1]

[1]Genitourinary Oncology, Memorial Sloan-Kettering Cancer Center, New York, NY, USA, [2]Medical Oncology, START, San Antonio, TX, USA, [3]Oregon Health and Science University, Knight Cancer Institute, Portland, OR, USA, [4]Eisai, Inc., Woodcliff Lake, NJ, USA, [5]Merck & Co., Inc., Kenilworth, NJ, USA

Background: Lenvatinib (LEN) is a multikinase inhibitor of vascular endothelial growth factor (VEGF) receptor 1 − 3, fibroblast growth factor receptor 1 − 4, platelet-derived growth factor receptor α, RET, and KIT. LEN was approved in combination with everolimus to treat advanced renal cell carcinoma (RCC) after 1 prior VEGF-targeted treatment. We report results for the RCC cohort of a phase 1b/2 trial of LEN+pembrolizumab (pembro) in patients (pts) with selected solid tumors (NCT02501096).

Methods: This was a multicenter open-label study. Pts had metastatic clear cell RCC, measurable disease according to immune-related Response Evaluation Criteria in Solid Tumors (irRECIST), and Eastern Cooperative Oncology Group performance status ≤1. LEN 20 mg/d plus pembro 200 mg intravenously every 3 weeks was assessed as the maximum tolerated dose and recommended phase 2 dose in phase 1b. Tumor

assessments were performed by trial investigators using irRECIST. The primary phase 2 endpoint was objective response rate (ORR) at 24 weeks. Secondary endpoints included ORR, progression-free survival (PFS), and duration of response (DOR).

Results: 30 Pts were enrolled in either the phase 1b (8 pts) or phase 2 cohort (22 pts). Data cutoff Feb 15, 2017. 11 (37%) Pts had 0, 11 (37%) pts had 1, and 8 (27%) pts had ≥2 prior anti-cancer therapies. Of pts who received prior medication (n = 19, 63%), 16 (53%) received prior VEGF-targeted therapy. Efficacy outcomes are summarized in the Table. At data cutoff, 17 (57%) pts were still receiving treatment, 8 (27%) completed treatment due to disease progression, and 5 (17%) discontinued treatment. The most common any-grade treatment-emergent adverse events were diarrhea, fatigue, hypothyroidism, nausea, and stomatitis. Toxicities were manageable with dose interruption and/or modification and no new safety signals were found. Updated data will be presented.

Table: 847O

Outcome	n = 30	95% CI
ORR, n (%)	19 (63.3)	43.9%–80.1%
Median PFS, mos	NE	9.9–NE
Median DOR, mos	NE	8.4–NE

NE, not estimable.

Conclusions: Combination treatment with LEN+pembro showed promising antitumor activity and an acceptable safety profile. A phase 3 trial of LEN+pembro and LEN+everolimus, vs sunitinib in first-line treatment for metastatic clear cell RCC is ongoing.

848PD Impact of zumor mutation burden on nivolumab efficacy in second-line urothelial carcinoma patients: Exploratory analysis of the phase ii checkmate 275 study

M.D. Galsky[1], A. Saci[2], P.M. Szabo[2], A. Azrilevich[3], C. Horak[2], A. Lambert[4], A. Siefker-Radtke[5], A. Necchi[6], P. Sharma[7]

[1]Department of Medicine, Icahn School of Medicine at Mount Sinai/Tisch Cancer Institute, New York, NY, USA, [2]Oncology, Bristol-Myers Squibb, Princeton, NJ, USA, [3]Global Clinical Research/Oncology, Bristol-Myers Squibb, Princeton, NJ, USA, [4]Oncology, Bristol-Myers Squibb, Braine-l'Alleud, Belgium, [5]Medicine, MD Anderson Cancer Center, University of Texas, Houston, TX, USA, [6]Medical Oncology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [7]Genitourinary Medical Oncology, MD Anderson Cancer Center, University of Texas, Houston, TX, USA

Background: Nivolumab, a programmed death (PD)-1 inhibitor, demonstrated efficacy in a single-arm phase II study in patients (pts) with metastatic or surgically unresectable urothelial carcinoma (UC) (CheckMate 275; Sharma et al. 2017). The current analysis explores the potential association between pretreatment tumor mutation burden (TMB) and response to nivolumab.

Methods: Tumor DNA from pretreatment archival tumor tissue and matched whole blood samples was profiled by whole exome sequencing. TMB was defined as the total number of missense somatic mutations per tumor, and was evaluated as a continuous variable and by tertiles (missense count: high ≥167, medium 85–166, low <85). Cox models were used to explore the association between TMB and progression-free survival (PFS) and overall survival (OS); and logistic regression for objective response rate (ORR). Tumor PD-ligand 1 (PD-L1) expression was assessed by Dako PD-L1 immunohistochemistry 28-8 assay and was categorized as </≥1%.

Results: 139 (51%) of 270 pts had evaluable TMB. Baseline characteristics, ORR, PFS, and OS were similar between all treated pts and the TMB subgroup. ORR, PFS and OS in all pts and TMB/PD-L1 subgroups are shown in the Table. TMB showed a statistically significant positive association with ORR (P=0.002) and PFS (P=0.005), and a strong association with OS (P=0.067), even when adjusted for baseline tumor PD-L1 expression, liver metastasis status, and serum hemoglobin. High TMB had the greatest impact on survival in pts with <1% PD-L1 expression (Table).

Conclusions: These exploratory findings suggest that TMB may enrich for response to nivolumab and may provide complementary prognostic/predictive information beyond PD-L1. Further analyses in randomized trials are warranted to define the prognostic/predictive value of TMB in the context of other biomarkers in UC pts treated with immunotherapy.

849PD Comparison of tumor mutational burden (TMB) in relevant molecular subsets of metastatic urothelial cancer (MUC)

S.K. Pal[1], N. Agarwal[2], T.K. Choueiri[3], P.J. Stephens[4], J.S. Ross[5], V.A. Miller[4], S.M. Ali[4], J. Chung[6], P. Grivas[7]

[1]Medical Oncology, City of Hope, Duarte, CA, USA, [2]Medical Oncology, Huntsman Cancer Institute, Salt Lake City, UT, USA, [3]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, USA, [4]R & D, Foundation Medicine, Cambridge, MA, USA, [5]Pathology, Albany Medical Center, Albany, NY, USA, [6]Pathology, Foundation Medicine, Cambridge, MA, USA, [7]Medical Oncology, Cleveland Clinic, Cleveland, USA

Background: Phase I and II studies suggest potential benefit with targeted therapy (TT) (e.g., FGFR3, ERBB2/3 and CDK4/6 inhibitors) in relevant molecular subsets of MUC. Given increasing data supporting PD-1/PD-L1 inhibitors in MUC, rationale for combinations of TT and immunotherapy (IO) is sought. TMB is a putative biomarker of IO response; we investigated differences in TMB in relevant molecular subsets of MUC.

Methods: DNA was extracted from 40 microns of FFPE sections from 2024 consecutive patients with MUC. Comprehensive genomic profiling (CGP) was performed on hybridization-captured, adaptor ligation based libraries to a mean coverage depth of 688X for up to 315 cancer-related genes plus 37 introns from 14 genes frequently rearranged in cancer. The CGP assay included base substitutions (SUB), INDELs, copy number alterations (CNA) and fusions/rearrangements. TMB was determined on 1.2 million Mb of sequenced DNA; results are reported for the overall cohort and in subsets segregated separately by presence or absence of FGFR3, ERBB2/3, PIK3CA and CDKN2A/B alteration.

Results: 2024 consecutive pts (1457:567 M:F) with MUC were assessed with a median age of 67 years. Median TMB in the overall cohort was 7.2 mutations/Mb. *FGFR3, ERBB2, ERBB3, PIK3CA,* and *CDKN2A/B* alteration were identified in 23%, 14%, 4%, 19% and 37% of pts, respectively. TMB was significantly different in pts segregated based on *ERBB2* alteration ($P = 1.8\text{x}10^{-7}$), *PIK3CA* alteration ($P = 1.7\text{x}10^{-6}$) and *ERBB3* mutation ($P = 0.01$) (Table). *ERBB2* and *FGFR3* genomic alterations (GAs) were significantly mutually exclusive, while *FGFR3* GAs significantly co-occurred with *PIK3CA* and *CDKN2A/B*. Further differences in CGP amongst these subsets will be presented at the meeting.

Table: 849PD

	TMB, muts/Mb Median (IQR 25%-75%)
All patients (n = 2024)	7.2 (3.6, 11.7)
FGFR3 alteration	
Yes (n = 461)	6.3 (3.8, 10.8)
No (n = 1564)	7.2 (3.6, 12.6)
ERBB2 alteration	
Yes (n = 277)	9.9 (5.4, 18.0)
No (n = 1747)	6.3 (3.6, 11.3)
ERBB3 alteration	
Yes (n = 72)	10.8 (6.3, 20.3)
No (n = 1952)	6.3 (3.6, 11.7)
PIK3CA alteration	
Yes (n = 383)	9.0 (4.8, 17.1)
No (n = 1641)	6.3 (3.6, 10.8)
CDKN2A/B alteration	
Yes (n = 742)	7.2 (3.6, 12.6)
No (n = 1282)	6.3 (3.8, 11.3)

Conclusions: Given the proposed correlation between TMB and IO response, these data may inform the utility of combination strategies. Specifically, given higher TMB in pts with ERBB2/ERBB3 or PIK3CA alteration, combination studies exploring IO with TT directed at these targets may be warranted.

850PD Epithelial-mesenchymal transition (EMT), T cell infiltration, and outcomes with nivolumab (nivo) in urothelial cancer (UC)

M.D. Galsky[1], L. Wang[1], A. Saci[2], P.M. Szabo[2], Y. Gong[1], J. Zhu[1]

[1]Medicine, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY, USA, [2]Oncology, Bristol-Myers Squib, Princeton, NJ, USA

Background: The presence of tumor infiltrating lymphocytes has been associated with a higher objective response rate (ORR) to PD-1/PD-L1 blockade. Across a variety of cancers, high EMT gene expression correlates with increased T cell infiltration. The impact of these interrelated processes on outcomes with PD-1/PD-L1 blockade has not been defined.

Methods: The TCGA UC cohort (n = 405) was utilized to determine the relationship between EMT gene signature (sig) expression (200 genes in MSigDB) and infiltrating T cell abundance (ITA). ITA was inferred using mRNA expression of 144 T cell genes. A phase 2 trial of nivo in metastatic UC (CheckMate 275, n = 212) was used to determine the impact of EMT sig (HTG EdgeSeq) and CD8 expression (IHC) on ORR, progression-free (PFS), and overall survival (OS).

Results: In the TCGA cohort, EMT sig correlated with ITA (CC = 0.60, $p < 2e\text{-}16$). The correlation remained significant after correction for sample purity (CC = 0.37, p = 1e-14) and UC molecular subtype (p = 1e-13). In the CheckMate 275 cohort, EMT sig correlated with CD8 expression (CC = 0.29, p = 2e-05). The impact of EMT sig and CD8 expression on outcomes is shown (Table). Higher CD8 expression was associated with longer PFS (p = 0.0003) and OS (p = 0.01). There was a significant interaction between EMT sig and CD8 (PFS, p = 0.038; OS, p = 0.064); in $CD8_{high}$ tumors, ORR, PFS, and OS were worse in EMT_{high} vs EMT_{low}.

Table: 850PD Outcomes with nivolumab

Group	N	ORR	Median PFS (95% CI)	Median OS (95% CI)
Entire cohort	212	18.4%	1.97 (1.87-2.46)	8.74 (5.58-NR)
$CD8_{low}$	106	11.3%	1.84 (1.71-1.94)	5.72 (4.3-8.74)
$CD8_{high}$	106	25.5%	3.12 (2.04-4.14)	11.30 (10.9-NR)
EMT_{low}	106	23.6%	2.10 (1.87-3.65)	8.74 (6.05-NR)
EMT_{high}	106	13.2%	1.91 (1.81-2.46)	6.57 (4.96-NR)
$CD8_{high}$ EMT_{high}	64	15.6%	2.04 (1.84-3.52)	NR (6.57-NR)
$CD8_{high}$ EMT_{low}	42	40.5%	5.52 (3.45-NR)	NR (11.3-NR)

Conclusions: While much effort has been focused on "turning cold tumors hot" as a strategy to improve the efficacy of PD-1/PD-L1 blockade, a large proportion of "hot tumors" do not respond. Among "hot" UC, EMT_{high} tumors are associated with a lower ORR to nivo and shorter PFS and OS. These findings substantiate EMT as a potential mechanism of immune escape and raise the possibility of co-targeting EMT and PD-1/PD-L1 in "hot" UC.

Background: In the open-label, phase 3 KEYNOTE-045 study (NCT02256436), overall survival (OS) was significantly longer with pembro vs investigator's choice of chemo (median, 10.3 vs 7.4 mo; hazard ratio [HR], 0.73; P = 0.002) in recurrent, advanced UC. In a post hoc analysis, pembro was compared with the individual agents in the chemo arm.

Methods: Pts with histologically or cytologically confirmed UC, progression after platinum, ECOG PS 0-2, measurable disease (RECIST v1.1), and ≤2 lines of systemic therapy were randomly assigned 1:1 to pembro 200 mg Q3W or investigator's choice of paclitaxel 175 mg/m^2 Q3W, docetaxel 75 mg/m^2 Q3W, or vinflunine 320 mg/m^2 Q3W. Primary end points: OS and PFS (RECIST v1.1, blinded central review). ORR (RECIST v1.1, blinded central review) was a secondary end point.

Results: 525 pts were included in these analyses (allocation: pembro, 270; paclitaxel, 84; docetaxel, 84; vinflunine, 87). Baseline demographics were generally balanced among the 4 groups. Median follow-up was 14 mo (range, 10-22 mo). Pembro was associated with an OS benefit over the individual chemo agents (HR [95% CI]: paclitaxel, 0.77 [0.57-1.06]; docetaxel, 0.78 [0.56-1.08]; vinflunine, 0.71 [0.52-0.96]). PFS was similar between pembro and each of the chemo agents. ORR (95% CI) was 21% (16%-27%) with pembro vs 12% (6%-21%), 6% (2%-13%), and 18% (11%-28%) with paclitaxel, docetaxel, and vinflunine, respectively. Treatment-related AEs occurred in 61% (pembro), 88% (paclitaxel), 92% (docetaxel), and 91% (vinflunine) of pts. 15% (pembro), 44% (paclitaxel), 54% (docetaxel), and 51% (vinflunine) experienced treatment-related AEs of grade ≥3 severity.

Conclusions: Results from subgroup analyses of KEYNOTE-045 demonstrate that pembro was associated with longer OS, higher antitumor activity, and lower incidence of toxicities than single-agent paclitaxel, docetaxel, or vinflunine in pts with advanced UC that progressed on/after platinum-based therapy. Pembro is the first agent to demonstrate OS improvement vs chemo in this setting and should be considered for use in recurrent, advanced UC.

852PD Atezolizumab (atezo) in platinum-treated locally advanced or metastatic urothelial carcinoma (mUC): Post-progression outcomes from the phase 2 IMvigor210 study

A. Necchi[1], R.W. Joseph[2], Y. Loriot[3], J. Hoffman-Censits[4], J.L. Perez Gracia[5], D.P. Petrylak[6], Q. Zhu[7], B. Ding[7], C. Kaiser[7], J.E. Rosenberg[8]

[1]Medical Oncology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [2]Department of Hematology/Oncology, Mayo Clinic, Jacksonville, AL, USA, [3]Oncology, Institut Gustave Roussy, Villejuif, France, [4]Thomas Jefferson University Hospital, Sidney Kimmel Cancer Center, Philadelphia, PA, USA, [5]Medical Oncology, Clinica Universidad de Navarra, Pamplona, Spain, [6]Smilow Cancer Center, Yale University School of Medicine Medical Oncology, New Haven, CT, USA, [7]Oncology, Genentech, Inc., South San Francisco, CA, USA, [8]Oncology, Memorial Sloan-Kettering Cancer Center, New York, NY, USA

Background: mUC remains a disease with few treatment (tx) options and short OS. IMvigor210 demonstrated efficacy and safety of atezo (anti–PD-L1) in mUC and led to approval in the US and elsewhere. Here, we evaluate outcomes in platinum-treated IMvigor210 patients (pts) treated with atezo beyond progression.

Methods: IMvigor210 (NCT02108652 cohort 2) enrolled pts with mUC that progressed during/following platinum. Atezo was given 1200 mg IV q3w until loss of clinical benefit per investigator. In this descriptive, post hoc analysis (data cut 4 Jul 2016), assessments included on-study RECIST v1.1 response (pre– and post–first progressive disease [PD]; central review), sum of target lesion diameters (SLD; % change from PD), OS, post-progression (pp) OS and safety grouped by tx status post-PD.

Results: 220 pts who experienced PD (of 310 total in study) were evaluable: 137 continued atezo post-PD, and 83 received other (n = 19) or no (n = 64) systemic tx. Pts who continued atezo had fewer poor prognostic factors (Table). Pre-PD tx duration was similar in pts who did or did not continue atezo post-PD (median, 1.5 and 1.4 mo, respectively), and median post-PD atezo duration was 1.6 mo. Pts continuing atezo beyond PD had higher pre-PD ORR vs other groups (Table). 45 pts who continued atezo following initial PD (of 108 with post–first PD measurements) experienced decreases in target lesion SLD. OS data are in Table. In pts continuing atezo, pre- and post-PD exposure-adjusted tx-related AEs were similar (Table), with no related G5 AEs.

Conclusions: Pts who continued atezo beyond PD derived prolonged clinical benefit including tumor burden reduction and numerically longer OS vs pts who discontinued atezo post-PD in this single-arm study. Atezo was well tolerated throughout tx. An important future challenge in the post-PD setting will be to identify pts most likely to respond to atezo and appropriate sequencing of chemo agents thereafter.

[1]Lank Center for Genitourinary Oncology, Dana-Farber Cancer Institute, Boston, MA, USA, [2]Medical Oncology, Moores Cancer Center in San Diego, San Diego, CA, USA, [3]Biostatistics and Computational Biology, Dana-Farber Cancer Institute, Boston, MA, USA, [4]Genitourinary Cancer Center, Massachusetts General Hospital Cancer Center, Boston, MA, USA, [5]Radiology, Dana-Farber Cancer Institute, Boston, MA, USA, [6]Nuclear Medicine, Dana-Farber Cancer Institute, Boston, MA, USA

Background: BM occur in 30% of patients (pts) with mRCC and are associated with symptomatic skeletal events (SSE) and worse outcomes with vascular-endothelial growth factor (VEGF)-targeted agents. Rad is a bone-seeking α-emitter that targets BM. We investigated the safety, efficacy and bone turnover markers (BTM) of Rad combined with P or S in pts with mRCC and BM.

Methods: 30 pts received therapy (15 treatment-naïve pts: P 800 mg/d +Rad; 15 treatment-refractory: S 400 mg BID +Rad). Rad was administered monthly for up to 6 infusions. The primary endpoint was BTM. Secondary endpoints included safety, SSE rate, time to SSE, objective response rate (ORR), narcotic use and survival.

Results: Of the 30 pts, 70% had clear cell histology, 17% were IMDC poor risk and 33% had liver metastases. Prior SSEs were reported in 100% and 65% of pts in the P and S cohorts, respectively. 1 pt had received denosumab. Median changes in BTM at cycle 2 and 4 compared to baseline are summarized in table and show declines in all BTMs. Best ORR by RECIST was partial response (PR) in 13% and stable disease (SD) 47%. Achieving > =50% decline in PINP at cycle 2 was associated with PR and SD (Fisher's exact p-value 0.01). Median treatment duration was 3.6 mo (IQR 1.5, 5.5). Progression-free survival was 8.2 mo [95%CI 5.6, NR] and 4.6 mo [95%CI 2.1, NR] in pts treated with P and S. Overall survival was 11.9 mo [95%CI 7.8, NR] and 8.7 mo [95%CI 6, NR], respectively. Overall rate of SSE on study was 47%; 67% in the P cohort (median time to SSE 6.3 mo [95%CI 3.6, NR]) and 27% in the S cohort (median time to SSE NR [95%CI 6.6 mo, NR]). There was no dose-limiting toxicity. The rate of treatment-related grade ≥3 toxicity was 39.3% including 3.6% grade 3 anemia.

Conclusions: Rad combined with P or S is safe and well tolerated. All BTMs significantly declined with Rad combined with P or S suggesting biologic activity in mRCC with BM. Randomized trials are needed to evaluate the role of Rad on SSE prevention in these pts.

Background: Pts with locoregional RCC at high risk (≥T3 and/or N+) of tumour recurrence post nephrectomy treated with adjuvant SU (50 mg daily; schedule 4/2) had significantly longer disease-free survival (DFS) vs. placebo (PBO; HR, 0.76; 95% CI, 0.59–0.98; P = 0.03). We report safety and therapy management data.

Methods: Reasons for SU treatment discontinuation (TDC), dose reduction (RED), dose interruption (INT), and pts TDC due to AEs by cycle, were summarized. Median time to SU TDC was calculated.

Results: Of the 615 pts enrolled, 306 were treated with SU at a median (range) daily dose of 45.9 (8.9–52.6) mg. 71% of pts remained on SU treatment for 9 months (mo) and 56% completed the full 1-year treatment. Most common reasons for TDC were AEs (28.1%) and relapse (7.2%) in SU arm, and relapse (19.4%) and AEs (5.9%) in PBO arm. Common AEs leading to TDC, RED and INT are summarized in the Table. TDC due to AEs in cycles 1, 3, 6, and 9, respectively: 7.8%, 3.3%, 2.6%, and 1.6% in SU arm, and 0.3%, 1.3%, 0.3%, and 0% in PBO arm. In the 86 pts who DC SU, median time to TDC was 4.5 mo. Median time to first RED and INT in SU-treated pts was 2.9 and 3.0 mo, respectively. Mean change from baseline in most PRO measures including Global Health Status for SU vs PBO was not clinically meaningful (difference, -4.76; 95% CI, -6.82, -2.71). More data, including time on RED/INT, time to onset of common AEs, and the impact of AEs on pts quality of life, will be presented.

Table: 855PD Most common AEs leading to TDC, dose RED and INT*

Treatment DC			Dose RED			Dose INT		
AE, %	SU	PBO	AE, %	SU	PBO	AE, %	SU	PBO
PPE	4.2	0	PPE	11.8	0.7	PPE	6.2	0
Hypertension	2.0	0	Fatigue	3.9	0.3	Hypertension	5.6	0
Asthenia	1.3	0	Diarrhoea	2.6	0	Neutropenia	5.2	0
Fatigue	1.0	0.3	Mucosal inflammation	2.6	0	Nausea	4.9	1.0
Pulmonary embolism	1.0	0.3	Neutropenia	2.6	0	Diarrhoea	4.6	1.3

*Many of the AEs leading to DC and INT were grade 1/2 TDC=treatment discontinuation; RED=reduction; INT=interruption; PPE=palmar-plantar erythrodysesthesia syndrome.

Conclusions: No new safety signals were identified with sunitinib use in the adjuvant RCC setting. Effective therapy management, including dose RED/INT if necessary, is important as it optimizes the possibility of receiving effective treatment.

Background: Avelumab, a human anti–PD-L1 monoclonal antibody, has shown promising efficacy and safety in patients (pts) with mUC. We report an updated analysis of avelumab treatment in 2 cohorts of pts from JAVELIN Solid Tumor (NCT01772004).

Methods: Pts with mUC whose disease had progressed after platinum-based therapy or were cisplatin ineligible received avelumab 10 mg/kg Q2W. Tumors were assessed every 6 weeks by independent review (RECIST v1.1). Endpoints included objective response rate (ORR), duration of response (DOR), progression-free survival (PFS), overall survival (OS), and safety (NCI CTCAE v4.0), and tumor PD-L1 expression. Kaplan-Meier (K-M) method was used to estimate DOR, PFS, and OS.

Results: As of Sep 2016, 249 pts had received avelumab and were followed for ≥6 mos (median 13.6 mos); 43 pts (17.3%) remained on treatment. 13 pts (5.2%) were cisplatin ineligible, including 7 (2.8%) platinum naïve. Confirmed ORR in all pts (n = 249) was 17.3% (95% CI 12.8–22.5; complete response in 4.4%) and the disease control rate was 44.6%. Response was ongoing in 34/43 pts (79.1%), median DOR was 20.1 mos (95% CI 9.7–20.1) and the K-M estimate of DOR of 6 mos was 92.7% (95% CI 79.1–97.6). In evaluable pts (n = 206), ORR in PD-L1+ and PD-L1– subgroups (≥5% tumor cell cut-off) was 25.6% and 13.7%, respectively. Median PFS was 1.6 mos (95% CI 1.4–2.7), median OS was 8.2 mos (95% CI 6.3–10.8), and the K-M OS rate at 12 mos was 41.9% (95% CI 34.8–48.7). 170/249 pts (68.3%) had a treatment-related adverse event (TRAE) of any grade, most commonly infusion-related reaction (23.3%) and fatigue (17.3%). 26 pts (10.4%) had a grade ≥3 TRAE, most commonly fatigue (1.6%), elevated lipase (1.6%), and pneumonitis (1.2%). 43 pts (17.3%) had an immune-related AE (grade ≥3 in 3.6%). 8 pts (3.2%) discontinued avelumab due to a TRAE. There was 1 treatment-related death (pneumonitis).

Conclusions: Avelumab showed durable clinical activity and had a manageable and tolerable safety profile in pts with mUC irrespective of PD-L1 expression. A phase 3 trial of avelumab as maintenance therapy after first-line platinum-based therapy for advanced UC is ongoing.

857P Pembrolizumab (pembro) as first-line therapy in cisplatin-ineligible advanced urothelial cancer (UC): Outcomes from KEYNOTE-052 in senior patients (pts) with poor performance status

P. Grivas[1], E. Plimack[2], A.V. Balar[3], D. Castellano[4], P.H. O'Donnell[5], J. Bellmunt[6], T. Powles[7], N. Hahn[8], R. de Wit[9], D. Bajorin[10], M.C. Ellison[11], T. Frenkl[11], S.M. Keefe[11], J. Vuky[12]

[1]*Department of Hematology/Medical Oncology, Cleveland Clinic, Cleveland, OH, USA,* [2]*Oncology, Fox Chase Cancer Center, Philadelphia, PA, USA,* [3]*Oncology, Perlmutter Cancer Center, NYU Langone Medical Center, New York, NY, USA,* [4]*Oncology, Hospital Universitario 12 de Octubre, Madrid, Spain,* [5]*Oncology, The University of Chicago Medical Center, Chicago, IL, USA,* [6]*Medicine, Dana-Farber Cancer Institute, Boston, MA, USA,* [7]*Centre for Experimental Cancer Medicine, Barts Cancer Institute, London, UK,* [8]*Oncology, Johns Hopkins University Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD, USA,* [9]*Oncology, Erasmus MC Cancer Institute, Rotterdam, Netherlands,* [10]*Oncology, Memorial Sloan Kettering Cancer Center, New York, NY, USA,* [11]*Medical Oncology, Merck & Co., Inc., Kenilworth, IL, USA,* [12]*Oncology, Oregon Health & Science University, Portland, OR, USA*

Background: Advanced UC is most often seen in senior pts, in whom age-related complications such as renal dysfunction and poor performance status (PS) preclude ~50% from receiving standard first-line cisplatin treatment. In the phase 2 KEYNOTE-052 trial (NCT02335424), first-line pembro had clinically meaningful antitumor activity (ORR, 24%) and was well tolerated in cisplatin-ineligible pts with UC. Results from the subgroup of pts who were considered senior (≥65 y or ≥ 75 y) and had ECOG PS 2 are presented.

Methods: Pts were cisplatin ineligible and had advanced UC, measurable disease (per RECIST v1.1), ECOG PS 0-2, and no prior systemic chemotherapy. Pts received pembro 200 mg Q3W. Radiographic imaging was performed at wk 9, then Q6W for the first year, and Q12W thereafter. The primary end point was ORR (RECIST v1.1, independent radiology review).

Results: Of 370 pts, 302 (82%) were ≥65 y, 179 (48%) were ≥75 y, 120 (32%) were ≥65 y with ECOG PS 2, and 78 (21%) were ≥75 y with ECOG PS 2. Median follow-up was 5 mo. ORR (95% CI) was similar to that reported in the overall study population regardless of age cutoff (Table). Poor PS did not impact ORR in senior pts (Table). 6-mo PFS rates were consistent across senior groups (Table). 64% (≥65 y), 66% (≥75 y), 58% (≥65 and ECOG PS 2), and 64% (≥75 y and ECOG PS 2) of pts experienced treatment-related AEs. 16% of pts ≥65 and ≥75 y and 17% of pts ≥65 and ≥75 y with ECOG PS 2 experienced grade ≥3 treatment-related AEs.

Conclusions: Results from subgroup analyses of senior pts with poor PS in KEYNOTE-052 confirm that first-line pembro elicits clinically meaningful responses consistent with the overall study population. Pembro is well tolerated in cisplatin-ineligible pts with UC, including those who are senior with poor PS.

Graham Cancer Center, Christiana Care Health System, Newark, NJ, USA,* [9]*Department of Medicine, Icahn School of Medicine at Mount Sinai, New York, NY, USA,* [10]*Oncology, Immunomedics, Inc., Morris Plains, NJ, USA*

Background: Pts with metastatic UC have limited therapy options. Immune checkpoint inhibitors (CPI) are now given to patients with advanced UC, but only about 25% respond. We are studying the safety and efficacy of sacituzumab govitecan (IMMU-132), an anti-Trop-2/SN-38 antibody-drug conjugate, in pts with UC refractory to other therapies.

Methods: In this phase I/II study (NCT01631552), pts with metastatic UC who progressed after ≥1 prior systemic therapy were treated with IMMU-132 at 10 mg/kg on days 1 and 8 of 21-day cycles, until progression or unacceptable toxicity. All intention-to-treat (ITT) pts, including those who relapsed/progressed after CPI therapy, are evaluated for safety, ORR by RECIST 1.1 (confirmed PR/CR), PFS, and OS. Response-evaluable (RE) pts received ≥ 2 doses and ≥ 1 post-baseline CT (RECIST 1.1) assessment.

Results: 41 pts (39M/2F; median age 68 y, range 50-91) were enrolled (RE = 36); ECOG 0/1: 31%/69%; median of 3 (range 1-6) prior therapies, including 34/41 platinum and 15/41 CPI regimens. Metastatic sites: lymph node 68%, lungs 54%, liver 32%, bone 27%; overall visceral disease, 31/41 (76%). Pts received a median of 12 (range 1-58) doses. ORR in the ITT population was 34% [14/41 (1 CR, 13 PR); ORR was 39% in the RE group, including 5/13 (39%) with liver mets]; 14 SD (39%); 8 PD (20%), and 5 inevaluable. In responders, 13/14 had prior platinum, 8/14 (57%) ≥3 prior therapies, and 4 prior CPI [4/13 in the RE group (31%), where IMMU-132 was ≥4th line of therapy in 11/13 pts]. Median time to response: 1.9 mos. Median duration of response: 12.9 mos (95%CI, 5.1-12.9), with 8/14 continuing therapy. Clinical benefit rate (CR+PR+SD≥6 mos) is 44%; 56% for SD ≥ 4 mos. In the 41 ITT pts, median PFS and OS are 7.2 (95% CI, 5.0-10.7) and 15.5 mos (95% CI, 8.9-17.2), respectively. Grade ≥3 adverse events ≥5% were 28% neutropenia, 9% febrile neutropenia, 9% fatigue, 9% anemia, 6% diarrhea.

Conclusions: With an ITT ORR of 34%, PFS of 7.2 mos, OS of 15.5 mos, and duration of response of 12.9 mos in 41 unselected pts with advanced pretreated UC (median of 3 prior therapies), these interim results show IMMU-132 is a promising agent in pts relapsed/refractory to chemotherapy and immune checkpoint inhibitors.

Background: Fibroblast growth factor receptor (FGFR) signaling is deregulated in urothelial carcinomas (UC). Rogaratinib is an oral inhibitor of FGFRs 1-4 with demonstrated antitumor activity in bladder cancer xenograft models. We report the results from a rogaratinib phase I trial expansion cohort in UC patients selected based on FGFR1-3 mRNA tumor overexpression and/or presence of activating mutations in the FGFR3 gene.

Methods: Patients with locally advanced or metastatic UC who have progressed or ineligible for standard therapy were screened for high FGFR1-3 mRNA expression levels by RNA *in situ* hybridization (RNAscope®) and Nanostring® assays utilizing fresh or archival FFPE tumor specimens. FGFR3-activating mutations were evaluated by a PCR based assay (Qiagen). Patients were treated with rogaratinib 800mg BID on a continuous regimen. Tumor response was assessed by RECIST, v1.1. Adverse events were classified using CTCAE v4.03 criteria.

Results: Biopsies from a total of 109 patients with advanced UC were screened, with 42.3% found to be FGFR positive; of which 87% due to FGFR3 mRNA overexpression, 4% FGFR1, and 9% mixed FGFR isoform mRNA expression. Co-ocurrence of FGFR3-activating mutations and high FGFR3 mRNA expression was seen in 8% of patients. Among 20 patients with UC treated with rogaratinib, 16 (75%) had tumor shrinkage in target lesions with 9 (45%) showing tumor shrinkage of more than 20%, and 6 (30%) having a partial response (PR). Disease control rate (CR+PR+SD>12w) was 75%. Three patients with a PR had elevated tumor FGFR3 mRNA levels without corresponding genomic alterations. The most frequent AEs were hyperphosphatemia and diarrhea.

Conclusions: Selection of UC patients for treatment with rogaratinib based on FGFR1-3 mRNA expression levels in archival tissue was feasible and identified patients benefitting from treatment without having aberrations of FGFR-encoding genes. Rogaratinib has a favorable safety profile and showed anti-tumor activity in biomarker-selected UC patients which warrants further clinical development.

860P Phase II California cancer consortium trial of gemcitabine-eribulin combination (ge) in cisplatin ineligible patients (pts) with metastatic urothelial carcinoma (mUC): Efficacy report (NCI-9653; 1UM1CA186717, NO1-CM-2011-00038)

S. Sadeghi[1], S. Groshen[2], R.A. Parikh[3], A. Mortazavi[4], T. Dorff[1], C. Hoimes[5], L. Doyle[6], D.I. Quinn[1], E. Newman[7], P. Lara[8]

[1]Oncology, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA, USA, [2]Preventive Medicine-Biostatistics, University of Southern California, Keck School of Medicine, Los Angeles, CA, USA, [3]University of Pittsburgh Medical Center, Pittsburg, PA, USA, [4]Internal Medicine, James Cancer Hospital and Solove Research Institute, Columbus, OH, USA, [5]Hematology and Oncology, Case Western Reserve University and University Hospitals Seidman Cancer Center, Cleveland, OH, USA, [6]NCI, National Cancer Institute, Bethesda, MD, USA, [7]Oncology, City of Hope, Duarte, CA, USA, [8]Medical Oncology, University of California Davis Cancer Center, Sacramento, CA, USA

Background: Cisplatin-based regimens are the mainstay of treatment (tx) for mUC. Unfortunately, pts with mUC are often elderly and have comorbid conditions that preclude cisplatin-based tx. This CTEP-sponsored trial seeks to assess the efficacy and tolerability of GE in this population.

Methods: A Simon 2 stage design was employed (7 + 14). To proceed to full accrual first stage required 2 or more confirmed responders- complete (CR) or partial (PR) response. To be a positive trial, 7 responders were required. Tx consisted of Gemcitabine 1gm/m2 and Eribulin 1.4mg/m2, both on Day (D) 1 and D8 of a 21-D cycle and continued until progression (PD) or unacceptable toxicities. Cisplatin ineligibility was defined as creatinine clearance (CrCl) <60 (but ≥30) ml/min, grade 2 neuropathy, or grade 2 hearing loss.

Results: Between 6/2015 and the report cutoff date of 5/2017, 24 eligible pts with a median age of 73 (range: 62-88) were enrolled. Demographics: 20 males, 4 females. ECOG performance status of 0/1/2 was seen in 11/11/2 pts. Sites of disease included: nodes 16, lungs 8, liver 7, bladder 5, bones 2. Median number of cycles was 3.5 (range 1-16). 2+ confirmed PRs in the first 7 pts allowed the trial to proceed to full accrual. Of 19 evaluable pts, 2 had a CR, 10 had a PR, 5 had SD and 1 had PD. The objective response rate (ORR) was 63%. Overall survival (OS) 14.9 months (5.6, 21.9+) and progression free survival (PFS) was 6.9 months (5.3, 16.1+). Duration of response (DOR) was 4.6 months (range: 0.5, 15.0). Among the first 21 pts 7 had a PR and 2 had a CR and 5 were inevaluable for response, with an ORR of 43%. All 24 pts were evaluable for toxicities; the most common any grade toxicities included fatigue 83%, neutropenia 75%, anemia 63%, alopecia 50%, elevated AST 46%, constipation and nausea 42% each and thrombocytopenia 36%.

Conclusions: GE exceeded the threshold for efficacy in this trial. The endpoints of ORR, OS and PFS compare favorably to the commonly used regimens in this setting such as gemcitabine-carboplatin with a confirmed ORR of 36.1% and OS of 9.3 months. These data support further development of this combination in pre-and post immunotherapy settings.

861P Expression of long non-coding RNA MFI2-AS1 is a strong predictor of recurrence in sporadic localized clear-cell renal cell carcinoma

R. Flippot[1], R. Mouawad[1], J-P. Spano[1], M. Rouprêt[2], E. Compérat[3], M-O. Bitker[2], J. Parra[2], C. Vaessen[2], F. Allanic[1], Q. Manach[2], N. Tannir[4], D. Khayat[1], X. Su[5], G. Malouf[1]

[1]Medical Oncology, Groupe Hospitalier Pitié Salpetriere, Paris, France, [2]Urology, Pitié-Salpêtrière Hospital, Paris, France, [3]Pathology, Tenon Hospital, Paris, France, [4]Genitourinary Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA, [5]Biostatistics and computational biology, MD Anderson Cancer Center, Houston, TX, USA

Background: Improved patient stratification is a challenge in adjuvant clear-cell renal cell carcinoma (ccRCC) trials. Long non-coding RNAs (lncRNAs) are genome-wide regulators with potent prognostic value. We aimed to predict risk of ccRCC recurrence based on lncRNA expression from two independent cohorts.

Methods: Identification of prognostic lncRNAs was performed in a training set of 351 samples of localized ccRCC from the Cancer Genome Atlas, using Cox regression based on disease-free (DFS) and overall survival. Functional annotation of differentially expressed genes according to lncRNA expression was performed. The validation cohort included 167 localized ccRCC patients. Gene expression was studied by qRT-PCR. Kaplan-Meier estimators and Cox regression models were used for survival and multivariate analyses. Primary endpoint was DFS.

Results: MFI2-AS1 was best candidate lncRNA in the developmental study. Its expression was associated with immune response genes expression. In the validation cohort, MFI2-AS1 expression was associated with shorter DFS (Hazard Ratio (HR) for relapse 3·5, $p = 0·0001$), independently from Leibovich recurrence classification and grade. Combined with Leibovich classification, MFI2-AS1 status improved prediction of recurrence, with a C-index of 0·70 compared to 0·67 for MFI2-AS1 alone and 0·66 for Leibovich classification alone. In patients with aggressive tumors (Leibovich ≥ 5), MFI2-AS1 expression was associated with a dramatically increased risk or relapse (HR 12·16, $p < 0·0001$) compared to patients with undetectable MFI2-AS1 who had ultimately favorable outcomes. MFI2-AS1 expression was also correlated with high tumor burden.

Conclusions: MFI2-AS1 is a potent predictor of recurrence in localized ccRCC. Combined with historical classifications, it provides a highly accurate patient stratification that may be useful in adjuvant settings.

862P Treatment and outcome after Immune checkpoint inhibitors (ICI) in metastatic Urothelial Carcinoma (mUC): A European perspective

A. Gomez de Liano Lista[1], A. Necchi[2], P. Lavaud[3], J. Carles Galceran[4], D. Castellano[5], A. Ravaud[6], I. Duran[7], N. van Dijk[8], P. Giannatempo[2], Y. Loriot[3], R. Morales Barrera[9], G. De Velasco Oria De Rueda[5], F. Lefort[6], G. Martínez Bernal[7], D. Raggi[2], M. Gross-Goupil[10], T. Powles[1], M. van der Heijden[8]

[1]Oncology, St. Bartholomew's Hospital, London, UK, [2]Medical Oncology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [3]Oncology, Institut Gustave Roussy, Villejuif, France, [4]Medical Oncology, Vall d'Hebron University Hospital, Barcelona, Spain, [5]Medical Oncology, University Hospital 12 de Octubre, Madrid, Spain, [6]Medical Oncology, Bordeaux University Hospital, Bordeaux, France, [7]Medical Oncology, Hospital Universitario Virgen del Rocio, Seville, Spain, [8]Medical Oncology, Het Nederlands Kanker Instituut Antoni van Leeuwenhoek (NKI-AVL), Amsterdam, Netherlands, [9]Oncology, Vall d'Hebron University Hospital, Barcelona, Spain, [10]Medical Oncology, CHU Bordeaux Hopital St. André, Bordeaux, France

Background: PD-1/PD-L1 inhibitors are changing the current landscape of mUC. Outcomes after discontinuation of ICI are unclear in this population.

Methods: Data from 8 European institutions was retrospectively collected. Target population was patients progressing on ICI. Univariate and multivariate analysis for overall survival (OS, calculated from the last date of ICI until death from any cause) as well as potential predictive factors of response to post-progression therapy (ppT) were performed. Tests were two-sided.

Results: From March 2013 to April 2017, 291 patients were identified. 227 (78%) experienced progression (PD) on ICI. Median post-progression OS of ICI was 5 months (95% CI 3.7-6.3), being 8.6 (95%CI 7.5-9.7) if receiving ppT vs 1.8 (95%CI 1.5-2.1) if best supportive care alone ($p < 0.001$, HR 0.23, 95%CI 0.16-0.32). OS increased according to number of lines received after PD ($p < 0.001$, HR 0.29, 95%CI 0.21-0.39). In the multivariate analysis, shorter duration of ICI, visceral metastases and female sex correlated with worse OS. Prior response to ICI was associated with improved OS in the univariate analysis only. Use of cisplatin-based chemotherapy, location of primary tumor, histology and age did not modify OS. Of patients progressing on ICI, 95 (42%) received subsequent treatment: 84% had 1 systemic line, 14% 2, and 2% 3 lines. RR to 1st ppT was 49% vs 21% for 2nd line or beyond. Median OS was 7.8 months when 1 line of therapy was received after ICI (95%CI 6.6-8.9) vs 18 (95%CI 8.5-27.4) when 2 or more (HR 0.29, p 0.02). Prior exposure to CT (OR 0.19, $p = 0.003$) and shorter duration of ICI (OR 0.24, $p = 0.012$) were correlated with worse RR in the multivariate study. Prior exposure to chemotherapy (CT) did not impact in the OS of these patients. RR to 1st line CT was 56% when used before exposure to ICI vs 66% when used after (p 0.3). Details on patient characteristics, univariate and multivariate analysis will be presented.

Conclusions: Many patients do not receive subsequent chemotherapy, including CT-naive patients. Patients who receive post-ICI therapy have good outcomes. ICI does not appear to confer resistance to CT. Retrospective analysis is prone to bias.

ORR, % (95% CI) [n/N]		
Overall population	26 (13, 43) [9/35]	20 (9, 36) [8/40]
PD-L1+ population	23 (8, 45) [5/22]	22 (9, 42) [6/27]
Median PFS, mo (95% CI)	1.6 (1.4, 4.2)	2.2 (1.4, 3.5)
Median OS, mo (95% CI)	11.4 (5.7, NE)	6.3 (3.6, 12.3)
12 mo OS, % (95% CI)	44.1 (27.2, 59.8)	38.5 (23.5, 53.3)

AE, adverse event; CI, confidence interval; mo, month; NE, not estimable; ORR, overall response rate; PFS, progression-free survival; SAE, serious adverse event; OS, overall survival.

2015 showed activation of Bruton tyrosine kinase (BTK) in myeloid cells of the pancreatic tumor microenvironment. As myeloid suppression impairs T-cell anti-tumor function, BTK inhibition may augment checkpoint inhibitor T-cell activation. This study assessed safety and efficacy of the PD-1 inhibitor pembrolizumab (P) alone or with the BTK inhibitor acalabrutinib (PA) in mUC.

Methods: Patients (pts) with mUC who progressed with ≥1 line of platinum chemotherapy were randomized 1:1 to P (200 mg Q3W IV) or PA (200 mg Q3W+100 mg BID PO). Pts who progressed (irRECIST) with monotherapy were permitted to cross over to combination therapy. Primary objectives were safety and ORR (local review, RECIST 1.1). Secondary endpoints included PFS and OS. Tumor PD-L1 expression was evaluated by Q^2Solutions.

Results: Between Jun 2015 and Jan 2016, 75 pts were treated with P (n = 35) or PA (n = 40); cross over, n = 10. Median age, 66 y; men, 76%; ECOG PS 0-1, 97%; median prior therapies, 2 (range, 1-4). In P/PA median (mos) time on study treatment, 2.96/1.94; median follow-up, 11.2/6.1. Grade 3-4 treatment-emergent AEs (%) in ≥ 15% of P or PA was anemia (20) in P and fatigue (23), increased alanine aminotransferase (23), urinary tract infection (18), and anemia (15) in PA. There were 3 fatal AEs in PA: hemoptysis and sepsis (unrelated); pneumonia (P-related). ORR was 26% (CR, 9%) with P and 20% (CR, 10%) with PA. Median PFS was similar between treatment arms; median OS was 11.4 and 6.3 mos in P vs PA (Table). Most pts (49/60) had PD-L1+ tumors; expression was not associated with improved ORR (Table).

Conclusions: Most pts tolerated the study treatment, although more PA-treated pts had grade 3-4 AEs. Acalabrutinib plus pembrolizumab did not improve ORR over pembrolizumab alone in pts with mUC, regardless of PD-L1 status.

864P Long non-coding RNAs are differentially expressed between bladder cancer subtypes

R. Sébastien[1], E. Rempel[2], T.S. Worst[3], M. Eckstein[4], A. Steidler[3], C.A. Weiss[5], C. Bolenz[6], A. Hartmann[7], P. Erben[3]

[1]Department of Oncology and Hematology, Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany, [2]Division of Signaling and Functional Genomics, Heidelberg University, Heidelberg, Germany, [3]Department of Urology, Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany, [4]Institute of Pathology, University Erlangen-Nuremberg, Erlangen, Germany, [5]Institute of Pathology, Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany, [6]Department of Urology, University of Ulm, Ulm, Germany, [7]Department of Pathology, University Erlangen, Erlangen, Germany

Background: The recent identification of molecular bladder cancer subtypes by whole transcriptome studies showed similarities to molecular breast cancer phenotypes. We here validate these subtypes with a sensitive 36 gene nCounter screening and analyse relevant lncRNA for their differential expression.

Methods: RNA has been extracted from chemotherapy-naïve muscle-invasive bladder cancer (MIBC) after radical cystectomy (follow-up: 12 years, n = 48). A multiple marker gene panel has been quantified with the nCounter technology. *In silico* validation of the classifier geneset on 170 MIBCs has been performed. All squamous carcinoma were excluded. LncRNAs were analyzed in a clustering-independent assessment. Multivariate analyses were performed by a Cox proportional hazards model.

Results: 36 consensus genes were generated by Venn diagrams based on the Mannheim, Lund, Chungbuk and MDA cohorts. This minimal set of genes generated 3 stable clusters: basal, luminal and infiltrated. The subtype specific assessment of 14 lncRNAs relevant in bladder cancer showed a highly subtype specific expression for 9 lncRNAs. The infiltrated subtype, characterized by an activated p53 downstream signature, showed an overexpression of SRA1 and MEG3 ($p \leq 0.003$) - the latter is known for promoting the expression of TP53. The lncRNAs H19, GAS5, TUG1 and CBR3-AS1 showed a significant upregulation in the luminal subtype ($p < 0.05$) whereas SNHG16 showed an exclusive suppression. MALAT1 was suppressed in the basal subtype. A distinct cutoff of the lncRNA H19 allowed a risk stratification into high- and low-risk patients. The luminal subtype and H19 were the only independent risk factors in multivariate analysis adjusted for TNM and were predictive for a 3- to 4-fold higher risk of death ($p < 0.03$).

Conclusions: In this study, MIBC subtypes have been validated by a sensitive quantification method. Molecular subtypes and H19 prove to be independent risk factors superior to TNM. This study demonstrates for the first time a differential expression of lncRNA between MIBC subtypes. The potential impact of lncRNA on phenotype determination has to be investigated in vivo.

Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Warsaw, Poland, [8]Urology, Penn State Health Milton S. Hershey Medical Center, Hershey, PA, USA, [9]Urology, UT M.D. Anderson Cancer Center, Houston, TX, USA, [10]Urology, UT Southwestern Medical Center, Dallas, USA, [11]Urology, Pitié-Salpêtrière Hospital, Paris, France, [12]Urology, Vita Salute San Raffaele University, Milan, Italy, [13]Urology, IRCCS San Raffaele, Milan, Italy, [14]Urology, Cochin Hospital, Assistance-Publique Hôpitaux de Paris, Paris, France, [15]Urology, Medical University of Vienna, Vienna, Austria

Background: In patients (pts) with upper tract urothelial carcinoma (UTUC) the benefit of adjuvant chemotherapy (ACT) after radical nephroureterectomy (RNU) is debated. We aimed to analyze the benefit of ACT vs observation (Obs) in an international study.

Methods: Data from 15 centers was collected, totalling 1,544 pts, treated between 2000 and 2015. Criteria for pt selection were: UTUC diagnosis, pT2-4N0/x and/or pN+ stage undergoing RNU. The standardized differences (SD) approach was used to compare subgroup characteristics. Overall survival (OS) was the primary endpoint. The adopted propensity scores (PS) techniques included 1:1 PS matching and inverse probability of treatment weighting (IPTW). Additionally, the IPTW analysis was performed with the inclusion of the covariates, i.e. with doubly robust estimation (DREP). 6-month landmark analysis (LA) was also performed.

Results: A total of 312 pts received ACT and 1,232 observations. Despite differences between the two groups, SD was generally <10% after matching. In the DREP-adjusted comparison, ACT was significantly associated with shorter OS (HR: 1.25, 95%CI: 1.02-1.54, p = 0.032), while no difference was observed in the matched analysis (HR: 1.14, 95%CI: 0.91-1.43, p = 0.268, table). These findings were confirmed in subgroup analyses (pT2N0/x; pT3-4N0/x; pTanyN+), and after LA. Relapse-free survival outcomes were overlapping to OS in the matched analyses (ACT, HR: 1.59 (95%CI: 1.25-2.02, $p < 0.001$). The limitations of the retrospective studies should be acknowledged.

Conclusions: ACT does not improve OS compared to Obs in pT2-4 and/or pN+ UTUC. These findings contribute to the uncertainties regarding ACT in UTUC and further support the need for dedicated prospective trials in UTUC, new more potent therapies, and enhanced pt selection criteria.

Background: Cisplatin-based chemotherapy is the treatment of choice in aUTC. Nevertheless, about 50% of patients are unfit for this treatment. Long-term survival of patients with aUTC has not been adequately studied outside the context of clinical trials. In addition, the impact of cisplatin utilization on long-term survival has not been adequately addressed. We used a multinational database to study long-term survival and the impact of treatment type in unselected aUTC patients as well as to provide benchmarks for future trials.

Methods: Selection criteria: Diagnosis of aUTC, non small-cell histologies, administration of 1st-line chemotherapy, survival data available. Major end point: Overall survival (OS). Fitness-for-cisplatin (FFC) was defined according to Galsky et al (2011). Landmark and conditional survival analysis was used to study the change of prognosis with time from initiation of 1st-line chemotherapy.

Results: 1361 patients (median fup: 31 months) were analysed. Survival analyses are shown in the table.

Cisplatin therapy and FFC were associated with improved long-term survival. FFC patients have a 28% probability of 5-year survival, which is increased to 74% for the 34% of patients who survive 3-years after initiation of cisplatin-based chemotherapy.

Conclusions: Published criteria for FFC accurately predict for long-term survival of aUTC patients, following cisplatin-based chemotherapy, while patients not treated with cisplatin have inferior outcome. Probability of long-term survival was increased with time after initiation of 1st-line (cisplatin or no-cisplatin) therapy.

867P Correlation of circulating tumor DNA (ctDNA) assessment with tissue-based comprehensive genomic profiling (CGP) in metastatic urothelial cancer (mUC)

B. McGregor[1], S.M. Ali[2], P. Grivas[3], J.S. Ross[4], P.J. Stephens[2], V.A. Miller[2], B. Forcier[2], J. Chung[4], S.K. Pal[5]

[1]Medical Oncology, Dana Farber Cancer Institute, Boston, MA, USA, [2]R & D, Foundation Medicine, Cambridge, MA, USA, [3]Medical Oncology, Cleveland Clinic, Cleveland, OH, USA, [4]Pathology, Foundation Medicine, Cambridge, MA, USA, [5]Medical Oncology, City of Hope, Duarte, CA, USA

Background: Tissue-based CGP reveals a multitude of actionable targets in patients (pts) with mUC (Ross et al Cancer 2015). Assessment of ctDNA from blood offers the benefit of avoiding risks of biopsy/surgery and allows for serial assessment.

Methods: In pts with mUC, 50-100 ng of ctDNA was extracted from plasma during routine clinical care. Using adapted sequencing libraries, hybrid capture and sample multiplexed sequencing was performed with an Illumina HiSeq 2500 platform to a median coverage depth of 6353X. This CLIA-certified test of 62 genes detected genomic alterations (GAs) at low allele frequencies (0.1% for substitutions, 1% for indels/rearrangements and 20% for copy number amplification). In several pts CGP data was available from separate tissue-based CLIA-certified tests for which methods have been previously reported (Frampton *et al* Nat Biotechnol 2013). In addition to examining intra-patient differences, we compared the cumulative frequency of GAs in ctDNA to a large pool of tissue-based CGP in pts with mUC (n = 2024).

Results: 27 pts (18:9 M:F) with mUC had ctDNA assessment; median age 68 (range, 52-86). There was evidence for ctDNA in the blood for 25/27 pts (93%), and at least 1 GA was observed in 20/27 (74%) cases. The most frequently altered genes were TP53 (63%), TERT-promoter (33%), PIK3CA (15%), FGFR3 (11%), NF1 (11%) and ERBB2 (7%). With the caveat of a limited sample size, the cumulative frequency of selected clinically relevant GAs was distinct in ctDNA and tissue. The frequency of FGFR3 alteration was lower in ctDNA as compared to tissue (11% vs 23%), as was the frequency of ERBB2 alteration (14% vs 7%). A pt with FGFR3 GA in baseline tumor tissue showed disappearance of FGFR3 GA and evolution of a TP53 alteration in ctDNA following treatment with an FGFR3 inhibitor. In a pt with ERBB2 and TP53 GAs in baseline tumor tissue, ctDNA collected at the time of resistance to cisplatin-based therapy showed persistence of ERBB2 and TP53 GAs and a new NF1 GA.

Conclusions: Using hybrid capture-based genomic profiling of ctDNA, ctDNA was detected in the vast majority of pts with mUC. Utility was demonstrated through detection of potential resistance mutations in pts receiving chemotherapy and targeted agents.

868P Comparison of circulating tumor DNA (ctDNA) profile in metastatic urothelial carcinoma (mUC) derived from the upper tract (UT) and lower tract (LT)

N. Agarwal[1], S.K. Pal[2], G. Sonpavde[3], L.A. Kiedrowski[4], R.J. Nagy[4], K. Banks[4], R. Lanman[4], P. Grivas[5]

[1]Internal Medicine, Huntsman Cancer Institute, Salt Lake City, UT, USA, [2]Medical Oncology, City of Hope, Duarte, CA, USA, [3]Medical Oncology, University of Alabama at Birmingham Hospital, Birmingham, AL, USA, [4]Medical Affairs, Guardant Health, Redwood City, CA, USA, [5]Medical Oncology, Cleveland Clinic, Cleveland, USA

Background: We have previously reported ctDNA profile in 246 patients (pts) with mUC derived from the LT (mLTUC) (Grivas et al ASCO GU 2017). mUC derived from the UT (mUTUC) is a clinically distinct entity with a more aggressive disease course. The ctDNA profile of mUTUC has not been previously characterized.

Methods: Data was obtained from pts with mUTUC who received ctDNA profiling as a part of routine clinical care using a CLIA-certified, CAP-accredited platform evaluating up to 70 genes. Genomic alterations (GAs) were pooled for the entire cohort. Comparison to the previously reported mLTUC was performed using the chi-square test.

Results: Between Oct 2014 and Apr 2017, ctDNA results from 75 pts (M:F 30:45) with mUTUC were assessed. Median age of the cohort was 69 (range, 40-90). A median of 6.2 months had elapsed from the time of diagnosis with mUC and ctDNA assessment. Genomic alterations (GAs) were detected in 71 pts (95%), with an average/median of 4.5/3 GAs per pt (range, 0-35). Treatment related data was available in 30 pts (40%). The frequency of GAs in mUTUC vs mLTUC was as follows: TP53 (51% vs 52%), PIK3CA (20% vs 18%), ARID1A (16% vs 17%), EGFR (8% vs 13%), ERBB2 (8% vs 7%), FGFR3 (7% vs 11%), BRCA2 (6% vs 7%) and NF1 (6% vs 8%) (P=NS for all comparisons). Alteration types were diverse; for instance, FGFR3 alterations included fusion (FGFR3-TACC3 [n = 5]) and mutation (S249C [n = 3] and Y373C [n = 2]). Correlation of ctDNA profile with treatment and clinical outcome will be presented at the meeting.

Conclusions: Despite representing a clinically distinct entity, mUTUC demonstrated a ctDNA profile similar to that of mLTUC. These data may inform the design of clinical trials of targeted therapy (e.g., FGFR3 and ERBB2 inhibitors) in mUC, suggesting that inclusion of both mUTUC and mLTUC may be warranted.

869P Modeling of Tumor Kinetics and Overall Survival to Identify Predictive Factors for Efficacy of Durvalumab in Patients with Urothelial Carcinoma (UC)

Y. Zheng[1], X. Jin[2], R. Narwal[1], C-Y. D Jin[1], A. Gupta[3], Y. Ben[4], P. Mukhopadhyay[5], B. Higgs[2], L. Roskos[2]

[1]Clinical Pharmacology & DMPK, Medimmune, Mountain View, CA, USA, [2]Clinical Pharmacology, Pharmacometrics and DMPK, MedImmune, Gaithersburg, MD, USA, [3]Clinical Development, MedImmune, Gaithersburg, MD, USA, [4]Immuno-oncology, AstraZeneca, Gaithersburg, MD, USA, [5]Biometrics & Information Sciences, AstraZeneca, Gaithersburg, MD, USA

Background: Durvalumab is a human mAb that binds to PD-L1 and blocks its interaction with PD-1 and CD80. The objectives of this analysis were to describe the longitudinal tumor size profiles, identify factors predicting tumor growth and regression, and associate tumor kinetics with overall survival (OS).

Methods: Longitudinal tumor size and OS data obtained from UC patients (Study 1108; NCT# CD-ON-MEDI4736-1108) who received durvalumab were analyzed using a nonlinear mixed effect model that describe tumor growth, tumor killing, and delay in immune response leading to tumor killing. An OS model was developed by linking model-predicted tumor size over time to survival hazard in a constant hazard model. Potential predictive factors of tumor growth and regression, as well as survival were evaluated in a multivariate covariate analysis in the tumor kinetic and OS model, respectively.

Results: Tumor kinetic and OS models adequately described the longitudinal tumor size and survival data from UC patients. The most influential factor associated with more rapid tumor growth was high baseline neutrophil-to-lymphocyte ratio (NLR), while lymph node disease was associated with decreased growth rate. Tumor (TC) or immune cell PD-L1 expression (IC), baseline tumor size and liver metastasis were identified as predictive factors for tumor killing. Simulations showed increased response rates with higher TC and/or IC (by 6/9%, and 18/24%, with 25% and 50% cutoff for TC/IC, respectively). After accounting for tumor response, the risk of death decreased with higher TC/IC and lower baseline hemoglobin and albumin levels, while liver metastasis, lymph node disease, and prior carboplatin treatment were associated with higher risk.

Conclusions: Tumor kinetic modeling identified factors that predict tumor growth and shrinkage following durvalumab therapy in UC patients, and permits investigation of predictive biomarker strategies considering confounding factors. Joint modeling that associates predicted tumor kinetics with OS allows model-based extrapolation of missing data and evaluation of other factors influencing OS after accounting for change in tumor size over time.

870P Expression of Galectin-1 Determines Tumor Recurrence and Cancer-specific Survival in Patients with pT3 Upper Urinary Tract Urothelial Carcinoma

H.Y-L. Su[1], H-L. Luo[2], C-C. Huang[3], M-C. Hsieh[1]

[1]Hematology Oncology, Chang Gung Memorial Hospital-Kaohsiung, Kaohsiung, Taiwan, [2]Urology, Chang Gung Memorial Hospital-Kaohsiung, Kaohsiung, Taiwan, [3]Radiation Oncology, Chang Gung Memorial Hospital-Kaohsiung, Kaohsiung, Taiwan

Background: Upper urinary tract urothelial carcinoma (UTUC) is an aggressive and lethal disease. For patients with locally advanced UTUC, recurrence of tumor is frequent, and lacks of predictive biologic markers limited the choice of postoperative treatment. Galectin-1 (GAL1) is a β-galactoside-binding protein, participating in many parts of tumorigenesis, including cell proliferation, invasiveness, metastasis, and angiogenesis. However, the role of GAL1 in UTUC has not been fully investigated. The aim of this study was to examine the prognostic impact of GAL1 in patients with UTUC.

Methods: The study enrolled 86 UTUC patients who underwent radical nephroureterectomy and bladder cuff excision with final pathologically diagnosed as pT3N0 stage between January 2005 and December 2012. Perioperative characteristics and pathologic features were recorded. Immunohistochemical staining of tumor specimens using anti-GAL1 antibody were performed. UTUC cell line (BFTC-909) was used for *in vitro* study of tumor invasiveness and migration. Kaplan-Meier analyses and Cox proportional regression models were used for univariate and multivariate survival analyses.

Results: Using 10% expression of GAL1 protein as a cuff-off point, the study population could be classified as GAL1-high (GAL1 $>$ 10%, n = 35) or GAL1-low (GAL1 $\leq$ 10%; n = 51) group. Basic clinicopathologic characteristics were comparable between two groups. In univariate analysis, high GAL1 expression was significantly associated with a worse recurrence-free survival (RFS; $p = 0.028$) and cancer-specific survival (CSS; $p = 0.025$). Multivariate analysis showed GAL1-high is an independent factor for RFS (HR 2.43; 95% CI 1.17-5.05, p = 0.018) and CSS (HR 4.04; 95% CI 1.25-13.03, p = 0.019). In vitro study, we found that knockdown of GAL1 reduced UTUC cancer cell migration and invasion significantly.

Conclusions: Galectin-1 expression is a reliable prognostic factor for locally advanced UTUC. GAL1 inhibition may serve as a potential therapeutic target for patients with UTUC.

871P Identification of genomic features underlying response of muscle-invasive bladder cancer (MIBC) to neoadjuvant sorafenib, gemcitabine, and cisplatin (SGC) in an open-label, single-arm, phase 2 study

D. Raggi[1], A. Paoli[2], M. Dugo[2], P. Giannatempo[1], L. De Cecco[2], M. Colecchia[3], M.G. Daidone[4], A. Necchi[1], M.L. Sensi[2]

[1]*Medical Oncology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy,* [2]*Functional Genomics Unit, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy,* [3]*Pathology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy,* [4]*Experimental Oncology and Molecular Medicine, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: Genomic analyses demonstrated that MIBC can be grouped into molecular subtypes that portend different outcomes with neoadjuvant chemotherapy (NACT). SGC was active in MIBC, showing a response rate (downstaging to pT $<$ 2) of 54.3% in 46 patients (pts) in a phase 2 trial (NCT01222676, *Necchi et al, GU ASCO 2017*). We analyzed gene expression profiles (GEP) and copy number variations (CNV) of transurethral resections (TURB) from these pts.

Methods: We analyzed 25 pts, 18 responders (R) and 7 non-responders (NR). GEP and CNV profiles were generated using Affymetrix Clariom™ D and OncoScan™ assays. Samples were assigned to claudin-low (CL), basal (B) or luminal (L) subtypes according to the BASE47 and BCL40 signatures. Genes differentially expressed or amplified/deleted between NR and R were functionally analyzed using Ingenuity Pathway Analysis (IPA) and Gene Set Enrichment Analysis.

Results: Transcriptional subtypes were robustly assigned to 24/25 pts: 13 were classified as L, 10 CL and 1 B. A significant association between subtypes and therapeutic response was observed (p = 0.002), with all L samples falling in the R group while CL were split between R and NR (5 *vs* 5). To avoid confounding related to the subtype we restricted the comparison of R and NR to CL samples. Through the use of IPA we identified activation of an IRF7-driven transcriptional program (p = 3.88E-12) in NR samples. In the NR group we found a positive enrichment of gene sets related to mRNA processing, cell cycle and oxidative phosphorylation and a negative enrichment of defensins. In addition, 19 genes were both significantly overexpressed and amplified in NR whereas copy number gains on chromosome 17, 18 and 20 characterized R samples. Limitations include the unassessable role of S contribution to GC.

Conclusions: Altogether, the results indicate that L tumors are responsive to SGC. Comparisons between R and NR within the CL group outlined potential genomic predictors of response. Once validated, pt selection criteria for NACT may be substantially improved. Comparison with profiling of response to NA pembrolizumab will be shown (NCT02736266).

Background: C inhibits tyrosine kinases that promote oncogenesis and resistance to antiangiogenic therapy in RCC, including MET, AXL, and VEGF receptors. In the phase 3 METEOR trial (NCT01865747), C significantly improved progression-free survival (PFS), overall survival (OS), and objective response rate (ORR) vs E in patients (pts) with advanced RCC after prior VEGFR-targeted therapy (Choueiri, Lancet Oncol 2016). The current study evaluated outcomes based on plasma biomarker levels.

Methods: Plasma samples collected at baseline and during treatment from 621 of 658 randomized pts were analyzed for HGF, MET, Gas6, AXL, VEGF, VEGFR2, CA9, and IL-8 by ELISA (Assay Gate, Ijamsville, MD). PFS and OS were analyzed based on low vs high ($<$ median vs $\geq$ median) biomarker levels at baseline.

Results: Analyses of PFS and OS based on baseline biomarker levels showed improvement with C vs E (hazard ratio $<$1) for all analyses of both low and high levels. PFS improvement for C vs E was most pronounced for low baseline levels of AXL and VEGF, while OS improvement for C vs E was most pronounced for low baseline levels of HGF, Gas6, AXL, and VEGF (Table). For a subset of biomarkers, medians for PFS and OS were longer for low baseline levels vs high for both treatment arms. Differences in OS medians for low vs high levels were largest for HGF (not reached [NR] vs 15.4 mo for C; 19.4 mo vs 13.0 mo for E), Gas6 (NR vs 17.2 mo for C; 18.4 mo vs 13.9 mo for E), VEGF (NR vs 16.1 mo for C; 18.4 mo vs 14.9 mo for E), and IL-8 (NR vs 17.2 mo for C; 19.4 mo vs 13.0 mo for E).

Table: 872P

Plasma Biomarker	C vs E, Hazard Ratio (95% CI) for OS	
	Low Biomarker	High Biomarker
HGF	0.48 (0.32, 0.70)	0.74 (0.56, 0.99)
MET	0.67 (0.48, 0.94)	0.62 (0.46, 0.84)
Gas6	0.53 (0.37, 0.75)	0.76 (0.56, 1.02)
AXL	0.54 (0.38, 0.76)	0.78 (0.58, 1.06)
VEGF	0.51 (0.36, 0.74)	0.78 (0.58, 1.04)
VEGFR2	0.63 (0.46, 0.86)	0.68 (0.49, 0.94)
IL-8	0.62 (0.43, 0.88)	0.69 (0.51, 0.93)

Conclusions: PFS and OS improved with C irrespective of baseline plasma biomarker levels in previously treated pts with advanced RCC vs E. However, low baseline levels of a subset of biomarkers were associated with better clinical outcomes with C.

873P RX-3117, an oral hypomethylating agent to treat advanced solid tumors (st): Interim results from an ongoing phase 2a study in advanced urothelial cancer

M.C. Maia[1], S.K. Pal[1], S.T. Tagawa[2], V. Chung[1], J. Picus[3], S. Gupta[4], J. Poore[5], C. Peterson[5], E. Benaim[6]

[1]Department of Medical Oncology & Experimental Therapeutics, City of Hope, Duarte, CA, USA, [2]Genitourinary Oncology, Weill Cornell Medical College, New York, NY, USA, [3]Internal Medicine, Washington University School of Medicine, St. Louis, MO, USA, [4]Division of Hematology, Huntsman Cancer Institute, Salt Lake City, UT, USA, [5]Clinical Operations, Rexahn Pharmaceuticals, Inc, Rockville, MD, USA, [6]Oncology, Rexahn Pharmaceuticals, Rockville, MD, USA

Background: RX-3117 is an oral small-molecule hypomethylating agent, cyclopentyl pyrimidyl nucleoside that is activated by uridine cytidine kinase 2. RX-3117 shows efficacy in various xenograft models, including those of gemcitabine resistant bladder and colorectal cancers. Data from the stage 1 of a Phase 2a clinical study of RX-3117 as a single agent in subjects with advanced urothelial cancer are described below.

Methods: This Phase 2a study with a 2-stage design (NCT02030067) evaluates the efficacy of RX-3117 in eligible subjects (aged $\geq$ 18 years) with advanced urothelial cancer previously treated with an unlimited number of prior therapies. Primary objectives include safety and efficacy of the recommended Phase 2 dose (RP2D) and schedule identified in the Phase 1 portion of the study. Subjects received 700 mg of oral RX-3117 daily for 3 weeks with 1 week of rest in each 4-week cycle. The response criteria of complete response or partial response in 1 or more subjects or stable disease for 4 cycles in 2 or more subjects in Stage 1 in order to proceed to Stage 2.

Results: As of May 2017, 10 subjects with advanced urothelial cancer were treated with RX-3117 (4 females, 6 males). Of those 10 subjects, 70% received $\geq$ 3 prior therapies, had performance score of 0-1 and multiple disease sites (lung, liver, lymph nodes and pelvis). Two subjects met the protocol defined response criteria of stable disease for 4 cycles of RX-3117 treatment; one subject received treatment for 168 days and another subject continues receiving therapy (147 days at abstract submission). In addition, 1 subject showed tumor shrinkage as measured by RECIST (-15%); another subject still on treatment showed a 19% tumor reduction after 2 cycles of RX-3117. Related adverse events were G2 anemia, G1 anorexia, G1 epistaxis, G1 fatigue, G1 nausea, G1 diarrhea, G1/G2 vomiting, G2 mucositis, G3 leukopenia, G1/G3 neutropenia, and G3 thrombocytopenia. One subject had a treatment delay and dose reduction.

Conclusions: Single agent RX-3117 appears to be safe and well tolerated and shows evidence of preliminary tumor activity. The predefined efficacy criteria was met in Stage 1, and Stage 2 is ongoing. Results from Stage 1 of the phase 2a will be presented.

874P Immune correlates for the efficacy of PEGylated Human IL-10 (AM0010) with nivolumab in renal cell cancer

A. Naing[1], J.R. Infante[2], D.J. Wong[3], M.W. Korn[4], R. Aljumaily[5], K. Papadopoulos[6], K. Autio[7], S. Pant[8], T.M. Bauer[9], A. Drakaki[10], N. Daver[11], A. Hung[12], P. Van Vlasselaer[12], G. Brown[12], M. Oft[12], N. Tannir[11]

[1]Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA, [2]Medical Oncology, Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN, USA, [3]Department of Medicine, University of California, Los Angeles, Los Angeles, CA, USA, [4]Cancer Center, UCSF, San Francisco, CA, USA, [5]Hematology/Oncology, Oklahoma University Medical Centre, Oklahoma City, OK, USA, [6]Oncology, South Texas Accelerated Research Therapeutics (START), San Antonio, TX, USA, [7]Genitourinary Oncology, MSKCC, New York, NY, USA, [8]Oncology, College of Pharmacy, OUHSC, Oklahoma City, OK, USA, [9]Drug Development Unit, Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN, USA, [10]Medicine and Urology, UCLA Medical Center, Los Angeles, CA, USA, [11]Cancer Center, MD Anderson Cancer Center, Houston, TX, USA, [12]Clinical Development, ARMO BioSciences, Redwood City, CA, USA

Background: At therapeutic concentrations AM0010 stimulates the cytotoxicity, survival and proliferation of CD8 T cells. IL-10 receptors and PD-1 are expressed on activated and exhausted CD8 T cells, providing a rationale for combining AM0010 and an anti-PD-1. AM0010 alone had partial tumor responses (PR) in 4 of 16 pts with poor to intermediate risk RCC. In dose escalation, 4 of 8 RCC patients receiving AM0010 plus pembrolizumab in 3rd line, had a PR. The mPFS was 16.7 months.

Methods: 29 pts with metastatic RCC were enrolled on AM0010 (10 or 20 ug/kg daily SC) and nivolumab (3mg/kg, q2wk IV). Two had favorable, 20 had intermediate and 4 had poor IMDC risk (3 data not available). Pts. had a median of 1 prior therapy (range 1-3), and at least one VEGFR-TKI. Tumor responses were assessed following irRC. Immune related cytokines in the serum, activation of blood derived T cells and clonal identity of peripheral T cell were measured.

Results: AMO010 plus nivolumab or pembrolizumab was well tolerated. TrAEs were reversible and transient. 14 patients on 20ug/kg AM0010 daily SC and nivolumab had at least 1 G3/4 TrAE, including anemia (10), thrombocytopenia (5), hypertriglyceridemia (5). Two pts had a reversible cytokine release syndrome with splenomegaly and increased immune mediated red blood cell phagocytosis most likely precipitated by T-cell activation, as both pts had objective tumor responses. Patients treated with 10ug/kg AM0010 and anti-PD-1 did not have hematologic G3/4 TrAEs. As of May 1 2017, PRs were observed in 9 of 26 evaluable pts (35%). An additional 12 pts have stable disease (46%), 7 of those have a tumor reduction $>$ 30% (in progress). The mPFS and mOS has not been reached, the mFU is 7.7 months (range 0.5-13.7). AM0010 + anti-PD1 increased Th1 cytokines in the serum, proliferation of PD1+ Lag3+ CD8 T cells and oligoclonal expansion of novel T cell clones in the blood. The expansion of invigorated T cells and the clonal expansion correlated with tumor responses.

Conclusions: AM0010 in combination with anti-PD-1 is well-tolerated in RCC pts, the recommended phase 2 dose is 10ug/kg. The efficacy and the observed CD8 T cell activation is promising and encourages the continued study of AM0010 in combination with nivolumab.

Background: Patients (pts) with aUC with exclusive bone metastatic spread represent a rare subgroup of pts with unique clinical features. These pts deserve special consideration, as they are usually excluded from clinical trials due to the lack of measurable disease according to RECIST criteria. We focused on their access to treatment and outcomes in a retrospective study.

Methods: Cases were extracted from the pool of 1,911 pts with a diagnosis of mUC from the RISC database (db). Data from 23 centers was collected. Results of 1st-line, platinum-based chemotherapy in bone-only pts were compared with those from the remaining pts in the RISC db. Summary statistics were used to describe pt characteristics and outcomes. Kaplan-Meier method was used to estimate time to event outcomes such as progression-free survival (PFS) and overall survival (OS). Both OS and PFS are measured from the date of diagnosis of metastatic disease. Univariable and multivariable Cox analyses were performed. All tests were two-sided and statistical significance was defined as a p-value $\leq$0.05.

Results: A total of 128 evaluable pts (6.7%), treated between 02/1997 and 04/2013, were identified. ECOG-PS was $\geq$1 in 85.9% vs. 66.3% of the remaining pts from RISC db. 73 (57%) received 1st-line chemotherapy, that was platinum-based in all pts, and 28 of them (38.4%) 2nd-line CT (vs. 75.8% and 42.5%, respectively, from the RISC db). On multivariable analyses, only the chemotherapy administration was significantly associated with improved OS among bone-only mUC pts ($p < 0.001$). Among platinum-treated pts (total evaluable N = 972), significantly-different PFS and OS estimates were observed according to the bone metastases status (no bone metastases vs. bone metastases only vs. bone + other, $p < 0.001$). 2-year PFS was: 37.4%, 28.8%, 25.9%. 2-year OS was: 35.5%, 15.8%, 23.0%, among the above subgroups, respectively.

Conclusions: Pts with bone only metastases are less likely to receive systemic therapy than pts with metastases to other sites, likely due to lower PS. The prognostic impact of having exclusive bone metastases or additional sites seems to be equally poor. Clinical trials with new agents should focus on this population.

876P Efficacy of cabozantinib (C) after PD-1/PD-L1 checkpoint inhibitors in metastatic renal cell carcinoma (mRCC): The Gustave Roussy experience

L. Derosa, J.A. Rouche, E. Colomba, G. Baciarello, B. Routy, L. Albiges, B. Escudier
Medical Oncology, Gustave Roussy, Villejuif, France

Background: Optimal treatment sequence in mRCC remains unclear, although PD-1/PD-L1 inhibitors are becoming standard of care in second or third-line. There is little evidence about the efficacy of antiangiogenic therapies after immune checkpoint inhibitors (ICI), especially of C, which was recently approved for mRCC. We report our initial experience of C efficacy after prior ICI.

Methods: We conducted a retrospective analysis of mRCC patients (pts) enrolled on clinical trials at Gustave Roussy with ICI with a special focus on C as subsequent therapy. Clinical outcome during C treatment, including Time to Treatment Failure (TTF), Objective Response Rate (ORR), Overall Survival (OS) and safety are reported.

Results: After a median follow-up of 60 months (mo), among 127 pts treated with ICI (n: 107; nivolumab), 44 (35%) were still on-treatment and 5 pts had stable disease after treatment interruption. Among the 78 pts who progressed after ICI, 22 pts (28%) never received further treatment. 56 pts (72%) received further therapies: 18 (32%) C, 25 (44%) Axitinib (A) and 13 (24%) other (O). C was given as third-line or beyond in 27% and 73% of pts, respectively. Before starting C, pts were only intermediate or poor prognosis by IMDC criteria. Considering all evaluable pts, ORR was 33%, median TTF was 7.99 mo and median OS was 12.33 mo. Focusing on C, ORR was 42% and no pts presented progressive disease as best response versus 37% for A with 2% progressive disease. Currently, median TTF and OS on C are not yet estimable (0.92-not reached); update on clinical outcome will be presented. Moreover, C demonstrated acceptable safety profile and the rate of treatment discontinuation because of adverse events was 11%.

Conclusions: In mRCC pts previously treated by ICI, treatment with C seems to be very active, irrespective of number of prior treatments or IMDC risk group. Prior PD-1/PD-L1 exposure did not influence safety of subsequent C therapy. Interestingly, activity of A also appears excellent, raising the hypothesis of enhanced efficacy of TKI after ICI.

877P Second-line treatment patterns and outcomes of metastatic bladder cancer patients in clinical practice

K. Flannery[1], J. Black-Shinn[2], M. Boyd[2], N. Robert[2], A. Kamat[3]
[1]Oncology Research, MSD, North Wales, PA, USA, [2]Outcomes Research, McKesson Specialty Health/The US Oncology Network, The Woodlands, TX, USA, [3]Department of Urology, MD Anderson Cancer Center, Houston, TX, USA

Background: There is no universally accepted standard therapy for second-line (2L) treatment of metastatic bladder cancer (mBC). We sought to evaluate treatment patterns and outcomes of patients (pts) receiving 2L treatment for mBC.

Methods: We identified pts receiving initial mBC treatment during an index period from January 2010-June 2014 by review of electronic health records (EHR) of McKesson Specialty Health/US Oncology, with follow-up through July 2016. Patients who subsequently received 2L therapy were included in this analysis. The Kaplan-Meier method was utilized to evaluate outcomes from 2L treatment initiation.

Results: Of 1155 pts receiving 1L treatment during the index period, 391 (33.9%) pts received 2L treatment and were eligible for analysis. The median age was 70 years (range 36-89) and 81.1% were men. Median time to initiation of 2L therapy following mBC diagnosis was 7.8 months(mos). 2L therapy was used in 33.6% of pts who received 1L cisplatin(cis)-based therapies and 34.0% of those who received other 1L therapies. 51.4% of 2L pts received combo-therapy; the common (>5% of total 2L utilization) regimens were carboplatin(carbo)/gemcitabine(gem) (14.8%), carbo/paclitaxel(pac) (12.0%), and cis/gem (7.7%). 48.6% of 2L pts received monotherapy; the common regimens were pac (17.4%), docetaxel (10.5%), pemetrexed (8.2%), and gem (6.6%). For the composite outcome of third-line therapy initiation or death, the median time-to-event for all 2L regimens was 5.2 mos (95% confidence interval [CI], 4.5 to 6.0). Median overall survival (OS) for all 2L regimens was 9.4 mos (95% CI, 8.2 to 11.1). Time-to-event outcomes were significantly different across the various regimens ($p = 0.0005$).

Conclusions: This real-world data provides important insights into patterns of care and outcomes for 2L mBC pts. These results concur with other observational studies in this time frame, suggesting that only one third of 1L mBC pts progress to 2L treatment. Taxane and platinum-based regimens predominated in the 2L, although patterns of treatment were consistent with prior research showing that no clear standard of care exists for these pts. Monotherapy and combination regimens are utilized in equal proportions, both producing poor outcomes for mBC pts.

878P Comparing ITC results from lenvatinib plus everolimus for second-line treatment of advanced/metastatic renal cell carcinoma: Crossover versus no crossover

S. Garib[1], G. Tremblay[1], G. Meier[2], H. McElroy[3], M. Guo[2]
[1]Purple Squirrel, Economics, New York, NY, USA, [2]Eisai, Inc, Woodcliff Lake, NJ, USA, [3]Covance, Pte Ltd, Singapore

Background: An indirect treatment comparison (ITC) involving lenvatinib plus everolimus (LEN+EVE) was conducted using networked data from HOPE 205, CHECKMATE-025, METEOR, AXIS, RECORD-1 and TARGET. The ITC incorporated adjustments for crossover to investigational treatment. Results showed superiority of LEN+EVE over EVE alone; and inferiority versus pazopanib (PAZ) or sunitinib (SUN) alone in overall survival (OS) for second-line treatment of advanced/metastatic renal cell carcinoma. No statistically significant differences in OS were found between LEN+EVE versus nivolumab (NIV), cabozantinib (CAB), axitinib (AXI), or placebo.

Methods: A subsequent analysis was conducted using intention to treat (ITT) to evaluate the impact of crossover correction on OS estimates and additionally to uncover any potential bias due to its absence. Three ITC scenarios were analyzed: A) all comparators plus placebo versus EVE; B) all comparators versus placebo; and C) LEN+EVE versus all comparators.

Results: Scenario "A" showed consistent variance in survival benefit for ITT versus crossover by an average of 20%. Hazard ratios for AXI versus EVE shifted from below null (0.98) to above null (1.27); and mortality risk (placebo vs. EVE) moved 51% further from null (1.15 vs. 1.67). ITT estimates for Scenarios "B" and "C" showed on average 9% and 14% differences in OS benefits, respectively, versus crossover. In Scenario "C", estimates for LEN+EVE versus PAZ or LEN+EVE versus SUN showed superiority with ITT data (0.82 or 0.75) but were inferior (1.2 or 1.09) with crossover.

Conclusions: Bias was observed in naive approaches to survival analysis in the presence of crossover. Failure to account for this in clinical trials may have implications on the comparative effectiveness profile and also on the cost-effectiveness results, and may lead to inconsistent resource allocation decisions.

879P Urine-derived lymphocytes (UDLs) as a non-invasive surrogate marker of tumour infiltrating lymphocytes (TILs) in patients with muscle invasive bladder cancer (MIBC)

Y.N.S. Wong[1], K. Joshi[1], P. Khetrapal[2], M. Ismail[3], J. Linares[4], A.U. Akarca[4], J.L. Reading[1], A. Furness[1], A. Feber[2], U. McGovern[5], C. Swanton[6], A. Freeman[7], T.P. Briggs[2], J. Kelly[2], T. Marafioti[4], K.S. Peggs[1], T. Powles[8], B.M. Chain[3], M. Linch[1], S. Quezada[1]
[1]UCL Cancer Institute, University College London, London, UK, [2]Department of Urology, University College London, London, UK, [3]Division of Infection and Immunity, University College London, London, UK, [4]Department of Cellular Pathology, University College London, London, UK, [5]Medical Oncology, University College London Hospital, London, UK, [6]Translational Cancer Therapeutics, The Francis Crick Institute, London, UK, [7]Department of Histopathology, University College London Hospital, London, UK, [8]Centre for Experimental Cancer Medicine, Barts Cancer Institute, Queen Mary University of London, London, UK

Background: The therapeutic targeting of PD-1 and PD-L1 has led to durable responses in metastatic bladder cancer, yet the majority of patients (pts) fail to respond. Here, we characterised the immune phenotype and TCR repertoire in tumour and UDLs in patients with MIBC for the identification of potential T cell biomarkers of response and resistance to checkpoint blockade.

Methods: Matched bladder tumour, normal urothelium (NU), urine and peripheral blood mononuclear cells (PBMC) were collected from 30 pts undergoing cystectomy. Multi-parametric flow cytometry and immunohistochemistry were used to determine the abundance of $CD8^+$, $CD4^+FoxP3^-$ (CD4eff) and $CD4^+FoxP3^+$ (Treg) T cell subsets and co-inhibitory (PD-1, CTLA-4, TIM-3) and co-stimulatory (ICOS, 4-1BB) immune

checkpoint molecules. T cell receptor (TCR) repertoire was determined using quantitative high throughput sequencing of α and β TCR chains followed by Decombinator bioinformatics analysis.

Results: UDLs were identified in 19/24 (80%) of MIBC pts with tumour *in situ* compared to 3/6 (50%) pts with pathological downstaging (pT0) following neo-adjuvant therapy. Urine, tumour and PBMC specimens were found to have a similar CD8/Treg ratio that was significantly higher in NU. Co-stimulatory and co-inhibitory checkpoint molecules were similarly distributed across $CD8^+$, CD4eff and Treg within tumour, urine and NU compartments, however significantly different to PBMC, irrespective of prior treatment. Preliminary analysis revealed a higher degree of similarity between the TCR repertoires of urine and matched tumour as compared with urine and NU or urine and PBMC samples.

Conclusions: These data suggest that UDLs are an accessible source of T cells from pts with MIBC that accurately map the immune landscape of TILs. UDL analysis represents a liquid biopsy to inform clinically relevant immunological parameters, including the CD8/Treg ratio, target checkpoint expression and TCR repertoire, irrespective of prior treatment. Further translational studies are ongoing to evaluate whether UDL analysis may serve as a non-invasive, dynamic biomarker to predict immunotherapy outcome in MIBC.

Background: Although many drugs are available in RCC, we still lack predictive biomarkers of disease recurrence or progression for personalized treatment. NEORAD clinical trial (NCT01715935) was designed to evaluate biomarkers modulation by everolimus (Ev) prior to nephrectomy on several tissue and circulating cells.

Methods: French open-label, exploratory, single-arm, multicenter trial, part of PREDICT consortium. Population: locally-advanced (LA), metastatic (M) RCC. Endpoints: primary: objective clinical benefit (CR, PR, SD upon RECIST 1.1) after 6 weeks neoadjuvant Ev (10 mg daily) prior nephrectomy; secondary: PFS, OS, toxicity. Multi-region sequencing (biopsy and surgery specimens) explored mutational status of genes of interest. After nephrectomy, Ev was reintroduced in M pts until PD or end of 12m follow-up. Treatment was continued until PD or unacceptable toxicity.

Results: 25 pts accrued (44 screened) between 05/2012 and 07/2015: LA = 14, M = 11 underwent biopsy at screening for tissue sampling then further nephrectomy. Population (LA/M): clear-cell=13/10, papillary=1/1, median age(y): 60/63, sarcomatoid component: 3 M pts, ECOG-PS: 0=10/4, 1=4/7, extra-renal metastatic sites: bone, lung, nodes, adrenal. Change in renal tumor size between baseline and D42: 0%. In M, Ev was resumed for 8 pts after nephrectomy with 2 PR and 6 SD. PFS (mo): M = 3.1 [1.41; 12.2]. Median follow-up (mo): 17.4 [3.3; 43.2]. PFS at 12 months: LA = 78%, M = 18% Toxicity of Ev was as expected and no adverse event in terms of surgical procedure was observed. Pts with following gene mutations exhibited a poor PFS: SEDT2: HR = 2.54 (0.63 – 10.28), BAP1: HR = 3.19 (0.78 – 13.12), TSC2: HR = 2.37 (0.49 – 11.53); further correlations will be presented at ESMO meeting.

Conclusions: NEORAD was the 1st neoadjuvant study of Ev in RCC. Despite limited number of pts, we generated a large amount of longitudinal data including exome sequencing, circulating biomarkers, angiogenesis and immunity factors. All these data could help decipher mechanisms of resistance, evaluate predictive signatures or add further knowledge to mechanisms involved in mTOR pathways.

[1]Renal Subcommittee, Australian and New Zealand Urogenital and Prostate Cancer Trials Group, Sydney, Australia, [2]Medical Oncology, NHMRC Clinical Trials Centre, Camperdown, Australia, [3]Medical Oncology, Monash University Eastern Health Clinical School, Box Hill, Australia, [4]Medical Oncology, Royal Perth Hospital, Perth, Australia, [5]Urology, Olivia Newton-John Cancer and Wellness Centre, Austin Hospital, Melbourne, Australia, [6]Medical Oncology, Prince of Wales Hospital, Sydney, Australia, [7]MRC Clinical Trials Unit, University College London, London, UK, [8]Cambridge Biomedical Campus, Cambridge University Hospitals NHS Foundation Trust - Addenbrooke's Hospital, Cambridge, UK, [9]Concord Cancer Centre, Concord Repatriation General Hospital, Sydney, Australia

Background: The effects on survival of adjuvant therapy with a VEGF-TKI after nephrectomy for RCC are uncertain. Survival rates, times and benefits were predicted by medical oncologists at baseline for each patient they recruited to SORCE.

Methods: Medical oncologists at 20 sites in ANZ and 12 in the UK answered the following questions at baseline for each patient they recruited: the predicted overall survival rate at 5 years (SR) and predicted overall survival time (ST) without adjuvant sorafenib; and, the predicted absolute improvements in SR and ST with 1 year of adjuvant sorafenib. We used Spearman's rank correlation (r_s) to assess associations, and Wilcoxon signed rank tests to assess differences between the paired SR–ST values. We assumed exponential survival distributions to calculate: (i) % alive at 5-yrs corresponding to ST estimates, and (ii) hazard ratios (HRs) corresponding to predicted benefits on overall survival. We hypothesized that these HRs should be less extreme (numerically larger) than the target HR of 0.75 for disease free survival used to design the trial.

Table: 881P

	ST[1] In Years	ST[1] Calculated % alive at 5-yrs [a]	SR[1] Estimated % alive at 5-yrs [b]	Difference[1] [a]-[b]	r_s [a] vs [b]
Survival without sorafenib	7	61	60	0 (-7 to 9)	0.62
	(5 to 12)	(50 to 75)	(50 to 70)	p = 0.6	p < .001
Improvement with sorafenib	1	6	7	−2 (-6 to 1)	0.53
	(1 to 5)	(3 to 10)	(5 to 15)	p < .0001	p < .001
Hazard Ratio	0.83	0.83	0.76	0.09 (-0.01 to 0.21)	0.41
	(0.67 to 0.91)	(0.67 to 0.91)	(0.62 to 0.82)	p < .0001	p < .0001

[1]Medians (IQRs)

Results: The table shows paired estimates of ST and SR from 61 medical oncologists for 176 of the 1711 SORCE patients. Predictions of survival without sorafenib were similar whether based on ST or SR. The predicted benefits of sorafenib based on SR were moderately correlated with those based on ST, but significantly larger. The proportion of HRs > 0.75 was 51% based on SRs vs 66% based on STs.

Conclusions: The predicted benefits of adjuvant sorafenib based on SRs were often larger than hypothesized, and larger than predictions based on ST, which were more consistent with the target HR. These data suggest that predictions of benefit in this setting may be more conservative and plausible when based on ST rather than SR.

882P Potential impact of avelumab+axitinib (A+Ax) on tumor size (TS) compared with historical data of sunitinib (S) as evaluated by a modeling and simulation (MS) approach

J. Zheng[1], A. Chang[2], J. Larkin[3], R.J. Motzer[4], M. Amantea[5], C. Bello[6], D. Pavlov[7], M. Geraldes[8], M. Martignoni[9], A. Di Pietro[9], G. Andrews[10]

Background: Combining an immune checkpoint inhibitor (A) with a targeted VEGF antiangiogenic agent (Ax) may leverage complementary mechanisms of action for treatment of metastatic renal cell carcinoma (mRCC). JAVELIN Renal 100 is a phase (Ph) 1b trial evaluating the clinical activity and safety of A+Ax in treatment-naïve patients (pts) with mRCC. An early evaluation of the effect of A+Ax on TS, i.e. sum of diameters for target lesions, compared to historical S, the standard of care[1], can inform on decisions for future drug development for A+Ax. Claret et al. have shown that a greater early TS reduction at week 8 of treatment (TR8) is correlated with a longer progression free survival time in trials of 1st line treatment of mRCC[2]. The objective of this analysis is to apply MS methodology to data from JAVELIN Renal 100 to evaluate the potential effect of A+Ax on TS as compared to historical S data.

Methods: A tumor dynamic model[3] was applied to the longitudinal TS data obtained from the Ph1b study of A+Ax and from the historical Ph3 trial of S. The model includes 3 parameters representing the rate of tumor growth (KL), the rate of drug effect in reducing tumor size (KD), and the rate of the loss of drug effect (DM). The TR8 for each patient can be derived from the model. A larger KD, smaller DM, and TR8 suggested a greater effect. The parameters and TR8 from the two treatments are estimated and compared using ANOVA.

Results: The summaries of the model parameters, TR8, and p-value of ANOVA analysis are presented in the Table below:

Table: 882P

	Avelumab + axitinib (N = 53) (mean ± SD)	Sunitinib alone (N = 349) (mean ± SD)	p-value
TR8	0.757 ± 0.162	0.808 ± 0.132	0.012
KL (1/week)	0.011 ± 0.014	0.009 ± 0.012	0.398
KD (1/week)	0.065 ± 0.027	0.054 ± 0.034	0.021
DM (1/week)	0.081 ± 0.024	0.095 ± 0.049	0.040

A+Ax resulted in a greater effect on TR8, a faster tumor size reduction and a more sustained effect than S.

Conclusions: MS is an effective tool to inform drug development. These results suggest that A+Ax results in a greater TS reduction than S, supporting further investigation of A+Ax vs S in the JAVELIN 101 randomized Ph3 trial. References: 1. Background: Patients (pts) with metastatic renal cell carcinoma (mRCC) may present with primary metastases (synchronous disease) or develop metastases during follow-up (metachronous disease). The impact of timing of metastatic disease outbreak on outcomes from targeted therapy (TKI) is unclear.

Methods: We used the International Metastatic Renal Cell Carcinoma Database Consortium (IMDC) to assess overall survival (OS) and time to treatment failure (TTF) on first line TKI, and performed Cox regression analyses comparing synchronous (metastases ≤ 3 mo of initial diagnosis of cancer) vs metachronous disease (metastasis diagnosed post initial diagnosis, evaluated by intervals >3-12 mo, >1-2 yrs, >2-7 yrs, and >7yrs).

Results: In 7386 pts with mRCC treated with first line TKI, 3906 pts (53%) had synchronous and 3480 pts (47%) had metachronous metastases. Synchronous *vs* metachronous disease by intervals >3-12 mo, >1-2 yrs, >2-7 yrs, >7yrs correlated with lower age at TKI initiation (mean 61 yrs vs 61, 62, 63, 66 yrs, respectively, $p < 0.0001$), higher rate of non-clear cell histology (14% vs 12%, 10%, 10%, 7%, respectively, $p < 0.0001$), and higher rate of IMDC risk features (mean 2.3 vs 1.6, 0.9, 0.9, 0.8, $p < 0.0001$). Compared with synchronous disease, the longer time to metastases was significantly associated with improved OS and TTF from TKI therapy initiation in multivariable Cox regression, adjusted for nephrectomy status, histology (cc vs ncc), IMDC risk factors (Hgb, Corrected calcium, Neutrophil, platelets, Karnofsky performance status), number of metastasis (1 vs > 1), age at TKI initiation and year of TKI initiation (2003-2007, 2008-2012, 2013-2016).

Conclusions: Timing of metastases post initial RCC diagnosis impacts outcome with targeted therapy in mRCC. This may need to be taken into consideration in clinical trial designs.

San Pedro de Alcántara, Cáceres, Spain

Background: Ineligibility for clinical trials (CT) may be an unfavorable prognostic factor in mRC. There is no information about the effectiveness of pazopanib in patients (pt) ineligible for CT. We aimed to assess the effect of ineligibility in outcomes in mRC, and the effectiveness of pazopanib in this setting.

Methods: SPAZO2 (NCT03091465) was a retrospective real-world study to analyze the effectiveness of 1st-line pazopanib and subsequent therapies in mRC in several settings. Data from 530 pt treated with frontline pazopanib outside CT in 50 centers in Spain were collected, and externally monitored. Ineligibility criteria: ECOG >1, pure nonclear-cell, brain metastases, Hgb < =9 g/dl, renal failure, severe ischemic disease, age >80 y, stroke, chronic liver disease, or recent neoplasia.

Results: A total of 217 pt (40.9%) fulfilled criteria for ineligibility. There were significant differences (I vs E) in age >75 (39% vs 15%), nephrectomy (61% vs 78%), IMDC (favorable: 8.8% vs 17.9%, intermediate: 50.2% vs 68.4%, poor: 41% vs 13.7%), metastases (lymph nodes: 51% vs 41%, lung: 65% vs 72%, liver: 21% vs 15%, bone: 31% vs 22%, skin/soft-tissue: 30% vs 16%, and CNS (13% vs 0%) but no in sex (68% vs 67% males). Discontinuation due to toxicity or comorbidities was 19% vs 17%. There were also differences ($p < 0.05$) in 2nd-lines (53% vs 61%), response, PFS and OS (Table). Median follow-up was 39 mo. Median PFS and OS were 9.8 and 19.6 mo respectively. After adjusting by IMDC and age (Cox regression), ineligibility was significantly associated with a higher risk of progression (HR: 1.4 95%IC: 1.1 - 1.7) and death (HR: 1.5 95%IC: 1.2 - 1.9). Only anemia and asthenia (all grades) were significantly higher in the I group.

Conclusions: In our series, "real world eligible pt" had similar outcome to the obtained in clinical trials. On the contrary, "real world ineligible pt" for clinical trials had significantly lower response rate, and shorter PFS and OS than elegible pt. Pazopanib was safe and effective in both subpopulations of patients.

885P Sunitinib versus pazopanib for patients with metastatic renal cell carcinoma: Two Turkish hospital experience, a retrospective comparative case series study

M. Ekenel[1], E. Aydin[1], I. Cil[2], A. Zirtiloglu[2], D. Tural[2], S. Karabulut[2]

[1]Medical Oncology, Istanbul University Institute of Oncology, Istanbul, Turkey, [2]Medical Oncology, University of Health Sciences, Bakirkoy Dr Sadi Konuk Education and Research Hospital, Istanbul, Turkey

Background: Pazopanib (PAZ) and Sunitinib (SUN), are two oral multikinase angiogenesis inhibitors which are prescribed frequently. However, the outcomes in real world of Turkish population have not extensively been studied.

Methods: Patients assessed retrospectively at two Turkish hospitals between 2006 and 2016.

Results: Median age of patients was 60 (28-87) years and 70% of patients were male. ECOG performance score was 0 and 1 in 73% of patients. Twelve patients (15%) had non-clear cell carcinoma histology. Pathological characteristics, MSKCC risk groups, median follow up, response rates and survival are shown in Table. In the SUN group, the patients had more grade 3-4 adverse events (Table).

Table: 885P Patient characteristics, responses to treatment, survival, and adverse events

	Sunitinib (n = 41)	Pazopanib (n = 38)	p value
MSKCC risk group	Favorable 31% Intermediate 56% Poor 12.5%	Favorable 31% Intermediate 47% Poor 21%	p = 0.66
T3-T4 stage	49%	47%	p = 0.38
Node positivity (%)	20%	8%	p = 0.10
Local recurrence (%)	20%	30%	p = 0.36
Median follow-up	18 months	13 months	p = 0.21
ORR	34%	37%	p = 0.96
DCR	78%	87%	p = 0.046
Progression	73% (n = 30)	50% (n = 19)	p = 0.08
Median PFS	8months	8months	p = 0.49
Median OS	22 months	21 months	p = 0.21
Fatigue, all grades	45%	74%	p = 0.48
Skin changes, all grades	44%	44%	p = 0.24
Anemia, all grades	35%	42%	p = 0.75
Grade 3-4 adverse events	59%	16%	p < 0.001
Dose reduction	50%	24%	p = 0.021
Treatment cessation	37%	26%	p = 0.37

Conclusions: In our study, there was no difference in terms of survival between two agents. However, patients treated with SUN had more grade 3-4 adverse effects which prompted dose reduction and cessation.

Background: Pivotal studies of axitinib and everolimus in 2nd-line mRC did not include pt treated with 1stPz. In addition, E vs A have not been directly compared in clinical trials in this setting. We aimed to compare the effectiveness of E vs A in real life, as second-line after pazopanib in mRC.

Methods: SPAZO2 (NCT03091465) was a retrospective real-world study to analyze the effectiveness of 1stPz and subsequent therapies in mRC in several settings in every day practice. Data from 530 pt treated with frontline pazopanib outside CT in 50 centers in Spain were collected by investigators, but monitored and entered in a database by an external CRO.

Results: Out of 285 pt receiving 2nd-line targeted therapies after 1stPz, 189 received either Ax (88, 46.6%) or Ev (101, 53.4%). There were no significant differences (Ax vs Ev), in age (63 y vs 66 y), sex (68% vs 64% males), nephrectomy (76% vs 67%), metastases in lymph nodes (58% vs 52%), liver (21% vs 28%), bone (45% vs 41%), CNS (6%), adrenal (4% vs 5%), pleura/peritoneum (4% vs 6%), or pancreas (4% vs 6%), but there were in age >75 (14% vs 25%), nonclear cell component (1 vs 16%), and lung (85 vs 72%) and skin/soft-tissue (20 vs 28%) metastases. According to the IMDC for 2nd-line targeted therapies, 17% vs 9% of pt were in the favorable risk group, 65% vs 69% in the intermediate risk, and 18% vs 22% in the poor risk. All-grades hypertension (32.6% vs 3.6%) and hypothyroidism (16% vs 6%) were significantly higher with Ax, whereas anemia (21.4% vs 55%), and mucositis (12.3% vs 39%) were more frequent with Ev. Subsequent therapies were given in 56% in Ax vs 46% in Eve. After median follow-up of 28 mo, 74.6 of pt have died. Outcomes and 95%CI are summarized in the table.

Table: 886P

	Response		PFS		OS	
	ORR	SD	Median	6 monts	Median	1 year
Axitinib	13.1%	42.9%	5.3 (3-7)	47%	11.6 (7-16)	49%
Everolimus	9.3%	43%	4.6 (3-6)	39%	9.5 (7-12)	43%
Overall	11.2%	42.9%	5.0 (4-6)	43%	10.7 (8-13)	46%
	p ns		HR*: 0.76 (0.5-1.1)		HR*: 0.81 (0.6-1.2)	

*Adjusted by IMDC, metastases, age, histology and subsequent therapies.

Conclusions: In this real world study in pt with mRC, we could not find statistically significant differences in effectiveness between axitinib and everolimus as 2nd-line after 1st line pazopanib. These results validate the use of both drugs in terms of clinical benefit, PFS and OS.

Background: In recent years, prognostic classifications have been considered an area of growing interest in mRCC. However, independently from the classification used (Memorial Sloan Kettering versus Heng's) the presence of brain, liver and bone metastases (mets) or sarcomatoid features (G4) resulted in a poorer outcome for pts with mRCC treated with targeted therapies (antiangiogenic agents or mTOR Inhibitors). Regarding this topic, the large Italian EAP represent an important opportunity to analyze the impact of nivolumab in pts treated in a daily clinical practice setting.

Methods: Nivolumab was available upon physician request for pts aged ≥18 years who relapsed after at least one prior systemic treatment in the advanced or metastatic setting. Nivolumab 3 mg/kg was administered intravenously every 2 weeks for a maximum of 24 months. Pts included in the analysis had received ≥ 1 dose of nivolumab and were monitored for adverse events (AEs) using Common Terminology Criteria for Adverse Events.

Results: Of 389 Italian pts with mRCC enrolled in the EAP, 32 pts (8%) had brain mets, 128 (33%) had liver and 193 (50%) had bone mets. Baseline characteristic are described in the Table. These pts achieved a disease control rate (DCR) of 53%, 45% and 47% respectively. Six and 12 months overall survival rates in the 3 groups of mets were 87.0% and 66.8%, 75.6% and 62.0%, 78.0% and 58.9%, respectively. Histological grading, a matter of high interest, was assigned according to Fuhrman's classification: 51 pts had G4 tumor. The objective response rates in these pts and in the overall population were 23% and 22%, respectively, with a 6 and 12 months OS rate of 61% and 53.6% for the G4 group. The safety profile of the subgroups described above was in line with the general population.

Conclusions: These results suggest that also pts with poor prognostic factors may derive relevant benefits with nivolumab, with safety results consistent with previously reported data.

888P Change in neutrophil-to-lymphocyte ratio (NLR) in response to immunotherapy for metastatic renal cell carcinoma (mRCC)

A-K.A. Lalani[1], W. Xie[2], D.J. Martini[1], C.K. Norton[1], J.A. Steinharter[1], D. Bossé[1], J. Bellmunt[1], E.M. Van Allen[1], B.A. McGregor[1], L.C. Harshman[1], T.K. Choueiri[1]

[1]Lank Center for Genitourinary Oncology, Dana-Farber Cancer Institute, Boston, MA, USA, [2]Dept. of Biostatistics and Computational Biology, Dana-Farber Cancer Institute, Boston, MA, USA

Background: Elevated NLR is associated with worse outcomes in several malignancies, including mRCC. However, its role in the current immunotherapy era is unknown. We investigated the utility of NLR at baseline and during therapy in mRCC patients treated with PD-1/PD-L1 immunotherapy (IO).

Methods: 116 patients from Dana-Farber Cancer Institute (Boston, MA) receiving IO-based therapies were included. NLR was examined at baseline and 6 (±2) weeks later. Landmark analysis at 6 weeks was conducted to explore the prognostic value of relative NLR change on overall survival (OS), progression-free survival (PFS), and objective response rate (ORR) using Cox or logistic regression models, adjusted for line of therapy, number of IMDC risk factors, histology and baseline NLR.

Results: Median follow up was 16.3 months (range: 1.4-64.2). Median duration on therapy was 7 months (<1-58.6). IMDC risk groups were: 21% favorable, 56% intermediate, 22% poor-risk. 43% were on first-line IO and 57% on 2nd line or more. Median NLR was 3.7 (1.3-16.1) at baseline and 3.9 (1.1-49.6) at week 6. Higher NLR at baseline and at 6-weeks showed a trend to reduced ORR and worse PFS and OS, and NLR at 6-weeks was a stronger prognostic than baseline values (Table). Compared with no change from baseline, increase in NLR by ≥ 25% at 6-weeks was associated with reduced ORR and significantly worse PFS and OS in multivariate analysis, whereas a decrease in NLR by ≥ 25% was associated with improved outcomes.

Conclusions: Early decline and NLR at 6-weeks are associated with significantly improved outcomes in mRCC patients treated with IO, whereas an increase is associated

Background: The impact of tyrosine kinase inhibitors (TKIs) on tumor immunity of patients (pts) with metastatic renal cell carcinoma (mRCC) is largely unknown. We investigated the activity of pazopanib in counteracting tumor-induced immunosuppression and boosting adaptive immune response.

Methods: Sixteen mRCC pts receiving first-line pazopanib were prospectively analyzed at baseline, 3 and 6 months for blood Immune profiling by multicolor cytofluorimetry. Gene expression analysis was performed by Illumina HT12v4 BeadChip Arrays. Data were evaluated by t-test, enrichment analysis and deconvolution algorithms.

Results: Pazopanib administration (800 mg per os/daily) was associated with a significant decrease of cell subsets involved in immunosuppression, including $CD14^+$ monocytes, monocytic $CD14^+$ $HLA\text{-}DR^{neg}$ myeloid derived suppressor cells (MDSC) and $CD14^+PDL\text{-}1^+$ cells. Similarly, low density $CD15^+$ granulocytic MDSC and $CD4^+$ $CD25^{high}$ $Foxp3^+$ regulatory T cells were reduced by treatment. Concomitantly, a boost of antitumor effectors, such as activated T lymphocytes (identified as $CD3^+PD\text{-}1^{dim}$ T cells) and cytotoxic $CD3^-CD16^+CD56^{dim}$ NK cells, was observed. Changes were more evident at 3 months and in pts achieving clinical benefit (69%), defined as the sum of partial response and stable disease at first restaging. Interestingly, a statistically significant increase of lymphocyte/monocyte ratio, as determined by routine blood test was also detected. Gene expression analysis confirmed the immunoregulatory effects of pazopanib. By comparing with those collected after 3 months after treatment start and pre-treatment samples, pathway-enrichment analysis revealed a coherent modulation of NK Granzyme A, IL8 signaling and other immune-related pathways. Similarly, using deconvolution algorithms, we observed an enrichment of NK and CD8+ T cell transcripts.

Conclusions: Pazopanib reshapes tumor immunity by reducing immunosuppressive cells (MDSC and Treg) and triggering T cells and NK effectors. These data provide a strong rationale for using Pazopanib both before an immunochecpoints inhibitors and also in combination strategies based on the synergism between TKIs and immunotherapy.

890P Prospective comparison of RECIST and alternative response assessment criteria in the evaluation of metastatic renal cell cancer patients from phase II of the multi-centre randomised STAR trial

C. Kelly-Morland[1], J. Zhong[2], V. Goh[1], T. Wah[2], C. Ralph[2], F. Thistlethwaite[3], P. Patel[4], P. Nathan[5], T. Eisen[6], W. Gregory[7], L. McParland[7], H. Cool[7], K-L. Royle[7], E. Best[7], L. Whincup[7], F. Collinson[7], J. Brown[8]

[1]Imaging Sciences, 4th Floor Rayne Institute St. Thomas' hospital, King's College London, London, UK, [2]Radiology, St James' hospital, Leeds, UK, [3]Medical Oncology, The Christie NHS Foundation Trust, Manchester, UK, [4]Medical Oncology, University of Nottingham, Nottingham, UK, [5]Department of Medical Oncology, Mount Vernon Cancer Centre, Northwood, UK, [6]Cambridge Biomedical Campus, Cambridge University Hospitals NHS Foundation Trust - Addenbrooke's Hospital, Cambridge, UK, [7]Institute of Clinical Trials Research, University of Leeds, Leeds, UK, [8]Academic Unit of Clinical Oncology, Weston Park Hospital, Sheffield, UK

Background: Combined size and enhancement criteria show potential to predict earlier disease response or progression in metastatic renal cancer (mRCC). We assessed categorisation differences using RECIST 1.1, Choi and modified Choi (mChoi) criteria with normalised rather than absolute enhancement values in phase II of the STAR trial (comparing conventional continuation versus drug free intervals of tyrosine kinase inhibitor treatment in mRCC).

Methods: 44 patients underwent contrast-enhanced computed tomography (CE-CT) at baseline, 12 and 24 weeks post therapy. Automated software was used by 2 independent readers to evaluate 104 target lesions. Target lesion sum of longest diameter, normalised enhancement values (relative to aortic attenuation) and subsequent percentage change at 12 and 24-week CT were measured. Response categorisation into stable disease (SD), partial response (PR) or progressive disease (PD) was undertaken by RECIST 1.1, Choi and mChoi response criteria, and discrepant cases scored. Reader agreement was assessed by Cohen's kappa test.

Results: By RECIST 1.1, patients were 68%(n = 30)/41% (18)SD, 27%(12)/45%(20) PR, 2%(1)/9%(4) PD and 2%(1)/2%(1) CR at 12 and 24 weeks respectively. At 12 weeks 27 patients had discrepant categorisation: PR by both Choi/mChoi criteria but SD by RECIST in 17 and PR by CHOI, SD by mCHOI in 10. With absolute versus normalised enhancement values, 3 further patients would have remained as SD by mChoi at 12 weeks. At 24 weeks 14 remained discrepant: both Choi/mChoi PR but SD by RECIST in 10, PR by Choi but SD in mCHOI/RECIST in 4 patients. 11 previously discrepant patients by RECIST versus Choi/mChoi became concordant (8 PR, 3 PD) at 24 weeks. The concordance was excellent for RECIST (k 0.9, k 0.8) and mChoi (k 0.9 k 0.79), and good/excellent reader for Choi criteria (k 0.76 k1.0) at 12 and 24 weeks respectively.

Conclusions: Early response, confirmed at 24 weeks, was more frequent for Choi/mChoi than RECIST. Substantial/excellent agreement was noted in response categorisation with normalised versus absolute enhancement indicating this is a potentially robust approach.

891P Outcomes of patients with metastatic renal cell carcinoma (mRCC) who were treated with second-line (2L) vascular endothelial growth factor receptor tyrosine kinase inhibitors (VEGFR-TKI) after first-line (1L) immune checkpoint inhibitor (ICI) therapy

A.Y. Shah[1], E.A. Lemke[1], G. Jianjun[1], A. Chandamohan[1], M.T. Campbell[1], A. Zurita Saavedra[1], L. Xiao[2], J. Wang[1], P.G. Corn[1], E. Jonasch[1], P. Sharma[1], N. Tannir[1]

[1]Genitourinary Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA, [2]Biostatistics, The University of Texas MD Anderson Cancer Center, Houston, TX, USA

Background: ICI therapy is an established strategy in mRCC after progressive disease on VEGFR-TKI. Little data exists in the reverse sequence on response rate, progression-free survival (PFS), safety, and tolerability of TKI after 1L ICI therapy.

Methods: This is a retrospective analysis of patients with mRCC treated from 2015 to present with 1L ICI, followed by 2L TKI. Response assessment was provided by a blinded radiologist using RECIST 1.1. Descriptive statistics, Fisher's test and Wilcoxon rank sum test were used.

Results: We report on 27 clear-cell mRCC patients with follow-up of at least 8 weeks on TKI post 1L ICI. Median age at diagnosis was 58 years. 78% of patients had lung, 37% bone, 37% lymph node, and 7% liver metastasis. As 1L therapy, 7 patients received nivolumab, 17 received nivolumab + ipilimumab, and 3 received nivolumab + bevacizumab. All 27 patients had resolution of Grade 3/4 toxicities from ICI and progressive disease at the time of TKI initiation. Median time from discontinuation of ICI to initiation of TKI was 4.1 weeks (range 0-23.3 weeks). 11 patients (41%) had PR (8 of whom had $\geq$40% tumor reduction), and 16 (59%) had SD as best response to TKI. Median PFS was 10.0 months (95% CI 6.8, not applicable). 9 patients discontinued 2L TKI after a median of 26.3 weeks (range 4.6-44 weeks), 8 patients because of PD and 1 because of toxicity. 2 patients developed Grade 3 transaminitis and 3 patients Grade 3 hand-foot skin reaction. Age, sex, IMDC risk score, nephrectomy status, and TKI agent did not predict PR or SD.

Table: 891P

Variable	Total n (%)	PR (n)	SD (n)	P value
Male	19 (70)	7	12	0.68
Female	8 (30)	4	4	
Localized at presentation	9 (33)	7	2	0.01
Metastatic at Presentation	18 (67)	4	14	
IMDC good risk	4 (15)	3	1	0.47
IMDC intermediate risk	19 (70)	7	12	
IMDC poor risk	4 (15)	1	3	
Nephrectomy	21 (78)	10	11	0.35
Primary in-situ	6 (22)	1	5	
Pazopanib	8 (30)	4	4	0.37
Axitinib	12 (44)	3	9	
Cabozantinib	7 (26)	4	3	

Conclusions: In this small retrospective study, we observed a high response rate (41%), median PFS 10 months, and manageable toxicity in patients with mRCC treated with TKI after ICI. No patients had outright PD on 2L TKI after ICI.

Cardarelli, Napoli, Italy, [20]Medical Oncology, Istituto Oncologico Veneto IRCCS, Padua, Italy

Background: Response patterns of immunotherapies differ from those seen with other approved cancer therapies. Therefore, immunotherapy clinical trials generally allow patients (pts) to continue treatment beyond investigator-assessed radiographic progressive disease (PD) as long as there is ongoing clinical benefit, but to date no data have been reported regarding treatment beyond PD in routine clinical practice. Here, we report the analysis about the subgroup of pts treated beyond initial PD in the Italian cohort of nivolumab EAP.

Methods: Nivolumab was available upon physician request for pts aged ≥18 years who had relapsed after a minimum of one prior systemic treatment for stage IIIB/stage IV RCC. Nivolumab 3 mg/kg was administered intravenously every 2 weeks to a maximum of 24 months. Pts included in the analysis had received ≥ 1 dose of nivolumab and were monitored for adverse events (AE) using Common Terminology Criteria for Adverse Events. Patients could continue treatment beyond PD as long as they met the following criteria: investigator-assessed clinical benefit, absence of rapid PD, tolerance of drug, stable performance status and no delay of an imminent intervention to prevent serious complications.

Results: Of 389 nivolumab-treated pts, 231 pts (59%) had PD. Of those, 100 pts (43%) were treated beyond PD. Before being treated beyond PD, the disease control rates (DCR) was 23%, with 5 partial responses (PR) and 18 stable diseases (SD). Post PD, 28 of all pts treated beyond PD achieved a non-conventional benefit, meaning a subsequent tumor reduction or stabilization in tumor lesions. With a median follow-up of 9.2 months (0.1-17.0), 1 year overall survival was 73.5% in pts treated beyond PD and 43.5% for pts who progressed but were not treated beyond PD. The safety profile was consistent to what already observed in the general population.

Conclusions: As already observed in previous studies, these preliminary EAP data seem to confirm that a proportion of pts who continued treatment beyond PD demonstrated sustained reductions or stabilization of tumor burden, with an acceptable safety profile. Further investigation is warranted in order to better define pts who can benefit from treatment beyond PD.

893P Improved long-term clinical outcomes and safety profile of sunitinib dosing schedule with 4/2 switched to 2/1 in patients with metastatic renal cell carcinoma

X. Zhang, G. Sun, J. Zhao, K. Shu, P. Zhao, J. Liu, Y. Yang, Q. Tang, J. Chen, P. Shen, H. Zeng

Department of Urology, Institute of Urology, West China Hospital, Chengdu, China

Background: Adverse events (AEs) have been a key issue for sunitinib administration with a standard dosing schedule. We aimed to identify the survival benefit and safety of alternative dosage schedules for sunitinib in patients with metastatic renal cell carcinoma (mRCC).

Methods: Clinicopathologic and survival data of patients treated with sunitinib as first-line therapy were retrospectively reviewed. Patients were classified into three groups: a standard dosing schedule (4/2 schedule), alternative dosing schedule (2/1 schedule), and switched dosing schedule (4/2-2/1 schedule). Treatment-related AEs were recorded and evaluated. Progression-free survival (PFS), overall survival (OS), and potential risk factors were also analyzed.

Results: A total of 99 patients were included. Seventy-five (75.8%) patients were initially administrated with a 4/2 schedule of sunitinib, while 24 were started with the 2/1 schedule. During treatment, 45 (60.0%) patients with an initial 4/2 schedule switched to a 2/1 schedule (4/2-2/1 schedule) due to severe AEs or poor tolerance. The median follow-up time was 37 months. Compared to that with a 4/2 schedule, patients with a 2/1 schedule had a much lower incidence of grade 3/4 AEs (69.6% vs. 40.6%, $p = 0.001$). Overall, the 4/2-2/1 schedule was associated with the best survival benefits. Among the 4/2, 2/1, and 4/2-2/1 schedule groups, the median PFS was 12.5, 11.0, and 25.0 months, respectively ($p = 0.003$), and the median OS was 21.0, 28.0, and 52.0 months, respectively ($p = 0.030$). Multivariate analysis identified the 4/2-2/1 schedule as an independent factor predicting favorable PFS. Although without statistical significance, 4/2-2/1 schedule could decrease 55% risk of death. Furthermore, patients with unfavorable IMDC risk seemed to have more opportunity to achieve better survival from the 4/2-2/1 dosing schedule.

Conclusions: Among the three dosing schedules in the treatment of mRCC, patients with a 4/2-2/1 schedule could minimize treatment-related toxicities; more importantly, patients with 4/2-2/1 schedule could achieve a superior survival benefit. However, prospective clinical trials are required to identify the optimal sunitinib schedule.

894P A retrospective study of the management of metastatic renal cell carcinoma brain tumors

G. Klausner[1], I. Troussier[1], G. Malouf[2], L. Feuvret[1], J. Jacob[1], J-M. Simon[1], C.H. Canova[1], I. Lamproglou[3], P-Y. Borius[3], C. Valery[3], P. Cornu[3], M. Rouprêt[4], J-J. Mazeron[1], J-P. Spano[2], P. Maingon[1]

[1]Radiotherapy, Pitié-Salpêtrière Hospital, Paris, France, [2]Medical Oncology, Groupe Hospitalier Pitié Salpetriere, Paris, France, [3]Neurosurgery, Pitié-Salpêtrière Hospital, Paris, France, [4]Urology, Pitié-Salpêtrière Hospital, Paris, France

Background: The purpose of this retrospective monocentric review was to evaluate the different techniques of stereotactic radiosurgery in the management of brain tumors from renal cell carcinoma (RCC).

Methods: From 2005 to 2015, 120 patients, with a total of 398 brain metastasis of RCC, were treated at least by stereotactic radiosurgery. Median age was 58 years (31–82). Median Karnofski performance status was 90 (50-100). One hundred ten tumors (92%) were clear cell carcinoma. Ninety-nine patients (82.5%) have undergone nephrectomy. The median time between the diagnosis of RCC and the first brain metastasis was 24 months (0-252).

Results: The median number of tumors per patient was 2 (1-46). The median diameter of the tumors was 13 mm (1-60). For the 120 patients, 222 procedures of treatment were recorded and 187 stereotactic irradiations were reviewed. Sixty-one patients (226

metastasis) were treated by Gamma Knife Surgery (GKS) and received a median dose on the 50% prescription isodose of 18 Gy (14-22). The minimal and maximal median dose was respectively 18.4 Gy (12.5-40.1) and 36 Gy (23.3-51.2). Sixty-three patients (136 metastasis) were treated by linear accelerator (photon 10 MV). The minimal (isodose 70%) and maximal (isocentre) median dose were respectively 16 Gy (9.8-25.8) and 20.3 Gy (15.3-33.74). The median disease-free survival time is 5.5 months (0-252). The median survival time between the first brain metastasis diagnosis and death is 13.5 months (0.5-147). The tumor growth control rates at 3, 6, 12 months are respectively 86%, 62%, 36%. Following the 187 stereotactic irradiations, 95 (51%) cerebral disease progressions are recorded, after a median time of 5 months (1-81); 81 progressions (85%) are due to new lesions and 25 (26%) due to local failures. Analyses of prognostic factors related to survival are still in progress.

Conclusions: Stereotactic radiosurgery is associated with a high local control of brain metastasis from RCC without whole brain radiotherapy. The two described modalities present different characteristics whose advantages will be further discussed with the assessment of prognostic and predictive factors of local control.

Mutua de Terrassa, Terrassa, Spain, [18]Medical Oncology, Hospital Infanta Sofia, Madrid, Spain, [19]Medical Oncology, Hospital Virgen De Las Nieves, Granada, Spain, [20]Medical Oncology, Complejo Asistencial Universiario de Leon, Leon, Spain

Background: Only 2% of pt included in the IMDC prognostic model for 2nd-line targeted agents in mRC had received 1stPz (Ko, Lancet Oncol 2015). We aimed to validate the IMDC model for this population of patients receiving 1stPz.

Methods: SPAZO2 (NCT03091465) was a retrospective real-world study to analyze the effectiveness of 1stPz and subsequent therapies in mRC in several settings in every day practice. Data from 530 pt treated with frontline pazopanib outside CT in 50 centers in Spain were collected by investigators, but monitored and entered in a database by an external CRO.

Results: A total of 285 pt received antiVEGF or mTOR inhibitor as 2nd line (37.6% everolimus, 2.5% temsirolimus, 36% axitinib, 9.9% sunitinib, 8.3% sorafenib, 2.9% cabozantinib, 2.1% pazopanib, 0.4% beva-Inf, 0.4% savolitinib), 242 after true progression and 43 due to other causes after 1stPz. Unlike in IMDC, no pt had received 1st-line immunotherapy. Mean age was 66 y, 67.7% were male, 74.4% nephrectomized, and 12.3% pure nonclear-cell. Metastatic sites were: lung 74%, lymph nodes 55%, bone 36%, soft tissue/skin 27%, liver 24.8%, CNS 7%, adrenal gland 5%, pleura/peritoneum 6%, pancreas 5%, kidney 3% and other organs 2%. Classification of pt into the IMDC risk groups were: favorable (FR, 14.4%), intermediate (IR: 64.2%), or poor (PR: 21.4%). Median follow-up since 2nd-line was 29 mo; 67% of pt has progressed, 64% had received or subsequent lines, and 73% had died. Response, PFS and OS (and 95%CI) since 2nd-line are showed in the table. Differences in PFS and OS were statistically significant among groups (FR vs IR and FR vs PR). The C-Index was 0.635 (95%CI: 0.627 – 0.642). We also provide an estimation of outcomes according to if pt received 2ndline after "true progression" or due to any cause.

Conclusions: Our results validate the use of the IMDC prognostic classification as a discrimination tool, for predicting prognosis in pt receiving 2nd-line targeted therapies after pazopanib in mRC. Pt who received 2nd-line after true progression had a poorer prognostic than the predicted by the IMDC.

Background: X4P-001 is an oral, selective, allosteric inhibitor of the chemokine receptor CXCR4, and has been shown to down-regulate hypoxia inducible factor-2α (HIF-2α) and myeloid-derived suppressor cell (MDSC) trafficking in the tumor microenvironment. In multiple RCC xenograft models, the addition of X4P-001 to tyrosine kinase inhibitors (TKIs), including axitinib, increases the efficacy and delays the onset of TKI resistance.

Methods: This is an ongoing phase 1/2 open-label study of X4P-001 in combination with axitinib in patients (pts) with histologically confirmed clear cell RCC who have received 31 prior systemic therapy. The Ph1 portion of the study evaluates safety, tolerability, PK, PD and anti-tumor activity of the combination using a 3 + 3 dose escalation schema (escalating doses of X4P-001+ axitinib at 5 mg BID).

Results: As of 27 April, 2017, sixteen (16) pts were enrolled in the Ph1 portion of the study. The median age was 64 years (range 50-76) and pts had received a median of 2 prior lines of therapy (range 1-5). The doses tested were 200 mg BID, 400 and 600 mg QD of X4P-001 + axitinib. Two doses limiting toxicities (DLTs) were observed at the X4P-001 600 mg QD dose level: one pt had multiple grade (G) 2 adverse events (AEs), including anorexia, cognitive disturbance, fatigue, nausea, vomiting, and somnolence; another pt had G3 dyspnea and fatigue. The MTD/RP2D was determined to be 400 mg QD of X4P-001 + axitinib. Treatment-related AEs (≥ 10%) of any grade were fatigue, diarrhea, hypertension, nausea, headache, anorexia, vomiting, dysphonia, proteinuria, dry eye, dry mouth, arthralgia, chest pain, cognitive disorder, dysgeusia, stomatitis, weight loss, and elevated creatinine. Treatment-related G3/4 AEs (≥ 10%) were fatigue and hypertension. In addition, one pt had SAE due to G2 diarrhea and G2 creatinine elevation. Of the 9 clinically evaluable pts, 3 had confirmed partial response, 5 had

A. Cardarelli, Napoli, Italy*

Background: The risk of developing renal cell carcinoma (RCC) increases with age, and given the constant gain in life expectancy of the general population, RCC is frequently observed in the elderly. More than 80% of cancer pts aged ≥ 70 years have at least one comorbidity requiring treatment, leaving them exposed to drug interactions. Due to high frequency of comorbidities, these pts are often under-represented in clinical trials. The purpose of this analysis is to evaluate the feasibility of treatment with nivolumab in the elderly (≥ 70 years) and very elderly (≥ 75 years) in the EAP in Italy, given a more realistic picture of real world setting.

Methods: Nivolumab was available upon physician request for pts aged ≥18 years who had relapsed after at least one prior systemic treatment in the advanced or metastatic setting. Nivolumab 3 mg/kg was administered intravenously every 2 weeks to a maximum of 24 months. Pts included in the analysis had received ≥ 1 dose of nivolumab and were monitored for adverse events (AEs) using Common Terminology Criteria for Adverse Events.

Results: Of 389 Italian pts with mRCC enrolled in the EAP in Italy 125 pts (32%) had ≥70 years and 70 (18%) had ≥75 years. With a median follow-up of 9.8 months (0.1-16.2) in the elderly population (≥70 years), the disease control rate (DCR) was 58% including 1 patient in complete response (CR), 32 pts in partial response (PR) and 40 patients in stable disease (SD). Regarding the very elderly population (≥75 years), with a median follow-up of 9.8 months (0.1 -14.9), the DCR was 60% including 1 patient with CR, 19 pts with PR and 22 with SD. As of May 2017, 6 and 12 months overall survival (OS) rate were 87.2% and 77.8% respectively in the elderly population. Regarding the very elderly, the 6 and 12 months OS rate was 83.6% and 77.7%, respectively. The safety profile was consistent to what already observed in the general population.

Conclusions: These results suggest that elderly population can benefit from nivolumab treatment with safety results consistent to what previously reported, supporting the use of nivolumab in this subpopulation.

898P Immune expression profile and sunitinib benefit in metastatic clear cell renal cell carcinoma (ccRCC)

O. Reig Torras[1], M. Marín-Aguilera[1], N. Jimenez[1], L. Paré[1], P. Galvan[1], C. Mallofre[2], A. Prat[1], B. Mellado Gonzalez[1]

[1]*Medical Oncology, Hospital Clinic y Provincial de Barcelona, Barcelona, Spain,* [2]*Pathology, Hospital Clinic y Provincial de Barcelona, Barcelona, Spain*

Background: The identification of predictive biomarkers may be useful to select anti-angiogenic or immunotherapy treatment in renal cell carcinoma. We here investigated the immune expression profile in sunitinib (SU) or anti-PD1/PD-L1 treated ccRCC patients.

Methods: Forty-two metastatic ccRCC patients treated with SU and 10 patients treated with anti-PD1/PD-L1 antibodies were included in this retrospective biomarker study. 730 immune-related genes (nCounter® PanCancer Immune Profiling Panel, Nanostring) were tested in FFPE tumor specimens. Different immune gene signatures were correlated with clinical outcome. A differential expression analysis between refractory (progression-free survival (PFS) < 3 months) and sensitive (PFS > 3 months) patients to SU and anti-PD1/PD-L1 therapies was performed.

Results: Patients who achieved a partial or complete (P/CR) response with SU had a higher score of B cell, CD8 T cell, T cell, Th1 cell, Th2 cell, Treg cell and Stromal signatures. Moreover, these signatures were predictive of P/CR to sunitinib (p-value for odds ratio < 0.05). T cell signatures (CD8 T cell, T cell, Th1 cell, Th2 cell and Treg cell) were correlated with a better PFS, while activated dendritic cell (aDC) and stromal signatures were correlated with a better OS (Table). In the cohort of anti-PD-1/PD-L1 treated patients, no differences in the immune signatures were found between responders and no-responders to these drugs. However, differential expression analysis revealed a single gene, TIM-3, that was associated with resistance to anti-PD1/PD-L1 therapies and benefit to SU in ccRCC patients.

Table: 898P

Signatures	Progression-Free Survival		Overall Survival	
	HR (95% CI)	P	HR (95% CI)	P
CD8Tcell	0.57 (0.37 – 0.89)	0.01235	0.64 (0.39 – 1.03)	0.0684
Th1cell	0.62 (0.41 – 0.95)	0.02841	0.70 (0.43 – 1.14)	0.1491
Tcell	0.68 (0.48 – 0.98)	0.03951	0.79 (0.52 – 1.19)	0.2649
Tregcell	0.67 (0.45 – 0.98)	0.04126	0.76 (0.49 – 1.18)	0.2146
Th2cell	0.48 (0.24 – 0.97)	0.04155	0.62 (0.30 – 1.26)	0.1853
Stromal	0.72 (0.50 – 1.03)	0.06923	0.64 (0.43 – 0.96)	0.0291
Bcell	0.69 (0.47 – 1.03)	0.07271	0.74 (0.48 – 1.14)	0.1698
aDC	0.78 (0.46 – 1.34)	0.37136	0.53 (0.29 – 0.95)	0.0330
iDC	0.91 (0.52 – 1.58)	0.74005	0.69 (0.37 – 1.32)	0.2649

Conclusions: T cell signatures may be associated with benefit to SU in ccRCC. The value of TIM-3 as a potential biomarker in ccRCC merits further exploration.

Background: The treatment (tx) of metastatic renal cell carcinoma (mRCC) has markedly changed over the last decade with the introduction of targeted therapies including vascular endothelial growth factor receptor (VEGFR) and mammalian target of rapamycin (mTOR) inhibitors. Current tx recommendations include the VEGFR inhibitor pazopanib (PAZ) as first-line option and the mTOR inhibitor everolimus (EVE) after VEGF-targeted therapy. The approval of programmed cell death 1 (PD-1) checkpoint inhibitor nivolumab (NIVO) in 2016 provides an additional second-line option.

Methods: PAZOREAL is a prospective, non-interventional study to evaluate the effectiveness, tolerability, safety and quality of life on the routine tx of 450 adult patients (pts) with histologically confirmed mRCC treated with first-line PAZ, second-line EVE or NIVO, or third-line EVE after NIVO. The main objective is time on drug (TD) in the respective tx lines and overall, other objectives include overall survival, dosing parameters, safety and quality of life.

Results: Between December 2015 and March 2017, 305 pts have been enrolled; 302 in the first-line PAZ cohort and 3 in third-line EVE after NIVO. The latter cohort was opened for documentation after approval of NIVO. 266 first-line pts had a documented first intake of PAZ and were eligible for analysis; 201 (75.6%) had a clear-cell histology. Median TD on PAZ was 6.5 months. For 98 pts (36.8%) discontinuation of PAZ tx was reported. The main reasons were progressive disease (N = 36), followed by toxicity (N = 18) and (serious) adverse event (N = 13). Details on subsequent tx with NIVO or EVE were documented for 24 and 4 pts, respectively, while 8 pts started other therapies in second line. During PAZ tx, the most frequently reported treatment-emergent adverse events (TEAE) of grade 1/2 were diarrhea (N = 57), nausea (N = 36), and fatigue (N = 24), of grade 3/4 were hypertension (N = 11), diarrhea and anemia (each N = 4). Fatal TEAEs were reported in 28 pts with progression being the most common term.

Conclusions: PAZ is an effective and safe first-line therapy for pts with mRCC in a real life setting. Second line therapy has rapidly shifted towards NIVO.

Background: Higher SUN exposure is associated with better outcomes but SUN PK on day 28 does not correlate with toxicity (# 363, ASCO-GU 2012).

Methods: Toxicity-driven dose/schedule individualization was tested in a prospective phase II study where all pts start on 50 mg/day (d). Pts with minimum toxicity on d 28 are dose escalated to 62.5 mg and then 75 mg. Samples for SU011248 and SU012662 were drawn on day 14 on the first course (100 pts) and again after the optimal dose/schedule had been established (58 pts). 11 patients had 2-3 more samples drawn during continued Rx on the optimal dose.

Results: 117 pts were enrolled. Of 108 pts evaluable for response, dose was escalated in 20 pts to 62.5 mg (12 pts) and then to 75 mg (8 pts). In 49 pts eligible for dose reduction by standard criteria, a 50 mg dose was maintained but for 7 - 24 d. Dose was reduced to 37.5 mg in 22 pts and to 25 mg in 10 pts with individualized days on Rx. For 100 pts sampled on the first course the mean concentration (standard error) was 93.8 (3.0) and 29.8 (1.4) ng/mL for SU011248 and SU012662 respectively. For 58 pts, sampled again when optimal dose was established, the mean change from the 1st course for SU011248 and SU012662 was significantly different between dose levels ($P < 0.001$, Table). The same was true even after dose optimization ($p = 0.01$). The mean PK values declined over time in 27 pts that remained on 50 mg and a continued decline was seen in 6/11pts with continued sampling. There was no significant difference in PFS and OS between dose levels for all 117 pts.

Table: 900P

Dose level (n pts)	SU011248 (standard error) During 1st course ng/mL mean change at optimal dose	SU012662 (standard error) During 1st course ng/mL mean change at optimal dose
50 mg (n = 27)	90.7 (5.2) −11.8 (5.6)	27.6 (2.6) 0 (2.3)
< 50 mg (n = 13)	95.4 (10.1) −22.6 (12.7)	33.6 (4.6) −12.7 (4.4)
>50 mg (n = 18)	77.1 (5.7) +29.6 (10.6)	24.1 (2.6) +12.4 (2.5)
After optimization	**SU011248 (SE) at optimal dose**	**SU012662 (SE) at optimal dose**
50 mg (n = 27)	78.9 (4.7)	27.5 (2.3)
< 50 mg (n = 13)	72.8 (8.0)	21.7 (2.8)
>50 mg (n = 18)	106.7 (11.9)	36.5 (3.6)

Conclusions: While dose individualization corrects for some of the differences in PK values on the 1st Rx course, differences remain even after dose optimization emphasizing the importance of pharmacodynamics for toxicity and outcome. An ongoing dose optimization may be important to correct for the decline in PK over time.

Background: Final results from the randomised phase III METEOR trial confirmed a survival benefit of cabozantinib over everolimus in patients (pts) with advanced clear-

cell renal cell carcinoma who progressed after at least one previous antiangiogenic inhibitor. The EAP provided the opportunity to treat pts in real world clinical practice.

Methods: Data were collected from 91 pts treated with cabozantinib across 23 Italian hospitals. Cabozantinib was available, upon physician request, from September to December 2016. Pts were aged 18 years and older, with mRCC and measurable disease, with Perfomance Status (ECOG) 0 to 2, who had relapsed after one or more prior systemic treatment. 73 pts had clear-cell RCC, while the other 18 had non-clear-cell histologies (type II papillary and chromophobe). The most frequent sites of disease were: lung 53 (58%), lymph nodes 41 (45%), bone 28 (31%), liver 15 (16%) and brain 5 (5%); 42 (46%) pts had two or more sites of disease. Cabozantinib was administered orally at 60 mg once a day in 28 days-cycles. Dose reductions to 40 or 20 mg were allowed if toxicity was encountered. Pts were monitored for adverse events (AEs) using the National Cancer Institute (NCI) Common Terminology Criteria for Adverse Events (CTCAE) v.4.0. The aim of this analysis was to evaluate the safety and activity of cabozantinib in a large unselected population.

Results: Cabozantinib was administered as second line therapy in 28 (30%) pts, as III line in 18 (19%) pts and as further lines in the remaining 45 (51%) pts. At the time of our analysis, grade 3 and 4 AEs were observed in 21% of pts. Among 91 pts, only 5 (5%) discontinued treatment due to AEs. The best overall response was partial in 28 cases (31%), whereas 23 (25%) pts had stable disease and 23 (25%) had progressive disease; 17 pts (18%) have not reached the first response assessment. With a median follow-up of 4 months, the median progression-free survival observed was 3.5 months irrespective of the line of treatment.

Conclusions: Our data suggest that cabozantinib is safe and active in a large unselected population treated according to everyday clinical practice.

902P Prognostic factors for overall survival of patients with advanced renal cell carcinoma – data from the German prospective RCC-Registry

P.J. Goebell[1], L. Müller[2], M. Staehler[3], M. Müller[4], M. Frank[5], L. Kruggel[6], M. Jänicke[6], N. Marschner[7]

[1]Department of Urology, University Erlangen, Erlangen, Germany, [2]Medical Oncology, Onkologie Leer–Emden–Papenburg, Leer, Germany, [3]Department of Urology, University of Munich, Munich, Germany, [4]Centre for Haematology and Oncology Offenburg, Centre for Haematology and Oncology Offenburg, Offenburg, Germany, [5]Statistics, IOMEDICO AG, Freiburg, Germany, [6]Clinical Epidemiology and Health Economics, iOMEDICO AG, Freiburg, Germany, [7]Praxis für interdisziplinäre Onkologie & Hämatologie, Praxis für interdisziplinäre Onkologie & Hämatologie, Freiburg, Germany

Background: The identification of prognostic factors is a central question in oncology. They help to predict the course of disease and ideally support the oncologist in treatment decision making in clinical practice. We analysed prognostic factors identified by MSKCC and additional factors for the overall survival (OS) of patients (pts) treated with currently approved agents.

Methods: The prospective German renal cell carcinoma (RCC) Registry includes pts with advanced or metastatic renal cell carcinoma at start of systemic first-line therapy. > 300 oncologists are recruiting pts since 2007. Pts and tumour characteristics, data on all systemic therapies and outcome are collected. The prognostic factors for OS were assessed using a multivariate cox regression model.

Results: Median OS of the 1039 pts (median age 70 years) was 18.6 months (95% CI 16.0 - 20.5 months, 55% events). Median OS in months for low, intermediate and high risk pts according to MSKCC 1999 was 27.3 (23.7-33.8, 48% events), 16.0 (12.7-18.8, 58% events) and 5.3 (3.7-7.2, 74% events). The following factors were significantly associated with shorter OS ($p < 0.05$: *; $p < 0.01$: **; $p < 0{,}001$: ***): higher age*, non-clear cell histology**, grading G3/4 at diagnosis*, Karnofsky Performance Status <80%***, haemoglobin < lower limit of normal (LLN)***, LDH >1.5x upper limit of normal (ULN)***. Factors significantly associated with longer OS were time from primary diagnosis to metastasis***, BMI 25-30 versus (vs) <25***, BMI>30 vs < 25***, lung metastasis only at start of treatment*, non-visceral metastasis only at start of treatment* and hypertension*. Factors not significantly associated with OS were sex, tumour stage at diagnosis (IV vs <IV), total calcium >ULN, tumour localisation (right/left), congestive heart failure, renal disease, diabetes and total nephrectomy.

Conclusions: 3 out of 5 MSKCC factors were significantly associated with OS in our cohort. Still, a clear separation of OS between pts with low, intermediate and high risk according to MSKCC could be confirmed. In addition, we identified novel factors also associated with OS.

903P The efficacy and safety of sorafenib in patients with renal insufficiency of advanced renal cell carcinoma: Real- world data of sorafenib in Japan

K. Tatsugami[1], M. Oya[2], K. Kabu[3], H. Akaza[4]

[1]Urology, Graduate School of Medical Science, Kyushu University, Fukuoka, Japan, [2]Urology, Keio University School of Medicine, Tokyo, Japan, [3]Medical Affairs Oncology and Hematology, Bayer Yakuhin, Ltd., Tokyo, Japan, [4]Strategic Investigation on Comprehensive Cancer Network, The University of Tokyo, Tokyo, Japan

Background: Multiple treatment options are available for patients with advanced renal cell carcinoma (aRCC). However, the safety/efficacy data of these agents in patients with renal insufficiency are limited. To assess the safety/efficacy of sorafenib in aRCC patients with renal insufficiency, we analyzed the real-world data of a nationwide prospective post-marketing surveillance applying propensity score-matched cohorts.

Methods: A total of 3,255 patients with aRCC were enrolled, and 1,226 patients of whom were selected by propensity score matching for estimated glomerular filtration rate (eGFR) <45 (n = 613) and ≥45 (n = 613). Progression free survival (PFS), tumor response, adverse events (AEs), and doses of sorafenib were compared between the two groups.

Results: The median PFS in eGFR<45 and ≥45 was 7.4 months (6.4, 8.8) vs. 8.3 months (6.6, 9.0), respectively. Complete response rates were 1.8% and 3.0%, partial response rates were 24.3% and 26.4%, stable disease rates were 59.8% and 57.7% in eGFR <45 and ≥45, respectively. The mean starting dose was lower in eGFR <45 group (687 mg vs. 726 mg, $p < 0.0001$), but the median duration of treatment (6.1 vs. 6.6 months) and median daily dose (484 vs. 481 mg) were similar in both groups. The discontinuation rates due to AEs were similar in both groups. Any grade AEs observed ≥20% were hand-foot skin reaction (HFSR) (57.8%), hypertension (37.9%), rash (27.0%), and increases in lipase/amylase (26.9%), and diarrhea (23.1%). The common serious AEs were rash (7.6%), hepatic dysfunction (7.3%), bleeding (6.9%), HFSR (4.9%) and cytopenia (4.6%). The incidence of these common AEs was similar between the groups, except for cytopenia and renal failure which were higher in eGFR <45 group. In the both groups, the eGFR value did not change from the baseline over a year, and it also did not deteriorate even at the time of discontinuation.

Conclusions: Sorafenib has little impact on the renal function in almost all patients with renal insufficiency and provide the fine therapeutic effects for these aRCC patients.

Maria della Misericordia, Perugia, Italy, [12]Medical Oncology, Azienda Ospedaliera di Ferrara St. Anna, Ferrara, Italy, [13]Medical Oncology, Azienda Ospedaliera St. Andrea, Rome, Italy, [14]Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy, [15]Medical Oncology, Istituto Dermopatico dell'Immacolata, Rome, Italy, [16]Medical Oncology, Ospedale di Saronno, Saronno, Italy, [17]Medical Oncology, Ospedale "S. Martino", Genoa, Italy, [18]Medical Oncology, Azienda Ospedaliera di Rilievo Nazionale "Antonio Cardarelli"-AORN A. Cardarelli, Naples, Italy, [19]Medical Oncology, Azienda Ospedaliera Sta Maria, Terni, Italy, [20]Department of Oncology, San Camillo and Forlanini Hospitals, Rome, Italy

Background: Biomarkers for outcome after immune-checkpoint blockade in mRCC are needed. We aimed to verify the prognostic impact of inflammatory indexes based

on baseline values of neutrophils (N), lymphocytes (L) and/or platelets (P) in pts with mRCC included in the Italian nivolumab EAP.

Methods: Pts who had received ≥ 1 dose of nivolumab 3 mg/kg every 2 weeks in the Italian EAP after at least one prior systemic therapy for mRCC were enrolled in this study. The pre-treatment systemic immune-inflammation index (SII) defined as P×N/L, neutrophil-to-lymphocyte ratio (NLR) defined as N/L and platelet-to-lymphocyte ratio (PLR) defined as P/L were evaluated to identify a potential correlation with overall survival (OS). X-tile 3.6.1 software was used to identify cut-off values. OS was estimated by the Kaplan-Meier method and compared with the log-rank test. The impact of SII, NLR, and PLR on OS was evaluated by Cox regression analyses and on best overall response rate (ORR) by binary logistic regression.

Results: A total of 346 mRCC pts treated with nivolumab were included. SII ≥ 1375, NLR ≥ 3 and PLR ≥ 232 were considered as elevated levels (high risk groups). One-year OS in low and high SII group was 77% and 36%, respectively ($p < 0.0001$); 1-year OS in low and high NLR was 76% and 58%, respectively ($p < 0.0001$); 1-year OS in low and high PLR was 76% and 45%, respectively ($p < 0.0001$). Likewise, best ORR was higher in pts with low SII ($p = 0.008$), low NLR ($p = 0.06$) and low PLR ($p = 0.004$). In multivariate analysis adjusted for age, gender, risk score (MSKCC), ECOG performance status, presence of liver, brain and/or bone mets, SII, NLR and PLR, the model identified SII as the strongest factor associated with OS ($p < 0.0001$).

Conclusions: SII, NLR, and PLR are robust inflammatory prognostic factors for predicting outcome in mRCC pts treated with nivolumab. SII is a more powerful predictive system than the other inflammatory indexes for these pts.

Ordine Mauriziano, Turin, Italy, [13]Medical Oncology, A.O. Ordine Mauriziano, Guastalla, Italy, [14]Nephrology Unit, Istituti Ospitalieri Cremona, Cremona, Italy

Background: Pazopanib has been approved for first-line treatment of patients (pts) with mRCC based on the prospective randomized trial that enrolled only pts with adequate renal function. There are no data on the efficacy and toxicity of pazopanib in pts with renal insufficiency (RI). The aim of this study is to investigate the effect of kidney function on treatment outcomes in pts treated with pazopanib for mRCC.

Methods: We retrospectively analyzed the data of the mRCC pts treated with pazopanib with respect to renal function in fourteen Italian institutions from January 2010 to June 2016. Baseline glomerular filtration rate (GFR) was calculated using the Modification of Diet in Renal Disease (MDRD) formula at the time of therapy initiation. Pts with MDRD<60 mL/min/1.73 m2 (group A) were compared with pts with MDRD≥60 mL/min/1.73 m2 (group B) in terms of response rates, progression free survival (PFS), overall survival (OS) and toxicities.

Results: Two hundred and twenty-nine pts with mRCC were included in this study: 128 pts in group A and 101 pts in group B. 68% of pts were male, median age was 67 years (34-88) and median CrCl was 49,7 ml/min in group A. In group B, 64% of pts were male, median age was 64 years (38-85) and median CrCl was 74 ml/min. Pts with MDRD<60 were more likely to have had a previous nephrectomy (87% vs 79%). Median PFS was 14 months (95% confidence interval [CI] 9.4-18.5) and 17 months (95% CI 11.4-22.8), OS was 30.5 months (95% CI 8-53) and 41.4 months (95% CI 21-62) for MDRD<60 group and MDRD≥60 respectively, with no statistical difference ($p = 0.6$). The disease control rate was 84% in group A, and 73% in group B ($p = 0.1$). About toxicity profile, no difference between the 2 groups was reported in terms of incidence of grade 1-2 (73% in group A vs 74% in group B, $p = 0.5$) and grade 3-4 (24% vs 33% respectively, $p = 0.2$). Dose reductions are statistically more frequent in pts in group A (66% vs 36%, $p = 0.04$), despite the same percentage of pts in both groups started at dose of 800 mg/day.

Conclusions: Although in this study it is necessary to reduce the dose of pazopanib more frequent in pts with RI, kidney function at therapy initiation does not adversely affect the efficacy and safety of pazopanib.

906P Impact of haptoglobin polymorphism on survival of renal cell carcinoma patients

T. Vermassen[1], N. Lumen[2], J. Delanghe[3], S. Rottey[1]

[1]Department Medical Oncology, Ghent University Hospital, Ghent, Belgium, [2]Department Urology, Ghent University Hospital, Ghent, Belgium, [3]Department Clinical Chemistry, Ghent University Hospital, Ghent, Belgium

Background: Renal cell carcinoma (RCC) accounts for 2.4% of all malignancies worldwide with 338,000 estimated new cases globally in 2012. With 144,000 deaths annually, RCC is the 16th cancer-related death worldwide. In the last decade, the use of targeted therapy for patients with metastatic RCC has increased exponentially, especially since the breakthroughs with cabozantinib and nivolumab. Apart from the Heng criteria in 1st-line therapy, no robust biochemical markers exist for the prognosis of RCC patients. Here we assessed the prognostic value of haptoglobin (Hp) polymorphisms on survival of RCC patients.

Methods: At interim analysis, 53 metastatic RCC patients were enrolled and Hp phenotypes were determined prospectively. Survival data was retrieved from the electronic patient files. Kaplan-Meier survival analyses were performed for disease-free survival (DFS), progression-free survival (PFS) after 1st- and 2nd-line therapy, and overall survival (OS).

Results: Fifty-eight percent of patients were male. Hp distribution was 19%, 49% and 32% for Hp 1-1, 2-1 and 2- phenotypes, respectively. Median follow-up since development of metastatic disease was 4.7 years (95% CI 3.3 – 6.5). Lowest DFS was found in patients with Hp 2-2 phenotypes. This was significant when Hp 2-2 phenotypes were compared with Hp 1-1/2-1 phenotypes (hazard ratio [HR] = 1.93 [95%CI 1.12 – 5.75], $P = 0.0255$). No significant difference between Hp phenotypes was noticed for PFS after 1st-line therapy. After 2nd-line therapy, longest PFS was observed in patients with Hp 2-1 and 2-2 phenotypes which was better compared with Hp 1-1 phenotypes. Lastly, OS was found to be longer in patients with Hp 2-1 and 2-2 phenotypes, although no significance was observed versus patients with Hp 1-1 phenotypes. Median durations of survival and HRs versus Hp 1-1 phenotypes are given in Table.

Table: 906P Hp survival analysis

Cohort	Hp	N	Median survival	HR vs Hp 1-1	P-value
DFS (years)	1-1	9	0.6 (0.2 – 4.3)	1	0.0616
	2-1	19	2.3 (0.6 – 5.0)	0.73 (0.34 – 1.59)	
	2-2	14	0.5 (0.1 – 0.9)	1.54 (0.60 – 3.97)	
PFS 1st-line (months)	1-1	9	11.7 (2.4 – 17.6)	1	0.7529
	2-1	26	14.7 (6.5 – 28.7)	0.90 (0.33 – 2.45)	
	2-2	17	6.7 (4.2 – 52.2)	1.20 (0.40 – 3.54)	
PFS 2nd-line (months)	1-1	5	3.2 (0.9 – 3.9)	1	0.0001
	2-1	16	6.2 (5.4 – 17.6)	0.21 (0.03 – 0.87)	
	2-2	12	16.4 (6.9 – 27.6)	0.13 (0.02 – 0.67)	
OS (years)	1-1	10	1.7 (1.2 – 2.7)	1	0.4205
	2-1	26	3.8 (2.3 – 6.2)	0.56 (0.20 – 1.60)	
	2-2	17	3.5 (1.6 – 7.1)	0.61 (0.20 – 1.87)	

Conclusions: Interim analysis shows that Hp phenotype has prognostic potential, especially in DFS and PFS during 2nd-line therapy. Continuation of the research on this topic is warranted.

907P Impact of CYP3A4*22 on pazopanib pharmacokinetics in cancer patients

S.L.W. Koolen[1], A. Huitema[2], P. Laven[1], S. El Bouazzaoui[3], H. Yu[2], N.P. Erp[4], C.M.L. Herpen[5], P. Hamberg[6], H. Gelderblom[7], N. Steeghs[8], S. Sleijfer[1], R.H.N. van Schaik[3], R.H.J. Mathijssen[1], S. Bins[1]

[1]Medical Oncology, Erasmus MC Cancer Institute, Rotterdam, Netherlands, [2]Dept. of Pharmacy & Pharmacology, Netherlands Cancer Institute, Amsterdam, Netherlands, [3]Clinical Chemistry, Erasmus University Medical Center, Rotterdam, Netherlands, [4]Clinical Pharmacy, Radboud University Medical Center, Nijmegen, Netherlands, [5]Medical Oncology, Radboud University Medical Center, Nijmegen, Netherlands, [6]Internal Medicine, Franciscus Gasthuis, Rotterdam, Netherlands, [7]Medical Oncology, Leiden University Medical Center (LUMC), Leiden, Netherlands, [8]Medical Oncology, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands

Background: Pazopanib is characterized by a large interpatient variability in systemic drug exposure. As pazopanib trough levels (>20.5 mg/L) are correlated with clinical outcome (Suttle et al, BJC 2014) in metastatic renal cell carcinoma (mRCC) patients, it is vital to identify factors that influence pazopanib pharmacokinetics (PK). The objective of the current analysis was to evaluate if single nucleotide polymorphisms (SNPs) in the metabolic pathway of pazopanib (i.e. *CYP3A4*, *ABCB1* and *ABCG2*) affect systemic pazopanib concentrations.

Methods: We analyzed 97 patients who participated in 3 pazopanib PK studies. Starting point of the current analysis was a population PK model for pazopanib (Yu et al, Clin Pharmacokinet 2017). Four SNPs located on 3 genes, that were associated with decrease of function were analyzed using real time PCR: *CYP3A4 15389 C>T (*22)*, *ABCB1 3435 C>T*, and the *ABCG2* SNPs *421 C>A*, and *34G>A*. The influence of these SNPs on pazopanib bioavailability and clearance (CL) was explored with NONMEM. Statistical significance was determined with the likelihood ratio test using the objective function value (OFV). Trough concentrations (C_{trough}) at 6 weeks after start with doses of 400 to 800 mg once daily (OD), were simulated. A threshold C_{trough} of 20.5 mg/L was used as reference.

Results: From 3 patients, insufficient DNA was isolated to run a PCR analysis. All SNPs were in Hardy-Weinberg equilibrium. Eleven patients (12%) had a variant allele at *CYP3A4*22*, all of whom were heterozygous. Incorporation of *CYP3A4*22* in the NONMEM model resulted in a 35% lower CL for the variant carriers (0.18 L/h vs 0.27 L/h; $\Delta OFV = -7.8$; $P < 0.01$). Simulated median C_{trough} of patients with *CYP3A4*22* with 400 mg OD, 600 mg OD or 800 mg OD were 16 mg/L, 25 mg/L and 33 mg/L, respectively. Simulated C_{trough} for the population excluding the *CYP3A4*22* heterozygotes after 800 mg OD was 21 mg/L. No effect of the *ABCB1* or *ABCG2* SNPs on systemic concentrations were found.

Conclusions: Our analysis shows that *CYP3A4*22* carriers have a clinically relevant lower pazopanib CL. Prospective analysis should point out whether *CYP3A4*22* carriers are at risk for more toxicity and require a lower pazopanib starting dose.

908P Association between biopsychosocial distress (BPSD) and overall survival (OS) in patients with metastatic renal cell carcinoma (mRCC)

C.D. Bergerot[1], K.L. Clark[2], K.T. Ashing[3], L. Almeida[1], P.G. Bergerot[1], R. Obenchain[2], N. Dizman[1], J. Hsu[1], M.C. Maia[1], E. Philip[4], M. Loscalzo[2], S.K. Pal[1]

[1]Department of Medical Oncology & Experimental Therapeutics, City of Hope, Duarte, CA, USA, [2]Department of Supportive Care Medicine, City of Hope, Duarte, CA, USA, [3]Department of Population Sciences, City of Hope, Duarte, CA, USA, [4]The Notre Dame Laboratory for Psycho-Oncology Research, University of Notre Dame, Notre Dame, IL, USA

Background: Depressive symptoms have been associated with poorer OS in pts with mRCC (Prinsloo et al J Behav Med 2015). In other malignancies, BPSD has also been linked to poorer OS, but in mRCC, this association is unclear.

Methods: From a single institution, clinicopathologic information from pts with mRCC diagnosed between 2001 and 2016 were collected. Corresponding data from an electronic survey tool was obtained, comprised of 22 core items spanning physical, practical, functional and emotional domains. Each item was self-assessed by the pt on a 5-point Likert scale. The cumulative score was used to characterize BPSD as either as low BPSD (not a problem/mild) vs high BPSD (moderate/severe/very severe). Associations between BPSD level and clinicopathologic criteria (e.g., Heng risk) were interrogated, and OS was compared between patients characterized as low BPSD vs high BPSD.

Results: A total of 102 pts (28.4% F/71.6% M) were assessed with a median age of 63 (range, 24-80). 73.4 and 26.6% pts were characterized as having good/intermediate and poor risk by Heng criteria, respectively. 79.3% pts and 20.7% pts were characterized as having low and high BPSD, respectively. No association was found between BPSD and age or gender. However, married patients have a longer survival (48.65 mos vs 34.52 mos, P=.07). Pts with poor risk mRCC were noted to have a higher BPSD as compared to pts with mild BPSD (75% vs 25%, P=.22). Median OS in the overall cohort was 44.2 months (mos). Although not statistically significant, a trend towards prolonged OS in pts with low BPSD vs high BPSD was observed (45.81 mos vs 35.95 mos, P = 81).

Conclusions: Our study suggests a potential link between Heng risk and BPSD, and further shows a compelling trend towards poorer OS in pts with higher BPSD. These results warrant confirmation in larger series. Targeted interventions to address elements related to BPSD have the potential to improve patient outcomes and should be developed.

909P Treatment reality and outcome data of patients with advanced papillary renal cell carcinoma: Data from the German prospective RCC-Registry

M. Staehler[1], L. Müller[2], P.J. Goebell[3], F. Overkamp[4], M. Frank[5], L. Kruggel[6], M. Jänicke[6], N. Marschner[7]

[1]Dept of Urology, Ludwig Maximilians University - Grosshadern, Munich, Germany, [2]Medical Oncology, Onkologie Leer–Emden–Papenburg, Leer, Germany, [3]Urology, University Erlangen, Erlangen, Germany, [4]Oncology, Praxis und Tagesklinik fuer Onkologie, Recklinghausen, Germany, [5]Biostatistics, IOMEDICO AG, Freiburg, Germany, [6]Clinical Epidemiology and Health Economics, IOMEDICO AG, Freiburg, Germany, [7]Oncology, Praxis für interdisziplinäre Onkologie & Hämatologie, Freiburg, Germany

Background: Because renal cell carcinoma (RCC) is diagnosed 75-80% with clear cell histology, there is little data on treatment and outcome of patients (pts) with non-clear RCC. They are reported to have a poorer prognosis and are often excluded from clinical trials. Here, we present data on papillary RCC, the most common non-clear cell subtype (10-15% of RCC).

Methods: The prospective German RCC-Registry includes pts with advanced or metastatic RCC at start of systemic first-line therapy. Data on patient and tumour characteristics, all systemic therapies and outcome are collected. More than 300 medical and uro oncologists are recruiting pts since 2007.

Results: Median age for pts with papillary RCC (n = 92) at start of first-line therapy was 66 years. According to MSKCC risk category, pts were classified into 30% low, 55% intermediate and 2% high risk (12% unknown). From 2007 to May 2016 (data cut) treatment changed. First-line, the use of sunitinib declined and the use of temsirolimus and pazopanib increased. Since 2011 (n = 46), first-line treatments included 33% (n = 15) temsirolimus, 30% (n = 14) sunitinib and 22% (n = 10) pazopanib. The most frequently used second-line treatments since 2011 (n = 28) are sunitinib (36%, n = 10), everolimus and pazopanib (18%, n = 5 each), temsirolimus (11%, n = 3) followed by axitinib and sorafenib (7%, n = 2, each). The most frequently used first -> second-line strategies (first-line since 2011, n = 23) are mTor inhibitors (temsirolimus) -> TKI (35%, n = 8) and TKI -> TKI (26%, n = 6) (TKI: sunitinib, axitinib, pazopanib or sorafenib). Updated data (data cut May 2017) including nivolumab will be presented. Median progression-free survival (PFS) for the first-line was 6.1 months (95% CI 4.0 - 9.9) for pts with papillary RCC versus (vs) 8.6 (7.7 - 9.7) for pts with clear cell RCC (ccRCC, n = 772). For the second-line, median PFS was 3.7 (2.3 – 4.9) vs 4.8 (4.2 – 5.8) (papillary vs ccRCC). Median overall survival (OS) was 12.7 (8.5 – 23.8) vs 20.8 (19.1 – 23.8) (papillary vs ccRCC).

Conclusions: We show first- and second-line treatment of pts with advanced papillary RCC. Our data indicate that prognosis for pts with papillary RCC might be inferior to that of pts with clear cell RCC.

910P Exome sequencing of tumor samples from S1107 "Randomized phase II evaluation of tivantinib and tivantinib in combination with erlotinib in patients with papillary renal cell carcinoma (pRCC)"

P. Twardowski[1], X. Wu[2], M. Plets[3], C. Tangen[3], E. Plimack[4], N. Agarwal[5], N.J. Vogelzang[6], J. Wang[2], S. Tao[2], I. Thomson[7], P. Lara[8]

[1]Department of Medical Oncology and Experimental Therapeutics, City of Hope, Duarte, CA, USA, [2]Molecular and Cellular Biology, City of Hope, Duarte, CA, USA, [3]SWOG Statistical Center, Fred Hutchison Cancer Research Center, Seattle, WA, USA, [4]Medical Oncology, Fox Chase Cancer Center, Philadelphia, PA, USA, [5]Medical Oncology, Huntsman Cancer Institute, Salt Lake City, UT, USA, [6]Medical Oncology, US Oncology Research c/o Comprehensive Cancer Crts of NV, Las Vegas, NV, USA, [7]Urology, University of Texas, San Antonio, San Antonio, TX, USA, [8]Medical Oncology, University of California Davis Cancer Center, Sacramento, CA, USA

Background: pRCC is associated with activation of MET pathway, overexpression of EGFR and inferior responses to VEGF inhibition than clear cell RCC. In S1107 we randomized patients (pts) with advanced pRCC and 0-1 prior systemic therapy to MET inhibitor tivantinib at 360 mg BID (Arm 1) or tivantinib 360 mg BID plus EGFR inhibitor erlotinib at 150 mg daily (Arm 2). 66% of pts had no prior systemic therapy; 6% had type 1 pRCC, 42% had type 2, and 52% had no subtype assigned. The study was closed at interim analysis after 55 pts were enrolled and 0% RR was noted. Median PFS was 2.0 and 3.3 months, and OS was 10.3 and 11.3 months in Arms 1 and 2 respectively. These results were inferior to previously reported clinical trials with pRCC. To better understand these outcomes we performed whole exome sequencing of tumor samples collected from pts participating in this study.

Methods: Exome of 16 pts were successfully sequenced using Agilent SureSelect probes. The mean coverage of target regions ranged from 45x to 91x. Only reads aligned to unique genomic location were retained. The single point mutations and small indels were identified using GATK HaplotypeCaller. Copy number analysis was performed using Bioconductor package "DNACopy" and customized R scripts.

Results: Most of the mutations were unique to individual pts indicating high diversity of variants in this patient cohort. Only 1 MET mutation was ascertained affecting tyrosine kinase domain (K1198I). Other mutations associated primarily with type 2 pRCC included CDKN2A, PBRM1, SETD2, KDM6A, FAT1, NF2, CUL. No EGFR and FH mutations were detected. The most affected pathways included WNT, cadherin and mitotic G2-G2/M phase. Somatic copy number variation was challenging to obtain since no matching normal tissues were collected, but MET amplification was suspected in minority of cases.

Conclusions: S1107 patient cohort had a high proportion of pts with molecular subtypes not driven by MET abnormalities and would not be expected to respond well to MET inhibition. Although MET remains a reasonable therapeutic target in pRCC, careful selection of pts exhibiting MET alterations is required to better benefit from therapy with MET inhibitors.

911P Patients (pts) with metastatic non-clear cell renal cell carcinoma (mnccRCC) treated with Nivolumab (Nivo) based immunotherapy as advanced treatment (ATL) line: analysis of a national early access program (EAP)

A. Peer[1], K. Savion[2], K. Rouvinov[3], R. Leibowitz-Amit[4], R. Berger[4], A. Sella[5], V. Neiman[6], E. Rosenbaum[6], W. Mermershtain[3], A. Neumann[1], M. Kolin[1], R. Perets[1], D. Keizman[7]

[1]Oncology, Rambam Health Care Center, Haifa, Israel, [2]School of Medicine, Technion, Haifa, Israel, [3]Oncology, Soroka University Medical Center, Beer Sheva, Israel, [4]Oncology, Chaim Sheba Medical Center, Ramat Gan, Israel, [5]Oncology, Asaf Harofeh Medical Center, Zerifin, Israel, [6]Oncology, Rabin Medical Center, Petah Tikva, Israel, [7]Oncology, Meir Medical Center, Kfar Saba, Israel

Background: Immunotherapy with the andi-PD1 Nivo is a standard ATL for clear cell mRCC. Data on its activity in the rare variant of mnccRCC is limited (case reports). We aimed to report the activity of Nivo in mnccRCC pts treated per a national EAP.

Methods: Records from consecutive mnccRCC pts treated with Nivo ATL per a national EAP in 6 centers were retrospectively reviewed. We report the clinical benefit, progression free survival (PFS), overall survival (OS), and toxicity.

Results: Between 7/2015 – 12/2016, 16 mnccRCC pts (median age 64, male 68%; papillary type 38%, n = 6; chromophobe 44%, n = 7; undifferentiated 12%, n = 2; pure sarcomatoid 6%, n = 1). 62% (n = 10) were treated with second line Nivo, and 38% (n = 6) as third and fourth line. Heng risk was good/intermediated/poor in 6% (n = 1)/ 75% (n = 12)/19% (n = 3). Clinical benefit (stable disease+ partial response) was 37% (4 partial response and 2 stable disease). Median PFS was 3.5 months (mos). After a median follow up time of 8 mos, 100% of the pts with a clinical benefit are still with a benefit and on treatment (range 5-18m). Most pts (69%, n = 11) are alive, with median OS not reached. Toxicity was mild grade 1-2 in the majority of pts (56%, n = 9).

Conclusions: Nivo as ATL may be active in mnccRCC pts, and associated with durable responses and predictable mild toxicity. Future and larger studies are needed to assess the activity of immunotherapy in this uncommon type of mRCC.

912P Cabozantinib for the treatment of patients with metastatic variant histology renal cell carcinoma (vhRCC): a retrospective study

M.T. Campbell[1], M.A. Bilen[2], C. Duran[3], E. Altinmakas[4], Z. Lim[1], A. Shah[1], E. Jonasch[1], N. Tannir[1]

[1]Genitourinary Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA, [2]Hematology and Medical Oncology, Winship Cancer Institute of Emory University, Atlanta, GA, USA, [3]Diagnostic Imaging, MD Anderson Cancer Center, Houston, TX, USA, [4]Diagnostic Imaging, MD Anderson Cancer Center, Houston, TX, USA

Background: Cabozantinib (C) prolongs overall survival (OS) and progression-free survival (PFS) in patients with metastatic clear-cell renal cell carcinoma (ccRCC) that progressed on first-line VEGFR-TKI. No standard of care systemic therapy exists for the management of patients with metastatic vhRCC.

Methods: This is a retrospective, IRB approved study of patients with vhRCC who received cabozantinib at MD Anderson Cancer Center from January 2014-January 2017. Information collected from the medical records included the baseline characteristics, toxicity, dose reductions, and OS. A blinded radiologist assessed the radiographic response using RECIST v1.1. Descriptive statistics, the Kaplan Meier method and the log rank test were applied using Microsoft Excel and GraphPad Prism version 6 software.

Results:

Table: 912P

	N = 30
Gender	Male = 26 (86.7%)
Age, median (range)	58.4 years (25-81)
Prior Nephrectomy	27 (90%)
Histology	Papillary (P) 17 Chromophobe (Chr) 6 Other: unclassified 3, translocation 2, sarcomatoid (sarc) 1, mucinous tubular/spindle cell 1
Prognostic Risk Group MSKCC IMDC	Good/Intermediate/Poor 2/20/8 2/ 23/5
Number of Prior Therapies 0 1 >1 Median (range) Previous VEGFR Tyrosine Kinase Inhibitor	3 7 20 2 (0-5) 26

Median PFS was 8.6 months (mos) (95%CI: 6.1-14.7), and median OS was 22.7 mos (95%CI:10.8-NR), median follow up 10.6 months (95%CI: 7.1-14.1). There were no significant differences detected between patients with papillary versus non-papillary histologies with respect to PFS or OS. At last follow up, 13 patients remain on treatment with median time on therapy for all patients of 15.0 months. Of the 28 patients with measurable disease, there were 4 confirmed PRs (2 P, 1 Chr, 1 unclassifed) for a 14% ORR. For the entire cohort, 20 of 30 (66.7%) with stable disease, and 6 of 30 with progressive disease (20%), for a disease control rate of 24 of 30 (80%). Of 21 patients who started C at 60 mg/d, 12 (57%) required dose reduction due to toxicity. Multiple patients required treatment breaks but none discontinued therapy due to toxicity.

Conclusions: In this retrospective study, C produced a clinically meaningful benefit in patients with metastatic vhRCC, the majority of whom had PD on prior VEGFR-TKIs. Prospective trials of C in vhRCC are warranted and planned.

913P Avelumab in patients with metastatic adrenocortical carcinoma (mACC): Results from the JAVELIN solid tumor trial

C. Le Tourneau[1], C. Zarwan[2], C. Hoimes[3], D.J. Wong[4], S. Bauer[5], M. Wermke[6], H.J. Grote[7], A. von Heydebreck[8], K. Chin[9], J. Gulley[10]

[1]Department of Medical Oncology, Institut Curie, Paris, France, [2]Medical Oncology, Lahey Hospital and Medical Center, Burlington, MA, USA, [3]Hematology and Oncology, Case Western Reserve University and University Hospitals Seidman Cancer Center, Cleveland, OH, USA, [4]Department of Medicine, University of California, Los Angeles Medical Center, Los Angeles, CA, USA, [5]Department of Medical Oncology, University Hospital Essen Westdeutsches Tumorzentrum, Essen, Germany, [6]Early Clinical Trial Unit, Universitätsklinikum Dresden, Dresden, Germany, [7]Oncology, Merck KGaA, Darmstadt, Germany, [8]Biostatistics, Merck KGaA, Darmstadt, Germany, [9]Immune-Oncology, EMD Serono, Inc, Billerica, MA, USA, [10]Genitourinary Malignancies Branch, National Cancer Institute, Bethesda, MD, USA

Background: Avelumab is a human anti–PD-L1 IgG1 antibody that has shown promising clinical activity in multiple tumor types, and is approved in the US for the treatment of metastatic Merkel cell carcinoma. Here, we report an updated analysis of avelumab in patients (pts) with mACC, representing the largest prospective monotherapy study performed to date in this rare cancer with limited therapeutic options.

Methods: In a phase 1b cohort (NCT01772004), pts with mACC and prior platinum-based therapy received avelumab at 10 mg/kg IV Q2W until progression, unacceptable toxicity, or withdrawal. Prior and ongoing treatment with mitotane was permitted. Tumors were assessed every 6 wks (RECIST v1.1). Endpoints included safety (NCI-CTCAE v4.0), best overall response, objective response rate (ORR), progression-free survival (PFS), and overall survival (OS).

Results: As of Dec 31, 2016, 50 pts from 6 countries received avelumab for a median of 3.4 mos (0.5–24.8). Median follow-up was 16.5 mos (11.7-27.6); 5 pts (10.0%) remained on treatment. Median age was 50 y (range 21–71) and median time since diagnosis of metastatic disease was 14.5 mos. 24 pts (48.0%) had received ≥2 prior lines of treatment for advanced disease (median 1, range 0–6). 41 pts (82.0%) had a treatment-related adverse event (TRAE) of any grade; the most common (>15%) were nausea (20.0%) and fatigue (18.0%). 8 pts (16.0%) had a grade ≥3 TRAE, of which only increased ALT (4.0%) occurred in > 1 pt. 12 pts (24.0%) had an immune-related AE of any grade. Confirmed ORR was 6.0% (3 partial responses; 95% CI 1.3–16.5); response was ongoing in 1 pt at data cutoff. 21 pts (42.0%) had stable disease as best response (disease control rate 48.0%). Median PFS was 2.6 mos (95% CI 1.4–4.0). Median OS was 10.6 mos (95% CI 7.4–not estimable) and the 12-mo OS rate was 47.0% (95% CI 31.8–60.9). Responses occurred in 2 pts with PD-L1+ tumors and 1 PD-L1 − (≥5% tumor cell cutoff). In PD-L1 + (n = 12) vs PD-L1 − (n = 30) subgroups, median PFS was 5.5 vs 1.7 mos (HR 0.66; 95% CI 0.3–1.4) and median OS was 14.4 vs 11.5 mos (HR 0.82; 95% CI 0.3–2.2), respectively.

Conclusions: Avelumab had a manageable safety profile and demonstrated clinical activity in pts with platinum-treated mACC.

914P Do patients (pts) with advanced nonseminomatous germ cell tumors (aNSGCT) and unfavorable time to normalization (TTN) of tumor markers benefit with prolongation of 1-st line chemotherapy (ChT)?

A. Tryakin[1], M. Fedyanin[1], J. Sergeev[2], A. Bulanov[1], B. Akhmedov[3], T. Zakharova[4], V. Matveev[5], I. Fainstein[2], A. Garin[1], S. Tjulandin[1]

[1]Clinical Pharmacology and Chemotherapy, Russian Oncology Research Center Named After Blokhin N.N., Moscow, Russian Federation, [2]Radiosurgery, Russian Oncology Research Center Named After Blokhin N.N., Moscow, Russian Federation, [3]Thoracic Surgery, Russian Oncology Research Center Named After Blokhin N.N., Moscow, Russian Federation, [4]Pathology, Russian Oncology Research Center Named After Blokhin N.N., Moscow, Russian Federation, [5]Urology, Russian Oncology Research Center Named After Blokhin N.N., Moscow, Russian Federation

Background: Three-four cycles of BEP are commonly recognized as a standard 1-st line ChT in aNSGCT. However, there were no trials studying optimal cycles numbers in this setting, especially in case of unfavorable TTN of tumor markers. We performed retrospective single center analysis to evaluate if pts with unfavorable TTN of tumor markers may benefit with prolongation of induction ChT.

Methods: Inclusion criteria were as follows: (1) ChT-naïve aNSGCT pts treated with etoposide- and cisplatin-based chemotherapy; (2) AFP and hCG levels available at days 0 and 18-22 of cycle 1 to calculate TTN (Fizazi K., JCO 2004). Pts who received less than "standard" number of cycles (3xBEP or 4xEP for IGCCCG good risk, 4xBEP for intermediate and poor risk) for any reason were excluded from the analysis. Cox regression multivariate analysis was also performed. TTN was calculated by K.Fizazi's methodic (JCO 2004).

Results: From 1987 to 2011 952 pts with aNSGCT received 1-st line ChT. 584 pts matched the inclusion criteria. Unfavorable TTN had 24 (11%), 61 (41%) and 122 (84%) of pts with good, intermediate and poor IGCCCG risk, respectively. More than standard number of cycles received 199 pts. Prolongation of ChT did not result in significant improvement of OS in any IGCCCG prognostic groups irrespectively of TTN (Table).

Table: 914P

IGCCCG risk group	TTN/# of cycles	N pts	5-y OS, %	p (HR, 95%CI)
Good	favorable/standard	176	92%	0,44
	favorable/>standard	42	98%	(HR 0,63, 0,23-1,89)
	unfavorable/standard	15	93%	0,65
	unfavorable/> standard	9	78%	(HR 1,48, 0.24-10.48)
Intermediate	favorable/standard	127	88%	0,14
	favorable/>standard	20	80%	(HR 2,1, 0,73-9,38)
	unfavorable/standard	32	81%	0,66
	unfavorable/> standard	29	86%	(HR 0,78, 0.25-2.41)
Poor	favorable/standard	12	91%	0,17
	favorable/>standard	10	100%	(HR 0,14, 0.01-2.27)
	unfavorable/standard	23	65%	0,55
	unfavorable/> standard	89	72%	(HR 0,79, 0.33-1.79)

Conclusions: Prolongation of 1-st line ChT beyond standard number of cycles does not improve outcome of pts with unfavorable TTN of tumor markers.

915P The prognostic role of neutrophil-to-lymphocyte ratio (NLR) in patients with metastatic germ cell tumors

D. Ribnikar[1], P.L. Bedard[1], R.J. Hamilton[2], M. Jewett[2], P. Warde[3], P. Chung[3], L. Anson Cartwright[3], A. Templeton[4], E. Amir[1], A.R. Hansen[1], J. Lewin[1]

[1]Division of Medical Oncology and Hematology, Princess Margaret Cancer Center, Toronto, ON, Canada, [2]Department of Surgery, Princess Margaret Cancer Center, Toronto, ON, Canada, [3]Department of Radiation Oncology, Princess Margaret Cancer Center, Toronto, ON, Canada, [4]Department of Oncology, St. Claraspital Basel, Basel, Switzerland

Background: NLR is a robust prognostic factor in many solid tumors. Limited data exist about its role in patients with metastatic germ cell tumors (GCTs).

Methods: We utilized a single institution database of patients diagnosed with metastatic GCTs between January 1990 and December 2013 who were treated with chemotherapy at Princess Margaret Cancer Centre. The peripheral blood count prior to first line chemotherapy was used to calculate the derived NLR (absolute neutrophil count divided by the total white blood cell count minus the absolute neutrophil count). Predictive accuracy was assessed as the association between NLR and overall survival and was evaluated using a Cox proportional hazard model adjusted for the International Germ Cell Cancer Collaborative Group (IGCCCG) risk classification. Discriminatory accuracy was evaluated by determining the area under the receiver operating characteristic curve (AUROC) for survival at 5 years. The optimal cut-off for NLR selection was chosen based on a highest AUROC.

Results: In total, 475 patients were identified of which NLR data were available from 354 (75%) patients. Among these, 63% were good risk, 23% intermediate risk and 15% poor risk. The 5-year survival for good, intermediate and poor risk groups was 96.3%, 92.4% and 62.9%, while 10-year survival was 94.8%, 92.4% and 62.9%, respectively. Over the whole cohort, a NLR cut-off of 2.5 provided the best discriminatory accuracy with an AUROC of 0.70 (95% CI 0.59-0.75, $p < 0.001$). In a univariable analysis, NLR >2.5 was associated with a hazard ratio (HR) of 3.91 (95% CI 2.01-7.60, $p < 0.001$) which persisted after adjustment for IGCCCG risk group (HR 2.33, 95% CI 1.14-4.76, $p = 0.02$). Among patients with IGCCCG high risk, 5-year survival was 87.5% if NLR $\leq$ 2.5, whilst if NLR $>$ 2.5, 5-year survival was only 51.3%.

Conclusions: A high NLR is associated with an adverse survival in patients with metastatic GCTs undergoing first line chemotherapy and provides moderate discriminatory accuracy in this setting. The utility of NLR appears particularly marked in patients with IGCCCG high risk disease.

916P Biological assessment of viable germ cell tumor (VT) in patients (pts) with seminoma (S) and non-seminoma (S) using miR371

L. Nappi[1], M. Thi[1], L. Fazli[1], K. Chi[2], B. Eigl[2], C. Nichols[3], M. Gleave[1], C.K. Kollmannsberger[2]

[1]Urologic Sciences, Vancouver Prostate Centre, Vancouver, BC, Canada, [2]Medicine, British Columbia Cancer Agency, Vancouver, BC, Canada, [3]Precision Genomics Cancer Research Clinic, Intermountain Health Care, Murray, UT, USA

Background: The pathological constitution of residual nodes after chemotherapy or of the borderline enlarged retroperitoneal (RP) lymph nodes in clinical stage I (CSI) germ cell tumor (GCT) pts on surveillance is challenging, especially in tumor markers (TM) negative pts. Currently, accurate assessment requires pathological confirmation with RPLND or clinical follow-up to establish a pattern of growth. A plasma-based approach to identify patients with VT would be uniquely valuable.

Methods: Formalin-fixed paraffin embedded (FFPE) and plasma from GCTs patients were used for miRNAs extraction. Non-cancer FFPE testicular tissue and plasma from healthy volunteers were used as negative controls. miR371 expression was detected by RT-PCR and relative expression calculated by the 2-ΔΔCt method. miR-93-5p was used as positive internal control. Results were analyzed for associations with clinicopathologic features using Fisher's exact test.

Results: miR371 was over-expressed in all the primary testicular ($n = 4$) and mediastinal ($n = 3$) samples while it was undetectable in the atrophic testis ($n = 1$) and mediastinal or gonadal teratoma ($n = 2$), confirming the applicability of the technique to the FFPE samples. 21 metastatic samples were analyzed: 2 lung, 1 brain, 17 lymph nodes and 1 IVC tumor thrombus. The samples were collected prior to ($n = 2$) or after ($n = 12$) chemotherapy, while 7 pts were treated only with surgery. miR371 was undetectable in any samples (0/9) with no VT on pathological examination and over-expressed in 11/12 (91.6%) of those with viable GCT (OR 145.7; $p < 0.0001$). 90% of pts with positive miR-371 had negative TM (100% of S and 75% of NS) while no pts with negative miR-371 had positive TM. Plasma miR-371 also showed high correlation with VT (Table).

Table: 916P

Pts	Initial stage	Stage at the suspicious relapse	Histology	miR71	Evidence of VT
1	I	IIA	S	+	+ (RPLND)
2	I	IIA	S	–	– (negative PET scan)
3	I	IIA	S	–	– (regressing CT scan)
4	I	IIA	NS	+	+ (progressing CT scan)

Conclusions: Elevated plasma levels of miR-371 correlate with the presence of active germ cell malignancy. These encouraging findings suggest that plasma miR371 levels may lead to biological rather than radiographic assessment of the presence of active GCT in patients with S and NS.

917P A single centre retrospective review of testosterone deficiency in germ cell cancer patients

L.S. Gibbs, G.L. Gullick, E. Allison, S. Brand, A. Addeo, A. Kuchel, J. Braybrooke

Bristol Cancer Institute, University Hospitals Bristol NHS Trust Bristol Haematology and Oncology Centre, Bristol, UK

Background: Testosterone deficiency syndrome (TDS) is frequently described in men treated for germ cell cancer with rates quoted between 11 and 38% (Huddart et al 2005). Observational studies show that TDS reduces quality of life and carries cardiovascular, metabolic and bone health risks. At our institute we observed that men with symptoms of TDS and 'low normal' testosterone (T) (8.6 – 12 nmol/L) were not reliably recognised.

Methods: We collected retrospective data from all germ cell cancer referrals to the Bristol Cancer Institute from 2011 – 2016. We documented age, treatment, at least one random T level within a year of diagnosis (grouped into < 8, 8 – 12 and > 12 nmol/L), details of symptoms and treatment of TDS.

Results: Data was collected on 462 patients (36 excluded with non germ cell diagnoses and 26 excluded due to T never being measured). Median age was 36 years (range 17 – 89) with 85% of patients aged under 50. 58% of men had seminoma, 32% non-seminoma and 10% combined germ cell cancer. 41% of all patients had a T level $<$ 12 nmol/L at first measurement (32% of 20 – 29 year olds, 42% of 30 – 49 and 58% of 50 – 59 year olds) and 16% had T $<$ 8 nmol/L. T therapy was prescribed in 19% of patients. Men receiving adjuvant carboplatin had the highest rate of T therapy (23%) compared with patients on surveillance (18%) and BEP or EP chemotherapy (14%).

Conclusions: In this retrospective series 41% of patients had at least one total T value $<$12 nmol/L. 19% received replacement. A TDS diagnosis should not be based on a single measurement but regardless of age, once T falls to $<$ 15 nmol/L, severity of TDS sequelae correlate with further decline (Morgentaler et al 2016). There is a range of what is regarded as normal T and it declines naturally with age. Recognition and management of late effects is important in men with curable cancer and diagnosis must be individualised; addressing symptoms alongside biochemical parameters. This is reflected by germ cell cancer social media websites where men frequently describe serum T in the defined normal range with symptoms of TDS. Further prospective multicentre studies could better define the prevalence of TDS in these patients and be used to inform a standard diagnostic approach.

918TiP Pembrolizumab and nanoparticle albumin bound paclitaxel (nab-paclitaxel) for metastatic urothelial carcinoma (UC) after chemotherapy failure: the open-label, single-arm, phase 2 PEANUT study

A. Necchi[1], L. Mariani[2], A. Anichini[3], P. Giannatempo[1], D. Raggi[1], G. Calareso[4], R. Salvioni[5]

[1]Medical Oncology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [2]Clinical Epidemiologi and Trials Organization Unit, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [3]Immunotherapy Unit, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [4]Radiology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [5]Urology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy

Background: Pembrolizumab (pembro) is a new standard of care in chemotherapy (CT) pre-treated UC patients (pts) and nab-paclitaxel (nPtx) has shown one of the highest activities among CT options in UC. Their combination may overcome resistance to immunotherapy (IT) and result in longer delay in the time to disease progression (PD). We will explore dynamic biomarkers of response to CT+IT.

Trial design: In an open-label, single-arm, single-center, phase 2 trial, pts receive pembro 200 mg intravenously (IV) on D1 and nPtx at the dose of 125 mg/m^2 IV on D1 and D8. Cycles are repeated every 3 weeks until PD or onset of unacceptable toxicity. Key inclusion criteria are: predominant UC, failure of $\leq$ 2 platinum-based CT for metastatic disease (2nd-to-3rd line only). Neoadjuvant/adjuvant CT is counted if relapse occurred $\leq$6 months of the last CT cycle. Response is evaluated by RECIST criteria v.1.1 every 2 cycles. PD-L1 expression will be assessed at the study conclusion on both immune cells (IC) and tumor cells at a centralized laboratory (Qualtek, Goleta, CA, USA). The primary endpoint of the study is the progression-free survival (PFS). The target is to detect an improvement in the median PFS from $\leq$3.0 months (H0) to $\geq$ 5.0 months (H1). To achieve 90% power with a one-sided non-parametric test at the 10% significance level,

we estimated that 64 pts must be accrued over 18 months, with follow-up duration of 12 months. PFS will be also analyzed according to the PD-L1 expression. Should the above investigation suggest that the treatment benefit is stronger in PD-L1+ pts, there is the option to expand this cohort up to a maximum of 50 pts. As such, we estimate 85.1% power to detect the target improvement in PFS. The decision of cohort expansion will rely on predictive power (PP) calculation: a PP $\geq$ 30% will be regarded as promising. Translational analyses will include multiparametric flow cytometry of blood samples, gene expression (RNA-seq, Illumina HiSeq) and mutation profiling of tumor samples (Ion Torrent Personal Genome Machine). These profiles will be matched with response to treatment and PFS/overall survival (EudraCT number 2017-000579-10).

Background: Inhibitors of programmed death 1 (PD-1) and its ligand PD-L1 are effective for treatment of recurrent, advanced urothelial cancer. Data from KEYNOTE-052 showed first-line pembrolizumab (anti–PD-1) had antitumor activity with an acceptable safety profile in cisplatin-ineligible patients (pts) with advanced urothelial cancer. This suggests pembrolizumab may be effective as first-line treatment, a setting in which only 50% of pts can receive the current standard-of-care, cisplatin-based chemotherapy. A randomized, open-label, phase 3 study in pts with advanced urothelial carcinoma is assessing first-line pembrolizumab ± chemotherapy versus chemotherapy (KEYNOTE-361; NCT02853305).

Trial design: Approximately 990 pts with histologically or cytologically confirmed unresectable/metastatic urothelial carcinoma will be randomly assigned 1:1:1 to pembrolizumab 200 mg every 3 weeks (Q3W), pembrolizumab + chemotherapy (investigator's choice of cisplatin [70 mg/m^2 Q3W] plus gemcitabine [1000 mg/m^2 on days 1 and 8 Q3W] OR carboplatin [AUC 5 Q3W] plus gemcitabine if cisplatin ineligible), or chemotherapy alone. Pts must have measurable disease per investigator review (RECIST v1.1), an ECOG PS 0–2, received no prior systemic chemotherapy for advanced urothelial cancer, and provided a tumor biopsy. Treatment allocation will be stratified by chemotherapy (cisplatin or carboplatin) and PD-L1 expression (+ or –). Patients will be treated for 35 cycles of pembrolizumab (pembrolizumab arms only), or until progressive disease or unacceptable adverse events. The primary end points are progression-free survival (RECIST v1.1 per blinded independent central review) and overall survival, assessed in all patients and PD-L1+ patients. Secondary end points are objective response rate and safety. Efficacy will be compared for pembrolizumab versus chemotherapy and pembrolizumab + chemotherapy versus chemotherapy. Patient accrual is ongoing; 1 interim efficacy analysis is planned.

KG, Biberach, Germany, [15]Oncology, Boehringer Ingelheim España, S.A., Barcelona, Spain, [16]Oncology, Boehringer Ingelheim Ltd, Bracknell, UK, [17]TA Oncology, Boehringer Ingelheim, Danmark A/S, Copenhagen, Denmark

Background: First-line treatment of patients (pts) with advanced or metastatic UC consists of platinum-based chemotherapy (CT), and currently, there is no well-established therapy following CT failure. Recently, checkpoint inhibitors have shown clinical benefit in this setting, and are likely to become a future standard of care. However, to date, no other targeted therapies have shown significant clinical activity. Given that ~20% of UCs harbour ERBB receptor alterations or abnormalities, the blockade of the ERBB pathway may be an effective therapeutic strategy. Indeed, afatinib, an irreversible ERBB family blocker, demonstrated activity in a Phase II trial in a subgroup of pts with UC harbouring ERBB2/ERBB3 aberrations. These data provide rationale for the current Phase II trial assessing afatinib in pts with UC, molecularly selected for ERBB receptor alterations (LUX-Bladder 1; NCT02780687).

Trial design: The Phase II, single-arm LUX-Bladder 1 trial evaluates the efficacy and safety of afatinib in pts with UC and ERBB2/ERBB3 mutations or ERBB2 amplification (Cohort A), or EGFR amplification (Cohort B). Eligible pts are $\geq$18 years of age, with histologically confirmed advanced/metastatic UC of the urinary tract not amenable to surgery and progression during or after platinum-based CT (previous immunotherapy allowed), ECOG PS 0–1, with archival tissue samples available for pre-screening biomarker analysis. Pts will receive oral afatinib 40 mg/day until disease progression or discontinuation for other reasons. Cohort A will enrol in two stages, with Stage (S) 2 enrolment depending on afatinib anti-tumour activity in S1. The primary endpoint and key secondary endpoint in Cohort A are PFS rate at 6 months and ORR; other secondary endpoints include PFS, OS, disease control rate, duration of response and tumour shrinkage. These endpoints will also be explored in Cohort B. Safety and biomarkers will be assessed in both cohorts. The trial commenced in June 2016. Recruitment is ongoing in Spain and planned in two additional European countries; planned enrolment: Cohort A, ~70 pts (S1, n=~25; S2, n=~45); Cohort B, ~10 pts.

921TiP A Phase III, randomized, double-blind, multicenter study of adjuvant nivolumab vs placebo in patients (pts) with high-risk invasive urothelial carcinoma (UC; CheckMate 274)

D. Bajorin[1], M.D. Galsky[2], J.E. Gschwend[3], Y. Tomita[4], A. Azrilevich[5], F. Witjes[6]

[1]Department of Medicine, Memorial Sloan-Kettering Cancer Center, New York, NY, USA, [2]Department of Medicine, Icahn School of Medicine at Mount Sinai, New York, NY, USA, [3]Department. of Urology, Technical University of Munich, Klinikum rechts der Isar, Munich, Germany, [4]Department of Urology, Niigata University, Niigata, Japan, [5]Global Clinical Research/Oncology, Bristol-Myers Squibb, Princeton, NJ, USA, [6]Department of Urology, Radboud University Medical Center, Nijmegen, Netherlands

Background: Standard of care for muscle-invasive bladder cancer (predominant form of UC) is cisplatin-based neoadjuvant chemotherapy followed by radical cystectomy + pelvic node dissection or cystectomy + pelvic node dissection alone if cisplatin-ineligible. Some pts undergo surgical resection followed by adjuvant cisplatin-based chemotherapy. Many pts are not candidates for adjuvant chemotherapy or are not treated due to lack of proven survival benefit. UC of the ureter or renal pelvis is typically managed with nephroureterectomy. Despite surgery ± chemotherapy, pts with invasive UC are at high risk of recurrence and death. Based on the efficacy and safety of the programmed death-1 (PD-1) inhibitor nivolumab for metastatic or unresectable UC progressing despite chemotherapy (CheckMate 032 and 275), we are conducting an international phase III study of adjuvant nivolumab vs placebo in pts with invasive UC (originating in bladder, ureter, or renal pelvis) following resection (NCT02632409).

Trial design: Pts must have had radical surgical resection ± cisplatin-based neoadjuvant chemotherapy within the past 120 days and be disease-free (by imaging) ≤4 weeks before randomization. Pts who did not receive cisplatin-based neoadjuvant chemotherapy must be ineligible for or refuse adjuvant cisplatin. Tumor tissue must be provided for biomarker analysis. Pts are ineligible if they had partial cystectomy or partial nephrectomy, or secondary treatment after surgical removal of UC (eg, cisplatin-based adjuvant chemotherapy), prior malignancy within 3 years except those treated with curative intent and in remission, or any condition requiring systemic treatment with immunosuppressants (eg, corticosteroids) within 2 weeks of treatment. Recruitment began in February 2016; target enrollment is ∼640 pts. Co-primary endpoints: Disease-free survival (defined as the time between date of randomization and date of first recurrence or death) in pts with tumors expressing ≥1% PD-ligand 1 and in all randomized pts. Secondary endpoints: Non-urothelial tract recurrence-free survival, disease-specific survival, overall survival.

922TiP KEYNOTE-564: Phase 3 trial of pembrolizumab in the adjuvant treatment of renal cell carcinoma (RCC)

T.K. Choueiri[1], T. Powles[2], T. Zhang[3], D.I. Quinn[4], J.E. Gschwend[5], S.S. Wan[6], C. Poehlein[6]

[1]Genitourinary Oncology, Dana-Farber Cancer Institute, Boston, MA, USA, [2]Centre for Experimental Cancer Medicine, Barts Cancer Institute, Queen Mary University of London, London, UK, [3]Oncology, Duke Cancer Center, Durham, NC, USA, [4]GU Oncology, USC Norris Comprehensive Cancer Center, Los Angeles, CA, USA, [5]Oncology, Technical University of Munich, Munich, Germany, [6]Medical Oncology, Merck & Co., Inc., Kenilworth, NJ, USA

Background: Effective adjuvant therapies for patients (pts) with RCC at risk of recurrence after nephrectomy are lacking. Programmed death ligand 1 (PD-L1) and 2 (PD-L2) expression predicts poor prognosis in RCC. Programmed death 1 (PD-1) inhibitors have demonstrated activity in metastatic RCC, and PD-1 may represent a novel therapeutic target in the adjuvant setting. Pembrolizumab is a PD-1 inhibitor that directly blocks the interaction between PD-1 and its ligands, PD-L1 and PD-L2. This randomized, double-blind, placebo-controlled phase 3 trial will evaluate the efficacy and tolerability of pembrolizumab as adjuvant therapy in pts with RCC who have T2 grade 4, T3, T4, N (+), or stage M1 with no evidence of disease (M1 NED) following nephrectomy and/or metastasectomy (NCT03142334).

Trial design: Key inclusion criteria are: age ≥18 years; histologically confirmed RCC with a clear cell component; intermediate-high or high risk of recurrence, or M1 NED; no prior systemic therapy for advanced RCC; disease-free following complete or partial nephrectomy (and metastasectomy in M1 NED pts) with negative surgical margins; and Eastern Cooperative Oncology Group (ECOG) performance status 0-1. Approximately 950 pts will be randomly assigned in a 1:1 ratio to receive pembrolizumab 200 mg every 3 weeks by intravenous infusion, or placebo, continued for up to 17 cycles (∼1 year) or until disease recurrence or treatment discontinuation. Randomization will be stratified by metastasis stage (M0 vs M1 NED); within the M0 group, randomization will be further stratified by ECOG performance status (0 vs 1) and region (US vs rest of world). The primary end point is investigator-assessed disease-free survival (DFS). Radiographic imaging will be performed every 12 weeks. Secondary objectives include overall survival (OS), safety, disease recurrence-specific survival, DFS and OS according to PD-L1 expression status, pharmacokinetics, anti-drug antibodies, and patient-reported outcomes. Molecular biomarkers that may be associated with response, safety, pharmacodynamic activity, or mechanism of action will be evaluated as exploratory objectives.

Clinical trial identification: NCT03142334; May 3, 2017

923TiP A phase 2 BIOmarker driven trial with Nivolumab and Ipilimumab or VEGFR tKi in naïve metastatic Kidney cancer: the BIONIKK trial

R.T. Elaidi[1], S. Oudard[2], E. Braychenko[1], C-M. Sun[3], C. Sautès-Fridman[3], Y-A. Vano[2]

[1]Medical Oncology, ARTIC - Association pour la Recherche de Thérapeutiques Innovantes en Cancérologie, Paris, France, [2]Medical Oncology, Hopital Européen Georges Pompidou, Assistance Publique-Hôpitaux de Paris, Université Paris-Descartes, Paris, France, [3]Cancer, Immune Control and Escape, INSERM1138, Paris, France

Background: Nine targeted agents have been approved for metastatic clear cell renal cell carcinoma (mccRCC) in the last 10 years, including VEGFR-tyrosine kinase inhibitors (TKI), mTOR inhibitors and checkpoint inhibitor (CI). Combination of CI nivolumab and ipilimumab is currently compared to sunitinib in a randomised phase III trial in first-line setting. While treatment opportunities of mccRCC are moving rapidly biomarker to select patients to receive TKI or CI are still lacking. Based on transcriptomic analysis, we have defined four distinct molecular groups (ccrcc1 to 4) in patients with mccRCC treated with sunitinib. These groups were mainly characterized by distinct responses to suntinib as well as distinct immune cell compositions and inhibitory receptor expressions.

Trial design: The proof of concept study BIONIKK is a French multicentric randomised phase II designed to assess the use of molecular groups to select treatment in first-line mccRCC. Molecular group is determined on frozen tumor sample within 2 weeks. Treatment is then allocated between TKI and nivolumab plus ipilimumab for ccrcc2 and 3 and between nivolumab alone and nivolumab plus ipilimumab for ccrcc1 and 4. Main objective is to assess efficacy of each treatment arm according to molecular group. Primary endpoint is overall response rate using RECIST 1.1. Main secondary endpoints include PFS, OS and their relationship to exploratory biomarkers. These latter include protein and gene expression analyses of tumor microenvironment (TME) from formalin-fixed and paraffin-embedded tumor samples. In addition, phenotype and functional status of peripheral blood lymphocytes will be analysed with flow cytometry before and during treatment. A Bayesian model was used to avoid independent analyses of the effect of drugs using hierarchical borrowing. Bionikk is not designed to be conclusive on the superiority of any treatment but will generate important hypotheses on putative biomarkers to select patients to receive TKI, CI alone or in combination. From this point of view, Bionikk is the first biomarker-driven trial in first line metastatic ccRCC.

Clinical trial identification: NCT02960906 First received: August 18, 2016

924TiP Savolitinib versus sunitinib in patients with MET-driven, unresectable and locally advanced or metastatic papillary renal cell carcinoma: SAVOIR, a randomised, phase III trial

T.K. Choueiri[1], R. Jakacki[2], D. Ghiorghiu[3], V. Haddad[4], A. Kohlmann[5], M.M. Frigault[6], L. Ottesen[3]

[1]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, USA, [2]Global Medicines Development, AstraZeneca, Gaithersburg, MD, USA, [3]Global Medicines Development, AstraZeneca, Cambridge, UK, [4]Biometrics & Information Sciences, AstraZeneca, Cambridge, UK, [5]Personalised Healthcare and Biomarkers, AstraZeneca, Cambridge, UK, [6]Translational Science, AstraZeneca, San Francisco, CA, USA

Background: Papillary renal cell carcinoma (PRCC) is the most common of the non-clear cell renal cell carcinomas (RCCs), accounting for 10–15% of RCCs. However, there are no therapies approved specifically for patients with PRCC, who currently receive treatments approved for clear cell RCC, such as sunitinib. PRCC is often MET-driven (defined as *MET* kinase domain mutations, *MET* amplification, chromosome 7 gain and/or *HGF* amplification). Savolitinib (AZD6094, HMPL-504, volitinib) is a highly selective MET tyrosine kinase inhibitor which demonstrated anti-tumour activity for patients with MET-driven PRCC in a phase II trial.

Trial design: SAVOIR (NCT03091192) is a global, phase III, open-label, randomised, controlled trial evaluating the efficacy and safety of savolitinib, compared with sunitinib, in patients with MET-driven, unresectable, locally advanced or metastatic PRCC. Approximately 180 patients will be randomised at ~50–75 sites across 5–10 countries. Eligible patients (aged ≥18 with MET-driven PRCC confirmed by a novel, sponsor designated, validated, targeted next-generation sequencing assay; a Karnofsky performance status ≥80; and measurable disease at baseline) will be randomised in a 1:1 ratio to receive either continuous savolitinib 600 mg (400 mg if < 50 kg) orally, once daily (QD), or sunitinib 50 mg orally QD (4 weeks on/2 weeks off). The primary objective is to determine the efficacy of savolitinib compared with sunitinib in terms of progression free survival (PFS). Tumour assessments (RECIST 1.1, confirmed by blinded independent central review [BICR]) will be performed at screening and the end of every 6-week cycle until 12 months, and every 12 weeks thereafter until disease progression. Secondary endpoints include overall survival, objective response rate, duration of response, best percentage change in tumour size, disease control rate at 6 and 12 months, safety and tolerability, and biomarkers. The impact of savolitinib compared with sunitinib on disease symptoms and quality of life, along with the pharmacokinetics of savolitinib will also be assessed.

Background: VEGF-targeted therapies are the cornerstone of first and subsequent lines of therapy in ccRCC; however, resistance develops almost invariably. Another proven therapeutic intervention in ccRCC is treatment with the allosteric mTOR inhibitor everolimus, which only partially inhibits TORC1 and thus results in increased phosphorylation of Akt and paradoxical hyperactive signalling. TAK-228, a highly selective ATP-competitive TORC1 and TORC2 inhibitor, has shown promising antitumor activity and acceptable safety in ccRCC. In a pooled analysis of 2 prior studies of 41 patients (pts) with ccRCC, TAK-228 treatment resulted in 1 CR, 5 PR and 21 pts with SD; 13 pts who achieved ≥SD had prior treatment with a rapalog. The median duration of overall response was 250 d (range, 55–1614). The most common AEs were fatigue, nausea and hyperglycemia. Also, combination of TAK-228 with TAK-117, a selective inhibitor of PI3Kα, has shown more complete and prolonged inhibition of TORC1 and TORC2. This phase 2, open-label, randomized study will evaluate the efficacy and safety of TAK-228 and TAK-228+TAK-117 vs everolimus in pts with advanced or metastatic ccRCC that have progressed on or after VEGF-targeted therapy (NCT02724020).

Trial design: 189 pts will be randomized 1:1:1 to TAK-228 30 mg once-weekly on d1, 8, 15, 22 with a light meal; TAK-228 4 mg once-daily (QD) + TAK-117 200 mg QD on d1–3, 8–10, 15–17, 22–24 on an empty stomach; or everolimus 10 mg QD, in 28-d cycles. Pts will be stratified by number of prior therapy lines and IMDC risk category. Pts with histologically confirmed advanced/metastatic ccRCC, ≥1 prior line of VEGF-targeted therapy with PD, KPS ≥70%, and adequate organ function, but no CNS metastasis or prior therapy with agents that target PI3K, AKT, or mTOR are eligible. Pts in the everolimus arm who progress may crossover. An interim futility analysis will be conducted after 30 pts in each arm have received 2 treatment cycles. Primary endpoint is PFS. Secondary endpoints are OS, TTP, ORR, CBR, safety, and QoL. As of January 24, 2017, 54 pts have been screened.

926TiP Phase Ib/II trial of interleukin-2 (IL-2) and nivolumab in metastatic clear cell renal cell cancer (RCC)

S. Yentz, A. Alva

Hematology Oncology, University of Michigan, Ann Arbor, MI, USA

Background: High dose Interleukin-2 (HD IL2) immunotherapy is standard therapy in suitable patients (pts) with metastatic clear cell RCC who have good performance status. HD IL-2 is unique among RCC therapies in eliciting durable complete responses (DCR) with a median duration of such responses of 12 years. However, the complete response (CR) proportion for HD IL-2 monotherapy is only 7-9%. There is an urgent need to evaluate HD IL2 combination therapies that could increase the response proportion. IL-2 promotes early steps in the lymphocyte activation cascade, increases trafficking of cytotoxic T lymphocytes to the tumor and induces Th1 differentiation of CD4 T helper cells. Nivolumab, an immune checkpoint inhibitor, blocks the interaction between PD-1 on activated T cells and its ligands that are expressed on immune cells and tumor cells. We hypothesize that the combination of HD IL2 and a PD-1 inhibitor would elicit a potent synergistic anti-cancer immune response reflected in improved response proportion and survival with acceptable toxicity in pts with metastatic clear cell RCC.

Trial design: This multi-site Ib/II trial will determine safety and efficacy of HD IL-2 in combination with nivolumab for RCC. Pts with metastatic clear cell RCC, 0-2 prior systemic therapies and candidates for HD IL2 and for nivolumab are eligible. Pts will be treated with HD IL-2 (600,000 IU/kg/dose every 8 hours for up to 14 doses) on Days 1-5 and again on Days 15-19, with nivolumab (240 mg IV every 14 days) starting on Day 8 +/- 3 wks. Pts will continue on nivolumab every 2 wks for up to 48 wks barring intolerable toxicities or consent withdrawal or progressive disease. Nivolumab may potentially be continued beyond first progression. The primary objective/endpoint of the phase 1b portion of the trial is safety of the combination/immune mediated grade 3/4 events of interest. The primary endpoint of the phase II portion of the trial is the overall response proportion (ORR) as assessed by RECIST 1.1. Secondary endpoints are safety/toxicity, overall survival and PFS at 2 years. Planned accrual is 23 evaluable subjects over 2 years. Whole blood and serum will be analyzed for circulating immune cell repertoire and baseline tumor tissue will be sequenced.

Clinical trial identification: NCT02989714

927TiP Cabozantinib in patients with advanced penile squamous cell carcinoma (PSCC): the open-label, single-arm, single-center, phase 2, CaboPen trial

A. Necchi[1], L. Mariani[2], M. Colecchia[3], P. Giannatempo[1], D. Raggi[1], G. Calareso[4], N. Nicolai[5], M. Catanzaro[5], T. Torelli[5], F. Perrone[6], R. Salvioni[5]

[1]Medical Oncology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [2]Clinical Epidemiologi and Trials Organization Unit, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [3]Pathology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [4]Radiology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [5]Urology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [6]Molecular Pathology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy

Background: Chemotherapy (ChT) exerts moderate activity in advanced and metastatic PSCC, and efficacy outcomes are poor. Neoadjuvant treatment is a reliable setting to address activity of new drug approach (Necchi A et al. ASCO-GU 2017). The vascular endothelial growth factor (VEGF) receptor is overexpressed in approximately 50% of PSCC. Cabozantinib (Cabo) is a multiple receptor tyrosine kinase inhibitor (TKI) primarily targeting MET and VEGFR2.

Trial design: In an open-label, single-arm, single-center, phase 2 trial, patients (pts) with clinical stage N2-3 (TNM 2009, locally-advanced [LA]) or M1 PSCC will receive Cabo, orally, at a dose of 60 mg/day continuously until surgery, evidence of disease progression or onset of unacceptable toxicity. Prior ChT administration is not allowed. Response will be evaluated by RECIST criteria v.1.1, matched with 18FDG-PET/CT assessment, every 2 months. At each time of disease restaging, responding pts with LA PSCC who will be considered eligible to radical lymphadenectomy will undergo surgery. After surgery, pts will be managed according to standard guidelines. The primary endpoint (EP) is the objective response-rate (ORR=CR+PR according to RECIST v1.1). Secondary EP are safety, progression-free survival (PFS) and overall survival (OS), and pathologic response. The study is planned according to Simon's Optimal two-stage design, with H1=20% and H0= 5%, and type I and type II error rates set at the 10% level. In stage 1, 12 evaluable pts will be accrued. If 1 pt at least will be responding, enrolment will be extended to the 2nd stage for further 25 pts. If, out of the total of 37 pts, 4 at least will be responding, treatment will be declared worthy for further investigations. Stopping rules based on the Bayesian posterior probability (PP) to demonstrate that the ORR exceeded 20% are set. Translational analyses on pre- and post-Cabo tumor samples and matched blood samples will include *in-situ* hybridization for HPV and next generation sequencing (Ion Torrent Personal Genome Machine). These profiles will be associated with response to treatment and PFS/OS (EudraCT number 2017-001963-19).

Background: The highly selective poly(ADP-ribose) polymerase (PARP) 1/2 inhibitor niraparib (ZEJULA™) concentrated in the tumor vs plasma in preclinical studies, delivering ≥90% durable PARP inhibition, and showed significantly longer progression-free survival vs placebo in patients (pts) with recurrent OC following complete (CR) or partial response (PR) to platinum-based chemotherapy (PBC) regardless of germline *BRCA* mutation (g*BRCA*mut) or homologous recombination deficiency (HRD) status in the phase 3 ENGOT-OV16/NOVA trial. Quality of life (QoL) measures are important to determine the benefit of drug therapy in this population. We evaluated patient-reported outcomes (PROs) associated with QoL and individual patient-reported symptoms using the Functional Assessment of Cancer Therapy-Ovarian Symptoms Index (FOSI) and European Quality of Life Scale 5-Dimensions (EQ-5D-5L) in ENGOT-OV16/NOVA pts treated with niraparib vs placebo.

Methods: A mixed-effects growth-curve model adjusted for baseline demographic values and 3 stratification factors was constructed to model the relationship between treatment and PRO score for each measure. The relationship between health status and PROs was evaluated through a cross-sectional analysis of adjusted EQ-5D-5L health utility index (HUI) scores. A disutility analysis of hematologic adverse events was conducted at different time points.

Results: No significant difference in mean PRO scores was observed between niraparib and placebo arms in either cohort. Adjusted HUI scores were similar in both arms at baseline, but average adjusted HUI pre-progression scores trended higher in the niraparib arm (0.812 vs 0.803 in g*BRCA*mut cohort; 0.845 vs 0.828 in non-g*BRCA*mut cohort). Hematologic toxicities had no detrimental effect on pts' overall health utility.

Conclusions: These data suggest pts with recurrent OC treated with niraparib following CR or PR to PBC can continuously maintain their QoL while on treatment.

D. Anderson Cancer Center, Houston, TX, USA

Background: There are limited therapeutic options available for patients (pts) with relapsed, recurrent, and/or metastatic cervical cancer. Historic data indicate dismal outcome with ORR of 0-15% and a median OS of 6-8 months (Mo). Tisotumab vedotin (Tv) is an antibody-drug conjugate (ADC) composed of a Tissue Factor specific human IgG1 monoclonal antibody conjugated to a microtubule disrupting agent Monomethyl Auristatin E (MMAE) and is being tested in an ongoing Ph I/IIa dose-escalation study (NCT02001623) in pts with locally advanced and/or metastatic solid tumors. Here, we present initial data on the pre-planned 30 pt expansion cohort in relapsed, recurrent, or metastatic cervical cancer.

Methods: Key eligibility criteria included recurrent or metastatic cervical cancer with at least 1 prior line of therapy, adequate liver and kidney function and ECOG 0-1. Tv was given as 2 mg/kg q3w until progression. Efficacy and toxicity were assessed according to RECIST 1.1 and CTCAE 4.03.

Results: Thirty pts were enrolled. Median age was 43 (21-73), median prior lines 2 (1-5). Twenty-nine pts had previously received cisplatin, 28 a taxane and 19 also bevacizumab. Preliminary efficacy data for 19 pts were available at time of submission. Ten pts (33%) experienced Gr 3 TEAE(s) related to GI (2 pts), anemia (2 pts), infections (1 pt), neuropathy (1 pt), bleeding (1 pt), other (7 pts). No Gr 4 or 5 AEs were reported. The toxicity profile appeared to be consistent with MMAE-based ADCs, including peripheral neuropathy and neutropenia with an identified compound-specific toxicity of conjunctivitis for which prophylactic management was introduced. Seven of the 19 pts (37%) evaluable for efficacy obtained a clinical response; hereof, 6 were confirmed at time of submission. With a mean follow-up of 5.5 Mo for the 7 responders, 5 remain on trial with none of the responders having relapsed. Full efficacy data for all 30 pts will be available at time of presentation.

Conclusions: Preliminary data demonstrated a manageable safety profile and encouraging efficacy (ORR 37%) in relapsed, recurrent or metastatic cervical cancer. Our findings in a high unmet medical need population warrant further investigation.

Background: In the Phase III SOLO2 trial (NCT01874353), maintenance treatment with the poly(ADP-ribose) polymerase inhibitor olaparib (Lynparza) was shown to significantly improve progression-free survival (PFS) vs placebo in pts with PSROC and a *BRCA1/2* mutation (*BRCA*m; hazard ratio [HR] 0.30, 95% CI 0.22–0.41; $P<0.0001$; median 19.1 vs 5.5 months; Pujade-Lauraine *et al.* SGO 2017). A previous retrospective analysis of data pooled from 6 studies of olaparib in pts with a germline *BRCA*m suggested that olaparib activity declined as the number of prior lines of chemotherapy received increased (Matulonis *et al. Ann Onc* 2016). We report an analysis of PFS in SOLO2, grouped by number of prior lines of platinum-based chemotherapy (PBC) received by pts, performed to identify the most appropriate use of olaparib in the maintenance setting.

Methods: SOLO2 enrolled pts who had received ≥2 prior lines of PBC before being in response to their most recent regimen. Pts were randomized 2:1 to receive olaparib tablets (300 mg bid) or placebo. PFS was investigator assessed with modified RECIST v1.1. For the PFS subgroup analyses, subgroups were predefined; HRs were calculated using a Cox proportional hazards model.

Results: Of 295 randomized pts, 195 received olaparib and 99 received placebo. 85 pts in the olaparib arm (43.4%) had received ≥3 prior lines vs 37 pts (37.4%) in the placebo arm. Pts who had received 2 prior lines of PBC were more likely to have had a platinum-free interval of > 12 months (70.9% vs 48.3% and 40.0% for 3 and ≥4 prior lines, respectively in the olaparib arm; 69.4% vs 60.0% and 23.5% placebo) and a complete response at baseline (50.9% vs 36.7% and 48.0% olaparib; 54.8% vs 35.0% and 35.3% placebo) vs pts who had received ≥3 prior lines.

Conclusions: In SOLO2, olaparib maintenance monotherapy improved PFS in pts with PSROC irrespective of the number of prior lines of PBC received.

Background: Niraparib (ZEJULA™) is a selective PARP1/2 inhibitor approved for maintenance treatment of adults with recurrent ovarian cancer who are in a complete or partial response to platinum-based chemotherapy. In preclinical studies, niraparib concentrates in the tumor versus plasma, delivering ≥90% durable PARP1/2 inhibition and a persistent antitumor effect. We report the relationship between exposure and response of niraparib in patients (pts) enrolled in the ENGOT-OV16/NOVA trial.

Methods: Preliminary modeling for niraparib was performed using Phase 1 study data (N = 104) to identify the initial parameters for the pharmacokinetic model, which was developed using combined Phase 1 and Phase 3 data (N = 512 pts) and the first-order conditional estimation with interaction method within NONMEM. Exposure-efficacy relationships were evaluated in the g*BRCA*mut and non-g*BRCA*mut cohorts separately;

Table 932PD: PFS subgroup analysis by number of prior lines of PBC received

	Prior lines of PBC received					
	2		3		≥4	
	Olaparib	Placebo	Olaparib	Placebo	Olaparib	Placebo
n*	110	62	60	20	25	17
PFS events,† n (%)	57 (51.8)	44 (71.0)	34 (56.7)	19 (95.0)	16 (64.0)	17 (100)
Median PFS, months	22.1	5.7	16.9	5.1	17.0	5.4
Hazard ratio (95% CI)	0.38 (0.26–0.57)		0.24 (0.13–0.42)		0.26 (0.13–0.51)	

*Number of prior lines of PBC was unknown for one olaparib-arm patient;
†Progression or death by modified RECIST v1.1

the efficacy was compared in pts with high exposure (> median exposure) vs low exposure (≤ median exposure). Maximum plasma concentration (C_{max}) and area under the curve over the dosing interval (AUC_{tau}) at steady state (SS) were the exposure metrics. Progression-free survival (PFS) was used as efficacy endpoint. Hazard ratios (HRs) and 95% confidence intervals (CI) for the low and high niraparib exposure groups in each cohort were provided, with exposure group as the independent variable and PFS as the dependent variable. Exposure and safety data of g*BRCA*mut and non-g*BRCA*mut cohorts were combined to evaluate exposure-safety relationships using logistic regression.

Results: In the g*BRCA*mut cohort, the HR was 0.91 (95% CI, 0.54-1.52) for niraparib exposure as measured by the SS AUC_{tau} for pts in the high exposure vs. the low exposure group. In the g*BRCA*mut cohort, the HR was 0.70 (95% CI, 0.49-0.99). Logistic regression analysis did not show any significant relationship between the incidence of thrombocytopenia or anemia Grade ≥ 3 and the SS Cmax or AUC increase.

Conclusions: Observed exposure-response relationships support the selection of 300 mg as the starting dose in both g*BRCA*mut and non-g*BRCA*mut pt populations. A trend towards increased efficacy associated with increased exposure was observed in the non-g*BRCA*mut cohort.

Background: Niraparib (Zejula™) is a selective poly(ADP-ribose) polymerase 1/2 inhibitor (PARPi) approved for maintenance therapy in adults with recurrent OC who are in response to platinum-based therapy. Here, we report safety and efficacy of niraparib in the subgroup of pts from the ENGOT-OV16/NOVA trial who were aged ≥65 years (y).

Methods: Pts were assigned to one of two independent cohorts based on germline BRCA mutation (gBRCAmut) status and randomized 2:1 within each cohort to receive either niraparib (300 mg) or placebo once daily. Pts were stratified by age (<65 vs ≥ 65 y) to analyze efficacy (measured by progression-free survival [PFS]) and safety. Efficacy and safety were also tested in patients <70 vs ≥ 70 y.

Results: Efficacy of niraparib was comparable in pts <65 vs ≥ 65 y in both gBRCAmut and non-gBRCAmut cohorts (Table). Efficacy was also similar in pts <70 vs ≥ 70 y in both cohorts (gBRCAmut: <70 y, HR = 0.30; ≥70 y, HR = 0.09. Non-gBRCAmut: <70 y, HR = 0.47; ≥70 y, HR = 0.35), although the sample size of pts who were ≥70 y in the gBRCAmut cohort was small (14 niraparib vs 7 placebo). The most common adverse events (AEs; nausea, constipation, fatigue, hypertension, anemia, thrombocytopenia, neutropenia) in the niraparib arm occurred with similar incidence in pts <65 vs ≥ 65 y as well as in pts <70 vs ≥ 70 y. Grade 3/4 AEs occurring in > 10% of niraparib-treated pts were consistent in pts <65 vs ≥ 65 y (thrombocytopenia, 27% vs 31%; anemia, 27% vs 20%; neutropenia, 12% vs 10%) and in pts <70 vs ≥ 70 y (thrombocytopenia, 28% vs 31%; anemia, 27% vs 13%; neutropenia, 11% vs 10%, respectively). There were no Grade 5 events.

Table: 934PD

Cohort	Patient Numbers		PFS Hazard Ratio (95% Confidence Interval)
	Niraparib	Placebo	
gBRCAmut			
<65 y	110	49	0.27 (0.16, 0.44)
≥65 y	28	16	0.27 (0.09, 0.81)
Non-gBRCAmut			
<65 y	130	69	0.54 (0.37, 0.80)
≥65 y	104	47	0.38 (0.23, 0.61)

Conclusions: Niraparib was safe and highly effective in elderly patients.

Background: PAOLA-01 is a randomized placebo-controlled, international phase III study, assessing olaparib in maintenance therapy in advanced high grade ovarian carcinoma patients responding to 1st line platinum-taxane-based chemotherapy plus bevacizumab. Stratification is performed on treatment outcome and on tumoral *BRCA1/2*

status (tBRCA) at screening. As secondary objective, the consistency between germline (gBRCA) and tBRCA testing is being explored.

Methods: This study is planned to recruit 762 pts in Europe and 24 in Japan. tBRCA is tested on FFPE tumor block within 5 French national institutional platforms using 2 different next-generation sequencing methods based either on capture or on re-sequencing technology. For French pts, gBRCA testing is performed in parallel in the same platforms.

Results: Since May 2015, 1181 pts have been screened and 662 pts randomized. tBRCA status was assessed in 962 samples with a median turn around time of 40 days (range 8-260). Only 44(4.6%) tumor samples were non-informative (too low tumor cellularity), 8 using capture method and 36 by re sequencing respectively. A deleterious variant (DV) was reported in 279 (29%) samples (191 (68%) in *BRCA1*, 87 (31%) in *BRCA2* and one in both genes). Twelve variants of unknown significance were identified for *BRCA2* and 13 for *BRCA1*. For the 384 French pts, where both gBRCA & tBCRA testing was performed in parallel we report the mutation rate detection in the Table below. Of note, only one large genomic rearrangement of *BRCA1* was detected in blood sample exclusively.

Conclusions: tBRCA testing is a reliable tool for clinical trials with acceptable delay for clinical practice. Proportion of tBRCA testing failure is low and consistency with germ line testing adequate for routine practice.

Table: 935PD

French Cohort	gBRCA + (%)	gBRCA-(%)	Total (%)
tBRCA +	67 (17)	23 (6)	90 (24)
tBRCA -	1 (0.3)	270 (70)	271 (71)
Inconclusive tumor testing	1 (0.3)	22 (5,7)	23 (6)
total	69 (18)	315 (82)	384 (100)

[1]Evaluation médicale et Sarcomes - HESPER EA7425, Centre Léon Bérard, Lyon, France, [2]Département d'Oncologie médicale adulte, Centre Léon Bérard, Lyon, France, [3]Département de recherche clinique, Centre Léon Bérard, Lyon, France, [4]Département de bioinformatique, Centre Léon Bérard, Lyon, France, [5]Département de recherche translationnelle, Centre Léon Bérard, Lyon, France, [6]CITOHL, IC-HCL, Hospices Civils de Lyon, Université Claude Bernard Lyon 1, Lyon, France

Background: Despite progresses in precision medicine, very few molecularly-targeted agents (MTA) are available for gynecologic cancer patients (pts). Objectives were to characterize tumor genomic alterations in the gynecological subpopulation of the ProfiLER program, to identify actionable alterations and to report clinical efficacy of MTA if used outside approved indications.

Methods: The ProfiLER program is a multicentric prospective trial to implement molecular profiling in pts with advanced disease. All potential pts with advanced gynecologic cancers were eligible. DNA extracted from either archival or fresh collected tumor samples was analyzed by targeted exon sequencing (NGS) of 59 cancer related genes and whole genome array comparative genomic hybridization (CGH). Genomic profiles were presented in a dedicated molecular tumor board (MTB) for recommendation of MTA when applicable.

Results: Out of the 2184 included pts in the ProfiLER program, 242 pts with advanced gynecologic cancer were recruited from March 2013 to April 2016. For 211 (87%) pts (ovary, n = 136; cervix, n = 22; uterus, n = 45; others, n = 8), molecular analyses have been performed (median delay 2.8 months). 101 pts (48%) had at least one actionable alteration: PIK3CA (n = 23), KRAS (n = 10), ERRB2 (n = 9) and 50 other alterations. 109 MTA were recommended in 83 pts: PI3K/AKT/mTOR inhibitors (n = 46), sorafenib (n = 19), lapatinib (n = 7) and 17 other MTA (n = 37). 54 pts have not received MTA at the time of the analysis (poor PS or death, n = 25; stable disease, n = 15; no dedicated clinical trial, n = 7; other, n = 7). Currently, 29 pts initiated MTA. Partial response was reported for 8 pts (28%) and a stable disease at 3 months for 6 pts (21%). 12 pts (41%) progressed and 3 were non-evaluable. Median progression-free survival was 2.7 months (95% CI 1.9-5.4). Median overall survival was 64.8 months (38-101) for pts receiving MTA and 49.8 months (39-63) for pts not receiving MTA.

Conclusions: CGH and NGS identified actionable alterations on 48% of pts with gynecologic cancer and are feasible in routine practice. Nearly half of patients treated derived benefit from the recommended MTA, but these represent a minority of the whole screened population.

937PD PD-L1 expression and prognosis significance in advanced ovarian cancer

E. Høgdall[1], C. Høgdall[2], T.T. Vo[3], W. Zhou[3], M. Busch-Sørensen[3], S.M. Soerensen[4], D. Chappell[3], J. Georgsen[5], E. Mejlgaard[5], L. Nedergaard[6], T. Steiniche[5]

[1]Pathology, Herlev Hospital, University of Copenhagen, Herlev, Denmark, [2]Gynaecology and Obstetrics, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark, [3]Medical Oncology, Merck & Co., Inc., Kenilworth, NJ, USA, [4]Oncology, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark, [5]Pathology, Aarhus University Hospital, Aarhus, Denmark, [6]Pathology, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark

Background: Recent data suggest that programmed death ligand 1 (PD-L1) expression may predict response to anti–programmed death 1 (PD-1) therapy. This retrospective observational study evaluated the prognostic effect of PD-L1+ expression in patients with histologically confirmed epithelial ovarian, primary peritoneal, or fallopian tube cancer (OCa).

Methods: Patients diagnosed with FIGO stages II-IV OCa from 2004-2012, at Aarhus University Hospital and Rigshospitalet, Copenhagen, Denmark, were included. PD-L1 expression was measured in tissue collected at OCa surgery, using immunohistochemistry with anti–PD-L1 22C3 antibody. PD-L1$^+$ expression was defined as staining in $\geq$ 1% of tumor or inflammatory cells. Patients partially sensitive (PPS; treatment-free interval [TFI] of 6-12 mo) or fully sensitive (FPS; TFI >12 mo) to platinum therapy were considered platinum sensitive, whereas those refractory (TFI <3 mo) or resistant (TFI of 3-6 mo) to platinum were platinum insensitive. Data were analyzed using Cox proportional hazard model, adjusting for age, stage, histology, residual tumor, surgery type, performance status, and/or TFI.

Results: Median age of the 376 patients at diagnosis was 63 years (range, 26-86). 77% had histologic grade 2/3 serous adenocarcinoma, 46% had residual tumor after surgery, and 9%, 70%, and 21% had FIGO stages II, III, and IV disease, respectively. FPS, PPS, platinum-resistant, and platinum-refractory disease comprised 49%, 27%, 15%, and 9% of patients, respectively. 50.5% of patients were PD-L1$^+$, with prevalence increasing with increased platinum sensitivity (P for linear trend <0.05). Median overall survival (OS) was 43 mo (50.4 mo in PD-L1$^+$ vs 38.3 mo in PD-L1$^-$ patients). A statistically significant association was seen between PD-L1$^+$ tumors and longer OS (adjusted hazard ratio [aHR], 0.71 [95% CI, 0.55-0.91]). The association was not significant in platinum-insensitive patients (aHR, 0.82 [0.50-1.36]), but there was a tendency towards significance in platinum-sensitive patients (0.77 [0.57-1.06]), driven by those with a TFI of 6-12 mo.

Conclusions: PD-L1 was frequently expressed in advanced OCa patients, and expression may be prognostic, particularly in those with partially platinum-sensitive OCa.

938PD Prognostic relevance of immune-related gene expression signatures (irGES) in patients (pts) with ovarian clear cell carcinomas (OCCC)

V. Heong[1], D. Lim[2], T.Z. Tan[3], J. Ye[3], Y.W. Lim[1], S.E. Lim[1], J. Ng[4], A. Ilancheran[4], J. Loh[4], R. Soong[3], D. SP. Tan[1], R. Huang[3]

[1]Haematology-Oncology, National University Hospital, Singapore, [2]Pathology, National University Hospital, Singapore, [3]Cancer science Institute, National University Singapore, Singapore, [4]Gynecology Oncology, National University Hospital, Singapore

Background: Little is known about the immune microenvironment of OCCCs and its impact on outcomes. We studied the expression of a panel of immune response genes in OCCC to identify the presence and prognostic relevance of irGES in these tumours.

Methods: Immune response gene profiling was performed on 84 FFPE OCCC samples with matched clinical outcomes, collected between 2003 – 2016, using the nanoString nCounter PanCancer Immune Profiling Panel. Unsupervised hierarchical clustering analysis was performed and each sample underwent analysis for protein levels of PD-1, PD-L1, MMR and ARID1A via immunohistochemistry (IHC).

Results: Total of 74/84 samples were successfully profiled. Median age at diagnosis was 53 yrs. 41 (55.4%) were stage 1, 7 (9.5%) stage 2, 24 (32.4%) Stage3, 2 (2.7%) stage 4. 64/74 (86.5%) of pts received adjuvant chemotherapy post debulking surgery with 38% recurrence rate (median PFS 27 months (m)). Median follow up was 36m. Based on irGES, 4 distinct molecular subgroups of OCCCs were identified. G1 was hallmarked by high NK cell markers/PD-1 expression, G2 by increased CTLA-4/PD-L1 expression, G3 by adhesion cell markers, and G4 by increased levels of pro - angiogenic genes. G1 was observed to have significantly poorer PFS (median PFS 20m vs 68m, p= 0.011) and a trend towards poorer OS when compared with G2/3/4 (median OS 38.8m vs undefined, $p = 0.0501$). G4 carried the best prognosis (median PFS 108m vs 26m, p= 0.0515; median OS undefined, p= 0.0726). This difference in OS and PFS was reflected in stage 1 pts ($p < 0.02$ and <0.05; respectively) with a similar trend observed but not significant in non-stage 1 pts. Significant correlation was observed between gene and protein expression of tumour PD-1, tumour and stromal PD-L1, and tumour IL-6 using IHC ($p < 0.0001$ for all comparisons). 6 (8.1%) pts were MMR deficient with no significant association between ARID1A and MMR expression across each irGES.

Conclusions: OCCCs are heterogeneous and can be classified into 4 molecular subgroups based on their irGES profiles with distinct clinicopathological characteristics and prognostic outcomes. If validated in larger datasets, these signatures may serve to inform a clinical trial.

939PD An increased ratio of cytotoxic to suppressive T cells after neoadjuvant chemotherapy (NACT) is prognostic in advanced ovarian cancer

A. Khairallah[1], A. Auguste[2], A. Leary[3], C. Genestie[4], P. Pautier[5], J. Michels[3], P. Morice[3], E. Bentivegna[3], A. Maulard[3], F. Drusch[3], S. Mesnage[5], S. Gouy[5]

[1]Pathology, Gustave Roussy, Villejuif, France, [2]Oncology, Gustave Roussy, Villejuif, France, [3]Gynaecologic Oncology, Gustave Roussy Cancer Center, INSERM U981, and Groupe d'Investigateurs Nationaux pour l'Etude des Cancers Ovariens (GINECO), Villejuif, France, [4]Department of Pathology, Institut Gustave Roussy, Villejuif, France, [5]Medical Oncology, Gustave Roussy Institut de Cancérologie, Villejuif, France

Background: At diagnosis, tumor-infiltrating lymphocytes (TILs) are prognostic in epithelial ovarian cancer (EOC). We recently demonstrated that neoadjuvant chemotherapy (NACT) significantly increased stromal TILs and stromal TILs remained prognostically significant after NACT. Here, we investigated the impact of NACT on different immune subpopulations and their relationship with clinical outcome.

Methods: Tissue microarrays of EOC (145 pre-NACT, 139 post-NACT, including 83 matched samples) were analyzed for CD3+,CD8+ and FOXP3+ by immunohistochemistry. Stromal TILs scored as percentage of stromal area, intraepithelial TILs as number of TILs in contact with tumor cells/HPF. Differences were evaluated by Mann-Whitney or Wilcoxon-signed-rank for unpaired or paired analyses, respectively and by Log-rank for PFS and OS.

Results: NACT significantly increased stromal CD3 + ($p = 0.005$) and CD8 + ($p = 0.009$) and intraepithelial CD8 + ($p = 0.02$) infiltration in unmatched samples and remained significant among paired samples for stromal CD3+ and CD8 + ($p = 0.03$ and $p = 0.009$). Neither CD3+ nor CD8+ expression correlated with outcome at diagnosis or post-NACT, however reduced accumulation of FOXP3+ post-NACT (<5%) was significantly associated with improved PFS (HR = 0.59; $p = 0.016$). A high stromal CD8+/FOXP3+ ratio post-NACT strongly correlated with improved PFS (median 30.9 vs.18.85 mos, $p = 0.005$) and OS (median 50.70 vs 37.10mos, $p = 0.029$). In contrast, at diagnosis, CD8+/FOXP3+ was not associated with prognosis.

Conclusions: NACT has a significant impact on the balance of cytotoxic versus suppressive T cells and a high ratio of CD8+/FOXP3+ post-NACT was most significantly associated with improved PFS and OS. Whether this could select patients for immune therapies in the post-operative setting should be investigated.

Background: If epithelial ovarian cancer (EOC) had a poor prognosis, more than 20% of patients (pts) can expected long remission. Few data are available on long term quality of life (QoL) in these pts and results reported were usually not compared to those of healthy controls. VIVROVAIRE was a large national case-control study comparing pts reported outcomes (PROs) among EOC pts without relapse within 3 years after first line treatment and a group of healthy women.

Methods: Pts were recruited in 27 French centers and clinical characteristics were issued from medical charts. Controls were randomized from electoral lists. Pts and controls matched on age. They filled in a form including PROs questionnaires: QoL, neurotoxicity and fatigue (FACT/G, FACT/O, FACT/GOG-Ntx, FACT/F), anxiety and depression (HADS), sleep disturbance (ISI) and Physical activity (IPAQ).

Results: 318 pairs were analysed (from 349 pts and 327 controls included). Median age: 65 (20-86), high level of education: 52% and 58%, respectively. Pts characteristics: FIGO stage I/II (49%), III/IV (47%) unknown (4%); major histology, serous (50%), endometrioid (16%), clear cells (8%), mucinous (4%). BRCA1/2 mutations (n = 21; 15%), unknown (n = 168). 99% of the pts had a surgery and 96% received platinum based chemotherapy, associated with antiangiogenic agent (14%) Interval from first line therapy: median 5 years [2 to 24]. Pts reported lower physical and functioning QoL scores ($p = 0.03$ and $p = 0.0002$), higher score of fatigue ($p < 0.0001$), and poorer quality of sleep ($p = 0.0003$) than controls. No difference of scores of anxiety and depression was observed between the 2 groups. TOI score (related to ovarian cancer and treatment) and score of neurotoxicity were higher among patients ($p < 0.0001$); 26% of pts reported severe fatigue, more than 70% of the pts were concerned about digestive symptoms and severe neurotoxicity. Only 18% of the pts and controls had an active physical activity.

Conclusions: Compared to healthy women, EOC pts presented poorer long term QoL, fatigue with important neurotoxicity and digestive symptoms. Physicians have to take in count of the late effects of treatments to help the pts to cope with the sequelae.

941PD An investigator initiated, open label, randomized, controlled, multicentric study, to assess the safety and efficacy of nimotuzumab (BIOMAb-EGFR) concurrent with cisplatin and radiotherapy (RT) in histologically documented squamous cell carcinoma of the cervix

B.S. Ajaikumar[1], K. Swamy[2], N. Radheshyam[1], S. Patil[1], H.P. Shashidhara[3], M.S.A. Vishweshwara[4], N.K. Rao[2], Y. Madhavi[4], N. Ravi[5], R. Bilimagga[2], R. Rao[6], D. Pawar[7]

[1]Medical Oncology, Healthcare Global Enterprises ltd., Bangalore, India, [2]Radiation Oncology, Healthcare Global Enterprises ltd., Bangalore, India, [3]Medical Oncology, HCG Bangalore Institute of Oncology Speciality Centre, Bangalore, India, [4]Radiation Oncology, Bharath Hospital and Institute of Oncology, Mysore, India, [5]Radiation Oncology, HCG Malnad Hospital Institute of Oncology, Shimoga, India, [6]Healthcare Global Enterprises ltd., CARE, HCG Foundation, Bangalore, India, [7]Medical Affairs, Biocon Limited, Bangalore, India

Background: EGFR inhibitors have proven to improve the efficacy of anticancer treatments in lung, colon, pancreas, or HNC. Results from studies show EGFR expression in cervical Ca to improve survival outcomes in the same. This study was designed to assess

safety and efficacy of Nimotuzumab with concurrent cisplatin and RT in patients with Ca Cervix.

Methods: In this open-label randomized controlled multicentric study 100 patients with histologically confirmed Ca Cervix were recruited over a 4 year period with an equal allocation of 1:1 for intervention (Standard arm- concurrent CTRT (Cisplatin 40mg/m2 weekly IV +RT) plus 200mg weekly BIOMAB IV (n = 50) on same day of cisplatin infusion) vs. standard arm only (n = 50). At 2 years data were available for 39 patients in the intervention arm and 35 patients in standard arm. The size of the lesion was documented using CT/PETCT at baseline. The response was analyzed using RECIST criteria at the following treatment every 3 months for subsequent 2 years. Toxicity was assessed using CTCAE v4 toxicity criteria.

Results: There were 74 evaluable patients at end of 2 years. The mean age was 49.6± 10.2 years. The complete response following treatment was seen in 37.8% (BIOMAB arm) of patients at two years following treatment compared to 38.2% in standard arm. However, progressive disease was seen more in standard arm (52.9%) compared to BIOMAB arm (35.1%). Best overall response was seen in 64.9% patients in the intervention arm compared to 47.1% patients in the standard arm at two years following treatment which is significant. At 2 years 60% progressed on standard arm compared to 37.5% in the intervention arm. The mean estimate of progression-free survival being 36 months vs. 56.5 months (BioMab arm) (Log rank Mantel-Cox $\chi 2 = 3.9$, $p = 0.05$). Except for one patient with Biomab sensitivity, there was no additional toxicity compared to the standard arm.

Conclusions: Nimotuzumab appears to be safe and effective targeted therapy in cervical cancer patients with long-term benefits.

942PD Vanucizumab (VAN) in combination with atezolizumab (ATEZO) for platinum-resistant recurrent ovarian cancer (PROC): Results from a single arm extension phase of the phase I study BP28179

A. Oaknin[1], I. Vergote[2], I. Ray-Coquard[3], A. Leary[4], V. Rodriguez Freixinos[1], N. Concin[2], P. Toussaint[3], C. Massard[4], L. Fariñas-Madrid[1], E. Van Nieuwenhuysen[2], A. Lahr[5], I. Franjkovic[5], S. Rossomanno[6], P. Gerber[6], T. Nayak[6], F. Heil[5], C. Boetsch[6], A. Sahbi[7], K. Longauer[6], O. Krieter[5]

[1]Medical Oncology Department, Vall d'Hebron University Hospital, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain, [2]Department of Obstetrics and Gynaecology and Gynaecologic Oncology, University Hospital, Leuven, Netherlands, [3]Oncologie Médicale, Université Claude Bernard Lyon I, Lyon, France, [4]Gynecology Unit, Institut Gustave Roussy, Villejuif, France, [5]Pharma Research and Early Development, Roche Innovation Center Munich, Penzberg, Germany, [6]Pharma Research and Early Development, Roche Innovation Center Basel, Basel, Switzerland, [7]Pharma Research and Early Development, Roche Innovation Center Welwyn, Welwyn, UK

Background: VAN is a bi-specific human IgG1 antibody, simultaneously blocking two key angiogenic factors, Ang-2 and VEGF-A. VAN as a single agent showed an objective response rate (ORR) of 29% in bevacizumab- naïve PROC. The anti-PD-L1 agent, ATEZO demonstrated a 22% ORR in advanced OC. Preclinical data suggested additive antitumor activity of VAN when combined with anti−PD-L1. Hence, treatment with VAN plus ATEZO has the potential to reverse pro-angiogenic and immune-suppressive signals, thereby resulting in improved clinical benefit.

Methods: Eligible patients (pts) had PROC measurable by RECIST 1.1. Pts with history of bowel obstruction, > 2 prior lines of systemic chemotherapy, or previous treatments with VEGF-A inhibitors or agents targeting Ang/Tie2 receptor axis were ineligible. Pts received VAN 2000 mg and ATEZO 840 mg, each IV Q2W, until disease progression or unacceptable toxicity. Primary efficacy endpoint was ORR as per RECIST 1.1, with tumor assessments every 8 weeks.

Results: 17 pts with median age of 63 years (range 45-74) were treated. Serous histology was present in all pts, except one clear cell subtype. 4 pts (24%) achieved confirmed PR, 8 pts (47%) experienced SD and 4 (24%) had PD, while one patient was not evaluable. The achieved RECIST ORR of 24% remained unchanged when evaluated as per immune-related response criteria. 9/17 pts were evaluable for CA-125 per GCIG criteria; three and two achieved a response with and without normalization respectively. The current estimate of PFS rate @ 6 months is 65% (median follow-up: 162 days). The most common adverse events (AE) of any grade (G) were decreased appetite, diarrhea (41% each), asthenia and constipation (35% each). AEs ≥ G3 included abdominal pain, LFT increase, asthenia, dyspnea, health deterioration, hypertension, GI obstruction, GI perforation (GIP), subileus, lymphedema, pleuritis and tonsillitis (6% each). One AE of GIP and asthenia each were fatal.

Conclusions: Our data suggest that VAN plus ATEZO does not improve upon monotherapy with VAN or ATEZO in PROC. The safety profile of this combination is consistent with reports for the single agents in this setting.

[1]Department of Oncology, Hôpitaux Universitaires de Genève - HUG, Geneva, Switzerland, [2]Department of Medical Oncology, Institut Curie, Paris, France, [3]Department of Surgery, Centre Léon Bérard, Lyon, France, [4]Department of Oncology, Hôpital Prive Jean Mermoz, Lyon, France, [5]Department of Gynecology, Hôpitaux Universitaires de Genève - HUG, Geneva, Switzerland, [6]Département d'Oncologie médicale adulte, Centre Léon Bérard, Lyon, France, [7]Department of Genetic and Laboratory Medicine, Hôpitaux Universitaires de Genève - HUG, Geneva, Switzerland, [8]Inserm U830, PSL Research University, Institut Curie, Paris, France, [9]Division of Molecular Genetics, Hospices Civiles de Lyon, Lyon, France, [10]13Unit of Prevention and Genetic Epidemiology, UMR CNRS 5558, Centre Léon Bérard, Lyon, France

Background: BRCA2 plays a central role in homologous recombination through loading RAD51 on DNA double strand breaks. Among ovarian cancer (OC) patients, carriers of *BRCA2* mutations have better survival than *BRCA1* carriers and non-carriers. The objective of this study is to determine whether location of mutations in *BRCA2* gene impacts survival of OC patients.

Methods: A study cohort of 340 women with OC, who underwent genetic germline testing for *BRCA1* and *BRCA2* genes and received platinum-based chemotherapy, were identified in four hospitals in Switzerland and France. Duration of follow-up was 4.14 years. The Cancer Genome Atlas (TCGA) cohort of high-grade serous ovarian carcinomas (n = 316) was used as a validation cohort. Progression-free survival (PFS) and overall survival (OS) were analyzed.

Results: In the study cohort, 74 and 78 patients were carriers of germline mutations of *BRCA1* and *BRCA2*, respectively. After adjustment for FIGO stage and macroscopic residual disease, *BRCA2* carriers having truncating mutations in the RAD51-binding domain (RAD51-BD; exon 11) have significantly prolonged 5-years PFS (58%; adjusted Hazard ratio [HR], 0.36; 95% CI, 0.20-.64; p=0.001) compared to non-carriers. *BRCA2* carriers with mutations located in other domains of the gene have not prolonged 5-years PFS (28%, adjusted HR, 0.67; 95% CI, 0.42-1.07; p=0.094). In the TCGA cohort, after adjustment for FIGO stage and macroscopic residual disease, only *BRCA2* carriers harboring germline or somatic mutations in the RAD51-BD had prolonged 5-years PFS (46%; adjusted HR, 0.30; 95% CI, 0.13-0.68; p=0.004) and 5-years OS (78%; adjusted HR, 0.09; 95% CI, 0.02-0.38; p=0.001), compared to non-carriers.

Conclusions: Among patients with ovarian cancer, *BRCA2* carriers having mutations located in RAD51-BD (exon 11) have prolonged progression-free survival and overall survival.

944P POLE mutations and MSI were positive predictive factors for progression free survival in endometrial cancer patients at the risk of recurrence

A. Nyuya[1], J. Haraga[2], T. Nagasaka[3], K. Nakamura[2], T. Haruma[2], T. Nishida[2], K. Yasui[3], T. Fujiwara[1], A. Goel[4], H. Masuyama[2]

[1]Department of Gastroenterological Surgery, Okayama University Hospital, Okayama, Japan, [2]Department of Obstetrics and Gynecology, Okayama University Hospital, Okayama, Japan, [3]Gastroenterological Surgery, Okayama University Hospital, Okayama, Japan, [4]Center for Gastrointestinal Research, Center for Translational Genomics and Oncology, Baylor Scott & White Research Institute, Charles A. Sammons Cancer Center, Baylor University Medical Center, Dallas, TX, USA

Background: The Cancer Genome Atlas (TCGA) reported the genomic subgroups of endometrial cancer (EC); POLE mutation, Microsatellite instability (MSI), copy number low, and copy number high. Cancer with POLE mutation or MSI indicates hyper or high mutated, and they are considered to have some potential for good prognosis through immunoactivity in tumor microenvironment. In this study, we investigated the POLE mutation and MSI status in EC, and the correlation between the subtypes and prognosis and considered about the necessity of adjuvant therapy to good prognosis group.

Methods: In this study, we extracted tumor DNA from formalin-fixed, paraffin-embedded tissue of 325 EC tissues surgically resected at Okayama University

Hospital.Then, we analyzed MSI status from 4 mononucleotide markers by a multiplex PCR assay and *POLE* mutation status by Sanger sequence for hot spot mutations (V411L and P286R), and compared with the clinical and pathological outcomes obtained from medical records retrospectively.

Results: MSI cancer accounted for 24.9% (81/325 cases) and POLE mutation cancer accounted for 7.4% (24/325 cases) of the cohort. Progression free survival (PFS) was significantly better in POLE mutation group, followed by MSI group, and the others group. All the 24 POLE mutation patients had no recurrence during the observation period (median: 46.5 months [1∼111months]). Next, we investigated prognosis of the cases limited to those who usually need adjuvant therapy (except for stage IA and G1/2) among three genotype groups. POLE mutation and MSI group was the positive predictive factors for PFS in multivariate analysis.

Conclusions: POLE mutations and MSI were good prognostic factors for EC patients, especially, for EC patients at the risk of recurrence. Our results recommend prospective clinical trials whether adjuvant chemotherapy decreases the risk of recurrence in EC patients with POLE mutations or MSI.

945P Evaluation of circulating tumor DNA in patients with ovarian cancer harboring somatic PIK3CA or KRAS mutations

A. Ogasawara[1], T. Hihara[2], A. Yabuno[1], S. Shimoyokkaichi[1], D. Shintani[1], Y. Ikeda[1], K. Tai[2], K. Fujiwara[1], K. Watanabe[2], K. Hasegawa[1]

[1]Department of Gynecologic Oncology, Saitama Medical University International Medical Center, Hidaka, Japan, [2]Tsukuba Research Laboratories, Eisai Co., Ltd, Tsukuba, Japan

Background: Circulating tumor DNA (ctDNA) is an important source for liquid biopsy to understand the molecular phenotype of a tumor non-invasively, and is also expected to be a diagnostic and prognostic marker in cancer patients. Our aim is to clarify the clinical features of ctDNA in patients with ovarian cancer.

Methods: We screened 304 patients with ovarian tumors for somatic PIK3CA or KRAS mutations by a PCR-based method. A total of 108 patients with ovarian tumors were found to have somatic PIK3CA and/or KRAS mutations. One hundred and four out of 108 patients were considered to be evaluable for ctDNA. Cell-free DNA from the plasma of patients before surgery was investigated using droplet digital PCR for PIK3CA or KRAS mutations. We defined ctDNA detection to be positive when the corresponding mutations were detected in the plasma cell-free DNA.

Results: In 104 patients, 75, 25, and 4 patients had malignant, borderline, and benign ovarian tumors, respectively. The detection rates for ctDNA were 32% (24/75), 16% (4/25), and 0% (0/4) in patients with malignant, borderline, and benign ovarian tumors, respectively. PIK3CA and KRAS mutations in the plasma cell-free DNA were detected in 33.3% (11/33) and 30.2% (13/43) of patients with malignant ovarian tumors, respectively. We investigated the relationship between ctDNA detection and clinicopathological features in 73 epithelial ovarian cancer (EOC) patients. The detection rate of ctDNA was associated with advanced stage ($p = 0.019$) and positive peritoneal cytology ($p = 0.011$), but not with the histologic subtype or residual tumor status. In addition, we examined the potential association of ctDNA with patient survival. In univariate analysis, ctDNA detection was associated with shorter progression-free survival in EOC patients ($p < 0.001$). Multivariate analysis revealed that the stage, residual tumors, and ctDNA were independently associated with an increased risk of recurrence.

Conclusions: ctDNA was detected in approximate 30% of EOC patients in this study regardless of histologic types or the genes examined. The presence of ctDNA in the blood was an independent prognostic factor for recurrence, which suggests potential tumor spread.

Background: In recent years there has been increasing interest in the study of circulating tumor cells (CTC) and plama cell-free circulating DNA (cfDNA) as a new biomarker in neoplastic diseases. Our work aims to clarify its clinical role in ovarian epithelial carcinoma (OEC).

Methods: A prospective, multicenter, observational study has been conducted for 3 years in patients with advanced or responsive OEC. The predictive value and prognosis of CTC and cfDNA have been determined for both progression-free survival (PFS) and overall survival (OS). Their values have been compared with a control group. CTC were analysed by the CellSearch method and cfDNA by ALU-sequences-based quantitative PCR using two primers (ALU115 and ALU247); cfDNA integrity was calculated by ALU247/ALU115 ratio. This study was approved by the Central Research Ethics Committee. Updated data are presented.

Results: This study was conducted from November 2013 until December 2016. We recruited 88 patients, 15 benign tumors and 16 healthy subjects. Clinical characteristics were similar to other series, with a mean age of 57 years, 68.2% serous high grade subtype and 55.7% with stage IIIC. CTC were positive in 23.8% of patients (>1CTC/7,5mL). Levels of cfDNA were significantly elevated in patients than in the group of benign tumors and healthy control. CTC proved to be a negative prognostic factor of OS, with an average of 19.8 months versus 30.4 months (log-rank 4,649, $p < 0.031$). A high cfDNA value was also a negative prognostic factor for OS, with 22.5 months versus 28.7 months (log-rank 7.308, $p < 0.007$). The reduction in the integrity of cfDNA greater than 50% after chemotherapy was an early marker of resistance, with PFS of 6.4 months versus 16.0 months (HR 0.027, $p < 0.02$). The baseline value of cfDNA was also a negative prognostic factor for SLP, with 10 months versus 18 months (log-rank 7.233, $p < 0.007$). The baseline level of cfDNA and its integrity presented a predictive value of response to chemotherapy and the outcome of surgery, respectively.

Conclusions: In summary, CTC and cfDNA in advanced ovarian epithelial carcinoma have been prognostic factors for survival. In addition, cfDNA has a predictive value of response. These two biomarkers may be useful in clinical practice.

Background: Circulating tumor cells (CTC) are detected in 12–30% of advanced stage/relapsing ovarian carcinoma (OC). We evaluated the prognostic value of CTC counts among patients (pts) from the ANTHALYA trial, an open-label randomized phase II study evaluating addition of bevacizumab (Beva) to neoadjuvant carboplatin-paclitaxel (CP) in first line for pts with unresectable FIGO stage IIIc/IV ovarian, tubal or peritoneal adenocarcinoma.

Methods: We obtained CTC counts at baseline and before interval debulking surgery (IDS). A CTC threshold of ≥ 1 CTC/7.5 mL blood was considered as CTC+. We assessed the prognostic impact of CTCs on objective response rate (ORR), interval

Table: 947P

Prognostic approach	**0 CTC at baseline (n = 59)**		**CTC+ at baseline (n = 29)**	
ORR at IDS	59.3%		75.9%	
Median PFS [95% CI]	25.8 m [18.5-27.2]		21.0 m [15.0-25.4]	
Predictive approach	**Beva (n = 36)**	**CP (n = 23)**	**Beva (n = 17)**	**CP (n = 12)**
ORR at IDS	61.1%	56.5%	82.4%	66.7%
Median PFS [95% CI]	25.8 [20.9-NE]	20.3 [13.8-27.2]	21.0 [15.0-30.6]	20.6 [8.0-25.4]
Progression rate at M36	36.1%	56.5%	52.9%	83.3%

debulking surgery (IDS) rate, complete resection rate and progression-free survival (PFS), and explored their potential predictive impact on ORR and PFS according to bevacizumab therapy.

Results: In 88 pts with an available CTC count at baseline, CTC+ pts (n = 29) had a 75.9% ORR (at IDS), vs 59.3% for pts with 0 CTC (n = 59): OR = 2.2 [0.8-5.8] (OR-adj=1.8 [0.8-5.8]). Respectively, 58.6% vs 66.1% were amenable to IDS and 55.2% vs 54.2% achieved a complete resection. Median PFS was 21 m [15.0-25.4] in CTC+ pts and 25.8 m [18.5-27.2] in pts with 0 CTC (HR = 1.5 [0.8-2.8] and HR-adj=1.7 [0.9-3.2]). CTC counts at IDS were available in 70 pts. At IDS, a complete resection was achieved in 66.7% of CTC+ pts (n = 6), and in 68.8% of pts with 0 CTC (n = 64). Exploration of the potential predictive impact of CTC is described in the table.

Conclusions: Baseline CTC counts in OC patients receiving neoadjuvant chemotherapy +/- bevacizumab carry dual prognostic information: CTC count at IDS do not add any information, CTC+ seems to be associated with a higher ORR, while 0 CTC count seems to be a prognostic factor with better PFS, in the whole population and among patients treated with bevacizumab.

981P Reactive stroma mediates CD8+ T cell spatial distribution and function in ovarian cancer

Y. Wang[1], L. Ryner[1], A.R. Udyavar[2], M. Desbois[1], C. Kozlowski[3], C-W. Chang[4], Y. Guan[1], S. Lu[1], H. Koeppen[5], J. Ziai[5], R. Bourgon[2], P.S. Hegde[1]

[1]Oncology Biomarker, Genentech Inc. - Roche - USA, South San Francisco, CA, USA, [2]Bioinformatics, Genentech Inc. - Roche - USA, South San Francisco, CA, USA, [3]Digital Pathology, Genentech Inc. - Roche - USA, South San Francisco, CA, USA, [4]Biostatistics, Genentech Inc. - Roche - USA, South San Francisco, CA, USA, [5]Pathology, Genentech Inc. - Roche - USA, South San Francisco, CA, USA

Background: Close proximity between cytotoxic T cells and tumor cells is key to effective immunotherapy. Ovarian cancer exhibits diverse immune phenotypes with distinct prevalence and spatial localization of CD8+ T cells. This study is aimed to characterize the molecular mechanisms orchestrating the localization and function of CD8+ T Cells in ovarian cancer.

Methods: CD8 IHC and RNAseq were performed on 277 ovarian tumor tissues from ICON7 phase 3 trial. CD8 T-cells in tumor vs. stromal area was assessed by digital pathology. A Random Forest regression model was constructed to identify molecular features associated with enumeration or spatial localization of CD8+ T cells. *In situ* validation was performed by MHCI IHC and FAP RNAish. Functional role of ovarian fibroblasts was characterized by *ex vivo* T cell function assays.

Results: We identified three main immune phenotypes, including T-cell infiltrated, T-cell excluded, and immune desert. The immune phenotypes are highly associated with prognosis and the molecular subtypes of ovarian cancer. The T-cell infiltrated phenotype is denoted by high expression of T-effector signatures and antigen presentation machinery. The T-cell excluded phenotype showed similar expression of T-effector signatures as the T-cell infiltrated phenotype, however, most of the CD8+ T-cells were excluded from the tumor bed. The T-cell excluded phenotype showed high expression of the reactive stroma signatures (i.e. FAP), and low expression of class I antigen presentation genes. Lastly, the immune desert phenotype featured low prevalence of CD8+ T-cells, and high expression of neuroendocrine and metabolic pathways. In situ analysis confirmed the two key molecular features associated with the T-cell excluded phenotype: 1) loss of the MHC I expression in the tumor compartment, and 2) high FAP expression in CAFs. Co-culturing of ovarian fibroblast cells with T-cells resulted in reduced T-cell activation and proliferation.

Conclusions: Our study uncovered key molecular mechanisms mediating the interplay between CD8+ T cell localization and function in ovarian cancer. Our findings underscore the potential of targeting reactive stroma as a novel therapeutic strategy to optimize immunotherapy for ovarian cancer patients.

948P Genomic instability is associated with increased immune infiltration and PDL1 expression in epithelial ovarian cancer

A. Leary[1], C. Genestie[2], Y. Boursin[3], J. Adam[4], A. Leformal-Ensarguex[5], S. Gouy[6], P. Morice[6], E. Bentivegna[6], P. Pautier[7], J. Michels[7], B. Job[3], M. Deloger[3], S. Mesnage[1], A. Auguste[5]

[1]Gynaecologic Oncology, Gustave Roussy Cancer Center, INSERM U981, and Groupe d'Investigateurs Nationaux pour l'Etude des Cancers Ovariens (GINECO), Villejuif, France, [2]Department of Pathology, Institut Gustave Roussy, Villejuif, France, [3]BiGR-Bioinformatic, Gustave Roussy, Villejuif, France, [4]Pathology, Institut Gustave Roussy, Villejuif, France, [5]U981 INSERM, Gustave Roussy, Villejuif, France, [6]Department of Surgery, Gustave Roussy, Villejuif, France, [7]Medical Oncology, Gustave Roussy Institut de Cancérologie, Villejuif, France

Background: High mutation load secondary to mutagenic exposures such as smoking or to mutations in mismatch DNA repair genes has been associated with increased tumor immune infiltration and response to immune therapies. Ovarian cancers (OC) demonstrate low mutation load, but high degree of genomic instability (GI) attributable to frequent defects in the homologous recombination DNA repair pathway. We sought to investigate whether GI predicted increased infiltration by tumor infiltrating lymphocytes (TILs) and PDL1 expression in OC.

Methods: TILs were evaluated on FFPE OC samples and scored as percentage of stromal area. PDL1 expression was quantified as percent positive immune cells. GI was measured as the number of copy number alterations >15Mb by Oncoscan SNParray on DNA from the same FFPE samples and high GI score (GIS) defined as > median. Correlations were evaluated using a Spearman rank and differences by Mann-Whitney.

Results: 66 tumor samples were evaluable for both GIS and immune infiltration. GIS and TILs showed significant variability ranging from 0 to 64 (median=28) and from 5 to 90% (median=20%) for GIS and TILs, respectively. GIS was significantly higher among high grade serous or endometrioid OC than among low grade tumors (GIS=29 vs 5; $p < 0.0001$) and non-significantly greater among patients with *BRCA* mutations and/or family history compared to wild-type OC with no family history ($p = 0.12$). GIS and TILs were highly correlated ($R = 0.4$; $p = 0.0019$) and median TILs were significantly increased in GIS-high vs -low tumors (29% vs 15%; $p = 0.0028$, Fig 1) as was immune cell PDL1 expression ($p = 0.025$). Fig 1 Increased TILs in tumors with high genomic instability

Conclusions: High genomic instability correlated with increased tumor infiltrating lymphocytes and PDL1 expression. Whether GIS could provide a simple and predictive biomarker for immune therapies in OC should be investigated.

Background: Lymphocytic infiltration areas (immunoreactive) are frequently found in ovarian cancer, which is associated with a better prognosis and increased survival. Therefore, the study of different patterns and degree of infiltration would help us to better understand the relationship between immune and tumor cells and its prognostic implications.

Methods: This retrospective study includes samples from 57 patients with high grade serous ovarian cancer (HGSOC) who underwent cytoreductive surgery. The pattern of infiltration, localization and degree of lymphocyte infiltration in the tumor was evaluated. A set of clinical variables such as smoking, age, type of surgery, intention of treatment, type of response, as well as lymphocytic infiltration were evaluated to assess prognosis.

Results: In our cohort, the median age was 61.5 years, there were 60% of smokers, and most of the cases were FIGO stages III and IV (15.3%, stage I, 8.5% stage II, 54.3% stage III and 22% stage IV). As expected, patients over 65 years, as well as the group of more advanced stages (III and IV) showed a shorter overall survival (OS, 30.17 vs 99.90 months, $p = 0.009$; 38.73 months vs NR, $p = 0.005$, respectively). Smoking status was also analyzed but no significant effect on survival was found (OS, $p = 0.935$). Interestingly, patients with an intratumoral lymphocyte infiltrate had better prognosis compared to the group that had only a peritumoral pattern (OS, 44.57 months vs NR, $p = 0.041$). In addition, those with a diffuse infiltration pattern presented a better prognosis compared to those with a focal pattern (OS, 20.20 months vs NR $p = 0.003$). Finally, a tendency for a better OS was seen for those patients with a strong degree of infiltration in the tumor.

Conclusions: HGSOC represents a group of highly immunoreactive tumors. Those with the best prognosis are represented by an intratumoral, diffuse pattern with a strong degree of infiltration, these findings could open a new window for therapeutic approaches in HGSOC.

950P Gene mutational analyses in 154 ovarian cancer (OC) samples from the ROSiA study of front-line bevacizumab (BEV)-containing therapy for OC

R. Deurloo[1], N. Colombo[2], C. Mendiola[3], F. Selle[4], J. Korach[5], M.Z. Oestergaard[1], M. Bylesjo[6], H-J. Urban[7], Y. Ghazi[8], A. Oza[9]

[1]Oncology Biomarker Development, F Hoffmann-La Roche Ltd, Basel, Switzerland, [2]Division of Medical Gynecologic Oncology, European Institute of Oncology and University of Milano-Bicocca, Milan, Italy, [3]Department of Medical Oncology, University Hospital 12 de Octubre, Madrid, Spain, [4]Medical Oncology Service, Groupe Hospitalier Diaconesses Croix Saint-Simon and Alliance Pour la Recherche en Cancérologie, Paris, France, [5]Gynecologic Oncology Department, Sheba Medical Center, Tel Hashomer, Israel, [6]Bioinformatics Department, Fios Genomics Ltd, Edinburgh, UK, [7]Product Development Medical Affairs Biometrics, F Hoffmann-La Roche Ltd, Basel, Switzerland, [8]Global Product Development/Medical Affairs, F Hoffmann-La Roche Ltd, Basel, Switzerland, [9]Cancer Clinical Research Unit, Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: In the single-arm ROSiA study (NCT01239732), 1021 patients (pts) with newly diagnosed OC received 12–24 wks of carboplatin + paclitaxel with BEV for up to 24 mo or until progression [Oza 2016]. Progression-free survival (PFS) was a secondary endpoint.

Methods: In an optional translational research substudy, tumour tissue samples collected before BEV were analysed using Foundation Medicine Inc.'s FoundationOne® (FMOne) gene panel. Prevalence of gene alterations, tumour mutational burden (TMB) and potential prognostic effects were assessed in exploratory gene mutational analyses using Cox proportional hazards models. Correlations between TMB and *BRCA1* mutation and immunohistochemical expression of the immune markers PD-L1 and CD8 were assessed.

Results: The FMOne population ($n = 154$) was representative of the ITT population ($n = 1021$) for baseline characteristics but had slightly more favourable PFS (median 30.2 vs 25.5 mo, respectively; hazard ratio [HR] 1.16 [95% CI 0.92–1.45]; $p = 0.21$). The most common gene alterations (predominantly short variant) were *TP53* (79% of pts), *BRCA1* (22%), *NF1* (14%), *KRAS* (10%), *PIK3CA* (9%) and *BRCA2* (7%). *MYC*, *TERC*, *GNAS* and *CCNE1* were amplified in 25%, 16%, 7% and 7%, respectively. The mean TMB (excluding germline polymorphisms and known cancer drivers) was 4.5/megabase (Mb; range 0–43). Only 2 pts had a TMB >15/Mb; 43 had a TMB ≥5/Mb. In univariate Cox regression analyses, none of the mutations explored showed a clear association with PFS. PFS slightly (not statistically significantly) favoured pts with ($n = 34$) vs without ($n = 118$) *BRCA1* mutation (median 30.4 vs 28.1 mo, respectively; HR 0.76 [95% CI 0.44–1.31]; $p = 0.32$). TMB and PFS showed no association. No meaningful correlations were seen between either TMB or *BRCA1* mutation and expression of the immune markers PD-L1 and CD8 on immune cells.

Conclusions: Samples from pts with newly diagnosed OC indicated relatively infrequent gene alterations and low TMB. None of the gene alterations evaluated suggested prognostic value, but low frequency of these mutations and the relatively small number of samples in ROSiA limit interpretation, particularly for the correlation analyses.

Clinical trial identification: NCT01239732

951P A retrospective study of endocrine therapy in high grade serous ovarian carcinoma

B. Stanley[1], R.L. Hollis[2], J.D. Towler[1], X. Yan[1], H.D.S.M. Nunes[3], T. Rye[2], S. Herrington[2], M. Churchman[2], M. MacKean[1], F. Nussey[1], C. Gourley[2]

[1]Edinburgh Cancer Centre, Western General Hospital, Edinburgh, UK, [2]Edinburgh Cancer Research UK Centre, University of Edinburgh, Edinburgh, UK, [3]Oncology, Instituto Português de Oncologia Francisco Gentil, Lisbon, Portugal

Background: The degree of oestrogen receptor (ER) expression in ovarian cancer correlates well with its endocrine sensitivity. However, the use of endocrine therapy (ET) in relapsed disease is variable in part due to the lack of phase III data. It is thus unlicensed and not a standard of care. Here we describe the endocrine sensitivity of high grade serous ovarian carcinoma (HGSOC) in a large retrospective cohort.

Methods: Patients were eligible if they had HGSOC treated with prior chemotherapy, and received at least 4 weeks of ET. Exclusion criteria included: ET as a maintenance treatment and unknown duration of therapy (DOT). The best CA125 response across the DOT was recorded as per modified GCIG criteria. Stable CA125 response had to be maintained for at least 12 weeks. The primary endpoint was DOT. Secondary endpoints

Table: 951P

ER histo-score	CA125 CBR (%)		DOT (days)		Median TTNT (days)	
≥150 vs < 150	51.5 vs 45.5	n/s	HR = 0.62 [95% CI 0.43-0.89]	Median: 133 vs 93 p = 0.039	164.5 vs 118	p = 0.075
≥200 vs < 200	57.3 vs 37.5	p = 0.029	HR 0.69 [95% CI 0.52-0.91]	Median 141.5 vs 92 p = 0.001	171 vs 118	p = 0.008

were time to next therapy (TTNT) from treatment initiation, CA125 objective response rate (ORR) and clinical benefit rate (CBR).

Results: 593 patients were identified from the Edinburgh Ovarian Cancer Database between January 1974 and December 2015. 267 patients met the eligibility criteria (78.3% letrozole, 19.5% tamoxifen, 2.2% megestrol acetate). Median DOT and TTNT were 122.5 days (range 28-1427 days) and 161 days (range 41-2345 days), respectively. 33.2% and 14.6% of patients received ET for ≥ 180 and ≥ 365 days, respectively. Of 38 patients on ET for ≥ 365 days, 29 (76%) received ET as 2nd line therapy, 9 (24%) as 3rd line therapy and none as 4th line or later. The CA125 ORR and CBR in evaluable pts was 11.4% (20/175) and 48.6% (85/175), respectively. The CA125 CBR, median DOT and TTNT between different ER histoscore ranges are compared in *Table.* In early (2nd line) vs late (3rd line onwards) use of ET, the median DOT and TTNT was 140 vs 98 days (HR = 0.68 [95% CI 0.53-0.87]) and 167 vs 138 days (p = 0.022), respectively.

Conclusions: The endocrine sensitivity of HGSOC is significantly influenced by the degree of ER expression and line of treatment that ET is used in. Early introduction of ET in the management of relapsed HGSOC should be considered particularly in tumours with an ER histoscore of ≥ 200.

952P Randomised prospective study of maintenance tamoxifen versus post adjuvant chemotherapy surveillance only in advanced ovarian cancer patients

V. Goel[1], A. Jain[2], S. Tiwari[3], M.C. John[4], V. Talwar[1], P. Dash[1], N. Patnaik[5], S. Raina[1], D.C. Doval[1]

[1]Medical Oncology, Rajiv Gandhi Cancer Institute & Research Center, New Delhi, India, [2]Medical Oncology, Jindal Institute of Medical Sciences, Haryana, India, [3]Medical Oncology, Jawaharlal Nehru Cancer Hospital, Bhopal, India, [4]Medical Oncology, Jubilee Mission Medical College and Research Institute, Trissur, India, [5]Pathology, Action Cancer Hospital, Delhi, India

Background: Treatment of advanced ovarian cancer results in a high objective response rate (> 70% to 80%), but disease recurs in most patients. Some studies have been done to understand the role of maintenance therapy after conventional adjuvant chemotherapy. Maintenance therapy must balance prevention of disease recurrence with cumulative toxic effects and reduction in quality of life. The effects of maintenance therapy with chemotherapy (e.g. paclitaxel maintenance) or antiangiogenetic agents (e.g. bevacizumab or pazopanib) have been studied, but results have been conflicting and without significant benefit in overall survival. We have performed this study to assess the role of maintenance tamoxifen post adjuvant chemotherapy in patients with advanced ovarian cancer.

Methods: In this prospective study, done in a tertiary care centre in northern India, patients with advanced ovarian cancer (stage III and IV), post conventional adjuvant chemotherapy, were randomly enrolled from Sep 2012 to April 2015. Tamoxifen maintenance was given at a dose of 20 mg twice a day for entire follow up period. The progression free survival (PFS) was analyzed.

Results: In total 100 patients were enrolled: 50 patients were given tamoxifen and 50 patients were put on post adjuvant treatment surveillance. The median age was 51.0 years (31-69 years). Median follow up of these patients was 14 months (6-22 months). Median increase in PFS was 6.3 months (95% CI: 4.52-6.14 months) in patients treated with maintenance tamoxifen and there were no grade 3/4 side effects seen in this group.

Conclusions: Maintenance tamoxifen prolongs PFS by 6.3 months when compared to no treatment after conventional adjuvant chemotherapy. Further studies should be planned for comparison of maintenance tamoxifen with maintenance chemotherapy (e.g. paclitaxel maintenance) or antiangiogenetic agents.

953P A phase 1 study to evaluate the safety and tolerability of bevacizumab-niraparib combination therapy and determine the recommended phase 2 dose (RP2D) in women with platinum-sensitive epithelial ovarian cancer (ENGOT-OV24/AVANOVA1)

M.R. Mirza[1], J. Wang[2], M. Mau-Sørensen[3], M.J. Birrer[4], X. Wang[2], M. Jørgensen[5], Z-Y. Zhang[2], H. Roed[5], S. Malander[6], F. Nielsen[7], L. Bjørge[8], U. Lassen[3], L. Boufercha[5], K. Brøsen[7], V. Kansra[2], J. Mäenpää[9]

[1]Oncology, Nordic Society of Gynecologic Oncology (NSGO) and Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark, [2]Clinical Pharmacology, TESARO, Inc., Waltham, MA, USA, [3]Oncology, Rigshospitalet, Copenhagen, Denmark, [4]Gynecologic Oncology, Massachusetts General Hospital, Boston, MA, USA, [5]Oncology, Nordic Society of Gynecologic Oncology (NSGO) and Rigshospitalet, Copenhagen, Denmark, [6]Oncology, The Nordic Society of Gynecological Oncology (NSGO) & Lund University Hospital, Lund, Sweden, [7]Clinical Pharmacology and Pharmacy, Department of Public Health, Environmental Medicine, University of Southern Denmark, Odense, Denmark, [8]Clinical Science, University of Bergen, Bergen, Norway, [9]Obstetrics and Gynecology, University of Tampere and Tampere University, Tampere, Finland

Background: A phase 2 randomized study has indicated that the combination of a poly(ADP-ribose) polymerase inhibitor (PARPi) with an anti-angiogenic drug is superior to PARPi alone.

Methods: Bevacizumab 15 mg/kg IV q 21 days (fixed dose) was administered with escalating dose of niraparib capsules (100, 200, 300 mg daily) in a classic 3 + 3 escalation design. Platinum-sensitive ovarian cancer patients (pts) with high-grade serous/endometrioid carcinoma and with measurable disease (RECIST or GCIG criteria) were eligible. The primary objective was to evaluate the safety and tolerability of the bevacizumab-niraparib combination therapy and determine the RP2D of bevacizumab-niraparib.

Results: Twelve pts (3 + 3+6) were enrolled to three dose levels. Three of 12 pts had g*BRCA*2 mutation, while the others were non-g*BRCA*mut. During the first cycle, patients experienced hypertension (G3=5 pts), anemia (G3=3 pts), thrombocytopenia (G3=1 pt), fatigue (G2=1 pt), constipation (G2=1 pt), and nausea (G2=1 pt). One dose-limiting toxicity (Grade 3 thrombocytopenia that persisted for ≥5 days) was observed at the highest dose level, and the RP2D is therefore bevacizumab 15 mg/kg with niraparib capsules 300 mg. Niraparib dose reductions occurred in four pts (cohort 2=1 pt; cohort 3=3 pts), and bevacizumab termination occurred in two pts. Three pts are still on treatment, while nine pts have discontinued treatment (8 progressive disease; 1 withdrawal of consent). Disease control rate was 91%, and response rate was 45% (1 CR; 4 PR). Niraparib pharmacokinetics were consistent with historical data. Overlapping exposure was observed across the dose range tested at both C1D1 and C2D1.

Conclusions: The bevacizumab-niraparib combination has hematologic dose-limiting toxicity and expected, manageable class toxicities with preliminary evidence of efficacy. The PK profiles of niraparib co-administered with bevacizumab are similar to historical data. A phase 2 randomized 2-arm trial is ongoing (AVANOVA2, NCT02354131).

954P Prospective cohort study of bevacizumab plus standard platinum based chemotherapy as front-line treatment for advanced epithelial ovarian cancer, fallopian tube cancer, or primary peritoneal cancer: Japanese Gynecologic Oncology Group study (JGOG3022)

K. Kato[1], S. Komiyama[2], N. Takeshima[1], H. Takano[3], A. Inoue[4], A. Hongo[5], M. Asai-Sato[6], A. Arakawa[7], K. Kubushiro[2], S. Kamiura[8], T. Sugiyama[9]

[1]Department of Gynecology, Cancer Institute Hospital of JFCR, Tokyo, Japan, [2]Department of Obstetrics and Gynecology, Toho University Ohashi Medical Center, Tokyo, Japan, [3]Department of Obstetrics and Gynecology, The Jikei University Kashiwa Hospital, Kashiwa, Japan, [4]Department of Obstetrics and Gynecology, Ehime University Hospital, Ehime, Japan, [5]Department of Obstetrics and Gynecology, Kagawa Prefectural Central Hospital, Takamatsu, Japan, [6]Department of Obstetrics and Gynecology, Yokohama City University Hospital, Yokohama, Japan, [7]Department of Obstetrics and Gynecology, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan, [8]Department of Gynecology, Osaka International Cancer Institute, Osaka, Japan, [9]Department of Obstetrics and Gynecology, Iwate Medical University School of Medicine, Morioka, Japan

Background: The GOG-218 and ICON-7 studies showed that addition of bevacizumab (BEV) to front-line treatment for patients (pts) with advanced ovarian cancer increased progression free survival. Based on this result, BEV has been widely used in the front-line treatment. However, sufficient safety information of addition of BEV is not available in Japan. This prospective cohort study is conducted to assess the safety of addition of BEV to front-line treatment.

Methods: Eligible pts have FIGO stage III–IV epithelial ovarian, fallopian tube or primary peritoneal carcinoma, were aged ≥20 years and have ECOG PS 0–2. Prior neoadjuvant chemotherapy was permitted. The primary cohort was defined as pts who received tri-weekly paclitaxel/carboplatin (PC) plus BEV, and the exploratory cohort as pts who received other platinum based regimen plus BEV. BEV is continued at the same dose as a single agent until disease progression or unacceptable toxicity. The primary objective is to assess safety (NCI-CTCAE v4.03) of the primary cohort.

Results: A total of 346 pts (Primary/exploratory cohort: 303/43) were enrolled from 79 institutions from Apr 2015 to Feb 2016. The data of primary cohort of 293 pts were analyzed as of 31 Mar 2017. The median age was 58 years (range: 27–83). The majority of the histologic type was Serous adenocarcinoma (65.2%) followed by Clear cell adenocarcinoma (12.3%) and Endometrioid adenocarcinoma (10.6%). Up-front surgery was performed in 203 pts (69.3%), and interval debulking surgery following neoadjuvant chemotherapy was performed in 90 pts (30.7%). A total of 45 serious adverse events occurred. Two pts (0.6%) developed a gastrointestinal perforation (grade 2) or fistula (grade 3). Thromboembolic events, hypertension, and hematuria of grade 3 or greater occurred in 3 (1.0%), 2 (0.7%), and 1 pt (0.3%), respectively.

Conclusions: Addition of bevacizumab to platinum based front-line chemotherapy can be safely administrated for advanced ovarian cancer pts in Japan. The rates of gastrointestinal and thromboembolic toxicity were relatively low as compared with the previous studies.

955P A landmark analysis of overall survival in PR-OC patients treated with chemotherapy and bevacizumab using early tumor shrinkage as covariate

A. Sostelly, F. Jaminion, F.J. Mercier

Clinical Pharmacometrics, Pharma Research and Early Development, Roche Innovation Center Basel, F. Hoffmann-La Roche Ltd, Basel, Switzerland

Background: We aimed at developing a OS model incorporating TK metrics in platinum-resistant (PR)-ovarian cancer (OC) patients using data from the randomized, open label, phase 3 AURELIA trial designed to compare PFS in patients treated with chemotherapy alone (CT) or in combination with Bevacizumab (B).

Methods: Individual data from 361 patients randomly allocated to the B+CT or CT were available. Three types of CT were evenly distributed in both arms. Tumor size reported as sum of lesion diameter (SLD, RECIST 1.0) was collected at baseline and every 8 to 9 weeks until disease progression. Patients continued to be followed for OS even after treatment discontinuation. A non-linear mixed effect TK model accounting for the dynamics of tumor growth, drug effect and treatment resistance was used to fit the SLD. The final TK model contained a term of resistance specific to each CT type in both study arms while drug effect and tumor growth rate were common to all patients. TK metrics indicated that most of the patients experienced tumor shrinkage with a more profound shrinkage in the B+CT arm. From this model, two TK metrics were derived for each patient: early shrinkage at week 8 (ETS8) and predicted SLD at treatment onset (TS0). Then a Cox proportional-hazard survival model was developed. Covariates including ECOG and FIGO score at baseline, histological grade and subtype, time from 1st diagnosis to treatment onset, presence of ascites, CA-125 at baseline, TS0, and ETS8 were tested as prognostic factors.

Results: In the bootstrap-based covariate analysis, two sets of factors were found to be influential on survival time: those reflecting the disease severity (ECOG, FIGO stage, presence of ascites) and those describing key features of the TK (ETS8 and TS0). Treatment group was not retained in the final model as its effect was masked by the influence of the other covariates.

Conclusions: For the 1st time, an OS model including individual TK metrics was developed for PR-OC patients. This analysis confirms previous findings indicating the low predictive value of CA-125 in this population. While treatment group and baseline CA-125 were not found to influence survival time, model derived TK metrics were predictive of OS, ETS8 notably.

956P Influence of comorbidities on clinical outcome in patients (pts) receiving chemotherapy (CT) + bevacizumab (BEV) for primary advanced ovarian cancer (OC)

H. Woopen[1], P. Wimberger[2], A. Mustea[3], G. Oskay-Oezcelik[4], M. Keller[5], R. Richter[1], J. Harde[6], S. Klawitter[7], A. Wegenaer[8], O. Tomé[9], J. Sehouli[1]

[1]Department of Gynecology and Gynecologic Oncology, Charité Campus Virchow Klinikum, Berlin, Germany, [2]Gynecology and Obstetrics, Carl-Gustav-Carus University Dresden TU Dresden, Dresden, Germany, [3]Gynecology, University Medicine Greifswald, Greifswald, Germany, [4]Gynecologic Oncology, Praxisklinik Krebsheilkunde fuer Frauen, Berlin, Germany, [5]C/o Charité Medical University of Berlin, North-Eastern German Society of Gynaecological Oncology (NOGGO e.V.), Berlin, Germany, [6]Statistics, Data Management and Medical Informatics, IOMEDICO AG, Freiburg, Germany, [7]Biostatistics and Epidemiology, Roche Pharma AG, Grenzach-Wyhlen, Germany, [8]Medical Affairs, Roche Pharma AG, Grenzach-Wyhlen, Germany, [9]Department of Gynecology, St. Vincentius-Kliniken, Karlsruhe, Germany

Background: Using interim data from the single-arm non-interventional OTILIA study (NCT01697488; NOGGO) of front-line BEV + CT for OC in routine practice, we explored the impact of pre-existing comorbidities on clinical outcome.

Methods: Pts with FIGO stage IIIB–IV OC received front-line BEV + CT according to the EU label. Adverse events (AEs; CTCAE v4.0) were recorded at each cycle. Post hoc analyses explored safety and effectiveness in subgroups of pts with diabetes mellitus, ongoing hypertension (HTN) or cardiovascular (CV) comorbidities (coronary heart disease, heart failure, arrhythmia, ongoing HTN, thromboembolic event).

Results: As of 31 Jan 2017, data were available for 808 of 1190 planned pts. Comorbidities were more common in pts aged ≥70 (n = 382) than <70 y (n = 426). Baseline characteristics and outcomes in the three subgroups are shown below. Logistic regression models suggested a higher risk of non-haematological AEs in pts with CV comorbidities (odds ratio [OR] adjusted for key prognostic factors: 1.75; $p = 0.009$) or HTN (OR 1.89; $p = 0.046$), and of CV events in pts with CV comorbidities (OR 3.12; $p < 0.001$). There was no relevant difference in progression-free survival (PFS) between subgroups. Further subgroup analyses of PFS according to HTN (pre-existing vs treatment emergent vs none) suggested the longest PFS in 132 pts developing HTN during therapy (median PFS 26.5 mo). However, a Cox regression analysis to account for the confounding effect of BEV duration indicated that HTN development was not a significant predictive factor for PFS.

Conclusions: In OTILIA, pts with comorbidities had similar PFS to the overall population, despite older age and worse ECOG PS. Grade 3/4 AEs were slightly more common, particularly in pts with diabetes mellitus, but did not lead to treatment discontinuation. These post hoc analyses suggest that with appropriate care, BEV is an option in pts with comorbidities.

957P Feasibility and effectiveness of multiple lines of bevacizumab-based therapy in patients with recurrent tuboovarian carcinoma

V. Kallage[1], A.T. Kurbacher[1], S. Herz[1], G. Kolberg[1], C. Schweitzer[1], J.A. Kurbacher[2], C.M. Kurbacher[1]

[1]Gynecologic Oncology, Gynecologic Center Bonn-Friedensplatz, Bonn, Germany, [2]General Gynecology and Obstetrics, Gynecologic Center Bonn-Friedensplatz, Bonn, Germany

Background: In metastatic breast cancer, bevacizumab (Bev)-based treatment beyond progression (TBP) has been found a valid option, whereas TBP with Bev in tuboovarian carcinoma (TOC) has not been intensively investigated so far. This retrospective study sought to investigate the feasibility and effectiveness of multiple lines of Bev-based systemic therapy (Tx) in patients (pts) with recurrent TOC.

Methods: From our database, a total of 90 pts with recurrent TOC (45 with platinum-sensitive or platinum-resistant disease each) receiving at least one line of Bev-based Tx were identified. 37 (41.1%) pts had one, 20 (22.2%) two, 13 (14.4%) three, and 20 had (22.2%) 4-9 lines of Bev. A total of 225 courses of Bev-based Tx were administered: 58 (25.8%) as monotherapy (Bev), 63 (28.0%) in combination with conventionally dosed chemotherapy (Bev+cCtx), and 104 (46.2%) in combination with metronomic Ctx (Bev+mCtx). Time to progression (TTP) was calculated from the start of each Bev-based Tx until progression, overall survival was calculated from the start of the first Bev-based Tx until death from any reason or loss to follow-up. Adverse effects in regard to Bev were scored according to CTCAE vs 4.02.

Results: Most frequent side effects of Bev were proteinuria occurring in 50%, hypertension in 41%, gastrointestinal toxicity in 31%, and infection in 17% of treatments. However, G3-4 toxicities were rare with hypertensive crisis in 2.2%, bowel obstruction in 0.9%, bowel perforation in 0.9%, nephrotic syndrome in 0.4% and infection seen in 1.3% of treatments. Both TTP and OS did not differ between different types of Tx. TTP: Bev, 5.4 months (mts); Btsv+cCtx, 6.1 mts; Bev+mCtx, 6.3 mts. OS: Bev, 28.6 mts, Bev+cCtx, 31 mts; B+mCtx, 21.4 mts. TTP for platinum-resistant vs platinum-sensitive pts was 4.5 and 7.6 mts (p=NS) and OS was 20.1 vs 12.2 mts ($p = 0.044$). TTP was comparable between one and multiple lines of Bev: one line, 6.6 mts; two lines, 6.3 mts, three lines 5.9 mts, and 4-9 lines 3.7 mts ($p = 0.130$). However, OS increased significantly with the number of Bev-based lines of Tx: one line, 8.8 mts; two lines, 16.8 mts; three lines 25.4 mts; 4-9 lines, 36.6 mts ($p = 0.0001$).

Conclusions: Our results demonstrate that retreatment with Bev can be safely given to pts with recurrent TOC in the clinical routine. The incidence of severe side effects was generally low and did not increase by the line of Bev-based Tx. However, the number of Bev-based lines had a significant impact on overall survival. Thus, rechallenge with Bev may be a valuable option in the treatment of recurrent TOC.

Background: The GOG-0218 and ICON7 randomised phase III trials demonstrated the efficacy and safety of front-line BEV + CT for OC. The single-arm OTILIA study is evaluating BEV + CT in German clinical practice. In a previously reported interim analysis (ESMO & IGCS 2016), the observed safety and effectiveness were consistent with phase III results (preliminary median progression-free survival [PFS] 21.7 months). To address the lack of data on the impact of BMI on safety and clinical outcome in pts receiving CT + BEV, we performed exploratory analyses of the OTILIA dataset.

Methods: In OTILIA (NCT01697488), pts with FIGO stage IIIB–IV OC received front-line BEV + CT according to the EU label. Adverse events (CTCAE v4.0) were recorded at each cycle. Investigators assessed response per local practice. We performed post hoc exploratory subgroup analyses of the third interim dataset according to BMI and a multiple Cox regression analysis of PFS vs BMI, age, ECOG performance status, FIGO stage, residual disease and ascites as covariates.

Results: BMI was available for 785 of 808 pts. Treatment duration was similar across BMI subgroups (Table). There were no significant differences in PFS between

Table: 958P

Parameter, n (%)		BMI, kg/m^2			
		≤20 (n = 107)	>20–25 (n = 329)	>25–≤30 (n = 237)	≥30 (n = 112)
Age ≥70 years		35 (33)	162 (49)	117 (49)	51 (46)
ECOG performance status ≥2		13 (12)	31 (9)	24 (10)	16 (14)
Median BEV duration, months (95% CI)		12.5 (10.3–13.6)	13.5 (12.4–13.8)	13.8 (12.6–14.0)	13.4 (11.6–14.3)
BEV discontinued		67 (63)	176 (53)	118 (50)	60 (54)
Main reason for discontinuing BEV	Disease progression	23 (21)	42 (13)	44 (19)	20 (18)
	Treatment-related AE[a]	13 (12)	27 (8)	16 (7)	9 (8)
	Death	1 (1)	14 (4)	2 (1)	2 (2)
	Pt request	6 (6)	17 (5)	17 (7)	6 (5)
	End of documentation period	13 (12)	33 (10)	21 (9)	12 (11)
Grade 3/4 adverse events	All	45 (42)	113 (34)	87 (37)	44 (39)
	Serious	27 (25)	60 (18)	43 (18)	23 (21)
	Leading to BEV discontinuation	11 (10)	27 (8)	20 (8)	8 (7)
Median PFS, months (95% CI)[b]		19.4 (16.0–21.7)	21.8 (19.9–25.1)	22.6 (20.8–26.5)	18.6 (16.6–22.2)

[a]Reported as 'side effects of therapy' until Aug 2013.
[b]Data cutoff for interim analysis: 31 Jan 2017; events in 352 pts (45%). ECOG= Eastern Cooperative Oncology Group.

subgroups with BMI ≤20 (hazard ratio [HR] 1.27; 95% CI 0.92–1.77) or ≥ 30 (HR 1.33; 95% CI 0.98–1.81) vs > 20–25 kg/m^2 (Cox regression model) but in pts with a BMI ≤20 kg/m^2, numerically more grade 3/4 and serious adverse events were observed.

Conclusions: In these post hoc exploratory analyses we were unable to identify any clear effect of BMI on PFS. The tolerability of BEV + systemic CT for advanced OC appeared to be influenced by BMI.

959P A prospective study to evaluate the role of Cytoreductive surgery (CRS)+ HIPEC in advanced epithelian ovarian malignancy -100 consecutive cases -INDIAN experience

S. Somashekhar[1], R. Kumar C[1], A. Rauthan[2], R. Ashwin[1], Y. Ramya[1]
[1]*Surgical oncololgy, Manipal Comphrehensive Cancer Center, Bengaluru, India,*
[2]*Medical Oncology, Manipal Comphrehensive Cancer Center, Bangalore, India*

Background: To study the outcome and role of cytoreductive surgery (CRS) + HIPEC in advanced upfront and recurrent epithelial ovarian cancer.

Methods: 100 consecutive patients with advanced epithelial ovarian cancer diagnosed between January 2011 to January 2017 were included in study after informed consent. IRB ethical clearance was obtained. All patients underwent CRS followed by HIPEC with dedicated machine (PERFORMER-HT) using only cisplatin 45mg/l for upfront and cisplatin 45mg/l and adriamycin 15mg/l in recurrent cases for 90 minutes in semi-open technique at 42 degrees Celsius. Descriptive study statistical analysis was done.

Results: Out of 100 patients, 74 were primary and 26 recurrent. Of 74 cases, 67.5% (n = 50) had upfront CRS+ HIPEC and 32.5% (n = 24) had interval CRS + HIPEC. Of 26 recurrent, 69.3% (n = 18) were platinum sensitive and 30.7% (n = 8) were platinum resistant. Median age 54.5(22-78) PCI 11.9(5-37) duration of surgery 9.5hrs (5-15),GI recovery 5.4 days, hospital stay 11.4 days. 12% (grade III) adverse morbidity and 3% 60 day mortality. Prolonged duration of surgery (p = 0.001), multivisceral resection (p = 0.039) hypoalbuminemia (p = 0.04) hypocalcemia (p = 0.01) were predictive factors for morbidity and prolonged hospital stay. With a median follow up of 50 months we had 6 systemic (3 lymph node, 2 bowel surface and 1 liver parenchyma) and 6 peritoneal recurrence and 7 deaths. Over all survival in primary was 70 months, platinum sensitive 32 months and platinum resistant 12 months.

Conclusions: CRS+HIPEC in advanced epithelial ovarian cancer can be done with accepted morbidity and mortality. Multivisceral resection, prolonged surgery, hypoalbuminemia, hypocalcemia were predictive factors for morbidity and prolonged hospital stay. Primary ovarian malignancies and platinum sensitive benefit the most with CRS + HIPEC whereas platinum resistant disease does not have any benefit.

960P Role of laparotomy-based parameters in assessment of optimal primary debulking surgery and long-term outcomes in patients with stage iiic epithelial ovarian cancer

M. Zhou, X. Wang, L. Li, C. Wang, D. Wang
Department of Gynecology, Liaoning Cancer Hospital & Institute, Shenyang, China

Background: We evaluated the ability of our newly developed laparotomy-based model to predict optimal primary debulking surgery (PDS) and long-term outcomes of stage IIIC epithelial ovarian cancer (EOC).

Methods: Data of 400 IIIC EOC patients who underwent laparotomy were retrospectively analyzed to investigate predictors of optimal PDS. Parameters including infiltration of the bowel, peritoneum, diaphragm, hepatic surface, spleen, and stomach; omental caking; mesenteric retraction; and metastasis of the pelvic and para-aortic lymph nodes increased the difficulty of surgery. The parameters with a specificity ≥75%, positive predictive value ≥50%, and negative predictive value ≥50% were included in the final predictive index value (PIV) model. Each parameter was assigned a score based on the strength of its statistical association, and a total PIV was tabulated for each patient. Receiver operating characteristic (ROC) curve analysis was performed to assess the predictive ability of the model. Subgroup analyses were performed in patients with RD > 1 cm and ≤1 cm.

Results: After PDS, 223 (55.8%) patients with RD ≤ 1 cm had longer progression-free survival (PFS) and overall survival (OS) than patients with RD > 1 cm (PFS: 24.3 vs. 15.9 months; P < 0.001 and OS: 48.6 vs. 35.6 months; P < 0.001). Nine parameters (excluding pelvic lymph node metastasis) were assigned a PIV of 2. Patients with a PIV of ≥ 14 were more likely to undergo suboptimal PDS with a specificity of 100%. The area under the ROC curve of our PIV model was 0.753. Among patients with RD ≤ 1 cm, those with a PIV <2 had longer PFS and OS. Among patients with RD of > 1 cm, those who were sensitive to platinum had longer PFS and OS, there was no difference in PFS and OS between patients with and without combined multiple-organ resection, and the median PFS of patients with a lymph node rate of > 32.5% was shorter than in patients who did not undergo lymph node dissection, but the difference in OS was not significant.

Conclusions: When PDS left RD of ≤ 1 cm, patients with a PIV of < 2 had a better prognosis. When PDS left RD of > 1 cm, patients who were sensitive to platinum had a better prognosis. Additionally, patients with a lymph node rate of > 32.5% were more likely to progress.

961P ICON7: Ovarian cancer, platinum second-line chemotherapy and overall survival

A. Cook[1], A. Embleton[1], G. Jayson[2], R. Kaplan[1], G. Kristensen[3], M.K. Parmar[1], J. Pfisterer[4], E. Pujade-Lauraine[5], A.M. Oza[6], T. Perren[7]

[1]MRC clinical trials unit, Institute of Clinical Trials and Methodology-UCL, London, UK, [2]Division of Molecular & Clinical Cancer Sciences, The Christie NHS Foundation Trust, Manchester, UK, [3]Department for Gynecologic Oncology and Institute for Cancer Genetics and Informatics, NSGO and Oslo University Hospital, Oslo, Norway, [4]Gynecologic Oncology Center, Womens Cancer Center, Kiel, Germany, [5]Centre des Cancers de la Femme, AP-HP, Hôpitaux Universitaires Paris Centre site Hôtel-Dieu, Paris, France, [6]Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada, [7]Leeds Institute of Cancer and Pathology, St. James's University Hospital Leeds, Leeds, UK

Background: The ICON7 trial reported increased progression-free survival with bevacizumab (bev) added to platinum-based chemotherapy in newly-diagnosed ovarian cancer, and increased overall survival (OS) in a poor prognosis subset. Most patients (pts) had further chemotherapy following progression. On average, pts receiving bev had later progression and were thus more likely to receive further platinum. We investigated the effect of second-line treatment type on the association between first-line bev and OS.

Methods: Second line chemotherapy regimens were categorised as platinum-containing or other. Platinum reuse varied with time to progression after end of 1st line (excl. maintenance bev) and also varied between centres. We categorised centres as high or low platinum use, from the proportion of their pts progressing in 0-8 months (mths) and retreated with platinum. The association between 1st line bev and OS was analysed separately at low-use centres and at high-use centres. Standard survival analysis techniques and methods appropriate for data with non-proportional hazards were used.

Results: ICON7 randomised 1528 pts 1:1 to reference treatment +/- bev. Reference pts were more likely to experience disease progression ≤8 mths (38% v 24%). Reuse of platinum varied with time to progression; 37% at 0-5 mths; 76% at 6-8 mths; 94% at ≥ 9 mths. 174 centres (covering 1290 pts) had ≥1 progression at 0-8 mths, 76 centres were classed low-use (<50% platinum 2nd line in 0-8mths) and 98 high-use. The earlier progression of reference pts resulted in fewer getting 2nd line platinum at low use centres (41% v 56%), but not at high-use centres (76% v 77%). There was evidence of significantly shorter OS among reference pts at low-use centres ($p = 0.05$, restricted mean survival 44.1 v 49.0 mths), but not at high-use centres ($p = 0.20$, restricted mean survival 52.2 v 50.0 mths).

Conclusions: Improved OS with bevacizumab may result from an association with platinum-containing second line treatment: bev increases time to progression, increased time to progression increases the likelihood of second line platinum, second line platinum increases OS. It is possible therefore that OS might be improved by a lower time threshold for second line platinum chemotherapy, whether or not bevacizumab has been used.

962P Disease burden during the "watchful waiting" period in patients with recurrent ovarian cancer

B. Harrow[1], K. Travers[1], B. Davis[2], P. Smith[2], A. Gilligan[2], M. Bala[1]

[1]Health Economics and Outcomes Research, TESARO, Inc., Waltham, MA, USA, [2]Research Analysis, IBM Watson Health, Cambridge, MA, USA

Background: The standard of care for patients (pts) with recurrent ovarian cancer (OC) who respond to platinum-based chemotherapy has been "watchful waiting". While studies have shown that pts experience anxiety and fear of recurrence during watchful waiting, the rate of serious clinical events that require hospitalizations or emergency room (ER) visits during this observation period has not been examined. The objective of this study was to assess the rate of such events using a claims database.

Methods: This retrospective study identified pts newly diagnosed with OC in January 2009 to September 2015 in MarketScan® Commercial and Medicare Supplemental Databases (US). Pts with commercial or Medicare coverage for 12 months prior to and ≥1 month after first diagnosis were included. Recurrence was defined by the presence of 2nd-line platinum-based therapy, and watchful waiting as the period without active treatment following chemotherapy. Rate of inpatient admissions and ER visits during watchful waiting were assessed.

Results: 1312 pts were identified who had a treatment-free interval after 2nd-line platinum treatment. During this watchful waiting period (median duration, 162 days), 30.1% had an inpatient admission and 27.4% had an ER visit. Median time to first hospitalization from end of 2nd-line chemotherapy was 56 days, and median time to first ER visit was 68 days. There was a total of 650 inpatient hospitalizations, for an average of 0.5 per pt. Mean length of stay per hospitalization was 10 days. Top 5 reasons for hospitalizations were (1) intestinal obstruction without mention of hernia (13.5%), (2) secondary malignant neoplasm of respiratory and digestive systems (10.5%), (3) malignant neoplasm of ovary and other uterine adnexa (9.2%), (4) septicemia (4.5%), and (5) secondary malignant neoplasm of other specified sites (4.2%).

Conclusions: A substantial proportion of 2nd-line recurrent OC pts were hospitalized or had ER visits during the watchful waiting period post platinum treatment. The timing of these hospitalizations suggests that they were not necessarily related to progression but rather reflective of the ongoing disease burden patients experience during this "waiting" period.

Background: Hallmarks of BMCOC are increased sensitivity to platinum-based CT (PCT) and PARP inhibitors (PARPi). Regulatory approvals of PARPi will affect CT strategies for heavily pretreated BMCOC pts. Effectiveness of CT in this population is investigated.

Methods: BMCOC pts who received CT from 2006-2016 at 4 cancer centers in Spain were retrospectively selected. OS and time to progression (TTP) were calculated with Kaplan Meier and Cox models.

Results: Out of 135 BMCOC pts identified (63% BRCA1; 37% BRCA2; 6 pts somatic), 87 (64%) had recurrent disease. After a median follow-up of 6 years, OS rate was 67% in BRCA1 and 66% in BRCA2 pts ($p = 0.98$). Median treatment lines after relapse was 4 (2-7); 42 pts (48%) were exposed to PARPi. At 3rd relapse, 78% pts remained platinum-sensitive (P-S). Out of 156 treatments given to 57 pts who had ≥3 treatment lines, 44% were PCT, 27% non-PCT, 14% PARPi and 15% PCT plus PARPi. Across all treatment lines, median TTP was 10.2 m (CI95% 8.4-11.9). In P-S context, TTP was improved with PCT plus PARPi (17.1 m), PCT (12.6 m) or PARPi (12.4 m) vs non-PCT (4.9 m, $p < 0.01$ all comparisons). We found longer TTP with Taxane/PCT compared with Gemcitabine/PCT (HR 4.0; CI95% 1.3-12.6, $p = 0.02$) and PLD/PCT (HR 3.8; CI95% 1.5-10.0, $p = 0.006$) in a model adjusted for treatment line. In platinum-resistant (P-R) setting, TTP was not significantly different with PCT (5.3 m) or PARPi (7.4 m) vs non-PCT (4.6 m, $p = 0.99$). For treatments administered beyond PARPi ($n = 27$), median TTP was not different with PCT in P-S (5.6 m) or PCT in P-R (4.1 m) vs. non-PCT (3.0 m, $p > 0.4$ all comparisons). Multivariate model (BRCA1/2 status, treatment line and prior PARPi) confirmed platinum sensitivity as the strongest predictor for longer TTP beyond 2nd relapse (*HR 0.28*; $p < 0.001$).

Conclusions: Heavily pretreated BMCC demonstrated increased CT sensitivity, including for non-PCT choices. In P-S setting, either PCT rechallenge (+/- PARPi) or PARPi monotherapy represent the best treatments options. PARPi exposure does not compromise benefit to subsequent CT. In this population, platinum-sensitivity remains the main prognostic factor to predict CT benefit.

964P Modeling and impact of organ function on the population pharmacokinetics (PK) of niraparib, a selective poly (ADP-Ribose) polymerase (PARP)-1 and -2 inhibitor

Z-Y. Zhang[1], X. Wang[1], J. Wang[1], H.S. Pentikis[2], V. Kansra[1]

[1]Clinical Pharmacology, TESARO, Inc., Waltham, MA, USA, [2]Clinical Pharmacology, SAJE Consulting LLC, Baltimore, MD, USA

Background: Niraparib (ZEJULA™) is a selective PARP-1 and -2 inhibitor approved for maintenance treatment in adults with recurrent ovarian cancer in complete or partial response to platinum-based chemotherapy. We developed a population PK (PPK) model for niraparib and determined the impact of hepatic and renal organ impairment on niraparib exposure.

Methods: Data from the phase 1 dose escalation and expansion (dose ranging from 30 to 400 mg once daily [qd]) and phase 3 ENGOT-OV16/NOVA (300 mg qd) studies were modeled using a compartmental population approach within nonlinear mixed-effects modeling (NONMEM). Patients (pts) who received a dose of niraparib were included in the PK analysis. The PPK base model was built using NONMEM techniques from the phase 1 study. The impact of pt variables (age, race, ethnicity, body weight), renal impairment (normal, mild, or moderate, based on serum creatinine clearance) and hepatic function (baseline serum alanine and aspartate aminotransferase, albumin, total bilirubin) on niraparib PK parameters was evaluated. A step-wise elimination procedure for each covariate was used to develop the final model. Model evaluation was performed via a visual predictive check.

Results: 512 pts (33–83 years old) were available for PK analysis (4109 measurements) from the phase 1 (n = 104) and phase 3 (n = 408) studies. A 2-compartment model (2CM) with first-order absorption and elimination best described the niraparib PK. In the base model, the typical value for niraparib apparent clearance was 16.2 L/h, with interindividual variability of 52.6%. The estimated volume of distribution was 1074 L (290 L central and 784 L peripheral compartment. Model diagnostics showed good agreement between predicted and observed individual niraparib plasma concentrations. No patient variables impacted niraparib PK. Neither the mild to moderate renal impairment nor the mild hepatic impairment significantly altered niraparib PK.

Conclusions: Niraparib disposition was best described by a 2-compartment model with moderate to high interindividual variability. Mild to moderate organ impairment did not significantly impact niraparib PK; no dose adjustments are recommended.

Background: In SOLO2 (NCT01874353), maintenance therapy with olaparib (Lynparza) significantly prolonged progression-free survival (PFS) vs placebo in pts with PSROC and a *BRCA1/2* mutation (*BRCA*m; hazard ratio 0.30, 95% CI 0.22–0.41; $P<0.0001$; Pujade-Lauraine *et al.* SGO 2017). Response rates achieved in SOLO2 are reported here for the first time, in addition to PFS outcomes grouped by pts' response to their most recent platinum-based chemotherapy (PBC) regimen (complete response [CR] or partial response [PR]).

Methods: The randomized, double-blind, Phase III SOLO2 study enrolled 295 pts previously treated with ≥2 PBC regimens who were in response after receiving their most recent cycle of PBC. Pts were randomized 2:1 to receive olaparib (300 mg bid; tablet) or placebo. Objective tumour responses were investigator assessed using modified Response Evaluation Criteria in Solid Tumors v1.1.

Results:

Table: 965P PFS subgroup analysis for pts with CR or PR at study entry

	Olaparib N = 196*	Placebo N = 99
Pts with CR at study entry		
n	91	47
Median PFS, months	NR	5.6
HR (95% CI)	0.26 (0.16–0.42)	
Pts with PR at study entry		
n	105	52
Median PFS, months	13.8	5.5
HR (95% CI)	0.37 (0.25–0.54)	

*One patient in the olaparib arm did not receive study treatment.
HR, hazard ratio; NR, not reached

At study entry, 73/196 (37%) olaparib pts and 35/99 (35%) placebo pts had measurable disease (evidence of target lesions at baseline); within this group, the adjusted objective response rate (number of pts with CR and PR divided by the number of pts with measurable disease at baseline) was 41.1% with olaparib vs 17.1% with placebo (odds ratio 3.52, 95% CI 1.34–10.59; P=0.0097). The placebo value is higher than expected, possibly due to a carry-over effect from last chemotherapy. In the olaparib arm, 17/113 pts (15.0%) with evidence of disease at baseline achieved CR following maintenance therapy (placebo arm, 5/55 [9.1%]).

Conclusions: Treatment with olaparib not only maintained the response achieved with PBC, but also induced additional antitumour activity in pts with measurable target tumour lesions at baseline. Olaparib monotherapy led to a significant PFS benefit in pts with both CR or PR at study entry, further supporting the role of olaparib as maintenance treatment for pts with PSROC and a *BRCA*m.

Background: T-PLD is an effective alternative for the treatment of recurrent platinum-sensitive OC, especially in the partially platinum-sensitive population with a platinum-

free interval (PFI) of 6-12 months. The aim of this work was to assess the clinical impact of the combination when used in routine practice.

Methods: This was a prospective, multicenter study carried out in 25 French centers. Eligible patients (pts) were women ≥18 years old with histologically proven relapsed disease following at least one platinum-based chemotherapy and candidates to receive T (1.1 mg/m^2) plus PLD (30 mg/m^2). Analysis were performed according to the PFI subgroups (PFI 6-12 and PFI>12 [fully platinum-sensitive]) using Stata and R software.

Results: From 07/2014 to 06/2016, 91 pts with platinum-sensitive OC were included (median age 65 years-old, range: 42-86). Most pts had PFI 6-12 (n = 58; 63.7%) vs. n = 33 with PFI>12. Pts were treated with a median of 6 cycles (range: 1-12) of T-PLD. 47 (51.6%) pts received T-PLD as ≥ 3rd line of chemotherapy (range: 2-8). The toxicity profile in the PFI subgroups was not different from that of the overall population. The number of pts with grade 3/4 hematological toxicities in the PFI 6-12 and PFI>12 cohorts was: neutropenia 29.6%/17.6%, febrile neutropenia 4.4%/3.3%, thrombocytopenia 7.7%/12.1%, anemia 5.5%/2.2%. Grade 3 hand and foot syndrome (1 pt) and mucositis (1 pt) were observed in the PFI 6-12 group. Increases in transaminases (grade 3/4) were experienced by 11 pts (10/1) in the PFI 6-12 group and by 5 pts (4/1) in the PFI>12 group. 3 patients in the PFI 6-12 group and 3 in the PFI>12 group discontinued treatment because of toxicities, 6 and 2 due to premature death. Partial and complete responses were achieved in 43 pts (PFI 6-12: n = 26; PFI>12: n = 17, p = 0.82). Median PFS after T-PLD was 5.9 months (95%CI 4.9-6.7) in the PFI 6-12 group and 5.8 months (95%CI 3.7-8.5, logrank p = 0.37) in the PFI>12 group. OS data were not mature at the time of this analysis.

Conclusions: The safety profile of T-PLD when used in real-life management of non-selected OC pts is similar to that observed in clinical trials. T-PLD remains a valuable option to pts with both partially and fully platinum-sensitive disease.

967P An observational, multicenter, prospective study of trabectedin plus pegylated liposomal doxorubicin (PLD) in patients with platinum-sensitive recurrent ovarian cancer (PSROC)

D. Reichert[1], P. Wimberger[2], U. Ringsdorf[3], M. Krohn[4], I. Runnebaum[5]

[1]Gemeinschaftspraxis für Onkologie, Medizinische Studiengesellschaft NORD-WEST GmbH, Westerstede, Germany, [2]Gynecology and Obstetrics, Carl-Gustav-Carus University Dresden TU Dresden, Dresden, Germany, [3]Gynäkologie und Geburtshilfe, Lahn-Dill-Kliniken GmbH, Wetzlar, Germany, [4]Frauenklinik - Gynäkologie und gynäkologische Onkologie, Geburtshilfe und Perinatologie, Agaplesion Diakonieklinikum Rotenburg GmbH, Rotenburg, Germany, [5]Medical Oncology, Klinikum der Friedrich-Schiller-Universität Jena - Klinik für Frauenheilkunde, Jena, Germany

Background: The OVA-YOND prospective non-interventional phase IV study evaluated trabectedin plus PLD in real-life clinical practice to assess the toxicity and efficacy of the combination when given in accordance with the marketing authorization to women with PSROC.

Methods: Data from patients treated with PLD 30 mg/m^2 and immediately followed by trabectedin 1.1 mg/m^2 3-h i.v. infusion every 3 weeks have been collected.

Results: From 02/2013 to 12/2016, 77 enrolled patients from 31 sites across Germany who received at least one cycle of trabectedin plus PLD were evaluated. All patients had a platinum-sensitive relapse with a median platinum-free interval of 12 months (range: 6-86 months). Median age of patients was 66 years (range: 40-78) and 80.5% had ECOG performance status 0/1. Serous carcinoma was the most prevalent histological type (n = 54; 70.1%), tumor was localized at the ovary in 88.3% of patients and 38 patients (49.4%) were diagnosed with FIGO IIIC stage. Median number of trabectedin plus PLD cycles received per patient was 6, with 39 patients (50.6%) receiving ≥6 cycles and up to a maximum of 21 cycles. Median treatment duration was 4.24 months, mostly on an outpatient basis (≥66.7-100% of cases). Five patients (6.5%) had a complete response and 19 patients (24.7%) achieved a partial response for an ORR of 31.2% with a median duration of 6.25 months. Additionally, 16 patients (20.8%) had disease stabilization for a disease control rate of 51.9%. With 64 PFS events recorded, median PFS was 6.3 months (CI95%: 5.1-7.3) and median OS was 16.4 months (CI95%: 11.3-19.3). A total of 278 trabectedin-related adverse events (TRAE) occurred in 57.1% of the patients who recovered in 70.9% cases. Most common grade 3/4 TRAE were leukopenia (18.2% of patients), neutropenia (15.6%), thrombocytopenia (9.1%), ALT (7.8%) and AST (6.5%) increase, and nausea/vomiting (5.2% each). No grade 5 or unexpected TRAE occurred.

Conclusions: Trabectedin plus PLD confer clinically meaningful benefit to patients with PSROC, being either comparable or better to those previously observed in selected population from clinical trials or other real-life studies, and with a manageable safety profile.

968P PRO-002, a phase Ib dose-escalation study of NUC-1031 with carboplatin for recurrent ovarian cancer

S.P. Blagden[1], A. Sukumaran[2], L. Spiers[1], V.K. Woodcock[1], A. Lipplaa[1], S. Nicum[3], C. Gnanaranjan[4], D.J. Harrison[5], E. Ghazaly[6]

[1]Early Phase Clinical Trials Unit, Churchill Hospital University of Oxford, Oxford, UK, [2]Surgery and Cancer, Imperial College, London, UK, [3]Oncology, Churchill Hospital University of Oxford, Oxford, UK, [4]Centre for Haemato-Oncology, Barts Cancer Institute-Queen Mary University of London, London, UK, [5]School of Medicine, University of St Andrews, Fife, UK, [6]Centre for Haemato-Oncology, Barts Cancer Institute, London, UK

Background: NUC-1031 (Acelarin) is a first-in-class nucleotide analogue that overcomes key cancer cell resistance mechanisms to generate high intracellular levels of dFdCTP. In the PRO-001 study, single agent NUC-1031 achieved impressive clinical activity across multiple solid tumors. In this PRO-002 study, NUC-1031 was combined with carboplatin in 25 pts with recurrent ovarian cancer (OC).

Methods: NUC-1031 was administered in a dose-escalation schedule as a 30-min infusion on days 1 & 8 with carboplatin on day 1, every 3 weeks for ≤6 cycles. Four dose cohorts of NUC-1031 (500, 625 and 750 mg/m^2) with carboplatin (AUC4 or 5) were studied. The primary endpoint was to determine RP2D. Secondary endpoints included safety, RECIST response, PFS and PK/PD.

Results: 25 pts (median age 64 yrs) participated, having received a median of 3 (range 2-6) prior lines of therapy. All had received prior platinum regimens (10 had prior carboplatin + gemcitabine). 23 pts were response-evaluable, of whom 7 were platinum refractory, 10 were platinum resistant, 4 were partially platinum sensitive and 2 were platinum sensitive. Strong efficacy signals were achieved with 1 unconfirmed CR at the end of treatment (4%), 8 PRs (35%, 4 confirmed), 12 SDs (52%, 10 confirmed) and 2 PD (9%). Median PFS was 7.4 months (range 1.2-11.2). The combination regimen was well tolerated. 5 DLTs occurred in 4 pts: 2 Grade (G) 4 thrombocytopenia; 2 G3 fatigue and 1 G4 neutropenia. No DLTs occurred in the NUC-1031 500 mg/m^2 + carboplatin AUC5 group. 7 pts reported treatment-related SAEs. The most common SAE was thrombocytopenia, reported in 3 pts. NUC-1031 was stable in plasma (apparent $t_{1/2}$=3.8 h). Combination with carboplatin rapidly generated very high intracellular dFdCTP levels (C_{max}=12.1 μM/mg, TP/500 mg/m^2 and T_{max}=30 min) that were maintained for 24 h.

Conclusions: NUC-1031 combined with carboplatin is well tolerated and effective in recurrent platinum resistant and sensitive OC. dFdCTP levels were increased 25% by the addition of carboplatin. The RP2D was 500 mg/m^2 NUC-1031 on days 1 & 8 with AUC5 carboplatin day 1, q21d. The efficacy and synergy of this schedule and the ability to deliver carboplatin at AUC5 makes this an attractive therapeutic combination.

969P Phase 1/2 trials of peptides cocktail vaccine for resistant cervical and ovarian cancer: QoI analysis

S. Takeuchi, M. Kagabu, T. Nagasawa, H. Omi, Y. Nitta, H. Itamochi, T. Sugiyama

Obstetrics and Gynecology, Iwate Medical University School of Medicine, Morioka, Japan

Background: We conducted phase 2(P2) studies of peptides vaccine (PV) immunotherapy for cervical (CC) and ovarian cancer (OC) using HLA-restricted tumor specific peptides and VEGF receptor 1 (R1)and 2(R2). All HLA0201(A02) and 2402 (A24) restricted peptides used were found from human CC and OC, respectively in GMP grade. The P1 showed feasible (presented in ECCO2013), and further P2 had completed in 66 accruals and the results showed efficacy (ASCO2015 5567). Approval of IRB had obtained. This time, QOL study using GOG FACT-O had analyzed and survival data were up-dated.

Methods: Heavily treated CC and OC with A24 or A02 within ECOG PS 2 were candidate. Fully written-IC had obtained. PV cocktails were as follows: for OC of A24 comprised FOXM1, MELK, HJURP, VEGFR1(R1) and R2. As for OC A02, PV comprised HIG2, R1 and R2. For CC of A24, it comprised of FOXM1, MELK and HJURP, and CC with A02, it comprised of URLC10 and HIG2. Each peptide was mixed at a dose of 1mg with adjuvant, MONTANIDE in total 1ml. Vaccination schedule included 12 subcutaneous weekly injections followed with additional 8 administrations (adm.) in two-week intervals and more 8 adm. in 1 month (m) intervals were performed. At pre- and every 8th post-adm., QOL sheet was obtained.

Results: PV was well tolerated with no major adverse events (AEs), and during first 8 adm. AEs had caused by prior-chemotherapy/radiotherapy (after 1 month (m) washout) had been improved. As for QOL, physical-, functional- social-, and mental QOL were getting preferable during first 16 adm., however, during longer observation beyond 3 m they were deteriorated gradually due to disease progression. The final mOS of CC and OV was 4.9 m + (0.6-76.6m+) and 7.2m(1.1-59.1m), respectively. As for

prognostic factors, significant benefits were seen among lower c-reactive protein (CRP), higher levels of peripheral lymphocytes count, younger age, and smaller residual tumors at baseline. They were strongly rerated to good QOL in $p < 0.003$ or more by Wilcoxon signed rank test.

Conclusions: This PV immunotherapy had efficacy not only in safeness, response, and overall survival, but also in maintenance of QOL in this cohort of patients Further PV trials for other cohorts such as adjuvant therapy would be warranted.

970P A phase 1 study of selinexor (S) in combination with paclitaxel (P) and carboplatin (C) in patients (pts) with advanced ovarian (OC) or endometrial cancers (EC)

V. Makker, N. Boucicaut, K.A. Cadoo, R. Grisham, D.M. Hyman, R. O'Cearbhail, A. Snyder Charen, W. Tew, M. Martin, C. Aghajanian

Medicine, Memorial Cloan Kettering Cancer Center, New York, NY, USA

Background: Selinexor (S) is an oral, first in class, inhibitor of exportin 1 (XPO1). In a Phase II clinical trial of pts with relapsed ovary cancer (OC) andendometrial cancer (EC), single agent S, demonstrated anti-cancer activity. In addition, clinical exploratory analysis has demonstrated S target engagement and a relationship between baseline circulating tumor cells and duration of response. Here we report results of a phase 1 study evaluating safety/tolerability of S combined with C and P in pts with advanced OC and EC or carcinosarcomas.

Methods: Patients (Pts) were enrolled using 3 + 3 dose escalation design for each regimen (reg). All pts with OC received 1 prior platinum (plt) therapy. Ptswith EC could be chemotherapy naïve or have received 1 prior plt therapy. Pts were enrolled to 1 of 4 regimens regardless of disease type as described in Table. Response was evaluated Q9 weeks (RECIST 1.1).

Results: 16 pts (12 EC, 3 OC, 1 endometrial carcinoma) were enrolled. 1 drug related DLT of G3 syncope occurred on Reg 2. Most common G2 AEs were hyperglycemia (43.8%), leukopenia (43.8%), anemia (31.3%). Most common Grade 3 and 4 AEs were anemia (62.5%), neutropenia (37.5%), lymphopenia (43.8%), neutropenia (31.3%) thrombocytopenia (12.5%). 50% of evaluable pts on Reg 1 and 2 were dose reduced due to S toxicity. One dose reduction of S on Reg 3. There were no dose reductions on Reg 4. 13 pts were evauble for efficacy: 2 CRs, 10 PRs, and 1 SD. Time on study ranged from 2–10.8 mos with 3 pts still on study.

Conclusions: Selinexor in combination with carboplatin and paclitacel (CP) chemotherapy in advanced OC, EC, and carcinosarcomas was well tolerated. The RP2Ds have been established at 30mg/m^{2}twice weekly of S and 60 mg flat dose weekly in combination with CP chemotherapy. Given encouraging response, expansion cohorts for Regs 3/4 are planned. Frequent molecular alterations seen in the EC pts included: TP53, PIK3CA, and KRAS. Evaluation of S target engagement/correlatives of response will be discussed.

Table: 970P

Regimen #	N	Regimen details
1	4	C AUC5 (day 1), P 175 mg/m^2 (day 1) and S 30 mg/m^2 (days 1, 4, 8, 11, 15, 18)
2	6	C AUC5 (day 1), P 80 mg/m^2 (days 1, 8, 15) and S 30 mg/m^2 (days 1, 4, 8, 11, 15, 18)
3	3	C AUC5 (day 1), P 80 mg/m^2 (days 1, 8, 15) and S 60 mg (days 1, 8, 15)
4	3	C AUC5 (day 1), P 175 mg/m^2 (day 1) and S 60 mg (days 1, 8, 15)

971P Pazopanib and oral cyclophosphamide in women with platinum resistant epithelial ovarian cancers

S. Gulia[1], S. Gupta[2], J. Ghosh[2], J. Bajpai[2], A. Maheshwari[2], R. Kerkar[3], S. Thumkur[4], K. Deodhar[5], M. Thakur[6]

[1]Medical Oncology, Tata Memorial Centre, Mumbai, India, [2]Medical Oncology, Tata Memorial Hospital Centre, Mumbai, India, [3]Surgical Oncology, Tata Memorial Centre, Mumbai, India, [4]Gynaec Ongology, Tata Memorial Centre, Mumbai, India, [5]Pathology, Tata Memorial Centre, Mumbai, India, [6]Radiology, Tata Memorial centre, Mumbai, India

Background: Women with recurrent, multiply treated epithelial ovarian cancer (EOC) have unfavorable prognosis with limited treatment options after failure of platinum based regimens. Antiangiogenic therapies have shown some efficacy in these patients. We report here a retrospective analysis of women with recurrent, platinum resistant EOC treated with an oral regimen of anti-angiogenic agent Pazopanib and Cyclophosphamide.

Methods: Women with histologically proven recurrent platinum-resistant EOC were treated with tablets pazopanib (600mg p.o. daily in two divided doses, 400 mg and 200 mg) and cyclophosphamide (50 mg p.o. daily for 14 days every 21 days) until disease progression or unacceptable toxicity. Response was evaluated radiologically every 12 weeks.

Results: Eighteen patients (16 platinum resistant and 2 platinum refractory) were treated between April 2014 and April 2017 with a mean age of 50 (38-60) years and median 4 (2- 8) previous lines of chemotherapy, including three patients with progressive disease on bevacizumab. Patients received a median of 6 (2-28) cycles of pazopanib and cyclophosphamide with partial response in 8 (44%) patients (including 1 of 3 prior bevacizumab treated patients), stable disease in 5 (28%) and disease progression in 5 (28%) patients, as best response. The median progression-free survival was 5.0 months. Common adverse events were fatigue (50%), diarrhea (50%), elevated liver enzymes (43%), mucositis (61%), myelosuppression (28%), Skin toxicity (33%), hypertension (6%) and hair depigmentation (6%). Dose reduction due to toxicity was required in 11 (61%) patients and no patient stopped treatment due to toxicity.

Conclusions: Pazopanib and oral cyclophosphamide is a well-tolerated regimen with clinically relevant benefit in platinum resistant, epithelial ovarian cancer patients.

Clinical trial identification: This is a retrospective analysis of Platinum resistant epithelial ovarian cancer patients treated at our instittute. The approval for doing this analysis was taken from Insitute s ethics committee.

972P Apatinib as a salvage treatment in gynecologic cancer patients failed from two or more lines of prior chemotherapy

C. Xie, X. Jin

Radiotherapy and Chemotherapy, The 1st Affiliated Hospital of Wenhzou Medical University, Wenhou, China

Background: Apatinib is an oral inhibitor of the vascular endothelial growth factor receptor (VEGFR)-2. There is currently no standard treatment for patients with gynecologic cancer who failed from ≥2 lines of chemotherapy. The purpose of this study is to evaluate the benefits and adverse events of apatinib in the treatment of patients with advanced cervical and ovarian cancer who failed from ≥2 lines of chemotherapy.

Methods: Patients with advanced cervical and ovarian cancer received at least two lines of prior chemotherapy before being treated with apatinib were retrospectively reviewed between April 2015 and January 2017. All included patients received continuous apatinib treatment until disease progression, death, or intolerable toxicity. Prognosis and toxicities were evaluated by the Kaplan-Meier method and according to NCI-CTC 3.0, respectively.

Results: Twenty-six patients were eligible (cervical cancer, n = 12 (46.2%); ovarian cancer, n = 14 (53.8%)). After apatinib dose adjustment, 14 patients (53.8%) received 500 mg/day, 8 received 250 mg/day, 3 received 425 mg/day, and one received 675 mg/day. The median progression-free survival (PFS) of cervical and ovarian cancer was 8 months (95% confidence interval (CI): 3.83-12.17) and 4 months (95%CI:1.57-6.44), respectively. The objective response rates in cervical cancer and ovarian cancer were 50% (n = 6/12) and 50% (n = 7/14), respectively. The disease control rates were 100% (n = 12/12) for cervical cancer and 71.4% (n = 10/14) for ovarian cancer. No complete response was observed. The toxicities associated with apatinib were generally acceptable: eight patients (30.8%) developed grade 3/4 toxicity. The most common adverse events were hypertension (n = 17; 65.4%), hand-foot syndrome (n = 24, 92.3%), and mouth mucositis (n = 20, 76.9%).

Conclusions: Apatinib monotherapy could be a promising and tolerable treatment for patients with advanced/recurrent cervical and ovarian cancer who failed from two or more lines of chemotherapy.

Background: Among ovarian cancer patients with early relapse after platinum chemotherapy, there is no convincing active treatment. In preclinical studies, we previously demonstrated promising activity of Navitoclax (ABT-263), an anti-apoptotic inhibitor of Bcl-2 family, in ROC tumors, suggesting a potential action in platinum resistant patients. In this prospective multicentric phase II study, we evaluated the efficacy of Navitoclax monotherapy in heavily pretreated ROC patients.

Methods: This study included high grade serous patients with platinum resistance. Navitoclax was orally administered at 150 mg/day during a lead in period (7 to 14 days) and then increased to 250 mg in the absence of dose-limiting thrombocytopenia (<G3). Treatment was continued until disease progression or toxicity. PFS was the primary endpoint. Response was assessed using RECIST criteria. Analyses of Bcl-2 family proteins were also planned.

Results: From January to September 2016, 47 patients were included in 13 institutions and 46 patients were analysed: 44 ovarian carcinomas, 1 peritoneal carcinoma and 1 fallopian tube, median age 63 (38-80); BRCA1/2 mutations (n = 7), negative (n = 25) and unknown (n = 14). The median number of prior treatment lines was 4 (2-12). PFS was 50 days [6-234] with 1 partial response (PR), 15 stable diseases (SD). Thrombocytopenia was the major expected side effect, with G3 (n = 11) and G4 (n = 1) leading to maintain the dose at 150 mg for 8 patients and to treatment discontinuation for 3 patients. Neither significant bleeding nor toxic death was observed. 26 patients were treated after progression, 23 with chemotherapy (10 receiving platinum agent): among the 21 evaluable patients, 1 PR and 8 SD were observed, including 6 patients treated with platinum, with 3 long responders (7 to 9 months). No BRCA mutation was observed among the responders.

Conclusions: Navitoclax monotherapy had modest activity without unacceptable toxicity. However, as shown by response to treatment after progression, Navitoclax may reverse platinum resistance in ROC patients. Complementary biological data in progress may help select patients who could benefit from Navitoclax.

N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation

Background: MOGCT generally affect young women, grow rapidly, usually involve one ovary and are highly chemosensitive. Only a few studies have evaluated the reproductive outcomes of pts following ChT. The aim of this study was analysis of long-term effects of ChT on reproductive function in a large population of young women treated for MOGCT in our center.

Methods: Inclusion criteria in our study were MOGCT, fertility-sparing surgery, cisplatin- and etoposide-based induction ChT (BEP/EP regimen), age under 40, no relapse following ChT at least 1 year. Blood tests were taken for hormones of ovarian function (follicle-stimulating hormone, luteinizing hormone, estradiol, anti-Müllerian hormone (AMH), inhibin B) to assess their menstrual, reproductive function, post therapeutic status of pregnancy or delivery.

Results: A total of 47/163 (28.8%) pts with MOGCT treated in our center between 1987-2015 satisfied to the criteria. Mean age was 21 years (range, 14-35). Median number of ChT cycles was 4 (range, 1-6). The 5-year OS was 85% for all pts and 100% for these 47 women. All pts recovered their menstrual function during the first year after completion of ChT. With median f.-up 90 mo. (range, 12-228), 23/47 (49%) pts attempted conception, 18/23 (78.3%) women conceived with 20 live birth deliveries. There were 2/18 (11%) miscarriages and 6/18 (33.3%) terminations. Four women were pregnant at the moment of the analysis. Inhibin B level was normal in all 15 evaluated pts (median 74,4 pg/ml, range 10-120). Median of AMH level was 0,97 ng/ml (range 0.08-6). In 10 (52.6%) of 19 pts AMH level was <1 ng/ml, that considered a decrease of ovarian reserve. The quantity of pregnancies and deliveries, levels of hormones didn't depend on the number of cycles.

Conclusions: Unilateral adnexectomy followed by modern cisplatin-based chemotherapy does not adversely affect young women's fertility and provides high chance for cure.

975P Preoperative MRI versus intra-operative frozen section in surgical management of clinically early endometrial cancer

A. Maheshwari[1], R. Ranade[2],R.A. Kerkar[1], T.S. Shylasree[1],K. Deodhar[3],B. Rekhi[3],S. Menon[3],S. Gupta[4]

[1]Gynecologic Oncology, Tata Memorial Centre, Mumbai, India, [2]Oncology, NH Hospital, Bangalore, India, [3]Pathology, Tata Memorial Centre, Mumbai, India, [4]Medical Oncology, Tata Memorial Centre, Mumbai, India

Background: The role of systematic lymphadenectomy in clinically early stage endometrial cancer is controversial. A number of factors can predict lymph node metastasis including myometrial invasion, tumor grade in endometrial cancers. The purpose of the present study is to evaluate the accuracy of preoperative MRI and intraoperative frozen section in determining the depth of myometrialinvasion, cervical involvement, tumor size and lymph nodal status. We also studied the accuracy of preoperative endometrial biopsy and intraoperative frozen section in determining the grade of the tumor.

Methods: Medical records of 160 consecutive cases of clinically early stage endometrial cancer were reviewed retrospectively. A record of depth of myometrial invasion, tumor size, cervical involvement and presence of enlarged lymph nodes was made on a preoperative MRI. Similar depth of myometrial invasion, tumor size, cervical involvement and grade of the tumor were recorded on an intraoperative frozen section. The grade of the tumor was also recorded on a preoperative endometrial biopsy. Standard statistical calculations were used.

Results: The sensitivity and specificity of MRI for myometrial invasion were 81.3 and 75%, respectively while that for frozen section were 80 and 96.2%, respectively. For tumor grade the sensitivity and specificity of preoperative endometrial biopsy were 60 and 95.6%, respectively while that of frozen section were 53.8 and 97.6%, respectively. For cervical involvement the sensitivity of MRI and frozen section was 62.5 and 98.4%, respectively.

Conclusions: Although the sensitivity of both frozen section and MRI for predicting deep myometrial invasion was similar (80 vs 81.3%) but the specificity (96.2 vs 75%) and negative predictive value (92.7 vs 88.2%) of frozen section were superior to MRI.Both preoperative biopsy and intraoperative frozen section had low sensitivity (60 vs 53.8%) for detecting a high-grade lesion.

976P Impact of the adjuvant management and risk factors on survival in FIGO stage 3 endometrial cancer patients

J.J. Ko[1], G. Gelowitz[1], A.V. Tinker[2], C. Holloway[3], A. Kumar[4]

[1]Systemic Therapy, Abbotsford Regional Hospital and Cancer Centre, Abbotsford, BC, Canada, [2]Systemic Therapy, BC Cancer Agency Vancouver, Vancouver, BC, Canada, [3]Radiation Oncology, BC Cancer Agency Victoria, Victoria, BC, Canada, [4]Systemic Therapy, Fraser Valley Cancer Centre, Surrey, BC, Canada

Background: Patients with FIGO stage 3 endometrial cancer often receive adjuvant therapy, but level I evidence is lacking. The purpose of this study was to evaluate

Table: 976P

Survival	RFS (%) (p < 0.00001)		DFS (%) (p < 0.00001)		OS (%) (p < 0.00001)	
	5 year	10 year	5 year	10 year	5 year	10 year
No Tx	7 (1.2-42.7.3)	NA	5 (0.08-32.1)	NA	11 (3.8-31.3)	NA
CT	34.1(18.3-63.4)	34.1(18.3-63.4)	31.6(17.4-57.4)	23.7(10.4-53.9)	47.5(31.9-70.9)	26.7(13.3-53.9)
RT	37.7(23.8-59.7)	18.8(4.4-81.1)	34.1(21.1-55.2)	9.5(1.7-52.4)	47.8(33.2-68.8)	9.7(1.8-51.5)
Both	61.6(53.8-70.5)	40.8(24.2-68.6)	58.3(50.4-67.3)	36.8(21.0-61.8)	65.2(57.5-74)	38.1(24.4-59.6)

relapse-free survival (RFS), disease-free survival (DFS) and overall survival (OS) in patients with FIGO stage 3A to 3C2 patients by treatment modality received and risk factors.

Methods: Consecutive patients with FIGO stage 3 endometrial cancer treated from 2000-2010 were identified in the provincial cancer registry. Clinicopathologic characteristics, adjuvant treatments and outcomes were compared using descriptive and multivariable analyses.

Results: 261 patients had stage 3 endometrial cancer, 132 with stage 3A, 9 with 3B, 85 with 3C1 and 35 with 3C2. 39 had FIGO grade 1 disease; 73, grade 2; 147, grade 3. 160 had endometrioid and 35 had serous carcinoma. 170 (65%) had >50% myometrial invasion;162 (62%) had presence of LVI. 161 patients received both adjuvant chemotherapy (CT) and radiotherapy (RT); 33 received RT only; 32 received CT only; 35 received neither. 5-year (5Y) RFS, DFS and OS were similar among stage IIIA (RFS 55.1%, DFS 46.7%, OS 58.5%), IIIB (RFS 50.8%, DFS 50.8%, OS 58.5%), IIIC1 (RFS 45.4%, DFS 44%, OS 49.9%) and IIIC2 (RFS 42%, DFS 42%, OS 41.6%). Use of adjuvant RT was associated with improved median RFS (57.2 vs. 16.9m, $p < 0.00001$), DFS (53.7 vs 14.7m, $p < 0.00001$), and OS (61.9 vs 25.7m, $p < 0.00001$) compared to no RT. Likewise, use of adjuvant CT was also associated with improved RFS (58.4 vs 20.4m, $p < 0.00001$), DFS (54.8 vs 16.5m, $p < 0.00001$), and OS (62.9 vs 26.5m, $p < 0.00001$) compared to no CT. The Table below shows 5Y and 10Y survival outcomes by adjuvant treatment received. On multivariate analysis, older age, grade 3 disease, deep myometrial invasion >50%, and no adjuvant RT or CT were identified as adversely impacting RFS, DFS and OS.

Conclusions: In FIGO stage III endometrial cancer patients, use of both CT and RT is associated with improved RFS, DFS and OS and therefore should be recommended in all eligible patients after resection. 5Y RFS, DFS and OS are similar across stages IIIA to IIIC2. Risk factors including age, high grade and deep myometrial invasion are independent predictors of survival.

977P Is chemotherapy worthwhile in patients with FIGO stage 1B, lymph nodes negative, grade 3 endometrial cancer?

C. Fontanella[1], S. Lepori[1], A. Barcellini[1], G. Maltese[1], C. Andreetta[2], E. Tripodi[1], F. Martinelli[1], A. Cerrotta[1], G. Bogani[1], A. Ditto[1], M. Signorelli[1], C. Scaffa[1], C. Sacco[3], F. Raspagliesi[1], D. Lorusso[1]

[1]Gynecologic Oncology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [2]Department of Oncology, University Hospital of Udine, Udine, Italy, [3]Department of Oncology, AOU Santa Maria della Misericordia, Udine, Italy

Background: FIGO stage 1b endometrial cancer represents a major treatment challenge and standard of care is still unclear.

Methods: From March 1996 to March 2016, we retrospectively collected patients diagnosed with endometrial cancer stage Ib (invasion ≥ 50% of the myometrium, 2009 FIGO staging), lymph nodes negative after lymphadenectomy, and grade 3. We performed descriptive analysis and Kaplan Meier test using SPSS 20.0.

Results: Overall, 39 consecutive patients have been collected (28 at the National Cancer Institute of Milan and 11 at the University Hospital of Udine). Median age was 65.8 years (range 35.6-84.9). Endometrioid adenocarcinoma was diagnosed in 32 patients (82.1%), 4 serous adenocarcinoma (10.3%), 2 papillary serous adenocarcinoma (5.1%), and 1 clear cell adenocarcinoma (2.6%). Taking into account only endometrioid histotype, 23 patients received adjuvant radiotherapy (RT): 13 patients (40.6%) received brachyRT, 7 patients (21.8%) received external RT, 3 patients (9.4%) received both; 13 patients underwent platinum-based adjuvant chemotherapy (CT): 7 patients only CT, 2 patients external RT followed by CT and 2 patients brachyRT followed by CT. After a median follow up of 45.8 months (range 27.3 -236.8), median disease-free survival was 23.3 months (range 4.7-157.4); 7 patients (21.9%) experienced disease relapse and 5 patients (15.6%) died due to endometrial cancer. Relapse rate was 21.7% in patients who received RT versus 22.2% who did not. To note, relapse rate was only 9.1% in patients who received CT versus 28.6% in patients who did not.

Conclusions: According to our study, patients with stage 1b, node negative, grade 3 endometrioid endometrial cancer seems to derive a great benefit from adjuvant chemotherapy. This data needs to be further investigated in a large prospective clinical trial.

978P Significance of MSH2 promoter methylation in endometrial cancer with MSH2 deficiency

J. Haraga[1], T. Nagasaka[2], K. Nakamura[1], T. Haruma[1], T. Nishida[1], A. Nyuya[2], K. Yasui[2], T. Fujiwara[2], A. Goel[3], H. Masuyama[1]

[1]Department of Obstetrics and Gynecology, Okayama University Hospital, Okayama, Japan, [2]Department of Gastroenterological Surgery, Okayama University Hospital, Okayama, Japan, [3]Center for Gastrointestinal Research, Center for Translational Genomics and Oncology, Baylor Scott & White Research Institute, Charles A. Sammons Cancer Center, Baylor University Medical Center, Dallas, TX, USA

Background: Inactivation of MSH2 was frequently observed in endometrial cancer (EC) with microsatellite instability (MSI) or mismatch repair complex deficiency (dMMR). With respect to MSH2 deficiency (dMSH2), most of dMSH2 were caused by germline mutations in the MSH2 gene or EpCAM deletions. Meanwhile, heritable germline epimutations in MSH2 reported in a few Lynch syndrome families that lacked germline mutations in the MSH2 gene. We previously provided evidence for frequent MSH2 hypermethylation in Lynch syndrome colorectal tumors with dMSH2 and MSH2 methylation may serve as the "second hit" at the wild-type allele. Herein, we examined precise epigenetic alteration in MSH2 promoter and tried to reveal associations to family history of Lynch syndrome related tumors.

Methods: We analyzed MSH2 promoter methylation status, as well as MLH1 methylation status, and expression status of the mismatch repair proteins (MLH1, MSH2, PMS2, and MSH6) by immunohistochemistry in 326 EC patients. DNA was extracted from formalin-fixed, paraffin-embedded tissue, and analyzed MSI status by four mononucleotide markers and both MLH1 and MSH2 promoter methylation status by a fluorescent quantitative bisulfite PCR assay.

Results: MSI or dMMR was observed in 82 (25.2%) or 89 ECs (27.3%), respectively. ECs with dMSH2 were observed in 18 (5.5%) of 326 ECs (20.2% of dMMR). MSH2 promoter methylation was detected in 8 tumors (2.5% in 319 tumors excluding not available 7 ECs), and significantly correlated with dMSH2 ($P = 0.0072$, Fisher's exact probability test). Then, we also examined the family history of first-degree relatives. In this cohort, although patients with dMMR were significantly associated with family history of Lynch syndrome related tumor ($P = 0.0312$), patients with this family history are more frequently observed in patients with dMSH2 ($P = 0.0052$). Interestingly, patients with MSH2 promoter methylation were strongly associated with the family history of Lynch syndrome related tumor ($P = 0.0053$), though patients with MLH1 methylation were not ($P = 0.8345$).

Conclusions: MSH2 methylation significantly correlated with ECs with dMSH2 and may have strong relation with family history of Lynch syndrome related tumor, suggesting it takes a role as "second hit" to the MSH2 gene.

979P Achievement of complete response (CR) in metastatic or recurrent cervical cancer (MRCC): Does it matter?

J.F. Grau Béjar[1], V. Rodriguez Freixinos[2], L. Fariñas Madrid[2], G. Villacampa Javierre[3], A. Gil-Moreno[4], R. Verges[5], M.A. Pérez Benavente[4], A. García[6], R. Dienstmann[7], A. Oaknin[1]

[1]Medical Oncology, Vall d'Hebron University Hospital, Barcelona, Spain, [2]Oncología Médica, Hospital Vall dHebron, Barcelona, Spain, [3]Biostatistics, Vall d'Hebron Institute of Oncology, Barcelona, Spain, [4]Gynaecology, Vall d'Hebron University Hospital, Barcelona, Spain, [5]Radiation Oncology, Vall d'Hebron University Hospital, Barcelona, Spain, [6]Pathology, Vall d'Hebron University Hospital, Barcelona, Spain, [7]Grupo de Oncology Data Science (ODysSey), Vall d'Hebron Institute of Oncology, Barcelona, Spain

Background: MRCC is a devastating disease with poor long-term outcomes. Bevacizumab (BEV) added to chemotherapy (CT) improves significantly overall survival (OS) in MRCC patients (pts). Aim: to characterize clinic-pathologic features associated to CR and its impact on pts outcome.

Methods: Single-institution chart review of MRCC pts who were treated with 1st line CT between 2005 and 2016. CR was defined by Response Evaluation Criteria in Solid Tumors (RECIST v1). The prognostic and predictive value of clinic-pathologic features, was evaluated.

Results: Seventy-two pts (62% squamous; 30% adenocarcinoma; 8% others); with median age of 48 years (28-77) were selected. Forty-five pts (62%) had prior CT-radiation; 55 pts (79%) had recurrent/persistent disease (27 pts > 12 months (m) disease free interval) and 15 pts (21%) were stage IVb (90% visceral involvement). Moore risk distribution: 7/44/21 pts were high/medium/low risk, respectively. Eleven pts (15%) received BEV + CT; 57 pts (79%) platinum-based-CT (PCT) (54% Cisplatin; 26% Carboplatin) and 4 (6%) non-PCT. After a median follow-up of 33 m, ORR 51%, median OS 13 m (9.5-NA) and median PFS 6 m (4.6 -7.7) were observed for overall population. Moore criteria correlated with prognosis (high-risk pts had significantly worse OS (HR = 0.04, $p<0.001$). No differences in ORR, PFS or OS were detected between BEV and non-BEV group ($p > 0.2$ all comparisons). Higher ORR was observed among low and intermediate risk pts (51%, 67%; $p = 0.006$). CRs occurred in 13/71 (18%) evaluable pts (BEV group 2/11; non-BEV 11/60, $p = 1$). Clinic-pathologic features, including Moore criteria, did not correlate with CR in univariate analysis. Median time to CR was 3.5 m (3 –NA) and median duration of CR was 7 m (4.3–NA). Five pts (7%) had CR in the irradiated field. CR significantly impacted on PFS (9.7 m vs 4.7 m non-CR, $p = 0.002$) and OS (31 m vs 9.5 m non-CR, $p = 0.001$). Eight pts discontinued treatment due to toxicity.

Conclusions: CR is a meaningful surrogate marker for improved PFS and OS in MRCC pts treated with 1st line CT, but no predictive features have been identified in our cohort. Moore prognostic score was validated in real-word practice but its capability guiding therapy needs further evaluation.

980P Factors Negatively Affecting Voluntary Cervical Cancer Screening Among Educated Indians Above Poverty Line

A. Shukla, R.M. Dokala, J.R. Philomen

Research & Consultancy Unit, Oncofocus Solutions, Bangalore, India

Background: Cervical cancer is the second highest cause of cancer mortality in Indian women with 67,477 reported deaths in 2012 and 83,370 estimated deaths in 2020. Pap Smear, an affordable screening test, has shown to reduce mortality by 50 - 80% in various developed countries. However, low cervical cancer screening rate (3.1%) in India has resulted in about 70% of cases being diagnosed at an advanced stage (stage III or IV). The aim of this study is to understand reasons behind lack of voluntary testing among those educated Indians who are above poverty line and who are aware of cervical cancer being a preventable disease.

Methods: We designed a two-part web-based questionnaire containing 18 questions (~90% multiple choice questions). While the first part was designed to capture demographic attributes of the participants, the second part aimed to understand reasons behind low screening levels. The study was distributed between 1st of January 2017 to 30th of April 2017 through social media.

Results: We received a total of 212 responses. After excluding participants who are not currently residing in India or who did not complete the survey, we had 167 evaluable responses. Notably, about 50% (n = 84) of valid participants were aware of cervical cancer, indicating a decent level of awareness among the evaluable population. Among respondents who were aware of cervical cancer, 75% (n = 63) were aware that cervical cancer is preventable by regular screening. However, only 22% of 63 respondents (n = 14) underwent or took their family members for cervical cancer screening. Out of the 49 participants who did not get tested, despite being aware that cervical cancer is preventable, 57% (n = 28) stated time, 18% (n = 9) stated lack of access, and 4% (n = 2) mentioned affordability as a constraint. The remaining 21% gave other reasons most of which are related to the belief that they or their family members have low probability of falling victim to cervical cancer.

Conclusions: Time constraint emerged as the predominant reason for low cervical cancer screening levels among educated Indians who are above poverty line. We propose a proactive approach wherein stakeholders organise well-advertised, easily-accessible screening camps in the residential areas during weekends.

981P Reactive stroma mediates CD8+ T cell spatial distribution and function in ovarian cancer

Y. Wang[1], L. Ryner[1], A.R. Udyavar[2], M. Desbois[1], C. Kozlowski[3], C-W. Chang[4], Y. Guan[1], S. Lu[1], H. Koeppen[5], J. Ziai[5], R. Bourgon[2], P.S. Hegde[1]

[1]Oncology Biomarker, Genentech Inc. - Roche - USA, South San Francisco, CA, USA, [2]Bioinformatics, Genentech Inc. - Roche - USA, South San Francisco, CA, USA, [3]Digital Pathology, Genentech Inc. - Roche - USA, South San Francisco, CA, USA, [4]Biostatistics, Genentech Inc. - Roche - USA, South San Francisco, CA, USA, [5]Pathology, Genentech Inc. - Roche - USA, South San Francisco, CA, USA

Background: Close proximity between cytotoxic T cells and tumor cells is key to effective immunotherapy. Ovarian cancer exhibits diverse immune phenotypes with distinct prevalence and spatial localization of CD8+ T cells. This study is aimed to characterize the molecular mechanisms orchestrating the localization and function of CD8+ T Cells in ovarian cancer.

Methods: CD8 IHC and RNAseq were performed on 277 ovarian tumor tissues from ICON7 phase 3 trial. CD8 T-cells in tumor vs. stromal area was assessed by digital pathology. A Random Forest regression model was constructed to identify molecular features associated with enumeration or spatial localization of CD8+ T cells. *In situ* validation was performed by MHCI IHC and FAP RNAish. Functional role of ovarian fibroblasts was characterized by *ex vivo* T cell function assays.

Results: We identified three main immune phenotypes, including T-cell infiltrated, T-cell excluded, and immune desert. The immune phenotypes are highly associated with prognosis and the molecular subtypes of ovarian cancer. The T-cell infiltrated phenotype is denoted by high expression of T-effector signatures and antigen presentation machinery. The T-cell excluded phenotype showed similar expression of T-effector signatures as the T-cell infiltrated phenotype, however, most of the CD8+ T-cells were excluded from the tumor bed. The T-cell excluded phenotype showed high expression of the reactive stroma signatures (i.e. FAP), and low expression of class I antigen presentation genes. Lastly, the immune desert phenotype featured low prevalence of CD8+ T-cells, and high expression of neuroendocrine and metabolic pathways. In situ analysis confirmed the two key molecular features associated with the T-cell excluded phenotype: 1) loss of the MHC I expression in the tumor compartment, and 2) high FAP expression in CAFs. Co-culturing of ovarian fibroblast cells with T-cells resulted in reduced T-cell activation and proliferation.

Conclusions: Our study uncovered key molecular mechanisms mediating the interplay between CD8+ T cell localization and function in ovarian cancer. Our findings underscore the potential of targeting reactive stroma as a novel therapeutic strategy to optimize immunotherapy for ovarian cancer patients.

982P Phase II study of the safety and efficacy of oral capecitabine in patients with platinum-pretreated advanced or recurrent cervical carcinoma

S. Lepori, C. Fontanella, G. Maltese, E. Tripodi, F. Martinelli, G. Bogani, A. Ditto, M. Signorelli, C. Scaffa, F. Raspagliesi, D. Lorusso

Gynecologic Oncology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy

Background: Cervical cancer is underrepresented in the gynecological clinical research. The objective of this observational study was to evaluate the activity and the safety of capecitabine in patients with platinum-pretreated recurrent cervical carcinoma.

Methods: In this phase II study we enrolled patients with advanced or recurrent cervical carcinoma pretreated with platinum-based therapy. All patients signed an informed consent and were treated at the Gynecological Units of the IRCCS National Cancer Institute of Milan (Italy). All patients received a starting dose of oral capecitabine 1250 mg/m^2 twice a day continuously from day 1 to day 14 every 21 days, dose reduction to 1000 mg/m^2 twice a day was permitted due to adverse events (AE). We used Response Evaluation Criteria in Solid Tumors (RECIST) version 1.1 to evaluate response to therapy and Common Terminology Criteria for Adverse Events (CTCAE) version 4.0 to evaluate adverse events. We performed descriptive analysis and Kaplan Meier test using SPSS 20.0.

Results: From December 2013 to January 2017, we enrolled 20 patients with advanced or recurrence cervical carcinoma, already exposed to platinum, to received oral capecitabine. All patients receive a combination of carboplatin plus paclitaxel as first-line therapy for advanced/recurrent disease. Median age at the first capecitabine administration was 56.9 years (range from 27 to 82 years). After three cycles of oral capecitabine the clinical benefit rate (CBR) was 60.0% (5.0% of CR, 30.0% of PR and 25.0% of SD). No grade 3 or worse adverse events were reported. CBR was 88.8% in adenocarcinomas

versus 36.4% in squamous cell carcinomas (P = 0.067). The most frequent grade 1 or 2 adverse events were fatigue (50%), hand-foot syndrome (38.9%) and diarrhea (22.2%).

Conclusions: Our study suggests that oral capecitabine should be considered an active and safe treatment in patients with platinum-pretreated advanced or recurrent cervical carcinoma. A greater activity has been documented in patients with adenocarcinomas compared with squamous cell carcinomas.

Background: Vulvar cancer is a rare malignancy in women. During the past 30 years, large surveys of vulva cancer have not been performed in Japan. We therefore conducted a multicenter study to clarify the clinicopathological features of vulva cancer in Japan (UMIN000017080).

Methods: In this multicenter retrospective cohort study, the clinical data of patients with vulva cancer were surveyed. The medical records of patients with vulvar cancer patients treated between 2001 and 2010 were retrospectively reviewed after obtaining approval from the Institutional Review Board of each institution. Survival analysis was performed using Kaplan-Meier curves. The effects of the clinical factors on OS were investigated using a Cox regression model.

Results: A total of 1082 patients treated in 108 centers were studied. The median age was 72 years (range, 20 to 96). The disease stage was stage I in 415 patients (38.3%), stage II in 249 (23%), stage III in 255 (23.6%), and stage IV in 163 (15.1%) (FIGO 2009). The diagnosis was squamous cell carcinoma in 779 patients (72%), Paget's disease in 158 (14.6%), adenocarcinoma in 63 (5.8%), and others in 82 (7.6%). Positive lymph nodes were found in 237 patients (21.9%). The median tumor diameter was 35 mm (range, 1 to 180). The 5-year overall survival was 86% in stage I, 74.7% in stage II, 48.2% in stage III, and 39.3% in stage IV ($P < 0.001$), and that according to histology was 63.9% in squamous cell carcinoma, 57.1% in adenocarcinoma, 79.7% in Paget's disease, and 85.4% in others. The hazard ratio was 0.51 in patients with a histology of Paget's disease or others (vs. squamous cell carcinoma or adenocarcinoma; P = 0.001; 95% CI, 0.35-0.75), 2.14 in patients with a number of positive lymph nodes 2 or more (vs. 0 or 1; $P < 0.001$; 95% CI, 1.50-43.05), 2.10 in patients with a tumor diameter of $\geq$ 35mm (vs. < 35mm; P = 0.001; 95% CI, 1.36-3.25).

Conclusions: Treatment outcomes in Japanese patients with vulvar cancer were similar to those reported previously. However, squamous-cell carcinoma, adenocarcinoma, positive lymph nodes, and bulky tumors were associated with poor outcomes. Multidisciplinary treatment might be required in patients with these characteristics.

984TiP Japan CHARLOTTE: Characterizing the cross-sectional approach to ovarian cancer: Genetic testing of BRCA

T. Sugiyama[1], D. Aoki[2], T. Enomoto[3], N. Takeshima[4], Y. Watanabe[5], K. Fujikawa[6], T. Jinnai[6], J. Kigawa[7]

[1]Department of Obstetrics and Gynecology, Iwate Medical University School of Medicine, Morioka, Japan, [2]Department of Obstetrics and Gynecology, Keio University School of Medicine, Tokyo, Japan, [3]Department of Obstetrics and Gynecology, Niigata University School of Medicine, Niigata, Japan, [4]Department of Gynecology, Cancer Institute Hospital, Tokyo, Japan, [5]Department of Obstetrics and Gynecology, Tohoku Medical and Pharmaceutical University, Sendai, Japan, [6]Department of Medical, AstraZeneca K.K., Osaka, Japan, [7]Department of Obstetrics and Gynecology, Matsue City Hospital, Matsue, Japan

Background: Approximately 5–10% of breast and ovarian cancers are inherited, a condition known as hereditary breast and ovarian cancer (HBOC). Two genes, *BRCA1* and *BRCA2*, are associated with the majority of HBOC cases. Information on the frequency of g*BRCA1* and g*BRCA2* (g*BRCA1/2*) mutations in Japanese patients with ovarian cancer is limited. In a recent study of 95 unselected Japanese ovarian cancer patients, 12 (12.6%) had g*BRCA1/2* mutations. There is a need for further examination of the prevalence of g*BRCA1/2* mutations in a large number of Japanese patients. The Japan CHARLOTTE study is the first epidemiological survey in a large number of Japanese ovarian cancer patients. The primary objective is to examine the frequency of g*BRCA1/2* mutations among newly diagnosed ovarian cancer patients in Japan. The secondary objectives are to examine the frequency of g*BRCA1/2* mutations in subpopulations (e.g. histological subtype, family history), and to evaluate patient satisfaction with the explanation of *BRCA* genetic testing.

Trial design: Japanese women aged $\geq$20 years with newly diagnosed, histologically confirmed epithelial ovarian cancer, primary peritoneal cancer or fallopian tube cancer, who provide written consent for study participation within 60 days of diagnosis, are eligible. Patients who have an acute or chronic disease or mental illness that could affect the study results as judged by the attending physician will be excluded. The following data will be collected from the medical records: demographics, past medical history and medication use, reproductive history and menopausal status; diagnosis and treatment of the gynecological cancer including staging based on the FIGO stage; and CA-125 levels. A detailed family history of cancer will be obtained by interview at consultation and a blood sample will be taken for *BRCA* genetic testing. Pathological slides will be sent to a central laboratory to confirm the pathological diagnosis. A questionnaire will be administered to assess patient satisfaction with the explanation of *BRCA* genetic testing. It is anticipated that 600 patients will be enrolled, with the involvement of around 50 institutions.

985TiP IMagyn050 / GOG3015 / ENGOT-ov39: A randomized, double-blind, phase III study of atezolizumab vs placebo combined with chemotherapy + bevacizumab in stage III-IV ovarian, fallopian tube & peritoneal cancers (OC)

K.N. Moore[1], A. Okamoto[2], F. Wu[3], Y.G. Lin[4], S. Pignata[5]

[1]Department of Obstetrics and Gynecology, University of Oklahoma Health Sciences Center, Oklahoma City, OK, USA, [2]OB/GYN, The Jikei University School of Medicine, Tokyo, Japan, [3]Product Development Biometrics, Roche, Beijing, China, [4]Product Development Oncology, Genentech, Inc., South San Francisco, CA, USA, [5]Urology and Gynecology, Istituto Nazionale Tumori "Fondazione G. Pascale" IRCCS, Naples, Italy

Background: Despite surgical advances and initial responses to chemo, OC has the highest mortality among gynecologic cancers, underscoring the need to improve long-term outcomes over standard platinum/taxane regimens. OC is a VEGF-driven tumor, susceptible to both the anti-angiogenic and immunomodulatory activities of bev. The immune response may also be enhanced by blocking the PD-L1/PD-1 and PD-L1/B7.1 pathways with atezo (anti–PD-L1), further potentiating anti-cancer T-cell activity. Atezo has shown safe and durable clinical benefit as a mono- and combinatorial therapy in human cancers, including OC. Here we present the first study in OC assessing dual immunomodulation with bev + atezo with standard chemo.

Trial design: IMagyn050 (NCT03038100) will enroll $\approx$ 1300 newly diagnosed stage III-IV epithelial OC patients (pts) globally. Pts must have ECOG PS $\leq$ 2, evaluable tissue for PD-L1 testing (VENTANA SP142 assay) and will either have gross residual disease postoperatively (primary surgery group) or receive neoadjuvant (neo) therapy followed by surgery then adjuvant (adj) therapy (neo group). A concurrent phase (IV AUC6 carboplatin [Cb] + 175 mg/m^2 paclitaxel [pac] + 15 mg/kg bev + 1200 mg atezo/PL × 6 cycles [C]) will be followed by maintenance bev + atezo/PL on 21-d C for a total of 22 C atezo/PL (Table), with pts treated until completion of maintenance therapy, toxicity or recurrence, whichever occurs first. The neo group will undergo neo therapy followed by interval surgery between C3-4 then adj therapy followed by maintenance bev + atezo/PL. Stratification factors are stage and/or residual disease, ECOG PS, PD-L1 status and treatment approach. Co-primary endpoints PFS and OS will be assessed in all and PD-L1−positive ($\geq$ 1%) pts. Safety, efficacy, PROs and translational data will also be evaluated.

Table: 985TiP

Treatment Groups (1:1 randomization)	Concurrent	Maintenance
Primary surgery	C1: Cb + pac + atezo/PL C2-6: Cb + pac + bev + atezo/PL	C7 onward: bev + atezo/PL
Neo	C1-2 and 5-6: Cb + pac + bev + atezo/PL C3-4: Cb + pac + atezo/PL	C7 onward: bev + atezo/PL

Background: Niraparib (ZEJULA™) is a selective poly (ADP-ribose) polymerase (PARP) 1/2 inhibitor. In preclinical studies, niraparib concentrated in the tumor vs plasma, delivering ≥90% durable PARP 1/2 inhibition and a persistent antitumor effect. In the ENGOT-OV16/NOVA trial, niraparib demonstrated clinical efficacy in patients with recurrent ovarian cancer (OC) following complete response (CR) or partial response (PR) to platinum-based chemotherapy (PBC) regardless of *BRCA* mutation or homologous recombination deficiency (HRD) status.

Trial design: The primary objective of the ongoing ENGOT-OV26/PRIMA trial is efficacy (measured as progression-free survival) of niraparib vs placebo in advanced OC patients with CR or PR following frontline PBC. Secondary objectives include overall survival, patient-reported outcomes (PROs), time to first subsequent therapy, time to progression on the next anticancer therapy, and safety and tolerability of niraparib. Target enrollment is ≈330 patients with stage III or IV OC with PR or CR after PBC. Eligibility criteria include all patients with stage IV disease and patients with stage III disease who were treated with neoadjuvant chemotherapy followed by interval debulking surgery or who have either inoperable disease or visible residual disease after primary debulking surgery. Patients are stratified based on HRD status (HRD positive, including the known deleterious *BRCA* mutations g*BRCA*mut or s*BRCA*mut/HRD negative), neoadjuvant chemotherapy (yes/no), and best response to PBC (CR/PR). Patients are randomized 2:1 to oral niraparib 300 mg or matched placebo once daily in 28-day cycles. PRO data will be collected.

Background: A significant progression-free survival (PFS) improvement in all-comer patients (pts) with platinum-sensitive, relapsed (PSR), high-grade serous ovarian cancer supported the approval of olaparib (Lynparza™) capsules as maintenance monotherapy (Ledermann *et al NEJM* 2012); these results were confirmed using the new olaparib tablet formulation in pts with a germline *BRCA1/2* mutation (*BRCA*m) (Pujade-Lauraine *et al* SGO 2017). Pts with epithelial ovarian cancer (EOC) often retain platinum sensitivity despite progression on PARP inhibitor (PARPi) maintenance therapy. After relapse, it is unknown whether such pts could derive clinical benefit from olaparib retreatment. The OReO/ENGOT Ov-38 trial (NCT03106987; D0816C00014) will evaluate efficacy and safety of maintenance retreatment with olaparib tablets in all-comer pts with EOC.

Trial design: OReO/ENGOT Ov-38 is a randomized, placebo-controlled multicentre trial of olaparib maintenance retreatment in pts with non-mucinous EOC, and a complete or partial response to their most recent platinum-based chemotherapy. Eligibility requires prior receipt of maintenance PARPi therapy, or prior participation by pts in a study with a PARPi experimental arm. Randomization 2:1 to olaparib (300 mg twice daily tablets) or matching placebo will be split across two cohorts (approximately 416 pts): pts with a known *BRCA*m in cohort one; *BRCA* wild-type pts in cohort two. Pts with a known *BRCA*m (germline or somatic) must provide a tumour sample (archival or fresh) and a blood sample for post-analysis *BRCA* testing. Primary endpoint is investigator-assessed PFS (RECIST v1.1). Cohorts are independently powered at 80% to detect a PFS benefit (assuming a hazard ratio [olaparib:placebo] of 0.5 [cohort one] or 0.65 [cohort two]) at the two-sided 5% level. Table lists the secondary endpoints, including outcome measures for health-related quality of life. Enrolment began in Q2 2017.

Background: Approximately 18% of patients (pts) with high-grade epithelial ovarian cancer (OC) harbour a deleterious germline BRCA1 or BRCA2 (BRCA1/2) mutation, and ≈7% harbour a somatic BRCA1/2 mutation (Pennington et al. Clin Cancer Res. 2014;20:764-75). The poly(ADP-ribose) polymerase (PARP) inhibitor rucaparib is approved in the United States for the treatment of pts with deleterious BRCA mutation (germline and/or somatic) associated advanced OC who have been treated with ≥2 chemotherapies. Data comparing PARP inhibitors to standard of care (SOC) treatment for relapsed OC are limited. Randomised studies are needed to assess the benefit-risk profile of PARP inhibitors vs SOC as treatment for BRCA1/2-mutated, relapsed, high-grade OC.

Trial design: ARIEL4 (EudraCT 2016-000816-14; NCT02855944) is evaluating rucaparib vs SOC chemotherapy as treatment for pts (n≈345) with relapsed, high-grade OC (regardless of histology) and a deleterious germline or somatic BRCA1/2 mutation who received ≥2 prior chemotherapy regimens. Pts stratified by progression-free interval after their most recent platinum regimen will be randomised 2:1 to receive rucaparib (600 mg BID) (n≈230) or chemotherapy (n≈115). Pts with platinum-resistant (progressive disease [PD] ≥1 to < 6 mo after last platinum) or partially platinum-sensitive disease (PD ≥ 6 to < 12 mo after last platinum) will receive rucaparib or weekly paclitaxel; pts with platinum-sensitive disease (PD ≥ 12 mo after last platinum) will receive rucaparib or platinum-based therapy (single-agent or doublet, per investigator discretion). Pts receiving chemotherapy have the option to cross over to rucaparib upon radiographic disease progression. The primary endpoint is investigator-assessed progression-free survival (RECIST version 1.1). Secondary endpoints include overall survival, objective response rate, RECIST/CA-125 response, duration of response, and patient-reported outcomes. Safety will be summarised descriptively using standard adverse event reporting.

989TiP OCTOVA: A randomised phase II trial of olaparib, chemotherapy, or olaparib and cediranib in patients with BRCA-mutated platinum-resistant ovarian cancer

S. Nicum[1], V.Y. Strauss[2], N. McGregor[3], I. McNeish[4], R. Roux[1], M. Hall[5], A. Michael[6], C. Roberts[2]

[1]Department of Oncology, Oxford University Hospitals NHS Foundation Trust, Oxford, UK, [2]Centre for Statistics in Medicine, University of Oxford, Oxford, UK, [3]Oncology Clinical Trials Office, Department of Oncology, University of Oxford, Oxford, UK, [4]Institute of Cancer Sciences, University of Glasgow, Glasgow, UK, [5]Mount Vernon Cancer Centre, East and North Hertfordshire NHS Trust, Middlesex, UK, [6]Royal Surrey County Hospital, University of Surrey, Surrey, UK

Background: Women with platinum resistant ovarian cancer (OC) have limited responses to standard therapy, and clinical trials with novel agents are therefore highly justified. Olaparib is a potent PARP inhibitor that has shown enhanced activity in women with relapsed *BRCA*-mutated OC in both platinum sensitive and resistant settings. Angiogenesis inhibitors, such as the oral tyrosine kinase inhibitor cediranib, are active in OC, and have shown additive effects when combined with PARP inhibitors preclinically, as hypoxia-induced downregulation of homologous recombination repair genes, BRCA1, 2 and RAD51 enhances PARP inhibitor sensitivity. Recent phase 2 trials in relapsed platinum-sensitive OC have also shown benefit from the combination of olaparib and cediranib compared to olaparib alone. The OCTOVA trial investigates the benefit of single agent olaparib compared to olaparib and cediranib or weekly paclitaxel in women with *BRCA*-mutated platinum-resistant OC.

Trial design: Eligible patients for OCTOVA are females aged ≥16 years with a germline or somatic *BRCA1* or *2* mutation who have progressed within 6 months of previous platinum-based therapy. Patients may have received prior PARP inhibitor and antiangiogenic therapy, with at least a 6-month interval since treatment. 132 patients will be randomised, with stratification for prior PARP inhibitor exposure and prior antiangiogenic therapy, to one of three treatment arms: paclitaxel (80mg/m^2 weekly), olaparib (300mg twice daily), or cediranib (20mg once daily) and olaparib (300mg twice daily), until disease progression or unacceptable toxicity develops, and will be followed up for 18 months. Patients who progress on weekly paclitaxel will be permitted to crossover and receive single agent olaparib therapy. The primary analysis will compare the efficacy (as measured by progression-free survival) of olaparib compared to combination of olaparib and cediranib, and independently olaparib compared to paclitaxel. Secondary endpoints include safety and tolerability of the combination of olaparib and cediranib, overall survival, objective response rate, and quality of life outcomes.

Key eligibility criteria include platinum resistant OC or fallopian tube/primary peritoneal cancer (recurrence <6 months; primary refractory excluded); measurable disease per RECIST v1.1; ≤2 prior lines of therapy; ECOG PS 0-1; and *TP53*m. Approximately 97 pts will be enrolled at 26 global sites from 28 January 2015 with expected study completion in Q2 2018. Pts are restaged every 2 cycles and can continue treatment until progressive disease or unacceptable toxicity. Arms A and D enrolled 9 and 12 pts, respectively. Enrolment in Arm B was initially 8 pts and is now expanded by another 30 pts following emerging data on clinical activity. In Arm C, 6 initial pts were enrolled followed by another 17 pts; a further 12 pts will be enrolled to explore an alternative AZD1775 dosing regimen (see Arm C2 above).

damage. This can lead to a dependency on WEE1, a multifunctional protein that can induce the G2/M checkpoint, promoting the repair of DNA damage before proceeding through mitosis and cell division. AZD1775 is a highly selective small-molecule inhibitor of WEE1 that showed promising antitumor activity in TP53m refractory/resistant ovarian cancer (OC) when combined with carboplatin (Leijen et al, JCO 2016). This Phase II study (GYN 49; D6010C00004; NCT02272790) is being conducted to further explore the safety, tolerability, and preliminary efficacy of AZD1775 when combined with 4 different chemotherapy regimens in patients (pts) with platinum resistant OC and fallopian and peritoneal cancers.

Trial design: This is an open-label four-arm study, with a primary endpoint of objective response rate. Study arms are:

991TiP FORWARD I: A phase 3 study to evaluate the safety and efficacy of mirvetuximab soravtansine (IMGN853) versus chemotherapy in adults with folate receptor alpha (FRa)-positive, platinum-resistant epithelial ovarian cancer, primary peritoneal cancer, or primary fallopian tube cancer

K.N. Moore[1], I. Vergote[2], A. Oaknin[3], N. Colombo[4], S. Banerjee[5], A.M. Oza[6], P. Pautier[7], C.M. Kelly[8], K. Malek[9], M.J. Birrer[10]

[1]Obstetrics and Gynecology, Stephenson Cancer Center/University of Oklahoma, Oklahoma City, OK, USA, [2]Gynaecologie-Verloskunde, University Hospital Leuven, Leuven, Belgium, [3]Medical Oncology Department, Vall d'Hebron University Hospital, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain, [4]Department of Gynecological Oncology, Istituto Europeo di Oncologia, Milan, Italy, [5]Gynaecology Unit, The Royal Marsden, London, UK, [6]Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada, [7]Medical Oncology, Gustave Roussy Institut de Cancérologie, Villejuif, France, [8]Medical Oncology, Mater Misericordiae University Hospital University College Dublin, Dublin, Ireland, [9]Clinical Development, ImmunoGen, Inc, Waltham, MA, USA, [10]Gynecologic Oncology, Massachusetts General Hospital, Boston, MA, USA

Background: Elevated FRa expression is characteristic of a number of solid tumors, including epithelial ovarian cancer (EOC), thus providing an attractive candidate for targeted therapeutic approaches. Mirvetuximab soravtansine is an antibody-drug conjugate (ADC) comprising a potent cytotoxic effector molecule, the tubulin-disrupting maytansinoid DM4, linked to a humanized anti-FRa monoclonal antibody. In a recently completed phase 1 trial in heavily pre-treated ovarian cancer patients, mirvetuximab soravtansine showed a favorable safety profile and promising single-agent clinical activity.

Trial design: FORWARD I is a randomized phase 3 study designed to evaluate the efficacy of mirvetuximab soravtansine compared to standard-of-care chemotherapy in adult patients with platinum-resistant EOC, primary peritoneal cancer, or fallopian tube cancer. Inclusion criteria include confirmation of tumor FRa positivity by immunohistochemistry (medium or high receptor expression; ≥ 50% of cells with at least moderate staining intensity) and ≤ 3 prior lines of therapy. A total of 333 patients are expected to be recruited, who will be randomized 2:1 to mirvetuximab soravtansine dosed intravenously at 6.0 mg/kg, calculated according to adjusted ideal body weight, on Day 1 of a 21-day cycle or investigators' choice chemotherapy (paclitaxel, pegylated liposomal doxorubicin, or topotecan). Progression-free survival (PFS; assessed by blinded independent central review) is the primary efficacy endpoint; secondary endpoints include objective response rate, quality of life, overall survival, safety and tolerability, and duration of response. The first patient enrolled in January 2017.

Clinical trial identification: NCT02631876

992TiP N-DUR: Matched pair pharmacodynamics study of neoadjuvant durvalumab in combination with chemotherapy in frontline ovarian cancer

J. Taylor[1], S. Westin[1], S. Sharafi[1], A. Jazaeri[1], M. Frumovitz[1], P. Soliman[1], A. Sood[1], K. Lu[1], K. Savelieva[2], G. Mills[2], A. Vergara-Silva[3], R. Coleman[1]

[1]Gynecologic Oncology, MD Anderson Cancer Center, Houston, TX, USA, [2]Systems Biology, MD Anderson Cancer Center, Houston, TX, USA, [3]MedImmune, Astra Zeneca, Gaithersburg, MD, USA

Background: Although upfront treatment for ovarian cancer (OC) achieves complete remission in over 70% of women, the majority of patients (pts, 80%) relapse and die from disease. Thus, there is great interest in improving standard of care and exploring maintenance strategies. Immune evasion and suppression is a central feature of the OC microenvironment. Immune abrogation has also been linked to primary and adaptive chemoresistance and angiogenesis. Prolongation of immunocompetence represents a promising intervention to achieve lasting tumor suppression promoting survival. Further, chemotherapy may increase immunogenicity by releasing tumor-specific antigens providing an environment for long-term tumor control. Governance of T cell regulation with immune therapy has been explored in advanced solid tumors. Clinical experience with agents targeting PD-1/PD-L1 in OC is limited but responses have been observed. Durvalumab is a novel PD-L1 inhibitor with activity across a number of different solid tumors in in vitro and in vivo models. As yet, it is unknown which pts stand to benefit the most from this agent.

Trial design: A total of 30 evaluable pts with untreated, advanced stage OC undergoing neoadjuvant chemotherapy will be treated with paclitaxel, carboplatin and durvalumab, followed by durvalumab maintenance. Pretreatment biopsies will be obtained at laparoscopy or by interventional radiology from up to 4 sites. Interval tumor reductive surgery (TRS) will be performed after 3 cycles. Matched biopsies will be obtained at TRS. The study incorporates a phase I safety lead in (n = 6) to ensure the combination has acceptable toxicity and pts undergo TRS in a timely fashion. Dose-limiting toxicities (DLTs) will be assessed. This will be followed by open enrollment on the phase II portion. The primary objective is to explore basal levels and effects of durvalumab in combination with chemotherapy on molecular markers in immune-related pathways and lymphoid populations including DNA copy number, mutation, RNA/protein expression, PD-L1 expression and T-cell infiltration, before and after treatment. Secondary objectives are progression free survival, overall survival, and patient reported outcomes.

993TiP Comparing doses and fractionation regimens for high dose rate brachytherapy in locally advanced cervical carcinoma: A randomized controlled trial

A. Manirakiza, F. Rubagumya, D. Msemo, N. Dharsee

Academic Department, Ocean Road Cancer Institute, Dar Es Salaam, Tanzania

Background: Cervical cancer is among the most common gynecologic malignancies encountered in Low and Middle Income Countries. Tanzania, and the whole East African region where it belongs, has cervical cancer as the first malignancy in women, in both incidence and mortality. Despite the advances in management of cervical carcinoma, most of the Low-Income Countries lag in terms of treatment planning and delivery, considering the loads of patients that consult on a regular basis. Locally advanced cervical cancer status, as defined by the International Federation of Gynecology and Obstetrics confers to the patient a high recurrence and low survival rate risks altogether. Survival rates have been shown to have a decreasing tendency as the cancer stage increase. According to FIGO classification, the management of a locally advanced cervical cancer consists of a course of combined radiotherapy and chemotherapy, with a few added weeks of brachytherapy. As it has been shown before, both exposure and toxicity to any of the available treatment options could be lowered if some factors are taken into consideration. Encouraging results have been shown elsewhere. This study compares two different dose fractionations of High dose rate brachytherapy for selected cases of cervical carcinoma, and seeks to prove feasibility of both.

Trial design: The study is an open-label, single institution, non-inferiority, phase 3 randomized controlled trial. Patients will be assigned (1:1), with a consecutive recruitment according to set randomization criteria, to receive two brachytherapy insertions of 8.5 Grays, one week apart (intervention group – A) or three brachytherapy insertions of 6.7 Grays, one week apart (control group – B). Patients will be enrolled then randomized to either group after satisfactory completion of a 5 week-course of both external beam radiotherapy, total dose of 50 Grays, on a 2 Gray daily in 25 fractions, combined with a weekly single agent cisplatin for a dose of 40 mg/m^2. The study will have a recruitment phase spanning between April to June 2017 and a follow up phase from May 2017 to May 2018.

Petrov, St. Petersburg, Russian Federation, [11]Dept. of Chemotherapy for Hematological Malignancies, Blokhin Cancer Research Center under the Russian Academy of Medical Sciences, Moscow, Russian Federation, [12]Clinical Pharmacology, Sandoz Inc., Princeton, NJ, USA, [13]Biostatistics, Sandoz Inc., Princeton, NJ, USA, [14]Medical Affairs, Hexal AG, Holzkirchen, Germany

Background: GP2013, a rituximab biosimilar, has been developed according to biosimilar development guidelines, with clinical trials in rheumatoid arthritis and follicular lymphoma (FL).

Methods: This confirmatory phase III, double-blind, randomized, controlled trial compared efficacy, safety, pharmacokinetics (PK) and pharmacodynamics (PD) of GP2013-CVP versus rituximab-CVP (R-CVP) in previously untreated, advanced-stage FL. The primary endpoint was equivalence in overall response rate (ORR), defined by 95% confidence interval [CI] with a margin of ± 12%. Secondary, non-powered endpoints comprised progression-free and overall survival, PK, PD, and safety. Patients were stratified by region and FLIPI risk score and randomized (1:1) to 8 cycles of GP2013-CVP (n = 314) or R-CVP (n = 315), followed by monotherapy maintenance for up to 2 years in responders (ClinicalTrials.gov identifier: NCT01419665).

Results: The primary endpoint, equivalence of ORR between treatments, was met (GP2013-CVP: 87.1%; R-CVP: 87.5%; difference [95%CI] –0.40% [–5.94%, 5.14%]). Subgroup analyses suggested that ORR was similar between GP2013-CVP and R-CVP regardless of age (<, ≥60 years), gender, race, geographic region or bulky disease. Subgroup analyses reported numerical treatment differences (95%CI) of –8.41 (–17.09, 0.28) and 5.74 (–1.70, 13.17) for patients with FLIPI score of 0–2 and 3–5, respectively. Safety data from an interim analysis with an additional year of follow up showed that the pattern and rates of AEs (combination period: GP2013-CVP, 92.9%; R-CVP, 91.4%; maintenance period: GP2013, 72.0%; R, 69.4%) and SAEs (combination period: GP2013-CVP, 22.8%; R-CVP, 20.0%; maintenance period: GP2013 7.9%; R, 7.1%) are similar between treatments.

Conclusions: The study demonstrated equivalence in ORR between the biosimilar GP2013 and reference rituximab in patients with previously untreated, advanced FL. Similarity in ORR was observed across subgroups and safety profiles were also comparable. Based on the totality of evidence, GP2013 was approved by the EMA and represents an important option for patients that need rituximab and to help sustain the cost of cancer care.

Background: Acute myeloid leukemia (AML) CD34+, CD38- cells highly express CD123, associated with high-risk disease and disease progression. CD123 expression on normal HSC is negligible, enabling a promising strategy of preferential ablation with a CD123-targeted approach. Flotetuzumab (MGD006/S80880), a novel CD123 x CD3 bispecific DART protein, is designed to target CD123+ cells for elimination by T cells.

Methods: The Ph 1 dose-escalation study will define the safety profile, maximum tolerated dose and schedule (MTDS), and preliminary anti-leukemic activity of flotetuzumab. Relapsed/refractory (R/R) AML or intermediate-2/high-risk MDS will be treated with 28 day cycles of continuous infusion at doses from 3 to 1000 ng/kg/day. During C1W1, patients receive a lead-in dose (LID) of 30 ng/kg/day for 3 days followed by 100 ng/kg/day for 4 days. During C1W2-4, patients receive the cohort target dose (300-1000ng/kg/day) on either a 4-day on/3-day off or a continuous 7-day on weekly schedule. At Cycle 2 and beyond, patients are treated on a 4-day on/3-day off schedule at the cohort target dose for a maximum of 12 cycles, 2 cycles after a CR, DLT or DP. Cohort expansion will enroll 24 AML and 24 MDS patients at the MTDS. Disease status is assessed by IWG criteria.

Results: Patients with R/R AML/MDS (35/3) have been treated with flotetuzumab, up to a dose of 500ng/kg/day. Flotetuzumab has demonstrated acceptable tolerability to date, with no MTDS yet defined for either schedule. The most common drug-related adverse event was infusion-related reaction/cytokine-release syndrome (29/38, 76% any grade; 3/38, 8% G3). Drug-related adverse events ≥G3 were observed in 14/38 (36%) of patients overall. A LID strategy and early use of tocilizumab ameliorated this toxicity and limits corticosteroid use. At 500ng/kg/day, anti-leukemic activity has been observed in 4/8 patients treated, including CRi (n = 2), morphologic leukemia free state (n = 1) and bone marrow blast reduction >50% (n = 1).

Conclusions: To date flotetuzumab has an acceptable safety profile and demonstrated early evidence of anti-leukemic activity.

996O Risk of developing acute myeloid leukemia (AML) in well-differentiated thyroid cancer (WDTC) patients treated with radioactive iodine (RAI): a population-based study

R.J. Molenaar[1], T. Radivoyevitch[2], H.E. Carraway[3], J.P. Maciejewski[4], M.A. Sekeres[3], S. Mukherjee[3]

[1]Medical Oncology, Academic Medical Center (AMC), Amsterdam, Netherlands, [2]Quantitative Health Sciences, Cleveland Clinic, Cleveland, OH, USA, [3]Leukemia Program, Taussig Cancer Institute, Cleveland Clinic, Cleveland, OH, USA, [4]Translational Hematology & Oncology Research, Taussig Cancer Institute, Cleveland Clinic, Cleveland, OH, USA

Background: Risks of leukemias increase after radiation treatment, including RAI, which is frequently used to treat WDTC. However, the risk of AML following RAI treatment in WDTC survivors has not been characterized.

Methods: In a population-based study, we queried all 18 Surveillance Epidemiology and End Results registries for WDTC cases treated with surgery or surgery followed by RAI. We assessed the risk dynamics of developing AML in WDTC patients and its association with RAI. We also studied the clinical outcome of AML that occurred after WDTC diagnoses in case-control studies.

Results: Of 148,215 WDTC patients identified between 1973-2014, 55% received surgery alone and 45% received surgery and RAI. After a median 4.3 person years of follow up (IQR, 1.9-7.4), 44 patients developed AML after surgery alone for WDTC and 56 patients developed AML after surgery and RAI. Compared to the background rates in the general population, patients treated with surgery and RAI had an increased risk of developing AML that peaked within the first three years after RAI treatment (RR: 5.6, 95% CI: 3.8-8.1, $P < 0.0001$). After correction for sex and WDTC tumor size in a multivariate analysis, patient age (HR: 1.03, 95% CI: 1.02-1.05, $P < 0.001$), WDTC tumor stage (HR: 1.36, 95% CI: 1.04-1.79, $P = 0.03$) and RAI treatment for WDTC as compared with thyroidectomy alone (HR: 1.38, 95% CI: 1.09-1.75, $P = 0.007$) were independent prognostic factors for AML development. WDTC patients that developed AML after surgery and RAI had a truncated survival as compared with matched WDTC control patients that did not develop AML (median OS: 7.5 years *vs.* 24.4 years, $P < 0.0001$). Finally, patients that were diagnosed with AML after RAI treatment for WDTC had a worse prognosis than patients with AML that occurred spontaneously (median OS: 1.2 years *vs.* 3.5 years, $P = 0.004$).

Conclusions: RAI treatment is associated with an increased risk of developing AML in WDTC survivors. RAI-related AML has a poor survival, similarly to t-AML that arises after radiotherapy or chemotherapy. Considering young patient ages at WDTC diagnosis and high survival rates, the rates of AML in WDTC survivors are likely to continue to rise.

997PD Split dosing of daratumumab (D) in a phase 1b study of D plus carfilzomib (K)-based regimens in patients (pts) with multiple myeloma (MM)

S.Z. Usmani[1], A. Jakubowiak[2], A. Chari[3], S. Lonial[4], M-V. Mateos[5], L. Benboubker[6], K. Wu[7], N.Z. Khokhar[7], J. Wang[8], P. Doshi[7], P. Moreau[9]

[1]Levine Cancer Institute, Carolinas HealthCare System, Charlotte, NC, USA, [2]University of Chicago Medical Center, Chicago, IL, USA, [3]Icahn School of Medicine at Mount Sinai, New York, NY, USA, [4]Department of Hematology and Medical Oncology, Winship Cancer Institute, Emory University, Atlanta, GA, USA, [5]University Hospital of Salamanca/IBSAL, Salamanca, Spain, [6]Service d'Hématologie et Thérapie Cellulaire, Hôpital Bretonneau, Centre Hospitalier Régional Universitaire (CHRU), Tours, France, [7]Janssen Research & Development, LLC, Spring House, PA, USA, [8]Janssen Research & Development, LLC, Raritan, NJ, USA, [9]Hematology, University Hospital Hôtel-Dieu, Nantes, France

Background: D, a human CD38 IgGκ mAb, induces deep, durable responses in pts with relapsed/refractory MM, as monotherapy and combined with other regimens. Infusion-related reactions (IRRs) occur in ~50% of D-treated pts, are generally mild to moderate, and usually occur during the 1st infusion. The median duration of the 1st infusion is ~7 hours. To determine if splitting the first dose would reduce IRRs and infusion times, split-dose D was evaluated in two K-based regimens (MMY1001: NCT01998971).

Methods: Pts received D plus K and dexamethasone (d; DKd) or DKd and lenalidomide (R; DKRd). Pts in the DKd arm had 1-3 prior therapies; pts in the DKRd arm were newly diagnosed. 28-day cycles comprised K 20 mg/m^2 intravenously (IV) over 30 minutes on Cycle 1 Day 1 (C1D1) and 70 mg/m^2 over 30 minutes weekly, thereafter; and weekly d 40 mg (20 mg if > 75 years). In the DKRd arm, R 25 mg was given orally on Days 1-21. Pts received IV D as a single or split dose (**Table**). If C1D1 and C1D2 D infusions were not well-tolerated, C1D8 was given in 1000 mL. Pts received treatment until progression (DKd) or for ≤13 cycles (DKRd). To mitigate IRRs, d (20 mg) was given ≤3 hours before dosing on C1D1 and C1D2, and ≤3 hours before and the day after subsequent infusions. Paracetamol and diphenhydramine were given ≤3 hours before infusion. Montelukast was given prior to first D dose (optional thereafter).

Results: Thirty-two pts received split-dose D. Median age (range) was 61 (34-76) years. Median number of D cycles received was 12 (1-14). Median first infusion time was 4.2 (4.0-10.3) hours. Among pts who received split-dose D, 9 (28%) pts had an IRR. Five (16%) and 4 (13%) pts had grade 1 and grade 2 IRRs, respectively. No grade 3/4 IRRs occurred. IRRs reported in ≥ 2 pts were cough, throat irritation, nausea, and headache (2 pts [6%] each). Data will be updated.

Conclusions: A split first dose of D was associated with shorter infusion times and reduced incidence and lower grade of IRRs.

Table: 997PD

	Split dose C1D1 and C1D2 (8 mg/kg)	Second dose C1D8 (16 mg/kg)	Subsequent doses (16 mg/kg)
Initial rate, mL/hour	50	50	100
Rate increment increase per hour, mL/hour	50	50	50
Maximum rate, mL/hour	200	200	200
Total infusion, mL	500	500	500

998PD Management of infusion-related reactions (IRRs) in patients (pts) receiving daratumumab plus standard of care for the treatment of multiple myeloma (MM) in the phase 3 studies CASTOR and POLLUX

P. Moreau[1], N. Rabin[2], T. Plesner[3], K. Weisel[4], P. Sonneveld[5], M-V. Mateos[6], J.M. Schecter[7], H. Amin[7], S. Trivedi[8], M.A. Dimopoulos[9]

[1]Hematology, University Hospital Hôtel-Dieu, Nantes, France, [2]Department of Haematology, University College London Hospitals NHS Trust, London, UK, [3]Vejle Hospital, University of Southern Denmark, Vejle, Denmark, [4]Universitaetsklinikum Tuebingen der Eberhard-Karls-Universitaet, Abteilung fuer Innere Medizin II, Tuebingen, Germany, [5]Department of Hematology, Erasmus MC, Rotterdam, Netherlands, [6]University of Salamanca Hospital, Salamanca, Spain, [7]Janssen Research & Development, LLC, Raritan, NJ, USA, [8]Janssen Research & Development, LLC, Spring House, PA, USA, [9]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, "Alexandra" General Hospital, Athens, Greece

Background: Daratumumab (D), a CD38-targeted monoclonal antibody, reduced the risk of MM progression or death by > 60% when combined with standard-of-care regimens in the phase 3 studies CASTOR (bortezomib [V] and dexamethasone [d] vs DVd; NCT02136134) and POLLUX (lenalidomide [R] and d vs DRd; NCT02076009). This analysis evaluated the management of D-related IRRs in the DVd and DRd arms of CASTOR and POLLUX.

Methods: Pts had MM and had received ≥1 line of therapy. In CASTOR, pts were given 8 21-day cycles of Vd (V 1.3 mg/m^2 subcutaneously on Days 1, 4, 8, and 11; d 20 mg per os [PO]/intravenously [IV] on Days 1-2, 4-5, 8-9, and 11-12) ± D (16 mg/kg IV, weekly [QW] for Cycles 1-3, every 3 weeks [Q3W] for Cycles 4-8, then every 4 weeks [Q4W] thereafter). In POLLUX, pts were given 28-day cycles of Rd (R 25 mg PO on Days 1-21; d 40 mg QW) ± D (16 mg/kg IV QW for Cycles 1-2, every 2 weeks for Cycles 3-6, then Q4W thereafter). In addition, pre-infusion medication consisted of 20 mg d (or equivalent) IV/PO, 650-1000 mg paracetamol, and 25-50 mg diphenhydramine (or equivalent). Pts with high-risk respiratory complications received diphenhydramine on Days 1 and 2, a short-acting β2 adrenergic receptor agonist and control medications for lung disease after D infusion.

Results: All pts receiving D were given pre-infusion medication. In CASTOR and POLLUX, 31 (13%) and 21 pts (7%) received post-infusion medications, respectively. In both trials, the median duration of D infusion was ~7.0, 4.3, and ~3.4 hours for the first, second, and subsequent infusions, respectively. IRRs occurred in 45% and 48% of pts and 98% and 96% of IRRs occurred during the first infusion in CASTOR and POLLUX, respectively. Most IRRs were grade 1/2 and no grade ≥4 IRRs were reported.

The median time to onset of IRRs after starting the first D infusion was 84 minutes in CASTOR and 90 minutes in POLLUX. In CASTOR, 2 pts discontinued treatment due to IRRs; in POLLUX, 1 pt discontinued D due to a grade 3 IRR, but continued Rd.

Conclusions: Most D-related IRRs occurred during the first infusion and were grade 1/2. D-related IRRs were easily managed with pre- and post-infusion medications.

Clinical trial identification: NCT02136134 and NCT02076009

999PD Comparison of efficacy of new therapies between younger and older patients with relapsed and refractory multiple myeloma: A meta-analysis

T. Landre[1], C. Al-Nawakil[2], F. Karaoud[3], C. Taleb[3]

[1]UCOG, Hopital René Muret APHP, Sevran, France, [2]Hématologie Centre Recherche Clinique, AP-HP Hôpital Avicenne, Bobigny, France, [3]Geriatric Oncology, AP-HP Hôpital René Muret, Sevran, France

Background: Multiple myeloma is a disease of age. With all of the new myeloma drugs being developed, there are number of treatment options for relapsed and refractory multiple myeloma (RRMM). However, in our knowledge, few data are available in patients older than 65 or 75 years. We performed a meta-analysis to compare the efficacy of new drugs to treat RRMM between younger and older patients.

Methods: PubMed and the Cochrane databases were searched up to April 2016. We included phases III randomized controlled trials (RCTs) of monoclonal antibodies (mAbs) targeting CD38 or SLAMF7 (daratumumab, elotuzumab), second generation proteasome inhibitors (carfilzomib, ixazomib) and histone deacetylase (HDAC) inhibitors (vorinostat, panobinostat) reporting subgroups comparison of progression-free survival (PFS) based of aged cut-offs. The summary hazard ratio (HR) and 95% confidential interval (CI) were calculated.

Results: A total of 5241 patients from eight RCTs of RRMM new therapies were included (CASTOR, POLLUX, ELOQUENT-2, ASPIRE, ENDEAVOR, TOURMALINE-MM1, PANORAMA-1 and VANTAGE-088). When patients are dichotomized into younger and older groups with an age cut-off of 65-75 years, RRMM new therapies improved PFS in both younger (HR, 0.62; 95% CI, 0.56–0.70) and older (HR, 0.67; 95% CI, 0.60–0.74) groups. An improvement in PFS with mAbs was observed in younger (HR, 0.57; 95% CI, 0.46–0.72) and older (HR, 0.52; 95% CI, 0.42–0.64) patients. An improvement in PFS with HDAC inhibitors was also observed in both younger (HR, 0.67; 95% CI, 0.56–0.80) and older (HR, 0.78; 95% CI, 0.63–0.97) as well as with second generation proteasome inhibitors (HR, 0.61; 95% CI, 0.52–0.73 and HR, 0.70; 95% CI, 0.60–0.81 respectively).

Conclusions: A benefit in PFS with new therapies was significant in both younger and older patients with relapsed and refractory multiple myeloma with a cut-off age of 65–75 years.

Seràgnoli", University of Bologna, Bologna, Italy, [19]Medizinische Klinik und Poliklinik III, Klinikum der Universität München-Grosshadern, Munich, Germany

Background: Copanlisib, a pan-class I phosphatidylinositol 3-kinase (PI3K) inhibitor with predominant activity against PI3K-α and PI3K-δ isoforms, has recently been shown to achieve a 59% objective tumor response rate (ORR) in a phase II study in patients with relapsed or refractory (r/r) indolent B-cell lymphoma. We report here the results of subgroup analyses conducted based on demographic and baseline disease characteristics.

Methods: Patients with indolent B-cell non-Hodgkin lymphoma (4 subtypes: follicular [FL], marginal zone [MZL], small lymphocytic [SLL] and lymphoplasmacytoid/Waldenström macroglobulinemia [LPL-WM]) and r/r to ≥ 2 prior lines of treatment were eligible. Previous treatment had to include rituximab and an alkylating agent. Copanlisib (60 mg, I.V.) was administered intermittently on days 1, 8 and 15 of a 28-day cycle. The primary efficacy endpoint was ORR as assessed per independent radiologic review (Cheson et al. 2007).

Results: The full analysis set comprised 142 patients, of which 141 patients had indolent lymphoma (FL/MZL/SLL/LPL-WM: 104/23/8/6). ORR per histological subgroup was 58.7%/69.6%/75.0%/16.7%, respectively. ORR based on demographics were generally consistent across categories. Likewise, there were no major differences in ORR between any of the baseline disease characteristics and prior therapy subgroups with regards to ECOG PS (0 [58.8%] vs. ≥ 1 [59.7%]), longest diameter of baseline lesion (< 7cm [59.8%] vs. ≥ 7cm [59.1%]), received prior bendamustine (yes [62.7%] vs. no [56.6%]), number of prior therapies (< 4 [59.8%] vs. ≥ 4 [57.5%]), or refractoriness to last regimen (yes [60.5%] vs. no [57.1%]). Median duration of response (DOR) by tumor histology for the subgroups with ≥ 10 responders was 370 days (range 33-687) for FL patients and had not yet been reached for MZL patients (2 of 16 responders having progressed).

Conclusions: Objective response rates were consistently high in patients with r/r indolent B-cell lymphoma treated with copanlisib with the exception of LPL-WM patients. There were no major differences in the ORR between any of the baseline disease characteristics and prior therapy subgroups, confirming the robustness of the primary efficacy endpoint.

1001PD Tumor gene expression signatures of BCR/PI3K dependence in association with copanlisib monotherapy activity in heavily pretreated patients with indolent NHL and follicular lymphoma

L. Liu[1], K. Köchert[2], H. Seidel[3], J. Garcia-Vargas[4], B.H. Childs[5], G. Follows[6], K. Bouabdallah[7], M. Dreyling[8], C. Peña[1]

[1]Biomarker Strategy, Bayer HealthCare Pharmaceuticals, Whippany, NJ, USA, [2]Clinical Statistics, Bayer AG, Berlin, Germany, [3]Bioinformatics, Bayer AG, Berlin, Germany, [4]Clinical Development, Bayer HealthCare Pharmaceuticals USA, Whippany, NJ, USA, [5]Clinical Development, Bayer HealthCare Pharmaceuticals, Whippany, NJ, USA, [6]Department of Haematology, Cambridge University Hospitals NHS Foundation Trust Addenbrooke's Hospital, Cambridge, UK, [7]Service d'Hématologie et de Thérapie Cellulaire, University Hospital of Bordeaux, Pessac, France, [8]Medizinische Klinik und Poliklinik III, Klinikum der Universität München-Grosshadern, Munich, Germany

Background: Copanlisib, a novel class I PI3K inhibitor with predominant activity against α and δ isoforms, has shown robust single agent anti-tumor activity in a phase 2 study in heavily pretreated patients with indolent NHL (iNHL) and follicular lymphoma (FL) (NCT01660451; Part B), with response rates of 59.6% and 58.7%, respectively. Baseline tumor gene expression profiling (GEP) was performed to confirm if gene signatures identified in patients with indolent or aggressive NHL (NCT01660451; Part A) are molecular determinants for copanlisib antitumor activity in Part B.

Methods: Signaling pathway gene sets (n = 33) were ranked by enrichment analysis (GSEA) for association with objective response based on normalized enrichment score (NES) and false discovery rate (FDR) q values. The association of weighted gene-expression score (WGS, reflecting the overall expression level for each gene set) with response was analyzed by logistic regression.

Results: Seventy-one patients with iNHL, including 54 FL, had both response data and evaluable gene expression data. All 5 gene sets reflecting upregulated PI3K/BCR signaling were top-ranked for association with higher response rates in iNHL (GSEA NES $\geq$ 1.93, FDR q $<$ 0.01; WGS AUC $\geq$0.65, nominal p $\leq$ 0.04) and FL (GSEA NES $\geq$1.50, FDR q $\leq$ 0.01; WGS AUC $\geq$0.60, nominal p $\leq$ 0.23). Among patients with objective responses, 66% (33/47) of iNHLs and 71% (24/36) of FLs had high PI3K/BCR gene signature expression levels; for patients with CR, 86% (6/7) iNHL and 83% (5/6) FL had high levels. Further, 4 gene sets enriched with T-cell signatures were associated positively with copanlisib response (NES $\geq$1.48, FDR q $\leq$ 0.08). In contrast, up-regulation of macrophage/stromal gene sets was potentially associated with a lower likelihood of response to copanlisib treatment in FL (NES $\leq$ -1.21, q $\leq$ 0.21).

Conclusions: Tumor gene expression profiling demonstrates that up-regulation of the BCR/PI3K pathway is frequent and dominant in iNHL and FL, and is associated with the high and durable copanlisib responses. These findings are consistent with copanlisib's mode of action and strongly support the rationale for treatment of iNHL and FL patients with copanlisib.

1002PD Standardized mortality ratios and event-free survival as new prediction tools of early increase in mortality in follicular lymphoma

F. Franco[1], A. Royuela[2], M. Torrente[1], J. Gómez-Codina[3], M. Llanos Rodríguez[4], J. Gumá Padró[5], C. Quero Blanco[6], D. Aguiar[7], A. Rueda Domínguez[8], M. Provencio Pulla[1]

[1]Medical Oncology, Hospital Universitario Puerta de Hierro Majadahonda, Madrid, Spain, [2]Biostatistics, Biomedical Sciences Research Institute Puerta de Hierro-Majadahonda University Hospital, Madrid, Spain, [3]Medical Oncology, La Fe University Hospital, Valencia, Spain, [4]Medical Oncology, Hospital University of Canarias, Santa Cruz De Tenerife, Spain, [5]Medical Oncology, Hospital Universitari Sant Joan de Reus, Reus, Spain, [6]Medical Oncology, Hospital Universitary Virgen de la Victoria Málaga, Malaga, Spain, [7]Medical Oncology, Gran Canaria Doctor Negrín University Hospital, Las Palmas De Gran Canaria, Spain, [8]Oncology, Costa del Sol Hospital, Marbella, Spain

Background: There are few studies that analyze follicular lymphoma (FL) mortality compared to the general population of the same -sex and age group. Given the recent clinical relevance of the predictive event-free survival (EFS) indexes EFS12 and EFS24, we obtained them in our study cohort in order to estimate their association with overall survival (OS).

Methods: Patients diagnosed with FL were prospectively enrolled from 1980 to 2013. Standardized mortality ratios (SMR) were obtained using yearly sex and age specific mortality rates in Spain, and OS was compared with age- and sex-matched general population data. EFS were defined as the time from diagnosis until relapse or progression, unplanned retreatment of lymphoma after initial management, or death due to any cause. EFS12 and 24 were defined as EFS status at 12 or 24 months from diagnosis, respectively. The crude probability of death was estimated by using the Kaplan–Meier method, and differences between patient groups were assessed by the log-rank test. In order to investigate the specific contribution of age, sex, period of diagnosis, treatment and FLIPI score, a multivariable Cox proportional hazards model was adjusted, all statistical tests were two-sided, and a p-value $<$0.05 was considered statistically significant.

Results: A total of 1074 patients with newly diagnosed FL were enrolled. The median OS was 231 months (CI 95% 195-267). EFS at 12 and 24 months was associated with increased probability of early death, with an SMR of 10.27 (95% CI: 8.26-12.77). The prognostic value of traditional scales such as FLIPI is maintained in our study, with a hazard ratio of 2.7 (95% CI: 1.9- 4.0) for a score of 2-5. Of note, no significant difference in mortality was observed between FL patients at 10 years since diagnosis compared to the general population (SMR of 1.02; 95% CI 0.57, 1.85).

Conclusions: EFS12 and 24 predicted an early increase in mortality. The long-term SMR, over 10 years of follow-up, shows that patients with FL have a similar risk of dying than the general population of the same sex and age.

1003PD A multicentre phase II trial addressing lenalidomide (LEN) maintenance in patients with relapsed diffuse large b-cell lymphoma (rDLBCL) who are not eligible for autologous stem cell transplantation (ASCT)

M. Sassone[1], F. Zaja[2], A. Re[3], M. Spina[4], A. Di Rocco[5], A. Fabbri[6], C. Stelitano[7], M. Frezzato[8], C. Rusconi[9], R. Zambello[10], T. Calimeri[1], L. Scarfò[1], C. Cecchetti[1], M. Chiozzotto[11], M. Ponzoni[12], A. Ferreri[1]

[1]Unit of Lymphoid Malignancies, Department of OncoHematology, IRCCS San Raffaele, Milan, Italy, [2]Hematology Unit, University of Udine, Udine, Italy, [3]Hematology Unit, Spedali civili di brescia, Brescia, Italy, [4]Hematology Unit, Centro di Riferimento Oncologico, Aviano, Italy, [5]Hematology Unit, University La Sapienza, Rome, Italy, [6]Hematology Unit, University of Siena, Siena, Italy, [7]Hematology Unit, A.O. Melacrino-Morelli, Reggio Calabria, Italy, [8]Hematology Unit, San bortolo Hospital, Vicenza, Italy, [9]Hematology Unit, Niguarda Hospital, Milan, Italy, [10]Hematology Unit, University of Padova, Padua, Italy, [11]Hematology Unit, AO Udine, Udine, Italy, [12]Haematopathology Diagnostic Area- Pathology Unit, IRCCS San Raffaele, Milan, Italy

Background: Single-drug maintenance after salvage therapy could prolong survival of pts with rDLBCL not eligible to ASCT. LEN could be an excellent candidate as it is an oral agent, active against DLBCL, with excellent safety profile. Herein, we report results of a multicentre phase II trial addressing LEN maintenance (mLEN) in pts with chemosensitive rDLBCL.

Methods: HIV-negative pts with DLBCL relapsed after R-CHOP or similar and responsive to salvage therapy were registered and treated with LEN 25 mg/day for 21 days out of 28 until lymphoma failure or unacceptable toxicity. Primary endpoint was the 1-year PFS. Estimated sample size (Simon's two-stage optimal design; type I error 5%, power 80%, P0 30%, P1 50%) was 47 pts; mLEN would be considered effective if $\geq$ 19 pts will be progression-free survivors at 1 year. The prognostic role of cell of origin, assessed by NanoString and Hans algorithm, was investigated.

Results: 46 of 48 enrolled pts were assessable (median age 72 years; 34-86); 26 pts started mLEN in CR and 20 in PR after salvage therapy. 639 LEN courses were delivered, with an average of 14 courses/pt (3-53). LEN was well tolerated: with the exception of neutropenia, grade 3-4 toxicities were uncommon ($\leq$3% of courses). LEN dose reduction was indicated in 25 pts. Three pts died of toxicity: intestinal infarction, meningitis, unknown cause; 2 pts developed a second cancer. The pre-determined efficacy threshold (n $\geq$ 19) was largely achieved: 32 pts were progression free at 1 year from registration. At a median follow-up of 38 (14-95) months, 23 events occurred: PD in 19 pts, death of toxicity in 3, death while off therapy in 1, with a 1-yr PFS of 70% (95%CI=59-81). The benefit of mLEN was observed both in pts with *de novo* or transformed DLBCL, and both in GCB- or nonGCB-DLBCL. 29 (63%) pts are alive, with a 3-yr OS of 64%.

Conclusions: With the limitations of a non-randomized design, this trial soundly promotes the use of mLEN in pts with chemosensitive rDLBCL not eligible for ASCT or experiencing relapse after ASCT. These results warrant further investigation of immunomodulatory drugs as maintenance in these high-risk pts.

1004PD Follicular lymphoma: clinical and mollecular characteristics of histologic transformation

M. Mendez Garcia[1], M. Sánchez-Beato Gomez[1], J. González Rincón[1], J. Gomez Codina[2], M. Llanos Rodríguez[3], A. Rueda Domínguez[4], C. Quero Blanco[5], L. De la Cruz Merino[6], J. Gumá Padró[7], M. Provencio Pulla[8]

[1]Medical Oncology, Hospital University Puerta de Hierro, Majadahonda, Spain, [2]Medical Oncology, Hospital Universitari i Politècnic La Fe, Valencia, Spain, [3]Medical Oncology, Hospital University of Canarias, Santa Cruz De Tenerife, Spain, [4]Oncology, Costa del Sol Hospital, Marbella, Spain, [5]Medical Oncology, Hospital Universitary Virgen de la Victoria Málaga, Malaga, Spain, [6]Medical Oncology, Hospital University Virgen Macarena Sevilla, Seville, Spain, [7]Medical Oncology, Hospital Universitari Sant Joan de Reus, Reus, Spain, [8]Servicio de Oncología Médica, Hospital Universitario Puerta de Hierro, Madrid, Spain

Background: Follicular lymphoma (FL) is the second most common type of non-Hodgkin lymphoma (NHL). Histological transformation (HT) refers to the evolution

of a clinically indolent NHL to an aggressive one. The rates of HT in published series range from 10% to 60%. There are no specific clinical characteristics that can predict transformation. Some molecular parameters associated with transformation are: p53 expression, expression of c-MYC, BCL-6 mutations. This suggests that multiple alternative mechanisms are likely to be involved in the pathogenesis of HT.

Methods: We report a prospective, multicenter (39 Spanish member institutions of Grupo Oncológico para Tratamiento de Linfomas-GOTEL-), observational study designed to collect data on disease presentation, treatment and clinical outcomes of HT. Inclusion criteria for this analysis were initial diagnosis of grade 1-3a FL and enrolment from 1990 to 2016. HT was defined as refractory/recurrent disease with clinical or pathologic diagnosis. Whole exome sequencing of the HT samples has been performed and compared with samples from patients with LF without transformation.

Results: Of the 975 evaluable patients, 64 had HT. Characteristics associated with an increased risk of HT were: the presence of B symptoms ($p = 0.001$), increased LDH ($p = 0.02$), high Follicular Lymphoma International Prognostic Index (FLIPI) ($p = 0.01$) and poor perfomance status ($p = 0.01$). In this group of patients, the cumulative incidence rate of HT at 5 years was 7.3%; the rate of HT remained constant, reaching a plateau after 14 years. Expectant management also predicted for a higher risk of HT ($p = 0.0001$). The median survival from transformation was 5 years. Regarding molecular characteristics, we found that all patients with HT had more than 4 mutations at diagnosis of FL in a group of 14 genes that are frequently mutated in patients with HT: CSMD3, DTX1, FOXO1, LRP1B, NOTCH2, PIM1, POU2F2, ATM, BCL7A, HIST1H1E, IRF8, PCLO, EZH2 and TNFAIP3.

Conclusions: There are clinical (increased LDH, B symptoms, high FLIPI, poor performance status) and molecular factors (more than 4 mutations in specific genes) at diagnosis correlate with an increased risk of HT. These predictors of HT could help to develop targeted therapies to prevent HT in high risk patients or improve current salvage approaches.

1005PD Prognostic nomogram for overall survival in previously untreated patients with diffuse large B-cell lymphoma

Y. Han, Y. Qin, P. Liu, J. Yang, X. He, S. Zhou, L. Gui, S. Yang, C. Zhang, Y. Huang, S. Jiang, Y. Shi, Q. Wang, Y. Sun, Y-K. Shi

Department of Medical Oncology, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: The purpose of this study was to develop a newly accepted prognostic nomogram to estimate overall survival (OS) in patients with diffuse large B-cell lymphoma (DLBCL) and assess its incremental value to the traditional International Prognostic Index (IPI) and NCCN-IPI for individual OS estimation.

Methods: The clinical data from 1,118 patients with DLBCL treated at Cancer Hospital Chinese Academy of Medical Sciences between 2006 and 2012 were reviewed. A nomogram was developed that predicted OS based on the Cox proportional hazards model. To contrast the utility of the nomogram against the widely used IPI and NCCN-IPI, we used the concordance index (C-index) and a calibration curve to determine its predictive and discriminatory capacity.

Results: The 5-year OS rate was 64.1% for the entire group. The entire group were divided into the primary ($n = 783$) and validation ($n = 335$) cohorts. The nomogram included eight important variables based on a multivariate analysis of the primary cohort: Ann Arbor stage; age; ECOG PS; LDH; β2-MG; CD5; Bcl-6 and Ki-67 index. The calibration curve showed that the nomogram was able to predict 5-year OS accurately. The C-index of the nomogram for OS prediction was 0.77 in the primary cohort and 0.76 in the validation, which was superior to the predictive power (range, 0.71-0.74) of the IPI and NCCN-IPI in the primary and validation cohorts. To detect the accuracy of the nomogram for rituximab plus CHOP (R-CHOP) like regimen, we took subgroup analysis. The C-index of the nomogram for OS prediction was 0.78 in the R-CHOP like regimen subgroup, and 0.76 in the CHOP like regimen subgroup.

Table: 1005PD Multivariate analysis of 783 patients in the primary cohort

Covariate	level	HR	95% CI	P-value	nomogram score
Age	>60y	1.32	1.02-1.72	0.036	28
	≤60y	–	–	–	0

1006PD Does the omission of vincristine affect outcome and survival in patients with diffuse large B-cell lymphoma?

C. Mörth[1], A. Valachis[1], A. Abu Sabaa[2], G. Hedström[2], M. Flogegård[2], G. Enblad[2]

[1]*Uppsala University, Centre for Clinical research Sörmland, Eskilstuna, Sweden,* [2]*Uppsala University, Department of Immunology, Genetics and Pathology, Uppsala, Sweden*

Background: The current standard treatment for diffuse large B-cell lymphoma (DLBCL) is Rituximab-CHOP (cyclophosphamide (CPM), doxorubicin(DXR), vincristine(VCR), prednisolone). It is well known that VCR causes peripheral neuropathy and is often dose-reduced or omitted from the treatment. Whether the omission of VCR from 1 or more cycles of therapy could jeopardize the survival of patients with DLBCL has not yet been adequately addressed. Our study aimed to investigate any differences in progression free (PFS) and overall (OS) survival in R-CHOP treated patients with DLBCL between those with omission of VCR or not.

Table: 1006PD

	PFS		OS	
	Hazard ratio (95% CI)	P value	Hazard ratio (95% CI)	P value
Age ≥ 60	Not included		1.94 (1.09-3.48)	0.025
Treatment[a]	Not included		1.76 (0.90-3.43)	0.096
PS ≥ 2	1.62 (0.74-3.57)	0.235	1.77 (0.84-3.74)	0.134
Stage > 2	2.04 (1.01-4.00)	0.047	1.59 (0.88-2.88)	0.127
IPI > 2	1.33 (0,70-2.50)	0.385	1.14 (0.60-2.17)	0.686
LDH > ULN	1.09 (0.63-1.89)	0.778	1.03 (0.63-1.69)	0.893
Bulky[b]	1.30 (0.81-2.10)	0.283	1.58 (1.03-2.42)	0.037
Oncovin omission[c]	1.21 (0,76-1.95)	0.421	1.12 (0.75-1.69)	0.571
Extranodal[d] >1	1.02 (0.59-1.78)	0.932	Not included	
Kidney/Adrenal[e]	1.72 (0.78-3.85)	0.171	2.45 (1.20-4.98)	0.014
BMI ≥ 25	0.89 (0.58-1.37)	0.591	0.98 (0.67-1.43)	0.904
DoxoRDI ≤ 70%	1.88 (0.97-3.67)	0.063	2.04 (1.15-3.57)	0.014

Methods: In this Swedish multi-institutional, retrospective, cohort study we included all adult patients diagnosed with and primarily treated for DLBCL or subgroups of high-grade malignant B-cell lymphoma with either R-CHOP/CHOEP (CHOP plus Etoposide) or mini-CHOP (dose-reduced), between 2000-2013. All information on patients' characteristics, treatment outcome, and survival was extracted from the in-hospital computer based systems. Any clinical variables significantly associated with PFS or OS in univariate analysis by the log-rank test were considered for entry into a multivariate Cox proportional hazard regression model. Omission of VCR was included in all models as an independent variable of interest. All statistical analyses were performed with IBM SPSS statistics version 22.

Results: In total 541 patients were included in the study cohort. In 95 (17.6%) patients, VCR was omitted due to toxicity. The omission was more often decided during the last 3 cycles of chemotherapy (86 patients, 90.5%). Univariate analysis revealed 9 potential prognostic factors associated with PFS and 10 with OS. Omission of VCR was not associated with either PFS or OS in both univariate and multivariate analyses (HR for PFS: 1.21, 95% Confidence Interval (CI) 0.76-1.95; HR for OS; 1.12, 95% CI 0.75-1.69). For PFS only advanced stage at diagnosis was found to be significantly associated with worse outcome ($p = 0.047$). In respect of OS kidney/adrenal involvement ($p = 0.014$), Doxorubicin –RelativeDoseIntensity<70% ($p = 0.014$), age ≥60 years ($p = 0.025$) and bulky disease ($p = 0.037$) were significant predictors of survival.

Conclusions: Omission of VCR does not affect either PFS or OS in patients with DLBCL treated with R-CHOP/CHOEP. As a result, clinicians can safely decide to omit VCR in case of severe neurotoxicity due to VCR. Considering the association of bulky disease and kidney/adrenal manifestation of lymphoma on survival, further studies should focus on whether the treatment options for these subgroups need to be individualized. Finally, clinicians should be aware of the importance of giving adequate dose of DXR during treatment given the growing body of evidence on the role of dose intensity on survival.

Sammons Cancer Center, Texas Oncology, Dallas, TX, USA, [9]Medicine, Hematology & Oncology, UCLA School of Medicine, Los Angeles, CA, USA, [10]Clinical Development, Kite pharma, Santa Monica, CA, USA, [11]Clinical Development, Kite Pharma, Santa Monica, CA, USA

Background: Outcomes for adult pts with R/R ALL are poor. Promising results were observed with axi-cel (KTE-C19), an anti-CD19 chimeric antigen receptor (CAR) T cell therapy, in B cell malignancies (Locke et al. AACR 2017, #9986). Severe cytokine release syndrome (CRS) and neurologic events (NE) have been observed in pts with R/R ALL who received anti-CD19 CAR T cell therapy.

Methods: Eligible pts were aged ≥18 years with R/R ALL (Ph+ pts eligible), >5% bone marrow (BM) lymphoblasts, ECOG status 0-1, and adequate organ function. Pts received 1 or 2 × 106 CAR T cells/kg after conditioning (cyclophosphamide + fludarabine). Phase 1 primary endpoint was incidence of dose-limiting toxicity (DLT). Secondary endpoints were efficacy outcomes.

Results: As of 12/31/2016, 12 pts were enrolled; 11 received KTE-C19. One pt was excluded due to a serious adverse event (SAE) prior to dosing. Pts were 64% men, had 56-100% BM lymphoblasts before conditioning and 64% vs 36% had relapsed vs primary refractory disease. No DLTs were observed in the DLT-evaluation period of this trial. Of the first 6 pts enrolled at the 2 × 106 dose, 1 experienced Gr5 CRS. No KTE-C19-related Gr5 AEs were observed at 1 × 106 dose in 5 subsequent pts. Overall, the most common Gr ≥ 3 AEs were cytopenias (64% thrombocytopenia, 55% neutropenia). Gr ≥ 3 CRS and NE were reported in 27% and 55% of pts. Tocilizumab (toci) or steroids was given for AE management in 10 and 7 pts, respectively. All CRS (except 1 Gr 5) and NE resolved. Of the 10 efficacy-evaluable pts, 9 (90%) achieved minimal residual disease-negative remission (8 CR or CR with partial/incomplete hematopoietic recovery; 1 blast-free hypoplastic/aplastic BM). Median follow-up was 3.8 mos; 3 pts relapsed: 2 CD19- and 1 CD19+ disease. Efficacy was similar across KTE-C19 doses. To refine dosing and AE management, additional pts were treated with lower CAR T cell doses and received prophylactic toci. Clinical outcomes and translational data from these pts will be presented.

Conclusions: KTE-C19 demonstrates promising efficacy with a manageable safety profile for adult R/R ALL pts. Novel approaches to reducing toxicity, namely CRS and NE, may improve the overall risk: benefit profile for this class of therapies.

Background: ALL is the most common childhood malignancy; up to 20% of pts relapse after initial therapy, and have poor clinical outcomes (Hoffman and Gore. Front Oncol 2014). Promising results were observed with KTE-C19, an anti-CD19 chimeric antigen receptor (CAR) T cell therapy, in B cell malignancies (Locke at al. AACR 2017, #9986). We present preliminary ZUMA-4 phase 1 results.

Methods: Pts aged 2-21 y with R/R ALL and adequate organ function received the planned dose of 1 or 2×10^6 CAR T cells/kg after low-dose conditioning chemotherapy (cyclophosphamide/fludarabine, CyFlu). Pts enrolled after the study's dose-limiting toxicities (DLTs) portion receive tocilizumab ≤36 h after CAR T cell infusion. Phase 1 primary endpoint is the incidence of DLTs. Secondary endpoints include efficacy and biomarker assessments.

Results: As of Dec 31, 2016, 4 of 5 enrolled pts have been treated; median follow-up, 5.3 mo (1.9-8.6). All pts had ≥2 prior lines of therapy and 1 pt had prior stem cell transplant (SCT). All pts received bridging chemotherapy due to high disease burden (baseline blasts, 41-99%) prior to KTE-C19. KTE-C19 was successfully manufactured in a centralized 6-7 d process across a range of baseline absolute lymphocyte counts (0.5–17.1 × 10^9/L) and CD4:CD8 ratios (0.1-0.7). KTE-C19 could not be manufactured for 1 pt who progressed with WBC >150,000/μL at apheresis and <0.2% T cells in the apheresis collection. There were no DLTs. One pt had a gr 5 AE due to intracranial hemorrhage from disseminated mucormycosis. All pts had cytokine release syndrome (all ≤gr 3; all resolved with supportive care) and 1 pt had gr 3 neurologic events. All pts achieved MRD- remission (1 ongoing). One pt received SCT post-remission. Peak CAR T cell expansion was 1-2 weeks post-KTE-C19 infusion. Data from additional pts and implemented safety measures (eg, mandatory tocilizumab) will be presented.

Conclusions: KTE-C19 after low-dose CyFlu was tolerable and appears safe for further analysis in pediatric and adolescent pts with R/R ALL. KTE-C19 can induce deep remissions in heavily pre-treated pts with high disease burden. Based on these results, ZUMA-4 continues to enroll (NCT02625480).

1009PD Treatment patterns in elderly patients (pts) with acute myeloid leukemia (AML) in routine clinical care in the united states (US)

J.A. Bell[1], A. Galaznik[1], E. Farrelly[2], M. Pollack[3], A. Raju[2], A. Ogbonnaya[2], M. Eaddy[2], R. Fram[1], D.V. Faller[1]

[1]Millennium Pharmaceuticals, Takeda Pharmaceuticals, Cambridge, MA, USA, [2]Global Health Economics and Outcomes Research, Xcenda LLC, Palm Harbor, FL, USA, [3]Scientific Consulting, Xcenda, Tampa, FL, USA

Background: AML is a cluster of hematopoietic syndromes characterized by proliferation of immature myeloid cells in the bone marrow resulting in cytopenias. While prognostic indices may predict therapy response, no consensus exists regarding optimal therapy for elderly AML pts.

Methods: Newly diagnosed AML pts aged ≥60 years were retrospectively identified from a large US electronic medical record from 1/1/2008-7/31/2015. AML diagnosis included ≥1 inpatient or ≥ 2 outpatient claims with an AML ICD-9/10 code (the first record was the index date). First-line therapy (1LT) was defined as an AML-specific treatment initiated on/after the index date; a switch in agent triggered second-line therapy (2LT). Pts were followed until death, end of follow-up, or end of study (9/31/2015).

Results: Of 704 eligible AML pts, 398 received 1LT. Mean age was 70.6 years, 55.5% were male, and 19.1% had a Charlson comorbidity index score of ≥ 2. 1LT regimens included cytarabine-based induction 1LT (C-IC) in 54.3% (n = 216, combined with an anthracycline [ie, 7 + 3 or 7 + 3-like] in 87.5% of these), hypomethylating agents (HMAs) (azacitidine and decitabine) in 30.2% (n = 110), other cytotoxic IC (other-IC) in 8.5% (n = 34), and sorafenib in 1.0% (n = 4). 44 pts (11.1%) had record of stem cell transplant during 1LT for AML. A higher proportion of pts who received HMAs (67.3%) were ≥75 years of age compared to those receiving C-IC or other-IC (18.5%; 23.5%). Overall, 84 pts (23%) received 2LT, with C-IC still predominating (n = 37; 44.0%), followed by HMAs (n = 31; 36.9%) and other-IC (n = 15; 17.9%). At a median follow-up of 8.5 months (interquartile range: 3.2, 20.1) for all pts with 1LT, 59.6% (n = 237) had died. During follow-up for all treated pts, 78.6% (n = 313) received erythrocyte or platelet transfusion support with a mean number of unique transfusion service dates per patient of 12.3 (standard deviation: 15.9), and 38.9% (n = 155) received colony-stimulating factors.

Conclusions: Overall, the majority of AML pts who are ≥60 years of age are treated with C-IC. Age ≥75 years may influence choice of 1LT between HMAs vs IC. More research is needed to evaluate other factors in therapy selection and prognosis for the elderly AML population.

1010P Event free survival at 24 months: A new endpoint in diffuse large B-cell lymphoma

B. Cantos, J.C. Sanchez, V. Calvo de Juan, M. Mendez Garcia, C. Maximiano Alonso, D. Perez Callejo, F.F. Franco, L. Gutierrez Sanz, A. Gonzaga López, B. Nuñez, M. Provencio Pulla

Medical Oncology, Hospital Puerta de Hierro Majadahonda, Majadahonda, Spain

Background: The monoclonal antibody rituximab has changed the natural history of Diffuse Large B-cell Lymphoma (DLBCL). Recent data show that patients with DLBCL achieving EFS24 (event-free survival at 24 months) after treatment with immunochemotherapy have a normal life expectancy. We have explored what happens in our patient population.

Methods: We reviewed our database of patients with lymphoma treated between 1987 and 2011. We selected DLBCL patients who had received a minimum follow up of 5 years. We included 228 patients in the analysis; 100 had received rituximab based treatment and 128 did not receive any antibody. We studied the pattern of relapse and event-free survival at 12 and 24 months from diagnosis in both populations.

Results: Our data show that the pattern of relapse in DLBCL patients has changed in the post-rituximab era. There are fewer relapses (24% versus 33%, p = 0,04) but those who relapse do so earlier: 75% of relapse occur in the first two years and late relapse (after 5 years) are rare (less than 8%) in rituximab treated patients. Patients who achieve EFS12 have a better prognosis than patients who did not achieve it (80% OS 5 years versus 15%, p < 0,001) but patients who achieve EFS24 have a very good prognosis compared to patients who do not achieve EFS24 (p < 0,001), regardless of the treatment received (90% versus 15% OS at 5 years, p < 0,001). Comparing EFS12 and ESF24, ESF24 is a better prognostic tool to determine long term survival.

Conclusions: Most of the patients who relapse after immunochemotherapy do so early, probably linked to a different biological behavior of the tumor. Patients who achieve EFS24 have a very good prognosis. We need to perform an accurate follow up with patients in the first 2 years after diagnosis to detect early relapses and focus on studying the molecular biology of these tumours to detect differences in relapsed patients. Follow up after 5 years from diagnosis will detect only a small account of relapses and probably will not impact on survival.

1011P Interpreting progression-free survival and overall survival data in biosimilar clinical studies: considerations based on a recent rituximab biosimilar study

J. Amersdorffer[1], Y. Li[2], S. Alexandrova[2], A. Zubel[1], E. Sasse[1], H. Mellstedt[3]

[1]Medical Affairs, Hexal AG, Holzkirchen, Germany, [2]Biostatistics, Sandoz Inc., Princeton, USA, [3]Department of Oncology-Pathology, Karolinska University Hospital Solna, Stockholm, Sweden

Background: Oncology trials often report data on progression-free survival (PFS) or overall survival (OS), but such endpoints are prone to be less sensitive than short-term overall response (ORR) for confirming biosimilarity when long median PFS or OS are expected. We outline considerations when interpreting survival data with a sensitivity analysis from a recent rituximab biosimilar study.

Methods: A confirmatory phase III study compared the efficacy of the EMA approved biosimilar rituximab, GP2013 (n = 314) with reference rituximab (R) (n = 315) in patients with previously untreated, advanced follicular lymphoma. Patients received CVP chemotherapy during induction and responders received GP2013 or R maintenance monotherapy. Primary endpoint was equivalence of ORR at the end of induction. Secondary endpoints included PFS and OS, and hazard ratios (HRs) were estimated by a Cox proportional hazard model, with treatment allocation as the main effect and FLIPI score as a stratification factor.

Results: As of 31 Dec 2016, the median follow-up was 23.6 and 24.2 months for GP2013 and R, respectively. Equivalence criteria for the primary endpoint were met, confirming biosimilarity. For time-dependent endpoints, there was a high level of censoring without PFS (~70%) or OS (~90%) events. Median PFS or OS could not be estimated. HRs for PFS and OS were 1.31 (90% CI [1.02–1.69]) and 0.77 (90% CI [0.49, 1.22]), respectively. Kaplan-Meier analysis showed that PFS survival curves diverged between 12–24 months yet ran parallel outside this period, violating the proportional hazards assumption of the Cox proportional hazard model. Complete response (CR) rates were similar between treatments at all time points, including 33 months.

Conclusions: Small sample size, low event rate, data immaturity and/or other aspects of study design can subject survival analyses to chance findings and decrease sensitivity for biosimilarity assessments. In this study, HRs for PFS and OS had opposite directions and CR rates between treatments were similar across time, emphasizing these challenges. The PFS and OS results should be interpreted with caution as they may not reflect a difference, or lack thereof, between treatments.

1012P Role of prephase treatment prior to definitive chemotherapy in diffuse large B -cell lymphoma (DLBCL)

A. Rudresha[1], V. Asati[1], L.C. Kuntegowdanahalli[1], G. Babu[1], D. Lokanatha[1], L.A. Jacob[1], S. Babu[1], C.S. Premalata[2], L. Rajeev[1], K.N. Lokesh[1], S.C. Saldanha[1], R. Patidar[1]

[1]Medical Oncology, Kidwai Memorial Institute of Oncology, Bangalore, India, [2]Pathology, Kidwai Memorial Institute of Oncology, Bangalore, India

Background: Treatment related toxicity during the treatment of Diffuse large B cell lymphoma (DLBCL) is highest during the initial phase of treatment (First cycle effect). The toxicity can be febrile neutropenia, tumour lysis syndrome, deterioration in performance status and death. Introduction of prephase treatment is popular method to reduce this toxicity. This study was undertaken to evaluate the benefit of prephase treatment in Indian patients.

Methods: This was a prospective study carried out at Kidwai memorial institute of oncology Bangalore, India from July 2015 to December 2016. The newly diagnosed patients of DLBCL, age>18years, stage II-IV were enrolled in study. Written consent taken from all patients before starting chemotherapy (CHOP/R-CHOP). Out of 50 patients, 25 patients received prephase treatment consisting of vincristine (1 mg) on -6th days and prednisone 100 mg daily for 7 day (-6 day to day 0). All patients received CHOP/R-CHOP chemotherapy on day 1. ECOG performance status, nadir absolute neutrophil count (ANC) on day 10, febrile neutropenia, and hospitalization, requirement of

antibiotics and mortality within 30 days of chemotherapy were compared in both the groups. Patients above 60 years received prophylactic growth factor.

Results: The median age of the patients were as 50.5 years (Range 20-74 years). Thirty patients were male and twenty patients were female. Twenty patients (40%) had stage 2 disease while the other 60% patients had stage 3 or stage 4 disease. Most of the patients (96%) attanined ECOG performance status of 0 or 1 after prephase treatment. The incidence of any grade neutropenia on D10 of chemotherapy in experimental arm was 44% (88% in control arm) while the grade 3/4 neutropenia was 12% (48% in control arm). Febrile neutropenia in the experimental arm was lower (12%) as compared to control arm (32%) (p value<0.05). The mortality within 30 days remains same (4%), in both the arms.

Conclusions: Prephase treatment significantly improves the performance status of DLBCL patients prior to receiving chemotherapy (CHOP±Rituximab). First cycle effect, including decrease chances of febrile neutropenia and improvement in nadir ANC are impressive benefits of prephase treatment.

1013P The role of FDG-PET/CT in detecting bone marrow involvement in diffuse large b-cell lymphoma

A. Bulbul[1], E.A. Mino[1], S. Chouial[1], A. Bautista[1], A. Mustafa[2], H. Abboud[3], S. Rashad[4], T. Braik[1], K. Masoud[1]

[1]Hematology/Oncology, Kymera Independent Physicians, Carlsbad, NM, USA, [2]Anesthesiology, Acharya Shri Chander College of Medical Sciences and Hospital, Jammu, India, [3]Medicine, Windsor University, Monee, IL, USA, [4]Medicine, All Saints University of Medicine, Roseau, Dominica

Background: The sensitivity and prognostic value of FDG-PET/CT in the staging of Diffuse Large B-Cell lymphoma (DLBCL) remain unclear. PET/CT provides a high level of accuracy for identifying focal skeletal marrow disease in Hodgkin's lymphoma (HL). Whether the omission of staging Bone Marrow Biopsy (BMB) would change treatment strategy of DLBCL is not known.

Methods: We retrospectively studied 114 patients with DLBCL from three rural community oncology practices in New Mexico between January 96- September 2016. Patients receiving BMB and PET/CT were included. Descriptive statistics and Chi-square methods were used to evaluate associations.

Results: Mean age at diagnosis was 66 years (23-92), 54% were males, 82% received RCHOP therapy. Out of 114 patients, 27 (23%) patients did not have a staging BM biopsy. The sensitivity of PET/CT scan was 73% and Specificity 87%. Positive predictive value (PPV) 50% and Negative predictive value (NPV) 95%. Patients with positive focal PET/CT were more likely (50% vs 5%), χ^2 (1, N = 74) = 19.9, (p < 0.001) to have a positive BMB in comparison those with negative PET/CT scan. There was correlation of bone marrow involvement with clinical stage IV (31%), III (13%), II (5%), I (0%), χ^2 (1, N = 74) = 10.14, (p = 0.02) and IPI score: High (14%), Int-High (40%), Low-Int (10%), Low (3%) %), χ^2 (1, N = 74) = 10.7, (p = 0.019). Cytopenia was not associated with BM involvement χ^2 (1, N = 74) = 1.37, (p = 0.242). The 5-year OS for PET/CT positive vs BM involved (38% [95%CI 14-61] vs 31% [95CI% 5-56] p = 0.69), and PET/CT negative vs BM uninvolved patients (44% [95%CI 32-55] vs 50% [95%CI 38-61] p = 0.46) were not statistically different.

Conclusions: PET/CT is valuable as having a high negative predictive value for detection of focal marrow involvement in DLBCL. This may help avoid BMB, especially if clinically early stage disease. Cytopenia did not predict marrow involvement. The long-term prognostic value of PET/CT is similar to that obtained by a bone marrow biopsy.

1014P Evaluation of various prognostic scores and impact of cell of origin on survival in limited stage DLBCL: retrospective study

M.S. Rauf, S. Akhtar, T. AhmedM. Elhassan, Q. Shaikh, F. A. Almugbel, M. N. Zahir, N. Bakshi, I. Maghfoor

Medical Oncology, King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia

Background: Utility of International Prognostic Index (IPI) as standard prognostic tool in limited stage diffuse large B-cell lymphoma (Li DLBCL) has been controversial. Variety of other prognostic scores have been proposed including Miller's stage modified IPI (M-IPI), NCCN-IPI (N-IPI), and stage adjusted IPI (St-IPI). We aimed to compare various prognostic scores. In addition, data is not clear regarding impact of cell of origin (COO) i.e. Germinal Center (GCB) and non-GCB COO in patients with Li DLBCL. Our aim is to identify difference in outcomes by COO.

Methods: All patients with newly diagnosed non-bulky Li DLBCL treated with standard first line CHOP±R chemotherapy with or without radiation from 1987 to 2013 were eligible. Discrimination ability of each prognostic model was also tested using bagging model. Model performance was evaluated using sensitivity, accuracy and Area under the Receiver Operating Characteristic Curve (AUC) and model which scored highest AUC, was selected. Survival times and survival proportions were estimated using the Kaplan Meier survival curves. In addition, we applied Hans's algorithm to study prognostic impact of COO.

Results: The median age of the 276 included patients was 47 years. 32% received limited combine modality treatment while 68% patients received extensive chemotherapy. Median follow up was 4.9 years. M-IPI was the best prognostic indicator of both PFS (AUC=0.67) and OS (AUC=0.72) when compared with IPI, N-IPI and St-IPI. Immunohistochemistry data of 152 patients treated homogeneously was available to determine COO. GCB phenotype seen in 61%. There was no significant difference in PFS (p = 0.6) or OS (p = 0.4).

Table: 1014P Comparison of prognostic models for Li DLBCL

Risk model	Sensitivity		F-statistical		AUC	
	PFS	OS	PFS	OS	PFS	OS
St-IPI	0.92	0.91	0.69	0.68	0.59	0.58
IPI	0.47	0.51	0.57	0.60	0.61	0.64
N-IPI	0.81	0.84	0.66	0.68	0.58	0.6
M- IPI	0.73	0.6	0.68	0.64	0.67	0.72

Conclusions: Our data identified that in limited stage non-bulky DLBCL, M-IPI is more robust tool for outcome prediction with better power for risk stratification in the CHOP±R as compare to other prognostic models. There was no significant difference in PFS or OS for patients in the GCB and non-GCB limited stage non-bulky DLBCL.

1015P The prognostic impact of serum albumin and absolute neutrophil count in patients with newly diagnosed diffuse large B-cell lymphoma

B. Spassov, D. Vassileva, G. Arnaudov, S. Nikolov, G. Mihaylov, G. Balatzenko, M. Guenova

Clinical Hematology, Specialized Hospital for Active Therapy of Hematological Diseases, Sofia, Bulgaria

Background: Patients (pts) with diffuse large B cell lymphoma (DLBCL) are treated with immunochemotherapy and are generally stratified by the NCCN International prognostic index (NCCN-IPI). It has been reported that some host-related factors such as nutritional status (NS) and systemic inflammation (SI) were associated with the outcome of pts with solid tumors. However, data regarding their prognostic contribution in DLBCL are limited. Therefore, we decided to access the possible prognostic significance of some laboratory markers associated with NS/SI in DLBCL pts.

Methods: We retrospectively reviewed the clinical outcome of 251 R-CHOP treated DLBCL pts. A receiver operating characteristic (ROC) curve analysis was used to illustrate the best cut off values of the serum albumin (SA), beta-2-microglobulin, absolute neutrophil (ANC), lymphocyte, monocyte and platelet counts, and hemoglobin level to predict overall survival (OS) by Kaplan-Meier method in our data set.

Results: The estimated 5-year OS of the whole group was 61%. The multivariate analysis showed that only SA and ANC remained independent predictors of OS by applying the best cut off values determined by ROC - 39.4 g/L and 5.33 x 10^9/L, respectively. Furthermore, the combination of dichotomized SA and ANC generated a prognostic index (SA/ANC PI) that stratified patients into 3 different risk groups: low risk [LR] (SA > 39.4 g/L and ANC ≤5.53 x 10^9/L), intermediate risk [IR] (SA > 39.4 g/L or ANC ≤5.53 x 10^9/L), and high risk [HR] (SA ≤ 39.4 g/L and ANC >5.53 x 10^9/L). The 5-year OS for LR, IR and HR pts was 86%, 65.7% and 22.5% (P < 0.001), respectively, and our PI was independent of the NCCN-IPI.

Conclusions: Our data showed that SA/ANC PI could predict OS in DLBCL pts and may present a reliable, convenient and sensitive predictor to identify pts with poor prognosis in addition to NCCN-IPI.

1016P Autologous stem cell transplantation (ASCT) is safe and effective for the treatment of non-hodgkin lymphoma (NHL) in an elderly population of patients over 65 years old: A single center experience

M.P. Tardy[1], J. Viotti[2], A. Boscagli Melaine[1], A. Thyss[3], F. Peyrade[4], L. Gastaud[1]

[1]Medical Oncology, Centre Anticancer Antoine Lacassagne, Nice, France, [2]Biostatistics, Centre Anticancer Antoine Lacassagne, Nice, France, [3]Medical Oncology, Centre Antoine Lacassagne, Nice, France, [4]Onco-hematology, Centre Antoine Lacassagne, Nice, France

Background: High-dose chemotherapy followed by ASCT is a widely used treatment for agressive or recurrent NHL for young patients (pts). Limited data are available on the feasibility and the results of this strategy for older pts, who are often excluded from agressive treatment. This study aimed at comparing pts ≥65 years old(yo) to a younger pts' population in term of tolerance, safety and results of ASCT.

Methods: We did a retrospective study in one center in France. We included every consecutive pts treated by ASCT for NHL from May 2007 to January 2016. We collected data on the characteristics of the pts and their disease, previous treatments, and tolerance and outcome after ASCT.

Results: 48 pts ≥ 65 yo (mean: 49.5) and 129 < 65 yo (mean: 68.7) at the time of the transplant were included. The most common histology was diffuse large B cell lymphoma ($p = 0.205$). There were only 2 differences between the 2 groups. First, the number of pts with comorbidities was higher in the elderly population ($p = 0.016$), especially cardio-vascular ($p < 0.001$). Secondly, the moment of the ASCT was mainly on first line for young pts *vs* at the time of relapse for older pts ($p < 0.001$). At the time of ASCT, in both groups ($p = 0,306$), a majority of patients were in complete response. No differences were found between the 2 groups for the conditionning regimen, number of $CD34^+$ cells reinjected, number of transfusion, weight loss, length of the hospital stay and duration of aplasia. There were no differences of grade ≥3 toxicities (hematologic, infections, digestive, renal, cardiac, mucositis.) for both groups ($p = 0,116$). Treatment Related Mortality (death within 30 days following ASCT) was: 2% for pts ≥65yo vs 3.9% ($p = 1$). The mean follow-up time was 56 months for young pts vs 77 months for older ($p < 0.001$). The specific survival was similar between the 2 groups, 65% for the young pts group vs 72% for the older ($p = 0.63$) 3 years after ASCT.

Conclusions: High-dose chemotherapy followed by ASCT is as safe and effective in a population of pts ≥65 yo compared to a younger population. Agressive treatment could be considered earlier in the management of elderly pts and should not be excluded only depending on the age of the patient.

1017P Phenotypic and functional characterization of tumor infiltrating lymphocytes (TIL) grown from non-hodgkin lymphoma tumors: Implications for the development of novel therapies for lymphoma

L. Karyampudi[1], A. Gokuldass[2], M. Blaskovich[2], M. Fardis[3], M.T. Lotze[2]

[1]Translational Research, Lion Biotechnologies, Tampa, FL, USA, [2]Translational Research, Lion Biotechnologies, Tampa, FL, USA, [3]Translational Research, Lion Biotechnologies, San Carlos, CA, USA

Background: Cell therapy with TIL is an effective treatment with acceptable safety profile for advanced metastatic melanoma patients. TIL products can be centrally manufactured for broad clinical application. Adoptive cell therapy with TIL involves collection of autologous lymphocytes from the tumor via surgical resection, ex vivo expansion of TIL, lymphodepletion of the patient prior to infusion of TIL, followed by infusion of TIL and treatment with IL-2. Here, we present findings related to expanding TIL directly from lymphoma.

Methods: Using methods for TIL isolation and growth developed at Lion, we expanded TIL from 5/5 lymphoma (1 MCL, 3 follicular, 1 DLBCL) with Interleukin 2 for 11-14 days and subsequent rapid expansion for 14 days using mitogenic anti-CD3 antibody and irradiated allogeneic PBMC.

Results: TIL were generated from all 5 lymphoma tumors with a maximum expansion index of 680-fold, significantly higher than previously reported. Mean CD3+ T cell population was 95% (vs 75% previously reported). As with TIL expansion from melanoma, we observed a marked relative increase in effector memory cells in lymphoma TIL. A significant increase in TEMRA ($p = 0.0013$; CD4, CD8) and CD28+CD4+ ($p = 0.008$) subsets was observed in lymphoma compared with melanoma TIL cultures. Bioluminescent Redirected Lysis Assay (BRLA) to assess TIL cytolytic activity at 4 hrs ranged from <1-6 LU_{50} in lymphoma TIL compared to melanoma TIL (11-75 LU_{50}, 4hrs). ELISpot and ELISA analysis revealed IFN-γ production by lymphoma TIL comparable to that of melanoma TIL. Consistent with the observation that lymphoma-reactive T-cells are primarily TH2 and TH17, nanostring analysis revealed that lymphoma TIL expressed higher levels of RORC and IL17A than melanoma TIL.

Conclusions: We demonstrate here the feasibility of growing TIL from lymphoma that have effector functions comparable to that of melanoma TIL. These findings serve as a rationale for considering TIL cell therapy for patients with lymphoma.

1018P International prognostic scores (IPS-7, IPS-3 and IPS-3 new) for prediction of FFS and OS in cases with Hodgkin Lymphoma. Which is more practical and accurate?

S. Paydas[1], M. Dogan[2], V. Ercolak[3], G. Seydaoglu[4]

[1]Medical Oncology, Cukurova University, Adana, Turkey, [2]Medical Oncology, Ankara Numune Hospital, Ankara, Turkey, [3]Medical Oncology, Mersin Hospital, Mersin, Turkey, [4]Biostatistics, Cukurova University, Adana, Turkey

Background: Hodgkin Lymphoma (HL) is one of the curable malignant diseases. International prognostic score7 (IPS-7) was a valuable scoring system predicting FFP and OS in cases with HL. A simpler prognostic score: IPS-3 has been proposed 2 years ago and in this scoring system age and stage were found to be significant for FFP and age, stage and hemoglobin were found to be significant for OS. Here we evaluated IPS-3 new system in cases with HL.

Methods: 364 patients with HL treated by ABVD have been included in this study. Two thirds of the patients had nodular sclerosing type HL, 76 had mixed cellularity type. Median follow up was 71 months.

Results: Seven clinical parameters on the basis of the IPS-7 determined to be associated with adverse clinical outcome were evaluated. The prognostic ability of seven IPS factors was evaluated for both FFP and OS. A new 3-factor prognostic score (IPS-3 new) was constructed utilizing factors that were significant in multivariate Cox models: age>45 years, stage IV disease and lymphocytopenia were found to be independent factors. Thus IPS-3-new was constructed utilizing these 3 factors that were significant in multivariate Cox models. Lymphocytopenia was used instead of hemoglobin <10.5g/dl that has been recommended for IPS-3 score. The prognostic performance of IPS-7, IPS-3 and IPS-3-new was evaluated. Patients classified into 3 risk groups low, intermediate, and high risk. Specifically, for cases that were re-classified to different risk group by IPS-3-new, the observed FFP and OS estimates were compared to survival rates predicted by IPS-7 and IPS-3 respectively. An alternative prognostic index, the IPS-3-new, was constructed using age, stage, and lymphocytopenia (FFP: $p = 0.0001$ and OS: $p < 0.0001$).

Conclusions: The IPS-3 new covering lymphocytopenia instead of anemia besides age and stage factors on risk prediction for FFS and OS may provide a more accurate and reliable framework for risk assessment for the patients with HL.IPS-3 new is important due to the predictive property of lymphocytopenia in HL in immunotherapy era.

1019P Evaluation of indoleamine 2,3-dioxygenase expression (IDO), transforming growth factor beta (TGF-β) and interleukin 13 (IL13) expression on clinical outcome in patients with Hodgkin's lymphoma

T. Skrypets[1], O. Novosad[1], Y. Pastushenko[1], O. Skachkova[2], O. Gorbach[2], N. Khranovska[2], I. Kryachok[1]

[1]Oncohematology, National Cancer Institute of the MPH Ukraine, Kiev, Ukraine, [2]Laboratory of Experimental Oncology, National Cancer Institute of the MPH Ukraine, Kiev, Ukraine

Background: Nowadays, patients with Hodgkin's lymphoma (HL) have a high cure rate. However, approximately 20% pts have relapse or progressive disease. The main histological feature in HL is presence by Hodgkin Reed-Sternberg (HRS) cells. HRS cells produce a diversity of cytokines and chemokines. There is still a limited information of prognostic role expression of cytokines in patients with HL. We assessed the impact on clinical outcome of the IDO, TGF- β and IL-13 expression in patients with HL.

Methods: 79 patients (pts) with HL were included in this study (median age: 41, range: 18-65 years; males: 26, females: 53). Early stages of HL have 53.3% and 46.7% pts had advanced stages. Patients were treated with ABVD or BEACOPP (14/esc) and radiation therapy. CR/PR was achieved in 86.1% of patients. 13.9% of pts had relapse or disease progression during the therapy. mRNA expression levels of IDO, TGF-β, IL-13 were measured in fresh pre-treatment tumor tissue specimens from HL patients using real-time qPCR analysis.

Results: 25 pts (31.6%) had IDO positive expression (IDO^+) and 54 (65.4%) pts was IDO negative (IDO^-). Multivariate analysis showed that IDO^+ expression correlated with worser EFS rate with HRs of 10.7 [95% confidence interval(CI) 0.4–0.6, $p = 0.01$], especially in 3-years EFS in IDO^+ males comparing to IDO^+ females (61% vs 71%, $p < 0,05$). We did not find significant corellation between such signs as B-symptoms, stages, response reate and IDO expression ($p = 0.14$). Expression of IL13 and TGF was performed in 69 pts. We divided patients in two groups: $IL13^+$ (high expression) vs. $IL13^-$ (low expression) and $TGF\text{-}\beta^+$ (positive expression) vs $TGF\text{-}\beta^-$ (negative expression). Number of pts with $IL13^+$ were 34 (49.3%) and 35 (50.7%) with $IL13^-$, while 47

pts were TGF-β^+ were (68.1%) and 22 pts (31.9) had TGF-β^- expression. It was found, that patients with high IL13 expression had worse EFS and OS rate compared to pts with low IL13 expression. 5-year EFS in patients with $IL13^-$ was 98% vs 65% in $IL13^+$ ($p < 0,05$), as well as 5 year OS in $IL13^-$ and $IL13^+$ groups was 98% and 87%, respectively ($p < 0,05$). Patients with TGF-β^- expression had better 5-years OS: 99% in pts with TGF-β^- vs. 87% TGF-β^+ pts ($p < 0.05$). We also analyzed two groups of double-positive (IDO^+/TGF-β^+) and double-negative(IDO^-/TGF-β^-) and three groups of pts with $TGF^+/IL13^+$ vs $TGF^-/IL13^-$ vs $TGF^+/IL13$ as potential prognosis biomarkers. ROC-analysis showed that response rate in pts with IDO^-/TGF-β^- was higher compared to IDO^+/TGF-β^+ pts ($p = 0.0001$). 5-years EFS rate was lower in pts from TGF-β^+/IL13+ group comparing to $TGF^-/IL13^-$ and $TGF^+/IL13^-$ groups and was 63% vs 99% vs 98% respectively ($p < 0.05$).

Conclusions: Our data showed that IDO, TGF-β and IL13 expressions have a role in predicting clinical outcome in pts with HL. Positive expression of IDO, TGF-β and high expression level of IL13 could be considered as a negative prognostic marker. Significantly worser outcome had pts with positive expression of two cytokines comparing with patients, who had only one positive marker.

1020P Clinical impact of atypical phenotypes in adult t cell lymphoma/leukemia among HTLV carriers

D. Enriquez Vera[1], G. De la Cruz Ku[2], J. Haro Varas[3], P. Rioja[1], Z. Morante Cruz[3], N.I. Valdiviezo Lama[1], R. Luque[2], E. Eyzaguirre[2], M. Lujan[2], A. Saavedra[2], M. Mayuri Monsefu[1], G. Ferreyros[1], M. Retamozo Alvarado[1], J. Vidal Ayllón[1], S. Neciosup Delgado[1], L.A. Mas Lopez[1]

[1]*Medical Oncology, Instituto Nacional de Enfermedades Neoplasicas - INEN, Lima, Peru,* [2]*Universidad Cientifica del Sur, Lima, Peru,* [3]*Medical Oncology, INEN, Lima, Peru*

Background: ATLL represents a fatal disease epidemiologically linked to chronic infection with human T-cell lymphotropic virus type 1 (HTLV1). The diagnosis is classically described based on morphology, immunophenotype (typically CD7, CD8, CD56, ALK, EBV and PAX5 negatives). Our aim was to describe characteristics and compare outcomes between patients with classical ATLL and those with mature T-cell lymphoma and HTLV1 infection (atypical ATLL).

Methods: We reviewed 276 medical records from pts with HTLV1 infection and T-cell lymphomas diagnosed between 2008-2014 at the Instituto Nacional de Enfermedades Neoplasicas (Peru). Groups were divided based on presence of classical characteristics of ATLL, outcomes and survival differences were calculated by log-rank test in the univariate analysis and Cox regression analysis for prognostic factors.

Results: From 276 pts, 126 (45%) had classical ATLL phenotype and 150 (54%) were atypical. Mean age was 56 years and 19% were <45y, tuberculosis was presented in 32 pts (11.6%). Pts with classical disease had shorter length of disease (3.5 versus 5.6 months, $p = 0.01$), more B symptoms (51.6% vs 38.7%), bone marrow (51 vs 28%) and peripheral blood involvement (54 vs 32%) than pts with atypical ATLL. According to Shimoyama classification, acute subtype was most common in classical ATLL (46%), as Lymphoma most frequent subtype in atypical ATLL (54%). Most pts received a CHOP-based chemotherapy (71%) and overall response were 28% for classical ATLL (CR:15%, PR:12%) and 41% for atypical ATLL (CR:25%, PR:16%). At 5 years follow-up, median PFS were 2 months in classical and 4 months in atypical ATLL (HR: 1.30, 95%CI [1.02-1.67], $p = 0.036$), and median overall survival (OS) were 4 and 7 months for classical and atypical ATLL respectively (HR: 1.51, 95%CI [1.17-1.95], $p = 0.002$). In multivariate analysis, high levels of calcium and LDH, status performance and neutrophil-to-lymphocite ratio were independent prognostic factors for relapse and death.

Conclusions: It seems that there are atypical presentations of adult T cell lymphoma/leukemia with slightly better response to chemotherapy and survival, further studies with integration of viral RNA to neoplastic tissues are needed to confirm this category.

1021P Evaluation of the PI3K pathway in peripheral t-cell lymphoma

S.T. Lim[1], M-L. Nairismägi[1], S.H. Tan[2], E.E. Thit[3], O. Politz[4], N. Liu[4], C.K. Ong[1]

[1]*Division of Medical Oncology, National Cancer Centre Singapore, Singapore,* [2]*Division of Clinical Trials and Epidemiological Sciences, National Cancer Centre Singapore, Singapore,* [3]*SingHealth Tissue Repository and Advanced Molecular Pathology Laboratory, Singapore Health Services, Singapore,* [4]*TRG-Oncology, Bayer AG, Berlin, Germany*

Background: Peripheral T-cell lymphomas (PTCL) are a heterogeneous group of aggressive malignancies with dismal outcomes and limited treatment options. While the PI3K pathway has been shown to be activated in many B-cell lymphomas, its therapeutic relevance in PTCL is not clear. The aim of this study was to investigate the expression and activation of the signaling molecules in the PI3K pathway in each subtype of PTCL and to identify the potential therapeutic options for clinical testing.

Methods: The expression of PI3Kα, PI3Kβ, PI3Kγ, PI3Kδ, AKT1, pAKT1 and PTEN was analyzed in 88 PTCL samples by immunohistochemistry. This included all major mature T- and NK-cell neoplasms. Uni- and multivariate analyses were also performed using the expression and patients' clinical data.

Results: Staining for PI3Kα and AKT1 was positive in 86 (98%), PI3Kδ in 85 (97%), PI3Kβ in 79 (90%), PI3Kγ in 50 (57%) and pAKT1 in 45 (51%) samples. No PTEN staining was observed in 9 (10%) cases and the expression was weak in 70 (80%) samples. There were no correlations between expression and PTCL subtype. Patients with positive pAKT1 had higher IPI score ($P = 0.004$) and higher stage ($P = 0.02$). Loss and low expression of PTEN were associated with older age at diagnosis ($P = 0.02$). In the univariate analysis, high PI3Kα, older age, high IPI and high ECOG score were significantly associated with inferior OS and PFS ($P < 0.05$). In addition, low PI3Kδ (in contrast to PI3Kα), male gender and elevated LDH were also associated with worse PFS ($P < 0.05$). The median OS of patients with low PI3Kα was 25 months (95% CI: 14.8-67.0 months) compared to 11 months (95% CI: 1.8-16.3 months) in patients with high PI3Kα. For PFS, the median survival was 11 months (95% CI: 8.0- 17.6 months) for patients with low PI3Kα and 4 months (95% CI: 1.1-8.6 months) for patients with high PI3Kα. PI3Kα, age and IPI, and PI3Kα, gender, ECOG score and stage remained independent prognostic factors for OS and PFS, respectively, in the multivariate analysis ($P < 0.05$).

Conclusions: All 88 samples demonstrated at least partial activation of the PI3K pathway. High PI3Kα expression was an independent poor prognostic factor for both OS and PFS. This study provides evidence that targeting the PI3K pathway, particularly inhibition of PI3Kα, could be a promising approach for the treatment of PTCL.

1022P Safety and tolerability of chemotherapy (CT) containing high doses of methotrexate (HD-MTX) and cytarabine (Ara-C) in patients with primary central nervous system lymphoma (PCNSL) and hepatitis B virus (HBV) infection

T. Calimeri[1], P. Lopedote[1], M. Repetto[1], A. Vignati[1], M. Sassone[1], C. Cecchetti[1], S. Perrone[1], M. Foppoli[1], G. Ciboddo[1], S. Girlanda[1], J. Peccatori[2], A. Chiara[3], M. Memoli[4], A. Ferreri[1]

[1]*Unit of Lymphoid Malignancies, Department of OncoHematology, IRCCS San Raffaele, Milan, Italy,* [2]*Hematology Unit, Dept. of Onco-Hematological Medicine, IRCCS San Raffaele, Milan, Italy,* [3]*Radiotherapy URadiotherapy Unit, Department of OncoHematology, IRCCS San Raffaele, Milan, Italy,* [4]*Immunopathology and Advanced Medical Care, IRCCS San Raffaele, Milan, Italy*

Background: HBV reactivation is a serious complication of some anticancer therapies. Preliminary studies suggested high rates of HBV reactivation, with fatal outcome, in pts with PCNSL treated with standard HD-MTX-based CT. Risk of HBV reactivation is further increased by the use of Rituximab (Rtx), which significantly improves efficacy of CT in PCNSL. Hence, HBV-positive pts are usually excluded from prospective trials, with a negative effect on accrual, and are treated with less intensive therapies, resulting in lower cure rates. Herein, we report the incidence of HBV infection and reactivation in a mono-institutional series of PCNSLs treated with modern strategies.

Methods: HIV-negative pts with newly diagnosed PCNSL treated with CT containing HD-MTX and Ara-C ± rituximab at our Institution, from 2010 to 2016, were analyzed to establish incidence of HBV infection, hepatotoxicity and treatment-related viral reactivation.

Results: 48 pts (median age 58, range 29–76) were considered. Eight (17%) pts had "resolved" HBV infection (negative HBsAg but positive anti-surface [anti-HBs] or anti-core [anti-HBc] Antibodies), one (2%) pt had active infection. HBV prophylaxis with lamivudine was indicated in 3/8 pts with resolved HBV. The pt with active infection was treated with entecavir. Induction comprised HD-MTX plus Ara-C in 2 pts, HD-MTX, Ara-C and Rtx in 2, and HD-MTX, Ara-C, thiotepa and Rtx in 5 (MATRix). Transient grade 1-2 elevation of hepatic enzymes (AST, ALT, GGT) was observed in all pts; grade 3-4 was recorded in 17/39 (44%) HBV-negative pts and in 5/9 (56%) HBV-positive pts (Fisher exact; $p = 0.71$). Eight out of 9 HBV-positive pts received the 4 planned CT courses without dose reductions due to hepatotoxicity; six pts achieved a CR and received consolidation (WBRT 2, ASCT 3, lenalidomide maintenance 1). At a median follow-up of 27 months for the whole series (12-88), no pt experienced HBV reactivation during first-line treatment, 5 pts remain relapse-free.

Conclusions: This study suggests that MTX-Ara-C-based therapy, MATRix regimen, in particular, can be safely used in PCNSL pts with HBV infection, without impaired life expectancy.

1023P Evaluation of safety, tolerability and efficacy of temsirolimus in patients (pts) with relapsed or refractory mantle cell lymphoma (rel/refr MCL) in routine clinical practice

M. Dreyling[1], G. Hess[2], G. Krekeler[3]
[1]Medizinische Klinik und Poliklinik III, Klinikum der Universität München-Grosshadern, Munich, Germany, [2]III. Medizinische klinik, Universitätsmedizin der Johannes Gutenberg-Universität, Mainz, Germany, [3]Medical, Pfizer - Germany, Berlin, Germany

Background: Temsirolimus (TEM), an mTOR inhibitor, is approved in the EU for the treatment of pts with rel/refr MCL. A pivotal study demonstrated significantly longer progression free survival (PFS) with TEM (175 mg weekly for 3 weeks followed by 75 mg weekly) in rel/refr MCL pts compared to investigator's choice therapy (4.8 vs 1.9 months (mo); P = .0009). To evaluate the safety profile and efficacy of TEM in this rare tumor entity, further data collection in an unselected routine clinical patient population is useful.

Methods: A German multicenter registry for rel/refr MCL pts treated with TEM was started in Germany in Oct 2009 with regulatory and ethic committeés approval. Objectives are the evaluation of the safety profile, tolerability and anti-tumor activity of TEM as well as patient's profile including comorbidities, characteristics, and the sequence of systemic therapies.

Results: From Oct 2009 to Feb 2017, 55 pts were recruited in 30 study sites. Baseline characteristics are available for 55 pts: 69.1% male; median age 74.4 years; bone marrow involvement in 38.2% of the pts; ECOG PS (n = 54) 0 or 1 in 83.3%, ECOG PS 2 in 16.7%. According to MIPI score (n = 53), 20.8%, 34.0%, and 45.2% are classified as low, intermediate, and high risk at the time of enrollment. Median number of prior therapies is 2 with 43.6% treated in $\geq 4^{th}$ line. Most common drug-related toxicities of any grade (incidence $\geq$ 15%) are observed in following categories: blood/lymphatic system disorders (49.1%), gastrointestinal disorders (27.3%), general disorders (21.8%), and skin/subcutaneous tissue disorders (18.2%). Efficacy analyses are available for 39 assessable pts with an objective response in 30.8%, a clinical benefit (CR, PR, MR and SD) in 59.0% and PD in 41.0% of the pts. Median PFS for all pts is 3.6 mo. For the subgroup of pts treated with TEM in 2^{nd} and 3^{rd} line PFS is 3.3 mo, for $\geq 4^{th}$ line pts 4.9 mo.

Conclusions: The registry was started to evaluate the safety and efficacy of TEM in pts with rel/refr MCL in routine clinical practice. In this comparatively poor-prognosis patient population, TEM showed a predictable, manageable tolerability profile. Efficacy parameters were consistent with published phase III data.

1024P Clinical impact of FISH analysis in extramedullary plasmacytomas

H.A. Jung[1], C.H. Maeng[2], J.H. Jang[3], C.W. Jung[3], K. Kim[3]
[1]Division of Hematology-Oncology, Department of Medicine, Dongtan Sacred Heart Hospital, Hwanseong-si, Republic of Korea, [2]Division of Hematology-Oncology, Department of Medicine, Kyoung Hee University school of Medicine, Seoul, Republic of Korea, [3]Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Seoul, Republic of Korea

Background: Extramedullary plasmacytomas (EMPs) is a rare presentation of plasma cell neoplasm and accounts for 7 to 15% of all plasma cell neoplasm. Fluorescence in-situ hybridization (FISH)-detected abnormalities, including del(17p), del(13q), and t(4;14), have been associated with inferior prognosis. However, there are few data about the prognostic significance of cytogenetic abnormalities in multiple myeloma (MM) patients with extramedullary plasmacytoma (EMP). This study aimed the clinical features, FISH data and outcome of patients with EMPs.

Methods: The data were collected from 70 patients with EMPs, retrospectively. We excluded skeletal plasmacytomas. The clinic-pathologic variables and treatment outcome retrospectively reviewed.

Results: Seventeen patients had solitary EMPs. Most common site of solitary EMP was nasal cavity and most patients received radiotherapy (n = 7) and surgery (n = 6). A total of 905 patients with newly diagnosed MM were included, and 53 patients (8.7%) had EMPs at diagnosis. Thirty-three patients had conventional FISH data. By conventional cytogenetic analysis and FISH, 35.8% (19/53) and 54.5% (18/33) patients were identified genetic abnormalities, respectively. By comprehensive cytogenetic/FISH approach, the most common genetic aberration was 1q21 amplification and/or 1p32 deletion (42.4%, 14/33), followed by -13 or del (13q) (24.3%, 8/33), del (17p) (15.2%, 5/33), IGH/FGFR3 rearrangement (15%, 2/33) and IGH/CCND1 rearrangement (12%, 2/33). Patients with initial EMPs had significantly worse overall survival compared to those without initial EMPs. Del(13q), and t (4;14) have been associated with inferior prognosis.

Conclusions: In the current study, del(13q), and t (4;14) were associated with worse survival in MM patients with EMP.

1025P Independent predictors of one year mortality in patients with primary systemic immunoglobulin light chain cardiac amyloidosis

V. Srinivasalu[1], M. Subramaniam[2], A. Shanmugam[2], A. Philip[1], A. Susan[1], R. Prabhu[3], M. Unni[3], N. Sidharthan[3], W. Jose[1], S.N V[4], H. Ahamed[2], N. Mathew[2], P. Keechilat[1]
[1]Department of Medical Oncology, Amrita Institute of Medical Sciences, Kochi, India, [2]Department of Cardiology, Amrita Institute of Medical Sciences, Kochi, India, [3]Department of Medical Oncology and Hematology, Amrita Institute of Medical Sciences, Kochi, India, [4]Department of Pathology, Amrita Institute of Medical Sciences, Kochi, India

Background: Immunoglobulin light chain amyloidosis (AL amyloidosis) is a monoclonal plasma cell proliferative disorder that is characterized by tissue deposits of misfolded insoluble κ and λ light chain derived amyloid fibrils, leading to organ dysfunction. The prognosis of patients depends on the number and severity of organ involvement, especially cardiac involvement. Nearly half of the patients with amyloidosis die within a year of diagnosis. We analysed factors predicting early mortality (within one year) in patients with systemic immunoglobulin light chain cardiac amyloidosis.

Methods: Retrospective analysis of patients between January 2007 and January 2016 from our hospital database. In patients with AL cardiac amyloidosis, cardiac involvement was defined as per American society of echocardiography (ASE) criteria. We evaluated the clinical, ECG and ECHO parameters of early relapse (ER) within one year in these cardiac AL amyloidosis patients. Log rank test was done to identify independent predictors of one year all cause mortality.

Results: Among the 72 patients (mean age 58.2 + 8.2 years, 59.7% males) of AL amyloidosis with cardiac involvement, 32 (44.4%) died within one year. Sixty five patients (90%) received melphalan/thalidomide/bortezomib/cyclophosphamide/dexamethasone based chemotherapy as a monotherapy or in combinations. Logistic regression analysis revealed NYHA Class III/IV (p = 0.024), BNP (p = 0.031), Troponin I (p = 0.042), Free light chain difference (p = 0.011) and restrictive pattern of diastolic dysfunction ($E/E^1 > 20$) to be independent predictors of all cause mortality (p = 0.021). Kaplan Meir survival analysis showed a worse prognosis in patients with $E/E^1 > 20$ (Log rank, $p < 0.001$). In addition, in patients who completed atleast 6 months of chemotherapy, a decrease in E/E^1 (survivors delta E/E^1 5.2+ 0.8, nonsurvivors 0.8+ 0.3, p = 0.001) is associated with better one year survival.

Conclusions: AL Cardiac amyloidosis carries a poor outcome. Baseline Troponin I, NYHA class III/IV, difference in free light chain, restrictive pattern of diastolic dysfunction and BNP were the independent predictors of early mortality within 1 year in patients with AL cardiac amyloidosis. In patients who completed atleast 6 months of chemotherapy, a decrease in the ECHO parameter E/E^1 is associated with better one year survival. This will help us in better prognostication of patients with AL cardiac amyloidosis.

1026P Endoscopic evaluation of acute intestinal GVHD after allogeneic hematopoietic cell transplantation?

I. Tek[1], R. Altun[2], A. Gokmen[3], E. Soydan[3], M. Kurt Yuksel[3]
[1]Medical Oncology and Bone Marrow Unit, Medicana Ankara Hospital, Ankara, Turkey, [2]Gastroenterology, Medicana Ankara Hospital, Ankara, Turkey, [3]Hematology and Bone Marrow Unit, Medicana Ankara Hospital, Ankara, Turkey

Background: Acute graft versus host disease (GVHD) is a common complication of hematopoietic cell transplantation (HCT). The exact incidence is unknown due to the difficulties in diagnosis. The gastrointestinal tract (GIT) is one of the main target organs in patients with acute GVHD. There is also lack of consensus regarding whether upper or lower GIS endoscopy is required first and the site with highest sensitivity for biopsy.

Methods: All patients (111) with suspected intestinal GVHD were evaluated with upper GIS endoscopy or both upper and lower GIS endoscopy according to presenting symptoms. Biopsies were stained using hematoxylin-eosin and evaluated by the same experienced pathologist. The presence of apoptotic bodies, crypt/glandular abscesses and crypt/glandular destruction was considered confirming findings in histologic specimen for the diagnosis of GVHD. And the criteria proposed by Washington were used for histological grading of acute intestinal GVHD.

Results: Allogeneic HCT was performed in 111 patients of whom 27 (24.3%) had developed acute GVHD. Nineteen of the 111 patients with intestinal symptoms were evaluated for intestinal involvement, and 17 were diagnosed with acute intestinal GVHD. Upper endoscopic findings had a sensitivity of 64.7%, a specificity of 50%, a positive predictive value of 91.6% and a negative predictive value of 14.2%. The diagnostic accuracy of upper endoscopy was 63.1%. Lower endoscopic findings had a sensitivity of 40% and a specificity of 0%. The diagnostic accuracy of upper endoscopy with duodenal biopsy and sigmoidoscopy was 94.1%.

Conclusions: Endoscopic findings are nonspecific in acute intestinal GVHD. There is little agreement between endoscopic findings and histopathology; thus, biopsies are

essential. In patients with intestinal symptoms after HCT, upper endoscopy with duodenal biopsy and sigmoidoscopy has an acceptable diagnostic yield for intestinal involvement.

1027P Surveillance stool culture and its association with febrile neutropenia in patients with acute leukemia (AL) undergoing induction chemotherapy

N.T. Jadhav[1], B. Dubashi[2], J. Mandal[3], S. Kayal[1], J. Pattnaik[1], P. Madasamy[1], J. Singh[1]

[1]Medical Oncology, Jawaharlal Institute of Postgraduate Medical Education and Research, Puducherry, India, [2]Medical Oncology, Regional Cancer Centre, JIPMER Jawaharlal Institute Postgraduate & Medical Research, Puducherry, India, [3]Microbiology, Jawaharlal Institute of Postgraduate Medical Education and Research, Puducherry, India

Background: Febrile neutropenia remains one of the major concerns of intensive chemotherapy and contributes significantly to morbidity, health care expenditure and mortality. Colonization of gut by MDR bacteria is regarded as a potential risk factor for subsequent infection with the same organism during febrile neutropenia. In this study, we aim to find the profile of surveillance stool culture and its association with febrile neutropenia in patients of acute leukemia undergoing induction chemotherapy.

Methods: Newly diagnosed patients of acute leukemia eligible for intensive chemotherapy were recruited for the study. Baseline stool microscopy and culture sensitivity was done to identify colonization with pathogenic bacteria. Blood and other samples were collected during febrile neutropenia. Association between surveillance stool culture and subsequent infections were studied.

Results: A total of 106 patients were recruited from November 2015 to March 2017. 59 patients were pediatric AL with median age of 10 years and 47 patients were adult AL with median age of 33 years. 68.86% of patients had gut colonization with bacteria of which 33.01% were MDR while 35.84% were non-MDR. Most common MDR bacteria colonizing gut were E. Coli (62.16%) and Klebsiella Pneumonia (21.82%). A total of 264 blood cultures were taken from 68 patients who developed 114 episodes FN during induction. Blood culture positivity rate was 17.80% with 68.08% of the isolates being MDR. Most common MDR isolates were Klebsiella (28.12%) and pseudomonas (18.75%). 34.28% of patients colonized with MDR bacteria developed MDR sepsis during induction compared to 23.68% non MDR colonizers. Induction mortality was 20% in MDR colonizers compared to 10.52% in non-colonizers.

Conclusions: Our study suggests that a significant proportion of patients are colonized with MDR bacteria and there is a high prevalance of MDR sepsis during induction. MDR sepsis and induction mortality were higher in patients colonized with MDR bacteria compared to non MDR bacteria.

1028P L-arginine – targeted for the anthracycline cardiotoxicity prevention in patients with acute leukemia of high cardiological risk

T. Lymanets, I. Skrypnyk, G. Maslova

Ukrainian Medical Stomatological Academy, Poltava, Ukraine

Background: The risk of anthracycline cardiotoxicity (AC) significantly increases in patients with comorbid ischemic heart disease (IHD), which requires monitoring and prevention during chemotherapy (CT) of acute leukemia (AL). In this study we aim to evaluate the effectiveness of L-arginine in AC prevention in AL patients with comorbid IHD during induction CT.

Methods: A total 66 patients with newly diagnosed AL and comorbid IHD were included in the study, ECOG I-II. The cohort consisted of 34 (51.5%) males and 32 (48.5%) females, age 54-72 years. The IHD duration was 3–15 years. CT included doxorubicin. We determined the level of troponin I, nitrite anions $[NO_2]^-$, performed daily ECG-monitoring: at baseline and in achieving a cumulative dose of anthracyclines (CDA) from 100 to 200 mg/m^2. Depending on AC prevention patients were divided into two groups: I (n = 36) – AL patients treated with CT; II (n = 30) – AL patients treated with CT and L-arginine.

Results: Prior to CT, according to the daily ECG-monitoring in 47 (71.2%) patients' periods of tachycardia were diagnosed, with single supraventricular extrasystoles (SEs) and ventricular extrasystoles (VEs) – in 35 (53%) and 17 (25.7%) pts, respectively. The decreased concentration of $[NO_2]^-$ in blood serum in 1.5 times relative to normal values ($p<0.05$) was noticed. Troponin I in all patients of both groups was <0.5 ng/ml. Reaching low CDA in group I we recorded: periods of tachycardia in 36 (100%) pts, increasing number of single and paired SEs – in 24 (66.6%), VEs episodes – in 19 (52%), clinically significant ST-segment depression – in 29 (80.5%) and interval QT prolongation – in 14 (38.8%) pts. Troponin I was >0.5 ng/ml in 7 (19.4%) pts. Simultaneously, deepening of endothelial dysfunction (ED) was noted: $[NO_2]^-$ was in 1.8 times lower vs norm. After 2 CT courses in 20 (66.6%) patients of group II on tachycardia background the single SEs were recorded and only in 1 (3.3%) patient troponin I level was >0.5 ng/ml. The ED leveled: $[NO_2]^-$ didn't significantly differ from the norm.

Conclusions: Thus, L-arginine in AL patients with comorbid IHD during induction CT leads to reducing the risk of necrotic injury of cardiomyocytes and improves endothelial function that prevents early AC.

1029P Multiple myeloma complicated by concomitant cardiac pathology

S. Semochkin, E. Yurova

Oncology, Hematology and Radiotherapy, Pirogov Russian National Research Medical University, Moscow, Russian Federation

Background: Patients with multiple myeloma (MM) often have cardiac comorbidities because of several factors, including the history of cardiac events, myeloma and treatment-related factors. Age is an important risk factor, given that the median age at the diagnosis of MM in Russia is 64 years. Additionally, the MM-related cardiac risk factors include underlying and undiagnosed cardiac amyloidosis, hyperviscosity, high-output failure, anemia and renal failure. Therefore, there are poorly understanding of real efficiency anti-myeloma treatment for this category of patients. In the presented work we have analyzed the efficiency of the most commonly used bortezomib-containing regimens in anti-myeloma treatment for patients with MM with concomitant cardiac diseases.

Methods: One hundred and forty-eight (males – 69, females – 79) patients were enrolled in this trial during March 2008 – May 2010. They divided on groups with (1) newly diagnosed and (2) relapsed and refractory MM. The median ages for patients of all groups was 64.7 years (ranges, 36.3 – 82.7). An obligatory condition was the presence in all patients of significant cardiac pathology. The bortezomib-containing regimens VCD (n = 95), VMP (n = 36) or VD (n = 15) were used as anti-myeloma treatment. IMWG (2006) criteria were used for anti-myeloma response assessment. Comparisons for categorical variables among different groups were wade with chi-square test. Overall survival (OS) was measured from the date of treatment initiation until the date of death or the date of last follow up. For multivariant analysis, factors associated with time to event were introduced into a Cox proportional model.

Results: ECOG performance status of ≤ 2 have 81 (54.7%) patients. The verified diagnosis of ischemic heart disease was in 109 (73.6%) patients and symptoms of chronic heart failure was in 86 (58.1%) patients. The overall response rate (ORR) documented in 65.7% cases with newly diagnosed and 59.5% cases with relapsed and refractory MM including complete and strong complete remission (CR/sCR) in 22.9% and 20.3% cases respectively. With a median follow-up of 4.9 years for the comparison groups, the 5-year overall survival (OS) was 22.8 $\pm$ 5.3% and 17.3 $\pm$ 4.4% (p = 0.295). The median OS was 40.0 and 31.8 months respectively.

Conclusions: In multivariate analysis only ECOG scores ≥ 2 were demonstrated an independent negative prognostic value both for the event-free survival (Hazard ratio 1.69; p = 0.006) and OS (Hazard ratio 1.76; p = 0.003). Overall, the bortezomib-based treatment in myeloma patients with concomitant cardiac pathology accompanied by no significant increase in the incidence of cardiovascular adverse events.

1030P Evaluation of dose intensification of cytarabine in postremission therapy in older AML patients within the prospective phase II AMLSG 06-04 study

L. Hä̈cker[1], M. Tassara[2], P. Brossart[3], G. Held[4], H.A. Horst[5], M. Ringhoffer[6], C-H. Köhne[7], S. Kremers[8], A. Raghavachar[9], G. Wulf[10], H. Kirchen[11], D. Nachbaur[12], M. Wattad[13], A. Benner[14], D. Weber[1], V.I. Gaidzik[1], P. Paschka[1], K. Döhner[1], H. Döhner[1], R. Schlenk[15]

[1]Internal Medicine, University Hospital Ulm, Ulm, Germany, [2]Medical Oncology, San Raffaele Hospital, Milan, Italy, [3]Medical Oncology, University Hospital Bonn, Bonn, Germany, [4]Medical Oncology, University Hospital Saarland, Homburg, Germany, [5]Medical Oncology, University Hospital Kiel, Kiel, Germany, [6]Medical Oncology, Klinikum Karlsruhe, Karlsruhe, Germany, [7]Medical Oncology, Klinikum Oldenburg, Oldenburg, Germany, [8]Medical Oncology, Krankenhaus Lebach, Lebach, Germany, [9]Medical Oncology, Klinikum Wuppertal, Wuppertal, Germany, [10]Medical Oncology, Universitätsmedizin Göttingen, Göttingen, Germany, [11]Medical Oncology, Krankenhaus der Barmherzigen Brüder, Trier, Germany, [12]Medical Oncology, University Hospital Innsbruck, Innsbruck, Austria, [13]Medical Oncology, Klinikum Essen, Essen, Germany, [14]Division of Biostatistics, German Cancer Research Center, Heidelberg, Germany, [15]NCT Trial Center, German Cancer Research Center, Heidelberg, Germany

Background: Progress in the treatment of acute myeloid leukemia (AML) in older patients (pts) is still limited. In the randomized part of the AMLSG 06-04 trial, valproic acid (VPA) was evaluated in combination with intensive therapy plus all-trans retinoic

acid (ATRA) in older pts (>60 years) with newly diagnosed AML. The randomized part of the study (cohort-1) was terminated due to excessive VPA-induced toxicity (Tassara et al, Blood 2014;123:4027-36.). The study was amended thereafter (cohort-2) to evaluate a cytarabine dose-intensifcation in first consolidation therapy. Here we report on the comparison of the two cohorts.

Methods: Between 2004 and 2008, patients were treated in cohort-1 (n = 186) and cohort-2 (n = 376). 2 cycles of induction therapy (ATRA, idarubicin, cytarabine, n = 93 with VPA) were followed by consolidation-1 (mitoxantrone, ATRA, cytarabine [cohort-1, 0.5g/m^2; cohort-2, 1g/m^2] bid, days 1-3) and consoldation-2 (idarubicin, etoposide, ATRA).

Results: Median age was 68 (range, 60-84) years without difference between the cohorts (p = 0.49). Complete remission (CR) rates after induction therapy were 45% and 48% (p = 0.59) in cohort-1 and -2, respectively. There were no significant differences in the cumulative incidences of relapse (CIR, p = 0.26) and death (p = 0.51) between cohort-1 and -2 with CIR of 63% (SE, 4.8%) in cohort-1 compared to 51% (SE, 6.3%) in cohort-2. A Cox regression model on overall survival revealed older age (hazard ratio (HR) for a 10 years difference, 1.97, p < 0.0001), 2010 European LeukemiaNet (ELN) unfavorable risk (HR, 1.57, p = 0.0003) as well as cohort-1 (HR, 1.31, p = 0.02) as unfavorable parameters and ELN favorable risk (HR 0.55, p < 0.0001) as favorable prognostic parameter. Survival was inferior (p = 0.03) in cohort-1 with 21% (95%-CI, 16-28%) compared to cohort-2 with 28% (95%-CI, 23-33%) at 2 years. In an age-adjusted analysis the molecular marker *FLT3*-ITD was associated with an unfavorable prognosis.

Conclusions: Although evaluated in a cohort- rather than a randomized study, intensification of cytarabine dosage in consolidation therapy seems to improve survival.

Klinik IV, Uniklinik RWTH Aachen, Aachen, Germany, [9]Klinik für Hämatologie, Onkologie und Immunologie, Universitätsklinikum Gießen und Marburg, Marburg, Germany, [10]Medizinisches Versorgungszentrum, Klinikum Straubing, Straubing, Germany, [11]Institut Bergonié, University Bordeaux, Bordeaux, France

Background: A substantial proportion of chronic myeloid leukemia (CML) patients in deep molecular response (DMR) reach treatment-free remission (TFR) after tyrosine kinase inhibitors (TKI) cessation. The aim of this study is to identify a gene signature predictive for TFR using whole transcriptome expression analyses.

Methods: RNA from peripheral blood (PB) leukocytes of 60 CML patients who stopped TKI therapy within the EUROSKI study and 10 healthy controls were isolated. CML patients were divided into two groups of whom n = 30 patients had ongoing TFR, while 30 patients encountered molecular recurrence. RNA was isolated at the last day of TKI intake. In order to investigate differentially expressed genes, whole transcriptome arrays (Clariom D, Affymetrix) were analyzed. Candidate biomarkers were tested in multivariate analyses and gene set enrichment analyses (GSEA).

Results: CML patients in DMR compared to healthy controls showed 16000 differentially expressed genes (p < 0.05). The natural killer cell marker *CD69* showed overexpression with highest fold change (> 8-fold) for CML patients versus healthy controls. Significant enrichment of NFκB mediated TNFα and TGFβ pathways (FDR<7%, p < 0.03) were found in CML patients. Comparing the CML TFR versus relapse cohort, we found 2600 differentially expressed genes. Most notably the toll-like receptors *TLR1*, *TLR6* and *TLR8* were upregulated in the relapse cohort (p < 0.03). Activated downstream signatures of NOD-like, TLR and TNFα pathways, known for their promotion of a protective CML microenvironment, were significantly enriched (p < 0.03, FDR<2%). In contrast, patients in TFR were characterized by an upregulation of T-cell receptor and granzyme gene family members (p < 0.03). Genes of interest showed distinct cut-offs predictive for TFR over a period of 12 months.

Conclusions: CML patients in DMR present a considerable inflammatory gene expression pattern in PB leukocytes in contrast to healthy controls. Alike previous studies, genes involved in immune exhaustion and immune surveillance were differentially expressed between patients with TFR and relapse. The specific inflammatory gene signature of the relapse cohort suggests 'stemness' as third mechanism and driver for relapse.

Background: SY-1425 (tamibarotene) is an oral, potent and selective synthetic RARα agonist previously approved for the treatment of relapsed/refractory acute promyelocytic leukemia (APL) in Japan. Given preclinical evidence of SY-1425 sensitive AML cell lines and patient samples with RARA pathway activation defined by elevated RARA or IRF8, SY-1425 is being investigated in a Phase 2 study of biomarker selected non-APL AML and MDS patients. DHRS3 is a direct RARα target gene with rapid and robust mRNA upregulation in both AML blasts and PBMCs in response to SY-1425. Here we present the first report of SY-1425 plasma levels with DHRS3 based evidence of RARα target engagement from AML and MDS patients enrolled in the Phase 2 study (NCT02807558).

Methods: Patients positive for RARA pathway biomarkers (RARA, IRF8, or both) initiated oral daily treatment with SY-1425 at 6 mg/m2/day in two divided doses. Sparse PK was collected twice on day 1 and twice on day 15. PD was sampled before the first dose and at 5-8 hours post dose on day 1 and once on day 15. DHRS3 expression was assessed by qPCR in PBMCs.

Results: PK data in 16 patients showed SY-1425 plasma levels were consistent with those observed in Japanese APL patients based on day 1 Cmax and day 15 steady state exposure. In 19 PD evaluable patients, upregulation of DHRS3 at 5-8 hours had a greater than 2-fold increase in 84% (16/19). Induction was consistent for AML and MDS, including patients positive for RARA, IRF8, or both biomarkers. DHRS3 expression remained elevated after 15 days of continuous treatment in evaluable patients. Using a parallel exploratory *ex vivo* flow cytometry assay from screening samples, SY-1425 induced differentiation and blast reduction that was correlated with biomarker status.

Conclusions: In a biomarker-selected AML and MDS patients with evidence of RARA pathway activation, SY-1425 causes strong transcriptional upregulation of the DHRS3 target gene, consistent with SY-1425 induced differentiation through myeloid gene activation. The dosing regimen of SY-1425 achieves plasma exposures sufficient to elicit a PD response with direct evidence of RARα target engagement.

1033P Quantitative assessment of inotuzumab ozogamicin (InO) response relative to investigator's choice of chemotherapy (ICC) in adults with relapsed or refractory (R/R) CD22+ B-Cell acute lymphoblastic leukemia (ALL)

A. Ruiz-Garcia[1], E. Vandendries[2], D.J. DeAngelo[3], H.M. Kantarjian[4], J. Boni[5]

[1]Clinical Pharmacology, Pfizer Inc, San Diego, CA, USA, [2]Clinical Research and Development Hematology, Pfizer Inc, Cambridge, MA, USA, [3]Center for Hematologic Oncology, Dana-Farber Cancer Institute, Boston, MA, USA, [4]Department of Leukemia, MD Anderson Cancer Center, Houston, TX, USA, [5]Clinical Pharmacology, Pfizer Inc, Collegeville, PA, USA

Background: InO is a humanized CD22-targeted antibody conjugated to N-acetyl-γ-calicheamicin, a potent cytotoxic antibiotic. InO was administered to adult patients with R/R CD22+ B-cell ALL in a phase 1/2 (B1931010) study, and a phase 3 (INO-VATE) study that compared single-agent InO with ICC. The goal of this analysis was to quantify differences in response for the endpoints complete response (CR)/CR with incomplete hematologic recovery (CRi) and minimal residual disease-negativity (MRD (-)) for patients treated with InO relative to ICC.

Methods: The efficacy endpoints analyzed were CR/CRi per investigator's assessment and MRD (-). The modeling analyses were performed using generalized binomial logistic regression, which allows constructing a linear continuous predictor for probabilities of response ranging from 0%–100%. 2 treatment arms were considered: single agent InO or ICC (fludarabine, cytarabine, granulocyte colony-stimulating factor; cytarabine with mitoxantrone; or high-dose cytarabine). Additional potential predictors of response (eg, baseline demographic/patient characteristics, laboratory values) were also tested.

Results: For the CR/CRi efficacy endpoint, only 3 variables were statistically significant predictors of achieving CR/CRi: treatment arm, baseline ECOG (BECOG) performance status, and baseline absolute blasts in peripheral blood (BLSTABL). For the MRD (-) endpoint, 5 variables were statistically significant predictors of achieving MRD(-): treatment arm, BECOG performance status, baseline cytogenetic characteristics, prior hematopoietic stem cell transplant before study therapy, and BLSTABL.

Conclusions: The odds of achieving CR/CRi and MRD(-) with InO were approximately 7 and 13 times higher, respectively, than ICC.

1034TiP Phase III randomized, double-blind, controlled studies of the PI3K inhibitor copanlisib in combination with rituximab or rituximab-based chemotherapy in subjects with relapsed indolent B-cell non-Hodgkin's lymphoma (iNHL): CHRONOS-3 and CHRONOS-4

J. Gerecitano[1], H. Zheng[2], L. Mongay Soler[2], R. Ito[3], D. Reis[4], C. Lu[5], J. Shen[5], B.H. Childs[2], P.L. Zinzani[6]

[1]Lymphoma Service/Developmental Therapeutics Clinic, Department of Medicine, Memorial Sloan-Kettering Cancer Center, New York, NY, USA, [2]Clinical Development, Bayer HealthCare Pharmaceuticals Inc., Whippany, NJ, USA, [3]Development Operations, Bayer HealthCare Pharmaceuticals Inc., Whippany, NJ, USA, [4]Development Operations, Bayer SA, São Paulo, Brazil, [5]Clinical Statistics, Bayer HealthCare Pharmaceuticals Inc., Whippany, NJ, USA, [6]Institute of Hematology "L. e A. Seràgnoli", University of Bologna, Bologna, Italy

Background: Copanlisib is a pan-Class I phosphatidylinositol 3-kinase (PI3K) inhibitor with predominant activity against PI3K-α and PI3K-δ isoforms. Recently, the CHRONOS-1 study demonstrated efficacy of copanlisib monotherapy in patients with relapsed or refractory iNHL with an acceptable safety profile (Dreyling et al., AACR 2017). Two randomized phase III studies are ongoing to evaluate the efficacy and safety of copanlisib in combination with standard therapy: Rituximab [R] either alone or in combination with chemotherapy including an alkylating agent (e.g. bendamustine [R-B] or CHOP [R-CHOP]) in $\geq 2^{nd}$ line iNHL patients who are relapsed but non-refractory to R or R-based chemotherapy.

Trial design: Both studies include iNHL patients (including follicular lymphoma, marginal zone lymphoma, small lymphocytic lymphoma, or lymphoplasmacytic lymphoma/Waldenström macroglobulinemia) who have relapsed but are non-refractory after at least 1 prior line of therapy including R. The primary efficacy variable is progression-free survival. In CHRONOS-3, 567 patients unfit/unwilling to receive chemotherapy or who have progressed or relapsed ≥12 months after the last R-based regimen will be randomized 2:1 to copanlisib (60 mg) or placebo administered intravenously on days 1, 8 and 15 of a 28-day cycle until progression in combination with 375 mg/m^2 of R days 1, 8, 15 and 22 followed by R bi-monthly up to cycle 9. For CHRONOS-4, a safety run-in phase will be conducted with 45 mg and 60 mg copanlisib with R-B or R-CHOP. Copanlisib will be admnistered (as above) with either B iv 90 mg/m2 days 1 and 2 each 28 days, or on days 1 and 8 of a 21-day cycle with CHOP per standard dosing. After the run-in phase, 520 patients eligible to receive R-B or R-CHOP will be randomized 1:1 to either copanlisib or placebo and receive up to 6 cycles followed by copanlisib or placebo monotherapy. Safety run-in of RB plus copanlisib was assessed by the Data Monitoring Committee and 60 mg was deemed as the copanlisib phase III dose (Gerecitano et al. ICML 2017). The phase III portion of the trial with copanlisib/placebo plus RB is ongoing.

1035TiP A multicenter, randomized, phase 3 study of pomalidomide and dexamethasone (Pom-dex) with or without daratumumab in patients with relapsed or refractory multiple myeloma (RRMM): APOLLO

E. Terpos[1], M.A. Dimopoulos[1], E. Kastritis[1], J.M. Schecter[2], J. Ukropec[3], E. Smith[4], P. Sonneveld[5]

[1]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, "Alexandra" General Hospital, Athens, Greece, [2]Janssen Research & Development, Raritan, NJ, USA, [3]Janssen Scientific Affairs, Horsham, PA, USA, [4]Janssen Research & Development, High Wycombe, UK, [5]Department of Hematology, Erasmus MC, Rotterdam, Netherlands

Background: Daratumumab (DARA), a human IgGκ monoclonal antibody targeting CD38, is approved in the United States and Europe for use in patients with RRMM, as a monotherapy and in combination with bortezomib/dexamethasone or lenalidomide/dexamethasone. In a phase 1b study, DARA plus pomalidomide and low-dose dexamethasone (Pom-dex) demonstrated efficacy and tolerability in patients with RRMM. Here, the safety and efficacy of DARA plus Pom-dex is evaluated in a phase 3 study.

Trial design: This is an ongoing, phase 3, multicenter, randomized, open-label study of DARA plus Pom-dex versus Pom-dex alone. Adults with RRMM who have received and responded to prior anti-myeloma therapy, including a proteasome inhibitor and a lenalidomide-containing regimen, and who have progressed on their last regimen are eligible. Patients who have received 1 prior line of therapy must have progressed ≤60 days of completing the lenalidomide-containing regimen. Patients will be randomized 1:1 to receive Pom 4 mg orally on Days 1-21 of a 28-day cycle plus dex 40 mg weekly (20 mg for patients ≥75 year of age), with or without intravenous DARA 16 mg/kg weekly in Cycles 1-2, every 2 weeks in Cycles 3-6, and monthly thereafter, until progression or unacceptable toxicity. To mitigate potential infusion-related reactions, all patients will receive pre-infusion medications (including dexamethasone, paracetamol,

*When CR/CRi was not achieved and MRD was missing, MRD was considered not achieved.

diphenhydramine, and an optional leukotriene inhibitor) and patients with a higher risk of respiratory complications will receive post-infusion medications (including diphenhydramine, a short-acting β2 adrenergic receptor agonist, and lung disease control medications). Safety evaluations will occur weekly during Cycles 1-2, every other week during Cycles 3-6, and monthly thereafter. Disease evaluations will occur monthly. The primary endpoint is progression-free survival. Secondary endpoints include safety, overall response rate, minimal-residual-disease-negative rate, duration of response, and overall survival. Approximately 302 patients will be enrolled across 10 countries.

Background: Dara is a monoclonal anti-CD38 antibody approved for the treatment of relapsed and refractory MM. Addition of dara to bortezomib and dexamethasone increased complete and overall response rates and improved progression-free survival (PFS) in pts with relapsed MM. CyBorD is a bortezomib based regimen which has been shown to be an effective therapy for MM. This study was designed to evaluate the combination of Dara-CyBorD in pts with MM who are previously untreated or have relapsed MM following only one line of prior therapy.

Trial design: This is a multicenter, single-arm, open label, Phase 2 study in pts with MM who have received ≤ 1 line of prior therapy. Approximately 100 pts (≥40 with untreated MM and ≥40 with relapsed MM) will receive Dara-CyBorD every 28 days for 4 to 8 cycles. Pts receive oral cyclophosphamide 300 mg/m2 on Days 1, 8, 15, and 22; subcutaneous bortezomib 1.5 mg/m2 on Days 1, 8, and 15; and oral or IV dexamethasone 40 mg weekly. Dara is administered concurrently on 28 day cycles at a dose of 8 mg/kg IV on Days 1 and 2 of Cycle 1, then 16 mg/kg IV weekly from Cycle 1 Day 8 through completion of Cycle 2. For Cycles 3-6, pts receive dara 16 mg/kg IV once every 2 weeks. From Cycle 7 onward, pts receive dara 16 mg/kg IV once every 4 weeks, whether with CyBorD or alone during the maintenance phase. Pts receive 4 to 8 induction cycles of Dara-CyBorD and eligible pts may undergo an autologous stem cell transplant. All eligible pts then receive 12 cycles of maintenance therapy with dara 16 mg/kg IV every 28 days. The primary endpoint is complete response (CR) plus very good partial response (CR+VGPR) following 4 cycles of induction therapy with Dara-CyBorD. Secondary endpoints include overall response rate (CR+VGPR+PR), time to VGPR and partial response, duration of response, PFS, overall survival rate, infusion reaction profile of split-dose infusions and safety. Inclusion criteria include ≥ 18 years of age; documented MM per IMWG 2015 criteria; an Eastern Cooperative Oncology Group performance status score of 0, 1, or 2; no or one prior line of therapy. The estimated primary endpoint analysis date is February 2018.

1037TiP A double blind randomized phase 2 PILOT study of ERYASPASE in patients with acute lymphoblastic leukemia/lymphoma

N. Soule[1], C. Holford[2], R. Kay[2], D. Tilton[1], N. Biswas-Baldwin[2], I. El Hariry[2]

[1]Clinical, Erytech Pharma Incorporated, Cambridge, MA, USA, [2]Clinical, Erytech Pharma, Lyon, France

Background: Asparaginase is a critical agent in the treatment of ALL. This enzyme deaminates asparagine, interfering with protein synthesis and resulting in cell death as lymphoblasts are deficient in asparagine synthetase. Eryaspase is a dispersion of homologous red blood cells (RBCs) encapsulating L-asparaginase formulated in a preservative solution for infusion. The formulation of eryaspase has evolved during its development. Two sources of L-asparaginase (drug substance) from Medac GmbH can be used as raw material and encapsulated in the RBCs: native (Kidrolase®) or recombinant L-asparaginase (Spectrila®). This study is designed to investigate the PK comparability of both eryaspase formulations: native or recombinant asparaginase as the starting material, when administered as monotherapy and in combination with chemotherapy during induction and consolidation phases for the treatment of children and young adults presenting with ALL/LBL.

Trial design: This is a multicenter, multinational, double-blind, randomized, parallel group Phase 2 study of patients with de novo or relapsed ALL/LBL. After obtaining informed consent and performance of screening procedures, patients will be randomized to receive either eryaspase-N or eryaspase-R. Major Inclusion: Male or female, aged between 1-55 years Confirmed diagnosis of Philadelphia chromosome negative ALL/LBL, de novo or first relapse Adequate Performance Status Major Exclusion: Second intention asparaginase treatment in first-line setting. (These are patients who develop hypersensitivity reactions to another asparaginase and require switch to a different asparaginase formulation to complete the intended course of therapy) Refractory ALL/LBL (failure to achieve complete remission in first-line treatment) Recruitment will continue until 38 patients with a PK evaluable profile are enrolled.

1038TiP Phase 2 randomized study of daratumumab (dara), lenalidomide (R), bortezomib (V), and dexamethasone (d; Dara-RVd) vs. RVd in patients (pts) with newly diagnosed multiple myeloma (MM) eligible for high-dose therapy (HDT) and autologous stem cell transplantation (ASCT)

T. Lin[1], L. Hydutsky[2], H. Parros[3], S. Murphy[1], H. Pei[4], A. Londhe[4], J. Ukropec[5], M. Qi[6], Y. Lutska[1], M. Sharma[1]

[1]Med Group Oncology, Janssen Pharmaceuticals, Horsham, PA, USA, [2]MASTT/PMC, Janssen Pharmaceuticals, Horsham, PA, USA, [3]Clinical Trials Operations, Janssen Research & Development, LLC, Titusville, NJ, USA, [4]Clinical Biostats, Janssen Research & Development, LLC, Titusville, NJ, USA, [5]Oncology, Janssen Research & Development, LLC, Horsham, PA, USA, [6]Clinical Oncology, Janssen Research & Development, LLC, Spring House, PA, USA

Background: Dara is an anti-CD38 antibody approved for the treatment of relapsed and refractory MM. Addition of dara to Vd and Rd improved complete (CR) and overall response (OR) rates and progression-free survival (PFS) in relapsed MM. RVd followed by HDT and ASCT achieves high response rates in previously untreated MM. The primary objective of this study is to determine if the addition of dara to RVd will increase the stringent CR (sCR) rate by the end of post-ASCT consolidation therapy.

Trial design: This is a multicenter, randomized, open-label, active-controlled study in newly diagnosed MM pts eligible for HDT and ASCT. Following a safety run-in for up to 16 pts to assess dose limiting toxicities, 200 additional pts will be randomized 1:1 to Dara-RVd or RVd. Pts receive 4 induction cycles of RVd +/- dara; followed by stem cell mobilization, HDT, and ASCT; 2 consolidation cycles of RVd +/- dara; and maintenance therapy with Rd +/- dara for 24 months. During induction and consolidation (cycles 1-6), all pts receive R 25 mg orally on Days 1-14; V 1.3 mg/m^2 subcutaneously on Days 1, 4, 8 and 11; and d 40 mg weekly; every 21 days. In the Dara-RVd group only, dara 16 mg/kg IV is given on Days 1, 8 and 15 of cycles 1-4 and on Day 1 of cycles 5-6. During maintenance, all pts receive R 10 mg daily on Days 1-21 every 28 days and d 20 mg every 56 days; dara 16 mg/kg IV is given every 56 days in the Dara-RVd group only. Inclusion criteria include age 18-70 years; eligibility for HDT and ASCT; documented MM; ECOG score of 0-2; adequate organ function; and no prior systemic therapy for MM. The primary endpoint is the sCR rate by the end of post-ASCT consolidation therapy. Secondary endpoints include rates of OR, CR, sCR, VGPR, and minimal residual disease negative status after induction, ASCT, consolidation and maintenance; time to initial response, VGPR, CR and sCR; duration of response; PFS; and overall survival. The study is being conducted at Alliance Foundation Trials (AFT) centers and other institutions in the US. The study has completed the 16 pt safety run-in phase and is currently enrolling pts in the randomized phase.

Background: Peripheral T-cell lymphoma (PTCL) refers to a heterogeneous group of tumors that comprise a subset of T-cell non-Hodgkin lymphomas. PTCL-not otherwise specified, angioimmunoblastic T-cell lymphoma, and anaplastic large cell lymphoma are among the most common of these rare tumors. Outcomes are often poor, particularly in the setting of relapsed or refractory disease, making PTCL an ideal candidate for the assessment of a novel agent with strong biologic rationale. ALRN-6924 is a cell-penetrating stapled alpha-helical peptide designed to equipotently disrupt the interaction between the p53 tumor suppressor protein and its endogenous inhibitors, murine double minute X (MDMX) and 2 (MDM2). For TP53 wild-type (WT) tumors, pharmacological disruption of this interaction offers a means to induce p53-dependent cell cycle arrest and apoptosis, resulting in antitumor efficacy via a novel mechanism. ALRN-6924 demonstrated intriguing antitumor activity in a first-in-human phase 1 trial across a variety of tumor types (Meric-Bernstam et al., ASCO 2017, abstract #2505).

Trial design: This open-label Phase 2a study (NCT02264613) will enroll up to 20 adults with relapsed or refractory PTCL, after at least one prior systemic anticancer chemotherapy. Enrolled patients must have TP53 WT T-cell lymphoma (as confirmed by a central NGS testing), ECOG status of 0 or 1, and adequate organ function. Patients will receive 3.1 mg/kg ALRN-6924 as a one-hour infusion on days 1, 8, and 15 of 28-day cycles. Treatment will continue until disease progression or unacceptable toxicity. Response will be assessed according to the revised 2014 International Working Group (IWG) criteria for Lymphoma (Lugano Classification), (Cheson et al., J Clin Oncol. 2014:32:3059-3067). Primary objectives are to assess overall response rate and to further evaluate the safety and tolerability of ALRN-6924. Secondary objectives include assessment of time to response, duration of response, progression free survival, and overall survival. Pharmacodynamic biomarkers will be measured in blood and tumor samples. Recruitment is ongoing.

Background: FLT3-internal tandem duplication (ITD) mutations occur in ∼25% of NDx AML pts and are associated with shorter response duration to standard chemotherapy (SC), higher relapse rate, and lower overall survival (OS) vs non–FLT3-ITD AML. Unlike the multi-kinase inhibitor, midostaurin, Quizartinib (Q), an oral, highly potent FLT3 inhibitor, has greater selectivity for FLT3. Early clinical studies of Q combined with SC demonstrated high clinical activity in NDx FLT3-ITD AML pts. This is an ongoing phase 3 trial of Q vs placebo (P) added to induction (IND) and consolidation (CON) chemotherapy and as maintenance therapy in NDx FLT3-ITD AML pts.

Trial design: Pts age 18-75 years with NDx *FLT3*-ITD AML and ECOG PS 0-2 are eligible. Key exclusion criteria: any prior treatment (including Q or any FLT3 inhibitors), investigational drug or device $\leq$30 days (d), immunotherapy $\leq$2 weeks, history of central nervous system leukemia, significant cardiovascular disease, QTcF >450 msec, active liver disease. Pts are randomized 1:1 to Q 40 mg (equivalent to 35.4 mg free base) or P administered with IND and CON chemotherapy ($\leq$4 cycles high-dose cytarabine $\pm$ hematopoietic stem cell transplant) then as maintenance (Q 30 mg titrated to 60 mg, $\leq$12 28-d cycles; or P). In IND cycle 1, pts receive cytarabine 100 (or 200 mg/m^2/d per updated protocol) for 7 d + anthracycline (daunorubicin 60 mg/m^2/d or idarubicin 12 mg/m^2/d) on days 1-3 (7 + 3). Starting day 8 of each IND and day 6 of each CON cycle, pts receive 14 d of daily Q 40 mg or P. On the second IND cycle, pts receive the 7 + 3 protocol, or investigators may substitute 5 + 2 d of cytarabine and anthracycline, per institutional standards, with Q or P starting on day 8 or day 6, respectively. The primary endpoint is event-free survival based on centrally adjudicated response assessment using local morphology results. Secondary endpoints are OS, CR, CRc (CR + CRi per latest IWG definitions). Enrollment is underway at 167 sites with a target enrollment of 536 pts at 275 sites worldwide.

1041TiP MP0250 – a dual inhibitor of VEGF and HGF - plus bortezomib + dexamethasone in a phase 2 open-label, single-arm, multicenter trial in patients with refractory and relapsed multiple myeloma (RRMM)

M.S. Raab[1], R. Ria[2], J. Schlenzka[1], T. Krahnke[3], J. Haunschild[4], F. Herrmann[4], U. Fiedler[5], K. Dawson[6], M.T. Stumpp[7], K. Tadjalli Mehr[4], A. Harstrick[4], A. Vacca[2], H. Goldschmidt[1]

[1]Department of Haematology, Oncology, and Rheumatology, Heidelberg University Hospital, Heidelberg, Germany, [2]Department of Biomedical Sciences and Human Oncology, Section of Internal Medicine, University of Bari Medical School, Bari, Italy, [3]Biostatistics, Gogitars GmbH, Heidelberg, Germany, [4]Clinical Development, Molecular Partners AG, Schlieren, Switzerland, [5]Preclinical, Molecular Partners AG, Schlieren, Switzerland, [6]Preclinical/Toxicology, Molecular Partners AG, Schlieren, Switzerland, [7]CSO, Molecular Partners AG, Schlieren, Switzerland

Background: Despite recent advances in the treatment of multiple myeloma (MM), patients eventually relapse, requiring multiple lines of treatment. Upregulation of both the vascular endothelial growth factor (VEGF) and hepatocyte growth factor (HGF) pathways has been implicated in loss of response to therapy and linked to poor prognosis through different mechanisms such as stimulation of angiogenesis, bone destruction, and myeloma cell proliferation and migration. MP0250 is a first-in-class, trispecific multi-DARPin® drug candidate neutralizing VEGF and HGF as well as binding to human serum albumin to increase plasma half-life. MP0250 shows activity in multiple preclinical tumor models amongst them an MM model in which it enhances the effects of bortezomib on e.g. M protein production and bone lysis. MP0250 has shown a favorable safety profile in a Phase 1 clinical trial in advanced solid tumors.

Trial design: This trial is recruiting adults ≥18 years of age with RRMM who have received ≥2 lines of therapy (including bortezomib and an immunomodulatory drug [IMiD]), have not shown any response to and have progressed on or within 60 days of the most recent treatment. The primary endpoint is efficacy in terms of overall response rate (ORR). Secondary endpoints include safety and immunogenicity. A total of 40 patients will be enrolled, 12 patients during a lead-in phase (Part 1) to establish a safe dose and an additional 28 patients in Part 2 to make a total of 34 patients at the target dose. Patients will receive study treatments (MP0250 in combination with bortezomib + dexamethasone) until the end of the study, disease progression, unacceptable toxicity, or other criteria for discontinuation, whichever occurs earlier. Cytogenetic analyses, response assessment, exploratory biomarkers, pharmacokinetics and immunogenicity will be determined in either bone marrow and/or blood/urine. The trial is currently recruiting patients.

Background: R/M HNSCC patients (pts) who have progressed on platinum-based chemotherapy have a poor prognosis and limited therapeutic options. Programmed cell death 1 (PD-1) and its ligand 1 (PD-L1) are frequently up-regulated in several tumor types, including HNSCC. The global, single-arm, Phase 2 HAWK study (NCT02207530) evaluated the anti-PD-L1 immunotherapy durvalumab as monotherapy in PD-L1 high pts with R/M HNSCC who have failed platinum-based chemotherapy.

Methods: Immunotherapy-naïve pts aged ≥18 years with confirmed PD-L1 high protein expression (≥25% of tumor cells [TCs] using the Ventana SP263 assay) who had progression or recurrence during/after 1 platinum-based regimen for R/M HNSCC received durvalumab 10 mg/kg IV every 2 weeks up to 12 months or until progression, starting another anticancer therapy, consent withdrawal, or unacceptable toxicity. The primary endpoint was objective response rate (ORR; blinded independent central review, RECIST v1.1); secondary endpoints included progression-free survival (PFS) and overall survival (OS).

Results: As of Sept 26, 2016, 112 pts from 12 countries had received treatment (median age 60 years, 71.4% male, 34.7% human papillomavirus [HPV]+, and 61.6% current/former smokers). Median durations of treatment and follow-up were 3.45 and 5.96 months, respectively. Among evaluable pts (n = 111), ORR was 13.5% (95% CI 7.8−21.3) overall and 26.5% (95% CI 12.9−44.4) and 7.9% (95% CI 2.6−17.6) for HPV+ and HPV- pts, respectively; among responders (n = 15), 12 (80%) had an ongoing response at data cutoff (DCO). 35 pts (31.5%) had stable disease ≥8 weeks. Median PFS was 2.3 months (95% CI 1.9−3.7) and 34 pts (30.4%) were alive at DCO (OS data were immature). The incidence of grade ≥3 treatment-related adverse events (AEs) was 9.8% and no treatment-related AEs led to death. 88 pts (78.6%) discontinued initial study treatment, 65 (58%) due to progressive disease and 10 (8.9%) due to all-causality AEs.

Conclusions: Durvalumab demonstrated promising antitumor activity with an acceptable safety profile in PD-L1 high pts with R/M HNSCC, supporting its potential use, and the opportunity to improve efficacy, in combination therapy.

Background: Treatment responses to immune checkpoint inhibitors may occur after initial radiologic evidence of progression. In CheckMate 141 (NCT02105636), a randomized phase 3 study in patients (pts) with R/M SCCHN, nivolumab (nivo) significantly prolonged overall survival (OS) vs single-agent of investigator's choice (HR = 0.70 [97.73% CI: 0.51, 0.96]). We provide a biomarker analysis and updated clinical outcomes of nivolumab treatment beyond first disease progression.

Methods: This analysis is based on a Sept 2016 database lock (minimum follow-up: 11.4 mo). Progression was assessed per RECIST 1.1. Treatment beyond first progression was permitted in the nivo arm for pts who met protocol defined criteria. Pts without progression or tumor assessment to determine progression were excluded. Immune cell phenotyping was conducted by flow cytometry for pts with samples available for both day 1 (D1) and D43 of treatment, and associated with clinical response status.

Results: Of 240 pts randomized to nivo, 146 (61%) experienced progression. Among them, 62 (42%) received ≥1 dose of nivo after progression (TBP group), and 84 (58%) were not treated beyond progression (NTBP group). Median OS was 12.7 mo (95% CI: 9.7, 14.6) in the TBP group. After initial progression, 15 (24%) pts in the TBP group had a reduction in target lesion size, with >30% reduction in 3 pts. Of these 15 pts, 8 were HPV+, 4 had PD-L1 ≥1%, and 5 had >20% increase in target lesion at first progression. Frequencies of grade 3−4 treatment-related adverse events were similar in the TBP and NTBP groups. At D1 and D43, the percentage of CD8+ T cells in peripheral blood for TBP pts (n = 5) was similar to that for responders (n = 15), which was significantly higher vs NTBP pts (n = 9). At D1, the percentage of PD-1+ CD8+ effector T cells was significantly lower in responders and TBP pts vs NTBP pts. At D1, TBP pts, similar to responders, had a significantly lower PD-1+ Treg percentage vs NTBP pts.

Conclusions: Nivo treatment beyond progression in some pts with R/M SCCHN was tolerable and associated with tumor size reductions. Certain immune cell profiles in the TBP group appear similar to those of responders.

1044O Long-Term Safety and Clinical Outcomes of Atezolizumab in Head and Neck Cancer: Phase Ia Trial Results

R. Bahleda[1], F.S. Braiteh[2], A.S. Balmanoukian[3], I. Braña[4], F.S. Hodi[5], L. Garbo[6], B. Liu[7], L. Molinero[8], C. O'Hear[9], X. Shen[9], A.D. Colevas[10]

[1]Early Drug Development Department, Gustave Roussy, Villejuif, France, [2]Medical Oncoloy, Comprehensive Cancer Centers of Nevada, Las Vegas, NV, USA, [3]Research, The Angeles Clinic and Research Institute, Los Angeles, CA, USA, [4]Medical Oncology, Vall d'Hebron Institute of Oncology, Barcelona, Spain, [5]Medical Oncology, Dana—Farber Cancer Institute, Boston, MA, USA, [6]Hematology, New York Oncology, Albany, NY, USA, [7]Biostatistics, Genentech, Inc., South San Francisco, CA, USA, [8]Oncology Biomarker Development, Genentech, Inc., South San Francisco, CA, USA, [9]Product Development Oncology, Genentech, Inc., South San Francisco, CA, USA, [10]Medicine, Stanford University, Stanford, CA, USA

Background: Checkpoint inhibitors have shown efficacy in pts with recurrent and/or metastatic head and neck cancer (HNC). Atezolizumab (atezo; anti—PD-L1) inhibits binding of PD-L1 to PD-1 and B7.1, thereby restoring tumor-specific T-cell immunity. Here, we examine single-agent safety and clinical activity of atezo in pts with advanced HNC.

Methods: Pts with HNC received atezo IV q3w (15 or 20 mg/kg or 1200 mg) in a Ph Ia study (NCT01375842). Pts were initially enrolled non-selectively (n = 10); once PD-L1 was identified as a potential biomarker, pts were selected by PD-L1 status (> 5% PD-L1 expression on IC [IC2/3]; centrally evaluated by VENTANA SP142 IHC assay, n = 22). HPV status was assessed by PCR. Treatment was originally for 16 cycles or up to 1 y; pts were subsequently treated until loss of clinical benefit. Primary endpoint was safety; tumor responses were evaluated by RECIST v1.1.

Results: As of 31 Dec 2016, with follow-up of ≥ 14 mo, 32 pts were safety and efficacy evaluable. 84% were male; 66% had ECOG PS of 1. Median age was 62 y (range, 32-78 y), pts were heavily pre-treated (53% had ≥ 2 prior lines of therapy) and 66% were current/previous tobacco users. Most common primary tumor sites were oropharynx (50%), oral cavity (22%) and nasopharynx (19%). Median treatment duration was 3.4 mo; 21/32 pts (66%) had a treatment-related AE. 3 pts (9%) had Gr 3 treatment-related AEs (tumor lysis syndrome, hyponatremia, pruritus, colitis). 1 pt (3%) had Gr 4 treatment-related cardiac tamponade. No Gr 5 treatment-related AEs were seen. In all pts (IC0/1, n = 7; IC2/3, n = 25), confirmed ORR was 22%, mPFS was 2.6 mo (range, 0.5-48.4 mo) and mOS was 6.0 mo (range, 0.5-51.6+ mo). Clinical activity by PD-L1 subgroups is shown in the Table. Preliminary analyses indicate that there was no association between HPV status and clinical outcomes.

Conclusions: In advanced HNC, atezo was well tolerated. Encouraging response and long-term survival were seen independently of PD-L1 IHC or HPV status and warrant further investigation.

Table: 1044O Clinical Activity per RECIST v1.1 in PD-L1 Subgroups

	IC0/1[a] (n = 7)	IC2/3[a] (n = 25)
ORR, n (%)	1 (14%)	6 (24%)
CR	0	0
PR	1 (14%)	6 (24%)
DCR, n (%)	3 (43%)	7 (28%)
mDOR, mo (range)[b]	7.4	26.2 (2.8-45.8)
mPFS, mo (range)	5.7 (0.5-13.5)	2.6 (0.5-48.4)
mOS, mo (range)	9.0 (0.5-26.5)	5.6 (1.1-51.6+)
1-year OS rate	43%	34%
2-year OS rate	29%	18%
3-year OS rate	NE	18%

[+]indicates a censored value.

[a]Data by PD-L1 expression on TC will be presented.

[b]n = 1 for IC0/1, no estimate for mDOR; n = 6 for IC2/3.

IC0 = PD-L1 expression on < 1%; IC1 = ≥ 1% to < 5%; IC2 = ≥ 5% to < 10%; IC3 = ≥ 10%.

PD-L1 subgroups do not reflect the natural prevalence as not enrolled as an all-comer cohort.

DCR, disease control rate: % of pts with CR, PR and SD ≥ 24 wk;

IC, tumor-infiltrating immune cells; mDOR, median duration of response; TC, tumor cells.

1045PD Adjuvant androgen deprivation therapy for high-risk androgen receptor-positive salivary duct carcinoma

W. Boxtel[1], L.D. Locati[2], S. Tooten[1], E. Bos[1], C. Bergamini[2], A.C.H. van Engen-van Grunsven[3], E. Boon[1], E. Fiets[4], S. Cavalieri[2], G. Verhaegh[5], J. Schalken[5], L. Licitra[2], C.M.L. Herpen[1]

[1]Department of Medical Oncology, Radboudumc, Nijmegen, Netherlands, [2]Medical Oncology Unit/Head and Neck Unit, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy, [3]Department of Pathology, Radboudumc, Nijmegen, Netherlands, [4]Department of Medical Oncology, Medical Centre Leeuwarden, Leeuwarden, Netherlands, [5]Laboratory of experimental urology, Radboudumc, Nijmegen, Netherlands

Background: Salivary duct carcinoma (SDC) is a rare and aggressive subtype of salivary gland cancer, with a median disease-free survival (DFS) of less than 3 years. SDC is androgen receptor-positive (AR+) in 67-96% of cases. In incurable recurrent AR+ SDC androgen deprivation therapy (ADT) has an overall response rate of 18-50%. In this study, high-risk AR+ SDC pts were treated with adjuvant ADT to study the efficacy.

Methods: In this retrospective study, surgical resected pts who received adjuvant ADT for stage 4a/b AR+ SDC at the Radboudumc (Nijmegen, the Netherlands) or Istituto Nazionale dei Tumori (Milan, Italy) were collected. As control group, surgical resected pts diagnosed with stage 4a/b SDC between 1990-2014, who did not receive adjuvant ADT were collected by a search of the Dutch pathology database (PALGA). Pts were analyzed for DFS and overall survival (OS) by using Kaplan-Meier survival curves.

Results: 18 AR+ SDC pts (median age 64 years [range 32-80]) were treated with adjuvant ADT (Nijmegen n = 11; Milan n = 7) for a median duration of 10 months [range 2-31 months]. All pts had a nuclear AR-staining pattern in > 70% of the cells. They were treated with bicalutamide monotherapy (n = 10), a LHRH analog (n = 1) or a combination of these (n = 7). Treatment was well tolerated. 17/18 pts (94.4%) also received postoperative radiotherapy, of which 4 pts received concurrent chemoradiotherapy (22.2%). The control group consisted of 110 SDC pts (median age 70 years [range 44-100]). 103/110 pts (93.6%) received postoperative radiotherapy, of which 1 pt received concurrent chemoradiotherapy (0.9%). After a median follow-up of 22 months in the ADT-treated SDC pts and 25 months in the control SDC pts, the 3-year DFS was 53.6% and 34.2% (p = 0.137), the 3-year OS was 68.2% and 52.3% (p = 0.198), respectively. The median DFS and OS were not reached in the ADT-treated SDC pts and were 21 months and 46 months in the control SDC pts.

Conclusions: Adjuvant ADT in high-risk AR+ SDC pts did not lead to a significant increase in DFS or OS, but the number of treated pts was limited. Due to the rarity of the disease we could not perform a formal phase II study. Translational research to identify pts which may benefit from ADT is warranted.

1046PD Overexpression of the c-MET proto-oncogene in salivary duct carcinoma patients

C.M.L. Herpen[1], W. Boxtel[1], U.E. Flucke[2], E. Bloemena[2], E. Boon[1], G. Verhaegh[3], M.W. Aalders[3], M.A. Jonker[4], J. Schalken[3], Y.M.H. Versleijen-Jonkers[1]

[1]Department of Medical Oncology, Radboud University Medical Centre, Nijmegen, Netherlands, [2]Department of Pathology, Radboud University Medical Centre, Nijmegen, Netherlands, [3]Laboratory of experimental urology, Radboudumc, Nijmegen, Netherlands, [4]Department for Health Evidence, Radboud University Medical Centre, Nijmegen, Netherlands

Background: Salivary duct carcinoma (SDC) is a rare and aggressive subtype of salivary gland cancer (SGC). Activation of the cellular MET (c-MET) receptor tyrosine kinase has been implicated in cell proliferation, survival, migration, and invasion. The aim of this study was to evaluate the frequency of MET overexpression and its correlation to clinicopathological factors in SDC.

Methods: 136 patients were collected by a retrospective search of the Nationwide Network and Registry of Histo- and Cytopathology (PALGA) in the Netherlands. Formalin-fixed paraffin-embedded tumor blocks and hematoxylin and eosin stained slides were requested for pathological review. MET expression was evaluated by immunohistochemical staining on primary tumors. These data were correlated to clinicopathological factors.

Results: c-MET was positive in 54 of 136 tumors (39.7%). Of these 54 tumors, 50 had a cytoplasmic staining pattern and 23 had a membranous staining pattern, so in 19 tumors both cytoplasmic and membranous staining was observed. No correlations were found between cytoplasmic or membranous MET and high stage disease (stage 3 and 4 versus stage 1 and 2, $p = 0.606$ and $p = 0.300$ respectively), number of positive lymph nodes ($p = 0.263$ and $p = 0.955$ respectively), lymph node ratio ($p = 0.192$ and $p = 0.771$ respectively), androgen receptor-status ($p = 0.858$ and $p = 0.258$ respectively), HER2-status ($p = 0.257$ and $p = 0.595$ respectively), time to recurrence ($p = 0.559$ and $p = 0.959$ respectively), time to distant metastases ($p = 0.398$ and $p = 0.666$ respectively), or overall survival ($p = 0.754$ and $p = 0.516$ respectively). Membranous MET staining occurred more frequently in SDC ex pleomorphic adenoma (14 of 52 tumors) than in the '*de novo*' SDC (9 of 84 tumors) ($p = 0.014$). In SDC ex pleomorphic adenoma we also found more HER2-positive tumors ($p = 0.041$).

Conclusions: Cytoplasmic and membranous MET are overexpressed in SDC and may be a target for MET-targeted therapy. It is not a prognostic factor for overall survival, possibly because frankly invasive SGCs often show less receptor expression then minimally invasive SGCs or pleomorphic adenomas. The higher expression of c-MET and HER-2 in SDC ex pleomorphic adenoma needs further investigation.

1047PD Mammary analogue secretory carcinoma (MASC): clinical characteristics in 28 ETV6-NTRK3 fusion gene confirmed patients

E. Boon[1], M.H. Valstar[2], W.T.A. van der Graaf[1], E. Bloemena[3], S.M. Willems[4], C.A. Meeuwis[5], L.A. Smit[6], M.A.W. Merkx[7], R.P. Takes[8], U.E. Flucke[9], C.M.L. Herpen[10]

[1]Department of Medical Oncology, Radboud University Medical Centre, Nijmegen, Netherlands, [2]Department of Head and Neck Oncology and Surgery, Antoni van Leeuwenhoek/Netherlands Cancer Institute, Amsterdam, Netherlands, [3]Department of Pathology, VU University Medical Centre, Amsterdam, Netherlands, [4]Department of Pathology, University Medical Centre Utrecht, Utrecht, Netherlands, [5]Department of Otorhinolaryngology/Head & Neck Surgery, Erasmus University Medical Centre, Rotterdam, Netherlands, [6]Department of Pathology, Antoni van Leeuwenhoek/Netherlands Cancer Institute, Amsterdam, Netherlands, [7]Department of Oral and Maxillofacial Surgery, Radboud University Medical Centre, Nijmegen, Netherlands, [8]Department of Otorhinolaryngology, Radboud University Medical Centre, Nijmegen, Netherlands, [9]Department of Pathology, Radboud University Medical Centre, Nijmegen, Netherlands, [10]Department of Medical Oncology, Radboud University Medical Centre, Nijmegen, Netherlands

Background: Recently, a new subtype of salivary gland cancer (SGC), mammary analogue secretory carcinoma (MASC), has been defined, which is characterized by the presence of ETV6-NTRK3 fusion gene. Previously, MASC was mixed up with acinic cell carcinoma (AciCC), polymorphous low grade adenocarcinoma and (cyst)adenocarcinoma. At present the clinical features and outcome of MASC patients are not well known. We aimed to describe the clinical presentation and outcome of MASC.

Methods: Firstly, we re-evaluated the pathological diagnosis of salivary gland cancers with a morphological resemblance to MASC, diagnosed in 4 of the 8 head and neck centres in the Netherlands, for their presence of ETV6-NTRK3 and also included genetically confirmed prospectively diagnosed cases. The ETV6-NTRK3 fusion gene was analyzed using RT-PCR. Secondly, the clinical characteristics were retrieved from the patient files.

Results: Twenty-eight patients with ETV6-NTRK3 fusion gene positive MASC were included (10 prospectively and 18 retrospectively). Of these 18 retrospective patients 13 patients were previously diagnosed as AciCC, the other 5 patients as (low-grade) adenocarcinoma. The median age at diagnosis was 49 years (range 19 – 83 years), 15 patients (54%) were male. The duration of symptoms varied from 6 weeks until 20 years with a median of 14 months. In 18 patients (64%) the tumour was located in the parotid gland; the other patients had tumours of the minor salivary glands (2), submandibular gland (1), oral mucosa/lip (5) or palate (2). All patients had a T1-2 tumour. One patient had lymph node metastasis at diagnosis. All patients underwent surgery of which 4 patients needed re-resection and 12 patients (43%) underwent postoperative radiotherapy. One patient had a local recurrence 50 months after primary surgery, but was cured after second resection. None of the patients had regional recurrences or distant metastases. The median follow-up was 49 months and both the 5- and 10-year overall survival rate were 94%.

Conclusions: MASC is a recently acknowledged new entity of SGC characterized by the ETV6-NTRK3 fusion gene. The clinical course seems to be favourable with a very low rate of recurrences and an excellent survival.

Background: Clinically meaningful antitumour activity and improved overall survival (OS) in recurrent and/or metastatic (R/M) head and neck squamous cell carcinoma (HNSCC) have been achieved by targeting the PD-1/PD-L1 axis. Tumoral PD-L1 expression correlates with response to blocking PD-1/PD-L1 antibodies. In a retrospective study, we investigated tumoral PD-L1 expression as a prognostic biomarker in R/M HNSCC patients (pts) treated with standard of care (SOC) therapy.

Methods: Archival tumor samples from R/M HNSCC pts diagnosed between March 2011 and June 2015 at 19 institutions in 7 countries were evaluated for PD-L1 expression using the validated Ventana SP263 assay and scored as PD-L1 high ($\geq$25% of tumor cells [TC]) or low/negative (<25% of TC). Clinical-demographic data, including treatment patterns and outcomes, were extracted from medical records. Descriptive analyses were conducted and survival estimated by the Kaplan-Meier method. Progression-free survival (PFS) was defined from start of first- (1L) or second-line (2L) therapy to time of progression (on/after therapy) or death due to any cause. OS was defined from diagnosis index date of R/M disease to time of death. The Cox proportional hazards model was applied.

Results: The final dataset included 412 pts. Median age was 62.0 years (range 28.0–93.0); 79.9% were male and 88.2% white. PD-L1 expression was high in 132 (32.0%), low/negative in 264 (64.1%), unknown in 16 (3.9%). Median OS (8.2 vs 10.1 months; $P = 0.55$) and PFS from the start of 1L chemotherapy (4.2 vs 4.8 months; $P = 0.37$) did not significantly differ between PD-L1 high and low/negative pts, respectively. Median PFS following 2L chemotherapy was statistically significantly longer in PD-L1 high versus low/negative pts (4.1 vs 2.2 months; $P = 0.04$). PD-L1 status was not statistically significant in multivariate analyses of OS ($P = 0.74$) or PFS following 1L chemotherapy ($P = 0.63$); however, there was a trend for improved PFS following 2L chemotherapy ($P = 0.09$).

Conclusions: Tumoral PD-L1 expression was not significantly associated with OS or PFS following 1L SOC chemotherapy; however, it was associated with prolonged PFS following 2L SOC chemotherapy.

1049PD Relationship between PD-L1 expression and survival in head and neck squamous cell carcinoma (HNSCC) patients (pts)

M. Stokes[1], R. Wang[1], S. Wildsmith[2], M. Secrier[3], H.K. Angell[4], C. Barker[2], J. Walker[2], P. Scorer[2], M.C. Rebelatto[5], N. Shire[6]

[1]Real-World Evidence, Evidera, Lexington, KY, USA, [2]Personalised Healthcare & Biomarkers, AstraZeneca, Cambridge, UK, [3]IMED Oncology, Bioinformatics (Biosciences), AstraZeneca, Cambridge, UK, [4]IMED Oncology, AstraZeneca, Cambridge, UK, [5]Biologic Safety Assessment, Pathology, MedImmune, Gaithersburg, MD, USA, [6]Global Medicines Development, AstraZeneca, Gaithersburg, MD, USA

Background: Programmed cell death 1 (PD-1) and its ligand 1 (PD-L1) are up-regulated in many cancers. The purpose of this study was to explore the relationship between PD-L1 expression and overall survival (OS) in HNSCC.

Methods: A retrospective study was conducted using data from pt medical records and analysis of archival tumor samples. Sample ages ranged from 8.2 to 227.5 months. Pts $\geq$18 years old diagnosed with HNSCC between 1989 and 2015 were selected. Demographic and tumor characteristics were compared by PD-L1 expression status. PD-L1 testing was performed using the Ventana PD-L1 SP263 assay. PD-L1 expression was scored separately using tumor cell (TC) and immune cell (IC) membrane staining and exploratory cut-offs of 1%, 5%, 10%, 25% and 50%. OS was calculated as the number of months from initial HNSCC diagnosis until death and estimated using the Kaplan–Meier method. The log-rank test was used to compare survival curves by PD-L1 status. PD-L1 status as a prognostic indicator of OS was further examined in Cox proportional hazards (PH) models.

Results: We identified 214 HNSCC pts with data available for date of death/last follow-up and PD-L1 status. Mean (SD) tumor sample age was 93.3 (40.5) months. Mean (SD) pt age was 62.3 (13.4) years and 70% were male. The Table presents baseline characteristics by PD-L1 subgroup. Median OS was similar between PD-L1 high and low/negative pts classified using the TC $\geq$ 25%, IC $\geq$ 1%, and IC $\geq$ 25% cut-offs. However, median OS was 21.2 months longer in PD-L1 high versus low/negative pts (68.9 vs. 47.7 months, respectively; P=0.03) in analyses using the TC $\geq$ 1% cut-off. This latter relationship remained after adjusting for baseline covariates using Cox PH models.

Conclusions: PD-L1 high expression based on a TC $\geq$ 1% cut-off appears to be associated with improved OS in this sample of pts with HNSCC. A small number of samples and resulting low statistical power limited our ability to assess prognosis for TC $\geq$ 25% and IC $\geq$ 25%, yet OS was numerically higher among PD-L1 high pts in these subgroups.

Background: About 47% and 10% of head and neck squamous cell carcinomas (HNSCC) occur in patients (pts) aged 65+ or 80+ respectively. This population being heterogeneous, balancing efficacy with toxicity is challenging.

Methods: ONCOVAL is the first step of the ELAN program for pts 70+ with HNSCC, not amenable to surgery. During ONCOVAL, pts were assessed for frailty before inclusion to appropriate trial depending on curative or palliative setting and fit or unfit status. The primary aim was to evaluate whether a suited geriatric evaluation (SGE) for use by oncologist is feasible to stratify pts as fit or unfit. The SGE was elaborated by GERICO (French UNICANCER group dedicated to clinical research in elderly cancer pts) specifically for HNSCC pts, derived from the comprehensive geriatric assessment (CGA) and evaluating functional status, comorbidity, cognition, mental health status, social status, nutrition. Full CGA performed by geriatricians was optional.

Table: 1049PD Baseline characteristics

Characteristic	TC PD-L1 expression			
	High (≥25%)	Low/negative (<25%)	High (≥1%)	Low/negative (<1%)
No. of pts (%)	33 (15.4)	181 (84.6)	118 (55.1)	96 (44.9)
Mean (SD) age, years	57.3 (12.3)	63.2 (13.4)	61.1 (12.9)	63.8 (13.8)
HPV positive, %	42.4	45.3	45.8	43.8
Present smoker, %	24.2	36.5	31.4	38.5
Stage IV, %	33.3	51.4	48.3	49.0
African American, %	27.3	16.6	22.9	12.5
Median OS, months	Not reached	62.9	68.9	47.7
p-value*	0.27		0.03	
	IC PD-L1 expression			
	High (≥25%)	Low/negative (<25%)	High (≥1%)	Low/negative (<1%)
No. of pts (%)	11 (5.1)	203 (94.9)	150 (70.0)	64 (30.0)
Mean (SD) age, years	63.8 (10.1)	62.2 (13.6)	61.3 (13.4)	64.6 (13.2)
HPV positive, %	8 (72.7)	88 (43.4)	75 (50.0)	21 (32.8)
Present smoker, %	3 (27.3)	71 (35.0)	53 (35.3)	21 (32.8)
Stage IV, %	6 (54.5)	98 (48.3)	68 (45.3)	36 (56.3)
African American, %	4 (36.4)	35 (17.2)	31 (20.7)	8 (12.5)
Median OS, months	157.1	68.9	79.0	52.5
p-value*	0.31		0.07	

*log-rank p-value comparing high vs. low/negative groups

Results: Between 06/2013 and 02/2017, 495 pts were included in 42 centers. Data available for 463 pts. Median age 79 years (70-95) with 46% over 80. 74% males. 67% of SGE was performed by oncologists and 33% by nurses/clinical research staff. Mean time to complete SGE was 22 minutes. After SGE, 72% pts were classified as unfit. 52% of pts were further assessed by CGA, 48% among SGE fit pts and 53% among SGE unfit pts. Concordance rate of classification Unfit/Fit by SGE and CGA was 81%. Among pts planned to be treated by curative radiotherapy (RT) or chemo(CT)-RT after oncologic evaluation alone, the planned treatment changed after SGE for 8% of pts: addition of CT/biotherapy to RT for 4% or deletion of CT for 4%. Rate of pts requiring multidisciplinary interventions was significantly higher when the assessment was also performed by geriatricians (71% vs 51%), even after adjusting for frailty.

Conclusions: A CGA-based SGE for use by oncologist in older pts with HNSCC seems feasible and is a first necessary step to define optimal care. Oncologists and geriatricians must keep going developing such close collaboration and data sharing before proposing tailored treatment.

1051PD A phase 1, multicenter, open-label, dose-escalation, combination study of RM-1929 and photoimmunotherapy in patients with recurrent head and neck cancer

S.T. Kochuparambil[1], D. McDonald[2], M. Fidler[3], K. Stenson[4], N. Vasan[5], M.A. Razaq[6]

[1]Oncology, Virginia Piper Cancer Institute, Minneapolis, MN, USA, [2]Otolaryngology, Virginia Piper Cancer Institute, Minneapolis, MN, USA, [3]Oncology, Rush University Medical Center, Chicago, USA, [4]Otolaryngology, Rush University Medical Center, Chicago, IL, USA, [5]Otolaryngology, Stephenson Cancer Center OU, Oklahoma City, OK, USA, [6]Oncology, Stephenson Cancer Center OU, Oklahoma City, OK, USA

Background: Patients with recurrent head and neck squamous cell cancer (rHNSCC) have a poor prognosis once they have failed definitive treatment. We have completed a Phase 1 dose-escalation study of a unique targeted light activated drug conjugate RM1929 consisting of the EGFR-directed monoclonal antibody cetuximab conjugated to the phthalocyanine dye IRDye 700DX.

Methods: This was a Phase I study of rHNSCC patients who could not be satisfactorily treated with surgery, radiation, or platinum chemotherapy. The study included a drug dose-escalation with a fixed fluence light application to determine the drug dose that could be safely given to activate the pharmacodynamics of anticancer responses. Twenty-four hours after drug infusion non-thermal red light was applied to the tumors either on the surface for mucosal/skin disease or within the tumor via fiber optic diffusers for submucosal or nodal disease. Primary safety endpoints were assessed at 1 week and secondary efficacy endpoints were assessed at 1 month post treatment.

Results: Nine patients were enrolled in the 3 cohort dose escalation study. There were no dose-limiting toxicities and the drug dose and light fluence for treatment was determined. No photosensitivity reactions were observed at any drug dose during solar simulator testing. Four patients experienced 3 SAEs that were probably or possibly related to treatment including oral pain, tumor hemorrhage, and tumor pain. For 8 patients who were assessed for best overall response rate after a single cycle of treatment using clinical and RECIST 1.1, the objective response rate (ORR) was 75% (6/8) with 3 complete responses which were durable (4-16 months). The disease control rate was 100% (DCR). 7/8 patients showed a decrease in tumor density, consistent with post-treatment necrosis.

Conclusions: The phase 1 dose escalation study demonstrated the safety and tolerability of photoimmunotherapy with RM1929. We have observed improvement in clinically significant endpoints in patients with rHNSCC who do not have other treatment options.

Background: This trial was conducted to investigate the efficacy and safety of paclitaxel plus carboplatin with/without bevacizumab in recurrent or metastatic nasopharyngeal carcinoma (NPC).

Methods: Patients with recurrent or metastatic NPC recruited from 12 hospitals in China were randomly assigned to receive carboplatin (area under the curve 6) and paclitaxel (175 mg/m^2) intravenously on day 1 once per 3 weeks for a maximum of 6 cycles, with (CP+B) or without (CP) bevacizumab (7.5 mg/kg) intravenously on day 1 of each cycle, until disease progression, untolerable toxicity, or death. The primary endpoint was progression-free survival (PFS). Secondary end points were objective response rate (ORR), disease control rate (DCR), overall survival (OS) and safety. This study is ongoing and registered with ClinicalTrials.gov (NCT02250599).

Table: 1052PD

Efficacy	CP+B (n = 41)	CP (n = 39)	p	
ORR [n (%)]	35(85.4)	27(69.2)	0.084	
DCR [n (%)]	40(97.6)	39(100%)	1.000	
PFS [m (95%CI)]	7.23 (6.80, 8.71)	7.00 (6.37, 8.41)	0.506	
Common drug-related AEs	**CP+B (n = 42)**		**CP (n = 40)**	
	All grades (%)	**Grade 3-4(%)**	**All grades (%)**	**Grade 3-4(%)**
Leucopenia	39(92.9)	14(33.4)	40(100)	16(40)
Neutropenia	33(78.7)	16(38.2)	40(100)	21(52.5)
Aneamia	29(69.1)	7(16.7)	27(67.5)	2(5.0)
Thrombocytopenia	23(54.8)	1(2.4)	20(50)	1(2.5)
ALT increased	10(23.9)	2(4.8)	12(30)	0
AST increased	5(12)	0	9(22.5)	0
Fatigue	9(21.4)	0	10(25)	0
Peripheral neuropathy	10(23.9)	0	19(47.5)	0
Nasal bleeding	4(9.5)	0	2(5)	0
Hemoptysis	1(2.4)	0	2(5)	0

Results: Between Jun 8, 2015 and Jan 1, 2017, 80 patients were randomly assigned, 41 to the CP+B group and 39 to the CP group. ORR showed a numerical improvement with CP+B group (85.4% vs 69.2%) although with no statistical difference ($p = 0.084$). The median PFS was 7.23 months in the CP+B group and 7.00 months in the CP group ($p = 0.506$). OS had not yet matured. Safety was similar in two groups. No bevacizumab related serious adverse events were observed specially including bleeding.

Conclusions: CP+B regimen showed a numerical advantage in ORR among NPC patients. Given the limited sample size of our study, further research is needed to evaluate efficacy of bevacizumab in NPC.

1053PD Refining staging system for nasopharyngeal carcinoma treated with intensity-modulated radiation therapy

V.H-F. Lee[1], D.L-W. Kwong[1], T.W. Leung[1], C-W. Choi[1], B. O'Sullivan[2], K.O. Lam[1], V. Lai[3], P-L. Khong[3], S-K. Chan[1], C-Y. Ng[1], C.C. Tong[1], P.Y.P. Ho[1], W.L. Chan[1], L-S. Wong[1], D.K-C. Leung[1], S-Y. Chan[1], A.W-M. Lee[1]

[1]Department of Clinical Oncology, The University of Hong Kong, Hong Kong, China, [2]Department of Radiation Oncology, Princess Margaret Cancer Centre, University of Toronto, Toronto, ON, Canada, [3]Department of Diagnostic Radiology, The University of Hong Kong, Hong Kong, China

Background: We incorporated baseline plasma EBV DNA into refinement of stage groups for nasopharyngeal carcinoma (NPC) treated with radical intensity-modulated radiation therapy (IMRT).

Methods: Patients with non-metastatic NPC treated with radical IMRT +/- adjunct chemotherapy based on 7th edition of American Joint Committee on Cancer (AJCC) system were recruited prospectively from 2010 to 2016. All patients had baseline and serial post-IMRT plasma EBV DNA (in copies/ml) measured and were staged with MRI and PET-CT. Recursive partitioning analysis (RPA) with repeated internal validations derived new stage groups with incorporation of baseline plasma EBV DNA. Multivariable analyses were used to calculate adjusted hazard ratios (AHRs) to derive a new set of AHR stages. Comparison of performance of survival prediction among these 3 sets of stage groups was done to find the best-performing stage set.

Results: The cohort included 520 patients treated with IMRT +/- adjunct chemotherapy with a median follow-up of 5.0 years. They were re-staged based on 8th edition of AJCC system. 5-year overall survival (OS) and cancer-specific survival (CSS) were as follows: stage I (OS 89.5%; CSS 100%), II (OS 87.8%; CSS 94.7%), III (OS 85.0%; CSS 90.0%) and IVA (OS 74.4%; CSS 79.9%) ($p = 0.058$ and $p = 0.003$ respectively). RPA derived NPC into 3 new stages with corresponding OS and CSS: RPA-I (T1-T4N0-N2 & T1-T2N3 & EBV DNA $<=2000$) (OS 89.1%; CSS 95.2%), RPA-II (T1-T4N0-N2 & T1-T2N3 & EBV DNA >2000) (OS 80.5%; CSS 84.1%) and RPA-III (T3-T4N3) (OS 58.2%; CSS 67.1%) (both $p < 0.001$ and $p < 0.001$ respectively). AHR (I: T1-T2N0-N2; II: T3-T4N0-N2 & T1-T2N3; III: T3-T4N3) after adjusting age, smoking status, treatment (chemoradiation vs. IMRT alone), baseline LDH and plasma EBV DNA also yielded a valid classification ($p < 0.001$ for both OS and CSS) but was worse on survival prediction compared to RPA. The RPA stages demonstrated better survival prediction especially on CSS after 1000 bootstrapping replicates (bootstrap scores – OS: 0.469; CSS: 0.752) than AHR stages (OS: 0.436; CSS: 0.206) and 8th edition AJCC (OS: 0.095; CSS: 0.043).

Conclusions: A novel RPA-based TNM stage groups revealed significantly better survival prediction compared with the 8th edition AJCC and AHR stages.

1054PD A New Classification for Nasopharyngeal Carcinoma

H.C.S. Cheng[1], C-F. Horng[2]

[1]Radiation Oncology, Koo Foundation Sun Yat-Sen Cancer Center, Taipei, Taiwan, [2]Clinical Research, Koo Foundation Sun Yat-Sen Cancer Center, Taipei, Taiwan

Background: This study is to develop and validate a new classification for nasopharyngeal carcinoma (NPC).

Methods: Fifteen hundred and twenty-eight (1528) newly diagnosed NPC patients treated between 1995 and 2010 were included in this study. Seven hundred and one patients ($n = 701$) were treated with 3D conformal radiotherapy (3D-RT) and 827 patients were treated with IMRT. Cox proportional hazards model was used to select the significant split node to partition patients into the different risk group. Recursive partitioning analysis derived a new classification in patients treated with 3D-RT objectively. This new staging system was then validated in patients treated with IMRT.

Results: The median follow-up interval was 84.6 months (ranging 2-175 months). According to the 7th AJCC staging system, the stage I patients showed a 5-year overall survival (OS) rate of 93.0%, stage II of 94.5%, stage III of 87.5%, stage IVA of 71.5%, stage IVB of 61.3%, and stage IVC of 5.8% ($p < 0.0001$). In the validation group ($n = 827$), the Group I in new system was patients with stages of T1-3N0-1 and T1N2 ($n = 364$); their 5-year OS was 92.4%. The Group II was patients with stages of T2N2 and T3N2 ($n = 175$); thier 5-year OS was 86.0%. The Group III was patients with stages of any T4 and N3 ($n = 249$); their 5-year OS was 72.0%. The Group IV was patients with distant metastasis ($n = 36$); their 5-year OS was 17.9%. This new classification system will be compared to the 8th AJCC staging system.

Conclusions: We propose a new staging system for NPC, which distributes more patients in the early stage.

Table: 1054PD Patient Distribution According to Chinese 2008 and the 7th AJCC staging systems

Stage	Chinese 2008 staging	2010 AJCC staging	Current proposal
Stage I	2.3%	2.3%	42.9%
Stage II	11.0%	23.7%	21.9%
Stage III	39.4%	49.1%	30.0%
Stage IV	47.3%	24.9%	5.2%

Background: In CheckMate 141, nivolumab monotherapy significantly prolonged overall survival (OS) vs IC (median [95% CI]: 7.5 [5.5, 9.1] mo vs 5.1 [4.0, 6.0] mo) and doubled response rate (13.3% vs 5.8%) in patients (pts) with R/M SCCHN. Here, we describe clinical outcomes by best overall response for the nivolumab and IC arms.

Methods: CheckMate 141 (NCT02105636) was a randomized, open-label, phase 3 trial in which pts ($N = 361$) with R/M SCCHN who progressed on or within 6 mo of platinum-based therapy were randomized 2:1 to nivolumab 3 mg/kg every 2 weeks ($n = 240$) or IC of methotrexate, docetaxel, or cetuximab ($n = 121$). We analyzed the

Table: 1055P

	CR/PR		SD		PD	
	Nivolumab (n = 32)	**IC (n = 7)**	**Nivolumab (n = 55)**	**IC (n = 43)**	**Nivolumab (n = 100)**	**IC (n = 42)**
Median OS, mo(95% CI)	NR (NR, NR)	13.6 (8.9, NR)	10.4 (8.7, 15.2)	7.1 (5.4, 9.5)	5.7 (4.8, 7.8)	4.5 (3.6, 5.8)
HR (95% CI)	0.08 (0.01, 0.47)		0.53 (0.33, 0.85)		0.74 (0.51, 1.09)	
12-mo OS rate, % (95% CI)	96.8 (79.2, 99.5)	57.1 (17.2, 83.7)	46.1 (32.4, 58.7)	29.4 (16.4, 43.7)	21.4 (13.9, 30.1)	11.9 (4.4, 23.6)
18-mo OS rate, % (95% CI)	86.1 (67.0, 94.6)	38.1 (6.1, 71.6)	32.6 (20.0, 45.8)	11.7 (3.6, 25.0)	3.0 (0.6, 8.9)	4.8 (0.5, 17.2)

NR = not reached

primary endpoint of OS and additional endpoint of safety by best overall response (complete or partial response [CR/PR], stable disease [SD], or progressive disease [PD]), assessed by investigators per RECIST 1.1 every 6 weeks beginning at week 9.

Results: The minimum follow-up was 11.4 mo. Baseline demographics were similar across response groups and treatment arms. Median duration of therapy for nivolumab-treated pts with CR/PR, SD, and PD was 12.5 mo, 4.2 mo, and 1.6 mo, respectively. Estimates of median OS, 12-mo, and 18-mo survival rates favored nivolumab vs IC in the CR/PR and SD response groups (Table). The incidence of grade 3–4 treatment-related adverse events was lower for nivolumab vs IC within each of the response groups (CR/PR, SD, and PD).

Conclusions: Pts with CR/PR and SD had improved median OS and survival rates with nivolumab relative to single-agent standard therapy. Nivolumab's safety profile was favorable vs IC, including for pts with CR/PR whose median duration of therapy was greater than a year.

1056P Estimated costs of treatment-related adverse events (TRAEs) for recurrent or metastatic (R/M) squamous cell carcinoma of the head and neck (SCCHN) in the checkmate 141 trial

M. Venkatachalam[1], S. Bobiak[2], J.W. Shaw[2], I. Santi[1], M. Contente[2], B. Korytowsky[2], D.D. Stenehjem[3]

[1]Oncology, PAREXEL International, Waltham, MA, USA, [2]Oncology (HEOR), Bristol-Myers Squibb, Princeton, NJ, USA, [3]Pharmacy Practice and Pharmaceutical Sciences, University of Minnesota, Duluth, MN, USA

Background: Nivolumab, a programmed death-1 (PD-1) immune checkpoint inhibitor antibody, is approved in the United States and the European Union for treatment of SCCHN progressing on or after platinum-based chemotherapy. In the phase 3 CheckMate 141 trial, nivolumab significantly improved overall survival vs investigator's choice (IC) of standard, single-agent systemic therapy (methotrexate, docetaxel, or cetuximab) in patients with R/M SCCHN. This study assessed the estimated costs of managing grade 3–4 TRAEs requiring treatment in CheckMate 141.

Methods: The frequency, grade, and attribution of TRAEs for which treatment was received were extracted from CheckMate 141 patient-level safety data. Grade 3–4 TRAE treatment costs were estimated based on principle diagnosis codes of the International Classification of Disease, 9th Revision in the Healthcare Cost and Utilization Project National Inpatient Sample data (2012–2014), adjusted to reflect 2013-equivalent US costs.

Results: Among the 347 patients in the safety population, 236 received nivolumab and 111 received IC. A total of 88 grade 3–4 TRAEs requiring treatment were observed: 28 among patients receiving nivolumab and 60 among patients receiving IC. The cost of managing TRAEs per treated patient was 4.5 times higher in the IC arm ($4913) than in the nivolumab arm ($1072). Patients receiving docetaxel and methotrexate had the highest incidence of TRAEs and estimated TRAE management costs (Table).

Table: 1056P

	Nivolumab (n = 236)	IC (combined) (n = 111)	IC		
			Cetuximab (n = 13)	**Docetaxel (n = 52)**	**Methotrexate (n = 46)**
Number of grade 3–4 TRAEs requiring treatment (%)	28/88 (31.8)	60/88 (68.2)	2/60 (3.3)	36/60 (60.0)	22/60 (36.7)
Total estimated cost of managing grade 3–4 TRAEs, $	253,067	545,374	17,855	333,307	194,211
Cost of managing grade 3–4 TRAEs, mean per treated patient, $	1072	4913	1373	6410	4222

Conclusions: Patients with platinum-refractory R/M SCCHN treated with nivolumab had fewer grade 3−4 TRAEs, lower estimated total costs of managing TRAEs, and reduced TRAE costs per treated patient compared with standard, single-agent systemic therapy.

1057P Phase I trial of cetuximab, intensity modulated radiotherapy (IMRT), and ipilimumab in previously untreated, locally advanced head and neck squamous cell carcinoma (PULA HNSCC)

R.L. Ferris[1], D.A. Clump[2], J. Ohr[3], W. Gooding[4], S. Kim[4], B.J. Karlovits[4], U. Duvvuri[4], J.T. Johnson[4], D. Petro[4], D.E. Heron[4], J. Bauman[3]

[1]Otoloaryngology, University of Pittsburgh, Pittsburgh, PA, USA, [2]Radiation Oncology, University of Pittsburgh, Pittsburgh, PA, USA, [3]Medicine, University of Pittsburgh, Pittsburgh, USA, [4]Medicine, University of Pittsburgh, Pittsburgh, PA, USA

Background: Concurrent IMRT with cetuximab (C), an EGFR-specific antibody for PULA HNSCC is suboptimal for intermediate-risk (IR) or high risk (HR) HNSCC. CTLA-4+ Tregs dampen cellular immunity and correlate negatively with clinical outcomes. Thus, we conducted a phase I study adding ipilimumab (ipi), an anti-CTLA-4Ab to standard C-IMRT in patients (pts) with intermediate or high risk PULA HNSCC.

Methods: Key eligibility: stage III-IVb PULA HNSCC [pharynx, larynx]; highrisk [HPV-] or intermediate risk [HPV+ and either: ≥ 10 pack-year tobacco and ≥ N2 disease; or T4 or N3 disease]. A phase I [3 + 3] dose escalation design was used to establish a recommended phase II dose [RP2D). Dose limiting toxicity [DLT] was defined as any grade 4 adverse event [AE] except in-field radiation dermatitis or any immune-related [ir] AE requiring ≥ 2 weeks of systemic steroids.

Results: From July 2013-May 2016, 18 pts enrolled: 5 larynx, 3 hypopharynx, 3 HPV-oropharynx, 7 HPV+ oropharynx; 14 smokers; 2 stage III, 13 stage IVa, 3 stage IVb. Two of 6 pts incohort 1 experienced grade 3 dermatologic DLT's: perforating folliculitis and autoimmune dermatitis. Cohort -1 was expanded to N = 12 without DLT's. irAE included: grade 1, 2, and 3 dermatitis [2, 1, and 3 cases], grade 4 colitis [1], and grade 1 hyperthyroidism [1]. Four pts recurred, 3 of whom died. Five patients remain disease-free for >2 years. Median follow up for disease-free patients was 14 months [range 5 - 37 months]. The probability of 2-year overall survival was 71% [95% CI: 49% - 100%]. The two-year probability of progression- free survival was 77% [95% CI: 59% - 100%]. Immune biomarkers demonstrated modulation of suppressive regulatory T cell [Treg] subsets.

Conclusions: Ipi plus C-IMRT is tolerable and yields acceptable survival without cytotoxic chemotherapy for IR and HR patients. The RP2D for ipi plus C-IMRT is 1mg/kg weeks 5, 8, 11, and 14. Treg biomarkers are modulated by this type of immunotherapy.

1058P Does hyper-progression exist among head and neck cancer patients treated with immunotherapy?

A. Ortega Franco[1], M. Plana[1], I. Braña[2], M. Taberna Sanz[3], M. Oliva Bernal[1], S. Vázquez[1], M. Domenech Vinyolas[4], G. Berenguer[1], E. Vilajosana[1], M. Bergamino[1], N. Baste[5], R. Mesia Nin[3]

[1]Medical Oncology, Institut Catala de Oncologia, Barcelona, Spain, [2]Molecular Therapeutics Research Unit, Vall d'Hebron Institute of Oncology, Barcelona, Spain, [3]Medical Oncology, Institut Català d'Oncologia Hospital Duran i Reynals, Barcelona, Spain, [4]Clinical Oncology, Institut Catala de Oncologia, Barcelona, Spain, [5]Medical Oncology, Vall d'Hebron Institute of Oncology, Barcelona, Spain

Background: Immunotherapy (IM) improves survival (OS) in recurrent/metastatic squamous cell carcinoma of the head and neck (HNSCC) patients after platinum progression. Hyper-progression (HP) is a pattern of accelerated tumor growth with ECOG deterioration (ECOGdt) that has been described in patients (p) with solid tumors within the first weeks of IM.

Methods: HP is defined by twofold increase in tumor growth rate (TGR) (1). Our aim was to detect HP in a cohort of HNSCC p treated with IM in clinical trials in 2 cancer centers (ICO, VHIO). 1 S Champiat. Clin Cancer Res, 2016.

Results: From 08/2014 to Dec/2016, 69p were included in IM trials. Among them, 46p were evaluable for TGR. Baseline characteristics and IM are listed in Table. After a median follow-up of 9.4 months (m) (1-27), 36p have progressed and 24 have died. Median overall survival (mOS): 14m (8-20), percentile 75% 5m (3-7). TGR decreased in 33 p. TGR increased in 13p, presenting two-fold TGR in 2p, with 2 IM discontinuation within 2 months and 1 ECOGdt, with no differences in mOS compare to the rest (p = 0.8). We also identify 9p with progression within 2m and rapid ECOGdt, which were defined as early progressors (EP). A comparative analysis between EP and no EP was performed (Table). Within EP p, there is a lower proportion of objective response (OR), PDL-1 positivity and cisplatin sensitive (CS) tumors (p > 0.1). EP p had significantly higher proportion of tumor complications (p = 0.013) and worse mOS: 3m (0.8-5.9) vs 15m (3.9-26), HR 3.9 (1.2-10) p 0.008.

Conclusions: In our cohort, we did not detect HP as previously defined. However, there is a proportion of p that has poor survival due natural HNSCC history, these p lack of benefit from IM monotherapy and other strategies should be explored.

1059P PD-L1 Detection and Assay Performance in Squamous Cell Carcinoma of the Head and Neck Using PD-L1 IHC 28-8 pharmDx

S. Alvarez[1], J. Chan[1], J. William[2], C. Felten[1], D.A. Hanks[1], A. Northrup[1], D. Jaiswal[1], M. Jansson[1], T. Phillips[1], A. Segal[1], I. Satnick[1], H. McDonald[1], H. Little[1], C. Pierce[1], B. Wynne[1], J. Carnahan[1], S.Y. Reddy[1], H.D. Inzunza[3], E. Oroudjev[1]

[1]Companion Diagnostics, Agilent Technologies, Carpinteria, CA, USA, [2]Pathology, NeoGenomics, Aliso Viejo, CA, USA, [3]Pathology, Halozyme Therapeutics, San Diego, CA, USA

Background: Detecting PD-L1 protein expression by immunohistochemistry has shown to be effective in identifying patients who may benefit from treatment with PD-1 targeted immune checkpoint inhibitors. The PD-L1 IHC 28-8 pharmDx assay has been applied in formalin-fixed, paraffin-embedded (FFPE) squamous cell carcinoma of the head and neck (SCCHN) tissues for measuring PD-L1 expression and its associated treatment effect with nivolumab. Assay performance results of PD-L1 IHC 28-8 pharmDx in SCCHN, including validation in external reproducibility, are described.

Methods: Antigen retrieval was conducted on Dako PT Link and automated staining was performed with Autostainer Link 48 platform using the PD-L1 IHC 28-8 pharmDx protocol, per instructions for use. The PD-L1 staining was assessed by tumor proportion score to report the percentage of PD-L1 expression in invasive SCCHN. Assay performance was validated at the $\geq$ 1% expression level on commercially procured FFPE SCCHN specimens.

Results: PD-L1 expression was measured on 236 unique specimens originating from squamous cell carcinoma of the tongue, tonsil, nasopharynx, oropharynx, hypopharynx, and larynx. The assay demonstrated acceptable sensitivity and reported a large range of PD-L1 expression from 0 to 95% positive tumor cells and 0 to 3+ staining intensity. Acceptable correlation was observed between primary and metastatic specimens and between "sister" blocks from the same patient. Validation of assay precision and robustness (to target retrieval solution pH, target retrieval solution temperature, target retrieval time, and cut section thickness) demonstrated agreement estimates above 97.5% with the lower bound of two-sided 95 percent confidence intervals at 95% or higher. When tested in external sites, intra- and inter-site reproducibility, and intra- and inter-observer agreements were estimated above 94% with the lower bound of two-sided 95 percent confidence intervals at 88% or higher. Stability of PD-L1 staining in aged cut sections demonstrated interim stability at 4 months with ongoing evaluation.

Conclusions: PD-L1 IHC 28-8 pharmDx has shown to be reproducible and robust in detecting PD-L1 expression in FFPE human SCCHN specimens using the Autostainer Link 48.

1060P Programmed death ligand-1overexpression is a poor prognostic factor for Human papillomavirus-positive tonsillar squamous cell carcinoma

M.J. Kwon[1], M. Hong[2], S.Y. Kang[3]

[1]Pathology, Hallym University Sacred Heart Hospital, Anyang, Republic of Korea, [2]Pathology, Kangnam Sacred Heart Hospital, Seoul, Republic of Korea, [3]Pathology, Samsung Medical Center Sungkyunkwan University School of Medicine, Seoul, Republic of Korea

Background: Programmed death-ligand 1 (PD-L1) plays a key role for immune evasion, contributing to carcinogenesis and tumor progression. Tonsillar squamous cell carcinomas (TSCCs) are the most common human papillomavirus (HPV)-associated oropharyngeal cancers and they frequently present with locally advanced diseases and cervical metastases, which are associated with poor prognoses. Recent studies have reported the close association between PD-L1 and HPV in head and neck SCCs. However, its clinical and prognostic significances in TSCCs remain controversial.

Methods: Immunohistochemical analysis of PD-L1 was performed in 79 formalin-fixed paraffin-embedded blocks of surgically resected specimens. Peptide nucleic acid-based HPV chip test was used for detection of HPV.

Results: PD-L1 expression was observed in 19 cases (24.1%), and clinicopathological features such as invasion to base of tongue, lymphatic invasion, infiltrative tumor border, younger age (<60 years), left side location, and lymph node metastasis represent significant risk factors associated with PD-L1 overexpression in TSCCs. HPV tended to be associated with PD-L1 overexpression, which showed borderline statistical significance ($P = 0.066$). PD-L1 expression was a strong indicator for poor overall survival but not for disease-free survival. Notably, PD-L1 overexpression had significant effects on worse overall and disease-free survivals in HPV-positive TSCCs. Multivariate analysis revealed that PD-L1 overexpression was an independent prognostic factor for overall survival ($P = 0.049$, hazard ratio 2.750).

Conclusions: PD-L1 overexpression may predict a poor prognosis and a high risk of recurrence in TSCC patients, especially in HPV-positive tonsil cancers, implying PD-L1 could be potent candidates for a new prognostic and predictive biomarker in tonsil cancers.

1061P The prognostic role of PD-L1 expression in tumor and immune cells in oral cavity squamous cell carcinoma

S. Kutukova[1], N. Beliak[1], G. Manikhas[2], G. Raskin[3], Y. Ivaskova[4], N. Popova[1]

[1]Chemotherapy Department, City Clinical Oncology Dispensary, Saint-Petersburg, Russian Federation, [2]Head physician, City Clinical Oncology Dispensary, Saint Petersburg, Russian Federation, [3]Department of Pathology, Russian Research Centre for Radiology and Surgical Technologies, St.-Petersburg, Russian Federation, [4]Maxillo-Facial Surgery Department, City Clinical Oncology Dispensary, Saint-Petersburg, Russian Federation

Background: The programmed death-ligand 1 (PD-L1) has an important role in anticancer immunity. The aim of our study was to examine the expression and prognostic value of PD-L1 in tumor and immune cells in patient with squamous cell carcinoma of oral cavity (OCSCC).

Methods: We detected tumor samples of 60 patients with OCSCC with stage I - IVB (37 men, 23 women; median age 59). We examined demographic data, clinical stage, tumor morphological characteristics and expression of PD-L1 in tumor and immune cells (clone BCDdx1020) by immunohistochemistry (55 samples were acceptable).

Results: The expression level in tumor cells varied from 0% to 70%: in 24 (43,64%) samples expression of PD-L1% were negative (0%), in 9 (16,36%) - from 1 to 4% (low rate), in 17 (30,91%) - from 5 to 49% (moderate rate) and in 5 (9,1%) - more than 50% (high). In immune cells expression of PD-L1 varied from 0% to 15%: in 7 (12,73%) samples - negative (0%), in 30 (54,55%) - from 1 to 4% (low), in 13 (23,64%) - from 5 to 9% (moderate) and in 5(9,10%) - >10% (high). In 5 samples with high level PD-L1 expression in tumor expression PD-L1 in immune cells was negative. Median OS of patients with PD-L1-negative' tumor was 17 mo (95% CI 8-185), with low rate (1-4%) of PD-L1 expression - 9 mo (95% CI 2-36), with moderate rate (5-49%) - 13 mo (95% CI 7,5-19) and median OS in patients with high rate (>50%) not reached for this time and mean of OS is 55 mo ($\sigma = 14{,}722$) (95% CI 26-84). Median OS of patients with negative PD-L1-status in immune cells was 12 mo (95% CI 4-185), with low rate (1-4%) PD-L1 in immune cells - 13 mo (95% CI 7,5-34,5), with moderate rate (5-9%) - 15 mo (95%CI 9-15) and with hight rate (>10%) - 17 mo (95%CI 3-36) with strong trend of increasing OS with rise of PD-L1 expression in immune cells.

Conclusions: PD-L1 expression in tumor and immune cells are favourable prognostic factors for oral cavity squamous cell carcinoma.

1062P Immune profile analysis of head and neck squamous cell carcinoma before and after neoadjuvant treatment with the IRX-2 regimen

G.T. Wolf[1], J.G. Newman[2], N.L. Berinstein[3], M.J. McNamara[4], A. Nguyen[1], J.E. Egan[5], M.J. Kaplan[6]

[1]Otolaryngology-Head and Neck Surgery, University of Michigan, Ann Arbor, MI, USA, [2]Otolaryngology, U of Penn, Philadelphia, PA, USA, [3]Medical Oncology, Sunnybrook Health Sciences Center, Toronto, ON, Canada, [4]Chiles Research Institute, Providence Portland Medical Center, Portland, OR, USA, [5]Reearch, IRX Therapeutics, New York, NY, USA, [6]Otolaryngology, Stanford University, Stanford, CA, USA

Background: IRX-2 is an injectable cancer immunotherapy composed of cytokines purified from stimulated peripheral blood mononuclear cells. In a phase 2a trial

(n = 27), neoadjuvant IRX-2 significantly increased lymphocyte infiltration (LI) into resected head and neck tumors. Increased LI was associated with changes in fibrosis and necrosis in resected tumors, 65% event-free survival (EFS) at 2 years, and 65% overall survival (OS) at 5 years, better than rates for historical matched controls. Patients with LI greater than the median had improved OS compared to those below the median. This substudy was undertaken to define the mechanisms responsible for the increase in LI with neoadjuvant IRX-2.

Methods: Matched pre- and post-treatment tumor specimens from 7 phase 2a study patients were interrogated with two immune-profiling technologies, multiplex immunohistochemistry (IHC, PerkinElmer, Waltham, MA) and transcriptome analysis (NanoString Technologies, Seattle, WA).

Results: Multiplex IHC provided detailed visualization and quantitation of various immune cells in the tumor microenvironment (TME), supporting previous phase 2a pathology findings. Transcriptome analysis provided a global snapshot of the TME, quantitative information on immune cell subsets, and insights into possible mechanisms for changes in LI. Consistent with IRX-2 activation of multiple immune cells in the TME, mRNA expression of B cell, CD4+ T cell, CD8+ T cell, and dendritic cell functional genes was increased on average by 87%, 106%, 6%, and 130%, respectively, following treatment with IRX-2. Increases in chemokine gene expression were observed, suggesting that IRX-2-induced production of chemokines may in part drive tumor LI. Strong evidence of functional immune activation uncovered by transcriptome analysis included an increase in interferon g pathway gene expression and induction of regulatory checkpoint pathways.

Conclusions: Neoadjuvant IRX-2 promotes tumor LI and prolongs EFS and OS in patients with head and neck squamous cell carcinoma. Immune profile analyses provided insights into the pathways potentially responsible for IRX-2-induced increases in LI and overall immune activation.

1063P Phenotyping of the immune infiltrate in oropharyngeal squamous cell carcinoma: Focus on materials and methods

A. De Meulenaere[1], T. Vermassen[1], S. Rottey[1], L. Ferdinande[2]

[1]*Department of Medical Oncology, Ghent University Hospital, Ghent, Belgium,* [2]*Department of Medical and Forensic Pathology, Ghent University Hospital, Ghent, Belgium*

Background: Stromal $CD8^+$ lymphocytic infiltration constitutes an independent prognostic marker for better overall survival in patients with oropharyngeal squamous cell carcinoma (OSCC). However, scoring of (novel) biomarkers is often complicated by the lack of standardised methodology which hampers their use in daily clinical practice. We therefore performed a comparative analysis to evaluate the importance of choice of materials and methods in CD8 assessment in patients with OSCC. Other immune cell markers, that is, CD3 and FoxP3 were taken into account as well.

Methods: Immunohistochemical analysis of CD3, CD8 and FoxP3 was performed on whole-tissue sections from 101 treatment-naive patients with OSCC. A comparison of different immune cell markers was made for biopsy material versus resection material when available. Also, different scoring strategies, that is, quantitative versus semi-quantitative analysis were compared with each other.

Results: Comparison of biopsy material versus resection material proved a good agreement for expression of the $CD3^+$ T cells ($\kappa = 0.712$, $\rho = 0.853$), $CD8^+$ T cells ($\kappa = 0.659$, $\rho = 0.764$) and $FoxP3^+$ T cells ($\kappa = 0.783$, $\rho = 0.802$). The comparison of quantitative versus semi-quantitative assessment demonstrated strong correlations for the $CD3^+$ T cells ($\rho_{biopt} = 0.617$, $\rho_{resection} = 0.634$), $CD8^+$ T cells ($\rho_{biopt} = 0.656$, $\rho_{resection} = 0.675$) and $FoxP3^+$ T cells ($\rho_{biopt} = 0.537$, $\rho_{resection} = 0.720$).

Conclusions: Immunohistochemical analysis of CD3, CD8 and FoxP3 can be performed adequately on biopsy as this appears to be representative for the whole tumour. In addition, this can be done adequately in a semi-quantitative manner without the use of more expensive and time consuming machinery.

1064P High-dose versus low-dose cisplatin with definitive concurrent radiotherapy for squamous cell carcinoma of the head and neck (SCC): An analysis of veteran's health registry data

J. Bauml[1], R. Vinnakota[2], Y-H.A. Park[3], S.E. Bates[2], T. Fojo[2], C. Aggarwal[4], S. Lunate[3], N. Damjanov[1], R. Mamtani[4], C.J. Langer[4], R.B. Cohen[4], K. Sigel[5]

[1]*Hematology/Oncology, Corporal Michael J Crescenz VA Medical Center, Philadelphia, PA, USA,* [2]*Hematology/Oncology, Columbia University Medical Center, New York, NY, USA,* [3]*Hematology/Oncology, James J Peters VA Medical Center, New York, NY, USA,* [4]*Hematology/Oncology, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, USA,* [5]*Infectious Diseases, James J Peters VA Medical Center, New York, NY, USA*

Background: Radiotherapy (RT) with concurrent high-dose cisplatin (HDC) improves outcomes for patients (pts) with SCC. Weekly low-dose cisplatin (LDC) is a widely used alternative approach. The comparative effectiveness and safety of these approaches is unknown. We compared the outcomes of pts treated with HDC and LDC within the Veteran's Administration Corporate Data Warehouse (CDW).

Methods: We identified stage III-IVb SCC patients treated non-surgically with RT and HDC or LDC from 2002 to 2014 in the CDW. Pts were grouped by the dose of their first cycle (HDC vs LDC; intent-to-treat). Variables including cancer site, stage, smoking/alcohol use, and comorbidities were used to generate propensity scores (PS) for the use of HDC. We compared overall survival (OS) by treatment group using Cox regression models, adjusting for PS. We also determined the risk of toxicities using PS-adjusted logistic regression models.

Results: A total of 2,820 pts were included in the analysis: 69.7% received HDC (mean initial dose 96 mg/m^2). The mean initial dose of LDC was 30 mg/m^2. HDC pts were younger ($p < 0.001$), with lower creatinine ($p = 0.002$), and lower incidence of baseline neuropathy ($p = 0.02$). In an unadjusted analysis, HDC was associated with improved OS (Table). After PS adjustment, this difference was no longer statistically significant ($p = 0.06$). On primary site sub-analysis, HDC provided a benefit only for oropharyngeal primaries (OP). Adjusting for PS, HDC was associated with more renal failure (OR 2.2, 95% CI 1.6-3), neutropenia (OR 2, 95% CI 1.1-3.5), dehydration/electrolyte disturbance (OR 1.3, 95% CI 1.04-1.6), and hearing loss (OR 1.6, 95% CI 1.3-2).

Conclusions: While HDC does not improve OS over LDC for the overall cohort of patients with SCC receiving RT with definitive intent, it is associated with a survival benefit for patients with OP. HDC is associated with more adverse events.

1065P 3-weekly or weekly cisplatin concurrently with radiotherapy for patients with locally advanced squamous cell carcinoma of the head and neck: A multicentre, retrospective analysis

S.I. Rothschild[1], S. Helfenstein[1], O. Riesterer[2], U.R. Meier[3], A. Papachristofilou[4], B. Kasenda[1], M. Pless[5]

[1]Medical Oncology, University Hospital Basel, Basel, Switzerland, [2]Radiation Oncology, University Hospital Zürich, Zurich, Switzerland, [3]Radiation Oncology, Cantonal Hospital Winterthur, Winterthur, Switzerland, [4]Clinic for Radiotherapy and Radiation Oncology, University Hospital Basel, Basel, Switzerland, [5]Medical Oncology, Cantonal Hospital Winterthur, Winterthur, Switzerland

Background: Concurrent chemoradiotherapy with cisplatin is standard for patients (pts) with loco-regionally advanced squamous cell carcinoma of the head and neck (LA-SCCHN). The standard regimen includes 3-weekly cisplatin, but weekly regimens are often used to lower toxicity. Reaching a cumulative dose of > 200 mg/m^2 cisplatin was shown being associated with improved outcome. We herein investigated cumulative dose reached and toxicity between the both widely used 3-weekly and weekly cisplatin regimens with concurrent radiotherapy.

Methods: Multicentre, retrospective analysis of all patients with LA-SCCHN treated at 3 centers in Switzerland between 06/2008 and 12/2015. We used descriptive statistics and logistic regression (uni- and multivariable) to investigate the association between the chosen cisplatin regimen (weekly versus 3-weekly) and the chance to reach the cumulative cisplatin dose of > 200 mg/m^2. Landmark approach (8 weeks after start of treatment) was applied for investigating the prognostic impact of the cumulative cisplatin dose on survival using Cox regression techniques.

Results: We included 314 eligible pts (3-weekly schedule, N = 127; weekly schedule, N = 187). Median cumulative cisplatin dose was 200 mg/m^2 (IQR 150-300) for pts treated with a 3-weekly schedule and 160 mg/m^2 (120-240) for the weekly schedule, consequently more pts treated with a 3-weekly schedule reached a cumulative dose >200 mg/m^2 (75.6% vs. 47.1%, $p < 0.001$). This association was also observed in multivariable analysis adjusted for age and sex (OR 3.46, 95% confidence interval [CI], 2.1 - 5.7). The 3-weekly regimen led to a higher rate of renal toxicity (33.1% vs. 20.9%, $p = 0.022$), but not ototoxicity (15% vs. 12.8%). In the landmark analysis, we could not confirm that a cisplatin dose >200 mg/m^2 is associated with better survival (HR 1.3, 95% CI 0.8 -1.9).

Conclusions: Significantly more patients receive a cumulative of dose of > 200 mg/m^2, when treated with a 3-weekly schedule compared to weekly dosing. This comes at the cost of more renal toxicity. Due to the non-randomized nature of this analysis, no conclusions on the efficacy of the respective schedules should be drawn.

1066P Hyperfractionated twice daily re-irradiation (bid re-RT) and chemotherapy (CT) for locoregionally recurrent head and neck squamous cell carcinoma (LR HNSCC): A systematic review (SR)

D. Day[1], G. Locke[2], K. Chan[3], S. Cheng[3], L. Wang[4], B. O'Sullivan[2], A.R. Hansen[1]

[1]Department Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, Canada, [2]Department of Radiation Oncology, Princess Margaret Cancer Centre, University of Toronto, Toronto, ON, Canada, [3]Medical Oncology, Sunnybrook Odette Cancer Centre, Toronto, ON, Canada, [4]Biostatistics Department, Princess Margaret Cancer Centre, Toronto, Canada

Background: Re-RT +/- CT is a salvage option for patients (pts) with LR HNSCC in a previously radiated field, although efficacy and toxicity, and the optimal treatment regimen remains undefined due to a lack of randomized trials. Hyperfractionated bid re-RT, by reducing the dose per fraction may improve radiation (RT) therapeutic ratio and is increasingly used in LR HNSCC. The aim of this SR is to assess the treatment outcomes of bid re-RT + CT in LR HNSCC.

Methods: We conducted a SR of MEDLINE, EMBASE and the Cochrane library up to Nov 2016 for clinical trials of bid re-RT + CT in pts with LR HNSCC. Paired reviewers selected studies for inclusion and extracted data. Individual patient level overall survival (OS) data were extracted where possible from published Kaplan-Meier (KM) curves to construct an aggregate KM curve.

Results: We identified 10 clinical trials (all were phase 1 or 2) with 404 pts. Median (of reported medians) prior RT dose was 64Gy, and median time from prior RT was 30.9m. Seventy-three and 156 pts respectively had CT and surgery as part of 1st line treatment. Median re-RT dose was 60Gy administered as continuous or split courses. The re-RT fields consisted of gross tumor volume plus a minimum margin (range 1-2cm). All CT regimens were combinations either with cisplatin (n = 6) or 5-FU (n = 4), given concurrently with (n = 9) or prior to (n = 1) re-RT. Twenty-eight (7%) pts had debulking surgery prior to re-RT. In pts who were analyzable for toxicities, acute events (>/=grade 3) were reported in 252 of 377 (67%) pts and late events (>90d post re-RT) in 87 of 333 (26%) pts. Treatment-related deaths occurred in 26 (6%) pts, mostly due to infection or vascular events. Of the 5 trials with extractable KM curves, estimated median OS was 10.2m (95% CI 8.7-12.6m); 1- and 3-y OS rates were 46.8% and 11.2% respectively. No differences were observed in median OS and toxicity rates based on CT type (Wilcoxon test).

Conclusions: This is the 1st aggregate analysis of bid re-RT and CT in LR HNSCC. Long-term OS was observed in a subset of pts, however treatment-related morbidity was apparent. The optimal re-RT and CT regimen is still undefined and further study is required.

1067P Raltitrexed versus 5-fluorouracil with cisplatin and concurrent radiotherapy (CCRT) for locally advanced head and neck squamous cell carcinoma (LA-HNSCC): A randomized controlled multi-centered trial

X. He[1], H. Yin[2], W. Guo[1], X. Sun[3], X. Hu[2], P. Yan[1], F. Li[1], S. Huang[1], H. Zhou[4], F. Zhang[5], B. Wang[6], X. Bian[1], Q. Wei[1], J. Wu[1], F. Wang[1], D. Song[1], J. Liu[1], B. Zhou[3]

[1]Department of Radiation Oncology, Nanjing Medical University Affiliated Cancer Hospital, Jiangsu Cancer Hospital, Jiangsu Institute of Cancer Research, Nanjing, China, [2]Department of Radiotherapy Oncology, Xuzhou Central Hospital, Affiliated to School of Medicine, Southeast University, Xuzhou, China, [3]Department of Radiotherapy, Cancer Center of PLA 81 Hospital, Nanjing, China, [4]Department of Radiotherapy Oncology, Nanjing BenQ Hospital, Nanjing, China, [5]Department of Radiotherapy Oncology, Fourth People's Hospital of Wuxi, Wuxi, China, [6]Department of Radiotherapy Oncology, Northern Jiangsu Province People's Hospital, Yangzhou, China

Background: CCRT has been considered to be the standard of treatment for LA-HNSCC. However, patients receiving CCRT experience a substantial number of treatment-related adverse events, primarily causing oropharyngeal mucositis(OM) and leading to interruption or discontinuation of treatment. Raltitrexed is a specific thymidylate synthase inhibitor with a convenient administration, acceptable toxicity and radiosensitizing property, as the published phase I/II trials have shown. This study aimed to compare the clinical efficacy and toxicity of cisplatin with raltitrexed (RP) or 5-fluorouracil (FP) for LA-HNSCC.

Methods: Eligible patients with LA-HNSCC were randomly assigned in a 1:1 ratio to receive CCRT with either RP or FP. The RP group consisted of 2.5mg/m^2 intravenous raltitrexed on day 1 and 25 mg/m^2 intravenous cisplatin on days 1-3. The FP group consisted of continuous intravenous infusions of 600 mg/m^2 5-fluorouracil on days 1-5 and 25 mg/m^2 intravenous cisplatin on days 1-3. Chemotherapy was administrated concurrently with radiotherapy and was repeated every 3 weeks with completion of at least 2 cycles. Primary endpoint was PFS. Secondary endpoints were complete response rates(CRR), OS and safety.

Results: A total of 108 patients with LA-HNSCC enrolled in this study, with 52 patients assigned to the RP group and 56 patients to the FP group. There was no significant difference in CRR between the two arms (42.9% vs 26.8%, respectively, $p = 0.074$), with the RP group showing a trend of increased CRR. Data of locoregional control, patterns of failure, and survival required further follow-up. The most frequent acute toxicities were bone marrow suppression, gastrointestinal side effects and OM in both arms. The incidence rate of severe OM was significantly lower ($P<0.05$) in the RP group than in the FP group. The incidence of other adverse effects seen in the two arms were similar ($P>0.05$).

Conclusions: The efficacy of the RP regimen was similar to that of the FP regimen. The RP regimen had a tolerable safety profile, with a lower incidence of severe OM and, consequently, an improved quality of life. In conclusion, RP is an effective, well-tolerated regimen for LA-HNSCC.

O. Oncologia Medica, Ospedale Vito Fazzi, Lecce, Italy, [5]Radiation Oncology, University of Florence, Florence, Italy, [6]Pneumo-Oncology, AORN dei Colli; Monaldi Hospital, Naples, Italy, [7]Medical Affairs, Merck KGaA, Darmstadt, Germany, [8]Biostatistics, Prometris GmbH, Mannheim, Germany, [9]Medical Oncology, Azienda Ospedaliero-Universitaria Pisana; Istituto Toscano Tumori, Pisa, Italy, [10]Medical Oncology, Ospedale SS. Giovanni e Paolo, Venice, Italy

Background: The randomized, phase 3 EXTREME study established cetuximab + platinum + 5-flurouracil (5-FU) followed by cetuximab maintenance until progressive

disease (PD) as the first regimen to yield survival benefits in the 1L management of patients with R/M SCCHN. In EXTREME, the addition of cetuximab increased the overall response rate from 20% to 36%, and extended progression-free survival from 3.3 to 5.6 months and overall survival from 7.4 to 10.1 months. ENCORE is a multinational, non-interventional, prospective, open-label study, seeking to determine how treatment decisions are made, planned and executed by oncologists treating patients with 1L therapy for R/M SCCHN in the real world.

Methods: ENCORE prospectively enrolled 219 patients with R/M SCCHN from Algeria, France, Italy, Portugal and Russia. The recommended treatment for these patients is cetuximab + PBT for up to 6 cycles followed by cetuximab maintenance until PD. Patient characteristics, drugs and schedule were recorded; as the study is still ongoing, safety and efficacy will not be reported here.

Results: ENCORE patients and the EXTREME patients who received cetuximab + platinum + 5-FU had similar performance status (PS: 13.7 and 12% with PS $\geq$ 2, respectively), but dissimilar median age (64 and 56 years, respectively). In ENCORE, 94.1% of patients had a planned treatment of cetuximab + PBT with cetuximab maintenance until PD. The remaining 13 (5.9%) had a fixed treatment duration of 4 to 24 weeks. 37.9% of treatment plans used cisplatin, 61.6% included carboplatin and 3.2% used a taxane. Also, only 53.4% of plans included 5-FU. When developing the treatment plan, 72.1% of all patients were discussed within the context of a multidisciplinary team (MDT). Most plans had the goal of palliative care, and 80% were formulated without a p16 or human papillomavirus status test. Updated data will be presented at congress.

Conclusions: The ENCORE study shows that a real-world R/M SCCHN patient population treated with the EXTREME regimen has diverse characteristics and is treated per current recommendations (e.g. in an MDT setting, with cetuximab until PD).

1069P Primary surgery versus chemoradiotherapy for advanced oropharyngeal and hypopharyngeal cancer: A propensity-score matched study using a nationwide database

C. Cheng

Medical Research, Koo Foundation Sun Yat Sen Cancer Center, Taipei, Taiwan

Background: Traditionally, advanced head and neck cancer has been managed through surgery with or without postoperative radiotherapy. Studies since the 1980s have been advocating organ preservation therapies by using various combinations of chemotherapy and radiotherapy. For treatment of advanced oropharyngeal and hypopharyngeal cancer, there has been a controversy in choosing between primary surgery and chemoradiotherapy. We aimed at conducting a propensity-score matched study from a national database to investigate the survival after primary surgery with or without postoperative radiotherapy versus chemoradiotherapy in patients with advanced oropharyngeal and hypopharyngeal cancer.

Methods: We identified patients with stage III & IVa oropharyngeal and hypopharyngeal cancers between 2004 and 2009 from Taiwan National Health Insurance Claims Database. The study cohort was followed until 2012. We matched patients who received primary surgery to those who received chemoradiotherapy by propensity score calculated by logistic regression. Age at diagnosis, Charlson comorbidity index score, year of cancer diagnosis, clinical stage, receiving chemoradiotherapy, and receiving radiation therapy were well matched in these two groups. Overall survival and disease-free survival were compared using the Kaplan−Meier method.

Results: We identified 1,603 oropharyngeal and 1,512 hypopharyngeal cancer patients. After propensity score matching, 614 patients with oropharyngeal cancer and 638 patients with hypopharyngeal cancer were included in the analysis. For advanced hypopharyngeal cancer (stage III and IVa), the overall survival and disease-free survival in patients receiving primary surgery with or without radiotherapy were statistically better than the matched sample who received chemoradiotherapy. For oropharyngeal cancer, the survival benefit only existed in stage IVa patients who received primary surgery with or without radiotherapy.

Conclusions: The study showed that primary surgery with or without radiotherapy might have survival benefit in patients advanced oropharyngeal or hypopharyngeal cancer as compared to chemoradiotherapy.

1070P Comparison of carboplatin with 5-fluorouracil (carbo-5FU) versus cisplatin as concomitant chemoradiotherapy (CRT) for locally advanced head and neck squamous cell carcinoma (LA-HNSCC)

S.H. Hanemaaijer[1], I.C. Kok[2], R.S.N. Fehrmann[2], B. van der Vegt[3], J.A. Gietema[2], B.E.C. Plaat[1], M.A.T.M. Vugt[2], M.R. Vergeer[4], J. Voortman[5], C.R. Leemans[6], J. Buter[5], J.A. Langendijk[7], S.F. Oosting[2]

[1]Otorhinolaryngology, University Medical Center Groningen, Groningen, Netherlands, [2]Medical Oncology, University Medical Center Groningen, Groningen, Netherlands, [3]Pathology, University Medical Center Groningen, Groningen, Netherlands, [4]Radiotherapy, VU University Medical Center/Cancer Center, Amsterdam, Netherlands, [5]Medical Oncology, VU University Medical Center/Cancer Center, Amsterdam, Netherlands, [6]Otolaryngology/, VU University Medical Center/Cancer Center, Amsterdam, Netherlands, [7]Radiation Oncology, University Medical Center Groningen, Groningen, Netherlands

Background: CRT including three cycles of cisplatin is considered the standard of care for LA-HNSCC. Around one third of the patients cannot complete cisplatin due to toxicity. Carbo-5FU can be used as an alternative. The aim of this study was to compare tolerability and efficacy between CRT with carbo-5FU and cisplatin.

Methods: This is a retrospective analysis of patients with LA-HNSCC treated with concomitant CRT in two Dutch cancer centers between 2007-2016. All patients received intensity modulated radiotherapy. One center routinely administered carboplatin 300-350 mg/m^2 at day 1, 22 and 43 followed by 5FU 600mg/m^2/day for 96 hours. The other center used cisplatin 100 mg/m^2 at day 1, 22 and 43. Primary endpoint was chemotherapy completion rate. Secondary endpoints included: reason for discontinuation, number of unplanned admissions, overall survival (OS) and disease free survival (DFS). Associations between clinicopathological parameters and OS were determined with multivariate Cox regression analyses.

Results: In the carbo-5FU cohort (n = 190), 61.6% of the patients completed chemotherapy versus 76.7% (p = 0.001) of the patients in the cisplatin cohort (n = 223). Discontinuation caused by chemotherapy specific toxicity occurred twice as often in the carbo-5FU cohort (odds ratio 2.2, 95%CI, 1.38-3.5). Patients in the cisplatin cohort were more likely to have an unplanned admission (OR 2.96, 95%CI, 2.21-4.27). The risk of death was higher in the carbo-5FU cohort (HR 1.50, 95%CI, 1.06-2.12, p = 0.02) with a three-year OS of 64.6% compared to 76.6% in the cisplatin cohort. Similar results were observed for DFS (HR 1.39, 95%CI, 0.99-1.93, p = 0.06). T-classification, N-classification, smoking and p16 status were independently associated with OS, but chemotherapy regimen was not (HR 1.04, 95%CI, 0.72-1.51, p = 0.84).

Conclusions: Patients treated with carbo-5FU less frequently completed chemotherapy because of chemotherapy specific toxicity. Better OS was observed in the cisplatin cohort, but chemotherapy regimen was not independently associated with OS.

1071P Postoperative radiotherapy with weekly cisplatin in locally advanced head and neck cancer

A. Hervás, J. Domínguez, D. Candini, M. Martín, C. Vallejo

Radiation Oncology, Hospital Universitario Ramon y Cajal, Madrid, Spain

Background: The aim of this study is to analyze the results of over 10 years experience with postoperative radiochemotherapy in patients diagnosed of locally advanced squamous cell carcinoma of head and neck based in cisplatin 40mg/m2/week.

Methods: From March 2004 to August 2015, 104 patients were treated in our department. All patients received chemoradiation therapy with adjuvant intent based in the same scheme: radiotherapy 50 Gy to clinical target volume (CTV) and 66-70 Gy to areas with close margin or extracapsular lymph node involvement and weekly cisplatin at 40mg/m2 concomitant to radiotherapy.

Results: The median age was 59 years (range 36-76), 85 patients were male (81.7%) and 19 were female (18.3%). The pathological stage was: 2.9 stage II, 8.7% stage III and 88.4% stage IV. Locations: 38.5% larynx, 38.5% oral cavity, 17.3% oropharynx, and 5.8% hypopharynx. 76.2% of patients received at least 5 cycles of chemotherapy. G3 toxicity was observed in 33% of patients being mucositis and epitelitis the most frecuents. G4 toxicity was not detected in any patient. Median follow-up was 81 months (range 18-137). Two-year and five-year overall survival (OS) were 90% and 76% respectively and disease-free survival (DFS) were 69.07% and 52.57% respectively. In multivariate analysis two or more positive nodes and longer time between surgery and

onset of radiotherapy were significant predictors of poorer OS and extracapsular extension, positive margin and longer time between surgery and onset of radiotherapy were significant predictors of poorer DFS.

Conclusions: In our serie, postoperative radiochemotherapy based in weekly cisplatin at 40mg/m2 in patients diagnosed of locally advanced squamous cell carcinoma of head and neck offers a good toxicity profile and results comparable to those published in the literature with 3-weekly cisplatin scheme. The number of positive nodes, longer time between surgery and onset of radiotherapy, extracapsular extension and positive margin were desfavorable prognostic factor related with SLE and OS in the multivariate analysis.

1072P Effectiveness and toxicities of cetuximab in combination with concurrent chemoradiotherapy in locoregionally advanced nasopharyngeal carcinoma: A propensity score-matched analysis

L-R. Wu, J-H. Xu, W-J. Guo, X. He*Department of Radiation Oncology, Nanjing Medical University Affiliated Cancer Hospital, Jiangsu Cancer Hospital, Jiangsu Institute of Cancer Research, Nanjing, China*

Background: There is increasing evidence showing that concurrent chemoradiotherapy (CCRT) may be inadequate for patients with locoregionally advanced nasopharyngeal carcinoma. Until now, no randomized controlled clinical trial has proved the effectiveness of cetuximab plus CCRT.

Methods: There were 681 consecutive stage III-IVB NPC were included in this retrospective study.75 underwent CCRT with cetuximab and 606 received CCRT.The nasopharyngeal and neck tumor of all patients were treated by intensity modulation radiated therapy (IMRT).

Results: After matching at a 1:2 ratio, 150 patients were treated with CCRT and 75 with CCRT plus C were selected. The 3-year PFS rates (83.7% vs 72.0%, P = 0.036) and 3-year LRFS rates (98.6% vs 90.2%, P = 0.034) were higher for patients in the CCRT plus C arm than with CCRT alone. Furthermore, a marginal trend of increasing risk of 3-year DMFS rates (83.9% vs 78.4%, P = 0.301) and 3-year OS rates (91.2% vs 85.8%, P = 0.123) was found. The results indicated that CCRT plus C treatment was a significant and independent protective predictor for 3-year PFS (P = 0.015) and LRFS rates(P = 0.047). When focusing on stage T4 and/or N3 in the subgroup, the CCRT plus C arm achieved significantly prolonged 3-year PFS (79.9% vs 62.6%, P = 0.022) and a marginally increased OS (88.0% vs 77.9%, P = 0.086) compared with that of CCRT alone. Additionally, the 3-year LRFS (97.0% vs 90.9%, P = 0.246) and DMFS (79.9% vs 67.8%, P = 0.161) were enhanced in patients with CCRT plus C compared to CCRT alone. When concentrating on stage III patients, there were no considerable statistically significant differences found in 3-year PFS, OS, LRFS, and DMFS rates between patients with and without cetuximab. No significant difference was observed in the late toxicities between the two treatments.

Conclusions: This propensity-matched study reveals that patients with T4 and/or N3 stage could benefit from the combination of cetuximab with the current chemoradiotherapy in locoregionally advanced NPC, although with more acute moderate to severe toxicities. However, this strategy remains to be validated in a prospective randomized controlled study.

Clinical trial identification: This retrospective study has no clinical trial identification.

1073P Safety and efficacy of nimotuzumab with concurrent chemoradiotherapy in unresectable locally advanced squamous cell carcinoma of head and neck: Indian rural hospital experience

S. Rawat[1], D. Pawar[2], H. Tandon[1], S. Patel[1], S. Chaudhari[2]
[1]*Medical Oncology, N.S.C.B Medical College and Government Hospital, Jabalpur, India,* [2]*Medical Affairs, Biocon Limited, Bangalore, India*

Background: The aim of this study was to evaluate the safety and efficacy of nimotuzumab, a humanized monoclonal antibody against epidermal growth factor receptor, in combination with chemoradiation for head and neck squamous cell cancer (HNC).

Methods: The hospital data of 42 patients with HNC who were treated with nimotuzumab from January 2012 to December 2016 were evaluated. Three patients who had undergone prior surgery were excluded and 39 patients diagnosed with locally advanced (stage III- IVb) unresectable HNC who were treated with concurrent chemoradiotherapy with weekly nimotuzumab were considered for final analysis. Tumour response was calculated as per RECIST criteria 1.1. Subgroup analysis was performed to assess association of tumour response with independent variables such as age, gender, histopathological grades and TNM stages using chi square or Fischer exact test. Overall survival (OS) and progression free survival (PFS) was calculated from date of diagnosis using Kaplan-Meier method. All patients were assessed for toxicity and adverse events (AE) were reported as per common terminology criteria for AE v 4.0. Statistical analysis was done using SPSS software (v19.0).

Results: At 24 weeks after completion of treatment, objective response rate (complete response [CR] + partial response [PR]) was 97.44% with 26 (66.67%) patients showing CR, 12 (30.77%) patients with PR and one patient (2.56%) had stable disease. Subgroup analysis did not show significant association of tumour response, although men, patients older than 65 years, laryngeal cancer, tumour grade III, TNM stage III showed more complete responses. OS at one year and two years was 100% and 72.9%, while PFS at one year and two years was 87% and 54.40%, respectively. Incidence of grade I, II, III and IV toxicity was 30%, 18.18%, 41.82%, 10%, respectively. No grade V toxicity was observed. Common AE observed were neutropenia (20.91%), mucositis (33.64%), vomiting (18.18%), diarrhea (2.73%), skin reaction (24.55%). Nimotuzumab was observed to be safe with no additional adverse events (hypersensitivity, allergic reaction and skin changes) were reported during the study period.

Conclusions: Nimotuzumab is an efficacious and safe option when added to concurrent chemoradiotherapy in patients with locally advanced Head and Neck cancer.

1074P A phase II study of combination chemotherapy with cetuximab/S-1/low dose cisplatin as neoadjuvant manner for oral squamous cell carcinoma patients

M. Nakazawa[1], T. Imai[1], Y. Matsumiya[1], M. Suematsu[2], Y. Ohta[3], T. Ohnishi[4], M. Ohmae[5], H. Chisoku[6], I. Kato[1], S-Y. Tada[2], A. Takeshita[1]
[1]*Oral & Maxillofacial Surgery 2, Osaka University Graduate School of Dentistry, Suita, Japan,* [2]*Oral & Maxillofacial Surgery, Meiwa Hospital, Nishinomiya, Japan,* [3]*Oral & Maxillofacial Surgery, Itami City Hospital, Itami, Japan,* [4]*Oral & Maxillofacial Surgery, Ikeda Municipal Hospital, Ikeda, Japan,* [5]*Oral & Maxillofacial Surgery, Rinku General Medical Center, Izumisano, Japan,* [6]*Oral & Maxillofacial Surgery, Higashiosaka City Medical Center, Higashiosaka, Japan*

Background: In oral cancer therapy, functional preservation, as well as survival, is a very important matter to consider. One of the methods for organ preservation is an effective preoperative (neoadjuvant) chemotherapy. We previously reported the good antitumor effect and good tolerance of low dose cisplatin/S-1 at ESMO 2004 and 2006. Cetuximab enhances the antitumor effect of cisplatin/5-Fluorouracil . We investigated the feasibility of combining cetuximab/low dose cisplatin/S-1 chemotherapy as a neoadjuvant regimen for patients with oral squamous cell carcinoma.

Methods: Consecutive patients (n = 14) with newly diagnosed stage II-IV oral squamous cell carcinoma were enrolled in this study from July 2014 to June 2016. Patients were administered S-1 80mg/m^2/day (day 1-14), cisplatin 5 mg/m^2/day (day 1-5,8-12) and cetuximab 400mg/m^2/day on day 1 and 250mg m^2/day on day 8. This was followed by definitive surgery. Clinical response was assessed by clinical findings and/or CT according to RECIST and histopathological effects were evaluated with surgical specimens.

Results: The rate of clinical response, including complete response (CR) and partial response (PR), was 85.7%: CR 21.8%, PR 64.3%, SD (stable disease) 14.3%. The rate of histological response was 71.4%: CR 21.4%, PR 50%, no change 28.6%. Toxicities above grade 3 were neutropenia (7.1%), hypokalaemia (7.1%), leukocytopenia (7.1%), thrombocytopenia (7.1%), anorexia (21.4%), diarrhoea (7.1%) and nausea (7.1%). Most toxicities disappeared within 8 weeks after chemotherapy. No serious adverse effects were observed in the majority of patients. Conservative surgery was applied to 12 patients, except 2 patients with SD and 5 of 9 patients who needed reconstruction were able to avoid reconstructive surgery.

Conclusions: Combination chemotherapy with cetuximab/low dose cisplatin/S-1 represents an effective antitumor therapy with mild to moderate toxicities. It is suggested that this regimen is superior to low dose cisplatin/S-1 and can promote function preserving surgery.

1075P Role of induction chemotherapy in locally advanced T4b oral cavity cancers: A single Institute experience

K.N. Lokesh, T. Chaudhuri, K.C. Lakshmaiah, G. Babu, D. Lokanatha, L.A. Jacob, S. Babu, A. Rudresha, L. Rajeev

Medical Oncology, Kidwai Cancer Institute, Bengaluru, India

Background: The standard of care for oral squamous cell carcinoma (OSCC) at present, consist of surgical resection followed by adjuvant radiotherapy and chemotherapy as indicated. However, indications of induction chemotherapy (IC) in oral cancers are not clearly defined. This retrospective analysis aimed to investigate the efficacy, toxicity and impact of induction chemotherapy in locally advanced T4b oral cavity squamous cell cancers.

Methods: Patients diagnosed with locally advanced T4b OSCC from January 2013 and March 2017 at our centre, who received 2-3 cycles of IC and then assessed for resectability, were reviewed retrospectively. Patients' profile, response and toxicity of IC, resectability status and overall survival (OS) were evaluated. Statistical analyses were done by SPSS version 17.0.

Results: Total 134 patients received IC, and out of them 98 (73.1%) were males. Median age at diagnosis was 44 years (range 31-60 years). 107 (79.8%) of our patients received doublet chemotherapy (with paclitaxel + cisplatin), and the rest of the patients received triplet regimen (with paclitaxel/docetaxel + cisplatin + 5-FU). Majority of the patients had buccal mucosa cancers (n = 92), followed by gingivo-buccal sulcus (n = 26) and oral tongue (n = 16) primaries. After IC, partial response was achieved in 25 (18.7%) patients, stable disease in 83 (61.9%) patients and disease progression was noted in 26 (19.4%) patients. Post-induction chemotherapy, resectability was achieved in 28 (21%) of 134 patients, but 8 of them did not undergo surgery due to logistic and personal reasons. The median OS of patients who underwent surgery followed by adjuvant local therapy (n = 20) was 18.7 months (95% CI: 16.2-21.5 months) and for those treated with non-surgical local therapy (n = 114) was 7.9 months (95% CI: 6.2-9.2 months) (log-rank p = 0.000).

Conclusions: IC may improve the resectability in our patients with T4b OSCC with a manageable toxicity profile. Patients underwent resection had a significantly better median OS than those who received non-surgical local treatment.

1076P Concurrent chemoradiotherapy (CCRT) versus induction docetaxel, cisplatin and 5-fluorouracil (TPF) followed by CCRT in locally advanced hypopharyngeal and base of tongue cancer: A randomized phase II study

S.H. Lim[1], J-M. Sun[1], J. Hong[1], D. Oh[2], Y.C. Ahn[2], M.K. Chung[3], H-S. Jeong[3], Y-I. Son[3], M-J. Ahn[1], C-H. Baek[3], K. Park[1]

[1]Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Seoul, Republic of Korea, [2]Department of Radiation Oncology, Samsung Medical Center, Seoul, Republic of Korea, [3]Department of Otorhinolaryngology-Head and Neck Surgery, Samsung Medical Center, Seoul, Republic of Korea

Background: To date, clinical trials have not consistently supported the use of induction chemotherapy (IC) for locally advanced head and neck squamous cell cancer (LASCC). Hypopharyngx and base of tongue (BOT) cancer has shown relatively poor survival compared to other LASCC. We tried to investigate the role of IC for improvement over current chemoradiotherapy (CRT) in patients with locally advanced hypopharynx and BOT cancer.

Methods: Treatment-naïve patients with nonmetastatic stage III/IV hypopharyngeal or BOT cancer were randomly assigned to receive CRT alone (CRT arm: cisplatin 100mg/m^2 3-weekly for 2 times plus radiotherapy 68.4Gy/30fraction on weekday) versus two 21-day cycles of IC (docetaxel 75mg/m^2 on day 1, cisplatin 75mg/m^2 on day 1, and fluorouracil 750mg/m^2 on days 1 to 4) followed by same CRT regimen (IC arm). The primary endpoint was progression-free survival (PFS) and 90 patients are required to show the superiority of IC arm with one-sided alpha 0.1 and power of 0.85.

Results: This study closed early after enrollment of 36 patients (19 in CRT arm and 17 in IC arm) because of slow accrual. After a median follow up of 47.2 months, there was no significant difference in PFS: the median PFS were 26.8 months for CRT arm and not reached for IC arm (Hazard ratio: 0.55, 95% CI 0.19-1.60). However, the survival curves widely separated with a plateau after 3-years, suggesting the survival benefit from induction chemotherapy: 3-year PFS rates were 45% and 68%, and 3-year overall survival rates were 56% and 86% (HR: 0.35, 95% CI: 0.07-1.69), in CRT and IC arms, respectively. In both subgroups with BOT and hypopharyngeal cancer, survival outcomes of IC arm were also insignificantly superior to those of CRT arm. All adverse events were manageable and there was no grade 3/4 toxicity except one patient had Gr3 stomatitis in IC arm.

Conclusions: This study failed to demonstrate that induction TPF chemotherapy improves survival in patients with BOT and hypopharyngeal cancer, possibly due to small number of subjects. However, it suggested favorable outcome with induction chemotherapy, and further large randomized studies are needed to this population.

1077P Do patients over 70 years with advanced head and neck squamous cell carcinoma tolerate curative intent concurrent chemo-radiation? Predictors of oncological outcomes

V. Srinivasalu[1], N. Subramaniam[2], N. Kumar[3], D. Balasubramaniam[2], A. Philip[1], A. Susan[1], A. Remesan Nair[4], C. G Prameela[4], K.U. Pushpaja[4], K. Thankappan[2], W. Jose[1], S. Iyer[2], P. Keechilat[1]

[1]Department of Medical Oncology, Amrita Institute of Medical Sciences, Kochi, India, [2]Department of Head and Neck Oncology, Amrita Institute of Medical Sciences, Kochi, India, [3]GCSRT Program, Harvard Medical School, Cambridge, UK, [4]Department of Radiation Oncology, Amrita Institute of Medical Sciences, Kochi, India

Background: Survival benefit of adding chemotherapy to radiotherapy (RT) in patients (pts) age>70 yrs of head and neck squamous cell carcinoma (HNSCC) has not been found in literature. Our institutional policy is to offer concurrent chemoradiation (CCRT) to patients > 70 years with a good ECOG status.

Methods: Retrospective analysis of stage III/IV HNSCC in pts > 70 years who received linac based radical CCRT with dose equivalent to 70Gy in conventional fractionation (n = 57) between 2006 to 2014 were included.

Results: Pts with stage III/IV (25.6%/75.4%) HNSCC (n = 57) of oropharynx (n = 15), larynx (n = 18) or hypopharynx (n = 24) underwent radical CCRT having mean age 75.18 yrs (range 70-86 years) and male to female ratio of 10.4:1. Pts on CCRT who got cisplatin (CIS) (n = 35) and carboplatin(CARBO) (n = 22) had mean weight loss of 3.53 (range 0-10) kgs. 61.4% completed chemotherapy (defined as cumulative dose of 200mg/m2 of CIS and 5 weekly dose of CARBO at AUC 2) and 98.2% completed RT without any treatment related death. Higher grades of neutropenia (33.3%) and hyponatremia (17.5%) with CIS and hypercreatinemia (10.5%) with CARBO was noted. Tube dependence (gastrostomy/tracheostomy) had 2.7-fold increase in risk of death in pts (n = 25; 44%) with hypopharynx/larynx cancer, compared with stage and subsite matched pair analysis in pts < 60 years. Factors predicting good PFS were ECOG (1 vs 2) HR = 0.25 (95%CI:0.09-0.70), Completion of treatment without any breaks while on CCRT, HR = 2.54 (95%CI:1.02-6.32, p = 0.04), and age in 70-75 years, HR = 1.09 (adjusted for alcohol and smoking) (95%CI: 1.01-1.20, p = 0.08). Factors suggestive of poor PFS were hyponatremia, hypercreatinemia and weight loss > 3kgs from their baseline. PFS (80%) in pts with stage III and IV disease was 22 (95%CI: 12.4-87.2) months and 15.53 (95%CI: 8.6-20.6) months respectively.

Conclusions: Curative intent CCRT should be considered as standard of care in elderly patients > 70 years with good ECOG status. Both cisplatin and carboplatin showed significant benefit in PFS with fewer side effects. Aggressive swallowing rehabilitation, abstinence from smoking and alcohol are likely to improve outcomes.

1078P Multidisciplinary team management in head and neck cancer: The real life experience

J-B. Guy[1], Y. Xia[1], A. Vallard[1], S. Espenel[1], J-C. Trone[1], J. Langrand-Escure[1], A. Hamrouni[1], M. Ben Mrad[1], C. Rancoule[1], S. Ouni[1], T. Muron[2], P. Fournel[2], N. Magne[1]

[1]Radiation Oncology, Institut de Cancérologie Lucien Neuwirth, Saint-etienne, France, [2]Medical Oncology, Institut de Cancérologie Lucien Neuwirth, Saint-etienne, France

Background: Multidisciplinary team (MDT) management in oncology is integrated in a legal framework in France. This practice is essential in Head and Neck cancer management with its complex and multimodal treatments. Some trials report a positive impact of MDT on overall survival of advanced head and neck cancers. The objective of this study was to report the experience of MDT management in Head and Neck Cancer in the Lucien Neuwirth Cancer Institute over the past 6 years.

Methods: Records from bi-monthly MDT meeting from 2010 to 2015 were selected for this study. Number of medical cases and type of present medical specialists were noticed. Data from MDT records were reported: clinical characteristics (performans status, weight), anatomical localisation, TNM and pathological classification, and the treatment plan decision. Impact of MDT meeting on treatment delay was also analysed.

Results: As of December 2015, 1848 clinical cases were discussed with 1786 patients and 138 MDT meetings. Majority of patients were discussed only once in meeting, and 3% (52) patients were discussed twice. An average of 16 patient's cases were discussed per-meeting. 1368 patients (74.1%) were presented at primo-diagnosis status and 481 (25.9%) in a recurrence status. 81% of patients were at stage III or IV. 969 (52.4%) patients had a treatment before MDT. Surgery (73.2%) was the main treatment operated before meeting. Radiation therapy delay after MDT was 9.8 days for dosimetric planification CT and 21 days for first radiation treatment session.

Conclusions: The percentage of presented recurrent patients is reasonable regarding epidemiologic data in head and neck location. MDT seems not delay radiation treatment occurring within 21 days after MDT. Unfortunately we underlighted a majority of patients surgically treated before MDT discussion.

Background: In the Phase III LHN1 trial, second-line afatinib (A) significantly improved PFS (primary endpoint) vs methotrexate (MTX) in pts with R/M HNSCC. Tumour biomarker analyses have shown that survival benefit with A vs MTX was more pronounced in pts with p16/ErbB3-negative, EGFR-amplified, PTEN-positive disease. We present post-hoc analyses of A long-term responders (LTRs).

Methods: Pts with incurable R/M HNSCC who had received first-line platinum-based therapy were randomised to A (40mg/day) or MTX (40mg/m^2/week) and treated until progression/intolerable AE. LTRs were defined as pts treated with A $\geq$ 12 mos. Tumour biomarkers were assessed by IHC (p16, ErbB3, PTEN, cMET) and FISH (EGFR amplification); pre-treatment (tx) serum samples were analysed with the VeriStrat® (VS) test and classified as VS-Good/Poor.

Results: 11/322 (3%) pts treated with A were LTRs with a median (range) tx-duration of 16 (12−39) mos. All pts had stopped tx at analysis. Baseline characteristics in LTRs were similar to the overall dataset, except (LTRs/overall): oral cavity primary tumour site (45%/29%); M1 disease (45%/66%); previous therapy with EGFR-antibodies (18%/59%). Median OS was 18.1 mos; median PFS (central independent review) was 14.9 mos. ORR was 45% (CR: 18%; n = 2). The frequency of pts who received $\geq$1 subsequent therapy was similar to the overall dataset (LTRs, 45%; overall, 51%). In LTRs with available biomarker data, 3/3 (100%) pts were p16-negative, 4/4 (100%) pts were ErbB3-negative, 2/4 (50%) pts were PTEN-positive, 3/3 (100%) pts were cMET-positive, 2/3 (67%) pts had EGFR-amplification, and 5/5 (100%) pts were VS-Good. Tolerability-guided dose reductions were more frequent among LTRs (55% vs 32% overall).

Conclusions: In the LHN1 study, some platinum-pre-treated pts with R/M HNSCC derived a long-term survival benefit from A; median OS was ~1.5 yrs and >11 mos longer than in the overall dataset. Limited biomarker data available in these LTRs suggests that p16/ErbB3-negativity and EGFR-amplification might be potential predictive biomarkers for long-term benefit from A; however, results were not conclusive due to small sample size.

1081P Benefit of cetuximab addition to a platinum-fluorouracil-based chemotherapy in an unselected population of metastatic head and neck cancer patients and effect of KRAS Lcs6 variation on cetuximab response

V. Bastit[1], N. Bon-Mardion[1], J-M. Picquenot[2], V. Rainville[3], C. Moldovan[4], A. François[5], F. El Ouakif[6], F. Jardin[3], J-P. Marie[1], F. Di Fiore[4], F. Clatot[4]

[1]ORL and Head and Neck Surgery, CHU de Rouen - Hôpital Charle Nicolle, Rouen, France, [2]Biopathology, Henri Becquerel Center, Rouen, France, [3]INSERM U1245, Henri Becquerel Center, Rouen, France, [4]Department of Medical Oncology, Henri Becquerel Center, Rouen, France, [5]Biopathology, CHU de Rouen - Hôpital Charle Nicolle, Rouen, France, [6]Head and Neck Surgery, Henri Becquerel Center, Rouen, France

Background: While the EXTREME protocol, including platinum (P) fluorouracil (FU) and cetuximab (Cx), is the gold-standard first line chemotherapy for metastatic head neck cancer patients (MHNC), its benefit in an unselected population has never been evaluated. Furthermore, KRAS Lcs6 variation was reported as a potential marker for greater efficacy of EGFR-targeted therapy. We investigated the benefit on progression-free survival (PFS) and overall survival (OS) of adding Cx to PFU as first line treatment for MHNC in an unselected population. We also assessed if there was a differential efficacy of Cx according to KRAS Lcs6 status.

Methods: This monocentric retrospective study included all the patients treated by at least two cycles of PFU+/-Cx between 2005 and 2014 as first line of palliative chemotherapy for MHNC. When tumor samples were available, the KRAS LCS6 variant status (rs61764370) was determined by pyrosequencing, and the p16 status by immuno-histo-chemistry.

Results: 134 patients were included: 59 (44%) treated with PFU and 75 (56%) with PFUCx. Baseline characteristics were comparable between the two groups. Of note 30% of the patients had a stage 2 or 3 performance status (PS). In univariate analysis, a longer median PFS was observed with PFUCx compared to PFU (6.1 vs 4.4 months respectively, HR 0.68, p = 0.02). Median OS were not different (11.1 months with PFUCx versus 9.1 with PFU, p = 0.2). Among the 110 tumor samples available, 29 (25%) had a KRAS-variant and 14 (12.7%) were p16 positive. No differences in OS nor PFS were observed according to the KRAS-variant status. When considering only the patients treated with PFUCx, presence of the KRAS-variant (n = 17) was not associated with a better response (p = 0.5). In a multivariate analysis including PS $\leq$ 1, addition of Cx, KRAS status, p16 status and age $\leq$ 55 as variables; addition of Cx to PFU was the only factor related to a better PFS (p = 0.008).

Conclusions: This retrospective study confirmed the effectiveness of the EXTREME protocol on PFS in an unselected population of MHNC patients. KRAS LCS6 variant was not related to a differential response to Cetuximab in MHNC population.

1082P A pilot study of apatinib in heavily pretreated metastatic adenocarcinoma of the head and neck

L. Gui, X. He

Medical Oncology, Cancer Institute and Hospital, Chinese Academy of Medical Sciences (CAMS), Beijing, China

Background: Although antiangiogenic therapy is effiective in advanced lung, breast, renal, hepatic, and colon cancers, limited is known about its value in the cancer of the Head and Neck. Apatinib is an oral, highly potent tyrosine kinase inhibitor targeting vascular endothelial growth factor receptor 2 (VEGFR-2). This prospective phase II study (NCT02989259) aims to investigate the efficacy and safety of apatinib in heavily pretreated patients (pts) with metastatic adenocarcinoma of the Head and Neck.

Methods: This study enrolled pts with metastatic adenocarcinoma of the Head and Neck, who failed in the metastatic setting at least one prior chemotherapy regimen. The primary end point of this study was progression free survival (PFS). Secondary end points included objective response rate (ORR), disease control rate (DCR), overall survival (OS), and safety. Patients were treated with apatinib 500 mg daily. Efficacy was assessed every 6 weeks.

Results: From December 2016, we recruited 10 pts, including 8 males and 2 females, with a median age of 53 years (26-71). Median number of previous chemotherapy regimens for the metastatic diseases was 2 (1-3). Median follow-up time was 4.3 months. 8 pts were eligible for efficacy analysis. ORR was 25% (2/8). DCR was 87.5% (7/8). Median PFS and median OS were not reached. The most common adverse events (AEs) of all grade were hypertension (n = 5), nausea (n = 4), fatigue (n = 4) and hand-foot syndrome (n = 3). The most common grade 3/4 AEs were hypertension (n = 2), thrombocytopenia (n = 1) and oral mucositis (n = 1). Toxicities were tolerable and manageable.

Conclusions: Our results so far indicated that apatinib exhibited objective efficacy in heavily pretreated, metastatic adenocarcinoma of the Head and Neck with acceptable safety.

Background: We performed a retrospective survey to study the natural history and the prognostic factors of patients (pts) with bone metastases (BMs) from head and neck cancers (HNCs).

Methods: Clinical records of pts treated at 11 oncologic centers across Italy were retrieved. All pts were selected on the base of BMs either at diagnosis or at subsequent time points. Pts with a diagnosis of nasopharyngeal carcinoma (NPC) were analyzed separately. The time-to-first bone metastasis was calculated from initial diagnosis. The skeletal-related events (SREs) (fractures, medullary compression, hypercalcemia) were recorded from the date of BMs diagnosis.

Results: From 2008 to 2016, 192 HNC pts with BMs (64 NPCs and 128 other-HNCs) were collected. Median time to first BM was 9 and 12 months for NPCs and other-HNCs, respectively. SREs occurred in 9% and 27% NPC and other-HNC pts, respectively. Pts received specific antineoplastic treatments (92%) or best supportive care (8%). Median progression free survival (PFS) and overall survival (OS) were 11 and 25 months in NPC-BM pts and only 5 and 6 months in other-HNC-BM pts, respectively. SRE did not affect the pt prognosis except for hypercalcemia that was associated with a poorer prognosis (not significant). Biphosphonates and/or denosumab were administered in 34% NPC and 33% other-HNC pts, respectively. The administration of bone-directed therapies, also including radiation therapy and surgery on BMs, was associated with a better survival at univariate analysis in both NPC and other-HNC (Hazard Ratio [HR]: 0.43, 95% confidence interval [CI] .008-.237, p <.0005 in NPC and HR 0.37, 95% CI: .191-.735, p .004 in other HNC, respectively).

Conclusions: In HNC pts destined to develop BMs, these events occur early in the natural history of these diseases. The onset of BMs predicts a poor survival in non-NPC HNC pts. SREs are more frequent in non-NPC HNC pts. Bone directed therapies are correlated with better outcome.

1084P Prognostic impact of the neutrophil-to-lymphocyte ratio (NLR) on overall survival in patients treated with chemoradiotherapy for head and neck cancer

S. Makhloufi[1], G. Lefebvre[1], I. Sakji[2], F. Feutry[2], T. Leroy[3], N. Penel[1], B. Coche[3], J. Fourquet[3], F. Ghestem[1], M. Julieron[4], D. Chevalier[5], E. Tresch[6]

[1]Medical Oncology, Centre Oscar Lambret, Lille, France, [2]Pharmacy, Centre Oscar Lambret, Lille, France, [3]Academic Radiation Oncology, Centre Oscar Lambret, Lille, France, [4]Head and Neck Surgery, Centre Oscar Lambret, Lille, France, [5]Head and Neck Surgery, University Hospital, Lille, France, [6]Statistics Unit, Centre Oscar Lambret, Lille, France

Background: The neutrophil-to-lymphocyte ratio (NLR), a marker of the systemic inflammatory response, has been reported to have prognostic value in different cancer settings. In this study we aimed to assess the prognostic impact of NLR in a cohort of patients with head and neck cancers.

Methods: Patients with head and neck cancer treated with concurrent chemo-radiotherapy (Cisplatin) between 01/2013 and 12/2015 were included in this study. NLR was analyzed as a continuous variable and as dichotomous variable (≤ 5 vs. > 5). The primary end point was overall survival (OS). Progression free survival (PFS) was the secondary endpoint. Univariate analysis was used to identify associations and to select variables included in multivariate Cox regression analysis to determine prognostic value.

Results: 146 patients (132 squamous cell carcinomas (SCC), 10 undifferencied nasopharyngeal carcinomas (UCNT) and 4 neuroendocrine carcinomas) were included in this analysis. The median follow up was 20.6 months (2.4-37.0 months). 1-year and 2-year OS were 87.1% and 82.3%, respectively.1-year and 2-year PFS were 75.9% and 68.0%, respectively. On univariate analysis, OS significantly differed between groups NLR ≤ 5 vs. > 5. In the overall population (OP) (HR: 2.6; IC95%: [1,05-6,53]; $p = 0036$) and in non-oropharyngeal subpopulation (HR: 3.67; IC95%: [1,19-11,4]; $p = 0,016$) but not in the oropharyngeal subpopulation ($p = 0,51$). In multivariate analysis NLR >5 was significantly associated with a poorer OS in the OP (HR: 2.89; IC95%: [1,14-7,33]; $p = 0.025$) and in non-oropharyngeal subpopulation (HR: 4.53; IC95%: [1,34-13,5]; $p = 0.014$). Body Mass Index (BMI) <18.5kg/m2 and poor performans status (PS: 1-2 vs 0) were also significantly associated with a shortened OS ($p = 0.010$ and 0.021, respectively). Only the BMI was found to be significantly associated with PFS ($p = 0.006$) in the OP.

Conclusions: In this cohort of patients treated with chemo-radiotherapy for head and neck cancer, pre-treatment NLR >5 was predictive of shorter overall survival. Further prospective clinical investigations are required to confirm these results and determine the clinical applicability as prognostic factor.

1085P Association of ERP29 genetic polymorphism in microRNA-binding site with oropharynx cancer risk and prognosis

J. Carron[1], E. Costa[1], L. Lopes-Aguiar[1], B. Sá Carvalho[2], J.A. Rinck-Junior[3], A.P. Dalla Costa[1], M. Ortega[4], C.S.P. Lima[3], G.J. Lourenço[1]

[1]Laboratory of Cancer Genetics, University of Campinas, Campinas, Brazil, [2]Department of Statistics, Institute of Mathematics, Statistic and Computer Science, University of Campinas, Campinas, Brazil, [3]Internal Medicine, University of Campinas, Campinas, Brazil, [4]Laboratory of Cell and Molecular Tumor Biology and Bioactive Compounds, São Francisco University, Bragança Paulista, Brazil

Background: Our previous large-scale genotyping study identified more than 6,000 single nucleotide polymorphisms (SNPs) associated with base of tongue (BT) squamous cell carcinoma (SCC) risk in 49 patients and 49 controls. The SNP c.*293A>G of the ERP29, a tumor-suppressor chaperone, was selected for further analyses. An in silico analysis showed that microRNA (miR)-4421 shared binding site with 3'-untranslated region of variant allele of referred SNP while wild-type allele disrupt this target site. However, the role of this SNP in the risk and prognosis of oropharynx SCC (OPSCC) patients is still unknown. We aimed to verify whether the distinct genotypes or ERP29 c.*293A>G SNP influence the OPSCC risk and prognosis, and the ERP29 and miR-4421 expressions.

Methods: DNA from 250 OPSCC patients and 250 controls was analyzed by RT-PCR. The patients were treated with surgery, radiotherapy and/or platinum based agents. The ERP29 and miR-4421 levels were evaluated by qPCR using RNA of 58 controls. The differences between groups were calculated by chi-square, logistic regression model and Mann-Whitney tests. Progression-free survival (PFS) and overall survival (OS) times were calculated by Kaplan-Meier and Cox regression methods.

Results: ERP29 variant GG genotype was more common in OPSCC patients than in controls (6.4% vs. 3.6%, $P = 0.002$). Individuals with GG genotype were under 8.86-fold increased risk of OPSCC than others (95% CI: 2.20-35.69). Considering only the BTSCC patients, at 36 months of follow-up, shorter PFS were seen in patients with variant GG genotype (0.0% vs. 39.1%, $P = 0.01$, Cox: HR: 2.68, 95% CI: 1.21-5.95, $P = 0.01$). Individuals with ERP29 wild-type genotype showed higher levels of ERP29 mRNA when compared to others (1.44 vs. 1.10 arbitrary units AUs, $P = 0.005$). In addition, lower miR-4421 expression was observed in individuals with ERP29 AA genotype when compared to those with AG or GG genotypes (0.42 vs. 0.73 AUs, $P = 0.05$).

Conclusions: Our data present, for the first time, that *ERP29* c.*293A>G SNP is associated with increased risk of OPSCC and with worst survival of BTSCC patients, possibly due to variation of *ERP29* mRNA levels modulated by miR-4421.

1086P Diagnostic and prognostic impact of plasma osteopontin in nasopharyngeal carcinoma

J-C. Lin[1], W-Y. Wang[2], Y.C. Liu[1]

[1]Radiotion Oncology, Taichung Veterans General Hospital, Taichung, Taiwan, [2]Department of Nursing, Hung Kuang University, Taichung, Taiwan

Background: We investigated the diagnostic and prognostic impact of plasma osteopontin (pOPN) concentrations in advanced nasopharyngeal carcinoma (NPC).

Methods: Pre-treatment plasma samples from 138 patients with previously untreated and biopsy-proven NPC were collected. Plasma samples from another 70 healthy volunteer were served as control. OPN concentrations were measured by the enzyme-linked immunosorbent assay (ELISA). The patient characteristics were- age range 24-83 and median 48 years, male/female=97/41, WHO pathology type I/II/III=1/105/32, stage III/IV(M0)/IVC(M1) = 57/73/8. The treatment consisted of radiotherapy alone (2), concurrent chemoradiotherapy (28), and neoadjuvant chemotherapy plus radiotherapy (100) for M0 patients, and systemic chemotherapy with or without radiotherapy for M1 patients (8).

Results: NPC patients (median 97.2 ng/mL; interquartile range 72.1-130.4) had significantly higher pOPN level than normal control (median 61.6 copies/ml; interquartile range 44.9-88.1), $P<0.0001$. The area under ROC curve is 0.754, $P=0.0001$. The median concentrations of stage III, IV(M0), and IV(M1) were 85.4, 104.2, and 217.7 ng/mL respectively ($P=0.0002$). We divided patients into two groups by pretreatment pOPN concentration and found that patients with higher pOPN (>100 ng/mL) correlated with some clinically poor prognostic factors, such as older age, male gender, advanced T-stage, and advanced overall stage. Pretreatment pOPN affected patients' survival as well as rates of distant failure. The 5-year overall survival (56.6% vs. 81.4%, $P=0.0036$) and metastasis-free survival (66.3% vs. 81.2%, $P=0.0726$) were significantly lower in patients with pretreatment pOPN > 100 ng/mL than in those with pOPN < 100 ng/mL.

Conclusions: Pretreatment pOPN levels can serve as a useful diagnostic and prognostic marker for advanced NPC.

1087P Head and neck cancer (HNC) and synchronic lung cancer: Impact of the lung cancer on the management and prognosis of these patients. Data from the SYNCHRON GFPC 15-04 Study

N. Paleiron[1], L. Saramon[2], G. Robinet[3], R. Gervais[4], P. Fournel[5], H. Le Caer[6], H. Berard[7], G. Valette[2], R. Marianowski[2], C. Chouaid[8]

[1]Pneumology, HIA Brest, Brest, France, [2]ORL, CHU Brest Morvan, Brest, France, [3]Pneumologie, CHU Brest Morvan, Brest, France, [4]Oncologie, Centre Francois Baclesse, Caen, France, [5]Pneumologie, Institute de Cancerologie de la Loire, St. Priest En Jarez, France, [6]Pneumologie, Hôpital de St Brieuc, St Brieuc, France, [7]Pneumologie, Hôpital d'Instruction des Armées (HIA) Ste Anne, Toulon, France, [8]Pneumologie, CHI créteil, Creteil, France

Background: Management of synchronous head and neck and lung cancer is almost difficult. The aim of this observational study was to describe the impact of the lung cancer on the management and prognosis of HNC.

Methods: Inclusion criteria were: consecutive patients diagnosed between January 2011 and December 2015 in 19 French centers with HNC and synchronous lung cancer (all stages). We describe: clinical characteristics, management and outcomes. Patient characteristics and treatment information was analyzed descriptively. Kaplan-Meier estimation was used to assess median overall survival.

Results: The study included 132 patients: men: 83%; 63,7 years old, current smokers: 59,8%; performans status: 0 and 1 for 22% and 66% of the patients respectively; high rate of comorbidities: cardiovascular: 63%, COPD: 33%. Main histology for HNC was squamous: 98%, (in oral cavity: 24%, oropharyngeal: 26%, hypo-pharyngeal: 22% and laryngeal: 28%) T classification was T1, T2, T3 and T4 in 16%, 24%, 28% and 18% of cases respectively, and N classification was N0, N1, N2, N3, for 36%, 18%, 20% and 8% of cases respectively. The main treatment was surgery, 37,1%, and chemo-radiotherapy, 35,6%. The diagnosis of lung cancer impacts the HNC management in 38% of the cases. Median delay between HNC and first day treatment was 54 days. HNC progressive free survival rate was 68% at 2 years. Lung cancers were mostly localized (stages I: 46%, stages II: 10%), squamous: 39%, or adenocarcinomas: 39%. Main treatments were surgery: 29%, mainly lobectomy, radiotherapy: 13%, radio-chemotherapy: 14% and chemotherapy alone: 35%. Seven patients didn't receive active treatment. Median delay of treatment was 82,3 days. Lung cancer progressive free survival rate was 35% at 2 years. OS was 40% at 2 years, better for stage I - II lung cancers (55%).

Conclusions: Synchronous lung cancer at HNC diagnosis significantly impacts the management and outcomes of HNC. Specific recommendations and multidisciplinary approach should be elaborate to improve the management of these patients.

1088P An estimation of the population survival benefit of first-course chemotherapy for head and neck cancers

V. Do, W. Ng, S. Jacob, G.P. Delaney, M. Barton

Collaboration for Cancer Outcomes Research and Evaluation (CCORE), Ingham Institute for Applied Medical Research, University of New South Wales, Sydney, Liverpool, Australia

Background: Randomised clinical trials describe the benefit of chemotherapy for specific head and neck patients with selected patient and tumour characteristics. This study estimates the overall survival benefit of chemotherapy above all other modalities for the whole population of head and neck cancer patients in Australia, if evidence-guidelines were followed.

Methods: Decision trees with evidence-based indications for chemotherapy have been previously defined. For all defined indications, the highest level of clinical evidence available was identified. Multiple electronic citation databases were systematically queried, including Medline and Cochrane library. The benefits of first-course chemotherapy were estimated for 1-year and 5-year overall survivals. To assess the robustness of our estimates, univariate and multivariate analyses were performed.

Results: The estimated 1-year and 5-year absolute population-based survival benefits of optimally utilised chemotherapy for head and neck cancer patients in Australia are 5.5% (95% Confidence Interval, CI, 4.5%-6.8%) and 4.2% (95% CI, 3.6%-5.0%), respectively.

Conclusions: First-course chemotherapy improved population-based survival in head and neck cancer patients, when used in accordence with guidelines recommendations. Measurement of population survival benefits of cancer treatment is important as these can provide salient inputs for economic analyses, aid in priority setting in cancer program and guide quality improvement according to evidence-based guidelines.

1089P GSTP1 c.313A>G, XPD c.934G>A, XPF c.2505T>C and CASP9 c.-1339A>G polymorphisms and severity of vomiting in head and neck cancer patients treated with cisplatin chemoradiation

C.S.P. Lima, J. Carron, L. Lopes-Aguiar, E.F.D. Costa, G.A.S. Nogueira, T.R.P. Lima, E.C. Pincinato, M.B. Visacri, J.C.F. Quintanilha, P. Moriel, G.J. Lourenço*Department of Internal Medicine, University of Campinas, Campinas, Brazil*

Background: Cisplatin (CDDP) chemotherapy associated with radiation (RT) has been used in head and neck squamous cell carcinoma (HNSCC) patients, and vomiting is a common side effect during treatment. This prospective study aimed to identify the roles of *GSTM1* and *GSTT1* (presents or nulls), *GSTP1* c.313A>G, *XPC* c.2815A>C, *XPD* c.934G>A and c.2251A>C, *XPF* c.2505T>C, *ERCC1* c.354C>T, *MLH1* c.−93G>A, *MSH2* c.211 + 9C>G, *MSH3* c.3133G>A, *EXO1* c.1765G>A, *TP53* c.215G>C, *CASP3* c.-1191A>G and c.-1168G>T, *CASP9* c.-1339A>G, *CASP8* c.-937_-932delAGTAAG, *FAS* c.-1378G>A and c.-671A>G, and *FASL* c.-157-687C>T single nucleotide polymorphisms, involved in CDDP metabolism, in vomiting severity in HNSCC patients treated with CDDP and RT.

Methods: We evaluated 88 HNSCC patients diagnosed June 2011-February 2014 which receive CDDP chemoradiation. Ondansetron and dexamethasone were administered as antiemetic therapy and evaluated using National Cancer Institute criteria. Genotypes were analyzed in genomic DNA by polymerase chain reaction based methods. The logistic regression model was used to identify variables influencing toxicities and significant results were validated using a bootstrap (bt) resampling to investigate the stability of risk estimates (1000 replications).

Results: GSTP1 c.313AG or GG genotype alone (46.7% vs 18.6%, P = 0.004) and combined with XPD c.934GA or AA (50.0% vs 16.7%, P = 0.02; P_{bt}= 0.008), XPF c.2505TC or CC (52.2% vs 16.7%, P = 0.02; P_{bt}= 0.007) and CASP9 c.-1339AG or GG (51.9% vs 16.7%, P = 0.02; P_{bt}= 0.01) genotypes were more common in patients with moderate/severe vomiting than other genotypes. Carries with GSTP1 c.313AG or GG genotypes alone and combined with XPD c.934GA or AA, XPF c.2505TC or CC and CASP9 c.-1339AG or GG genotypes had 4.28, 5.00, 5.45, and 5.38 more chances of presenting moderate/severe vomiting than others.

Conclusions: Our data suggest, for the first time, that inherited abnormalities in DNA repair and apoptosis pathways are capable of modulating emesis in HNSCC patients under CDDP chemoradiation, and may be used for selecting patients who deserve to receive distinct doses of antiemetics or association of potent antiemetics in clinical practice.

1090P Analysis of the impact of the tumours committee on the multidisciplinary approach to head and neck epidermoid cancer in our institution

M.J. Martínez-Ortiz[1], P. Cerezuela[1], G. Marin Zafra[2], J. Balsalobre[1], J. Díaz-Manzano[3], J. Trujillo[4]

[1]Medical Oncology, Hospital Universitario Santa Lucia, Cartagena, Spain, [2]Hematology and Medical Oncology, Hospital Universitario Morales Meseguer, Murcia, Spain, [3]ORL, HCU Virgen de la Arrixaca, El Palmar, Spain, [4]Internal Medicine, Hospital Universitario Santa Lucia, Cartagena, Spain

Background: The objectives are to define the characteristics of people with HNSCC treated in our area and quantify the impact of the committee on the staging, the change in the initial treatment proposed to determine whether the selection of treatment by the multidisciplinary team (MDT) influences therapeutic compliance.

Methods: Observational retrospective study of two cohorts, which aims to analyse the variables in the cohort of patients handled by an MDT with respect to the patients without an MDT. We included all patients with an initial diagnosis of HNSCC at our centre between 2005 and 2012. The MDT cohort comprised those from 01/01/2009 to 31/12/2012. With access to the Pathological Anatomy database, the records of the MDT, the archived and computerised medical history, we collected the endpoints related to the patient (age, sex, ECOG), the tumour (date of diagnosis, location, and TNM stage), the treatment (therapy selected, change in treatment, compliance, reason for default). Definitive sample consists of 408 patients. A descriptive analysis is given of the clinical characteristics of the sample, together with the comparative bivariate analysis of these characteristics in the cohorts.

Results: Our population presents age (mean) 64.2y (SD 12.4), male 82.6%, ECOG<2 89%, 32.1% laryngeal location, tumour stage IVA 31.6%. Treatment with surgery (S) 43.4%, S and radiotherapy (RT) 14.7%, RT 10% and chemo-radiotherapy 9.8%. From our comparative analysis we want to highlight (C1 vs C2) change in stage 26 vs 19.7%, increase 1.5 vs 15.4%($p < 0.001$), change of treatment 34.5 vs 39.9% ($p < 0.001$), organ-preservation without surgery 3 vs 6.3% ($p < 0.001$) and therapeutic compliance 91 vs 92.3% ($p = 0.72$).

Conclusions: The population served in our area presents clinical characteristics similar to those of other series published in our and other countries. The MDT improved the staging of the tumour before treatment in a statistically significant way. The change in treatment is higher, so as to be statistically significant, when the therapeutic planning is addressed by an MDT. No statistically significant difference was observed in therapeutic compliance rates when treatment was decided by the MDT.

1091P Prognostic nutritional index (PNI) is an independent prognostic factor in locoregionally advanced squamous cell head and neck cancer (LAHNSCC)

G. Bruixola[1], J. Caballero[2], F. Papaccio[3], A. Petrillo[3], M. Pastor[2], A. Cervantes[1]

[1]Medical Oncology, Biomedical Research Institute INCLIVA - University of Valencia, Valencia, Spain, [2]Medical Oncology, Hospital Universitari i Politècnic La Fe, Valencia, Spain, [3]Oncology, Università degli Studi della Campania Luigi Vanvitelli, Naples, Italy

Background: There is increasing evidence that the presence of an ongoing systemic inflammation response and the nutritional status are a stage-independent predictor of poor outcome in cancer patients. This study aims to investigate association of the Prognostic Nutritional Index (PNI), a proposed marker of cancer-related inflammation and nutritional status, with survival in LAHNSCC patients (pts).

Methods: We included 137 LAHNSCC pts treated with induction chemotherapy (ICT) followed by concurrent chemoradiotherapy (CCRT) at Hospital La Fe (HFV) (n = 50) and Hospital Clínico (HCV) (n = 87) between 2011-2016; they were used as a training (HFV) and validation (HCV) set respectively. Demographic and clinical data were collected. All nutritional factors were measured within 5 days before ICT. PNI was calculated as: 10× serum albumin concentration (g/dL) + 0.005× lymphocyte count (number/mm2) in peripheral blood (Nozoe et al, 2010). Receiver operating characteristic (ROC) curve was used to determine the optimal cutoff for PNI in the HFV set. Cox regression models were used to investigate the association of PNI with OS.

Table: 1091P The Prognostic Nutritional Index (PNI): definition

Score	Definition	Meaning
0 points	PNI ≥ cutoff = PNI-high group	Normal nutritional status – Low risk
1 point	PNI < cutoff = PNI-low group	Moderate severe nutritional impairment - High Risk

Results: At baseline, HFV pts were younger with a median age of 54.5 (41-59 years) vs 60.6(43-77 years) and with less advanced stage (stage III 18.8 vs 20.5%; stage IVA: 78.1 vs 62.1%; stage IVB:3.1 vs 17.2%). The optimal cutoff established in the HFV set was 45. According to this cutoff, 10 pts (20%) in HFV set had a low PNI. In HFV set, OS at 12-months follow-up (FU) was 75% in PNI-high group vs 37.5% in PNI-low group ($P = 0.032$) with a Hazard ratio of (HR) of 2.84 (95%CI 1.04-7.78) in the multivariate analysis. In the HCV set, a low PNI was found in 23 (26.4%) out of 87 pts. OS at 12-months FU was 95% in PNI-high group and 45% in PNI-low group ($p = 0.007$) with a HR of 3.9 (95% CI 1.45-10.98) in the multivariate analysis.

Conclusions: PNI is a valuable prognostic marker in LAHNSCC associated with survival in pts treated with ICT followed by CCRT. PNI could be useful for stratification in future clinical trials.

1092P CASP9 c.-1339A>G and CASP3 c.-1191A>G polymorphisms in susceptibility and outcome of head and neck squamous cell carcinoma

E.F.D. Costa, L. Lopes-Aguiar, G.A.S. Nogueira, T.R.P. Lima, V.T. Liutti, F. Leal, V.C.A. Santos, J.A. Rinck-Junior, G.J. Lourenço, C.S.P. Lima

Department of Internal Medicine, University of Campinas, Campinas, Brazil

Background: We analyzed herein the roles of *CASP9* c.-1339A>G (rs4645978) and *CASP3* c.-1191A>G (rs12108497) single nucleotide polymorphisms (SNPs) of intrinsic apoptosis pathway on risk and behavior of head and neck squamous cell carcinoma (HNSCC).

Methods: DNA of 350 HNSCC patients and 350 controls was analyzed by polymerase chain reaction method and enzymatic digestion for genotyping. Patients were treated according to the Institutional protocol, including surgery, radio and chemotherapy. The statistical analyses were realized using chi-square, logistic regression model, multifactor dimensionality reduction (MDR), Kaplan-Meier, and univariate and multivariate Cox analyses.

Results: *CASP3* c.-1191AG or GG genotype was more common in patients with overall HNSCC (63.4% *versus* 53.4%, $P = 0.013$), male patients with overall HNSCC (65.5% *versus* 53.4%, $P = 0.011$), patients with SCC of oral cavity (OCSCC) (68.0% *versus* 53.4%, $P = 0.02$) and SCC of pharynx (PSCC) (62.7% *versus* 53.4%, $P = 0.010$) than in controls; carriers of genotypes were under 2.15 and 2.34-fold increased risks of overall HNSCC, 2.75 and 2.67-fold increased risks of OCSCC and PSCC, respectively. Interactions of *CASP9* and *CASP3* SNPs and tobacco on HNSCC, OCSCC, PSCC, and laryngeal SCC risks were evident in study ($P < 0.01$). At 60 months of follow-up, event-free survival was worst in patients with *CASP9* c.-1339GG genotype (35.9% *versus* 45.1%, $P = 0.04$) compared to others (Kaplan-Meier estimates). Patients with *CASP9* c.-1339GG genotype and *CASP9* c.-1339GG plus *CASP3* c.-1191GG genotypes had 1.46 more chances of disease progression or relapse and 2.66 more chances of evolving to death in univariate and multivariate analyses, respectively.

Conclusions: We present, for the first time, preliminary evidence that inherited abnormalities in the intrinsic apoptosis pathway, related to *CASP9* c.-1339A>G and *CASP3* c.-1191A>G SNPs, are important determinants of HNSCC risk and outcome. **Financial support**: Fundação de Amparo à Pesquisa do Estado de São Paulo (FAPESP).

1093P Resource-stratification of national comprehensive cancer network (NCCN®) head and neck cancers guideline

R.W. Carlson[1], E. Nardi[2], J. Bacigalupo[3], S. Darlow[4], J.S. McClure[4], D. Pfister[5]

[1]Management Team, National Comprehensive Cancer Network (NCCN), Fort Washington, PA, USA, [2]Quality of Oncology Care, National Comprehensive Cancer Network (NCCN), Fort Washington, PA, USA, [3]Business Development, National Comprehensive Cancer Network (NCCN), Fort Washington, PA, USA, [4]Clinical Information and Publications, National Comprehensive Cancer Network (NCCN), Fort Washington, PA, USA, [5]Head and Neck Oncology Service, Memorial Sloan Kettering Cancer Center, New York, NY, USA

Background: Resource constraints in low- and middle- income countries (LMICs) often impede critical medical care. 65% of new cases of lip and oral cancer, and 76% of related deaths occur in LMICs, where patients lack access to standard diagnostic tests and/or treatment approaches. The development of resource-stratified clinical guidelines promotes access to critical diagnostic and treatment pathways in LMICs.

Methods: To address the unmet need in LMICs, a multi-disciplinary committee of NCCN Member Institution experts developed the NCCN Framework™ for Head and Neck Cancers: Lip and Oral. In the evidence-based, resource-stratified Guidelines, recommendations from the NCCN Guidelines for Head and Neck Cancers were assigned to specific resource levels, based on access to various interventions and importance in

achieving clinical outcomes. International experts reviewed the resource-stratified Guidelines to assess utility in LMICs and NCCN approved and published the finalized guidelines.

Results: The NCCN Framework for Head and Neck Cancers: Lip and Oral has four resource levels: Basic, Core, Enhanced, and Parent guideline. The Framework for Basic Resources identifies essential services required for minimal standard of care for improvement in outcome; the Core Resources lead to improved outcomes but are not cost prohibitive; the Enhanced Resources recommend additional services that may improve outcomes, but may be cost prohibitive in certain settings. For initial treatment of early stage cancer of the oral cavity (T1-2, N0) as an example, the Enhanced Framework recommends surgical resection and radiation therapy (RT), but not sentinel lymph node (SLN) biopsy, which is recommended in the NCCN parent Guidelines and requires more advanced resources. The Basic Framework recommends surgical resection as the only primary treatment option, since RT may not be available at this resource level.

Conclusions: The NCCN Framework for Head and Neck Cancers: Lip and Oral provide LMICs with a system to optimize care in limited resource settings, and a map to improve cancer care incrementally as resources become available. Use of this framework facilitates improved patient care in resource-constrained settings.

1094P Long-term results of chemoradiotherapy for stage III nasopharyngeal carcinoma patients and risk grouping by pretreatment EBV viral load

P-J. Lin[1], W-Y. Wang[2], Y.C. Liu[3], J-C. Lin[3]

[1]Department of Radiation Oncology, Tungs' Taichung MetroHarbor Hospital, Taichung, Taiwan, [2]Department of Nursing, Hung Kuang University, Taichung, Taiwan, [3]Radiotion Oncology, Taichung Veterans General Hospital, Taichung, Taiwan

Background: No previous study reported the treatment outcome of stage III nasopharyngeal carcinoma (NPC) patients. The aim of this study is to investigate the long-term clinical outcome of stage III NPC patients and do risk grouping by plasma EBV DNA assay for future therapy improvement.

Methods: A total of 356 previously untreated, pathologically-proven NPC patients with stage III disease and available pretreatment plasma EBV DNA data were enrolled in this retrospective study. Initial definitive treatment consisted of concurrent chemoradiotherapy or induction chemotherapy plus radiotherapy. Eighty-four of 356 (23.6%) patients also received post-RT adjuvant chemotherapy. Patients with pretreatment EBV DNA $>$ 1000 copies/mL were defined as a high-risk subgroup (n = 106) and the remaining patients as a low-risk subgroup (n = 250).

Results: After a median follow-up of 90 months, there were 66 recurrences (18.5%) and 57 deaths (16.0%). The 5-year overall survival (OS), progression-free survival (PFS), distant metastasis failure-free survival (DMFFS), and locoregional failure-free survival (LRFFS) for all 356 patients were 88.4%, 83.9%, 90.5%, and 90.5%, respectively. Thirty-five of 105 (33.0%) high-risk patients developed tumor relapse later, whereas only 12.4% (31/250) low-risk patients had tumor relapse ($P < 0.0001$) Survival analysis revealed that the high-risk subgroup had significantly worse OS (5-year rate, 79.% vs. 92.8%, $P < 0.0001$), PFS (73.7% vs. 88.4%, $P < 0.0001$), DMFFS (80.2% vs. 95.0%, $P < 0.0001$), and LRFFS (85.6% vs. 92.6%, $P = 0.0045$) than those of the low-risk subgroup.

Conclusions: Long-term treatment results for Stage III NPC patients were good. Risk grouping identified a subgroup of patients with high pretreatment EBV DNA had a significantly higher relapse rates and worse survivals. Future trial should strengthen treatment intensity for these high-risk patients.

1095P Nasopharyngeal cancer in children: Long term results the experience of the university hospital of Sfax (Tunisia)

P-J. Lin[1], W-Y. Wang[2], Y.C. Liu[3], J-C. Lin[3]

[1]Department of Radiation Oncology, Tungs' Taichung MetroHarbor Hospital, Taichung, Taiwan, [2]Department of Nursing, Hung Kuang University, Taichung, Taiwan, [3]Radiotion Oncology, Taichung Veterans General Hospital, Taichung, Taiwan

Background: Nasopharyngeal carcinoma in children is frequent in Mediterranean area. We aimed to report our experience in the treatment of this entity.

Methods: We retrospectively review the records of 76 young patients (<21 years) presenting with nasopharyngeal cancer during the period 1993 -2015. Diagnosis was confirmed with histological study of the biopsy of nasopharynx. Initial work-up included nasofibroscopy, CT scan and/or MRI of the nasopharynx and neck, chest X-ray, abdominal ultrasonography and bone scan. TNM 2009 classification was used. Patients treated before 2009 were retrospectively reclassified. Metastatic patients were excluded. Patients had cisplatin based regimen chemotherapy (neoadjuvant, concomitant or both). Radiotherapy was delivered at the dose of 70 to 75 Gy targeting the nasopharynx and involved cervical nodes. Prophylacting dose up to 50 Gy was delivered to the remaining cervical areas. Survival was studied with Kaplan Meier test. Late toxicities were assessed according to SOMA-LENT and RTOG scales in patients with a minimal follow-up of 24 months.

Results: Mean age was 16 years (9 – 20). Sex-ratio was 1,1. Seventy two percent of patients (n = 55) had locally advanced tumor (T3 or T4). Cervical nodal involvement was seen in 95% of cases (n = 71). There were 52 cases (68%) of N2 or N3. Sixty-six patients had neoadjuvant chemotherapy, 10 had concomitant and 5 had both. Five patients had exclusive irradiation. Radiotherapy was monofractionated in 45 cases and bifractionated in the remaining cases. Acute toxicities were tolerable. Mean follow-up was 198 months (28- 289). One patient experienced a local failure. Twenty-six presented metastatic failures. Overall survival rate at 10 years is 67,4%. Disease free survival rate at 10 years is 66,7%. Xerostomia was the most frequent late toxicity (97%). Patients experienced endocrine troubles (hypothyroidism in 19%, amenorrhea in 13%), cerebral necrosis (5cases), osteoradionecrosis (10 cases) and secondary cancer (3 cases).

Conclusions: Pediatric nasopharyngeal carcinoma has good prognosis despite frequent locally advanced disease at presentation. Combining radiotherapy and chemotherapy is the standard of care. Late toxicities are often severe and affect the quality of life.

1098P Incidence and impact of DPD mutation on neoadjuvant chemotherapy in head and neck cancers

S.W. Turkar[1], A. Chougule[1], V. Patil[1], V. Noronha[2], A. Joshi[2], N. Pande[1], A. Chandrashekharan[1], K. Prabhash[1]

[1]Medical Oncology, Tata Memorial Hospital Centre, Mumbai, India, [2]Medical Oncology, Tata Memorial Centre, Mumbai, India

Background: Dihydropyrimidine dehydrogenase (DPD) is an enzyme essential for metabolism of 5FU. The incidence of polymorphisms or mutation in variable across different ethnic populations. This study is first report highlighting the high incidence of DPYD mutation is seen in head and neck cancers in India.

Methods: Consecutive patients with head and neck cancer undergoing TPF neoadjuvant chemotherapy at our centre between May 2015 - December 2016 underwent DPD mutation analysis. The haematological toxicities consisting of neutropenia and thrombocytopenia while gastrointestinal toxicities consisting of mucositis and diarrhea were considered as 5FU related toxicities for this analysis. Toxicities were graded in accordance with CTCAE (Common terminology criteria for adverse events) version 4.03. DPYD mutation analysis by Sanger sequencing on ABI 3500 platform, for the most prevalent exonic regions {Exon 13 –c1627 A>G(DPYD*5) p1543V (ATA>GTA); Exon 14 – 1845 G>T; (E615D) missense mutation, Exon 14 splice variant G>A and Exon 18 (DPYD*6) pV7321) - c2194 G>A (GTT>ATT)}. Descriptive statistics was performed using SPSS version 16 and RStudio. Proportions with 95% CI were described. Fisher's exact test was performed to see the relationship between DPD mutation status and grade 3-5 adverse events.

Results: Consecutive 118 patients were included in this analysis. The median age was 45 years (IQR 37.25-54.00 years). The median cycles of TPF received were 2 (range 1-4). DPD mutation was seen in 29 patients (24.59%, 95%CI 16.94-32.23%). The mutations were seen in exon 18 in 17 patients (14.4%), exon 13 in 9 patients (7.6%) and in both exon 13 & 18 in 3 patients (2.5%). 100 patients were eligible for assessment of adverse events (84.7%). The rate of grade 3-5 haematological and gastrointestinal adverse events was 64% and 35% respectively. The rate of grade 3-5 haematological (88.5% versus 55.4%, p-0.002) and gastrointestinal adverse events (57.7% versus 27.0%) were higher in DPYD mutated cohort.

Conclusions: This study signifies the importance of ethnic difference in drug polymorphism and mutations. The impact of these adverse events in DPD mutated patients justifies doing a DPD mutation prior to subjecting patient to 5FU in head and neck cancer.

1099P Radiotherapy related xerostomia in head and neck oncology: A systematic review

D. Johns

Dentistry, DM WIMS Medical College, Kozhikode, India

Background: Radiotherapy in the head and neck region can lead to salivary gland hypofunction and as a result dry mouth ensues. We have undertaken this systematic review and meta-analysis to estimate the effectiveness of available interventions for radiotherapy-induced xerostomia and hyposalivia.

Methods: A systematic review and meta-synthesis techniques were adopted to identify, appraise and synthesize the relevant literature regarding the experience of nutritional symptoms of HNC patients conducted according to the PRISMA guidelines. Several

electronic databases such as PubMed, CINAHL, Scopus, PsycINFO and the Cochrane Library databases were searched.

Results: 1598 patients from Eighteen studies were included in the systematic review. Cholinergic agonists like Pilocarpine, cevimeline and bethanechol were tested in most studies. Other drugs tested include malic acid, physostigmine, specific monoclonal antibodies like Rituximab, fluoroquinolones, saliva substitutes/mouthcare systems, hyperthermic humidification, acupuncture, acupuncture-like transcutaneous electrical nerve stimulation, low-level laser therapy and herbal medicine. A recent study evaluated the salivary parameters in 4 phases. Results of meta analysis suggests cholinergic agonists were the most effective to improve salivary flow, compared to placebo, although some aspects of the relevant effect size, duration of the benefit, and clinical meaningfulness remain unclear.

Conclusions: Pilocarpine, bethanechol and cevimeline should represent the first line of therapy in head and neck cancer survivors with radiotherapy-induced xerostomia and hyposalivation. The use of other treatment modalities cannot be supported on the basis of current evidence.

1100P The phase II study of HMB/Arg/Gln against oral mucositis induced by chemoradiotherapy for head and neck cancer patients

T. Yokota[1], S. Hamauchi[1], Y. Yoshida[1], T. Yurikusa[2], M. Suzuki[2], A. Yamashita[3], H. Ogawa[4], T. Onoe[4], K. Mori[5], T. Onitsuka[6]

[1]Division of Gastrointestinal Oncology, Shizuoka Cancer Center, Shizuoka, Japan, [2]Division of Dental and Oral Surgery, Shizuoka Cancer Center, Shizuoka, Japan, [3]Division of Nutrition, Shizuoka Cancer Center, Shizuoka, Japan, [4]Division of Radiation Oncology, Shizuoka Cancer Center, Shizuoka, Japan, [5]Clinical Trial Coordination Office, Shizuoka Cancer Center, Shizuoka, Japan, [6]Divisions of Head and Neck Surgery, Shizuoka Cancer Center, Shizuoka, Japan

Background: Opioid-based pain control and systemic oral care program are effective for the chemoradiotherapy (CRT)-induced severe oral mucositis (OM) in patients with head and neck cancers (HNC). This phase II trial assessed the clinical benefit of beta-Hydroxy-beta-Methylbutyrate, Arginine, and Glutamine (HMB/Arg/Gln) in the prevention of CRT-induced OM in patients with HNC.

Methods: Patients with HNC who were scheduled to receive definitive or postoperative cisplatin-based CRT were enrolled. HMB/Arg/Gln was administered orally or per percutaneous endoscopic gastrostomy from the first day of CRT up to completion of CRT. All patients received opioid-based pain control and oral care programs we previously published. The primary endpoint was the incidence of grade $\geq$3 OM (functional/symptomatic) according to the Common Terminology Criteria of Adverse Events version 3.0. QOL (EORTC QLQ-C30/PROMS) and intake of nutrition at baseline and 50Gy were also assessed.

Results: From February 2015 to June 2016, 35 patients with HNC were enrolled. Sixteen patients (45.7%) developed grade $\geq$3 OM (i.e., functional/symptomatic). The incidence of grade $\leq$1 OM (functional/symptomatic) was 51.5% at 2 weeks and 82.9% at 4 weeks after completion of RT. Clinical examination revealed that 10 patients (28.6%) developed grade $\geq$3 OM. The incidence of grade $\leq$1 OM (clinical exam) was 80.0% at 2 weeks and 100% at 4 weeks after completion of RT. Only 5.7% of patients had unplanned breaks in radiotherapy, and all patients completed treatment. Adverse events related to HMB/Arg/Gln were increase in blood urea nitrogen and diarrhea, but were easily managed.

Conclusions: Addition of HMB/Arg/Gln to opioid-based pain control and oral care programs was feasible but still insufficient in reducing the incidence of severe CRT-induced oral mucositis. However, the benefit of HMB/Arg/Gln should not be neglected in terms of findings of clinical examination and the recovery from severe oral mucositis.

1101P Oral mucosa dose parameters predicting grade $\geq$3 acute toxicity in locally advanced nasopharyngeal carcinoma patients treated with concurrent intensity-modulated radiation therapy and chemotherapy

K. Li[1], L. Yang[2], Y-Y. Chen[3], M. Chen[3]

[1]Department of Radiation Oncology, First Hospital of Quanzhou Affiliated to Fujian Medical University, Quanzhou, China, [2]Department of Oncology, Xinyu Peole's Hospital, Xinyu, China, [3]Radiotherapy, Zhejiang Cancer Hospital, Hangzhou, China

Background: To determine whether volumes based on the contours of the mucosal surface can be used instead of the contours of the oral cavity to predict for grade $\geq$3 acute oral mucosa toxicity in patients with locally advanced nasopharyngeal carcinoma (LANPC) treated with concurrent intensity-modulated radiation therapy (IMRT) and chemotherapy.

Methods: A standardized method for the oral cavity (oral cavity contours, OCC) and a novel method for the mucosal surface (mucosal surface contours, MSC) were developed for the oral mucosa and prospectively applied to the radiation treatment plans of 92 patients treated with concurrent IMRT and chemotherapy for LANPC. Dose–volume histogram (DVH) data were extracted and analyzed against patient toxicity. Receiver operating characteristic analysis and logistic regression were carried out for both contouring methods.

Results: Grade $\geq$3 oral mucosa toxicity occurred in 20.7% (19/92) of patients in the study. A highly significant dose–volume relationship between oral mucosa irradiation and acute oral mucosa toxicity was supported by using both oral cavity and mucosal surface contouring techniques. In logistic regression, body weight loss was an independent factor related to grade $\geq$3 toxicity for OCC and MSC (p=0.017 and 0.005, respectively), and the independent factor of dosimetric parameters for OCC and MSC were V30Gy (p=0.003) and V50Gy (p=0.003), respectively. In the receiver operating characteristics curve, the areas under V30Gy of the OCC curves was 0.753 (p=0.001), and the areas under V50Gy of MSC curves was 0.714 (p=0.004); the cut-off value was 73.155% (sensitivity, 0.842; specificity, 0.671) and 14.32% (sensitivity, 0.842; specificity, 0.575), respectively.

Conclusions: DVH analysis of mucosal surface volumes accurately predicts grade $\geq$3 oral mucosa toxicity in patients with LANPC receiving concurrent IMRT and chemotherapy, but the MSC method is still no better than the OCC method in clinical application.

1102P Sinonasal non-glandular cancers relapsing after multimodal treatments

S. Cavalieri[1], R. Granata[1], L.D. Locati[1], C. Bergamini[1], S. Alfieri[1], C. Resteghini[1], D. Galbiati[1], E. Orlandi[2], N.A. Iacovelli[2], G. Calareso[2], M. Guzzo[3], P. Quattrone[4], L. Licitra[5], P. Bossi[1]

[1]Head and Neck Medical Oncology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [2]Radiotherapy, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [3]Otorhinolaryngology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [4]Pathology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [5]Head and Neck Medical Oncology, Fondazione IRCCS - Istituto Nazionale dei Tumori - Università degli studi di Milano, Milan, Italy

Background: Multimodality treatment (MMT) is the current approach to advanced sinonasal cancers (SC). We lack salvage treatment standardization especially for pts already receiving MMT. No clinical factors able to predict outcome have been identified in this disease setting.

Methods: We retrospectively analyzed a series of pts with recurrent/metastatic (RM) SC after multimodal curative treatment, consisting in induction chemotherapy (iCT) followed by locoregional therapy. Overall survival (OS) was measured as the interval from relapse to death.

Results: Among 106 pts with SC treated with MMT at our Center from 1997 to 2016, 50 (M/F 31/19) relapsed. Median age was 53 yrs (16-73). Median follow-up was 26 months (m) (5-192). WHO 2005 histotypes were: 36% sinonasal undifferentiated carcinoma (SNUC), 34% squamous cell cancer (SCC), 30% carcinomas with neuroendocrine differentiation (CND). Median time to first relapse after curative treatment was 13.5 m. Median OS was 13 m from recurrence: 19 m in SCC, 16 m in SNUC and 6 m in CND ($p = .34$). Relapse occurred as distant metastasis in 40%, as nodal recurrence in 6% and at primary site in 54% of cases. First line salvage treatment was surgery in 38% (14 pts received surgery on T, 2 on N and 3 on M), CT in 30%, RT in 8%, best supportive care in the remaining pts. Median OS was 31 m in surgically treated pts and 4.8 m in those receiving CT ($p < .0001$). In pts with disease control (PR+SD) after iCT, median OS after recurrence was longer than in pts with PD (13.4 vs 1.5 m, $p = .07$). Median OS from relapse was 29.6 m in pts with CR after definitive treatment, 7.1 m in those with PR and 3.4 m in those with PD ($p = .002$). Pts with an objective response to palliative CT had a longer median OS than those with PD (20 vs 4 m, $p = .002$).

Conclusions: Prognosis of SC relapsing after MMT is dismal. With the caveat of a retrospective analysis and a case series that has been collected in a long time frame, we showed that feasibility of salvage surgery, objective response to prior definitive treatment and response to palliative CT are factors associated with better outcomes. Pts with relapsed or metastatic SC not amenable to salvage surgery should be considered for enrolment in clinical trials.

1103P Survival outcome and optimal treatment of intermediate-grade salivary gland carcinoma

G. Park

Otolaryngology, Samsung Changwon Hospital Sung Kyun Kwan University, Changwon, Republic of Korea

Background: Histological grade is the most important factor for defining treatment strategies and predicting prognosis for salivary gland carcinoma (SGC). Although several studies have addressed low- and high-grade SGCs, intermediate-grade SGC (IGSGC) has received minimal attention. Therefore, we examined factors affecting long-term recurrence and survival among IGSGC patients to define optimal treatment modalities and outcomes.

Methods: We reviewed the clinical and pathological data of 108 IGSGC patients who underwent definitive surgery with or without postoperative radiotherapy at our tertiary referral center between 1994 and 2014. We performed univariate and multivariate analyses of variables predictive of locoregional control (LRC), distant metastasis-free survival (DMFS), and overall survival (OS). We compared treatment outcomes by treatment strategies such as surgical extent, primary tumor, neck dissection, or postoperative radiotherapy.

Results: During a median 103 (range, 24−282)-month follow-up, local, regional, and distant recurrences were detected in 14 (13.0%), 3 (2.8%), and 21 (19.4%) patients, respectively. The 10-year LRC, DMFS, and OS rates were 83.1%, 76.0%, and 80.1%, respectively. Multivariate analyses identified a non-parotid primary site as an independent prognostic factor for LRC ($P = 0.018$), Adenoid cystic carcinoma and positive pN classification were significantly unfavorable prognostic factors for DMFS ($P = 0.025$ and $P = 0.030$, respectively); overall advanced stage was an independent prognostic factor for OS ($P = 0.020$). Surgical extent, elective neck dissection, and postoperative adjuvant radiotherapy did not significantly affect treatment outcomes.

Conclusions: Patients with early-stage IGSGC of parotid origin can achieve favorable treatment outcomes with conservative surgery alone.

1104P Incidence and survival of secondary malignances (SM) in oropharingeal squamous cell carcinoma (OPSCC): A homogeneous single report institution

M. Napolitano[1], F. Bertolini[1], E. D'Angelo[2], A. Spallanzani[1], S. Tassi[3], B. Meduri[2], S. Bettelli[4], R. Depenni[1], A. Ghidini[3], F. Lohr[2], L. Presutti[3], S. Cascinu[1]

[1]Department of Oncology, Modena University Hospital, Modena, Italy, [2]Radiotherapy Service, Modena University Hospital, Modena, Italy, [3]ENT Surgery Dept, Modena University Hospital, Modena, Italy, [4]Molecular Biology Lab, Modena University Hospital, Modena, Italy

Background: SM in HNSCC patients (pts) are common, due to the presence of risk factors (smoking habit or alcohol abuse). Aim of this report is to evaluate the incidence and characteristics of SM in a series of OPSCC.

Methods: We retrospectively reviewed clinical data of 266 pts with OPSCC seen at Modena University Hospital between 2006 and 2016. We recorded data from a web platform in which every pt has a personal form filled with clinical information. In particular, we analyzed the rate of SM and described clinical and survival data.

Results: SM was diagnosed in 37 pts (13,9%): 15 NSCLC (5% on all; 40,5% of SM); 7 HNSCC (18,9%), 8 GI (21,6%), 2 prostate (5,4%), 2 thyroid cancer (5,4%), 2 hematologic malignancy (5,4%) and 1 melanoma (2,7%). Clinical features at diagnosis for OPSCC: 30 (81%) male, 7 (19%) female; median age 68 years (range 37-90). Twenty-five pts (67,6%) were current/former smokers, 26 (70,3%) HPV-positive; stage at diagnosis was I-II in 5 (13,5%) and III-IV in 32 pts (86,5%). Eleven pts developed SM < 12 vs 26 ≥ 12 months (mo) after the diagnosis of OPSCC. Stage at diagnosis for SM was: for lung 10 (66, 6%) I-II vs 5 (33,4%) III-IV; for HNSCC 3 (42,8%) I-II vs 4 (57,2%) III-IV; for GI 2 (25%) I-II vs 6 (75%) III-IV. Treatments for SM: 18 surgery, 2 RT, 8 CT, 5 combined treatment; 4 pts did not need or not received therapy. Death occurred in 18 pts (48,6%): SM-related in 12 (66,6%), OPSCC-related in 3 (16,7%) and not cancer-related in 3 (16,7%). mOS from diagnosis of OPSCC vs SM were 68,5 and 21,3 mo, respectively. Pts with lung or HNSCC SM (mOS 6,7 mo) had worse OS than pts with other SM (mOS 20,7 mo), but not statistically significant. Pts with SM diagnosed ≥ 12 mo vs < 12 mo after OPSCC had a significantly better OS (mOS 81 vs 25,1 mo; $p < 0.001$).

Conclusions: In our retrospective series, we confirmed that secondary lung cancer was the most frequent SM; it was diagnosed at earlier stage, because these pts underwent a periodical follow-up for their previous OPSCC with a chest X-ray/CT. Smokers may benefit from a more intensive follow-up for a higher risk of smoking related SM (lung, HNSCC). Survival is more influenced by the occurrence of SM than by OPSCC. All these considerations should be applied to a larger series.

1105TiP Pembrolizumab plus chemoradiation (CRT) for the treatment of locally advanced head and neck squamous cell carcinoma (LA-HNSCC): Phase 3 KEYNOTE-412 trial

J-P. Machiels[1], L. Licitra[2], D. Rischin[3], J. Waldron[4], B. Burtness[5], V. Grégoire[1], T. Shekar[6], H.M. Brown[6], J. Cheng[6], L.L. Siu[7]

[1]Oncology, Cliniques Universitaires Saint-Luc, Brussels, Belgium, [2]Oncology, Fondazione IRCCS Istituto Nazionale Tumori Milano, Milan, Italy, [3]Oncology, Peter MacCallum Cancer Centre, East Melbourne, Australia, [4]Oncology, Princess Margaret Cancer Centre, Toronto, ON, Canada, [5]Medicine, Yale University School of Medicine, New Haven, CT, USA, [6]Medical Oncology, Merck & Co., Inc., Kenilworth, NJ, USA, [7]Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: Despite significant advancements in oncologic treatment, the outcome for patients with advanced or recurrent HNSCC is poor. Identification of abscopal effects by use of radiotherapy (RT) in combination with immunotherapy in a patient with metastatic melanoma has prompted interest in the use of combination regimens. The objective of the KEYNOTE-412 trial (NCT03040999) is to assess efficacy and safety of pembrolizumab in combination with CRT as maintenance therapy for subjects with LA-HNSCC.

Trial design: KEYNOTE-412 is a phase 3, randomized, placebo-controlled, double-blind trial enrolling subjects with newly diagnosed, treatment-naive, oropharyngeal p16 positive (any T4 or any N3), oropharyngeal p16 negative (any T3-T4, or N2a-N3), or larynx/hypopharynx/oral cavity (any T3-T4, any N2a-N3) SCC. Approximately 780 subjects will be randomly assigned (1:1) to receive pembrolizumab plus cisplatin-based CRT or placebo plus cisplatin-based CRT. Subjects will be stratified by RT regimen, tumor site/p16 status, and disease stage. Treatment will include a priming dose of pembrolizumab 200 mg or placebo 1 week before initiation of CRT, followed by 7 weeks' CRT (cisplatin 100 mg/m^2 every 3 weeks [Q3W] [3 doses]; accelerated RT [70 Gy, 6 fractions/week] or standard RT [70 Gy, 5 fractions/week]) plus pembrolizumab 200 mg Q3W or placebo Q3W. Treatment with pembrolizumab 200 mg Q3W or placebo Q3W will continue up to 1 year (maximum 17 doses). Treatment will continue until disease progression, unacceptable toxicity, withdrawal of consent, or investigator decision to withdraw the patient. Response will be assessed by computed topography or magnetic resonance imaging 12 weeks after completion of CRT, every 4 months for a subsequent 2 years, and every 6 months thereafter up to year 5. Safety will be monitored throughout the study. The primary end point is event-free survival by blinded independent central review per RECIST v1.1. Secondary end points include overall survival, safety, and quality of life. Exploratory biomarker analyses will be conducted.

1106TiP Hope for salivary gland cancer (SGC): EORTC HNCG/UKCRN 1206 randomized phase II study to evaluate the efficacy and safety of Chemotherapy (CT) vs androgen deprivation therapy (ADT) in patients with recurrent and/or metastatic androgen receptor (AR) expressing SGC

L.D. Locati[1], C. Caballero[2], C. Fortpied[2], F. Perrone[3], S. Pilotti[4], K.J. Harrington[5], V. Grégoire[6], L. Licitra[1]

[1]Head and Neck Medical Oncology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [2]Medical, EORTC, Brussels, Belgium, [3]Molecular Pathology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [4]Anatomic Pathology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [5]Radiotherapy and Imaging, Royal Marsden NHS Foundation Trust/The Institute of Cancer Research, London, UK, [6]Dept. Radiation Oncology, Cliniques Universitaires St. Luc, Brussels, Belgium

Background: SGCs are rare and heterogenous tumors (<1% of all malignancies in Europe). Among more than 20 histotypes, only salivary duct carcinoma (SDC) and adenocarcinoma NOS expresses AR. These variants are aggressive and associated with poor prognosis. Surgery is the main curative treatment but upon relapse, patients are left with very few options. There is an urgent need to understand their biology to enable progress in this rare disease. This study (NCT01969578) aims to evaluate the efficacy and safety of ADT (experimental arm) vs chemotherapy (standard arm) in patients with recurrent and/or metastatic, AR overexpressing SDC and adenocarcinoma, NOS

by demonstrating a 15% improvement in Progression Free Survival (PFS) rate at 6 months in favor of ADT.

Trial design: In this multicenter, randomized, phase II intergroup study a total of 76 treatment naïve patients (Cohort A) are planned to be randomized to receive ADT or platinum-based chemotherapy. Previously treated patients will be enrolled in a separate Cohort B to receive ADT. Patients from Cohort A randomized to chemotherapy can also enter Cohort B at disease progression. The primary endpoint is PFS for Cohort A and best overall response for Cohort B. Central testing of AR expression is based on staining intensity (0 = negative to 3 = strong) and percentage of positive nuclear stained cells (0 = ≤10% to 3 = ≥70%). AR overexpression requires a maximum score of 3 on both scales. Mechanisms of AR activation and resistance will be studied. This study is led by EORTC Head and Neck Cancer Group with UNICANCER/REFCOR, International Rare Cancer Initiative UK Salivary Gland Cancer Group and RARECARENet. It will run in 35 sites in 10 countries: Austria, Belgium, France, Germany, Greece, Hungary, Italy, Portugal, The Netherlands, and United Kingdom. Sites from the EURACAN European Reference Network are participating. Currently, 36 patients are registered; 20 have AR overexpression, of which 16 have been randomized in Cohort A. Identification of AR as a treatment target in SGC can be practice changing.

1107TiP Phase II trial of abiraterone acetate in patients with relapsed and/or metastatic, castration resistant AR expressing salivary glands carcinomas (SGCs)

L.D. Locati, A. Gambaro, L. Licitra

Medical Oncology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy

Background: Expression of androgen receptors (AR), is reported in more than 80% of salivary duct carcinomas (SDC) and in 50% of adenocarcinomas, NOS. Similary to prostate cancer (Pca), androgen deprivation therapy (ADT) has been employed with success in patients with metastatic AR-expressing SDC and adenocarcinoma, NOS in so much as an international randomized trial is ongoing to assess the efficacy of ADT over chemotherapy as first line treatment in this setting of patients (NCT01969578). Abiraterone acetate was approved in advanced, castration resistant Pca in 2011. We tested the activity of abiraterone in two patients with AR-positive castration resistant adenocarcinoma, NOS obtaining two partial responses (Locati LD, Cancer Biol Ther 2014).

Trial design: This is a phase II trial (NCT02867852) aimed at assessing the activity (CR+ PR) of abiraterone in castration resistant AR-positive SGCs. The drug will be considered effective and worth of further evaluation if the response rate will be at least 20%. The null hypothesis will be RR 5% versus the alternative RR20%. A 2-stage Simon design will be applied. Type I and type II error rates are set at the 10% and 20% levels. If at least 1/9 response will be observed in the first step, patients' enrolment will go on up to a final overall sample size of 24 subjects. If at least 3/24 responses will be recorded, the null hypothesis will be rejected in favor of the alternative and the drug considered promising and worthy of further investigation. Objective tumor response and time to progression will be measured according to RECIST criteria 1.1 and to PCWG2 recommendations for bone lesions. Twenty four patients with AR-expressing SGC, progressed on ADT, will be enrolled over two years. Four 250 mg tablets of abiraterone acetate will be administered daily to patients until progression of disease or intolerable toxicity. Disease control rate, incidence of adverse events, overall survival and progression free survival will be assessed as well. Tumor samples will be also collected for translational analyses (e.g. CYP17 expression; PI3K mutations). Blood and saliva samples will be collected as well.

1108TiP Chemoradiotherapy versus radiotherapy in the treatment of salivary glands and nasal tumors: The GORTEC 2016-02 study

F.R. Ferrand[1], J. Thariat[2], N. Vulquin[3], V. Calugaru[4], O. Malard[5], C. Murariu[6], F. Janot[7], F. Louat[8], C. Michel[9], J. Bourhis[10]

[1]*Medical Oncology, Bégin Military Teaching Hospital, Saint-Mandé, France,* [2]*Radiotherapy, Centre Antoine Lacassagne, Nice, France,* [3]*Radiotherapy, Centre Georges-François Leclerc (Dijon), Dijon, France,* [4]*Centre de protonthérapie d'Orsay, Institut Curie, Paris, France,* [5]*Head and Neck surgery, CHU Nantes, Nantes, France,* [6]*Radiotherapy, Institut Jean Godinot, Reims, France,* [7]*Head and Neck surgery, Gustave Roussy, Villejuif, France,* [8]*Clinical Research, GORTEC, Tours, France,* [9]*Clinical Research, GORTEC, Nice, France,* [10]*Radiotherapy, Centre Hospitalier Universitaire Vaudois - CHUV, Lausanne, Switzerland*

Background: Carcinomas of sinuses and salivary glands are rare and heterogeneous in terms of anatomical sites and histology subtypes. For these reasons and because of the absence of prospective study results, their treatment is still largely extrapolated from data of frequent carcinomas of the upper digestive tract. Treatment is based on surgery and radiotherapy (proof level grade C). Despite the advances, the 5-year overall survival does not exceed 65%, mainly due to locoregional recurrence. In this context, chemotherapy administered concomitantly with radiotherapy could increase the efficacy of locoregional treatment by radiosensitization, regardless of the histology.

Trial design: The GORTEC launched a multicenter, phase III randomized, open-label, study evaluating in case of high-risk of locoregional relapse, the impact of the addition after surgery of cisplatin 100 mg/m^2 (every 3 weeks; 3 cycles) to radiotherapy. The population is defined as patients with radioresistant histologies (e.g. cystic adenoids carcinomas) or patients with unfavorable histoprognostic critera (e.g. incomplete resection, T4 tumor, malignant lymph node(s) with capsular rupture, presence of emboli, . . .). The primary endpoint is the progression free survival. Secondary outcomes are: overall survival, quality of life, time to progression (locoregional and distant) and toxicities. Two hundred and sixty patients will be enrolled in 5 years. Eligible patients are adults, with a performance status ≤ 2 and an adequate hematological and renal function for cisplatin treatment. Recruitment is ongoing in France. The study comprises a quality insurance program in radiotherapy and surgery. Coordinating investigators are Drs Ferrand and Thariat.

Clinical trial identification: NCT02998385.

1109TiP MEDINDUCTION: Phase I trial evaluating the safety of durvalumab in combination with Docetaxel, Cisplatin and 5-FU (DCF) in induction for locally advanced squamous cell carcinoma of the head and neck (SCCHN)

C. Even[1], M. Texier[2], C. Le Tourneau[3], A. Marabelle[4], N. Chaput[5], J. Adam[6], A. Paci[7], S. Broutin[7], C. Ferté[1], I. Breuskin[1], D. Cupissol[8], J. Fayette[9]

[1]*Head and Neck, Gustave Roussy, Villejuif, France,* [2]*Biostatistiques et Epidémiologie, Institut Gustave Roussy, Villejuif, France,* [3]*Dept of Medical Oncology, Institut Curie, Paris, France,* [4]*Drug Development Department (DITEP), Gustave Roussy, Villejuif, France,* [5]*Laboratory of Immunomonitoring in Oncology, Institut Gustave Roussy, Villejuif, France,* [6]*Pathology, Institut Gustave Roussy, Villejuif, France,* [7]*Pharmacology, Gustave Roussy, Villejuif, France,* [8]*Oncology, Institut régional du Cancer de Montpellier, Montpellier, France,* [9]*Medical Oncology, Centre Léon Bérard, Lyon, France*

Background: SCCHN represents the sixth most common malignancy with 650 000 new cases and 350 000 SCCHN-related deaths reported annually worldwide. A majority of patients present with stage III or IV M0 disease, with a 5 year overall survival from 30% to 50%. Results of recent randomized trials evaluating induction chemotherapy by DCF are conflicting, and benefit on overall survival is uncertain. It is needed to improve efficacy of induction chemotherapy without increase toxicities. Tumours can actively evade destruction by the immune system by exploiting inhibitory checkpoint pathways that suppress antitumour T-cell responses. Antibody therapy to block immune checkpoints activated by the programmed cell death ligand-1 (PD-L1) has shown survival benefit in recurrent or metastatic SCCHN. Durvalumab is a selective, high affinity, engineered human IgG1 mAb that blocks PD-L1 binding to PD-1 and CD80. Durvalumab has shown encouraging antitumour activity in SCCHN with a manageable safety profile. The aim of this open-label, multi-center, Phase 1-b study is to characterize the safety profile of the combination of DCF with durvalumab.

Trial design: Patients aged ≥ 18 yr with histologically confirmed SCC of the oral cavity, oropharynx, larynx or hypopharynx, previously untreated, with indication of induction chemotherapy will be eligible. The primary objective is to determine the recommended Phase 2 dose (RP2D). The secondary objectives are to document any antitumor activity (PFS, ORR, RECISTv1.1 criteria), to estimate the pharmacokinetic parameters of durvalumab, to explore the relationships between immune capacity, specificity, activation state and clinical outcome. The study will be conducted in 2 parts: a dose-deescalation part to determine the RP2D (6 pts), and an expansion part (30 pts). The durvalumab will be administered every 3 weeks for 3 injections at week 1, 4, 7. The durvalumab first dose level is 1120 mg and the dose level -1 is 750 mg Q3W. The chemotherapy will be administered every 3 weeks at week 1, 4, 7 at the following doses: Docetaxel 75mg/m^2 on D2, Cisplatin 75mg/m^2 on D2, 5 Fluorouracil 750mg/m^2/day from D2 to D6.

ESMO GOOD SCIENCE BETTER MEDICINE BEST PRACTICE

Annals of Oncology 28 (Supplement 5): v395–v402, 2017
doi:10.1093/annonc/mdx375

HEALTH ECONOMICS

1111PD Economic burden of cancer patients and the job assistance from the society

N. Koinuma

Medicine, Tohoku Medical and Pharmaceutical University, Sendai, Japan

Background: Cancer patients who face the financial difficulties and are obliged to retire for the treatment are increasing in number. It is urgently important that they keep working to receive the optimal treatment. We investigate the actual situation of the patients who retired for treatment and examine the feasible measures including the desirable balance of work and treatment.

Methods: The cancer patients and the attending doctors were surveyed in 40 cancer centers, university hospitals and regional hospitals in Japan.

Results: The number of replies from patients was 3.204. The ratio of patients who were at work before treatment was 50.7%. The ratio of employees was 89.7%. Of these, 31.8% of patients quitted their work for treatment. It was as the highest as 38.7% in lung cancer, and as the lowest as 27.1% in breast cancer. In case of retirees, the ratios of stage I, II, III and IV were 20.6%, 17.9%, 13.9% and 43.7% respectively. The ratio of stage IV was 26.8% in the whole patients, and therefore the retirees tend to be higher in stage. The annual out-of-pocket expense, including direct and indirect expense in the retirees was an average of 6,940 EUR. This was slightly smaller than that of the whole patients. The ratios of patients who felt heavy about the economic burden were 73.7% in retirees and 61.9% in the whole patients. 7.0% of retirees and 5.3% of the whole patients had to change or abandon the most suitable treatment due to the economic reasons. 58.5% of retirees answered that the income was decreased during the cancer treatment and this was significantly higher than that of the whole patients. The percentage of retirees whose tax-included annual income was less than 24,200 EUR was 48. 6%. This was 39.2% in the whole patients. 46.7% of retired employees had no choice but to quite the work, while 42.7% answered that they wanted to continue their work.

Conclusions: One of three patients with cancer is in a working generation, and it is important for patients to balance the treatment with the work. It became clear in the survey that one third of the patient who was working was obliged to retirement. In Japan, the Cancer Control Act was revised in December, 2016 and it became the efforts duty of the company to continue the employment of cancer patients.

1113PD Using the ASCO's quality oncology practice initiative (QOPI) metrics and standards to improve value, meaningful use of resources and reduce waste

C.F. Pinto, F. Loiola, T. Garcia, E. Romano, L. Altoe, L. Garcia, D. Oliveira, A. Rodrigo, H.Z. Fernandes

Medical Oncology, Institute of Oncology, Sao Jose Dos Campos, Brazil

Background: The Institute of Oncology (IOV) is using the ASCO's QOPI since 2013 in Brazil. QOPI is a retrospective analysis by data abstraction submited to a database pulling over 180 quality measures based on care guidelines and expert consensus. Data collection are twice a year and provides reports based on practice wide data sample comparing overall quality score for the practice and for the participants aggregate.

Methods: IOV participates in rounds at least once a year. At each round current performance is reviewed and select gaps are translated into improvement projects that focus on meaningful use of resources, safety, accountability of care, and value. Meaningful use of PET-CT; lab tests; and G-CSF are samples of specific projects the past. IOV's Patient Navigation System (PNS) was adapted to track QOPI standards/measures that are monitored by clinical navigators as checkpoints in real time transitions of care and handovers. Potentially hazardous checkpoints are actively chased using a daily signaling process.

Results: Between Feb/2016 and Mar/2017, the PNS checked 9,372 patient iteractions (surgery, exams, outside appointments, optimal sequencing of care); 138 (1.5%) potentially hazardous events were identifiifed and managed in advance: missing "readiness to care data" and lab tests (36%); delayed radiation or chemo (38%); delayed surgery (7%); and missing echocardiogram for patients using cardiotoxic drugs (6%). The Pain Management Navigation System was created to meet another set of QOPI measures that also translated into 17% reduction of emergency room admissions for 141 patients involved. A dedicated flow was created to meet oral chemo standards, and patient satisfaction improved from 67% to 93% by reducing door-to-door time from 40 to 12 minutes, including check in, interview, drug refill and reconciliation.

Conclusions: One of the big challenges of healthcare is how to introduce changes that translates into real improvements. The use of evidence-based measures and standards to evaluate quality of care provides a clear and straight path to deliver higher value; meaningful use of resources; focus and alignment for improvements initiatives where it matters most: patient care and outcomes.

Background: In industrialised countries, about 20% of healthcare spending is currently wasted on ineffective interventions. With growing cancer prevalence and the increasing complexity of care, efficiency must improve – defined as delivering better outcomes to patients for the resources available.

Methods: The All.Can initiative was set up as a multi-stakeholder platform to engage policymakers on the need to remove obsolescence and focus resources on what matters most to patients across the cancer care continuum. Members of the group include patient organisations, policymakers, healthcare professionals, research and industry representatives from across Europe and Canada. All.Can has a continued programme of research and policy engagement to achieve its aims.

Results: The group issued the following policy recommendations: focus care on what matters most to patients; invest in data to evaluate and monitor whether care is delivering optimal outcomes; instil accountability mechanisms across the cancer care pathway, creating a cycle of continuous improvement; and build political to drive meaningful change to systematise good practice. As a starting point however, we need clear definitions of waste and inefficiency from the patient perspective. All.Can will conduct a comprehensive qualitative survey of cancer patients to create a patient-relevant conceptual framework for waste and inefficiency. The survey will also be extended to oncology specialists. Findings will help determine where greatest opportunities lie to improve efficiency in cancer care, and serve as a basis for concrete policy proposals that may make the greatest difference to cancer patients.

Conclusions: Improving efficiency across the entire cancer care pathway is a complex and pressing challenge that will require close collaboration between all stakeholders. The All.Can initiative is a promising way forward.

1115P Cost-effectiveness of nivolumab+ipilimumab in first-line treatment of advanced melanoma: Analysis using 28-month overall survival from CheckMate 067

J. Sabater[1], T. Baker[2], V. Paly[2], K. Gupte-Singh[1], M. Lorenzi[3], A. Jeffers[3], H. Beyhaghi[1], S. Kotapati[1], S. Rao[1], A. Briggs[4]

[1]Health Economics Outcomes Research, Bristol-Myers Squibb, Princeton, NJ, USA, [2]Health Economics, ICON Health Economics & Epidemiology, New York, NY, USA, [3]Health Analytics, Precision Health Economics, San Francisco, CA, USA, [4]Health Economics, University of Glasgow, Glasgow, UK

Background: The objective of this study is to evaluate the cost-effectiveness of nivolumab+ipilimumab (NIVO+IPI) versus existing treatments in first-line treatment of patients with advanced melanoma from a US payer perspective using recently reported 28-month survival data from the CheckMate 067 phase III trial.

Methods: This three-state partitioned survival model was developed from projections of overall survival (OS) and progression-free survival (PFS) based on a network meta-analysis that considers time-varying hazard ratios to estimate accrued quality adjusted survival, total drug acquisition, follow-up, and toxicity costs over a lifetime time horizon (30 years). Competing treatments included NIVO, IPI, pembrolizumab (PEM), dabrafenib+trametinib (DAB+TRA), DAB, vemurafenib+cobimetinib (VEM+COB), VEM, and dacarbazine (DTIC). Costs and adverse event frequencies were obtained from expert input, publically available sources, and literature. Utility weights were estimated from the CheckMate 067 trial. Incremental analysis is summarized as incremental cost-utility ratios (ICURs) for NIVO+IPI. A 3.5% discount rate is applied to costs ($US 2016) and utilities.

Results: NIVO+IPI is projected to have the greatest accrued survival among the competing treatments with 6.015 LY and 4.979 QALY and also the highest costs ($291,096 including treatment acquisition, follow-up, management of adverse events, and post-progression costs) over the 30-year time horizon. Pairwise ICURs for NIVO+IPI vs. other treatments ranged from $34,774 per QALY (vs. DAB+TRA) to $92,647 per QALY (vs. NIVO). In extended dominance analysis, DTIC, NIVO, and NIVO+IPI form the cost-effectiveness frontier, showing that these are the most cost-effective options at different willingness to pay thresholds. Probabilistic sensitivity analysis generated results consistent with the base case for NIVO+IPI.

Conclusions: The large survival gains of NIVO+IPI make it a cost-effective option for first-line treatment of advanced melanoma when compared to other immune-oncologic therapies, targeted agents, and chemotherapy.

Clinical trial identification: Cost study based on the 067 trial NCT01844505 protocol number is CA209-067 (CheckMate 067)

1116P Palbociclib in advanced breast cancer: A cost-utility analysis

J. Raphael, J. Helou, D.M. Naimark

Institute of Health Policy, Management and Evaluation, University of Toronto, Toronto, ON, Canada

Background: The addition of *palbociclib* to *letrozole* improves progression free survival (PFS) and response rates compared to *letrozole* alone in the 1st line treatment of hormone receptor positive advanced breast cancer (ABC). This study assesses the cost-utility of *palbociclib* from the Canadian healthcare payer perspective.

Methods: To evaluate the cost-utility of *palbociclib*, a probabilistic discrete event simulation model was developed. The model was parameterized with data from the phase 2 and 3 PALOMA 1 and 2 trials and other sources. The incremental cost per quality-adjusted life-month (QALM) gained for *palbociclib* was calculated. A time horizon of 15 years was used in the base case with costs and effectiveness discounted 5% annually. The time to progression and death were derived from Weibull and exponential distributions, respectively. Expected costs were based on Ontario fees and other sources. Probabilistic sensitivity analyses were conducted to account for parameter uncertainty.

Results: Compared to *letrozole* alone, the addition of *palbociclib* provided an additional 14.7 QALM at an incremental cost of $161,508. The resulting incremental cost-effectiveness ratio was $10,999/QALM gained. Assuming a willingness to pay (WTP) of $4167 per QALM, the addition of *palbociclib* was not cost-effective and the probability of *palbociclib* to be cost-effective was 0%. Cost-effectiveness acceptability curves derived from a probabilistic sensitivity analysis showed that at a WTP of $11,667/QALM gained, the probability of *palbociclib* to be cost-effective was 50%.

Conclusions: Compared with *letrozole* alone, the addition of *palbociclib* is unlikely to be cost-effective for the treatment of ABC from a Canadian healthcare perspective with its current price. While ABC patients derive a meaningful clinical benefit from *palbociclib*, considerations should be given to increase the WTP threshold and reduce the drug pricing, to render this strategy more affordable. Model validation and calibration are needed to confirm those results.

1117P Real-world survival outcomes in patients with advanced urothelial cancer in Germany

G. Niegisch[1], H. Gerullis[2], S-W. Lin[3], J. Pavlova[4], A. Gondos[5], A. Rudolph[5], G. Haas[5], N. Hennies[5], M.W. Kramer[6]

[1]Department of Urology, Heinrich-Heine-University Düsseldorf, Düsseldorf, Germany, [2]Clinic for Urology, University Clinic Oldenburg, Oldenburg, Germany, [3]Real World Science, Genentech, Inc., South San Francisco, USA, [4]Oncology, F. Hoffmann-La Roche AG - Switzerland, Basel, Switzerland, [5]Real World Insights, QuintilesIMS, Frankfurt, Germany, [6]Clinic for Urology, University Clinic Schleswig-Holstein, Lübeck, Germany

Background: Contemporary data from the advanced urothelial cancer (UC) setting are scarce. Here, we describe treatment (tx) patterns and outcomes among > 350 patients (pts) in Germany.

Methods: Data were extracted from pt medical records from office-based urologists and urology clinics in Germany. Adult pts (age ≥ 18 y) diagnosed with T4b, N2-3 and/or M1 UC and received first-line (1L) or second-line (2L) palliative chemotherapy from 2009 to 2016 were included. The index date was the start date of first systemic therapy. We described tx patterns and clinical characteristics; Kaplan-Meier method assessed overall survival (OS). Cox regression adjusted for age, Eastern Cooperative Oncology Group performance status (ECOG PS) and liver metastases, stratified by hospital/office, compared tx.

Results: Among 368 included pts, 356 and 107 received 1L and 2L tx, respectively. At the start of 1L therapy, mean age was 68 y, 73% of pts were male, 74% were current/ex-smokers and 63% had metastatic disease. In 1L, 75% of pts received dual-combination tx, most commonly gemcitabine + cisplatin (GemCis; 83%). In 2L, 74% received single-agent tx, most commonly vinflunine (66%). In 1L, 12-month OS was 60%, slightly higher with GemCis (65%) than with other tx (52%). No difference in OS by sex or smoking status was noted. Pts with and without renal impairment (creatinine clearance </≥ 60 mL/min) had a 12-month OS of 47% and 70%, respectively. 12-month OS among pts with ECOG PS 0-1 was 62% vs 54% among pts with ECOG ≥ 2. There was no OS difference between vinflunine and other 2L tx (Table) (hazard ratio, 1.11 [95% CI: 0.65, 1.90]). Median PFS was 6.8 months in 1L pts and 3.3 months in 2L pts.

Table: 1117P Milestone Overall Survival, %

	1L n = 356	2L n = 107[a]
Overall		
12 mo	60%	37%
24 mo	37%	17%
36 mo	21%	5%
GemCis[b] 1L vs other 1L		
12 mo	65% vs 52%	—
24 mo	40% vs 34%	—
36 mo	20% vs 21%	—
Vinflunine[b] 2L vs other 2L		
12 mo	—	38% vs 37%
24 mo	—	20% vs 16%
36 mo	—	9% vs NA[c]

[a]A total of 368 pts were included; shown here are 356 pts who initiated 1L tx and 107 pts who initiated 2L tx during the study (2009-2016). 88.8% (n = 95) of the 107 pts are a subset of the 356 pts who initiated both 1L and 2L during the study.
[b]Most common tx per line of therapy.
[c]Estimate could not be calculated due to insufficient follow-up time

Conclusions: Outcomes in advanced UC tx in pts in this large real-world data study are comparable with clinical trials. Despite frequent use of cisplatin-based 1L tx and vinflunine 2L tx, per recent guidelines, outcomes are generally still poor.

1118P Health related quality of life and utility weights of medical oncology inpatients

M.A. Vicente Conesa, M. Zafra Poves, M.A. Ivars, I. Ballester, A. Carmona-Bayonas, F. Ayala de la Peña

Hematology and Medical Oncology, Hospital Universitario Morales Meseguer, Murcia, Spain

Background: Health related quality of life (HRQoL) data and utilities derived from preference-based scales are needed for pharmacoeconomic studies. However, available data for hospitalized Medical Oncology patients are scarce or restricted to specific neoplasms. The aim of this work was to obtain health state utilities (HSU) from a heterogeneous population of cancer inpatients admitted to a Medical Oncology department.

Methods: Between Dec-15 and March-16, we prospectively collected HRQoL data from consecutive patients admitted to a Medical Oncology ward using EuroQoL 5-domains 5-levels instrument (EQ-5D-5L) and EQ-5D-5L visual analogic scale (VAS). Utility weights were assigned according to Spain social tariff using EuroQol crosswalk value sets. Non-parametric tests (Mann Whitney U, Kruskal-Wallis) were used to evaluate differences of HSU between groups.

Results: 215 patients were included; median age: 62 (16-88); ECOG: 1 (45%), 2 (43%), 3-4 (12%); site: lung (27%), breast (15%), colorectal (15%), urogenital (15%); stage: I-II (11%), III (15%), IV (74%); active anticancer treatment: 87%; death during admission: 17 (8%). Mean (SD) EQ-5D-5L HSU for all patients was 0.52 (0.41); VAS: 52 (2). Mean (SD) values for EQ-5D-5L domains: mobility, 2.21 (1.24); self-care, 2.23 (1.49); usual activities, 2.89 (1.41); pain/discomfort, 1.94 (1.29); anxiety/depression: 2.12 (0.94). Differences between groups are shown in Table.

Conclusions: Average utility (EQ-5D-5L) for Medical Oncology inpatients is 0.52; lowest scores in this population were obtained for pain/discomfort and anxiety/depression domains. Significant differences were observed between different ECOG levels, tumor stages, admission causes and type of treatment.

1119P A trial-based EUROQOL EQ-5D health utility analysis in patients with classical Hodgkin's lymphoma

E. Wu[1], J. Liao[2], A. Balakumaran[3]

[1]Economic and Data Science, Merck & Co Inc, West Point, NY, USA, [2]BARDS, Merck & Co Inc, North Wales, PA, USA, [3]MRL, Merck & Co Inc, North Wales, PA, USA

Background: Pembrolizumab has shown a high response in patients classic Hodgkin lymphoma (cHL) patients who have experienced disease progression after brentuximab vedotin in KEYNOTE (KN)-087 and the results have been presented. This study aimed to evaluate the health-related quality of life (HRQoL) of the trial patients in KN087.

Methods: KN-087 is an ongoing single-arm multi-center, non-randomized Phase II trial evaluating pembrolizumab 200mg Q3W IV in patients with relapsed or refractory cHL. In KN-087, HRQoL data were collected at baseline and every drug administration over the 18 months of follow-up. HRQoL was assessed using both the EQ-5D and EORTC QLQ-C30 instruments. The generic health statuses assessed from both instruments were converted to population-based utility values using published algorithms. More specifically, US-based scoring was applied to US patients, UK-based scoring for UK patients and EU-based scoring for all other patients. HRQoL was reported by status of respond and disease progression. Response was defined based upon IWG criteria. Furthermore, stratified analyses were conducted to examine the health disabilities of the patients who experienced grade 3+ adverse events (AEs), and by ECOG performance and the number of prior therapies.

Results: Among 210 trial patients, HRQoL data were collected for 205 patients at baseline and the mean health utility score was 0.759 (95% CI 0.730-0.788). Mean health utility score among responders and non-responders was 0.826 (95% CI 0.811-0.842) and 0.760 (95% CI 0.718-0.801), respectively. The difference is considered clinically significant. Mean utility decreased from 0.820 (95% CI 0.807-0.833) for time spent prior to progression to 0.806 (95% CI 0.780-0.832) post disease progression. Progression-free patients who experienced grade 3+ AEs (N = 17) had a mean health utility of 0.736 (95% CI 0.662-0.811), compared with 0.825 (95% CI 0.811-0.838) among those did not.

Conclusions: The results showed a substantial HRQoL impact of R/R cHL. Treatment response was associated with significant clinically meaningful improvement in HRQoL. The utility estimates from the study are important for economic evaluations of treatments in R/R cHL patients.

Clinical trial identification: NCT02453594

1120P Real world comparison of common patient reported symptoms with health utility scores in cancer outpatients

M. Moskovits[1], K. Jao[2], C.M. Brown[1], S. Su[3], H. Naik[4], L. Eng[1], T. Wang[5], Y. Leung[6], W. Xu[7], G. Liu[1], M. Li[6], G. Devins[6], D. Howell[6]

[1]Department of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University of Toronto, ON, Toronto, Canada, [2]Department of Medical Oncology and Hematology, Hopital Sacre-Coeur, McGill University, Montreal, QC, Canada, [3]Department of Biostatistics, Ontario Cancer Institute, Department of Biostatistics, Ontario Cancer Institute, Toronto, ON, Canada, [4]Department of Medicine, University of British Columbia, Vencouver, Canada, [5]Faculty of Pharmacy, University of Toronto, Toronto, ON, Canada, [6]Palliative Care and Psychosocial Oncology, Princess Margaret Cancer Centre, University of Toronto, Toronto, ON, Canada, [7]Department of Biostatistics, Ontario Cancer Institute, Princess Margaret Cancer Centre, University of Toronto, Toronto, ON, Canada

Background: Health utility scores (HUS), a form of health-related quality of life (HRQoL) assessments useful in economic analyses, such as the EuroQol (EQ-5D) were originally standardized to health state preferences in healthy individuals. To demonstrate clinical appropriateness in cancer patients, we assessed the association of common cancer symptoms with EQ-5D HUS.

Methods: Adult cancer outpatients were surveyed cross-sectionally using the Edmonton Symptom Assessment System (ESAS), the EQ-5D-3L, and clinico-demographic variables. ESAS rated symptoms from 0-10. HUS were derived from the EQ-5D-3L (Canadian conversion). ESAS symptoms were correlated with HUS using Spearman correlation coefficients (R). Multivariable regression analyses identified independent variables associated with HUS.

Results: Of 764 patients across multiple cancers, 27% were palliative at assessment. There were significant correlations between each ESAS symptom score and HUS ($p < 0.0001$ for each comparison; Spearman coefficients: 0.20 to 0.42); the highest were for pain ($R = 0.42$), fatigue ($R = 0.39$), and depression ($R = 0.35$). In multivariable analyses, pain and depression symptom scores remained highly associated with HUS ($p < 0.0001$ each), while fatigue was of borderline significance ($p = 0.059$). Despite correlations, prediction of HUS by global ESAS scores was poor, with the highest prediction ability at 0.25. Because ESAS and EQ5D shared common symptom questions (pain, depression/anxiety), we evaluated if we could map and replace these EQ5D questions with ESAS. Spearman correlation of pain symptoms by EQ5D and ESAS was 0.95, while for depression/anxiety, 0.90. Replacing both questions yielded a correlation of 0.83.

Conclusions: HUS is associated with many cancer symptoms, including pain, fatigue, nausea, depression, anxiety, drowsiness, loss of appetite, and shortness of breath. EQ-5D-3L derived HUS have clinical utility. On exploratory analysis, we cannot replace

Table: 1118P HRQoL values (mean) and differences according to clinical characteristics

Clinical characteristics	Patients (n = 215)	EQ-5D-5L utility	p	EQ-5D-5L VAS	p
ECOG 1 2 3-4	96 92 27	0.77 0.41 0.04	<0.001	63 45 34	<0.001
Stage I-II III IV	23 32 154	0.79 0.68 0.46	<0.001	64 56 49	0.001
Active treatment Yes No	187 28	0.56 0.26	0.001	53 45	0.04
Cause of admission Febrile neutropenia Symptom worsening Others	18 53 129	0.81 0.16 0.61	<0.001	65 38 55	<0.001

accurately the EQ5D with ESAS, although we can replace two symptom questions within EQ5D with ESAS with high correlation.

Davis-Jewish General Hospital, Montreal, QC, Canada, [12]Medical Oncology, Notre Dame du CHUM, Montreal, QC, Canada, [13]Medical Oncology, University of Alberta Cross Cancer Institute, Edmonton, AB, Canada, [14]Medical Oncology, Chris O'Brien Lifehouse, Camperdown, Australia, [15]Medical Oncology, Auckland City Hospital, Auckland, New Zealand, [16]Medical Oncology, British Columbia Cancer Agency, Surrey, BC, Canada, [17]Oncology, The Ottawa Hospital Cancer Centre, Ottawa, QC, Canada, [18]Oncology, Cancer Clinical Research Unit (CCRU), Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: Dacomitinib, a potent irreversible pan-HER kinase inhibitor, has activity in EGFR mutant (mt) lung cancer. BR.26, completed in 2013, compared dacomitinib versus placebo in unselected pts who had received both chemotherapy (1 or 2 lines) and a first-generation EGFR TKI for advanced NSCLC. Dacomitinib pts had significantly improved tumour response rate, PFS, and time to symptom deterioration but not improved survival (OS). A trend towards improved OS was seen in pts with KRAS wildtype (wt) tumours (KRAS unknown in 42%). A prospective economic evaluation was planned for Canadian and Australian pts.

Methods: Resource utilization and utility scores (EQ5D-3L) were collected prospectively in 385 trial participants from Canada and Australia. Direct medical costs were applied to resources in 2015 Canadian dollars (CAD) from the Canadian public health care payer perspective. Dacomitinib is not approved for marketing, thus we used a range of plausible drug costs (0-$120/mg). Restricted mean survival time, utility, and costs per arm were calculated, and explored in KRAS wt and EGFR mt subgroups.

Results: Incremental outcomes and costs by treatment arm are shown below. Mean utility scores were similar, although higher in dacomitinib-treated pts with KRAS wt or EGFR mt tumours (range u = 0.41- 0.55). Mean quality-adjusted survival was approximately 1 month longer with dacomitinib in both KRAS wt and EGFR mt subgroups. Direct medical costs excluding dacomitinib were similar between arms. Exploratory estimates of cost-utility ranged from $26,369-$184,701/QALY in KRAS wt, and $2,243-$133,953/QALY in pretreated EGFR mt pts.

Conclusions: Dacomitinib in previously treated, unselected NSCLC may yield minor gains in quality-adjusted survival without increasing other costs of care. Analyses of mutation status by ctDNA are ongoing.

Table: 1121P

Incremental mean outcome with dacomitinib over placebo	All patients (n = 385)	*KRAS* wild type (*KRAS* known n = 165)	*EGFR* mutant (*EGFR* known n = 80)
Survival (ΔE, years)	0.0014	0.104	0.129
Quality-adjusted survival (ΔE, QALY)	0.011	0.069	0.088
Cost (ΔC, 2015 CAD) Set drug price at: $0/mg $40/mg $80/mg $120/mg	$524 $3,944 $7,363 $10,783	$1,829 $5,489 $9,149 $12,809	$199 $4,083 $7,968 $11,853

1122P Feasibility of routine collection of health state utilities using EQ-5D in a breast cancer outpatient clinic

S. Torres[1], M. Trudeau[1], K. Pritchard[1], N. Mitsakakis[2], N. Li[3], M. Krahn[2]

[1]Department of Medicine, Division of Medical Oncology, Sunnybrook Health Sciences Centre, Toronto, ON, Canada, [2]Toronto Health Economics and Technology Assessment Collaborative, University of Toronto, Toronto, ON, Canada, [3]Imaging Research, Sunnybrook Research Institute, Toronto, ON, Canada

Background: Routine collection of health state utilities in the clinical setting may produce data more representative of the real-world population for use in cost-utility models and guide decision making. We are currently carrying out a cross-sectional study to assess the feasibility of routine administration of EQ-5D to breast cancer patients in a multidisciplinary oncology clinic, in an academic cancer centre in Ontario, Canada.

Methods: English literate women undergoing treatment or on follow-up for their breast cancer (stage I to IV), are being recruited during their scheduled visit to the cancer centre, preferably after completing the implemented routine symptom screening using the Edmonton Symptom Assessment System (ESAS). Consenting patients complete EQ-5D-5L in tablets, followed by a socio-demographic questionnaire and feedback questions pertaining to study conduct. Answers are stored in a research database and linked to diagnostic and treatment data. Feasibility will be assessed primarily by the proportion of patients who fully complete EQ-5D and by their willingness to complete the instrument at each clinic visit.

Results: To date, 474 women were approached; 262 (55%) were eligible and consented to participate (target enrolment: 341). Median age of participants was 56 years (range:28-90); 24% had metastatic disease. All participants were English literate, but 59% were born outside Canada and speak primarily other languages at home. Ninety-eight percent of recruited patients completed EQ-5D, compared with 84% who completed ESAS on the same day (63% completed ESAS voluntarily prior to enrolment; 21% agreed on completing ESAS for study purposes only). Median time for EQ-5D completion was 84 seconds. Most patients (82%) had no problems using the tablet. Willingness to continue to complete EQ-5D at each clinic visit was not affected by disease status (stage I to III versus stage IV) and 74% would "definitely"/"very likely" continue to answer EQ-5D regularly at each clinic visit.

Conclusions: These preliminary results indicate that routine collection of EQ-5D in clinical practice might be feasible, although the completion rate might be overestimated by the cross-sectional design of the study.

1123P The cost of expensive breast cancer drugs

S. Berghuis[1], H. Koffijberg[1], L.W.M.M. Terstappen[2], S. Sleijfer[3], M.J. Ijzerman[1]

[1]Health Technology and Services Research, University of Twente, Enschede, Netherlands, [2]Medical Cell BioPhysics, University of Twente, Enschede, Netherlands, [3]Medical Oncology, Erasmus MC Cancer Institute, Rotterdam, Netherlands

Background: Increasing healthcare costs are a major challenge in medical oncology, since the total costs of oncology can account for up to 30% of the total hospital expenditures. As many novel (expensive) cancer treatments are being developed, it is important to be transparent about drug prices from an early research stage on. To assess the potential financial impact of pipeline drugs, their expected future prices can be deducted from prices of currently used drugs. As an overview of the standard prices of expensive breast cancer treatments in European countries is lacking, this review aimed to synthesize all evidence on costs of approved, expensive breast cancer drugs in the Netherlands.

Methods: A literature review was performed to create an overview of all approved, expensive drugs in the Netherlands. Standard drug costs were retrieved via the Dutch administrative health authority (ZINL). Drugs were considered expensive if the standard price of the drug was more than €10 per unit or if the cost of a treatment with that particular drug exceeded €1000 on average per patient.

Results: In the Netherlands 25 breast cancer drugs are approved with a standard price of more than €10 per unit. After excluding drugs with expected treatment costs less than €1000, 19 drugs were included in the analysis. The standard drug price is €7,943 on average (range €63 - €45,452), and the average number of cycles per patient is 10.5 (range 4 - 25.3 cycles). This results in average treatment costs per patient of expensive drugs of €17,968 (range €1,103 - €87,123). Four drugs that initially ranked low based on standard drug unit prices (rank 10-19), rank substantially higher (rank 1-10) when ranking total treatment costs.

Conclusions: Ranking standard drug prices per unit may not be very informative. It would be valuable to rank drug treatment costs, based on treatment length and dosage estimates. However, in the Netherlands the expected treatment length for a particular drug is not standardly reported in official approval reports. Furthermore, actual prices of expensive drugs may differ from standard drug prices, by which treatment costs might be deviant. Extending standardization of reporting and calculation of drug treatment costs would be valuable and particularly relevant when extending this type of cost calculations to other countries.

1125P The cost-effectiveness of EndoPredict to inform adjuvant chemotherapy decisions in early breast cancer

S. Hinde[1], C. Theriou[2], S. May[3], L. Matthews[3], A. Arbon[4], L. Fallowfield[3], D. Bloomfield[4]

[1]Centre for Health Economics, University of York, York, UK, [2]Faculty of Medicine & Health Sciences, University of Nottingham, Nottingham, UK, [3]SHORE-C/BSMS, University of Sussex, Brighton, UK, [4]Oncology, Brighton&Sussex University Hospitals, Brighton, UK

Background: Chemotherapy alongside endocrine treatment in ER +ve breast cancer patients post resection of a primary tumour has been estimated to reduce mortality rates by up to 30%. However, the high cost of the therapies, heterogeneous nature of the disease and adverse event profile implies that not all patients should receive the treatment. Many existing prognostic tools such as the NPI, PREDICT, and Adjuvant! Online may not definitively estimate the risk profile of patients, resulting in an *indeterminate* risk classification. In such cases gene expression profiling tests such as EndoPredict can aid the treatment decision. It is important to examine if the test represents a cost-effective use of limited NHS resources in such intermediate risk patients.

Methods: This small (n = 151) multi-centre, two-stage study evaluated the cost-effectiveness of EndoPredict in patients with no clear treatment based on current prognostic criteria. The primary analysis examined whether EndoPredict test results increased or decreased the use and intensity of chemotherapy and the associated direct cost implications. Secondly, a mathematical model was constructed to determine how the change in treatment decisions impacted the long term health of the population, and the future cost implications to the NHS.

Results: A cost increase per patient treated with chemotherapy was identified when EndoPredict test results were available (£149), alongside no significant change in the total number being prescribed chemotherapy. However, chemotherapy was offered to a very different patient population, with 36.9% of patients having a change in treatment decision. The long term analysis found the use of EndoPredict to be associated with greater total costs but a potential increase in population health, resulting in an incremental cost-effectiveness ratio of £26,836 per quality adjusted life year.

Conclusions: While EndoPredict was found to be more expensive overall, the ability of the EPClin score to affect a more optimal allocation of chemotherapy, resulted in long term health gains. However, this result was on the margin of what is conventionally considered a cost-effective use of limited NHS resources and subject to significant uncertainty.

1126P The evolution of value with filgrastim in oncology

P. Cornes[1], A. Krendyukov[2]

[1]Comparative Outcomes Group, Bristol, UK, [2]Hexal AG, Holzkirchen, Germany

Background: The value of drugs will evolve over time as new evidence for risks and benefits emerge and the price of a drug changes.

Methods: A NICE Evidence Search on March 1, 2017 revealed 25 systematic reviews and 55 economic evaluations of filgrastim.[1]

Results: Initial Health Technology Assessments (HTA) suggested low value due to high drug cost and no evidence for significant gain in Overall Survival (OS). More recent metanalyses of placebo-controlled randomized trial data show absolute OS gains of 3.2% (95% CI:2.1—4.2%) from filgrastim support of cytotoxic chemotherapy[2] and falling costs due to biosimilar competition.

Conclusions: Physicians and payers need to be aware that HTA decisions need constant re-evaluation, especially following the launch of biosimilar alternatives. This explains the first inclusion of filgrastim in the WHO essential Drug List for cancer more than 20 years after its original approval in 1991,[3] and demonstrates the power of biosimilar medicines in transforming healthcare. 1127P Tyrosine kinase inhibitors (TKI): Awareness of drug-drug interaction

N. Ozdemir[1], S. Toptas[2], M.A.N. Sendur[1], O. Yazici[2], B. Öksüzoğlu[3], K. Silay[4], N. Zengin[2]

[1]Department of Medical Oncology, Ankara Yıldırım Beyazıt Universtiy Faculty of Medicine, Ankara, Turkey, [2]Medical Oncology, Ankara Numune Education and Research Hospital, Ankara, Turkey, [3]Medical Oncology, Dr. Abdurrahman Yurtaslan Ankara Oncology Training and Research Hospital, Ankara, Turkey, [4]Department of Geriatrics, Ankara Yıldırım Beyazıt Universtiy Faculty of Medicine, Ankara, Turkey

Background: Since TKI are metabolized with cytochrome P450 system which is a common pathway for drug-drug interactions. However, these interactions might be overlooked by clinicians. The aim of this study is to evaluate the drug-drug interactions in patients receiving TKI.

Methods: Between May 2007 and March 2015, the data of 265 patients receiving TKI for any reason were evaluated retrospectively. All prescribed medications (PMs) received during TKI therapy for 6 months period were noted and drug-drug interactions with TKI were evaluated. Additionally the nature of interaction was described as 'increase or decrease in TKI level or cautious use of TKI recommended'. The interaction between TKI and PMs was checked from Up-To-Date web site or "medscape.com/drug-interaction checker".

Results: In the study, 265 patients who are taking TKI were noted. 251 patients (94.8%) have been taking PMs additional to TKI. The median age was 56 year (17-87), most common diagnosis was gastrointestinal stromal tumor (27.5%) followed by kidney tumor (26.3%). Most common TKI has been used was Imatinib (21.9%) and Lapatinib (21.9%). The most common PM groups during 6 months period was non-steroidal anti inflammatory and acetaminophen (50.2%), proton pomp inhibitors (41.4%), antibiotics (33.1%), cardiovascular system drugs (33.5%) and narcotic analgesics (21.1%). The interaction rate between TKI and PMs was 54.2%. The nature of interaction was; decrease in TKI level in 39.7% of patients and increase in TKI level in 30.1% of patients. 77.1% of patients have been warned as cautious use of TKI due to increase risk of side effect. The side effect was emphasized as QT prolongation.

Conclusions: TKI drug interaction is usually overlooked by clinicians. Our study revealed that more than 90% of patients who are taking TKI are also prescribed another medication. There is a drug-drug interaction between TKI and prescribed medications in more than half of these patients. TKI-prescribed drug interaction has been caused decrease effectiveness of treatment and increase the rate of side effects and medical cost. The TKI –drug interaction risk might be decreased by increasing the knowledge of the physicians from other specialties about recent molecular treatments.

1128P Anti-PD1 inhibitors: Assessment of proper use, efficacy and economic impact in daily practice

A. Gobert[1], A. Jaeger[2], L. Taillade[1], N. Osman[2], D. Lassoued[1], C. Mateescu[1], P. Maingon[3], P. Tilleul[2], J-P. Spano[1], A. Bellanger[2]

[1]Medical Oncology Unit, Groupe Hospitalier Pitié Salpetriere, Paris, France, [2]Pharmacy Unit, Groupe Hospitalier Pitié Salpetriere, Paris, France, [3]Radiotherapy Unit, Groupe Hospitalier Pitié Salpetriere, Paris, France

Background: Nivolumab, an anti-PD-1 inhibitor, has been approved in France in treatment of first-line BRAF wild-type advanced melanoma and of advanced non-small cell lung cancer after platinum-based chemotherapy, with an approximate monthly processing cost of €5,550 per patient. The objective of our study was to evaluate efficacy and correct use of anti-PD1 antibodies in daily practice since its approvals.

Methods: This retrospective study was conducted between July 2015 and December 2016 on 62 patient files at the Pitié-Salpêtrière hospital, using patient medical records and Multidisciplinary Medical Board (MMB) software. According to the Summary of Product Characteristics (SPC), the correct use of nivolumab required compliance with indications, a WHO status <2 and a limit of 10 mg per day of corticosteroids.

Results: Sixty patients were treated for lung cancer: 38 patients (62%) with adenocarcinoma, 14 (22%) with squamous cell carcinoma and 8 (13%) with large cell lung cancer. At the cut-off analysis, 28 patients (47%) had a progressive disease, 20 (32%) were still receiving treatment and 41(65%) were still alive, with a median follow-up of 6.5 months (0,3 to 17.7 months). Thirteen patients received more than 10 injections and 13 received less than 5 injections. The correct use of nivolumab was observed in 45 patients (73%), 12 patients had a WHO status of 2, 1 patient had a WHO status of 3, and 4 patients received concomitant corticosteroids. The poor utilization of treatment for these 17 patients (27%) totaled 149 injections, costing about €410,000 for a total of €1,615,000 of expenditures using this treatment. Survival rates were not statistically different in these patients compared to those respecting SPC criteria (53% versus 70%; $p = 0.2$).

Conclusions: Although a high cost of inappropriate use of nivolumab, there was no significant difference in survival rates in these patients. These preliminary findings highlight the differences between study populations and daily practice, reflecting willingness of practitioners to give patients access to innovative treatments. Cost effectiveness and efficacy/tolerance data will be updated at the meeting presentation to better determine treatment criteria in daily practice.

1129P Real world treatment costs and resource utilization among patients with metastatic bladder cancer

K. Flannery[1], X. Cao[1], J. He[1], Y. Zhong[1], A.Y. Shah[2], A. Kamat[3]

[1]Oncology Research, MSD, North Wales, PA, USA, [2]Genitourinary Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA, [3]Department of Urology, MD Anderson Cancer Center, Houston, TX, USA

Background: First-line (1L) cisplatin, followed by second-line (2L) taxane or other systemic chemotherapy, has been the historic standard of care in metastatic bladder cancer (mBC). Little is known regarding longitudinal costs and resources consumed during treatment of mBC patient (pts). This study investigated drug utilization, health care (HC) resource use, and disease-related costs among pts with mBC.

Methods: Pts with an initial diagnosis of mBC between Jan 2007 - Dec 2011 were retrospectively identified using SEER-Medicare linked data. Annual survival rates were calculated for treated and untreated pts. Total costs were estimated during the treatment exposure window for HC visits and treatment for mBC-related, AE-related, and other costs; all costs were converted to 2016 US dollars.

Results: Overall, 411 eligible pts received 1L therapy and 189 (46.0%) subsequently received 2L therapy. For all 1L treated pts, the 1, 2, and 3-year survival rates from mBC diagnosis were 56.5%, 25.6%, and 15.5%, compared to 12.9%, 6.0%, and 4.7% for untreated pts (n = 804). For 2L pts, the 1, 2, and 3-year survival rates from 2L treatment initiation were 32.8%, 14.9%, and 7.7%. For all regimens, the highest per-patient cost occurred in the outpatient setting, followed closely by emergency, then inpatient, SNF, and lastly by hospice.

Conclusions: In general, mBC pts had poor survival outcomes, particularly for untreated pts. Less than half of mBC pts received guideline-endorsed 1L cis-combo therapy. mBC-related outpatient and emergency HC utilization were primary drivers of the per-patient economic burden. During the treatment exposure window, total costs were considerable across treatment regimens, with the average total cost during 1L and 2L treatment exceeding sixty thousand dollars per patient.

Other costs per patient, mean (SD)	$12,990 ($16,906)	$10,363 ($14,753)	$11,900 ($15,817)	$7,992 ($6,823)	$13,708 ($17,587)	$11,468 ($16,895)	$13,673 ($17,670)	$10,090 ($14,416)

1130P Investigating discrepancies in assessments of PFS by study investigators and independent review

C.F. Jones, J.F. Soto Barrientos, G. Monnickendam

Oncology, PRMA Consulting, Fleet, UK

Background: OS is considered the gold standard trial endpoint, particularly for health technology assessment. However OS faces challenges – from subsequent therapy bias to needing long trials that delay patients' access to promising medicines. PFS is often used either instead of, or alongside, OS – by regulators, clinicians, payers, and more recently, value frameworks in oncology. PFS is without a standardized measure. We examine the extent of differences between independent central review (ICR) and investigator assessed (INV) PFS. We aim to increase understanding of potential variability in PFS measurement, relevant associations and possible causal factors to inform appropriate use of PFS in payer and clinician decision-making.

Methods: We searched Clinicaltrials.gov for 'progression free survival' and 'cancer', filtering for interventional phase 2 or 3 studies with results. Studies were extracted and the primary and secondary outcomes filtered for ICR and INV based PFS. We searched PubMed with the same criteria; full articles were reviewed and studies reporting for ICR and INV based PFS included. For comparative trials, we calculated difference in median PFS between intervention and control arms for ICR and INV based PFS. For single arm trials, the difference between ICR and INV based PFS was calculated where both were reported.

Results: Of 365 studies from clinical trials.gov; 48 reported ICR based PFS and 45 reported INV. 6 studies reporting both were included. Of 49 studies from PubMed; 21 were included. There was 1 duplicate. The majority of studies were comparative (23/26), in solid tumors (21/26), and published in the last 5 years (21/26).

Calculating the PFS gain at the median, the difference between the ICR based gain and the INV based gain ranged from 0.1 to 4.3 months. In 9 comparisons the gain with ICR

was greater than the gain with INV. In 6 comparisons the difference in PFS gain was ≥2 months, a difference of up to 54% of the gains alone.

Conclusions: ICR and INV based PFS produce different estimates of PFS gain in clinical trials, but it remains uncommon for studies to report both ICR and INV based PFS. Both measures should be required, to improve consistency of comparison across trials and transfer of trial results to real world practices and decision-making.

1131P Medical costs and health care resource use (HCRU) in elderly us patients (pts) with newly diagnosed metastatic or surgically unresectable urothelial carcinoma (mUC) using surveillance, epidemiology, and end results (SEER) medicare data

A. Aly[1], C. Johnson[1], S. Yang[2], S. Rao[3], M. Botteman[1], A. Hussain[4]

[1]Real-World Evidence and Data Analytics, Pharmerit International, Inc, Bethesda, MD, USA, [2]HEOR, Bristol-Myers Squibb, Princeton, NJ, USA, [3]Immunooncology, US HEOR, Bristol-Myers Squibb, Princeton, NJ, USA, [4]Medicine, University of Maryland Medical Center, Baltimore, MD, USA

Background: Most elderly mUC pts receive platinum-based therapy as first line of treatment (LOT) but invariably progress, requiring additional LOT and HCRU. This analysis estimated medical costs and HCRU associated with each LOT in US elderly pts.

Methods: Pts ≥66 years of age newly diagnosed with mUC (urothelial transitional cell carcinoma) between 2004 and 2011 were identified from the SEER-Medicare database. Pts were followed from diagnosis to death, Medicare disenrollment, HMO enrollment, or till 31 December 2013 to characterize treatments by LOT (first [1L], second [2L], and third + [3L+] LOT). The per-pt HCRU was examined. Cumulative mean costs (overall and by type of LOT) were reported.

Results: Among 1,873 eligible mUC pts (median age, 77 years; male, 63%; Charlson comorbidity index ≥2, 29%; median follow-up, 7.5 months), 1,035 (55%) pts did not receive any chemotherapy. Among the 838 chemotherapy-treated pts, 510 (61%), 204 (24%), and 124 (15%) received 1L, 2L, and 3L+ LOT, respectively. Compared with 2L, 3L+ pts had significantly higher mean (standard deviation) per-pt hospital admissions (4.1 [2.9] vs 4.8 [3.3]), computed tomography (CT) scans (7.4 [4.4] vs 9.9 [5.8]), positron emission tomography–CT scans (1.0 [1.5] vs 2.0 [2.9]), and bone scans (1.1 [1.1] vs 1.8 [2.3]). Pts who received 3L+ LOT had significantly higher cumulative mean costs than 2L pts, mostly attributed to physician and outpatient services where chemotherapy is administered (Table).

Conclusions: For pts with mUC, cumulative mean costs increased with additional LOT, although further analysis of cumulative costs over the treatment duration of each LOT is warranted. As the treatment landscape evolves to include immunotherapy, this analysis provides a benchmark for the relative costs associated with mUC treatment across different traditional LOT in the United States.

1132P Chasing the survival curve tail: The effect on cost-effectiveness of nivolumab for second-line treatment of advanced renal cell carcinoma

M. Sarfaty[1], A. Moore[2], V. Neiman[1], E. Rosenbaum[1], D. Goldstein[1]

[1]Oncology, Rabin Medical Center Davidoff Cancer Centre, Beilinson Campus, Petah Tikva, Israel, [2]Oncology, Rabin Medical Center, Petach Tikva, Israel

Background: Treatment of metastatic cancer has been revolutionized in recent years with the incorporation of immunotherapy. In some metastatic settings there is a clear plateau in the overall survival curve, representing long-term survivors. As survival data is still immature with immunotherapy in most cancers it is unclear how to tackle the unknown tail of the survival curve, as it greatly affects the presumed effectiveness. To further understand this issue we present here the example of CEA of nivolumab in 2nd line RCC.

Methods: A Markov model was developed to compare the costs and effectiveness of nivolumab with those of everolimus or placebo in the second-line treatment of advanced RCC. Health outcomes were measured in life-years and quality-adjusted life-years (QALYs). Drug costs were based on Medicare reimbursement rates in 2016. Model robustness was addressed in univariable and probabilistic sensitivity analyses. We examined the effect of different anticipated ends of the survival curve on the cost effectiveness.

Results: The total mean cost per-patient of nivolumab versus everolimus was $101,070 and $50,935, respectfully. Nivolumab generated a gain of 0.24 LYs (0.34 QALYs) over everolimus and 0.89 LYs (0.96 QALYs) over placebo. The incremental cost-effectiveness ratio (ICER) for nivolumab was $146,532/QALY versus everolimus. A theoretical durable response in 10%, 15% or 20% of patients treated with nivolumab reduced the ICER to $86,660/QALY, $64,809/QALY or $48,493/QALY, respectively, compared with everolimus.

Conclusions: Our analysis shows that any durable response changes the ICER dramatically and improves the likelihood that a drug will be considered cost effective. Therefore, we must thrive to understand the long term benefit of immunotherapy in different cancers.

[a]Physician costs are non-institutional claims largely from physicians who bill for services provided in the office

[b]Outpatient costs are claims from institutional outpatient providers

1133P Non-elective admissions in cancer care - A review of acute oncology services (AOS) implementation in a north-west region of England

S. Chow, R. Leach, C. Mitchell

Medical Oncology, The Christie NHS Foundation Trust, Manchester, UK

Background: Parallel to advances in cancer therapeutics in the clinics, high quality and patient-centred management of cancer or treatment-related complications during non-elective attendance especially to a non-specialist hospital is crucial in achieving excellent patient outcome. AOS was innovated in the UK to meet this need and has rapidly expanded in recent years. Here, we describe findings of an on-going audit of this expanding networked service within Greater Manchester and Cheshire East County consisting of 10 district general hospitals in collaboration with a regional specialist cancer centre (The Christie NHS Foundation Trust).

Methods: Information related to any hospital episodes warranting AOS input was collated from all participating hospitals using standardised proforma and analysed.

Results: Between Jan 2015 - Sep 2016, 7638 non-elective hospital attendances were recorded of which 58% occurred within working hours. Common cancer sites were lung 16%, breast 15%, lower GI 12%, urology 12%, upper GI and HPB 9%, haematology 7%, gynaecology 6%, cancer of unknown primary(CUP) 6%, and others 7%. Majority were related to cancer complication 40% (Type III), treatment - related 32% (Type II), new cancer diagnosis 10% (Type I) and others 17%. 94% of AOS involvement occured within 24hr of attendance. Level of intervention by AOS was considered major in 60% while 30% and <10% was intermediate or minor respectively. Median length of stay (LOS) is 4 days, 20% of episodes lasted <24hr (11.2% admission avoidance), 50% 1-7 days, and 30% 2-6 weeks (predominantly type I and III).

Conclusions: This large multi-sites audit documented the service delivery pattern of a growing oncology subspecialty at the same time provided a glimpse into the healthcare implication of unplanned admission in the current era of advancing oncology lanscape. Excellent median LOS in this region compared to national average likely a reflection of pertinent AOS team involvement in a timely manner. AOS is now an integral component to the cancer care in the UK and its role in the non-elective setting serves to ensure excellent patient experience as well as providing far-reaching potential in healthcare efficiciency.

1134P Changing treatment patterns in metastatic colorectal cancer in EU5 countries from 2014 to 2016

N. Schmidt, L. Hoyer

RWI CESE BU Oncology, IMS Health GmbH & Co. OHG, Frankfurt am Main, Germany

Background: Colorectal cancer is the third most common cancer type nowadays in Europe. Lately however, no treatment has been approved for 1st or 2nd line treatment in metastatic colorectal cancer, only a new treatment option in 3rd line for pretreated patients is available. Therefore it will be interesting to see whether also the existing treatment patterns and testing results have not changed over time.

Methods: This study is based on IMS Oncology Analyzer®, a quarterly survey among a physician panel covering retrospective patient data about the disease and the treatment (tx) history across all types of cancer. Metastatic colorectal cancer patients treated in the EU5 countries (France, Germany, Spain, Italy and UK) within 2014, 2015 and 2016 were analyzed.

Results: Comparing the tx guidelines to the tx patterns derived from IMS Oncology Analyzer®, it shows that physicians are following the guidelines for K-RAS wildtype and K-RAS mutant colorectal cancer patients. An analysis of the K-RAS testing shows, that the share of wildtype patients remains almost stable from 2014 to 2016. Unlike in Germany, here the shares of wildtype patients are shrinking from 57.2% to 51.3%. A similar trend accounts for UK. In Spain, France and Italy however, the number of patients, who are wildtype is increasing. Accordingly to the decreasing rate of wildtype patients, the share of Anti-EGFR-therapies is going down in Germany from 38.8% to 25.3%. Also in Italy and Spain the trend of the K-RAS testing is mirrored in the usage of Anti-EGFR-therapies. However, in UK, the use of these therapies increases drastically from 23.9% to 77.8%, despite the decreasing number of K-RAS wildtype patients. In France Anti-EGFR-therapies only lose 1.7% in terms of market shares, even though the K-RAS wildtype population is increasing.

Conclusions: While the general tx guidelines are still followed, some tx patterns have changed due to a difference in K-RAS test results. Further research needs to investigate why there are changes in K-RAS test results. Also studies have shown that tumor localization (right, left, transversum) has an impact on the efficacy. Future studies therefore need to evaluate whether the tumor localization is impacting the tx pattern as well.

IMMUNOTHERAPY OF CANCER

1144O Phase III randomized controlled trial of adjuvant chemoimmunotherapy in patients with resected primary lung cancer

H. Kimura[1], Y. Matsui[2], T. Nakajima[3], T. Iizasa[4], A. Ishikawa[3]

[1]Thoracic Surgery, Saiseikai Narashino Hospital, Narashino City, Chiba, Japan, [2]Thoracic Surgery, Chiba Cancer Center, Nitona-cho-, Chiba, Japan, [3]General Thoracic Surgery, Graduate School of Medicine, Chiba Univercity, Chu-o-ku, Chiba, Japan, [4]Thoracic Surgery, Chiba Cancer Center, Chu-o-ku, Chiba, Japan

Background: Adoptive cellar immunotherapy is not widely approved as a treatment option for cancer treatment. The preliminary results from our phase III, randomized controlled trial (RCT) of adjuvant chemoimmunotherapy for lung cancer indicated significant advantages in patients receiving immunotherapy. Here we report the final results and long-term analysis of this RCT.

Methods: A hundred and three postsurgical non-small-cell lung cancer patients were randomly designated to receive either chemoimmunotherapy (group A, immunotherapy arm, n = 51) or chemotherapy (group B, control arm, n = 52). The immunotherapy consisted of adoptive transfer of autologous activated killer T cells and dendritic cells obtained from regional lymph nodes of the patients.

Results: The 2- and 5-year overall survival (OS) rates were 96·0% and 69.4% in group A and 64·7% and 45.1% in group B, respectively. The hazard ratio (HR) was 0.451 (0.235∼0.807) by multivariate analysis. The 2- and 5-year recurrence-free survival rates were 70.0% and 57·9% in group A and 43.1% and 31.4% in group B, respectively. P values of Log-rank test between groups were 0.0059. Subgroup analysis for the OS between treatment groups indicated males (HR, 0·474), adenocarcinoma patients (HR, 0·479), stage III cancer patients (HR, 0·399), and those who did not receive preoperative chemotherapy (HR, 0·483) had lower HRs than those in the other groups. Immunological analysis of cell surface markers in regional lymph nodes of subjects receiving immunotherapy indicated that the $CD8^+/CD4^+$ T-cell ratio was elevated in survivors.

Conclusions: Non-small-cell lung cancer patients benefited from adoptive cellular immunotherapy as an adjuvant to surgery. Immunological analysis of cell surface markers indicated cytotoxic T cells were essential for a favorable chemoimmunotherapy outcome.

1135O Phase 1b/2 Study (SCORES) assessing safety, tolerability, and preliminary anti-tumor activity of durvalumab plus AZD9150 or AZD5069 in patients with advanced solid malignancies and squamous cell carcinoma of the head and neck (SCCHN)

E.E. Cohen[1], D.S. Hong[2], T. Wise Draper[3], W. Nassib William[4], D. Schrijvers[5], R. Mesia Nin[6], M.L. Scott[7], P. Lyne[8], G. Mugundu[7], P. McCoon[8], C.E. Cook[7], M.M. Mehta[7], U. Keilholz[9]

[1]Medicine, University of California, San Diego Moores Cancer Center, La Jolla, CA, USA, [2]Investigational Cancer Therapeutics, The University of Texas M. D. Anderson Cancer Center, Houston, TX, USA, [3]Division of Hematology-Oncology, Department of Internal Medicine, Cincinnati, USA, [4]Department of Thoracic/Head & Neck Medical Oncology, University of Texas MD Anderson Cancer Center, Houston, TX, USA, [5]Department of Medical Oncology, Ziekenhuis Netwerk Antwerpen (ZNA) Middelheim, Antwerp, Belgium, [6]Servicio de Oncologia Medica, ICO L'Hospitalet, Barcelona, Spain, [7]Early Clinical Development, AstraZeneca Pharmaceuticals, Waltham, MA, USA, [8]IMed Oncology, AstraZeneca Pharmaceuticals, Waltham, MA, USA, [9]Charite Comprehensive Cancer Center, Berlin, Germany

Background: Anti-tumor activity of durvalumab (D), a programmed death ligand (PDL1) blocking antibody, may be enhanced by overcoming intratumoral immune suppression. The selective Generation 2.5 antisense oligonucleotide STAT3 inhibitor AZD9150 (STATi), a small molecule CXCR2 inhibitor AZD5069 (CX2i), and CTLA4 inhibitor tremelimumab (T) are in evaluation.

Methods: Part A, dose escalation in solid tumors, evaluated STATi + (D or D+T) and CX2i + (D or D+T) for safety, pharmacokinetics, pharmacodynamics and maximum tolerated dose. Part B, dose expansion in SCCHN, tested STATi (3 mg/kg)+D and CX2i (40 mg BID)+D in PDL1 pretreated/naive pts and as monotherapy for Objective Response Rate (ORR) and Disease Control Rate (DCR).

Results: Part A showed STATi+D and CX2i+D as safe and tolerable combinations with confirmed partial responses (cPR) in multiple tumor types and 2 confirmed complete responses (cCR) in breast and prostate cancer (>64 weeks [wks] on treatment). STATi+DT had a cPR in sarcoma at 12 wks. In Part B (STATi+D reported here), the PDL1 naive arm had 25% ORR (4 cPR, 1 unconfirmed PR (uPR); 3 Human Papilloma Virus negative and 2 unknown), 45% DCR (9/20) was observed at 12 wks, and 30% of pts (6/20) remain on treatment at 25 wks. One cPR pt is unconfirmed CR at data cut off. In the PDL1 pretreated arm, 1 pt had complete metabolic response and 1 pt had uPR; 20% DCR (3/15) was observed at 12 wks. Safety and tolerability were confirmed for STATi+D in SCCHN pts, with manageable and reversible adverse events of thrombocytopenia and liver enzyme increases (for each, Grade 3/4 in 3.4% of 58 pts dosed); 2 STATi+D related discontinuations occurred.

Conclusions: Initial ORR and DCR data suggest enhanced antitumor activity results from combining a PDL1 antagonist (D) with an agent targeting immunosuppression in the tumor microenviornment (STATi) compared to PDL1 monotherapy. The combination may prove to provide a tolerable and effective option for patients with recurrent/metastatic SCCHN in the naive and PDL1-pretreated setting and other solid tumor types being studied.

Background: Vaccines directed against Human Papilloma Virus (HPV) do not generally mediate regression of invasive cancer. To test the hypothesis that the efficacy of vaccine-induced T cells may be amplified through treatment with immune checkpoint antibodies, we conducted a phase II trial of ISA 101, a synthetic long-peptide HPV-16 vaccine, and nivolumab in pts with incurable HPV-16+ cancer.

Methods: Tumors were HPV-genotype 16 by Cervista HPV16/18. Patients were ECOG PS 0-1 with up to one prior regimen for recurrence. ISA101 100 mcgs/peptide was given Days 1, 22, 50. Nivolumab 3 mg/kg was given iv every 2 wks beginning day 8 for up to one year. Imaging was obtained baseline, 11 wks and every 6 wks thereafter. The primary objective was assessment of overall response rate (ORR) targeting 30%. Secondary objectives: tolerability, PFS, OS. A Simon two stage design required response in 2/15 first stage and 5/25 in second stage.

Results: The trial accrued 24 patients; 22 with oropharynx cancer (OPC) and 1 pt each with anal and cervical cancer. 18 pts (75%) had progression within 6 mos of prior platin and 1 was platin-naïve. 12 pts (50%) had prior cetuximab. Treatment was frontline for recurrence in 10/24 and second line in 14/24. ORR is 33% (8/24): 1 CR, 7 PR (1 unconfirmed), 3(13%) SD, 13 (54%) PD. ORR in OPC pts is 36% (8/22). 6/8 pts with PR progressed within 6 mos of prior platin. Median duration of response 30.1+ wks (6- 49+ wks); 5/8 pts with PR remain in response. Median PFS is 2.7 mos [95% CI 2.3-8.0 mos] and median OS is not reached with median follow up time among censored pts 8.6 mos. PFS rate at 6 mos: 33%, [16-52%] OS rate at 6 mos 74%, [51-87%] . Toxicity:

grade 3 transaminase and grade 4 lipase elevation in 1 pt each, grade 1-2 toxicity: fever (5 pts), injection site reaction (6 pts), transaminase elevation, fatigue, nausea (3 pts each).

Conclusions: The primary endpoint was met and ORR of 36% in OPC pts compares favorably to 16% for nivolumab monotherapy in p16+ OPC pts in Checkmate 141 (Ferris RL et al N Engl J Med 2016; 375:1856). These data suggest that the efficacy of vaccine-induced T cells can be augmented by anti-PD-1 therapy, mitigating the influence of an immunosuppressive microenvironment. Our findings merit confirmation in a larger randomized trial. Correlation of efficacy outcomes with immunoprofiling of tumors will be presented.

1137O Interim analysis of the phase 3 ADAPT trial evaluating rocapuldencel-T (AGS-003), an individualized immunotherapy for the treatment of newly-diagnosed patients with metastatic renal cell carcinoma (mRCC)

R. Figlin[1], C. Nicolette[2], N. Tannir[3], S.S. Tykodi[4], D. Chen[5], V. Master[6], B. Lane[7], M. Debenedette[2], T. Monesmith[2], W. Tan[2], S. Leland[2], C.G. Wood[8]

[1]Division of Hematology Oncology, Cedars-Sinai Medical Center, Los Angeles, CA, USA, [2]Research and Development, Argos Therapeutics, Durham, NC, USA, [3]GU Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA, [4]Medical Oncology, University of Washington and Fred Hutchinson Cancer Research Center, Seattle, WA, USA, [5]Surgical Oncology, Foz Chase Cancer Center, Philadelphia, PA, USA, [6]Department of Urology, Emory University, Atlanta, GA, USA, [7]Urology, Spectrum Health Cancer Center, Grand Rapids, MN, USA, [8]Urology, UT M.D. Anderson Cancer Center, Houston, TX, USA

Background: Rocapuldencel-T is an investigational immunotherapy formulated with RNA isolated from the patient's tumor to program autologous dendritic cells with tumor-specific antigens. It is administered chronically via intradermal injection to activate a tumor-specific memory T-cell response.

Methods: The Phase 3 ADAPT trial was designed to evaluate overall survival (OS) of rocapuldencel-T in combination (Combo) with standard-of-care (SOC) for the treatment of newly diagnosed mRCC as compared to SOC alone (Control). It included adults with synchronous, clear cell mRCC who were eligible for nephrectomy at 107 sites across North America, Europe and Israel.

Results: 462 patients were randomized 2:1 from February 2013 - October 2015. In February 2017, an interim analysis by the Independent Data Monitoring Committee after 75% of the targeted number of 290 events (deaths) prompted a recommendation to stop the trial because the OS hazard ratio was greater than the pre-defined futility boundary (0.98) for the 3rd interim assessment. However, in consultation with investigators and the FDA, the sponsor has continued the trial due to the still maturing survival data, the mechanism of action of rocapuldencel-T, which involves the induction of long-term memory immune responses, and its' safety profile. The median duration of follow-up was 20 months and more than half the patients in both treatment groups were still alive. Data from the first third of patients randomized (n = 154), and, therefore the longest follow up time and least censored data (44%), suggest a potential survival benefit for the combination worthy of further assessment. Additionally, a statistically significant correlation was observed between the increase in the number of rocapuldencel-T induced memory T cells (CD8+/CD28+/CD45RA-) and OS in patients for whom data has been analyzed and 7 doses of rocapuldencel-T has been administered (n = 114). Updated long-term response and immune data will be presented.

Conclusions: The ADAPT trial is ongoing to further assess the long-term effects of this well-tolerated individualized immunotherapy.

1138PD Immune checkpoint inhibitor (ICPI) efficacy and resistance detected by comprehensive genomic profiling (CGP) in non-small cell lung cancer (NSCLC)

J.S. Ross[1], M.E. Goldberg[2], L.A. Albacker[2], L.M. Gay[3], V. Agarwala[4], J.A. Elvin[3], J-A. Vergilio[3], J. Suh[3], S. Ramkissoon[3], E. Severson[3], S. Daniel[3], S.M. Ali[5], A.B. Schrock[5], G.M. Frampton[2], D. Fabrizio[6], V.A. Miller[7], G. Singal[8], A. Abernethy[9], P.J. Stephens[2]

[1]Pathology, Albany Medical Center, Albany, NY, USA, [2]Cancer Genomics, Foundation Medicine, Cambridge, MA, USA, [3]Pathology, Foundation Medicine, Cambridge, MA, USA, [4]Product, Flatiron Health, Inc., New York, NY, USA, [5]Clinical Development, Foundation Medicine, Cambridge, MA, USA, [6]Cancer Immunotherapy, Foundation Medicine Inc., Cambridge, MA, USA, [7]Medical Group, Foundation Medicine, Cambridge, MA, USA, [8]Data Strategy, Foundation Medicine, Cambridge, MA, USA, [9]Medical Group, Flatiron Health, Inc., New York, NY, USA

Background: The prediction of outcome to ICPI in advanced NSCLC is of great clinical interest. We considered CGP, PD-L1 IHC, and real world data to investigate potential biomarkers for ICPI response.

Methods: CGP and IHC was performed on 1,619 FFPE NSCLC samples in the FoundationCORE database (FMI). The SP142 antibody was used to capture PD-L1 tumor expression (PD-L1 TE) for these 1,619 samples. NSCLC patients (n = 2139) in the Flatiron Health Analytic Database with FoundationOne testing CGP results and real world IHC results for PD-L1 TE were analyzed separately (FMI-FIH). CGP used ≥50 ng of DNA and a hybrid-capture, adaptor ligation-based assay (median coverage depth >600X). TMB (mut/Mb) was determined on 1.1 Mb of sequenced DNA.

Results: PD-L1 IHC TE correlated weakly with TMB (FMI samples) (Spearman's ρ 0.085, p = 6.16e-4); mean TMB was 10.9 mut/Mb, median 8.1 mut/Mb and 14.5% had high TMB (≥20 mut/Mb). From FMI-FIH, high TMB but not PD-L1 status predicted longer mean duration on therapy (DOT) (p = 0.001). Analysis of the FMI and FMI-FIH datasets revealed relationships between GA, PD-L1 TE, TMB, and mean DOT. Inactivating *STK11* GA were seen in 12.1% of FMI-FIH and 15.1% of FMI samples, most often adenocarcinomas (aCa). *STK11* GA correlated with high TMB/low PD-L1 (FMI; p = 0.0014) and preliminary analyses suggest correlation with negative ICPI treatment outcome. Several genes were commonly co-altered with *STK11* (FMI): *KRAS* (54.5%), *TP53* (43%), *CDKN2A* (27.5%), *CDKN2B* (20.1%), *KEAP1* (18.9%), and *MYC* (13.5%). *BRAF* GA, most often short variants (SV) in aCa, were associated with prolonged DOT on ICPI regardless of TMB score (FMI-FIH; p = 0.0073). *MET* SV also predicted prolonged DOT on ICPI, but insufficient events prevented calculation of statistical significance (FMI-FIH). Analysis of the TCGA lung aCa dataset revealed *MET* SV (2.8%) linked with immune activation gene expression profiles ($p < 0.05$) and *STK11* mutations (14.2%) with immune evasion profiles ($p < 0.05$).

Conclusions: Although TMB powerfully predicts ICPI outcome independent of tumor cell PD-L1 expression, considering GA in STK11, BRAF or MET may significantly increase the precision and improve outcomes when using genomics with IHC to guide to ICPI selection.

1139PD Analyzing biomarkers of cancer immunotherapy (CIT) response using a real-world clinico-genomic database

G. Singal[1], P.G. Miller[2], V. Agarwala[3], G. Li[4], A. Gossai[5], L.A. Albacker[6], M.E. Goldberg[6], J. He[4], S. Frank[5], D. Bourque[1], I. Ivanov[5], D. Fabrizio[7], T. Caron[5], A. Parker[1], A. Guria[4], V.A. Miller[8], J.A. Elvin[9], J.S. Ross[9], A. Abernethy[10], P.J. Stephens[6]

[1]Data Strategy, Foundation Medicine, Cambridge, MA, USA, [2]Oncology, Dana Farber Cancer Institute, Boston, MA, USA, [3]Product, Flatiron Health, Inc., New York, NY, USA, [4]Data Science, Foundation Medicine, Cambridge, USA, MA, [5]Data Science, Flatiron Health, Inc., New York, NY, USA, [6]R&D, Foundation Medicine, Cambridge, MA, USA, [7]Cancer Immunotherapy, Foundation Medicine, Cambridge, MA, USA, [8]Medical Group, Foundation Medicine, Cambridge, MA, USA, [9]Pathology, Foundation Medicine, Cambridge, MA, USA, [10]Medical Group, Flatiron Health, Inc., New York, NY, USA

Background: Highly discriminating biomarkers of response to cancer immunotherapies (CIT) remain elusive. Characterization of large real-world populations treated with CIT as part of routine care may enable better stratification.

Methods: Patients in the Flatiron Health Analytic Database with non-small cell lung cancer (NSCLC) who underwent comprehensive genomic profiling (CGP) by Foundation Medicine were included (n = 2139). CGP included >300 genes and tumor mutation burden (TMB), stratified into low (TMB-L; <6 mut/MB), intermediate (TMB-I; 6-20 mut/MB), and high (TMB-H; > =20 mut/MB) tertiles (Johnson, CIR 2016). PD-L1 expression was obtained from results reported to clinicians from multiple labs (using varying antibodies). Genomic data was linked to de-identified electronic health record (EHR) data, from which nivolumab response was measured as overall response rate (ORR = SD, PR, or CR), median duration of therapy (mDOT), and median overall survival (mOS) from advanced diagnosis and from nivolumab initiation.

Results: In patients treated with nivolumab (n = 444, 20.8%), TMB-H predicted longer mDOT than TMB-L/I (7.5 vs 4.6 months, p = 0.001), mOS from start of nivolumab treatment (median not reached vs 10 months, p < 0.01), and mOS from advanced diagnosis (65 vs 29 months, p = 0.10). In contrast, PD-L1 status (n = 282) was not associated with ORR, DOT, or OS. Among patients negative for PD-L1, TMB-H predicted longer DOT (mDOT 391 vs 166 days, p = 0.08) and higher ORR (100% in TMB-H [n = 5] vs 62% in TMB-I/L [n = 28], p = 0.03). TMB remained predictive of DOT and OS from nivolumab start when controlled for histology, age, stage, smoking, gender, and race in multivariate analysis. Multivariate analysis of TMB-L patients identified two additional genomic predictors of duration on nivolumab: BRAF (HR 0.12, p = 0.04), and BRCA 1/2 (HR 0.05, p = 0.01).

Conclusions: Real-world datasets combining clinical outcomes with genomic profiling may enable biomarker discovery in CIT. These data demonstrate the predictive power of TMB, which can augment and significantly improve on the currently approved PD-L1 expression as a predictor of CIT response. They may also enable discovery of novel biomarkers that can identify potential CIT responders among TMB-L populations.

1140PD Predictive biomarkers for hyper-progression (HP) in response to immune checkpoint inhibitors (ICI) – analysis of somatic alterations (SAs)

A.K. Singavi[1], S. Menon[1], D. Kilari[1], A. Alqwasmi[1], P.S. Ritch[1], J.P. Thomas[1], A.L. Martin[1], C. Oxencis[1], S. Ali[2], B. George[1]

[1]*Hematology and Oncology, Medical College of Wisconsin, Milwaukee, WI, USA,* [2]*Clinical Development, Foundation Medicine, Cambridge, MA, USA*

Background: Pseudo-progression associated with ICI has been well described. HP - characterized by paradoxically accelerated tumor growth rate (TGR) - while on ICI is increasingly being recognized. Preliminary data have reported murine double minute (MDM2/MDM4) amplification as a possible predictive biomarker for HP based on pre-treatment next generation sequencing (NGS) of tumor tissue. We sought to identify patients that hyper-progressed at our institution, characterize the SAs in those patients (pts) and conversely, estimate the incidence of HP in pts with such SAs.

Methods: HP was defined as: 1. progression at first restaging on ICI 2. Increase in tumor size > 50%, 3. >2-fold increase in TGR. Data were obtained by interrogating our institutional electronic medical record and molecular database (MDB). Next Generation Sequencing (NGS -Foundation Medicine, Cambridge MA) was performed on pre-treatment tumor tissue; DNA was extracted, NGS was performed on hybrid-capture, adaptor ligation based libraries to a mean coverage depth of > 600 for up to 315 genes plus 47 introns from 19 genes frequently rearranged in cancer.

Results: 5 pts met criteria for HP, NGS data was available on 4 (80%) pts. Most frequently encountered SAs were MDM2/MDM4 amplifications (amp -50%), EGFR amp (25%) and amp of several genes located on chromosome 11q13 -CCND1, FGF3, FGF4, FGF19 (75%). Tumor mutational burden ranged from 4-13/Mb for all pts with HP. Review of our MDB (N = 696) identified MDM2/MDM4, EGFR and 11q13 amp in 26 (4%), 26 (4%) and 25 (4%) pts respectively. Of the 70 patients with these SAs, 10 received ICI. The incidence of HP in pts with MDM2/MDM4, EGFR and 11q13 amp was 2 (66%), 1 (50%) and 3 (43%) respectively. Patient details are summarized below.

Conclusions: A subset of pts treated with ICI develop HP. Copy number alterations in MDM2/MDM4, EGFR and several genes located on 11q13 are associated with HP. The role of these SAs as putative predictive biomarkers for HP needs further validation in larger cohorts of pts. Immune escape/editing, leading to HP needs mechanistic elucidation; prospective identification of pts at risk for HP is crucial and merits further investigation.

Background: Programmed-death 1 (PD-1) and V-domain Ig suppressor of T-cell activation (VISTA) are independent immune checkpoints that inhibit T cell function. Preclinical studies demonstrated that dual blockade of these checkpoints can be synergistic. CA-170 is an oral small molecule antagonist of PD-L1 and VISTA, currently undergoing Phase (Ph) 1 clinical testing.

Methods: Pre-clinically, CA-170 inhibition of PD-L1 or VISTA-mediated suppression of T cell function was tested *in vitro* using human, monkey, or mouse cells. *In vivo* anti-tumor activity was examined in multiple syngeneic mouse models. Pts with advanced solid tumors or lymphomas, age ≥ 18, ECOG ≤1 and adequate organ function are treated with escalating doses of oral CA-170 daily during Ph 1a. Ph 1b dose expansion will enrich enrollment for selected pt population possibly responsive to this novel inhibitor. Primary objectives: safety, maximum tolerated dose and recommended Phase 2 dose. Secondary objectives: pharmacokinetics and anti-tumor activity. Exploratory endpoints: biomarkers and pharmacodynamic (PD) effects in periphery and tumor tissues.

Results: CA-170 rescues *in vitro* T cell effector function with activity comparable to that of PD-1 or VISTA blocking antibodies. Oral CA-170 inhibits the growth of mouse syngeneic tumors (B16 melanoma, CT26 and MC38 colon carcinoma), enhances peripheral T cell activation, and promotes the activation of tumor infiltrating $CD8^+$ T cells *in vivo*. In humans, a total of 19 patients have been treated across 6 dose levels (50 - 800 mg). No dose limiting toxicity has been observed. CA-170 exhibits generally dose proportional plasma exposure with $T_{1/2}$ of ~ 4-9.5 hours. Evidence of peripheral T cell activation was observed with an increased proportion of circulating $CD8^+$ and $CD4^+$ T cells expressing activation markers, CD69 and CD134, following oral dosing.

Conclusions: These pre-clinical and preliminary clinical PD data warrant the continued clinical development of CA-170, the first oral, small molecule immune checkpoint antagonist for the treatment of advanced cancers. Dose escalation is currently ongoing (NCT02812875).

Background: PF-8600 and utomilumab are fully human IgG2 agonistic monoclonal antibodies directed at tumor necrosis factor receptor superfamily receptors OX40 and 4-1BB, respectively. In general, OX40 has a greater impact on CD4 T cell function, while 4-1BB has more impact on CD8 T cell function. Dual targeting of OX40 and 4-1BB synergistically induced CD8 and cytotoxic CD4 T cell clonal expansion in pre-clinical models. A Phase I study (NCT02315066), evaluated PF-8600 alone and in combination with utomilumab. As seen previously for utomilumab alone, PF-8600 monotherapy was tolerable at all dose levels, providing rationale to combine PF-8600 with utomilumab.

Methods: Non-small cell lung cancer, head and neck squamous cell carcinoma, melanoma, bladder, gastric or cervical cancer patients (pts) unresponsive to available therapies or where no standard therapy is available are treated with PF-8600 at dose levels 0.1 mg/kg to 3 mg/kg q2w in combination with utomilumab at either 20 mg or 100 mg q4w intravenously. Blood was collected for PK/PD analysis.

Results: At time of data cut-off on 30-Jan 2017 (study ongoing), 28 pts had enrolled in 4/5 planned dose cohorts. No drug-related deaths, dose-limiting toxicities, or suspected unexpected serious adverse reactions have been confirmed to date. All drug-related adverse events (AEs) were grade (G) 1-2. The most common were nausea (10.7%), decreased appetite (7.1%) and fatigue (7.1%). Nine (32.1%) G3, 3 (10.7%) G4 and 2 (7.1%) G5 all-causality AEs were reported (G5 AEs in lowest dose cohort). Combination treatment resulted in greater increases in expression of activation and proliferation markers on CD8 memory T cells, in particular, and memory T cell subsets overall, than PF-8600 alone. Preliminary PK and efficacy data will be shown.

Conclusions: To date, dose escalation combining active monotherapy doses of PF-8600 and utomilumab has not demonstrated toxicity beyond that expected from either alone. Safety, efficacy, PK, and PD data from dose escalation will aid selection of optimal biologic doses for further evaluation and expansion.

1143PD Dose-finding combination study of niraparib and pembrolizumab in patients (pts) with metastatic triple-negative breast cancer (TNBC) or recurrent platinum-resistant epithelial ovarian cancer (OC) (TOPACIO/Keynote-162)

P.A. Konstantinopoulos[1], J.C. Sachdev[2], L. Schwartzberg[3], U.A. Matulonis[4], P. Sun[5], J.Y. Wang[5], W. Guo[6], D. Bobilev[5], G. Aktan[7], V. Karantza[8], B. Dezube[5], S. Vinayak[9]

[1]Gynecologic Oncology, Dana-Farber Cancer Institute, Boston, MA, USA, [2]Oncology, HonorHealth Research Institute, Scottsdale, AZ, USA, [3]Medical Oncology, The West Clinic, Memphis, TN, USA, [4]Gynecologic Oncology, Dana Farber Cancer Institute, Boston, MA, USA, [5]Clinical Science, TESARO, Inc., Waltham, MA, USA, [6]Biostatistics, TESARO, Inc., Waltham, MA, USA, [7]Clinical Research, Merck & Co., Inc., Kenilworth, NJ, USA, [8]Oncology, Merck & Co., Inc., Kenilworth, NJ, USA, [9]Hematology and Oncology, Case Comprehensive Cancer Center, Case Western Reserve University, Cleveland, OH, USA

Background: Platinum-resistant OC represents an unmet medical need with progression free survival (PFS) of 3.5 to 6 months. Niraparib, an oral PARP 1/2 inhibitor (PARPi), improved PFS in pts with recurrent OC following response to platinum (NEJM, 2016). Preclinical evidence suggests synergy between PARPis and PD-1 inhibitors in OC and TNBC. We report data from a phase 1 niraparib + pembrolizumab (pembro) combination study leading to recommended phase 2 dose (RP2D).

Methods: Primary objectives were to assess dose limiting toxicities (DLTs) in a 6 + 6 dose escalation design and determine RP2D. Eligible pts had metastatic TNBC treated with ≤4 prior lines of chemotherapy OR platinum-resistant recurrent OC treated with ≤5 prior lines of chemotherapy having responded with CR or PR for >6 months to 1st line platinum based chemotherapy.

Results: The 14 pts (≥18 yrs) enrolled received pembro 200 mg IV on day 1 and niraparib 200 mg (dose level [DL] 1, n = 7; 2 TNBC, 5 OC) or 300 mg (DL2, n = 7; 3 TNBC, 4 OC) PO on days 1–21 of each 21-day cycle. In DL1, 1 pt had DLTs (neutropenia, anemia and thrombocytopenia) and discontinued niraparib but continued pembro. In DL2, 1 pt had DLT and 1 had DLT-equivalent (both thrombocytopenia); both resumed treatment with 200 mg niraparib and continued pembro. RP2D was determined as niraparib 200 mg PO daily + pembro 200 mg IV on day 1 of each 21-day cycle. Based on RECIST v1.1, 4/8 evaluable OC pts responded; the other 4 pts achieved SD (Table). 1/5 TNBC pts (BRCA wildtype) had SD for 10 cycles. BRCA & PD-L1 status will be presented.

Table: 1143PD

Best response OC N = 8	Time to response[$] Cycle (weeks)	Time on study Cycle*
CR	3 (9)	11+
PR	6 (18)	9
PR	6 (18)	13+
PR	3 (9)	8
SD	2 (6)	3
SD	3 (9)	6
SD	3 (9)	5
SD	3 (9)	6

* + = ongoing

[$]Assessed every 3 cycles

Conclusions: This study established a RP2D, and showed preliminary efficacy of niraparib and pembro combination for treatment of heavily pretreated TNBC or platinum-resistant OC. No significant overlapping toxicity was noted. A phase 2 study is currently enrolling. Supporting translational work funded by SU2C.

1145PD Adoptive cell therapy with tumor-infiltrating lymphocytes for patients with metastatic ovarian cancer: A pilot study

M. Pedersen[1], M. Westergaard[1], M. Nielsen[1], T.H. Borch[1], L.G. Poulsen[2], H. Hendel[3], T. Juhler-Nøttrup[4], Ö. Met[1], M. Donia[1], I-M. Svane[1]

[1]Center for Cancer Immune Therapy, Department of Haematology and Department of Oncology, Herlev and Gentofte Hospital, Herlev, Denmark, [2]Department of Gynecology and Obstetrics, Herlev and Gentofte Hospital, Herlev, Denmark, [3]Department of Clinical Physiology and Nuclear Medicine, Herlev and Gentofte Hospital, Herlev, Denmark, [4]Department of Oncology, Rigshospitalet, Copenhagen, Denmark

Background: Metastatic ovarian cancer (OC) is often diagnosed at an advanced stage and treated with standard platinum-based chemotherapy after which the majority of patients will experience recurrent/progressive disease with a poor prognosis. Adoptive cell therapy (ACT) with tumor-infiltrating lymphocytes (TIL) has shown impressive results in malignant melanoma, but has only been investigated scarcely in other cancers. This pilot study has tested TIL based ACT in patients with metastatic OC. Preliminary data has previously been presented at the European Society of Medical Oncology (ESMO), the Society of Immunotherapy of Cancer (SITC) and the Cancer Immunotherapy & Immunomonitoring (CITIM) conferences. In this abstract the final results of the study is presented.

Methods: Patients with platinum-resistant metastatic OC were treated with an infusion of TIL preceded by standard lymphodepleting chemotherapy (Cyclophosphamide 60 mg/kg for 2 days and Fludarabine 25 mg/m^2 for 5 days) and followed by stimulation with a continuous IL-2 infusion in accordance with the decrescendo regimen for up to 5 days. Stem cell harvest was performed before TIL therapy. Primarily, the feasibility and tolerability of the treatment was assessed. Secondarily, potential immune responses against tumor cells were monitored and objective response of the treatment was described.

Results: Only expected and manageable toxicities related to the treatment were observed. All patients had stable disease (SD) for a minimum of 3 months with 4 patients experiencing progressive disease (PD) at this time point. The last two patients had SD for 5 months. Modest antitumor reactivity was observed in expanded TIL, but not in peripheral blood lymphocytes (PBL) collected after treatment.

Conclusions: ACT with TIL in combination with decrescendo IL-2 is feasible and tolerable in patients with metastatic OC with only expected and manageable toxicities. Methods of altered TIL expansion or combining TIL therapy with checkpoint inhibitors in future studies could possible enhance the mainly transient clinical responses observed in this pilot study.

1146PD Adjuvant therapy with autologous dendritic cell (DC) vaccine based on cancer-testis antigens (CaTeVac) in melanoma patients

A. Novik[1], I. Baldueva[1], S. Protsenko[2], T. Nehaeva[1], A. Danolova[1], N. Pipia[1], N. Olisova[1], M. Kornienko[1], T. Danilova[1]

[1]Department of Oncoimmunology, N.N. Petrov Research Inst. of Oncology, Saint Petersburg, Russian Federation, [2]Department of chemotherapy, N.N.Petrov Research Institute of Oncology of the Ministry of Health of the Russian Federation, Saint-Petersburg, Russian Federation

Background: Interferon-alfa (IFN) is still a standard and most widely used adjuvant therapy for patients (Pts) with skin melanoma. Nevertheless, the efficacy of this approach is doubtful despite decades of clinical trials. CaTeVac is autologous DC, derived from peripheral mononuclear cells of the patient, loaded with lysate of allogenic melanoma cell lines with high expression of cancer-testis antigens. We compared cohort of Pts receiving adjuvant therapy with CaTeVac with a cohort of consecutive Pts in our center who received IFN in the adjuvant setting.

Methods: Pts with morphologically proven melanoma received CaTeVac or IFN. CaTeVac was injected subcutaneously in doses from 5 to 20*10^6 cells per cycle (C.) in the following regimen: C.1 – 14 days, C.2-4 – 21 days, C.5-14 – 30 days. After a year of the therapy Pts were allowed to receive additional cycles: C.15-18 (3 mo each) and C.19-20 (6 mo each). Each C. consisted from cyclophosphamide 300 mg injection on day 1 and CaTeVac injection on day 4. Pts in control group received IFN until progression, toxicity or at least 1 year of therapy whatever comes first. Both groups of patients were followed with the same clinical and laboratory methods and in the same time intervals.

Results: Ninety Pts treated from 2009 to 2016 were included in the study: 48 received CaTeVac, 42 – IFN (2-high doses of IFN, 36 – low doses of IFN, 4 – IFN with dose escalation from 3 MIU until maximum tolerated dose achieved). Median of follow-up was 23 mo. Patients with stage III and IV were presented more often in CaTeVac group (79,2% and 20,8%) when compared to IFN group (68% and 4%, respectively). Stage I-II patients composed 28% of IFN group, none were in CaTevac group; X^2 test for stage p = 0,001. Median time to progression in CaTeVac was 11,4 mo, for IFN group - 6,9 mo (p = 0,097). Two-year progression-free survival was 42% and 17% for CaTeVac and IFN, respectively. Relative risk for progression in 2 years was 0,74 (95% CI 0,57-0,96) for CaTeVac. Median of overall survival was 79,8 mo in IFN group and was not reached in CaTeVac group (p = 0,352) with plateau at 58% after 41 months.

Conclusions: Rather promising results received in our study justify performing of randomized trials with CaTeVac versus IFN in adjuvant setting for patients with melanoma.

1147PD Germline determinants of immune related adverse events (irAEs) in melanoma immunotherapy response

T. Kirchhoff[1], R. Ferguson[1], D. Simpson[1], E. Kazlow[1], C. Martinez[1], M. Vogelsang[1], M. Wilson[1], A.C. Pavlick[2], J.S. Weber[1], I. Osman[1]

Background: Single line or combination immune checkpoint inhibition (ICI) therapies in metastatic melanoma have shown high response rates and durable survival. However, while at least 50% of patients show positive response to ICI treatments, ~60% of treated patients develop severe irAEs with high morbidity, substantially reducing treatment benefits. To date, no clinical or molecular indicators have been identified to predict irAEs.

Methods: Using data from our germline whole-exome sequencing scan of 69 anti-CTLA-4 (ipilimumab; IPI) treated patients, 30 with grade 3-5 irAEs and 39 with grade 0-2 irAEs, we assessed the association of exonic variants with irAEs by logistic regression analysis. Next, we cross-referenced the signification associations with irAEs against 1,140 risk variants previously found in GWAS on autoimmunity. Finally, pathway analyses of germline associations have been performed to identify biological networks involved in the susceptibility of IPI-related irAEs.

Results: We found most significant associations with increased risk of severe irAEs for two germline variants: rs504963 (OR = 2.57, p = 0.005697) in 3'UTR of FUT2, previously associated in GWAS with multiple autoimmune traits, including psoriasis, lupus,

rheumatoid arthritis and celiac disease; and rs1738074 (OR = 2.209, p = 0.02528) in TAGAP found in GWAS for association with celiac disease and multiple sclerosis. While additional variants were also identified as significant, pathway analyses have found enrichment of associated variants in chemotaxis biological processes (p = 0.04).

Conclusions: Our approach provides the first evidence that germline variants previously associated with autoimmune risk modulate the susceptibility to irAEs in patients treated by ICI. This includes associations with severe irAEs for FUT2, a protein involved in H-antigen production and linked with multiple autoimmune diseases. We have also found enrichment of variants associated with irAEs in chemotaxis processes, critically important in migration of dendritic cells upon treatment with anti-CTLA4 ICI. Upon validation in larger patient subsets, these findings suggest novel personalized biomarkers predictive of IPI-related toxicty, potentially extending to other ICI treatments.

Anderson Cancer Center, Houston, TX, USA, [3]Oncology, MD Anderson Cancer Center, Houston, TX, USA, [4]Phase I Unit, Copenhagen University Hospital, Copenhagen, Denmark, [5]Oncology, The Institute of Cancer Research/Royal Marsden NHS Foundation Trust, Sutton, UK, [6]Medical Department, Genmab, Copenhagen, Denmark, [7]Department of Oncology, Phase 1 Unit, Rigshospitalet, Copenhagen, Denmark

Background: Tisotumab vedotin (Tv) is an antibody-drug conjugate composed of a Tissue Factor (TF) specific human IgG1 monoclonal antibody conjugated to a microtubule disrupting agent Monomethyl Auristatin E (MMAE). Tv is being tested in an ongoing Ph I/II dose-escalation study (NCT02001623) in patients (pts) with locally advanced and/or metastatic solid tumors known to express TF. Preliminary data were presented at ASCO 2015, abstract #2570; here, we present the full data set from the dose-escalation part.

Methods: Key eligibility criteria include PS 0-1, normal organ function and no bleeding disorder or invasion of large vessels. Pts were treated with a classic 3 + 3 dose escalation regimen of Tv once every 3 weeks (q3Wk). The primary study objective was to assess tolerability of Tv. Safety was reported according to CTCAE 4.03. Responses were evaluated according to RECIST 1.1.

Results: Twenty-seven pts were enrolled across 8 dose cohorts (0.3-2.2 mg/kg). Demography: mean age 61 yrs (range 43-73); gender 9 males and 18 females; median number of prior lines of therapy 3 (range 1-14). Three dose-limiting toxicities (diabetes mellitus type II, mucositis and neutropenic fever, all Gr 3) were seen in 3 pts in the 2.2 mg/kg dose cohort. The most common AEs seen in $\geq$ 20%: epistaxis (48%), fatigue (48%), anemia (41%), alopecia (30%), constipation (30%), nausea (30%), pyrexia (30%), decreased appetite (26%), abdominal pain (22%) and diarrhea (22%). SAEs (all pts): 29 events in 15 pts (56%), 1 SCCHN pt in the 0.6 mg/kg cohort died from tumor related bleeding. AEs Gr $\geq$ 3: 19 pts (70%) experienced 41 events. Efficacy: 14 pts (52%) achieved SD or better; 1 cervical cancer pt dosed 1.2 mg/kg with 2 prior treatment lines before trial entry achieved and maintained PR during entire study period. After study period, the pt was transferred to named patient use.
Immunohistochemistry (IHC): Samples from 25 pts were evaluable. TF expression was present in 20 (80%) samples.

Conclusions: Tisotumab vedotin demonstrated a manageable toxicity profile. Recommended Ph II dose was identified as 2.0 mg/kg q3Wk. Biological activity included SD in 13 pts and 1 pt with prolonged PR (cervical cancer).TF was found widely expressed across investigated indications by IHC. Data warrant further exploration in solid tumors.

Background: Anti PD-1/L1 (PD1) agents are being used to treat various tumor types. Most trials have excluded patients (pts) who have had a solid organ transplant (SOT), HIV, or Hepatitis (Hep) B and Hepatitis C. The safety and efficacy of PD1 in this setting is unknown.

Methods: Pts treated at 16 centres that had a transplant, HIV, Hep B/C were included. Patient demographics, tumour characteristics, toxicity, response and survival data, and the effect on the underlying condition were collected.

Results: 42 pts were identified; 29 with melanoma, 6 bladder carcinoma (BC), 2 hepatocellular carcinoma (HCC), 2 renal cell carcinoma (RCC), 2 mesothelioma (meso), and 1 each of gastric carcinoma, glioblastoma multiforme (GBM) and non-small cell lung cancer (NSCLC). 5 pts with SOT (4 renal,1 liver) had melanoma received pembrolizumab; 3 had progressive disease (PD), 1 partial response (PR), and the pt with liver transplant had graft rejection and died from this after 1 dose. 11 pts had HIV; 2 with detectable viral load. 8 pts had pembrolizumab (7 melanoma, 1 HCC), 2 nivolumab (1 melanoma, 1 RCC) and 1 atezolizumab (BC). No pt had loss in viral control or immune reconstitution inflammatory syndrome. 2 had complete response (CR), 1 PR, 4 stable disease (SD) and 4 PD. 14 pts had Hep C; 9 with detectable viral load, 6 on anti-viral therapy and 5 with cirrhosis. 6 received pembrolizumab (5 melanoma, 1 meso), 7 nivolumab (4 melanoma, 1 each of NSCLC, BC, RCC) and 1 atezolizumab (BC). No pt had loss in viral control, 1 developed grade 3 colitis but no one developed hepatitis. 2 had CR, 9 SD and 3 PD. 12 pts with Hep B; 8 with detectable viral load, 6 on anti-viral therapy and none with cirrhosis. 8 had pembrolizumab (5 melanoma, 1 each of GBM, gastric carcinoma and meso), 4 nivolumab (2 melanoma, 1 BC, 1 HCC). No pt had loss in viral control.1 had CR, 1 PR, 8 SD and 2 PD. None of Hep B or Hep C pts developed immune related hepatits.
