Abstract Book of the
43rd ESMO Congress (ESMO 2018)

Munich, Germany
19–23 October 2018

Guest Editors: ESMO 2018 Congress Scientific Committee

Annals of Oncology

Official Journal of the European Society for Medical Oncology and the Japanese Society of Medical Oncology

Executive editor: Lewis Rowett
Editorial office: Paola Minotti Bernasconi, Giovannella Porcu, Annals of Oncology, Via Ginevra 4, 6900 Lugano, Switzerland

Annals of Oncology is covered in C.A.B. International, Current Clinical Cancer, Current Contents/Clinical Medicine®, Current Contents/Life Sciences, Elsevier BIOBASE/Current Awareness in Biological Sciences, EMBASE/Excerpta Medica, IBIDS, Index Medicus/MEDLINE, The International Monitor in Oncology, Medical Documentation Service, Science Citation Index® and Science Citation Index Expanded.

Subscriptions

A subscription to *Annals of Oncology* comprises 12 issues plus supplements in each volume. Prices include postage, and for subscribers outside the UK delivery is by Standard Air.

Annual Subscription Rate (Volume 29, 12 issues, 2018)

Institutional - Academic / Non profit only
Print and Online £1754.00/$3508.00/€2631.00
Online Only £1202.00/$2404.00/ €1803.00
Print Only £1617.00/$3233.00/€2425.00

Institutional - Corporate
Print and Online £2193.00/$4385.00/€3289.00
Online Only £1503.00/$3005.00/€2254.00
Print Only £2021.00/$4041.00/€3031.00

Personal
Print and Online £1262.00/$2526.00/€1893.00
Please note: US$ rate applies to US & Canada, Euros applies to Europe, UK£ applies to UK and Rest of World.

There may be other subscription rates available, for a complete listing please visit https://academic.oup.com/annonc/subscribe

Full prepayment, in the correct currency, is required for all orders. Orders are regarded as firm and payments are not refundable. Subscriptions are accepted and entered on a complete volume basis. Claims cannot be considered more than FOUR months after publication or date of order, whichever is later. All subscriptions in Canada are subject to GST. Subscriptions in the EU may be subject to European VAT. If registered, please supply details to avoid unnecessary charges. For subscriptions that include online versions, a proportion of the subscription price may be subject to UK VAT. Personal rate subscriptions are only available if payment is made by personal cheque or credit card and delivery is to a private address.

The current year and two previous years' issues are available from Oxford Journals. Previous volumes can be obtained from the Periodicals Service Company at http://www.periodicals.com/oxford.html or Periodicals Service Company, 11 Main Street, Germantown, NY 12526, USA. Email: psc@periodicals.com. Tel: (518) 537-4700. Fax: (518) 537-5899

Methods of payment. (i) Cheque (payable to Oxford University Press, to Oxford University Press, Cashiers Office, Great Clarendon Street, Oxford OX2 6DP, UK) in GB£ Sterling (drawn on a UK bank), US$ Dollars (drawn on a US bank), or EU€ Euros. (ii) Bank transfer to Barclays Bank Plc, Oxford Group Office, Oxford (bank sort code 20-65-18) (UK), overseas only Swift code BARC GB 22 (GB£ Sterling to account no. 70299332, IBAN GB89BARC20651870299332; US$ Dollars to account no. 66014600, IBAN GB27BARC20651866014600; EU€ Euros to account no. 78923655, IBAN GB16BARC20651878923655). (iii) Credit card (Mastercard, Visa, Switch or American Express).

Annals of Oncology (ISSN 0923-7534) is published monthly by Oxford University Press, Oxford, UK and distributed in the USA by UKP Worldwide, 3390 Rand Road, South Plainfield, NJ 07080. Periodicals postage paid at Rahway, NJ. POSTMASTER: Send address changes to *Annals of Oncology*, Oxford University Press, C/O 3390 Rand Road, South Plainfield, NJ 07080.

Subscription records are maintained at Oxford University Press, Oxford, UK.

Supplements, reprints and corporate sales

For requests from industry and companies regarding supplements, bulk article reprints, sponsored subscriptions, translation opportunities for previously published material, and corporate online opportunities, please email: special. sales@oup.com, fax: +44 (0) 1865 353774 or visit http://www.oupmediainfo.com/#!/reprints-eprints.

Permissions

For information on how to request permissions to reproduce articles/information from this journal, please visit https://academic.oup.com/journals/pages/access_purchase/rights_and_permissions.

Advertising

Advertising, inserts and artwork enquiries should be addressed to Advertising and Special Sales, Oxford Journals, Oxford University Press, Great Clarendon Street, Oxford, OX2 6DP, UK. Tel: +44 (0)1865 354767; Fax +44 (0)1865 353774; E-mail: jnlsadvertising@oup.com

Environmental and ethical policies

Oxford Journals, a division of Oxford University Press, is committed to working with the global community to bring the highest quality research to the widest possible audience. Oxford Journals will protect the environment by implementing environmentally friendly policies and practices wherever possible. Please see https://academic.oup.com/journals/pages/about_us/ethical_policies for further information on environmental and ethical policies.

Drug disclaimer

All reasonable precautions have been taken by the authors, editors and publisher to verify drug names and doses, the results of experimental work and the clinical findings published in this journal. The opinions expressed are those of the authors, and not necessarily those of the editors or publisher. The ultimate responsibility for the use and dosage of drugs mentioned in *Annals of Oncology* and in the interpretation of published material lies with the medical practitioner. The editors and publisher can accept no liability whatsoever in respect of any claim for damages arising therefrom. Please inform the editors of any errors.

Notice:

The content of the abstracts contained in this Abstract Book is subject to an embargo.

Abstracts accepted for presentation at ESMO 2018 as Poster will be published online via the ESMO website at 00:05 CEST on **Tuesday, 9 October 2018.**

Abstracts accepted for presentation at ESMO 2018 as Proffered Paper (oral presentation) or Poster Discussion will be published online via the ESMO website at 12:00 CEST on **Friday, 19 October 2018.**

All Late-breaking abstracts (Proffered Paper and Poster Discussion) will be made public at the start of the official Congress session during which they are presented.

The Publication schedule of Abstracts and Late-breaking abstracts selected for inclusion in the **ESMO Press Programme,** will be available 10 days before the Congress.

Disclaimer:

No responsibility is assumed by the organizers for any injury and/or damage to persons or property as a matter of products liability, negligence or otherwise, or from any use or operation of any methods, products, instructions or ideas contained in the material herein. Because of the rapid advances in medical sciences, we recommend that independent verification of diagnoses and drug dosages should be made.

Every effort has been made to faithfully reproduce the abstracts as submitted. However, no responsibility is assumed by the organizers for any omissions or misprints.

The European Society for Medical Oncology (ESMO)

ESMO is the leading professional organisation for medical oncology. With 18,000 members representing oncology professionals from over 150 countries worldwide, ESMO is the society of reference for oncology education and information. ESMO is committed to offer the best care to people with cancer, through fostering integrated cancer care, supporting oncologists in their professional development, and advocating for sustainable cancer care worldwide.

Founded in 1975, ESMO has European roots with a global reach. Home for all oncology stakeholders, ESMO connects professionals with diverse expertise and experience. Its education and information resources support an integrated multi-professional approach to cancer care, from a medical oncology perspective. ESMO seeks to erase boundaries in cancer care, whether between countries or specialities, and pursue its mission across oncology, worldwide.

Drawing on 40 years of experience and around 500 expert committee members, ESMO serves its members and the oncology community through:

- Post-graduate oncology education and training
- Career development and leadership training for the next generations of oncologists
- International congresses and workshops to share expertise and best practice, learn about the most up-to-date scientific advances, and connect with colleagues in related disciplines
- Continuously reviewed, evidence-based standards for cancer care in Europe
- Advocacy and consultation to foster a favourable environment for scientific research

Cancer care is rapidly becoming more integrated and more specialised; whether their field is research, diagnosis, treatment, care, or advocacy, oncology professionals need to both build their specialist knowledge and connect with the best practitioners in other disciplines worldwide. ESMO membership makes this possible.

www.esmo.org.

ESMO Executive Board

The European Oncology Nursing Society (EONS)

The **European Oncology Nursing Society (EONS)** is an independent charity dedicated to the professional support and development of cancer nurses across Europe and beyond. EONS consists of individual members and national societies, providing leadership in all areas of cancer nursing with a core focus on communications, advocacy, research and education.

Our **mission** is to ensure that all people affected by cancer benefit from the care of highly educated, well-informed and competent cancer nurses.

Our **vision** is that cancer nursing will be recognised by the cancer community, national and European-level policy makers, as a profession with specialised training and qualifications available across the continent. Working conditions for cancer nurses will be optimal, providing a commensurate financial income as well as protecting and promoting individual well-being. We anticipate that this will produce a relatable improvement in the health and clinical outcomes for people affected by cancer.

EONS' strategic goals

By the end of 2020, EONS will have achieved the following:

1. Cancer nursing is recognised across Europe for its positive impact on the lives of people affected by cancer through C.A.R.E. - Communication, Advocacy, Research and Education.
2. All cancer nurses have access to specialised education that is aligned with the EONS Cancer Nursing Education Framework.
3. All cancer nurses gain official recognition, reward and respect as a result of the RECaN and advocacy campaigns.
4. All cancer nurses are connected in order to exchange and share information and support for their work.
5. EONS facilitates, leads and promotes collaborative cancer nursing research across Europe.
6. EONS leads EU-wide advocacy initiatives at EU policy level.
7. EONS provides evidence-based advice to people and organisations affected by cancer on healthy lifestyles and cancer prevention.

Finally, we envisage that all our members will become confident and empowered cancer nurses operating as leaders in research, practice and education within multi-professional teams.

EONS Executive Board

ESMO 2018 Congress Officers

2018 ESMO and Congress President
Josep Tabernero, Barcelona, Spain

Scientific Chair
Solange Peters, Lausanne, Switzerland

Educational Chair
Andrés Cervantes, Valencia, Spain

Congress Press Officer
Pilar Garrido, Madrid, Spain

Local Officer
Volker Heinemann, Munich, Germany

Scientific Committee

Basic science
Chair: Richard Marais, Manchester, UK
David Adams, Cambridge, UK
Alberto Bardelli, Turin, Italy
Anton Berns, Amsterdam, The Netherlands
Leonor David, Porto, Portugal
Thomas Helleday, Sheffield, UK
Yardena Samuels, Rehovot, Israel
Sheila Singh, Hamilton, ON, Canada
Therese Sørlie, Oslo, Norway
Charles Swanton, London, UK
Emmy Verschuren, Helsinki, Finland
Christof von Kalle, Heidelberg, Germany

Breast cancer, early stage
Chair: Carlos Caldas, Cambridge, UK
Hervé Bonnefoi, Bordeaux, France
Jean-Marc Classe, Nantes-Saint-Herblain, France
Charlotte Coles, Cambridge, UK
Javier Cortés, Madrid, Spain
Suzette Delaloge, Villejuif, France
Carsten Denkert, Berlin, Germany
Angelo Di Leo, Prato, Italy
Véronique Diéras, Paris, France
Helena Earl, Cambridge, UK
Claire Isacke, London, UK
Jos Jonkers, Amsterdam, The Netherlands
Sabine Linn, Amsterdam, The Netherlands

Breast cancer, metastatic
Chair: Fatima Cardoso, Lisbon, Portugal
Joan Albanell, Barcelona, Spain
Lisa Carey, Chapel Hill, NC, USA
Giuseppe Curigliano, Milan, Italy
Nagi S. El Saghir, Beirut, Lebanon
Prudence Francis, Melbourne, Australia
Nadia Harbeck, Munich, Germany
Sibylle Loibl, Neu-Isenburg, Germany
Olivia Pagani, Bellinzona, Switzerland
Frederique Penault-Llorca, Clermont-Ferrand, France
Roman Rouzier, Paris, France
Britta Weigelt, New York, NY, USA

CNS tumours
Chair: Matthias Preusser, Vienna, Austria
Carmen Balaña, Badalona, Spain
Anna S. Berghoff, Vienna, Austria
Priscilla Brastianos, Boston, MA, USA
Roger Henriksson, Stockholm, Sweden
Emilie Le Rhun, Lille, France
Stefan Pfister, Heidelberg, Germany
Michele Reni, Milan, Italy
Joan Seoane, Barcelona, Spain
Joerg Tonn, Munich, Germany
Martin van der Bent, Rotterdam, The Netherlands
Michael Weller, Zurich, Switzerland
Frank Winkler, Heidelberg, Germany

Developmental therapeutics
Chair: Alex A. Adjei, Rochester, MN, USA
Udai Banerji, London, UK
Christian Blank, Amsterdam, The Netherlands
Maria Grazia Daidone, Milan, Italy
Christian Dittrich, Vienna, Austria
Boon Cher Goh, Singapore
Allan Jordan, Manchester, UK
Matthew Krebs, Manchester, UK
Christophe Le Tourneau, Paris, France
Paul Morten Mau-Sorensen, Copenhagen, Denmark
Christian Rolfo, Baltimore, MD, USA
Teresa Troiani, Naples, Italy

Gastrointestinal tumours, colorectal
Chair: Dirk Arnold, Hamburg, Germany
Alfredo Falcone, Pisa, Italy
Matthias Guckenberger, Zurich, Switzerland
Miriam Koopman, Utrecht, The Netherlands
Roberto Labianca, Bergamo, Italy
Tim Maughan, Oxford, UK
Peter Naredi, Gothenburg, Sweden
Gerald Prager, Vienna, Austria
Jens Ricke, Munich, Germany
Ramon Salazar, Barcelona, Spain
Owen Sansom, Glasgow, UK
Karen-Lise Spindler, Aarhus, Denmark
Alexander Stein, Hamburg, Germany
Julien Taieb, Paris, France
Vincenzo Valentini, Rome, Italy

Gastrointestinal tumours, non-colorectal
Chair: Yoon-Koo Kang, Seoul, Republic of Korea
Stefano Cascinu, Modena, Italy
Ann-Lii Cheng, Taipei, Taiwan
Michel Ducreux, Villejuif, France
Manuel Hidalgo, Madrid, Spain
Florian Lordick, Leipzig, Germany
Eileen Mary O'Reilly, New York, NY, USA
Cornelis van de Velde, Leiden, The Netherlands
Marcel Verhei, Nijmegen, The Netherlands
Ian Chau, Sutton, UK
Claus-Henning Koehne, Oldenburg, Germany
Andrew Biankin, Glasgow, UK
Claus Jorgensen, Manchester, UK

Genitourinary tumours, prostate
Chair: Silke Gillessen, Manchester, UK and St. Gallen, Switzerland
Himisha Beltran, New York, NY, USA
Johann de Bono, Sutton, UK
Ignacio Durán, Seville, Spain
Chris Parker, London, UK
Eleni Efstathiou, Houston, TX, USA
Nicholas James, Birmingham, UK
Bertrand Tombal, Brussels, Belgium
Scott Tomlins, Ann Arbor, MI, USA
Aristotelis Bamias, Athens, Greece
Ronald de Wit, Rotterdam, The Netherlands
David Waugh, Belfast, UK
Robert Bristow, Manchester, UK

Genitourinary tumours, non-prostate
Chair: Karim Fizazi, Villejuif, France
Axel Bex, Amsterdam, The Netherlands
Petri Bono, Helsinki, Finland
Gedske Daugaard, Copenhagen, Denmark
Jourik Gietema, Groningen, The Netherlands
Marco Gizzi, Charleroi, Belgium
Andrea Necchi, Milan, Italy
Thomas Powles, London, UK
Anna Patrikidou, Sutton, Surrey, UK
Maria De Santis, Coventry, UK
Cora Sternberg, Rome, Italy
Laurence Albiges, Villejuif, France
Fernando Calais da Silva, Lisbon, Portugal

Gynaecological cancers
Chair: Susana Banerjee, London, UK
Antonio González-Martin, Madrid, Spain
Philipp Harter, Essen, Germany
David Huntsman, Vancouver, BC, Canada
Domenica Lorusso, Milan, Italy
Christian Marth, Innsbruck, Austria
Ana Oaknin, Barcelona, Spain
Sandro Pignata, Naples, Italy
Isabelle Ray-Coquard, Lyon, France
Cristiana Sessa, Bellinzona, Switzerland
Karina Dahl Steffensen, Vejle, Denmark
Jonathan Ledermann, London, UK

Haematological malignancies
Chair: Marco Ladetto, Alessandria, Italy
Christian Buske, Ulm, Germany
Elias Campo, Barcelona, Spain
Martin Dreyling, Munich, Germany
Andrea Filippi, Turin, Italy
Martin Jädersten, Stockholm, Sweden
Steven Le Gouill, Nantes, France
Andrés José María Ferreri, Milan, Italy
Bruno Paiva, Pamplona, Spain
Michele Ghielmini, Bellinzona, Switzerland
John Radford, Manchester, UK

Immunotherapy of cancer
Chair: George Coukos, Lausanne, Switzerland
Helen Gogas, Athens, Greece
Periklis Foukas, Lausanne, Switzerland
John Haanen, Amsterdam, The Netherlands
Fernanda Herrera, Lausanne, Switzerland
Aurélien Marabelle, Villejuif, France
Inge-Marie Svane, Herlev, Denmark
Fiona Thistlethwaite, Manchester, UK
Ulrich Keilholz, Berlin, Germany
Athanasios Kotsakis, Heraklion, Greece
Eli Pikarsky, Jerusalem, Israel
Johanna Joyce, Lausanne, Switzerland

NETs and endocrine tumours
Chair: Marianne Pavel, Erlangen, Germany
Eric Baudin, Villejuif, France
Detlef K. Bartsch, Marburg, Germany
Martin Fassnacht, Würzburg, Germany
Rocio Garcia Carbonero, Madrid, Spain
Andreas Kjaer, Copenhagen, Denmark
Matthew Kulke, Boston, MA, USA
George Pentheroudakis, Ioannina, Greece
Guido Rindi, Rome, Italy
Alfredo Berruti, Brescia, Italy
Nicola Fazio, Milan, Italy
Jérôme Bertherat, Paris, France

Head and neck cancer
Chair: Amanda Psyrri, Athens, Greece
Ana Castro, Porto, Portugal
Ezra Cohen, San Diego, CA, USA
Sandrine Faivre, Paris, France
Alessandro Franchi, Florence, Italy
Jean-Pascal Machiels, Brussels, Belgium
Hisham Mehanna, Birmingham, UK
Marco Merlano, Cuneo, Italy
Esat Mahmut Ozsahin, Lausanne, Switzerland
Irene Braña, Barcelona, Spain
Lisa Licitra, Milan, Italy
Paul Brennan, Lyon, France
Kevin Harrington, London, UK

Melanoma and other skin tumours
Chair: Caroline Robert, Villejuif, France
Paolo Ascierto, Naples, Italy
Reinhard Dummer, Zurich, Switzerland
Paul Lorigan, Manchester, UK
Georgina Long, Sydney, Australia
Celeste Lebbé, Paris, France
Antoni Ribas, Los Angeles, CA, USA
Piotr Rutkowski, Warsaw, Poland
Susana Puig Sarda, Barcelona, Spain
James Larkin, London, UK
Ignacio Melero, Pamplona, Spain
Daniel Peeper, Amsterdam, The Netherlands
Marisol Soengas, Madrid, Spain

Non-metastatic NSCLC and other thoracic malignancies
Chair: Enriqueta Felip, Barcelona, Spain
Lukas Bubendorf, Basel, Switzerland
Wilfried Eberhardt, Essen, Germany
Cécile Le Pechoux, Villejuif, France
Silvia Novello, Orbassano, Italy
Suresh Ramalingam, Atlanta, GA, USA
Paul Van Schil, Edegem, Belgium
Johan Vansteenkiste, Leuven, Belgium
Heather Wakelee, Stanford, CA, USA
Corinne Faivre-Finn, Manchester, UK
Pieter Postmus, Leiden, The Netherlands
Mariano Barbacid, Madrid, Spain
John Brognard, Bethesda, MD, USA

NSCLC, metastatic
Chair: Martin Reck, Grosshansdorf, Germany
Benjamin Besse, Villejuif, France
Dirk De Ruysscher, Maastricht, The Netherlands
Simon Ekman, Stockholm, Sweden
Keith Kerr, Aberdeen, UK
Tony SK Mok, Hong Kong, China
Sanjay Popat, London, UK
Noemi Reguart, Barcelona, Spain
James Spicer, London, UK
Raffaele Califano, Manchester, UK
Federico Cappuzzo, Ravenna, Italy
Charles Rudin, New York, NY, USA

Public health and health economics
Chair: Carin Uyl-de Groot, Rotterdam, The Netherlands
Peter Boyle, Ecully, France
Elisabeth de Vries, Groningen, The Netherlands
Ferry A.L.M. Eskens, Rotterdam, The Netherlands
Jan de Maeseneer, Ghent, Belgium
Maarten IJzerman, Enschede, The Netherlands
Michel Coleman, London, UK
Beth Woods, New York, NY, USA
Alex Eniu, Cluj-Napoca, Romania
Francesco Perrone, Naples, Italy

Sarcoma
Chair: George Demetri, Boston, MA, USA
Sebastian Bauer, Essen, Germany
Sylvie Bonvalot, Paris, France
Rick Haas, Amsterdam, The Netherlands
Robin Jones, London, UK
Daniela Katz, Jerusalem, Israel
Maud Toulmonde, Bordeaux, France
Eva Wardelmann, Muenster, Germany
Paolo G. Casali, Milan, Italy
Axel Le Cesne, Villejuif, France
Jonathan Fletcher, Boston, MA, USA

Supportive and palliative care
Chair: Karin Jordan, Heidelberg, Germany
Matti Aapro, Genolier, Switzerland
Guido Cavaletti, Milan, Italy
Annie Young, Coventry, UK
Joern Herrstedt, Odense, Denmark
Stein Kaasa, Trondheim, Norway
Dorothy Keefe, Adelaide, Australia
Christina Ruhlmann, Odense, Denmark
Anton Snegovoy, Moscow, Russia
Florian Scotté, Paris, France
Florian Strasser, St. Gallen, Switzerland

Translational research
Chair: Fabrice André, Villejuif, France
Caroline Dive, Manchester, UK
Gert Attard, Sutton, UK
René Bernards, Amsterdam, The Netherlands
Emiliano Calvo, Madrid, Spain
Rodrigo Dienstmann, Barcelona, Spain
Dennis Lo, Hong Kong, China
Peter Kuhn, Los Angeles, CA, USA
Sergio Quezada, London, UK
Pierre Saintigny, Lyon, France
Bakhos A. Tannous, Boston, MA, USA
Nicola Normanno, Naples, Italy
Giampaolo Tortora, Verona, Italy

The European Society for Medical Oncology wishes to express its appreciation and gratitude to all of the above experts for their major effort in reviewing and selecting the content of this Abstract Book.

EONS11 at ESMO 2018

Scientific Committee
Co-Chair: Lena Sharp, Stockholm, Sweden
Valentina Biagioli, Rome, Italy
Eileen Furlong, Dublin, Ireland
Patrick Jahn, Halle, Germany
Gabi Knotgen, Munich, Germany
Co-Chair: Daniel Kelly, Cardiff, UK
Harald Titzer, Vienna, Austria
Emma Woodford, Brussels, Belgium
Christian Wylegalla, Freiburg, Germany

The European Oncology Nursing Society wishes to express its appreciation and gratitude to all of the above experts for their major effort in reviewing and selecting the Cancer Nurses content of this Abstract Book

Breast Surgery, Kyoto University-Graduate School of Medicine, Kyoto, Japan

6P Molecular characterization and search for founding effects in Canarian families with hereditary breast and ovarian cancer syndrome

E. Llabres Valenti[1], A.M. Sanchez de Abajo[2], J. Brenes Castro[1], A. Ramchandani Vaswani[1], A. Gómez de Liaño[1], A. Hernández[1], M. Cejuela[1], J.A. Rodriguez Garcia[1], E. González[1], E. Vicente[1]

[1]Medical Oncology, Hospital Universitario Insular de Gran Canaria, Las Palmas, Spain, [2]Biochemistry, Hospital Universitario Insular de Gran Canaria, Las Palmas, Spain

Background: The Hereditary Breast and Ovarian Cancer Syndrome (HBOC) is an autosomal dominant disease caused by germline mutations in BRCA1 (17q21) and BRCA2 (13q12) genes. The identification of BRCA1/2 genes has represented a great advance in the management of families with HBOC allowing carriers to follow up personalized and early detection of tumors at a very early stage.

Methods: Descriptive study of the Canarian families with mutation in BRCA1/2, analyzing clinical, anatomopathological and resulting parameters of the genetic analysis. The screening of point mutations was performed in all exons encoders and adjacent intron sequences by HRM (High Resolution Melting) and subsequent characterization of the patterns altered by sequencing direct. The study of large genomic rearrangements was carried out by MLPA (Multiplex Ligation-dependent Probe Amplification).

Results: Of the 611 families evaluated in the hereditary cancer clinic, 385 have genetic test completed. 55 families have been identified with a pathogenic mutation (14.2%); 36 different mutations (19 in BRCA1 (32 families) and 17 in BRCA2 (23 families). The spectrum of pathogenic mutations identified in the BRCA1 gene suggested strong founder effects on the island of Gran Canaria, where we have detected a recurrent mutation [c.3582-3589del8] (p.His1195PhefsTer21)] that explains more than 70% of families with mutation in BRCA1.

Conclusions: The percentage of pathogenic mutations in Canary HBOC families was 14.2%, similar to that detected in other populations. However, our data showed the presence of a founding mutation which explains more than 70% of our families in Gran Canaria with mutation in BRCA1, which could help us to optimize the algorithms for the study of mutations in these genes.

7P Effect of the polymorphism rs2066844 of the NOD2 gene on colon cancer incidence in a high cardiovascular risk population: Modulation by gender

J.B. Ramirez Sabio[1], J.V. Sorlí[2], I. González-Monje[2], C. Ortega-Azorín[2], Ó. Coltell[3], D. Corella[2]

[1]Medical Oncology, Hospital de Sagunt, Sagunt, Spain, [2]Preventive Medicine Department and CIBER Fisiopatología de la Obesidad y Nutrición, Universitat de València, Valencia, Spain, [3]Computer Languages and Systems, Universitat Jaume I, Castellón, Spain

Background: The nucleotide-binding oligomerization domain containing 2 (NOD2) gene is located on chromosome 16q21. It is expressed in monocytes, macrophages, epithelium of the digestive tract, breast, lung and in the kidney and is associated with the chronic inflammatory process and regulating apoptosis. A crucial role has been described in the maintenance of immune homeostasis and in the relationship with the microbiota. This gene has been linked to diseases such as Crohn's disease but also to gastric cancer, colon, endometrium, breast, ovary, bladder, lung or larynx. Our aim has been to estimate the association between polymorphism rs2066844 of the NOD2 gene on colon cancer by gender in a Mediterranean population.

Methods: We have carried out an observational study at baseline and longitudinally in the PREDIMED-Valencia study including 1094 participants (696 women) at high cardiovascular risk aged 67±6 years. We prospectively analyzed cancer incidence as a secondary outcome in this study. Lifestyle, clinical and biochemical variables were assessed by standardized methods. DNA was isolated from blood and the selected polymorphisms were determined.

Results: We detected 21 new cases of colon cancer from 2003 to 2014, representing 1.9% of all cancers and 10% of all cancer cases in men and 11% in women respectively. In our study it was observed that the variant rs2066844 was related to the new cases of colon cancer in women but not in men. The allelic frequency of the T allele was 0.054, for which the carriers of the T allele were grouped in front of the CC carriers. When assessing the risk of having suffered colon cancer according to the genotype of this variant, it was observed that the individuals carrying the T allele presented a higher risk OR = 8.7: CI 95% (2.2-23.4); P = 0.002 after adjustment for sex, age, intervention group, tobacco smoking, alcohol drinking and intake of omega-3 fatty acids.

Conclusions: rs2066844 of the NOD2 gene could be associated with colon cancer in women in a high cardiovascular risk population.

Clinical trial identification: ISRCTN35739639.

8P Effect of the polymorphisms rs1476413, rs1801131, rs4846052 and rs6541003 of the MTHFR gene on prostate cancer in a high cardiovascular risk population

J.B. Ramirez Sabio[1], J.V. Sorlí[2], C. Ortega-Azorín[2], J.A. Pérez-Fidalgo[3], E.M. Asensio[2], D. Corella[2]

[1]Hospital de Sagunt, Sagunt, Valencia, Spain, [2]Preventive Medicine and CIBER Fisiopatología de la Obesidad y Nutrición, Universitat de València, Valencia, Spain, [3]Medical Oncology, Hospital Clínico Universitario de València, Valencia, Spain

Background: Some genetic variants of the Methylenetetrahydrofolate Reductase (MTHFR) gene can lead to high levels of homocysteine and hinder the ability to process folate. Some genetic variants of this gene are related to susceptibility of many diseases such as cancer. Our aim has been to estimate the association between polymorphisms rs1476413, rs1801131, rs4846052 and rs6541003 of the MTHFR gene on prostate cancer in a Mediterranean population.

Methods: We have carried out an observational study at baseline and longitudinally in the PREDIMED-Valencia study including 398 men at high cardiovascular risk. We prospectively analyzed cancer incidence as a secondary outcome in this study. Lifestyle, clinical and biochemical variables were assessed by standardized methods. DNA was isolated from blood and the selected polymorphisms were determined.

Results: We detected 21 new cases of prostate cancer from 2003 to 2014, representing 1.9% of all cancers and 5.3% of all cancer cases in men. The analysis of the risk of prostate cancer in the variants described was carried out grouping the carriers of the allele less frequent. The allelic frequency of the rs1476413 was 0.219 for not affected participants while it was 0.074 in the cases. The crude OR = 0.24 (95%CI 0.08-0.74) p = 0.013 and OR = 0.23 (95%CI 0.08-0.71) p = 0.010 after adjustment (by age, intervention group and smoking habit). For the rs1801131, the allelic frequency was 0.271 for not affected participants while it was 0,148 in the cases. The crude OR = 0.33 (95%CI 0.13-0.83) p = 0.019 and OR = 0.33 (95%CI 0.13-0.84) p = 0.020 after adjustment. For the rs4846052, the allelic frequency was 0.390 for not affected participants while it was 0.278 in the cases. The crude OR = 0.43 (95%CI 0.19-0.95) p = 0.038 and OR = 0.43 (95%CI 0.19-0.97) p = 0.043 after adjustment. For the rs6541003 was the allelic frequency was 0.380 for not affected participants while it was 0.259 in the cases. The crude OR = 0.39 (95%CI 0.17-0.87) p = 0.021 and OR 0.39 (95%CI 0.17-0.88) p = 0.023 after adjustment.

Conclusions: The rs1476413, rs1801131, rs4846052 and rs6541003 of the MTHFR gene were protective against the development of prostate cancer in a high cardiovascular risk population.

Clinical trial identification: ISRCTN35739639.

9P Association of a genetic variant in cyclin-dependent kinase inhibitor 2A gene with the increased risk of breast cancer

S. Shahid Sales[1], M. Mehramiz[2], S.A. Aledavood[3], M. Joudi Mashhad[4], S. Ahmadi Simab[3], A. Avan[2]

[1]Clinical Oncology, Cancer Research Center, Mashhad University of Medical Sciences, Mashhad, Iran, [2]Metabolic Syndrome Research Center, School of Medicine, Mashhad University of Medical Sciences, Mashhad, Iran, [3]Cancer Research Center, School of Medicine, Mashhad University of Medical Sciences, Mashhad, Iran

Background: Breast cancer is second leading cause of cancer-related-deaths in women, supporting the need for the detection of novel prognostic biomarkers for risk stratification. There is growing body of evidence showing the association of common genetic variants on chromosome 9p21 with an increased risk of developing different tumors and metabolic disorders. Here we investigated the association of a genetic variant in CDKN2A/B, rs1333049, for the first time in 303 subjects with and without breast cancer.

Methods: Method: Genotyping was carried out using TaqMan real time PCR method in case and control groups. The associations of this genetic variant were evaluated with breast cancer risk and pathological information of patients.

Results: We observed that the minor allele homozygote situation of this genetic variant in total population was 10%, while this condition in heterozygote was 38%. the logistic regression under recessive genetic model revealed that breast cancer patients with GG genotype had higher risk of breast cancer, compared to CC/CG genotypes (e.g., OR = 2.8, 95% CI:1.4-5.4, p = 0.001), after adjusted for age, and BMI.

Conclusions: We demonstrated that patients carrying the GG genotype for CDKN2A/B rs1333049 polymorphism had an increased risk of breast cancer susceptibility, indicating further studies in a larger and prospective setting to show the value of emerging marker as a risk stratification biomarker in breast cancer.

10P Investigating the role of HAT protein TIP60 in regulating functional dynamics of nuclear receptor PXR

K. Bakshi

Lifescience, Shiv Nadar University, Greater Noida, India

Background: PXR (Pregnane Xenobiotic Receptor) belongs to the class II family of nuclear receptor (NR). PXR is considered as a master regulator of xenobiotic metabolism. PXR gets activated in a ligand-dependent manner and then heterodimerizes with RXR. PXR can also get activated via post-translational modifications and leads to cross-talk between signaling pathways. PXR is shown to be acetylated in vivo and this acetylation regulates its selective functions independent of ligands. However, the molecular players behind this acetylation and the impact of this acetylation in intracellular dynamics of PXR is not known. TIP60 is a lysine acetyltransferase which acetylates histones as well as non-histone proteins like ATM/ATR kinases and p53, and plays a role in DNA damage and repair pathway and in apoptosis. TIP60 is shown to interact with class I of NR. Thus, it might be interesting to reveal the role of TIP60 in acetylation of class II NR PXR.

Methods: We performed in vitro and in vivo co-immunoprecipitation assay and live cell imaging to show interaction as well as domain mapping. We found the site of acetylation in PXR by in silico and in vitro assay. To examine whether TIP60-PXR complex has any influence on these cellular processes, we performed cell migration, cell adhesion, cell proliferation and cell invasion assays.

Results: In this study, we are trying to dissect the mechanism of PXR activation and functional dynamics by TIP60 dependent acetylation. We found the sites of interaction as LBD of PXR with NR box of TIP60 and thus TIP60 mediated subcellular dynamics of PXR. Also, we have found TIP60 mediated the acetylation site of PXR at lysine 170. This novel complex is independent of ligand and does not form a complex with RXR. Also, this complex does not activate ligand dependent PXR target genes. Interestingly, PXR augments TIP60 acetylation on histones. We further discovered TIP60-PXR complex promotes cell migration and adhesion, which might lead to their involvement in physiological or pathophysiological conditions.

Conclusions: This is the first report demonstrating the exclusive interaction of TIP60 with unliganded PXR and uncovers a potential role for the TIP60-PXR complex in cell migration and cell adhesion.

11P The role of downregulated SIRT3 expression in patients with hepatocellular carcinoma

H. Jo, S. Hwang, M. Lee

Division of Life Sciences, College of Life Science and Bioengineering, Incheon University, Incheon, Republic of Korea

Background: Hepatocellular carcinoma (HCC) is the fifth leading cause of cancer-related deaths worldwide. The only drug currently approved for clinical use in the treatment of advanced HCC is sorafenib, a tyrosine kinase inhibitor. However, many patients with HCC are resistant to sorafenib and sensitivity to sorafenib differs according to the progression of liver cancer. SIRT3, a member of the mammalian sirtuin family, is localized to the mitochondria and regulates metabolic activity. To date, a few studies have investigated the effects of SIRT3 on prognosis and drug resistance in patients with HCC.

Methods: A correlation study between SIRT3 and other genes was conducted through the TCGA online data portal site (http://cancergenome.nih.gov). To determine the protein expression of SIRT3, immunohistochemistry (IHC) was performed with liver cancer tissue using various antibodies. To investigate whether the expression of SIRT3 in HCC is related to the resistance to sorafenib, we treated sorafenib after the modulation of SIRT3 levels in HCC cell lines (overexpression in Huh7, knockdown in HepG2 and Hep3B cells) and conducted functional assays.

Results: We identified that SIRT3 expression is downregulated in patients with HCC and high GLUT1 (glucose metabolism index) and Ki67 (proliferation index) expression. In addition, analysis of Cancer Imaging Archive data (TCGA) revealed a negative correlation between GLUT1 and SIRT3 mRNA expression and also HIF1a and SIRT3 mRNA expression. There was also a negative correlation between Ki67 and SIRT3 mRNA expression. After sorafenib treatment, SIRT3 protein expression was highly downregulated in various HCC cell lines (HepG2/Hep3B/SK-Hep1/Huh7). These cells altered their therapeutic resistance to sorafenib via SIRT3 modulation through a 2 dimensional (D)/3D cell culture system.

Conclusions: Taken together, our results show that SIRT3 acts as a tumor suppressor and plays an important role in therapy resistance for HCC.

12P Prediction of and intervention in colorectal cancer risk with artificial intelligent system

Y. Ge[1], C.W. Ma[2], L. Tao[1], M.F. Han[1], L. Ma[3], G. Li[4], L.M. Ma[3], Q. Lu[2], Z. Wu[3], P.F. Yu[3], Y.F. Yang[3], Y.Y. Ma[2], B.B. Song[3], W. Gao[3]

[1]Research Center, Fuyang City No.2 Hospital, Fuyang, China, [2]Scientific Research, American Intelligent Health, Bellevue, WA, USA, [3]Scientific Research, Beijing Yiwang Data Technology, Beijing, China, [4]Research Support, Fu Wai Hospital, Beijing, China

Background: Colorectal cancer is the third most common cancer worldwide, with nearly 1.4 million new cases diagnosed in 2012. It is also one of the most common cancers in China, with nearly 200,000 people dying annually as a result of colorectal cancer. Prediction and intervention of colorectal cancer risk would save millions of lives worldwide. The purpose of this study is to provide a simple, effective and economic method to help people predict and intervene in colorectal cancer risk.

Methods: A total of 720182 subjects including 18406 colorectal cancer patients and 701776 normal people (see the table for details) were involved in the study. The data were used in the study including demographic, CBC, CMP, lipids and urinalysis data. Analysis of covariance, logistic analysis and discriminant analysis were used to identify the significant factors and to build the colorectal cancer risk prediction model and the significant level was set at $p < 0.05$. SAS was used as the primary statistical analysis tool.

Table: 12P Subject by gender

Subject	2012-2015				2016			
	Male	Female	Total	% of Males	Male	Female	Total	% of Males
Colorectal cancer patients	8,002	5,224	13,226	60.5%	3,115	2,065	5,180	60.1%
Healthy individuals	335,021	205,678	540,669	62.0%	99,349	61,728	161,077	61.7%
Total	343,023	210,902	553,925	61.9%	102,464	63,793	166,257	61.6%

Results: The analysis showed that CBC, CMP, lipids and urinalysis data can significantly distinguish healthy individuals from colorectal cancer patients and those data can be used to build colorectal cancer risk prediction models. The predicting accuracy was 96.1% and the clinical verification rate was 95.7%. Top parameters were selected through the discriminant analysis and logistic analysis. Some parameters, such as red cell distribution width, red cell count, leukocyte percentage and age are positively correlated with colorectal cancer risk, and others, such as albumin, platelet count, hematocrit and platelet distribution width are negatively correlated with colorectal cancer risk.

Conclusions: This research shows that the routine blood and urine test results can be used to predict colorectal cancer risks and the accuracy of the prediction is over 95%. The research would provide an effective, convenient and economical method to help people predict and intervene in colorectal cancer risk.

13P Measuring the efficiency of cancer care in Europe

R. Althin[1], R. Färe[2], S. Grosskopf[2], B. Jönsson[3], N. Wilking[4]

[1]Research, The Swedish Institute for Health Economics, Lund, Sweden, [2]Economics, Oregon State, Corvallis, OR, USA, [3]Economics, Stockholm School of Economics, Stockholm, Sweden, [4]Oncology, Skane University Hospital, Lund, Sweden

Background: The rationale of this study is to develop the use of Data Envelopment Analysis (DEA) to measure and compare the efficiency of breast and lung cancer care in Europe in order to inform related policy discussions. In the wake of the increasing prevalence of cancer and pressures on constrained healthcare budgets, understanding how to make the most of available resources is essential to sustainable cancer care. DEA is a well-established instrument capable of identifying best practice in a complex production process such as cancer care with rapid change in technologies. DEA could be used to compare different production units such as e.g., countries, regions, or hospitals. In this study, we use real life data to evaluate the country specific performance of cancer care in Europe.

Methods: DEA is capable of handling many inputs and many outputs simultaneously to estimate the best practice of cancer care. The method is independent of unit of measurement allowing for the use of input and output quantities measured in different units. No data on prices are needed. For this application publicly available, aggregate, retrospective, and comparable data on breast cancer (BC) and lung cancer (LC) from Eurostat, WHO, and OECD was used in the analysis. In the model input variables such as number of radiation units, number of oncologists, and oncology drugs was used to produce survival and quality of life.

Results: The data displayed large differences in both inputs and outputs between countries and over time (2001-2015) and this was reflected in the performance measures. The efficiency base case in 2015 in BC identified 6 efficient countries out of the 23 included with a mean inefficiency of 80% and a minimum of 0.49%, i.e. the same outcome could have been produced with 49% of the inputs used. In the 2015 LC base case there were 8 efficient countries with a mean inefficiency of 82% (minimum 0.51%).

Conclusions: DEA is a policy relevant approach to measure and improve cancer care efficiency in Europe in order to provide information for decisions aimed at reducing waste and ensure better outcomes for patients. The research highlights key inefficiencies and opportunities to improve resource allocation in European cancer care.

14P Circulating cell-free DNA isolated from plasma of mesenteric veins predicts prognosis in stage II colorectal cancer patients

C-Y. Yang[1], C-H. Lin[2], J-K. Jiang[3]

[1]Department of Education and Research, Taipei City Hospital, Taipei, Taiwan, [2]Institute of Microbiology and Immunology, National Yang-Ming University, Taipei, Taiwan, [3]Department of Surgery, Taipei Veterans General Hospital, Taipei, Taiwan

Background: It is difficult to predict relapse in patients with stage II colorectal cancer (CRC). In recent years, circulating cell-free DNA (cfDNA) from peripheral blood represents a promising biomarker for detection, monitoring and survival prediction of metastatic colorectal cancer (CRC). However, its prognostic significance in patients with stage II CRC remains uncertain.

Methods: In this study, the blood samples were drawn from mesenteric vein (MV) and peripheral vein (PV). MV and PV cfDNA level was quantified by real-time quantitative PCR of ALU repeats. The cfDNA from MV and PV was quantified and the correlation among the cfDNA concentration, clinicopathological features and multivariate survival was analyzed in CRC patients.

Results: Our results showed the MV cfDNA concentrations were lower in early stage than late stage CRC. We also found that MV cfDNA level was positively correlated with tumor size. Stage II CRC patients with higher cfDNA concentrations have better prognosis than those with lower cfDNA concentrations.

Conclusions: These results indicated that MV cfDNA concentration has prognostic value in stage II CRC patients and may act as an additional biomarker in stage II CRC patients for receiving chemotherapy criteria.

15P Clonality of uterine carcinosarcoma as a factor of clinical prognosis

N. Levitskaya[1], O. Vostriukhina[2], I. Poddubnaia[1]

[1]Oncology, Russian Medical Academy of Continuous Vocational Training, Moscow, Russian Federation, [2]Molecular and Radiation Biophysics, Petersburg Nuclear Physics Institute Named by B.P. Konstantinov, Leningradskaya Oblast, Gatchina, Russian Federation

Background: Uterine carcinosarcoma is a malignant mixed Mullerian tumour, composed of epithelial and stromal components. Most uterine carcinosarcomas are monoclonal tumours, but a small proportion of them is a collision of carcinoma and sarcoma.

Methods: This research is based on the investigation of formalin-fixed, paraffin-embedded tissue blocks from 13 women undergoing primary surgical treatment between 1961–2010, that were retrieved from the archival collections of the pathoanatomical department of the Institute of Oncology named after N.N. Petrov. Mutations of TP53, PTEN and K-RAS genes were analyzed to determine clonality of uterine carcinosarcoma. DNAs were extracted by proteinase K digestion («Fisher» US) by the method of Herrington, C.S. & McGee, J.O. Mutations of TP53, PTEN and K-RAS were defined by single-strand conformation polymorphism with the next sequence. The found mutations in the TP53 (exons 5-9), PTEN (exons 5, 8), K-RAS (exon 1) genes were compared in epithelial and stromal components of 13 uterine carcinosarcomas. The tumours were classified as monoclonal in the presence of identical mutations in epithelial and stromal components, in the presence of different mutations - as biclonal. Of 13 cases 7 (53.8%) were monoclonal, 6 (46.2%) – biclonal.

Results: We evaluated clinical and histopathologic features of monoclonal and biclonal uterine carcinosarcomas. Monoclonal tumours showed worse prospects than the biclonal ones: 1-yr overall survival - 20% vs 37% ($p = 0.0078$). In all cases (100%) of monoclonal tumors the average length of full remission was three times shorter than in cases of biclonal tumours.

Table: 15P Comparison of monoclonal and biclonal carcinosarcomas

Clinical and morphological features of uterine carcinosarcoma	Monoclonal tumours	Biclonal tumours	p ≦
Tumours invades the serosa of the corpus uteri, %	100 %	50 %	$p < 0.0001$
Lymphovascular invasion	80%	0	$p < 0.0001$
Average size of the tumour (cm^3)	1305.8	131.5	$p < 0.05$
Length of full remission	7.75	24.6	$p < 0.05$

Conclusions: Clonality of the uterine carcinosarcomas may be a clinical marker as it determines the prospects of the disease, influencing the overall survival rate. Biclonal carcinosarcomas have a lesser potential for malignant development and are characterized by stronger survival capacity compared with the monoclonal tumours.

16P ODM-207: A novel BET bromodomain inhibitor with antitumor activity in nonclinical models of ER+ breast cancer

A. Moilanen[1], J. Lindqvist[1], M. Björkman[1], R. Riikonen[1], D. Nicorici[1], E. Mattila[1], C. Abbineni[2], M. Jaleel[2], J. Eriksson[3], P. Kallio[1]

[1]Orion Corporation, Orion Pharma, Espoo, Finland, [2]Aurigene Discovery Technologies Limited, Bangalore, India, [3]Åbo Akademi University, University of Turku, Turku, Finland

Background: The bromodomain and extraterminal (BET) family of proteins are chromatin readers that promote the transcription of several important cell identity genes. BET inhibitors have shown promising antitumor activity in a variety of pre-clinical cancer models, as BET inhibition abrogates the transcription of several key oncogenes in a cell type-specific manner. Hence, the purpose of this study was to determine the anticancer activity of the novel BET inhibitor ODM-207 in ER+ breast cancer models and to look for cancer-associated signaling pathways suppressed by BET inhibitors.

Methods: ER+ breast cancer cell lines were studied for sensitivity to ODM-207 and the in vivo efficacy was assessed using the ER+ Ma3366 patient-derived xenograft model. For gene expression analyses, breast cancer cells were treated with ODM-207 or reference BET inhibitor JQ1 and differentially expressed genes were analysed by RNA-sequencing. The ability of ODM-207 to regulate anticancer signaling pathways was validated by western blotting. Synergistic drug interactions were profiled using five-concentration dose response matrices.

Results: ODM-207 is a novel BET inhibitor structurally distinct from JQ1 and its benzodiazepine-related derivatives. In this study, we show that ODM-207 effectively inhibits the proliferation of ER+ breast cancer cell lines as well as suppresses the growth of patient-derived xenograft tumors. Furthermore, ODM-207 and the JQ1 targeted several pathways important for cancer progression such as the DNA damage and repair pathways.

Conclusions: Our results indicate that ODM-207, which is currently in Phase I clinical trials for treating solid tumors, causes significant growth inhibition in pre-clinical models of ER+ breast cancer, and regulates signaling pathways involved in breast cancer cell survival.

17P HER2-positive breast cancer resistance to trastuzumab is associated with metabolic switch

R. Dubianski[1], E. Sarnowska[2], M. Leszczynski[2], S. Kubala[3], W. Olszewski[4], N. Rusetska[2], A.I. Jagiello-Gruszfeld[1], R. Konopinski[2], T.J. Sarnowski[3], J.A. Siedlecki[2], Z.I. Nowecki[1]

[1]Department of Breast Cancer and Reconstructive Surgery, The Maria Skłodowska Curie Memorial Cancer Centre and Institute of Oncology (MCMCC), Warsaw, Poland, [2]Department of Molecular and Translational Oncology, The Maria Skłodowska Curie Memorial Cancer Centre and Institute of Oncology, Warsaw, Poland, [3]Department of Protein Biosynthesis, Institute of Biochemistry and Biophysics PAS, Warsaw, Poland, [4]Department of Pathology and Laboratory Medicine, The Maria Sklodowska-Curie Memorial Institute and Oncology Centre, Warsaw, Poland

Background: Overexpression of the HER2 (ErbB2 or HER2/neu) receptor occurs in 20-25% of breast cancer patients population and is related to more aggressive disease. Implementation of trastuzumab to the treatment of HER2-positive breast cancer improved the results of the treatment in this subgroup of patients. However, the resistance to trastuzumab occurs in some patients. The presence of the nuclear localization of HER2 was also noticed. The aim of this work was to verify the molecular basis of resistance to transtuzumab and correlation between the resistance and the nuclear localization of HER2 protein.

Methods: Among more than 650 patients treated with trastuzumab in MSCMCC 50 patients with resistance to trastuzumab, and 50 well responding to the treatment were chosen. The percentage of the cells with HER2 localized in the nucleus were counted. Additionally, the transcriptomic analysis of HER2 positive breast cancer cell line resistant to trastuzumab was performed. The HER2 ChIP seq and Co-IP from SK-BR3 cell nuclei followed by mass spectrometry analysis were obtained.

Results: In breast cancer with HER2 overexpression nuclear staining was present in immunochemistry. The comparative transcriptomic reanalysis of GEO datasets performed on trastuzumab resistant cell lines and sensitive cell lines revealed that in trastuzumab resistant cell lines the reprogramming of cell metabolism takes place. The most common disturbances were detected in the expression of genes involved in the lipids metabolism, glycolysis and vitamin A metabolism. Moreover, among 308 genes upregulated in trastuzumab resistant breast cancer cells the 216 genes were directly bound/regulated by BRG1 ATPase-the core subunit of SWI/SNF chromatin remodeling complex which is known regulator of metabolism related genes. Among 151 downregulated genes 67 were directly targeted by BRG1. Similarly, the another SWI/SNF ATPase (BRM) – directly targeted 151 of 308 upregulated and 32 of 151 downregulated genes. These results strongly suggested the direct regulation or interdependence of HER2 and SWI/SNF complex.

Conclusions: In HER2 cancer cells resistant to transtuzumab treatment the strong metabolic switch is observed. Moreover, the SWI/SNF complex and nuclear HER2 can be involved in this process.

18P Combination treatment with the PARP inhibitor niraparib and chemotherapeutics in a preclinical model of KRAS/BRAF mutated colorectal cancer cell lines across the four consensus molecular subtypes

P.P. Vitiello, C. Cardone, D. Ciardiello, V. Belli, N. Matrone, C. Borrelli, L. Poliero, V. De Falco, E.F. Giunta, P. Vitale, N. Zanaletti, G. Tirino, T. Troiani, F. Ciardiello, E. Martinelli

Medicina di Precisione, Università degli Studi della Campania Luigi Vanvitelli, Naples, Italy

Background: DNA damage response (DDR) is crucial in a variety of tumours. Colorectal cancer (CRC) shows some features of dependency upon DDR such as frequent activation of RAS-MAPK pathway, that is strongly associated with mitotic stress. Moreover, several approved chemotherapeutics in CRC are typical DNA damaging agents that require active DDR systems in cancer cells to be tolerated (e.g. irinotecan and oxaliplatin). It has been recently shown that PARP inhibitors are able to potentiate the anti-proliferative effect of irinotecan and oxaliplatin, particularly in MSI tumours. However, there is still no correlation between niraparib response and Consensus Molecular Subtypes (CMS).

Methods: We analysed the sensitivity using MTT proliferation assay to the PARP-inhibitor niraparib used alone or in combination with either 5-fluorouracil (5FU), irinotecan (active metabolite SN38) or oxaliplatin in a panel of 8 KRAS (HCT15, LOVO, LS1034, SW1116, SW948, HCT116, SW480) or BRAF (WiDr) mutated CRCs, from the four CMS clusters. Combination index analysis was performed in order to evaluate the synergism between niraparib and the chemotherapeutics. Further characterization of sensitive cell lines was performed using western blot, cell cycle and apoptosis analyses.

Results: Niraparib showed synergistic activity when used in combination with chemotherapeutics in most cell lines used. In particular, the combination with SN38 exhibited the strongest synergism, while synergism with 5FU was only evident in a minority of the analysed cell lines. Synergistic effect between niraparib and chemotherapy was evidenced across all the four CMS. Cell cycle and apoptosis assays revealed differences in sensitive cell lines in terms of increased induction of apoptosis.

Conclusions: Combination of niraparib and chemotherapy in RAS/BRAF mutated CRC is synergistic irrespectively of CMS. SN38 is the best candidate for combination. Further analyses are needed in order to find other markers predictive of good response to PARP inhibitors and chemotherapy in this model.

19P Exosomal microRNA-32-5p induces multidrug resistance in hepatocellular carcinoma via the PI3K/AKT pathway

X. Fu[1], M. Liu[1], S. Qu[1], J. Ma[1], Y. Zhang[1], T. Shi[1], H. Wen[1], Y. Yang[2], S. Wang[1], J. Wang[1], K. Nan[1], Y. Yao[1], T. Tian[1]

[1]Medical Oncology, First Affiliated Hospital of Xi'an Jiaotong University (School of Medicine), Xi'an, China, [2]The Third Department of Cardiology, Shaanxi Provincial People's Hospital, Xi'an, China

Background: Multidrug resistance is the main obstacle for hepatocellular carcinoma (HCC) treatment. Through bioinformatics prediction, literature review, and real-time PCR, we found that elevated miR-32-5p was associated with tumorigenesis in different cancer types, including HCC. miR-32-5p also contributes to castration resistance, radioresistance and chemoresistance in prostate cancer, but its function in multidrug resistance is still unclear. Exosomes are the most abundant type of extracellular vehicles (EVs), containing RNAs (especially miRs), proteins and other bioactive molecules. Recently, exosomes generated from chemoresistant cells have been proven to deliver miRs and transfer malignant phenotype to sensitive cells. Here we aim to find out the function of miR-32-5p in inducing multidrug resistance and the possible underlying mechanisms.

Methods: We detected the expression of miR-32-5p and PTEN in the cells and exosomes from both the multidrug-resistant and the sensitive cell lines, HCC and para-carcinoma liver tissues through real-time PCR. Dual-luciferase reporter assay verified PTEN is the target of miR-32-5p. Exosomes were obtained and confirmed through ultracentrifuge and Nano Analyzer. Gain- and loss-of-function experiments, rescue experiments, an exosome biogenesis inhibitor, and nude mice xenograft models were used to determine the underlying mechanisms of miR-32-5p and PTEN, as well as exosomal miR-32-5p in inducing multidrug resistance in vitro and in vivo.

Results: miR-32-5p was significantly elevated in multidrug-resistant HCC cell line, Bel/5-FU as well as the exosomes derived from Bel/5-FU. An inverse correlation between miR-32-5p and PTEN was confirmed in HCC cell lines and patients; moreover, high expression of miR-32-5p and low expression of PTEN were positively associated with poor prognosis. Both in vitro and in vivo expriments reveal that exosomal miR-32-5p leads to multidrug resistance by targeting PTEN and activating the PI3K/Akt pathway through promoting EMT and angiogenesis.

Conclusions: Our study demonstrated that the multidrug-resistant cell, Bel/5-FU delivers miR-32-5p to sensitive cell, Bel7402 by exosome and activates the PI3K/Akt pathway to further induce multidrug resistance by modulating angiogenesis and EMT.

20P Effect of the polymorphism rs2470893 of the CYP1A1 gene on ovarian and endometrial cancer in Mediterranean women

J.B. Ramirez Sabio[1], J.V. Sorlí[2], R. Barragán[2], F-C. Rebeca[2], E.M. Asensio[2], D. Corella[2]

[1]Medical Oncology, Hospital de Sagunt, Sagunt, Spain, [2]Preventive Medicine Department and CIBER Fisiopatología de la Obesidad y Nutrición, Universitat de València, Valencia, Spain

Background: The CYP1A1 gene is located on chromosome 15 (15q22-q24.1) and is part of the cytochrome P450 family. This catabolizing enzyme has an important role in the activation / deactivation of various chemical agents, including xenobiotics and sex hormones. It is related to the synthesis of cholesterol and steroids, and to the metabolism of drugs, coffee, or different metabolites such as those of tobacco. It is found mainly in extrahepatic tissues such as lung, breast or ovarian follicles, and participates in the metabolism of a large number of xenobiotics as well as one of endogenous substrates. Human cytochrome P450 1A 1 is one of the most important enzymes involved in the human carcinogenesis because it metabolizes several procarcinogens to active carcinogens. There are previous studies that have linked rs2470893 with ovarian cancer. Our aim has been to estimate the association between polymorphism rs2470893 of the CYP1A1 gene on ovarian and endometrial cancer in a Mediterranean population.

Methods: We have carried out an observational study at baseline and longitudinally in the PREDIMED-Valencia study including 696 women at high cardiovascular risk. We prospectively analyzed cancer incidence as a secondary outcome in this study. Lifestyle, clinical and biochemical variables were assessed by standardized methods. DNA was isolated from blood and the selected polymorphisms were determined

Results: We detected 8 new cases of ovarian and endometrial cancer from 2003 to 2014, representing 0.6% and 0.1% respectively, of all cancers. In our study it was observed that the variant rs2470893 was related to ovarian and endometrial cancer. The allelic frequency of the A allele was 0.246. The carriers of the G allele were grouped in front of the AA carriers. When assessing the risk of having suffered from ovarian or endometrial cancer according to the genotype of this variant, it was observed that the individuals carrying the AA allele presented a higher risk OR = 8.7: CI 95% (2.4-31.9); P = 0.001 after adjustment for age, intervention group, tobacco smoking and obesity (BMI $\geq$ 30 Kg/m^2).

Conclusions: rs2470893of the CYP1A1 gene could be associated with ovarian and endometrial cancer in a high cardiovascular risk population.

21P Cisplatin in NIPEC or HIPEC?

I.K. Alvovsky, V.G. Bespalov, G.S. Kireeva

Scientific Laboratory of Cancer Chemoprevention and Oncopharmacology, N.N. Petrov National Medical Research Center of Oncology, St. Petersburg, Russian Federation

Background: Eliminating minimal residual disease in patients with advanced ovarian cancer (AOC) is necessary to prevent recurrencies and could be achieved with hyperthermic intraperitoneal chemoperfusion (HIPEC). Cisplatin comprises the majority of HIPEC regimens due to its known synergic efficacy with hyperthermia. However, emerging report are impugning its role. Our goal was to compare the survival of rats treated with cisplatin by hyperthermic and normothermic intraperitoneal chemoperfusion (HIPEC and NIPEC) and to evaluate, whether the outcome of HIPEC would depend on its opened (oHIPEC) or closed (cHIPEC) delivery.

Methods: A rodent model of ascitic ovarian cancer was used. 1*10^7 tumor cells were inoculated i.p. 48 hours prior to the treatment to 48 female Wistar rats. As indicated by our previous research, this time limit of tumor progression reflects the biological pattern of optimally debulked AOC in women. Each 12 rats were randomized into four groups to receive either cisplatin at a maximum tolerated dose of 20 mg/kg in NIPEC, cHIPEC, and oHIPEC or i.p. 20 mg/kg saline as a control without treatment.

Results: The mean survival in the untreated control was 31.8 days. Cisplatin in NIPEC increased the mean survival by 22 days (P = 0.0007), while in cHIPEC and oHIPEC by 19.9 (P = 0.003) and 31.5 (P = 0.003) days, respectively. Cisplatin in oHIPEC was shown to be the most effective combination. The differences between NIPEC and cHIPEC with cisplatin were not statistically significant.

Conclusions: Our results prompt that NIPEC with cisplatin might be just as effective as cHIPEC in increasing survival in AOC.

22P Matrix metalloproteinase-mediated regulation of programmed-death ligand in the human head and neck squamous cell carcinoma microenvironment

M. Hirai[1], Y. Kobayashi[2], M.H. Miyazawa[2], H. Kitahara[2], S. Kawashiri[2], H. Nakamura[2]

[1]Oral and Maxillofacial Surgery, Tonami General Hospital, Tonami, Japan, [2]Oral and Maxillofacial Surgery, Kanazawa University Hospital, Kanazawa, Japan

Background: Recurrent and/or metastatic head and neck squamous cell carcinoma (R/M HNSCC) is a devastating malignancy with a poor prognosis. According to recent clinical studies, tumour growth can be effectively reduced and survival can be improved by blocking the programmed death receptor 1 (PD-1)/programmed death-ligand 1 (PD-L1) pathway. However, anti-PD-1 treatment is beneficial only for certain patients. Therefore, the mechanisms controlling PD-L1 expression warrant further investigation in order to provide a better understanding of the predicting efficacy of and optimising anti-PD-1 therapy, alone or in combination.

Methods: MMP-mediated regulation of PD-L1 expression was examined in three human HNSCC cell lines (OSC-20, OSC-19 and HOC313). Enzymatic activity of MMP against PD-L1 was evaluated in vitro using purified recombinant proteins or MMP synthetic inhibitors.

Results: PD-L1 protein extracted from the cell membrane was found to be downregulated in OSC-20 cells compared with OSC-19 cells, despite a higher PD-L1 expression in the total cell lysate of the OSC-20 compared with the OSC-19 cells. Several matrix metalloproteinases (MMPs) were found to be upregulated in HNSCC; in particular, MMP-7 and -13 were upregulated in the OSC-20 compared with the OSC-19 cells. Purified PD-L1 was degraded by recombinant MMP-13 and -7. The expression of PD-L1 was significantly restored by a specific inhibitor of MMP-13 (CL82198), which suggested the involvement of MMP-13 in the shedding/cleavage of PD-L1 in the OSC-20 cells. Among the anti-cancer drugs conventionally used in the treatment of patients with HNSCC, paclitaxel increased MMP-13 expression in R/M HNSCC cells (HOC313 cells) co-cultured without/with dendritic cells (DCs).

Conclusions: These results suggest that the shedding/cleavage of PD-L1 by MMP-13 is one of the mechanisms behind the protective effect against invasion and metastasis. Thus, MMP-13 has potential value as a marker predictive of the decreased efficacy of anti-PD-1 therapy. In addition, paclitaxel is a particularly promising candidate for combination therapy in R/M HNSCC with anti-PD-1 therapy.

24P Trametinib synergizes with dexamethasone in KRAS-mutant myeloma cell lines through modulation of NDRG1 and induction of apoptosis

P. Sriskandarajah[1], K. Macleod[2], N. Carragher[2], M.F. Kaiser[3], S.R. Whittaker[1]

[1]Division of Cancer Therapeutics, Institute of Cancer Research, Sutton, UK, [2]Protein and Antibody Microarray Facility, Edinburgh Cancer Research Centre, Edinburgh, UK, [3]Division of Molecular Pathology, Institute of Cancer Research, Sutton, UK

Background: Multiple myeloma (MM) remains incurable despite advances in available therapy. Mutations within the RAS-MAPK pathway are frequently associated with relapsed/refractory disease, with KRAS being particularly prevalent. Increased efforts to target this pathway with the MEK inhibitor, trametinib (Tr) have been limited by toxicities and the development of resistance due to adaptive signalling networks. Dexamethasone (Dex) is a corticosteroid commonly used in clinical practice, to synergistically enhance efficacy of anti-myeloma therapy. Therefore, we hypothesised that the combination of Tr and Dex would yield synergistic activity in KRAS-mutant MM.

Methods: Sensitivity to Tr and Dex was determined via CellTiter-Blue (CTB) assay in the KRAS-mutant multiple myeloma cell lines (MMCLs): MM1R (Dex-refractory) & MM1S (Dex-sensitive). Apoptosis and cell cycle were evaluated by flow cytometry. Reverse phase protein array (RPPA) was employed for quantitative analysis of 60 proteins and validated by Western blotting.

Results: CTB assay demonstrated a dose-dependent reduction in cell proliferation with Tr and Dex individually in MM1S, while MM1R was resistant to both treatments. TrDex demonstrated synergistic cytotoxicity in MM1S using CTB and annexin V staining. An accumulation of sub-G_1 cells was observed during cell cycle analysis in MM1S, confirming increased cell death. These effects were accompanied by activation of pro-apoptotic proteins, such as cleaved PARP and increased BIM. RPPA revealed the following phospho-proteins were downregulated with TrDex in MM1S compared to MM1R: FAK, PYK2, FLT3, NDRG1 and 4EBP1. Changes in phospho-NDRG1 were statistically significant ($P < 0.001$; 2-way ANOVA). This was confirmed by Western blotting, where expression levels were downregulated by TrDex in MM1S but unaffected in the resistant cell line MM1R.

Conclusions: TrDex demonstrates synergistic activity in KRAS-mutant MMCLs by suppression of pro-survival signalling and engagement of apoptotic pathways. Our data support further investigation of this combination in KRAS-mutant MM.

25P Functional inhibition of TGF-β in colorectal cancer cells and its interaction with AXL receptor

D. Ciardiello[1], G. Martini[2], N. Matrone[1], V. Belli[1], P.P. Vitiello[1], C. Cardone[1], V. Ciaramella[1], G. Barra[1], L. Poliero[1], C. Borrelli[1], T. Troiani[1], D. Melisi[3], F. Morgillo[1], E.F. Giunta[1], V. De Falco[1], F. Ciardiello[1], E. Martinelli[1]

[1]Medicina di Precisione, Università degli Studi della Campania Luigi Vanvitelli, Naples, Italy, [2]Centro Cellex, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain, [3]Medicina, AOU Integrata Verona "Borgo Roma", Verona, Italy

Background: AXL and transforming growth factor β (TGF-β) are correlated with epithelial to mesenchymal transition, invasiveness, angiogenesis and immune modulation in colorectal cancer (CRC). We have previously demonstrated that targeting AXL caused a significant blockade of cancer cell proliferation and migration. Here we have evaluated the role of TGF-β signalling and the potential interaction between TGF- β and AXL in human CRC cell lines.

Methods: We assessed the expression and activation of TGF-β and AXL in a panel of human CRC cell lines (HCT116, SW480, LOVO, LIM 1215 and SW48) by Western Blot (WB) and Real time PCR. We tested the sensitivity of Galunisertib (LY21209761), a TGF-β R1 inhibitor, in HCT116 and LOVO cells the treatment by using MTT, soft-agar colony forming, cell invasion and wound healing assays. To study the correlation between these two pathways, we generated stable LOVO short hairpin RNA (shRNA)-sh-AXL cells clones, in which AXL expression was decreased, and stimulated both parental and shAXL LOVO cells with TGF-β1.

Results: TGF-β receptors 1 and 2 were expressed in all cell lines, whereas AXL was expressed only in HCT116, SW480, LOVO cells. Treatment with Galunisertib had a modest effect on cancer cell growth, whereas it significantly decreased TGF-β induced cell migration, invasion and colony formation in HCT116 and LOVO cells (that co-expressed both TGF-β receptors and AXL). The stimulation of HCT116 and LOVO cells with TGF-β1 resulted in increased levels of phosphorylated (p) AXL, pAKT, and p38 MAPK proteins. However, in contrast to parental LOVO cells, no increase in p38 MAPK was found in LOVO shAXL clones, upon TGF-β stimulation.

Conclusions: In HCT116 and LOVO cells, TGF-β mediated cell migration, invasion and soft agar colony growth formation were significantly inhibited by Galunisertib treatment. Furthermore, a functional potential cross talk between TGF-β induced signalling and AXL could converge on p38 MAPK activation. In this respect, combined treatments with Galunisertib and AXL inhibitors are ongoing to evaluate their antitumor effects in CRC cells.

26P Isoform-specific AKT inhibition differentially affects cell functions in pancreatic adenocarcinoma

H. Arasanz[1], M. Gato-Cañas[1], M. Zuazo[2], M. Ibáñez-Vea[2], G. Fernández-Hinojal[3], J. Fernandez-Irigoyen[4], E. Santamaria[4], G. Kochan[2], R. Vera[3], D. Escors[2]

[1]Inmunomodulación, Navarrabiomed / Fundación Miguel Servet, Pamplona, Spain, [2]Immunomodulation-Oncology, Navarrabiomed, Pamplona, Spain, [3]Medical Oncology, Complejo Hospitalario de Navarra, Pamplona, Spain, [4]Proteomics, Navarrabiomed, Pamplona, Spain

Background: AKT/PKB is a protein kinase that plays a key role in cancer, as different oncogenic pathways on it. Three isoforms with a similar structure have been described: AKT1/PKBα, AKT2/PKBβ and AKT3/PKBγ. Although there is evidence that each isoform yields specific functions, which may vary depending on the cell type, the data available about downstream pathways is scarce. Our project evaluates the consequences of the individual inhibition of each isoform in pancreatic adenocarcinoma cells.

Methods: We have individually silenced each AKT isoform short hairpin RNAs (shRNAs) delivered by lentiviral transduction. Cells transduced with an unspecific shRNA were used as controls. Then, high-throughput quantitative proteomic analyses were performed to evaluate the differential signaling routes altered by silencing of each AKT isoform. Lastly, Western Blot and proliferation, apoptosis and chemosensitivity experiments have been completed.

Results: 3930 proteins were identified with a false discovery rate (FDR) lower than 1%. Proteome pairwise comparisons were performed with the cells lines. The specific silencing of each isoform lead to differential protein expression profiles, although KEGG pathway analysis tools revealed that many of the pathways altered were common. Individual silencing of any AKT isoform caused an inhibition of glycolysis and a subsequent increase of mitochondrial activity, as seen by fluorescent mitochondrial staining. AKT silencing increased gemcitabine sensitivity for all isoforms. AKT1 and AKT2 increased 5-FU sensitivity, while AKT3 had a comparable value. Western Blot demonstrated an increase in mTOR expression after AKT1 and AKT2 silencing. p-EIF4B expression was decreased after AKT2 and AKT3 silencing. No differences were observed in ERK expression.

Conclusions: AKT isoforms have specific functions in pancreatic adenocarcinoma. Its silencing drives cancer cells from aerobic glycolysis to mitochondrial dependent metabolism. A deeper knowledge of its downstream molecular pathways might give the rationale for individual pharmacological inhibition and combination with other therapies, thus improving the efficacy of the available treatments.

27P Lymphocytes express receptor tyrosine kinases in patients with renal cell carcinoma and healthy donors

I. Tsimafeyeu[1], M. Volkova[2], A. Olshanskaia[2], G. Raskin[3], S. Aschuba[4], Y. Khochenkova[4], A. Bondarenko[5], D. Khochenkov[4]

[1]Moscow Office, Kidney Cancer Research Bureau, Moscow, Russian Federation, [2]Department of Urology, N.N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation, [3]Department of Pathology, A.M. Granov Russian Scientific Centre of Radiology and Surgical Technologies, St. Petersburg, Russian Federation, [4]Laboratory of Angiogenesis, N.N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation, [5]Department of General Medicine, I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Background: Very little is known about receptor tyrosine kinases (RTK) expression on peripheral blood mononuclear cells (PBMC) in humans including renal cell carcinoma (RCC) patients. The primary objective of study was to evaluate expression levels of major RTKs on PBMC and tumor infiltrating lymphocytes (TIL) isolated from RCC patients. The secondary aim was to compare levels of RTK expression in RCC patients before surgery and on the 180th day after surgery (lymphocyte lifetime) and to compare with expression in healthy donors (HD). In addition, we compared RTK and PD-L1 expression in TIL.

Methods: Tumor and blood samples were obtained from 20 patients with primary RCC immediately after surgical resection. Blood samples were collected from 10 HD. Tumors were harvested into RPMI1640 medium (Gibco) and processed within 4 h. TIL isolation was performed under modified protocol [Baldan 2015]. Isolated TIL and PBMC were prepared for flow cytometry. Cells were double stained with anti-CD45

FITC-conjugated mouse antibody and with PE-conjugated mouse antibodies to VEGFR1-2, PDGFRα-β, FGFR2 (all Sony Biotech) and were analyzed on NovoCyte 2000R flow cytometer (ACEA Biosciences). Expression of RTK was evaluated with NovoExpress Software. 20 tumors from same patients were stained with PD-L1 IHC assay (clone SP142 (Ventana).

Results: PBMC/TIL express RTKs (Table). In HD PBMC express all RTKs in 2-3 times higher than PBMC of RCC patients (all $P < 0.05$). TIL also had lower expression of RTK (all $P < 0.05$). There was no significant recovery of RTK expression on 180th day except of VEGFR2. Level of FGFR2 was lower on TIL ($P = 0.03$). 50% of patients had PD-L1 expression (1-11% of positive TIL). We found negative correlation of PDGFRα, β and PD-L1 expression ($P = 0.04$).

Table: 27P

Expression of RTK, %, mean	PBMC, HD	PBMC, RCC, before surgery	PBMC, RCC, 180 days after surgery	TIL, RCC
VEGFR1	78.1	28.8	43.4	28.1
VEGFR2	79.6	27.1	57.8	44.3
PDGFRα	80.1	44.9	49.1	52.3
PDGFRβ	75.5	62.6	47.4	52.3
FGFR2	72.1	41.4	35.1	23.2

Conclusions: PBMC and TIL had similar low RTK expression levels in RCC patients. Lymphocytes of healthy humans had significantly higher expression of RTK. PD-L1 and PDGFRa-b expression could correlate.

Clinical trial identification: KCRB11022016.

28P Oncogenes analysis using GO-based clustering

D. Babenko[1], Y. Babenko[2]

[1]Research Center, Karaganda State Medical University, Karaganda, Kazakhstan, [2]Dentistry, Karaganda State Medical University, Karaganda, Kazakhstan

Background: New technology, including next-generation sequencing, has been contributing to discover novel genes and a genetic mechanism connected to oncology. Oncogenes are of particular interest to biologists, as they can provide a direct target for small molecule inhibitors. However, recent studies show that tumor suppressors and oncogenes are separable using rates of truncating mutations, mutation clustering, and copy number data. At the same time, existing literature suggested a higher intensity of purifying selection on cancer-related genes. This has led to hypothesize those oncogenes and tumor suppressor genes are more closely related physically, than noncancer-related genes. The aim of this study was to carry out clustering protein genes based on GO-terms and determine cluster structure and oncogene positions on it.

Methods: List of protein-coding genes was obtained with biomaRt Bioconductor package. ClusterProfiler Bioconductor package was used to get gene ontology data of the genes. The association of genes to cancer was calculated with OncoScore Bioconductor package. Data associated with biological processes, cellular components, and molecular functions were presented in a binary format that was used for clustering analysis. SeqSphere software used for generating minimum spanning trees (MST).

Results: 15521 out 19295 protein-coding genes (85.5%) had full information about biological processes, cellular components, and molecular functions. Among 15521 genes (1.5%), 226 genes were high associated with cancer (75 and higher oncoscore). 1441 protein-coding genes had a medium association with cancer (50-74 oncoscore). 5694 genes were between 21 and 49 oncoscores. 7345 genes were not oncogenes (based on oncoscore). In 815 cases it was not possible to determine the oncoscore. MST created on 206 unique GO terms (10% cutoff) of 15521 genes revealed grape-like structure with many clusters. High associated gene to cancer (oncogenes with high oncoscore) was distributed across different clusters and located on the outer layer of clusters.

Conclusions: Cluster analysis of protein-coding genes based on GO-terms (on biological process, molecular functions, and cell localization data) demonstrated cluster (grape-like) structure. Oncogenes were located mostly outside the cluster center.

29P PNU-74654 enhances the antiproliferative effects of 5-FU in breast cancer and antagonizes thrombin induced cell growth via the Wnt pathway

S. Shahid Sales[1], A. Avan[2], F. Rahmani[3], S.M. Hassanian[2], M. Hashemzehi[2], F. Amerizadeh[2], G. A. Ferns[4], M. Khazaei[5]

[1]Clinical Oncology, Cancer Research Center, Mashhad University of Medical Sciences, Mashhad, Iran, [2]Metabolic Syndrome Research Center, School of Medicine, Mashhad University of Medical Sciences, Mashhad, Iran, [3]Department of Medical Biochemistry, Faculty of Medicine, Mashhad University of Medical Sciences, Mashhad, Iran, [4]Division of Medical Education, Brighton & Sussex Medical School, Falmer, UK, [5]Department of Physiology, Faculty of Medicine, Mashhad University of Medical Sciences, Mashhad, Iran

Background: The Wnt/beta-catenin pathway is one of the main pathways that are dysregulated in several malignancies, including breast cancer, and may therefore be a potential therapeutic target. We have investigated the anticancer activity of PNU-74654 in breast cancer, as a Wnt/ β-catenin inhibitor, either alone or in combination with 5-FU in vitro and in vivo.

Methods: Cell viability was assessed in 2 and 3-dimensional (D) cell culture models. The ability of PNU-74654 to inhibit the chemotaxis of cells was investigated using an in vitro migration assay, and the expression of several candidate genes involved in the cell cycle, migration, as well as the markers of Wnt/b-catenin pathway were investigated by qRT-PCR and/or Western blotting as well as cell cycle analysis by flow cytometry. The effect of PNU-74654 on oxidative balance was evaluated by determining the malondialdehyde (MDA) and concentration of total thiols (T-SH), and the activity of catalase (CAT) and superoxide dismutase (SOD). We reconstructed a Boolean network in order to understand dynamic behavior of genes, while the robustness of this model was assessed by Hamming distance.

Results: PNU-74654 suppressed cell growth at an IC50 of 122±0.4 umol/L and synergistically enhanced the antiproliferative activity of gemcitabine by modulating the Wnt pathway. The 3-D cell culture model showed that PNU-74654 caused tumor shrinkage. It reduced the migration of MCF-7 cells (by an 18% reduction in invasive behavior) after treatment with PNU-74654 through perturbation of E-cadherin and MMP3/9. PNU-74654/5-FU combination enhanced the percentages of cells in S-phase, and significantly increased apoptosis. Moreover, our data showed that this agent was able to inhibit the growth of tumor in a xenograft model, although this effect was more pronounced in the animals treated with PNU-74654 plus 5-FU.

Conclusions: The antitumor activity of PNU-74654 were shown in breast cancer.

30P P21 has the potential to become the monitoring marker for the CDK4/6 inhibitors resistance in breast cancer

M. Iida[1], M. Nakamura[1], E. Tokuda[1], T. Niwa[1], T. Ishida[2], S-I. Hayashi[1]

[1]Molecular and Functional Dynamics, Tohoku University Hospital, Sendai, Japan, [2]Breast and Endocrine Surgical Oncology, Tohoku University Hospital, Sendai, Japan

Background: CDK4/6 inhibitors have been widely used around the world for advanced estrogen receptor positive breast cancer patients in the past several years. However, the benefit offered by CDK4/6 inhibitors is individually different, therefore it is imperative need to identify the biomarker and/or monitoring marker.

Methods: We established CDK6 over expression cell lines (MCF7-C6) from MCF-7 by stably transfected CDK6 expression vector. We also established Ribociclib-resistant cell lines (RIBR) after long-term culture under the condition of sufficient doses of Ribociclib from estrogen deprivation-resistant cell lines (EDR) which established from MCF-7 cultured with steroid depleted medium as aromatase inhibitor resistance models. We further established RIBR(-R) cell lines from RIBR by long-term cultured without Ribociclib.

Results: First, we assessed IC50 of Ribociclib in several cell lines. Luminal cell lines exhibited lower Ribociclib IC50 than non-luminal cell lines. Immunoblot analysis of Luminal cell lines showed extremely lower levels of CDK6 compared with others. Then we established MCF7-C6. MCF7-C6 reduced Ribociclib sensitivity equivalent to non-luminal cell lines. Next, we established RIBR to understand the characteristics in acquired resistance. We confirmed RIBR showed higher Ribociclib IC50 than EDR. Surprisingly the expression levels of CDK6 were not reduced in RIBR, indicating that the mechanism of resistance to Ribociclib would be different between MCF-7-C6 and RIBR. Then, we explored the efficacy of other CDK4/6 inhibitors on MCF7-C6 and RIBR. MCF7-C6 and RIBR cells showed cross-resistant not only to Palbociclib but Abemaciclib. The expression levels of p21 were reduced in both cell lines though the mechanisms of resistance to CDK4/6 inhibitors were different. Finally, we established RIBR(-R). RIBR(-R) showed more sensitive to Ribociclib than RIBR. In addition, p21 levels of RIBR(-R) were restored to the same degree as EDR.

Conclusions: Ribociclib sensitivity was proportional to the expression levels of p21, suggesting that p21 levels might be the monitoring marker for the CDK4/6 inhibitors resistance in breast cancer.

31P Overexpression of NAMPT in adult T-cell leukemia/lymphoma patients and anti-tumor activity of a NAMPT inhibitor in vivo

T. Kozako[1], T. Ohsugi[2], M. Yoshimitsu[3], Y-I. Uchida[3], K. Ishitsuka[3], K. Naho[1], A. Aikawa[1], S-I. Honda[1]

[1]Department of Biochemistry, Faculty of Pharmaceutical Sciences, Fukuoka University, Fukuoka, Japan, [2]Department of Hematology and Immunology, Rakuno Gakuen University, Ebethu, Japan, [3]Center for Chronic Viral Diseases, Kagoshima University, Kagoshima, Japan

Background: Adult T-cell leukemia/lymphoma (ATL) is a malignancy of mature T lymphocytes induced by human T-cell leukemia virus (HTLV) that has poor outcomes. New molecular targets for prevention and treatment of ATL are urgently needed. We reported that SIRT1, a nicotinamide adenine dinucleotide (NAD^+)-dependent histone/protein deacetylase, is highly expressed in primary acute-type ATL cells. NAD^+ biosynthesis via nicotinamide phosphoribosyltransferase (NAMPT) modulates SIRT1 activity. We examined the expression and inhibition of NAMPT, a rate-limiting enzyme in NAD^+ biosynthesis, in ATL cells.

Methods: Peripheral blood mononuclear cells from ATL patients were carried out in accordance with the guidelines of the Committees for Ethical Review of Research involving Human Subjects at Kagoshima University Hospital. Cell viability was evaluated in the S1T cell line derived from an ATL patient, MT-2 cell line derived from normal human leukocytes transformed by leukemic T-cells from an ATL patient, and primary ATL cells. Animal experiments were approved by the Animal Care and Use Committee of Rakuno Gakuen University in accordance with the Guide for the Care and Use of Laboratory Animals.

Results: Peripheral blood mononuclear cells from acute-type ATL patients expressed significantly higher NAMPT protein levels than cells from healthy controls. FK866, a NAMPT inhibitor, induced apoptosis in cell lines and fresh ATL cells, accompanied by caspase activation, DNA fragmentation, and mitochondrial transmembrane potential disruption in vitro. A pan-caspase inhibitor failed to prevent the FK866-induced cell death, while FK866 increased endonuclease G, a caspase-independent cell death mediator. Intriguingly, FK866 activated autophagy, revealed by increased LC3-II protein levels. Thus, FK866 simultaneously activated apoptosis and autophagy. Finally, FK866 treatment markedly decreased human ATL tumor xenograft growth in immunodeficient mice.

Conclusions: These results demonstrate that NAMPT inhibition induces autophagy and caspase-dependent and -independent cell death in ATL cells, suggesting a novel therapeutic strategy for patients with this fatal disease.

32P 9-ING-41, a clinically relevant inhibitor of glycogen synthase kinase-3 (GSK-3), is active pre-clinically in human bladder and renal cell cancers

H. Kuroki[1], T. Anraku[1], V. Bilim[1], M. Tasaki[1], D. Schmitt[2], A. Mazar[3], A. Ugolkov[4], Y. Tomita[1]

[1]Urology, Niigata University Medical and Dental Hospital, Niigata, Japan, [2]Actuate Therapeutics, Fort Worth, TX, USA, [3]Monopar Therapeutics, Wilmette, IL, USA, [4]Developmental Therapeutic Program, Division of Hematology/Oncology, Feinberg School of Medicine, Northwestern University, Chicago, IL, USA

Background: Glycogen Synthase Kinase-3b (GSK-3b) is a serine/threonine protein kinase that has been established as a therapeutic target in a broad spectrum of human malignancies. We have previously identified aberrant GSK-3b nuclear expression in urothelial cancer (UC) and renal cell carcinoma (RCC), and demonstrated that GSK-3b positively regulated UC and RCC cell survival and proliferation. Our objective was to evaluate the antitumor effects of clinically viable agent 9-ING-41, a maleimide-based ATP-competitive GSK-3 inhibitor, which demonstrated broad spectrum antitumor activity and marked activity in reversing chemoresistance in a variety of human cancers.

Methods: We used flow cytometry, Western immunoblotting, quantitative RT-PCR, BrDU incorporation and MTS assays to examine the pre-clinical antitumor activity of 9-ING-41 in UC (T24, HT1376 and RT4 cell lines) and RCC (ACHN, Caki2, A498 and KRC/Y cell lines).

Results: A dose-dependent decrease in cancer cell proliferation was observed by MTS assay and BrdU incorporation assay with GI50 ranging from 0.7 to 4.7 mM (UC) and 7.2 to 11.5 mM (RCC). Treatment with 9-ING-41 induced prominent cell cycle arrest (predominantly G2 arrest) in UC and RCC cell lines. Expression of cell cycle related proteins, including Cyclin D, and anti-apoptotic proteins, such as XIAP and Bcl-2, were decreased as detected by Western immunoblotting and real time RT-PCR. Treatment with 9-ING-41 significantly potentiated the growth inhibitory effect of cisplatin and gemcitabine in both UC and RCC cell lines.

Conclusions: Our data provide a rationale for the inclusion of patients with advanced and/or chemo-refractory UC or RCC in 9-ING-41 clinical studies.

33P A new natural compound identified through a metabolomic approach has cytotoxic activity against human colorectal cancer cell lines with acquired resistance to cetuximab

V. De Falco, E.F. Giunta, V. Belli, N. Matrone, S. Napolitano, E. Martinelli, P. Vitale, N. Zanaletti, M. Terminiello, P.P. Vitiello, F. Ciardiello, T. Troiani

Dipartimento di Medicina di Precisione, Università degli Studi della Campania Luigi Vanvitelli, Naples, Italy

Background: The discovery of bioactive compounds from natural sources is an important resource to develop new weapons against cancer. In a previous study, we have used a rapid NMR-based metabolomic approach to select plant species belonging to Fabaceae family with anti-proliferative properties. Fourteen species of this family were studied with high-resolution 2D NMR spectroscopy and then several molecules were purified from plant extracts. The family of Fabaceae is widely distributed in the Northern hemisphere and putative pharmacologic effects are described in traditional Chinese pharmacopoeia.

Methods: We analysed the cytotoxic activity of an *Astragalus boeticus* compound on a panel of human colon cancer cell lines sensitive (SW48, GEO and CACO-2) and with acquired resistance to anti-EGFR inhibitors such as cetuximab (SW48-CR, GEO-CR and CACO-2-CR).

Results: Among a panel of human CRC cell lines, three with acquired resistance to cetuximab (SW48-CR, GEO-CR and Caco-2-CR) were highly sensitive to the *Astragalus* compound. The treatment with this compound determines a transition to an epithelial phenotype in all three cell lines with reduction of vimentin and an increase of E-cadherin expression. Moreover, *Astragalus* treatment determines an induction of apoptosis and a significant increase in cell death in SW48-CR, GEO-CR and Caco-2-CR cells, but not in the parental cell lines. These findings were confirmed by western blot assay with activation of caspase cascade only in cetuximab-resistant cells. Moreover, the antiproliferative effect of *Astragalus* compound on cetuximab-resistant cells is mediated by the inhibition of AKT/mTOR signalling pathway. In particular, western blot analyses have shown a significant reduction in the expression of 4-EBP1 and p-4EBP1 in cetuximab-resistant cell lines following *Astragalus* treatment. Moreover, the combined treatment with cetuximab and *Astragalus* induced a synergistic antiproliferative and apoptotic effects with blockade in AKT/mTOR pathway in h cetuximab-resistant cells.

Conclusions: *Astragalus* compound induces antiproliferative activity in a panel of human CRC with acquired resistance to cetuximab by inhibiting AKT/mTOR pathway.

34P Multiple myeloma metal levels and proteasome activity

K.U. Stumpf[1], H. Einsele[2], T. Nekova[3]

[1]Biocomposition, Institute of Mineral Analysis, Würzburg, Germany, [2]Medical Policlinic II, University Hospital Wuerzburg, Würzburg, Germany, [3]Hematology, University Hospital Wuerzburg, Würzburg, Germany

Background: The biologically active metal-based compounds are of interest in both prevention and treatment of cancer. Metal-containing complexes are essential for the normal biochemical processes, and due to their reactivity, imbalance in the metal concentration is linked to the development of diverse malignancy. Several proteasome inhibitors contain metal complexes. Bortezomib (a boron complex) is the first successfully used therapeutic proteasome inhibitor in multiple myeloma (MM). However, major clinical limitations of the drug are the severe side effects caused by the inhibition of proteasomal and non-proteasomal activity in normal cells. Here we analyze the associations between individual metals and proteasome activity.

Methods: The study was performed on MM cell lines MM.1S and L363. Chymotrypsin–like (CT-like) proteasome activity is the primary measure of the degradation potential of the proteasome. In order to determine how metals are linked to proteasome activity, we expose MM cells to bortezomib or 5-amino-8-hydroxyquinoline dihydrochloride (5AHQ) proteasome inhibitors. The CT-like activities of β5 and β5i

subunit were measured and evaluated based on a cumulative inhibition of β5 and β5i CT-like sites. Metal content analysis of MM.1S and L363 cells was performed by total reflection X-ray fluorescence spectrometer.

Results: The metal content analysis demonstrated rigorous imbalances for calcium, phosphorus and potassium, moderate to no imbalances for iron and zinc accompanied by 65% MM.1S (54% L363) reduction of CT-like activity under bortezomib. However, under 5AHQ treatment, a decrease in the concentration of phosphorus and potassium was accompanied by minor to no change of iron and zinc levels and an increase of calcium. As metals may positively correlate or be antagonistic to one another, we evaluated the correlations between metals and proteasome activity.

Conclusions: Overall, our analysis suggests that the modulation of metal interactions specific to the proteasome activity is a strategy worth exploring to improve the efficacy of proteasome inhibition therapies.

35P A translational drug-screening tool for interrogating the effect of anti-TGF-*β* therapy on fibroblast activity and the desmoplastic reaction

N.I. Nissen[1], N. Willumsen[2], N. Gudmann[3], S. Rønnow[3], M. Karsdal[2], D. Leeming[3], J. Sand[3]

[1]Cancer, Nordic Bioscience A/S, Herlev, Denmark, [2]Biomarkers and Research, Nordic Bioscience A/S, Herlev, Denmark, [3]Fibrosis, Nordic Bioscience A/S, Herlev, Denmark

Background: Numerous clinical trials are currently evaluating anti-transforming growth factor beta (TGF-β) therapy for treating lung cancer patients. However, interrogating stromal reactivity, and enhancing the mechanistic understanding of desmoplasia in relation to TGF-β signaling represents unmet medical needs and may allow for discovery of novel TGF-β associated biomarkers for use in the clinical setting. Cancer associated fibroblasts are major contributors to the desmoplastic reaction (ECM deposition) upon TGF-β stimulation. Applying the "Scar-in-a-jar" (SiaJ) model, we evaluated the impact of TGF-β, and inhibitors, on lung fibroblasts' expression of different collagens.

Methods: Primary human healthy lung fibroblasts were cultured for up to 15 days in the presence of ficoll and TGF-β, with or without addition of 1nM-10μM ALK-5/type I TGF-β receptor kinase inhibitor (iTGFβ. ELISAs quantified pro-peptides from type I (PINP), type III (PRO-C3) and type VI (PRO-C6) collagen in cell supernatant as surrogate measures of the TGF-β induced ECM deposition. Cytotoxicity (lactate dehydrogenase (LDH) release) and metabolic activity (AlamarBlue) were evaluated.

Results: Stimulating lung fibroblasts with TGF-β induced PINP, PRO-C3 and PRO-C6 increase up to 8-fold compared to TGF-β ($p < 0.001$). iTGFβ dose-dependently reduced the PINP, PRO-C3 and PRO-C6 increase induced by TGF-β. No cytotoxicity could be detected. The metabolic activity was decreased at 1uM iTGFβ.

Conclusions: The SiaJ model can be used to evaluate the impact of TGF-β, and inhibitors, on lung fibroblasts' viability and expression of different collagens. The findings suggest that SiaJ together with PINP, PRO-C3 and PRO-C6 can be used as a translational drug screening tool for interrogating the effect of anti-TGF-β therapy on fibroblast activity and the desmoplastic reaction.

36P Eribulin demonstrate selectively high sensitivity to recurrent and/or metastatic head and neck squamous cell carcinoma (R/M HNSCC) cells and xenograft tumors

H. Kitahara, Y. Kobayashi, M. Hirai, S. Kawashiri, H. Nakamura

Oral and Maxillofacial Surgery, Kanazawa University Hospital, Kanazawa, Japan

Background: Recurrent and/or metastatic head and neck squamous cell carcinoma (R/M HNSCC) is a devastating malignancy with a poor prognosis. Eribulin (a microtubule inhibitor) reportedly renders breast cancer less aggressive, and less likely to metastasise, by triggering the mesenchymal-to-epithelial (MET) transition. Previously we reported that eribulin-induced MET was associated with re-sensitization of resistant HNSCC cell lines to cetuximab. In this study, we evaluated eribulin activity in preclinical R/M HNSCC models.

Methods: In vitro antiproliferative activities (IC50) were determined in three human HNSCC cell lines (OSC-20, OSC-19 and OLC01) treated with eribulin or other microtubule inhibitors (paclitaxel and vinblastine). The effects of eribulin were evaluated in eribulin-sensitive and -resistant HNSCC xenograft tumors.

Results: Eribulin demonstrate selectively high sensitivity to OLC01 cells (R/M HNSCC) in comparison with other cell lines. Eribulin has sub-0.1 nM growth inhibitory activities in vitro against OLC01 cells as well as marked in vivo activities at 0.1–0.5 mg/kg against OLC01 cells xenografts. Inducible TUBB3 correlates with lower sensitivity to eribulin in HNSCC cells and xenograft tumors.

Conclusions: Understanding the mechanisms involved in the overall drug response to eribulin may help in the design of therapeutic strategies that enhance drug activity and improve benefits of eribulin in R/M HNSCC patients.

37P Tranilast inhibits TGF-beta-induced EMT and invasion/metastasis via the suppression of smad4 in lung cancer cell lines

K. Takahashi, S. Nishikawa, R. Miyata, M. Noguchi, H. Ishikawa, Y. Yutaka, D. Nakajima, M. Hamaji, A. Ohsumi, T. Menju, F. Chen-Yoshikawa, T. Sato, M. Sonobe, H. Date

Thoracic Surgery, Kyoto University-Graduate School of Medicine, Kyoto, Japan

Background: Epithelial-mesenchymal transition (EMT) is a key event in cancer metastasis and promotes cancer cell migration and invasion. Transforming growth factor-beta (TGF-β), a well-known inducer of fibroblast proliferation, plays a crucial role in cancerous EMT via regulating E-cadherin or vimentin expression through TGF-β/Smad signaling. Tranilast is an anti-allergic drug clinically used for the treatment of keloids and hypertrophic scars to inhibit tissue fibrosis. We investigated whether tranilast could inhibit TGF-β-induced EMT in non-small cell lung cancer (NSCLC) cell lines.

Methods: We used A549 and PC14 NSCLC cell lines which are epithelial type cultured under normal conditions, but changes their phenotype into mesenchymal type with TGF-β stimulation. Western blottings were applied to examine epithelial or mesenchymal markers, and signal transductions of TGF-β/Smad pathway in these cell lines exposed to tranilast. To downregulate Smad signaling, siRNA methods were applied. Next, to investigate the capability of in vitro invasion, matrigel invasion assays were performed in which TGF-β was used as a chemoattractant. To develop orthotopic in vivo cancer models, A549 cells mixed with matrigel were injected into left lung of nude mice. Subsequently, mice were treated with or without tranilast for one month, then, the number of micrometastasis in both lungs were counted and compared between the two groups.

Results: In mesenchymal phenotype of A549 and PC14 stimulated with TGF-β, tranilast reinstated EMT via suppressing Smad4. The downregulation of Smad4 by siRNA methods also induced the recovery of EMT in these cell lines, resulting in the inhibition of in vitro invasion. The number of tumor spread through air space (STAS) in lung parenchyma was more suppressed in the tranilast administerd mice group.

Conclusions: Tranilast suppressed TGF-β-induced EMT via the downregulation of Smad4 resulting in the inhibition of in vitro and in vivo invasion/metastasis in lung cancer cell lines.

38P Integrin beta-like 1 overexpression stimulates invasiveness of ovarian cancer cells in vitro

A.J. Cortez, K.A. Kujawa, P.A. Tudrej, K.M. Lisowska

Center for Translational Research and Molecular Biology of Cancer, Maria Skłodowska-Curie Institute - Oncology Center, Gliwice Branch, Gliwice, Poland

Background: In our previous microarray study we analyzed gene expression profile of over 100 ovarian cancer samples [1]. We identified two molecular subgroups of high grade serous ovarian cancers (HG-SOC) with distinct gene expression profiles and survival [2]. Among differentially expressed genes was an Integrin beta-like1 gene (ITGBL1). ITGBL1 is a poorly characterized protein, structurally cognate with integrin β. Our aim was to study whether and how ITGBL1 can influence the phenotype of ovarian cancer cells.

Methods: ITGBL1 coding sequence was PCR-amplified from cDNA and cloned into pLNCX2 vector. Retroviral system was used to obtain two ovarian cancer cell lines: OAW42/ITGBL1(+) and SKOV3/ITGBL1(+) with overexpression of ITGBL1. Control cell lines were obtained by transduction with empty vector. A Matrigel cell invasion assay was performed using 24-well transwell inserts (coated with fibronectin and matrigel). Crystal violet staining of invaded cells was performed, then the dye was solubilized with 10% acetic acid and the absorbance was measured at a wavelength of 595 nm.

Results: We compared invasion rate of control OAW42 and SKOV3 cells with that of isogenic cell lines containing ITGBL1 construct. The results indicate that ITGBL1 overexpression increases invasiveness of ovarian cancer cells.

Conclusions: Our results indicate that ITGBL1 may increase ovarian cancer cell invasion rate. Along with our previous reported results that overexpression of ITGBL1 may

increase migration, decrease adhesion [3] and has no effect on proliferation rate [4], these results suggests that ITGBL1 may play an important role in ovarian cancer progression enabling easier spreading of the cells within peritoneal cavity.

39P MiR-449a suppresses endometrial cancer invasion and metastasis by targeting NDRG1

L. Qiu

Department of Obstetrics and Gynecology, Ren Ji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China

Background: Endometrial cancer (EC) is the most common gynecologic malignancy in western counties. Generally, a five-year survival of patients with localized disease remains at approximately 96% and this rate drops to 67% and 17% for the patients suffering from regional and distant metastasis, respectively. Therefore, an improved understanding of the molecular mechanisms in metastasis of endometrial cancer has the potential to significantly impact the outcomes for this disease. Studies has outlined the essential roles for miR-449a in regulating pathogenesis of cancers. A number of reports have identified the role of microRNAs in EC, but little is known about miR-449a in it.

Methods: FISH was used to detect the expression of miR-449a in the 55 tissues and IHC was performed to measure the NDRG1 expression in the above samples. The alterations of NDRG1 gene were analyzed by cBioPortal for Cancer Genomics online. The human EC cell lines were cultured in DMEM/F12 medium supplemented with 10% fetal bovine serum and Penicillin/Streptomycin in a humid atmosphere incubator with 5% CO2 at 37 °C. The expression of miR-449a and NDRG1 were assayed by quantitative real time-PCR Wound healing assay, migration and invasion assays were performed to detect the ability of migration and invasion in EC cells. NDRG1 and PTEN/AKT pathway were detected by immunoblotting.

Results: In this study, our analysis found that miR-449a expression is inversely correlated with the stage of endometrial cancer. Overexpression of miR-449a in human EC cells alleviated cell invasion and metastasis in vitro. Conversely, miR-449a knock-down promoted migration and invasion of EC cells. Moreover, we identified N-myc Downstream-Regulated Gene 1 (NDRG1) as a direct and functional target gene of miR-449a in EC cells, and the expression NDRG1 in 55 endometrial cancer specimens were inversely correlated with that of miR-449a. In addition to this, further studies show that down-regulation of NDRG1 inhibited migration and invasion of EC cells through PTEN/AKT pathway.

Conclusions: miR-449a suppresses metastasis of EC cells by directly targeting NDRG1 gene and activation of miR-449a may represent an effective therapeutic strategy in endometrial cancer.

40P Cancer-associated fibroblasts-derived VEGFA mediates the migration of gastric cancer cells through VEGFR1

X. Wang, X. Che, Y. Fan, M. Bai, X. Qu

Department of Medical Oncology, The First Hospital of China Medical University, Shenyang, China

Background: Cancer-associated fibroblasts (CAFs) are major components of the tumor stroma and regulators of tumor progression. CAFs are also involved in the intraperitoneal dissemination of gastric cancer cells. However, the molecular mechanism by which CAFs promote gastric cancer peritoneal dissemination should be further explored.

Methods: 1. Cell migration ability was measured using Transwell assay. 2. Protein expression was analyzed by western blot. 3. Mouse model detects peritoneal metastasis of gastric cancer cells. 4. Affymetrix scanner 3000 was used to analyse the microarray genome-wide expression. 5. Statistical analysis. All values are expressed as means ± SD. The differences of the results between two groups were evaluated by Student's t-test. $P<0.05$ was considered to be statistically significant.

Results: In our study, we found CAFs enhance the migration of gastric cancer cells through the expression of VEGFA. While VEGFA neutralizing antibody bevacizumab markedly attenuated these CAFs-induced phenotypes in gastric cancer cells. Moreover, VEGFA enhances the gastric cancer cells' ability to diffuse and metastasize in the peritoneum. And the Bevacizumab could inhibit peritoneal metastatic nodules. We further found the migration of MGC-803 was increased with VEGFA stimulation, mainly through VEGFR1 but not VEGFR2.

Conclusions: Taken together, these results revealed that the activation of VEGFR1 by CAFs-derived VEGFA enhances the migration of gastric cancer cells. And VEGFA enhances the peritoneal metastasis capacity of gastric cancer cells. Our results suggested that inhibition of VEGFA and its receptor VEGFR1 to control downstream signaling may provide a promising therapeutic target for the treatment of tumors.

41P Risk prediction of metastasis through study of circulating tumor cells

P. Apostolou, I. Papasotiriou

Research & Development, Research Genetic Cancer Centre S.A., Florina, Greece

Background: The study of circulating tumor cells (CTCs) has rapidly increased in the last decade, as this entity of cells is implicated in cancer prognosis and progression. CTCs constitute a non-homogeneous population of cells, with metastatic ability. The present study tested the gene expression profile of genes involved in metastasis in particular organs, in CTCs from cancer patients representing different cancer types and stages.

Methods: Blood samples were randomly collected from 35 patients, suffering from breast, prostate, ovarian, lung, colorectal, peritoneal, bladder, endometrial and stomach cancer. CTCs were isolated using enrichment protocols and cellular-molecular based assays were used to enumerate and study their expression profiles. qRT-QPCR for genes correlated with risk metastasis in principle (TGFBR2, ITGB5, ITGB6), risk of metastasis to pleura (CCR6), skin (CCR7), lung (IGF2R, ERK1, ERK2), bone (BMPR1A, BMPR1B, BMPR2, CXCR4, BST2), liver (CXCR4, TRAILR2, FAS, MET) and brain metastasis (STAT3, CX3CR1, DSC2) performed by using ACTB as housekeeping gene. All the reactions were performed in triplicates. A normal and a reference cancer RNA was used as control.

Results: Samples mainly from prostate, breast and squamous cancer overexpressed markers involved in general metastasis. These samples were at stage III and IV, and CTCs were 6.7±2.35/ml. For pleura and skin, overexpression was observed in samples with higher CTCs number (8.2±1.3/ml) than in prostate and ovarian cancer, respectively. Markers correlated with liver metastasis were expressed higher in breast and ovarian samples at stage IV. The majority of breast and prostate cancer samples also expressed markers correlated with bone metastasis, while squamous and ovarian cancer samples expressed genes involved in brain metastasis. By contrast, samples with lower CTCs exhibited expression in markers correlated with metastasis to lung (5.8±2.3/ml), involving breast, prostate and ovarian cancer.

Conclusions: Among same cancer type samples, different metastasis profiles were revealed, demonstrating that analysis of CTCs and particularly, their enumeration in comparison with their expression profile might be useful to focus the follow up and screening to specific organs.

42P First step to metastasis: MiRNAome abnormalities impair cell-cell adhesion and facilitate detachment of breast cancer cells

V. Halytskiy

Molecular Immunology Department, Palladin Institute of Biochemistry of the National Academy of Sciences of Ukraine, Kiev, Ukraine

Background: In order to metastasize, cancer cells must detach from neighboring cells and extracellular matrix. With regard to data that microRNAs (miRNAs) miR-18, miR-19, miR-21, miR-23, miR-29, miR-155, miR-181, miR-206, miR-210, miR-221/222 and miR-375 are usually overexpressed in breast cancer cells, this research aims to identify in what way the abnormality in miRNA signature can contribute to the disintegration of cell-cell contacts.

Methods: MiRNA targets within gene transcripts were predicted in silico using the TargetScan software.

Results: Targets of overexpressed miRNAs miR-18, miR-23, miR-25, miR-150, miR-181, miR-221/222 and miR-372/373 were found in transcript of CDH1 gene encoding E-cadherin. Transcripts of genes F11R and JAM3 encoding junctional adhesion molecules JAM-A and JAM-C carry targets of miRNAs miR-23, miR-29, miR-155, miR-181 and miR-221/222. Binding sites for miRNAs miR-23 and miR-150 were revealed in transcripts of TJP1 and TJP2 genes encoding tight junction proteins ZO-1 and ZO-2. MiRNAs miR-21, miR-29, miR-155 and miR-375 can silence CLDN1 gene encoding claudin 1. Up-regulated miRNAs miR-19, miR-21 and miR-155 can target transcript of CGN gene encoding cingulin. MiRNAs miR-18, miR-29, miR-155, miR-181 and miR-375 suppress OCLN gene coding occludin. Overexpressed miRNAs miR-21, miR-23,

miR-29, miR-155, and miR-221/222 can target transcripts of PVRL1 and PVRL3 genes encoding nectin 1 and 3. In addition, up-regulated miRNAs can silence other genes responsible for cell-cell adhesion - CADM1/3 (encoding nectin-like molecules 2/1), CTNNA1 (alpha-catenin), CTNND1 (p120-catenin) as well as genes encoding tropomyosin 1, vinculin, alpha-actinins.

Conclusions: MiRNAs, hyperexpressed in breast cancer cells, can silence genes encoding E-cadherin and numerous other epithelial junction components. This causes disruption of cell-cell adhesion, and, in addition, affects cell polarity and contact inhibition, predetermines epithelial-mesenchymal transition, detachment, movement and invasiveness of the breast cancer cells.

43P Extracellular matrix of normal brain tissue is affected by temozolomide during anti-glioblastoma treatment

A. Tsidulko[1], C. Bezier[2], G. de La Bourdonnaye[3], A.V. Suhovskih[1], G. Kazanskaya[4], S. Aidagulova[5], E.V. Grigorieva[1]

[1]Laboratory of Glycobiology, Federal Research Center of Fundamental and Translational Medicine, Novosibirsk, Russian Federation, [2]Molecular and Cellular Biology, Pierre et Marie Curie University, Paris, France, [3]Biochemical Engineering, National Institute for Applied Sciences, Toulouse, France, [4]Department. of Pathomorphology, Meshalkin National Medical Research Center, Novosibirsk, Russian Federation, [5]Department. of Histology, Embryology and Cytology, Novosibirsk State Medical University, Novosibirsk, Russian Federation

Background: Temozolomide (TMZ) is a main drug for chemotherapy of glioblastoma multiforme (GBM). During the treatment, both GBM tumour and surrounding normal brain are exposed to the drug, and its effects on the normal brain tissue are not investigated. Survival and invasion of GBM cells depend not only on their characteristics but also on the structure of extracellular matrix (ECM) of brain tissue, which consists mainly of glycosylated molecules such as proteoglycans (PGs) and glycosaminoglycans (GAGs). Here, we aimed to investigate the effects of TMZ on PGs and GAGs expression in normal brain tissue.

Methods: Two-month-old Wistar rats were used in the study, and effects of TMZ treatment on PGs (syndecan-1, glypican-1, perlecan, decorin, biglycan, lumican, brevican, neurocan, CSPG4/NG2, aggrecan) were studied using real-time RT-PCR and IHC analyses.

Results: Treatment with TMZ had almost no effects on the overall transcriptional activity of the PGs core proteins in normal brain tissue but resulted in a 2-fold increase of GAGs content (both heparin sulfates and chondroitin sulfates). Different TMZ-based drugs demonstrated different effects on the PGs core proteins expression - treatment with some of them resulted in significant decrease in syndecan-1, glypican-1, perlecan and lumican expression. Moreover, treatment with combination of TMZ and dexamethasone, commonly used to treat glioma-induced edema, led to the most dramatic changes in PGs composition in the brain tissue at both core protein and GAG levels.

Conclusions: The obtained results demonstrate that chemotherapy with temozolomide affects proteoglycan composition and ECM structure in normal brain tissue. These changes might be involved in the formation of the tumourigenic niche for the expansion of the residual glioma cells and the disease progression.

44P Study of the activation of TLR receptors in neurospheres from glioblastoma cells in vitro

D. Albert Bellver[1], R. Gil-Benso[1], A. Martínez[2], T. San-Miguel[1], L. Muñoz-Hidalgo[1], A. Carratalá[1], D. Gozalbo[2], C. López-Ginés[1], M. Cerdá-Nicolás[1], M.L. Gil[2], J. Megías[1]

[1]Pathology, University of Valencia, Valencia, Spain, [2]Microbiology and Ecology, University of Valencia, Burjassot, Spain

Background: Glioblastoma (GB) is the most aggressive brain tumor known. GB stem cells (GSC) are resistant to ordinary therapy and contribute to the development of recurrences. Toll-like receptors (TLR) are expressed in immunity cells to recognize multiple ligands from multiple infectious agents to unleash the immune response. TLRs are also expressed in neural cells, such as GB and neural stem cells, where its activation may imply cell differentiation. The aim of this study was to prove whether the stimulation of GSC TLRs induces a phenotype more sensitive to therapy and less aggressive.

Methods: Two GB cell lines were used: U-87 and U-118 (ATCC), cultured in the presence of Neurobasal® medium and in the absence of fetal bovine serum. The culture obtained was formed by neurospheres, which include a high proportion of GSC. On the one hand, the enrichment in GSC was confirmed by flow cytometry by the expression of stem cell markers CD133 and CD44. On the other hand, the analysis of TLR expression was performed by RT-PCR. According to its TLR expression, neurosphere cells were exposed to the pertinent TLR ligands for 24 hours in vitro and cultured in the presence or absence of temozolomide (TMZ). After stimulation, the expression of CD133 and CD44 was measured by flow cytometry.

Results: Flow cytometry results showed a higher proportion of GSC in the culture with Neurobasal®. RT-PCR results demonstrated expression in stem cells of the genes corresponding to TLR2, TLR3, TLR4 and TLR6 receptors. Flow cytometry post-stimulation proved a decrease of stem cell markers in the ligands of the TLR2 and TLR4 in both lines. Cultures with TMZ did not show significantly altered expression of GSC, although survival was lower than cultures without TMZ.

Conclusions: These results show a relation between the activation of the TLR and the increase of the differentiation rate in GSCs, especially through TLR2 and TLR4. Based on the results obtained, a new therapy for GB treatment, might be possible, which would include the differentiation of GSC by the exposition to TLR2 and TLR4 ligands, previous or concomitant to chemotherapy.

45P 5-fluorouracil-induced up-regulation of exosomal PD-L1 causing immunosuppression in gastric cancer patients

Z. Min, F. Yibo, C. Xiaofang, H. Kezuo, Q. Xiujuan

Department of Medical Oncology, The First Hospital of China Medical University, Shenyang, China

Background: Although 5-fluorouracil chemotherapy has been thought to directly kill cancer cells and even play an immunostimulatory role, accumulating evidence indicates 5-fluorouracil also damages function of T cells through up-regulating programmed death-1-ligand 1(PD-L1), which is a negative regulator of T cell immune ability. Previous study has shown that PD-L1 has exosomal forms secreted in the microenvironment, except for membrane bound forms and extracellular soluble forms. In addition, exosomal PD-L1 retains stronger immunosuppressive activity. However, whether 5-fluorouracil can change the expression of exosomal PD-L1 and induce immunosuppression is unknown.

Methods: We retrospectively detected exosomal PD-L1, by ELISA, in 17 stage III/IV gastric cancer patients before and after 2,4,6,8 repeated cycles of 5-fluorouracil chemotherapy treatment.

Results: Compared with the expression at baseline, exosomal PD-L1 was up-regulated gradually in the plasma of patients when 2,4,6,8 repeated cycles of 5-fluorouracil were administered, accompanied with the decreased amounts of $CD4^+$ and $CD8^+$ T cells. Mechanistically, 5-fluorouracil up-regulated PD-L1 and exosomal PD-L1 in gastric cancer cell lines. Moreover, exosomal PD-L1 derived from gastric cancer cells induced apoptosis of T cells after 48h treatment, which could be reversed by nivolumab.

Conclusions: 5-Fluorouracil up-regulated exosomal PD-L1 which induced apoptosis of T cells and caused immunosuppression in gastric cancer patients.

46P Thrombocytosis and leukocytosis: Are they negative prognostic factors in solid tumours?

F. Kohutek[1], B. Bystricky[1], M. Kohutekova[2]

[1]Department of Oncology, Faculty Hospital Trencin, Trencin, Slovak Republic, [2]Department of Otorinolaryngology, Faculty Hospital Trencin, Trencin, Slovak Republic

Background: Induction of thrombocytosis and leukocytosis by tumour is a part of complex propagative strategy of malignancy. Activated leukocytes and thrombocytes produce several cytokines and enzymes that are crucial for tumour growth, invasion and dissemination. Therefore, leukocytosis and thrombocytosis might be a negative prognostic factor in malignancies.

Methods: Thrombocyte and leukocyte count were determined before the beginning of treatment. Patients with recent bleeding, elevated CRP or treated with best-supportive care were excluded. Relationship between thrombocytosis, leukocytosis and known negative prognostic factors was assessed. The impact of thrombocytosis and leukocytosis on progression-free survival (PFS) was determined. Chi- squared test, Kaplan-Meier and Cox- regression statistical analysis were used.

Results: 500 patients with breast cancer (BC), ovarian cancer (OC), colorectal cancer (CrC), head and neck tumours (H&N) or lung cancer (LC) were included to our

retrospective study. Thrombocytosis was more frequent in patients with metastatic cancer (whole population of patients) (17.4%, 95%CI :8.1125-26.7381, p = 0.0001); in patients with CrC (27%, 95% CI: 4.1554-47.9434, p = 0.0111); in patients with OC (27.7%, 95%CI: 6.5334- 46.4296, p = 0.0063) and in patients with H&N (46.9%, 95%CI: -9.5975-72.7755, p = 0.0459). Grading, estrogen- receptor (ER) progesteron-receptor (PR) and her2 status had no impact on frequency of thrombocytosis. Thrombocytosis had no impact on PFS. Leukocytosis was more frequent among patients with metastatic malignancies (10.6 %, 95%CI: 1.4352- 19.9713, p = 0.0174). This result reflected only in the subgroup of patients with H&N (46.9%, 95%CI: -9.5975- 72.7755, p = 0.0459). Grading, PR and her2 status had no impact on frequency of leukocytosis. Leukocytosis was more frequent in BC patients with negative ER status (18.7%, 95%CI: 1.0068- 40.1859, p = 0.0158). Leukocytosis shortened PFS in patients with LC (hazard ratio 2.1126, 95%CI:1.2712- 3.5109, p = 0.0014).

Conclusions: Leukocytosis might be a negative prognostic factor in patients with LC. More studies are needed to identify the subpopulation of leukocytes responsible for this effect.

47P Evaluation of stemness and proliferation of human breast cancer stem cells (ALDH+) supplemented with heat-activated TGF-beta1 in the secretomes of stem cells from human exfoliated deciduous teeth (SHED)

S.I. Wanandi[1], G. Wideani[2], M. Zainuri[3], R.R. Putri[4], E.W. Bachtiar[5], S.W.A. Jusman[1]

[1]Biochemistry and Molecular Biology, Faculty of Medicine, Universitas Indonesia, Jakarta, Indonesia, [2]Master Program in Biomedical Sciences, Faculty of Medicine, Universitas Indonesia, Jakarta, Indonesia, [3]Doctoral Program in Biomedical Sciences, Faculty of Medicine, Universitas Indonesia, Jakarta, Indonesia, [4]Center of Biomedical and Basic Technology of Health, National Institute of Health Research and Development, Ministry of Health, Jakarta, Indonesia, [5]Oral Biology, Faculty of Dentistry, Universitas Indonesia, Jakarta, Indonesia

Background: Our previous studies have reported that the secretomes of umbilical cord- and adipose-derived mesenchymal stem cells (MSCs) affected the stemness properties of human breast CSCs (BCSCs). However, little is known about specific factors in MSC secretomes, particularly those from human exfoliated deciduous teeth, which involved in tumor aggressiveness such as stemness and proliferation of CSCs. This study aimed to evaluate the stemness and proliferation of human BCSCs after supplemented with heated secretomes of stem cells from human exfoliated deciduous teeth (SHED) to activate latent TGF-β1.

Methods: To collect SHED conditioned medium (SHED-CM) containing secretomes, SHED were grown in serum-free a-MEM for 24 and 48 hours, respectively. SHED-CM 24-h was then heated at 80^{0}C for 10 min. Human BCSCs (ALDH+) cultured in DMEM-F12 were supplemented with 50% (v/v) non-heated SHED-CM 24- and 48-h, as well as with heated SHED-CM 24-h followed by 72-h incubation. Control was BCSCs supplemented with non-heated 50% (v/v) a-MEM/DMEM-F12. Following the supplementation, we measured the mRNA expression of TGF-β1 receptor (TβRI), as well as stemness genes ALDH1A1 and OCT4 of BCSCs using qRT-PCR. BCSC proliferation was determined using trypan blue dye.

Results: This study demonstrates that relative mRNA expression levels of TβRI, OCT4 and ALDH1A1 in BCSCs supplemented with non-heated SHED-CM 24- and 48-h were increased compared to their control. Interestingly, the increase of TβRI, OCT4 and ALDH1A1 expressions after TGF-β1 heat activation was significantly higher than in non-heated SHED-CM. Conversely, BCSC proliferation was significantly reduced after supplemented with non-heated SHED-CM 24- and 48-h, but drastically increased higher than control when treated with heated SHED-CM 24-h, suggesting the involvement of other factors in SHED-CM that restrain TGF-β1 signaling and suppress cell proliferation.

Conclusions: Heated SHED secretomes contained activated TGF-β1 that increased the expression of stemness genes, OCT4 and ALDH1A1, as well as proliferation of human BCSCs (ALDH+) via TGF-β1 paracrine signaling.

48P Estrogen-related receptor α as a potential molecular target for endometrial cancer therapy

T. Kokabu, T. Mori, H. Matsushima, Y. Tarumi, K. Yoriki, H. Kuroboshi, M. Sawada, S. Umemura, J. Kitawaki

Obstetrics and Gynecology, Kyoto Prefectural University of Medicine, Kyoto, Japan

Background: Estrogen-related receptor α (ERRα) is considered to be a potential molecular target against several cancer types. We previously demonstrated that ERRα knockdown regulated tumor progression in uterine endometrial cancer. The purpose of this study was to elucidate the effects of XCT790, a selective inverse agonist of ERRα, on endometrial cancer.

Methods: HEC-1A and KLE cells, endometrial cancer cells with high expression of ERRα, and HEC-1A-derived xenograft mouse model were treated with XCT790. Cell proliferation was evaluated with WST-8 and colony formation assays. The cell cycle was examined with flow cytometry, fluorescent immunocytochemistry. The apoptotic effect was determined with TUNEL assay and caspase-3/7 assay. Proteins and mRNA levels were detected by western blotting and real-time PCR.

Results: XCT790 significantly inhibited ERRα-induced transcriptional activity in a dose-dependent manner ($P < 0.01$) without reduction of mRNA level of ERRα. XCT790 suppressed colony formation and cell proliferation in a concentration- and time-dependent manner ($P < 0.01$), without cytotoxicity. Flow cytometry, fluorescence immunocytochemistry, and western blotting indicated that XCT790 induced apoptosis ($P < 0.01$), and caused cell cycle arrest at the mitotic phase. Western blotting revealed that XCT790 inhibited Akt/mTOR signaling pathway without the alteration of the expression level of PI3K. Additionally, XCT790 significantly suppressed tumor progression in the xenograft mouse model ($P < 0.05$). XCT790 induced apoptosis and decreased Ki-67 positive cells in tissue sections ($P < 0.01$).

Conclusions: The findings of the present study suggested that XCT790 could be a novel therapeutic agent in uterine endometrial cancer.

49P Good tolerability and limited target-specific tissue distribution of an anti-L1CAM antibody administered to cynomolgus monkey indicates favorable safety profile of L1CAM-targeting therapies

J. Gaudreault[1], A. Schmidt[1], P. Altevogt[2], G. Spohn[1]

[1]RD, Elthera AG, Schlieren, Switzerland, [2]Translational Immunology, DKFZ, Heidelberg, Germany

Background: L1 cell adhesion molecule (L1CAM) is a ∼200 kDa transmembrane protein which is overexpressed in several tumor types. Its expression has been shown to be a predictor of poor outcome in several independent publications. Anti-L1CAM antibody therapy, is expected to lead to tumor regression through inhibition of tumor growth, inhibition of migration/cell adhesion, reversal of chemoresistance and cell killing via ADCC. In addition to tumors, L1CAM is expressed in a restricted set of healthy tissues, including the nervous system and kidney tubules. The current study was conducted to investigate the acute tolerability and tissue distribution of an antibody directed against L1CAM and inform about the potential target organs which might be affected by anti-L1 CAM therapy.

Methods: The acute tolerability and biodistribution of an antibody that binds with high affinity to cynomolgus monkey L1CAM was evaluated. The antibody was administered in two IV bolus injections of 20 mg/kg, 24 hours apart to a single cynomolgus monkey. Clinical signs were recorded and the animal was sacrificed 48 hours after administration of the second dose, followed by macropathological inspection and tissue collection. A second untreated control animal was used as control for subsequent analyses. Tissues from both animals were collected, paraffin-blocked, and the presence of tissue-bound anti-L1CAM antibody was detected by immunohistochemistry.

Results: Administration of the anti-L1CAM antibody was well tolerated with no signs of acute local or systemic intolerance observed. In cynomolgus monkey, specific binding was observed in kidney tubules and Kupffer's cells of the liver, while no binding was observed in the central nervous system, peripheral nerves, or any other tissues.

Conclusions: Administration of L1CAM antibody was well tolerated and the observed tissue distribution was consistent with the known expression profile of L1CAM. These data support the safety of anti-L1CAM therapy using an antibody approach.

66P TCR beta chain convergence defines the tumor infiltrating T cell repertoire of melanoma and non-small cell lung carcinoma

T. Looney[1], G. Lowman[1], L. Miller[1], E. Linch[2]

[1]*Clinical Next-Generation Sequencing Division, Thermo Fisher Scientific, South San Francisco, CA, USA,* [2]*Clinical Next-Generation Sequencing Division, Thermo Fisher Scientific, Carlsbad, CA, USA*

Background: T cell convergence refers to the process whereby antigen-driven selection enriches for T cell receptors having a shared antigen specificity but different amino acid or nucleotide sequence. T cell recruitment and expansion within the tumor microenvironment (TME) may be directed by responses to tumor neoantigen, suggesting that elevated T cell convergence could be a general feature of the tumor infiltrating T cell repertoire. Here we evaluate evidence for T cell convergence in tumor biopsy from

research subjects with melanoma and non-small cell lung carcinoma (NSCLC) and peripheral blood leukocytes (PBL) from healthy donors.

Methods: Total RNA from 63 melanoma and 19 NSCLC tumor biopsy research samples (non-FFPE) was extracted for use in long-amplicon TCRB chain sequencing (mean amplicon of 330bp covering CDR1, 2 and 3) via the Oncomine TCR Beta-LR Research Assay. To evaluate T cell convergence, we searched for instances where TCRB chains were identical in amino acid space but had distinct nucleotide sequences owing to N-addition and exonucleotide chewback within the V-D and D-J junctions of the CDR3. To provide context, we evaluated evidence for T cell convergence in PBL T cell repertoires derived from 16 healthy donors.

Results: Sequencing of melanoma biopsy research samples typically yielded within the range of 2000 to 8000 clones per sample. Convergent T cell receptors were identified in the great majority of melanoma and NSCLC tumor infiltrating T cell repertoires having greater than 100 detected clones (92% and 100%, respectively). The frequency of convergent T cell rearrangements was significantly greater in melanoma and NSCLC tumor biopsies than T cell repertoires derived from healthy PBL research samples.

Conclusions: These data suggest that T cell convergence may be a common feature of the melanoma and NSCLC infiltrating T cell repertoire. Convergence was more frequently observed within the TME than T cell repertoires derived from healthy PBL, consistent with elevated antigen-driven T cell selection within the TME. The finding of elevated T cell convergence in melanoma and NSCLC suggests that convergence may be a hallmark of immunogenic tumors. For research use only.

Background: Copanlisib, a pan-class I phosphatidylinositol 3-kinase (PI3K) inhibitor with predominant activity against α and δ isoforms, shows immune stimulating effects and anti-tumor activity in combination with immune checkpoint blockers in tumor models. Here we explore tumor PI3K signaling and the effects of copanlisib on immune and tumor microenvironment modulation in subjects with NHL and solid tumors (ST) in a phase I pharmacodynamic study (NCT02155582).

Methods: Patients received 0.4 or 0.8 mg/kg (equivalent to a flat dose of 60 mg) copanlisib on an intermittent schedule (QW, IV, 3 wks on/1 wk off). Tumor biopsies were performed at baseline and Day 15. Tumor PI3K isoforms, PTEN, and CD3, CD4 and CD8 tumor infiltrating lymphocytes (TILs) were assessed by IHC. Plasma protein markers were measured using multiplexed immunoassay. Tumor and lymphoma responses were based on RECIST 1.1 and modified Cheson 2007 criteria, respectively.

Results: A total of 61 patients were treated: 33 NHL (20 at 0.4 mg/kg and 13 at 0.8 mg/kg) and 28 ST (14 at 0.4 mg/kg and 14 at 0.8 mg/kg). Among patients treated at 0.8 mg/kg, 2 had CR (PTCL and DLBCL) and 5 had PR (MCL, FL, 2 DLBCL, and endometrial adenocarcinoma); 1 additional PR (DLBCL) occurred at 0.4 mg/kg. Tumor PI3K α was detected in most NHL (18/19) and ST (22/25) samples with comparable intensity. PI3K δ was predominantly present in NHL (18/19). PI3K ß and γ were present in a subset of NHL and ST. PTEN loss was more frequent in ST than NHL. CD3, CD4 and CD8 TIL numbers were higher in NHL than in ST. At 0.8 mg/kg copanlisib decreased tumor pAKT and pS6 in both NHL and ST, and reduced CD4 TILs in NHL (mean -81%, $n = 7$), with little effect on CD8 TILs in both NHL and ST. In plasma, copanlisib decreased cytokine/chemokines (e.g. CCL2, CCL5, CCL17), and factors associated with macrophages (e.g. CD163, CCL4, CCL22) and Treg cells (IL-2Ra). High baseline levels of CD27 and IL2Ra were associated with tumor reduction in NHL ($p < 0.05$, unadjusted).

Conclusions: The high prevalence of the PI3K isoforms – especially α in both NHL and ST and δ in NHL – is consistent with a role for PI3K signaling in immune suppression. The immune modulation profile for copanlisib supports combination studies with immunotherapy.

68P Pan-squamous genomic profiling stratified by anatomic tumor site and viral association

M. Montesion[1], C.H. Chung[2], E.S. Sokol[1], S.A. Khan[3], H. Kang[4], L.A. Albacker[1], J.M. Johnson[5], G.M. Frampton[1], V.A. Miller[6], J.S. Ross[7], S.M. Ali[6]

[1]Cancer Genomics Research, Foundation Medicine, Inc., Cambridge, MA, USA, [2]Department of Head and Neck-Endocrine Oncology, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL, USA, [3]Department of Internal Medicine, University of Texas Southwestern Medical Center, Dallas, TX, USA, [4]Department of Oncology, Johns Hopkins University School of Medicine, Baltimore, MD, USA, [5]Department of Medical Oncology, Thomas Jefferson University, Philadelphia, PA, USA, [6]Clinical Development, Foundation Medicine, Inc., Cambridge, MA, USA, [7]Pathology, Foundation Medicine Inc., Cambridge, MA, USA

Background: Squamous cell carcinomas (SCC) have diverse anatomic etiologies but may share common genomic biomarkers. We profiled 7,871 unique SCCs across nine anatomic sites to investigate commonality in genomic alterations (GA), tumor mutational burden (TMB), human papillomavirus (HPV) association, and mutational signatures.

Methods: Tissue from over 8,100 unique SCC samples originating from nine anatomic sites (anogenital (anus, cervix, penis, vagina, vulva), esophagus, head and neck, lung, and skin) were sequenced by hybrid capture-based comprehensive genomic profiling to evaluate GA and TMB. About 3% of non-cutaneous SCC samples had UV signatures, indicative of potential primary site misdiagnoses, and were filtered from the analysis. Detection of HPV, including high-risk strains 16, 18, 31, 33, and 45, was implemented through de novo assembly of non-human sequencing reads and BLASTn comparison against all viral nucleotide sequences in the NCBI database.

Results: The proportion of HPV+ patients by anatomic site varied, with the highest being anal (91%) and cervical (83%). The mutational landscape of each cohort was similar, regardless of anatomic origin, but clustered based on HPV status. The largest differences in GA frequency as stratified by HPV- vs. HPV+ were TP53 (87% vs. 12%), CDKN2A (45% vs. 6%), and PIK3CA (22% vs. 33%). The median TMB in cases originating from HPV-associated sites was similar, regardless of HPV status. Higher median TMB was observed in lung and skin cases, which exhibited significant enrichment of mutational signatures indicative of tobacco- and UV-induced DNA damage, respectively.

Conclusions: HPV+ and HPV- SCC populations have distinct genomic profiles and, for the latter, anatomic site is correlated with TMB distribution, secondary to associated carcinogen exposure. As such, biomarkers such as TMB and UV signature can provide unexpected insight into site of origin misdiagnoses and may correlate with benefit from immune checkpoint inhibitors.

Table: 68P

Tumor Site	% HPV+	Median TMB (Interquartile Range)	% TMB >= 10	% TMB >= 20
Anogenital (n = 1213)	76	5 (6)	17	5
Head and Neck (n = 1843)	36	4 (5)	15	5
Esophageal (n = 416)	6	5 (4)	13	2
Lung (n = 3977)	5	9 (8)	43	9
Skin (n = 422)	8	40 (69)	68	62

69P Toward the standardization of bioinformatics methods for the accurate assessment of tumor mutational burden (TMB)

H. Chang, S. Srinivasan, A. Sasson, R. Golhar, D. Greenawalt, S. Kirov, J.D. Szustakowski

Translational Medicine, Bristol-Myers Squibb, Princeton, NJ, USA

Background: TMB has emerged as a predictive biomarker of response to immune checkpoint inhibitors. CheckMate 227 demonstrated that patients with non-small cell lung cancer (NSCLC) with TMB ≥10 mutations/megabase derived enhanced benefit from first-line treatment with nivolumab + ipilimumab vs chemotherapy (Hellmann et al. NEJM 2018). Standardized approaches for the measurement and reporting of TMB are essential for the real-world implementation of TMB. This study aimed to refine a bioinformatic pipeline for mutation calling and annotation of whole exome sequencing (WES) data for TMB assessment.

Methods: In CheckMate 026, TMB was assessed by WES on formalin-fixed, paraffin-embedded tumor samples and matched blood from 312 patients with NSCLC (Carbone et al. NEJM 2017). Data from each sample were aligned to a reference human genome and somatic mutations were called by comparing matched tumor and blood samples using the TNsnv and Strelka algorithms. The somatic mutations were additionally filtered for germline variants in public databases. TMB scores were compared with data from 710 NSCLC samples in The Cancer Genome Atlas (TCGA) dataset. We examined the concordance of TMB estimates using several mutation filtering schemes, with and without matched germline controls.

Results: TMB scores including synonymous, indel, frameshift, and nonsense mutations (all mutations) were ~3-fold higher than matched data filtered for missense mutations only, but values were highly correlated (Spearman's $r = 0.99$). Scores including missense mutations only were similar to those generated from TCGA, but those including all mutations were on average higher. Using public databases for germline subtraction showed a trend for race-dependent increases in TMB scores.

Conclusions: Standardization of bioinformatic analyses is critical to the clinical implementation of TMB assessment. TMB assessment is sensitive to variations in bioinformatic parameters (eg, which type of mutation to include), which may affect the identification of patients likely to respond to immunotherapy. These results show that data from different pipelines are highly correlated, suggesting that reliable assessment of TMB across different centers and platforms is achievable.

70P Prediction of primary resistance to anti-PD1 therapy (APD1) in second-line NSCLC

E.F. Smit[1], J.G. Aerts[2], M. Muller[1], A-L.N. Niemeijer[3], H. Roder[4], C. Oliveira[4], J. Roder[4]

[1]Pulmonary Diseases, The Netherlands Cancer Institute, Amsterdam, Netherlands, [2]Medical Oncology, Erasmus University Medical Center, Rotterdam, Netherlands, [3]Department of Pulmonology and Respiratory Medicine, Vrije University Medical Centre (VUMC), Amsterdam, Netherlands, [4]Research, Biodesix, Inc., Boulder, CO, USA

Background: APD1, while capable of restoring immunity, does not benefit all patients. While molecular tests like PD-L1 expression and TMB help in enriching response in respective subsets, a test identifying patients showing primary resistance to APD1 which does not require tissue samples could help in optimizing treatment regimens.

Methods: Outcome data (PFS/OS) were correlated with protein profiles from mass spectrometry of the circulating proteome of pretreatment serum from 116 2nd line NSCLC patients treated with nivolumab (development set S) using multivariate machine learning methods related to deep learning. The resulting test stratified patients into three groups: group A having very poor outcomes, group B having intermediate outcomes, and group C having very good outcomes. Development results were obtained using out-of-bag estimators. Two additional patient cohorts treated with nivolumab, V1($N = 58$) and V2($N = 75$), were used for validation.

Results: The proportions of patients in A, B, and C were 41:43:32 in S, 23:18:17 in V1, and 32:19:24 in V2. Median PFS/OS in the poor prognosis group A was 43/132 days in S, 105/189 days in V1, 90/278 days in V2, and in the good prognosis group C 276/528 days in S, 192/459 days in V1, and 155/not reached days in V2. In a comparison with historical controls treated with single agent chemotherapy and analyzed with the same technique, nivolumab appeared substantially superior in the good prognosis group C, while there was no evidence of superiority in the poor prognosis group A. In multivariate analysis including performance status, smoking history, and histology, the test remained an independent predictor of outcome. The patterns of protein expression related to poor prognosis in group A patients were associated with elevated complement, wound healing, and acute phase reactants.

Conclusions: We developed and validated a test stratifying patients into three groups with significantly different outcomes on nivolumab. The poor prognosis group showed little benefit from nivolumab, and other treatments may be needed, while in the good prognosis group outcomes were very good for a 2nd line population. These results emphasize the importance of the host immune response in the prediction of APD1 efficacy.

71P Immunomodulatory germline variation impacts the development of multiple primary melanoma (MPM)

R. Ferguson[1], A. Archambault[1], D. Simpson[1], E. Kazlow[1], R. Lax[1], U. Moran[1], M.A. Wilson[2], R. Shapiro[2], A. Pavlick[2], I. Osman[3], D. Polsky[3], T. Kirchhoff[4]

[1]Perlmutter Cancer Center, New York University Medical Center, New York, NY, USA, [2]Department of Medicine, New York University - Perlmutter Cancer Center - Langone Medical Center, New York, NY, USA, [3]Dermatology, New York University Medical Center, New York, NY, USA, [4]Perlmutter Cancer Center, New York University, New York, NY, USA

Background: During their lifetime about 8% of patients with single primary cutaneous melanoma (SPM) will develop multiple primary melanomas (MPM), which are associated with significantly higher mortality compared to patients with SPM. Based on the evidence that the immune system plays a role in regulating melanoma progression we explored whether germline genetic variants controlling the expression of immunomodulatory genes (immunomodulatory quantitative trait loci, eQTLs) discern risk of MPM compared to patients with SPM or healthy controls.

Methods: Previously, we identified 50 eQTLs significantly associated with the expression of 265 immunomodulatory genes using the MuTHer twin cohort. These 50 SNPs were genotyped in 837 SPM and 104 MPM individuals using MassARRAY system. 1047 healthy controls were obtained from a publically available GWAS on CM ascertained at MD Anderson (phs000187.v1.p1). We employed multivariate logistic regression to test the association of SNPs with MPM vs cancer-free controls and MPM vs SPM.

Results: When comparing MPM vs SPM, rs2071304, previously linked to expression of SPI1 in MuTHer data, showed a strong association with reduction of MPM risk ($OR = 0.60$; 95% CI = 0.45-0.81; $p = 0.0007$). Intriguingly, this variant also trended toward significance when comparing MPM vs controls ($OR = 0.61$; 95% CI: 0.44-0.85; $p = 0.003$). Finally, our most significant association when comparing MPM to controls was for rs2276645 ($OR = 0.60$; 95% CI = 0.45-0.81; $p = 0.0008$), an eQTL associated with Zap-70 expression.

Conclusions: Our data, for the first time, indicate that the inherited host immunity impacts risk of MPM in individuals with SPM, highlighting an importance of immune involvement in melanoma progression. The MPM risk-predicting genetic variants identified here or in expanded efforts, currently underway, may eventually lead to a diagnostic tool allowing for enhanced screening and clinical management of patients at risk of MPM, hence reducing elevated MPM-associated mortality. Additionally, our results further support that MPM and SPM may have different genetics underpinnings and should be treated as separate clinical entities.

72P Leukocyte telomere length and recurrence risk after EGFR-TKIs therapy in patients with advanced lung adenocarcinoma

M. Yang[1], J. Li[2], N. Zhang[2], H. Xing[1], J. Liu[1]

[1]Shandong Provincial Key Laboratory of Radiation Oncology, Cancer Research Center, Shandong Cancer Hospital, Jinan, China, [2]Department of Radiation Oncology, Shandong Cancer Hospital, Jinan, China

Background: Gefitinib is currently one of the mostly used epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKIs) recommended for treating non-small cell lung cancer. However, the factors that predict treatment prognosis and drug resistance to EGFR-TKIs remain elusive. The objective of this study is to exam the association between leukocyte relative telomere length (RTL) and prognosis or drug resistance of advanced lung adenocarcinoma to gefitinib treatment.

Methods: In this study, three hundred and sixty-nine patients with stage IIIB or IV lung adenocarcinoma were recruited between January 2009 and June 2013. All patients were treated with gefitinib orally at a daily dose of 250 mg as first-line monotherapy. Leukocyte RTL of each patient was measured using quantitative polymerase chain reaction (qPCR) protocol on an ABI PRISM 7900HT Sequence Detection System (Applied Biosystems) and calculated according to Cawthon's formula. Differences in patients' characteristics were calculated by Pearson's χ^2 tests or Student's t test. Cox proportional hazard regression analyses were used to calculate univariate and multivariate hazard ratios (HRs). Survival differences were examined using the log-rank test. Two-sided $P < 0.05$ indicated a significant difference.

Results: Among 369 patients, EGFR mutations were positive in 181 patients (49.1%). Compared to long RTL, short leukocyte RTL was significantly associated with poor prognosis in all patients after gefitinib treatment (overall survival: 12.9 months vs. 17.8 months, $P = 1.2 \times 10^{-4}$; progression free survival: 7.8 months vs. 13.0 months, $P = 0.043$). Additionally, statistically significant association between short leukocyte RTL and shorten OS still existed among the EGFR mutant patients with gefitinib treatment (HR = 1.65, 95% CI = 1.28-2.12; $P = 0.006$). Besides EGFR mutation status, short RTL also contributed to significantly elevated risk of gefitinib primary resistance (HR = 1.50, 95% CI = 1.05-2.15, $P = 0.027$).

Conclusions: Our results highlight the potential of leukocyte RTL as a novel biomarker in advanced lung adenocarcinoma treated with EGFR-TKIs and the possibility of patient-tailored decisions based on leukocyte RTL.

73P Gene embedding: A novel machine learning approach to identify gene candidates related to immunotherapy responsiveness

C.T. Choy[1], C.H. Wong[2], S.L. Chan[2]
[1]Department of Clinical Oncology, Faculty of Medicine, The Chinese University of Hong Kong, Hong Kong, China, [2]The Cancer Drug Testing Unit, State Key Laboratory of Oncology in South China, Department of Clinical Oncology, Faculty of Medicine, The Chinese University of Hong Kong, Hong Kong, China

Background: Apart from PD-L1 and mutational load, there are no genetic predictive biomarkers for checkpoint inhibitors treatment. In this study, gene embedding, a machine learning technique, was used to single out related genes of immune checkpoint proteins (i.e. PD-1, PD-L1, CTLA-4) as new potential predictors for such responders.

Methods: TCGA RNASeqV2 level 3 RSEM normalized read counts (January 2016) were downloaded from the Broad Institute TCGA GDAC Firehose. A shallow neural network, aka embedding layers for samples and genes, were trained using log2 transformed data. Neighbors closeness were evaluated by euclidean distance. The model was kept blind from any additional information, including cancer types, protein-protein interactions and gene ontologies.

Results: Gene expressions of 13045 samples from 36 cancer types were embedded into 50-dimension space, while cancer types were learnt by the model without supervision. Immunotherapy responders and non-responders were stimulated from melanoma (SKMC) and lung squamous cell carcinoma (LUSC) data, and hepatocellular carcinoma and prostate cancer data respectively. 9 genes (TNFRSF8, CLEC10A, FCN1, CD8B, SLA2, IL2RA, CTLA4, GZMH), 3 (CD101, LOC154761, RNF152) genes, and 6 (SH2D1A, MEI1, PDCD1, GFI1, SIT1, SIRPG) genes were found to be closely related neighbors with PD-1, PD-L1, and CTLA-4 respectively in responders but not in non-responders. All neighbors were neither co-expressed in SKMC/LUSC dataset nor indicated as interacting partners on existing databases (BioGRID, MINT, iRefWeb, STRING, HPRD and Reactome). 88.8% genes were evidenced as either directly related to checkpoint proteins and/or T cells activation in literature. Further evaluation of the role of identified targets in immune checkpoint blockade therapy would be warranted.

Conclusions: We identified potential biomarker candidates for immune checkpoint blockade therapy by TCGA data mining and demonstrated the utility of gene embedding learned from big gene expression dataset as a powerful tool to uncover gene relationships that may not be discovered otherwise without prior knowledge on functional interactions.

74P Common and rare DPYD variants are predictive for 5FU/capecitabine (5FU) toxicity: The MRC COIN and COIN-B trials

A. Madi[1], D. Fisher[2], T.S. Maughan[3], J.P. Colley[4], A.M. Meade[2], J. Maynard[4], V. Humphreys[4], H. Wasan[5], R.A. Adams[4], S. Idziaszczyk[4], R. Harris[4], R.S. Kaplan[2], J.P. Cheadle[4]
[1]Medical Oncology, Clatterbridge Cancer Center, Wirral, UK, [2]Clinical Trials Unit, MRC, London, UK, [3]CRUK/MRC Oxford Institute for Radiation Oncology, University of Oxford, Oxford, UK, [4]Division of Cancer and Genetics, Cardiff University, Cardiff, UK, [5]Hammersmith Hospital, Imperial College Healthcare NHS Trust, London, UK

Background: Rare genetic variants in DPYP increase toxicity and screening for them prevents serious complications by upfront reduction in 5FU dose; however, most patients with severe toxicities do not have a rare mutation. We have previously shown that 2 common DPYD variants were associated with toxicity in patients with advanced colorectal cancer treated on COIN & COIN-B (abstract 3509, ASCO 2013): Cys29Arg [rs1801265] (Minor Allele Frequency (MAF) 0.21) and Val732Ile [rs1801160] (MAF 0.04). We have now genotyped 4 rare variants using the same cohort.

Methods: Blood samples were available from 2183 patients treated with first line oxaliplatin-5FU ± cetuximab. We assayed IVS14 + 1G>A [rs3918290], Asp949Val [rs67376798], Lys259Glu [rs45589337] and Ser534Asn [rs1801158] using KASPar. Primary endpoint was dose reduction or delay in chemotherapy in the first 12 weeks of treatment due to any toxicity except neuropathy. Secondary endpoints were grade $\geq$2 versus grade <2 for neutropenia, lethargy, Nausea & Vomiting (N&V), diarrhoea, stomatitis, Hand-Foot Syndrome (HFS) and infection.

Results: Two rare variants were associated with toxicity (OR (95% CI)): Asp949Val with neutropenia 3.2 (1.2-8.2) P = 0.019, N&V 3.4 (1.5-7.3) P = 0.002, diarrhoea 4.6 (2.1-10.1) P < 0.001 and infection 5.5 (1.3-24.2) P = 0.024; IVS14 + 1G>A with lethargy 5.3 (1.9-14.9) P = 0.002, diarrhoea 4.4 (1.7-11.0) P = 0.002, stomatitis 4.6 (1.7-12.6) P = 0.003, HFS 3.8 (1.2- 11.8) P = 0.021 and infection 19.2 (5.0-73.8) P < 0.001. MAF was 0.007 and 0.005, respectively. The effect on toxicity for our 2 common variants was not as marked (OR (95% CI)): Cys29Arg 0.8 (0.7-1.0) P = 0.008 (protective) and Val732Ile 1.6 (1.1-2.1) P = 0.006 for the primary endpoint.

Conclusions: We have validated 2 mutations, Asp949Val and IVS14 + 1G>A, as predictors for 5FU toxicity in a large cohort of patients and recommend they should be screened for. Our data suggest that common DPYD variants are also associated with toxicity but not to the same level seen with rare ones. While the presence of a single common variant is not an indication for dose modification, the presence of multiple variants in a patient might be. Further work is needed to establish what combinations of common DPYD variants would necessitate 5FU dose alteration.

75P The landscape of NTRK fusions in Chinese patients with solid tumor

Q. Ling[1], B. Li[2], X. Wu[3], H. Wang[4], Y. Shen[5], M. Xiao[6], Z. Yang[6], R. Ma[7], D. Chen[8], H. Chen[9], X. Dong[8], W. Wang[10], M. Yao[7]
[1]Department of Hepatobiliary & Pancreatic Surgery, The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China, [2]Department of General Medicine, Affiliated Tumor Hospital of Guangxi Medical University, Nanning, China, [3]Department of Thoracic Surgery, Nanfang Hospital, Guangzhou, China, [4]Respiratory Oncology Department, Cancer Hospital of Shantou University Medical College, Shantou, China, [5]Department of Gynecology, Zhongda Hospital, Medical School, Southeast University, Nanjing, China, [6]Department of Hepatobiliary & Pancreatic Surgery, Shu Lan (Hangzhou) Hospital, Zhejiang University International Hospital, Hangzhou, China, [7]Medical Department, OrigiMed, Shanghai, China, [8]Department of Pathology, OrigiMed, Shanghai, China, [9]Department of Bioinformatics, OrigiMed, Shanghai, China, [10]Department of Cancer Immunology, OrigiMed, Shanghai, China

Background: NTRK gene fusions resulting in the elevated expression of TRK kinases were discovered in a wide variety of tumor types but generally at a low frequency. TRK inhibitors such as LOXO-101 and entrectinib had remarkable and durable antitumor activities in patients (pts) with TRK fusion-positive cancers, regardless of age or tumor type.

Methods: FFPE tumor samples of over 3700 Chinese solid tumor pts were collected for NGS-based assay. We measured the gene fusions, mutations, and copy number alterations in tumor tissue against matched blood. Pan-Trk IHC testing was performed on five NTRK1 fusions.

Results: 12 pts were idendified as NTRK fusion positive, which accounted to approximately 0.3% of the Chinese solid tumor pts in our cohort. Seven out of 12 pts harbored NTRK1 fusions with 6 partners, and the remaining ones were NTRK3 fusions with 2 partners. The half fusions with novel partner genes or breakpoints were defined as likely fusions. The tumor types of pts with NTRK fusions included NSCLC, colorectal cancer (CRC), prostate cancer and fibrosarcoma. NTRK fusions were more likely t occur in NSCLC and CRC, which accouted for 0.3% and 1.4%, respectively. Three predicted likely fusions and two known fusions were selected to perform pan-Trk IHC assay, and four were IHC positive. One known TPR-NTRK1 fusion not detected by IHC, which highlighted the necessity to use NGS to detect NTRK fusions due to higher sensitivity and capability. NTRK fusions were not always mutually exclusive with driver mutations. Three lung cancer pts with NTRK fusions also harbored EGFR-sensitive mutations.

Table: 75P

Gene fusion	Cancer type	IHC	Pathogenic
NTRK1			
TPM3 exon10-NTRK1 exon8	Colorectal cancer	Positive	Likely
IRF2BP2 exon1-NTRK1 exon8	Prostate cancer	Positive	Likely
PRDX1 exon5-NTRK1 exon12	Lung adenocarcinoma	Positive	Likely
LMNA exon2-NTRK1 exon11	Fibrosarcoma	Positive	Known
TPR exon21-NTRK1 exon 9	Lung adenocarcinoma	Negative	Known
TPM3 exon10-NTRK1 exon8	Colorectal cancer	NA	Likely
AMOTL2 exon6-NTRK1 exon12	Lung adenocarcinoma	NA	Likely
NTRK3			
ETV6 exon5 -NTRK3 exon15	Colorectal cancer	NA	Known
ETV6 exon5 -NTRK3 exon15	Colorectal cancer	NA	Known
ETV6 exon5 -NTRK3 exon15	Squamous cell lung cancer	NA	Known
ETV6 exon4 -NTRK3 exon14	Small cell lung cancer	NA	Known
AKAP13 exon3-NTRK3 exon14	Lung adenocarcinoma	NA	Likely

Conclusions: This study revealed NTRK fuisons in approximately 0.3% of Chinese solid tumor pts for the first time. The NTRK gene fusions more commonly occurred in NSCLC (0.3%) and CRC (1.4%), but may occur with other targetable alterations such as EGFR-activating mutations. NGS panel sequencing showed the advantage of detecting NTRK fusion and providing structure information of partners which could potentially guide more precise treatment options.

76P Correlative analyses of serum biomarkers and efficacy outcomes in the randomized phase II trial of lenvatinib (LEN), everolimus (EVE), or LEN+EVE in patients with metastatic renal cell carcinoma

C-H. Lee[1], R.J. Motzer[1], H. Glen[2], M.D. Michaelson[3], J. Larkin[4], Y. Minoshima[5], M. Kanekiyo[5], R. Dairiki[5], P. Sachdev[6], C.E. Dutcus[6], Y. Funahashi[5], M.H. Voss[1]

[1]Department of Medicine, Memorial Sloan-Kettering Cancer Center, New York, NY, USA, [2]Medical Oncology, Beatson West of Scotland Cancer Centre, Glasgow, UK, [3]Hematology/Oncology, Massachusetts General Hospital, Boston, MA, USA, [4]Department of Medical Oncology, Royal Marsden NHS Hospital, London, UK, [5]Eisai Co., Ltd., Ibaraki, Japan, [6]Oncology Business Group, Eisai Inc., Woodcliff Lake, NJ, USA

Background: In a randomized, 3-arm, phase 2 trial of patients (pts) with metastatic renal cell carcinoma (mRCC) following 1 VEGF-targeted therapy, LEN+EVE improved median progression-free survival (PFS) compared with EVE (hazard ratio [HR] 0.40; 95% confidence interval [CI] 0.24–0.68; $P < 0.001$) or LEN (HR 0.66; 95% CI 0.39–1.10; $P = 0.121$).(Motzer et al. Lancet Oncol 2015) We present biomarker analyses from this study.

Methods: Serum samples collected at baseline were analyzed by Luminex-based xMAP® assays for 40 candidate biomarkers. Baseline biomarker levels were correlated with PFS using Cox regression analysis. Biomarkers with the strongest associations (top 5 ranked by log-rank P-value and HR) with PFS in the LEN+EVE arm were integrated into composite biomarker scores (CBS)(Voss et al. Br J Cancer 2016) All P-values are nominal.

Results: Serum samples from 145 pts (LEN+EVE, n = 49; LEN, n = 50; EVE, n = 46) were analyzed. HGF, MIG, IL-18BP, IL-18, and ANG-2 concentrations demonstrated the strongest correlation with PFS and were selected for the CBS analysis. Associations with PFS are summarized in the table. In the LEN+EVE arm, median PFS for pts with high (3–5) vs low (0–2) CBS was 20.1 vs 5.6 months, respectively (HR 0.28; $P = 0.002$), whereas no significant difference between high vs low CBS was seen in the EVE arm (3.6 vs 5.5 months; HR 1.02; $P = 0.951$). Median PFS differed significantly between treatment arms for pts with high CBS (LEN+EVE vs EVE, 20.1 vs 3.6 months; $P < 0.001$), but not for pts with low CBS (LEN+EVE vs EVE, 5.6 vs 5.5 months; $P = 0.329$).

Table: 76P

	LEN+EVE		EVE		LEN+EVE vs EVE HR (95% CI)
	n	Median PFS (months)	n	Median PFS (months)	
Total	51	14.6	50	5.5	0.40 (CI 0.24–0.68) $P < 0.001$
High CBS	28	20.1	20	3.6	0.19 (0.09–0.41) $P < 0.001$
Low CBS	20	5.6	24	5.5	0.70 (0.34–1.43) $P = 0.329$
High vs low HR (95% CI)	0.28 (0.12–0.63) $P = 0.002$		1.02 (0.52–1.99) $P = 0.951$		

Conclusions: In pts treated with LEN+EVE, high CBS was correlated with PFS benefit; further research is needed to determine if the score can be used to identify pts who may benefit from combination therapy. Altogether, these biomarkers may be predictors of response to LEN+EVE therapy in pts with mRCC.

Clinical trial identification: NCT01136733.

77P End-to-end learning to predict survival in patients with gastric cancer using convolutional neural networks

A. Meier[1], K. Nekolla[1], S. Earle[2], L. Hewitt[3], T. Aoyama[4], T. Yoshikawa[5], G. Schmidt[1], R. Huss[1], H.I. Grabsch[3]

[1]Research, Definiens AG, Munich, Germany, [2]Leeds Institute of Cancer and Pathology, University of Leeds, Leeds, UK, [3]Department of Pathology, Maastricht University, Maastricht, Netherlands, [4]Department of Surgery, Yokohama City University Hospital, Yokohama, Japan, [5]Department of Gastric Surgery, National Cancer Center Hospital, Tokyo, Japan

Background: While established deep learning approaches for histopathology usually consist of a two-step process, a cell or region segmentation and subsequent feature calculation, end-to-end learning has been used to predict patient survival directly from digital tissue sections. We aimed to apply a deep learning approach in a series of gastric cancer (GC) tissue microarrays (TMAs) in order to identify regions in the tissue related to a high-risk of poor survival, and subsequently stratify patients into two risk groups.

Methods: Image patches (size 80µm) were extracted from 469 TMA cores constructed from 248 GC resection specimens which were scanned after immunohistochemistry for CD8 and KI67. For each stain, a survival convolutional neural network (CNN) was trained to maximize a log partial likelihood derived from the Cox proportional hazards model [Mobadersany, PNAS, 2018] and to predict patch-based risks for cancer-specific death in a 10-fold pre-validation procedure, creating risk heatmaps for each core. Aggregation from patch to patient level was done by averaging the risks from all patches of each patient.

Results: We generated risk heatmaps comprising on median 1300 image patches per patient for the CD8 and KI67 stained tissue sections. Stratifying patients into low- and high-risk groups by taking the cohort median as threshold led to a significant log-rank test p-value (<0.01). Regarding the Lauren classification, the diffuse type was associated with higher risks than the intestinal type (T-test p-value < 0.015). Visual assessment of the risk heatmaps revealed an association of low-risk regions in CD8-stained sections with clusters of CD8(+) cells and presence of CD8(+) cells in stroma, whereas tumor epithelium and stroma regions with a low density of CD8(+) cells are associated with higher risks.

Conclusions: We applied survival CNNs to IHC stained gastric cancer tissue samples to directly associate image regions with cancer-specific death risks. This information may be used to deepen our knowledge on how tissue morphology relates to survival risk, and to stratify patients into high and low risk groups. Our results will be extended to other biomarkers and will be validated using data from another clinical site.

78P Detection of targetable kinase fusions in 7260 patients in an integrated cancer system

A. Parikh[1], S.M. Ali[2], A. Moran[3], P. Crilley[1], A.B. Schrock[4], A. Tan[5], P. Reddy[2], V.A. Miller[4], J.S. Ross[6], S. Zook[3], R.H. Alvarez[3], M. Markman[1]

[1]Medical Oncology, Cancer Treatment Centers of America, Philadelphia, PA, USA, [2]Oncology, Foundation Medicine, Boston, MA, USA, [3]Medical Oncology, Cancer Treatment Centers of America, Newnan, GA, USA, [4]Genetics, Foundation Medicine, Inc., Cambridge, MA, USA, [5]Medical Oncology, Cancer Treatment Centers of America, Goodyear, AZ, USA, [6]Pathology Group, Foundation Medicine Inc., Cambridge, MA, USA

Background: Kinase fusions (KF), such as those involving ALK, are eminently targetable genomic alterations (GA) in lung and other cancers, the latter suggested by early clinical evidence (PMID: 29079636). We undertook a review of 7260 patient samples from a tertiary cancer care-focused network of five hospitals assayed with comprehensive genomic profiling (CGP).

Methods: Hybrid capture based CGP was performed on 7260 advanced cancer cases (12/2012-2/2018), with assessment of at least 186 genes (intronic baiting for at least 14) in tissue, and 62 genes (intronic baiting for 6) in circulating tumor DNA samples. Tumor mutational burden (TMB) was determined up to 1.2 Mbp of sequenced DNA.

Results: 77/7260 (1%) samples in this series harbored KF. Patients (pts) with KF+ tumors had a median age of 53 years vs. 56 years in the overall population. The TMB in KF+ cases was 3.51 mut/Mb vs. 4.39 mut/Mb for all cases. KF were found in 55 lung (71%) and 22 (29%) non-lung samples. Of KF+ cases, 71% were non-small cell lung cancer, and the remainder were sarcoma (5%), breast cancer (4%), thyroid (4%), cancer of unknown primary (4%), pancreatic (3%), colorectal (3%) and others (1% each).

Of KF+ non-lung cases, 39% had BRAF fusions, 30% had ALK fusions, 26% had RET fusions, and 4% had ROS1 fusions. One KF+ sarcoma pt received matched targeted therapy with ALK inhibitors including ceritinib and crizotinib. More recently, in 2017 samples alone, 42% (10/24) of KF+ cases were non-lung.

Conclusions: Greater access to CGP has led to increased detection of advanced cancer patients with tumors harboring KF, particularly those with non-lung cancers. The low frequency of the latter is a challenge for clinical investigation. As such, innovative solutions such as basket trial for kinase inhibitors are needed, which may be feasible in an integrated cancer care system with high patient volume.

79P Clinical and analytical validation of an FDA approved comprehensive genomic profiling (CGP) assay incorporating multiple companion diagnostics for targeted and immunotherapies

Y. Li[1], J.X. Sun[1], J. Skoletsky[1], C. Milbury[1], C. Burns[1], W-K. Yip[1], N. Dewal[2], J. He[1], J. Tuesdell[3], E. Peters[4], E. Schleifman[5], J. Noe[6], S. Jenkins[7], J.A. Elvin[2], G. Otto[1], D. Lipson[8], J.S. Ross[2], V.A. Miller[2], M. Doherty[1], C. Vietz[1]

[1]Product Development, Foundation Medicine, Inc., Cambridge, MA, USA, [2]Genetics, Foundation Medicine, Inc., Cambridge, MA, USA, [3]Product Marketing, Foundation Medicine, Inc., Cambridge, MA, USA, [4]Companion Diagnostics, Genentech, Inc., San Francisco, CA, USA, [5]Companion Diagnostic Development, Oncology Biomarker Development, Genentech, Inc., South San Francisco, CA, USA, [6]Oncology Biomarker Development, Hoffmann La Roche, Basel, Switzerland, [7]Personalised Medicine and Biomarkers, Astrazeneca, Macclesfield, UK, [8]Foundation Medicine, Cambridge, MA, USA

Background: Due to the compelling predictive value of companion diagnostic (CDx) biomarkers tied to targeted and immune-based therapies, well-characterized robust analytic and clinical validation of genomic assays has become mandatory. An NGS-based CGP (comprehensive genomic profiling) platform was developed in compliance with FDA guidelines for CDx indications.

Methods: DNA extracted from FFPE tumor tissue underwent whole-genome shotgun library construction and hybridization-based capture, followed by sequencing using Illumina HiSeq 4000. Sequence data were processed using a proprietary analysis pipeline designed to identify sub substitutions, indels, copy number alterations, genomic rearrangements, microsatellite instability (MSI), and tumor mutational burden (TMB) in 324 genes.

Results: Clinical validity was demonstrated by establishing statistical non-inferiority between CGP and the respective approved CDx, e.g. cobas EGFR and BRAF mutational testing, ALK rearrangements with FISH and IHC, ERBB2 amplification with FISH, and others. For analytical validity, concordance with an orthogonal NGS platform was 94.6% for substitutions and indels, and within-assay reproducibility had positive percent agreement (PPA) of 99.4%. TMB was analytically validated via concordance with whole-exome sequencing. For the first 616 patients (25% non-small cell lung cancer) assayed in clinical care, 6.8% of cases had TMB exceeding 20 mut/Mb, with 25% of these also harboring microsatellite instability. For 143 NSCLC cases, >50% harbored 10 mut/Mb. Of 354 cases with CDx findings possible, 25.6% had such findings, which were split nearly evenly between indications to benefit from and contraindications to targeted therapies.

Conclusions: We developed a CGP assay and demonstrated clinical and analytical validity for CDx biomarkers for targeted therapy, with clinical validation for TMB in progress via correlation with prospective immunotherapy trials. Initial oncologist feedback indicates impact of assay results on course of treatment decisions in patient care.

80P SET overexpression promotes colorectal cancer progression and determines poor outcome in patients with localized disease

B. Torrejón[1], M. Pedregal Trujillo[2], A. Santos[1], J. Rubio[2], M. Luque[1], M. Sanz[1], C. Carames[2], S. Zazo[1], J. Madoz-Gurpide[1], F. Rojo[1], J. Garcia Foncillas[2], C. Ion[1]

[1]Molecular Biology, University Hospital "Fundacion Jimenez Diaz", Madrid, Spain, [2]Clinical Oncology, University Hospital "Fundacion Jimenez Diaz", Madrid, Spain

Background: SET deregulation is an alteration that determines poor outcome in metastatic colorectal cancer (CRC) patients promoting cell growth and decreasing sensitivity to standard chemotherapeutic agents such as oxaliplatin and 5-fluorouracil. Moreover, this alteration represents a key event to inhibit the tumor suppressor PP2A in metastatic CRC. However, the role of SET in CRC progression and its potential clinical impact in early-stage CRC patients still remain to be investigated.

Methods: In this work, we studied the biological effects of SET on migration using wound-healing and transwell migration assays, and cell invasion ability was determined by colony-forming assays after SET silencing or overexpression. Moreover, we analyzed SET expression by immunostaining in a cohort of 231 CRC patients without metastatic disease at diagnosis. We also quantified the expression of the negative SET regulator miR-199b in a set of CRC patient samples.

Results: We observed that SET deregulation promotes cell migration and markedly affects invasion ability of CRC cells. At the clinical level, SET overexpression was detected in 14.7% of cases. We found this alteration associated with worse ECOG performance status, and with relapse in the subgroup of stage II CRC patients. Moreover, SET overexpression determined significantly shorter overall survival and time to metastasis. Interestingly, its prognostic value was particularly evident in patients older than 70 years. We also identified miR-199b downregulation as a molecular mechanism to deregulate SET in CRC patients with localized disease.

Conclusions: Of importance, our results indicate that SET could serve to anticipate undesirable relapses in stage II CRC patients and define a subgroup of early stage CRC patients that could benefit by the use of SET antagonists or PP2A-activating drugs such as FTY720 in anticancer protocols.

81P The functional MDM4 genetic variant in advanced lung adenocarcinoma patients treated with EGFR-TKIs

N. Zhang[1], M. Yang[2], H. Xing[2], J. Liu[2]

[1]Department of Radiation Oncology, Shandong Cancer Hospital, Ji'nan, China, [2]Shandong Provincial Key Laboratory of Radiation Oncology, Cancer Research Center, Shandong Cancer Hospital, Jinan, China

Background: As a mostly used epidermal growth factor receptor (EGFR)-tyrosine kinase inhibitor (TKI), gefitinib significantly prolongs survival of lung adenocarcinoma patients with EGFR mutations. However, more than 10% of EGFR mutation-positive patients do not respond and a substantial fraction of responded patients progress after 8-12 months' treatment. Identification of new biomarkers for EGFR-TKIs prognosis is vital. The objective of this study is to explore associations between MDM4 genetic variant and survival of lung adenocarcinoma patients treated with gefitinib.

Methods: 384 patients with stage IIIB or IV lung adenocarcinoma were recruited between January 2009 and June 2013. Patients were treated with gefitinib orally at a daily dose of 250 mg as 1st-line monotherapy. MDM4 rs4245739 A>C genotypes were determined using MassArray system. Dual luciferase reporter gene assays evaluated the function of MDM4 rs4245739 genetic variant in lung adenocarcinoma cell lines A549 and H1299. The differences of patient clinical characteristics were calculated by student's t test or χ^2 test. Survival differences were examined by log-rank test. Multivariate Cox regression analysis assessed prognostic factors for PFS or OS. Two-sided $P < 0.05$ indicated a significant difference.

Results: Among 384 patients, EGFR mutations were positive in 181 patients (47.1%). Median progression-free survival (PFS) and overall survival (OS) for all patients with the rs4245739AC genotype were significantly longer than that of the AA carriers (PFS: 22.9vs.10.9 months, $P < 0.001$; OS: 27.3vs.16.5 months, $P = 0.003$). Notably, in the EGFR mutation-positive subgroup, individuals with MDM4 rs4245739AC genotype showed 14.1 months prolonged PFS (28.8 months vs. 14.7 months; $P = 0.022$) and 12.2 months prolonged OS (31.4 months vs. 19.2 months; $P = 0.047$) compared to the AA group. Reporter gene assays showed that the rs4245739A allele leads to significantly increased MDM4 expression in lung adenocarcinoma cells compared to the C allele ($P < 0.05$).

Conclusions: MDM4 rs4245739 genotypes may act as prognostic biomarker for patients' survival to gefitinib therapy and offer help to individualized treatment in lung adenocarcinoma patients with EGFR mutations.

82P PD-L1 expression on pre-treatment circulating tumour cells, but not serum VEGF, is predictive of response to pembrolizumab in melanoma

M.A. Khattak[1], E.S. Gray[2], A. Reid[2], M. Periera[2], A. McEvoy[2], C. Aya-Bonilla[2], T. Meniawy[3], A. Didan[1], M. Millward[3], M. Ziman[2]

[1]Medical Oncology, Fiona Stanley Hospital, Perth, Australia, [2]School of Medical and Health Sciences, Edith Cowan University, Perth, Australia, [3]Oncology, School of Medicine and Pharmacology Sir Charles Gairdner Hospital, Nedlands, Australia

Background: Immune checkpoint inhibitors including pembrolizumab and nivolumab have revolutionised treatment of melanoma with a small proportion of patients deriving durable disease control lasting up to 5 years. However, majority of patients do

not respond to these drugs that are costly and can lead to substantial toxicity. Therefore, there is an urgent need for biomarkers that can identify patients that will respond to these therapies.

Methods: We used multi-parametric flow cytometry to identify circulating tumour cell (CTC) subpopulations based on the expression of melanoma markers MCAM, MCSP, ABCB5, CD271 and RANK in metastatic melanoma patients prior to commencing treatment with pembrolizumab (n = 40) or with ipilimumab alone or in combination with nivolumab (n = 14). In particular, we evaluated the expression of PD-L1 on CTCs in relation with response to treatment and progression free survival (PFS). Serum vascular endothelial growth factor (VEGF) concentrations were also evaluated.

Results: Pre-treatment serum VEGF concentrations were significantly higher in patients not responding to ipilimumab treatment (alone or in combination with nivolumab) (p = 0.0094). In contrast, serum VEGF was not predictive of response to pembrolizumab. Pre-treatment CTC positivity was not associated with response or PFS in either cohorts. However, PD-L1 expression on CTCs was associated with response to therapy. PD-L1 expression was found in 13 of 16 responders with detectable CTCs, while only 4 of 10 non-responders had PD-L1 detectable on their CTCs (p = 0.0425). Expression of PD-L1 on CTCs was also associated with longer PFS (p = 0.0117).

Conclusions: Our results provide evidence for the first time in melanoma, that detection of PD-L1 on CTCs is predictive of response to pembrolizumab and longer PFS.

Background: Study 39 (NCT01063517) showed a significant improvement in overall survival (OS) following olaparib plus paclitaxel (OP) vs paclitaxel (P) alone in advanced gastric cancer, with improvements greatest in patients (pts) with low or undetectable tumour ATM protein levels. The Phase III GOLD study (NCT01924533) also showed a survival benefit trend for OP vs P. We investigated biomarker subgroups, candidate genes and homologous recombination repair (HRR) deficiency using predefined and post-hoc exploratory analyses, to determine if a predictive relationship exists between such biomarkers and clinical outcome in gastric cancer pts treated with OP.

Methods: Candidate genes, HRR deficiencies, loss of heterozygosity (LoH) and microsatellite insufficiency (MSI) were assessed in formalin-fixed, paraffin-embedded gastric tumour samples from GOLD by next-generation sequencing. HRR deficiencies were identified as carrying pathogenic mutations in any 15 HRR genes and LoH using allele-specific copy number information coupled with assessed tumour purity. ATM protein level was assessed by immunohistochemistry (IHC). Clinical outcomes analyzed were OS, PFS and ORR.

Results: Efficacy in the genetics evaluable population (n = 400) was broadly consistent with the overall GOLD population (n = 525) for each outcome investigated. ATM-negative patients by IHC had better prognosis independent of treatment. No statistically significant associations with clinical outcomes were identified (Table). Post-hoc exploratory analyses indicated good prognosis (OS) in pts with an ATM mutation, and poor prognosis in pts with CDH1, FGFR2 or KRAS mutations.

Table: 83P

Pre-specified subgroup		Patients/events in OS, PFS, ORR, respectively	OS Hazard ratio [<1 favours OP] (P value)	PFS Hazard ratio [<1 favours OP] (P value)	ORR Odds ratio [>1 favours OP] (P value)
Overall population		525/381, 449, 72	0.80 (0.026)*	0.84 (0.065)	1.68 (0.057)

84P A diagnostic model for hepatitis B virus-related hepatocellular carcinoma in China: A large-scale, multi-center study

T. Yang[1], H. Xing[1], G. Wang[2], S. Cai[3], F. Shen[4]

[1]Department of Hepatobiliary Surgery, Eastern Hepatobiliary Surgery Hospital, Second Military Medical University, Shanghai, China, [2]Department of Public Health, Peking University Health Science Center, Beijing, China, [3]Department of Public Health, The Second Xiangya Hospital of Central South University, Hunan, China, [4]Department of Hepatobiliary Surgery IV, Eastern Hepatobiliary Surgery Hospital, Second Military Medical University, Shanghai, China

Background: Almost one third of carriers of hepatitis B virus (HBV) world-wide are in China and more than 80% hepatocellular carcinoma (HCC) in China are associated with HBV infection. So early detection of HCC in HBV-infected patients is necessary. In the present study, we aimed to develop a diagnostic model by combining protein induced by Vitamin K absence or antagonist-II (PIVKA-II) and α-fetoprotein (AFP) for HBV-related HCC.

Methods: We recruited consecutive patients with HBV-related HCC, chronic hepatitis B, HBV-related cirrhosis and healthy controls at 11 hospitals in China from June 2016 to May 2017 for a training cohort. A validation cohort was enrolled at the same sites from FebruaryJune 2017 to September 2017. HCC was defined on the basis of ultrasound, CT, or MRI characteristics and confirmed by histopathology. Serum PIVKA-II level was measured by ARCHITECT immunoassay and AFP was measured with commercially available ELISA. Receiver operating characteristics (ROC) were used to calculate diagnostic accuracy.

Results: The training cohort consisted of 2019 participants, 908 with HBV-related HCC, 289 with chronic hepatitis B, 314 with HBV-related cirrhosis, and 508 healthy controls. The validation cohort comprised 655 participants, 289 with HBV-related HCC, 113 with chronic hepatitis B, 98 with HBV-related cirrhosis, and 155 healthy controls. Levels of PIVKA-II in serum were significantly higher in HBV-related HCC than all controls. ROC curves showed the optimum diagnostic cutoff for PIVKA-II was 44.18 mAU/mL (area under curve [AUC], 0.907 [95% CI 0.892-0.922], sensitivity 81.13%, and specificity 94.97% in the training cohort; 0.909 [0.883-0.934], 79.02%, and 95.46% in the validation cohort). PIVKA-II maintained diagnostic accuracy for patients with HBV-related HCC who were AFP negative. A model combined PIVKA-II, AFP, age, gender and liver cirrhosis improved diagnostic accuracy for HBV-related HCC versus all controls compared with either test alone (0.951 [0.929-0.973] in the training cohort; 0.954 [0.945-0.962] in the validation cohort).

Conclusions: PIVKA-II could complement measurement of AFP in the diagnostic of HBV-related HCC and distinguish HCC from non-malignant chronic liver disease.

Clinical trial identification: NCT03047603.

85P Dissecting gastric cancer biology and how and when to use immunotherapy

M. Das Thakur, K. Okrah, D. Shames, P. Hegde, C. Bais

Oncology Biomarker Development, Genentech Inc. - Roche - USA, South San Francisco, CA, USA

Background: Gastric cancer (GC), is a leading cause of cancer-related death, is a heterogeneous disease where survival depends on factors such as biological differences, MSI status, EBV status, region, ethnicity and patterns of care. The biological context for immune responsiveness and resistance in the clinical are only now starting emerge. Although GC has similar levels of PDL1 IC and TC expression to lung cancer, the approvals and success of immunotherapy in GC to date has been mixed.

Methods: We explored 2 randomized MetMAb trials (Ph3 Study 1 YO28322 and Ph2 Study 2 YO28252) in combination with mFOLFOX6 in metastatic HER2-negative and MET-positive GC. We used Study 1 (n = 146) to uncover novel GC biology using Nanostring based gene expression analyses and Study 2 (n = 70) to confirm the findings. Late Stage GC (Stage IV biopsies) GC from the Study 1 and 2 were compared against early stage GC (Stage I, II and III) in resections from the ACRG GC dataset.

Results: Retrospective analysis revealed key biological differences between early and late stage GC. In 1L mGC with stage IV tissue, unbiased prognostic analyses uncovered genes that grouped into: Immune/Effector T cell genes (Teff), Stromal genes and Differentiation/Proliferation genes as significantly associated with OS. Patients with high Teff genes had poor prognosis (Low/High HR: 0.43, p- value 0.01) and the worst prognosis was seen when both Teff and stromal genes were high. Furthermore, we confirmed these findings in Study 2. We found that EMT, Notch and TGFb pathways interacted with the Teff genes and were all associated with the poor Teff prognosis. Importantly immune/Teff genes have good prognosis in early stage GC and this is largely driven by MSI-H patients. Finally, when assessing what genes changed going from early to late stage, EMT, Notch, Wnt genes played a role in the transition to a more aggressive and metastatic disease.

Conclusions: Although GC has been challenging to treat, it may be possible to increase the success of immunotherapy with carefully tailored combination therapies in the Stage IV setting with molecules that inhibit pathways such as Notch, Wnt and TGFb. Furthermore, it may make a lot of sense to take immunotherapies into Stage I, II and III GC where the immune and Teff gene prognosis is good and the disease is less convoluted.

86P Longitudinal assessment of multiplex patient-specific ctDNA biomarkers in bladder cancer for diagnosis, surveillance and recurrence

K. Birkenkamp-Demtröder[1], E. Christensen[2], H. Sethi[3], S. Sharma[3], H.-T. Wu[3], A. Taber[2], M. Agerbæk[4], R. Swenerton[3], R. Salari[3], D. Hafez[3], I. Nordentoft[5], P. Lamy[5], R. Srinivasan[3], M. Balcioglu[3], S. Navarro[3], Z. Assaf[3], B. Zimmermann[6], J. Lin[6], J. Bjerggaard Jensen[7], L. Dyrskjøt[2]

[1]Molecular Medicine MOMA, Aarhus University Hospital / Skejby, Aarhus, Denmark, [2]Department of Molecular Medicine, Aarhus University Hospital, Aarhus, Denmark, [3]Natera Inc., San Carlos, CA, USA, [4]Department of Oncology, Aarhus University Hospital, Aarhus, Denmark, [5]Aarhus University Hospital, Aarhus, Denmark, [6]RND, Natera, San Carlos, CA, USA, [7]Department of Urology, Aarhus University Hospital, Aarhus, Denmark

Background: The use of circulating tumor DNA (ctDNA) as a biomarker for disease staging at diagnosis (DX), treatment response, and recurrence monitoring is an emerging field in many cancer types. In bladder cancer, the utility of ctDNA has shown promising results. Here we present a highly sensitive and specific NGS-based approach to ctDNA monitoring.

Methods: A cohort of 50 patients with locally advanced muscle-invasive bladder cancer treated with neoadjuvant chemotherapy were included prospectively. For each patient, a panel of 16 tumor-specific mutations was designed (Signatera™ RUO) based on whole-exome sequencing of tumor and germline DNA. In total, we analyzed ctDNA from longitudinally collected plasma samples from 386 time points procured at diagnosis, during treatment, at cystectomy (Cx), and during monitoring until disease recurrence or up to 2 years follow-up. Results of ctDNA analyses were compared to radiographic imaging and clinical outcomes. ctDNA from longitudinally-collected urine samples will also be analyzed for treatment response and disease recurrence.

Results: At DX, plasma ctDNA status was strongly prognostic of recurrence-free survival. Specifically, 62% (8/13) of the ctDNA+ patients at DX recurred after neoadjuvant treatment and Cx; conversely, none (0/22) of the ctDNA- patients recurred (log-rank; $p < 0.0001$). In addition, a strong correlation was also observed between presence of ctDNA after CX and disease relapse. Specifically, relapse after Cx was detected in 100% (10/10) of ctDNA+ patients ∼120 days (0–245 days) prior to radiographic imaging, while 0% (0/38) of ctDNA- patients relapsed (log-rank; $p < 0.0001$).

Conclusions: We demonstrate a strong prognostic potential of ctDNA in bladder cancer at time of DX, suggesting a potential role for ctDNA in the staging of bladder cancer. Furthermore, we show ctDNA is detected in all patients with disease recurrence after

Cx. Incorporation of ctDNA analysis into routine follow-up for early detection of relapse may allow earlier initiation of alternate treatment modalities.

87P Distinct functional consequences of HER2 gene amplification in colorectal and lung adenocarcinomas

E.N. Imyanitov[1], T.N. Sokolova[1], G. Raskin[2], A.O. Ivantsov[1], A.G. Iyevleva[1], A.P. Sokolenko[1]

[1]Department of Tumor Growth Biology, N.N. Petrov Institute of Oncology, St. Petersburg, Russian Federation, [2]Department of Pathology, A.M. Granov Russian Scientific Centre of Radiology and Surgical Technologies, St. Petersburg, Russian Federation

Background: HER2 oncogene amplification, being accompanied by its overexpression, is an established driver event in breast and gastric carcinomas. The functional role of HER2 in pathogenesis of other tumor types is less defined.

Methods: 2401 archival samples of lung carcinomas (LC) and 1969 samples of colorectal carcinomas (CRC) were subjected to HER2 copy number analysis. Selected tumors with amplification of this oncogene were further subjected to HER2 immunohistochemistry and mRNA quantitation. In addition, the expression levels of some neighbouring genes located in 17q12-21 amplicon were analyzed.

Results: Frequency of HER2 amplification was similar in both groups, being 100/2401 (4.2%) in LC and 84/1969 (4.3%) in CRC, respectively. 10 (82%) out of 12 analyzed HER2-amplified CRCs demonstrated clear evidence for HER2 protein and mRNA overexpression, while this estimate approached to only 3 (27%) out of 11 for LCs. Expression analysis of GRB7, STARD3, and LASP1 revealed a statistically significant correlation between HER2 and STARD3 levels [$r = 0.571$, Spearman test]. High STARD3 expression was observed in HER2-amplified CRCs but not LCs [$p = 0.03$].

Conclusions: HER2 amplification is frequently accompanied by gene overexpression in colorectal but not lung adenocarcinomas. STARD3 gene belonging to 17q12-21 amplicon demonstrates evidence for activation in HER2-amplified colorectal neoplasms and therefore deserves further analysis.

88P Role of AR-V7 and AR-FL in resistance to hormonal therapy in mCRPC: Independent actors or reciprocal drivers? A translational study by Meet-Uro group

M. Del Re[1], S. Crucitta[1], A. Sbrana[2], E. Rofi[3], F. Paolieri[3], L. Galli[4], A. Falcone[3], R. van Schaik[5], G. Jenster[6], R. Morganti[2], S. Pignata[7], R. Danesi[1]

[1]Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, [2]Medical Oncology 2 Unit, Azienda Ospedaliera Universitaria S. Chiara, Pisa, Italy, [3]Medical Oncology, Azienda Ospedaliera Universitaria S. Chiara, Pisa, Italy, [4]UO Oncologia Medica 2 Universitaria, Azienda Ospedaliero-Universitaria Pisana Istituto Toscano Tumori, Pisa, Italy, [5]Clinical Chemistry, Erasmus University, Rotterdam, Netherlands, [6]Josephine Nefkens Institute, Erasmus University, Rotterdam, Netherlands, [7]Urology and Gynecology, Istituto Nazionale Tumori – I.R.C.C.S - Fondazione Pascale, Naples, Italy

Background: The androgen receptor splice variant 7 (AR-V7) is strongly associated with resistance to hormonal therapy (HT) in castration-resistant prostate cancer (CRPC), although it is not implemented in clinical practice as a biomarker. The AR-full length (AR-FL) is also overexpressed in CRPC but its role has yet to be clarified. The aim of the present work was to investigate the role of AR-V7 and AR-FL as predictors of resistance to HT in plasma-derived exosomal RNA.

Methods: 6 ml of blood were collected in EDTA tubes before the start of abiraterone/enzalutamide; blood was centrifuged and plasma stored at -80 °C until analysis. Exosomes isolation and RNA extraction were performed using the exoRNeasy kit (Qiagen) as per manufacturer instructions. The analysis of AR-FL and AR-V7 were performed by digital droplet PCR using the One-Step RT-ddPCR kit (BioRad). The absolute target concentration as copies/ml in samples was calculated by ddPCR QuantaSoft and statistical analyses were performed by SPSS v.24.

Results: 52 patients (pts) were enrolled; AR-FL was detected in all pts (median: 700 copies/ml), while 15 subjects (28.8%) were AR-V7 + (median: 310 copies/ml) at baseline. The amount of AR-FL was significantly higher in pts AR-V7+ vs AR-V7- (6700 vs 490 copies/ml, $p < 0.0001$). Median PFS and OS were longer in AR-V7- vs AR-V7+ pts (median PFS 25 vs 4 mo, $p < 0.0001$; median OS 38 vs 9 mo, $p < 0.0001$). A ROC curve was calculated for AR-FL in the overall population and 950 copies/ml was identified as cut-off value. Pts were then stratified across this value and it was found that PFS was 22 mo in pts with <950 AR-FL copies/ml vs 4 mo in pts with ≥950 copies/ml ($p = 0.0003$). In 12/15 AR-V7+ pts the AR-FL expression was ≥950 copies/ml while in 3/15 AR-V7+ pts, AR-FL expression was <950 copies/ml; however, their PFS reflected the AR-V7 better than AR-FL status, being, respectively 6, 10, 4 mo. No other clinical variables were correlated with worse PFS at the univariate analysis (i.e. Gleason score ≤7 vs > 7, age).

Conclusions: This study demonstrates that resistance to HT may be predicted by AR-V7, making it a clinically relevant biomarker. AR-FL over-expression may contribute to hormone resistance although AR-V7 plays a primary role.

89P Validation of a 90-gene assay for tissue origin diagnosis of brain metastases

Y. Zheng[1], Y. Ding[1], C. Xiao[1], W. Zhong[2], X. Teng[2], Q. Gao[2], Q. Wang[3], Y. Sun[4], C. Chen[4], L. Chen[4], J. Zhu[4], Q. Xu[4], N. Xu[1]

[1]Department of Medical Oncology, The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China, [2]Department of Pathology, The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China, [3]Department of Pathology, Fudan University Shanghai Cancer Center, Shanghai, China, [4]Research and Development, Canhelp Genomics Ltd., Hangzhou, China

Background: Brain metastases (BM) are the most common intracranial tumors affecting about 8-10% of all cancer patients. Morphology and immunohistochemical staining are two common approaches used to identify the primary sites of BM samples, but morphology fails to identify poorly differentiated tumors and IHC markers usually lack specificity. About 2% to 14% of BM patients still present with unknown primary sites. A 90-gene assay, proposed in our previous study, is an RNA-based gene expression test to identify the tissue of origin in poorly differentiated and undifferentiated tumors. This study aims to evaluate the performance of the 90-gene assay in determining the primary sites for BM samples.

Methods: The sequence-based gene expression profiles of 708 primary brain tumors (PBT) collected from The Cancer Genome Atlas database were performed by a 90-gene expression signature, with a similarity score for each of 21 tumor types. We used Optimal Binning algorithm to generate a threshold for separating PBT from BM. Eighteen PBT samples from Fudan University Shanghai Cancer Center were analyzed to substantiate reliability of the threshold. In addition, the performance of the 90-gene assay for identifying the tissue of origin was validated in a cohort of 48 BM samples with known origin from The First Affiliated Hospital, Zhejiang University. For each BM sample, the tumor type with the highest similarity score was considered tissue of origin. When a sample was diagnosed as PBT but the similarity score below the threshold, the second prediction was considered as primary site.

Results: A threshold of the similarity score, 70, was identified to discriminate PBT from BM (PBT: ≥ 70, BM: < 70) with an accuracy of 99% (703/708). Eighteen PBT and 44 BM were performed by the 90-gene assay. The results of 18 PBT samples matched reference diagnosis with a concordance rate of 100% and all similarity scores were above 70. Of 44 BM samples, the 90-gene assay accurately predicted primary sites in 89% (39/44, 95%CI: 0.75-0.96) of the cases.

Conclusions: The 90-gene assay showed promising discriminatory ability to separate PBT from BM and identify the primary site of BM. Our findings demonstrated the potential that 90-gene assay can serve as a powerful tool for accurately identifying the tissue of origin for BM samples.

90P Development of a pan-cancer biomarker panel for improved detection of MSI across all cancer types

J. Bacher[1], R. Halberg[2], P. Ward[3], E. Udho[1], K. Murphy[4], M. Uhr[5], L. Dubeau[3], J. Pettersson[3], D. Storts[1], S. Gallinger[6], D. Buchanan[7], M. Jenkins[7], N. Lindor[8], J. Eshleman[9]

[1]RD Nucleic Acid Technologies Group, Promega Corporation, Madison, WI, USA, [2]Department of Medicine, University of Wisconsin-Madison, Madison, WI, USA, [3]USC Keck School of Medicine, University of Southern California, Los Angeles, CA, USA, [4]Pathology, ProPath, Dallas, TX, USA, [5]RD Protein & Nucleic Acids, Promega Corporation, Madison, WI, USA, [6]Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada, [7]Melbourne School of Population and Global Health, The University of Melbourne, Melbourne, Australia, [8]Health Science Research, Mayo Clinic, Scottsdale, AZ, USA, [9]Pathology, Johns Hopkins University, Baltimore, MD, USA

Background: A new multiplexed biomarker panel is being developed for detection of microsatellite instability (MSI) that is more sensitive than currently available systems. Preliminary research data shows increased MSI sensitivity for colon polyps and

endometrial (EC), skin and prostate cancers. The sensitivity of this Pan-Cancer MSI System is being further verified on 14 different cancer types.

Methods: Selection of the new microsatellite biomarkers was done by screening 160 patients ≤55 years with ≥1 polyp and 100 EC patients ≤ 50 years for MSI. The expanded study uses samples from 100 Lynch syndrome colorectal cancers (CRC), 100 sporadic MSI-High CRC, 100 sporadic MSI stable CRC and 219 extra-colonic cancers obtained from the Colon Cancer Family Registry. DNA samples are being tested for MSI using two pan-cancer systems: Promega's MSI Analysis System version 1.2 and the improved prototype Pan-Cancer MSI System. Mutations in mismatch repair (MMR) and BRAF genes were tested, as well as MMR expression by IHC.

Results: 2.3% of colon polyps were MSI-High for the MSI Analysis System compared to 5.4% with the new prototype Pan-Cancer MSI System. Sensitivity and specificity of the new biomarker panel for detection of MMR deficient lesions was 100% and 96%. Similarly, sensitivity of the new biomarker panel for EC was about 2-fold higher. Allele size changes for MSI-High samples were significantly larger with the new biomarkers making MSI classification highly accurate and robost. The MSI and IHC results were highly correlated. Evaluation of the new biomarker panel is being performed on over 500 cancer samples from 14 different cancer types.

Conclusions: Research results indicate that MSI sensitivity for colonic polyps and many extra-colonic cancers can be increased by at least 2-fold over current MSI systems using the new MSI biomarker panel. The improved sensitivity of the Pan-Cancer MSI System should improve detection of MSI in an expanded number of cancer types and facilitate identification of individuals with both sporadic and hereditary MSI-High cancers.

Background: Microsatellite instability (MSI) has been approved as the first pan-cancer biomarker in immune checkpoint inhibitors (ICI) therapies. The tumor tissues of most metastatic cancer patients receiving ICI therapies are usually unavailable. However, polymerase chain reaction (PCR) or immunohistochemistry (IHC), the two conventional MSI evaluation methods, could only be applied to the tumor tissues. Hence, we aimed to develop a next-generation sequencing based method to detect MSI from blood circulating tumor DNA (bMSI).

Methods: A training cohort of 40 metastatic cancers patients before first-line treatments were collected to train a linear-based detection model. Then, a validation cohort of 47 metastatic gastrointestinal cancer patients before ICI therapies were collected. The prediction to the responses of ICI by bMSI was compared with that by the mismatch repair (MMR) or MSI from historical tissue specimens.

Results: bMSI showed 87.5% accuracy to predict the MMR/MSI status from tissue specimens in the training cohort, and 95.2% sensitivity in the validation cohort. bMSI-H patients had 31.4% objective response rate (ORR) and 45.7% disease control rate (DCR), which were comparable to the dMMR of historical FFPE specimens (33.3% and 47.6% respectively). However, 57.7% pMMR patients were classified as bMSI-H and showed similar ORR (27%) , DCR (40%) and progress free survival to those of dMMR patients. Furthermore, 17% bMSI-H patients with high bMSI scores (larger or equal to 28) showed 66.7% ORR and 100% DCR. Finally, 91.7% patients with controlled diseases over 6 months showed decreasing bMSI scores, and 60% patients with progressive diseases showed increasing bMSI scores during therapies.

Conclusions: A significant proportion of pMMR metastatic gastrointestinal cancer patients could be rescued by bMSI and get benefits from ICI. bMSI could further classify the patients to three groups and more precisely predict the response of ICI. The level of bMSI is dynamically related to the response during the therapies. bMSI could potentially improve clinical practices in the future.

92P Vall d'Hebron Institute of Oncology (VHIO) immuno-oncology prognostic index (VIO): A new tool for improved patient (pt) selection in phase I (Ph1) trials with immune checkpoint inhibitors (ICI)

C. Hierro[1], I. Matos[1], J. Martin-Liberal[1], M. Ochoa De Olza Amat[1], E. Felip[2], M. Costa Rivas[3], M. Vieito Villar[1], I. Brana[1], A. Azaro[1], M.C. Perez-Gago[1], A. Gros[4], J. Carles[1], A. Oaknin[1], T. Macarulla[1], C. Saura[1], N. pardo[1], E. Muñoz-Couselo[1], J. Tabernero[1], R. Dienstmann[5], E. Garralda[1]

[1]Medical Oncology, Vall d'Hebron University Hospital, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain, [2]Medical Oncology Department, Germans Trias i Pujol Hospital, Catalan Institute of Oncology (ICO)-Badalona, Badalona, Spain, [3]Oncology, Complexo Hospitalario Universitario de Vigo, Vigo, Spain, [4]Tumor Immunology and Immunotherapy, Vall dHebron Institute of Oncology (VHIO)-Cellex Center, Barcelona, Spain, [5]Oncology Data Science Group (ODysSey), Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain

Background: The Royal Marsden Hospital score (RMHs) (albumin <35 g/L, lactate dehydrogenase [LDH]>upper limit of normal [ULN], and >two sites of metastases [met]) is a validated prognostic index for Ph1 pt selection. Recently, a lung immune prognostic index (LIPI) (derived neutrophil/(leukocytes minus neutrophils) ratio [dNLR]>3, and LDH>ULN) proved to be useful for identifying pts with different outcomes under ICI. We aimed to improve pt selection for ICI Ph1 trials by developing a composite VIO that included all clinical-laboratory (CL) variables linked with worse median Overall Survival (mOS).

Methods: Retrospective analysis of pts treated with ICI at VHIO Ph1 Unit from Jan'12 to Oct'17. VIO includes four CL factors previously described (albumin<35g/L, LDH>ULN, >two sites of met, dNLR>3) and a fifth variable (liver met) as per univariate Cox modeling. The following VIO clusters were defined based on Kaplan Meier OS estimates: low risk (0 and 1), intermediate risk (2 and 3) and high risk (4 and 5).

Results: In total, 174 out of 214 pts (81%) treated with ICI (antiPD1/PDL1 ICI in 93%, combination regimens in 53%) had complete CL data for modeling. Most common tumor types were melanoma (22%) and lung (14%). Overall, best response was PD 47%, SD 38%, PR 12%, CR 2% and mOS 9.8 (95% CI 7.3-12.7) months (m). Concordance index of OS models including LIPI, RMHs or VIO scores were 0.62, 0.66 and 0.69, respectively. Estimated mOS in low risk (40.2% of all pts), intermediate risk (50.3%) and high risk (9.2%) were 22.0 m (10.5.4-33.4), 6.7 m (4.1-9.3) and 3.8 m (2.5-5.1), respectively (log rank test, $p < 0.001$). PD as best response was higher in high risk VIO group (81%) as compared to intermediate (50%) and low risk (34%, Chi-square $p = 0.002$). 6m OS rates were 85% (77%-94%), 55% (44%-67%) and 30% (14%-65%) in low, intermediate and high risk VIO groups (log rank test, $p < 0.001$).

Conclusions: Our results suggest that the VIO is a better predictor of OS on ICI in Ph1 trials as compared to existing prognostic scores. The VIO is a helpful tool for identifying Ph1 candidates unlikely to benefit from ICI and with higher chances of death within 6 m of trial recruitment.

93P Augmenting TNM staging with machine learning-based immune profiling for improved prognosis prediction in muscle-invasive bladder cancer patients

N. Brieu[1], C.G. Gavriel[2], D.J. Harrison[2], G. Schmidt[1], P.D. Caie[2]

[1]Research, Definiens AG, Munich, Germany, [2]School of Medicine, University of St Andrews, St Andrews, UK

Background: Muscle-invasive bladder cancer (MIBC) is a highly aggressive disease whose clinical reporting is based on TNM staging. A more accurate and personalized prognosis could be achieved by profiling the immune contexture alongside clinical TNM staging. This study reports on features captured from the labelling of cells for CD3, CD8 and PD-L1 expression, within both the tumor and stroma of MIBC patients. This data is distilled to identify a novel immune-based prognostic signature which augments TNM staging.

Methods: An image analysis solution was developed to quantify the density of cell populations across immunofluorescence (IF) labelled whole slide images from 105 MIBC patients with known survival data. A regression random forest was used for the detection of nuclei using the Hoechst channel [Brieu et al., ISBI2017] and a convolutional neural network employed for the segmentation of the tumor from the stroma using the pan-cytokeratin channel [Brieu et al., SPIE2018]. The CD3, CD8 and PD-L1 channels were used to classify the cells and calculate their proportion within either the tumor or stroma regions. A decision tree of depth two was trained on these proportions as well as cross-validated. More explicitly, the patients were recursively partitioned during training to maximize at each node their survival difference, leaves showing low survival difference (p-value>0.5) being finally merged.

Results: The method yielded a decision tree which stratified patients into three groups utilizing only two parameters: the proportion of CD8(+) cells in the stroma and the

proportion of PD-L1(+) cells across the whole tissue, which were negatively and positively correlated with cancer-specific death respectively. This method was used to replace TNM stages 1 to 3 while retaining the original stage 4 stratification. Testing for survival curve differences showed that this combined system yielded a higher prognostic value (Chisq=41.5, p-value=5.0x10-9) than the standalone TNM staging system (Chisq=34.9, p-value=1.25x10-7).

Conclusions: Our results suggest that immune profiling derived from image analysis provides additional prognostic value to TNM scoring for MIBC.

Background: The Epitopes-HPV02 single arm phase II study (NCT02402842) demonstrated the efficacy of Docetaxel, Cisplatin and 5FU as first line chemotherapy (CT) for advanced squamous cell carcinoma of the anal canal (SCCA), with a 1-year progression-free survival rate (PFS) of 47% (Kim, Lancet Oncol 2018 in press). We previously reported the validity of HPV ctDNA detection and its prognostic value in localized SCCA (Cabel, Clin Cancer Res 2018 in press). This ancillary study reports the impact of HPV ctDNA detection in patients enrolled in the Epitopes-HPV02 trial.

Methods: Per protocol, serum samples (1 ml) were collected twice: before CT and, in non-progressive patients, at CT discontinuation which occurred after 5 months on CT. HPV16 ctDNA was quantified by ddPCR at both time points and correlated with prospectively registered patient characteristics and outcomes; for post-CT survival analyses, a landmark was set at the time of CT discontinuation.

Results: Among 59 patients with HPV16+ advanced SCCA, 52 (88%) had ctDNA detected at baseline (sensitivity: 91.1%; 95%CI[81.1;96.2]) with a median level of 7,148 copies/ml (range: 8.3- 3,147,000). Baseline ctDNA levels were not associated with any of the patient characteristics; ctDNA level below the median at baseline was correlated with a longer PFS (HR = 2.6, 95%CI[1.1;5.9], p = 0.02). Among 38 patients who completed the 5 months CT, residual ctDNA after CT was detected in 14 patients (36.8%; 95%CI[23.4;52.7]) with a median level of 2,662 copies/ml (range: 31.5–211,950). Residual ctDNA detected at CT discontinuation was strongly associated with shorter post-CT PFS (measured from the time of CT discontinuation, median PFS: 5.4 months vs not reached; HR = 6.2, 95%CI[2.3;16.3], p < 0.001) and OS (HR = 9.6, 95%CI[2.0;46.9], p = 0.005).

Conclusions: In this prospective study in advanced SCCA, we observed a strong prognostic impact of HPV ctDNA before 1st line CT and, in non-progressive patients, after 6 months of DCF. With a limited cost and short turnaround, this quantitative assay is a promising tool to optimize the therapeutic management of SCCA with e.g. maintenance anti PD-1/PD-L1 therapy in ctDNA-positive patients after the completion of first line CT.

95P Predicting toxicity and response to pembrolizumab (P) through germline genomic HLA class I analysis

M. Iafolla[1], C. Yang[2], V. Chandran[3], M. Pintilie[4], A. Hansen[1], P. Bedard[1], S. Lheureux[1], A. Spreafico[1], A. Razak[1], P. Ohashi[5], S. Hakgor[1], A. Giesler[1], T. Pugh[4], L.L. Siu[1]

[1]Medical Oncology, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada, [2]Medical Biophysics, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada, [3]Laboratory Medicine and Pathobiology, University Health Network, Toronto, ON, Canada, [4]Biostatistics, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada, [5]Immunology, Campbell Family Institute for Cancer Research, University Health Network, Toronto, ON, Canada

Background: HLA class I-dependent immune activity is linked to autoimmune diseases, and HLA class I-dependent CD8+ T cells are required for immune checkpoint blockade (ICB) anti-tumor activity. It is unknown if HLA class I is predictive of toxicity to ICB.

Methods: 100 patients (pts) with mixed solid tumors received single agent P (anti-PD-1) 200 mg IV Q 3 weeks in the investigator-initiated Phase II trial (INSPIRE study, NCT02644369). Germline whole exome sequencing (WES) of peripheral blood mononuclear cells was analyzed using the Illumina HiSeq2500 platform. Consensus HLA class I alleles were predicted from WES using HLAminer and HLAVBSeq. Using univariate Fisher's exact test and logistic models adjusting for HLA features, heterozygosity of HLA-A, -B and -C, individual HLA alleles and HLA haplotype dimorphism at positions −21M and -21T of the HLA-A and -B leader sequence were analyzed as predictors of: 1) toxicity defined as ≥ Gr 2 immune-related adverse events (irAE) with at least possible attribution to P; and 2) clinical benefit (CBR) defined as either partial response or stable disease lasting ≥ 6 cycles of P.

Results: In the overall cohort of 100 pts, the frequency of irAE and CBR from P was 21% and 25%, respectively. Thus far, 99 patients had their HLA class I genotype determined. Univariate analysis showed heterozygosity of HLA-A, -B and -C, compared to homozygosity of at least one HLA locus, was not predictive of toxicity (≥ Gr 2 irAE 16.7% vs 27.3%, p = 0.29) but did trend to less response (CBR 19.7% vs 36.4%, p = 0.088). Individual heterozygosity of HLA-A, -B or -C, and HLA-A and -B haplotype dimorphism was not predictive of either toxicity or response. HLA-A*02 allele showed a trend to toxicity (≥ Gr 2 irAE 26.8% vs 11.6%, p = 0.079). A pertinent exploratory toxicity model is summarized in the table.

Table: 95P

	Toxicity
A*01 and A*02 (n = 7)	4(57%)
A*01 and no A*02 (n = 13)	2(15%)
A*02 and no A*01 (n = 49)	11(22%)
Neither A*01 nor A*02 (n = 30)	3(10%)

Table Fisher exact p-value=0.0503

Conclusions: This study is the first to assess the association between HLA class I genotype and toxicity to P. There is a possible association of HLA-A*01 and HLA-A*02 with toxicity to P.

Clinical trial identification: Trial protocol number: NCT02644369.

96P AXL has a prognostic role in metastatic colorectal cancer (mCRC) and is a predictive biomarker of lack of efficacy of chemotherapy (CT) + cetuximab in RAS wild type (WT) patients (pts)

C. Cardone[1], B. Blauensteiner[2], V. Moreno-Viedma[2], M.C. Paul[2], G. Martini[1], P.P. Vitiello[1], D. Ciardiello[1], C. Borrelli[1], L. Poliero[1], P. Vitale[1], N. Zanaletti[1], V. Famiglietti[1], A.M. Rachiglio[3], D. Rizzi[4], E. Maiello[5], T.P. Latiano[5], N. Normanno[3], M. Sibilia[2], F. Ciardiello[1], E. Martinelli[1]

[1]Medical Oncology, Università degli Studi della Campania Luigi Vanvitelli, Naples, Italy, [2]Institute of Cancer Research, Medical University of Vienna, Vienna, Austria, [3]Cell Biology and Biotherapy Unit, National Cancer Institute 'Fondazione Giovanni Pascale', Naples, Italy, [4]Clinical Research, GOIM Trial Office, Bari, Italy, [5]Oncology, Hospital Casa Sollievo della Sofferenza-IRCCS, San Giovanni Rotondo, Italy

Background: AXL expression promotes tumour growth, angiogenesis, epithelial to mesenchymal transition (EMT), resistance to CT and targeted agents. AXL is overexpressed in CRC. We aimed to evaluate AXL expression in mCRC pts and to correlate it with clinical outcomes.

Methods: AXL expression was assessed by immunohistochemistry in tumor samples of a consecutive series of 109 mCRC pts (75 RAS mutant and 34 RAS WT) treated at our Institution and 68 mCRC RAS WT pts enrolled in CAPRI-GOIM trial. Pts received a first line treatment according to RAS status: RAS mutant pts (n = 75) received CT + anti-angiogenic drugs, RAS WT pts (n = 102) CT + cetuximab.

Results: AXL stained positively in 20/177 samples with different intensity: 13 weak, 5 moderate, 2 intense. In RAS WT cohort 9/102 cases (9%) were positive while in RAS mutant 11/75 (15%). Tumor stroma was assessable in 166 samples. AXL expression was high (moderate + intense) in 47/96 (49%) RAS WT and in 28/70 (40%) RAS mutant cases. No significant correlation was found between AXL expression and clinico-pathological features. In RAS WT cohort, AXL positive pts had a significantly worse median PFS [4.3 m (CI95% 3.2-5.5) vs 12.1 m (CI95% 11.0-13.3) p = 0.001], in RAS mutant no impact on PFS was observed. AXL expression in tumor was a negative prognostic factor in both cohorts although statistical significance was reached only in RAS mutant [median OS: 30.2 m (CI95% 18.4-42.0) vs 20.1 m (CI95% 10.6-29.6) p = 0.007]. Intriguingly, high AXL expression in stroma correlated with lower median OS in both cohorts (Table).

Conclusions: AXL, marker of EMT phenotype, might represent an additional predictive biomarker of lack of efficacy in RAS WT mCRC pts treated with CT + cetuximab. Moreover, its expression in tumor and stroma might have a negative prognostic relevance in mCRC. Targeting AXL could overcome resistance to anti-epidermal growth factor receptor and represent a novel therapeutic strategy in mCRC.

97P Multimodal detection of homologous recombination repair gene mutations (HRRm) in a phase II trial of olaparib plus abiraterone in metastatic castrate resistant prostate cancer (mCRPC)

T.H. Carr[1], C. Adelman[1], A. Barnicle[1], I. Kozarewa[1], S. Luke[1], Z. Lai[2], S. Menon[1], S. Hollis[3], B. Dougherty[2], E.A. Harrington[1], J.C. Barrett[2], C. Goessl[2], F. Saad[4], N. Sala[5], N.W. Clarke[6], D. Hodgson[1]

[1]AstraZeneca, Cambridge, UK, [2]AstraZeneca, Gaithersburg, MD, USA, [3]Phastar, London, UK, [4]University of Montreal Hospital Research Centre, Montreal, QC, Canada, [5]Catalan Institute of Oncology, Hospital Josep Trueta, Girona, Spain, [6]The Christie NHS Foundation Trust, Manchester, UK

Background: Study 8 [NCT01972217] was a randomized Phase II trial that tested the hypothesis that the combination of PARP inhibition plus abiraterone benefits unselected patients (pts) with mCRPC. The primary endpoint was progression-free survival. A key secondary objective was to understand the relationship between HRRm status and outcome, which was challenged by low-tissue acquisition and high-test failure. The primary biomarker analysis focused on testing plasma when tumour data were not available and germline mutations were not evident. Here we describe additional analyses of circulating tumour DNA (ctDNA) to further characterize HRRm status and evaluate concordance between different testing modalities.

Methods: Tumour specimens were sequenced via Foundation Medicine. Germline analysis was performed via Color Genomics. An inhouse (RUO) sequencing assay was used for baseline ctDNA analysis. A subset of plasma samples was analyzed via GuardantOMNI™ and a custom assay (Resolution Bioscience). CtDNA libraries were also subjected to shallow whole genome sequencing (~4–5x). From 142 enrolled pts, we obtained HRRm data for 136 (from any source).

Results: Previous tumour/germline analyses identified 8 HRRm pts: 1 somatic, 7 germline (tumour success rate 38/68 [56%]; germline success rate 102/102). CtDNA analyses yielded a success rate of 93% (127/136 pts with plasma analyzed), with tumour variants detectable with high confidence in 79% (100/127). Plasma sequencing identified additional HRRm pts, including homozygous deletions, approximately tripling the number known to have a HRRm. Plasma testing in pts with tumour data revealed high concordance between tumour and ctDNA.

Conclusions: Comprehensive, sensitive sequencing of ctDNA for HRRm is feasible in mCRPC pts with a high success rate. Both targeted and whole genome approaches add value. There was good concordance across testing modalities where gene coverage overlapped, highlighting the considerable value of ctDNA testing in mCRPC where access to tissue of sufficient quality for molecular analysis is challenging, and somatic alterations are common. The first two authors contributed equally.

98P Identification of a highly suppressive Treg subset associated to immunotherapy response

E.F. Giunta[1], S. Romano[2], P. D'Arrigo[2], A. Rea[2], M. Tufano[2], G. Matarese[2], C. Procaccini[2], N. Novizio[2], V. Vigorito[2], D. Faicchia[2], G. Argenziano[3], V. De Falco[1], F. Ciardiello[1], M.F. Romano[2], T. Troiani[1]

[1]Dipartimento di Medicina di Precisione, Università degli Studi della Campania Luigi Vanvitelli, Naples, Italy, [2]Dipartimento di Medicina Molecolare e Biotecnologie Mediche, Università Federico II, Naples, Italy, [3]Dipartimento di Salute Mentale e Fisica e Medicina Preventiva, Università degli Studi della Campania Luigi Vanvitelli, Naples, Italy

Background: Cancer immunotherapy, particularly monoclonal antibodies against immune checkpoint inhibitors, has shown surprising efficacy in several types of advanced incurable tumors, including malignant melanoma. Tregs, a subset of lymphocytes involved in immune-surveillance and self-tolerance, are usually increased in melanoma patients. Lymphocytes are particularly rich in FKBP51, the intracellular receptor for FK506 and rapamycin. Melanoma aberrantly expresses this immunophilin, which supports cancer resistance and invasion. Recently, our group has shown that melanoma interaction with immune cells, through PD-L1/PD1, generated the splicing of FKBP5 gene inducing a lower molecular weight form (FKBP51s), in both melanoma and lymphocyte. Aim of this study is to assess the role of Treg FKBP51s+ as potential biomarker of response to anti-PD1 drugs.

Methods: Treg FKBP51s+ were measured in peripheral blood by flow cytometry. To date, we have outcomes of 11 patients. For 6 patients, we have collected from 4 up to 16 blood samples, before each anti-PD1 administration, with a total of 80 sample analysis. iTregs were generated by purified CD4+ T lymphocytes from normal donor, stimulated with CD3+CD28+beads. The suppressive capacity was assessed according to the parameters $CD25^{high}$, $Ki67^{high}$ and $p70S6k^{high}$.

Results: In 5 responder patients, Treg FKBP51s+ was 1.2-4.8%; in 5 non-responders, the count was 0.04-0.8%. Interestingly, a patient with count 0.72% developed autoimmune side effects that led to drug discontinuation. Resolution of side effects was accompanied by an increase in Treg FKBP51s+ value to 9.9%. In vitro iTreg generation suggested that FKBP51s was induced in Treg $CD25^{high}$ $Ki67^{high}$ $p70S6k^{high}$, corresponding to a highly metabolically active profile associated with strong suppressive capability. Use of a siRNA for FKBP51s silencing resulted in reduction of this subtype of iTreg.

Conclusions: Our data reinforce the hypothesis that melanoma patients that benefit from immunotherapy are recognizable by an expansion of a Treg subset which plays a central role in tumor immune evasion. This Treg subset is marked by FKBP51s, a splicing protein isoform generated by triggering of surface antigens (PD-L1, PD1) abundantly expressed on highly suppressive Tregs.

99P A novel framework for evaluating biomarker response relationships in immuno-oncology (IO)

J.L. Evelhoch[1], R. Mogg[1], R. Cristescu[1], D. Aurora-Garg[1], L.Q. Chow[2], S. Loi[3], D.V.T. Catenacci[4], U.A. Matulonis[5], P.A. Ott[6], E.S. Antonarakis[7], C.H. Poehlein[1], A. Joe[1], S.M. Keefe[1], P. Kang[1], V. Karantza[1], J. Cheng[1], E.H. Rubin[1]

[1]Clinical Research, Merck & Co., Inc., Kenilworth, NJ, USA, [2]School of Medicine, University of Washington, Seattle, WA, USA, [3]Translational Breast Cancer Genomics Lab, Division of Research, Peter MacCallum Cancer Center, Melbourne, Australia, [4]Medicine, University of Chicago, Chicago, IL, USA, [5]Medical Oncology, Dana Farber Cancer Institute, Boston, MA, USA, [6]Center for Immuno-Oncology, Dana-Farber Cancer Institute, Boston, MA, USA, [7]School of Medicine, Johns Hopkins University, Baltimore, MD, USA

Background: Unlike biomarkers of dichotomous genetic mutations/fusions required for response, biomarkers for checkpoint inhibitors are continuous biologic variables with context specific cutpoints. Selecting the cutpoint of a continuous biomarker for higher response rate in a given therapy decreases the number of biomarker positive patients (prevalence). To facilitate interpretation of biomarkers in IO, we introduce a framework for understanding how cutpoints, response rate and prevalence are interrelated.

Methods: Objective response rate (ORR) in biomarker positive patients is the product of ORR in all patients and the fraction of responding patients who are biomarker positive (FR+), divided by the prevalence. FR+ depends on the difference in biomarker distributions between responding and nonresponding patients. Biomarker [PD-L1 IHC, tumor mutation burden (TMB), T-cell activated gene expression profile (GEP)] and response data were pooled from 595 patients in 7 clinical trials of pembrolizumab monotherapy across 16 tumor types. A Bayesian model was used to estimate biomarker distributions in responders and nonresponders for each biomarker assuming normality.

Results: ORR prevalence data generated by varying the cutpoint were fit well by the biomarker distribution model for all 3 biomarkers. Individual biomarker ORR prevalence curves and 95% credible intervals overlapped substantially with each other, consistent with indistinguishable areas under the receiver operating characteristics curve (AUROC) for PD-L1, TMB and GEP in this pan tumor population. Thus, although PD-L1 or GEP identify populations only partially overlapping with that of TMB, the predictive ability is similar for all 3 biomarkers.

Table: 99P

Biomarker	Value (95% CI)			
	ORR @ 60% Prevalence	ORR @ 30% Prevalence	ORR @ 10% Prevalence	AUROC
PD-L1	15.5 (12.0, 19.0)	21.5 (15.8, 27.4)	33.6 (22.3, 45.7)	0.69 (0.63, 0.76)
GEP	17.5 (14.1, 21.2)	24.8 (19.2, 30.1)	33.5 (24.2, 44.1)	0.76 (0.70, 0.82)
TMB	15.0 (11.7, 18.6)	21.5 (15.7, 27.7)	35.9 (24.0, 49.0)	0.67 (0.59, 0.74)

CI = Credible interval for ORR and confidence interval for AUROC

Conclusions: A model using biomarker distributions in responding and nonresponding patients accounts for the relationships among cutpoints, response rate and prevalence, and may provide a framework for interpretation of biomarker response data in IO.

100P Comparison of OncoBEAM and NGS methods to detect plasma EGFR T790M mutations at progression of NSCLC

J. Garcia[1], A. Delherme[1], F. Geigeur[1], P. Merle[2], C. Tissot[3], F.S. Jones[4], D. Edelstein[5], P-J. Souquet[6], C. Rodriguez-Lafrasse[1], S. Couraud[6], L.F. Payen[1], Z. Xu[7]

[1]Biochemistry and Molecular Biology Department of Lyon Sud, Hospices Civiles de Lyon, Lyon, France, [2]Oncology, Centre Jean Perrin, Clermont-Ferrand, France, [3]Oncology, CHU de Saint Etienne, Hôpital du Nord, St. Priest en Jarez, France, [4]Oncology, Sysmex-Inostics, Inc., New York, NY, USA, [5]Oncology, Sysmex Inostics, Baltimore, MD, USA, [6]Oncology, Centre Hospitalier Lyon Sud, Pierre Bénite, France, [7]Bio-informatics, Sophia-Genetics, Lausanne, Switzerland

Background: Various methods have been employed to detect plasma EGFR mutations in patients with non-small cell lung cancer patients (NSCLC). Therefore, we evaluated the performance of digital PCR and next generation sequencing (NGS) to detect the p.T790M EGFR mutation in prospectively collected patient samples. Paired plasma samples from patients (CIRCAN cohort) that progressed on first-line EGFR TKI therapy were compared using two platforms: OncoBEAM^{TM}-EGFR (Sysmex Inostics) and NGS (Illumina), utilizing the 56G oncology panel (Swift Biosciences).

Methods: 196 stage 4 NSCLC patients with EGFR alteration under TKI were included from various center. Blood was collected in a routine setting, when physician noted

changes in CT scans that were suspicious of progression. CfDNA analysis is recommended in front line in this setting in France. Replicate plasma samples were analysed using OncoBEAM and NGS. The thresholds for calling EGFR plasma mutations were 0.5% and 0.02% for NGS and OncoBEAM, respectively and were validated using cfDNA reference standards (Horizon Discovery).

Results: OncoBEAM detected the p.T790M mutation in 36/196 patients (18.3%), whereas NGS detected T790M in 20/196 patients (10.2%). The agreement of NGS vs OncoBEAM for T790M detection was 55.6%. The p.T790M-positive samples detected by OncoBEAM but missed by NGS were all found to have low mutant allelic fractions (under 0.35%). With regard to sensitizing EGFR mutations, 28/36 OncoBEAM T790M+ patients had accompanying EGFR mutations, whereas all 20/20 NGS T790M+ samples showed presence of sensitizing mutations. In contrast to OncoBEAM, NGS testing revealed other somatic alterations including ERBB2 amplification, and mutations in TP53.

Conclusions: In conclusion, these findings highlight the value of OncoBEAM^{TM}-EGFR and NGS for detecting T790M at early progression. While less sensitive, NGS provided broader genomic coverage which may reveal diverse mechanisms of resistance. In contrast, OncoBEAM delivers superior sensitivity for focused detection of known resistance alterations such as EGFR T790M. Thus, OncoBEAM may provide the sensitivity required to monitor the kinetics of circulating tumor DNA and correlations with therapeutic response.

101P Differential expression of PD-L1 and immune biomarkers by age: Decreased expression in pediatric/AYA patients with advanced cancer

O. Hamid[1], A.M. Vanderwalde[2], C. Szeto[3], S. Reddy[3], S.K. Pal[4]

[1]Research/Immuno-Oncology, The Angeles Clinic and Research Institute, Los Angeles, CA, USA, [2]Hematology/Oncology, University of Tennessee, Memphis, TN, USA, [3]Bioinformatics, NantOmics, Culver City, CA, USA, [4]Medical Oncology and Therapeutics Research, City of Hope, Duarte, CA, USA

Background: The activity of immune checkpoint inhibitors (ICIs) varies substantially at the extremes of age. We interrogated our tissue database (n = 1,467) to determine if expression of checkpoint molecules or variations in tumor mutational burden (TMB) could explain this phenomenon.

Methods: Whole transcriptomic sequencing (RNA-Seq; ~200x10^6 reads/tumor) was performed across 1,467 unselected clinical cases (NantHealth; Culver City, CA), with breast, colon, lung and sarcoma reflecting the most common tumor types assessed. To reflect the extremes of age, patients age < 25 and ≥ 80 were compared to the remainder of the cohort. PD-L1 expression was compared across these age-based subsets, along with CTLA4, TIGIT, FOXP3, LAG3, OX40, TIM3 and IDO expression. Putative markers of ICI resistance (e.g, VEGF-A/B/C) were also explored. Tumor mutational burden (TMB; defined as exonic nonsynonymous mutations/megabase [muts/Mb]) was characterized in each subset.

Results: Median age of the cohort was 59 (range, 2-97). Of 1,467 patients, 84 and 65 were age < 25 and ≥ 80, respectively. In patients < 25, significantly lower PD-L1, CTLA4, FOXP3, OX40, LAG3 and TIGIT levels were observed ($P < 0.001$ for each). No significant differences in IDO, LAG3 or TIM3 were observed in this younger cohort. Older patients had no significant differences in checkpoint molecule expression; curiously, a nonsignificant trend towards increased expression of PD-L1, FOXP3 and LAG3 was observed in the small subset of patients age ≥ 85. No differences in TMB were observed by age. Expression and TMB in each decile of age will be reported.

Conclusions: In pediatric and adolescent and young adult (AYA) patients, lower expression of multiple immune checkpoint molecules may have implications for immune combinatorial strategies. An opposing trend was seen in octagenarians and nonagenarians in our cohort. A detailed further breakdown by histologic subtype will be presented.

102P Potential resistance mechanisms revealed primary resistance to crizotinib in ROS1+ non-small cell lung cancer using next generation sequencing: A multicenter study

Q. Zhang[1], C. Xu[1], W. Wang[2], W. Zhuang[3], Z. Song[2], Y. Zhu[4], Y. Chen[1], G. Chen[1], M. Fang[2], T. Lv[5], Y. Song[5]

[1]Pathology, Fujian Cancer Hospital, Fuzhou, China, [2]Chemotherapy, Zhejiang Cancer Hospital, Hangzhou, China, [3]Medical Thoracic Oncology, Fujian Cancer Hospital, Fuzhou, China, [4]Thoracic Disease Center, Zhejiang Rongjun Hospital, Jiaxing, China, [5]Respiratory Medicine, Jinling Hospital, Nanjing, China

Background: Crizotinib have greatly improved the prognosis of ROS1+ lung adenocarcinoma. However, approximately 5% to 10% of patients with ROS1+ non-small-cell lung cancer (NSCLC) have primary resistance to crizotinib treatment. The underlying mechanism is unknown.

Methods: We screened 2617 patients with NSCLC for ROS1 fusion. Among them, 23 patients received crizotinib treatment, and a total of 20 patients with stage IIIb-IV ROS1+ NSCLC were undergoing tumor biopsies or blood withdrawing by the time of primary or acquiring resistance to crizotinib, in including 4 formalin-fixed paraffin-embedded (FFPE) samples, 13 serum samples and 3 serous effusions. We used targeted NGS to detect genes status of patients.

Results: Among 23 patients treated with crizotinib, 73.9% (17/23) developed acquired resistance, and 13.04% (3/23) had primary resistance. Using the specimens at the baseline, there was 1 (33.3%) patient with BCL2L11 loss (BIM deletion polymorphism), 1 (33.3%) patient with PTEN mutation, and 1 (33.3%) patient with KIT mutation. Median PFS was significantly shorter in patients with primary resistance than those with acquired resistance (2.3 vs. 14.5 months, $P < 0.001$).

Conclusions: BCL2L11 loss, PTEN mutation, and KIT mutation might contribute to molecular mechanisms of primary resistance to crizotinib in ROS1+ NSCLC. Further investigations are warranted to overcome these primary resistances.

103P Prevalence of CLDN18.2, HER2 and PD-L1 in gastric cancer samples

D. Moran[1], D. Maurus[2], C. Rohde[3], A. Arozullah[4]

[1]Oncology Biomarkers, Astellas Pharma US, Inc., Northbrook, IL, USA, [2]Data Science and Biomarker Analysis, BioNTech AG, Mainz, Germany, [3]Medical Oncology, Merck KGaA, Darmstadt, Germany, [4]Development Medical Sciences - Oncology, Astellas Pharma US, Inc., Northbrook, IL, USA

Background: In gastric cancer (GC) there is a need for therapeutic targets/biomarkers beyond HER2 and PD-L1; Claudin 18.2 (CLDN18.2) is a promising target. In healthy tissue, CLDN18.2 is confined to gastric mucosa tight junctions; however, upon malignant transformation, perturbations in cell polarity lead to exposure of CLDN18.2 on the surface of GC cells. In a randomized clinical study (FAST; NCT01630083), patients with CLDN18.2-positive advanced GC and gastroesophageal junction (GEJ) cancers treated with EOX and zolbetuximab (an anti-CLDN18.2 monoclonal antibody) had prolonged survival compared with EOX alone. The CLDN18.2, HER2, and PD-L1 prevalence in global GC/GEJ tissue samples were assessed in this study.

Methods: FFPE GC/GEJ tissue samples were stained using antibodies against CLDN18.2, PD-L1, and HER2. IHC assays were run on an automated platform; HER2 amplification was determined by HER2 CISH. Stained samples were evaluated by a trained pathologist using established scoring criteria.

Results: A total of 298 GC/GEJ tissue samples (North America, n = 100; Asia, n = 100; Europe, n = 98) were assessed; 148 (50%) were histologically classified as intestinal, 123 (41%) diffuse, 18 (6%) mixed, and 9 (3%) other. In American samples, intestinal histology was the most prevalent; diffuse and intestinal were similar within Asian and European samples. Of the 286 evaluable samples, 30% (n = 86/286) were CLDN18.2^{high} (moderate-to-strong CLDN18.2 membrane staining in $\geq$75% of tumor cells). CLDN18.2^{high} prevalence ranged from 24% (n = 22/92) in Asian samples to 34% (n = 33/97) in American samples. CLDN18.2^{high} prevalence was 30% (n = 35/115) in diffuse and 28% (n = 40/145) in intestinal subtypes. HER2+ and PD-L1+ ($\geq$1% membrane-stained tumor cells) occurred in 10% (n = 29/291) and 37% (n = 107/289) of the evaluable samples, respectively. Of CLDN 18.2^{high} samples with evaluable status for HER2, CLDN18.2 overlapped with HER2 in 12% (n = 10/83) of cases.

Conclusions: CLDN18.2 was found globally to be a high prevalence target in GC/GEJ cancer with limited overlap with HER2. In light of the clinical activity observed for zolbetuximab, CLDN18.2 may serve as a therapeutic target for a large subgroup of patients with GC/GEJ cancer.

104P Epigenetic markers in circulating cell-free DNA for detection of early stage colorectal cancer

Y. Liu[1], C.K. Tham[2], S. Ong[2], C.L. Tang[1], Y. Zhao[3]

[1]Colorectal Surgery, Singapore General Hospital, Singapore, [2]Medical Oncology, National Cancer Centre Singapore, Singapore, [3]Clinical Research, Singapore General Hospital, Singapore

Background: The detection of early stage colorectal cancer (CRC) significantly improves chances of a cure and is a key factor in reducing CRC mortality rates. Colonoscopy is currently the gold standard for CRC diagnosis, but a somewhat troublesome and invasive procedure makes its acceptance not high in the general public as a screening tool. Epigenetic silencing of tumor-related genes by promoter methylation is common in CRC, but no biomarker has been proven to be individually of sufficient sensitivity or specificity in routine clinical practice. Objective: To identify tumor-derived methylated genes in the serum of stage IIA CRC and assessed their diagnostic potentials for early stage of colorectal cancer.

Methods: In this prospective study, DNA methylation levels were measured by quantitative methylation-specific PCR. Seven genes were screened in an exploratory set of case-control serum samples. Promising methylation markers were selected and verified in the serum of a test set compromising 60 stage IIA CRC and 60 age-gender-matched healthy controls. Receiver operating characteristic curve (ROC) was constructed for assessment of assay performance.

Results: Serum methylation levels of TAC1, EYA4 and SST were significantly higher in stage IIA patients as compared to healthy controls (all $P < 0.001$, Mann-Whitney U test). Area under the receiver operating curve (AUC) using serum methylation of TAC1 and EYA4 was 0.76 [95% confidence interval (CI), 0.68-0.85] and 0.73 (95% CI, 0.64-0.82), respectively. At a specificity of 85%, the assay sensitivity of TAC1 and EYA4 was 58.3% and 43.3%, respectively. Combination of serum methylation levels of EYA4 and SST improved the assay sensitivity to 52.5%. With TAC1 and SST being investigated in tumor DNA as well, we noticed that methylation of both genes in the serum DNA always mirrored that of tumor DNA, exhibiting 100% concordance.

Conclusions: Serum methylation levels of TAC1, EYA4 and SST might be useful for minimally invasive detection of early stage of colorectal cancer. Validation study in larger and independent cohorts is necessary.

105P Detection and clearance of RET variants in plasma cell free DNA (cfDNA) from patients (pts) treated with LOXO-292

B. Besse[1], V. Subbiah[2], A. Drilon[3], M. Shah[4], L.J. Wirth[5], T.M. Bauer[6], V. Velcheti[7], N. Lakhani[8], V. Boni[9], B.J. Solomon[10], M. Johnson[6], K. Park[11], J. Patel[12], M.E. Cabanillas[13], E. Sherman[3], E. Zhu[14], K. Gordon[14], K. Ebata[14], B. Tuch[14], G. Oxnard[15]

[1]Dept of Cancer Medicine, Gustave Roussy Institut de Cancérologie, Villejuif, France, [2]Investigational Cancer Therapeutics (Phase 1 Program), The University of Texas, MD Anderson Cancer Center, Houston, TX, USA, [3]Medical Oncology, Memorial Sloan-Kettering Cancer Center, New York, NY, USA, [4]Comprehensive Cancer Center, The Ohio State University, Columbus, OH, USA, [5]Cancer Center, Massachuetts General Hospital, Boston, MA, USA, [6]Oncology, Sarah Cannon Research Institute, Tennessee Oncology, Nashville, TN, USA, [7]Hematology and Oncology Department, Cleveland Clinic, Cleveland, OH, USA, [8]Developmental Therapeutics, START - Midwest, Grand Rapids, MI, USA, [9]Medical Oncology, START Madrid-CIOCC HM Hospital Sanchinarro, Madrid, Spain, [10]Molecular Therapeutics and Biomarkers Laboratory, Peter MacCallum Cancer Center, Melbourne, Australia, [11]Div. of Heamatology/Oncology, Medicine, Samsung Medical Center Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [12]Thoracic Oncology, University of Chicago, Chicago, IL, USA, [13]Department of Endocrine Neoplasia and Hormonal Disorders, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [14]Translational Medicine, Loxo Oncology, Inc, South San Francisco, CA, USA, [15]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, USA

Background: LOXO-292 is a novel, highly-selective, small molecule inhibitor of RET currently in clinical development (Phase 1, NCT03157128) for pts with advanced cancers harboring oncogenic RET alterations (e.g. non-small cell lung cancer [NSCLC], medullary thyroid cancer [MTC], papillary thyroid cancer [PTC], etc.). Here, we update data previously presented at ASCO 2018 on modulation of RET variant allele frequencies (AF) in plasma cfDNA with LOXO-292 therapy.

Methods: Blood was collected pretreatment, after 15 days of treatment, and at each restaging for cfDNA analysis by next-generation sequencing (NGS, Guardant).

Results: As of 4/2/18, 82 pts were enrolled (38 RET fusion NSCLC, 29 RET mutated MTC, 9 RET fusion PTC, 2 RET fusion pancreatic cancer and 4 others) to 8 dose cohorts (20mg QDà240mg BID), and 343 plasma samples were collected. Here we report on 65 pts with plasma NGS results available. Of 62 pts enrolled based on a RET variant detected in a tumor sample, concordant RET alterations were detected in 41 (66%) of the corresponding pre-treatment plasma samples, including 19/30 (63%) pts with RET-fusion NSCLC and 16/21 (76%) pts with RET-mutant MTC. Median AF was higher for MTC (7.03%) than NSCLC (0.51%). In RET alteration-negative pre-treatment samples, peak AF for other detected alterations was generally low (0.28% median), suggesting low tumor DNA shed into plasma. Of 34 pts with a detectable pre-treatment plasma RET alteration and day 15 plasma NGS, RET alteration AF decreased by a median of 96%, with complete clearance in 15 pts (44%). Day 15 plasma clearance was observed at multiple doses, and was more common in RET fusion-positive (67%) than RET-mutant (8%) pts. Data for additional pts will be updated at the time of presentation.

Conclusions: The rapid clearance of RET variants from plasma cfDNA on LOXO-292 supports its observed clinical activity across a range of doses, tumor types and RET alterations. NGS of plasma cfDNA can detect a range of targetable RET variants, though tumor genotyping remains critical if the initial plasma NGS is negative. Serial plasma genotyping warrants continued study as an early pharmacodynamic marker for novel targeted therapies.

Clinical trial identification: NCT03157128.

106P A prediction panel with DNA methylation biomarkers for lung adenocarcinoma

N. Shen[1], Y. Pan[2], X. Mo[3]

[1]Department of Rehabilitation, Xinhua Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China, [2]Functional Genome Analysis, Deutsches Krebsforschungszentrum, Heidelberg, Germany, [3]Institute for Pediatric Translational Medicine, Shanghai Children's Medical Center, Shanghai, China

Background: Lung adenocarcinoma accounts for more than 40% of lung cancer incidence. Thus, it is urgent to identify early-stage related markers. In this study, the effectiveness of CpG methylation on predicting lung adenocarcinoma was investigated.

Methods: In total, 1,170 patients with lung adenocarcinoma from four independent databases and one medical center were sorted by three phases. In the discovery phase, 338 lung adenocarcinomas and nonmalignant samples were collected from the GEO databases which used Illumina Infinium HumanMethylation27K BeadChip for the methylation analysis. The K-Means Clustering algorithm was used to select significant CpGs. In the training phase, recursive feature elimination was performed to evaluate the importance of selected CpGs to classification model. In the validation phase, four candidate CpGs were validated using two cohorts ($n = 832$ and $n = 10$). To explore the potential biological function of selected CpGs, GO enrichment analysis was performed using the Database for DAVID version 6.8.

Results: After the selection of CpGs by the K-Means Clustering algorithm, 62 CpGs showed great different methylation profiles between lung adenocarcinomas and adjacent nonmalignant lung tissue ($p < 0.05$). Among these selected CpGs, 95.16% were hypermethylated in the malignant samples comparing to only 4.84% were hypomethylated. With the evaluation of recursive feature elimination, four CpGs corresponding to HOXA9, KRTAP8-1, CCND1, and TULP2 were highlighted as candidate predictors in the training phase. The performance of these four candidate CpGs were validated in two validation cohorts ($p < 0.01$). These disparate hypermethylated genes were significantly enriched in GO biological processes including negative regulation of transcription from RNA polymerase II promoter, DNA-templated transcription, while the hypomethylated gene was obviously enriched with the terms including adenylate cyclase-activating G-protein coupled receptor signaling pathway. The direction of methylation did not affect the enrichments for Out-CpG sites.

Conclusions: A four-CpG-based signature, including HOXA9, KRTAP8-1, CCND1 and TULP2, is useful for the prediction of lung adenocarcinoma.

107P Novel genomic classifier for early stage colorectal cancer patients

E. Letellier[1], M. Schmitz[1], A. Ginolhac[1], E. Koncina[1], M. Marchese[2], L. Antunes[3], S. Rauh[4], S. Haan[1]

[1]Life Sciences Research Unit, University of Luxembourg, Belval, Luxembourg, [2]Biomarker Validation, Integrated Biobank of Luxembourg, Dudelange, Luxembourg, [3]Pathology, Integrated Biobank of Luxembourg, Dudelange, Luxembourg, [4]Hématome Oncologie, Centre Hospitalier Emile Mayrisch CHEM, Esch-sur-Alzette, Luxembourg

Background: Identifying patients at risk of relapse in early colorectal cancer (CRC) stages is an unmet clinical need. Due to the limitations of clinicopathological variables in predicting individual risk of recurrence in CRC patients, genomic information has

increasingly gained prominence as a potential method for patient stratification. We have previously shown that Myosin Vb (MYO5B) expression alone or in combination with the expression of its adapter protein RAB8A shows strong prognostic value in early CRC patients (PMID 29024942).

Methods: We are currently setting up a meta-analysis including multiple CRC datasets, which allows to further validate the prognostic value of the genomic classifier. Additionally, this meta-analysis will determine the predictive value of the classifier on chemotherapy efficiency. Furthermore, pre-analytical and analytical assays will assess the reproducibility, sensitivity and specificity of the biomarker. Finally, we will prospectively collect stage II CRC tumor samples to clinically validate our classifier.

Results: In the follow-up study, we have now validated the prognostic value of the classifier in independent datasets. By multivariate analysis, we show that the gene expression signature is independent of clinicopathological features currently used in the clinics (stage, grading, T3, MSI status among others). Importantly, the identified molecular classifier outperformed the other three molecular tests (Oncotype DX, Coloprint and Oncodefender) that are commercially available but not FDA approved for predicting patient relapse. We will report on the predictive value of our molecular classifier on chemotherapy efficiency. In addition, first results on the pre-analytical and analytical analysis of the classifier will be presented.

Conclusions: Altogether, MYO5B together with RAB8A might allow delineating a high-risk population in early CRC stages. This stratification could potentially help oncologists to choose the best treatment plan, especially for stage II patients, where adjuvant chemotherapy may not always lead to beneficial results, but still results in significant side-effects.

108P Baseline blood immune profiling to predict response to antiPD-1 in patients with advanced non-small cell lung cancer

E. Romano[1], T. Le Bourgeois[1], S. Lopez-Lastra[1], V. Servois[2], S. Beaucaire-Danel[3], C. Daniel[3], J-Y. Pierga[3], F-C. Bidard[3], O. Lantz[1]

[1]Center of Cancer Immunotherapy, Department of Oncology, Institut Curie, PSL Research University, Paris, France, [2]Department of Radiology and Nuclear Medicine, Institut Curie, Paris, France, [3]Department of Oncology, Institut Curie, Paris, France

Background: Immune checkpoint inhibitors have remarkably improved the natural history of patients (pts) with non-small cell lung cancer (NSCLC), with improved clinical responses and overall survival compared to standard therapy. However, over 80% of unselected NSCLC pts do not respond, highlighting the need of theranostic biomarker discovery. In a cohort of NCSLC pts treated with antiPD-1, we investigated blood immune parameters at baseline and pts characteristics as potential theranostic biomarkers.

Methods: Thirty-four pts with locally advanced/metastatic NSCLC received antiPD-1 therapy as ≥ 2 line treatment in a prospective biomarker study (NCT02866149). Peripheral blood mononuclear cells and plasma were analyzed at baseline by multiparametric flow cytometry and Luminex technology, respectively. Primary endpoint was to correlate cellular and soluble immune parameters with clinical outcome based on RECIST criteria.

Results: Baseline $CD3^+/CD14^+$ ratio was a robust predictive biomarker with pts achieving progression free survival (PFS) $\geq$4 months showing an average ratio of 1.91 vs 1.11 in pts with PFS <4 months ($p = 0.003$). Furthermore, we found a strong positive correlation between the proportion of $HLA\text{-}DR^{hi}CD14^+$ monocytes and the PFS ($r = 0.471$), with objective responders showing higher CD86 expression, suggesting an improved antigen-presenting capacity. In addition, pts with a PFS $\geq$4 months, displayed higher proportions of $CCR7^-CD45RA^-$ effector memory $CD8^+$T cells and regulatory $CD4^+$T cells suggesting pre-existing adaptive immune responses. In line with previous reports, our results confirmed the association of baseline plasma albumin with clinical outcome, with levels $\geq$ 3.9 g/dL associated with improved PFS ($p = 0.026$), likely due to the lower plasma levels of the pro-inflammatory mediator IL-6. Finally, soluble CD40 ligand was elevated in pts with reduced PFS, probably in relation with an elevated platelet activation, further supported by a 2-fold increase in plasma concentration of baseline platelet-derived growth factors (PDGFs) in these pts.

Conclusions: Our study identifies promising, predictive, immune-related biomarkers in NSCLC pts treated with PD-1 blockade.

Clinical trial identification: NCT02866149.

109P Evaluation of clinicopathological and molecular criterias for screening of exonucleasic domain POLE (edPOLE) mutated patients in proficient mismatch repair (pMMR) colorectal and endometrial cancers

J. Cohen[1], B.J-C. Rousseau[2], R. Bourgoin[1], C. Tournigand[2], L. Larnaudie[1], A. Dupuy[3], M. Ollier[1], A. Pujals[1]

[1]Departement of Pathology, Centre Hospitalier Universitaire Henri-Mondor, Créteil, France, [2]Service d'Oncologie, Centre Hospitalier Universitaire Henri-Mondor, Créteil, France, [3]U955 Équipe 9, INSERM, Créteil, France

Background: Mismatch Repair Deficiency (dMMR) and edPOLE mutations (mt) are responsible for hypermutated tumoral phenotype. Immunotherapy have shown efficacy in dMMR/high mutation burden patients (pts) and could be also active in edPOLEmt tumors. These mt occur in 6-12% of endometrial cancers (EC) and in 1-2% of Colorectal Cancer (CRC) and are likely infrequent in advanced setting. We aimed to define the most relevant clinicopathogical and molecular criterias to facilitate screening for edPOLE mt pts.

Methods: EdPOLE mutational status was evaluated in cohorts of pMMR CRC and EC using High Resolution Melting PCR on the hotspots described in literature (codons 286, 411 and 459). CRC subcohorts were enriched for BRAF mt, RAS mt, unusual BRAF/RAS mt and young pts ($\leq$40 yrs). Pts harboring a mutated profile were confirmed by Sanger sequencing.

Results: 245 pts were screened: 49 EC and 196 CRC. Among CRC, 41 were BRAF mt (30 V600E, 11 non V600E), 79 were KRAS mt (30 on codon 12/13, 49 other mt), 20 were selected because of the presence of $\geq$ 2 simultaneous BRAF/KRAS/NRAS mt, 30 were BRAF/KRAS/NRAS wild type (wt) and 30 were $\leq$40 yrs. Using our method, 9 edPOLE mt tumors were identified (Table): 4 among EC and 5 among CRC. edPOLE mt EC were all endometrioid ADK. edPOLEmt CRC were all localized in the left colon or rectum with unusual molecular alterations: 1 BRAF (p.D594G), 3 KRAS mt (p.A59T p.A146T et p.N116H) and 1 with two NRAS mt (p.Q61R et p.T58A).

Table: 109P

Tumor subcohort	% of edPOLE mt (n/N)	Clinical and molecular profile of edPOLE mt pts
Whole cohort	3.6 (9/245)	pMMR: 100% (9/9)
EC Endometrioid adenocarcinomas Other histologies	8 (4/49) 13 (4/31) 0 (0/18)	3 codon 286 POLE 0 codon 411 POLE 1 codon 459 POLE
CRC BRAF/KRAS/NRAS wt p.V600E BRAF mt Non p.V600E BRAF mt Codons 12 or 13 KRAS mt Non codons 12 or 13 KRAS mt Multiple BRAF/KRAS/NRAS mt	2.6 (5/196) 0 (0/30) 0 (0/30) 9 (1/11) 0 (0/30) 6 (3/49) 5 (1/20)	Left colon or rectum: 100% (5/5) Age $\leq$ 40 years old: 20% (1/5) 2 codon 286 POLE 1 codon 411 POLE 2 codon 459 POLE

Conclusions: Our screening strategy identified edPOLEmt in 13% of endometrioid ADK and 2.6% of CRC. Pts selection on clinicopathological (histology for EC, young age, left colon or rectum), and molecular criterias (pMMR, unusual BRAF/KRAS/NRAS mt) seem to increase the proportion of edPOLEmt. The use of these criteria in practice could help select patients for edPOLE screening. Additional clinicopathological and molecular data will be shown.

110P Immune prognostic index (IPI) and hyper-progressive disease (HPD) in patients (pts) exposed to targeted agents (TAs) in phase I trials (Ph1T): Can lessons from immune checkpoint inhibitors (ICIs) be translated to other scenarios?

I. Matos Garcia[1], A. Azaro[2], C. Viaplana[3], C. Hierro[4], J. Martin-Liberal[4], I. Brana[5], I. Gardeazabal[1], P. Gomila[6], M. Vieito Villar[4], M. Ochoa De Olza Amat[7], E. Elez Fernandez[7], M. Oliveira[7], A. Oaknin[7], H. Verdaguer[1], A. Navarro Mendivil[2], M. Alsina[8], J. Tabernero[9], T. Macarulla Mercade[1], R. Dienstmann[10], E. Garralda[11]

[1]Medical Oncology, Vall d'Hebron Institute of Oncology (VHIO)-Cellex Center, Barcelona, Spain, [2]Oncology Department, Vall d'Hebron University Hospital, Barcelona, Spain, [3]Oncology Data Science (ODysSey) Group, Vall d'Hebron University Hospital, Barcelona, Spain, [4]Oncology, Vall d'Hebron Institute of Oncology (VHIO)-Cellex Center, Barcelona, Spain, [5]Department of Medical Oncology, Vall d'Hebron Institute of Oncology, Barcelona, Spain, [6]Oncology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [7]Medical Oncology, Vall d'Hebron University Hospital, Barcelona, Spain, [8]Medical Oncology, Vall d'Hebron University Hospital and Vall d'Hebron Institute of Oncology, Barcelona, Spain, [9]Medical Oncology, Vall d'Hebron University Hospital, Barcelona, Spain, [10]Oncology Data Science, Vall d'Hebron University Hospital, Barcelona, Spain, [11]Early Drug Development Unit, Vall d'Hebron Institute of Oncology (VHIO)-Cellex Center, Barcelona, Spain

Background: IPI score (derived neutrophil/(leukocytes minus neutrophils)ratio [dNLR]>3 plus LDH>upper limit normal) is a emerging tool to predict overall survival (OS) with ICIs in different tumor types. HPD has been reported in 15% of pts on ICIs using different criteria, including ours (PD at first restaging with ≥40% increase in sum of target lesions or ≥ 20% with appearance of multiple new lesions; Matos et al, ASCO 2018). We aimed to assess the prognostic value of IPI and the relevance of HPD in pts enrolled in Ph1T with TAs.

Methods: Retrospective analysis of a consecutive cohort of pts treated with experimental TAs at VHIO Ph1T Unit over the last 3 years (we excluded pts in the first dose escalation cohorts of each trial as well as TAs matched to validated biomarkers). Overall survival (OS) was correlated with VHIO HPD criteria and IPI.

Results: In total, 180 pts were treated with TAs (34% FGFR, 26% PI3K, 19% MET, 13% NOTCH, 5% IDH, 3% RAF). In 39% of the cases, TAs were matched to an emerging enrichment molecular alteration. Median age 59y, 58% female, most common tumor types: 20% colorectal, 17% breast, 9% gynecological, 8% biliary tract. Best response was PD in 55%, SD in 41%, PR in 4%. Our HPD criteria was met in 10% of the cases, across all tumor types and targets (highest prevalence in colorectal pts treated with PI3K inhibitors, 5/18, 28%). Median progression-free survival was 1.8 months (m) [95% CI 1.7-2.2], not affected target selected, molecular match or IPI score ($p > 0.2$). Median OS was 7.9 m [6.7-10], significantly different as per IPI score (IPI0 18 m [7.8-NA]; IPI1 7.7 m [6.5-9.9]; IPI2 2.6 m [1.7-NA]; $p < 0.001$). Importantly, in pts with PD as best response while on TAs, HPD did not negatively affect OS ($p = 0.43$).

Conclusions: Our results show that a prognostic score developed in cohorts treated with ICIs also predicts long-term outcome with TAs in Ph1T. HPD criteria can be met with TAs treatment, but the lack of survival impact (different from internal and external cohorts exposed to ICIs) suggests that it is not a relevant clinical finding.

111P Combination of baseline LDH, performance status and age to identify solid tumor patients with higher probability of response to anti-PD1 and PDL1 monoclonal antibodies

M.S. Cona[1], M. Lecchi[2], S. Damian[1], M. Del Vecchio[1], C. Cimminiello[1], S. Cresta[3], M. Duca[3], A. Necchi[1], D. Signorelli[3], M. Poggi[3], D. Raggi[2], R. Ratta[2], P. Verderio[2], F.G.M. de Braud[1], M. Di Nicola[3]

[1]Department of Medical Oncology and Hematology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [2]Department of Applied Research and Technological Development, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [3]Department of Medical Oncology and Hematology, Istituto Nazionale dei Tumori di Milano - Fondazione IRCCS, Milan, Italy

Background: The advent of immune check point inhibitors (ICIs) has improved prognosis of various cancers. To better select responding patients (pts) and for a more accurate management of economic resources, biological and biochemical factors have been investigated. To date, no predictive biomarkers have been validated. The aim of this study is to identify manageable and routinely detectable parameters to use in clinical practice to select pts with higher change of response to ICIs.

Methods: 271 consecutive metastatic solid tumor pts treated in our Institute from 2013 to 2017 with ICIs were evaluated for baseline LDH serum level, ECOG score, age, type of ICI, number of metastatic sites, histology and sex. A training and validation set were used to build and test models, respectively. Variables' effects were assessed through odds ratio estimates (OR) and area under the receive operating characteristic curves (AUC), from univariate and multivariate logistic regression models. The validated estimates were used to develop an Excel algorithm to calculate probabilities of response.

Results: As best response, 55.4% of pts achieved disease control and 44.7% had progressive disease. On the training set, LDH, age and ECOG showed a significant OR (p:<.001, 0.009, 0.042, respectively) and were combined in a multivariate model with an AUC of 0.771 (95%CI: 0.701;0.842). These results were statistically validated on the validation set (AUC: 0.685, 95%CI: 0.569;0.801). By fitting the validated model on all pts, the 3 variables retained a significant OR and a satisfactory cross-validated AUC.

Conclusions: We confirm, as reported in literature, that baseline LDH serum levels are inversely associated with response probability. It's reasonable to jointly consider age and ECOG, which give a significant contribution to model performance. The developed algorithm, once validated on an independent prospective series, might be a base to guide physicians in clinical practice to better plan ICI therapy tailored on pts characteristics.

112P Effects of concomitant genetic alterations on cancer patient overall survival

Y. Wang[1], P. Peng[2], L. Shang[3], Y-A. Dong[4], Z. Yang[5], H. Zhong[6]

[1]Tumor Research and Therapy Center, Shandong Provincial Hospital Affiliated to Shandong University, Ji'nan, China, [2]Oncology Department, Guangdong Second Provixcial General Hospital, Guangzhou, China, [3]Department of Gastrointestinal Surgery, Shandong Provincial Hospital Affiliated to Shandong University, Ji'nan, China, [4]OrigiMed, OrigiMed, Shanghai, China, [5]Courage, Shu Lan (Hangzhou) Hospital; Zhejiang University International Hospital, Hangzhou, China, [6]Department of Thoracic and Cardiovascular Surgery, People's Hospital of Beihai, The Ninth Affiliated Hospital of Guangxi Medical University, Beihai, China

Background: Genomic alterations have a profound impact on all aspects of cancer biology and therapy. Concomitant mutations involving multiple genes are intrinsically complex, and their relationship with biomarkers such as TMB and clinical outcomes such as drug response is only beginning to be explored. In this study, we systematically analyzed the impact of pairwise co-mutations of common genes on patient overall survival (OS).

Methods: We downloaded the publicly available TCGA datasets and used the LUAD lung adenocarcinoma subset for our pilot study. To limit noise, we restricted our attention to the top 48 most commonly mutated genes among LUAD patients. For each pair of genes g1 and g2 in this list, we compared the survival data of three groups of patients: those with g1 mutations only, those with g2 mutations only, and those with both g1 and g2 mutations. Kaplan-Meyer survival curves were plotted and p-values computed.

Results: We obtained a large number of double mutants (223 out of 1128 possible pairs, ∼20%) with significantly different OS from single mutants. There was a wide spectrum of "co-mutation potential": on one hand, genes such as AHNAK2 and ANK2 readily co-mutated with many other genes, all leading to double mutants with distinguishing OS; on the other hand, genes such as DMD or DNAH9 co-mutated with few or no other genes that led to distinguishing double mutants. In terms of OS, double mutants could be put into three broad categories: those better than either single mutant ("synthetic rescue"), those worse ("synthetic lethal"), and those in between ("averaging"). Surprisingly, many double mutants exhibited synthetic-rescue behaviors. For example, ANK2- and LRP1B-mutant patients had very similar OS, but double-mutants exhibited significantly better OS than either single mutant ($p < 0.001$ in each case).

Conclusions: In our proof-of-concept study we systematically explored the impact of co-mutations on OS. A large number of double mutants exhibited "synthetic rescue" behaviors, and we pinpointed many distinguishing gene pairs for further investigation. It remains to be seen whether co-mutations of the same pair of genes always have the same effect across cancer types, and how they interact with other bio- and clinical markers.

113P Circulating exosomal integrin αvβ5 predicts liver metastasis and prognosis in human colorectal cancer

D. Chu

Gastroenterology, First Affiliated Hospital of Xi'an Jiaotong University (School of Medicine), Xi'an, China

Background: Ever since the "seed-and-soil" hypothesis, the mechanism of cancer metastatic organotropism is still an unsolved mystery. In colorectal cancer (CRC), there is still no robust metastasis predictive biomarkers for distant organ metastasis, which is the most common cause of deaths. In spite of the function of exosome in RNA and

protein delivery, its clinical significance in CRC metastasis remains uncertain. Here, we evaluated the potential role of serum exosome integrin in CRC metastasis.

Methods: Tissue integrin $\alpha_v\beta_5$ was quantified by quantitative reverse-transcription PCR in 31 pairs of primary CRC and corresponding matched liver metastasis (LM), with non-LM as control. Serum exosomal integrin $\alpha_v\beta_5$ was accessed by ELISA in 126 CRC patients with LM and 166 CRC patients without, as well as when LM was diagnosed in these 166 patients in exploratory cohort. In prospective validation cohort, serum exosomal integrin $\alpha_v\beta_5$ was investigated in 135 initially diagnosed CRC patients without metastasis. CRC-associated metastasis mouse models were established to verify the role of serum exosomal integrin $\alpha_v\beta_5$.

Results: Integrin $\alpha_v\beta_5$ level in LM was significantly increased compared with that in non-LM, which was correlated with its expression in primary CRC. Serum exosomal integrin $\alpha_v\beta_5$ was significantly increased in CRC patients with LM than those without, in a TNM stage-dependent manner. Moreover, it was found that serum exosomal integrin $\alpha_v\beta_5$ in CRC patients was significantly upregulated when LM occurred and associated with unfavorable survival. In validation cohort, increased serum exosomal integrin $\alpha_v\beta_5$ indicated higher risk of LM and unfavorable prognosis. Serum exosomal integrin $\alpha_v\beta_5$ was significantly increased in mice with LM compared with controls.

Conclusions: Our clinical and animal model data indicate that increased levels of serum integrin $\alpha_v\beta_5$ associate with CRC LM and unfavorable survival. These results suggested that circulating integrin $\alpha_v\beta_5$ could be a promising non-invasive predictor for CRC LM and prognosis.

114P Circulating and tumor-associated caspase-4: A novel diagnostic and prognostic biomarker for non-small cell lung cancer patients?

R. Sorrentino[1], M. Terlizzi[1], C. Colarusso[1], A. Saccomanno[1], R. Salvi[2], R.P. Aquino[1], A. Pinto[1]

[1]Department of Pharmacy, University of Salerno, Fisciano, Italy, [2]Thoracic Surgery Unit, AORN, Monaldi, Naples, Italy

Background: Late diagnosis limits therapeutic options and survival rate of non-small cell lung cancer (NSCLC) patients. Therefore, the identification of biomarkers represents an emerging medical need.

Methods: A highly sensitive and specific ELISA test was developed to identify/quantify a novel/selective diagnostic biomarker for NSCLC patients, caspase-4, which was detected into the plasma and tissues of NSCLC patients. This test was validated by using plasma from 125 NSCLC patients and 79 healthy (non-pathological) subjects. Caspase-4 quantification was also assessed in the lung tumor mass of 98 paired-matched NSCLC patients compared to 10 non-tumor lung tissues (i.e. tuberculosis).

Results: Circulating caspase-4 was detected in both healthy and NSCLC patients; however, at different range values: 2.603-3.372 ng/ml for NSCLC patients (95% CI) compared to 0.3994-0.6219 ng/ml for healthy subjects (95% CI). The sensitivity of the test ranged from 97.07% to 100%; the specificity was 88.1% with a positive predictive value of 92.54%, accuracy of 95.19% and AUC of 0.971. Tissue levels of caspase-4 in the tumor mass showed that 72 (72.7%) out of 99 patients were positive. More importantly, higher levels (cut-off value= 0.307 ng/ml) of caspase-4 in the tumor mass were associated to reduced overall survival (median 0.92 years) compared to NSCLC patients with lower levels (median 3.02 years).

Conclusions: We report for the first time caspase-4 as a novel diagnostic and prognostic biomarker, opening new therapeutic perspectives for NSCLC patients.

115P Smokers and COPD patients have high circulating caspase-4 levels: Is it an alarm?

M. Terlizzi, R. Sorrentino, C. Colarusso, A. Molino, A. Saccomanno, R.P. Aquino, A. Pinto

Department of Pharmacy, University of Salerno, Fisciano, Italy

Background: Lung cancer is the leading cancer-related death disease worldwide. This alerting data is mainly due to late diagnosis of lung cancer, especially non-small cell-lung cancer (NSCLC), limiting the therapeutic options. Therefore, the identification of non-invasive, selective, sensitive and specific biomarker/s represents the emerging medical need for the clinical practice to avoid late diagnosis and ameliorate the personalized therapy with an ensuing higher survival rate. It is well known that smoking and chronic obstructive pulmonary disease represent two high risk factors for NSCLC. Therefore, in this study we aimed to evaluate the levels of a novel diagnostic tool for NSCLC patients in order to understand whether caspase-4 could represent a predictive biomarker.

Methods: In order to evaluate the circulating caspase-4 in the blood, we developed an ELISA test.

Results: Smokers ($\geq$15 cigarettes/day) had higher levels of circulating caspase-4 (95% CI, 1.331-1.94 ng/ml) than healthy subjects (95% CI, 0.395-0.619 ng/ml). Though, these levels were statistically lower than those observed in NSCLC patients. Moreover, there were no statistical differences between the levels of circulating caspase-4 in smokers younger or older than 60 years. Similarly, no gender differences were noted. Similarly, COPD patients, who are smokers and former smokers, had higher levels of circulating caspase-4 (95% CI, 1.703-2.995 ng/ml). According to $\chi 2$ test, the expected frequency of smokers, positive to the circulating caspase-4, who could develop NSCLC is robustly significant (calculated $\chi 2$=82.884 vs tabulated $\chi 2$=3.845, df = 1). Moreover, according to the independence test, smoker who were positive to the circulating caspase-4 are at high risk to develop NSCLC.

Conclusions: In conclusion, we report for the first time that the circulating caspase-4 could represent a predictive diagnostic tool to avoid the occurrence of NSCLC.

116P Genomic characteristics of standardized uptake value of 18F-fluorodeoxy-glucose positron emission tomography in breast cancer

S-K. Kim[1], S.G. Ahn[2], S-H. Leem[3], J. Jeong[2], I-S. Chu[4]

[1]Personalized Genomic Medicine Research Center, Korea Research institute of Bioscience and Biotechnology, Daejeon, Republic of Korea, [2]Department of Surgery, Gananam Severance Hospital, Seoul, Republic of Korea, [3]Department of Biological Science, Dong-A University, Busan, Republic of Korea, [4]Korean Bioinformation Center, Korea Research Institute of Bioscience and Biotechnology, Daejeon, Republic of Korea

Background: Standardized uptake value (SUV), an indicator of the glucose uptake degree in ^{18}F-fluorodeoxy-glucose positron emission tomography (FDG-PET), has been used as a prognostic factor in various malignant tumors. The aim of this study is to identify a molecular signature reflecting prognostic SUV characteristics in breast cancer (BRC).

Methods: We sought to identify a molecular signature associated with SUV by a gene expression profiling using a dataset obtained from 60 BRCs who underwent preoperative FDG-PET. The prognostic value of the signature was verified in three BRC cohorts including TCGA dataset (n = 1,616). Various statistical methods, including log-rank and Cox regression analyses, were applied to estimate an association between the signature and BRC prognosis. To compare somatic variants between two patient subgroups divided by the signature, we obtained predefined gene sets involved in oncogenic or metabolic pathways and estimated a difference of their mutation frequencies between subgroups in the TCGA cohort.

Results: By a gene expression profiling, we defined a signature, namely SUV signature, consisting of 723 genes significantly associated with SUV (Pearson correlation test, $|r| > 0.35$, $p < 0.001$). The patient subgroups classified by the signature [i.e., SUV-high-cluster and SUV-low-cluster] were significantly similar with patient classification by SUV [Fisher exact test, odds ratio 8.02, 95% confidence interval (CI) = 2.45-29.3, $p < 0.001$]. When estimating prognostic value of the SUV signature in three cohorts, the signature showed a strong prediction ability (log-rank tests, each $p < 0.05$) and an independent clinical utility (multivariate Cox regression model, hazard ratio = 1.51, 95% CI = 1.07-2.22, $p = 0.01$) in BRC prognosis. Gene network and mutation analyses revealed that a signaling defined by TP53-FOXM1 and its downstream effectors involved in glycolysis-gluconeogenesis might be important mediators in FDG-PET operation.

Conclusions: Our results uncover genomic and metabolomic characteristics of glucose uptake captured by FDG-PET, supporting an understanding of glucose metabolism as well as a poor prognosis in BRC patients with high SUV.

117P Characterization of PD-L1, CD8, CD3, CD68 and PanCK in tumor microenvironment of GI tract tumors with respect to patients' mismatch repair status and anti-PD-1 treatment outcome using 5Plex IHC and whole slide image analysis

W. Zhang[1], M. Khojasteh[2], A. Hubbard[3], J. Martin[4], X. Wang[4], S. Kamthamraju[3], J.L. Munoz-Rodriguez[1], D. Jiang[5], Z. Cai[6], J. Li[6], R. Anders[7], L. Diaz[8], L. Pestic-Dragovich[3], L. Tang[3]

[1]CDx Pharma Service, Roche Tissue Diagnostics - USA, Tucson, AZ, USA, [2]Digital Pathology, Roche Tissue Diagnostics USA, Mountain View, CA, USA, [3]CDx Pharma Service, Roche Tissue Diagnostics - USA, Tucson, AZ, USA, [4]Digital Pathology, Roche Tissue Diagnostics - USA, Mountain View, CA, USA, [5]R&D, Roche Tissue Diagnostics - USA, Tucson, AZ, USA, [6]Biostatistics, Roche Tissue Diagnostics - USA, Tucson, AZ, USA, [7]Pathology, John Hopskin University Hospital, Baltimore, MD, USA, [8]Division of Solid Tumor Oncology, Memorial Sloan Kettering Cancer Center, New York City, NY, USA

Background: Mismatch repair deficiency predicts response of solid tumors to PD-1 blockade. However, not all patients with mismatch repair deficiency respond to the PD-1 blockade treatment. To understand the different responses, we evaluated tumor

micro-environment such as PD-L1 expression in relationship with tumor infiltrating immune cells.

Methods: FL multiplex IHC for PD-L1, CD8, CD3, CD68, and pan-cytokeratin (panCK) on BenchMark ULTRA instrument stained 54 pre-pembrolizumab treatment patient resection and biopsy specimens including pancreatic, colorectal and cholangiocarcinoma. 17 are mismatch-repair proficient (13 PD, 3 SD, and 1 CR) and 37 deficient (5 PD, 10 SD, 9 CR, and 13 PR). Whole slide images by Zeiss AXIO Z1 were analyzed with in-house dPath automated algorithm. PD-L1+/- T-cells (CD3+), cytotoxic T-cells (CD3+ and CD8+), T helper cells (CD3+ and CD8-), macrophages (CD68+), and tumor cells (panCK+) were identified. Fractions of PD-L1+ phenotypes, area density and spatial relationships of phenotypes in pathologist-annotated tumor/peritumor regions, the panCK+ epithelial tumor and panCK- stroma were computed.

Results: Random forest modelling, logistic regression and Relieff feature selection followed by quadrant discriminant analysis were used to assess the relationship of multiplex IHC readouts to anti-PD-1 treatment responses. Different groupings were used, e.g. PR + CR vs. SD + PD, and PR + CR + SD vs. PD, etc. Fraction of PD-L1+ macrophages and fraction of PD-L1+ T helper cells in tumor region, stroma, and epithelial tumor were identified most important features. Mpx IHC achieves 89% accuracy over 70% with mismatch repair status alone.

Conclusions: Multiplex IHC together with automated image analysis provides a tool to evaluate multiple biomarkers and their special relationships in the tumor micro-environment. In a cohort of 54 patient specimens, exploratory analysis of multiplex IHC data suggests that the knowledge of PD-L1 expression on various immune cell phenotypes aids in better predicting response to anti-PD-1 therapy compared to mismatch repair status alone.

118P Exhaustion of platelet kinetics and its implication in post-resection HCC recurrence

B. Aryal[1], T. Shimizu[2], J. Kadono[1], A. Furoi[1], T. Komokata[1], K. Gejima[1], M. Yamakuchi[2], T. Hashiguchi[2], Y. Imoto[1]

[1]Cardiovascular and Gastroenterological Surgery, Graduate School of Medical and Dental Sciences, Kagoshima University, Kagoshima, Japan, [2]Department of Laboratory Medicine, Graduate School of Medical and Dental Sciences, Kagoshima University, Kagoshima, Japan

Background: Platelet activation and the release of various growth factors from platelet granules in response to tumor cell profoundly influence tumor biology. Platelet hyperreactivity in cancer patients is a frequently discussed phenomenon; however, cancer patients were also found to have platelet dysfunction. Considerably less is known about exhaustion of platelet kinetics in cancer.

Methods: In this study, we investigated kinetics of intra-platelet growth factors in hepatocellular carcinoma (HCC) recurrence. We prospectively recruited forty patients diagnosed with HCC who were undergoing liver resection. The patients were followed every three months with imagings after the resection. Platelet fractions were separately isolated before and after a month of radical resection of the tumor. Growth factors/cytokines were measured using enzyme-linked immunosorbent assay (ELISA) kits. Follow-up was standardized to two years. HCC recurrence was diagnosed on the basis of imaging.

Results: Fifteen patients developed post-resection HCC recurrence during 2-year follow-up. The concentrations of platelet-alpha granules secreted growth factors [vascular endothelial growth factor-A (VEGF-A), angiopoietin-1(Ang-1)] and dense granules secreted growth factors (serotonin) were significantly depleted in patients with early HCC recurrence. In addition, the post-resection platelet count was also significantly lower in patients with recurrence than those without recurrence. A combined receiver-operating characteristic (ROC) curve generated to determine the cut-off values for these growth factors yielded both specificity and sensitivity of greater than 80%, area under curve (AUC) > 0.8, and $P < 0.001$. Furthermore, in the binary logistic regression model, VEGF-A was able to independently predict early HCC recurrence ($P < 0.05$); accordingly, the disease-free interval was substantially worse in accordance with the exhausted intra-platelet growth factors.

Conclusions: We found a qualitative and quantitative platelet crisis, and its prognostic implication in patients with post-resection HCC recurrence. This study provides an avenue to identify the pathophysiological mechanism of the impaired platelet-kinetics and its relevance in cancer biology.

Department of Public Health, Centre Hospitalier Lyon Sud, Pierre Bénite, France, [8]Service d'Anatomie Pathologique, CHU de Caen, Caen, France, [9]Plateforme Transversale IC-HCL, Institut de Cancérologie des Hospices Civils de Lyon, Pierre Benite, France, [10]Canton de Vaud, ECS-Screening, Lausanne, Switzerland

Background: Progastrin is abnormally released in the blood of patients with different cancers (colorectal, gastric, ovarian, breast, uterus, melanoma. . .), as the progastrin gene is a direct target of the WNT/ß-catenin oncogenic pathway involved in tumorigenesis of many organs (ASCO 2017, Prieur et al CCR 2017). The value of progastrin as a diagnostic, and as a therapeutic monitoring marker, was assessed in patients treated for peritoneal carcinomatosis from gastro-intestinal (GI) cancers in the prospective BIG-RENAPE study (NCT02823860).

Methods: Patients were enrolled during management of peritoneal carcinomatosis (before or after neo-adjuvant chemotherapy, or surgery) and then regularly sampled for blood. Progastrin was measured using the ELISA DECODE LAB test®. The diagnostic value of progastrin concentrations at inclusion in 190 GI cancer patients (test set) was assessed against 80 samples from French donors (control set with non-cancer subjects). The longitudinal therapeutic monitoring value of progastrin test was also investigated.

Results: The Area Under the ROC curve of prograstrin for cancer diagnosis was 0.87, 95% CI [0.83-092]. Progastrin was significantly elevated at inclusion in all GI tumor subtypes ($p < 0.0001$; median 3.08, 95% CI [1.15-7.23], including colo-rectal & small bowel ($n = 151$; median 2.78) and oeso-gastric ($n = 33$; median 4.75) carcinomas). During monitoring, progastrin levels decreased after neoadjuvant treatment (median value 2.20, $n = 23$), decrease that became significant after surgery ($p < 0.0001$, median value 1.57, $n = 84$), with patients going back to normal value and others not. A trend for better PFS was observed in patients with progastrin decline after surgery. Progastrin baseline value did not correlate with renal function.

Conclusions: Progastrin assay is a simple and inexpensive blood test exhibiting high diagnostic accuracy in patients with GI carcinomas, along with promising therapeutic longitudinal changes across sequential managements. Assessment of progastrin value as a multi-tumor screening assay, and as a monitoring test, is on-going.

120P A new biomarker of breast cancer stage and patient response to neoadjuvant chemotherapy: HLA-DR expression in cytotoxic and regulatory T cells

D.P. Saraiva[1], A. Jacinto[1], S. Braga[2], M.G. Cabral[1]

[1]CEDOC, Nova Medical School, Lisbon, Portugal, [2]Instituto CUF de Oncologia, CUF, Lisbon, Portugal

Background: Neoadjuvant chemotherapy (NACT) is the treatment option for locally advanced breast cancer (BC). However, approximately half of the patients have no response. To promptly direct non-responders to personalized therapies, there is an urgency to find a clinical biomarker that could predict treatment response. Tumor infiltrating lymphocytes, namely CD8+ T cells (CTLs) and regulatory T cells (Tregs) are being appointed as biomarkers of response. Nonetheless, tumor cells can escape the immune system by releasing cytokines or expressing immune checkpoint inhibitors, dampening CTLs and increasing Tregs activation. CTLs and Tregs with HLA-DR, a T cell activation marker, by reflecting the tumor immune status, should be a more reliable biomarker of NACT success.

Methods: Fresh biopsies, surgical specimens and blood were collected from 150 BC patients. Immunophenotype was performed by flow cytometry, ELISA and qRT-PCR. Peripheral blood mononuclear cells (PBMCs) were isolated and cultured under canonical stimuli.

Results: 67.3% of BC analysed were ER+, 15.5% HER2+ and 17.2% triple negative. Prior to treatment and independent of BC type, BC with no metastasis in the lymph nodes (53%) have HLA-DR^{hi} CTLs ($p = 0.003$) and HLA-DR^{lo} Tregs ($p = 0.002$), although the average percentage of lymphocytes and myelocytes are similar between more or less advanced disease. Biopsies from NACT responders also have HLA-DR^{hi} CTLs ($p = 0.0006$) and HLA-DR^{lo} Tregs ($p = 0.0002$). A ROC curve revealed a threshold of HLA-DR in CTLs bellow which patients will not respond to NACT. Moreover, HLA-DR+ CTLs express IFN-g, Granzyme B, Perforin, Eomes and TNF-a, essential for CTLs cytolytic activity. HLA-DR+ CTLs negatively correlate with pro-tumorigenesis molecules, such as TGF-b, PD-L1, IL-6, IL-1b and IL-8 ($p < 0.005$); while HLA-DR+

Tregs positively correlate with them. HLA-DR expression in tumor T cells correlates with its level in systemic T cells (CTLs: r = 0.58 p = 0.001; Tregs: r = 0.65 p = 0.0002). PBMCs stimulated in vitro from NACT responders reveal higher IFN-g and lower IL-10 (p = 0.04).

Conclusions: We propose HLA-DR levels in T cells as a biomarker of BC stage and response to NACT, with the advantage of being systemically evaluated.

Background: Liquid biopsy is a promising approach to improve the management of NSCLC patients, as it offers a minimally-invasive alternative to tumor tissue testing and enables timely monitoring of patients on-therapy. The goal of the present study was to evaluate the clinical value of longitudinal testing of EGFR mutation status in plasma of tissue EGFR mutation-positive NSCLC patients during first-line EGFR TKI therapy across 19 Spanish hospitals to: 1) determine the timing of T790M mutation emergence and 2) monitor EGFR mutation levels in plasma during first-line EGFR TKI therapy with respect to radiological progression.

Methods: Blood samples from 109 therapy-naïve advanced NSCLC patients were collected at baseline and monthly throughout EGFR TKI standard therapy. Results from OncoBEAM EGFR mutation were performed by Sysmex in Hamburg, and compared to those obtained by the EGFR tissue testing obtained at the referring hospital. The times at which T790M were first detected in blood were compared to the date of progression as determined by radiological imaging in standard clinical practice.

Results: At baseline, the initial positive percent agreement (PPA) for EGFR mutation status in 78 out of 109 patients enrolled in this study was 71.6%. From a total of 60 patients out of 89 who completed the study showing either clinical or radiological progression, 20 patients (33.3%) showed presence of the T790M mutation in plasma during follow-up. In 13 of these patients plasma T790M-positivity was detected an average of 14 weeks prior to radiological progression. Furthermore, the clearance of EGFR mutations in plasma at 8 weeks after initiation of EGFR TKI was a favorable indicator for PFS (37.3 weeks with clearance vs 25.5 weeks in patients without clearance). Patients showing EGFR mutation clearance at 8 weeks had an average baseline MAF of 3.6%, whereas patients with detectable mutations at 8 weeks showed an average baseline value of 13% MAF.

Conclusions: Overall, these results show high PPA of plasma and tissue EGFR mutation status at baseline. Early EGFR mutation clearance may be predictive of response to first-line EGFR TKI therapy. Plasma detection of T790M mutation anticipates clinical progression.

122P Immune checkpoints and liver resection after neoadjuvant chemotherapy including bevacizumab in patients with colorectal liver metastases

S. Stremitzer[1], A. Graf[2], B. Neudert[3], M. Herac[3], A. Beer[3], C. Schwarz[1], F. Wrba[3], K. Kaczirek[4], J. Stift[3]

[1]Department of Surgery, Medical University of Vienna, Vienna, Austria, [2]Center for Medical Statistics, Informatics and Intelligent Systems, Medical University Vienna, Vienna, Austria, [3]Clinical Institute of Pathology, Medical University Vienna, Vienna, Austria, [4]Department of Surgery, Vienna General Hospital (AKH) - Medizinische Universität Wien, Vienna, Austria

Background: Liver resection after neoadjuvant chemotherapy including bevacizumab offers the possibility of cure in patients with colorectal liver metastases. The clinical value of immune checkpoint expression as prognostic biomarker is unclear.

Methods: Expression analyses of IDO-1, PD-L1 and CTLA-4 were performed by immunohistochemistry in resected colorectal liver metastases in patients who underwent liver resection after neoadjuvant chemotherapy including bevacizumab (2005-2011). Association of expression of immune checkpoints in tumor cells and immune cells with response, RFS and OS was investigated.

Results: One hundred forty-six patients were enrolled [88 (60.3%) male/58 (39.7%) female, median age 63.0 years (31.0-80.4)]. High expression of CTLA-4 in tumor cells was associated with shorter OS (median OS 48.2 months versus not reached, HR 2.04, P = 0.028). High expression of IDO-1 and PD-L1 in immune cells was associated with longer OS (not reached versus 47.1 months, HR 0.43, P = 0.016 and not reached versus 47.1 months, HR 0.41, P = 0.017). Results of IDO-1 remained significant in multivariable analysis (HR 0.29, P = 0.006). Low expression of CTLA-4 in tumor cells was associated with better histologic response (26 major, 19 partial, 18 none versus 14 major, 23 partial, 30 none, P = 0.032). No association of expression was found with RFS and radiologic response.

Conclusions: The clinical meaning of immune checkpoint expression and its association with response and survival were dependent on the expressing cell types. IDO-1 and CTLA-4 may be new prognostic and/or predictive biomarkers in patients with colorectal liver metastases. The role of immune checkpoint inhibitors in a multidisciplinary treatment approach remains to be elucidated.

123P Gene expression (GE)-based biomarkers associated with nivolumab response in a real-life cohort of patients with metastatic non-small cell lung cancer (mNSCLC)

N. Radosevic-Robin[1], S. Ong[2], S.E. Warren[3], M. Kossai[1], C. Godfraind[4], M. Masson[5], H. Janicot[6], P. Merle[6], P. Dubray-Longueras[5], X. Durando[5], P. Morel[7], A. Cesano[7], F. Penault-Llorca[1]

[1]Pathology, Centre Jean Perrin, Clermont-Ferrand, France, [2]Bioinformatics, NanoString Technologies, Inc., Seattle, WA, USA, [3]Biology, NanoString Technologies, Inc., Seattle, WA, USA, [4]Pathology, University Hospital Center of Clermont-Ferrand, Clermont-Ferrand, France, [5]Medical Oncology, Centre Jean Perrin, Clermont-Ferrand, France, [6]Pneumology, University Hospital Center of Clermont-Ferrand, Clermont-Ferrand, France, [7]Medical Affairs, NanoString Technologies, Inc., Seattle, WA, USA

Background: Robust and versatile biomarkers are urgently needed to identify cancer pts who are likely to benefit from immune checkpoint inhibitors (ICI). The Tumor Inflammation Signature (TIS) is an 18-gene signature measuring the suppressed adaptive immune response necessary for pts clinical benefit from ICI (Ayers, J Clin Invest 2017). This retrospective study evaluated the performance of TIS and additional GE signatures assessing pathways associated with immune evasion in mNSCLC pts, treated with nivolumab as per label (2nd+ line), in two French cancer centers.

Methods: RNA from primary FFPE tumor samples from 77 immunotherapy-naïve mNSCLC pts, treated with nivolumab monotherapy, was profiled with a β-version of the NanoString® IO 360 GE panel, which includes the TIS and other tumor and immune biology signatures. The statistical analysis treated associations of GE and clinical response.

Results: In the whole cohort analysis, samples from pts who experienced clinical benefit showed an "inflamed" phenotype. Specifically, TIS was significantly higher in the responder group compared to non-responders (p = 0.005, non-adjusted). A similar association was observed for myeloid and macrophage scores (p = 0.001 and p = 0.002, respectively) as well as for PDCD1 (PD1), CD274 (PDL1), and CTLA4 (p = 0.05, 0.001, 0.02, resp.). In a subtype analysis, squamous carcinomas showed a less inflamed phenotype than adenocarcinomas but had elevated proliferation, glycolysis and hypoxia scores, as well as increased ARG1 and NOS2. In contrast, in the independent subtype analysis, both TIS and additional immune signatures remained associated with clinical response.

Conclusions: TIS and other immune signatures predicted response to nivolumab single agent in a real-life cohort of pts, in both adeno- and squamous mNSCLC. Thus, assessing GE patterns can give insight into different mechanisms of immune evasion operating at the single patient level. Additional analyses of this cohort, evaluating the

NanoString® IO 360 signatures and single gene expressions, with regard to various other clinical and molecular tumor features, will be presented.

Background: FIRE-3 compared first-line therapy with FOLFIRI plus either cet or bev in KRAS exon 2 wildtype (wt) patients with mCRC. Identification of RAS mutations as a predictor for the efficacy of EGFR-antibody therapy raised the question of whether miR-21 as a potential regulator of the EGFR dependent pathway influences therapy outcome.

Methods: A reverse-transcription quantitative polymerase chain reaction (RT-qPCR) assay was used to identify quantitative miR-21 expression in formalin-fixed paraffin-embedded (FFPE) tumor samples of FIRE-3 patients. The median of miR-21 expression within the FIRE-3 population was determined and subsequently used to segment the population into low and high miR-21 expression groups. Overall response rate (ORR) between treatment groups was compared using Fisher's exact test. Median progression free (PFS) and overall survival (OS) were calculated using Kaplan-Meier estimation and compared through log-rank test.

Results: RAS wt population with low miR-21 expression (n = 146) showed a significantly higher ORR when cet instead of bev was added to FOLFIRI chemotherapy (80.0% vs. 57.9%; p = 0.005). High miR-21 expression in RAS wt population (n = 149) showed no significant difference in ORR between treatment groups (74.6% vs. 64.0%; p = 0.21). ORR of RAS mutated patients with high miR-21 expression (n = 48) showed no significant difference between cet or bev when added to FOLFIRI (38.1% vs. 59.3%; p = 0.24). ORR (50.0% vs. 48.3%; p > 0.99) also showed no significant difference in RAS mutated patients with low miR-21 expression (n = 59). The following table presents statistical results of PFS and OS by comparing FOLFIRI plus cet versus FOLFIRI plus bev depending on RAS and miR-21 status.

Table: 124P

	RAS wt		RAS mut	
	low miR-21 (n = 166)	high miR-21 (n = 167)	low miR-21 (n = 67)	high miR-21 (n = 62)
PFS (months)	10.6 vs. 10.3 p = 0.3	10.1 vs. 9.9 p = 0.5	8.5 vs. 12.2 p = 0.3	7.7 vs. 8.9 p = 0.044
OS (months)	35.8 vs. 25.9 p = 0.005	24.5 vs. 23.8 p = 0.4	20.2 vs. 26.0 p = 0.4	16.4 vs. 20.2 p = 0.2

Conclusions: Along with RAS status, miR-21 expression level may be a promising predictive biomarker for anti-EGFR-therapy.

Background: NSCLC is characterized by genome alterations that promote cancer cell growth. TO what extent co-mutations cooperate with the EGFR driver and explain the variable response to EGFR TKI is not well understood. Here, we screened additional co-mutations (ACMs) and evaluate their clinical impact in patients (pts) with advanced NSCLC.

Methods: We identified 204 pts with EGFR mutated tumors from the IFCT Biomarkers France study cohort with available tumor DNA who received first or second line first-generation EGFR-TKIs. Samples were assessed by NGS using the AmpliSeq Cancer Hotspot Panel v2. Among the 204 samples, 167 were fully contributive.

Results: EGFR mutations were: classical with del 19 (74; 44%) and L858R (59; 35%), complex (17; 10%) including T790M (9; 5%) or uncommon (17; 10%). EGFR was amplified in 27 (17%) samples. ACMs were identified in 120 (72%) samples with an average of mutations at 2.9 (2-8). Recurrent ACMs (more than 6 samples) were in TP53 (84; 50.3%), CTNNB1 (16; 10%), PI3KCA (15; 9%), RB (12; 7%), APC (10; 6%), PTEN (8; 5%) and ATM (7; 4.5%). EGFR complex mutations were more frequent in smokers (p = 0.01) whereas RB1 mutations were more frequent in non-smokers (p = 0.03). CTNNB1 mutations were mutually exclusive with TP53 (p = 0.01) or PI3KCA (p = 0.05) mutations. High EGFR variant allelic fraction was associated to EGFR amplification (p < 0.001) suggesting mutant allele amplification and to TP53 mutations (p = 0.003). Non-classical or complex EGFR mutations were linked to rapid (< 3 months) versus normal (3-20 months)/slow (> 20 months) progression (p = 0.07 and p = 0.05 respectively). In the non-T790M group, ATM and PTEN mutations were negative predictors of first-line TKI efficacy (mPFS 3.7 versus 8.9 months, HR 2.85, 95CI% 1.14-7.15 and mPFS 5.6 versus 9.0 months, HR 2.46, 95CI% 1.16-5.9, respectively).

Conclusions: EGFR mutated NSCLC have heterogeneous molecular profiles. This work suggests that PTEN and ATM mutations could limit EGFR inhibitor efficacy. However, large series of EGFR mutated NSCLC will be needed to validated links between clinical outcomes and specific EGFR altered pathways.

126P Simultaneous identification and profiling of tumor-specific T cells by mass cytometry

M. Fehlings, E. Newell

*SIgN, A*STAR, Singapore*

Background: immunoSCAPE leverages the high-dimensional immune profiling capabilities of mass cytometry combined with a unique technology for the identification of antigen-specific T-cells to support the development of immunotherapy strategies in cancer and immune-related diseases. In cancer, there is now strong evidence that immunotherapy-mediated tumor rejection can rely on tumor-specific (neoantigen-specific) $CD8^+$ T-cells. Consequently, the discovery of neoantigens becomes valuable for personalized cancer immunotherapies. Although in silico pipelines exist, that are capable of predicting non-synonymous mutations potentially giving rise to tumor-specific neoantigens, it is not clear how accurate these methods are in identifying immunogenic and therapeutically relevant epitopes, since T-cell epitope usage can be influenced by many factors. Moreover, analysis of T-cells in cancer patients is challenging as it requires detecting rare antigen-specific T-cell populations in samples that are usually limited in volume and availability.

Methods: By applying cytometry by time of flight in conjunction with combinatorial peptide-MHC tetramer staining and high-performance dimensional analysis tools, we are able to map broadly MHC-class I epitope with a high sensitivity for rare antigen-specific T-cells and perform concurrently in-depth characterization of these cells.

Results: We will show here the application of this technology in the context of immunotherapy, through the example of a murine in vivo tumor model responsive to checkpoint blockade inhibitors, as well as through the analysis of different human cancer samples.

Conclusions: Together, by providing insights into the nature of neoantigen-specific T-cells, immunoSCAPE's unique target discovery and high-dimensional immune profiling platform is a valuable tool for the development of novel diagnostic biomarkers and therapeutic strategies at different stages of drug development.

127P Over-expression of S100B protein as a serum marker of brain metastasis in non-small cell lung cancer and its prognostic value

L. Chen, Y. Zhao, X. Hu, H. Wu, J. Liu, X. Mu

Oncology, Affiliated Cancer Hospital of Zhengzhou University, Zhengzhou, China

Background: Validated serum biomarkers for patients suffering from non-small cell lung cancer (NSCLC) brain metastasis are urgently needed for early diagnosis, treatment monitoring, and prognostic classification in daily clinical practice and trials. Serum S100B was reported to be a marker of leaky blood-brain barrier (BBB), which was often caused by brain tumors. This study aimed to investigate the role of S100B and S100B antibody in the early detection of NSCLC brain metastasis and the prognostic significance.

Methods: 100 patients with NSCLC brain metastasis, 50 patients of stage IV NSCLC without brain metastasis, and 50 patients with cerebrovascular diseases were enrolled in this prospective study. S100B and S100B antibody were measured in serum samples of all patients before and after treatment by ELISA, and the correlations with brain metastasis were assessed by ANOVA. Kaplan-Meier survival analyses and COX regression were used to unveil the prognosis significance.

Results: The results showed that serum S100B correlated significantly with NSCLC brain metastasis ($p < 0.001$), but not S100B antibody ($p > 0.05$). When evaluated by the ROC curve, at the cutoff point 13.83 pg/ml, the sensitivity and specificity were 94% and 93%, respectively (AUC= 0.938, $p < 0.001$). The PFS and OS of NSCLC patients with brain metastasis were significantly shorter in the patients with high levels of serum S100B. In addition, S100B was an independent prognostic factor.

Conclusions: In conclusion, serum S100B was a sensitive and specific marker for early detection of brain metastasis in NSCLC and could be used as a surveillance tool for prognosis evaluation.

Background: Vinflunine is an antimicrotubule agent approved by the EMA for second-line treatment in p with aUC. However, no molecular biomarkers are currently available that can predict response to vinflunine in aUC. In the randomized phase II MAJA trial (NCT01529411) in p with aUC with disease control after a platinum-based regimen, maintenance vinflunine conferred a significant improvement in progression-free survival compared to best supportive care (Garcia-Donas et al. Lancet Oncol 2017). Pre-planned gene expression analyses aimed to identify biomarkers to predict response to maintenance vinflunine.

Methods: In the MAJA trial, 44 p received vinflunine. We have compared the gene expression profiles of eight poor responders to vinflunine (<4 cycles) and nine good responders (>12 cycles). RNA was isolated from FFPE tumor tissue collected during screening using the Covaris kit and gene expression levels were analyzed with Clariom S array (Thermo Fisher). Differential expression (DE), defined as $p < 0.05$ and $|FC| > 1.5$, was determined with linear models for microarray data included in the limma and sva packages. Pre-ranked Gene Set Enrichment Analysis (GSEA) was used for the functional classification of the DE genes.

Results: Hierarchical clustering of genes showed a DE between good and poor responders. DE were found in 31 genes, 13 of them were unregulated in good responders and 18 were unregulated in poor responders. In good responders, GSEA revealed overexpression of 72 genes related to G2M-checkpoint and of 61 genes related to E2F transcription factor. In poor responders, 73 genes related to epithelial-mesenchymal transition and 39 related to IL6/JAK/STAT3 were downregulated. We are currently validating these genes using qPCR to determine a gene expression profile associated with response to maintenance vinflunine.

Conclusions: Our preliminary results suggest that microarray analysis could identify a gene expression signature to predict response to maintenance vinflunine, which will be useful in selecting treatment for p with aUC. Complete results of the analyses will be reported.

Clinical trial identification: NCT01529411; EudraCT: 2011-001271-39.

129P Pre-diagnostic measurements of high-sensitive C-reactive protein and risk of prostate cancer: The PROCA-life study

E. Stikbakke[1], H.S. Haugnes[2], I. Thune[1], T. Wilsgaard[3], T. Knutsen[4], E.H. Richardsen[5]

[1]Department of Clinical Medicine, University of Tromso The Arctic University of Norway, Tromso, Norway, [2]Department of Oncology, University Hospital of North Norway, Tromso, Norway, [3]Department of Community Medicine, University of Tromso The Arctic University of Norway, Tromso, Norway, [4]Department of Urology, University Hospital of North Norway, Tromso, Norway, [5]Department of Pathology, University Hospital of North Norway, Tromso, Norway

Background: Inflammation may promote prostate cancer development, which can be characterized by elevated circulating levels of inflammation markers, such as high-sensitivity C-reactive protein (hs-CRP). Whether pre-diagnostic measurements of hs-CRP are associated with prostate cancer remains unknown.

Methods: In the Prostate Cancer Study throughout life (PROCA-life), a total of 11 064 initially healthy men, who participated in the Tromsø Study between 1994 and 2008,

were included. Pre-diagnostic hs-CRP was assessed and height and weight were measured at study entry. During a mean follow-up time of 14.2 years, a total of 459 men developed histological verified prostate cancer and detailed medical and histological records were obtained.

Results: At study entry, the cohort participants had a mean age of 60.5, mean level of hs-CRP of 2.18 mg/l and a mean body mass index (BMI) of 25.8 kg/m^2. The 459 prostate cancer cases identified had a mean age at diagnosis of 72.0 years. Among normal weighted men (BMI<25kg/m^2), we observed a positive linear relationship between pre-diagnostic hs-CRP levels and prostate cancer risk after adjustments, both when using single and repeated measurements of hs-CRP, with hazard ratio 1.09 (95% CI 1.03-1.14) and 1.08 (95% CI 1.01-1.16), respectively. This relationship was not present in the overweight (BMI 25-30 kg/m^2) or obese (BMI>30kg/m^2) group.

Conclusions: Our study supports the hypothesis that inflammation may play a role in prostate cancer development, but this association may vary by body composition.

130P Training and validation of a gene expression signature for microsatellite instability

S.E. Warren[1], P. Danaher[2], S. Ong[3], N. Elliott[4], A. Cesano[5]

[1]Research, NanoString Technologies, Seattle, WA, USA, [2]Bioinformatics, NanoString Technologies, Seattle, WA, USA, [3]Bioinformatics, NanoString Technologies, Inc., Seattle, WA, USA, [4]Research, NanoString Technologies, Inc., Seattle, WA, USA, [5]Clinical, NanoString Technologies, Inc., Seattle, WA, USA

Background: Clinical response to cancer immunotherapy can be predicted from two biologically distinct variables: tumor foreignness, manifested in some tumors as deficient DNA mismatch repair (dMMR)/microsatellite instability (MSI), typically measured by qPCR or IHC, and anti-tumor immunity, typically measured by gene expression signatures or IHC. Clinical benefit should be more accurately predicted by the combination of the two variables than by either alone, but measuring both variables requires multiple clinical assays. Here, we investigate the ability of gene expression alone to provide a surrogate measure of both tumor foreignness and immunogenicity, empowering a single assay to measure both axes of predictive biology. In addition, we explore the relationships between tumor foreignness and immunogenicity in both dMMR and MMR-proficient (pMMR) tumors.

Methods: Using TCGA datasets from colon, esophageal, stomach and uterine cancers, we trained two algorithms predicting hypermutation: the first detecting loss of expression of mismatch repair genes (MLH1, MSH2, MSH6 and PMS2) and the second identifying expression patterns shared by hypermutated tumors across these four cancer types. A final algorithm synthesizes the two above algorithms into a single score. For independent validation, we evaluated 60 colorectal cancer (CRC) FFPE samples, 30 dMMR and 30 pMMR as previously identified by IHC, and a cohort of 10 MSI and 5 MSS endometrial and neuroendocrine tumors with the NanoString nCounter® platform.

Results: We show that our algorithms successfully predicted hypermutation phenotypes and MMR status in TCGA training data and in the independent CRC and endometrial datasets analyzed with NanoString; with an AUROC of 0.94. Additionally, we demonstrate that higher mutational burden is linked to a heightened tumor immune environment as shown by adaptive immune gene signatures.

Conclusions: Gene expression proves to be a powerful predictor of microsatellite instability and hypermutation in cancers where dMMR subtypes are known to exist. This discovery raises the possibility that a gene expression algorithm measuring both hypermutation and immune activity may be advantaged in predicting response to checkpoint inhibition in these cancer types.

131P Development and analytical validation of a plasma-based tumor mutational burden (TMB) score from next-generation sequencing panels

K. Quinn[1], E. Helman[1], T. Nance[1], C. Artieri[1], J. Yen[1], J. Zhao[1], S. Fairclough[1], M. Sikora[1], D. Chudova[1], R.B. Lanman[2], A. Talasaz[3]

[1]Bioinformatics, Guardant Health, Redwood City, CA, USA, [2]Medical Affairs, Guardant Health, Redwood City, CA, USA, [3]Guardant Health, Redwood City, CA, USA

Background: The advantages of plasma-based tumor mutational burden (TMB) include non-invasive, real-time assessment of mutational load, without the limitations of insufficient tissue. However, at low levels of tumor DNA shedding, TMB may be underestimated if a fraction of the genomic alterations is below assay limit of detection. Currently available blood TMB panels report a 1% tumor content limit of detection, which would result in about half of all clinical plasma samples (based on > 30,000 patients) with unevaluable TMB. Hence, clinically effective blood-based diagnostics must be highly sensitive and account for tumor shedding. Here, we present a comprehensive cfDNA-based TMB using a 500-gene (GuardantOMNI) and a 73-gene (Guardant360) panel.

Methods: We developed a statistical model to calculate TMB on plasma samples with low cell-free circulating tumor DNA (ctDNA) content. Theoretical panel performance was assessed in silico by subsetting mutations from whole exome sequencing (WES) to the Guardant panel space (2Mb for GuardantOMNI and 200Kb for Guardant360) from 9,104 TCGA samples and 30 lung cancer samples with published immunotherapy outcomes. Sensitivity was evaluated using 50 serially diluted cfDNA specimens. Analytical validation was performed against tissue-based WES TMB using matched plasma and tissue samples across multiple tumor types.

Results: High correlation was observed between TMB called on the Guardant panel and WES mutations from the TCGA dataset ($r = 0.99$ with GuardantOMNI; $r = 0.92$ with Guardant360). Subsetting WES from clinical outcome cohorts to each panel recapitulated the association with PFS on immunotherapy (HR = 0.41 with GuardantOMNI; HR = 0.27 with Guardant360). The sensitivity of detection was assessed down to 0.3% tumor content and 5ng cfDNA input. Lastly, we show high quantitative concordance between matched plasma and tissue WES samples for both GuardantOMNI and Guardant360.

Conclusions: We describe a plasma-based TMB score that correlates with tissue-derived TMB at tumor fractions down to 0.3%, enabling TMB calculation on > 70% of all clinical samples. Accurate reporting of TMB from a plasma sample has the potential to accelerate clinical trial enrollment and improve outcomes.

132P Carbohydrate antigen 19-9 and apolipoprotein A2 isoform as early detection biomarkers for pancreatic cancer: A prospective evaluation by the EPIC study

K. Honda[1], V. Katzke[2], A. Hüsing[2], S. Okaya[1], H. Shoji[3], K. Onidani[1], F. Canzian[4], R. Kaaks[2]

[1]Department of Biomarkers for Early Detection of Cancer, National Cancer Center Research Institute, Tokyo, Japan, [2]Division of Cancer Epidemiology, German Cancer Research Center, Heidelberg, Germany, [3]Gastrointestinal Medical Oncology Division, National Cancer Center Hospital, Tokyo, Japan, [4]Genomic Epidemiology, German Cancer Research Center, Heidelberg, Germany

Background: This study prospectively evaluated the performance of an apolipoprotein A2 isoform (ApoA2-ATQ/AT) in combination with carbohydrate antigen 19-9 (CA19-9) as early detection biomarkers for pancreatic cancer.

Methods: Using ELISA, we measured CA19-9 and ApoA2-ATQ/AT in plasma samples collected ≤60 months before diagnosis from 159 pancreatic cancer patients and 217 matched controls within the EPIC (European Prospective Investigation into Cancer and Nutrition) cohort. The diagnostic sensitivity, specificity, and C-statistics were calculated for risk scores by strata of the time before diagnosis.

Results: The C-statistics of CA19-9 and CA19-9+ApoA2-ATQ/AT for distinguishing pancreatic cancer patients from cancer-free individuals were 0.87 and 0.68, respectively, for samples taken ≤6 months before diagnosis, and 0.74 and 0.72, respectively, for samples taken <6 to 18 months before diagnosis. The joint diagnostic model using CA19-9+ApoA2-ATQ/AT showed significantly improved diagnostic discrimination in samples taken ≤18 months before diagnosis. Before diagnosis, the specificity of CA19-9+ApoA2-ATQ/AT was 98%, while the sensitivities of CA19-9+ApoA2-ATQ/AT were 57%, 36%, and 43%, respectively, and those of CA19-9 alone were 50%, 29%, and 36%, respectively. This joint model also showed significantly improved C-statistics for the diagnostic discrimination of samples taken >6 to 18 months (0.80 for CA19-9+ApoA2-ATQ/AT, 0.74 for CA19-9; $p = 0.004$) and ≤18 months (0.8 for CA19-9+ApoA2-ATQ/AT, 0.78 for CA19-9; $p = 0.003$) before diagnosis.

Conclusions: Compared to CA19-9 alone, CA19-9+ApoA2-ATQ/AT showed improved diagnostic discrimination for early detection ≤18 months before diagnosis. This plasma biomarker panel may provide a useful first measure for detecting pancreatic cancer prior to imaging. We have reported those results on behalf of the EPIC Europe.

133P Sarcopenia and inflammation predicts survival in advanced stage cancer patients (pts) treated with immunotherapy (IO)

M.A. Bilen[1], D.J. Martini[2], J.M. Shabto[2], Y. Liu[3], A.I. Khan[2], M.A. Williams[2], C. Lewis[1], H.H. Collins[1], H. Kissick[4], B.C. Carthon[1], M. Akce[1], W.L. Shaib[1], O.B. Alese[1], D.H. Lawson[1], R. Kudchadkar[1], B. El-Rayes[1], S.S. Ramalingam[5], T.K. Owonikoko[1], R.D. Harvey[1], V.A. Master[4]

[1]Department of Hematology and Medical Oncology, Winship Cancer Institute of Emory University, Atlanta, GA, USA, [2]Hematology and Medical Oncology, Emory University School of Medicine, Atlanta, GA, USA, [3]Departments of Biostatistics and Bioinformatics, Emory University, Atlanta, GA, USA, [4]Department of Urology, Emory University, Atlanta, GA, USA, [5]Department of Hematology and Medical Oncology, Winship Cancer Institute of Emory University, Atlanta, GA, USA

Background: Sarcopenia is associated with poor prognosis in cancer pts and inflammation has been recognized as a hallmark of cancer. In this study, we investigated the synergistic effect of sarcopenia and inflammation on survival in advanced stage cancer pts treated with IO.

Methods: We performed a retrospective analysis of 90 pts treated on IO-based phase 1 clinical trials at Winship Cancer Institute of Emory University from 2009-2017. CT images at mid-L3 were obtained at baseline. Skeletal muscle density was obtained using SliceOmatic v5.0 by TomoVision and converted to skeletal muscle index (SMI) by dividing by height^2. We defined sarcopenia as SMI<39. Neutrophil-to-lymphocyte ratio (NLR) was obtained at baseline and used as a surrogate of inflammation. Pts were categorized based on recursive partitioning methods into three groups: (1) low NLR, (2) high NLR without sarcopenia, (3) high NLR with sarcopenia. Overall survival (OS) and progression-free survival (PFS) were measured from date of first dose of IO to date of death or clinical or radiographic progression, respectively. Multivariable analysis (MVA) was carried out using Cox proportional hazard model.

Results: The majority of pts (n = 53) were males and most (68.9%) had at least 2 prior lines of therapy. Melanoma (33%) and GI (22.2%) tumors were the most common histologies. Low NLR was associated with longer OS and PFS (Table). Sarcopenic pts with high NLR had shorter survival than pts with high NLR who were not sarcopenic (Table).

Conclusions: Sarcopenia may have a synergistic effect with inflammation on decreasing survival in pts treated with IO. Prospective validation of the impact of body composition parameters on survival and whether adipose tissue plays a role in the relationship may be warranted. Equal contribution: MAB, DJM, JMS.

134P Prediction of irAEs in ipilimumab-treated melanoma patients based on serum autoantibodies

J.C. Hassel[1], J. Mangana[2], R. Dummer[3], C. Pföhler[4], K. Wistuba-Hamprecht[5], B. Weide[6], L. Hakim-Meibodi[1], F. Meier[7], J. Roth[1], H-D. Zucht[8], P. Budde[8], M. Tuschen[8], P. Schulz-Knappe[8]

[1]Section of Dermato-Oncology, Department of Dermatology and NCT, University Hospital Heidelberg, Heidelberg, Germany, [2]Department of Dermatology, University Hospital Zürich, Zurich, Switzerland, [3]Dermatology, Universitätsspital Zürich, Zurich, Switzerland, [4]Department of Dermatology, University Hospital Homburg/Saar, Homburg/Saar, Germany, [5]Department of Dermatology, University Hospital Tübingen, Tübingen, Germany, [6]Dermatologische Onkologie, Universitäts-Hautklinik, Tübingen, Germany, [7]Skin Cancer Center at the University Cancer Center and NCT, University Hospital Carl Gustav Carus Dresden, Dresden, Germany, [8]Science, Protagen AG, Dortmund, Germany

Background: Checkpoint inhibition is an effective treatment in patients with metastatic melanoma (MM). T cell activation can induce tumor rejection but also possibly severe autoimmune side effects (irAE). Autoantibody biomarkers from serum have potential to predict irAEs such as an ipilimumab-induced colitis.

Methods: We use a cancer immunotherapy array consisting of 850 human protein antigens from 4 classes: 1. Tumor-associated antigens (TAA), 2. cancer pathway proteins, 3. autoimmune antigens, 4. cytokines/interleukins. Protein antigens were covalently coupled to magnetic beads and serum AABs were analyzed by Luminex FlexMap 3D. First, we screened pre-immunotherapy sera from 142 patients with MM (Heidelberg Cohort: 82 Ipilimumab (Ipi) treated; 11 Ipi/Nivolumab (Nivo); 40 Pembrolizumab (Pembro), 119 healthy controls (HC)). In this cohort, 41.5% (n = 59) experienced irAEs of any grade and 7% (n = 10) had colitis of grade 3 or 4. In a second study, 200 MM patients from 5 European sites (53 Ipi/Nivo; 111 Pembro, 100 HC) were analyzed. 25.6% (n = 42) had grade 3 or 4 irAEs, 12.8% (n = 21) had diarrhea or colitis of any grade and 9.8% (n = 16) had grade 3 or 4 colitis.

Results: 40 different AABs were significantly more prevalent in MM compared to HC including NY-ESO1, NY-ESO 2 and other TAAs, cytokines, and nuclear proteins. Significant correlations of AABs were seen in Ipi-treated patients who experienced irAEs, both in mono- but also in combination therapy, allowing to dichotomize MM in risk groups. Also different sets of AABs were seen in Pembro-treated patients with irAEs. The protein antigens represent a variety of biological processes: they are involved in melanoma progression including transcription factors or components of the E3 ubiquitin ligase complex, cytokeratins, and proteins involved in cell adhesion.

Conclusions: In MM, screening of AABs prior to start of Checkpoint inhibition holds potential to predict risk for irAEs such as colitis. As irAEs are especially frequent in Ipi-based treatment regimes, AABs presented here may serve as useful biomarkers for a risk-based treatment decision.

135P Combined tumor-based BRCA/TP53 mutation testing in ovarian cancer

B. Edith[1], A. Leary[2], P. Pautier[2], E. Santana[3], L. Lacroix[4], O. Cabaret[3], M. Guillaud-Bataille[3], J. Michels[5], A. Auguste[6], C. Genestie[7], E. Rouleau[7]

[1]Gynecology Unit, Gustave Roussy, Villejuif, France, [2]Gynecological Unit, Gustave Roussy Cancer Center, INSERM U981, and Groupe d'Investigateurs Nationaux pour l'Etude des Cancers Ovariens (GINECO), Villejuif, France, [3]Cancer Center, Gustave Roussy, Villejuif, France, [4]Department of Medical Biology and Pathology, Laboratory of Translational Research and Biological Resource Center, AMMICA, INSERM US23/CNRS UMS3655, Gustave Roussy, University Paris-Saclay, Villejuif, France, [5]Gynecological Unit, Gustave Roussy Cancer Center, Villejuif, France, [6]INSERM U981, Gustave Roussy Cancer Center, Gustave Roussy - Cancer Campus, Villejuif, France, [7]Department of Medical Biology and Pathology, Gustave Roussy, University Paris-Saclay, Villejuif, France

Background: Somatic or germline BRCA mutations remain the best predictive biomarker for PARP inhibitor benefit and > 95% of high grade serous ovarian cancers (HGSOC) have a clonal somatic TP53 mutation. Combined tBRCA/TP53 testing might provide the advantages of i) rapid results, ii) identification of somatic BRCAm, and iii) indirect evidence of the '2nd hit' event, ie loss of heterozygosity (LOH).

Methods: Between 1/1/2016 and 1/2/2018 182 pts with HGOC underwent tBRCA/TP53 testing with a capture NGS panel and were oriented to a germline BRCA (gBRCA) testing via a dedicated genetics consultation. The ratio of allelic fractions (AF) for BRCAm/TP53m was calculated to estimate the proportion of cells carrying the BRCAm and derive LOH.

Results: At the time of data cut-off, gBRCA results were available for 125/182, and still pending for 61 pts. 15/125 (12%) demonstrated a deleterious (DEL) gBRCA1m (N = 12) or gBRCA2m (N = 3). Tumor testing was performed on 182 with a median testing turn-around time of 16 days (range 7-539 days). Twenty-seven (15%) were non-contributive. Among 155 contributive tumor samples, 31 DEL tBRCAm (21%) were identified. All gBRCAm (15/15) were identified on tumor testing including one large re-arrangement. 16 additional DEL BRCA1m or BRCA2m were detected: 10 somatic BRCAm in pts with confirmed wild-type (WT) germline status, and 6 among pts with pending germline results. Median TP53m AF was 0.48 (range 0.012-0.92) confirming a huge variability in tumor cellularity among samples. Among gBRCAm cases, ratio AF BRCAm/TP53m was always>1 confirming germline origin and suggesting LOH. AF BRCAm/TP53m was lower among known sBRCAm tumors (median AF BRCAm/TP53m=1.1) but always>0.8 suggesting acquired BRCA mutation was clonal and associated with LOH. For 3 gBRCA WT samples with <10% tumor cellularity and very low DEL BRCAm AF (0.04, 0.04 and 0.05), TP53m AF were also <0.05, thus validating the somatic BRCAm.

Conclusions: Combined BRCA/TP53 tBRCA testing is fast, sensitive and identifies somatic BRCA mutations. In addition, information on TP53 AF is useful to validate % neoplastic cells, identify somatic BRCAm in low cellularity samples and provides indirect evidence for LOH as the '2nd hit'.

136P EML4-ALK fusion variants associate with gender and age in Chinese NSCLC patients

W. Zhao[1], G. Liang[2], L. Wang[3], L. Dai[2], D. Wu[4], K. Wang[4], A. Wang[5], H. Chen[6], Y-A. Dong[7], M. Wang[4]

[1]Department of Thoracic Surgery, The First Affiliated Hospital of Kunming Medical University, Kunming, China, [2]Department of Thoracic Surgery, First Affiliated Hospital of Guangxi Medical University, Nanning, China, [3]Department of Thoracic Surgery, Fourth Hospital of Hebei Medical University, Shijiazhuang, China, [4]Department of Thoracic Surgery, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China, [5]Department of Clinical Analysis, OrigiMed, Shanghai, China, [6]Department of Bioinformatics, OrigiMed, Shanghai, China, [7]OrigiMed, OrigiMed, Shanghai, China

Background: EML4-ALK fusion is one of the major activating kinase mutations in NSCLC. It occurs with varying frequency in different populations and is known to associate with clinical features such as smoking history and age. Based on different breakpoints in EML4 and ALK genes, there exist several fusion subtypes (variants), which have been reported to respond differently to ALK inhibitors. In this study, we investigated the landscape of EML4-ALK in Chinese NSCLC patients and correlated fusion variants with clinical factors.

Methods: FFPE tumor and matched blood samples of over 1000 Chinese NSCLC patients were collected for NGS-based 450 cancer genes panel assay. Genomic alterations including single nucleotide variations (SNV), short and long insertions/deletions (Indel), copy number variations (CNV) and gene rearrangements in selected genes were assessed.

Results: A total of 73 EML4-ALK fusion samples were identified. In our cohort, younger patients were more likely to harbor ALK fusions, consistent with previous reports. In terms of EML4-ALK fusion variants, we observed three major subtypes: 30 E6:E20 (variant 3) cases, 20 E13:E20 (variant 1), and 11 E20:E20 (variant 2). Interestingly, E6-E20 was enriched in male patients (18 vs 12), while E13-E20 was enriched in female patients (13 vs 7); furthermore, for the E13-E20 variant all 13 female patients were younger than 60, while 4 out of 7 male patients were older than 60 ($p = 0.007$). To complete the picture, other subtypes of EML4-ALK fusion in our cohort included: 4 E18:E20, 4 E14:E20, 3 E2:E20, and 1 E21:E20.

Conclusions: EML4-ALK fusion is known to associate with clinical features including race, age, and smoking history. Our profiling of EML4-ALK alteration in Chinese NSCLC patients not only revealed the composition of fusion subtypes, but also connected variants with demographic factors such as gender and age. Our initial results need to be validated in larger cohorts and/or different populations. Given that different fusion variants respond differently to ALK inhibitors, our findings could have important implications.

137P Multi-dimensional immuno-oncology assays for understanding the immune system and tumor microenvironment

F. Hyland[1], T. Looney[2], R. Chaudhury[1], A. Kamat[1], A. Pankov[1]

[1]CSD, Thermo Fisher Scientific, South San Francisco, CA, USA, [2]Clinical Next-Generation Sequencing Division, Thermo Fisher Scientific, South San Francisco, CA, USA

Background: The promise of immuno-oncology (IO) is the potential for activating the immune system of an individual with cancer to destroy the tumor and metastases, and cause a complete and persistent response. A percentage of patients treated with checkpoint inhibitors or Car-T cell therapies exhibit complete response. However understanding all the determinants of response, and what combination of therapies can maximize efficacy and minimize adverse events, is still poorly understood. Further understanding the properties of the tumor micro-environment, the immune system, and driver mutations in the tumor provides the most comprehensive picture, enabling personalized oncology research.

Methods: We describe a suite of Oncomine assays that use a single chemistry and instrument with 20ng of input material each. The first measures patterns of gene expression of 395 genes that capture interferon and chemokine signaling, T and B cell activation, checkpoint pathway, antigen presentation, and tumor proliferation, measuring the expression of markers specific to different effector cell types. We demonstrate highly sensitive detection of low expressing genes including Interferon-Gamma. The second is the T-cell Repertoire sequencing assay. This assay uses total RNA from blood for long-amplicon TCRB chain sequencing, covering CDR1, 2 & 3. This assay provides an estimate of T cell diversity and other properties. The third is the Tumor Mutation Load assay. This 400-gene panel measures somatic mutations/Mb on FFPE samples, without requiring a matched normal. We demonstrated high reproducibility on FFPE, concordance with matched normal, correlation with exome mutation load, and accuracy on control cell lines.

Results: Together, these IO panels provide sensitive, accurate, complementary information to further elucidate biological factors underlying response, resistance, and adverse events. A single software for these diverse assays supports joint interpretation of this data.

Conclusions: These IO assays enable deep, broad, multidimensional characterization of biomarkers to explore predictors of response, optimal combination therapy, and avoidance of adverse events, accelerating research into immunotherapy for personalized oncology.

138P Monitoring the effect of PI3K inhibition on HER2 therapy resistant breast cancer using serial analysis of PIK3CA mutant tumour DNA in plasma

N. Keegan[1], S. Toomey[2], A. Farrelly[2], A. Carr[2], G. Calzaferri[3], J. Walshe[4], G. Gullo[4], J.P. Crown[4], K. Egan[5], A. Hernando[6], A. Teiserskiene[6], L. Grogan[7], O.S. Breathnach[7], P.G. Morris[5], B. Hennessy[8]

[1]Department of Molecular Oncology, RCSI Beaumont Hospital, Dublin, Ireland, [2]Oncology Molecular Medicine, Royal College of Surgeons in Ireland, Beaumont Hospital, Dublin, Ireland, [3]Department of Medical Oncology, Cancer Clinical Research Trust, Dublin, Ireland, [4]Medical Oncology, St Vincent's University Hospital, Dublin, Ireland, [5]Cancer Clinical Trials and Research Unit, Beaumont Hospital, Dublin, Ireland, [6]Breast DSSG, Cancer Trials Ireland, Dublin, Ireland, [7]Medical Oncology, Beaumont Hospital, Dublin, Ireland, [8]Cancer Clinical Trials and Research Unit and Cancer Trials Ireland, RCSI Beaumont Hospital, Dublin, Ireland

Background: PIK3CA is mutated in up to 20% of HER2 positive breast cancers, contributes to HER-2 therapy resistance and may be predictive of response to PI3K inhibitor therapy. PIK3CA mutations in breast cancer occur primarily at hotspots E545K at exon 9 and H1047R at exon 20. Copanlisib (C) is a pan-class I PI3K inhibitor that shows particular activity against PI3Kα, the isoform encoded by the PIK3CA gene. The aim of this study was to assess PIK3CA mutation status in matched tumour and plasma samples pre copanlisib treatment and to monitor PIK3CA mutation concentration changes in plasma over the course of PI3K inhibition therapy.

Methods: For 12 patients with advanced HER2 positive, breast cancer treated on a clinical trial of copanlisib and trastuzumab, we prospectively examined serial plasma samples to quantify the PIK3CA hotspot mutations in circulating tumour DNA by droplet digital PCR (ddPCR). Samples were taken pre-treatment, then every two weeks on treatment and immediately after radiological disease progression. Archival formalin fixed paraffin embedded (FFPE) primary tumour tissue were examined using MassArray® to detect PIK3CA mutation.

Results: PIK3CA mutations were detected in 6/12 (50%) archival FFPE primary tumours ; either an exon 9 (n = 2) or exon 20 (n = 4), all of which were also oestrogen receptor positive and had at least one prior line of anti Her2 therapy in the advanced cancer setting. There were 106 plasma samples included in the mutation analysis. PIK3CA mutation (H1047R or E545K) >500copies/mL were detected in 66% (70/106) of the samples. Of the six tumour samples that had no PIK3CA mutation detected, three had >500copies/mL (range: 0-25,500copies/mL) of mutated PIK3CA detected in serial plasma samples. Variations in plasma DNA mutation levels over time were found in all 12 patients.

Conclusions: Our data demonstrate that PIK3CA mutation is detectable in the plasma of a large proportion of a cohort of patients with HER2 therapy resistant advanced breast cancer, is potentially a more meaningful representation of current mutation status than archival primary tumour tissue given discordance and levels of mutation fluctuate with PI3K inhibition combined with trastuzumab.

139P Analysis of circulating biomarkers in a randomized phase II trial of maintenance oral metronomic vinorelbine in advanced NSCLC following platinum-based chemotherapy: A correlative MA.NI.LA. trial study

M. Boeri[1], F. Nichetti[2], L. Porcu[3], V. Torri[4], A. Del Conte[5], A. Martinetti[2], E. Sottotetti[2], E. Vattemi[6], F. Verderame[7], M.C. Garassino[8], L. Cavanna[9], A. Tuzi[10], L. Irtelli[11], F.G.M. de Braud[12], M. Platania[2]

[1]Research Department, Istituto Nazionale dei Tumori di Milano - Fondazione IRCCS, Milan, Italy, [2]Medical Oncology 1, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [3]Oncology, ASUIUD Azienda Ospedaliero-Universitaria di Udine, Udine, Italy, [4]Oncology, IRCCS Istituto di Ricerche Farmacologiche Mario Negri, Milan, Italy, [5]Oncology, Azienda Ospedaliera Sta Maria degli Angeli, Pordenone, Italy, [6]Medical Oncology, Ospedale Centrale di Bolzano ASDAA/SABES, Bolzano, Italy, [7]Oncology, Presidio Ospedaliero Cervello, Palermo, Italy, [8]Thoracic Unit, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [9]Oncology Department, Azienda Ospedaliera Piacenza, Piacenza, Italy, [10]Oncology, Ospedale di Circolo Fondazione Macchi, Varese, Italy, [11]Oncology, P.O. Clinicizzato Ss. Annunziata Universita' Degli Studi, Chieti, Italy, [12]Medical Oncology & Haematology, Istituto Nazionale dei Tumori di Milano - Fondazione IRCCS, Milan, Italy

Background: The efficacy of maintenance chemotherapy (CT) in advanced NSCLC is still under investigation. The multicenter, open label, randomized, phase II MA.NI.LA trial aimed to assess the activity of metronomic oral vinorelbine versus close observation as maintenance treatment following platinum-based CT in patients with advanced NSCLC. Serum angiogenesis biomarkers and the plasma microRNA signature classifier (MSC) associated with tumor aggressiveness in NSCLC patients were here investigated as prognostic and predictive factors.

Methods: 119 advanced NSCLC patients with stable disease after platinum-based CT received maintenance metronomic oral vinorelbine (ARM A) or close observation (ARM B). The primary endpoint of the trial was progression free survival (PFS). Plasma samples for biomarkers evaluation were collected at the baseline from all patients. Concentrations of VEGFA and THBS1 were determined using EIA kit (Chemicon International). To determine MSC risk level, custom made microfluidic cards (Thermo Fisher) were adopted to analyze 8 samples simultaneously by RT-qPCR. Cox regression model was used to evaluate the association of biomarkers to PFS and OS.

Results: In the whole cohort, median age was 68.8; M/F: 79/40; stage IIIb/IV:14/105; adeno/other:73/46; PS 0-1/2:113/7. In front of a median follow up of 23.9 months, median PFS was 4.3 and 2.8 months for ARM A and ARM B, respectively (HR = 0.73; 90%CI 0.53-0.999; p = 0.0493). Considering all 119 patients, high VEGFA and THBS1 plasma levels and positive MSC expression were associated with shorter both PFS and OS. HR for 1000 unit, VEGF: 1.56 (90%CI 0.99-2.46; p = 0.054); HR for 10000 unit, THBS1: 1.16 (90%CI 0.97-1.38; p = 0.114); HR for MSC pos vs neg: 1.61 (90%CI 1.05-2.47; p = 0.028). Similar results were obtained considering OS. No interaction between treatment effect and biomarker values were detected.

Conclusions: In advanced NSCLC following platinum-based induction CT, metronomic oral vinorelbine showed a modest, but significant improvement in PFS. In addition, VEGF and MSC could be considered as prognostic but not predictive factors

140P Oral cavity immune response in pancreatic ductal adenocarcinoma (PDAC)

J.P. Marquez, P.A. Lucero-Diaz, J.A. Matute-Briseno, M.O. Rosas-Delgado, A. Camacho-Hernandez, Y. Cortez-Vargas, I. Nava-Sanchez, G.T. Montano, L.N. Montijo-Fernandez, M.A. Perez-Astorga

Clinical ImmunoOncology and Relapse Prevention Clinic, Centro de Investigacion de Cancer en Sonora-CICS, Ciudad Obregon, Mexico

Background: We studied the humoral immune response in patients with pancreatic ductal adenocarcinoma (PDAC) using mouthwashes from the oral cavity. We found lower immune response against recall antigens, fusobacterium nucleatum and tumor associated antigens before immunotherapy treatment. We also found better prognosis when the antibodies against tested antigens got higher. Finally, we found significant differences in the humoral immune response in the oral cavity against serum.

Methods: Antigens from fusobacterium nucleatum, recall and tumor associated antigens were tested by IgG + IgM + IgA ELISA in both oral cavity and serum of PDAC patients n = 50. We provided 5 ml of saline solution to all the patients and controls to rinse the oral cavity hardly for 5 minutes and deposit the content in 15 ml tube. Sera were obtained. All was done after the approval of the local IRB committee.

Results: All the evaluated antigens were lower in the oral cavity of PDAC patients compared with controls (p = 0.001). Serum responses for all antigens were significantly different than oral cavity (p = 0.03). At the end of the immunotherapy treatment consisting in a combination of immunomodulation, multi peptide antigen specific active immunotherapy and immunogenic chemotherapy with doxorubicin and oxaliplatin the levels of antibodies were increased significantly. For example, FAP (p = 0.0001), EGFR (p = 0.005), Fascin-1 (p = 0001), VCP (P = 001). Also, the immunotherapy combination significantly increased antibody immune response against fusobaterium lysate (p = 0001).

Conclusions: PDAC is a challenge disease especially in late stages. PDAC patients had low antibody titters against several antigens in comparison with controls and before treatment the oral cavity. Serum antibodies were lower than oral cavity even after treatment. Oral cavity antibodies may be a useful early biomarker in patients in high risk of PDAC. This data also suggest that antibodies get low when the cancer or premalignant lesions of PDAC are present.

141P Tumor mutational burden (TMB) standardization initiative: Establishing a consistent methodology for TMB measurement in clinical samples

A. Stenzinger[1], J. Allen[2], J. Maas[3], M. Stewart[4], D. Merino[4], M. Dietel[5]

[1](On behalf of QuIP® GmbH, Berlin, Germany) Institute of Pathology, University Hospital Heidelberg, Heidelberg, Germany, [2]Leadership Department, Friends of Cancer Research, Washington, DC, USA, [3]Management Department, QuIP® GmbH, Berlin, Germany, [4]Science Policy Analysis, Friends of Cancer Research, Washington, DC, USA, [5](On behalf of QuIP® GmbH, Berlin, Germany) Pathology, Charité Berlin, Berlin, Germany

Background: Clinical studies have established TMB, a measurement of mutations in the tumor genome, as a predictive biomarker for clinical efficacy of immune checkpoint inhibitors (ICIs). There is a lack of standardization for TMB estimation and reporting, which is critical for ensuring consistency for clinical implementation. An international collaboration organized by Friends of Cancer Research (Friends) and Qualitätssicherungs-Initiative Pathologie GmbH (QuIP) is establishing recommendations for achieving consistency in TMB estimation and reporting.

Methods: Friends and QuIP are using complementary TMB harmonization approaches. Friends will conduct in silico analyses where TCGA data will be compared between TMB estimates derived from whole exome sequencing (WES) and commercial targeted gene panels, followed by the use of patient-derived tumor cell lines to establish a universal reference standard for the alignment of panel-derived estimates. QuIP will compare TMB estimates from selected tissue (NSCLC and other solid tumors) using a WES-derived reference standard with commercial next-generation sequencing panels and lab-developed tests at several German academic institutions. These data will inform consistency of TMB estimation, assay comparability, and TMB cutoff values for potential clinical use.

Results: Preliminary data indicate several components influence TMB estimation: pre-analytical factors (eg, input material quality/quantity), sequencing parameters (eg, enrichment technologies), library preparation, bioinformatics (eg, filtering of germline variants), FFPE-induced deamination artifacts, mutation types, and clonal vs subclonal events. Analyses of panel size and composition suggest that larger panels may yield more reliable TMB estimation and that the panel should include actionable targets, genes associated with mutagenesis (eg, microsatellite instability), and potential negative predictors of response (eg, mutated β2M, JAK1/2, PTEN).

Conclusions: The Friends and QuIP collaboration will establish recommendations for reliable and reproducible TMB measurement to ensure consistent identification of patients who are likely to respond to ICIs.

142P DNA damaging agents and immunotherapy in NSCLC: Is there a STING in the tale?

C.M. Della Corte[1], K. Ramkumar[1], T. Sen[1], P. Tong[2], D.L. Gibbons[1], J.V. Heymach[1], J. Wang[2], Y-H. Fan[1], R. Cardnell[1], L. Byers[1]

[1]Thoracic Head and Neck, MD Anderson Cancer Center, Houston, TX, USA, [2]Department of Bioinformatics & Computational Biology, MD Anderson Cancer Center, Houston, TX, USA

Background: In NSCLC patients, several clinical trials are testing the efficacy of DNA damage response inhibitors (DDRi) and chemotherapy in combination with anti-PDL1 drugs. DDRi activate antitumor immune responses in cancer through release of cytosolic DNA leading to STING activation, stimulation of neo-antigens and release of pro-inflammatory cytokines. Our group has previously demonstrated a strong correlation between EMT and immune activation, showing that tumors with high EMT score have the highest levels of targetable immune markers.

Methods: We analyzed mRNA and protein expression of immune and EMT genes in the lung adenocarcinoma (LUAD) and lung squamous carcinoma (LUSC) TCGA NSCLC and in a panel of NSCLC cells, correlating them with the presence of somatic mutations in DDR genes. Contemporary, we treated NSCLC cell lines in vitro with cisplatin and various DDRi combinations, including PARP/ATR/ATM/WEE-inhibitors, to determine the effect on DNA damage and immune markers expression (by western blot and RPPA analysis).

Results: In both TCGA cohorts, immune markers mRNA expression clustered together and were positively correlated with EMT genes. In the LUAD cohort, high expression of CD274 (PDL1) was associated with high levels of other immune suppressive markers (LAG3, IDO1, PDCD1LG2, HAVCR2, CTLA4, ICOS, CD4, and CD40) and chemokines (CXCL10, CCL5, CCL2). Notably, expression of STING pathway mediators (TBK1 and TMEM173) and mesenchymal markers (TWIST1/2, SNAI1, SMO, and TGFB1) were positively related with CD274. Moreover, we found that mutations in DDR related genes TP53, RB1, POLE, FANCM and BRCA1 were allied with higher levels of targetable immune suppressive markers (LAG3, IDO1, and CD274) and the mesenchymal marker, TWIST1, but lower levels of TMEM173. Finally, in vitro treatments with DDRi and cisplatin increased DNA damage, as demonstrated by increased p-H2AX, and proportionally upregulated PDL1 and STING in some cell lines.

Conclusions: Our findings provide rationale to combine DNA damaging agents with immunotherapy drugs targeting immune suppressive markers in NSCLC. From our data, expression of EMT genes and deleterious mutations in DDR genes represent the best candidates to select patients that can benefit from these combinations.

[1]Oncology, Vall d'Hebron Institute of Oncology (VHIO)-Cellex Center, Barcelona, Spain, [2]Department of Advanced Biomedical Sciences, Pathology Section, Naples University Federico II, Naples, Italy, [3]Oncology Data Science (ODysSey) Group, Vall d'Hebron University Hospital, Barcelona, Spain, [4]Medical Oncology, Vall d'Hebron University Hospital, Barcelona, Spain, [5]Gastrointestinal and Endocrine Tumor Unit, Vall d'Hebron University Hospital, Barcelona, Spain, [6]Early Drug Development Unit, Vall d'Hebron Institute of Oncology (VHIO)-Cellex Center, Barcelona, Spain, [7]Molecular Oncology, Vall d'Hebron University Hospital, Barcelona, Spain

Background: Patients (pts) enrolled in ECT with CI are mainly selected based on tumor type. Genomic markers are informative in few cases. We assessed microenvironment markers as prescreening tool to identify pts with higher chances of clinical benefit from CI.

Methods: Pts treated with anti PD1/PDL1 drugs in monotherapy or in combination with other CI in ECT at our centre were evaluated for TILs on hematoxylin-eosin stained sections and PDL1 expression in tumor (tumcells) and immune cells (immcells) by immunohistochemistry (SP263 antibody). Results were correlated with clinical outcomes.

Results: From June 16 to June 17, 64 pts were recruited. TILs and PDL1 expression were available for all and 39 pts, respectively. Tumor types were melanoma (16 pts), neuroendocrine (9), gyne (8), breast (5), H&N (4), others (22). In total, 38 pts received anti PD1/PDL1 in monotherapy, the rest received anti PD1/PDL1 based combinations (12 pts had prior CI treatment). Response rate (RR) was 22%; median PFS was 4 months (m) (CI95% 3.30-5.57). We found no differences in PDL1 expression in tumcells according to tumor type (Kruskal test $p = 0.33$) and a weak correlation between TILs and PDL1 in tumcells (Pearson 0.44; $p = 0.004$) or immcells (Pearson 0.57; $p = 0.0001$). Median TILs was 7% (range 1-90), with no difference according to tumor type (Kruskal test $p = 0.45$). Median TILs was higher in pts with response to CI (17.5% v 5%, Kruskal test $p = 0.06$). RR in pts with TILs $\geq$7% was 32% v 9% if TILs <7% (Fisher test $p = 0.06$). In a multivariable logistic model adjusting for tumor type and CI regimen, RR was significantly higher in pts with TILs $\geq$7% (odds ratio 8.2; $p = 0.05$). Median PFS in pts with TILs $\geq$7% was 5 m v 3.7 m if TILs <7% (HR = 0.57 in a multivariable Cox model, $p = 0.06$). In univariate models, there was a trend for higher RR if PDL1 $\geq$1% in tumcells (35% v 12%, fisher test $p = 0.28$) or if PDL1 $\geq$1% in immcells (35% v 16%, fisher test $p = 0.27$). PFS was not correlated with PDL1 expression.

Conclusions: Quantifying TILs is a simple prescreening strategy that may help select pts for CI therapy in ECT from otherwise unselected population. The value of adding PDL1 expression needs further investigation.

144P Cyclin D1 differential activation and its prognostic impact among advanced breast cancer patients treated with trastuzumab

G. Mountzios, V. Kotoula, G-A. Koliou, K. Papadopoulou, G. Lazaridis, C. Christodoulou, G. Pentheroudakis, M. Skondra, A. Koutras, H. Linardou, E. Razis, P. Papakostas, S. Chrisafi, G. Aravantinos, I. Nicolaou, A. Goussia, K.T. Kalogeras, D.G. Pectasides, G. Fountzilas

Data Office, Hellenic Cooperative Oncology Group (HeCOG), Athens, Greece

Background: The cyclin D1-mediated molecular pathway depicts significant cross-talk with the ER/PR and HER2 pathways in patients with advanced breast cancer and these correlations may have clinical implications. We sought to determine the level of activation of the critical components of the cyclin D1-mediated pathway and to evaluate their

prognostic significance across the different molecular subtypes of advanced breast cancer.

Methods: The study population included 219 trastuzumab-treated women with advanced breast cancer who had been found to have HER2-positive disease by local testing. For all tumors, central testing for HER2 was performed and cyclin D1 (CCND1) gene amplification and mRNA and protein expression were assessed by FISH, qRT-PCR and IHC, respectively.

Results: Only 134 of the 219 patients (61.2%) were HER2-positive (HER2 gene amplification and/or 3+ HER2 protein expression). After a median follow-up of 136.0 months, 105 HER2-positive patients (78.4%) and 76 HER2-negative patients (89.4%) had died, while 80.0% of the former and 87.1% of the latter had disease progression. Median PFS was 14.0 months for HER2-positive and 8.9 months for HER2-negative patients, while median survival was 48.1 months and 35.0 months, respectively. Cyclin D1 mRNA expression was higher in patients with positive ER/PgR. Cyclin D1 (as assessed by FISH, qRT-PCR and IHC) did not reach significance in terms of PFS or survival either in the entire study population or in HER2-positive patients. In the HER2-negative subgroup, negative cyclin D1 protein expression was associated with higher risk of progression (HR = 1.66, 95% CI 1.01-2.72, Wald's p = 0.045), while in de novo metastatic patients, the risk of progression was higher for patients with non-amplified CCND1 tumors (HR = 2.00 95% CI 1.03-3.90, p = 0.041).

Conclusions: Aberrant activation of the cyclin D1-mediated pathway appears to reduce the risk of progression in HER2-negative tumors, but not in HER2-positive ones. If our results are validated by larger prospective trials, further evaluation of the cyclin D1-mediated pathway might identify prognostic and therapeutic implications in patients with advanced breast cancer.

145P Expression of TK1 and CDK9 in plasma-derived exosomes is associated with clinical response to CDK4/6 inhibitors in breast cancer

S. Crucitta[1], M. Del Re[1], A. Fontana[2], I. Bertolini[2], E. Rofi[1], C. De Angelis[2], L. Diodati[2], D. Cavallero[2], B. Salvadori[2], A. Falcone[2], R. Morganti[3], R. Danesi[1]

[1]Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, [2]Medical Oncology Unit, Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy, [3]Section of Statistics, University of Pisa, Pisa, Italy

Background: Cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) improve PFS in patients with hormone receptor-positive (HR+) advanced breast cancer (Finn et al., 2016). In order to better characterize the response to these agents and increase our knowledge on the pharmacogenetic profile of CDK4/6i, the aim of this study was to analyse the expression of targets relevant to the activity of CDK4/6i in plasma-derived exosomes.

Methods: Blood samples were collected from patients affected by HR+, HER2- advanced breast cancer receiving palbociclib/ribociclib in association with hormonal therapy. Three ml of plasma were taken at the beginning of treatment (baseline) and at the first clinical evaluation (after 3 months). Objective responses were defined following the RECIST criteria v.1.1. RNA from plasma-derived exosomes was extracted by the ExoRNeasy kit (Qiagen) and analysed for the expression of thymidine kinase 1 (TK1), CDK 4, 6 and 9 by digital droplet PCR (BioRad). Mann-Whitney test was applied.

Results: Thirty-four metastatic breast cancer patients were prospectively enrolled in this study. The comparison of mRNA levels of TK1, CDK4, 6 and 9 between baseline and the first clinical evaluation was available in 22 patients treated with letrozole/anastrozole + palbociclib and 22 patients given fulvestrant + palbociclib. 18 patients had newly diagnosed advanced breast cancer while 16 patients received ≥1 line of treatment. Objective responses were: 1 (2,9%) CR, 4 (11,8%) PR, 16 (47,1%) SD and 13 (38,2%) PD. The comparison of changes in the expression between TK1, CDK 4, 6 and 9 at baseline compared to first evaluation was statistically significant for TK1 (PR+SD vs. PD p = 0.009), CDK4 (PR+SD vs. PD p = 0.020), CDK6 (PR+SD vs. PD p = 0.047) and CDK9 (PR+SD vs. PD p = 0.008). The univariate analysis didn't find any significant correlation between patients clinical variable and PFS (i.e. type of hormonal treatment, the line of treatment, performance and menopausal status, visceral metastasis, bone only metastasis, number of metastasis, previous hormonal or lines of chemotherapy received).

Conclusions: Exosomal expression of CDK4, CDK6 and in particular of TK1 and CDK9 may be useful to early identify patients who are likely to respond to CDK4/6i.

146P HER2 amplification is associated with higher tumor mutation burden in breast cancer

Y. Yin[1], W. Li[1], X. Huang[1], H. Wu[1], Y. Zhang[2], S. Cai[2], S. Zhou[3]

[1]Department of Oncology, Jiangsu Province Hospital, Nanjing, China, [2]The Medical Department, 3D Medicines Inc., Shanghai, China, [3]Department of Breast Surgery, The Third Affiliated Hospital of Kunming Medical University, Yunnan Cancer Hospital, Kunming, China

Background: ErbB family consists of four transmembrane proteins (ErbB1/EGFR/HER1, ErbB2/HER2, ErbB3/HER3 and ErbB4/HER4) and plays a prominent role in the process of cell growth. Previous studies suggested that EGFR gene driven non-small-cell-cancer exhibited a suppressive immunity with lower tumor mutation burden (TMB) level. HER2 gene amplification ($HER2^+$) is a well-known poor prognosis predictor in breast cancer and anti-HER2 target therapy has significantly improved the clinical prognosis of $HER2^+$ patients. However, the association between HER2 gene alteration and TMB in breast cancer is still unclear.

Methods: Whole-exome sequencing data and clinical data of 366 breast tumors from The Cancer Genome Altas (TCGA) and next generation sequencing (NGS) data of 335 breast tumors from clinical dataset were analyzed to explore the association between HER2 gene alteration and TMB. TMB was defined as total number of somatic non-synonymous mutations in coding region.

Results: 20.5% (75/366) of breast tumors in TCGA cohort and 20.3% (68/335) in clinical cohort harbored HER2 amplification. HER2 amplification was significantly associated with higher TMB in both TCGA cohort (P = 0.010) and clinical cohort (P = 0.008). HER2 somatic alteration occurred in 3.7% (12/366) of breast tumors in TCGA cohort and 7.2% (24/335) in clinical cohort. HER2 somatic alteration was also associated with higher TMB level in TCGA cohort (P = 0.016), but no association was observed in clinical cohort (P = 0.339). In addition, hormonal receptor (HR) + HER2- breast tumors exhibited the lowest TMB level compared with HR+ HER2 + (P = 0.001), HR-HER2 + (P = 0.052) and triple negative breast cancer (P = 0.000). Patients with low TMB level also tended to have a better overall survival than patients with higher TMB level (median, 216.6 vs. 112.0 months; HR, 0.572; 95% CI 0.31-3.05; P = 0.067).

Conclusions: HER2 amplification is associated with higher TMB in breast cancer. These findings may assist the selection of breast cancer patients likely to benefit from immunotherapy.

147P Application of CRISPR/Cas9 system for identification of genes involved in the regulation of pancreatic cancer cells platinum sensitivity

V. Skripova[1], I. Serebriiskii[1], R. Kiyamova[1], I. Astsaturov[2]

[1]Biochemistry and Biotechnology, Kazan Federal University, Kazan, Russian Federation, [2]Institute for Cancer Research, Fox Chase Cancer Center, Philadelphia, PA, USA

Background: Pancreatic cancer (PC) is an aggressive disease with high lethality rate due to multiple resistance mechanisms. We used in vitro CRISPR/Cas9 genetic drop-out screening to identify genes involved in the regulation of PC cell line sensitivity to platinum chemotherapy drugs.

Methods: We used two sgRNA libraries: 1) enriched for genes regulating cell cycle and nuclear proteins genes (CC, 50 000 sgRNA targeting 4 716 genes); 2) genome-wide (GW, 90 000 sgRNA targeting 18 164 genes). We performed screens in MIA PaCa-2 cells expressing doxycycline-inducible Cas9. Cells were treated with established IC30 of oxaliplatin (1 uM) or cisplatin (3 uM) for 9 cell divisions (12 days). Genomic DNA was extracted and sgRNA-containing regions were amplified and barcoded by PCR for further analysis by NGS. Statistical analysis for sgRNA enrichment or depletion was performed using R package comparing cells treated with the drugs vs. vehicle in the presence of Cas9/doxycycline.

Results: We identified 755 genes which significantly changed in cisplatin or oxaliplatin-treated cells (FDR 5%, p < 0.05). Candidate genes (n = 130) were further selected if at least 2 sgRNA per gene showed more than 2-fold change vs. vehicle. Among the 130 genes, 16 were known platinum sensitivity regulators involved in the double stranded break DNA repair pathway; 11 genes were positive platinum sensitivity regulators as their inactivation reduced sensitivity; 119 genes were negative platinum sensitivity regulators as their inactivation increased sensitivity. Gene Ontology analysis of the 130 candidate genes allowed us to identify regulators of cell cycle (n = 46), DNA replication and repair (n = 43), cellular compromise (n = 15), cellular assembly and organization (n = 35) and cell morphology (n = 48). Analysis of protein-protein interaction network showed that the majority of the hits (n = 74) are directly involved into cell cycle regulation and DNA repair processes.

Conclusions: We identified 130 candidate genes potentially involved in the modulation of platinum resistance most of which are regulating the cell cycle and DNA repair which is in keeping with the known DNA damaging mechanisms of action of platinum chemotherapy.

148P Elevated 70kDa heat shock protein (hsp70) and autophagy levels in peripheral blood mononuclear cells (PBMCs) in women with a malignant breast mass

A.I. Athanasiou[1], T. Orfanelli[2], D. Lapolla[3], E. Andreopoulou[3], T.A. Moo[4], J. Marti[4], T. Cigler[3], A.M. Bongiovanni[1], S.S. Witkin[1]

[1]Department of OBGYN, Weill Cornell Medical College, New York, NY, USA, [2]Department of OBGYN, Rutgers-Robert Wood Johnson Medical School, New Brunswick, NJ, USA, [3]Department of Medical Oncology, Weill Cornell Medicine/New York Presbyterian Hospital, New York, NY, USA, [4]Department of Surgical Oncology, Weill Cornell Medicine/New York Presbyterian Hospital, New York, NY, USA

Background: PBMCs respond to adverse physiological conditions to maximize survival and to alleviate the threat. Hsp70 is produced to maintain protein function and activates an immune response. Autophagy is induced to provide sufficient nutrients in response to accelerated gene activation. We tested the hypothesis that PBMCS respond to the presence of a malignant breast mass by increasing production of hp70 and manifesting a higher level of autophagy.

Methods: In this pilot study seventy women had their breast mass evaluated by mammogram and/or breast ultrasound. A core biopsy and surgery was performed as indicated. PBMCs were isolated from peripheral blood, lysed and intracellular levels of hsp70 and p62 (a measure of autophagy) were quantitated by ELISA. Extracellular hsp70 in plasma was also measured. Differences in lab measurements between women with a diagnosis of a benign or malignant breast mass were determined. All assays were performed by personnel blinded to the clinical data.

Results: A breast malignancy was diagnosed in 42 women while 28 had a benign lesion. Plasma hsp70 levels were higher in women with a malignant lesion ($p = 0.03$). PBMCs from 46 women were available for analysis. Mean hsp70 levels were higher in PBMCs from 38 women with a malignant lesion than in 8 women with a benign breast mass ($p = 0.04$). The PBMC p62 levels were higher in women with a benign breast lesion than in those with a malignant breast mass ($p < 0.0001$). Since p62 is inversely related to the level of autophagy this indicates that autophagy is higher in PBMCs from women with a malignant breast lesion. There was no difference in the concentration of hsp70 or p62 between women with different histological types or stage of breast cancer.

Conclusions: Detection of elevated levels of hsp70 and autophagy in PBMCs, and higher plasma hsp70 levels, may differentiate between women with a malignant or benign breast lesion. Further studies on a larger sample are needed to confirm if the extent of autophagy and hsp70 induction in PBMCs may be of value in the preoperative triage of women with a breast mass.

149P Only estrogen receptor "positive" is not enough to predict the prognosis of breast cancer running head: Revisiting estrogen positive tumors in 8th AJCC staging era

J.M. Ryu[1], S.K. Lee[1], J.E. Lee[1], S.J. Nam[2], J. Yu[1], H.J. Choi[2], I. Kim[2], S.W. Kim[1]

[1]Department of Surgery, Samsung Medical Center Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [2]Breast Surgery, Samsung Medical Center Sungkyunkwan University School of Medicine, Seoul, Republic of Korea

Background: Beginning in 2018, biomarkers including estrogen receptor (ER) status were incorporated in the 8th AJCC staging system. ER expression levels were not considered in these changes. We hypothesized that the levels of ER expression could affect the prognosis of breast cancer.

Methods: A retrospective review was conducted to identify all female patients with invasive breast cancer between 2003 and 2012. ER negative (group I), weakly ER-positive (group II), and strongly ER-positive (group III) were defined as Allred total scores of 0-2, 3-5, and 6-8, respectively. We examined a multigene panel, designated the BCT score, which is a newly developed prognostic model for predicting the risk of a distant metastasis.

Results: Among the 4,949 patients enrolled in this study, 1,310 (26.5%), 361 (7.3%), and 3,277 (66.2%) were categorized as group I, II, and III, respectively. Median F/U duration was 57.8 months. Compared to group III, patients in group II were younger, had larger tumors, and were also more likely to have PR-negative tumors, HER-2 amplification, high Ki-67, and high nuclear grade. Between group II and III, there was a significant difference in OS ($P = 0.0764$, .909, and 0.010, respectively). After adjusting for additional factors that may affect OS, the HR for OS showed higher in group II than in group III. The baseline median BCT score indicated that lower ER expression was associated with significantly higher BCT score ($P < 0.0001$) and significantly more likely to have high risk group ($P < 0.0001$) relative to higher levels of ER expression group.

Conclusions: ER expression levels affect the prognosis of breast cancer. The risk for patients with weakly ER-positive breast cancer should not be underestimated.

150P Adjuvant radiation therapy leads to an up-regulation of programmed death ligand 1 (PD-L1) on circulating epithelial tumor cells (CETCs) which might contribute to radioresistance in primary breast cancer patients

D. Schott[1], M. Pizon[1], U. Pachmann[1], K. Pachmann[1], M. Mäurer[2]

[1]Transfusion Center Bayreuth, Bayreuth, Germany, [2]Radio-Oncology, University Hospital of Jena, Jena, Germany

Background: Radiation therapy (RT) is an integral part of the treatment of breast carcinoma but unfortunately many patients experience local recurrence. During the inflammatory response that accompanies radiation tumor cells may develop multiple resistance mechanisms for example the up-regulation of PD-L1 on tumor cells which leads to immune evasion. Since CETCs arise from the tumor it is conceivable that under evolutionary pressure they might share some of the immune escape mechanism inherent to tumor cells. In this study we demonstrate that RT leads to a transitory adaptive up-regulation of PD-L1 expression on CETCs.

Methods: CETCs and the expression of PD-L1 and Ki-67 were analyzed from 25 patients with primary non-metastatic breast cancer using the maintrac method. The fraction of PD-L1 and Ki-67 positive CETCs were assessed at baseline, 3 and 6 weeks after start of RT and 6 weeks after end of therapy. Additionally, copy number status of PD-L1 was determined using FISH.

Results: Fractionated-dose RT leads to a significant increase in PD-L1 expression on CETCs with the highest expression level midterm of irradiation as compared to baseline (49% vs. 74%, $p < 0.01$). 6 weeks after end of RT the number of PD-L1 positive CETCs returned to baseline value. The up-regulation of PD-L1 was dose dependent. Patients who received higher total dose had significantly more PD-L1 positive CETCs as compared to patients treated with lower total dose midterm of RT (64% vs. 43, $p < 0.05$). Before start of therapy there was a correlation between the fraction of PD-L1 and Ki-67 positive CETCs ($r = 0.6$, $p < 0.01$). PD-L1 copy number gains were significantly associated with PD-L1 expression ($r = 0.6$, $P < 0.05$).

Conclusions: RT leads to an up-regulation of PD-L1 expression on CETCs, which could be a possible mechanism of acquired radioresistance. Combining immunomodulatory agents with radiation might have the potential to overcome this resistance and could improve clinical outcome in breast cancer.

151P Recurrent and metastatic carcinomas of the lacrimal gland: High frequency of ERBB2 driven disease

N. Girard[1], R.J. Corona[2], J. Chung[3], S.Z. Millis[3], L.M. Gay[4], J.A. Elvin[3], J-A. Vergilio[3], S. Ramkissoon[3], E. Severson[3], S. Daniel[3], J.K. Killian[3], S.M. Ali[3], A.B. Schrock[3], V.A. Miller[3], J.S. Ross[5]

[1]Institut du Thorax Curie Montsouris, Institut Curie, Paris, France, [2]Medical Oncology, Upstate Medical University, Syracuse, NY, USA, [3]Genetics, Foundation Medicine, Inc., Cambridge, MA, USA, [4]Pathology, Foundation Medicine, Inc., Cambridge, MA, USA, [5]Medicine, SUNY Upstate Medical University, Syracuse, NY, USA

Background: Lacrimal gland carcinomas (LGC) are uncommon primary malignancies that have a propensity to recur locally but rarely undergo metastasis. We performed comprehensive genomic profiling (CGP) on a series of 12 LGC to uncover genomic alterations (GA) that could possibly be used to design novel routes to targeted and immunotherapies for these rare neoplasms.

Methods: From a series of 158,360 clinically advanced cancer cases, FFPE tissue samples from 12 cases of LGC underwent CGP to find base substitutions, short indels, copy number changes and gene fusions. Microsatellite instability (MSI) was determined on 114 loci andtumormutational burden (TMB) was determined on 1.1 Mbp of sequenced DNA and reported as mutations (mut) per megabase (Mb).

Results: The 12 LGC patients ranged in age from 34 to 76 years (median 61 years) and 67% of the patients were male. The LGC included 7 (58%) adenocarcinomas, 2 (17%) squamous cell carcinomas, 2 (17%) adenoid cystic carcinomas and 1 (8%) undifferentiated carcinomas. There were 1 (8%) grade 1, 8 (67%) grade 2 and 3 (25%) grade 3 tumors. 2 (17%) of LGC were stage III and 10 (83%) were stage IV at the time of sequencing. There were an average number of 4.25 GA per tumor. Three (25%) of the LGC featured ERBB2(HER2) gene amplification. One (33%) of the 3 ERBB2amplified

LGC also featured TOP2A amplification. ERBB2copy numbers in the amplified LGC ranged from 5 to 35 copies. Additional potentially targetable GA included PTENand PIK3CAboth at 25%, NF1 at 17% and RET, BRCA2, FGFR3and NTRK3all at 8% of cases. No (0%) LGC were MSI-High and the median TMB was 4.3 mut/Mb (range 0 to 12 mut/Mb) with no (0%) of LGC having >20 mut/Mb.

Conclusions: The high frequency ofERBB2amplification in clinically advanced LGC is similar to that seen in the approved indications for breast and upper gastrointestinal carcinomas raising opportunities for anti-HER2 therapies for these patients. In addition, a smaller cohort of LGC patients have opportunities for other targeted therapies with TKIs directed at RET, FGFR3 and NTRK. Given the lack of MSI-high and high TMB in LGC, the opportunities for immunotherapies for these patients appears limited.

152P Circulating tumour DNA experience in patients with cancer of unknown primary

H. Winter[1], I. Faull[2], P. Bains[1], C. Murias[1], M. Kushnir[1], M.D. Forster[3], A. Kulkarni[4], D. Moore[3], C. Swanton[5], K. Shiu[3], H-T. Arkenau[6]

[1]Early Phase Trials, Sarah Cannon Research Institute, London, UK, [2]Business Development & Medical Affairs, Guardant Health, Barcelona, Spain, [3]Medical Oncology, University College London Cancer Institute, London, UK, [4]Clinical Genetics, Guy's and St Thomas' NHS Foundation Trust, London, UK, [5]Translational Cancer Therapeutics, The Francis Crick Institute, London, UK, [6]SCRI, Sarah Cannon Research Institute UK, London, UK

Background: Improving the outcome for patients diagnosed with Cancer of Unknown Primary (CUP) is an unmet clinical need where survival is usually less than 1 year. Molecular characterisation of the disease may have diagnostic and therapeutic implications. The circulating tumour DNA test - Guardant 360™ is designed to detect gene alterations with a range of clinical utility.

Methods: Twenty-five patients were referred to Sarah Cannon Research Institute for the Guardant 360™ test. Panel version 2.10 reports single nucleotide variants in 73 genes, gene copy number amplifications in 18 genes, fusions/rearrangements in 6 genes as well as indels in 23 genes. The panel covers all NCCN somatic mutations. Digital Sequencing™ technology essentially eliminates false positives allowing sequencing of targeted regions at very low DNA concentrations. Variants of unknown significance (VUS) were also measured. All patients were discussed at our institutional Genomics Review Board.

Results: Twenty-five patients (14 female; 11 male) were recruited from 24 August 2017 to 17 April 2018. Median age was 67 years (range 27-76). Main sites of disease were: lymph nodes (8); pelvis (8); liver (6); bone (3) and adrenal glands (2). The median turnaround time (TAT) from sample collection to report was 10 days (range 6-15). Seventeen patients (68%) had potentially actionable mutations; 4 patients had no mutations detected: 1 post resection; 2 were responding to chemotherapy; 1 was sampled prior to commencing chemotherapy. Genetic alterations detected included: BRAF V600E; KRAS; FGFR; MYC; KIT; PIK3CA and HER2. Twelve patients had ≥ 3 somatic mutations (including variants of uncertain significance (VUS)); ≥ 6 mutations were found in six of these patients.

Conclusions: ctDNA is feasible with an acceptable TAT and the identification of significant potentially actionable targets. Targetable mutations were detected including BRAF, V600E, HER2 and FGFR. Two patients now have access to BRAF and MEK inhibitors. Twelve patients had ≥ 3 mutations that is emerging as potential biomarker of response to immunotherapy. The burden of VUS and presence of actionable targets supports more research on personalised medicine in patients with CUP.

153P Reproducibility of the mRECIST criteria for the assessment of HCC treated by anti-VEGFR therapy: Impact of readers' expertise

H. Beaumont[1], S. Egels[2], N. Faye[1], C. Klifa[1], A. Iannessi[3], E. Bonnard[4], O. Lucidarme[2]

[1]R&D, Median Technologies, Valbonne, France, [2]Radiology, Groupe Hospitalier Pitié Salpetriere, Paris, France, [3]Radiology, Hopital Antoine Lacassagne, Nice, France, [4]Radiology, Hopital Pasteur, Nice, France

Background: The imaging criteria mRECIST, which was initially introduced to assess the efficacy of HCC vascular bed destruction induced by TACE, is now often used to assess subtler vascular effects induced by anti-VEGFR therapy. However, variability of mRECIST assessment has been only partially investigated. In this study, we evaluated the inter-reader variability and its sources in the mRECIST assessment of treatment response for HCC treated by anti-VEGFR drugs.

Methods: A subset of 41 advanced HCC tumors in 24 patients treated by anti-VEGFR drugs were selected from a phase I/II nalysedre study (the original study). These data were retrospectively reviewed according to mRECIST criteria by 3 mRECIST non-expert radiologists each having different levels of experience. Each liver lesion measurement was hand drawn using an electronic caliper. Results from these 3 radiologists were then compared to those extracted by an mRECIST expert at the time of the original study. The precision of measurements among the 3 non-experts and between the expert and the 3 non-experts were nalysed by assessing bias and standard deviation (SD) using the Bland-Altman method. The agreement of readers' responses was assessed using the Kappa coefficient statistic. The causes of discrepancies were nalysed.

Results: Among the 3 non-experts, SD of measurements ranged [24.9%; 36.3%] and the Kappa coefficients were moderate 0.41 [0.28; 0.55]. SD in measurements of expert versus non-experts ranged [33.2%; 41.1%] and Kappa coefficients were poor 0.20 [0.06; 0.35]. Pooling the four readers together, the rate of discrepancy at declaring either Progressive Disease (PD) or Partial Response (PR) per patient was identical at 41.7% (10/24). The main cause of discrepancy at declaring PD came from the complexity of HCC enhancement patterns and the poor definition of tumors boundaries. Discrepancies at detecting PR came from the reader variability at selecting only the viable part or the entire liver tumor.

Conclusions: When used by mRECIST non-experts to assess the subtle vascular effect induced on HCC by anti-VEGFR therapy, mRECIST appears to lack reproducibility. It is therefore important when using mRECIST to require specific training to reduce readers variability.

Background: Large cell neuroendocrine carcinomas of the lung (LCNECs) are rare neoplasms with limited therapeutics options. Pathological diagnostic of LCNECs is morphologically based, may be difficult and need immunohistochemical (IHC) analysis. Immune checkpoint inhibitors targeting tumoral and immune cells interaction have changed the NSCLC treatment but few data are available on LCNECs immune environment and particularly the expression of PD-L1 on both tumors (TC) and immune infiltrating (IC) cells. The objective of the present study is to determine the expression and pattern of PD-L1 staining in a cohort of LCNECs patients.

Methods: Clinical files and tumors biopsies of patients (pts) with a LCNEC diagnosed between 01.01.2014 and 31.12.2016 were retrospectively collected (GFPC 03-2017). All histological samples were centrally reviewed by six pathologists, according to the latest WHO 2015 classification. LCNEC was confirmed and PD-L1 expression was determined both in TC and IC, using the anti-PD-L1 antibody 22C3 (kit and automat Dako). PD-L1 expression was scored on TC as the percentage of PD-L1 positive cells (0 to 100%). PD-L1 expression on IC was determined as follows: IC0: positive IC representing $<$ 1% of the tumor surface; IC1 : positive IC representing $\geq$1% but $<$5 % of the tumor surface ; IC2 : positive IC representing $\geq$ 5% but $<$10% of the tumor surface ; and IC3 : positive IC representing $>$10% of the tumor surface.

Results: 86pts were initially included in the study, 28 (32%) were excluded for non-LCNEC diagnosis. Among the 58 pts with LCNEC, five (8%) had a composite LCNEC with a NSCLC component. The mean age of the population was 65 years, mainly mens (86%) and former or current heavy smokers (93%). PD-L1 was positive on TC for only 12% of the samples, while 76 % of the samples shows IC PD-L1 positive, with respectively 18 (35%) IC3, 8(14%) IC2, and 13(25%) IC1.

Conclusions: LCNEC display a particular PDL1 expression pattern, different from NSCLC and from SCLC and may suggest a potential effectiveness of therapeutic anti PD-L1 antibodies, this hypothesis have to be addressed in clinical trial.

155P Inter-rater reliability of programmed death ligand 1 (PD-L1) scoring using the VENTANA PD-L1 (SP263) assay in non-small cell lung cancer (NSCLC)

G.H. Williams[1], A.G. Nicholson[2], D.R.J. Snead[3], E. Thunnissen[4], S. Lantuejoul[5], P. Cane[6], K.M. Kerr[7], M. Loddo[1], M. Scott[8], P.W. Scorer[8], C. Barker[8]

[1]Oncologica UK Ltd., Cambridge, UK, [2]Department of Histopathology, Royal Brompton and Harefield NHS Foundation Trust, National Heart and Lung Institute, Imperial College, London, UK, [3]Department of Pathology, University Hospitals Coventry and Warwickshire NHS Trust, Coventry, UK, [4]Department of Pathology, VU University Medical Center, Amsterdam, Netherlands, [5]Department of Biopathology, Centre Léon Bérard UNICANCER, Grenoble Alpes University, Lyon, France, [6]Department of Histopathology, Guy's and St Thomas' NHS Foundation Trust, London, UK, [7]Department of Pathology, Aberdeen University Medical School and Aberdeen Royal Infirmary, Aberdeen, UK, [8]Precision Medicine Laboratories, Precision Medicine and Genomics, IMED Biotech Unit, AstraZeneca, Cambridge, UK

Background: The VENTANA PD-L1 (SP263) assay has been developed as a companion diagnostic for anti-PD-L1 immune checkpoint inhibitors. Here we investigate assay inter-rater reliability, applied to PD-L1 scoring of tumour cells (TCs) and immune cell (IC) infiltrates in NSCLC.

Methods: Six expert European pulmonary pathologists independently scored 200 NSCLC samples stained using the VENTANA PD-L1 (SP263) assay. Archival, commercially-sourced formalin-fixed paraffin-embedded resections were selected to represent the dynamic range of PD-L1 expression. Each pathologist scored the proportion of TCs expressing PD-L1 (TM score), tumour-associated IC population as a percentage of total tumour area (PIC value), and percentage of ICs expressing PD-L1 (IC score). Scores were analysed using intra-class correlation coefficient (ICC) and patient classification using Fleiss' Kappa.

Results: Interim results were available for 3 pathologists and 180 cases. TM scoring between pathologists showed strong pair-wise correlations between individuals (R^2>0.90) with an ICC >0.95. Pair-wise and overall agreement was ≥85% for TC ≥ 1% and >93% for TC ≥ 20%, TC ≥ 25%, and TC ≥ 50%. Fleiss' Kappa showed substantial agreement for TC ≥ 1% and excellent agreement for TC ≥ 20%, TC ≥ 25%, and TC ≥ 50%. There were systematic and substantial differences in PIC values and IC scores between pathologists with poor pair-wise correlations. ICC indicated poor reliability for both IC score (0.36) and PIC values (0.044). Fleiss' Kappa showed poor agreement for IC ≥ 25% (0.183).

Conclusions: Assessment of TM score in NSCLC was highly reproducible using VENTANA PD-L1 (SP263) assay, building confidence in the accuracy of this assay in patient selection for anti-PD-L1 therapy. However, expert pathologists were unable to reproducibly assess IC score in NSCLC suggesting assessment methodology is unreliable for this tumour type and assay. This contrasts with urothelial cancer (UC) in which pathologist agreement for PIC values and IC scores was generated as part of UC VENTANA PD-L1 (SP263) IHC assay CE marking and FDA approval. This difference in pathology of the different tumour types requires further investigation.

156P Relationship between ring-type dedicated breast PET and tumor-infiltrating lymphocytes in early breast cancer

S. Sasada[1], N. Shiroma[2], E. Suzuki[1], S. Sueoka[1], N. Goda[1], K. Kajitani[1], A. Emi[1], N. Masumoto[1], T. Kadoya[1], R. Haruta[1], T. Kataoka[1], K. Arihiro[2], M. Okada[1]

[1]Breast Surgery, Hiroshima University Hospital, Hiroshima, Japan, [2]Pathology, Hiroshima University Hospital, Hiroshima, Japan

Background: FDG uptake on PET is related to biological parameters and prognosis in breast cancer. The predominance of stromal tumor-infiltrating lymphocytes (TILs) in breast cancer is a biomarker for prognosis and pathological complete response after neoadjuvant chemotherapy. However, whether whole-body PET (WBPET) and dedicated breast PET (DbPET) can reflect the amount of TILs is unclear. This study investigated the relationship between TILs and maximum standardized uptake value (SUVmax) in WBPET and ring-type DbPET.

Methods: A total of 125 invasive breast cancers underwent WBPET and ring-type DbPET and resected specimens were pathologically assessed. The impact on SUVmax on the tumor biological parameters and TILs was retrospectively evaluated. SUVmax was classified as high and low relative to the median values (WBPET-SUVmax: 2.2 and DbPET-SUVmax: 6.0).

Results: SUVmax correlated with tumor size, nuclear grade, Ki-67 labeling index, and TILs in both WBPET and DbPET (all $P < 0.001$). The cut-off values of tumor size, Ki-67 labeling index, and TILs predicting high SUVmax were 20 mm, 20%, and 20%, respectively. In multivariate analysis, the predictive factors for high SUVmax were tumor size and Ki-67 labeling index for WBPET and tumor size and TILs for DbPET. A high SUVmax in DbPET was related to high numbers of TIL tumors after propensity score matching analysis; however, WBPET was not ($P = 0.007$ and $P = 0.624$, respectively).

Table: 156P Logistic regression analysis for predicting high SUVmax tumor on WBPET and DbPET

Factors	Univariate analysis		Multivariate analysis	
	Odds ratio	P	Odds ratio	P
<WBPET>				
Histology_IC-NST	6.71	0.003	1.35	0.655
T2–3	6.18	< 0.001	13.0	< 0.001
Nuclear grade 3	6.48	< 0.001	2.70	0.071
ER positive	0.39	0.285	0.32	0.404
HER2 positive	1.62	0.486	0.31	0.211
Ki-67 labeling index ≥ 20%	3.03	0.005	3.68	0.020
TILs ≥ 20%	1.99	0.084	2.29	0.144
<DbPET>				
Histology_IC-NST	3.18	0.003	1.68	0.393
T2–3	4.38	< 0.001	4.81	< 0.001
Nuclear grade 3	4.43	< 0.001	1.82	0.238
ER positive	0.98	0.929	0.70	0.758
HER2 positive	0.97	0.857	0.53	0.450
Ki-67 labeling index ≥ 20%	3.54	0.001	1.39	0.513
TILs ≥ 20%	7.50	< 0.001	6.98	< 0.001

Conclusions: Unlike WBPET, the SUVmax in ring-type DbPET can represent the immune microenvironment after adjusting for tumor biological factors. DbPET might be a biomarker of pathological response to neoadjuvant chemotherapy and prognosis.

157P Short-term responders of non-small cell lung cancer patients to EGFR tyrosine kinase inhibitors display high prevalence of TP53 mutations and primary resistance mechanisms

Y. Fan[1], Y. Xu[1], X. Tong[2], J. Yan[3], X. Wu[2], Y.W. Shao[2]

[1]Key Laboratory on Diagnosis and Treatment Technology on Thoracic Cancer, Zhejiang Cancer Hospital, Hangzhou, China, [2]Geneseeq Technology Inc, Translational Medicine Research Institute, Ontario, ON, Canada, [3]Medical Department, Nanjing Geneseeq Technology Inc, Nanjing, China

Background: Non-small cell lung cancer (NSCLC) with activating EGFR mutations in exon 19 and 21 usually responds to EGFR tyrosine kinase inhibitors (TKI), but sometimes the responses can only be maintained for a few months. The underlying mechanisms of such short responses have not been fully elucidated.

Methods: The genomic profiles of sixteen short-term responders (SR) that had progression free survival (PFS) of less than 6 months on the first-generation EGFR TKI were interrogated, in comparison to twelve long-term responders (LR) that had more than 24 months of PFS. All patients were diagnosed with advanced lung adenocarcinoma and harbored EGFR 19del or L855R mutation before treatment. Paired tumor samples collected before treatment and after relapse (or at the last follow-up) were subjected to next-generation sequencing of 416 cancer-relevant genes.

Results: SR patients were significantly younger than LR patients ($p < 0.001$). 88% of SR patients have TP53 variations compared to 13% in LR patients ($p < 0.001$), and 37.5% SR patients carry EGFR amplification, which is much higher than LR patients (8%). In

addition, 12 SR patients (75%) were identified with other potential primary resistance mechanisms in pre-treatment samples, including PTEN loss, BIM deletion polymorphism, amplifications of EGFR, ERBB2, MET, HRAS and AKT2. Comparatively, only 3 LR patients (25%) were detected with EGFR or AKT1 amplification that could possibly exert resistance.

Conclusions: The diversified pre-existing resistance mechanisms in SR patients revealed the complexity of defining treatment strategies even for EGFR sensitive mutations.

158P Assessment of cfDNA in patients with metastatic colorectal cancer treated with cetuximab monotherapy

L. Angus[1], E.J. van Helden[2], S.C. van Es[3], E. Boon[4], C.M.L. van Herpen[4], D.J. de Groot[3], E.G.E. de Vries[3], C.W. Menke-van der Houven van Oordt[2], S. Sleijfer[1], H.M. Verheul[2], M.P.H.M. Jansen[1]

[1]Medical Oncology, Erasmus MC Cancer Institute, Rotterdam, Netherlands, [2]Medical Oncology, Cancer Center Amsterdam, VU University Medical Center, Amsterdam, Netherlands, [3]Medical Oncology, University Medical Center Groningen, Groningen, Netherlands, [4]Medical Oncology, Radboud University Medical Center, Nijmegen, Netherlands

Background: Third line systemic treatment for patients with RAS wild-type metastatic colorectal cancer (mCRC) includes anti-EGFR monoclonal antibodies such as cetuximab. Here, we examined cell-free DNA (cfDNA) to gain insight into mechanisms underlying primary and acquired resistance in patients with mCRC receiving cetuximab.

Methods: 34 patients with RAS wild-type mCRC (KRAS and NRAS exon 2-4) received biweekly cetuximab monotherapy (500mg/m^2). cfDNA was isolated from plasma obtained at baseline, after 2 weeks of treatment and at disease progression (PD). ± 20 ng DNA was used for targeted next generation sequencing using the Oncomine™ Colon cfDNA Assay (14 genes, 242 hotspots). Mutation analysis of tumor tissue was performed according standard of care, at least including KRAS and NRAS. Outcome was defined as clinical benefit (CB; PD $>$ 8 weeks, n = 21) versus no CB (NCB; PD $\leq$ 8 weeks, n = 13).

Results: Baseline cfDNA concentration correlated with the sum of diameters on CT ($p = 0.043$) and metabolically active tumor volume on [^{18}F]FDG PET ($p < 0.001$). In 6/13 (46%) of patients with NCB, mutations in KRAS (n = 3) and BRAF (n = 3) were detected in baseline cfDNA. Two KRAS mutations were detected cfDNA, but not in tissue. All BRAF mutations in cfDNA were present in tissue, one BRAF mutation in tissue was not detected in cfDNA. In one patient (5%) with CB a polyclonal KRAS mutation was detected in cfDNA, which was not found in tumor tissue. In 9 patients with CB, cfDNA concentrations were measured and decreased from a median of 45 ng/mL plasma (range 13 – 784 ng/mL) at baseline to 19 ng/mL after 2 weeks of treatment (range 9 – 42 ng/mL) ($p = 0.008$). In patients with CB an enrichment of mutations in genes associated with resistance (KRAS, NRAS and BRAF) was found in 12/17 (70%) at PD compared to baseline. Moreover, in 8/17 (47%) of these patients EGFR mutations in codons coding for the epitope binding site of cetuximab emerged and in 9/17 patients (53%) multiple mutations in the same gene occurred suggesting the presence of multiple subclones.

Conclusions: A subset of mCRC patients with NCB could be identified based on baseline cfDNA mutations in genes associated with cetuximab resistance. By using cfDNA we can optimize patient selection for cetuximab therapy and elucidate mechanisms of resistance.

Clinical trial identification: NCT02117466.

159P Quantifying circulating cell-free DNA as clinical biomarker

M. Romain[1], Z.A.A. Dache[1], A. Otandault[1], R. Tanos[1], B. Pastor[1], C. Sanchez[1], J. Azzi[1], G. Tousch[1], S. Azan[1], C. Mollevi[1], S. Thezenas[2], P. Blache[1], A.R. Thierry[1]

[1]Integrated Research for Personalized Medicine in Digestive Oncology, ICM Regional Cancer Institute of Montpellier, Montpellier, France, [2]Biostatistics, ICM Regional Cancer Institute of Montpellier, Montpellier, France

Background: This is the first comprehensive study on the effect of pre-analytical and demographic parameters that could be a source of variability in the quantification of nuclear and mitochondrial circulating DNA (NcirDNA and McirDNA, respectively).

Methods: We set an optimal calculation of the simultaneous quantification of circulating nuclear and mitochondrial genome copy number based on a clinically validated q-PCR method. We report data from a total of 217 subjects, 99 healthy individuals and 118 metastatic colorectal cancer (mCRC) patients. We also investigated the influence of blood storage and collection time on cirDNA concentration from healthy volunteers.

Results: Approximately 26,650 and 3,000-fold more mitochondrial than nuclear genome copies were found in healthy subjects and mCRC patients, respectively. Neither NcirDNA nor McirDNA plasma concentrations depended on age in the healthy and mCRC cohorts taken as a whole. Remarkably however NcirDNA levels were significantly higher in healthy men as compared to women (n = 99, P = 0.010). Men and women did not differ in McirDNA levels. NcirDNA levels increased slightly with age in healthy women, suggesting a potential influence of menopause. A highly significant statistical difference was found between mCRC patients and healthy individuals for NcirDNA ($P < 0.0001$) and McirDNA ($P = 0.019$). In healthy volunteers, there was a higher level of NcirDNA at 9:00 AM with no food intake.

Conclusions: Nuclear and mitochondrial cirDNA levels do not vary in the same way with regards to blood stability, collection time, and pathological status. Our observations, of pre-analytical, analytical and demographical factors, could serve to set standard operating procedures and to transpose cirDNA analysis into clinical practice in oncology. Guidelines on the preanalytical conditions will be also presented from data from this study and a complete review of the literature.

160P Gene expression profile (GEP) and survival among patients with advanced ovarian cancer

E. Høgdall[1], C.K. Høgdall[2], P-T. Vo[3], W. Zhou[3], L. Huang[3], M. Marton[3], S.M. Keefe[3], M. Busch-Sørensen[3], S.M. Sørensen[4], J. Georgsen[5], E. Mejlgaard[5], L. Nedergaard[6], T. Steiniche[5]

[1]Department of Pathology, Herlev Hospital, Copenhagen, Denmark, [2]Gynecology and Obstetrics, Rigshospitalet, Copenhagen, Denmark, [3]Medical Oncology, Merck & Co., Inc., Kenilworth, NJ, USA, [4]Oncology, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark, [5]Pathology, Aarhus University Hospital, Aarhus, Denmark, [6]Pathology, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark

Background: The ability of T-cell–inflamed GEP (Ayers et al. J Clin Inv. 2017) to predict clinical outcome in ovarian cancer is not fully understood. A retrospective observational study was conducted to evaluate the prognostic value of GEP and its association with programmed death ligand 1 (PD-L1) expression in patients with advanced epithelial ovarian, primary peritoneal, or fallopian tube cancer (OvCa).

Methods: Patients diagnosed as FIGO stages II-IV OvCa from 2004 to 2012 at Aarhus University Hospital and Rigshospitalet, Copenhagen, Denmark, were included. Patients were considered platinum sensitive if treatment-free interval [TFI] was $\geq$6 months. PD-L1 was assayed using the 22C3 antibody, and positivity was defined as $\geq$ 1 stained tumor or immune cells per 100 tumor cells. T-cell–inflamed GEP score was defined as low ($<$ –0.318), intermediate (–0.318 to $<$ –0.162), or high ($\geq$ –0.162). The log-rank test and Cox proportional hazards model were used for survival analyses, adjusting for age, stage, histology, residual tumor, surgery type, performance status, platinum sensitivity, and PD-L1 expression status.

Results: Median age of the 376 patients was 63 years (range, 26-86); 9%, 70%, and 20% were FIGO stages II, III, and IV disease, respectively. Of these patients, 80% had type II histologic type, and 76% were platinum sensitive; 49% had a GEP score of low, 16% had intermediate, and 35% had high. Baseline characteristics between GEP groups were similar; PD-L1 and GEP scores were correlated (Spearman r, 0.71; Kendall tau r, 0.57). Median overall survival (OS) was 43 months (95% CI, 38-49) in all patients and was similar for patients with low GEP (41 months) and intermediate GEP (40 months), compared with patients with high GEP (52 months). There was no significant association between GEP status (intermediate/low vs high) and OS among all patients (adjusted hazard ratio, 1.00 [95% CI, 0.72-1.38]), by platinum sensitivity or by PD-L1 expression status.

Conclusions: GEP correlated with PD-L1 expression in patients with advanced OvCa, but OS was not significantly different between GEP categories.

161P Predicting survival benefit of capecitabine plus cisplatin in patients with metastatic gastric cancer patients using quantitative proteomics

D. Yan[1], M-H. Ryu[2], E. An[1], Y.S. Park[3], H. Na[2], J. Ma[2], Y. Tian[1], F. Cecchi[1], T. Hembrough[1], Y-K. Kang[2]

[1]R&D, NantOmics, LLC, Rockville, MD, USA, [2]Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [3]Department of Pathology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea

Background: Capecitabine plus cisplatin (XP) is a standard treatment for metastatic gastric cancer (mGC). Capecitabine activation requires the enzymes uridine-cytidine kinase 2 (UCK2) and orotate phosphoribosyl transferase (OPRT). We previously used mass spectrometry to quantitate UCK2 in tumor samples from 5-FU-treated patients with stage II/III colorectal cancer; UCK2 protein expression > 319 amol/ug of tumor protein was associated with improved survival. Here, we assessed whether these biomarkers would predict survival among mGC patients treated with XP.

Methods: Archived tumor samples from patients with mGC were microdissected and solubilized for mass spectrometric quantitation of 16 protein biomarkers. Kaplan-Meier survival curves were compared using a log-rank test. Multivariate Cox models of survival included clinical covariates and protein biomarkers.

Results: mGC tumor samples from 116 XP-treated patients were analyzed (males: 64%; median age: 55 years). All samples expressed OPRT protein (range: 202 – 1719 amol/ug), and 114 of 116 expressed UCK2 (range: 119 – 933 amol/ug). Patients with UCK2 expression above the pre-defined cutoff of 319 amol/μg (n = 30) had longer time to progression (TTP) (HR: 0.60; p = 0.020) than patients below the cutoff. Results for overall survival (OS) were similar (HR: 0.59; p = 0.015). OPRT protein expression > 790 amol/ug (n = 24) was associated with longer TTP (HR: 0.58; p = 0.019) and longer OS (HR: 0.60; p = 0.029). In multivariate analysis, UCK2 and OPRT remained independent predictors of survival after adjustment for age, gender, ECOG performance status, metastatic sites, and other clinical covariates.

Conclusions: We validated a pre-defined UCK2 expression cutoff and discovered an OPRT cutoff in an XP-treated mGC patient cohort. Patients with tumor expression of UCK2 and OPRT proteins above quantified thresholds survived longer than patients with lower expression. Mass spectrometric quantitation of these common tumor proteins at diagnosis may improve patient selection for XP. Studies to validate these and other chemopredictive biomarkers are ongoing.

162P Detection of microsatellite instability (MSI) with a novel set of 7 Idylla biomarkers on colorectal cancer samples in a multi-center study

B. De Craene[1], J. Van de Velde[1], E. Bellon[1], M. Gazin[1], E. Rondelez[1], L. Vandenbroeck[1], T. Vanhoey[1], N. Elsen[1], L.C. Melchior[2], G.L. Willemoe[2], E. Watkin[3], N. Arens[4], C. Altmann[4], K. Decanniere[1], E. Sablon[1], G.G. Maertens[1]

[1]Create, Biocartis NV, Mechelen, Belgium, [2]Department of Pathology, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark, [3]Pathology, Selas Cypath, Villeurbane, France, [4]Pathology, Molekularpathologie Trier (MPT), Trier, Germany

Background: Detection of microsatellite instability (MSI) is recommended for all patients with colorectal cancer (CRC). Current clinical reference methods are immunohistochemical (IHC) staining of mismatch repair (MMR) proteins and/or PCR analysis of frequently mutated repetitive regions of DNA. The prototype Idylla™ MSI Test has been developed using a new set of short homopolymers located in the ACVR2A, BTBD7, DIDO1, MRE11, RYR3, SEC31A & SULF2 genes. This marker set allows probe-based detection with great specificity in a simplified workflow compared to current methods.

Methods: Repeat length with this set of biomarkers was determined on 333 formalin-fixed and paraffin-embedded (FFPE) CRC samples using Idylla™ MSI Test prototype cartridges, which allow a fully automated workflow including sample preparation, DNA amplification and automated repeat length calling. A neural network based algorithm was built on a large cohort of reference/patients samples (n > 3000) obtained from different clinical sites (n > 10) and different ethnic groups (n = 5). Three-hundred fourteen samples were characterized by means of the Promega MSI analysis system and 272 samples by means of MMR protein IHC staining. Approximately 30% of the samples included in the study were previously characterized to be MSI-H by either one of these methods.

Results: Concordance analysis revealed an overall agreement of 98.7% (96.7%-99.5% 95% CI) with Promega and 97.6% (94.8%-98.9% 95% CI) with IHC analysis. Analysis of consecutive sections of 182 samples with the three methodologies revealed a higher number of invalid results for Promega (3.8%) and IHC (13.2%) compared to the prototype Idylla™ MSI Test (2.2%).

Conclusions: This study verified the robustness of the prototype Idylla™ MSI Test including novel MSI biomarkers to discriminate MSI-H from MSS status on a large and diverse set of CRC samples. The study was conducted in multiple centers demonstrating the possibility of a rapid and fully automated analysis for MSI testing close to the point of need. The prototype Idylla™ MSI Test provided accurate and reliable results within 150 minutes from just one FFPE tumor section (no normal reference sample required).

163P Accurate measurement of tumor mutation burden in liquid biopsy (bTMB) using a 500 gene panel

T. Jiang, S. Zhang, A. Jager, S. Katz, J. Lococo, P. Le, B. Andrian, C. Zhao, D. Baker, T. Pawlowski, S. Bilke

Clinical Genomics, Illumina, Inc, San Diego, CA, USA

Background: Tumor mutation burden (TMB) has been shown as a new predictive biomarker for immune checkpoint inhibitor in various cancer types. It is typically measured by processing tumor tissue with substantial input which limits its clinical utility in patients with metastatic or unresectable disease. Meanwhile, there is increasing interest in circulating tumor DNA (ctDNA) that act as a noninvasive real-time biomarker for cancer patients. Therefore, here we develop a new next generation sequencing assay that can identify patients with sufficient tumor fraction in plasma and accurately measures the TMB from blood (bTMB).

Methods: Cell free DNA (cfDNA) was extracted from plasma across four original tissue types by different tumor stages. CfDNA Assay was performed with unique molecular identifier (UMI) , sequenced on the Illumina® platforms and analyzed using an internal pipeline for variants down to 0.4%. By integrating the fragment size distribution and the clonal mutation frequency, we were able to estimate the tumor fraction per plasma sample. A bTMB score was also derived using all the coding variants on a 1.3M panel across 500+ genes. The matched TMB score is derived by the same assay using FFPE tissue.

Results: Our assay has generated sufficient results from 1-4ml plasma for variant detection down to 0.4%. Across four tissue types by various cancer stages, our assay and pipeline yield a variant concordance of 70% between cfDNA and FFPE. Majority of mutations only found in plasma may be associated with clonal hematopoiesis in genes such as TET2, DMBT3A and etc. By combining fragment size distribution and driver mutation frequency, we were able to estimate tumor fraction in plasma. Tumor fraction in plasma is significantly associated with tumor stage that >50% of metastatic cancers and > 25% early stage lung cancers contain high tumor fraction. In patients with at least 1% tumor content, there is high correlation between bTMB measured by plasma and TMB measured by FFPE (R^2=0.92).

Conclusions: We have developed a ctDNA assay to detect somatic variants and determine bTMB with high accuracy and precision with input as low as 10 ng of cfDNA. Our assay yield accurate measurement of TMB compared to tissue biopsy.

164P Circulating tumor DNA and RNA as an exploratory biomarker to evaluate GT0918 in a phase I/II clinical trial in mCRPC patients

M. Tan[1], S. Zhang[1], Z. Zhao[2], A. Wang[3], D. Cheung[3], P. Du[4], J. Yu[3], S. Jia[3], C. Guo[5], Y. Tong[6], K. Zhou[7]

[1]Translational Medicine, Predicine, Inc, Hayward, CA, USA, [2]Research & Development, Predicine, Inc, Hayward, CA, USA, [3]Clinical Research, Predicine, Inc, Hayward, CA, USA, [4]Bioinformatics, Predicine, Inc, Hayward, CA, USA, [5]Research & Development, Suzhou Kintor Pharmaceuticals, Inc., Suzhou, China, [6]Business Development, Suzhou Kintor Pharmaceuticals, Inc., Suzhou, China, [7]Medical Oncology, Suzhou Kintor Pharmaceuticals, Inc., Suzhou, China

Background: Metastatic castration resistant prostate cancer (mCRPC) is a complex disease with distinct molecular features in relation to genomic instability and selective treatment pressure. Circulating tumor DNA and RNA fragments (ctDNA & ctRNA) found in blood offers the potential of disease diagnosis, monitoring and resistance mechanism interrogation by detecting genomic alterations from tumor. We explored ctDNA & ctRNA-based biomarkers from patient blood to assess their associations with clinical response of GT0918, a potent AR antagonist, in a Phase 1/2 clincal study in mCRPC who progressed after abiraterone or enzalutamide and docetaxol, or cannot tolerate either or both therapies.

Methods: We performed a retrospective analysis of blood samples from mCRPC patients collected at baseline, on- and after study during the trial. A highly sensitive ctDNA- & ctRNA-based NGS assay was developed to detect mutation, copy number gain, fusion and splicing variants. Statistical analyses were performed in R.

Results: 20 blood samples were collected at multiple time points from 8 patients. CtDNA-based variants are detected in all of patients. The most frequent mutations are TP53 (55.0%) and AR (30.0%). Combined mutation rates in PTEN-PI3K-AKT and DNA damage repair pathways (BRCA1/BRCA2/ATM) are both 35.0%. Importantly, AR hotspot mutations (W742C, T878A, and S889G) and amplifications are detected in 4 subjects. AR splicing variants (AR-V3, AR-V7) were found in 3 patients by ctRNA assay. Interestingly, one AR-V3+ patient became negative during the treatment accompanied by a decrease of other molecular biomarkers including prostate-specific SPOP mutation and cfDNA yield. In contrast, another patient who was AR-V3+ at C4D1, had constantly high AR amplification and increasing cfDNA yields over treatment. Last, as a hallmark of prostate cancer, TMPRSS2-ERG fusion was also detected in 2 patients.

Conclusions: This is a preliminary study to explore genomic alterations in mCRPC in response to GT0918 treatment. As a non-invasive assay, the ctDNA & ctRNA-based assay was highly sensitive and provided useful molecular insights for monitoring treatment effect and deciphering drug sensitivity & resistance mechanisms.

Clinical trial identification: NCT02826772.

165P The frequency of primary cilia, CD8+ tumor infiltrating lymphocytes and PD-1 expression in renal cell carcinoma of clear-cell type

J. Dvorak[1], B. Rosova[2], A. Filipova[3], D. Hadzi Nikolov[4], L. Dusek[5], A. Rozsypalova[1], J. Proks[1], I. Richter[6], B. Melichar[7], T. Buchler[1], R. Zachoval[8], R. Matej[2]

[1]Oncology, Thomayer University Hospital, Prague, Czech Republic, [2]Pathology, Thomayer University Hospital, Prague, Czech Republic, [3]Radiobiology, Faculty of Military Health Sciences in Hradec Kralove, University of Defense in Brno, Hradec Kralove, Czech Republic, [4]Pathology, Regional Hospital, Kolin, Czech Republic, [5]Institute of Biostatistic and Analyses, Masaryk University Brno, Brno, Czech Republic, [6]Oncology, Regional Hospital, Liberec, Czech Republic, [7]Oncology, University Hospital Olomouc, Olomouc, Czech Republic, [8]Urology, Thomayer University Hospital, Prague, Czech Republic

Background: Primary cilium (PC) is considered to represent a functional homologue of the immune synapse due to morphological and functional similarities in architecture. Both microtubule structures, i.e. primary cilia of cancer-associated fibroblasts and immune synapses between cytotoxic CD8+ tumor infiltrating lymphocytes (TILs) and antigen-presenting or cancer cells, are regularly found in varying amounts in the microenvironment of solid tumors. These could, in fact, represent two sides of the same coin. However, so far both parameters have not been evaluated simultaneously within the same group of patients.

Methods: The presence of PC in cells, programmed cell death protein-1 receptor (PD-1) expression and the frequency of intraepithelial CD8+ TILs was retrospectively evaluated in tumor tissue blocks of the resected specimens of the kidney in 104 patients with renal cell carcinoma of clear-cell type, 71 males and 33 females, with a median age of 64 years (range 38-82 years). Twenty-eight patients had stage I, 15 stage II, 31 stage III and 30 patients had stage IV tumor. Grade was as follows: grade 1 in 27 patients, grade 2 in 15 patients, grade 3 in 31 patient and grade IV in 30 patients.

Results: The median frequency of PC was 0.0028% (0-0,0465%). The frequency of intraepithelial CD8+ TILs was negative in 1 patient, <25% in 63, 26-50% in 29 and 26-50% in 11, respectively. The expression of PD-1 was <5% in 52 patients, 5-25% in 34 patients, 26-50% in 13 patients, 51-75% in 4 patients and 75% in 1 patient. During the follow-up, recurrence occurred in 42 patients and 43 patients died. Median PFS was 44% (95% CI: 34-67%) and median OS was 98% (95% CI: 84-117%).

Conclusions: The present study provides the first data on the potential association frequency of PC, PD-1 and CD8+ TILs in patients with renal cancer.

Background: DNA mismatch repair (MMR) deficiency is a genetic abnormality that has important clinical implications related to therapeutic option, familial cancer risk assessment, and checkpoint inhibitor response. It occurs in approximately 15% of colorectal cancers (CRC). Associations between MMR protein expression, microsatellite instability (MSI), and gene mutations remain under investigation.

Methods: Thirty-one FFPE samples from primary CRC patients (pts) were collected for immunohistochemistry (IHC) assay of MMR proteins, PCR-based MSI assay if available and NGS-based panel assay. Genomic alterations including single base substitutions, short and long insertions/deletions, copy number variations, and gene rearrangement were assessed. MSI status were predicted based from NGS data.

Results: Out of 31 sample, 12 CRC were identified as MMR deficiency (dMMR) by IHC including 5 males and 7 females (median age: 66 years), and 19 samples as MMR proficiency (pMMR) including 13 males and 6 females (Median age: 53 years). Eight of the 12 dMMR samples (67%) harbored at least one MMR gene mutations predicted as loss of functions,[u1] including nonsense mutations or truncations in MSH2, MSH6 or MLH1. No MMR gene mutation was detected in any of the 19 pMMR samples (p value<0.001). In addition, 2 BRAF and 6 KRAS hotspot mutations were detected in dMMR samples, and 8 KRAS, 1 BRAF and 1 NRAS mutations in pMMR samples. NGS panel based MSI algorithm successfully predicted the MSI status of all the 31 samples with 100% concordance with the MMR results. Neither copy number variation nor rearrangement was detected. Five pMMR samples were identified as microsatellite stability (MSS) by PCR, 6 dMMR were high level of microsatellite instability (MSI-H), and the rest were failed due to DNA contents.

Table: 166P

	n	MMR gene mutations (n, %)	KRAS mutations (n, %)	NRAS mutations (n, %)	BRAF mutations (n, %)	NGS MSI-H status (n, %)
dMMR (IHC)	12	8 (66.7%)	6 (50%)	0 (0%)	2 (16.7%)	12 (100%)
pMMR (IHC)	19	0 (0%)	8 (42.1%)	1 (5.2%)	1 (5.2%)	0 (0%)

Conclusions: We observed a significant association between MMR deficiency and MMR gene mutations from deep DNA sequencing. The results suggested that CRC pts with MMR gene mutations could be more likely to have dMMR status.

Background: Gastric cancer is a high incidence malignancy in China, but the disease is often diagnosed at an advanced stage with limited therapeutic options and poor prognosis. Unfortunately, limited progress of target and immune therapy has achieved in gastric cancer due to tumor heterogeneity and the lack of effective biomarkers in the clinical. Thus the precise understanding of gastric cancer genomic profiling is urgent for exploring clinical strategy of this malignancy.

Methods: Formalin Fixed Paraffin Embedded (FFPE) samples of 110 Chinese gastric cancer patients were collected for next-generation sequencing (NGS)-based 450 genes

panel assay. Genomic alterations including single base substitution, short and long insertions/deletions, copy number variations, gene fusions and rearrangement were assessed. Microsatellite instability (MSI) status and tumor mutational burden (TMB) were also acquired by NGS algorithm.

Results: There were 71 males (64.6%) and 39 females (35.4%) diagnosed as gastric cancer with a median age of 62 years old. The most frequent genomic alterations in Chinese gastric cancer patients were revealed as TP53 (66.4%), ARID1A (18.2%), LRP1B (17.3%), CDH1 (15.5%), CCNE1 (14.5%), FAT4 (13.6%), ERBB2 (11.8%), SMAD4 (10.9%), KMT2D (10.9%), RNF43 (10.9%), TGFBR2 (10.0%), KRAS (10.0%), APC (10.0%). Some actionable aberrantly activated mutations were identified in genes such as FGFR1/2/3 (10.0%), BRCA1/2 (6.4%) and PI3K/mTOR pathway including FBXW7, MTOR, PIK3CA, PTEN, STK11, TSC1 and TSC2 (20.0%). In total, 39.1% of patients carried one or more actionable genomic alterations, which indicated the potential clinical benefits of targeted therapies for them. The percentage of patients with germline mutations was 9.1% in current cohort. These germline mutation genes were mainly in homologous recombination (HR) pathways such as BRCA1/2, ATM and BARD1.

Conclusions: In this study, 39.1% of Chinese gastric cancer patients carried actionable genomic alterations which could potentially guide and influence personalized treatments. About 9.1% patients harbored germline mutations mainly in HR pathway. All these genomic identifications in Chinese gastric cancer cohort may provide useful information on drug discovery and biomarker exploration.

[1]Department of Gynecology and Obstetrics, Universitätsklinik Erlangen, Erlangen, Germany, [2]Gynäkologie, BioNTech Diagnostics GmbH, Mainz, Germany, [3]Statistic, German Breast Group (GBG) Forschungs GmbH, Neu-Isenburg, Germany, [4]STRATIFYER Molecular Pathology GmbH, Cologne, Germany, [5]Institute of Pathology, Charite Berlin Mitte, Berlin, Germany, [6]BioNTech Diagnostics GmbH, Mainz, Germany, [7]Brustzentrum, Elisabeth Krankenhaus, Kassel, Germany, [8]Brustzentrum, Hufeland Klinikum, Bad Langensalza, Germany, [9]Gynäkologie, Gynäkologisch-Onkologische Praxis, Hannover, Germany, [10]Gynecol. & Obstetrics, Universitaetsfrauenklinik Ulm, Ulm, Germany, [11]Klinik für Frauenheilkunde und Geburtshilfe, Universitätsklinikum Frankfurt(Johannes-Wolfgang Goethe Institute), Frankfurt am Main, Germany, [12]Clinic for Gynecology and Obstetrics, University Hospital Schleswig-Holstein, Kiel, Germany, [13]Gynecologic Oncology, Nationales Zentrum für Tumorerkrankungen (NCT), Heidelberg, Germany, [14]Department of Gynecology, Hamburg-Eppendorf University Medical Center, Hamburg, Germany, [15]Mammazentrum Hamburg, Hospital Jerusalem, Hamburg, Germany, [16]Gynäkologie und Geburtsmedizin, Uniklinik RWTH, Aachen, Germany, [17]Management, BioNTech AG, Mainz, Germany, [18]Department of Medicine and Research, German Breast Group (GBG) Forschungs GmbH, Neu-Isenburg, Germany, [19]Gynäkologie und Geburtshilfe, Helios Klinikum Berlin-Buch, Berlin, Germany

Background: Prediction of the response to NACT in early BC patients (pts) can lead to improved treatment decisions. The MammaTyper® test can be used to predict the probability of pCR after NACT by integrating accurate and reproducible assessment of ERBB2, ESR1, PGR and MKI67 mRNA into a standardized prediction model (Varga et al. Breast Cancer Research 2017).

Methods: Total RNA was extracted from formalin-fixed paraffin-embedded (FFPE) tumor samples of pts with cT1-2 BC enrolled in in the single arm phase II TECHNO trial (Untch et al. JCO 2011) and the randomised phase III PREPARE trial (Untch et al. Ann Oncol. 2011). MammaTyper®, a molecular in vitro diagnostic RT-qPCR test, was used to assess the expression of ERBB2 (HER2), ESR1 (ER), PGR (PR) and MKI67 (Ki67) genes from which a predefined continuous score was calculated. The study aimed to validate the MammaTyper® pCR-score for predicting pCR (ypT0 ypN0) after NACT in BC. Pts were classifed into a low or high score group according to a predefined cutoff: score $\leq$41 predicts a low probability of pCR; score $\geq$42 predicts a high pCR rate.

Results: A total of 324 pts with available FFPE samples and MammaTyper® measurements were analyzed. The MammaTyper® score was significantly associated with an increased pCR rate (AUC=0.805, $p < 0.001$). Similarly, pts with high MammaTyper® score (N = 159) had more frequently pCR compared to pts with low score (N = 165) (30.2% vs 3.0%, respectively; OR = 13.84 [95%CI 5.34-35.86], $p < 0.001$). In addition, the MammaTyper® pCR-score remained significantly predicitve when adjusted for age, nodal status, tumor grade and treatment (OR = 10.90 [95%CI 3.38-35.16], $p < 0.001$). Within the non-pCR subgroup, pts with low score had a significantly longer disease-free (DFS) and overall (OS) survival compared to pts with high score (DFS HR = 1.59, 95%-CI 1.04-2.44, $p = 0.032$; OS HR = 2.85, 95%-CI 1.62-5.00, $p < 0.001$).

Conclusions: The MammaTyper® pCR-score predicts pCR after NACT and seems to improve prognosis additionally to clinical predictors in pts with early BC. Its utility with regard to conventional ER, PR, Ki67 and HER2 has to be analyzed in future studies.

Chiara, Pisa, Italy, [9]Clinical and Experimental Medicine, University of Pisa, Pisa, Italy

Background: Pancreatic ductal adenocarcinoma (PDAC) is considered a poorly immunogenic tumor and treatment with immune checkpoint inhibitors lacks efficacy in this disease. Recently, the use of immune checkpoint inhibitors with radiation therapy in PDAC has demonstrated synergistic activity. The aim of this study was to evaluate the effect of FOLFIRINOX and GEMnPAC on PD-L1 expression in plasma-derived exosomes of PDAC patients.

Methods: Four ml of plasma were obtained at baseline (before initiation of chemotherapy) and at the time of first radiological evaluation (3 months) from patients undergoing first-line FOLFIRINOX or GEMnPAC chemotherapy. Exosomes and RNA extraction from plasma were performed using the exoRNeasy kit (Qiagen®, Valencia, CA, USA); PD-L1 expression was evaluated by digital droplet PCR (Bio-Rad®, Hercules, CA, USA).

Results: A total of 22 pancreatic cancer patients were enrolled in this study; 15 (68.2%) were treated with GEMnPAC and 7 (31.9%) with FOLFIRINOX. In the GEMnPAC group one patient had a partial response (RP), 11 patients had stabilization of disease (SD) and 3 progressed (PD). In the FOLFIRINOX group there were 1 RP, 5 SD and 1 PD. Eleven patients treated with GEMnPAC had a significant increase of PD-L1 expression at 3 months vs. baseline. Indeed, the mean PD-L1 copies/ml was 90 at baseline and 170 at 3 months ($p = 0.02$). On the contrary, in the FOLFIRINOX group, PD-L1 levels were increased in 3 patients and remained stable/decreased in 4 subjects; the mean baseline copies/ml were 70 vs. 80 at 3 months ($p = 0.4$). The selective induction of PD-L1 expression was independent from tumor response.

Conclusions: These pilot data suggest that, due to its ability to increase PD-L1 expression, GEMnPAC regimen may be used as induction-treatment for immunotherapy in pancreatic cancer, either sequentially or concomitantly.

170P Ecological diversity indices as measurements of tumor heterogeneity correlates with clinical outcomes in late stage small cell lung cancer (SCLC)

S. Yaung[1], L. Xi[1], C. Woestmann[2], S. McNamara[2], B. Hinzmann[3], S. Froehler[2], N. Tikoo[4], C. Ju[4], A. Balasubramanyam[4], H-P. Adams[5], M. Thomas[6], F. Lasitschka[6], M. Meister[6], M. Schneider[6], F.J.F. Herth[6], T. Muley[6], B. Wehnl[7], J. Palma[8], X.M. Ma[8]

[1]Bioinformatics, Roche Sequencing Solutions, Inc., Pleasanton, CA, USA, [2]Bioinformatics, Roche Sequencing Solutions, Inc., Potsdam, Germany, [3]Assay Development, Roche Sequencing Solutions, Inc., Potsdam, Germany, [4]Biostatistics, Roche Sequencing Solutions, Inc., Pleasanton, CA, USA, [5]Biostatistics, Roche Sequencing Solutions, Inc., Potsdam, Germany, [6]Translational Research Unit, Thoraxklinik at Heidelberg University Hospital, Heidelberg, Germany, [7]Clinical Operations, Roche Diagnostics GmbH, Penzberg, Germany, [8]Medical Scientific Affairs, Roche Sequencing Solutions, Inc., Pleasanton, CA, USA

Background: Tumor heterogeneity is difficult to characterize with tissue biopsies in late stage cancers, in which primary and metastatic tumors may have diverged in their mutational profiles. Assessing the diversity of mutations detected by sequencing circulating tumor DNA (ctDNA) from liquid biopsies can quantify the genetic complexity of tumors shedding DNA into the blood.

Methods: In a prospective, observational study, we obtained pre-treatment plasma samples from 56 subjects with Stage IV small cell lung cancer (SCLC) treated with first-line chemo or chemoradiation therapies. Plasma samples were analyzed with the AVENIO ctDNA Surveillance Kit, a targeted next-generation sequencing panel of 198 kilobases. We applied the Shannon and Simpson diversity indices by considering each somatic variant as a species and the number of detected duplex molecules with that mutation as the abundance of that species. Samples were ranked as low tumor heterogeneity if their plasma variant diversity score was below the first tertile of the cohort.

Results: Stage IV SCLC subjects with low tumor heterogeneity evaluated by the Shannon diversity had shorter overall survival (hazard ratio = 1.8; 95% CI 1-3.3; log-rank p = 0.034; median survival difference = 4.5 months). Furthermore, subjects with low tumor heterogeneity evaluated by the Gini-Simpson or inverse Simpson diversity index had shorter overall survival (hazard ratio = 1.8; 95% CI 1-3.3; log-rank p = 0.033; median survival difference = 4.5 months).

Conclusions: The molecular barcoding scheme in the AVENIO kit allows for each strand of the original double-stranded ctDNA molecule to be tracked. From this reconstructed profile of circulating duplex molecules harboring tumor variants, we derived a tumor heterogeneity measure based on the Shannon and Simpson diversity indices commonly used in ecology. We found that late stage SCLC subjects with low tumor heterogeneity had shorter overall survival, suggesting that highly heterogeneous SCLC tumors may respond better to chemotherapy or radiation. Studies to further validate these findings are ongoing.

171P MET exon 14 splicing mutation and its correlation with clinocopathological features in subjects with non-small cell lung cancer

D. Katalinic[1], I. Aleric[2], A. Vcev[1]

[1]Department of Clinical Medicine, Faculty of Medicine and Faculty of Dental Medicine and Health, Josip Juraj Strossmayer University of Osijek, Osijek, Croatia, [2]Department of Internal Medicine, Faculty of Medicine, Josip Juraj Strossmayer University of Osijek, Osijek, Croatia

Background: Driver mutations are genomic alterations important for tumor initiation and growth. They are found in genes that control cellular proliferation and long-term survival. Mesenchymal-to-epithelial transition (MET) exon 14 splicing mutation occurs in about 3% of cases of non-small cell lung cancer (NSCLC). It has been recognized as an important biomarker to predict response to MET tyrosine-kinase inhibitor therapy. The aim of this study was to investigate possible connection among the MET exon 14 mutations and genomic as well as clinicopathological features in patients with NSCLC.

Methods: The study was performed among 270 patients (58% males and 42% females; mean age of 57.14 ± 16.48 years) with histologically confirmed diagnosis of NSCLC. The distribution of MET exon 14 splicing mutation was detected using the quantitative real-time polymerase chain reaction restriction fragment length polymorphism assay. RNA was extracted from formalin-fixed paraffin-embedded samples. The study was conducted according to the Declaration of Helsinki, the protocol was reviewed and approved by the institutional Ethics committee and all patients provided written informed consent.

Results: MET exon 14 splicing mutation was detected in 9 patients (3.4%). It was found in 7 adenocarcinomas (18.9%) and in 2 squamous cell carcinomas (5.4%). Most adenocarcinomas occurred in females and non-smokers. Squamous cell carcinoma predominantly occurred in male smoking patients. All subjects with MET exon 14 splicing mutation had earlier pathology stage of disease (IA, IB, IIA, IIB) (31%) and older age (>75 years) (43%). Overall survival (OS) of these patients were statistically longer than in patients with KRAS and EGFR mutations (2.2 vs. 1.3 months and 2.4 vs. 1.8 months).

Conclusions: We found that MET exon 14 splicing mutation occurs at a frequency of 3.4%, in older age, and mostly in early stage of NSCLC. OS of patients harboring MET exon 14 splicing mutation has lasted longer than in patients harboring KRAS and EGFR mutations. Patients with MET exon 14 splicing mutation may respond well to MET tyrosine-kinase inhibitor therapy. Further studies are needed to confirm our results.

172P Cancer stem cell markers in pancreatic ductal adenocarcinoma

F. Aksoy[1], E. Kaya[1], U. Egeli[2], H.Z. Dundar[1], P. Tasar[1], S.A. Aksoy[2], Y. Ozen[1], B. Tunca[2], G. Cecener[2], O. Yerci[3]

[1]General Surgery, Uludag University Medical Faculty, Bursa, Turkey, [2]Medical Biology, Uludag University Medical Faculty, Bursa, Turkey, [3]Pathology, Uludag University Medical Faculty, Bursa, Turkey

Background: Pancreatic ductal adenocarcinoma (PDAC) is one of the leading causes of cancer deaths in both men and women world-wide. Despite development of scientific, PC remains lethal disease. Recently, cancer stem cells (CSC) of pancreatic cancer that often are resistant to treatment have been identified. Present study aims to investigate the existence and prognostic value of CSC markers in PDAC patients.

Methods: 52 hematoxylin and eosin-stained slides cut from formalin-fixed, paraffin-embedded (FFPE) PDAC tissues were evaluated by a pathologist, and the areas of the slide representing tumor and normal were identified. The samples were analyzed for the presence and differential expression of LGR5, CD44 and CD133 using RT2 Profiler PCR Array Data Analysis (http://www.sabiosciences.com/pcr/arrayanalysis.php) to compare the PCR array analysis results and the characteristics of the tumors and cases.

Results: Of the 52 patients, 29 were men and 23 were women, with an average age of 63 years (range, 26-91 years). All patients underwent pancreaticoduodenectomy (Whipple prosedure). The median size of tumors was 2.3 cm (range, 0.5-6.0 cm). Lymphatic, vascular, and perineural invasions were observed in the tumors of 23 (44.2%), 9 (17.3%), and 5 (9.6%) patients, with 2 patients showing concurrent lymphatic, vascular, and perineural invasions. Tumors were classified as stage IA (n = 4), stage IB (n = 11), stage IIA (n = 7), stage IIB (n = 10), and stage III (n = 22). All surgically resected specimens showed negative (R0) resection margin status. The CD44 was not significantly expressed in eCC tumors compared to normal tissue. LGR5 and CD133 expression level was significantly higher in tumors than in corresponding normal tissues (4.5 fold, P = 0.034; 3.7 fold P = 0.045, respectively). Increased CD133 expression was associated with ampulla vateri tumor localization (P < 0.001). Over expression of LGR5 and CD133 were associated with short overall survival.

Conclusions: Here, we report that CD133 and LGR5 may acts as a functional CSC in the aggressivite of PDAC. Our results suggest that these molecules may serve as a candidate prognostic biomarker and target for new therapies in PDAC.

173P Tumor mutation burden assessment on FFPE samples using a targeted next-generation sequencing assay

R. Chaudhary[1], D. Cyanam[2], V. Mittal[3], W. Tom[1], J. Au-Young[1], C. Allen[4], S. Sadis[3], F. Hyland[1]

[1]Clinical Next-Generation Sequencing, Thermo Fisher Scientific, South San Francisco, CA, USA, [2]Clinical Next-Generation Sequencing, Thermo Fisher Scientific, Santa Clara, MI, USA, [3]Clinical Next-Generation Sequencing, Thermo Fisher Scientific, Ann Arbor, MI, USA, [4]Clinical Next-Generation Sequencing, Thermo Fisher Scientific, Liverpool, UK

Background: Tumor mutation burden (TMB) predicts durable benefit from immune checkpoint blockade in several cancer types. We demonstrate the ability of a targeted panel with fast turn-around time and low input needs to estimate TMB from research samples.

Methods: We developed a single sample analysis workflow to estimate mutation burden (TMB; nonsynonymous mutations/Mb) from FFPE and fresh frozen tumor research samples. The assay utilizes a PCR-based targeted panel that covers 409 genes and 1.7 Mb of genomic regions. The workflow requires only 10 ng of input DNA and

enables a 2.5-day turn-around time from sample to the final report. Sequencing is performed on high throughput semiconductor sequencing platform to achieve sufficient depth (~500x coverage) and accuracy. The workflow is tumor sample only, with no matched normal sample required; germ-line variants, along with background noise, are removed through filters based on population databases. The assay is research use only, not for diagnostic procedures.

Results: A comparison with whole exome sequencing (WES) on 12 FFPE tumors, where WES was performed on tumors and their matched normal using Agilent's exome enrichment kit (~150x coverage for tumor; ~100x coverage for normal) on illumina platform and our assay ran on tumors only, showed high correlation (r2=0.83) between TMB estimates by our assay with that from WES. To assess reproducibility, we compared raw somatic mutations/Mb in library replicates for a cohort of 21 FFPE research samples (19 CRC, 2 Melanoma) and observed high correlation (r2=0.97). Our pipeline identifies mutation signatures consistent with specific mechanisms such as UV and tobacco damage, as well as substitutions from FFPE processing.

Conclusions: A simple workflow has been developed on the Ion Torrent sequencing platform with an AmpliSeq panel to estimate TMB from FFPE and fresh frozen tumor research samples. This solution will advance research in immuno-oncology.

174P Microsatellite instability-high (MSI-H) colorectal cancers with elevated microsatellite alterations at selected tetranucleotide repeats (EMAST) signature represent a target population for immune checkpoint and DNA damaging therapies

K.T. Tan[1], P-N. Yu[1], S-J. Chen[1], Y-T. Liu[1], S-C. Chang[2], M-H. Chen[3]

[1]Medical Informatics, ACT Genomics, Co., Ltd, Taipei, Taiwan, [2]Department of Surgery, Faculty of Medicine, National Yang-Ming University, Taipei, Taiwan, [3]Department of Oncology, Taipei Veterans General Hospital, Taipei, Taiwan

Background: Elevated microsatellite alterations at selected tetranucleotide repeats (EMAST) is a different type of genomic instability in colon cancer (CRC) in contrast to mono-, and dinucleotide based instability microsatellite instability (MSI). In this study, we performed comprehensive genomic profiling (CGP) of CRC patients with different EMAST and MSI status to understand their genomic structure, which may help match them with relevant therapies.

Methods: 99 formalin-fixed, paraffin-embedded (FFPE) CRC tissues consisting of four subtypes based on their EMAST and MSI status, namely (1) EMAST+ and MSI-high (MSI-H), (2) EMAST+ and microsatellite-stable (MSS), (3) EMAST- and MSI-H, and (4) EMATS- and MSS, were subjected to next-generation sequencing (NGS) with a 440-gene panel to identify mutations and copy number variants (CNVs). Tumor mutational burden (TMB) was determined using mutations detected on exonic regions sequenced while CNV index was calculated to infer genome instability.

Results: In line with previous studies, the prevalence of TP53 (17.6%; n = 3) and APC (23.5%; n = 4) mutations was much lower whereas BRAF V600 mutation (41.2%; n = 7) was much higher in the subtype (1) CRCs which had both MSI-H and EMAST signatures. Interestingly, these dual positive tumors had a significant higher TMB and lower CNV index than other subtypes (TMB: (1) vs (2), (3) and (4); 54 vs 19, 25; and 16; $p < 0.0001$, CNV index: (1) vs (2), (3), and (4); 3.9 vs 13.7, 9.9, and 17.8; $p < 0.0114$, 0.006, and 0.0003), suggesting there are more likely to benefit from immune checkpoint inhibitors. Notably, ATM and ARID1A genes mutated in a mutually exclusive way in up to 13/17 (76.5%) of tumors with MSI-H and EMAST signatures, which may predict treatment benefit from the PARP inhibitors.

Conclusions: MSI-H and EMAST+ CRCs show distinctive genomic features that give them the potential opportunity for checkpoint inhibitors in combination with PARP inhibitors.

175P Levels of circulating fibroblast growth factor (FGF) 23 and prognosis of cancer patients with bone metastasis

A.B. Mansinho[1], A.R. Ferreira[1], S. Casimiro[2], I. Alho[2], I. Vendrell[1], A.L. Costa[1], R.T.D. Sousa[1], C.D. Abreu[1], C. Pulido[3], D. Macedo[1], T. Pacheco[1], L. Correia[4], L. Costa[1]

[1]Medical Oncology, Centro Hospitalar Lisboa Norte - Hospital Sta Maria (HSM-CHLN), Lisbon, Portugal, [2]LCosta Lab, Instituto de Medicina Molecular, Lisbon, Portugal, [3]Oncology, Hospital da Luz, Lisbon, Portugal, [4]Pathology, Centro Hospitalar Lisboa Norte - Hospital Sta Maria (HSM-CHLN), Lisbon, Portugal

Background: The FGF signaling network plays a key role in tumorigenesis and is recognized as a potential therapeutic target. FGF23 is predominately expressed in bone osteocytes and can act as an autocrine, paracrine and/or endocrine growth factor in cancer. In this study, we aimed to assess the role of circulating FGF23 levels in the prognosis of cancer patients with bone metastases.

Methods: This study included a cohort of 112 patients with cancer (63% breast;16% prostate) and metastatic bone disease treated with bone targeting agents (BTA), in which serum baseline FGF23 was quantified by ELISA and further dichotomized in two groups ($FGF23^{high}$ and $FGF23^{low}$). Cut-off was defined by mean + one standard deviation. The association of FGF23 with overall survival (OS) and with time to skeletal related events (TTSRE) was investigated. Time to event outcomes was calculated using the Kaplan-Meier method and tested using univariate/multivariate Cox regression models controlling for established prognostic factors across patients with solid tumors and bone metastases: extra-bone involvement, urinary N-terminal telopeptide (uNTX), presence of bone fractures, and calcemia.

Results: Mean FGF23 was 38.16 ± 26.15 pg/mL (interquartile range [IQR] 19.77-50.72). 16.8% of patients were classified as $FGF23^{high}$ (n = 19). Baseline characteristics were balanced between groups, except for the median uNTX level, which was higher in the $FGF23^{high}$ group (824.30 vs 118.02 nmol BCE/mmol creatinine, $p = 0.040$). Median time from beginning of BTA was similar between groups (1.28 vs 1.10 months, $p = 0.161$). After a median follow-up of 26.0 months (IQR 13.0-47.0), median OS was 34.4 months in the $FGF23^{low}$ group and 12.2 months in the $FGF23^{high}$ group (multivariate HR 0.18, 95% CI 0.07 – 0.44, $p = 0.001$; univariate $p = 0.001$). As a continuous variable, FGF23 at baseline kept its prognostic association ($p = 0.001$). Patients with $FGF23^{low}$ status at baseline had a longer TTSRE (13.0 vs 2.0 months, $p = 0.04$).

Conclusions: In this exploratory cohort, patients in the $FGF23^{low}$ group had a longer OS and TTSRE. Further studies are warranted to define its role as a prognostic biomarker and as a potential predictor of response to drugs targeting the FGF axis.

176P Clinical significance of RCAS1 and CD3 expression in non-small cell lung cancers in immunotherapy era

N.G. Tsoukalas[1], E. Aravantinou[1], K. Tsapakidis[1], C. Giaginis[2], M. Tolia[3], I. Binas[1], P. Baxevanos[1], M. Galanopoulos[1], M. Kiakou[1], M. Tsiatas, I. Kostakis[2], C. Nikolaou[1], I. Litos[1], M. Liontos[4], E. Tsiambas[1], I. Gioulbasanis[1], I. Sfiniadakis[2], A. Karameris[1], G. Kyrgias[3], S. Theocharis[2]

[1]Oncology, Veterans Hospital (NIMTS), Athens, Greece, [2]First Department of Pathology, Medical School, National and Kapodistrian University of Athens, Athens, Greece, [3]Department of Radiotherapy-Radiation Oncology, Faculty of Medicine, School of Health Sciences, University of Thessaly, Larissa, Greece, [4]Oncology Unit, Department of Clinical Therapeutics, Alexandra Hospital, Athens, Greece

Background: Lung cancer is the first cause of cancer related deaths. RCAS1 (Receptor-binding Cancer Antigen expressed on SiSo cells) is a protein that is expressed in different types of cancer and seems to be involved in the process of the tumour cells' escape from the immune system surveillance (immunoescape). CD3 (cluster of differentiation CD3), is an antigen that is part of the T cell receptor (TCR) complex on a mature T lymphocyte. Tumor infiltrating lymphocytes (TILs) have been correlated with patients' survival in several neoplasms.

Methods: The aim of this study was to evaluate the clinical importance of RCAS1 and CD3 expression in non-small cell lung cancer (NSCLC). Tissue microarrays of tumor specimens from 112 patients with newly diagnosed NSCLC were constructed. The sections were stained with monoclonal antibodies against RCAS1, Ki-67 and CD3 using immunohistochemistry and they were studied through classical pathological evaluation and computerized image analysis. Correlations among RCAS1, Ki-67 and CD3 expression, clinicopathological variables and survival were analyzed. In all cases p-value ≤ 0.05 was considered significant.

Results: 112 patients were included in this study with mean age 63.6 years old and 83% were males. RCAS1 expression was higher in grade III tumors comparing with grade I ($p = 0.004$) and grade II ($p = 0.005$) regardless of the histological type and in adenocarcinomas with lymphovascular invasion ($p = 0.014$). A positive correlation between RCAS1 and Ki-67 levels was observed ($p = 0.002$). There was an inverse correlation of overall survival with RCAS1 and Ki-67 levels and patients with higher expression of RCAS1 or Ki-67 had a significantly shorter survival. Also, an inverse correlation between RCAS1 expression and the percentage of CD3(+) TILs was found. Finally, a positive correlation between the percentage of CD3(+) TILs and the patients' overall survival ($p = 0.094$) was observed.

Conclusions: CD3 expression was negative correlated with RCAS1 and positive with overall survival in patients with NSCLC. RCAS1 could be a useful biomarker indicating tumor aggressiveness and immunoescape of cancer cells. Further studies needed to elucidate the possible role of RCAS1 as a biomarker in immunooncology era.

177P Comparative study of EGFR mutations detected in malignant pleural effusion, plasma and tumor tissue in patients with adenocarcinoma of the lung

S. Wang[1], H. Chen[1], J. Zhao[1], J. Zhong[1], J. Wang[2]

[1]Thoracic Medical Oncology, Peking University Cancer Hospital, Beijing, China, [2]Department of Medical Oncology, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China

Background: The utility of malignant pleural effusion (MPE) as a source of tissue for determining EGFRmutations to guide EGFR TKI therapy in advanced adenocarcinoma of the lung (LUAD) remains unclear. This study compared MPE, plasma and tumor as sources of tissue for EFGR mutational analysis in LUAD patients.

Methods: MPE samples were collected from 295 LUAD patients. Matched tissue and plasma samples were available for 92 patients, and 248 patients had plasma samples. EGFRexon 19-deletion and exon 21-L858R mutation were detected. The concordance of EGFR mutation status in MPE, tissue, and plasma were evaluated, and the predictive value of EGFRmutations in MPE with respect to efficacy of EGFR-TKI was investigated.

Results: The EGFRmutation rate in MPE samples was 39.3% (116/295). The concordance between MPEs and tissues was 87.1% (Kappa=0.712); the sensitivity and specificity of EGFRmutation in MPEs according to tissues was 71.4% and 96.5%,, respectively. 219 patients received EGFR-TKI, and the objective response rate of patients with EGFRmutations was similar for patients with EGFRmutation either in MPE, tissues or plasma (57.6 % vs 56.0 % vs 47.4%, $p = 0.51$). Similar results were found in progression free survival (8.9 months vs 9.0 months vs 7.7 months, $p = 0.077$ and overall survival (29.8 months vs 25.9 months vs 25.3 months, $p = 0.33$).

Conclusions: MPE is a reliable surrogate for tumor tissue for identifying EGFRmutations. MPE could offer reference of EGFRmutation to EGFR-TKIs treatment decision for advanced LUAD patients even when tissue and plasma were available.

178P XmaI-RRBS DNA methylation screening resolves breast cancer epigenetic heterogeneity

A.S. Tanas[1], T. Kekeeva[1], V.O. Sigin[1], E.B. Kuznetsova[1], E. Poddubskaya[2], I. Trotsenko[3], D.V. Zaletaev[4], V.V. Strelnikov[1]

[1]Epigenetics, Research Centre for Medical Genetics, Moscow, Russian Federation, [2]Surgery, N. N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation, [3]Oncology, Moscow Clinical Research Center, Moscow, Russian Federation, [4]Laboratory of Medical Genetics, Sechenov First Moscow State Medical University, Moscow, Russian Federation

Background: Breast cancer (BC) heterogeneity calls for molecular subtyping that would assist in personalized treatment. An advantage of DNA methylation markers is that their detection in tumors is not compromised by the presence of normal tissues. With a perspective to develop methylation-based BC diagnostic markers, we have performed a genome-wide DNA methylation profiling of a collection of breast tissues and cell lines.

Methods: XmaI-RRBS method was used to profile DNA methylation of 170 BC samples obtained before chemotherapy, six BC cell lines, and 10 normal breast autopsy specimens. Unsupervised hierarchical cluster analysis was used to discern intrinsic DNA methylation BC subtypes; clustering uncertainty was assessed with pvclust R package using bootstrap permutation approach.

Results: We have identified 10 epigenetic BC subtypes different in the DNA methylation profiles. Of these, BC cell lines constitute a separate extremely high methylated subtype clustering far from any tissues assessed. In turn, BC tissues are classified into two major epigenetic subtypes, high- and low-methylated at the promoter regions of genes. We identified 114 genes that distinguish between high- and low-methylated BC subtypes. Noteworthy are the genes of adenylate cyclases ADCY4, ADCY8 and adenylate cyclase stimulants ADORA2B, ADCYAP1; proteins of cell adhesion and extracellular matrix (CDH4, NRXN2, MXRA5, COMP, integrins A8 & A11, ADAM19; potassium channels (KCNH8, KCNJ2, KCNG1, KCNK10, KCNK17, ATP1A3). More than a third among differentially methylated are homeobox genes (VAX2, TLX3, GSX1, IRX1, FOXC2, FOXE3, NKX6-2, VSX1, SOX21, POU4F1) and genes encoding proteins involved in early development and morphogenesis (ZIC1, SPOCK2, DPYSL3, ATOH1, ITGA8). Expectedly, there is no statistically significant difference in methylation of the classical tumor suppressor genes between epigenetic subtypes of BC, as their abnormal methylation is ubiquitous in cancers and thus non-discriminative between tumor types.

Conclusions: Intrinsically epigenetically heterogeneous BC may be classified into a reasonable number of DNA methylation subtypes, promising the discovery of new diagnostic and prognostic markers, as well as of new therapeutic targets.

179P Prognostic value of change in neutrophil-lymphocyte ratio during treatment with first-line anti-PD1 therapy in metastatic melanoma

J.A. Soon, E. Blackley, M. Moore, L.E. Lim, H.L. Yeoh, M. Voskoboynik, A. Haydon

Medical Oncology, The Alfred Hospital, Melbourne, Australia

Background: With the advent of immunotherapy, the overall survival (OS) of patients (pts) with advanced melanoma has seen significant improvement. Multiple studies have demonstrated a negative correlation between elevated baseline serum neutrophil-lymphocyte ratio (NLR) and OS in melanoma and other solid tumours. This retrospective analysis aimed to identify a relationship between change in NLR during treatment and OS.

Methods: 83 consecutive pts with metastatic melanoma who received first-line anti-PD1 immunotherapy (mono or combination therapy) were identified at a single institution between May 2015 and August 2017. NLR was measured at baseline and following 4-6 weeks (4-6W) of therapy, with the result at each time point correlated with OS. An elevated NLR was defined as > 4.

Results: Median follow-up was 17 months. Median OS of pts with baseline NLR <4 was not reached (NR) compared with 17.1 months with NLR >4 (HR 0.29, 95% CI 0.13-0.65, $p = 0.003$). Pts whose NLR started and remained high after 4-6W of treatment performed significantly worse than pts whose NLR fell to < 4 at 4-6W (median OS 6.5 months vs NR, HR 0.18, $p = 0.028$). Survival in the latter group was comparable to those with a baseline NLR <4. NLR was more prognostic at 4-6W (HR 0.17, 95% CI 0.07-0.41, $p = 0.000091$) than at baseline (HR 0.29, 95% CI 0.18-0.65, $p = 0.003$). On Cox regression multivariate analysis including age, sex, M stage, lactate dehydrogenase level, presence of brain and/or liver metastases and NLR at the two time points, NLR >4 at 4-6W was the strongest prognostic factor (HR 0.14, 95% CI 0.06-0.37, $p = 0.00005$).

Conclusions: NLR is a simple and inexpensive prognostic biomarker in metastatic melanoma. NLR >4 at baseline is associated with a significantly poorer OS. In this cohort, NLR at 4-6W was the strongest predictor of outcome. Persistent elevation of NLR >4 at 4-6W after initiation of treatment was associated with a significantly poorer prognosis than those with a change in NLR to < 4 at this time point. Further analysis of a larger cohort may strengthen this association and potentially allow early identification of poor-risk pts and an opportunity to escalate treatment.

180P A serum microRNA expression signature for radiosensitivity of non-small cell lung cancer

L. Fan[1], B. Li[2]

[1]Radiation Department, Shandong Provincial Western Hospital, Ji'nan, China, [2]Radiation Department, Shandong Cancer Hospital affiliated to Shandong University, Jinan, China

Background: Chemoradiotherapy represents the main treatment for non-small cell lung cancer (NSCLC), especially for the advanced lung cancer. However, the curative effect varies significantly. Many microRNAs are verified to be associated with it and microRNA signature may be a good biomarker to predict the radiosensitivity.

Methods: Genome-wide microRNA profiling was analyzed by microarray and validated by qRT-PCR in radio-resistant cell lines and their parent cell lines (A549 and PC9, the corresponding cell lines named A549-R and PC9-R). Then we used colony formation by transfecting miRNA-mimics into A549 and PC9 for functional verification. Finally, a potential microRNA signature was established by an independent set of non-small cell lung cancer (NSCLC) serum samples and validated by available corresponding formalin-fixed paraffin-embedded tissue (FFPE) samples.

Results: 73 up-regulated and 24 down-regulated miRNAs were found by microarray and 11 up-regulated, 3 down-regulated and 3 non-different miRNAs were rechecked by qRT-PCR. A miRNA signature, including miR-1290, miR-2861, miR-25-5p and miR-92a-1-5p was selected for further exploration. Overexpression of miR-1290 and miR-2861 increased the radio resistance of A549 and PC9 while overexpression of miR-25-5p and miR-92a-1-5p reversed the radio resistance of A549-R and PC9-R. The four-miRNAs signature could predict the chemotherapeutic response with high accuracy, 83.4% and 79.5% in both the test (serum samples) and validation (FFPE samples) cohorts respectively.

Conclusions: It is the first report of a miRNA signature for cell lines, serum and tissues. Serum and tissue miRNAs represent novel biomarkers to predict radiotherapy response clinically and may represent potential molecular targets to sensitize resistant cancers.

181P Anti-tNASP antibodies as a diagnostic marker for malignant tumors

O. Alekseev[1], K. Admire[2], J. Brogdon[2], B. Gorman[2], C. Davis[2], Z. Vaskalis[2]
[1]Physiology and Pathophysiology, Campbell University, Lillington, NC, USA, [2]School of Osteopathic Medicine, Campbell University, Lillington, NC, USA

Background: Nuclear Autoantigenic Sperm Protein (NASP), a facilitator of chromatin assembly, is expressed as two splice variants: tNASP, specific for testis and cancer cells, and sNASP, expressed in all somatic cells. Exposure of tNASP to the immune system induces a robust humoral immune response. We suggested that patients with malignancies have a higher level of serum anti-tNASP antibodies than those without malignancies. We hypothesized that detection of anti-tNASP antibodies in serum can be used as a cancer screening test.

Methods: Sera from cancer patients and healthy individuals (negative control) were tested for the presence of antibodies against tNASP using enzyme-linked immunosorbent assay (ELISA) with a recombinant tNASP fragment as bait. A total of 139 serum samples from patients with a known malignancy were tested. These included bladder (11), brain (12), breast (12), endometrial (10), gastrointestinal (10), lung (10), ovarian (10), prostatic (12), skin (10), soft tissue (12), thyroid (10), or urinary (10) malignancy, as well as sera from 10 control patients with no known cancers (negative control).

Results: The majority of samples (56.5%) demonstrated elevated levels of anti-tNASP antibodies compared to negative control: glioblastoma, astrocytoma, colorectal adenocarcinoma, pulmonary adenocarcinoma, large-cell and squamous cell lung carcinoma, ovarian serous carcinoma, ovarian adenocarcinoma, bladder urothelial and squamous cell carcinoma, adenocarcinoma of the urinary bladder, prostate adenocarcinoma, and endometrial adenocarcinoma. Samples from patients with melanoma, renal, thyroid, breast carcinomas, and different types of sarcomas demonstrated similar levels of anti-tNASP antibodies as control samples.

Conclusions: Serum anti-tNASP antibody levels are markedly elevated in the majority of cancer patients tested as compared to healthy controls. These data demonstrate that detection of anti-tNASP antibodies is a viable diagnostic approach and has the potential to be used as an early noninvasive screening method for detection of multiple cancers.

182TiP EXPRESS study: A multicenter, prospective trial in progress exploring the association between low level of genomic alteration and exceptional and unexpected response to targeted therapies in patients with solid tumors

Background: Most anticancer drugs are approved by making marginal improvements in terms of tumor response or survival in non-selected populations, and are highly heterogeneous at the molecular level. Studying patients who present an exceptional and unexpected response (ER) to these drugs could enable the rapid identification of novel treatment response biomarkers, accelerate drug development and, more broadly, lead to a better understanding of the biology of cancer cells. Several studies are currently recruiting to build cohorts of patients, in order to subsequently analyze their tumors and reveal in detail the molecular anomalies associated with exceptional response.

Trial design: This is an exploratory, multicenter, multicohort, prospective trial conducted in 264 adult patients, with advanced breast, lung, colorectal, ovarian, kidney cancers and melanoma, having presented an ER to an approved antineoplastic targeted therapy. ER is defined using the definition chosen by the NCI which combines the three criteria: -complete or partial response -lasting >6 months -and not expected in $>10\%$ of the patients in this drug – organ situation. The primary objective is to assess whether ER can be associated with a low level of genomic instability in the tumor. Low genomic instability is defined by the presence of less than the 5th quantile of genomic alterations (mutations, amplifications, deletions) to be expected in the given tumor type as per TCGA database. For each tumor type, the null hypothesis H0: $\pi = 0.05$ will be tested, against the one-sided alternative hypothesis $\pi > 0.05$. For each of the 6 cohorts, a sample size of 44 patients is necessary to achieve 80% power at $\pi = 15$ with a one-sided level 5% test. Patients presenting an ER will be identified retrospectively, in a nationwide manner, then monthly reviewed and validated for inclusion by a panel of pathology experts. As of May 2018, 56 patients have been included. The identification of molecular traits associated with ER might serve the development of predictive classifiers for precision medicine. This study also represents a unique opportunity to better understand cancer biology.

Background: Palbociclib (P) is a CDK4/6 inhibitor used in combination with endocrine therapy (ET) in metastatic estrogen receptor (ER)+/HER2- breast cancer (BC). The role of P in early BC treatment is currently being tested in phase III trials. Biomarkers that help us predict primary resistance to P may lead to better patient selection and thus avoid toxicity and reduce costs. In vitro studies suggest that CDK4 T172 phosphorylation is associated with sensitivity to P and an 11-gene expression signature has been developed that can predict the CDK4 modification profile in breast tumors. In order to identify biomarkers of resistance to P/ET and validate the 11-gene signature, we have launched the NeoRHEA study.

Trial design: Single arm, phase II trial, enrolling patients with ER+/HER2- breast tumors $\geq$ 15mm, N0-N1. Subjects will receive 4 months of neoadjuvant P/ET (tamoxifen$\pm$ goserelin or letrozole). Subjects' response to therapy will be evaluated before and after treatment by ultrasound, using WHO criteria. Biopsy samples will be collected at baseline and surgery. Primary objective is to identify biomarkers of resistance to P/ET (defined as stable or progressive disease by ultrasound) using RNA-sequencing of baseline samples. A key secondary objective is to validate the 11-gene signature as a biomarker of resistance to P/ET. Other secondary objectives include: to evaluate the safety of P/ET; to identify biomarkers of resistance to P/ET, defined as residual cancer burden of 3 or high tumor proliferation by the Genomic Grade Index; to understand mechanisms of resistance to P/ET by comparing tumors transcriptome at baseline and at surgery; to assess the role of plasma ctDNA in monitoring response to P/ET. Assuming a resistance rate of 20%-25% and a 10% dropout, 100 subjects are needed to develop a binary predictor. Any biomarker identified will be further validated in other studies e.g. NeoPAL (preliminary agreement in place). Accrual started in July 2017 and 38 patients have been enrolled thus far. The study is expected to be completed in 2019. Trial number is NCT03065621. Study sponsor is Institut Jules Bordet with a research grant from Pfizer.

Background: Oncotype DX® (ODX) is a multigene assay allowing physicians to tailor treatment in HR+, HER2- early-stage breast cancer patients. Clinical validation and utility of ODX have been demonstrated across multiple studies in over 63,000 breast cancer patients worldwide. It provides level 1A evidence and has been incorporated in major international clinical guidelines. A market access program was initiated in 2015 in France and 2016 in Italy to assess real-life test utilization and its impact in current clinical practice.

Methods: The program allows for prospective data collection reflecting real life use of ODX by physicians in various clinical practice settings throughout France and Italy. Patient data were collected through an online dedicated platform including classical pathological and clinical parameters (e.g. histology, tumor grade and size, ER, PR, HER2 and Ki67), patient age, ODX Recurrence Score (RS) Results and recommended treatment both before and after the test results have been reported.

Results: A total of 53 and 19 qualified breast cancer centers, in France and Italy respectively, participated in the program and collected 2632 case reports. Study results demonstrated that ODX is used among a wide variety of patient profiles: 24% N1, 7% Nmic & 69% N0, 11% G1, 64% G2 and 25% of G3, 32% pre-, 8% peri- & 59% are post-menopausal, 34% are 35-50, 52% 51-70 and 13% are older than 70, 13% have Ki67%<10%, 35% KI67 10-20%, 30% KI67 21-30% & 18% Ki67>30%, 12% tumor <1cm, 59% 1-2cm and 27% tumor 2.1-5cm. RS distribution is the following: <18 (56%), 18-30 (35%) and >30 (9%). In addition, pre-ODX 60% and 48% patients had a treatment recommendation for chemo-hormonotherapy (CT-HT) in France and Italy respectively. Post-testing, the number of patients recommended CT-HT decreased to 29% and 31% for France and Italy respectively, highlighting that the test reduced unnecessary use of CT and homogenized treatment decisions.

Conclusions: In France and Italy, the use of the ODX test results in an overall reduction in CT recommendations, while also identifying patients more likely to benefit from CT.

Background: Invasive lobular carcinoma (ILC) is the second most common histologic breast cancer subtype and represent approximately 10% of all breast cancers. Despite this high frequency, benefit of adjuvant chemotherapy (CT) in ILC is still unclear.

Methods: Our objective was to investigate the impact of CT on survival in ILC. Patients were retrospectively identified from a cohort of 23,537 patients who underwent primary surgery in 18 French centres between 1990 and 2014. Only ILC, hormone-positive, HER2-negative patients who received adjuvant endocrine therapy (ET) were included. Endpoints were disease-free survival (DFS) and overall survival (OS). A propensity score for receiving CT was estimated using a logistic regression including age, tumour size, nodal status, lymphovascular invasion (LVI), grade, type of surgery, period and CT.

Results: Of a total of 2,318 patients with ILC, 1,485 patients (64%) received ET alone and 823 (36%) received ET+CT. Patients receiving ET+CT had more adverse prognostic features, such as young age, larger tumour size, high grade, macroscopic lymph-node involvement and LVI, received more adjuvant radiotherapy and underwent more often mastectomy. In a multivariate Cox model, we observed a beneficial effect of addition of CT to ET on both DFS and OS, (HR = 0.61, 95% CI [0.41-0.90]; p = 0.01 and 0.52, 95% CI [0.31-0.87]; p = 0.01, respectively). This effect was even more pronounced when propensity score-matching, aiming to compensate for baseline characteristics, was used. Ten-year estimates DFS in case-matched patients for propensity score analysis were 90% (95% CI [87%-93.4%]) in the ET+CT group vs. 66% (95% CI [61.4%-71.4%]) with ET alone and 10-year estimates OS were 96% (95% CI [93.8%-98%]) in the ET+CT group vs. 71% (95% CI [66.6% et 76.2%]) with ET alone. Regarding subgroup analysis, low-risk patients without CT did not have significant differences in DFS or OS compared to low-risk patients with CT.

Conclusions: Patients receiving adjuvant ET for hormone receptor-positive, HER2-negative ILC could derive significant DFS and OS benefits from CT. Our results highlight that patients with high-risk ILC should not be denied adjuvant CT because of such histologic subtype.

Background: The presence of pretreatment lymphopenia or high NLR (neutrophil-lymphocyte ratio) has been reported as poor prognostic factor in breast cancer. Here, we investigated whether baseline lymphocyte counts and NLR are associated with overall survival (OS), breast cancer specific survival (BCSS), and distant recurrence free survival (DRFS) in large early breast cancer (EBC) patient cohort.

Methods: We reviewed demographic, clinical, pathologic, and survival data from Yonsei Breast Cancer Center Registry. Patients who underwent surgery with stage I-III

Table: 196P Baseline demographics

	All Patients (n = 5,252)	Baseline Lymphopenia (n = 158)	No Baseline Lymphopenia (n = 5,094)
Age			
Median (Range)	50 (19-92)	48 (31-77)	50 (19-92)
TNM Stage			
I	2672 (50.9)	81 (51.3)	2591 (50.9)
II	1890 (36)	53 (33.5)	1837 (36.1)
III	450 (8.6)	18 (11.4)	432 (8.5)
Subtype			
ER+/HER2-	3286 (62.6)	90 (57)	3196 (62.7)
ER+/HER2+	558 (10.6	19 (12)	539 (10.6)
ER-/HER2+	496 (9.4)	22 (13.9)	474 (9.3)
ER-/HER2-	912 (17.4)	27 (17.1)	885 (17.4)
Neoadjuvant chemotherapy			
Yes	983 (18.7)	124 (78.5)	4145 (81.4)

Unknown	651 (12.4)	18 (11.4)	633 (12.4)
Baseline Lymphopenia			
Yes	158 (3)		
No	5094 (97)		

EBC at the Yonsei Cancer Center between 2006 and 2015 were included. Baseline complete blood counts data were collected from electronic medical records system. Multivariable regression models adjusted for age, stage, neoadjuvant/adjuvant chemotherapy use, subtype were used to evaluate associations between baseline absolute lymphocyte count (ALC) and OS/BCSS/DRFS.

Results: A total of 5,785 stage I–III EBC patients were underwent breast surgery from 2006 to 2015; 533 patients were excluded due to lack of complete data (n = 262) and the diagnosis of second primary cancer (n = 270). Median follow up duration was 72.73 months (95% confidence interval (CI), 73.85-75.64). Of 5,252 eligible patients, only 159 (3.0%) had baseline lymphopenia (ALC < 1,000/mL). The incidence of baseline lymphopenia was similar among age group, stage, and subtype, but patients with HBsAg (+) showed higher baseline lymphopenia than HBV negative patients (7.7% vs. 2.9%, p = <0.001). In univariate analysis, baseline lymphopenia was significantly associated with poor OS, BCSS and DRFS. In multivariable analysis, baseline lymphopenia predicted lower DRFS [HR 0.502; 95% CI, 0.307–0.820]. The prognostic significance of baseline lymphopenia regarding to DRFS was highest in HER2 positive subtype.

Conclusions: Baseline lymphocyte counts predicted distant recurrence in early breast cancer.

Gemelli I.R.C.C.S., Rome, Italy, [13]UOC Oncologia Medica, Università Cattolica del Sacro Cuore - Fondazione Policlinico Universitario Agostino Gemelli, Rome, Italy

Background: Patients (pts) resected for luminal early breast cancer are assigned to receive aCT according to international guidelines based upon clinico-pathological features, regardless of the histotype, given the lack of prospective data for ILC. Thus, the magnitude of the benefit of the addition of aCT to aHT for ILC is still not sizable. The aim of this analysis was to investigate the effect of aCT in a multi-center series of luminal early stage pure ILC.

Methods: Clinico-pathological data of consecutive pts affected by luminal pure ILC, undergone surgery between 2000 and 2014, were correlated with disease-free and overall survival (DFS/OS) using a Cox model. A propensity score analysis was performed to evaluate the prognostic impact of aCT. Kaplan-Meier curves were compared with Log-Rank analysis.

Results: Data from 576 pts were gathered (median age 58 years (yrs)). At median follow-up of 72 months, 5-/10-yrs DFS and OS were 81.5%/71.8% and 91.8%/80.4%, respectively. Tumor-size according to TNM (T, HR 1.78, 95% CI 0.91-3.49, p = 0.09) and lymph-node (N) status (HR 2.97, 95% CI 1.69-5.19, p < 0.0001) were independent predictors for DFS at multivariate analysis. N status (HR 3.93, 95% CI 1.79-8.70, p = 0.001), Ki67 (HR 2.66, 95% CI 0.92-7.70, p = 0.072), and age (HR 2.32, 95% CI 1.09-4.93, p = 0.029) were predictors for OS. A significant prognostic effect of aCT upon OS was found after adjusting for T, N, Ki67, grading and age at diagnosis with the propensity score method, as shown in the table. Particularly, aCT significantly prolongs DFS in pts with T > 2 (p = 0.03) and OS in pts with Ki67 >4% (p < 0.0001).

Table: 197P

Outcome	Category	5-yrs (%)	10-yrs (%)	Log-Rank
DFS	aHT	76.6	54.4	p = 0.08
	aCT + aHT	85.0	76.4.	
OS	aHT	80.9	55.6	p = 0.001
	aCT + aHT	98.1	95.9	

Conclusions: Despite the retrospective nature of this analysis, the propensity score analysis indicates that pts with luminal ILC may significantly benefit from the addition of aCT to aHT in terms of long-term survival, particularly for larger and more aggressive tumors.

Background: Hormone receptor-positive, HER2-negative, pT1ab N0 breast cancers (BC) are generally estimated as having a low risk of recurrence after locoregional treatment and adjuvant treatment decisions could be challenging. We examined the impact of endocrine therapy (ET) +/- chemotherapy on outcomes in this population.

Methods: A total of 4,788 patients with pT1ab N0 HR+ HER2- BC were identified from a large cohort of 22,475 consecutive patients who underwent primary surgery at 15 French centres between 2000 and 2014. Endpoints were disease-free survival (DFS) and overall survival (OS). Analyses of causal effect using propensity scores were realized using a logistic regression including age, tumour size, histology, grade, and lymphovascular invasion (LVI).

Results: Of 4,779 patients with pT1ab HR+ HER2- BC, 846 patients did not receive any adjuvant treatment and 3,933 received ET, among which 251 received chemotherapy. Age ≥ 70y, ductal histology, high grade and tumour size > 5mm were independently associated with ET prescription. Age ≤ 40y, LVI and high grade, were independently associated with chemotherapy prescription. At a median follow-up of 47.7 months, ET was independently associated with a significant DFS benefit in multivariate analysis (HR: 0.60 [0.41-0.89]; p = 0.011) with 5-year estimate DFS of 94% (CI95 [92-96%]) without ET vs. 96% (CI95 [95-97%]) with ET, while addition of adjuvant chemotherapy was not (HR: 0.90 [0.39-2.09]; p = 0.813). These results were supported by the analyses of causal effect using propensity scores (HR: 0.48 [0.28-0.83]; p = 0.009 for ET, and HR: 1.54 [0.11-21.8]; p = 0.78 for chemotherapy). OS was not significantly impacted by systemic treatments despite a trend for ET in multivariate (HR: 0.60 [0.36-1.00]; p = 0.051) and in propensity score analyses (HR: 0.52 [0.24-1.11]; p = 0.092).

Conclusions: Adjuvant endocrine therapy is associated with a survival benefit in pT1ab N0 HR+ HER2- BC even with a relatively short follow up. Consistent with current consensus guidelines that do not recommend adjuvant chemotherapy in these tumours, we did not find any benefit of adding chemotherapy to ET. These data provide additional clues to the issue of adjuvant systemic treatments in these tumours.

Background: The anti-proliferative effect of oral metronomic vinorelbine (mVNB) alone or in combination with endocrine therapy in patients with hormone receptor (HR)-positive/HER2- breast cancer has been scarcely addressed.

Methods: Postmenopausal women with untreated stage I-III breast cancer were randomized (1:1:1) to receive 3 weeks of letrozole (LTZ) 2.5mg/day, oral mVNB 50mg 3 days/week or the combination. The 1^{ary} objective was to evaluate, within PAM50 Luminal A/B disease, if the anti-proliferative effect of mVNB+LTZ was superior to monotherapy. An anti-proliferative effect was defined as the mean relative decrease of the PAM50 11-gene Proliferation Score in each arm. 2^{ary} objectives included safety and the comparison of the anti-proliferative effect between arms. An unplanned analysis of stromal tumor infiltrating lymphocytes (TILs) was performed. PAM50 analyses were performed using the nCounter®-based Breast Cancer 360^{TM} panel.

Results: A total of 61 patients were randomized and 54 paired samples (89%) were analyzed. Main patient characteristics were mean age 67, mean tumor size 1.7 cm, stage I (55.7%) and grade 1-2 (90%). Grade 3 toxicities occurred in 3.3% of cases. Most baseline samples were Luminal A (74.1%) or B (22.2%). The anti-proliferative effect of mVNB+LTZ (-73.2%) was superior to both monotherapy arms combined (-49.9%; $p = 0.001$) and mVNB (-19.1%; $p < 0.001$). The anti-proliferative effect of mVNB+LTZ (-73.2%) was higher compared to LTZ (-65.7%) but did not reach statistical significance ($p = 0.328$). Stromal TILs ($\geq$10% at week 3) were observed across arms in 6.6% (mVNB), 15% (LTZ) and 26% (mVNB+LTZ) of the cases. In tumors with $\leq$10% TILs at baseline, a significant increase in TILs was observed following VNB+LTZ (paired analysis $p = 0.012$).

Conclusions: mVNB is well-tolerated and presents antiproliferative activity alone and in combination with LTZ. Further investigation comparing these biological results with other metronomic schedules or drug combinations is warranted. Of note, the increase of TILs observed with the combination opens the possibility of studying this combination with immunotherapy.

200P Clinicopathologic significance of androgen receptor expression and discordant receptor status during progression in breast cancer

C.H. Park[1], E.Y. Kim[1], S-I. Do[2]

[1]General Surgery, Kangbuk Samsung Hospital Sungkyunkwan University, Seoul, Republic of Korea, [2]Pathology, Kangbuk Samsung Hospital Sungkyunkwan University, Seoul, Republic of Korea

Background: The role of androgen receptor (AR) as a prognostic marker has been proposed in breast cancer. This study investigated AR status and its clinical significance in breast cancer, especially in triple negative breast cancer (TNBC). We also evaluated discordant AR status during the process of lymph node metastasis, locoregional recurrences (LRR) and distant metastasis.

Methods: From January 2005 to December 2010, we retrospectively reviewed 120 patients including 55 TNBC patients diagnosed as invasive carcinoma with no special type (NST), who were treated at the Kangbuk Samsung Hospital. Tissue microarray was constructed and immunohistochemical expression of AR was performed for 120 invasive carcinomas, NST specimens and matching samples from 28 lymph node metastasis, 2 LRR and 8 distant metastases.

Results: AR expression was found in 35.0% (42/120) of the total patients and 14.5% (8/55) of those diagnosed as TNBC. Positive expression of AR was significantly correlated with smaller tumor size, early T stage, fewer lymph node metastases, early AJCC stage, lower histologic grade, estrogen receptor/progesterone receptor positivity, more luminal A type, less TNBC, longer disease-free survival and overall survival, fewer distant metastasis and no deaths from breast cancer (all $P < 0.05$). AR was a favorable prognostic marker for disease free survival in univariate analysis ($P = 0.041$). The discordance rate of AR status between primary and recurrent/metastatic disease was 21.6%.

Conclusions: AR expression was associated with favorable clinicopathological outcomes in the whole study population. AR status can be altered during tumor progression.

201P The outcomes of early breast cancers utilizing the oncotype Dx recurrence score (RS) instead of clinico-pathological (CP) factors for prognostic risk assessment: A single institution experience

A.N. Alsayed[1], T. Al-Twejeri[1], K. Suleman[1], A. Tulbah[2], D. Ajarim[1]

[1]Oncology Centre, King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia, [2]Pathology, King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia

Background: Genomic profiling of hormone receptor positive breast cancer outperforms CP factors in predicting the outcomes. This has led to wider application of genomic testing for risk stratification. This can lead to avoidance of chemotherapy in patients with favorable outcomes.

Methods: Patient with T1, T2, node negative estrogen and or Progesterone receptor positive Her 2 Negative breast cancer, regardless of age, menopausal status, Grade or Ki67 were eligible for risk prediction using the Oncotype DX RS. All patient who had RS were included from March 2012- September 2017. The test was sent out and done in reference laboratory (Genomic Health). The original cut off of Low RS (<18), Intermediate RS18-31 and high RS > 31 was used. Patient with low RS were spared chemotherapy. While those high score received chemotherapy. Intermediate risk was preferably given chemotherapy. The changes in therapy based on RS score were reordered as compared to CP factors (St. Gallen Criteria). The disease free and overall survival was analyzed.

Results: Complete data was available for 141 Patients. Median age was 51 years (30-78). 54% premenopausal. 97% ductal histology. Grade correlated with RS with higher grade having higher RS. There was 67% reduction in use of adjuvant chemotherapy when compared to decision based on CP factors while 1 patient had escalation of therapy based on RS. Median follow up was 32 months (3-73 months). The 5 year estimated DFS was 95%. The overall survival was 98%. Only recurrence score correlated with DFS $p = 0.04$ while age, Ki67, grade, tumor size did not.

Conclusions: Our data in a younger group of mainly premenopausal women with early breast cancer is consistent with the published date about the prognostic value of RS. A substantial percentage of these patient can be spared chemotherapy and its related toxicity without adversely affecting the long-term outcomes. Utilizing RS in decision making may potentially be cost effective.

202P Circulating tumor cells as a prognostic marker in non-metastatic breast cancer patients

S.M. Elmorshidy[1], O.N. Abd Elffatah[1], H.H. Essa[1], A.K. Ibrahim[2], D. Sayed[3], S. Shehata[1]

[1]Clinical Oncology, Assiut University Hospitals, Assiut, Egypt, [2]Community Medicine Department, Assiut University Hospital, Faculty of Medicine, Assiut, Egypt, [3]Clinical Pathology, South Egypt Cancer Institute, Assiut, Egypt

Background: Still, there is no clinically reliable marker to detect micro-metastasis or breast cancer relapse. This study aimed to evaluate the role of circulating tumor cells (CTCs) as a biomarker in non-metastatic breast cancer patients.

Methods: CTCs quantification was carried out using flow cytometry for 50 breast cancer patients post-operatively on three intervals; before starting, after three cycles and at the end of adjuvant chemotherapy. The relationship between CTCs and other tumor characteristics and outcomes were studied.

Results: The median follow-up duration was 35 months. Before starting adjuvant chemotherapy, CTCs were positive (cut off point $\geq$5) in 36% of the patients and dropped to 20% after finishing chemotherapy ($P = 0.04$). There was a strong negative correlation (r=-0.89) between change in the CTC levels from baseline till mid-treatment (3 cycles)

and from this point to the end of treatment (6 cycles) (R2=79.2). CTCs were detected in 88.9% (n = 16 of 18) of node-positive patients and in 11.1% of node-negative patients (n = 2 of 18, p-value =0.04). No significant association was found with tumor size, grading, or hormone receptor status. Distant metastasis was detected in 20% (n = 10 of 50) of patients and was significantly associated with CTCs ≥ 5 in 80 % of them (n = 8 of 10) p-value =0.01. The presence of ≥ 5 CTCs at baseline was associated with reduction in both the disease-free survival and overall survival (p-value <0.001 and =0.003, respectively) . Baseline CTCs ≥5 were confirmed as an independent prognostic factor in multivariate cox hazard regression analysis for DFS (HR = 3.71; 95% CI = 1.62-8.48; p-value=0.002 and OS (HR = 3.14; 95% CI = 1.34-7.37;p-value= 0.009).

Conclusions: The findings of the current work suggested that the presence of ≥ 5 CTCs at baseline would predict early disease recurrence and reduce the overall survival in primary, non-metastatic breast cancer patients receiving adjuvant chemotherapy. Thereby, peripherally detected CTCs could be used as a new prognostic marker for identification of early relapse and survival reduction.

203P Molecular subtyping of breast cancer by dedicated breast PET

S. Sueoka, S. Sasada, E. Suzuki, N. Goda, K. Kajitani, A. Emi, N. Masumoto, T. Kadoya, R. Haruta, T. Kataoka, M. Okada

Breast Surgery, Hiroshima University Hospital, Hiroshima, Japan

Background: Therapeutic strategies for treating breast cancer differ according to molecular subtype. We investigated whether dedicated breast PET (DbPET), a high-resolution molecular breast imaging system, could stratify breast cancer by subtype.

Methods: We included 390 patients with invasive breast cancer who underwent ring-type DbPET between January 2016 and March 2018. The association between SUV_{max} and various tumor characteristics such as size, nuclear grade, estrogen receptor (ER) status, human epidermal growth factor receptor 2 (HER2) status, and Ki-67 labeling index, were assessed. Tumor subtypes were classified as luminal A-like, luminal B-like, ER+/HER2+, ER-/HER2+, or triple negative on the basis of the St. Gallen International Expert Consensus.

Results: The median patient age was 57 years, the median tumor size was 1.5 cm, and the median SUV_{max} on DbPET was 6.9. The number of patients with each subtype was luminal A-like in 113, luminal B-like in 185, ER+/HER2+ in 40, and ER-/HER2+ in 12, and triple negative in 40 patients. SUV_{max} significantly correlated with tumor size ($P < 0.001$), nuclear grade ($P < 0.001$), ER status ($P = 0.004$), HER2 status ($P < 0.001$), and Ki-67 labeling index ($P < 0.001$). The median SUV_{max} values of the luminal A-like, luminal B-like, ER+/HER2+, ER-/HER2+, and triple negative subtypes were 4.6, 8.2, 9.5, 16.1, and 10.4, respectively (Table, all values of $P < 0.001$ relative to luminal A-like). Thus, DbPET distinguished luminal A-like tumor subtype from other subtypes.

Table: 203P

SUVmax on dedicated breast PET according to molecular subtypes.

Subtypes	Median SUVmax (IQR)	P value reffered to luminal A-like
Luminal A-like	4.6 (3.0-6.8)	
Luminal B-like	8.2 (4.6-12.4)	< 0.001
ER+/HER2+	9.5 (5.5-16.6)	< 0.001
ER-/HER2+	16.1 (7.5-20.2)	< 0.001
Triple negative	10.4 (4.2-17.0)	< 0.001

Conclusions: DbPET can be used to classify breast cancer into molecular subtypes, which may help determine the necessity of adjuvant chemotherapy. SUV_{max}, as assessed on DbPET, may thus contribute to the selection of proper therapeutic strategies in invasive breast cancer.

204P Analytical validation of OncoMasTR, a multigene test for predicting risk of distant recurrence in hormone receptor-positive early stage breast cancer

T. Loughman[1], A. Chan-Ju Wang[1], P. Dynoodt[1], B. Fender[1], C. Lopez Ruiz[1], S. Barron[1], S. Stapleton[1], D. O'Leary[1], A. Fabre[2], C. Quinn[2], B. Nodin[3], K. Jirstrom[4], A. Bracken[5], W.M. Gallagher[6]

[1]OncoMark Limited, NovaUCD, Dublin, Ireland, [2]Histopathology, St. Vincent's University Hospital, Dublin, Ireland, [3]Oncology and Pathology, Clinical Sciences, Lund, Sweden, [4]Department of Clinical Sciences, Lund University, Lund, Sweden, [5]Smufit Institute of Genetics, Trinity College Dublin, Dublin, Ireland, [6]UCD Conway Institute, University College Dublin, Dublin, Ireland

Background: OncoMasTR is a new multigene prognostic test that was discovered via a novel transcriptional network analysis method that identified upstream Master Transcription Regulators (MTRs), which regulate previously identified prognostic biomarkers. The optimised OncoMasTR signature incorporating clinicopathological information has been shown to be significantly prognostic for predicting distant recurrence in two independent cohorts (TransATAC & a subset of TAILORx from participating Irish centres). The analytical performance characteristics of the OncoMasTR test, comprising solely three prognostic MTRs, were determined.

Methods: Relative gene expression levels were measured by RT-qPCR. Assay precision and input ranges were determined using a panel of samples representative of low and high recurrence risk tested across a number of runs incorporating different sources of variation. Serial dilutions of a pooled patient RNA sample was used to establish the linear range and efficiency of the individual gene assays.

Results: The overall standard deviation of the OncoMasTR risk score was 0.15, which represents less than 2% of the 10-unit risk score range. The majority of the variability in OncoMasTR results was related to within-run variation (78.2%) with other between-run variation sources contributing relatively little (PCR instrument (0.6%), assay operator (5.2%), reagent lots (7.3%) or loading position (8.7%)). Consistent risk scores were measured for individual samples from 40ng down to < 1ng RNA per PCR reaction. Individual gene assays were linear over >500-fold RNA input range corresponding to C_T values of 23 – 36, demonstrating the ability of the test to reliably detect low level expression of the OncoMasTR panel. Importantly, PCR efficiencies were similar for the individual MTR and reference gene assays which ranged from 79 – 95%.

Conclusions: The OncoMasTR prognostic test displays robust analytical and clinical performance and is being launched as a CE-marked test. The concise nature of the three gene signature and a simplified workflow that can be readily adopted using standard laboratory equipment will enable convenient qualification by local laboratories for decentralised use.

205P Comparing the prognosis of favourable-histology breast cancers between younger women of less than 45 years of age at diagnosis with their older counterparts

G.E. Lee[1], W.H. Hor[2]

[1]Medical Oncology, National Cancer Center, Singapore, [2]Business School, Imperial College London, Singapore

Background: Tubular, cribriform and mucinous carcinomas account for <10% of all breast cancer histology. They have excellent prognosis and aggressive treatment with chemotherapy is usually not warranted. Younger age at breast cancer diagnosis is often associated with a poorer prognosis in early breast cancers, however little is known about the natural history of favourable-histology breast cancers for younger women compared to their older counterparts. We aim to compare the prognosis of younger women less than 45 years of age with their older counterparts for early breast cancers with favourable histology.

Methods: Using the SEER dataset from 1988-2015, we identified 20 577 women diagnosed with early stage breast cancers of favourable histology i.e. tubular, cribriform, and mucinous carcinoma. We extracted the information on age of diagnosis, estrogen receptor (ER) status, progesterone receptor status (PR), HER2 status, ethnicity, cause of death, and survival months. The survival was compared between women < 45 years of age at diagnosis versus ≥ 45 years using log-rank test and cox-regression to give a univariate and multi-variate analysis.

Results: Among 20577 women with early stage favourable-histology breast cancers, we identified 1308 (6.4%) tubular, 6486 (31.5%) cribriform, and 12 783 (62.1%) mucinous breast cancer. The median age of diagnosis is 42 and 64 years of age for the younger group of < 45 years of age and older group of ≥ 45 years of age respectively. 85% of the breast cancer in younger women were ER+ while 88% in the older age group were ER+. In a univariate analysis, the median breast cancer specific survival for early stage favourable histology breast cancer was 120 months for women < 45 years of age and 100 months for women ≥ 45 years of age ($p < 0.001$). In multi-variate analysis,

accounting for tumour size, nodal status, stage, grade, hormone receptor status, HER2 receptor status, histologic type and year of diagnosis, younger age still predicts for a better outcome ($p < 0.001$).

Conclusions: Younger women diagnosed with early stage favourable-histology breast cancers have a better prognosis compared to older women. This will help in counselling on prognosis and management of younger patients.

206P TNBC universe: A monocentric retrospective analyses of TILs and AR as prognostic markers

A. Losurdo[1], R. De Sanctis[1], B. Fernandes[2], V. Errico[3], A. Sagona[3], G. Masci[1], M. Zuradelli[1], E. Agostinetto[1], R. Torrisi[1], W. Gatzemeier[3], A. Testori[3], M. Roncalli[2], M. Alloisio[3], C. Tinterri[3], A. Santoro[1]

[1]Medical Oncology and Hematology, Humanitas Cancer Center, Istituto Clinico Humanitas, Rozzano, Italy, [2]Pathology, Humanitas Cancer Center, Istituto Clinico Humanitas, Rozzano, Italy, [3]Breast Surgery, Humanitas Cancer Center, Istituto Clinico Humanitas, Rozzano, Italy

Background: TILs have been proposed as a prognostic biomarker in many tumor types both in the adjuvant and neoadjuvant setting. In TNBC, TILs are present at the highest level and have been demonstrated to be associated with better prognosis. TNBC is a highly diverse group of cancers and subtyping is necessary to better identify patient-tailored therapies. Cluster analysis by gene expression identified 6 TNBC subtypes among which the so called "luminal androgen receptor subtype".

Methods: We retrospectively collected 160 early stage TNBC consecutively treated at our Institution from 2006 to 2015. Data were obtained for clinico-pathological patients' characteristics. On IHC archive slides we analyzed stromal TILs scored as a continuous variable and androgen receptor's (AR) percentage and intensity of expression. We performed Cox analyses for DFS and for OS, and we used chi-square and Fisher test to evaluate the correlation between TILs, AR and other clinical variables. To define high vs low TILs, an internal dataset cut-off of 10% was considered.

Results: 150 patients were eligible for IHC analyses of TILs and AR. With a median follow-up of 6.5 years, 41 local and/or distant relapse events were observed and 28 patients died of disease. Interestingly, TILs were found to be significantly associated with nodal status (N0 vs N1-3), grading (G2 vs G3) and Ki-67 ($<20\%$ vs $\geq 20\%$) ($p = 0.007$, $p = 0.055$ and $p = 0.002$, respectively). AR was also significantly associated with proliferation, specifically AR-positive cases presented mostly with a Ki-67$<20\%$ ($p = 0.008$). Probably due to the paucity of events, no statistically significant association of TILs and AR with either DFS or OS was observed.

Conclusions: TILs are a promising prognostic marker, but still prospective validation is needed to integrate them into clinical practice. Among TNBC, the identification of AR-expressing luminal subtype might provide a targeted therapy chance for a low proliferation TNBC subtype. Larger prospective trials are likely to validate TILs prognostic role and to explore the universe of TNBC subtypes targeted therapies opportunities.

207P Genomic spectrum of Asian breast cancer based on targeted next-generation sequencing in 150 consecutive primary breast cancer

C. Cha[1], S.J. Bae[1], C-I. Yoon[1], S.E. Park[1], Y. Kim[2], S.G. Ahn[1], K.A. Lee[2], J. Jeong[1]

[1]Department of Surgery, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Republic of Korea, [2]Department of Laboratory Medicine, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Republic of Korea

Background: Application of next-generation sequencing (NGS) enables to reveal genetic diversity of malignant tumors. Here we report our experience with targeted NGS in Asian patients with primary breast cancer.

Methods: We identified 150 Asian patients who had genotyping by targeted NGS between April 2017 and Mar 2018 in a single institution. The genetic mutation patterns of the patients were analyzed retrospectively. Targeted NGS with the Oncomine^{TM} comprehensive panel including 143 genes was conducted on Ion Torrent S5 XL (Thermo Fisher Scientific, Waltham, MA, USA). All patients had stage I-III by AJCC 7th edition.

Results: Targeted NGS was conducted in a total of 150 primary breast cancer including 98 (65.3%) patients of the luminal/HER2-negative subtype, 28 (18.7%) patients of the HER2 subtype, and 24 patients of the (16.0%) TNBC subtype. Of the 150 patients, 138 patients had 432 genomic alterations including 306 mutations and 126 aberrant copy number variations (CNV). The most common genetic mutation was PIK3CA mutation (64 patients, 42.7%), followed by TP53 mutation (48 patients, 32.0%), TET2 mutation (26 patients, 17.3%) and ERBB2 mutation (6 patients, 4.0%). Of the 6 patients with ERBB2 mutations, 5 patients were in the luminal/HER2-negative subtype and 1 in the HER2 subtype. When ERBB2 amplification excluded, most common CNV was found in FGFR1 (12 patients, 8.0 %) followed by CCND1 (10 patients, 6.7 %). In 35 ER-positive/HER2-negative patients who agreed to receive Oncotype DX assay, 18 patients (48.6%) had PIK3CA mutation. In patients with PIK3CA mutation, 13 (72.2%) had a low RS, and 5 patients (27.8%) had an intermediate RS. A patient with RS of 27, which is recognized as high score by the criteria of TAILORx trial, had co-mutations as PIK3CA^{H1047R} and P53^{K132N}.

Conclusions: Our data with targeted NGS panel suggested that genomic landscape of Asian breast cancer is in accordance with previous NGS studies with Western women. In addition, our subgroup study with Oncotype DX supports early notion that ER-positive breast cancer patients with PIK3CA mutation show a better prognosis compared with those without PIK3CA mutation.

208P The impact of the 21 gene recurrence score (RS) on chemotherapy (CHemoRx) prescribing in hormone receptor (HR) positive, lymph node positive (LN+) early-stage breast cancer (BC) in Ireland: A national, multi-centre, prospective study (CTRIAL-IE 15-34)

A. Hassan[1], N. Keegan[1], C. O'Leary[1], L. McSorley[1], T. Mahgoub[1], S. O'Reilly[2], J. Walshe[3], M.J. Kennedy[4], L. Coate[5], M. O'Connor[6], M. Keane[7], C.M. Kelly[8], M. Milewski[1], S. Molloy[1], K. Eagan[1], V. Murphy[9], O.S. Breathnach[1], L. Grogan[1], B. Hennessy[1], P.G. Morris[1]

[1]Cancer Clinical Trials and Research Unit, Beaumont Hospital, Dublin, Ireland, [2]Department of Medical Oncology, Cork University Hospital, Cork, Ireland, [3]Department of Medical Oncology, St Vincent's University Hospital, Dublin, Ireland, [4]Oncology Directorate, St James's Hospital, Dublin, Ireland, [5]Department of Medical Oncology, Mid-Western Cancer Centre, University Hospital Limerick, Dooradoyle, Ireland, [6]Department of Medical Oncology, University Hospital Waterford, Waterford, Ireland, [7]Department of Medical Oncology, University Hospital Galway, Galway, Ireland, [8]Department of Medical Oncology, Mater Misericordiae University Hospital University College Dublin, Dublin, Ireland, [9]Translational Research Unit, Cancer Trials Ireland, Dublin, Ireland

Background: The 21 gene RS has improved the selection of patients (pts) for ChemoRx in early BC. Internationally, the RS is used in LN+ disease, but has not been reimbursed for this indication in Ireland. We conducted a prospective study to determine the extent to which use of the RS could alter Oncologists' ChemoRx recommendations in pts with LN+ BC.

Methods: Eligible patients had 1-3 LN+, HR+ HER2- BC. All pts gave written informed consent. Baseline demographics were collected. Questionnaires were completed by a Consultant Oncologist before and after the RS, which examined expectations of tumour chemo-sensitivity, strength of ChemoRx recommendation and type of planned ChemoRx. The primary endpoint was the % reduction in pts recommended ChemoRx ($N = 75$).

Results: RS was available on 74/75 pts; median age 54 (range 32-78) years. Most pts had T1 (43%) / T2 (47%), grade 2 (72%) tumours with 1 LN + (68%). The RS was <11 in 10 (13%), 11-25 in 56 (76%) and >25 in 8 (11%) pts. Access to the RS led to a 27% reduction in ChemoRx recommendations from 68 (92%) to 48 (65%) pts. This was most notable in pts with 1 LN + (46 vs 24) and 2 LN + (13 vs 7). Access to the RS led to a reduction in physician perception of tumour chemosensitivity and strength of ChemoRx recommendation (Table). Use of the RS led to a decrease in Anthracycline (A)-Taxane (T) ChemoRx (30 vs 17 pts) and T-based ChemoRx (30 vs 21 pts) with a resultant increase in non-A, non-T ChemoRx (8 vs 10 pts). The use of the RS did not impact on ChemoRx recommendations in women <40yrs (all got ChemoRx). The biggest reduction in ChemoRx occurred in women age 51-70 with 1LN + (28 vs 18 pts). Overall, in 47 (64%) cases, Oncologists thought the RS significantly changed their treatment recommendations.

Table: 208P

Physician questionnaires before and after RS

1. How sensitive will the tumour be to ChemoRx?				
1	2	3	4	5
Not very sensitive				Very sensitive
Before RS				
10 (13)	32 (43)	21 (28)	10 (13)	1 (1)
After RS				
21 (28)	26 (35)	15 (20)	11 (15)	5 (7)
2. How strongly do you recommend ChemoRx?				
1	2	3	4	5

Continued

Table: 208P *Continued*

Physician questionnaires before and after RS				
Not very strongly				Very strongly
Before RS				
7 (9)	22 (30)	20 (27)	20 (27)	5 (7)
After RS				
23 (31)	16 (22)	10 (13)	21 (28)	4 (5)

Conclusions: Broader access to the 21 gene RS could result in a reduction in the use of ChemoRx in Ireland.

209P Lymphocyte-predominant breast cancer has a significant lower mean of absolute neutrophil counts compared to non-lymphocyte-predominant breast cancer: Analyses with 576 cases

D.Y. Lee, S.E. Park, C. Cha, C-I. Yoon, S.J. Bae, S.G. Ahn, J. Jeong

Department of Surgery, Gananam Severance Hospital, Seoul, Republic of Korea

Background: Tumor-infiltrating lymphocytes (TILs) in surgical-specimen might be associated with host-cell mediated immunity, which could be partly reflected by blood cell counts from peripheries. We investigated whether peripheral blood cell counts are associated with TILs in 577 patients with breast cancer.

Methods: Between August 2016 and April 2018, we evaluated the percentage of stromal TILs in breast cancer patients who underwent primary surgery according to standardized methodology proposed by the international TIL Working Group. Lymphocyte-predominant breast cancer (LPBC) was defined as tumors having high TIL levels ($\geq$ 50%). Blood cell counts including absolute neutrophil counts (ANC), absolute lymphocyte counts (ALC), percentages of ANC and ALC, and neutrophil-to-lymphocyte ratio (NLR) was obtained from pretreatment laboratory data.

Results: Of 577 tumors, 99 (17.2%) was LPBC, and 478 (82.8%) was non-LBPC. When 5 markers of peripheral blood counts were compared, LPBC had a significantly higher mean ANC than non-LPBC (3,671 vs. 3,336; $P = 0.004$), but other means were not different. Further, in luminal/HER2-negative breast cancer, mean ANC of LPBC was still higher than that of non-LPBC ($P = 0.025$), whereas it tended to be higher in LPBC in other subtypes ($P = 0.385$ in HER2, $P = 0.260$ in TNBC).

Conclusions: Our results suggest that low peripheral ANC might be linked with LPBC, supporting the hypothesis that systemic immune cell counts might be associated with tumor-immune microenvironment. Further study on an association between peripheral ANC and tumor-associated neutrophil consisting tumor micromileu is warranted.

210P Genetic alterations of early-stage breast cancers by next-generation sequencing (NGS)

Y. Xu[1], M. Zhang[2], R. Chen[2], X. Xia[2]

[1]General Surgical Department, Daping Hospital of Chongqing, Chongqing, China, [2]Medical Center, Geneplus-Beijing Institute, Beijing, China

Background: Breast cancer is the most frequently diagnosed cancer and the leading cause of cancer death in women. Patients diagnosed with early stage generally have better survival. However, disease free survival differed significantly for different molecular subtypes. Understanding the genetic alterations of early-stage breast cancer may help to identify patients at high risk for relapse.

Methods: We retrospectively reviewed genetic profiling of 53 early-stage breast cancer samples in our institute. Surgical specimens were analyzed using hybridization capture-based NGS ER-seq method, white blood cells as control, which enables simultaneously assess single-nucleotide variants (SNV), insertions/deletions (indel), rearrangements and somatic copy-number variation(CNV) of 1021 genes.

Results: Fifty-three surgical specimens from 51 female patients with early-stage breast cancer were analyzed, including two bilateral primary breast cancers with different molecular subtypes. There were 29 HR+/HER2-, 6 HER2+, 6 HR+/HER2+ and 12 TNBC. The median diagnosis age was 43(range 31-67). In addition to TP53, there were 16 genes carried actionable mutations identified (details in table). The most frequently mutant genes were TP53 and PIK3CA, in all molecular subtypes. Among PIK3CA mutations, the H1047R/L were tested in all subtypes. Other gene alterations were highly heterogeneous in different molecular subtypes. HRAS or KRAS mutation was always identified with other genes. For instance, HRAS/PIK3CA and KRAS/AKT1 concurrent in 2 HR+/HER2-, KRAS/PIK3CA concurrent in 1 TNBC. Interestingly, for the two bilateral primary breast cancers, one patient had no overlapping mutation in 2 samples within total 6 variants, the other one only had common HER2 CNV in 2 samples within total 13 variants.

Table: 210P

Signaling Pathways	Genetic Alterations	HR+/HER2-(29)	HER2+(6)	HR+/HER2+(6)	TNBC(12)
p53	TP53	14	5	4	11
PI3K/AKT/mTOR	PIK3CA	12	3	1	3
	AKT1	6	-	-	-
	PTEN	3	-	-	-
	NF1	1	-	-	-
	FLCN	1	-	-	-
Homologous recombination repair	BRCA1(gm)	-	-	-	1
	BRCA1(sc)	-	1	-	-
	BRCA2(gm)	2	-	-	-
	BRCA2(sc)	-	1	-	-
	ATM(gm)	-	-	1	-
Ras/Raf/MAPK	HRAS	1	-	-	-
	KRAS	1	-	-	1
Cell cycle	RB1	1	-	-	-
	CDKN2A	1	-	-	-
	CCND1	1	-	-	-
RTKs	FGFR1	1	-	1	-
	HER2 CNV	-	4	5	-
	EGFR CNV	-	-	-	1

sc, somatic mutation; gm, germline mutation.

Conclusions: Genetic alterations were highly heterogeneous in different molecular subtypes of early-stage breast cancers. And this may contribute to the different relapse risk.

211P Oncotype Dx results in patients ≤40 years: Does age matter? New insights

F. Namuche[1], R.E. Ruiz[2], Z.D. Morante Cruz[2], D. Urrunaga[3], G. Ziegler[4], R. Mantilla[4], M. Leon Rivera[5], M. Chavez Mac Gregor[6], H.L. Gomez Moreno[7]

[1]Oncology, Oncosalud, Lima, Peru, [2]Oncology, Instituto Nacional de Enfermedades Neoplasicas - INEN, Lima, Peru, [3]Medicine, USMP, Lima, Peru, [4]Mastology, URP, Lima, Peru, [5]Oncology, Clinica Ricardo Palma, Lima, Peru, [6]Health Services Research, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [7]Medicine, Instituto Nacional de Enfermedades Neoplasicas - INEN, Lima, Peru

Background: The 21-gene recurrence score (RS) predicts the benefit of adjuvant chemotherapy (CT) in ER-positive, HER2-negative breast cancer (BC) and has been validated in a population where women under 40 are underrepresented. Young BC pts are more likely to receive adjuvant chemotherapy (CT) in addition to endocrine therapy (ET). Our objective was to assess the RS results in young ($\leq$40 yo) vs older (>40 yo) pts and evaluate the impact of age on clinical decision making according to RS categories.

Methods: We retrospectively reviewed electronic medical files of all patients with early stage hormone receptor BC for whom RS was available between 2007 and 2017 in 3 specialized cancer centers. We used the Mann-Whitney and Chi-squared tests to assess differences between age group. Similarly, we evaluated the association between age groups and treatment, within each ODx category. To determine if age was associated with CT use in the low-risk category, a logistic regression model was constructed.

Results: A total of 551 pts were included, 53 (9.6%) $\leq$40 yo and 498 (90.4%) >40 yo. No statistical differences were found between the younger and older groups in T ($p = 0.874$), N ($p = 0.794$), stage ($p = 0.188$), or grade ($p = 0.791$). Young patients underwent radical surgery more frequently than their older counterparts (41.5% vs 25.7%, $p = 0.014$). Statistically significant differences were also observed in ER mean, which was lower in the younger group (80% vs 90%, $p < 0.001$). The median RS result was significantly higher in the younger group (19 vs 16, $p = 0.009$). Also, high-risk recurrence score category was significantly more frequent in the younger group (22.6% vs 9.2%, $p = 0.009$). In the intermediate-risk category there were no differences in the

proportion of patients who received CT according to age groups ($p = 0.484$). In the low-risk category, 28.0% of patients ≤40 years vs 11.3% of patients >40 years received CT ($p = 0.037$).

Conclusions: Our results indicate that RS tends to be higher in patients with BC ≤ 40 yo and that the frequency of high-risk RS is significantly higher in the younger group, suggesting biological differences between groups. 28% of young patients with low-risk RS from our cohort are overtreated. Based on these results, it should be considered to develop a test adjusted to the age of the patients.

212P Impact of BRCA status on outcomes and survival in high-risk early breast cancers

E. Klajer[1], S. Paget-Bailly[2], G. Meynard[1], A. Meurisse[2], F. Bazan[1], L. Chaigneau[1], E. Dobi[1], N. Meneveau[1], P. Montcuquet[1], C. Villanueva[1], A. Thiery-Vuillemin[1], E. Kalbacher[1], C. Populaire[3], M.-A. Collonge-Rame[3], J. Gligorov[4], E. Curtit[1], X. Pivot[5], L. Mansi[1]

[1]Medical Oncology, CHU Besançon, Hôpital Jean Minjoz, Besançon, France, [2]Methodology and Quality of Life in Oncology Unit, UMR 1098, CHU Besançon, Hôpital Jean Minjoz, Besançon, France, [3]Medical Biologic Genetic and Clinical Oncogenetic, CHU Besançon, Hôpital Jean Minjoz, Besançon, France, [4]Medical Oncology APHP, CancerEst, Tenon University Hospital, Paris, France, [5]Medical Oncology, Centre Paul Strauss Centre de Lutte contre le Cancer, Strasbourg, France

Background: Relationship between the presence of the BRCA mutation (BReast CAncer) and outcomes is unclear, especially in high-risk breast cancers. The aims were to describe clinical and pathological outcomes considering mutational status and to assess the prognostic impact of germinal BRCA mutated status (BRCAm) in this high-risk population.

Methods: A multi-center retrospective cohort of patients treated in Franche-Comté between 2003 and 2013 for an early breast cancer (eBC) by neoadjuvant and/or adjuvant chemotherapy was analyzed. Clinical and pathological outcomes were described and distributions were compared in regards of mutational status group performing Fisher exact tests. Kaplan-Meier method and log-rank tests were used to compare survival in terms of overall survival (OS. Univariate and multivariate Cox proportional hazards models were estimated for OS.

Results: A total of 2,295 patients were included. Among them, 240 patients were tested (10.5%) including 60 patients diagnosed with BRCAm (2.6%). Among them, 36 were BRCA1 (1.6%), 22 BRCA2 (1%) and two BRCA1 and 2 (0.01%). Age at diagnosis ($p < 0.0001$), histological type ($p = 0.0043$), size ($p = 0.0021$), nodal status ($p < 0.0001$), histologic grade ($p = 0.0009$), triple negative status ($p < 0.0001$) and in situ component ($p = 0.0163$) were significantly different between BRCAm, BRCAwt and untested patients. BRCA1 mutated tumors were mostly triple negative tumors contrary to BRCA2 mutated tumors, which were mostly locally advanced luminal tumors. In multivariate analysis, OS was not associated with BRCAm status ($p = 0.5690$).

Conclusions: Among this French cohort of high-risk eBC, incidence of BRACm cases was 2.6%. BRCA1 and BRCA2 breast cancers were two distinct tumors in term of pathological outcomes. BRCAm status had no significant impact on OS.

213P Early breast cancer classified as intermediate risk by the Prosigna assay: Characteristics and treatment strategy

N. Hajjaji[1], Y.M. Robin[2], D. Bertin[2], J.M. Bonneterre[1]

[1]Breast Cancer Department, Centre Oscar Lambret, Lille, France, [2]Pathology, Centre Oscar Lambret, Lille, France,

Background: Genomic-based signatures are implemented in clinical practice to guide adjuvant treatment strategy in early breast cancer patients with luminal tumors. One of the main signatures, the PAM50-based Prosigna assay classifies patients into 3 risk categories based on their score of recurrence, thus providing clear guidance in low or high risk tumors. This study aimed at assessing in real life the proportion of patients with intermediate (ITD) risk results with the Prosigna assay, their tumor profile and the factors influencing treatment decision.

Methods: This monocentric retrospective study was conducted in 107 patients with luminal early-stage breast cancer treated at Oscar Lambret Cancer Center (Lille, France). Their tumors were analyzed with the Prosigna assay from July 2016 through April 2018.

Results: The Prosigna assay classified 15% of the patients in the low risk group, 41% were high risk, and 44% ITD risk. In this group, approximately one third were node negative and two third node positive. The tumor profiles with the highest proportion of ITD risk results had the following characteristics: 14≤Ki67≤20% and grade 2 in node negative or positive patients, or Ki67<14% and grade 2 in node positive patients (Table). 83% of the patients with an ITD risk result (39 of 47) were spared chemotherapy. Among them, 34 had luminal A and 5 luminal B tumors. Among the 8 patients proposed chemotherapy, luminal A and B tumors were evenly split. The main determinant of this decision was an estimated 10-year risk of relapse over 10 or 11%.
Table: Prosigna risk groups distribution within patients' main tumor profiles.

Table: 213P

	Prosigna risk groups						
	Low		Intermediate		High		
Main Tumor Profiles (99 of 107 patients)	n	%	n	%	n	%	Total (n)
14≤Ki67≤20% - G2 - N0	5	33	7	47	3	20	15
14≤Ki67≤20% - G2 - N1	0		10	59	7	41	17
Ki67<14% – G2 - N0	6	60	3	30	1	10	10
Ki67<14% – G2 - N1	0		13	65	7	35	20
Ki67>20% – G2 - N0	2	17	4	33	6	50	12
Ki67>20% – G2 - N1	0		1	9	10	91	11
Ki67>20% – G3 - N0 - T1	0		3	43	4	57	7
Ki67<14% – G1 - N1	2	29	4	57	1	14	7

G: grade; N0/N1: node negative / positive (1 to 3); T1: tumor size ≤ 20mm

Conclusions: Our study showed that a significant proportion of patients were classified in the intermediate risk group, and most were spared chemotherapy. A specific guidance is needed in this risk group.

214P Ki67 as an important predictor for oncotype Dx recurrence score risk groups in early breast cancer

F. Namuche[1], R.E. Ruiz[2], Z.D. Morante Cruz[2], D. Urrunaga[3], A. Aguilar Cartagena[4], H.L. Gomez Moreno[5]

[1]Oncology, Oncosalud, Lima, Peru, [2]Oncology, Instituto Nacional de Enfermedades Neoplasicas - INEN, Lima, Peru, [3]Medicine, USMP, Lima, Peru, [4]Oncology, Oncosalud SAC, Lima, Peru, [5]Medicine, Instituto Nacional de Enfermedades Neoplasicas - INEN, Lima, Peru

Background: The gene expression profiling assay OncotypeDx (ODx) prognosticates the risk of estrogen receptor positive (ER+) breast cancer (BC) recurrence and assesses the likely benefit from adjuvant chemotherapy in addition to endocrine therapy. There have been several attempts to develop algorithms that provide similar outcome prediction to the ODx assay with the use of routine clinicopathological characteristics. Ki67 is frequently incorporated into these assessments, although there is no standard cut-off for its use.

Methods: We retrospectively reviewed the electronic medical records of 330 patients with early stage ER+ BC for whom ODx recurrence score (RS) was available. Patients were diagnosed and treated at two specialized cancer centers between 2014 and 2017. Our objective was to determine the ki67's median differences between ODx risk groups. We used Spearman rho for the correlation between Ki67 and ODx score and used Kruskal-Wallis test for compare medians, pairwaise comparison for the intergroup relations.

Results: Mean age at diagnosis was 57.42 years (range 28-89). Mean tumor diameter was 15.67 mm. 78.9% were intermediate histologic grade and 9.7% patients had lymph node involvement. Median expression of ER and PR were 90% (5-100) and 70% (0-100), respectively. We assessed the correlation between Ki67 and ODx score, with a pearson r:0.31, $p < 0.001$. The data showed a directly proportional trend between Ki67 and ODx score. Median Ki67 was 20 (1-100). According to ODX RS, 61.5% of tumors were low risk, 30.3% were intermediate risk and, 8.2% were high risk. Median Ki67 within each category group is as follows: low: 15 (IQR:15), intermediate: 20 (IQR:18) and high: 40 (IQR:35), with a statistically significant difference between medians ($p < 0.001$). In the Pairwise comparison intergroup the data showed: Low-Intermediate ($p < 0.05$), Low-High ($p < 0.001$), Intermediate-High ($p < 0.001$).

Conclusions: The data showed directly proportional trend between Ki67 and ODx score. In our population there is a statistically significant difference between Ki67 medians according to ODx risk groups.

215P Genetic signatures always suggest undertreatment? Experience with PAM50

C. Sales[1], I. Vieira[1], M. Cassiano[1], C. Oliveira[1], C. Vieira[1], M. Ferreira[1], A. Rodrigues[1], A. Ferreira[1], M.I. Pousa[1], R. Couto[1], C. Leal[2], J. Abreu[3], M. Teixeira[4], D. Pereira[1], S. Sousa[1], M.H. Abreu[1]

[1]Medical Oncology, Instituto Portugues de Oncologia Centro do Porto(IPO-Porto), Porto, Portugal, [2]Pathology, Instituto Portugues de Oncologia Centro do Porto(IPO-Porto), Porto, Portugal, [3]Surgical Oncology, Instituto Portugues de Oncologia Centro do Porto(IPO-Porto), Porto, Portugal, [4]Clinical Genetics, Instituto Portugues de Oncologia Centro do Porto(IPO-Porto), Porto, Portugal

Background: PAM50 (Prosigna®) identifies a gene-expression profile that categorises early breast cancer (BC) in intrinsic subtypes and gives prognostic estimation based on a 10 year-recurrence risk score (ROR). The purpose of this study was to evaluate the impact of PAM50's information on adjuvant treatment decisions.

Methods: Prospective collection of BC cases treated in a Cancer Centre in the last 10 months, in which PAM50 was used to define treatment strategy. Demographic, clinic and pathologic characteristics are described. Concordance between immunohistochemistry (IHC) and PAM50 subtypes were assessed as well as therapeutic decision changes according to risk stratification, using blind revision. Categorical variables were compared used chi-square test.

Results: Inclusion of 101 patients, median age of 52 years (34-79 years). Fifty-five patients (54.5%) were premenopausal, 71 (70.3%) had ductal carcinomas, 71 (70.3%) pT1c, 99 (98%) G2, 72 (71.3%) pN0, ER positive and HER2 negative. Eighty five(84.2%) had a PR expression above 20% and 63 (62.4%) had a Ki67≤15%. Overall discordance rate between BC subtypes by IHQ and PAM50 was 34%, ($p < 0.001$). By IHC, 51 (50.5%) were luminal A-like. Forty seven(92%) remained luminal A with PAM 50 [(low ROR: 28 (60%), intermediate:16 (34%), high:3 (6%)]. Four (8%) changed to luminal B [intermediate ROR:1 (25%), high:3 (75%)]. Of the 50 luminal B-like tumours (49.5%), 20 (40%) remained luminal B [intermediate ROR: 8 (40%); high:12 (60%)] and 30 (60%) changed to luminal A [low ROR:18 (60%), intermediate:12 (40%)]. Based on PAM50, adjuvant strategy was changed in 28 patients (28%), ($p = 0.001$): 15 (54%) changed from endocrine therapy (ET) only to chemotherapy (CT) also and 13 (46%) changed from CT and ET to ET only.

Conclusions: PAM50 availability results in 28% change in adjuvant plan with more cases of chemotherapy. The 34% discordance with classic IHC subgroups, especially in luminal B tumours, underlines the need for more accurate tests in this heterogeneous population to define the adequate adjuvant strategy. A longer follow up is important to evaluate the prognostic value of clinical decisions based on genetic signatures.

216P Significance of receptors expression, mitotic index and Ki67 in breast cancer patients with Nottingham Prognostic Index (NPI) poor prognosis score

M. Nesrine[1], H. El Benna[1], Y. Berrazegua[1], S. Labidi[1], N. Daoud[1], H. Boussen[2]

[1]Medical Oncology Abderrahmen Mami Hospital, Ariana, Tunisia, [2]Department of Medical Oncology, Hopital Abderrahman Mami, Ariana, Tunisia

Background: Nottingham Prognostic Index (NPI) is a used prognostic model for breast cancer patients, but new histological prognostic factors are today defined. We evaluated their effect within patients with poor prognosis NPI score.

Methods: We retrospectively selected 351 non-metastatic breast cancer patients with High NPI score (>5,4). They were classified according to surrogate definition of intrinsic subtypes of breast cancer (St Gallen 2015). Several prognostic factors were evaluated. We used log rank test, cox regression model to evaluate the significance of clinic-pathological factors.

Results: Median age of our population was 50 years. They were luminal A in 30%, Luminal B in 43%, HER overexpression in 10% and basal like in 17%. On univariate analysis, menopausal status (HR = 0,32 [0.13-0,76]), endocrine receptors expression (HR = 6,52 [2,57-16,54]), HER2 expression (HR = 3,08 [0.191-10.39]), Mitotic index (HR = 1,05 [1,02-1,09]) and obesity (HR = 3,49 [1,27-9,58]) were significant prognostic factors. There was no prognostic value of age<35 years, Ki 67 cut-off of 20% and nodal capsule rupture. There was a highly significant difference ($p < 0.0001$) in overall survival between the 4 intrinsic subtypes. Five-year overall survival was 95% for Luminal A, 90% for Luminal B, 56% for HER2 and 36% for basal-like. On multivariate analysis receptors expression and intrinsic subtype were significantly associated to survival ($p < 0.05$).

Conclusions: In NPI aggressive disease, the most important prognostic factors were receptors expression and intrinsic subtype. The elaboration of a histology-matched NPI score could afford better prognostic evaluation of early stage breast cancer.

217P Subgroup analyses of efficacy from a phase III study comparing SB3 (trastuzumab biosimilar) with reference trastuzumab in early breast cancer patients

J. Cortes Castan[1], M. Pegram[2], X. Pivot[3], G. Curigliano[4], J.Y. Lim[5], S. Song[6], Y.C. Yoon[7]

[1]Breast Cancer and Gynecological Tumors, Vall d'Hebron University Hospital, Barcelona, Spain, [2]Medicine, Stanford Comprehensive Cancer Institute, Stanford, CA, USA, [3]Medical Oncology, Centre Paul Strauss Centre de Lutte contre le Cancer, Strasbourg, France, [4]Early Drug Development for Innovative Therapies Division, Istituto Europeo di Oncologia, Milan, Italy, [5]Clinical Development, Samsung Bioepis, Suwon, Republic of Korea, [6]Biometrics, Samsung Bioepis, Suwon, Republic of Korea, [7]Medical Affairs, Samsung Bioepis, Suwon, Republic of Korea

Background: SB3 has been approved by the European Commission as a biosimilar of reference trastuzumab (TRZ). Equivalence for efficacy between SB3 and TRZ based on breast pathologic complete response (bpCR) rates has been demonstrated and previously reported.[1] Here we report results of subgroup analyses of efficacy by baseline disease characteristics and demographics.

Methods: Patients received either SB3 or TRZ for 8 cycles concurrently given with chemotherapy (docetaxel followed by 5-fluorouracil/epirubicin/cyclophosphamide). Then patients underwent surgery followed by 10 cycles of SB3 or TRZ. The primary endpoint was bpCR rate. Subgroup analyses of bpCR rate, total pathologic complete response (tpCR) rate, and overall response rate (ORR) by region, age, ethnicity, hormone receptor status, breast cancer type, and menopausal status was performed.

Results: 800 patients (SB3, n = 402; TRZ, n = 398) were included in the per-protocol set (PPS). The bpCR rates were 51.7% for SB3 and 42.0% for TRZ with adjusted difference of 10.70% (95% CI, 4.13, 17.26). Subgroup analysis results are provided in the table. A trend of favourable efficacy of SB3 compared to TRZ was maintained in most of subgroup analyses. Similar trends were observed in the subgroup analysis of tpCR rate and ORR. Table: bpCR rates by baseline demographics and disease characteristics.

Table: 217P

	SB3 n/n′ (%)	TRZ n/n′ (%)	Adjusted difference (%) (SB3-TRZ, 95% CI)
Region			
Europe	53/108 (49.1)	44/98 (44.9)	3.44 (-9.63, 16.51)
Non-Europe	155/294 (52.7)	123/300 (41.0)	13.18 (5.59, 20.77)
Age			
Age <45	59/121 (48.8)	48/119 (40.3)	9.20 (-3.08, 21.48)
Age ≥45	149/281 (53.0)	119/279 (42.7)	11.51 (3.76, 19.26)
Ethnicity			
Asian	68/124 (54.8)	51/124 (41.1)	15.52 (4.27, 26.78)
White	135/269 (50.2)	112/264 (42.4)	8.45 (0.28, 16.62)
Hormone receptor status			
ER and/or PR positive	119/254 (46.9)	78/230 (33.9)	12.87 (4.45, 21.28)
ER and PR negative	89/148 (60.1)	89/168 (53.0)	7.34 (-3.14, 17.83)
Breast cancer type			
Operable	120/241 (49.8)	97/238 (40.8)	10.14 (1.44, 18.85)
Locally advanced	88/161 (54.7)	70/160 (43.8)	11.53 (1.58, 21.48)
Menopausal status			
Yes	105/198 (53.0)	92/198 (46.5)	7.65 (-1.33, 16.64)
No	103/204 (50.5)	75/200 (37.5)	12.97 (3.81, 22.14)

CI, confidence interval; ER, oestrogen receptor; PR, progesterone receptor; n, number of patients achieving bpCR; n′, number of patients with available assessment results.

Conclusions: Subgroup analysis results of bpCR, tpCR, and ORR showed a tendency of favourable efficacy in SB3 compared to TRZ, which were consistent with the overall bpCR analysis result. Reference: 1. Pivot X et al. J Clin Oncol. 2018; 36:968-74.

Hoffmann-La Roche AG - Switzerland, Basel, Switzerland, [13]Department of Biostatistics and Computational Biology, Dana-Farber Cancer Institute, Boston, MA, USA, [14]Royal Marsden Hospital, Academic Department of Biochemistry, London, UK, [15]Department of Molecular and Experimental Medicine, Avera Cancer Institute, Sioux Falls, SD, USA, [16]Medicine, Institute Jules Bordet, Brussels, Belgium, [17]Oncology, Institute Jules Bordet, Brussels, Belgium

Background: A growing body of evidence demonstrates that the immune system contributes to the therapeutic effects of trastuzumab. We sought to determine whether autoimmune background could identify patients with HER2 positive early breast cancer (EBC) who derive differential benefit from adjuvant primary trastuzumab-based therapy.

Methods: HERA (BIG 1-01) is an international, multicenter, open-label, phase 3 randomized trial of 5,102 women with HER2-positive EBC, who were enrolled after completion of their postoperative chemotherapy to receive trastuzumab for 1 year, 2 years, or no trastuzumab. In this exploratory analysis, we evaluated whether there is an interaction between autoimmune history and the magnitude of trastuzumab benefit with respect to disease-free survival (DFS) and overall survival (OS).

Results: A total of 5,099 patients were included in the current analysis: 4,774 patients (93.6%) had no history of autoimmune disease at baseline while 325 patients (6.4%) had autoimmune disease history, 295 of whom had active disease. Median follow-up was 11 years (IQR 10.09–11.53); 1,631 patients experienced a DFS event and 1,037 patients experienced an OS event. Random assignment to 1 or 2 years of trastuzumab compared with no trastuzumab yielded similar reductions in the risk of events for patients with no autoimmune history as for patients with autoimmune history (interaction $p = 0.95$ for DFS, and $p = 0.62$ for OS). Trastuzumab reduced the risk of DFS event for both the no autoimmune (HR 0.77, 95% CI 0.69–0.85) as well as the autoimmune history group (HR 0.76, 95% CI 0.51–1.12). The risk of death was also similarly reduced for both groups: no autoimmune history: (HR 0.74, 95% CI 0.65-0.84); autoimmune history: (HR 0.65, 95% CI 0.40-1.07).

Conclusions: We found no evidence of a differential benefit from trastuzumab in patients with a medical history of autoimmune disease.

Background: While hormone receptor-positive (HR+) and negative (HR-) HER2+ breast cancers (BC) are thought to be distinct diseases, only few studies have investigated the impact of HR status in the context of trastuzumab (TRZ)-treated BC. We evaluated the impact of HR status on outcomes of HER2+ early BC, before and after generalization of TRZ.

Methods: Patients were identified from a cohort of 23,374 women who underwent primary surgery in 18 centers between 2000 and 2017. Since the year 2005 marked the generalization of TRZ, we conducted distinct analyses in patients treated between 2000 and 2004 and those treated between 2005 and 2017. Impact of HR status analyses were done with censorship of events occurring after 5 years in both cohorts. Proportionality tests included all events.

Results: Of 970 HER2+ patients, 349 were treated between 2000 and 2004 without TRZ, and 621 between 2005 and 2017, with TRZ-based adjuvant chemotherapy. Endocrine therapy was received by 92 and 94% of HR+ patients, respectively. In the first group, HR status impacted disease-free survival (DFS) in univariate analysis (Hazard ratio: 2.44 [1.43-4.19]; $p < 0.001$, log-rank test). Conversely, HR status did not significantly impact DFS in the cohort with TRZ (1.34 [0.66-2.71], $p = 0.414$). Overall survival was also impacted by HR status in the group without TRZ (Hazard ratio: 2.49 [1.23-5.04]; $p = 0.009$), but not in the TRZ group (0.68 [0.23-2.00]; $p = 0.482$). These results were maintained in multivariate analysis including age, LVI, lymph node involvement, histology, grade and tumor size. Evolution of Hazard ratio over time for cumulative incidence of first recurrence according to HR status in patients without TRZ showed a non-proportionality of risks on metastatic ($p = 0.027$, AD-test) recurrences, with a decreasing risk for HR- over time. Conversely, the analysis of cumulative incidence of first recurrence did not show such a trend in patients treated with TRZ, suggesting the proportionality of the risks over time for HR status.

Conclusions: Instead patients treated without TRZ, HR status was no longer determinant of outcomes when patients received TRZ. These observations are supported by the analysis of Hazard ratio's evolution over time for cumulative incidence of first metastatic recurrence.

220P Safety profile of subcutaneous trastuzumab in patients with HER2-positive early breast cancer: The French HERMIONE non-interventional prospective study

J-P.P. Jacquin[1], L. Uwer[2], A. Savignoni[3], J-M. Ferrero[4], A. Lortholary[5], D. Solub[6], H. Attar-Rabia[7], S. Deblay[7], S. Pibre[7], Y. Belkacemi[8]

[1]Oncology Unit, Institut de Cancérologie de la Loire, Saint-Etienne, France, [2]Oncology Unit, Institut de Cancérologie de Lorraine - Alexis Vautrin, Vandœuvre-lès-Nancy, France, [3]Pole Biométrie, Institut Curie, Paris, France, [4]Oncology Unit, Centre Antoine Lacassagne, Nice, France, [5]Oncology Unit, Hopital Prové du Confluent, Institut de Cancérologie Catherine de Sienne, Nantes, France, [6]Oncology Unit, Hôpitaux de Chartres, Chartres, France, [7]Oncology Unit, Roche S.A.S - France, Boulogne-Billancourt, France, [8]Henri Mondor Breast Cancer Center and Department of Radiation Oncology, AP-HP, Henri Mondor University Hospital, University of Paris-Est Créteil (UPEC), Créteil, France

Background: The HERMIONE study was conducted to assess, in HER2-positive early breast cancer, the safety profile of subcutaneous formulation of trastuzumab (SC T) in real life in France.

Methods: This prospective, multicenter, noninterventional study included 511 patients planned to be treated in both neoadjuvant and adjuvant settings with a follow-up (FU) of 12 months maximum. The safety analyses concerned 505 patients, either naïve (40.4%) or non-naïve (59.6%) of intravenous trastuzumab (IV T). According to routine practice, patients received concomitant locoregional radiotherapy (68.7%), endocrine therapy (59.9%) and chemotherapy (37.8%). Primary endpoint was the description of systemic and local Adverse Events (AEs) of SC T assessed by NCI-CTCAE. Congestive Heart Failure (CHF), hepatobiliary toxicity and suspected transmission of an infectious agent by SC T were AEs of Special Interest (AESIs). Secondary endpoints included description of patients, disease characteristics and modalities of SC T administration. Quality of life (QoL) was assessed by QLQ-C30.

Results: Patients were included in 101 sites between January and November 2015. The median age was 58 years. Over the FU period, AEs occurred in 422 patients (83.6%): 92 AEs (3.8%) were grade ≥ 3, 76 (3.1%) were serious, 87 (3.6%) were AESIs and 336 (13.7%) were related to SC T. Most frequent AEs (> 10% of patients) were asthenia, arthralgia, radiation skin injury, myalgia, hot flush and diarrhea. Main grade ≥ 3 events were radiation skin injury (1.8% of patients) and febrile neutropenia (1.4%). Serious AEs (SAEs) included febrile neutropenia (9.2% of SAEs) and pulmonary embolism (6.6%). Main AESI was CHF in 11.5% of patients and was related to SC T only in 4.5%. Injection site pain was the main SC Trelated AE (9.1% of patients). Few AEs (1.4%) led to permanent SC T discontinuation. Only 1 death assessed as not related to SC T (pulmonary thromboembolism) was reported. QoL analyses showed no deterioration of global health status.

Conclusions: The Hermione study showed that the safety of SC T (HERCEPTIN®) in a real-life setting is consistent with the known profile, without new safety concerns or QoL deterioration.

Clinical trial identification: NCT02286362.

221P Real-life data on the cardiac toxicity of adjuvant fixed-dose subcutaneous trastuzumab in HER2-positive breast cancer

R. De Sanctis[1], F. D'Antonio[1], E. Agostinetto[1], A. Marinello[1], G. Masci[1], M. Zuradelli[1], A. Losurdo[1], D. Guiducci[2], C. Tinterri[3], A. Testori[3], W. Gatzemeier[3], V. Errico[3], R. Torrisi[1], A. Santoro[1]

[1]Medical Oncology and Hematology, Humanitas Cancer Center, Istituto Clinico Humanitas, Rozzano, Italy, [2]Cardiology, Humanitas Cancer Center, Istituto Clinico Humanitas, Rozzano, Italy, [3]Breast Surgery, Humanitas Cancer Center, Istituto Clinico Humanitas, Rozzano, Italy

Background: Fixed-dose adjuvant subcutaneous (s.c.) trastuzumab (T) has been approved in the treatment of early HER2-positive breast cancer (BC), based on the evidence of its non-inferiority to standard intravenous (i.v.) infusion. Few data from real-life are available regarding cardiac toxicities associated with fixed-dose subcutaneous T administration. We conducted a retrospective study in order to compare cardiac toxicity profile of adjuvant fixed-dose s.c.-T and weight-based i.v.-T, according to anthropometric data which takes into account more than simply weight.

Methods: Patients treated with adjuvant T for HER2-positive breast cancer at Humanitas Research Hospital from December 2013 to October 2017 were evaluated. T was administered at a either fixed dose of 600 mg s.c. or 6 mg/kg i.v, respectively. Data regarding previous chemotherapy, Body Mass Index (BMI), and development of cardiotoxicity (decrease in LVEF >10% points, to a value < 50%) were extracted from medical records. Four BMI classes were considered: underweight (BMI < 18 kg/sqm), normal weight (18-24.9 kg/sqm), overweight (25-29.99), and obesity (≥30). All variables were compared with categorical tests (Pearson Chi-squared with Yates correction or Fisher exact test).

Results: A total of 260 HER2-positive BC patients receiving adjuvant T were analyzed. Median age was 56 (range, 32-88), median BMI 23.5 (range, 15.8-50.2 kg/sqm). 196 (75.38%) patients received s.c.-T and 64 (24.62%) i.v.-T. 156 had a normal weight, while 11 were underweight, 54 overweight and 39 obese. The incidence of cardiotoxicity was not different among the BMI classes according to the route of administration of T ($p = 0.28$). In the subset of the patients who had developed cardiac toxicity, BMI did not result as a risk factor, as well as a previous treatment with anthracyclines ($p = 0.89$).

Conclusions: Cardiac toxicity profile of fixed-dose s.c.-T is consistent with that of weight-based i.v.-T in the real-world setting regardless differences in anthropometric data as BMI. Our study confirms safety of subcutaneous T administration, which still represents a valid and more convenient alternative to intravenous administration.

222P Comprehensive evaluation of the pharmacokinetic profiles of SB3 and reference trastuzumab

X. Pivot[1], Y.J. Lee[2], J.Y. Lim[2], S.J. Song[3], H.S. Kim[4], Y.C. Yoon[5]

[1]Medical Oncology, Centre Paul Strauss Centre de Lutte Contre le Cancer, Strasbourg, France, [2]Clinical Development, Samsung Bioepis, Suwon, Republic of Korea, [3]Biometrics, Samsung Bioepis, Suwon, Republic of Korea, [4]Clinical Bioanalysis, Samsung Bioepis, Incheon, Republic of Korea, [5]Medical Affairs, Samsung Bioepis, Suwon, Republic of Korea

Background: SB3 has been approved by the European Commission as a biosimilar of reference trastuzumab (TRZ). Physicochemical and functional studies showed that SB3 was highly similar to TRZ. Here, the pharmacokinetic (PK) results comparing SB3 and TRZ in cynomolgus monkeys, healthy male subjects, and early breast cancer patients are reported.

Methods: PK profiles were evaluated in cynomolgus monkeys following intravenous administration of 25 mg/kg of SB3 or TRZ every week for 4 weeks. In healthy male subjects, the PK equivalence between SB3 vs. EU-TRZ, between SB3 vs. US-TRZ, and between EU-TRZ vs. US-TRZ were assessed in a Phase I, 6 mg/kg single dose study.[1] The trough concentration was evaluated in a Phase III study of early breast cancer patients receiving either SB3 or EU-TRZ in combination with neoadjuvant chemotherapy.[2] Equivalence was to be concluded if the 90% confidence interval (CI) for the ratio of geometric lead squares means (LS Means) of the PK parameters were within the standard margins of 80.00% to 125.00%.

Results: Maximum concentration C_{max}, time to reach C_{max} (T_{max}), and the area under the concentration-time curve from time zero to 168 hour ($AUC_{0\text{-}168}$) were similar in cynomolgus monkeys treated with SB3 or TRZ. In 108 healthy subjects, the 90% CIs for the AUC from time zero to infinity (AUC_{inf}), AUC from time zero to the last quantifiable concentration (AUC_{last}) and C_{max} for all pairwise comparisons were within the pre-defined equivalence margin. The PK population in Phase III study consisted of 313 patients (SB3, n = 161; TRZ=152). Mean trough concentrations were similar from cycle 3 to 8 of SB3 ranging from 37.71 to 55.80 µg/mL and TRZ ranging from 39.83 to 53.13 µg/mL and the corresponding 90% CIs fell within the pre-defined equivalence margin. The proportion of patients with C_{trough} exceeding 20µg/mL was similar between the treatment groups at each cycle.

Conclusions: In addition to the non-clinical study in cynomolgus monkeys, similar PK profiles were well demonstrated between SB3 and TRZ in healthy subjects and in breast cancer patients. Reference 1. Pivot X et al. Clin Ther. 2016; 38:1665-73; 2. Pivot X et al. J Clin Oncol. 2018; 36:968-74.

223P The impact of neoadjuvant dual HER2 targeting with pertuzumab and trastuzumab on pathological complete response (pCR) rates: Kent Oncology Centre (KOC) experience

S. Forner, V.R. Sim, J.L. Glendenning, R. Burcombe

Oncology, Maidstone Hospital Maidstone & Tunbridge NHS TRUST, Maidstone, UK

Background: Neoadjuvant chemotherapy (NACT) with dual HER2 targeting improved pCR rates (ypT0ypN0) compared with Herceptin plus chemotherapy in the TRYPHAENA and NeoSphere registration trials. Pertuzumab-containing regimens were adopted at KOC following NICE approval (December 2016).

Methods: A retrospective case notes study of 110 (stage 1-3) HER2+ breast cancer patients receiving HER2-directed NACT at KOC was conducted. Age, clinical stage, ER status, treatment regimen and pCR status were recorded.

Results: Single targeting treatment (S) used FEC-TH. Dual targeting (D) regimens were FEC-THP or TCHP. Patients were well matched for age, clinical stage and ER status. Overall, dual targeting increased pCR rates: 62% vs 31% (S). pCR rates were higher with dual targeting regardless of ER or nodal status. The highest pCR rate was seen amongst ER negative patients receiving D (81%). Amongst D regimens, an excess of ER+ patients was seen in the TCHP group (75% TCHP vs 37% FEC-THP). Despite this, pCR rates were comparable (61% TCHP vs 63% FEC-THP). All 9 ER negative patients treated with TCHP achieved pCR (100%) compared with FEC-THP (67%). Table: Demographics and pCR rates for single and dual HER2 targeted NACT.

Table: 223P

	Single targeting (S)	Dual targeting (D)
Time period	Oct 15-Nov 17	Dec 16-Nov 17
N	55	55
Age Median (range)	55 (36-78)	53 (29-77)
Regimen		
FEC-TH	55	
FEC-THP		19
TCHP		36
ER status		
ER +	31 (56%)	34 (62%)
ER -	24 (44%)	21 (38%)
Node status at diagnosis		
N +	37 (67%)	29 (53%)
N -	18 (33%)	26 (47%)
pCR [n (%)]	17 (31%)	34(62%)
ER +	11 (35%)	17 (50%)
ER -	6 (25%)	17 (81%)
N +	11 (30%)	22 (76%)
N -	6 (33%)	12 (46%)

Conclusions: A substantial increase in pCR rates was observed with dual targeting, regardless of ER and nodal status, reproducing the registration trial data in real world clinical practice. pCR rates were greatest in ER negative patients, regardless of regimen. The small subgroup most likely to achieve pCR were ER negative patients treated with TCHP.

224P Neoadjuvant trial of nab-paclitaxel and atezolizumab (Atezo), a PD-L1 inhibitor, in patients (pts) with chemo-insensitive triple negative breast cancer (TNBC)

J.K. Litton[1], S.L. Moulder[1], K.R. Hess[2], S. Damodaran[3], G.M. Rauch[4], R. Candelaria[5], B.E. Adrada[4], F. Symmans[6], R.K. Murthy[1], T. Helgason[1], A. Clayborn[1], S. Prabhakaran[1], V. Valero[1], A.M. Thompson[7], E.A. Mittendorf[8]

[1]Breast Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [2]Biostatistics, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [3]Breast Medical Oncology, The MD Anderson Cancer Center, Houston, TX, USA, [4]Diagnostic Radiology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [5]Diagnostic Imaging, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [6]Pathology, MD Anderson Cancer Center, Houston, TX, USA, [7]Breast Surgery, MD Anderson Cancer Center, Houston, TX, USA, [8]Surgical Oncology, Dana-Farber Cancer Insitute, Boston, MA, USA

Background: Achieving a residual cancer burden (RCB) 0-1 portends an excellent prognosis for TNBC pts receiving neoadjuvant (NACT) anthracycline (AC) and taxane chemotherapy while pts with high residual disease (RCB II-III) have a 40-80% recurrence risk. The GeparTrio and Aberdeen trials demonstrated that pts with poor response by ultrasound (US) during NACT had pathologic complete response (pCR) rates of 2-5% even if NACT was changed based on US response. Immunotherapy is a promising strategy for chemo-insensitive TNBC; however, given toxicity and potential for long-term morbidity, pt selection is important.

Methods: Pts identified as having chemo-insensitive TNBC with AC using US or through previous participation in a separate trial, ARTEMIS, were eligible. To identify insensitive TNBC, ARTEMIS used an algorithm combining a CLIA-certified chemosensitivity mRNA gene signature with US response to AC X4. Eligible pts then received weekly nab-paclitaxel (100 mg/m2 IV for 12 weeks) and atezo (1200mg IV q 3 weeks). Atezo continued for 3 months after surgery. Using a 2-stage Gehan-type design, if > 1 pt had an RCB 0-I in the first 19, the protocol would continue to accrue a total of 37 pts to estimate an RCB-0/I rate for atezo + nab-paclitaxel in chemo-insensitive TNBC for future trials. We report the interim analysis of the first 19 pts.

Results: 19 pts enrolled from 02/2016- 12/12/2017. One pt received 1 cycle, then withdrew consent. Median age was 54 (range 35-75). Presenting clinical stage was II in 7 pts and III in 12 pts. Final pathology status was: RCB 0=5; RCB I = 1; RCB II = 5 and RCB III=7. RCB 0-I= 6/19 (32%). Toxicity included 6 serious adverse events in 3 pts: fever, elevated creatinine and post-surgical pain. Most common toxicities included fatigue, neuropathy, pain, anemia, rash, elevated transaminases, hyperglycemia, nausea and dyspnea. Six pts required atezo to be held and/or discontinued.

Conclusions: The combination of nab-paclitaxel and atezo resulted in moderate toxicity but increased the expected RCB 0-I rates from 5% to 32% for TNBC patients with chemotherapy-insensitive disease. Given these promising results, this study will continue to full accrual.

Clinical trial identification: NCT02530489.

225P Prognostic implications of circulating tumor cells (CTCs) after neoadjuvant chemotherapy for triple negative breast cancer (TNBC)

C. Hall[1], K.R. Hess[2], L. Ravenberg[3], A. Clayborn[4], G.M. Rauch[5], R. Candelaria[6], E.A. Mittendorf[7], S.L. Moulder[4], A. Thompson[8], A. Lucci[8]

[1]Breast Surgical Oncology, MD Anderson, Houston, TX, USA, [2]Biostatistics, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [3]Breast Medical Oncology, MD Anderson, Houston, TX, USA, [4]Breast Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [5]Diagnostic Radiology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [6]Diagnostic Imaging, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [7]Surgical Oncology, Dana-Farber Cancer Insitute, Boston, MA, USA, [8]Breast Surgical Oncology, The University of Texas M. D. Anderson Cancer Center, Houston, TX, USA

Background: ARTEMIS (A Randomized, TNBC Enrolling trial to confirm Molecular profiling Improves Survival) is a randomized trial to determine if precision guided neoadjuvant chemotherapy (NACT) impacts rates of pathologic complete response in the breast and axillary nodes (pCR). We hypothesized that CTCs in peripheral blood at the time of surgery, after completion of NACT, would be prognostic in TNBC.

Methods: Venous Blood taken following completion of NACT and immediately prior to surgery was assessed for CTCs after NACT as part of two IRB approved studies, ARTEMIS (2014 – 0185/PA15-1050) and LAB04-0698. CTCs (per 7.5 ml blood) were identified using the Cell Search® System (Menarini Silicon Biosystems). Samples with one or more cells having morphologic criteria for malignancy were deemed CTC+. Log-rank test and Cox regression analysis were applied to evaluate associations between CTC+, pCR, and overall survival.

Results: pCR was achieved in 24/68 (35%) patients with TNBC. Twenty four patients (35%) were CTC+. 3 year overall survival was evaluated in 4 groups of patients: pCR-no CTCs (n = 20), pCR-CTC + (n = 4), non-pCR-no CTCs (n = 24) and non-pCR-CTC + (n = 20). Three year OS was higher in the pCR-no CTCs cohort (100%), compared to pCR-CTC + (50%), non-pCR-no CTCs (83%), non-pCR-CTC + (19%); log rank $p < 0.0001$. In this data set, the presence of CTCs was associated with significant risk of death at 3 years [hazard ratio of 12.3 (95% CI 3.4-454, $p = 0.00002$)], whereas a favorable, but non-significant trend was noted for pCR [hazard ratio of 0.2 (95% CI 0.0, 1.4, $p = 0.11$)].

Conclusions: The presence of CTCs at the time of surgery after NACT has prognostic significance beyond that of pCR and should be considered in evaluation of patients for adjuvant clinical trials.

226P A prediction model for pathological complete response after neoadjuvant chemotherapy of HER2-negative breast cancer patients

L. Häberle[1], R. Erber[2], P. Gaß[1], A. Hein[1], S.M. Jud[1], H. Langemann[1], C. Rauh[1], C.C. Hack[1], R. Schulz-Wendtland[3], A. Hartmann[2], M.W. Beckmann[1], M.P. Lux[1], P.A. Fasching[1]

[1]Department of Gynecology and Obstetrics, Erlangen University Hospital, Erlangen, Germany, [2]Institute of Pathology, Erlangen University Hospital, Erlangen, Germany, [3]Institute of Radiology, Erlangen University Hospital, Erlangen, Germany

Background: Pathological complete response (pCR) is an established surrogate marker for survival in breast cancer (BC) patients treated with neoadjuvant chemotherapy. Prediction of pCR based on clinical information available at biopsy, particularly the biomarkers estrogen receptor (ER), progesterone receptor (PgR) and Ki-67 expression, might assist in the identification of patients who benefit of preoperative chemotherapy. Although biomarker assessment is mostly reported as the percentage of positively stained cells with values from 0 to 100%, cut-off points are used to classify patients into groups. Aim of this study was to examine established cut-off points and to develop a prediction tool estimating a patient's pCR likelihood obtained from clinical predictors and these biomarkers as assessed during clinical routine or categorically with established or newfound thresholds.

Methods: This study included all HER2-negative BC patients from one German institution treated with neoadjuvant chemotherapy from 2002 to 2017, having complete observations (N = 829). Various logistic regression models for predicting pCR which differ from each other by the usage of the biomarkers were set-up: (M1) continuous biomarkers from 0 to 100% as assessed during clinical routine, (M2) categorical (positive/negative) biomarkers with established thresholds, (M3) categorical biomarkers with newfound thresholds. Prediction accuracy (e.g., AUC) was assessed using cross-validation.

Results: A total of 163 (19.7%) patients achieved a pCR. The optimal cut-off points for ER, PgR and Ki-67 were 30%, 10% and 35%, respectively. The prediction model M1 with continuous biomarkers was more precise (cross-validated AUC, 0.863) than the prediction models M2 and M3 (both 0.854). The most accurate model M1 had a sensitivity of 0.80 at a specificity of 0.78. Beside these biomarkers, a patient's likelihood of achieving a pCR depended on age at diagnosis, clinical tumor stage and grading.

Conclusions: Using biomarkers as continuous variables yielded more precise predictions than when used categorically. Therapy decisions should base on predicted pCR probabilities obtained from multivariable prediction models rather than single biomarker values.

Background: According to molecular and genetic features BC can be divided into subtypes which show differences in the response to systemic therapy and in long-term outcome. Thus, effective and reliable molecular analysis of tumor material at the time of BC diagnosis is needed.

Methods: Total RNA was extracted from formalin-fixed paraffin-embedded (FFPE) tumor samples of BC patients (pts) enrolled in the single arm phase II TECHNO (Untch et al. JCO 2011) and the randomised phase III PREPARE (Untch et al. Ann Oncol. 2011) trials. MammaTyper®, a molecular in vitro diagnostic RT-qPCR test, was used to assess the expression of ERBB2 (HER2), ESR1 (ER), PGR (PR) and MKI67 (Ki67) genes as continuous and binary variables using predefined cutoffs. Pts were classified into 6 intrinsic BC subtypes according to St Gallen guidelines (Goldhirsch et al. Ann Oncol. 2013). In both trials the ER, PR, HER2 and Ki67 expression was assessed by immunohistochemistry (IHC). Predefined cutoffs for increased ESR1 (+1.8 Cq) and PGR (+3.7 Cq) expression defined a subgroup of ultra-high tumors. The study aimed to evaluate the MammaTyper® test for predicting pCR (ypT0 ypN0) after NACT and outcome in the BC subtypes. The degree of agreement between the MammaTyper® and the IHC test for determining BC subtypes was also estimated.

Results: A total of 418 pts were assessed. The BC subtypes defined by MammaTyper® and IHC showed good agreements (ERBB2/HER2, kappa [κ]=0.674; ESR1/ER, $\kappa = 0.815$; PGR/PR, $\kappa = 0.648$). MKI67 significantly predicted pCR (AUC=0.686, $p < 0.001$). In HER2+ pts from the TECHNO trial the ERBB2 significantly predicted pCR in ESR1-positive sybtype ($n = 59$, AUC=0.708, $p = 0.006$). HER2-negative pts from the PREPARE trial with ultra-high ESR1 and/or PGR expression had significantly better disease-free (DFS) and overall survival (OS) than the non-ultra-high pts ($n = 153$; DFS HR = 1.80, [95%CI 1.18-2.76], $p = 0.007$; OS HR = 2.54 [95%-CI 1.50-4.31], $p = 0.001$).

Conclusions: The MammaTyper® significantly predicts response after NACT in BC subtypes. A subgroup of pts with ultra-high ESR1/PGR expression had a good prognosis. Further analysis is required.

[1]Breast Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [2]Genomic Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [3]Biostatistics, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [4]Surgical Oncology, Dana-Farber Cancer Insitute, Boston, MA, USA, [5]Pathology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [6]Breast Surgical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [7]Epigenetics and Molecular Carcinogenesis, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [8]Diagnostic Radiology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [9]Bioinformatics and Computational Biology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA

Background: MpBCs are morphologically heterogeneous, frequently triple-negative and resistant to chemotherapy. To better understand why MpBCs are resistant to chemotherapy, we investigated associations between response to NAST and clinical, morphologic, as well as molecular characteristics in a cohort of MpBC patients (pts).

Methods: 19 MpBC pts were identified from a prospective cohort of 242 triple-negative breast cancer (TNBC) pts treated with anthracycline-based NAST. Histologic subtype of MpBC was determined by light microscopy. TNBC subtypes were determined using the Vanderbilt gene expression signatures (GES). Residual cancer burden (RCB) was assessed after surgery.

Results: Of the 19 MpBCs, 37% (7/19) were matrix producing and 63% (12/19) were not. Analysis of GES revealed the following subtype distributions: mesenchymal (M)=32% (6/19), mesenchymal stem-like (MSL)=11% (2/19), basal-like 2 (BL2)=32% (6/19), immunomodulatory (IM)=11% (2/19), unstable (UNS)=11% (2/19), basal-like 1 (BL1)=5% (1/19). Fifty-seven percent (4/7) and 33% (4/12) of the matrix producing and non-matrix producing MpBCs were of the M/MSL subtype, respectively. Twenty-one percent (4/19) of pts had a pathologic complete response (pCR)/minimal residual disease (RCB-I) following NAST. MpBCs that were matrix producing or of the M/MSL subtype were associated with worse response to NAST as none (0/11) of the pts with MpBC that was matrix producing and/or of the M/MSL subtype had a pCR/RCB-I, compared with 50% (4/8) of the remaining pts ($p = 0.018$).

Table: 228P Associations between response to NAST and clinical, morphological as well as molecular characteristics

	pCR/RCB-I (n = 4)	RCB-II/III (n = 15)
Median age (range)	57.3 (42.4-67.2)	57.8 (34.2-74.0)
Mean tumor size - cm (SD)	2.4 (1.2)	4.7 (3.8)
Clinical nodal status		
Negative - n (%)	4 (25)	12 (75)
Positive - n (%)	0	3 (100)
Stage		
I - n (%)	2 (40)	3 (60)
II - n (%)	2 (20)	8 (80)
III - n (%)	0	4 (100)
Histologic grade		
1 - n (%)	0	1 (100)
2 - n (%)	1 (25)	3 (75)
3 - n (%)	3 (21)	11 (79)
Metaplastic subtype		
Matrix producing - n (%)	0	7 (100)
Non-matrix producing - n (%)	4 (33)	8 (67)
TNBC subtype		
M/MSL - n (%)	0	8 (100)
BL1/2 - n (%)	3 (43)	4 (57)
Other - n (%)	1 (25)	3 (75)

Conclusions: Analysis of GES suggest that MpBC is enriched for subtypes less likely to achieve pCR/RCB-I with NAST (BL2, M, MSL). Matrix-producing (light microscopy) and the M/MSL subtypes (GES) appear to be associated with resistance to anthracycline-based NAST in MpBC.

(IPOLFG EPE), Lisbon, Portugal, [5]Francisco Gentil de Lisboa, Instituto Portugues de Oncologia, Lisbon, Portugal, [6]Medical Oncology, Hospital Beatriz Ângelo, Loures, Portugal, [7]Oncology, Hospital da Luz, Lisbon, Portugal

Background: HER2+ occurs in 15-20% of BC and is associated with worse prognosis. While previous studies reported that NAT-associated changes in HER2 status adversely affect patients (pts) prognosis (Guarneri et al), others did not (Yoshida et al). To assess the efficacy of NAT in pts with HER2+ BC and its influence on HER2 status and associated prognostic impact. HER2 status was determined by immunohistochemically (IHC) or Silver in situ hybridization (SISH).

Methods: Retrospective chart review and pathologic evaluation of all consecutive pts with HER2+ BC (defined as IHC 3+ or IHC 2+ confirmed by SISH) submitted to NAT between Jan2010 and Oct2015 in 3 Portuguese Hospitals. All diagnostic tumor biopsies and surgical specimens were assessed for IHC.

Results: 108 female pts were included (median age 52yo, range 30-82; TNM stage was III in 68, II in 40. Hormone receptor (HR) were positive (ER and/or PR) in 68. HER2 status at diagnosis was IHC 3+ in 100 pts and IHC 2+ SISH amplified in 8. NAT included chemotherapy (CT) in all pts (anthracyclines (AC)/ taxanes (Tax) 102, AC/ non-Tax 3, non-AC regimen 3), trastuzumab (T) in 87 and T and pertuzumab (P) in 3. Pathological complete response (pCR) (ypT0/isN0) was achieved in 48 pts (44.4%): 28 of 70 HR+ and 20 of 38 HR neg ($p = 0.2$), 27 of 40 with stage II and 21 of 68 with stage III ($p < 0.001$). pCR rate was 46% after CT+T/P and 39% with CT alone ($p = 0.6$). With a median follow-up of 55 months, there were 5 disease free survival (DFS) events (4 relapses and 1 non-BC death) among pCR pts and 19 among non-pCR (16 relapses and 3 non-BC deaths) ($p = 0.02$, log rank test). Of the 60 pts with residual invasive tumor at surgery, 52 remained HER2+ and 8 (13.3%) lost Her2+. 5y-DFS and 5-OS is 70% and 84%, respectively, for pts whose tumors remained HER2 + (14 DFS events; 8 deaths), and 21% and 50% for pts whose residual tumors became HER2 negative (5 DFS events; 4 deaths) ($p = 0.02$ and <0,001, log-rank test).

Conclusions: We confirmed the negative prognostic impact of NAT-induced HER2 loss on residual tumor leading to worse DFS. Despite the retrospective design and small sample size, these results suggest the importance of retesting HER2 after NAT, to better refine pts prognosis.

230P Complete response (CR) to anthracycline-based chemotherapy using magnetic resonance imaging (MRI) predicts high rates of pathologic complete response (pCR) for triple negative breast cancer (TNBC) patients treated preoperatively with anthracycline and taxane-based regimens

M. Marin Alcala[1], G. Llort Pursals[1], J.H. Del Riego Ferrari[1], J. Giner[1], F.X. Andreu Navarro[1], S. Medina[1], O. Aparicio[1], E. Dalmau Portulas[1], P. Ribera Fernandez[1], H. Oliveres[1], C. Martinez Vila[1], J.M. Cabrera Romero[2], M.A. Segui Palmer[1], L.A. Fernandez Morales[1]

[1]Oncology, Hospital de Sabadell Corporacis Parc Tauli, Sabadell, Spain, [2]Medical Oncology, Hospital de Sabadell Corporacis Parc Tauli, Sabadell, Spain

Background: Predictors of pCR to neoadjuvant chemotherapy (NAC) for breast cancers have been studied extensively. We focused on CR to antracycline-based chemotherapy using MRI for prediction of pCR, in patients treated with NAC with anthracycline and taxane-based regimens.

Methods: Tumor measurements were done at diagnosis, after anthracyclines and at the end of taxanes. pCR was defined as absence of residual invasive foci and no lymph nodeinvolvement. Associations of clinicopathologic parameters with pCR were evaluated with the $\chi 2$ test. All test results with a p value of less than 0.05 were considered significant.

Results: A total of 114 TNBC patients were treated with NAC. Median age was 53 (28-77) years. 44 patients (38.6%)had stage II and 67(58.8%)stage III. Mutation in BRCA was detected in 9 patients and variants of uncertain significance in 5. 49 patients (43%) with tumor size by MRI > 50 mm, 49 (43%) with positive results on fine needle aspiration of axilla (FNAA), and 88 (77.2%) with histologic grade III. NAC regimen consisted in 108 patients (94.7%) of 4 cycles of epirrubicin+cyclophosphamide (CP) and in 3 patients (2.6%) 4 cycles of doxorubicin+CP, followed by taxane-based regimens. 43 patients (37.7%) had pCR. CR by MRI occurred in 22 patients (19.3%) after anthracycline-based regimen. At the end of NAC there were 37 patients (32.5%) with CR by MRI. Association of clinicopathologic parameters with pCR were: 62.8% pCR in patients with tumor size $\leq$ 50mm ($p = 0.389$); 58.1% in patients with FNAA + ($p = 0.238$); 81.4% in grade III tumors ($p = 0.700$); 46.5% pCR in patients with CR by MRI after anthracycline-based regimen ($p = 0.0001$) and 65.1% pCR in patients with CR by MRI before surgery ($p = 0.0001$). All the patients with CR by MRI after anthracycline-based regimen had a CR by MRI before surgery.

Conclusions: CR by MRI after treatment with anthracyclines could be a clinically useful predictor of pCR in patients with TBNC treated preoperatively with anthracylcines and taxane-based regimens and patients who not reach CR after anthraclines could benefit from improve taxans regimen.

231P Immunomonitoring of triple negative breast cancer patients undergoing neoadjuvant therapy (GBG89, Geparnuevo trial)

B. Seliger

Institute of Medical Immunology, Martin Luther University of Halle, Halle, Germany

Background: The Geparnuevo trial is a randomized, double-blind, multi-center phase II trial of neoadjuvant therapy in patients with early-stage triple negative breast cancer (TNBC) investigating the role of durvalumab, an anti-PD-L1 inhibitor in addition to standard chemotherapy with nab-paclitaxel followed by epirubicin plus cyclophosphamide.

Methods: In order to determine possible predictive and / or prognostic biomarkers, blood samples were taken before and during the different treatment phases and evaluated by multicolor flow cytometry.

Results: Evaluation of the absolute cell count in the whole blood highlighted a mixed behavior of the total leukocytes, whereas there was a statistically significant reduction in the lymphocytes, particularly during the last phase of the treatment. Further dissection into the different immune populations highlighted an almost complete loss of B cells that in some patients was also accompanied by a reduction of NK cells, mostly regarding the $CD16^+$ subset. However, the loss of $CD4^+$ and $CD8^+$ T cells has been less pronounced resulting in an overall enhancement of their percentages within the total lymphocytes. The different populations have also been evaluated for the expression of activation and exhaustion markers, whose behavior will be more deeply evaluated when the clinical outcome and the treatment received by the various patients will be made available.

Conclusions: We expect that with such analysis possible biomarkers for the treatment of TNBC patients will be identified thus leading to better patient selection for chemo/ immune combination therapy.

233P Impact of breast cancer subtype on survival after lumpectomy versus mastectomy for early stage invasive breast cancer

Y-C. Tsai, H.C. Cheng, C.C. Horng

Radiation Oncology, Koo Foundation Sun Yat-sen Cancer Center, Taipei, Taiwan

Background: Randomized clinical trials (RCT) have demonstrated equivalent survival for breast-conserving therapy with radiation (BCT) and mastectomy for early-stage breast cancer. Early stage breast cancer patients who underwent BCT or mastectomy was studied to observe whether outcomes of RCT were achieved in a single institution series, and whether survival differed by surgery type when stratified by breast cancer subtypes.

Methods: Information was obtained from the institutional breast cancer data base with stage I or II breast cancer between 1990 and 2010, who were treated with either BCT or mastectomy and followed for vital status through December 2014. Cox proportional hazards modeling was used to compare overall survival (OS) and disease-specific survival (DSS) between BCT and mastectomy groups. Analyses were stratified by breast cancer subtype.

Results: A total of 3486 women fulfilled eligibility criteria. Women undergoing BCT had improved OS and DSS compared with women with mastectomy (adjusted hazard ratio for OS = 0.69, 95% CI = 0.51-0.95, $p = 0.0.023$; adjusted hazard ratio for DSS =0.68, 95%CI =0.48 -0.96, $p = 0.029$). 10 year overall survival rate in women undergoing BCT was 95.2% in Luminal A, 94.8% in Luminal B, 84.8% in Luminal/HER2, 91.5% in HER2 enriched and 92.1% in Triple negative. 10 year overall survival rate in women with mastectomy was 91.2% in Luminal A, 82.3% in Luminal B, 89.5% in Luminal/HER2, 86.2% in HER2 enriched and 88.4% in Triple negative.The group achieving greatest benefit in OS and DSS with BCT relative to mastectomy were stage II

luminal B patients (adjusted hazard ratio for OS = 0.28, 95% CI = 0.1-0.82, p = 0.02; adjusted hazard ratio for DSS =0.31, 95%CI =0.11 -0.91, p = 0.0329).

Conclusions: Among patients with early stage breast cancer, BCT was associated with improved DSS and OS. These data provide confidence that BCT remains an effective alternative to mastectomy for early stage disease. The group achieving greatest benefit in DSS and OS with BCT relative to mastectomy were stage II Luminal B patients.

234P Survival outcomes of dose dense neoadjuvant and adjuvant chemotherapy in triple-negative breast cancer patients: Indian scenario

T. Sood[1], A. Rauthan[1], P. Patil[1], S. Kulkarni[1], S.P. Somashekhar[2], S. Zaveri[3], V. Ahuja[3], K.R. Ashwin[3]

[1]Medical Oncology, Manipal Comprehensive Cancer Center Manipal Hospital, Bangalore, India, [2]Surgical Oncology, Manipal Comprehensive Cancer Care, Bangalore, India, [3]Surgical Oncology, Manipal Comprehensive Cancer Center Manipal Hospital, Bangalore, India

Background: Breast cancer is the most common cancer in Indian women. Triple negative breast cancer (TNBC) is associated with poor prognosis at any stage of diagnosis. It is an aggressive disease with a 5-year survival rate of 77% compared to 93% for other subtypes. Prevalence of TNBC in India is higher compared to western populations, making it an important target for early detection and treatment. Potential superiority of dose-dense chemotherapy in comparison with conventional regimen has been recently demonstrated in a meta-analysis in 2017 across various subsets of breast cancer. Aim of this study was to analyse survival outcomes in TNBC treated with dose dense chemotherapy at a tertiary care centre in India.

Methods: Retrospective analysis of patients diagnosed with TNBC stage I-III in last 8 years treated with 2 weekly dose dense AC regimen (adriamycin at 60mg/m^{2}and cyclophosphamide at 600mg/m^2 for 4 cycles followed by 2 weekly Paclitaxel at175 mg/m^2 for 4 cycles or weekly Paclitaxel at 80 mg/m^2 for 12 cycles) with growth factor support in adjuvant or neoadjuvant (NACT) setting. Locally advanced breast cancer (LABC) was defined as T > 5cm and ≥N2 disease. Kaplan–Meier method and log rank test were used to estimate survival functions.

Results: 97 patients with ER, PR and Her2neu receptor negative status were evaluated. Median age at diagnosis was 44 years (range 26 - 68 years). 56.7% had stage II disease, 36% stage III and rest stage I (7.2%). Disease free survival (DFS) rate ± SE at 2 years and 5 years was 90% ± 3% and 75% ± 5% respectively. Overall survival (OS) rate ± SE at 5 years was 82% ± 6%. 24 patients received NACT out of which 12 (50%) patients had pathCR. The DFS rate did not differ significantly between adjuvant and neoadjuvant subgroups. Early breast cancer and LABC subgroups had a statistically significant difference in DFS rates (p = 0.0002).

Conclusions: To our knowledge, this is the first study in India to evaluate survival outcomes of dose dense therapy in TNBC. The improved DFS (75%) and OS (82%) in this high risk subgroup are very promising, especially in patients with early disease. We advocate use of dose dense regimen in all patients of TNBC in curative setting.

235P Prognostic factors associated with pathological complete response in early breast cancer patients undergoing neoadjuvant chemotherapy: The importance of Ki-67 and molecular subtype

B.L. Rapoport[1], J.A. Barnard-Tidy[1], T. Smit[2], S.J. Nayler[3], C.A. Benn[4]

[1]Medical Oncology, The Medical Oncology Centre of Rosebank, Sandton, South Africa, [2]Pharmacy, The Medical Oncology Centre of Rosebank, Sandton, South Africa, [3]Anatomical Pathology, Grtizman & Thatcher, Parklands, South Africa, [4]Surgery, Breast Care Centre of Excellence, Parklands, South Africa

Background: Ki-67 immunohistochemical determination is a widely used biomarker of cell proliferation in patients (pts) undergoing endocrine treatment for breast BC. The role of Ki-67 in pts undergoing neoadjuvant chemotherapy (NAC) for early BC remains controversial.

Methods: We analyzed retrospectively data on 137 patients undergoing taxane and/or anthracycline, transtuzumab based NAC. Luminal A was documented in 6 pts, Luminal B in 29 pts, Her-2 positive in 30 pts and triple negative breast cancers (TNBC) in 72 pts. Pathological complete response (pCR) was defined as the complete disappearance of the invasive cancer in the breast and absence of tumor in the axillary lymph nodes examined by axillary clearance.

Results: The pCR rate of the entire cohort was 41.6%. At 2 years 92% of pts who attained a pCR were disease free compared to 80% of pts who did not attain a pCR (log rank test p < 0.0147). On univariate analysis factors associated with higher pCR included primary tumor size (T1 68% vs. T2 41% vs. T3 or T4 0%, Chi^2=20.05, p < 0.00017), nodal disease (N0 49% vs. N1 39% vs. N2 8%, p < 0.02948), ER receptor status (negative 59% vs. positive 14%, p < 0.00000), PR receptor status (negative 53% vs. positive 17%, p < 0.00002), molecular subtype (TNBC 53.4%, Her2=50% and Luminal A + B was 8.5%, p < 0.00002), Ki67 (>40=55% vs. 15-39=34% vs. <15=0%, p < 0.00060) and Stage (I = 85% vs. IIA=49% vs. IIB=36% vs. III=5%, p < 0.00006). Factors not associated with a higher pCR included age, menopausal status, extranodal spread and lympho-vascular invasion. In a logistic regression model Ki-67 as a continuous variable (p < 0.01203) and molecular subtype (p < 0.02228) retained its significance; while tumor size, stage of disease, nodal status, ER and PR loss significance.

Conclusions: Ki67 and molecular subtype (Her-2 positive disease and TNBC) are independent prognostic factors of pCR in pts with early BC undergoing NAC.

236P The accuracy of sentinel lymph node biopsy following neoadjuvant chemotherapy in clinically node positive breast cancer patients: A single institution experience

N. Sistany Allahabadi[1], H. Yahyazadeh[1], M. Hashemian[1], M. Rajabpour[1], S. Aminmozaffari[1], M. Zaree[1], A. Rezazadeh Mafi[2]

[1]Milad General Hospital, Clinical Cancer Research Center, Tehran, Iran, [2]Radiation Oncology, Shahid Beheshti University of Medical Sciences, Teheran, Iran

Background: Sentinel lymph node dissection (SLND) after neoadjuvant chemotherapy (NAC) is of questionable accuracy. In this study we evaluated the feasibility and accuracy of SLND in breast cancer patients with clinically positive axillary nodes.

Methods: We conducted a prospective cross-sectional study on breast cancer patients diagnosed at Milad Hospital of Tehran, Iran from June 2014 to February 2015. Biopsy-proven node positive patients who converted to clinically node-negative following NAC and had a successful SLND (more than three identified SLNs) were included in the study. We used a 2 × 2 contingency table to analyze the feasibility of SLNB (sensitivity, specificity, false negative ratio, and accuracy). STATA statistical software (version 13.0, StataCorp LP, Texas, USA) was used for statistical analysis.

Results: Among 52 patients who entered the study, 47 had a successful SLND (more than three identified SLNs) in whom we achieved a sensitivity of 100% (16/16), false-negative rate of 0% (0/21), a negative predictive value of 100% (16/16), and an overall accuracy of 89.4%.

Conclusions: SLND seems to be feasible and accurate in clinically lymph node positive breast cancer patients who achieve a clinically negative node status following neoadjuvant chemotherapy.

237P Index BRCA1/2 testing under a multidisciplinary program

D.H.R. Machado[1], S. Fragoso[1], A. Opinião[1], A. Clara[1], S. Bento[2], A.C. Luís[1], I. Miguel[1], S. Santos[3], P. Machado[3], P. Rodrigues[2], J. Parreira[2], F. Vaz[2]

[1]Medical Oncology, Instituto Português de Oncologia de Lisboa Francisco Gentil, E.P.E. (IPOLFG EPE), Lisbon, Portugal, [2]Risk Family Clinic, Instituto Português de Oncologia de Lisboa Francisco Gentil, E.P.E. (IPOLFG EPE), Lisbon, Portugal, [3]Molecular Pathology, Investigational Center, Instituto Português de Oncologia de Lisboa Francisco Gentil, E.P.E. (IPOLFG EPE), Lisbon, Portugal

Background: Germline BRCA1/2 mutations are the main cause of Hereditary Breast and Ovarian Cancer syndrome (HBOC). Whenever possible, Index testing should be done in a family member with a previous breast or ovarian cancer (affected individuals, AI) and not in non-affected individuals (NAI). In here we review the characteristics, decisional process and BRCA1/2 mutation detection rate of index testing in AI and NAI.

Methods: Analysis of all consecutive HBOC files registered from November 2000-December 2017. The BRCAPRO model was applied to affected patients (pts) and the Tyrer-Cuzick model to all non-affected female individuals. Comprehensive BRCA1/2 analysis was done, including MLPA and c.156_157insAlu testing (Machado PM et al., 2007)

Results: 6112 individuals were counseled and 4642 (76%) consented on genetic BRCA1/2 testing: 3420 (56%) index pts and 1222 (20%) family relatives. Index pts: 3361 (98.3%) had a previous cancer diagnosis (AI) and 59 were NAI. Both groups included mostly women (AI-95.2%; NAI-97%). The mean age for NAI was 40.7 years (20-79) and 79% had at least one-first degree relative with breast or ovarian cancer. Testing decision for NAI: either affected relatives were dead (80%), refused testing (15%) or were unreachable (5%). The global BRCA1/2 detection rate for index pts was 10.44%, being higher (13.6%) for NAI index cases (8 pathogenic variants: 2 BRCA1, 6 BRCA2). The mean pretest BRCA mutation probability (P) for NAI was 10.72% (range

0.06-42.8). This P was 18,5% for those who tested positive and 9,45% for inconclusive results ($p > 0.05$). The pre-test lifetime breast cancer risk was 26.69% for all NA cases, being higher for those found to be BRCA1/2 carriers (36.07% vs 28.04%).

Conclusions: Our conservative approach allowed for a detection rate in NAI that compared favorably to affected index pts. Although some groups propose widespread BRCA1/2 screening we suggest that NAI should be tested as index only if no cancer relatives are available. Despite the small sample size, the BRCA pre-test probability of 10% or higher seems to increase the detection rate in this subgroup.

238P BRCA1/BRCA2 germline mutations and chemotherapy-related hematological toxicity in breast cancer patients

A. Friedlaender[1], A. Vuillemier[1], V. Viassolo[1], A. Ayme[2], S. De Talhouet[3], J-D. Combes[4], J. Peron[5], A. Bodmer[1], S. Giraud[6], A. Buisson[6], V. Bonadona[7], I. Gauchat-Bouchardy[8], O. Tredan[3], P. Chappuis[1], S.I. Labidi-Galy[1]

[1]Department of Oncology, Hopitaux Universitaires de Geneve, Geneva, Switzerland, [2]Department of Genetics, Hopitaux Universitaires de Geneve, Geneva, Switzerland, [3]Department of Oncology, Centre Léon Bérard, Lyon, France, [4]Infections and Cancer Epidemiology Group, International Agency for Research on Cancer, Lyon, France, [5]Departement of Medical Oncology, Hospices Civils de Lyon, Pierre-Bénite, France, [6]Division of Molecular Genetics, Hospices Civils de Lyon, Pierre-Bénite, France, [7]Unit of Prevention and Genetic Epidemiology, Centre Leon Berard, Lyon, France, [8]Department of Genetic Medicine, Hopitaux Universitaires de Geneve, Geneva, Switzerland

Background: BRCA1 and BRCA2 proteins play a central role in DNA repair process. We hypothesize that BRCA1/BRCA2 germline mutation carriers may exhibit increased hematological toxicity when receiving genotoxic chemotherapy.

Methods: We included women with primary breast cancers treated with (neo)adjuvant chemotherapy and screened for BRCA1/BRCA2 germline mutations in Geneva (Swiss cohort). The primary endpoint was the incidence of febrile neutropenia following the first chemotherapy cycle (C1). Secondary endpoints were the incidence of grade 3-4 neutropenia, grade 4 neutropenia and hospitalization during C1, G-CSF use, and chemotherapy dose reduction during the entire chemotherapy regimen. Long-term toxicities (hematological, cardiac and neuropathy) were assessed in the Swiss cohort and a second cohort of patients from Lyon (French cohort).

Results: Overall, 221 patients were assessed for acute hematological toxicity, including 23 BRCA1 and 22 BRCA2 carriers. None of the patients received dose-dense (every 14 days) chemotherapy. Following the C1, febrile neutropenia had an incidence of 35% ($p = 0.002$), 14% ($p = 0.562$) and 10% among BRCA1, BRCA2 and non-carriers, respectively. Grade 4 neutropenia was found in 57% of BRCA1 ($p < 0.001$), 14% of BRCA2 ($p = 0.861$) and 18% of non-carriers. G-CSF support was necessary in 86% of BRCA1 ($p = 0.005$), 64% of BRCA2 ($p = 0.285$) and 51% of non-carriers. Among patients with triple-negative breast cancers, febrile neutropenia (35% vs. 12%, $p = 0.038$), grade 3-4 neutropenia (73% vs. 28%, $p = 0.003$) and grade 4 neutropenia (60% vs. 13%, $p = 0.001$) were significantly more frequent in BRCA1 carriers compared to non-carriers. Among BRCA1 carriers, the majority of patients were likely to have grade 3-4 neutropenia (88%; $p < 0.001$), but none of those having mutations located in the RING domain (0%, $p = 0.165$) compared to non-carriers. For long-term toxicity analysis, 898 patients were included (167 BRCA1-, 91 BRCA2- and 640 non-carriers). There was no difference between the three groups.

Conclusions: BRCA1 germline mutations predispose breast cancer patients to greater acute hematological toxicity. This has implication for primary prophylaxis with G-CSF.

239P PALB2 germ-line mutations in Russian breast cancer patients: Identification of recurrent alleles and analysis of phenotypic characteristics of the tumors

E.N. Imyanitov[1], E.V. Preobrazhenskaya[1], A.Y. Shlejkina[1], A.P. Sokolenko[1], E.I. Anisimova[2], A.O. Ivantsov[1], A.V. Togo[1]

[1]Department of Tumor Growth Biology, N.N. Petrov Institute of Oncology, St. Petersburg, Russian Federation, [2]Outpatient Department, Leningrad Regional Oncological Dispensary, St. Petersburg, Russian Federation

Background: PALB2 is a well-known gene for hereditary breast cancer (BC). However, PALB2-driven BCs are less studied as compared to BRCA1/2-related malignancies, due to rarity of PALB2 deleterious alleles.

Methods: PALB2 germ-line mutation analysis was performed using blood-derived DNA.

Results: Sequencing of the entire coding region of PALB2 gene in 190 BC patients, who had evident clinical features of hereditary disease, but lacked BRCA1/2 germ-line mutations, led to the identification of 5 PALB2 mutation carriers. In addition, we considered 4 PALB2 heterozygotes, which were identified in our earlier study [Sokolenko et al., 2015]. The mutation spectrum was represented by 7 distinct pathogenic alleles (c.1317delG, c.172-175delTTGT, c.509-510delGA, R414X (n = 2), Q921X, c.1592delT and Y1055X (n = 2)). These 7 mutations were further screened in 1126 consecutive BC cases. This analysis revealed 8 additional instances of PALB2 mutations (c.509-510delGA (n = 5), c.172-175delTTGT (n = 2), c.1592delT (n = 1)). None of the above mutations was detected in 638 elderly tumor-free controls. Among 18 patients with PALB2-related BC, only 8 women were younger than 50 years; 6 patients reported family history of BC disease and 4 suffered from bilateral BC. IHC data were available for 10 tumors: 1 case was triple-negative, 1 BC demonstrated HER2 activation coupled with negative staining for hormone receptors (HR), and the remaining 8 cases were HR+. Loss-of-heterozygosity (LOH) analysis of 8 chemonaive BCs revealed somatic deletion of the remaining PALB2 allele in 5 tumors and retention of heterozygosity in 3 cases. In addition, we analysed 2 residual BC samples obtained after neoadjuvant therapy and revealed the intact PALB2 wild-type allele in both cases.

Conclusions: PALB2 germ-line mutations contribute to a fraction of BC morbidity in Russia, with PALB2 c.509-510delGA allele being the most frequent pathogenic variant. Interpatient variability with regard to somatic inactivation of the wild-type PALB2 allele deserves attention, given that intratumoral PALB2 status is likely to influence the drug sensitivity of BC.

240P Landscape of germline mutations in hereditary breast and ovarian cancer (HBOC) patients in Russia revealed by target panel sequencing

E. Shagimardanova[1], L.H. Shigapova[1], R.F. Enikeev[2], M. Druzhkov[2], A. Nikitin[3], O. Gusev[1], M. Gordiev[4]

[1]Institute of Fundamental Medicine and Biology, Kazan Volga Region Federal University, Kazan, Russian Federation, [2]Chemotherapy Department, Kazan Clinical Oncology Center, Kazan, Russian Federation, [3]Genetic Laboratory, Federal Research and Clinical Center, FMBA, Moscow, Russian Federation, [4]Laboratory of Molecular Genetics, Tatarstan Cancer Center, Kazan, Russian Federation

Background: Hereditary breast and ovarian cancer (HBOC) is one of the most frequent disorders among other cancers, caused by presence of germline pathogenic variants in patients. Awareness about presence of actionable mutations (BRCA1,2, ATM and others) is beneficial for patients with breast and ovarian cancer due to possibility of targeted treatment, monitoring risk groups among healthy carries and other aspects. In this study we reveal and characterize pathogenic germline mutations in HBOC patients from different regions in Russian Federation.

Methods: Individuals with "family history" were chosen to be included in this study according to the following criteria: (1) young age of disease onset, (2) the presence of relatives with breast or ovarian cancer diagnosis. Information about nationality, age at diagnosis, family cancer history, estrogen, progesterone and Her2 receptor status was collected. The NimbleGen SeqCap EZ Choice kit ("Roche") was used for target enrichment, and sequencing was performed using Illumina MiSeq ("Illumina") using paired-end 2 × 251 nucleotide single-index sequencing. HGMD Professional 2017.4 and BIC databases were used to identify pathogenic mutations.

Results: 568 patients with breast or ovarian cancer aged from 21 to 82 years old were included in this study. 103 woman has their first cancer diagnosis before 40 years old, 305 – between 40 and 60 years old, 160 - were older than 60. 193 patients had first degree kinship relatives suffered from HBOC syndrome and 165 patients had relatives with other cancers. Of the 568 patients, 22,5% (128) carried pathogenic or likely pathogenic mutation in BRCA1 gene, 9,2% (52) in BRCA2 gene, 17,6% (100) in one of other HBOC related genes, including CDK12, ATM, CDH1, APC, FANCI, CHEK2, FANCL, BARD1, RAD51C, MUTYH, RAD51D, PALB2, FANCA, XRCC2, RAD54L, CHEK1.

Conclusions: Among patients with fulfilling NCCN criteria of hereditary breast or ovarian cancer, only 30% of cases might be explained by BRCA1 or BRCA2 mutation. Panel sequencing is powerful strategy to find variants in other genes, which may play a role in cancer development. It has to be noted that many variants in non-BRCA genes were identified is of unknown significance (VUS) due to absence of database with common variants for Russian population.

241P Lynch syndrome-associated hereditary mutations cause breast and ovarian cancer: Results from Russian Heredetary Oncogenomics project

M. Gordiev[1], L.H. Shigapova[2], O. Brovkina[3], R.F. Enikeev[4], M. Druzhkov[4], A. Nikitin[5], E. Shagimardanova[2], O. Gusev[2]

[1]Molecular-Diagnostic Laboratory, Tatarstan Cancer Center, Kazan, Russian Federation, [2]Institute of Fundamental Medicine and Biology, Kazan Volga Region Federal University, Kazan, Russian Federation, [3]Genetic Laboratory, Federal Research and Clinical Center, FMBA of Russia, Moscow, Russian Federation, [4]Chemotherapy Department, Kazan Clinical Oncology Center, Kazan, Russian Federation, [5]Genetic Laboratory, Federal Research and Clinical Center, FMBA, Moscow, Russian Federation

Background: Lynch syndrome is a hereditary disease caused by mutations in DNA mismatch repair system (MMR), which includes ML1, MS2, MS6, PMS2, EPCAM genes. Clinical manifestation of the Lynch syndrome is usually colorectal cancer (CRC), endometrial cancer, ureteral cancer and kidney cancer. We aimed to analyze occurrence of mutations in MMR system genes in patients with hereditary breast and ovarian cancer.

Methods: We have analyzed 228 samples of blood from patients with hereditary breast (BC) and ovarian cancer (OC) in Tatarstan Regional Clinical Cancer Center, Russia. The criteria for inclusion was at least one out of three observations: Young age of manifestation of breast or ovarian cancer (before 50 y.o. for BC and 55 y.o. for OC), first or second-degree relatives with breast or ovarian cancer, primary-multiple BC and OC. The libraries for sequencing were prepared using NimblGen SepCapEZ Choice (Roche) with custom gene panel followed by sequencing on MiSeq platform.

Results: Eight out of 101 (8%) patients with hereditary OC and five out of 127 (4%) patients with hereditary BC carried pathogenic mutation in one of MMR genes. Average age of manifestation of BC and OC in the patients with Lynch syndrome was 54 y.o. in case of OC and 56 y.o. in case of BC group: 50 y.o. Nine women had first and second-degree relatives with either BC, OC, colon or esophagus cancer. The distribution of affected genes in HBOC cohort was as follows: 3 patients with mutation in MSH6 gene, 4 patients with mutation in PMS2 gene, 2 patients with mutation in MSH2 gene, 3 patients with mutation in mlH1 gene. One patient carried mutation in EPCAM gene.

Conclusions: To date, the clinical standard for screening for Lynch syndrome is the Amsterdam criteria II, which are not oriented to the occurrence of OC and BC in patients, as well as to the presence of these cancers in a hereditary history in patients with colorectal cancer. However, our experience shows that patients with signs of hereditary OC and BC also can be carriers of mutations in the genes of the MMR system, which determine the Lynch syndrome. Thus, impact of Lynch syndrome-associated germline mutation on other types of cancer should be reconsidered and studied in detail.

242P Impact of deleterious germline BRCA mutations, addition of taxanes and use of adjuvant endocrine therapy (ET) on anti-müllerian hormone (AMH) levels in early breast cancer (EBC) patients treated by adjuvant chemotherapy (CT)

N. Olympios[1], M. Lambertini[2], C. Calbrix[3], M. Saint-Ghislain[1], M. Fontanilles[1], A. Loeb[4], M. Leheurteur[1], I. Demeestere[5], F. Di Fiore[1], A. Perdrix[3], F. Clatot[1]

[1]Medical Oncology, Centre Henri Becquerel, Rouen, France, [2]Department of Medicine Institute Jules Bordet, Brussels, Belgium, [3]Biopathology, Centre Henri Becquerel, Rouen, France, [4]Medical Information Department, Centre Henri Becquerel, Rouen, France, [5]Fertility Clinic, Hopital Erasme, Brussels, Belgium

Background: AMH is a promising biomarker of treatment-induced gonadal damage. The impact of carrying a deleterious germline BRCA mutation, adding a taxane to anthracycline-based CT and using adjuvant ET on gonadal function following CT remains unclear. We assessed the influence of these 3 factors on AMH levels before and after adjuvant CT in EBC patients.

Methods: This monocentric retrospective study included consecutive EBC patients aged ≤40 years treated with adjuvant FEC CT between 2008 and 2016, known germline BRCA status and available frozen plasma samples before and after CT. AMH levels (ng/mL) were assessed before starting CT, 1 year and over 3 year after diagnosis.

Results: 148 patients were included. 35 (24%) patients harbored a deleterious germline BRCA mutation, 127 (86%) received a taxane following FEC CT and 90 (61%) had adjuvant ET after CT. Overall median age was 35 (range 22-40). In the whole cohort, median AMH levels dropped after adjuvant CT (from 1.69 to 0.06, $p < 0.0001$) and slightly recovered after 3 years (0.17, $p < 0.0001$). No difference in baseline (1.94 vs 1.66, $p = 0.53$), 1-year (0.09 vs 0.06, $p = 0.39$) or 3-year (0.25 vs 0.16, $p = 0.43$) AMH levels was observed between patients with or without a BRCA mutation. Significant lower AMH levels were observed for patients who received a FEC-taxane regimen as compared to those treated with FEC only CT 1 year after diagnosis (0.04 vs 0.22, $p = 0.0006$), with no difference at 3 years (0.18 vs 0.06, $p = 0.47$). Patients treated with adjuvant ET had slightly higher AMH levels than those who did not receive ET 1 year after diagnosis (0.12 vs 0.02, $p = 0.008$) with no difference at 3 years (0.11 vs 0.20, $p = 0.22$).

Conclusions: Use of adjuvant CT is associated with a significant and durable alteration in ovarian reserve measured by AMH levels. Addition of taxanes to FEC increased CT-induced gonadotoxicity immediately after CT exposure but not at longer follow-up. Carrying a germline BRCA mutation and using adjuvant ET following CT were not associated with additional negative impact on patients' ovarian reserve after treatment.

Background: The phase III neoadjuvant GeparOcto trial (NCT02125344) randomized patients with triple negative breast cancer (TNBC) to receive treatment with intensified dose-dense epirubicin (E), paclitaxel (P), and cyclophosphamide (C; iddEPC) or weekly paclitaxel/liposomal doxorubicin (PM), plus carboplatin (Cb). Data on germline mutational analysis of patients with TNBC and the correlation with pathological complete response (pCR ypT0/is ypN0) were analysed.

Methods: NGS-based germline mutational analysis of BRCA1/2 and further 16 BC predisposition or candidate predisposition genes was carried out in 393 patients (iddEPC n = 194, PMCb n = 199). Deleterious (IARC class 4/5) variants were validated by Sanger sequencing. Detection of copy number variations (CNV) was carried out using an in-house CNV detection tool and established open access tools. Validation of CNVs was performed by either multiplex ligation-dependent probe amplification or real-time PCR.

Results: Overall, 69 of 393 (17.6%) patients carry pathogenic mutations in the BRCA1/2 genes. In 324 BRCA1/2-negative patients, 30 patients carry mutations in at least one of the 16 further analysed genes (9.3%). Of those, two patients carry mutations in two genes (ATM/CHEK2, PALB2/XRCC2) and 28 carry mutations in one gene (n = 2 BARD1, n = 5 BRIP1, n = 1 CHEK2, n = 9 FANCM, n = 1 NBN, n = 8 PALB2, n = 1 RAD50, n = 1 RAD51C); no mutations were found in CDH1, MRE11A, PTEN, RAD51D, STK11, and TP53). Overall patients with a BRCA1/2 mutation had a pCR of 69.6% vs 46.0% without a mutation ($p < 0.001$). In the iddETC group, patients with a BRCA1/2 mutation had a pCR of 64.7% vs 45.0% without a mutation ($p = 0.040$); in the PMCb arm, patients with a BRCA1/2 mutation had a pCR of 74.3% vs 47.0% without a mutation ($p = 0.005$).

Conclusions: Our data confirm that BRCA1/2 germline mutations represent a predictive biomarker for the achievement of pCR following neoadjuvant anthracycline-taxane-containing chemotherapy for TNBC.

Clinical trial identification: NCT02125344.

244P BRCA1/BRCA2 predictive genetic testing in an Irish population: A missed opportunity

D.E. O Reilly[1], L. Dooley[2], G. Watson[3], R. Clarke[3], A. Nolan[3], C. Nolan[3], E. Berkeley[3], M.P. Farrell[4], D. Gallagher[1]

[1]Medical Oncology, St James's Hospital, Dublin, Ireland, [2]Radiation Oncology, St Lukes Hospital, Dublin, Ireland, [3]Department of Cancer Genetics, St James's Hospital, Dublin, Ireland, [4]Department of Cancer Genetics, Mater Private Hospital, Dublin, Ireland

Background: The diagnosis of a BRCA1/2 mutation has significant implications for both probands and their families, with both screening and prophylactic surgical interventions available. Underutilisation of genetic testing services has been reported in other jurisdictions. BRCA1/2 testing is requested in only 29-53% of eligible women and 11-12% of eligible men, represented a missed cancer prevention opportunity. Possible explanations include lack of family disclosure, poor access or lack of awareness of genetic counselling services, or patient preference. We investigated the rates of BRCA1/2 predictive testing in an Irish population.

Methods: We performed a multicentre, retrospective analysis of 63 pedigrees from two Irish tertiary hospitals over a five-year period (2012-2017). By manually examining pedigrees, we identified eligible family members who should receive BRCA1/2 mutation testing as per national guidelines.

Results: A total of 1048 candidates for predictive BRCA1/2 mutation testing were identified. 318 (30.4%) proceeded to BRCA1/2 mutation testing including 215 (37.5%) females and 99 males (21.5%). Uptake of testing favouring women was statistically significant ($T = 3.7$, $p < .0002$).

Conclusions: We demonstrate suboptimal uptake of BRCA1/2 mutation testing in the Irish population, particularly among Irish males. Predictive BRCA1/2 testing and subsequent screening/surveillance/prophylactic intervention in mutation carriers can meaningfully impact breast cancer survival. This represents a missed cancer prevention opportunity for Irish society.

245P Incidence and survival among young women with stage I-III breast cancer

A. Thomas[1], A. Rhoads[2], E. Pinkerton[2], M.C. Schroeder[3], J.J. Oelson[2], L.R. McNally[4], W.G. Hundley[1], K. Conway[2], C.F. Lynch[2], P.A. Romitti[2]

[1]Internal Medicine, Wake Forest University, Winston Salem, NC, USA, [2]Public Health, University of Iowa, Iowa City, IA, USA, [3]Pharmacy, University of Iowa, Iowa City, IA, USA, [4]Cancer Biology, Wake Forest University, Winston Salem, NC, USA

Background: De novo Stage IV breast cancer (BC) is increasing in premenopausal women. Less is known about current incidence and survival among these women with Stage I-III BC.

Methods: Women ages 20-29 ($N = 3,826$), 30-39 ($N = 34,585$), 40-49 ($N = 126,552$) and 50-59 ($N = 172,448$) diagnosed with Stage I-III BC from 2000-15 were identified from the US Surveillance, Epidemiology and End Results database. Age-adjusted, annual percentage changes (APC) in incidence and 10-year Kaplan-Meier survival curves were estimated by stage, hormone receptor (HR) status, and grade (low: well/moderately differentiated; high: poorly/undifferentiated) for each age decade.

Results: Stage III BC at presentation decreased with age (20-29 [23.9%], 30-39 [21.9%], 40-49 [16.1%], 50-59 [14.1%]); the opposite pattern was observed for Stage I (23.6%, 28.8%, 42.0%, 48.3%, respectively). HR+ high grade and HR- BCs also decreased with age (20-29 [34.5%, 36.5%], 30-39 [31.1%, 31.6%], 40-49 [23.9%, 21.4%], 50-59 [20.9%, 21.1%]). Among all BC presentations, age-adjusted APC in incidence was higher for women 20-29 (1.6) than those 30-39 (0.3), 40-49 (0.3) or 50-59 (-1.1). Incidence of HR+ low and high-grade BC increased for women <50 with the highest APC (5.7 and 3.8, respectively) for women 20-29; HR- BC incidence decreased for all ages. Among women 20-29, 10-year survival was lowest for those with HR+ high grade BC (Table); for this group, the greatest survival difference between HR+ high grade and HR- BC was for Stage I BC (79.8% vs 89.3%) compared to Stage II (77.2% vs 80.7%) or Stage III (44.9% vs 45.0%). Comparing Stage III BC across age decades, 10-year survival was lowest for women 20-29, notably for HR+ BC.

Table: 245P

Stage	HR Status	Grade	10-Year Survival % (Standard Error)			
			Age (years)			
			20-29	30-39	40-49	50-59
Any	+	Low	81.2 (1.9)	85.4 (0.5)	91.1 (0.2)	89.2 (0.1)
	+	High	67.7 (2.0)	75.3 (0.6)	80.2 (0.3)	77.1 (0.3)
	-		73.8 (1.5)	74.3 (0.5)	75.1 (0.3)	74.3 (0.3)
Stage III	+	Low	54.2 (5.7)	62.8 (1.6)	73.7 (0.7)	68.3 (0.7)
	+	High	44.9 (3.9)	55.7 (1.3)	60.1 (0.8)	54.2 (0.8)
	-		45.0 (3.5)	49.2 (1.2)	49.8 (0.8)	47.5 (0.7)

Conclusions: Among young women, HR+ BC is increasing in incidence and associated with reduced survival for those 20-29. Understanding the etiologies underlying these trends may inform strategies directed toward improving outcomes for these women.

246P Toxicity and clinical outcomes of partial breast irradiation (PBI) compared to whole breast irradiation (WBI) for early stage breast cancer: A systematic review and meta-analysis

H. Goldvaser[1,3], A. Fyles[2], D. Shepshelovich[1], E. Amir[1], Y. Korzets[2,3]

[1]Medical Oncology, Princess Margaret Cancer Centre, Toronto, ON, Canada, [2]Radiation Oncology, Princess Margaret Cancer Centre, Toronto, ON, Canada, [3]Davidoff Cancer Center, Beilinson Hospital, Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel

Background: There is uncertainty about efficacy and toxicity differences between adjuvant PBI and WBI in women with early-stage breast cancer treated with breast conservation.

Methods: We identified randomized trials that compared PBI to WBI in early-stage invasive breast cancer using PubMed. Odds ratios (ORs), 95% confidence intervals

Table: 246P

	OR, 95% CI	P value all/ subgroup difference	Weighted absolute difference
5-year local recurrence			
All	2.28 (1.66-3.15)	<0.001	1.47%
EBRT IORT Brachytherapy	0.64 (0.25-1.62) 3.1 (2.12-4.51) 1.44 (0.63-3.29)	0.004	
5-year regional recurrence			
All	1.49 (0.88-2.53)	0.14	0.3%
EBRT IORT Brachytherapy	1.96 (0.20-18.92) 1.45 (0.80-2.63) 1.56 (0.39-6.27)	0.97	
5-year contralateral breast cancer			
All	0.94 (0.59-1.47)	0.77	-0.1%
EBRT IORT Brachytherapy	0.85 (0.44-1.63) 1.54 (0.65-3.66) 0.64 (0.25-1.62)	0.37	
5-year death without breast cancer recurrence			
All	0.55 (0.41-0.73)	<0.001	-1.6%
EBRT IORT Brachytherapy	0.71 (0.42-1.20) 0.45 (0.29-0.69) 0.57 (0.29-1.13)	0.41	
5-year overall survival			
All	0.76 (0.61-0.95)	0.02	-1.1%
EBRT IORT Brachytherapy	0.79 (0.51-1.22) 0.78 (0.59-1.04) 0.61 (0.32-1.14)	0.75	

(CI) and absolute risks were computed for pre-specified efficacy and toxicity outcomes including cosmetics. Subgroup analysis evaluated the effect of PBI modality (external beam radiation treatment [EBRT], intraoperative radiation treatment [IORT] or brachytherapy) on efficacy. Meta-regression analysis explored the influence of median follow-up as well as patients and tumor characteristics on results.

Results: Eight trials comprising 10298 patients were included. Efficacy results, weighted absolute differences and subgroup analysis are shown in the table. PBI was associated with increased odds of local recurrence compared to WBI. However, PBI was associated with reduced odds of death without breast cancer recurrence and improved overall survival (OS). Subgroup analysis showed the effect on local recurrence was influenced by modality of radiation; odds of local recurrence were increased with IORT and brachytherapy, but not with EBRT. Nodal involvement was associated with higher local recurrence risk while larger tumors were associated with lesser improvement in death without breast cancer recurrence and OS. PBI was associated with higher odds of fat necrosis ($p = 0.002$). Worse cosmetic outcome with PBI approached significance ($p = 0.06$).

Conclusions: Compared to WBI, PBI is associated with higher odds for local recurrence and toxicity, but less death without breast cancer recurrence and improved OS. The balance between benefit and risk of PBI appears optimal for women with smaller ER positive tumors and without nodal involvement.

247P Should anthracyclines always be present in the adjuvant treatment of breast cancer (BC)? A systematic review and meta-analysis of randomized controlled trials (RCTs)

R. Caparica[1], M. Bruzzone[2], F. Poggio[1], M. Ceppi[2], E. de Azambuja[3], M. Lambertini[1]

[1]CTSU, Institute Jules Bordet, Brussels, Belgium, [2]Biostatistics, IRCCS AOU San Martino - IST-Istituto Nazionale per la Ricerca sul Cancro, Genoa, Italy, [3]Medical Oncology, Institute Jules Bordet, Brussels, Belgium

Background: Anthracycline and taxane-based (A+T) chemotherapy (CT) is the current standard adjuvant CT for HER2-negative BC patients. However, anthracyclines can be associated with important short and long-term toxicities (e.g. cardiotoxicity and leukemias). After a phase 3 trial demonstrated that docetaxel+cyclophosphamide (TC) was more effective than doxorubicin + cyclophosphamide (AC), the use of TC has increased. Nevertheless, RCTs could not demonstrate that TC is non-inferior to the standard A+T. This is a systematic review and meta-analysis of RCTs comparing A+T versus TC as adjuvant CT in HER2-negative BC patients.

Methods: A literature search using PubMed, EMBASE, Cochrane, ASCO, ESMO and SABCS websites was performed up to March 30, 2018, to identify RCTs comparing TC vs A+T as adjuvant CT in HER2-negative BC patients. Disease-free survival (DFS) and overall survival (OS) were assessed. A subgroup analysis of DFS in hormone receptor positive (HR+) and negative (HR-) disease was also performed. Hazard ratios (HR) and 95% confidence intervals (CI) for DFS were extracted from each trial, and a pooled analysis was conducted using the random-effect model. The Higgins' I-Squared Test was used to quantify heterogeneity.

Results: A total of 8 RCTs that randomized 12,741 early BC patients were included. Five RCTs were published as pooled results: ABC trials comprised 3 RCTs, and PlanB + Success-C comprised 2 RCTs. The comparison of TC versus A+T demonstrated a non-significant benefit in favour of A+T for both DFS (HR 1.08, 95% CI 0.96 - 1.20) and OS (HR 1.05; 95%CI 0.90 – 1.22). The magnitude of the benefit of A+T was more pronounced in patients with HR- disease, (N = 1,947, HR 1.12, 95% CI 0.93 – 1.34) compared to those with HR+ disease (N = 4,867, HR 1.05, 95%CI 0.86 – 1.27).

Conclusions: Globally, our results showed that A+T was associated with a slight non-significant improvement in DFS and OS as compared to TC. Nevertheless, in selected patients such as those with HR+ disease, TC may be considered an alternative option to avoid the toxicities of anthracycline-based CT.

248P Taxane & cyclophosphamide vs anthracycline & taxane combination therapy as adjuvant treatment of breast cancer: A meta-analysis of randomized-controlled trials by the Hellenic Academy of Oncology (E.AK.O.)

P. Ntellas[1], N. Spathas[2], D. Zylis[3], S. Agelaki[4], E. Zintzaras[1], E. Saloustros[5]

[1]Biostatistics and Clinical Bioinformatics, Faculty of Medicine, University of Thessaly, Larissa, Greece, [2]Oncology Unit, Attikon University Hospital, Athens, Greece, [3]1st Department of Medical Oncology, Agios Savvas Regional Cancer Hospital, Athens, Greece, [4]Department of Medical Oncology, School of Medicine, University of Crete, Heraklion, Crete, Greece, [5]Oncology Unit, Venizeleio General Hospital, Heraklion, Greece

Background: Adjuvant chemotherapy has an indisputable value for early breast cancer. Taxane + cyclophosphamide combination (TC) has demonstrated superiority against cyclophosphamide + anthracycline (AC) in disease-free (DFS) and overall survival (OS). However, 5 randomized clinical trials (RCTs) failed to show non-inferiority of TC compared to an anthracycline-taxane combination (TaxAC). We conducted a meta-analysis of these RCTs to better estimate the cumulative evidence for non-inferiority of TC against TaxAC, in the adjuvant setting of HER2-negative, breast cancer.

Methods: The ABC trials, the Plan B trial and a trial by the Hellenic Oncology Research Group (HORG) were meta-analyzed. The DFS was the primary endpoint. A DFS-HR of 1.18 for TC versus TaxAC, was chosen to demonstrate inferiority, as it was the most conservative measure among the included studies. Secondary endpoints were OS and toxicity profile.

Results: Overall, 7,341 patients composed the meta-analysis population. We didn't encounter heterogeneity between the trials (Q-test $p = 0.55$, I^2:0%) and no publication bias was detected. Non-inferiority of TC was not established (DFS-HR=1.11, 95%CI: 0.95-1.30, $p = 0.18$). The combined DFS rates, according to the time points set by each study, were 89.04% versus 90.35% for TC and TaxAC respectively. Non-inferiority of TC was also not proven for the node-negative population either (HR = 1.05, 95%CI: 0.82-1.34, $p = 0.71$). Grade 3-4 leucopenia (OR: 1.2, 95%CI:1.068-1.348, $p = 0.002$) and thrombocytopenia (OR = 6.455; 95%CI:2.902-14.359, $p < 0.001$) prevailed in the TaxAC group, while cardiotoxicity was also increased (OR = 2.283; 95%CI:1.155-4.514, $p = 0.015$).

Conclusions: Although the TC combination was not proven to be non-inferior to TaxAC, the present analysis narrows the HR of recurrence risk of recurrence with a difference in the DFS rate of only 1,31%. Taking into account the more favorable safety profile of the TC combination, the question as to which treatment regimen should be preferred under what circumstances needs to be individualized according to patients' characteristics and desires.

249P Risk of cardiovascular late effects in breast cancer survivors: A population-based study

J. Lee[1], I.Y. Chung[2], Z. Kim[3], H. Hur[4], J.W. Lee[2], H.J. Youn[5]

[1]Surgery, Soonchunhyang University Hospital Seoul, Seoul, Republic of Korea, [2]Surgery, Asan Medical Center, Seoul, Republic of Korea, [3]Surgery, Soonchunhyang University Hospital, Bucheon, Republic of Korea, [4]Surgery, National Health Insurance Service Ilsan Hospital, Goyang, Republic of Korea, [5]Surgery, Chonbuk National University Medical School, Jeonju, Republic of Korea

Background: Cardiovascular diseases are one of the late effects of breast cancer treatment that can impair survival. We reviewed the development of cardiac disease in breast cancer survivor using nationwide database.

Methods: A nation-wide retrospective cohort study was conducted using National Health Information Database which provides a whole set of claimed medical information, such as ICD-10 diagnosis and prescription data. We performed 1:5 age-sex matching with the non-cancer controls. Incidence of MI and CHF was evaluated for adjuvant treatment modalities, with adjustment of age and previous comorbidities (diabetes, hypertension, and hyperlipidemia).

Results: A total of 112,058 cases (554,801 person-years) and 560,290 controls (2,916,459 person-years) were evaluated. Risk of MI (hazard ratio (HR) 1.258, 95% confidence interval (CI) 1.168 - 1.355) and CHF (HR 1.86, 95% CI 1.753 – 1.973) was higher in breast cancer survivors than in non-cancer controls. Younger survivors (age 50 or less) showed the highest risk of MI (HR 1.73, 95% CI 1.512 – 1.979) and CHF (HR 3.557, 95% CI 3.174 – 3.986). Within one year of breast cancer diagnosis, the cumulative incidences of MI and CHF were significantly high in survivors. The cumulative incidence of CHF in breast cancer survivors was continuously higher than the control group, in contrast to that of MI showed similar pattern to controls. Taxane use was associated with development of MI (HR 1.284, 95% CI 1.074 – 1.534) and CHF (HR 1.65, 95% CI 1.444 – 1.887).

Conclusions: Incidence of MI and CHF were higher in breast cancer survivor than the non-cancer controls. The elevated risk of MI and CHF in early phase of survivorship should be noted, especially in young age group.

250P Diagnostic value of contrast enhanced digital mammography versus contrast enhanced MRI for preoperative evaluation of breast cancer

E.Y. Kim, I. Youn, C.H. Park, S.H. Kook

General Surgery, Kangbuk Samsung Hospital Sungkyunkwan University, Seoul, Republic of Korea

Background: This study aimed to compare the diagnostic performance of pre-operative evaluation of contrast-enhanced digital mammography (CEDM) and contrast-enhanced magnetic resonance imaging (CEMRI) and to evaluate the effect of each modality to the surgical management in women with breast cancer.

Methods: This single-institution prospective study was approved by the Institutional Review Board and informed consent was obtained from all patients. From November 2016 to October 2017, 84 patients, who were diagnosed as invasive carcinoma (69/84) and ductal carcinoma in situ (DCIS) (15/84) underwent both CEDM and CEMRI, were enrolled. We correlated the imaging findings and surgical management with pathologic results, and compared the diagnostic performance of both modalities in the detection of index and secondary cancers (multifocality and multicentricity), and occult cancer in contralateral breast. We also evaluated whether CEDM or CEMRI made changes in surgical management of the affected breast attributed to imaging-detected findings.

Results: Eighty-four women were included for analysis. CEDM, in comparison to CEMRI, had a significantly higher specificity (66.7% vs 22.2%, $P = 0.021$), similar sensitivity (94.6% [78/84] vs 93.5% [81/84]), PPV (93.5% vs 86.0%) and a fewer false positive findings (66.7% [10/15] vs 93.3% [14/15]) in detecting index cancer. For detection of secondary cancers on ipsilateral breast and occult cancer in contralateral breast, no significant differences were found between CEDM and CEMRI (all $P > 0.05$). Regarding changes in surgical management, CEDM made less change (36.9% [31/84] vs 41.7% [35/84]) than CEMRI, owing to less false positive findings (48.4% [15/31] vs 54.3% [19/35]).

Conclusions: CEDM showed comparable diagnostic performance with CEMRI in depicting index, secondary cancers, and occult cancer in contralateral breast. The CEDM, owing to fewer false positive results, made less change in surgical management compared to CEMRI.

252P Relationship between androgen receptor and tumor-infiltrating lymphocytes in triple-negative breast cancer

L.F. Sánchez-Cousido[1], A. López-González[1], E. Honrado Franco[2], E. Vallejo Pascual[3], O. Sanz[4], L. Lopez Gonzalez[5], I. Delgado[1], M. López-Flores[6], A. García Palomo[6]

[1]Oncology, Complejo Asistencial Universitario de León, León, Spain, [2]Pathology, Complejo Asistencial Universitario de León, León, Spain, [3]Economic and Statistic, Universidad de León, León, Spain, [4]General Surgery, Complejo Asistencial Universitario de León, León, Spain, [5]Radiology, Complejo Asistencial Universitario de León, León, Spain, [6]Oncología Médica, Complejo Asistencial Universitario de León, León, Spain

Background: Triple-negative breast cancer (TNBC) is considered a poor prognostic subtype and a heterogeneous entity. Its only treatment is chemotherapy. Immunotherapy and antiandrogen therapies are being tested. Androgen receptor (AR) is expressed in up to 53% of TNBC. It is associated with a better disease-free survival and overall survival. The relation between tumor infiltrating lymphocytes (TIL) and AR in urothelial cancers has been assessed, unlike in TNBC.

Methods: 50 stage I-III TNBC patients diagnosed between 2008 and 2013 were analyzed. Minimum follow-up was 57 months or until death. On these samples fixed in 10% formalin and included in paraffin, the evaluation of the expression of AR, CD20, CD4 and CD8 was performed by immunohistochemistry. AR+ was defined by more than 1% expression. Lymphocytes were evaluated as per the recommendations of the International Expert Consensus. We also analyzed total lymphocytes as high/low if they were over/under 80%. Data was analyzed by SPSS version 23.

Results: Clinical characteristics are as follows: mean age of 61 years old, and postmenopausal 68%. 74% of the patients did not relapse and progression-free survival (PFS) was 95,6 months. Main tumor characteristics were Ki67>20%, 67,3%; T1-T2 88%; high grade 67,4%; lymph node (N) positive 51%. Early stage (stage I-II) was the 80%. High level of lymphocytes (HiL) was present in 70% of them. AR + (26%) was associated with younger patients ($p = 0.009$), low Ki67 ($p = 0.014$) and N + ($p=0.025$). No relation was obtained between AR and TIL, tumor size, grade, stage or survival. CD8+ were more present in AR + ($p=0.002$) and so the proportion CD4/CD8 (CD8>CD4 in AR+; CD4>CD8 in AR-. $p = 0.026$) HiL was related with higher Ki67 ($p = 0.021$) and grade 3 ($p = 0.029$). However, lower relapse and also lower deaths were observed in those with HiL (15.4% vs 84.6%; 21.4% vs 78.6%). In HiL, percentage of CD8+ was inversely proportional ($p = 0.021$ mean 27,7%).

Conclusions: High grade tumors and higher Ki67 unleash a higher immune response, protecting from a worse prognosis. CD8+ lymphocytes are associated with AR expression. More studies are needed to understand the relationship between AR and TIL and also the role of AR blockade in TNBC and its role in immune-mediated lysis.

253P Use of red clover in premenopausal breast cancer patients receiving hormonal adjuvant treatment: Biological and clinical implications from a randomized clinical trial

C. Ferraris[1], B. Ballestra[1], V. Cappelletti[2], C. Listorti[1], P. Miodini[3], I. Pulice[4], L. Mariani[5], E. Ferrari[6], A. Gambaro[7], I. Maugeri[1], G. Martelli[1], S. Folli[1]

[1]S.C. Chirurgia Generale Indirizzo Oncologico 3 (Senologia), Istituto Nazionale dei Tumori di Milano - Fondazione IRCCS, Milan, Italy, [2]Dipartimento di Oncologia Sperimentale e Medicina Molecolare, Istituto Nazionale dei Tumori di Milano - Fondazione IRCCS, Milan, Italy, [3]S.C. Biomarcatori, Istituto Nazionale dei Tumori di Milano - Fondazione IRCCS, Milan, Italy, [4]Direzione Scientifica Studi Clinici, Istituto Nazionale dei Tumori di Milano - Fondazione IRCCS, Milan, Italy, [5]Direzione Scientifica Statistica Medica, Istituto Nazionale dei Tumori di Milano - Fondazione IRCCS, Milan, Italy, [6]S. C. Farmacia, Istituto Nazionale dei Tumori di Milano - Fondazione IRCCS, Milan, Italy, [7]Scienze Farmacologiche e Biomolecolari, Università degli Studi di Milano, Milan, Italy

Background: Premenopausal women with breast cancer (BC) experience early onset of treatment-induced menopausal syndrome with adjuvant hormone therapy (HT). Isoflavones in the red clover (RC) are biologically active agents providing a source of rapidly available phytoestrogens acting as natural selective estrogen receptor modulators. Aims of the study are: to improve quality of life reducing menopausal symptoms from HT in BC premenopausal women and preventing weight gain and metabolic syndrome with personal lifestyle intervention; to evaluate in vitro safety profile of RC used in combination with adjuvant anti-estrogenic HT.

Methods: Eighty-eight premenopausal BC women (DCIS, T1/T2N0-N1M0) receiving adjuvant HT were randomly assigned to have 80 mg/die of RC dry extract (MCE-11) (verum group) or a tablet without active principle (placebo group) for 2 years. Menopausal Rating Score (MRS) questionnaire was given every three months during the first year then biannually. Diet program was personalized with the WCRF/AICR recommendations and Mediterranean diet. Body Max Index (BMI), hip and waist circumference, homeostatic model assessment index (HOMA) and lipid profile (total LDL, HDL cholesterol, triglycerides) were recorded. Pool serum of women from the two groups was run for in vitro evaluation of the safety profile using specific cell lines selected to be representative of hormone-sensitive BC with high expression of estrogen receptor a (MCF7, T47D) and β (BT20).

Results: Menopausal symptoms significantly decreased in both groups over time ($p < 0.0001$). In the verum group BMI, hip and waist circumference were more reduced than in placebo group ($P < 0.0001$). HDL cholesterol significantly improved over time ($p < 0.01$). There was no significant difference in endometrial rhyme, while mammary density significantly decreased in both arms ($p < 0.0001$). In vitro, no significantly differences were observed in cell growth and induction of estrogen regulated/related genes in the cell lines treated with serum from women of the two arms.

Conclusions: Isoflavones can be safely used in premenopausal BC women under HT to contrast symptoms related to treatment.

Clinical trial identification: Protocol number INT 101/11 release date 25/06/2012 - EudraCT: 2011-005518-12 2-2-24-01-2012.

254P PROMs following breast-conserving therapy for breast cancer: Results from a prospective longitudinal monocentric study

I. Kindts[1], A. Laenen[2], M. van den Akker[3], C. Weltens[1]

[1]Radiation Oncology, University Hospitals Leuven - Campus Gasthuisberg, Leuven, Belgium, [2]Leuven Biostatistics and Statistical Bioinformatics Centre (L-Biostat), KU Leuven University, Leuven, Belgium, [3]Family Medicine, School CAPRI, Maastricht University, Maastricht, Netherlands

Background: To evaluate patient-reported outcomes (PROs) and long-term aesthetic outcome (AO) related to radiotherapy (RT) in the breast-conserving therapy setting for breast cancer over time. To explore the agreement between PROs and AO.

Methods: Patients treated with breast-conserving therapy at one institute between April 2015 and April 2016 were prospectively included in the cohort. The AO was scored by the patient and by the BCCT.core software. Further PROs were measured with the EORTC QLQ-C30, QLQ-BR23 and the BIBCQ. Patients were evaluated at preset time points over two years. First, we assessed the evolution in time of the PROs and AO. Second, we tested the differences in mean scale scores of the PROs between patients with a favourable and an unfavourable AO.

Results: 175 patients were included in the analysis. At baseline unsatisfactory levels were already present for several global, functional, symptom and body image scales. Most unsatisfactory PROs improved significantly up to one year after RT. Fatigue showed a small deterioration at the start of RT, but improved medium thereafter up to one year after RT (mean difference (MD) 7.6, -12.3, respectively and $p < 0.001$). Cognitive functioning showed a small decrease from at the start of RT with no further significant decrease (MD -4.73, -0.21 and p 0.003, 0.894, respectively). Breast symptoms significantly increased during RT but decreased afterwards up to two years after

RT to lower values than at baseline and were then considered satisfactory (MD 15.6, -19.7, -4.1 and $p < 0.001$, <0.001, 0.005, respectively). AO scored by the patient and with the BCCT.core associated well with each other and with the body image measures. There was no association between AO and global cancer-related QOL in the present cohort.

Conclusions: Small quality of life impairments present during RT with good recovery up to one year after RT. Body image is disturbed during RT and improves up to two years after RT. Around one third of patients score their long-term AO as unfavourable and these PROs correlate well with body image.

255P Impact on disease-free survival (DFS) of the surgical waiting time (SWT) for patients (Pts) with early breast cancer (BC)

R. Nakamura[1], N. Yamamoto[1], T. Miyaki[2]

[1]Breast Surgery, Chiba Cancer Center Hospital, Chiba, Japan, [2]Breast Oncology, Chiba Cancer Center Hospital, Chiba, Japan

Background: SWT is distressing for patients and impairs their quality of life. There are few studies and no consensus in the literature concerning the impact of BC biology on SWT, particularly in each subtype. However, a randomized trial is not possible to study the SWT. We aimed to assess the impact of the SWT and the histological grade (HG) of tumor on DFS.

Methods: We retrospectively reviewed the data of Pts with invasive BC who received core needle biopsy (CNB) as diagnosis between January 2007 and June 2017. Pts who required neo-adjuvant chemotherapy were excluded. The primary analysis was a comparison of the DFS between patients who have SWT for 1 month or less (early group) and those who have them for longer than 1 month (late group). Propensity score matching in these groups was calculated based on the menopausal status, cT, cN, ER, PgR and HER2 status. Furthermore, we divided the Pts into 4 groups for the survival analysis as follows: the HH [high grade CNB/high grade surgical specimen (SS)], the LL (Low grade CNB/Low grade SS), LH (Low grade CNB/high grade SS) and the HL group (high grade CNB/low grade SS).

Results: We analyzed the data of 1513 patients. Based on the propensity score, the early group and late group had 530 matched patients each. The median age was 62 years, cT1:58%, cT2:36%, cN0:75%, cN1;25%, ER(+) 82%, PgR(+) 68%, HER2(+):12% in both groups. The median diagnosis to curative SWT was 24.2 days in the early group and 46.7 days in the late group. A propensity score-matched model showed the significant difference in the DFS between the early group and the late group (5-year DFS rate, 92.9 vs. 86.6%; $p = 0.0014$ HR:1.98 1.30 to 3.08). Multivariate analysis revealed that the prognostic factors were significantly associated with cT (HR:2.02 95% CI 1.34 to 3.07), cN (HR:2.68 95% CI 1.78 to 4.04) and SWT (HR: 1.98, 95% CI, 1.30 to 3.08). ER, PgR and HER2 were not independent prognostic factors. The LH group for early group had a shorter DFS than the HL, HH and LL group ($p = 0.0013$). The HG for late group was not associated with survival.

Conclusions: The late group was significant worse in DFS compared with the early group. The histological up-grading of tumor for the early group was associated with worse survival.

256P Oncological outcome of fat grafting for breast reconstruction after cancer

G. Griguolo[1], F. Miglietta[1], M.V. Dieci[1], V. Vindigni[2], F. Bassetto[2], E. De Antoni[2], I. Polico[3], A. Marchet[4], E. Baldan[3], G. Vernaci[1], T. Saibene[5], S. Michieletto[5], V. Guarneri[1]

[1]Department of Surgery, Oncology and Gastroenterology, University of Padova, Istituto Oncologico Veneto IRCCS, Padua, Italy, [2]Plastic Surgery Clinic, University of Padova, Padua, Italy, [3]Diagnostic Senology Unit, Istituto Oncologico Veneto - IRCCS, Padua, Italy, [4]Clinica Chirurgica 1, Azienda Ospedaliera di Padova, Padua, Italy, [5]Breast Surgery Unit, Istituto Oncologico Veneto - IRCCS, Padua, Italy

Background: Fat grafting (FG) has become widely used in breast reconstruction after breast cancer (BC). FG might express protumorigenic factors or alter radiological aspect of the breast, raising some concerns on its oncological safety. The aim of the study was to describe clinical outcome of patients (pts) undergoing FG.

Methods: Records of 424 pts who underwent FG between 2010 and 2017 at the Plastic Surgery Dept. of Padova University were reviewed. Pts without invasive BC or not followed at Istituto Oncologico Veneto were excluded, leaving 206 pts for analysis. Cumulative Incidence of relapse was calculated from first FG. Association between clinico-pathological factors and relapse was explored.

Results: Patients were mostly post-menopausal ($n = 115$, 56%) and the majority had HR+/HER2- BC ($n = 134$, 65%). Eight pts (4%) were BRCA-mut carriers. Disease stage at diagnosis was: I (42%), II (34%), III (24%). Median interval from surgery to first FG was 23 months (range 0-257). 336 FG interventions were performed (median per patient: 1, range 1-9). At median follow-up of 38.9 months, 35 pts relapsed (10 locoregional, 25 distant relapses). Cumulative Incidence of relapse according to clinico-pathological subgroups is reported in the table. Semestral hazard rates of relapse in the three years after FG were: 0.010, 0.053, 0.034, 0.007, 0.039, and 0.038, respectively. 59 pts (29%) underwent additional breast imaging over standard recommendation (range 1-6 per patient), and 40 (20%) pts underwent breast biopsies (range 1-4, 10 confirmed a local recurrence).

Table: 256P

Clinicopathological factors		Number of patients (%)	3-years cumulative incidence of relapse	Hazard Ratio (95% CI)
HR status	HR negative	26 (13%)	13%	ref
	HR positive	170 (87%)	16%	1.57 (0.47-5.18)
HER2 status	HER2 positive	46 (24%)	10%	ref
	HER2 negative	143 (76%)	16%	1.93 (0.74-2.05)
Stage at diagnosis	Stage I	81 (42%)	11%	ref
	Stage II	67 (34%)	17%	2.84 (1.06-7.62)
	Stage III	47 (24%)	23%	4.42 (1.68-11.63)
Interval from surgery to first FG	>2 years	99 (48%)	16%	ref
	<2 years	107 (52%)	17%	1.07 (0.55-2.08)
Type of breast surgery	Mastectomy	180 (87%)	15%	ref
	Conservative	26 (13%)	25%	1.53 (0.63-3.69)
Overall Population		206 (100%)	17%	-

Conclusions: This study describes a not negligible rate of recurrence in BC pts receiving FG, especially in stage III and conservative surgery pts. High risk of relapse in the first years after FG might suggest a potential relation between the procedure and events. Moreover, a significant proportion of pts underwent additional breast imaging and biopsies, which can adversely affect quality of life. A careful discussion in multidisciplinary setting is crucial for proper pts selection.

257P Changes in body weight over 18-months follow-up among Chinese patients after breast cancer diagnosis

W. Yeo[1], Y.Y. Lei[1], A.C. Cheng[2], C.C. Kwok[2], K.L. Cheung[1], I.C. Lee[1], R. Lee[1], S. Ho[3]

[1]Clinical Oncology, The Chinese University of Hong Kong, Hong Kong, China, [2]Clinical Oncology, Princess Margaret Hospital, Kowloon, Hong Kong, China, [3]School of Public Health, The Chinese University of Hong Kong, Hong Kong, China

Background: Weight gain has commonly been reported among patients after breast cancer diagnosis in western countries. Based on limited data in the literature, weight gain in Asian counterparts appears to be less. In this prospective study, we investigate the weight changes among Chinese breast cancer patients during 18-month follow-up from diagnosis.

Methods: This is part of the ongoing Hong Kong NTEC-KWC Breast Cancer Survival Study (HKNKBCSS). Chinese patients with newly diagnosed early-stage breast cancer were consented. Studied patients had their weights recorded at breast cancer diagnosis (T0), at study entry (T1; within 12 months from T0) and at 18-month follow-up (T2). Potential associating factors including socio-demographic, lifestyle and clinical factors were assessed.

Results: A total of 1265 patients had detailed weight at the 3 time-points of assessment. The mean age at diagnosis was 51.8 years. The proportion of patients who received chemotherapy, radiotherapy and endocrine therapy were 77%, 70% and 72% respectively. Compared to T0, the median weight change was -0.5 kg (range: -11.4, 18.3) at T1 and 0 kg (range: -18.6, 19.5) at T2. At T1 and T2, 2.4% and 16.1% of women respectively gained weight between 2-5kg; 0.5% and 4.7% respectively gained >5kg, while 6.1% and 24.2% of women respectively had weight loss >2kg. On univariate analysis, patients who received radiotherapy had more weight loss at T1; no significant difference in weight change was noted with other factors including socio-demographic, lifestyle and clinical factors. When comparison was made between T0 and T2, patients who did not receive radiotherapy, those who remained premenopausal at T2 and those who were underweight at T0 were significantly associated with more weight gain.

Conclusions: In this cohort study, weight gain was not common among Hong Kong breast cancer patients within the first 18 months post-diagnosis. The findings from the present study differ from those conducted in western patient population, in whom average reported weight gains ranged between 1.0 and 6.0 kg over the first year after

breast cancer diagnosis. Funding: World Cancer Research Fund International (Grant Number WCRF 2010/249 and WCRF 2014/1197).

258P Incidence of clinically significant toxicities in patients with high endoxifen concentrations

S.L. Groenland[1], A.B. Sanchez-Spitman[2], D.J.A.R. Moes[2], S.L. Koolen[3], V.O. Dezentjé[4], N. van Erp[5], R.H.J. Mathijssen[6], H-J. Guchelaar[2], A.D.R. Huitema[7], N. Steeghs[8]

[1]Department of Clinical Pharmacology, The Netherlands Cancer Institute - Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, [2]Department of Clinical Pharmacy and Toxicology, Leiden University Medical Center, Leiden, Netherlands, [3]Department of Medical Oncology, Erasmus University Medical Center, Rotterdam, Netherlands, [4]Department of Medical Oncology, The Netherlands Cancer Institute - Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, [5]Department of Clinical Pharmacy, Radboud University Medical Center (LUMC), Nijmegen, Netherlands, [6]Department of Medical Oncology, Erasmus MC Cancer Institute, Rotterdam, Netherlands, [7]Department of Pharmacy & Pharmacology, The Netherlands Cancer Institute and MC Slotervaart, Amsterdam, Netherlands, [8]Department of Medical Oncology & Clinical Pharmacology, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands

Background: Tamoxifen is essential in the treatment of estrogen receptor positive breast cancer. Concentrations of its active metabolite endoxifen > 5.97 ng/mL have been associated with a 26% lower recurrence rate in the adjuvant setting (Madlensky 2011), providing a rationale for therapeutic drug monitoring. However, the risk of high endoxifen concentrations has not been established. Therefore, we investigated whether extremely high endoxifen levels are correlated with a higher incidence of clinically significant toxicities.

Methods: Patients receiving adjuvant tamoxifen treatment (20 mg) with a steady state endoxifen level above 25 ng/mL were retrospectively identified in databases of the CYPTAM study (n = 667, NTR 1509) and of samples collected in routine care (n = 1768). The percentage of patients with clinically significant toxicities, defined as toxicities leading to either dose reduction or treatment discontinuation, was compared to the overall tamoxifen population. As historical comparison, studies described in the EBCTCG overview (2011) in which patients received adjuvant tamoxifen (20 mg) and which reported clinically significant toxicities were selected.

Results: 26 patients (1.5%) had an endoxifen level > 25 ng/mL, of which 4 patients (15%) had clinically significant toxicities, compared to 10.2% in the overall tamoxifen population (p = 0.39, weighed average of 10 clinical trials, n = 9688, Baum (2002), Margolese (2016), Chirgwin (2016), Morales (2007), Bartlett (1987), Colleoni (2006), Bonneterre (2001), Kaufmann (2005), Bramwell (2010), Tevaarwerk (2014)). Reported toxicities were mood disturbances (n = 3), hot flushes (n = 2) and musculoskeletal disorders (n = 1). Median time on treatment was 28 months in patients with high endoxifen levels, compared to 47 months reported in literature.

Conclusions: The incidence of clinically significant toxicities is relatively low and is similar in patients with extremely high endoxifen levels and the overall tamoxifen population. Therefore, dose reductions are not indicated in patients with high endoxifen concentrations without toxicity.

Clinical trial identification: CYPTAM study: NTR 1509 (release date 27 October 2008).

259P Male breast cancer: Clinical and epidemiological patterns in the United States

M.A. Gouda

Department of Clinical Oncology, Faculty of Medicine - Menoufia University, Shebin El Kom, Egypt

Background: Male breast cancer is a rare disease that have different outcomes in comparison with the same disease in female counterparts. Due to rarity of its occurrence, data available on breast cancer in male population are relatively scarce. The aim of this study was to summarize data available in the SEER (National Cancer Institute Surveillance, Epidemiology, and End Results) program's database about male breast cancer. SEER incorporates data from 18 cancer registries all over the United States. Data about clinical and epidemiological patterns as well as survival were analyzed and are subsequently presented.

Methods: Data were obtained using SEER*Stat version 8.3.5 where (SEER 18 Regs Nov 2017 Submission) database was used as the data source. Only males diagnosed between 2000-2015 with malignant breast cancer, known age, and microscopic confirmation were included. Relative survival was calculated using Ederer II method. Further data analysis was made using SPSS version 21.

Results: A total of 6790 patients were identified with a median age of 68. White race constituted the majority of cases (81.3%; n = 5519). Incidence rate was 10.2 per million (95% CI 10 – 10.5) with increasing trend over time (annual percent change = 1.9%, $p < 0.05$). The disease showed slight predilection to occur on the left side (52.3%; n = 3550). Most cases were staged as regional (n = 2974) or localized (n = 3152) at time of diagnosis. The disease was the only primary cancer in 4502 patients (66.3%) and the first of 2 or more primaries in 787 cases (11.6%). It occurred as a second or later multiple primary in remaining cases (22.1%). Median observed survival was 117.2 months with a 5-years and 10-years observed survival of 70.6% (CI: 69.1%-71.9%) and 48.8% (CI: 46.9%-50.6%) respectively. 5-years relative survival was 84% (CI: 82.3%-85.6%) while 10-years relative survival was 71.1% (CI: 68.3%-73.7%).

Conclusions: Male breast cancer is a rare tumor with an incidence rate of 10.2 per million. This tumor is more likely to occur in old age and white race and occurs more on left side. Disease occurred as a second (or later multiple) primary in 22% of cases. 5-years relative survival is 84% with a median survival of 117.2 months.

260P The aesthetic results after oncoplastic surgery in early breast cancer

A. Zikiryahodjaev[1], A. Sukhotko[2], A. Tukmakov[1]

[1]Oncology and Plastic Surgery, P.A. Herzen Moscow Oncology Research Institute, Ministry of Health of Russia, Moscow, Russian Federation, [2]Oncology and Plastic Surgery, Herzen Cancer Research Institute, Moscow, Russian Federation

Background: To create of the new concept of surgical treatment as a component of multi-therapy treatment of patients with breast cancers on postoperative quality of life (Qol). According to Clough K. B. (2010), the advantage of the oncoplastic approach is the expansion of indications for operations in achieving the best aesthetic results. "Oncoplastic surgery is the' third way ' between standard organ preservation surgery and mastectomy."

Methods: We assessed 570 women who underwent breast conserving surgery (BCS) or total mastectomy (TM) with immediate reconstruction in P.A. Gertsen Moscow Research Institute from 2013 to 2017. Of the 437 patients, 300 (66,4%) had oncoplastic breast surgery. OBS included glandular reshaping (rotation flap, round-block technique, batwing mastopexy, wise pattern-inverted T, vertical pattern). The distribution of patients according to the stage of disease was as following: stage I-II – 348 (79,6%), IIIA – 89 (22,4%). A median follow-up period was 58 months. Only 94 (21,5%) patients received adjuvant polychemotherapy, combinations adjuvant polychemotherapy and radiation therapy – 27 (6,1%) or endocrine therapy – 37(8,5%).

Results: During a median follow-up period local recurrent were detected at 5 (0,8%), distant metastasis – 15 (2,6%) patients. Overall disease-free survival in patients with BCS stage I was 96,2%, IIA– 90%, IIB – 86,7%, IIIA – 86,2% (p>0,05). Overall disease-free survival in patients with SSM stage I was 92,9%, IIA– 91,2%, IIB – 84,4%, IIIA – 91,4% (p>0,05). The postoperative cosmetic result after BCS was assessed in 79,3% patients.

Conclusions: In breast reconstructive the most effective method is using breast tissue after BCS. Oncoplastic surgery contributes is the better phychological adaptation of patients. Variety of modifications and options of reconstructive surgery causes problem of choice, which should be solved with patient taking into account the clinical data. The extent of surgical intervention does not affect the performance of the 5-year overall and recurrent survival and depends on the distribution process.

261P The application of indocyanine green fluorescence navigation method to a sentinel lymph node biopsy after neoadjuvant chemotherapy in node-positive breast cancer

K. Yamagami[1], H. Matsumoto[1], T. Hashimoto[2], S. Yanai[1], S. Yuen[1], Y. Yata[1], Y. Ichinose[1], T. Deai[3], M. Toi[4]

[1]Department of Breast Surgery and Oncology, Shinko Hospital, Kobe, Japan, [2]Breast Surgery, Hashimoto Clinic, Kobe, Japan, [3]Breast Surgery Deai Clinic, Kobe, Japan, [4]Department of Breast Surgery, Kyoto University, Kyoto, Japan

Background: Approximately 40% of patients with node positive in axilla (N1) will have axillary pathologic complete response (pCR) after neoadjuvant chemotherapy (NAC). The application of sentinel lymph nodes (SNs) biopsy (SNB) following NAC for initially node-positive breast cancer is unclear because of high false-negative results in previous studies (SENTINA, ACOSOG Z1071). These trials, using blue dye (BD) and/or radioisotope (RI) agent, showed the diagnostic accuracy of SNB was closely related to the number of SNs. We presented the efficacy of indocyanine green (ICG) fluorescence navigation method for SNB in clinically node-negative (cN0) patients (ASCO2008). The fluorescent ICG method can provide higher number of SNs. Moreover, some reports showed that florescence SNs with metastases could not be identified by radioactivity. To determine the detection rate, the false-negative rate of SNs using the fluorescent ICG method after NAC for biopsy-proved N1 breast cancer retrospectively.

Methods: Of 2301 patients (January 2010 - March 2018), 135 women with N1 (fine needle aspiration or core needle biopsy proved) received NAC. Node status after NAC was evaluated by ultrasound findings: Group 1 (N1 converted ycN0, n = 105) and Group 2 (N1 remained ycN1, n = 30). All patients underwent SNB using both ICG- and BD-method and axillary lymph node dissection.

Results: The average number of SNs removed were Group 1 (ICG: 3.65, BD: 1.37), Group 2 (ICG: 2.99, BD: 0.93). Detection rate of SNs: Group 1 ICG 97.1% (95% CI 91.9-99.0, 102 of 105), BD 77.1% (95% CI 68.2-84.1, 81 of 105), Group 2 ICG 86.7% (95% CI 70.3-94.7, 26 of 30), BD 53.3% (95% CI 36.1-69.8, 16 of 30). Resulting of a false-negative rate: Group 1 ICG 7.69% (95% CI 2.65-20.3, 3 of 39), BD 35.7% (95% CI 20.7-54.2, 10 of 28), Group 2 ICG 11.5% (95% CI 4.00-29.0, 3 of 26), BD 18.8% (95% CI 6.59-43.0, 3 of 16). Axillary pCR was 46.7% (63 of 135).

Conclusions: In patients whose axillary nodal status converted from N1 to ycN0, the fluorescent ICG method with higher number detection of SNs showed a remarkable high detection rate and a low false-negative rate of SNs, compared with those of Blue dye which is one of conventional method.

262P Use of sentinel lymph node biopsy after neoadjuvant chemotherapy in patients with cytology proven axillary node-positive breast cancer at diagnosis

H.J. Choi[1], S.M. Jung[1], J.M. Ryu[2], I. Kim[1], S.J. Nam[1], S.W. Kim[2], J. Yu[2], S.K. Lee[2], J.E. Lee[2]

[1]Breast Surgery, Samsung Medical Center Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [2]Department of Surgery, Samsung Medical Center Sungkyunkwan University School of Medicine, Seoul, Republic of Korea

Background: This study aimed to evaluate the prognostic effects of sentinel lymph node biopsy (SLNB) on recurrence and survival after neoadjuvant chemotherapy (NAC) in patients with cytology-proven axillary node metastasis breast cancer.

Methods: This study is a registered medical record review based on a prospectively collected cohort. We selected 506 patients who were diagnosed with invasive breast cancer and axillary lymph nodes metastasis and treated with NAC followed by curative surgery at Samsung Medical Center between January 2007 and December 2014. We classified patients into three groups: Group A, negative SLN status and no further dissection; Group B, negative SLN status with backup axillary lymph node dissection (ALND); and Group C, no residual axillary metastasis on pathology with ALND regardless of clinical response. We analyzed and compared outcomes including prognoses and survival among all groups.

Results: The median age at the time of surgery was 44.4 years. The median follow-up time was 47.0 months (range: 3-115 months) and the median number of retrieved SLNs was 5.0. The SLN identification rate was 98.3% (234/238 patients), and the false negative rate (FNR) of SLNB after NAC was 7.5% (8/106 patients). There was no significant difference in disease-free survival (DFS, p = 0.578) or overall survival (OS, p = 0.149) among Groups A, B, and C.

Conclusions: These results suggest that SLNB can be feasible and oncologically safe after NAC for node-positive breast cancer and could help reduce arm morbidity by avoiding standard ALND in negative SLN patients.

263P Omission of axillary lymph node dissection after positive sentinel lymph node: Validity and safety among early breast cancer patients treated with mastectomy

A. Matsumoto, Y. Umemoto, H. Jinno

Department of Surgery, Teikyo University School of Medicine, Tokyo, Japan

Background: ACOSOG Z0011 trial showed that axillary lymph node dissection (ALND) had no impact on recurrence and survival in patients with positive sentinel lymph node (SLN) after breast-conserving surgery. However, it is still unknown if omission of ALND can be applicable to patients treated with mastectomy. The aim of this study was to evaluate whether ALND could be safely omitted for patients with SLN–positive breast cancer after mastectomy.

Methods: From a prospective database of 296 patients with clinically node-negative breast cancer who underwent mastectomy and sentinel lymph node biopsy (SLNB) from March 2006 to December 2016, 81 patients who had positive SLNs were analyzed. Patients treated with neoadjuvant chemotherapy were excluded from the analysis. Lymphatic mapping was performed with a combined method of blue dye and radioisotope.

Results: The median age was 57.0 (range: 32-85) years and the median tumor size was 2.5 (range: 0.6-7.9) cm. Of 81 patients, 23 (28.4%) patients omitted ALND. Patients with SLNB alone were more likely to have smaller SLN involvements ($p < 0.001$): micrometastasis was identified in 13 (56.5%) patients in SLNB-alone group and 9 (15.5%) patients in ALND group. The number of positive SLN was comparable between SLNB-alone (median: 1.0, range: 1-6) and ALND groups (median: 1.0, range: 1-5) (p = 0.063). There was no significant difference in characteristics including age, tumor size and tumor subtypes between the two groups. Post-mastectomy radiotherapy was performed in 5 (21.7%) patients with SLNB alone and 16 (27.6%) patients with ALND (p = 0.588). The majority of patients with macrometastatic SLN received adjuvant chemotherapy in both groups (83.3% vs. 75.5%, p = 0.562). After a median follow-up of 54.7 months, no axillary recurrence was observed in both groups and 5-year disease-free survival was not significantly different between the two groups (75.0% vs. 88.8%, p = 0.489). Lymphedema was observed significantly more often after ALND than after SLNB (22.4% vs. 4.3%, p = 0.045).

Conclusions: These data suggested that ALND could be safely omitted in SLN-positive breast cancer patients treated with mastectomy and appropriate systemic therapy.

264P Pathologic response as a strong predictor of survival irrespective of phenotype in early breast cancer

A. Gasol Cudos[1], S. Morales Murillo[1], J. Veas Rodriguez[2], F. Vilardell Vilellas[2], D.R. Sanchez Guzman[2], E. Iglesias Martinez[1]

[1]Breast Cancer Unit, Hospital Arnau de Vilanova, Lleida, Spain, [2]Oncology, Hospital Arnau de Vilanova, Lleida, Spain

Background: Pathologic complete response after neoadjuvant chemotherapy is considered as a surrogate of survival by most authors, although there are special phenotypes, such HER2 positive, where their potential as apredictor of survival is stronger.

Methods: Overall survival was analyzed according to pathologic response in a cohort of early breast cancer patients (all subtypes) treated with standard neoadjuvant chemotherapy. Between March 2000 to October 2016, 459 breast cancer patients were treated with neoadjuvant chemotherapy with anthracicline and taxane regimens.

Table: 264P

Phenotype	RCB type 0	RCB1 type I	RCB type II	RCB type III
Overall	Median DFS:167 HR: 1	Median DFS:156 HR: 2,6	Median DFS:130 HR: 4,5	Median DFS:85 HR: 9,6
HER 2 positive	Median DFS: 126 HR: 1	Median DFS: 90 HR: 1,6	Median DFS:100 HR: 2,5	Median DFS:96 HR: 4,4
Luminal	Median DFS: 176 HR: 1	Median DFS: 160 HR: 2,8	Median DFS:115 HR: 4,8	Median DFS: NA HR: NA
Triple negative	Median DFS:188 HR: 1	Median DFS: 141 HR: 8,8	Median DFS: 117 HR: 16,7	Median DFS:122 HR: 28.4

Results: Median age was 52 (range 28-87), 173 tumors (38%) were classifyed as HER2 positive, 148 (32%) triple negative and 138 (30%) as luminal breast cancer. Median initial size was 34 mm (10-100) and 237 patients (51%) had initial node involvement. We achieved a total of 152/459 complete pathologic response with a 43% rate in HER2 positive, 44% in triple negative and 9% in luminal breast cancer patientes. Ten years disease free survival in the whole serie was 83%, with a 72% for patients without complete pathologic response versus 90% for complete pathologic response (long rang <0,00001). A strong correlation between pathologic response and survival wass found in all subtypes (long rang p:0,033; 0,028 and 0,027 in HER2 positive, luminal and triple negative respectively). A table with survival results according the RCB response by Symmans method in the whole series and different phenotypes is attached.

Conclusions: Pathologic response is a strong predictor of overall survival in all breast cancer phenotypes althoug in the triple negative has the highest magnitude with a HR of 28,4 in patients with worse pathologic response (RCB type III). Neoadjuvant chemotherapy should be considered in the majority of patients who are candidates to chemotherapy, specially in triple negative and HER2 positive; however, in luminal phenotype a better selection for neoadyuvant chemotherapy is needed.

265P Nomogram to predict non-sentinel lymph node status of breast cancer using total tumor load determined by one-step nucleic acid amplification (OSNA)

P. O-charoenrat, D. Sa-nguanraksa, A. Kulprom

Surgery, Siriraj Hospital, Mahidol University, Bangkok, Thailand

Background: Axillary dissection might be omitted in selected breast cancer patients with positive sentinel node (SLN). Total tumor load (TTL) in SLN expressed by cytokeratin 19 (CK19) mRNA, detected by automated molecular technique-one-step nucleic acid amplification (OSNA), can quantitatively determine tumor burden in SLN. This study aimed to create nomogram to predict non-sentinel lymph node (NSLN) status.

Methods: Breast cancer patients were recruited at Division of Head Neck and Breast Surgery, Department of Surgery, Siriraj Hospital, Mahidol University, Thailand from November 2015 to January 2018. The patients with invasive breast cancer T1-T3, clinically negative axillary lymph node and able to give informed consent underwent SLN biopsy assessed by OSNA. The patients with positive SLN underwent axillary lymph node dissection. Correlations between TTL, clinicopathological parameters and NSLN status were analyzed by chi-square statistic and logistic regression. Model discrimination was evaluated using receiver-operating characteristic (ROC) analysis.

Results: Total number of the patients who underwent SLN biopsy was 262. There were 85 patients with positive SLN. Mean age at diagnosis of the patients in this group was 54.52±11.66 years. NSLNs were positive in 37 patients. Larger tumor size (25.35±9.02 mm vs 37.78±16.88 mm) and presence of lymphovascular invasion (24.5% vs 67.6%) were the independent factor that predict positive NSLN. TTL expressed by CK19 mRNA copy number can discriminate NSLN status with the area under ROC curve of 0.784 (95%CI 0.683-0.885). At the cut off level at 6550 copies/μL, sensitivity, specificity, and negative predictive value were 86.49%, 57.14%, and 84.85%, respectively. Nomogram containing tumor size and SLN status can predict NSLN involvement with area under ROC curve of 0.827 (95%CI 0.737-0.918).

Conclusions: Nomogram using the results by OSNA technique can predict NSLN status and help in decision for axillary lymph node dissection.

266P Detecting bone density in early breast cancer survivors: The arm-DXA method

Y. Al-Farhat

Department of Oncology, Tolna County Teaching Hospital, Szekszard, Hungary

Background: Breast cancer survivors who are on adjunct therapy with Aromatase Inhibitors (AIs) or premature menopause due to chemotherapy are known to have an increased risk of osteoporosis and bone fracture. Being at high risk for osteoporosis, these patients should be screened using with dual energy X-ray absorptiometry (DXA) to measure bone mineral density (BMD) according to national guidelines. This study screened the population of patients with early Breast cancer utilizing the Arm-DXA as a user friendly and efficient method.

Methods: All Breast cancer patients at the Tolna County Cancer Center, Szekszárd who are diagnosis of early invasive breast cancer were scanned using Arm-DXA during their regular visit to the center. Cancer patients under hormone therapy were scanned annually. Patients who have metastatic disease or known to have osteoporosis were excluded from the study. A total of 431 patients were subject of an arm-DEXA scan for BMD during the period February 2015 to September 2017.

Results: Out of the 431 patients, normal T score −1,5 detected in 223 patients (51,7%), clinically significant osteopenia (CSO) T score −1,5, −2,5 detected in 129 patients (29,9%), and osteoporosis T score < −2,5 detected in 79 patients (18,3%). For the 224 Patients who were under hormone therapy or/and chemotherapy about 29,9% (n: 67) had a CSO, and 20,5% (n:46) had osteoporosis.

Conclusions: This study highlights the fact that osteoporosis is under-detected in early breast cancer survivors who are on or after hormone and chemotherapy. About 48% of early breast cancer survivors found to have osteoporosis or clinically significant osteopenia in our study. Our BMD test results shows that half the 224 patients who were under hormone therapy need to take treatment (zoledronic -acid or denosumab) to prevent bone fracture.

267P Voluntary deep inspiration breathhold (DIBH) experience in the radiotherapy for left sided breast cancer

I.V. Gueorguiev, N. Nedev, A. Avramov, A. Tonev, N. Velikova

Radiation Oncology, Acibadem City Clinic Cancer Center, Sofia, Bulgaria

Background: The adjuvant radiotherapy to the whole breast or the chest wall is an integral part of the treatment of breast cancer. This study is aimed at evaluating the potential for sparing the heart and lung using voluntary deep inspiratory breath-hold (DIBH) technique for radiotherapy of left sided breast or chest wall.

Methods: During the period 09.2016 – 09.2017, 95 patients with breast cancer had planning CT scans in the both respiratory phases, using Varian Real Time Positioning Management System® for monitoring of the respiratory chest wall excursions. Each patient had two planning CT scans: one during free breathing (FB) and another one with voluntary deep inspiration breath-hold (DIBH). The Planning Target Volume (PTV) included the whole breast/chest wall with or without the supraclavicular nodal groups (SCL). For each patient, two radiotherapy plans were prepared using the FB and the DIBH planning scans.

Results: The DIBH was very well tolerated. The mean anterior-posterior chest wall shift during FB was 3.1 mm. With the DIBH, the front chest wall position was between 10 mm and 18 mm anteriorly to its mid-FB position. In the post-lumpectomy cases the portion of the heart that received more than 50% of the prescribed dose, was decreased from 2.07% to 0% (39.7 % max dose). At the same time, relative lung volume irradiated to > 50% of the prescribed target dose was reduced from 17.63% (for FB) to 13.2% (for DIBH). In one extreme case with SCL, the volume of the heart, receiving more than 50% of the prescribed dose, was: 5.74% for FB and 0% for DIBH (36% max dose); the ipsilateral lung received: 21.2% with FB and 8% with DIBH. The median ipsilateral relative lung volume receiving >50% was higher for DIBH – 14.17% and 10.91% for FB.

Conclusions: This is the first study in Bulgaria, which demonstrates the dosimetric benefits of breathing adapted radiotherapy (BART). Our results showed that irradiated cardiac volumes can be consistently reduced for left-sided breast cancers by using DIBH.

Background: Breast cancer (BC) diagnosis may have a high emotional impact in patients. Health-related quality of life (HRQL) can be impaired by the psychological impact of the diagnosis, by choices having to be made about treatment and by treatments themselves.

Methods: Cross-sectional analysis of HRQL in BC women from the Epi-GEICAM case-control study carried out in 23 Spanish hospitals. Women fulfilled a questionnaire about sociodemographic and lifestyle factors, HRQL (SF-36), mental health (GHQ-28) and social support (Duke-UNC). Spanish population norm-based scores were calculated for the SF-36 scales. Physical (PSS) and mental (MSS) summary scores $\geq$5 points under the norm were considered suboptimal. Psychological distress (PD) was defined as GHQ-28 >5. Factors associated with PD and suboptimal PSS were identified by multivariable mixed logistic regression models.

Results: Among 1017 cases, 896 had complete SF-36 and GHQ-28. Median time since diagnosis was 77 days, 82% had been operated on, and 41% were on radiation/chemotherapy. Prevalence of PD was 54.4% (95% CI: 51.1-57.6). PD increased with TNM stage (p = 0.03). Other factors associated with PD were chemotherapy (OR = 1.7; 95% CI: 1.2-2.6), low social support (OR = 2.0; 95%CI: 1.2-3.5) and low education (OR = 2.1; 95% CI: 1.2-3.8). SF-36 scores are described in the table. Factors related to suboptimal PSS were surgery (OR = 3.2, 95% CI: 2.0-5.1), low education (OR = 1.9, 95% CI: 1.1-3.6) and number of comorbidities (OR = 1.3, 95% CI: 1.0-1.5). No differences in PD or PSS were observed according to BC subtype.

Conclusions: PD is very frequent during the initial stages of BC diagnosis and treatment. Advanced disease stage, lack of social support and low education are strong determinants of PD. The highest impact in HRQL was observed in the role-physical domain. PD and low PSS are interrelated and both are more frequent in patients with low education.

Table: 268P

	Mean*	95% CI	
Physical function	41.2	40.3	42.1

[1]Oncology Center, Medical Oncology, King Saud University Medical City (KSUMC), Riyadh, Saudi Arabia, [2]Oncologie Médicale, Centre Hospitalo Universitaire de Blida, Blida, Algeria, [3]Hematology and Medical Oncology, King Hussein Cancer Center, Amman, Jordan, [4]Oncologie Médicale, Institut National d'Oncologie Université Mohammed V, Rabat, Morocco, [5]Medical Oncology, National Guard Health Affairs (NGHA) - King AbdulAziz Medical City, Riyadh, Saudi Arabia, [6]Medical Oncology, National Guard Health Affairs (NGHA) - King AbdulAziz Medical City, Jeddah, Saudi Arabia, [7]Hematology - Oncology Department, Hôtel-Dieu de France, Université Saint-Joseph, Beirut, Lebanon, [8]Medical Oncology, National Cancer Institute (NCI)/ Cairo, Cairo, Egypt, [9]Department of Clinical Oncology and Nuclear Medicine, Clinical Research Center, Faculty of Medicine, Alexandria University, Alexandria, Egypt, [10]Clinical Research/ Data Management, International Cancer Research Group (ICRG), Sharjah, United Arab Emirates

Background: Neo-adjuvant (NA) chemotherapy (CT) +/- anti-Her2 treatment of operable breast cancer (BC) is considered a standard option in the management of BC. However, pathologic complete response (pCR) rates with CT in hormonal receptor+/Her2 negative BC are usually low: 7% (Luminal A) to 16% (Luminal B). Alternatively, NA endocrine therapy (ET) has not been established as a standard treatment because of low pCRs (i.e. 5% using 8 months of ET).

Trial design: This is a multicenter phase III, 3rd generation neo-adjuvant trial performed in 34 centers and 8 countries of Middle-East and Maghreb with the objective to investigate the potential role of the addition of a CDK 4/6 inhibitor (Palbociclib) to ET (Fulvestrant+/- Goseriline) compared to ET alone as neo-adjuvant therapy of HR+/Her2- operable BC sensitive to ET. The question Is whether or not ET plus CDK 4/6 inhibitor would yield high enough pCR rates to establish this strategy as a reasonable therapeutic option in this group of patients (pts) with luminal HER2- BC. A total of 400 pts with stage II and IIIA are planned to be recruited in this trial. Oncotype DX will be performed upfront in order to eliminate CT candidates. All pre/peri and post-menopausal pts with a recurrence score < 31 will be treated with 4 months of Fulvestrant (500 mg Day (d.) 1, 14, 28 then q. 28 d. (+/- Goseriline 3.6 mg q.28 d.). Patients with responding/stable disease will then be randomized in double blind fashion to Fulvestrant (+/- Goseriline) either with Palbociclib 125mg po daily 3 weeks/4 or placebo. Four additional cycles will be delivered before surgery. The study primary endpoint is pCR while clinical/radiological response, rate of conservative surgery, safety, disease-free and overall survival are secondary endpoints. Exploratory endpoints encompass biomarker serial analysis of liquid biopsies with Quantum Optic and DNA methylation technologies. The SAFIA trial aims to identify a new neo-adjuvant standard with ET plus CDK 4/6 inhibitor in luminal - Her2 negative operable BC.

Clinical trial identification: SAFIA Study (ICRG 1201); NCT03447132.

269TiP Multicenter study to evaluate the efficacy and standardize radiofrequency ablation therapy for early breast cancer (RAFAELO study)

T. Kinoshita[1], S. Ohtani[2], H. Doihara[3], M. Takahashi[4], T. Fujisawa[5], N. Yamamoto[6], K. Aogi[7], T. Hojo[8]

[1]Division of Breast Surgery, National Cancer Center Hospital, Tokyo, Japan, [2]Department of Breast Surgery, Hiroshima City Hospital, Hiroshima, Japan, [3]Department of Breast and Endocrine Surgery, Okayama University Hospital, Okayama, Japan, [4]Department of Breast Surgery, Hokkaido Cancer Center, Sapporo, Japan, [5]Breast Oncology, Gunma Prefectural Cancer Center, Gunma, Japan, [6]Division of Breast Surgery, Chiba Cancer Center, Chiba, Japan, [7]Department of Breast Oncology, Shikoku Cancer Center, Matsuyama, Japan, [8]Department of Breast Surgery, National Cancer Center Hospital East, Chiba, Japan

Background: Given the increasing number of early-stage breast cancers detected by screening mammography, we aim to establish RFA as a minimally invasive, cost-efficient, and cosmetically acceptable local treatment. In our Phase I study, localized tumors with a maximum diameter of 2 cm, preoperatively diagnosed by imaging and histopathology, were treated with RFA. A 90% complete ablation rate was confirmed histopathologically.

Trial design: The objective of our study is to demonstrate the non-inferiority of RFA compared with standard treatment in terms of local recurrence-free survival, which is the best index of local control. The inclusion criteria are untreated pts with histologically confirmed ductal carcinoma with a single localized tumor of 1.5 cm or less in the greatest dimension on preoperative imaging, no prior treatment for breast cancer.

RFA is defined as a procedure in which a radiofrequency electrode needle is inserted into the breast lesion from the surface of the body under imaging guidance and thermal

ablation with radiofrequency waves is performed. The Cool-tip™ RF Ablation Single Electrode Kit (Medtronic, Boulder, CO, USA) is recommended to standardize the evaluation of the effect of ablation. All pts receive RT and systemic therapy according to the ER, HER2, tumor grade and lymph node status of the primary breast cancer after RFA. Residual lesions after RFA will be assessed in all patients approximately 3 months after RT using imaging studies and pathological examination. VAB will be performed in all patients regardless of imaging results. If biopsy specimens reveals suspicious of viable tumor, additional excision will be performed. Follow-up evaluation for residual tumor every 12 months after RFA included clinical breast examination, diagnostic imagings (ultrasound, magnetic resonance, and mammography). The primary endpoint is 5-year local recurrence-free survival, and the secondary endpoints are residual lesion rate after treatment, overall survival, distant recurrence-free survival and adverse events of RFA. The pts accrual was started in August 2013. From 9 participating institutions, enrollment of 372 pts is planned over a 5-year accrual period.

Clinical trial identification: UMIN-CTR: UMIN000005586.

Background: Treatment of triple negative breast cancer (TNBC) is hampered by lack of established therapeutic targets like hormone receptors or HER-2. Surgery, chemotherapy and radiotherapy are the standard of care yet cure rates in patients with TNBC remain inferior compared to other BC subtypes. Approaches tailored to the patient's individual tumor signature may lead to improvement. The "Mutanome Engineered RNA Immuno-Therapy (MERIT)" consortium is validating an innovative individualized mRNA-based vaccine for TNBC treatment. MERIT is a collaboration of 5 European partners (academia and industry) dedicated to realize a personalized approach for TNBC treatment. The consortium set up a clinical workflow covering drug development from target discovery and validation to GMP manufacturing and drug release for each individual patient (MUTANOME). Moreover, the consortium established a pre-synthesized mRNA vaccine warehouse containing the most frequently shared tumor-associated antigens (TAA) in TNBC for drug supply (WAREHOUSE).

Trial design: A phase I trial in 2 European countries assesses the feasibility, safety and biological efficacy of this personalized immunotherapy. TNBC patients (pT1cN0M0 – T_xN_xM0) after surgery and (neo-)adjuvant chemotherapy will be allocated to one of two study arms. Patients in ARM1 receive 8 WAREHOUSE vaccinations with personalized TAA combinations corresponding to the patient tumor's antigen-expression profile. Patients in ARM2 are first treated with the WAREHOUSE approach followed by 8 vaccination cycles of an on-demand manufactured MUTANOME vaccine encoding the unique mutation signature of the individual patient identified by NGS. The mRNAs are administered intravenously as a RNA-lipoplex formulation which protects RNA from degradation, activates innate immunity, transfects APCs and consequently induces highly potent antigen-specific T-cell responses. Three clinical sites are open for recruitment; >12 patients were screened and vaccinations with WAREHOUSE or MUTANOME RNAs have started. We give insights into features of the established process and present first stratification data. MERIT was funded by the EU Commission's FP7 and is led by BioNTech AG.

271TiP Preoperative pembrolizumab (Pembro) with radiation therapy (RT) in patients with operable triple-negative breast cancer (TNBC)

H.L. McArthur[1], R. Basho[1], S. Shiao[1], D. Park[1], C. Dang[1], S. Karlan[1], S. Knott[1], M. Mita[1], C. Dilauro Abaya[1], A.E. Giuliano[1], F. Dadmanesh[1], A. Ho[2]

[1]Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles, CA, USA, [2]Harvard University, Massachusetts General Hospital, Boston, MA, USA

Background: Radiation therapy (RT) induces immune-mediated cell death. If administered pre-operatively, RT could also generate a rich supply of tumor antigens. The addition of PD-1 mediated checkpoint blockade to pre-operative RT could thus, generate robust anti-tumor immune responses, induce long-term tumor-specific memory, and ultimately, improve cure rates. This study aims to establish the safety of pre-operative pembrolizumab (pembro)-mediated immune modulation with a RT "boost" equivalent in patients with operable triple negative breast cancer (TNBC) for whom lumpectomy and adjuvant RT are planned (NCT03366844). Serial research biopsies will permit interrogation of conventional biomarkers including tumor infiltrating lymphocytes (TILs) and novel immune correlates as potential predictors of response to pembro alone versus pembro with RT.

Trial design: Women with operable, primary TNBC >2cm for whom breast-conserving therapy is planned are enrolled in this single-institution pilot study. Study treatment consists of 1 cycle of pre-operative pembro (200 mg IV) alone, followed 3 weeks later by a RT boost (24 Gy/3 fractions) to the primary breast tumor concurrently with pembro (+/- 5 days). Curative-intent, standard-of-care, neoadjuvant chemotherapy or breast-conserving surgery is then undertaken within 8 weeks of study enrollment (i.e. within 5 weeks of pembro #2). Adjuvant RT is administered per standard-of-care after surgery, but without a boost dose. Research blood and fresh tumor biopsies are obtained at baseline and after cycles 1 and 2 of pembro. Correlative analysis will include single-cell RNA sequencing of the tumor immune infiltrate and multispectral immunohistochemistry. Co-primary endpoints are: 1) safety/tolerability, as defined by the number of patients who do not necessitate a delay in standard-of-care chemotherapy or surgery and 2) change in TIL score. Secondary endpoints include safety/toxicity up to 19 weeks after study enrollment and disease-free survival.

272TiP Development of mPRO Mamma mobile application and its impact on the quality of life and health resource usage in patients with early stage and locally advanced breast cancer receiving chemotherapy

T. Gortnar[1], C. Grasic Kuhar[2], E. Drmota[1], T. Kovač[3], M. Kukar[3]

[1]Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia, [2]Department of Medical Oncology, Institute of Oncology Ljubljana, Ljubljana, Slovenia, [3]Faculty of Computer and Information Science, University of Ljubljana, Ljubljana, Slovenia

Background: Many possible adverse effects, from mild to life threatening, accompany the systemic treatment of cancer patients. Recognition and appropriate action is essential for optimal quality of life of patients. Consequently, patient-reported outcomes have become essential in clinical oncology. The purpose of this study is to involve the patients in ongoing monitoring, recording, and resolution of adverse effects resulting from chemotherapy via a self-developed smartphone application. We aim to assess the effect of this mobile application on improving symptom management and optimising health care usage, thus positively affecting the quality of life of our patients.

Trial design: We plan to develop a mobile application mPRO Mamma, which includes: symptom reporting module, useful measures and tips for managing adverse events based on intensity of symptoms, cancer-specific educational materials and an option to share collected data with the oncologist. Between December 2017 and June 2018, we plan to enrol 90 patients with early-stage or locally advanced breast cancer who own an Android-based smartphone and are proficient in using mobile applications in the open trial prior to them starting chemotherapy. Pending completion of mPRO Mamma mobile app development, half of the patients will be assigned to the control group. Upon the release of mPRO Mamma, the other half of the patients will be assigned to the experimental group and given access to the app. The primary objective is to determine the effect of using mPRO Mamma on the quality of life, measured by self-report using EORTC QLQ - BR23 and EORTC QLQ-C30 (version 3.0). Assessment will be performed before the first cycle, after 1 week, at the end of the first cycle, and at the end of chemotherapy. The quality of life index scores in each group will be compared to baseline scores. The secondary objectives are to assess the usage of health resources and to build a database of incidences of adverse events related to chemotherapy for breast cancer.

Clinical trial identification: EudraCT: 2018-001869-16.

BREAST CANCER, LOCALLY ADVANCED

274P CD8+, CD4+ and FOXP3+ cell profiles and their change after neoadjuvant chemotherapy in patients with triple negative breast cancer

N.O. Verovkina[1], S. Lyalkin[1], L.A. Syvak[2], A. Askolskyi[2], N. Majdanevych[2],

[1]Research Department, Chemotherapy of Solid Tumors, National Cancer Institute of the MPH Ukraine, Kiev, Ukraine, [2]Chemotherapy of Solid Tumors, National Cancer Institute, Kiev, Ukraine

Background: Neoadjuvant therapy for breast cancer has been increasingly used in recent years as first-line treatments for breast cancer. A high lymphocytic infiltration is known to correlate with response to neoadjuvant chemotherapy and prognosis, however little attention has been paid to changes in CD8+, CD4+, FOXP3+ immune call profiles during perioperative chemotherapy.

Methods: Treatment results of 43 patients with TNBC stages IIB-IIIB homogeneously treated with neoadjuvant chemotherapy were analyzed. We studied the baseline and post-treatment FOXP3+, CD4+, CD8+ tumor-infiltrating immune cells by immunohistochemistry. Therapeutic pathomorphism was evaluated in terms of the residual tumor burden identification (RCB) (using Miller-Payne classification). Variables distribution was scored using ANOVA test. Survival probabilities were estimated by the Kaplan-Meir method. Hazard ratios and their 95% confidence interval were calculated with the Cox proportional hazards model.

Results: Pathological complete response (pCR) to neoadjuvant chemotherapy was identified in 12% of patients. In group without pCR high baseline levels of the stromal CD4+ cells were identified in 39,4% of patients, peritumoral CD4+ cells – in 44,7%; high levels of stromal CD8+ cells were identified in 28% and peritumoral CD8+ – in 52% of patients; and high levels of FOXP3+ were identified 47,3% of patients. The levels of CD8+ and FOP3+ cells decreased during treatment in 13% of patients. The levels of peritumoral CD4+ cells deceased during treatment in 34, % of patient, whereas levels of stromal CD4+ increased during treatment in 10,6% of patients. We found that in the population with residual disease after neoadjuvant chemotherapy the high baseline levels of peritumoral CD4+ immune cells were strongly associated with adverse outcome (HR 3,33, CI 1,29 – 8,58; p = 0,013).

Conclusions: The high baseline levels of peritumoral CD4+ lymphocytes in triple negative breast cancer tumor failing to achieve pCR were associated with adverse outcome. Further studies are required for identifying patients who are likely to benefit from immunotherapeutic adjuvants to conventional treatment approaches.

275P Multiplex immunoassays analysis of plasma biomarker levels and response to neoadjuvant chemotherapy for locally advanced breast cancer

J.H. Cho[1], K. Park[2], E. Lee[2], Y. Kim[1], S. Park[1], S.E. Yoon[1], K.K. Lee[1], J.Y. Hur[1], S.K. Lee[3], J.E. Lee[3], S.W. Kim[3], S.J. Nam[3], J. Yu[3], J-Y. Kim[1], H.H. Jung[4], Y.H. Park[1]

[1]Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [2]Samsung Genome Institute, Samsung Medical Center Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [3]Division of Breast Surgery, Department of Surgery, Samsung Medical Center Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [4]Biomedical Research Institute, Samsung Medical Center Sungkyunkwan University School of Medicine, Seoul, Republic of Korea

Background: Neoadjuvant chemotherapy (NAC) has become as the preferred initial therapy for locally advanced breast cancer (LABC) patients. A pathologic complete response (pCR) following NAC correlates strongly with both prolonged disease-free survival and overall survival especially for patients with HER2+ or triple negative breast cancer (TNBC). A lot of modalities and molecular markers for assessing chemotherapy response have been evaluated; however, they have demonstrated only limited predictive value.

Methods: Plasma samples have been collected from 167 patients diagnosed with LABC and received NAC from month, year to month, year prospectively. Samples were collected three times from each patient, prior to NAC (pre-treatment), prior to second cycle of NAC (on-treatment), and after breast surgery (post-treatment). Samples were assayed by multiplex immunoassays for 45 biomarkers. Plasma biomarker levels using Cytokine/Chemokine/Growth Factor 45-Plex Human ProcartaPlex™ Panel were compared with pathologic treatment responses. pCR was defined as the absence of residual tumor both in breast and axillary lymph nodes. This study was approved by the Institutional Review Board of Samsung Medical Center (SMC 2014-11-015-017).

Results: A median age at diagnosis of the 167 patients was 42 (range, 23-68 years). Most of the patients were treated with anthracycline and taxane-based regimen including adriamycin with cyclophosphamide plus docetaxel (AC-T), or AC-T plus trastuzumab. The patients were divided into the following four groups: HR+/HER2- (n = 46, 28%), HR+/HER2 + (n = 26, 16%), HR-/HER2 + (n = 32, 19%), and TNBC (n = 63, 38%). Thirty four patients (20%) achieving a pCR were compared with 133 patients (80%) demonstrating no pCR. Several groups of biomarker expression, BDNF, bNGF, HGF, IFN-gamma, IL-18, IP-10, MCP-1, RANTES, and SCF, were significantly different among pre-treatment, on-treatment and post-treatment. Multivariate analysis on pCR showed that analysis using the multiplex panel has predictive power.

Conclusions: Plasma biomarkers including immune-cytokine may have a role to predict treatment response in the neoadjuvant setting.

276P Prognostic role of changes in neutrophil-to-lymphocyte ratio, tumor-infiltrating lymphocyte with programmed death ligand-1 in triple-negative breast cancer

E.K. Joung[1], J.E. Lee[2]

[1]Medical Oncology, Incheon St. Mary's Hospital, The Catholic University of Korea, Incheon, Republic of Korea, [2]Medical Oncology, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Republic of Korea

Background: Neutrophil-to-lymphocyte ratio (NLR), tumor-infiltrating lymphocyte (TIL) and programmed death-ligand 1 (PD-L1) expression is known to be associated with immunogenicity and prognosis of breast cancer. We analyzed baseline NLR and its clinical association in triple-negative breast cancer (TNBC). The changes of NLR, TIL and PD-L1 during neoadjuvant chemotherapy (NAC) and their association to recurrence was analyzed.

Methods: Between Jan 2008 to Dec 2015, 358 TNBC patients were analyzed. NLR was based on initial complete blood count (CBC). Fifty paired NLR (initial diagnosis, after completion of NAC) and 34 paired tissues (initial diagnosis, surgical specimen) were collected. The changes of TIL, CD4, CD8, forkhead box P3 (FOXP3) and PD-L1 expression were assessed with immunohistochemical stain. The relationship of prior markers and tumor recurrence was analyzed.

Results: Low NLR (NLR$\leq$3.16) was associated to superior survival [overall survival; 41.83 vs. 36.5 months, P = 0.002; disease-free survival (DFS) 37.85 vs. 32.14 months, P = 0.032]. After NAC, patients with radical NLR changes (NLR change $<$ -30% or $>$ 100%) showed inferior DFS (38.37 vs. 22.37 months, P = 0.015). Same or increased TIL after NAC showed trends for superior DFS (80.0 vs. 46.0 months, P = 0.366). Positive PD-L1 ($\geq$1%) in tumor cells at baseline was associated to superior DFS (97.45 vs. 33.02 months, P = 0.031), and positive tumor PD-L1 at post-NAC tissues showed trends for superior DFS (86.43 vs. 38.76 months, P = 0.056).

Conclusions: In TNBC patients, low NLR might be associated with superior survival. Modest changes of NLR or increased TIL after NAC may reflect good prognosis. Positive tumor PD-L1 was associated with superior DFS in our study.

277P Expression of Sp17 and its association with clinicopathological parameters of breast cancer

Y-T. Zhou

Breast Department, West China Hospital, Sichuan University, Chengdu, China

Background: Sperm protein 17 (Sp17) was found to be only expressed in breast cancer and not the normal breast tissue. Although Sp17 antibody can effectively inhibit the growth of human cancer cells, suggesting a potential therapeutic target, the role of Sp17 in tumor remains unclear. Hence, we examined the expression status of Sp17 in breast cancer and analyzed the correlation between Sp17 expression and clinicopathological parameters of breast cancer. We then proceeded to assess whether the expression of Sp17 has any effect on patient prognosis.

Methods: Quantitative real-time PCR and immunohistochemistry were conducted to test expression rate of Sp17 mRNA and protein in breast cancer samples, respectively.

Clinicopathological parameters of each patient were collected by reviewing medical records. Reliable follow-up information was obtained via phone call. Kaplan–Meier regression was conducted for survival analysis. Univariate and multivariate analyses were used to identify the variables associated with Sp17 expression.

Results: We studied 100 primary breast cancer and 20 normal breast specimens. Sp17 was expressed in 27% of breast cancer samples. The difference between expression and non-expression of Sp17 was statistically significant in disease-free survival and overall survival. Lymph node metastasis and molecular subtyping were independent factors associated with Sp17 expression.

Conclusions: Our findings suggest a role for Sp17 in tumor metastasis and aggressiveness. Whether Sp17 can be used as a prognostic marker for breast cancer will require a study of a larger sample size.

278P Intratumoral heterogeneity on dedicated breast positron emission tomography before chemotherapy predicts the outcome of neoadjuvant chemotherapy in breast cancer

N. Masumoto[1], T. Kadoya[2], E. Suzuki[2], S. Sueoka[2], N. Goda[2], S. Sasada[3], A. Emi[2], R. Haruta[2], T. Kataoka[2], M. Okada[1]

[1]Surgical Oncology, Hiroshima University, Hiroshima, Japan, [2]Breast Surgery, Hiroshima University Hospital, Hiroshima, Japan, [3]Surgical Oncology Hiroshima University, Hiroshima, Japan

Background: Dedicated breast positron emission tomography (DbPET) can detect intratumoral heterogeneity using ^{18}F-fluorodeoxyglucose (FDG). We have proved that intratumoral heterogeneous distribution of FDG on DbPET was significantly related with high nuclear grade and high Ki-67 proliferation index (Breast Cancer Res Treat 2018; 171:315–23). We aimed to evaluate whether intratumoral heterogeneous distribution of FDG on DbPET can predict the effects of neoadjuvant chemotherapy (NAC) on breast cancer.

Methods: We evaluated 58 consecutive patients with breast cancer who underwent DbPET before NAC concurrently between August 2016 and March 2018. The relationships between the pathological response for NAC and the maximum standard uptake values (SUVmax) of DbPET, including estrogen receptor (ER) and human epidermal growth factor receptor type-2 (HER2) statuses, and the intratumoral heterogeneous distribution of FDG on DbPET, were evaluated.

Results: Breast cancer with intratumoral heterogeneous distribution of FDG on DbPET showed a tendency to be related with pathological complete response (pCR) (Table). The SUVmax of DbPET showed an increasing tendency with intratumoral heterogeneous distribution. ER positive-breast cancer with intratumoral heterogeneous distribution showed a tendency to be related with pCR.

Table: 278P Relation between biological factors and pathological response

	pCR	Non-pCR	p
Grade			0.17
1–2	3	10	
3	20	25	
Ki-67			0.35
< 20%	1	4	
≥ 20%	22	31	
ER		0.07	
positive	15	24	
negative	8	11	
HER2		0.06	
positive	13	11	
negative	10	24	
DbPET, intratumoral distribution		0.23	
Heterogeneity	19	24	
Homogeneity	4	11	

Conclusions: The SUVmax of DbPET associates with intratumoral heterogeneous distribution. In addition, intratumoral heterogeneity on DbPET provides predictive value for achieving pCR on ER positive-breast cancer and might inform therapeutic decisions.

279P Results from NRG oncology/NSABP protocol DMP-1: Physician counseling

C. Holmberg[1], H. Bandos[2], W. McCaskill-Stevens[3], D.L. Wickerham[4], T. Battaglia[5], T.B. Bevers[6], A. Fagerlin[7]

[1]Social Medicine and Epidemiology, Institute of Social Medicine and Epidemiology, Medical School Brandenburg Theodor Fontane Brandenburg/Havel, Berlin, Germany, [2]Biostatistics, NRG Oncology, Pittsburgh, PA, USA, [3]Cancer Prevention, National Cancer Institute Div. Cancer Treatment, Rockville, MD, USA, [4]Oncology, NRG Oncology/NSABP, The Allegheny Health Network Cancer Institute, Pittsburgh, PA, USA, [5]Medicine, Women's Health Unit, Section of General Internal Medicine, Boston, MA, USA, [6]Clinical Cancer Prevention, The University of Texas M.D. Anderson Cancer Center, Houston, TX, USA, [7]Population Health, University of Utah School of Medicine/VA Salt Lake City, University of Michigan, Ann Arbor Center for Clinical Management, Salt Lake City, UT, USA

Background: Although selective estrogen receptor modulators (SERMs) reduce the risk of developing breast cancer (BC) in women at increased risk of the disease, there are also risks to consider. Guidelines suggest that such women should be counseled on risk-reducing options including SERMs. However, overall uptake is low. Previous results of DMP-1 showed that the health care provider's (HCP) recommendation plays an important role in a woman's decision to use a SERM. In this secondary analysis we aimed to better understand the counseling process of HCPs in the clinical care setting.

Methods: Women (N = 1,023) and their HCP discussed SERM use for BC risk reduction and were asked about the counseling, including risks and benefits presented and whether the HCP recommended SERM use. HCPs were also asked to report on the reasons for their recommendation and if the patient was likely to take a SERM or not. We describe the counseling and evaluate the agreement between the HCPs' and women's responses.

Results: HCPs reported on 1,022 counseling sessions. Benefits of SERMs in BC risk reduction were discussed in 96% of consultations; the risk of thromboembolism, endometrial cancer, and menopausal symptoms was discussed in > 86%; the risk of cataracts and decrease in libido in < 58%. Five HCPs reported no SERM discussion and were excluded. 66% of HCPs based their recommendation of SERM use on the Gail model risk score. Data for 895 participants were available to evaluate agreement. There was a modest agreement between the women's and the HCPs' statements on SERM recommendation (kappa=0.50), with fair agreement on the strength of the recommendation (weighted kappa=0.22) and substantial agreement between a woman's decision and the HCP's assumption of what his/her patient would do (kappa=0.65).

Conclusions: Most severe medical risks associated with SERM use were discussed during the counseling. The fairly low percentage of discussions about potential sexual consequences was comparable to that of other studies. Overall, there was fair to moderate agreement between HCPs and women's perceptions of the counseling. Of note, HCPs had a good sense of what treatment the counseled women would choose. Support: U10CA180868, -180822; UG1-CA189867.

280P Neoadjuvant eribulin plus carboplatin vs. paclitaxel plus carboplatin in patients with triple-negative breast cancer (TNBC)

L. Gigolaeva[1], P. Krivorotko[1], S. Khadzhimatova[1], E. Zhiltsova[1], S. Yerechshenko[1], M. Nikitina[1], V. Ni[1], A. Emelyanov[1], E.N. Imyanitov[2], A.P. Sokolenko[2], T. Tabagua[1]

[1]Breast Tumors Department, Petrov's National Medical Research Center for Oncology, St. Petersburg, Russian Federation, [2]Department of Tumor Growth Biology, Petrov's National Medical Research Center for Oncology, St. Petersburg, Russian Federation

Background: Eribulin is a novel microtubule poison, which has certain advantages as compared to taxanes in some laboratory experiments and shows clinical efficacy in breast cancer patients after failure of taxane and anthracycline treatment. Promising activity of neoadjuvant eribulin plus carboplatin combination was shown in previous TNBC studies [Kaklamani et al. Breast Cancer Res Treat, 2015]. This investigation aimed to directly compare the efficacy of neoadjuvant eribulin/carboplatin vs. paclitaxel/carboplatin doublets in TNBC patients.

Methods: 61 TNBC patients (median age 45, range 31-76) were randomized to receive carboplatin AUC6 with either eribulin (1.1 mg/m^2 on days 1 and 8, every three weeks) or paclitaxel (80 mg/m^2 on days 1 and 8, every three weeks). Each patient was treated with four cycles of neoadjuvant therapy followed by surgery and four cycles of adjuvant FAC (5-fluorouracil 500 mg/m^2, doxorubicin 50 mg/m^2, cyclophosphamide 500 mg/m^2). After adjuvant chemotherapy, patients with breast-conserving surgery or with positive lymph nodes also received radiation treatment.

Results: The rates of clinical complete responses were similar in both cohorts (eribulin/carboplatin: 12/24 (50%); paclitaxel/carboplatin: 19/37 (51%)). Pathologic complete responses (pCR) were numerically less frequent in patients receiving eribulin [9/24 (38%) vs. 20/37 (54%)], although the difference was below statistical significance (p = 0.2). Five patients were carriers of deleterious BRCA1 alleles; pCRs were observed

in 2/3 (67%) and 2/2 (100%) women in eribulin and paclitaxel arms, respectively. 56 patients had a follow-up above 12 months at the time of data analysis. 4/24 (17%) disease recurrences were documented in the eribulin arm, while only 1/32 (3%) TNBC relapse was noticed for paclitaxel ($p = 0.15$).

Conclusions: Eribulin plus carboplatin combination does not outperform, in terms of pathomorphological response to treatment, paclitaxel plus carboplatin doublet while given as a neoadjuvant treatment for triple-negative breast cancer.

281TiP A phase Ib/II study of durvalumab combined with dose-dense EC in neoadjuvant setting for patients with locally advanced luminal B HER2(-) or triple negative breast cancers (B-IMMUNE)

A. Devaux[1], J-L. Canon[2], F.P. Duhoux[3], P. Delrée[4], C. Galant[5], P.G. Coulie[1], I. Bar[4], M. Constant[4], S. Haussy[4], O. Bricard[1], K. Missault[1], M. Berlière[6], T. Willems[7], J. Carrasco[2]

[1]GECE Unit, De Duve Institute, UCL, Brussels, Belgium, [2]Oncology, Grand Hopital de Charleroi Site Notre Dame, Charleroi, Belgium, [3]Medical Oncology, King Albert II Cancer Institute, Cliniques Universitaires Saint-Luc, Brussels, Belgium, [4]Laboratoire d'Oncologie Translationnelle, Grand Hopital de Charleroi/Institut de Pathologie et Génétique, Gosselies, Belgium, [5]Pathology, Cliniques Universitaires Saint-Luc, Brussels, Belgium, [6]Gynecology, Cliniques Universitaires Saint-Luc, Brussels, Belgium, [7]Gynecology, Grand Hopital de Charleroi Site Notre Dame, Charleroi, Belgium

Background: Most patients with advanced breast cancer (BC) do not respond to immunotherapy with immunostimulating antibodies. Breast tumours are considered poorly antigenic due to a low mutational load, yet they contain tumour-infiltrating lymphocytes (TILs). As continuous immune pressure selects tumours that escape immune destruction, there is growing interest for the use of immunostimulatory antibodies for early-stage cancers. Based on data suggesting that anthracyclines increase tumour immunogenicity, we initiated a phase Ib/II trial to study the safety and efficacy of the anti-PD-L1 antibody durvalumab combined to epirubicin in the neoadjuvant setting for localized BC.

Trial design: B-IMMUNE study is a multicentric prospective trial including luminal B HER2(-) and triple negative BC (TNBC) patients. The study includes two parts. First a phase Ib with a 3 + 3 design whose primary objective is to evaluate the safety of an increasing number of durvalumab infusions associated to dose-dense Epirubicin-Cyclophosphamide (EC) after weekly paclitaxel for 12 weeks in the neoadjuvant setting. Then, if the durvalumab-EC combination is safe, a phase II will be initiated with an open-label 4:1 randomization in favour of the experimental durvalumab arm. Its primary objective is to evaluate clinical efficacy based on the complete pathological response rate (pCR) compared to historical controls (15% for luminal B HER2(-) BC and 30% for TNBC). The phase II will include 24 luminal B HER2(-) BC patients and 22 TNBC patients, allowing to detect pCR rate improvements of 40% and 60%, respectively ($\alpha \leq 0.1$ and $\beta \leq 0.1$). Exploratory objectives include the identification of predictive biomarkers for anti-PD-L1 efficacy with a focus on the TCR repertoires of tumour-infiltrating T cells collected before and after durvalumab. Translational research will evaluate the presence of tumour-specific CD8 T cells among TILs and the influence of durvalumab on this population using the control arm as a reference.

282TiP Real-world effectiveness of ribociclib + aromatase inhibitor, or endocrine monotherapy, or chemotherapy as first-line treatment in postmenopausal women with HR-positive, HER2-negative locally advanced or metastatic breast cancer: The RIBANNA study

P.A. Fasching[1], T. Decker[2], G. Guderian[3], J. Heim[4], C. Jackisch[5], H-J. Lueck[6], D. Lüftner[7], F. Marmé[8], T. Reimer[9], A. Woeckel[10]

Background: In the double blind, placebo-controlled phase III MONALEESA-2 trial, the selective CDK4/6 inhibitor ribociclib in combination with letrozole significantly prolonged progression free survival (PFS) in patients who were treatment-naïve for HR+/HER2- advanced breast cancer (aBC). In 2017, Ribociclib was approved in combination with an aromatase inhibitor (AI) for the treatment of HR+/HER2- aBC (locally advanced or metastatic). However, real-world evidence for the effectiveness, safety and tolerability of ribociclib+AI in routine clinical practice is needed to further support its use.

Trial design: RIBANNA is a non-interventional study (NIS) running in Germany since Oct 2017. Up to 400 German sites are expected to enroll 3020 postmenopausal patients receiving ribociclib+AI, or endocrine monotherapy, or chemotherapy as first-line treatment for HR+/HER2- aBC. Data will be collected from clinical practice on the effectiveness, safety, tolerability, and duration of therapy, including impact on quality of life (QoL) in all three cohorts prescribed in line with the respective German prescribing guidelines. These data and the corresponding outcomes will be described for the three different cohorts. Further lines of treatment will also be documented in RIBANNA to gain insight into the outcome of sequential therapy. For this purpose, patients will be documented for up to 7 years in total. In addition, RIBANNA will collect information on QoL using validated patient reported outcome measures to assess the impact of routine ribociclib+AI treatment, endocrine monotherapy or chemotherapy. The RIBANNA study will provide the first real-world evidence regarding the treatment of HR+/HER2- aBC/mBC with the novel CDK4/6 inhibitor ribociclib, including insights into treatment regimen, sequence of therapies and impact on QoL.

Background: The purpose of the VicTORia trial was to evaluate efficacy and safety of the combined treatment of everolimus (EVE) and vinorelbine (VIN) compared to VIN monotherapy as second-line treatment for HER2-negative advanced breast cancer. The study was accompanied by an exploratory analysis of phosphoinositide 3 kinase subunit (PIK3CA) as potential predicitve marker for response.

Methods: Patients were randomized 1:1 to receive i.v. VIN at a dose of 25 mg/m2 on days 1, 8 and 15 q3w plus 5 mg EVE once daily or i.v. VIN at a dose of 25 mg/m2 on days 1, 8 and 15 q3w. The primary objective was progression-free survival (PFS). Safety and tolerability, overall survival (OS) and overall response rates were secondary objectives. The mutational status of PIK3CA was determined at baseline from plasma samples.The study was initially planned to enroll 166 patients.

Results: Between December 2011 and February 2016 138 patients were enrolled from 32 sites across Germany. Of 69 patients randomized to receive VIN plus EVE, 68 received treatment and 65 of 69 patients randomized to VIN monotherapy received treatment. Baseline characteristics were balanced. Median age was 63 and 62 years, ECOG 0-1 98.5% and 90.7%, postmenopausal status 79.4% and 80.0%, and visceral metastases 89.7% and 87.7%, respectively. Median PFS was 4.01 months [95% CI, 2.40-6.09] for the combination vs. 4.08 months [95% CI, 2.80-5.33] for VIN monotherapy (HR = 1.05 [0.730-1.512], log rank p = 0.7908). The median OS was not statistically different between treatment arms (VIN+EVE: 16.25 months [95% CI, 11.38-18.95] vs. VIN: 13.78 months [95% CI, 10.23-19.05]), log rank p = 0.9361). PIK3CA mutational status was neither associated with PFS nor with OS in the total patient cohort, in patients treated with VIN+EVE and in patients treated with VIN monotherapy, respectively.

Conclusions: The addition of EVE to VIN was not associated with a benefit in PFS. Overall survival also did not significantly differ between treatment arms. No correlation between PIK3CA mutation status and outcome was detected.

296P Applicability of the lung immune prognostic index (LIPI) to metastatic triple negative breast cancer (mTNBC) patients treated with immune checkpoint targeted monoclonal antibodies (ICT mAbs)

A. Vozy[1], A. Simonaggio[1], E. Auclin[2], L. Mezquita[3], C. Baldini[1], P. Martin-Romano[1], B. Pistilli[4], A. Gazzah[1], R. Bahleda[1], V. Ribrag[1], S. Postel-Vinay[1], S. Champiat[1], J-C. Soria[5], F. André[6], C. Massard[7], B. Besse[8], S. Delaloge[4], A. Varga[1]

[1]DITEP, Gustave Roussy Institut de Cancérologie, Villejuif, France, [2]Oncology, Hopital European George Pompidou, Paris, France, [3]Department of Cancer Medicine, Gustave Roussy Institut de Cancérologie, Villejuif, France, [4]Breast Cancer Unit, Department of Medical Oncology, Gustave Roussy - Cancer Campus, Villejuif, France, [5]DITEP, Medimmune, Gaithersburg, MD, USA, [6]Breast Cancer Unit, Department of Medical Oncology, Gustave Roussy - Cancer Campus, Villejuif, France, [7]DITEP, Gustave Roussy Institut de Cancérologie, Villejuif, France, [8]Department of Cancer Medicine, Gustave Roussy Institut de Cancérologie, Villejuif, France

Background: Tumor-infiltrating lymphocytes are prognostic and predictive in TNBC. However, the level of activity of Immune Checkpoint Targeted Monoclonal Antibodies (ICT mAbs) remains low in this indication and biomarkers are needed to select for patients who could benefit from these treatments. Pretreatment LIPI, based on derived NLR (dNLR = neutrophils/[leucocytes-neutrophils]) and lactate dehydrogenase (LDH) assessment has been associated with outcomes for ICT mAbs in advanced NSCLC patients. We tested whether LIPI has the same impact on mTNBC patients' outcome.

Methods: Biological and clinical data were retrospectively collected from mTNBC patients treated with ICT mAbs between Jan 2014 & Apr 2018 in our Drug Development Department. Three LIPI risk groups were studied: good (dNLR<3 & LDH<upper limit of normal (ULN)), intermediate (dNLR>3 or LDH>ULN), poor (dNLR>3 & LDH>ULN). The primary endpoint was progression-free survival (PFS) and the secondary endpoint was overall survival (OS).

Results: Forty-two patients were included with a median age of 45, 48% were ECOG 0 and the median prior chemotherapy lines was 3. Twenty-one percent of patients received a PD1/PD-L1 inhibitor as monotherapy, 79% had ICT mAbs combination. The median PFS and OS under ICT mAbs was 1.35 months (IC 95% 1.27; 2.93) and 13.5 months (5.9; not reached) respectively according to RECIST v1.1. LIPI classified 18 patients as good (43%), 18 patients (43%) as intermediate and 6 patients (14%) as poor risk group. Median PFS was 2.65, 1.32 and 0.85 months for good (GP), intermediate (IP) and poor prognosis (PP) respectively (P = 0.002). Median OS was 18.10 months for GP, 9.8 months for IP and 1.6 months PP (P = <0.0001). Metastatic cutaneous lesions were also associated with poor PFS with ICT mAbs in our cohort, HR 3.189, P = 0.0028. The PDL1 status does not seem to influence LIPI risk groups.

Conclusions: Applying baseline LIPI in mTNBC patients is feasible and is correlated with ICT mAbs outcomes for this population. A larger retrospective validation cohort is being evaluated and more data will be available for the ESMO presentation.

297P Peripheral blood mononuclear cell biomarkers predict response to immune checkpoint inhibitor therapy in metastatic breast cancer

Y. Yuan[1], W. Hou[2], S. Padam[1], P. Frankel[3], M.S. Sedrak[1], J. Portnow[1], J. Mortimer[1], C. Yeon[1], A. Hurria[1], A. Tang[1], N. Martinez[1], P. Lee[2]

[1]Medical Oncology, City of Hope, Duarte, CA, USA, [2]Immunology, City of Hope, Duarte, CA, USA, [3]Biostatistics, City of Hope, Duarte, CA, USA

Background: The role of immune checkpoint PD-1/PD-L1 inhibitor (ICI) in breast cancer (BC) is being investigated in clinical trials. Preclinical evidence strongly supports the synergistic effects of CDK4/6 inhibitor and ICI. A phase II trial is testing the safety and efficacy of the combination of letrozole, palbociclib and pembrolizumab in patients with hormone receptor positive (HR+) BC (NCT02778685). Currently, there is no well-defined circulating biomarker to predict response to ICI.

Methods: Peripheral blood mononuclear cells (PBMC) were collected at day 1 of cycles 1 (pre-treatment), 2, 4, 6 and 8. The comprehensive characterization of 14 innate cell types, 7 adaptive T-cells, and 16 exhaustion-related T-cells was performed using 15-color flow cytometry. Core biopsies were taken at baseline and optionally on-study to assess immune cell subsets.

Results: Preliminary analysis included nine patients with the following responses by RECIST 1.1: 1 complete response, 4 partial responses, 2 stable disease, and 2 progression of disease. Analysis showed correlation of clinical response to high baseline levels of γδ T-cells (r = 0.74, p = 0.02) and exhausted T-cells: $CD4^+PD\text{-}1^+KLRG1^+$ (r = 0.74, p = 0.02), $CD4^+PD\text{-}1^+CD160^+$ (r = 0.71, p = 0.02), and $CD4^+PD\text{-}1^+TIM3^+$ (r = 0.71, p = 0.03). Most patients showed a decrease in the number of $CD33^{hi}$ myeloid-derived suppressor cells (p = 0.04) and $CD4^+PD\text{-}1^+TIGIT^+$ exhausted T-cells (p = 0.04) in peripheral blood at C2D1. Strong indicators of clinical response included increased $CD33^{low}$ myeloid-derived suppressor cells (r = 0.70, p = 0.04) and decreased type-1 CD8+ T-cells (r = 0.81, p = 0.009) at C4D1.

Conclusions: High pre-treatment peripheral blood exhausted CD4+ T-cells is associated with clinical response to ICI in HR+BC. Further analysis including tumor tissue immune profiling is currently ongoing to verify these findings.

Clinical trial identification: NCT02778685.

298P Circulating exosomal microRNA profiling to depict mechanisms of chemotherapy resistance among triple negative breast cancer

Y. He[1], T. Jinhai[2]

[1]Department of General Surgery, Jiangsu Province Hospital, Nanjing, China, [2]Department of General Surgery, The First Affiliated Hospital with Nanjing Medical University, Nanjing, China

Background: Chemotherapeutic resistance leads to high mortality among triple negative breast cancer (TNBC) patients and underlying mechanisms are poorly understood. Exosomes have become new area of interest for liquid biopsy. MicroRNAs (miRNAs), as the most important inclusions in exosomes, are ideal candidate biomarkers and therapeutic targets.

Methods: We isolated exosomes and analyzed exosome-carried miRNA signatures in several TNBC cells lines sensitive or resistant to adariamycin, docetaxel or cisplatin. The resistance transfer capacity was determined by flow cytometry after sensitive cells incubated 48 hours with exosomes from drug-resistant cells. Locked nucleic acid probes and enzyme-labeled fluorescence (LNA-ELF-FISH) was performed to detect exosomal miRNA molecule transfer. Animal mode was constructed to evaluate treatment feasibility using miRNA-modified exosomes. Serum exosomes from 40 TNBC stage IV patients who underwent chemotherapy before or after progressive disease (PD) status were isolated to analyze miRNA profiling for potential biomarker identification.

Results: We successfully isolated and identified exosomes from several drugsensitive and resistant TNBC cell lines and patients. Exosomal miR-222, miR-4443, miR-100, miR-17, miR-210 were found significantly upregulated from chemotherapy-resistant cells. Incubation of exosomes from the resistant cells with the sensitive cells resulted in increasing resistant capacity among sensitive cells. Exosomal miRNA molecule transfer was detected using LNA-ELF-FISH. Transfection of synthesized miRNAs competitors into exosomes increased drug sensitivity in vivo. Exosomal miR-222, miR-4443, miR-100, miR-17, miR-210 were also found upregulated significantly from serums of patients after PD status. These five miRNAs were able to differentiate patients with PD status from those with CR or PR status with at least 89% accuracy.

Conclusions: Exosomes from chemotherapy-resistant TNBC cells could transfer drug resistance to sensitive cells via exosomal miRNAs. A circulating exosomal microRNA profiling was estabilished for potential biomarkers and therapeutic target identification.

299P The prevalence of PIK3CA mutations in HR+/HER2– metastatic breast cancer (BELLE2, BELLE3 and BOLERO2 clinical trials)

K. Wan[1], Y.A. Wang[2], M. Kaper[3], M. Fritzemeier[4], N. Babbar[5]

[1]Biostatistics, Novartis Pharma AG, Basel, Switzerland, [2]Biostatistics, Novartis Institutes for BioMedical Research, Cambridge, MA, USA, [3]Biostatistics, Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA, [4]Oncology Precision Medicine, Novartis Institutes for BioMedical Research, Cambridge, MA, USA, [5]Oncology Precision Medicine, Novartis, East Hanover, NJ, USA

Background: Breast cancer (BC) is the most common form of malignant tumor in women worldwide. 60-70% of BC are hormone receptor-positive (HR+), HER2-negative (HER2–). The purpose of this analysis was to enhance understanding on the epidemiology for women with PIK3CA-mutant HR+/HER2– metastatic breast cancer (mBC).

Methods: PIK3CA mutations were tested from tumor biopsy (N = 1617) and circulating tumor DNA (ctDNA) (N = 1466) from patients enrolled into BOLERO-2, BELLE-2 and BELLE-3, which are three randomized Phase III studies in HR+/HER2– mBC. Various PIK3CA mutation testing methods were applied, including Next-Generation Sequencing (NGS) and Polymerase Chain Reaction (PCR) for tumor biopsies, as well as BEAMing and droplet digital PCR for ctDNA samples.

Results: Prevalence of the PIK3CA mutations among tissue biopsies ranged from 34.1% to 41.1% while prevalence of the PIK3CA mutations among liquid biopsies ranged from 27.5% to 43.3%. Besides gene-level analysis, the PIK3CA prevalence by hot spots and by exons was examined as well. Further, subgroup analysis of PIK3CA prevalence had been conducted based on patient cohort (2L vs 3L), mutation testing methods, ethnicity, biopsy source (primary tissue vs metastatic) and previous treatment.

Conclusions: PIK3CA mutations (specifically hotspots H1047R, E545K and E542K) frequently occur in HR+/HER2– mBC. The prevalence of PIK3CA mutations are in a relatively narrow range across the three randomized Phase III studies in HR+/HER2– mBC regardless of tissue types and testing methods.

300P Differential molecular signature in patients from African origin with triple-negative breast cancer

A.T. Matias[1], A. Jacinta-Fernandes[2], R. Magno[2], J. Xavier[2], M.G. Cabral[1], A. Jacinto[1], A.T. Maia[2], S. Braga[1]

[1]CEDOC, Nova Medical School, Lisbon, Portugal, [2]Department of Biomedical Sciences and Medicine (DCBM), Centre for Biomedical Research (CBMR), Algarve Biomedical Center (ABC), University of Algarve, Campus de Gambelas, Faro, Portugal

Background: Breast cancer (BC) is more aggressive in pre-menopausal women of Black race (BW). These women usually have worse prognosis and higher mortality rate when compared with patients of other races, even when socioeconomic factors are accounted for. Triple-negative BC (TNBC), the most aggressive and less treatable BC, due to the lack of therapeutic targets, such as oestrogen and progesterone receptor or HER2, is more frequently diagnosed in these young BW.

Methods: To identify the driving biological factors of this racial disparity we performed a comprehensive differential gene expression (DGE) analysis using the R package edgeR and RNA-sequencing BC data from The Cancer Genome Atlas, which has specifically USA data. In a total of 1097 BC patients, 183 are BW, 32 with TNBC (17.5% of all BW); 757 are White, 69 with TNBC (9.1%); and 61 are Asian, 8 with TNBC (13.1%).

Results: DGE between BW with TNBC and TNBC patients of other races revealed 251 up- and 269 downregulated genes (adjusted p-value ≤ 0.05, $|\log_2(\text{Fold Change})| \geq 1$, applied in all the analysis). To remove genes associated with race alone and not with TNBC in BW per se, we performed a DGE analysis between all non-TNBC cases in BW and all non-TNBCs in the other races, resulting in 315 up- and 139 downregulated genes in non-TNBCs of BW. Common genes between the two analyses were identified and extracted from the first list, resulting in 198 up- and 250 downregulated genes exclusively differentially expressed in TNBC of BW. Our candidates include genes related to insulin-resistance and obesity (e.g. FBXO2 [p-adj = 2.07E-04, $\log_2$FC = 1.58], POU2AF1 [p-adj = 1.80E-03, $\log_2$FC = 1.43]), and epithelial-mesenchymal transition and metastasis (e.g. FOXF2 [p-adj = 9.51E-05, $\log_2$FC = 1.39], NOTCH3 [p-adj = 9.51E-05, $\log_2$FC = 1.35]). These genes are being validated using formalin-fixed paraffin-embedded TNBC tissues from BW, collected from different Portuguese hospitals and from a Mozambican hospital, where tumour tissue is compared to normal adjacent tissue by qRT-PCR, immunohistochemistry and Western blot.

Conclusions: Our work will unveil the molecular signature(s) that characterise and define molecularly TNBC in BW and, ultimately, will guide the development of new therapeutics for this unmet medical problem.

301P Analysis of the JAK2 gene in triple-negative breast cancer (TNBC)

L. Stanek[1], P. Tesarova[2], M. Vocka[2], L. Petruzelka[2]

[1]Department of Oncology, First Faculty of Medicine of Charles University in Prague, Prague, Czech Republic, [2]Department of Oncology, General Faculty Hospital, VFN Charles University, Prague, Czech Republic

Background: The JAK2 gene is located on chromosome 9p24.1, its product is a tyrosine kinase protein that plays a role in signal transduction between membrane receptors for growth factors and intracellular signaling molecules and is also involved in cytokine signaling. Mutation V617F of JAK2 (Janus kinase 2) causes violation of autoinhibiting activity and promotes malignant transformation and proliferation. Recent studies, however, indicate a possible amplification of somatic chromosome 9p24.1 region encoding the JAK2 in triple-negative breast cancer (TNBC) in connection with a poorer prognosis and shorter survival.

Methods: The aim of our pilot study was to perform a cytogenetic and molecular biological analysis of the JAK2 gene in a cohort of 40 patients diagnosed and confirmed with TNBC. The FISH method was used to analyze numerical changes and translocations, including the detection of possible merger partners. In the next step mutation analysis was by PCR and direct sequencing performed.

Results: On the basis of cytogenetic and molecular changes of the JAK2 gene, it can be stated that the numerical, structural and molecular changes occur in TNBC at a high frequency. In addition to amplification which is a potential predictor of ruxolotinib inhibition, a number of numerical and structural changes (including point mutations) of the gene was detected (amplification detected in 25% of cases, polysomy detected in 15% of cases, monosomy detected in 5% of cases, break detection in 10% of cases, amplification/break detected in 10% of cases). Mutational analysis showed the presence of the V617F mutation in 15% of cases where there was normal cytogenetics.

Conclusions: These changes may potentially cause worse response to treatment with an inhibitor and will require us to focus attention in this direction.

302P A risk score integrating lymphocytes ratios (LRs) and lactate dehydrogenase (LDH) levels to predict prognosis in metastatic breast cancer (MBC) patients

G. Pelizzari[1], L. Gerratana[1], D. Basile[1], S. Zago[2], M.G. Vitale[1], M. Bartoletti[1], C. Lisanti[1], V. Fanotto[1], C. Corvaja[1], L. Bortot[1], A. Liguori[3], M. Cinausero[1], S. Russo[4], C. Andreetta[4], M. Bonotto[4], M. Mansutti[4], A.M. Minisini[4], F. Curcio[5], G. Fasola[4], F. Puglisi[6]

[1]Department of Medicine (DAME), University of Udine, Udine, Italy, [2]Clinical Pathology, Hospital "Santa Maria degli Angeli", Pordenone, Italy, [3]Medical Oncology Unit, Department of Human Pathology "G. Barresi", AOU Policlinico G. Martino Università di Messina, Messina, Italy, [4]Department of Oncology, ASUIUD Santa Maria della Misericordia, Udine, Italy, [5]Clinical Pathology Institute, ASUIUD Santa Maria della Misericordia, Udine, Italy, [6]University of Udine - Udine, Italy, Department of Medical Oncology and Cancer Prevention, CRO National Cancer Institute, Aviano, Italy

Background: Monocyte-to-lymphocyte ratio (MLR), neutrophil-to-lymphocyte ratio (NLR) and LDH levels have been associated with worse prognosis in several malignancies, including MBC. This study aimed at exploring the prognostic impact of a novel risk score, integrating baseline LRs and LDH levels in MBC patients (pts).

Methods: This retrospective study analyzed 396 consecutive pts with a diagnosis of MBC, treated between 2007 and 2017 at the Oncology Department of Udine (Italy). MLR and NLR cut-offs were previously obtained through ROC analysis using propensity score-matched healthy controls (Gerratana et al 2018). The LDH cut-off value (480 U/L) was chosen according to the local laboratory upper reference limit. Based on these data, an integrated LRs-LDH score (LLS) was calculated ranging from 0 (LRs and LDH low), through 1 (LRs or LDH high), to 2 (both LRs and LDH high). The prognostic impact of baseline LLS was investigated through Cox regression, and differences in survival were tested by log-rank test.

Results: After a median follow-up of 52.8 months, median overall survival (OS) was 30.9 months and median progression free survival (PFS) was 9.2 months. Pts with baseline elevated MLR, NLR or LDH were 64.2% (251/391), 70.8% (277/391), and 31.5% (70/222), respectively. The 78.8% (308/391) of pts had elevated LRs (MLR, NLR or both). Considering subgroup analysis, no interaction was seen between LDH and LRs. By multivariate analysis, after adjustment for molecular profiles, performance status, number of metastatic sites, central nervous system and liver involvement, a worse prognosis in terms of OS was seen for pts with elevated levels of both LRs and LDH (LLS 2: HR 2.41, 95% CI: 1.31-4.37, p=.003), compared to pts with normal LRs and LDH (LLS 0). Notably, significant differences in OS were observed according to the LLS (LLS 2: median OS 19.2 months, LLS 1: median OS 43.9 months, LLS 0: median OS 54.9 months; p<.0001).

Conclusions: Baseline LLS is able to predict survival in pts with MBC and provides independent prognostic information. Prospective studies are needed to validate this novel score and to explore how it may affect different treatment strategies.

303P EMBRACA: Comparison of efficacy and safety of talazoparib (TALA) and physician's choice of therapy (PCT) in patients (pts) with advanced breast cancer (aBC), a germline BRCA1/2 mutation (gBRCAm), and prior platinum treatment

M. Martín[1], W. Eiermann[2], H.S. Rugo[3], J. Ettl[4], S.A. Hurvitz[5], A. Gonçalves[6], R. Yerushalmi[7], D. Markova[8], I.C. Tudor[8], J.L. Blum[9], A.L. Hannah[10], J.K. Litton[11]

[1]Medical Oncology, Instituto de Investigación Sanitaria Gregorio Marañón, CIBERONC, GEICAM, Universidad Complutense, Madrid, Spain, [2]Chest Surgery, Interdisziplinäres Onkologisches Zentrum München, Munich, Germany, [3]Breast Cancer Center, UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA, USA, [4]Obstetrics and Gynecology, Klinikum Rechts der Isar, Technische Universität München, Munich, Germany, [5]Hematology/Oncology, University of California, Los Angeles, CA, USA, [6]Medical Oncology, Institut Paoli-Calmettes, Marseille, France, [7]Medical Oncology, Rabin Medical Center, Beilinson Hospital, Petah Tikva, Israel, [8]Biostatistics, Pfizer, Inc., San Francisco, CA, USA, [9]Medical Oncology, Baylor Sammons Cancer Center, Dallas, TX, USA, [10]Medical Oncology, Pfizer, Inc., San Francisco, CA, USA, [11]Breast Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA

Background: TALA is a dual-mechanism PARP inhibitor that prevents DNA damage repair by trapping PARP on DNA, resulting in cell death in BRCA1/2-mutated cells.

Methods: EMBRACA is an open-label, randomised, 2-arm phase 3 trial in which efficacy and safety of TALA (1 mg/day) is compared with standard single-agent PCT (capecitabine, eribulin, gemcitabine, or vinorelbine) in pts with aBC and gBRCAm. In this analysis clinical outcomes were assessed in 2 subgroups of pts who had either received prior platinum (PP) or had no prior platinum (NPP) treatment.

Results: Of 431 pts randomised, 76 had PP in any setting (46 TALA; 30 PCT) and 355 were NPP (241 TALA; 114 PCT). Mean (SD) age was 46.4 (11.15) years. Pts in all groups had received a median of 1 prior cytotoxic regimen for aBC. TALA demonstrated a statistically significant improvement in both objective response rate (odds ratio [OR] [95% CI]: PP 3.16 [0.88-15.67], P=.0456; NPP 5.36 [2.89-9.89], P<.0001) and progression-free survival (hazard ratio [95% CI]: PP 0.76 [0.40-1.45], P=.41; NPP 0.52 [0.39-0.71], P<.0001) compared with PCT. Mean (SD) duration of TALA therapy was 7.2 (6.52) mo (PP) and 8.7 (7.09) mo (NPP), with 15% (PP) and 19% (NPP) of pts receiving TALA for ≥12 mo. Median duration of response (DOR) to TALA was longest in NPP pts (5.4 mo), followed by PP pts (4.2 mo); pts receiving PCT had a DOR of approximately 3.0 mo regardless of prior platinum status. Pts on TALA achieved a clinical benefit rate at 24 weeks (PP 59%; NPP 71%) with OR significantly favouring TALA over PCT in both groups. Of pts receiving TALA, nausea was the most common adverse event (AE) in PP pts (59%) and anaemia in NPP pts (53%). Serious AEs occurred in both PP (33%) and NPP pts (32%) taking TALA.

Conclusions: In pts with advanced gBRCAm breast cancer, TALA demonstrated statistically significant improvements in clinical outcomes for both PP and NPP subgroups compared with PCT. Although TALA treatment benefitted both groups, the benefit was greater if TALA was used before platinum therapy.

Clinical trial identification: NCT01945775.

Methods: EMBRACA is an open-label, randomized, 2-arm phase 3 trial comparing the efficacy and safety of TALA (1 mg/day) with standard single-agent PCT (capecitabine, eribulin, gemcitabine, or vinorelbine) in pts with aBC and a gBRCAm). In this analysis clinical outcomes were assessed in BRCA1 and BRCA2 subgroups.

Results: Of 431 pts randomized, 196 were BRCA1 (133 TALA; 63 PCT), 235 were BRCA2 (154 TALA; 81 PCT). Mean (SD) age was 45.4 (11.66) years (BRCA1) and 50.4 (11.45) years (BRCA2). Pts in all groups had received a median of 1 prior cytotoxic regimen for aBC. TALA demonstrated a statistically significant improvement in both objective response rate (odds ratio [OR] [95% CI] BRCA1 7.01 [2.99-19.54]; BRCA2 4.15 [1.90-8.52]; both P<.0001) and progression-free survival (hazard ratio [95% CI] BRCA1 0.59 [0.39-0.90]; BRCA2 0.47 [0.32-0.70]) in BRCA1 and BRCA2 subgroups compared with PCT. Mean (SD) duration of TALA therapy was 7.5 (7.07) mo (BRCA1) and 9.2 (6.88) mo (BRCA2), with 15% (BRCA1) and 22% (BRCA2) of pts receiving TALA for ≥12 mo. Median duration of response (DOR) to TALA was longest in BRCA2 pts (6.3 mo), followed by BRCA1 pts (4.2 mo); BRCA1 and BRCA2 pts receiving PCT had a DOR of approximately 3.0 mo. Pts on TALA achieved a clinical benefit rate at 24 weeks (BRCA1 62%; BRCA2 74%) with OR significantly favouring TALA over PCT in both groups. Of pts receiving TALA, anaemia was the most common adverse event (AE) in BRCA1 pts (56%) and fatigue in BRCA2 pts (50%). Serious AEs occurred in both BRCA1 and BRCA2 pts (32%) receiving TALA.

Conclusions: In pts with advanced gBRCAm breast cancer, TALA demonstrated statistically significant improvements in clinical outcomes for both BRCA1 and BRCA2 subgroups compared with PCT.

Clinical trial identification: NCT01945775.

305P Exposure-efficacy progression-free survival (PFS) analyses of breast cancer patients with germline BRCA1/2 mutations receiving talazoparib in the phase III EMBRACA trial

Y. Yu[1], M. Elmeliegy[1], J.K. Litton[2], I.C. Tudor[3], A. Czibere[4], J. Zheng[5], D.D. Wang[1]

[1]Oncology, Pfizer, Inc., La Jolla, CA, USA, [2]Breast Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [3]Biostatistics, Pfizer, Inc., San Francisco, CA, USA, [4]Oncology, Pfizer, Inc., Cambridge, MA, USA, [5]Oncology, Pfizer, Inc., Collegeville, PA, USA

Background: Talazoparib is a potent, orally bioavailable, poly (adenosine diphosphate-ribose) polymerase (PARP) inhibitor that is currently under development for the treatment of a variety of cancers. This exposure-response (ER) analysis characterized the relationship between talazoparib exposure and PFS in patients with locally advanced and/or metastatic breast cancer with germline breast cancer susceptibility gene (BRCA) mutations based on the phase 3 EMBRACA trial.

Methods: 285 patients, who were treated with talazoparib and had available pharmacokinetic (PK) parameters from the phase 3 EMBRACA trial, were included in the analysis. There were 185 PFS events at the data cut of the analysis. The apparent talazoparib clearance (CL/F) for each patient was obtained from a population PK analysis. To account for dose modifications over time, the ER analysis used a time-varying exposure metric ($C_{avg,t}$) for talazoparib exposure. At each PFS event, the talazoparib exposures up to the time of the PFS event t were calculated for all patients at risk using average daily dose intensity up to time t and CL/F and correlated with the probability of having a PFS event using the Cox proportional hazards model. Other potential prognostic factors were also tested as covariates for PFS. The significant covariates identified in univariate analyses were further examined for significance in multi-variate analyses.

Results: The ER analysis for PFS showed that there was a significant correlation between PFS and talazoparib exposure. A longer PFS was associated with higher talazoparib exposure. In addition, longer PFS was also associated with lower baseline lactate dehydrogenase. PFS was longer in patients without visceral disease than patients with visceral disease. A diseasefree interval of >12 months was associated with a longer PFS than that of ≤ 12 months.

Conclusions: PFS was found to be associated with $C_{avg,t}$, and a longer PFS was associated with a higher talazoparib exposure. This supports using 1 mg QD, the maximum tolerated dose, as the recommended dose for talazoparib.

Clinical trial identification: NCT01945775.

306P Exposure-safety analyses in breast cancer patients with germline BRCA1/2 mutations receiving talazoparib (TALA) in EMBRACA and ABRAZO trials

M. Elmeliegy[1], Y. Yu[1], J.K. Litton[2], N.C. Turner[3], A. Czibere[4], G.G. Wilson[5], I.C. Tudor[6], J. Zheng[7], D.D. Wang[1]

[1]Oncology, Pfizer, Inc., La Jolla, CA, USA, [2]Breast Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [3]Toby Robins Breast Cancer Research Centre, The Royal Marsden, London, UK, [4]Oncology, Pfizer, Inc., Cambridge, MA, USA, [5]Oncology, Pfizer, Inc., New York, NY, USA, [6]Biostatistics, Pfizer, Inc., San Francisco, CA, USA, [7]Oncology, Pfizer, Inc., Collegeville, PN, USA

Background: TALA is a potent PARP inhibitor. Efficacy and safety profiles of once-daily TALA 1 mg were established in advanced breast cancer patients (pts) in the phase 3 EMBRACA and phase 2 ABRAZO trials. Approximately 60% of pts experience dose modification due to an adverse event (AE). This analysis characterized the relationship between TALA exposure and grade 3 or higher anemia, neutropenia, and thrombocytopenia, the most common AEs leading to dose modification.

Methods: Safety and pharmacokinetic (PK) data from 367 TALA-treated pts (285 EMBRACA, 82 ABRAZO) were included in a pooled analysis. To account for dose modifications over time, individual time-varying concentration from time 0 up to the time of each safety event ($C_{avg,t}$) was calculated at each event time using average daily dose intensity and apparent TALA clearance as obtained from population PK analysis. The relationship between $C_{avg,t}$, as well as other potential prognostic factors and the selected safety events was evaluated using Cox proportional hazard (PH) models. Significant covariates in univariate analyses were further examined in multi-variate analyses.

Results: Visual examination suggested a higher $C_{avg,t}$ in pts with anemia and thrombocytopenia events vs pts without events. Cox PH models indicated that a higher risk of anemia and thrombocytopenia was associated with higher $C_{avg,t}$. For anemia, the HR (95% CI) for $C_{avg,t}$ (ng/mL) was 1.3 (1.12, 1.4), $P = 3.03$. For thrombocytopenia, the HR (95% CI) for $C_{avg,t}$ (ng/mL) was 1.2 (1.01, 1.3), $P = 0.0394$. A trend for association between higher $C_{avg,t}$ and neutropenia was observed although the relationship was not statistically significant ($P = 0.0633$). Higher risk of all tested safety endpoints was associated with lower baseline hemoglobin. Higher risk of neutropenia was associated with lower absolute neutrophil count and lower body weight.

Conclusions: A higher risk of anemia and thrombocytopenia was associated with higher TALA exposure. This finding supports the proposed management of TALA-related AEs through dosing interruption and reduction.

Clinical trial identification: NCT01945775, NCT02034916.

307P An international systematic review (SR) of breast cancer (BC) BRCA mutation (BRCAm) prevalence

N. Armstrong[1], S. Ryder[1], C. Forbes[1], A. Chalker[1], J. Ross[1], R. Quek[2]

[1]Health Economics, Kleijnen Systematic Reviews Ltd, York, UK, [2]Health Economics, Pfizer, Inc., San Francisco, CA, USA

Background: Carriers of BRCAm have an increased risk of developing BC. Considering the availability of BRCAm-targeted advanced breast cancer (aBC) drugs and evolving treatment guidelines, an SR was conducted to summarise the prevalence of BRCAm carriers in the overall BC population and stratified by clinical and demographic subgroups in different countries.

Methods: This SR adhered to the Cochrane method. Electronic databases (eg, Medline & Embase; $n = 7$) and grey literature sources were searched (Jan 2012 to Nov 2017). Studies reporting on BC BRCAm prevalence were included. BRCA1/2m prevalence (including germline) in BC (overall and aBC), clinical (TNBC, HR+/HER2- BC), and demographic subgroups (race/ethnicity) were summarised.

Results: 17,872 records were retrieved; 70 studies were included. Regions/countries: Europe ($n = 16$), USA ($n = 33$), Canada ($n = 2$), Australia ($n = 2$), Japan ($n = 1$), South Korea ($n = 11$), Russia ($n = 2$), and Israel ($n = 3$). Only 29 studies explicitly reported BRCA germline status with prevalence ranging from 1.8% in an overall BC population (Sardinia) to 59.52% in a study of BC with family history (Spain). BRCAm prevalence varied widely in 16 overall BC population studies ranging from 2.7% (France) to 23.6% (Italy). Broader BRCAm prevalence ranges were observed in 5 aBC studies, varying from 2% in an overall BC population (France) to 53.8% in a study of Ashkenazi Jews (Israel). 42 reported BRCA1m and BRCA2m separately with no consistent distribution pattern between the 2. In the 24 TNBC studies, prevalence varied from 9.3% in an overall BC population (Australia) to 73.3% in a study of BC with a family history (Israel). BRCA1m prevalence was higher in TNBC studies that reported

BRCA1m separately from BRCA2m (16 of 24 studies). In 3 studies of HR+/HER2- BC, BRCAm prevalence varied from 5% (USA) to 9.9% (South Korea). BRCAm prevalence ranged from 14.2% (USA) to 53.8% (Israel) in those of Ashkenazi Jewish ancestry.

Conclusions: Reported BRCAm prevalence in BC varies widely in clinical and demographic subgroups across countries; there are few studies on aBC and most lack germline BRCAm status specification. Further BC BRCAm epidemiologic studies are warranted to validate the prevalence of BRCAm with germline status.

308P Genetic screening, counselling, and treatment of BRCA mutation (BRCAm) carriers: A systematic review (SR) of international breast cancer (BC) guidelines

C. Forbes[1], D. Fayter[1], C. Clar[1], K. Reid[1], S. de Kock[1], R. Quek[2]

[1]Health Economics, Kleijnen Systematic Reviews Ltd, York, UK, [2]Health Economics, Pfizer, Inc., San Francisco, CA, USA

Background: Considering the availability of BRCAm-targeted therapeutic drugs in BC and an evolving clinical guidelines landscape, an SR of international guidelines on screening and management of BRCAm BC patients was carried out.

Methods: The current SR adhered to Cochrane's guidance. Major electronic databases (eg, Medline & Embase; n = 7) and grey literature sources were searched (Jan 2007 to Dec 2017). Latest guideline reporting recommendations (and evidence grades) on genetic screening, counselling, and BC treatment of BRCAm carriers were summarised. Guidelines specific to germline (gBRCAm) (ie, hereditary) were captured where available.

Results: 3775 records were retrieved and 33 guidelines from Europe (n = 17), USA (n = 11), Canada (n = 3), Australia (n = 1), and Japan (n = 1) were included. Genetic counselling was recommended at multiple points in the care pathway, though the format (eg, frequency, decision tools) was not always clearly defined. US guidelines emphasised BRCAm testing should occur after specialised genetic counselling; other European guidelines were less prescriptive. BRCA testing eligibility criteria differed with some guidelines being less restrictive; US NCCN BC guidelines specified that HER2- BC patients eligible for single-agent therapy should strongly consider gBRCAm testing, while also having separate more restrictive high-risk BRCA testing criteria. Similar restrictive criteria were observed in some European guidelines. Fast-track BRCAm testing was recommended in the Netherlands if treatment choice affects BC survival, but only as part of a clinical trial in the UK. Other guidelines suggest testing only if it affects therapy decisions. ESMO ABC3 guidelines recommended platinum therapy for advanced BRCAm BC; more recent ESO-ESMO BCY3 and US NCCN guidelines recommended newly approved gBRCAm-targeted PARP inhibitor therapy.

Conclusions: Differences exist between regions and within organizations for guidelines regarding genetic screening, counselling, and treatment of BRCAm BC patients. Harmonisation of guidelines could optimise the identification and management of BRCAm BC patients.

309P Efficacy and toxicity of endocrine therapy + cyclin-dependent kinases 4/6 inhibitors (iCDK4/6) in metastatic breast cancer patients according to gBRCA status

L.I. Bruno, M.V. Costanzo, C.A. Ostinelli, A.A. Nervo, J. Nadal, F. Colo, J. Loza, C.M. Loza, C. Ponce, V. Fabiano, A.G. Blanco, C. Perez de la Puente, R.D. Chacon

Clinical Oncology, Alexander Fleming Institute, Buenos Aires, Argentina

Background: Endocrine therapy (ET) and iCDK4/6 has demonstrated efficacy in terms of progression free survival (PFS), and clinical benefit as first and second line treatment in hormone receptor positive (HR+), Her2 negative, metastatic breast cancer (MBC). Cost and toxicity has limited its worldwide indication. No predictive biomarkers of response or toxicity have been validated. The aim of this analysis is to explore the utility of the gBRCA status as a predictive factor of efficacy and toxicity in HR+, Her2 negative, MBC treated with the combination of ET + iCDK4/6.

Methods: Prospective cohort study of patients under ET+ iCDK4/6 toxicity registry. Next Generation Sequencing (NGS) for gBRCA1 and 2 and genetic counseling was offered according to physician regular practice.

Results: 92 patients were available for analysis, 24 had been studied for gBRCA. Still 3/24 (12%) have pending results, but 21% (5/24) were positive (2 gBRCA1+, and 3 gBRCA2+), and 67% (16/24) were negative (gBRCAneg). Median age of the global cohort was 46 years old (range 27-84), only 21% were stage IV at onset. The overall clinical benefit was 48%, significantly better for gBRCAneg 81% (13/16) versus 20% (1/5), p-value 0.011213. PFS was 46 weeks for the global cohort (CI95% 43.7-57.4 months), with tendency to better results among gBRCAneg 57 weeks (CI95% 42.2-80.5) versus 47 weeks (CI95% 21.2-72.7) for gBRCA+. The overall toxicity grade 3-4 was 24% (23/96) without differences according to gBRCA status (gBRCA+ 20% versus gBRCAneg 25%, p-value 0.818769).

Conclusions: We observed a significantly higher clinical benefit with a tendency to higher PFS in gBRCAneg HR+, Her2 negative MBC under ET + iCDK4/6 treatment and similar toxicity in both groups. This exploratory analysis suggests a potential role for gBRCA status as a biomarker of efficacy in this scenario. We believe that prospective, pre-stratified and adequately powered studies warrants further investigation and could help to design the proper sequence of treatments in light of the availability of upcoming target therapies such as PARP inhibitors.

310P Clinical outcomes, treatment patterns and health resource utilization (HRU) among metastatic breast cancer (mbc) patients (pts) with germline BRCA mutation (gBRCAm)

R. Quek, J. Mardekian

Health Economics, Pfizer, Inc., San Francisco, CA, USA

Background: With evolving gBRCAm BC guideline landscape, we present latest gBRCA testing rates among mBC US pts with HR+/HER2- or triple negative BC (TNBC); including clinical outcomes, treatment patterns and HRU in gBRCAm pts.

Methods: The Flatiron Health database was used in a real world retrospective analysis of mBC pts with HR+/HER2- or TNBC, ≥18 yrs old, diagnosed between Jan 2011-Feb 2018. Rates of gBRCA testing were assessed. One- to 5-yr overall survival (OS) post mBC diagnosis for gBRCAm HR+/HER2- and TNBC pts were estimated. Cox proportional hazards model was used to estimate OS of TNBC vs HR+/HER2-. Outcomes between TNBC vs HR+/HER2- pts were compared while adjusting for imbalances. Antineoplastic treatment was summarized and HRU patterns were analyzed using t-tests.

Results: The study included 12,021 mBC pts (10,291 HR+/HER2-; 1730 TNBC). Results for gBRCA testing were available for 16.7% of pts overall; (HR+/HER2-: 15.4%, TNBC: 24.2%). The most common 1st line treatments for gBRCAm TNBC were capecitabine (19%) and carboplatin/gemcitabine (15%) and 1st line treatments for gBRCAm HR+/HER2- included letrozole (10%) and fulvestrant (7%). Pts counts, OS estimates and HRU for gBRCAm carriers are shown in the table; Cox regression results showed lower OS for gBRCAm TNBC pts vs gBRCAm HR+/HER2- mBC pts, Hazard Ratio (HR+/HER2- / TNBC) and 95% CI 0.59 (0.34, 1.01). Estimated median OS and 5-yr OS rates are (33.9 mths, 22.3 mths) and (28.9%, 26.4%) for gBRCAm HR+/HER2- and TNBC pts respectively. Number of HRU visits per-pts-per-year were significantly higher among TNBC pts.

Conclusions: gBRCA testing rates among mBC pts with HR+/HER2- or TNBC were low. Among mBC pts with gBRCAm, 5-yr OS rates were < 29% for both HR+/HER2- and TNBC; poor prognosis and HRU burden demonstrates a significant unmet need for more targeted, less HRU-intensive treatment options among these pts.

Table: 310P

	HR+/HER2-	TNBC
Total Patients (N = 12,021) n (%)	10,291 (85.6)	1730 (14.4)
Patients with gBRCA test results (n = 2005) n (%)	1587 (79.2)	418 (20.8)
Patients with gBRCAm (n = 229) n (%)	165 (72.1)	64 (27.9)
gBRCAm patients with ≥ 1st Line antineoplastic treatment (n = 188) n (%)	142 (75.5)	46 (24.5)
Year	Overall Survival Estimates (%)

311P Early results from an open-label phase 1b/II study of eribulin mesylate (EM) + pegvorhyaluronidase alfa (PEGHP20) combination for the treatment of patients with HER2-negative, high-hyaluronan (HA) metastatic breast cancer (MBC)

M. Shum[1], V.J. Assikis[2], C. Savulsky[3], W. Zhu[4], P. Iyer[4], D. Xing[5], C. Berman[6], N.A. Lokker[6], R.H. Alvarez[7]
[1]*The Oncology Institute Whittier, Oncology Institute of Hope and Innovation, Whittier, CA, USA,* [2]*Medical Department, Piedmont Cancer Institute, Newman, GA, USA,* [3]*Clinical Research, Eisai Ltd., Hatfield, UK,* [4]*Clinical Research, Eisai Inc., Woodcliff Lake, NJ, USA,* [5]*Clinical Biostatistics, Eisai Inc., Woodcliff Lake, NJ, USA,* [6]*Clinical Development, Halozyme Therapeutics, Inc, San Diego, CA, USA,* [7]*Southeastern Regional Medical Center, Cancer Treatment Centers of America, Atlanta, GA, USA*

Background: HA in the tumor microenvironment can inhibit the effectiveness of anti-cancer agents. The novel biologic PEGPH20 degrades pathological HA accumulation. EM is a microtubule inhibitor approved for the treatment of pts with MBC who previously received ≤2 lines of systemic anticancer therapy for metastatic disease. Preclinical data showed the PEGPH20+EM combination resulted in enhanced anti-tumor effectiveness in HAaccumulating, triple-negative breast cancer (TNBC) xenografts. The primary objective of this Phase 1b study (NCT02753595) was to determine safety, tolerability and RP2D of PEGPH20+EM in pts with HER2neg MBC previously treated with ≤2 lines of systemic anticancer therapy in the metastatic setting.

Methods: Overall, 14 enrolled pts were treated IV at 2 PEGPH20 dose levels (DL1=3 μg/kg or DL0=1.6 μg/kg on D1, D7) + EM 1.4 mg/m^2 on D1, D8 of a 21day cycle. 5 pts were treated at DL1, with 2 DLTs observed (G3 muscle cramp, G3 knee/leg pain); 6 pts were enrolled in DL0 with no further DLTs. An additional 3 pts were enrolled at DL0 (RP2D).

Results: All 14 pts were evaluable for safety and efficacy. Median age was 53 years (33–78 years); 14% (2/14) of pts had TNBC. Median number of treatment cycles was 6.0. Drug-related TEAEs occurred in 86% of pts during PEGPH20+EM therapy. 79% of pts had G ≥ 3 TEAEs. There were 3 SAEs (1 in DL1 and 2 in DL0). As of April 2018, the individual safety profile was as expected for PEGPH20 and EM; no new significant safety signals identified. Key pt characteristics and BORs are shown below. Out of the 5 pts with confirmed PR, 3 had 1 prior and 2 had no prior systemic anticancer therapy in the metastatic setting.

Table: 311P

Category	PEGPH20 (3 μg/kg)/ EM (1.4 mg/m^2) (n = 5)	PEGPH20 (1.6μg/kg)/ EM (1.4 mg/m^2) (n = 9)	Total (N = 14)

312P Phase II clinical trial of first-line eribulin plus trastuzumab for advanced or recurrent HER2-positive breast cancer

K. Sakaguchi[1], K. Nakatsukasa[2], T. Taguchi[2]
[1]*Endocrine and Breast Surgery, Kyoto Prefectural University of Medicine, Kyoto, Japan,* [2]*Department of Endocrine and Breast Surgery, Kyoto Prefectural University of Medicine, Kyoto, Japan*

Background: Eribulin mesylate has been approved for advanced or metastatic breast cancers subjected to at least two previous chemotherapy regimens. The present multicenter, phase II, single-arm study assessed the efficacy and safety of a first-line regimen of eribulin plus trastuzumab for untreated advanced or metastatic HER2-positive breast cancer.

Methods: Enrolled patients received eribulin (1.4 mg/m^2 intravenously; I.V.) on days 1 and 8 of each 21-day cycle, an initial trastuzumab dose (8 mg/kg I.V.) on day 1, and 6 mg/kg of trastuzumab on day 1 of each subsequent cycle. The primary endpoint was the RR. The secondary endpoints were PFS, OS, DOR, and safety. Twenty-eight patients (median age: 62.5 years) received a median of 12 (range: 2–53) cycles of eribulin plus trastuzumab.

Results: The RR was 53.6% (CR, 4; PR, 11) with a median PFS of 344 days. The clinical benefit rate was 64.0%. Grade 3/4 adverse events were observed in 12 (42.9%) patients. For details, neutropenia in 8 (28.6%) patients, peripheral neuropathy in 2 (7.1%) patient, interstitial pneumonia in 1 (3.6%) patient, ALT elevation in 1 (3.6%) patient, osteonecrosis of the jaw in 1 (3.6%) patient, and fatigue in 1 (3.6%) patient. The patient with osteonecrosis received denosumab, too. No symptomatic congestive heart failure was observed.

Conclusions: Combination therapy of eribulin plus trastuzumab is acceptable in efficacy and safety, and a capable option for first-line advanced or recurrent HER2-positive breast cancer.

313P Eribulin in metastatic breast cancer the UK experience: A multi-centre retrospective 577 patient study

M. Jafri[1], H. Kristeleit[2], V. Misra[3], M.A. Baxter[4], S. Ahmed[5], A. Jegnnathen[6], A. Jain[7], D. Maskell[8], U. Barthakur[9], G. Edwards[10], H. Walter[11], R. Walter[3], M.A. Khan[12], A. Borley[10], P. Nightingale[1], D. Rea[13]

[1]*Medical Oncology, Queen Elizabeth-University Hospital Birmingham NHS Foundation Trust, Birmingham, UK,* [2]*Medical Oncology, Guy's Cancer Centre, London, UK,* [3]*Clinical Oncology, The Christie NHS Foundation Trust, Manchester, UK,* [4]*Medical Oncology, Beatson West of Scotland Cancer Centre, Glasgow, UK,* [5]*Leicester Cancer Research Centre, University Hospitals of Leicester NHS Trust Leicester Royal Infirmary, Leicester, UK,* [6]*Clinical Oncology, University Hospitals of North Midlands, Stoke, UK,* [7]*Oncology, The Royal Wolverhampton Hospitals NHS Trust New Cross Hospital, Wolverhampton, UK,* [8]*Oncology, Norfolk and Norwich University Hospitals, Norfolk, UK,* [9]*Medical Oncology, Taunton and Somerset NHS Foundation Trust, Taunton, UK,* [10]*Clinical Oncology, Velindre Cancer Centre, Cardiff, UK,* [11]*Medical Oncology, University Hospitals of Leicester NHS Trust Leicester Royal Infirmary, Leicester, UK,* [12]*Oncology, Guy's and St. Thomas' Hospital NHS Trust, London, UK,* [13]*Clinical Trials Unit, The University of Birmingham Institute for Cancer Studies, Birmingham, West Midlands, UK*

Background: The EMBRACE trial demonstrated significantly improved survival with eribulin compared to physicians' choice (13.1 vs 10.9 months ($p = 0.041$). Eribulin has been funded by the NHS in the UK for the management of locally advanced or metastastic breast cancer after at least two lines of treatment. We describe the UK experience of eribulin in this setting.

Methods: Data from 577 patients was analyzed on an individual patient basis from 14 different hospitals after institutional review board approval. Data was collected retrospectively using computerized records and chemotherapy records. Data was collated on: age, breast cancer characteristics, prior chemotherapy regimes, toxicity, PFS and OS. Statistical analysis was performed using SPSS.

Results: Data from 577 patients who received eribulin in specialist cancer centres, teaching hospitals and cancer units throughout the UK between 2011-2017 were included. The median age of patients was 56 (33-84). 447 were ER positive, 129 triple negative, 100 patients were Her2 positive, 1 unknown. The cohort was heavily pre-treated with eribulin being received on average 4thline (median (range 2-11)). The median number of eribulin cycles received were 4 (range 1-29). The OS of the cohort was 288 days (95%CI 260-315), triple negative patients had a worse outcome than ER/Her2 expressing patients (198 c.f. 278 days ($p = 0.02$)). Less heavily pre-treated patients ($\leq$2 prior treatments) had significantly better survival (328 c.f. 264 days). Patients aged over 65 had better survival 325 c.f. 285 days. 11% experienced grade 3-4 neuropathy, 14% experienced nausea, 19% experienced G3-4 neutropenia, there were no treatment related deaths.

Conclusions: This real world data demonstrates that even in a heavily pretreated population eribulin was associated an OS approaching a year. Eribulin was well tolerated even in patients over 65 and is associated with better survival if used earlier in metastatic patients.

314P Eribulin as first- or second-line chemotherapy for advanced or metastatic HER2-negative breast cancer: A real-world prospective study

M. Takahashi[1], K. Inoue[2], H. Mukai[3], T. Yamanaka[4], C. Egawa[5], Y. Sakata[6], H. Ikezawa[7], T. Matsuoka[6], J. Tsurutani[8]

[1]*Breast Surgery, National Hospital Organization Hokkaido Cancer Center, Sapporo, Japan,* [2]*Breast Oncology, Saitama Cancer Center, Kita-adachi Ina, Japan,* [3]*Breast and Medical Oncology, National Cancer Center Hospital East, Kashiwa, Japan,* [4]*Breast and Endocrine Surgery, Kanagawa Cancer Center, Yokohama, Japan,* [5]*Breast Surgery, Kansai Rosai Hospital, Amagasaki, Japan,* [6]*Oncology Medical, Eisai Co., Ltd., Tokyo, Japan,* [7]*Clinical Data Science, Eisai Co., Ltd., Tokyo, Japan,* [8]*Medical Oncology, Kindai University Faculty of Medicine, Osaka, Japan*

Background: A global phase III study confirmed the effect of eribulin mesylate (ERI) as third- or later-line chemotherapy on overall survival (OS) for advanced or metastatic breast cancer. Meanwhile, in Japan, ERI can be used as first- or second-line. However, limited reports can be found on time to treatment failure (TTF) and/or OS for ERI as first- or second-line therapy comparing to late-line therapy in clinical practice.

Methods: We conducted a prospective study in patients with inoperable or recurrent HER2-negative breast cancer starting in September, 2014. We enrolled a similar number of patients receiving ERI as first- or second-line therapy and those receiving ERI as third- or later-line therapy, and with follow-up planned for up to two years (ClinicalTrials.gov: NCT02371174). The data collected by November 2017 was analyzed. TTF and OS were estimated using the Kaplan–Meier method. Multivariate Cox regression was used to identify the factors influencing TTF and OS.

Results: We analyzed 634 patients. The mean age ($\pm$ standard deviation) was 59.6 years ($\pm$ 11.0), and 157 patients (24.8%) had triple-negative breast cancer. Of these patients, 319 received ERI as first- or second-line therapy and 315 as third- or later-line therapy. The median TTF (95% confidence interval [CI]) was 135 (121–164) and 119 (106–128) days, and the median OS (95% CI) was 555 (475–628) and 383 (342–459) days for first- or second-line- and third- or later-line therapy, respectively. A history of radiation therapy, complication of diabetes, liver metastasis, ECOG performance status, blood hemoglobin and aspartate aminotransferase levels at baseline, triple-negative breast cancer, and development of peripheral neuropathy after ERI treatment were significant factors influencing both TTF and OS.

Conclusions: Our real-world study showed patients with first- or second-line therapy of ERI have longer OS and TTF than those in third- or later-line therapy. These results suggested that patients with first- or second-line therapy of ERI have the potential for similar or more favorable outcomes from the ERI treatment compared with patients with third- or later-line therapy of ERI.

Background: The prognosis for triple negative (TN) and hormone-refractory metastatic breast cancer (MBC) remains poor and treatment options are limited to cytotoxic agents. Furthermore, the optimal sequence of chemotherapy (CT) is unclear. In this prospective cohort study (E-SPEC), we observed optimal sequences of CT for improving long-term survival. This trial was registered with ClinicalTrials.gov (no. NCT02551263).

Methods: The study was conducted under a multi-institutional prospective observational design and involved patients with HER2-negative hormone-refractory MBC. Eligibility criteria were age 20-75 years; refractory to hormone therapy defined as TN type or recurrence during or within 6 months after the end of adjuvant treatment or refractory to at least one previous hormone therapy for MBC; and scheduled for first- and second-line CT after registration. All treatments were performed according to physician's choice. Treatment regimens, efficacies and quality of life (QoL) were prospectively surveyed. Baseline data analysis included patient characteristics, real-world CT sequence of first- and second-line CT regimen and the reason for cessation of first-line CT.

Results: Between June 2015 and July 2017, a total of 201 patients were enrolled, 194 of whom were analyzed. Mean age was 58.9 years; 142 patients (73.2%) had ER- and/or PgR-positive disease; 52 patients (26.8%) had TN. Most frequent regimen for first- or second-line CT was eribulin (ERI) (88.9%) among patients who received second-line CT. Frequent sequences were oral fluorouracil (FU) followed by ERI (18.3%), bevacizumab/paclitaxel (Bev/PTX) followed by ERI (13.5%), and ERI followed by Bev/PTX (11.1%). Patients who received taxanes as first-line CT had significantly more adverse event discontinuation than those with oral FU or ERI ($p < 0.01$).

Conclusions: In this real-world setting, ERI was administered in almost all first- or second-line regimens and taxane-based regimens were associated with more adverse event discontinuations. We intend to further investigate overall survival among CT sequences, as well as progression-free survival, new metastasis-free survival, type of progression and QoL.

316P Comparative effectiveness of nab-paclitaxel vs. paclitaxel monotherapy as first-line (1L) treatment of metastatic triple-negative breast cancer (mTNBC) in US clinical practice

T. Luhn[1], S. Chui[2], A. Hsieh[3], J. Yi[4], A. Mecke[5], P. Bajaj[6], W. Hasnain[7], A. Falgas[8], T.G.N. Ton[9], A. Kurian[10]

[1]Product Development, Genentech, Inc., South San Francisco, CA, USA, [2]Product Development Oncology, Genentech, Inc., South San Francisco, CA, USA, [3]Center for Outcomes Research and Evaluation, Genentech, Inc., South San Francisco, CA, USA, [4]Epidemiology, Genesis Research, Hoboken, NJ, USA, [5]PDB Biostatistics, Roche, Basel, Switzerland, [6]Health Economics, Genentech, Inc., South San Francisco, CA, USA, [7]Global Pricing and Market Access, Genentech, Inc., South San Francisco, CA, USA, [8]PDR Department, Roche, Basel, Switzerland, [9]Real World Data Oncology, Genentech, Inc., South San Francisco, CA, USA, [10]Medicine - Med/Oncology, Stanford University School of Medicine, Stanford, CA, USA

Background: Taxanes are commonly used as a standard of care treatment for 1L mTNBC. Few studies have directly compared the effectiveness of nab-paclitaxel and paclitaxel in the real world setting, however. This study investigated the overall survival (OS) of nab-paclitaxel vs. paclitaxel as monotherapy in 1L treatment of mTNBC in routine practice.

Methods: A total of 200 patients in the Flatiron Health EHR-derived database were included based on a confirmed diagnosis of mTNBC from 1 Jan 2011 and 31 October 2016 and receipt of nab-paclitaxel or paclitaxel monotherapy as 1L treatment. The primary outcome, OS, was estimated by Kaplan-Meier methods and compared by the log-rank test and by univariate and multivariate Cox regression models. Time to next treatment (TTNT) was assessed as a secondary outcome.

Results: Compared with pts who received paclitaxel (n = 95), at baseline, those who received nab-paclitaxel (n = 105) were more likely to have been diagnosed at an earlier stage (I-III), have a treatment free ≤ 12 months (in pts with recurrent disease), adjuvant treatment with a taxane, a prior diagnosis of neuropathy and coverage by commercial healthcare insurance. Other characteristics were balanced between groups. Over 90% of pts with evaluable dosing data (179 of 195) received weekly doses of either taxane, with 100 mg/m^2 as the most common dose for nab-paclitaxel and 80 mg/m^2 for paclitaxel. Median OS was 11.2 months in pts treated with nab-paclitaxel and 10.8 months in paclitaxel-treated pts (log-rank P = 0.82). The OS hazard ratio (HR) from the adjusted Cox model was 0.90 (95% CI: 0.61, 1.32), indicating a similar risk of death between the two groups. The robustness of this result was confirmed in several sensitivity analyses. TTNT for nab-paclitaxel and paclitaxel was 4.7 and 4.3 months (log-rank P = 0.44), respectively, and did not differ in adjusted analyses (HR = 0.95 [95% CI: 0.65, 1.38]).

Conclusions: Nab-paclitaxel and paclitaxel monotherapy demonstrated similar outcomes, suggesting they may be considered interchangeable as 1L treatments for mTNBC.

[1]Breast Surgery, Hokkaido Cancer Center, Sapporo, Japan, [2]Breast Oncology, Shikoku Cancer Center, Matsuyama, Japan, [3]Breast Disease Center, Asahikawa Medical University Hospital, Asahikawa, Japan, [4]General Surgery, Chiba University Graduate School of Medicine, Chiba, Japan, [5]Breast Surgery, Hiroshima City Hospital, Hiroshima, Hiroshima, Japan, [6]Breast Surgery, Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Tokyo, Japan, [7]Breast Surgery, Matsuyama Red Cross Hospital, Matsuyama, Japan, [8]Breast Oncology, Gunma Prefectural Cancer Center, Gunma, Japan, [9]Breast Surgery, National Nagasaki Medical Center, Omura, Japan, [10]Breast Surgery, Yao Municipal Hospital, Yao, Japan, [11]Biomedical Statistics and Bioinformatics, Kyoto University Graduate School of Medicine, Kyoto, Japan, [12]Breast Surgery, National Hospital Organization Osaka National Hospital, Osaka, Japan, [13]Surgery, Kyoto University-Graduate School of Medicine, Kyoto, Japan, [14]Breast Oncology Center, The Cancer Institute Hospital of JFCR, Tokyo, Japan

Background: Anthracycline- or taxane-based regimens are the standard early-line chemotherapy for metastatic breast cancer. However, adverse effects of these treatments, such as neutropenia, peripheral neuropathy, edema, and alopecia, are a concern. The EMBRACE study has shown that eribulin is effective for metastatic breast cancer, even as a late-line treatment. The aim of this study was to investigate the usefulness of eribulin as first- or second-line treatment.

Methods: Patients with recurrent HER2-negative breast cancer who had received previous chemotherapy including both an anthracycline and a taxane were eligible for this phase II study. They were randomly allocated to receive eribulin or treatment of physician's choice (TPC) as first- or second-line treatment. TPC was selected in advance from paclitaxel, docetaxel, nab-paclitaxel, and vinorelbine. The primary endpoint was progression-free survival (PFS). Secondary endpoints included time to treatment failure (TTF), response rate (RR), duration of response, and safety. (UMIN000009886).

Results: From May 2013 to January 2017, 72 patients were enrolled. The full analysis set comprised data from 58 patients (median age, 58 years; range, 33–82 years); 38 (65.5%) received first-line treatment and 20 (34.5%) received second-line treatment. 43 patients (74.1%) were ER- positive. The per protocol set comprised data from 57 patients. PFS, TTF, RR, and duration of response in both groups are shown in the table. The most common grade 3 or worse adverse events were neutropenia (6/27 [22.2%] in the eribulin group versus 5/31[16.1%] in the TPC group). The incidence of sensory neuropathy was low in both groups.

Table: 317P

		Eribulin (n = 26)	TPC (n = 31)	p-value
PFS	Median(M)	6.6(5.0-8.1)	4.2(0.8-7.6)	0.273
TTF	Median(M)	6.0(4.7-7.3)	3.6(2.3-4.9)	0.131
Tumor response	CR	0(0.0%)	0(0.0%)	0.190
	PR	5(19.2%)	6(19.4%)	
	SD	16(61.5%)	11(35.5%)	
	PD	5(19.2%)	13(41.9%)	
ORR		5(19.2%)	6(19.4%)	
Duration of response	Median(M)	3.0(2.1-3.9)	2.8(2.4-3.3)	0.794

Conclusions: Eribulin was not shown to be superior to TPC in terms of efficacy. However, patients in the eribulin group had slightly longer PFS and TTF.

318P Clinical utility of hepatic arterial infusion chemotherapy for heavily pretreated metastatic breast cancer patients: A review of a single institution

M. Furuta[1], J. Watanabe[1], T. Aramaki[2]

[1]Division of Breast Oncology, Shizuoka Cancer Center, Shizuoka, Japan, [2]Division of Radiology, Shizuoka Cancer Center, Shizuoka, Japan

Background: Liver metastasis is recognized as a risk factor for metastatic breast cancer (MBC). Hepatic arterial infusion chemotherapy (HAIC) is a treatment option for MBC in patients with extensive hepatic lesions; however, there is no standard regimen, and the effects have not been well discussed.

Methods: We reviewed our medical records of MBC to extract patients with resistance to standard systemic chemotherapies, critical liver metastasis, and who received HAIC with an FEM regimen (5-fluorouracil 333 mg/m^2 [weekly], epirubicin 30 mg/m^2 [every 4 weeks], and mitomycin-C 2.7mg/m^2 [every 2 weeks]) in our institute.

Results: We identified 58 patients who received HAIC (median age at initiation, 58 [30-80] years) in our institute between 2002 and 2017. Their ECOG performance (PS) statuses were as follows: PS0, 44; PS1, 10; and PS 2, 4. Their receptor statuses were as follows: hormone receptor positive (HR+)/HER2+, 9; HR+/HER2-, 38; HR-/HER2+, 4; HR-/HER2-, 7. The median number of systemic regimens (including endocrine therapy) prior to HAIC was 6 (2-17). The median number of liver metastases was 8 (1-≥20); the median maximum size of liver metastases was 5.2 cm (1.6-20.1). The median number of extrahepatic metastatic site was 2 (0-5). The median overall survival (days) was as follows: overall, 371 (95% confidence interval [CI] 260-475); HER2+, 441 (95% CI 166-652); HER2-, 344 (95% CI 279-475). The median time to progression of

intrahepatic lesions (days) was as follows: overall, 303 (95% CI 184-491); HER2+, 491 (95% CI 90-NR); HER2-, 298 (95% CI 184-387). An objective response (CR+PR) of intrahepatic lesions was observed in 37 patients (63.8%). The reasons for the discontinuation of HAIC included: progression of extrahepatic lesion(s), 20 (34.5%); progression of intrahepatic legion(s), 16 (27.6%); clinical progression, 7 (12.1%); transition to maintenance therapy, 6 (10.3%); catheter-related events, 5 (8.6%); and duodenal ulcer, 1 (1.7%).

Conclusions: HAIC with an FEM regimen offers an effective treatment for patients with liver metastasis from MBC that shows resistance to systemic therapy.

Background: The combination of LAP+CAP is approved for the treatment of pts with HER2+ mBC who progressed on prior therapy, which must have included anthracyclines, taxanes and trastuzumab. Octreotide long acting release (OCT) is approved for the treatment of severe diarrhea and flushing episodes associated with metastatic carcinoid and vasoactive intestinal polypeptide-secreting tumors. Here we investigated the efficacy of the prophylactic use of OCT in the prevention or reduction of diarrhea associated with the treatment involving LAP+CAP.

Methods: Pts (N = 62) were randomized (1:1) to OCT (0.1mg/mL) + LAP (1250 mg/day) + CAP (2000 mg/m^2/day) (n = 30) or LAP+CAP (n = 32), between 17-Dec-2014 and 13-Jan-2016. The primary objective was to determine the efficacy of prophylactic OCT in reducing the proportion of pts experiencing diarrhea with a severity of ≥grade 2 based on NCI-CTCAE version 4.03 during the first 3 cycles. The secondary objectives were ORR, CBR and other safety. Pearson chi-square test was used to compare the superiority of OCT+LAP+CAP arm with LAP+CAP arm.

Results: All pts enrolled in the study (database lock: 13-Feb-2018) were female with a median age of 56.5 years, and the majority was non-Hispanic or Latino (98%). Seven (23.3%) pts in the OCT+LAP+CAP arm and 9 (28.1%) pts in the LAP+ CAP arm had at least one episode of ≥grade 2 diarrhea within the first 3 cycles. The difference between the 2 arms was -4.8% with 95% exact CI: (-29.2%, 20.0%) and was not statistically significant (P = 0.775). The ORR and CBR in OCT+LAP+CAP vs LAP+CAP arms was 20.0% vs 18.7%, and 23.3% vs 28.1%, respectively. Two (7%) pts from OCT+LAP+CAP arm and 3 (9%) pts from LAP+CAP arm, died due to the disease under study. The most common all grade adverse events in OCT+LAP+CAP and LAP+CAP (>15% in either arm), respectively, were diarrhea (59% vs 45%), palmar-plantar erythrodysesthesia syndrome (45% vs 33%), rash (14% vs 21%), asthenia (7% vs 21%) and anemia (3% vs 18%).

Conclusions: Prophylactic use of OCT did not result in a lower incidence of ≥grade 2 diarrhea in mBC pts receiving LAP+CAP. No new safety issues were identified.

Clinical trial identification: NCT02294786.

Papardo, Messina, Italy, [2]Department of Surgical, Oncological, and Oral Sciences, Section of Medical Oncology, University of Palermo, Palermo, Italy, [3]La Maddalena Clinic for Cancer, Medical Oncology Unit, Palermo, Italy, [4]ARNAS Civico, Medical Oncology Unit, Palermo, Italy, [5]Instituto Oncologico del Mediterraneo, Medical Oncology Unit, Viagrande, Italy, [6]Cannizzaro Hospital, Medical Oncology Unit, Catania, Italy, [7]Ospedale Barone Lombardo-Presidio Ospedaliero Canicattì, Medical Oncology Unit, Canicattì, Italy, [8]Azienda Ospedaliera St. Giovannino di Dio, Medical Oncology Unit, Agrigento, Italy, [9]Buccheri La Ferla Fatebenefratelli Hospital, Medical Oncology Unit, Palermo, Italy, [10]Medical Oncology Unit, Cervello Hospital, Palermo, Italy, [11]Medical Oncology Unit, Humanitas Centro Catanese di Oncologia, Catania, Italy

Background: Elderly patients (pts) with MBC are under-represented in clinical studies and treatment is largely based on limited retrospective subgroup analyses. However, the 3 ESO-ESMO guidelines for Advanced Breast Cancer suggest that the management decisions should not be based on age alone.

Methods: This is an observational, retrospective, multicenter study conducted in 11 Oncology Sicilian Centers that evaluated safety and efficacy of nab-P in pts with HER2 negative MBC with age ≥ 65 years. We included 70 pts. Intrinsic molecular subtype: Luminal A (18.8%), Luminal B HER-2 negative (62.5%) and Triple negative (18.8%). The most common metastatic sites were: visceral plus bone (31.4%), bone (15.7%), lung (10%), visceral plus lymph nodes (10%). 33% of pts received nab-P as 4th line treatment. 87.1% of all pts received nab-P at doses 260 mg/m^{2}3-weekly and 12.9% received nab-P 125 mg/m^{2}weekly. 28.6%, 25.7% and 26.2% of pts received previous treatment with taxanes in the neo-adjuvant and metastatic setting, respectively. Primary endpoint was safety of nab-P treatment. Secondary endpoints were overall response rate (ORR), progression free survival (PFS) and overall survival (OS).PFS and OS curves were estimated using the Kaplan-Meier method. ORR was defined as complete or partial response (CR+PR) according to RECIST 1.1 criteria. Adverse events (AEs) were assessed according to CTCAEv4.0.

Results: Median (m) age of pts who received nab-P: 67 years (65-83). mECOG PS: 1 (range 0-2). The m cycles administrated was 6 (range 1-21). 35.5% of pts had a dose reduction and 11.5% of pts had treatment interruptions due to toxicity. The most frequent AEs were G2-3 and were observed in 47% of pts. The main toxicities were fatigue (61.5%), neuropathy (53.8%) and leukopenia (39.1%) and occurred in the 85.7% of pts treated with 3-weekly nab-P. ORR was 31.3% (CR in 6.3% and PR in 25% of pts). 39.1% of pts reported a stable disease. mPFS was 6 months (95% CI 2-38) and mOS was 40.5 months (95% CI 7-255).

Conclusions: Our real-life study showed that the treatment with nab-P is an effective and well-tolerated regimen in MBC elderly pts, even if previously treated with other taxanes. In particular, our data indicate that the weekly nab-P can be safely administered in elderly MBC pts.

321P Response evaluation of cancer therapeutics in metastatic breast cancer to the bone: A single arm phase II study of whole-body magnetic resonance imaging

M. Kosmin[1], A.R. Padhani[2], A. Gogbashian[2], D. Woolf[3], M-L. Ah-See[1], P. Ostler[4], S. Sutherland[1], D. Miles[1], J. Noble[5], A. Marshall[6], J. Dunn[6], A. Makris[1]

[1]Breast Cancer Research Unit, Mount Vernon Cancer Centre, Northwood, UK, [2]Radiology, Paul Strickland Scanner Centre, Northwood, UK, [3]Clinical Oncology, The Christie NHS Foundation Trust, Manchester, UK, [4]Clinical Oncology, Mount Vernon Cancer Centre, Northwood, UK, [5]Medical Oncology, The Royal Marsden Hospital, Sutton, UK, [6]Warwick Clinical Trials Unit, University of Warwick, Coventry, UK

Background: Accurate and reliable evaluation of response to systemic anti-cancer therapy (SACT) is fundamental in the management of metastatic breast cancer (MBC). CT and bone scans (BS) have significant limitations in assessing SACT response in bone disease in MBC, whereas whole-body magnetic resonance imaging (WB-MRI) shows significant promise. Published retrospective data show that the addition of WB-MRI to body CT alters treatment decisions in MBC. The primary objective of this study was to evaluate whether WB-MRI identifies progressive disease (PD) earlier than CT scans in patients with bone-only MBC.

Methods: Participants were enrolled when starting first or subsequent SACT for bone-only MBC, as established initially by BS and CT thorax, abdomen and pelvis. Baseline WB-MRI was performed within 2 weeks of trial entry. CT and WB-MRI were performed every 12 weeks until definitive PD was evident in one or both modalities. At PD, BS was assessed for bone disease progression. Radiologists independently reported CT, WB-MRI or BS and were blinded to the other modalities. Participant questionnaires were undertaken at weeks 12 and 36 to evaluate tolerability and satisfaction with WB-MRI and CT.

Results: Forty-five participants were enrolled, with a median time on-study of 24 weeks (range 1-84 weeks). Two patients were excluded due to unequivocal liver metastases on

baseline WB-MRI; two had clinical progression before imaging PD; one was lost to follow up. Twenty-nine have had PD on imaging; eleven continue on-study. In 65.5%, PD was evident on WB-MRI only; 34.5% had PD on CT and WB-MRI concurrently; none had PD on CT only (McNemar's test $p < 0.0001$). PD on BS was reported in 55.6% of cases of bone CT/MRI progression. Overall questionnaire response rate was 63.8%. No differences were found between CT and WB-MRI in levels of concern, comfort or pain at week 12 or 36. All participants reported satisfaction levels as 'good' or 'very good' for both modalities.

Conclusions: WB-MRI identifies PD before CT in most patients with bone-only MBC. Further studies will evaluate whether earlier identification of PD with WB-MRI and earlier SACT changes can lead to improved patient outcomes.

Clinical trial identification: NCT03266744.

322P Anti-tumor cell activity and in vitro profile of the next generation CXCR4 antagonist Balixafortide

J. Zimmermann[1], T. Remus[2], G. Lemercier[2], D. Barker[3], D. Obrecht[1], G. Gambino[1], G. Douglas[2]

[1]BUP, Polyphor Ltd, Allschwil, Switzerland, [2]Clinical Development, Polyphor Ltd, Allschwil, Switzerland, [3]Clinical Development, Polyphor AG, Allschwil, Switzerland

Background: Balixafortide is a very potent, well tolerated and highly selective next generation CXCR4 antagonist derived over the past decade through multiple rounds of optimization starting from the natural product polyphemusin. Clinical proof-of-concept was achieved in a Ph 1/2 study in combination with Eribulin in metastatic HER2-neg breast cancer. The anti-cancer effects and pluripotent action of Balixafortide may include sensitization of tumor cells to chemotherapy, suppression of metastatic spread, inhibition of angiogenesis, and activation of the immune system.

Methods: Balixafortide was tested in a HTRF-based CXCR4 ligand binding assay, in functional assays (Calcium flux and beta arrestin), and further profiled in a large panel of other receptors including CXCR7. Effects on tumor cell sensitization were followed with an intracellular pERK / pAKT signaling assay. Tumor cell migration was assessed by chemotaxis assays, and inhibition of angiogenesis was determined by HUVEC sprouting. Evidence for immune cell activation came from evaluation of corresponding marker such as interferon gamma. Balixafortide was in detail profiled in an extensive in vitro ADME panel.

Results: Balixafortide binds CXCR4 with high affinity (IC50 < 10nM). It blocks beta arrestin recruitment and Calcium flux with IC50s < 10nM. A high 1000-fold selectivity window was demonstrated in a large panel of receptors including CXCR7. Balixafortide potently inhibits pERK / pAKT signaling in the lymphoma lines Namalwa (IC50 < 200 nM) and Jurkat (IC50 < 400 nM). Balixafortide efficiently blocks SDF-1 dependent chemotaxis of MDA MB 231 breast cancer cells (IC50 < 20 nM), Namalwa and Jurkat cells (IC50 < 10 nM). Receptor occupancy wash-out studies with competitive antibody 12G5 revealed prolonged binding of Balixafortide to CXCR4. In addition, Balixafortide was optimized for favorable mouse and human ADME properties with balanced plasma protein binding, greater plasma and microsomal stability.

Conclusions: Balixafortide is a product of an extensive optimization process which started from polyphemusin and now represents a favorable balance between ADMET properties, potency and tolerability which allows high and frequent dosing of a CXCR4 antagonist in cancer patients.

Hoffmann-La Roche Ltd, Basel, Switzerland, [13]Global Product Development, Genentech, Inc., South San Francisco, CA, USA, [14]Instituto de Investigación Sanitaria Gregorio Marañón, CIBERONC, GEICAM, Universidad Complutense, Madrid, Spain

Background: H SC (Herceptin® SC) was approved based on the HannaH study (Ismael Lancet Oncol 2012). The single-arm, open-label MetaPHER study (NCT02402712) is the first large Phase IIIb study to evaluate the safety and tolerability of H SC + P IV (PERJETA®) + D IV as first-line treatment in patients (pts) with HER2-positive metastatic/locally advanced BC. Here, we report interim safety and preliminary efficacy.

Methods: Pts are ≥18-year-old females whose disease was not previously treated with systemic non-hormonal anticancer therapy. Pts receive 600 mg fixed-dose H SC q3w + 840 mg loading/420 mg maintenance P IV q3w + ≥6 cycles D IV q3w (>6 at investigator's discretion; 75 mg/m^2 initial dose) until disease progression (PD), unacceptable toxicity, withdrawal of consent, death or predefined study end. The primary endpoint is overall and cardiac safety and tolerability. Adverse events (AEs) are graded per NCI–CTCAE v4.0.

Results: Of 418 enrolled pts, 412 started study treatment; 330 (196 on treatment, 134 in follow-up [FU]) were on study by data cutoff (5 Jan 18). Median FU duration was 16.3 months. In the safety population 406/412 pts (98.5%) experienced ≥1 any-grade AE; 213 (51.7%) grade ≥3 AEs; 101 (24.5%) serious AEs (SAEs); and 86 (20.9%) AEs leading to P IV, H SC or D IV discontinuation. 47 pts (11.4%) died: 38 (9.2%) due to PD; 9 (2.2%) due to AEs; none from cardiac death. AEs of interest included grade ≥3 cardiac AEs (3 pts; 0.7%); ejection fraction decrease to < 50% and ≥10% points from baseline (32; 7.8%); investigator-reported administration-related and local injection-site reactions (80; 19.4%, including 19 [4.6%] with an AE related to H SC only). No MedDRA-preferred-term congestive heart failure was reported. 249/336 pts with baseline measurable disease had an objective response (74.1% [95% CI 69.1–78.7]). The clinical benefit rate was 81.1% (334/412 pts [95% CI 77.3–84.9]). 1-year progression-free survival was 63.1% (95% CI 58.4–68.2).

Conclusions: Safety and efficacy profiles of H SC + P IV as first-line treatment for pts with HER2-positive advanced BC were consistent with the known profiles for the H IV + P IV combination, and no new safety signals identified. The final analysis is planned for 2019.

Clinical trial identification: NCT02402712.

324P Settings-based efficacy comparison of trastuzumab biosimilars in breast cancer: A systematic literature review

H.S. Rugo[1], G. Curigliano[2], F. Cardoso[3], W.J. Gradishar[4], M. Pegram[5], C.H.H. Barrios[6], J. Cortes Castan[7], E. Pennella[8], R. Muniz[8]

[1]Breast Cancer Center, UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA, USA, [2]Early Drug Development for Innovative Therapies Division, Istituto Europeo di Oncologia, Milan, Italy, [3]Breast Unit, Champalimaud Foundation Cancer Center, Lisbon, Portugal, [4]Department of Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL, USA, [5]Medicine, Stanford Comprehensive Cancer Institute, Stanford, CT, USA, [6]School of Medicine, PUCRS-Pontifícia Universidade do Rio Grande do Sul, Porto Alegre, Brasil, [7]Medical Oncology, Hospital Universitario Ramon y Cajal, Madrid, Spain, [8]Medical Affairs, Mylan, Canonsburg, PA, USA

Background: The US Food and Drug Administration (FDA) recently approved the trastuzumab biosimilar Ogivri™ (trastuzumab-dkst) for treatment of breast cancer based on physicochemical and functional biosimilarity and phase 3 efficacy and safety data in metastatic breast cancer (MBC). Clinical trials evaluating trastuzumab biosimilars for treatment of ERBB2-positive breast cancer have assessed bioequivalence through comparative efficacy outcomes as neoadjuvant therapy for early-stage breast cancer (EBC) or first-line therapy for MBC. We conducted a systematic review to examine whether demonstrating bioequivalence in terms of efficacy is different in EBC vs MBC.

Methods: MEDLINE and conference abstracts were identified using the search terms "biosimilar" AND "trastuzumab" from 1 January 2013 to 14 March 2018. Abstracts and manuscripts were manually reviewed to assess availability of efficacy data comparing the proposed biosimilar with reference trastuzumab.

Results: A total of 84 results were obtained. After selection for studies with comparative clinical efficacy results, 8 phase 3 clinical trials for 6 proposed biosimilars were included in the final analysis: 4 in EBC (primary efficacy outcome, pathologic complete response [pCR]) and 4 in MBC (primary efficacy outcome, overall response rate [ORR]). In all trials, the proposed biosimilar was equivalent to reference trastuzumab in terms of efficacy. Two biosimilars (CT-P6 [2 different formulations], Celltrion, Incheon, Republic of Korea; PF-05280014, Pfizer, New York, NY) showed equivalent efficacy in both the EBC and MBC settings.

Conclusions: All biosimilars assessed demonstrated equivalent efficacy to reference trastuzumab, regardless of clinical setting. Two biosimilars demonstrated equivalent efficacy in both the EBC and MBC settings. Although the FDA and European Medicines Agency determine biosimilarity based on totality of evidence, both the EBC and MBC settings appear to have similar sensitivity and be appropriate for determination of equivalent efficacy based on regulatory guidelines and clinical results. Together, these data support extrapolation between settings.

Background: Anti-HER2 agents were a breakthrough in the treatment of HER2-enriched breast cancer (BC). In this study, we aimed to describe the real-life efficacy and safety of pertuzumab-trastuzumab-taxane (PTT) combination in BC patients.

Methods: This study was conducted by the Turkish Oncology Group and reached 35 centers nationwide. 309 visceral metastatic, and trastuzumab naive patients who received first line PTT were included.

Results: Patients' characteristics and treatment details are summarized in the table. Median progression-free survival (PFS) was 28.5 months (95% CI:15.6-41.4), while median overall survival (OS) was 40.3 months (95%CI: 26.9-53.7). Brain metastatic patients (n = 13, 4.2%) had worse PFS (16.8m vs. 28.5m; HR:3.9, 95% CI:1.7-9.2, p = 0.002) and OS (26.7m vs. 40.3m; HR:3.2, 95% CI:1.3-7.6, p = 0.009). Elderly patients (>65y) had significantly lower OS results (19.8m vs. 40.3m; HR:0.4, %95 CI:0.2-0.8, p = 0.01). Docetaxel was the choice in 268 patients (86.7%), while 41 patients (13.3%) received paclitaxel. There was no statistically significant difference in PFS (28.5 m vs. 24.1 m; p = 0.61) and OS (40.3 m vs. NR; p = 0.17) between taxane groups. Additionally, ≥10 cycles of docetaxel were not associated with improvement in outcomes compared with 6-10 cycles. One treatment-related death due to sepsis was noted. In 8 patients (2.6%), 5-40% ejection fraction decrease from baseline was detected without any sign of heart failure.

Table: 325P Demographic characteristics and treatment details

	N = 309	%
Median age (year, range)	51 (22-82)	
>65 years-old patients	39	12.6
De-novo metastatic patients	258	83.5
Histopathology		
IDC	290	93.9
ILC	3	1
Mixt	5	1.6
Others	11	3.5
Hormone receptor status		
ER and/or PR positive	170	55.2
ER/PR negative	138	44.8
Unknown	1	0.3
Metastatic site distribution		
Liver ± LN/skeletal	112	36.3
Lung ± LN/skeletal	120	38.8
Brain only	6	1.9
Brain + liver + lung	7	2.3
Liver + lung	16	5.2
Other	48	15.5
Only skeletal or only LN	-	-
Prior therapies		
Prior anthracyclines	51	16.5
Prior trastuzumab	NA	NA
Treatment details		

Continued

Table: 325P *Continued*

	N = 309	%
	Median number of cycle (range)	
Pertuzumab-trastuzumab	10 (1-75)	
Docetaxel	6 (1-23)	
Paclitaxel	3 (1- 26)	

IDC: Invasive Ductal Carcinoma ILC: Invasive lobular carcinoma LN: Lymph Node

Conclusions: This real-life practice population differs from the CLEOPATRA study in terms of visceral only metastatic disease, and inclusion of brain metastatic patients. Regardless of these negative prognostic characteristics, results are concordant with the pivotal study. Elderly patients had overall lower PFS, which necessitates further investigation of pertuzumab-trastuzumab combination with cytotoxic/antihormonal therapies. To our knowledge, this is the largest scale real-life clinical practice study of PTT to date.

326P Effectiveness of trastuzumab emtansine (TDM1) in patients with HER2-positive advanced breast cancer (ABC) progressing after taxane plus pertuzumab plus trastuzumab

B. Conte[1], A. Fabi[2], F. Poggio[3], E. Blondeaux[1], C. Dellepiane[1], A. D'Alonzo[1], A. Staiano[1], G. Buono[4], G. Arpino[4], V. Magri[5], G. Naso[5], D. Presti[6], S. Mura[7], A. Fontana[8], F. Cognetti[2], C. Molinelli[1], S. Pastorino[1], C. Bighin[1], M. Lambertini[3], L. Del Mastro[1]

[1]Medical Oncology, Ospedale Policlinico San Martino, Genoa, Italy, [2]Medical Oncology, Istituto Nazionale Tumori Regina Elena, Rome, Italy, [3]Medical Oncology, Institut Jules Bordet, L'Université Libre de Bruxelles, Brussels, Belgium, [4]Medical Oncology, AOU Policlinico Federico II, Naples, Italy, [5]Medical Oncology, Policlinico Umberto I, Rome, Italy, [6]Medical Oncology, Istituto Fondazione Maugeri, Pavia, Italy, [7]Medical Oncology, Ospedale Santissima Annunziata, Sassari, Italy, [8]Medical Oncology, Azienda Ospedaliera Universitaria Pisana, Pisa, Italy

Background: In patients with HER2-positive ABC who were previously treated with taxane and trastuzumab without pertuzumab, TDM1 showed a progression free survival (PFS) of 9.6 months and an overall survival (OS) of 29.9 months. Paucity of data is available on the efficacy of TDM1 in patients progressing after the current standard first-line therapy in this setting, based on the association of a taxane plus trastuzumab and pertuzumab (i.e. the TPH regimen). The present study aims to evaluate the effectiveness of TDM1 after first-line TPH.

Methods: The Gruppo Italiano Mammella (GIM) 14/BIOMETA is a retrospective/prospective multicenter study on treatment patterns and outcomes of patients with ABC. The present analysis was performed on patients who received second-line TDM1 after previous TPH between January 2012 and March 2017. Median PFS, 1-year OS (i.e. percentage of patients alive 1 year after the starting of TDM1) and clinical benefit rate (CB) were calculated. Descriptive statistics are reported with point estimated and 95% CIs. PFS was estimated with the Kaplan-Meier method.

Results: Out of 1858 patients included in the GIM14/BIOMETA study, 70 were eligible for the present analysis. Median age was 54 years; 36 patients (51%) had hormone receptor-positive/HER2-positive disease, and 27 (39%) had visceral involvement. All patients received TPH in the first-line setting, and 35 (50%) received taxane and trastuzumab in the adjuvant setting. At the time of data cutoff (April 30, 2018; median duration of follow-up 17.8 months), 30 patients (43%) were still receiving TDM1. Disease progression was the reason for treatment discontinuation in the remaining cases. Median PFS was 8.5 months (95% confidence intervals [CI] 5.3-12 months), and CB rate was 73%. One-year survival rate was 91%.

Conclusions: Our findings suggest that TDM1 is effective in patients progressing after TPH. A better performance was observed as compared to data previously published on TDM1 effectiveness after first-line TPH.

Clinical trial identification: NCT02284581.

327P Survival of HER2-positive advanced breast cancer patients treated with lapatinib plus capecitabine: A national population-based study: Long-term analysis

B. Jagielska[1], P. Tokajuk[2], T. Pieńkowski[3], A. Czubek[1], M.J. Krzakowski[4], M.Z. Wojtukiewicz[5]

[1]Department of Oncology Diagnostics, Cardioncology and Palliative Medicine, Maria Sklodowska Curie Memorial Cancer Centre and Institute of Oncology (MCMCC), Warsaw, Poland, [2]Clinical Oncology, Comprehensive Cancer Center Bialostockie Centrum Onkologii, Bialystok, Poland, [3]Onkologia Kliniczna, Radomskie Centrum Onkologii, Radom, Poland, [4]Department of Lung & Thoracic Tumours, The Maria Sklodowska-Curie Memorial Institute and Oncology Centre, Warsaw, Poland, [5]Clinical Oncology, Comprehensive Cancer Center Bialostockie Centrum Onkologii, Bialystok, Podlaskie, Poland

Background: In Poland, governmental policy was to offer a uniform, national therapeutic programme for the treatment of HER2-positive advanced breast cancer (ABC) patients (pts). Accordingly, the Polish Breast Cancer Treatment Programme was introduced. Herein, we present first results of this effort from the cohort of previously-treated patients who underwent anti-HER2 palliative therapy with lapatinib plus capecitabine.

Methods: The aim of the study was to assess the population-based value of lapatinib plus capecitabine therapy of HER2-positive ABC patients treated within the Polish Breast Cancer Treatment Programme during the years 2008-2015. Patients have been prospectively enrolled into aforementioned programme and treated according to the specified protocol. We used Kaplan-Meier method to evaluate progression-free survival (PFS), time to tumor progression (TTP) and overall survival (OS). The effects of clinical and demographic factors on PFS and OS were assessed using Cox's proportional hazards regression model.

Results: A total of 1018 HER2-positive ABC women were enrolled into the Polish Breast Cancer Treatment Programme on a national level. Patients who progressed after regimens that included, but were not limited to, anthracyclines, taxanes, and trastuzumab were eligible to this study. Median age of the patients was 56.6 years (range, 22.8 to 86.1). Previous adjuvant therapy: 35.7% pts; ER(+)/PgR(+): 47.5% pts; number of metastatic sites $\geq$2: 45.9% pts. The median PFS was 6.4 months and median TTP was 6.7 months. The median OS was 11.76 months (range, 0.36-70.32). The overall response rate was 13%. Cox regression model data will be presented.

Conclusions: To our knowledge this study represents one of the first reports assessing the population-based value of a lapatinib/capecitabine treatment in clinical practice. Our data essentially corroborated findings obtained from randomized clinical trials. It seems that treatment with lapatinib and capecitabine is associated with a meaningful clinical effectiveness and therefore warrants consideration in the treatment algorithm of HER2-positive ABC patients.

Orsola-Malpighi - "F. Addarii", Bologna, Italy, [8]Novartis Pharmaceuticals, East Hanover, NJ, USA, [9]Instituto de Investigación Sanitaria Gregorio Marañón, CIBERONC, GEICAM, Universidad Complutense, Madrid, Spain

Background: CDK4/6 inhibitor RIBO significantly improved progression-free survival in combination with ET versus placebo + ET in pre- and postmenopausal women with HR+, HER2– ABC and no prior therapy for advanced disease in the pivotal phase 3 MONALEESA-7 and MONALEESA-2 trials (Tripathy et al. SABCS 2018; Hortobagyi et al. NEJM 2016). Here, we report additional safety data for RIBO+LET in premenopausal female pts enrolled in CompLEEment-1, an open-label, phase 3b trial evaluating RIBO+LET as first-line therapy in an expanded pt population.

Methods: Premenopausal pts with HR+, HER2– ABC, $\leq$1 line of prior chemotherapy, and no prior ET for ABC received RIBO (600 mg/day, 3 wk on/1 wk off) + LET (2.5 mg/day) and goserelin (3.6-mg subcutaneous implant every 28 days). The primary outcome was safety and tolerability. A pre-planned interim analysis was conducted $\sim$15 months after first pt first visit.

Results: Of the first 1,008 pts enrolled who completed 56 days of follow-up or discontinued before data cut-off, 153 were premenopausal women. Median age was 45.0 years

and the majority of pts (99.3%) had an Eastern Cooperative Oncology Group performance status ≤1; 40.5% had stage IV disease at diagnosis. Bone (73.9%), lung (31.4%), and liver (30.7%) were the most common metastatic sites. The most frequent adverse events (AEs) were neutropenia (53.6%), nausea (30.1%), hot flush (20.9%), headache (17.0%), and asthenia (16.3%). The most frequent grade ≥3 AE was neutropenia (34.0%). QT prolongation was infrequent (2.0%). Dose adjustment/treatment interruption due to AEs was required for 48.4% of pts. Four patients (2.6%) discontinued treatment due to AEs.

Conclusions: Initial safety results from CompLEEment-1 demonstrate the tolerability of RIBO+LET + ovarian functional suppression in premenopausal women, consistent with previous reports. NCT02941926.

Clinical trial identification: NCT02941926.

329P Abemaciclib with fulvestrant in patients with HR+, HER2- advanced breast cancer (ABC) that exhibited primary or secondary resistance to prior endocrine therapy (ET)

E-M. Grischke[1], P. Neven[2], Y. Lin[3], P.A. Kaufman[4], G.W. Sledge[5]

[1]Women's Clinic, University Clinics Tuebingen, Tuebingen, Germany, [2]Gynaecological Oncology / Multidisciplinary Breast Center, University Hospitals Leuven - Campus Gasthuisberg, Leuven, Belgium, [3]Oncology, Eli Lilly and Company, Indianapolis, IN, USA, [4]Hematology Oncology, Norris Cotton Cancer Center Dartmouth-Hitchcock Medical Center, Lebanon, NH, USA, [5]Medical Oncology, Stanford University, Stanford, CA, USA

Background: Abemaciclib, a selective inhibitor of CDK4 & 6, dosed on a continuous schedule is approved for the treatment of HR+, HER2- ABC. In the intent-to-treat population, abemaciclib with fulvestrant (F) demonstrated improved progression-free survival (PFS) and objective response rate (ORR) compared to placebo (P) + F (16.4 vs 9.3 mos, HR: 0.553; P<.0000001; ORR in measurable disease 48.1 vs 21.3%; P<.001). ET resistance (ETR) were classified into primary ETR, which includes pts whose disease relapsed while receiving the first 2 years of (neo)adjuvant ET or progressed while receiving the first 6 mos of ET for ABC, and secondary ETR. Here, we compare the efficacy and safety of abemaciclib + F vs P + F in the primary and secondary ETR subgroups.

Methods: MONARCH 2 was a phase 3 randomized, double-blind, placebo-controlled study of abemaciclib + F vs P + F in pts with HR+, HER2- ABC that progressed on ET. Key eligibility criteria were previously discussed. Pts received orally administered abemaciclib 150 mg Q12H + 500 mg F (per label) or P + F. Pts were stratified by sensitivity to ET. Primary objective was investigator-assessed PFS. Secondary objectives included efficacy, safety and tolerability.

Results: 169 pts (25.3%) had primary ETR and 489 pts (73.1%) had secondary ETR. Key efficacy endpoints are summarized (Table). The most frequent adverse events in primary and secondary ETR population are similar. For primary ETR, abemaciclib + F vs P + F were diarrhea (87.3 vs 22.4%), neutropenia (43.6 vs 5.2%), nausea (41.8 vs 25.9%), abdominal pain (36.4 vs 13.8%), and anemia (31.8 vs 5.2%), respectively.

Table: 329P Summary of PFS and ORR in primary and secondary ETR population

	Primary Resistance		Secondary Resistance	
	Abemaciclib + F	Placebo + F	Abemaciclib + F	Placebo + F
PFS				
Median (months)	15.3	7.9	16.6	9.6
Hazard Ratio [HR] (95% CI)	0.45 (0.31, 0.67)		0.59 (0.46, 0.75)	
Pvalue	<.001		<.001	
ORR in measurable disease, (%)	53.9	17.9	46.2	22.6
Pvalue	<.001		<.001	

Conclusions: Abemaciclib + F improved PFS and ORR in pts with primary and secondary ETR, and had a generally tolerable safety profile. Although pts with primary ETR typically have poor prognosis the benefit for abemaciclib + F was maintained in pts HR+, HER2- ABC.

Clinical trial identification: NCT02107703.

330P Tamoxifen (TAM) or a non-steroidal aromatase inhibitor (NSAI) with ribociclib (RIB) in premenopausal patients (pts) with hormone receptor-positive (HR+), HER2-negative (HER2–) advanced breast cancer (ABC): MONALEESA-7 subgroup analysis

A. Bardia[1], S. Campos-Gomez[2], S.A. Hurvitz[3], Y-S. Lu[4], S-A. Im[5], F. Franke[6], L. Chow[7], P. Wheatley-Price[8], F. Melo Cruz[9], J. Alam[10], O. Kong[10], I. Diaz-Padilla[11], M. Miller[10], D. Tripathy[12]

[1]Harvard Medical School, Massachusetts General Hospital Cancer Center, Boston, MA, USA, [2]Instituto de Seguridad Social del Estado de México y Municipios, Centro Oncológico Estatal, Toluca, Mexico, [3]UCLA Jonsson Comprehensive Cancer Center, UCLA Jonsson Comprehensive Cancer Center, Los Angeles, CA, USA, [4]National Taiwan University Hospital, National Taiwan University Hospital, Taipei, Taiwan, [5]Seoul National University College of Medicine, Seoul National University Hospital, Seoul, Republic of Korea, [6]CACON, Hospital de Caridade de Ijuí, Ijuí, Brazil, [7]Organisation for Oncology and Translational Research, Organisation for Oncology and Translational Research, Hong Kong, China, [8]Ottawa Hospital Cancer Centre, Ottawa Hospital Cancer Centre, Ottowa, ON, Canada, [9]ABC Foundation School of Medicine, ABC Foundation School of Medicine, Santo André, Brazil, [10]Oncology, Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA, [11]Oncology, Novartis Pharma AG, Basel, Switzerland, [12]MD Anderson Cancer Center, The University of Texas MD Anderson Cancer Center, Houston, TX, USA

Background: In the MONALEESA-7 study (NCT02278120), RIB + TAM/NSAI + goserelin significantly prolonged progression-free survival (PFS) and had a manageable safety profile vs placebo (PBO) + TAM/NSAI in premenopausal pts with HR+, HER2– ABC. Here we present data for the TAM and NSAI subgroups.

Methods: Premenopausal pts (N = 672) with HR+, HER2– ABC (≤1 line of chemotherapy; no prior endocrine therapy [ET] for ABC) were randomized 1:1 to RIB (600 mg/day, 3 weeks on/1 week off) or PBO + either TAM (20 mg/day) or NSAI (letrozole [2.5 mg/day] or anastrozole [1 mg/day]) + goserelin (3.6 mg every 28 days). Primary endpoint: locally assessed PFS. A predefined subgroup analysis evaluated PFS by ET partner (TAM or NSAI).

Results: 177 (26%) pts received TAM (RIB vs PBO: 87 vs 90) and 495 (74%) received an NSAI (248 vs 247). As of August 20, 2017, treatment was ongoing in 49% vs 31% of pts in the TAM subgroup and 53% vs 38% in the NSAI subgroup; the most common reason for discontinuation was disease progression (TAM 39% vs 54%; NSAI 35% vs 51%). PFS was prolonged for RIB vs PBO in the TAM (median 22.1 months [mo] vs 11.0 mo; hazard ratio 0.585; 95% CI 0.387–0.884) and NSAI (median 27.5 mo vs 13.8 mo; hazard ratio 0.569; 95% CI 0.436–0.743) subgroups. The most common Grade (G) 3 adverse events (AEs; regardless of causality; ≥5% of pts; RIB vs PBO) were neutropenia (TAM 39% vs 2%; NSAI 55% vs 3%), leukopenia (TAM 8% vs 1%; NSAI 15% vs 1%), elevated GGT (TAM 6% vs 3%; NSAI <1% vs 4%), elevated ALT (TAM 7% vs 2%; NSAI 5% vs 1%), and hypertension (TAM 6% vs 2%; NSAI 2% vs 3%); the only G4 AE in ≥ 5% of pts was neutropenia (TAM 9% vs 1%; NSAI 10% vs < 1%). Increases >60 ms from baseline in the QTcF interval (RIB vs PBO; TAM 16% vs 7%; NSAI 7% vs 0%) and new QTcF >480 ms (TAM 11% vs 1%; NSAI 5% vs 1%) were more common with TAM; there were no associated clinical symptoms or arrhythmias.

Conclusions: RIB demonstrated consistent treatment benefit vs PBO in premenopausal pts with HR+, HER2– ABC regardless of ET partner (TAM or NSAI). The safety profiles of RIB + ET were manageable and consistent, with the exception of QTc findings, which were more prevalent with TAM.

Background: RIB + FUL prolonged PFS vs placebo (PBO) + FUL in postmenopausal patients (pts) with HR+, HER2– ABC in the Phase 3 MONALEESA-3 study (NCT02422615). Consistent PFS benefit was observed in pts receiving treatment in either the first- (1L) or combined second-line (2L)/early relapse settings. Here we present additional efficacy and pain reduction results from MONALEESA-3.

Methods: Pts who received no or ≤ 1 line of prior endocrine therapy for ABC (i.e. receiving treatment in the 1L or 2L/early relapse settings, respectively) received RIB + FUL (n = 484) or PBO + FUL (n = 242). Endpoints included, primary: local PFS; secondary: overall response rate and health-related quality of life (HRQoL).

Results: As of Nov 3, 2017, median PFS was prolonged for RIB vs PBO in the separate 2L and early relapse settings (Table). Amongst the full population, 155/379 pts with measurable disease at baseline (41%; 95% CI 35.9–45.8) in the RIB arm and 52/181 (29%; 95% CI 22.1–35.3) in the PBO arm had a complete or partial response (P=0.003). The probability of a response by 6 months (RIB vs PBO arm) was 27% (95% CI 22.7–31.0) vs 16% (95% CI 12.0–21.6). At Week 8, a decrease from baseline in target lesion(s) size per RECIST was observed in (RIB vs PBO) 232/484 (48%) vs 92/242 (38%; P=0.006). A decrease in best % change from baseline in target lesion(s) size per RECIST was reported in 79% of 344 pts in the RIB arm and 66% of 166 pts in the PBO arm. At Cycle 3 Day 1 (Week 8), the absolute mean change from baseline in EORTC QLQ-C30 pain score was similar in both arms: –4.2 RIB (n = 361); –2.9 PBO (n = 169; P=0.517).

Conclusions: RIB + FUL consistently prolonged PFS in the separate 2L and early relapse settings. In the full population, RIB + FUL demonstrated early tumor size reduction and a higher response rate vs PBO + FUL, consistent with other RIB studies. Pain reduction was similar in both arms, suggesting addition of RIB to FUL does not negatively affect HRQoL.

Background: In the phase 3 PALOMA-2 trial, palbociclib (PAL) + letrozole (LET) significantly improved progression-free survival (PFS) vs placebo (PBO) + LET in pts with ER+/HER2– ABC. We investigated clinical outcomes of pts who achieved a confirmed OR compared with those who did not (data cutoff date: 31 May 2017).

Table: 331P

	2L setting		Early relapse setting	
	• Relapse >12 months from (neo)adjuvant endocrine therapy and subsequent progression on endocrine therapy for ABC • ABC at diagnosis that progressed after 1 line of endocrine therapy for ABC		Relapse on or ≤ 12 months after (neo)adjuvant endocrine therapy with no treatment for ABC	
	RIB + FUL	**PBO + FUL**	**RIB + FUL**	**PBO + FUL**
Pts, n	99	38	137	71
Median PFS, months	18.8	11.4	13.1	8.6
Hazard ratio (95% CI)	0.539 (0.333–0.873)		0.591 (0.422–0.830)	

Methods: Postmenopausal pts untreated for ER+/HER2- ABC were randomized 2:1 to PAL (125 mg/d [Schedule 3/1]) + LET (2.5 mg/d) or PBO+LET. Median PFS (mPFS), median duration of OR (mDOR), baseline characteristics, safety, and PAL exposure were compared in pts with or without OR by treatment arm.

Results: The PAL+LET and PBO+LET groups comprised 444 and 222 pts, respectively; 338 and 171 pts had measurable disease (MD) at baseline. Baseline characteristics were similar in OR and non-OR pts. OR was achieved by 194 (overall, 44%; MD, 57%) and 77 (35%; 45%) pts in the PAL and PBO arms, respectively. Of the pts who achieved OR in the PAL arm, 49% occurred within the first 3 months, 75% within 6 months, and 90% within 1 year. In the PAL arm, more OR than non-OR pts had visceral disease (62% vs 38%), de novo metastatic disease (50% vs 28%), and no prior hormonal therapy (55% vs 35%); fewer OR than non-OR pts had a disease-free interval of ≤ 12 months (14% vs 28%). mPFS was significantly prolonged with PAL+LET vs PBO+LET in both OR and non-OR pts (overall and with MD; Table); in OR pts, mDOR was longer with PAL+LET vs PBO+LET. Safety profiles were similar and independent of response; neutropenia was the most common all-grade AE in the PAL arm (OR, 86%; non-OR, 78%) and rates of PAL dose reduction due to AEs were similar (41%; 38%).

Conclusions: PAL+LET provided significant clinical benefit vs PBO+LET in both OR and non-OR pts; the safety profile was similar to previously reported results in the overall population. PAL is an effective treatment regardless of OR. Pfizer (NCT01740427)

333P Ribociclib (RIBO) + letrozole (LET) in patients (pts) with hormone receptor-positive (HR+), human epidermal growth factor receptor-2–negative (HER2–) advanced breast cancer (ABC) who received prior chemotherapy (CT) for advanced disease: Preliminary subgroup results from the phase IIIb CompLEEment-1 trial

F. Cardoso[1], K. Papazisis[2], M. De Laurentiis[3], A. Ring[4], J. Lu[5], M. Martín[6], H.A. Azim[7], C. Zamagni[8], K. Zhou[9], J. Wu[9], J.P. Zarate[9], P.H. Cottu[10]

[1]Breast Unit, Champalimaud Foundation Cancer Center, Lisbon, Portugal, [2]Department of Medical Oncology, Euromedica General Clinic, Thessaloniki, Greece, [3]Department of Breast and Thoracic Oncology, Istituto Nazionale Tumori, Naples, Italy, [4]Medical Oncology, The Royal Marsden NHS Foundation Trust, Sutton, UK, [5]Keck School of Medicine, Division of Medical Oncology, University of Southern California, Los Angeles, CA, USA, [6]Instituto de Investigación Sanitaria Gregorio Marañón, CIBERONC, GEICAM, Universidad Complutense, Madrid, Spain, [7]Department of Clinical Oncology, Cairo Oncology Center, Cairo University-CairoCure, Cairo, Egypt, [8]Addarii Medical Oncology Unit, Policlinico S. Orsola-Malpighi-"F.Addarii", Bologna, Italy, [9]Novartis Pharmaceuticals, East Hanover, NJ, USA, [10]Department of Medical Oncology, Institut Curie, Paris, France

Background: CDK4/6 inhibitor RIBO is approved in combination with an aromatase inhibitor (AI) for HR+, HER2– ABC in postmenopausal women with no prior therapy for ABC, based on the MONALEESA-2 trial (Hortobagyi et al. NEJM 2016). Previous first-line studies of CDK4/6 inhibitors plus an AI have excluded pts who have received prior CT for ABC, and as such it is important to define safety in this population. Here, we report early safety results for pts who had received prior CT for ABC enrolled in CompLEEment-1, an open-label, phase 3b trial evaluating RIBO+LET as first-line endocrine-based therapy in an expanded pt population.

Methods: Pts with HR+, HER2– ABC, ≤1 line of prior CT, and no prior endocrine therapy for ABC received RIBO (600 mg/day, 3 wk on/1 wk off) + LET (2.5 mg/day); men and premenopausal women received concomitant goserelin (3.6-mg subcutaneous implant q28 days). The primary outcome was safety and tolerability. A pre-planned interim analysis was conducted ~15 months after first pt first visit.

Results: Of the first 1,008 pts enrolled with 56 days of follow-up or discontinued before the data cut-off, 188 had received prior CT for ABC. In this subgroup, the median age was 56.5 years; 2 pts were men and 39 were premenopausal women. The majority of pts (95%) had an Eastern Cooperative Oncology Group performance status ≤1; 45.7% presented with stage IV disease at diagnosis. The most common sites of metastasis were lung (38.8%), liver (33.0%), and lymph nodes (30.0%). The most common all-grade adverse events (AE) were neutropenia (48.9%), nausea (30.3%), and fatigue (20.7%). The most common grade ≥3 AEs were neutropenia (28.2%) and leukopenia (3.2%). QT prolongation events were mild and occurred in 5.9% of pts. Dose reduction or interruption due to AEs occurred in 48.4% of pts; 5 pts discontinued due to AEs.

Conclusions: Initial safety results from CompLEEment-1 demonstrate the tolerability of RIBO+LET in pts who had received prior CT for ABC, consistent with previous reports in pts without CT for ABC. NCT02941926.

Clinical trial identification: NCT02941926.

334P Health related quality of life in women with HR+/HER2- advanced or metastatic breast cancer treated in real world settings in Italy and Germany

M. De Laurentiis[1], A. König[2], K.L. Davis[3], D. Mitra[4], C.M.A. Nuzzo[5], M. Ajmera[3], S. de Placido[6], S. Brucker[7], N. Harbeck[2]

[1]Department of Breast and Thoracic Oncology, National Cancer Institute "Fondazione Pascale", Naples, Italy, [2]Department of Obstetrics and Gynecology, Brustzentrum der Universitaet Muenchen (LMU), Munich, Germany, [3]Health Economics, RTI Health Solutions, Research Triangle Park, NC, USA, [4]Patient Health & Impact, Pfizer Inc, New York, NY, USA, [5]Pfizer Oncology, Pfizer Inc, Rome, Italy, [6]Department of Clinical Medicine and Surgery, University of Naples Federico II, Naples, Italy, [7]Department of Obstetrics and Gynecology, Tübingen University Hospital, Tübingen, Germany

Background: Real-world data on health-related quality of life (HRQoL) in women with HR+/HER2- advanced/metastatic breast cancer (ABC/mBC) are limited. This study aims to address this gap.

Methods: MARIA is a non-interventional, prospective, multi-center study that includes women in Italy and Germany initiating their first or second therapy in the HR+/ HER2- ABC/mBC setting. Breast cancer specific HRQoL was assessed using the Functional Assessment of Cancer Therapy-Breast (FACT-B). We report baseline clinical characteristics and HRQoL assessments at enrollment (baseline) and at 3 and 6 months for the first 262 patients enrolled. Change from baseline was calculated for patients with both baseline and follow-up measurement and tested for statistical significance using t-tests for the overall cohort and within subgroups stratified by visceral and bone metastases status.

Results: Median age was 61 years and 46% had visceral disease. At enrollment, 32% were receiving endocrine monotherapy, 34% chemotherapy alone, 28% endocrine/ targeted therapy combinations, and 7% other regimens. A statistically significant ($p < 0.05$) deterioration was observed in the overall cohort at Month 3 for both FACT-B (-4.9 [14.9]) and FACT-G (-4.1 [13.2]) and at Month 6 for the total FACT-G score (-2.1 [12.7]). In the subgroup with visceral and bone metastases, a statistically significant ($p < 0.05$) deterioration was observed in FACT-G scores at 3 months: (-6.6 [16.1]) and at 6 months (-3.6 [12.3]) while no significant change was observed in FACT-B scores. A statistically significant ($p < 0.05$) deterioration from baseline was observed in the subgroup with visceral disease and without bone metastases in FACT- B score at 3 months (mean [SD]: -6.7 [13.9] and at 6 months (-3.9 [16.6]), respectively while no significant change was observed in FACT-G scores.

Conclusions: A statistically significant deterioration was observed in HRQOL scores at some time points after initiating a new line of therapy in the overall cohort and some subgroups of HR+ HER2- MBC patients in a prospective study In Italy and Germany. Further follow-up is ongoing to examine the longer-term impact of therapy on HRQoL.

Background: TANGO is a French observational prospective study of women with advanced BC treated with EVE/EXE. The main objective was to describe the management of stomatitis and noninfectious pneumonitis (NIP) in clinical practice. Overall safety, duration of EVE/EXE tx and progression-free survival (PFS) were also assessed.

Methods: Eligible patients (pts) were postmenopausal women ≥18 years with advanced HR+/HER2− BC, for whom EVE/EXE was initiated. Statistical analyses were mainly descriptive. Tx duration and PFS were estimated with Kaplan-Meier methods.

Results: From Nov 2014 to Mar 2016, 596 pts had received EVE/EXE (Pts characteristics: see table).

Table: 335P Pts baseline characteristics at EVE/EXE initiation

	Pts who received EVE/EXE (N = 596)
Age	
Mean (standard deviation) age, years	65.1 (10.8)
Pts aged ≥75 years – n (%)	131 (22%)
Median (range) time since initial BC diagnosis to inclusion, years	7.5 (0.1 – 44.3)
Pts with de novo metastatic BC at diagnosis n (%)	145 (24%)
Pts with ECOG ≤1 n (%)	527 (88%)
Metastases	
Pts with bone-only metastases – n (%)	199 (33%)
Pts with visceral metastases – n (%)	290 (49%)
Previous lines of tx for metastatic disease	
Pts without previous line – n (%)	113 (19%)
Pts with 1 previous line – n (%)	208 (35%)
Pts with 2 previous lines – n (%)	126 (21%)
Pts with ≥3 previous lines – n (%)	149 (25%)
BC relapses relative to adjuvant hormonal tx (N, available data)	375
<2 years after the beginning of tx – n (%)	57 (15%)
≥2 years after the beginning of tx and <1 year after the end of tx – n (%)	165 (44%)
≥1 year after the end of tx – n (%)	142 (38%)

305 pts (51%) experienced stomatitis and 80 (13%) experienced NIP (median time to 1st event [range]: 21 [1 – 333] and 104 days [1 – 396], respectively). Most stomatitis (87%) and NIP (91%) were grade 1-2. Stomatitis were mainly treated with mouthwashes (77%), topical analgesics (19%) and antifungals (15%), and NIP with corticosteroids (40%) and antibiotics (10%). 509 pts (85%) had EVE-related adverse events (AE), the most common (excluding stomatitis/NIP) being asthenia (19%), diarrhoea (11%) and rash (10%). 90 pts (15%) had EVE-related serious AE, the most common (excluding stomatitis/NIP) being asthenia (2%). 5 pts (<1%) had EVE-related fatal AE: health deterioration, multiple organ failure, epistaxis, interstitial lung disease, pleural metastases and disorientation. With 562 analysed pts, the median PFS was 6.9 months (95% confidence interval [CI]: 6.2 – 7.8) and median duration of EVE/EXE tx was 5.3 months (95% CI: 4.8 – 6.0). After EVE discontinuation, most pts continued EXE alone (55%) or had chemotherapy (8%).

Conclusions: Results from this real-life observational study reinforce the known safety profile of EVE and better characterize stomatitis and NIP, as well as their management in EVEtreated pts.

Clinical trial identification: EU PAS: EUPAS7325.

336P Everolimus in advanced breast cancer: A systematic review and meta-analysis

J. Raphael[1], C. Lefebvre[1], A. Allan[2], J. Helou[3], G. Boldt[1], T. Vandenberg[1]

[1]Oncology, Western University, London Regional Cancer Program, London, ON, Canada, [2]Oncology and Anatomy and Cell Biology, Western University - London Regional Cancer Program, London, ON, Canada, [3]Radiation Oncology, Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: Everolimus (E) plus exemestane are approved for advanced hormone receptor (+) breast cancer (BC) after progression on non-steroidal aromatase inhibitors. The role of E is less well defined in other BC phenotypes and with other drugs. We conducted a systematic review and meta-analysis to assess the efficacy and safety of adding E to standard of care (SoC) in advanced BC regardless of tumor phenotype and treatment type.

Methods: The electronic databases PubMed and EMBASE, were searched for eligible randomized trials. Pooled hazard ratios (HR) for progression free survival (PFS) and overall survival (OS) and pooled risk ratios (RR) and odds ratios (OR) for objective response rates (ORR), clinical benefit rates (CBR) and grade 3 or higher toxicity were meta-analyzed using the generic inverse variance, the Mantel-Henszel and Peto method. To account for between-studies heterogeneity, random-effect models were used. Subgroup analyses compared survival outcomes by tumor phenotype.

Results: Data of 2,693 patients from 7 trials were analyzed. The addition of E to the SoC reduced the risk of disease progression by 33% (7 trials, HR 0.67, 95%CI 0.52-0.86). This did not translate into an OS benefit (4 trials, HR 0.91, 95%CI 0.62-1.33). In addition, E improved the ORR (6 trials, RR 0.91, 95%CI 0.85-0.97) and CBR (7 trials, RR 0.79 95%CI 0.65-0.97) while it increased the risk of developing $\geq$ grade 3 toxicity including stomatitis (OR 5.00, 95%CI 3.63-6.89) and pneumonitis (OR 3.13, 95%CI 1.83-5.36). The PFS benefit was more prominent for patients with hormone receptor (+) / HER2 (-) (HR 0.51, 95%CI 0.43-0.59) than HER2 (+) disease (HR 0.83, 95%CI 0.73-0.96; p for subgroup differences<0.001). For the HER2 (+) subgroup, the PFS benefit was restricted to hormone receptor (-) patients (HR 0.65, 95%CI 0.53-0.81 and HR 0.99, 95%CI 0.83-1.19 for hormone receptor (+) patients; p for subgroup differences 0.004).

Conclusions: E reduces the risk of disease progression in hormone receptor (+) advanced BC independent of endocrine therapy type. In HER2 (+) patients, the benefit is limited for hormone receptor (-) patients. Given the use of newer drugs in the first line, real-world data are needed to confirm whether the benefit persists for patients who develop resistance to CDK4/6 inhibitors.

337P First-line treatment for endocrine sensitive bone-only metastatic breast cancer: Is more always better?

A. Toss[1], M. Venturelli[1], I. Sperduti[2], C. Isca[1], E. Barbieri[1], F. Piacentini[1], C. Omarini[1], L. Cortesi[1], S. Cascinu[1], L. Moscetti[1]

[1]*Department of Oncology and Haematology, Azienda Ospedaliero - Universitaria Policlinico di Modena, Modena, Italy,* [2]*Bio-Statistics Unit, IRCCS Regina Elena National Cancer Institute, IRCCS Regina Elena National Cancer Institute, Rome, Italy*

Background: The standard first-line for endocrine sensitive metastatic breast cancer (BC) is represented by endocrine therapy. Several phase III clinical trials searched for more effective strategies. The SWOG, FACT and FALCON trials analyzed the role of Fulvestrant (Fv), producing contradictory results. The Monaleesa2, Monaleesa7, Monarch3 and Paloma2 trials showed that the addition of a CDK4/6 inhibitor to an aromatase inhibitor (AI) increases the PFS. The use of the combination for the first-line treatment of bone-only disease (BoD) is widely discussed. Our meta-analysis aims to explore the role of the new endocrine strategies in BoD.

Methods: The Prisma statement was used. A systematic review of electronic databases identified the phase III clinical trials comparing the standard AI to a novel experimental strategy. The hazard ratios (HR) for PFS for the subgroup of BoD were pooled in a meta-analysis. The heterogeneity of the data was evaluated by Chi-square Q test and I^2 statistic.

Results: 7 studies were included in the analyses. 4 trials explored the role of CDK4/6 inhibitors (Monaleesa2 and 7, Monarch3 and Paloma2), 2 trials analyzed Fv + AI (SWOG and FACT), while one trial studied Fv monotherapy (FALCON). 5 trials reported data regarding the BoD, while 2 trials included the BoD in the non-visceral disease. Overall, the meta-analyses showed a PFS advantage for the experimental arms [HR 0.67 p 0.01], with a significant moderate/high heterogeneity [I^2 69.88% p 0.003]. Only the FALCON and Paloma2 showed a significant improvement in PFS, respectively for Fv and Palbociclib + Letrozole. Considering only trials reporting data for BoD, the experimental arms significantly improved the PFS [HR 0.60 p 0.001], with a low/moderate non-significant heterogeneity [I^2 37.73% p 0.17].

Conclusions: The meta-analyses of trials reporting data for BoD, showed that the novel strategies are able to improve the PFS. Nonetheless, only Palbociclib + Letrozole provided statistically significant data of advantage in this setting. In clinical trials, BoD is often included in the non-visceral disease subgroup. Future clinical trials should take into account the differences in natural history and better prognosis of BoD, in order to define the best approach to these patients.

338P Real world treatment patterns associated with palbociclib combination therapy in Germany: Results from the IRIS study

D. Mitra[1], G. Taylor-Stokes[2], J. Waller[3], K. Gibson[3], G. Milligan[4], S. Iyer[1]

[1]*Patient Health & Impact, Pfizer Inc., New York, NY, USA,* [2]*Oncology, Adelphi Real World, Bollington, UK,* [3]*Observational Research, Adelphi Real World, Bollington, UK,* [4]*Statistics, Adelphi Real World, Bollington, UK*

Background: Following the approval of palbociclib as the first CDK4/6 inhibitor for HR+/HER2- advanced/metastatic breast cancer (ABC/ MBC), a need exists to understand treatment patterns associated with palbociclib combination therapies in real world clinical settings. The Ibrance Real World Insights (IRIS) study aims to address this evidence gap.

Methods: A retrospective chart review of HR+/HER2- ABC/ MBC patients who received palbociclib combination therapies was conducted in Germany. Physicians completed electronic case report forms (eCFRs), extracting data on patient demographics, clinical characteristics and treatment patterns from an index date (60 days after physician's first prescription of palbociclib) until the most recent record available.

Results: 42 physicians completed 257 eCRFs with 48% representing academic centers. The mean (SD) age of patients at palbociclib initiation was 59.6 (9.4) years (median, 60 years). ECOG status at palbociclib initiation was mostly 0 (48.2%) or 1 (33.5%). Visceral disease was present in 65.6% of patients. Approximately 75% of patients received palbociclib in combination with aromatase inhibitors (AI) and 25% in combination with fulvestrant. Overall, 97% patients received palbociclib + AI as 1st line advanced therapy, the remaining having received chemotherapy previously in the advanced setting. Letrozole was the most common AI partner therapy (63.4%) followed by anastrozole (23.2%), and exemestane (13.4%). Palbociclib + fulvestrant was mostly used in first (44.4%) and second (52.4%) lines. The most frequently prescribed starting dose was 125 mg/day (73.2%), followed by 100mg/day (26.1%) and 75 mg/day (0.8%). 76% of palbociclib + AI patients started on 125 mg compared to 65% of palbociclib + fulvestrant patients. Dose reductions occurred in only 28 (10.9%) patients (7.4% of those who started at 125 mg/day) and a cycle delay occurred in 1 (3.4%) patient. Dose reduction rates were 10.8% in palbociclib + AI and 11.1% in palbociclib + fulvestrant.

Conclusions: In the real world setting, rates of dose reduction were low, and were similar between palbociclib + AI and palbociclib + fulvestrant in HR+/HER2- ABC/ MBC patients in Germany.

339P Management of abemaciclib associated adverse events in patients with hormone receptor positive (HR+), HER2- advanced breast cancer: Analysis of the MONARCH trials

H.S. Rugo[1], S.M. Tolaney[2], J. Huober[3], M. Toi[4], V. André[5], S. Barriga[6], T. Forrester[7], G.W. Sledge[8], M.P. Goetz[9]

[1]*Breast Cancer Center, UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA, USA,* [2]*Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, USA,* [3]*Gynecol. & Obstetrics, Universitaetsfrauenklinik Ulm, Ulm, Germany,* [4]*Breast Surgery, Kyoto University-Graduate School of Medicine, Kyoto, Japan,* [5]*Oncology, Eli Lilly and Company, Paris, France,* [6]*Oncology, Eli Lilly and Company, Madrid, Spain,* [7]*Oncology, Eli Lilly and Company, Indianapolis, IN, USA,* [8]*Medical Oncology, Stanford University, Stanford, CA, USA,* [9]*Alliance Foundation for Clinical Trials in Oncology, Mayo Clinic, Rochester, NY, USA*

Background: Abemaciclib is a CDK4 & 6 inhibitor dosed continuously with demonstrated efficacy and an acceptable safety profile in pts with HR+, HER2-negative advanced breast cancer as monotherapy (MONARCH 1) and in combination with endocrine therapy; with fulvestrant (MONARCH 2) or with non-steroidal aromatase inhibitors (MONARCH 3). The most frequent adverse event (AE) is low-grade diarrhea; neutropenia is the most frequent grade 3/4 AE. We describe the timing and management of common AEs in the MONARCH trials.

Methods: Enrollment criteria, study designs and key eligibility criteria of MONARCH 1, 2 and 3 have been reported (Dickler et al. 2017; Sledge et al. 2017; Goetz et al. 2017). Pts were advised to initiate antidiarrheal therapy at first sign of diarrhea and notify the investigator, drink fluids. If not improved within 24 hours to < grade 1, treatment was suspended until diarrhea resolved. Dose reductions required for grade $\geq$3 or persistent grade 2 diarrhea. For grade 3 neutropenia, abemaciclib was held until < grade 2. The dose was reduced for recurrent grade 3 or grade 4 neutropenia.

Results: Across MONARCH, the median time to onset of diarrhea was between day 6-8. First dose reductions for diarrhea occurred at a median of 28-41 days. Dose holds for diarrhea were brief, constituting 1.7-3.8% off total treatment time. The median time to onset of grade 3/4 neutropenia was 29-36.5 days, and resolved at a median of 11-15 days. AEs were managed by dose adjustments and/or supportive medication (Table).

Table: 339P

Summary of Dose Adjustments in Pts Experiencing Diarrhea or Neutropenia

Characteristics	MONARCH 1 Abemaciclib N = 132	MONARCH 2 Abemaciclib + F N = 441	MONARCH 3 Abemaciclib + NSAI N = 327
Diarrhea (any grade), n(%)	119 (90.2)	381 (86.4)	269 (82.3)
Grade 3	26 (19.7)	59 (13.4)	31 (9.5)
Incidences per patient, n (%)			
1	60 (50.4)	185 (48.6)	124 (46.1)
2	29 (24.4)	90 (23.6)	52 (19.3)
≥3	30 (25.2)	106 (27.8)	93 (34.6)
Outcome, number (%) of events	263	995	802
Not recovered/resolved	15 (5.7)	106 (10.7)	70 (8.7)
Treatment change, n (%)	119	381	269
Dose reduction of study drug	27 (22.7)	83 (21.8)	45 (16.7)

Treatment discontinuation	1 (0.8)	13 (3.4)	6 (2.2)
Antidiarrheal medication, n (%)	80 (60.6)	333 (75.5)	226 (69.1)
Neutropenia (any grade), N (%)	49 (37.1)	203 (46.0)	143 (43.7)
Grade ¾	32 (24.2)	117 (26.5)	78 (23.9)
Treatment change, n (%)			
Dose reduction of study drug	14 (10.6)	44 (10.0)	42 (12.8)
Dose omission	21 (15.9)	72 (16.3)	57 (17.4)
Treatment discontinuation	0	7 (1.6)	9 (2.8)

Conclusions: The dose adjustment strategy used in the MONARCH studies was effective at managing AEs by dose adjustment and/or supportive medication. Understanding the safety profile of abemaciclib can inform AE management and can extend time on treatment.

Clinical trial identification: NCT02102490 (MONARCH 1), NCT02107703 (MONARCH 2), NCT02246621 (MONARCH 3).

340P Progression free survival (PFS) benefit from first line endocrine based therapies in postmenopausal women with HR+ HER2- metastatic breast cancer (MBC) according to different prognostic subgroups: A combined analysis of data from PALOMA 2, MONALEESA 2, MONARCH 3, FALCON, SWOG and FACT trials

V. Rossi[1], D. Giannarelli[2], P. Berchialla[3], C. Nisticò[4], G. Ferretti[5], S. Gasparro[4], P. Malaguti[4], M. Russillo[6], G. Catania[4], L. Vigna[1], R.L. Mancusi[6], F. Cognetti[6], A. Fabi[9]

[1]Breast Unit, Azienda Ospedaliera S. Camillo Forlanini, Rome, Italy, [2]Statistica Medica, Istituto Regina Elena, Rome, Italy, [3]Department of Clinical and Biological Sciences, University of Turin, Turin, Italy, [4]Medical Oncology, Istituto Regina Elena, Rome, Italy, [5]Medical Oncology, Istituto Regina Elena, Rome, Italy, [6]Medical Oncology, Istituto Nazionale Tumori Regina Elena, Rome, Italy, [7]Scienze Statistiche, Università Tor Vergata, Rome, Italy

Background: This analysis combines data from six phase III trials investigating the role of endocrine-based therapies in the first-line setting of MBC to identify which factors may guide the clinical choice among available drugs.

Methods: For PFS, Hazard Ratio (HR) and 95% CI were reported. Subgroup meta-analysis was conducted stratifying by age, ECOG, ethnicity, prior chemotherapy or endocrine therapy exposure, measurable disease at the time of metastasis occurrence, visceral or bone only disease, time from the initial diagnosis of breast cancer to the metastasis onset. Random-effect model was used and heterogeneity was quantified by I^2 statistics. Test of interaction was performed to compare treatment effect in sub-groups. Data analysis was performed using R Statistical Software version 3.4.3.

Results: In absence of indirect comparison between cycline dependend kinase (CDK) 4/6 inhibitors (Palbociclib, Ribociclib, Abemaciclib) combined to nonsteroidal aromatase inhibitors (AIs) and Fulvestrant endocrine-based therapies, all these therapeutic options resulted in significant PFS benefit compared to AIs endocrine-monotherapy (HR: 0.74; 95% CI 0.67-0.80). Test of interaction showed similar treatment effects among sub-groups with the exception of Ethnicity and ECOG. Specifically, a longer PFS from CDK 4/6 inhibitors plus AIs strategies was observed in Asian (Asian HR: 0.38; 95% CI 0.20-0.72 versus non-Asian population HR: 0.61; 95% CI 0.50-0.75, $p < 0.001$) and ECOG≥1 patients (ECOG≥1 HR: 0.53; 95% CI 0.51-0.56 versus ECOG=0 HR: 0.60; 95% CI 0.49-0.74, $p < 0.02$).

Conclusions: CDK 4/6 inhibitors or Fulvestrant endocrine-based therapies as first-line treatment for postmenopausal women with HR+/HER2- MBC showed significant PFS improvement in comparison with AIs endocrine-monotherapy. Further indirect comparison by a network meta-analysis is needed to explore which patients may derive the greatest benefit from the different therapeutics options.

341P Palbociclib in combination with letrozole as first or later line therapy for patients with locally advanced, inoperable or metastatic HR+/HER2- breast cancer in Germany: Interim results of the INGE-B phase II study

M.K. Welslau[1], M. Zaiss[2], U. Söling[3], M. Untch[4], L. Müller[5], D. Lüftner[6], J. Meiler[7], A. Welt[8], J. Sahlmann[9], L. Houet[10], E. Runkel[10], N.W. Marschner[10]

[1]Medical Oncology, MVZ am Klinikum Aschaffenburg GmbH, Aschaffenburg, Germany, [2]Medical Oncology, Praxis für Interdisziplinaere Onkologie, Freiburg, Germany, [3]Medical Oncology, Onkologische Gemeinschaftspraxis, Kassel, Germany, [4]Clinic for Gynecology, Gynecologic Oncology and Obstetrics, Helios Klinikum Berlin Buch, Berlin, Germany, [5]Medical Oncology, Onkologie UnterEms, Leer, Germany, [6]Klinik für Hämatologie, Onkologie und Tumorimmunologie, Charité Campus Benjamin Franklin, Berlin, Germany, [7]Medical Oncology, Klinik Dr. Hancken GmbH, Stade, Germany, [8]Klinik für Innere Medizin/ Tumorforschung, Universitätsklinikum Essen (AöR), Essen, Germany, [9]Data Management, Statistics and Medical Informatics, iOMEDICO, Freiburg, Germany, [10]Medical Department, iOMEDICO, Freiburg, Germany

Background: Based on the pivotal PALOMA trials investigating the combination of the CDK4/6 inhibitor palbociclib with letrozole or with fulvestrant after prior endocrine therapy, extended European approval was granted for this patient population to receive palbociclib in combination with any aromatase inhibitor or with fulvestrant after prior endocrine therapy. The prospective multi-centre phase 2 study INGE-B was designed to a) investigate the combination of palbociclib with letrozole or with fulvestrant in accordance with the PALOMA trials in Germany and b) to obtain so far lacking data on the combination of palbociclib with the aromatase inhibitors exemestane or anastrozole.

Methods: In total, 360 patients with locally advanced, inoperable or metastatic HR+/HER2- breast cancer were recruited at 82 sites across Germany. Eligible patients are treated with palbociclib either in combination with letrozole, anastrozole, exemestane or fulvestrant as first-line therapy or in combination with letrozole or fulvestrant as later-line therapy. Primary objective is the clinical benefit rate (CBR), defined as the percentage of patients with response or stable disease at week 24. Key secondary endpoints include progression-free survival (PFS), overall survival (OS), overall response rate (ORR) and safety. Quality of life, fatigue, anxiety and depression are assessed with validated questionnaires. Data were analysed for each treatment group separately with descriptive statistics.

Results: The first interim analysis of the INGE-B study was scheduled to analyse data of patients receiving palbociclib and letrozole in first or later line. Between 09/2016 and 01/2018, 63 first- and 59 later-line patients were enrolled at 38 sites and observed for at least 6 months of treatment, unless discontinued earlier for disease progression or any other reason. Baseline patient and tumour characteristics will be presented. Efficacy in terms of CBR and best response and treatment-emergent adverse events will be described.

Conclusions: The results of the first interim analysis of the INGE-B study will be discussed with respect to data from the PALOMA 1/2 trials.

Clinical trial identification: NCT02894398.

342P Response to primary treatment for first recurrence independently influences survival of patients with hormone receptor-positive, HER2-negative breast cancer: A multicenter study of 236 recurrent metastatic patients

J. Yamamura[1], S. Kamigaki[1], M. Tsujie[1], J. Fujita[1], H. Osato[1], C. Higashi[2], H. Kanaizumi[2], Y. Tanaka[2], M. Hamada[2], W. Shinzaki[2], Y. Hasimoto[2], Y. Komoike[2]

[2]*Department of Breast and Endocrine Surgery, Kindai University Faculty of Medicine, Sayama, Japan*

Background: There is little current evidence for the optimal primary treatment (PT) for patients with recurrent metastatic hormone receptor-positive (HR+), HER2-negative (HER2-) breast cancer. These patients may be resistant to metastatic treatment due to continuous adjuvant endocrine therapy (ET). Here, we identify the significant factors correlating to prognosis in a retrospective study. Recognizing the prognostic factors for recurrent HR+/HER2- breast cancer may improve the delivery of healthcare to at-risk groups and play an important role in the treatment and care for these patients.

Methods: We performed a retrospective review of records from 236 patients with recurrent metastatic HR+/HER2- breast cancer who were diagnosed between January 2000 and December 2013 at Sakai City Medical Center and Kindai University Hospital, Japan. We assessed the clinicopathologic features, treatment patterns, and overall survival (OS) following diagnosis of first distant recurrence.

Results: Median OS after first recurrence was 3.73 years. Patients with longer disease free-survival (DFI) ($\geq$2 years), a longer interval after the end of adjuvant ET ($\geq$1 year), or first recurrence without liver metastasis had a significantly better prognosis ($p < 0.001$, $p = 0.007$, and $p < 0.001$, respectively). Patients with a good response to PT for first recurrence also had significantly better prognosis, regardless of ET or chemotherapy ($p < 0.001$). Longer DFI, no liver metastasis, and good response to PT were found to be independent prognostic factors for better OS in multivariate analysis (HR:0.467; 95%CI:0.291-0.750, $p = 0.002$, HR:0.443; 95%CI:0.285-0.688, $p < 0.001$, and HR:0.312; 95%CI:0.201-0.484, $p < 0.001$, respectively). Good responders to PT were also shown to have a significantly longer response to subsequent lines ($p = 0.007$).

Conclusions: Good response to PT for first recurrence may be the key to favorable OS for recurrent metastatic HR+/HER2- patients, regardless of visceral metastasis. In addition to a novel targeted agent, more optimal treatment to first recurrence could improve drug resistance and eventually lead to better prognosis.

343P Application of CDK4/6 inhibitors in practice: Effect of online education on clinician competence and confidence

C. Day[1], D. Middleton[2], S. Loibl[3]

[1]*Global Education, Medscape, London, UK,* [2]*Global Education, Medscape, New Jersey, NJ, USA,* [3]*Department of Medicine and Research, German Breast Group (GBG) Forschungs GmbH, Neu-Isenburg, Germany*

Background: This study determined whether online continuing professional development (CPD) activity could improve oncologists (Oncs) and obstetrician/gynaecologists (Obs/Gyns) competence and confidence in the use of CDK4/6I in practice.

Methods: An interactive text-based activity that included discussion of 2 detailed patient cases was launched for countries outside the United States in March 2017, with data collected until April 2017. Educational effect was assessed with a repeated-pairs pre-/post-assessment study design, where individual participants served as his/her own control. 3 multiple-choice, knowledge questions and 1 self-efficacy, 5-point Likert scale (confidence) question were analyzed. Chi-squared test assessed pre- to post-assessment change (5% significance level, $P < .05$). Magnitude of change in proportion of correct responses overall, and for each question, were determined with Cramer's V (effect size: <0.05 none/minimal; 0.06-0.15 small, 0.16-0.30 medium, >0.30 large).

Results: 204 Oncs and 51 Obs/Gyns completed both pre- and post-assessments. A large education effect was observed for both Oncs ($V = 0.311$) and Obs/Gyns ($V = 0.459$). At baseline, 46% of Oncs and 16% of Obs/Gyns answered all 3 questions correctly, increasing to 91% and 76%, respectively, post-assessment. An average of 75% of oncs selected the best response on pre-assessment (range, 66% to 80%), improving to 96% post-assessment (range, 96% to 97%). Statistically significant change for all 3 questions and a medium to large education effect was observed for the questions covering appropriate treatment selection, patient monitoring and management of neutropenia. Baseline understanding was lower for obs/gyns with a large education effect seen for all 3 questions. 38% of Oncs and 45% of Obs/Gyns reported increased confidence managing neutropenia due to CDK4/6I.

Conclusions: This on-demand, text-based activity with 2 interactive cases resulted in a significant, positive education effect. Baseline findings indicate that both specialties, would benefit from education to facilitate application of CDK4/6I in practice. Online medical education is important in supporting the practical application of new treatment regimens in practice.

Background: This study describes real-world use and population characteristics in HR+/HER2- advanced breast cancer (ABC) patients receiving palbociclib (PAL) in routine practice.

Methods: This prospective, noninterventional study has a targeted enrollment of 1500 men and women from ~110 sites. Site and patient data, monitored remotely for clarity/completeness, are collected from medical charts, physician surveys, and patient-reported outcomes; optional blood samples are collected during standard-of-care lab draws.

Results: This is an interim report of the first 312 patients with completed baseline case report forms as of 9Mar18 from 66 US sites (data snapshot: 9Apr18). Most sites were community sites (79%) with 1-10 treating physicians (61%). Of 33 sites that use clinical pathways, 45% were based on NCCN and 42% on US Oncology guidelines. Selected patient characteristics are shown (Table). Before starting PAL at enrollment, 18% of patients received chemotherapy, 21% hormonal therapy, 11% radiotherapy, 4% surgical resection, and 66% had no prior ABC therapy. Overall, 72% of patients received PAL combination first-line, of whom 56% received PAL+letrozole or anastrozole, 41% PAL+fulvestrant, and 4% PAL+exemestane. Of patients receiving $\geq$second-line PAL, 46% received prior hormonal monotherapy, 43% prior chemotherapy alone, and 6% both.

Table: 344P Selected patient demographic and clinical characteristics

	All Patients (N = 312)
Age at study enrollment, y

Gastrointestinal disorders, n (%)	225 (72.1)
Metabolism and nutrition disorders, n (%)	190 (60.9)
Cardiac disorders, n (%)	49 (15.7)

*Disease-free interval was defined as the time from first diagnosis of breast cancer to onset of advanced/metastatic disease among patients with available initial breast cancer diagnosis dates and available date of first ABC diagnosis.

Conclusions: This is the first large, prospective multicenter study assessing real-world use of a CDK4/6 inhibitor. In the first 312-patient cohort, most were treated at community sites. A heterogeneous real-world population received PAL, including elderly, premenopausal, African-American, Latino/Hispanic, and male patients not commonly represented in clinical trials. Hormone partners received with PAL included steroidal and nonsteroidal aromatase inhibitors or fulvestrant, predominantly first-line.

Clinical trial identification: NCT03280303.

345P Everolimus-based therapy versus conventional therapy for refractory breast cancer patients with PI3K/AKT/mTOR mutations

Z. Chen[1], Y. Zheng[1], W. Cao[1], Y. Zhang[2], S. Cai[2], X. Shao[1], J. Huang[1], W. Ye[1], Y. Huang[1], Y. Yin[3], X. Wang[1]

[1]Department of Breast Medical Oncology, Zhejiang Cancer Hospital, Hangzhou, China, [2]The Medical Department, 3D Medicines Inc., Shanghai, China, [3]Department of Oncology, Jiangsu Province Hospital, Nanjing, China

Background: Molecular screening using next generation sequencing (NGS) with the aim of guiding therapy for patients with refractory cancer, is becoming increasingly more common in clinical practice. Given that tumors with alterations in PI3K/ATK/mTOR (PI3K) pathway exhibit sensitivity to mTOC1 inhibitor everolimus, everolimus is often off-label used to target PI3K pathway. However, efficacy of off-label-use of everolimus in refractory breast cancer is unknown. We conducted this retrospective study to assess the efficacy of molecular matched off-label use of everolimus for refractory breast cancer patients with mutations in PI3K pathway, compared with conventional therapy.

Methods: Patients with refractory metastatic breast cancer who received NGS with the aim of guiding therapy between 2015 and 2017, were screened for eligibility at two sites in China. Patients with mutations in PI3K pathway and treated with everolimus-based or conventional therapy were included. Everolimus was used outside its indications. The primary outcome was progression-free survival (PFS). Secondary outcomes were overall response rate (ORR), disease control rate (DCR) and safety profile.

Results: 33 patients with mutations in PI3K pathway were included in this analysis. 18 (54.5%) patients were hormone receptor positive and 14 (42.4%) patients were HER2 positive. 20 patients received everolimus-based therapy and 13 patients received conventional therapy. The PFS was shorter in everolimus group than conventional group (median, 2.05 vs 6.1 months; HR, 4.45; 95% CI, 1.64-12.10; P = 0.0016). ORR was 14.3% (2/14) in everolimus group and 23.1% (3/13) in conventional group (P = 0.648). DCR was 35.7% (5/14) in everolimus group and 100% (13/13) in conventional group (P = 0.001). The incidence of grade 3 or worse treatment-related adverse event was similar between groups (5 [38.5%] of 13 in everolimus group, 5 [25.0%] of 20 in conventional group, P = 0.393).

Conclusions: The off-label use of everolimus to target the PI3K/AKT/mTOR pathway is associated with poorer outcome in patients with refractory breast cancer. These data suggests that off-label use of everolimus to target PI3K/AKT/mTOR should not be encouraged.

346P Ribociclib (RIB) + fulvestrant (FUL) in hormone receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2–) advanced breast cancer (ABC): MONALEESA-3 biomarker analyses

P. Neven[1], K. Petrakova[2], G.V. Bianchi[3], L. De La Cruz Merino[4], G. Jerusalem[5], J.T. Beck[6], G.S. Sonke[7], S. Chia[8], S. Brucker[9], Y. Wang[10], W. He[11], K. Rodriguez Lorenc[12], F. Su[12], S-A. Im[13]

[1]Multidisciplinary Breast Center, Universitair Ziekenhuis Leuven, Leuven, Belgium, [2]Medical Oncology, Masaryk Memorial Cancer Institute, Brno, Czech Republic, [3]Oncology, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy, [4]Clinical Oncology, Hospital Universitario Virgen Macarena, Seville, Spain, [5]Medical Oncology, CHU Liege and Liege University, Liège, Belgium, [6]Medical Oncology and Hematology, Highlands Oncology Group, Fayetteville, AR, USA, [7]Department of Medical Oncology, Netherlands Cancer Institute/BOOG Study Center, Amsterdam, Netherlands, [8]Medical Oncology, BC Cancer Agency, Vancouver, BC, Canada, [9]Department of Gynaecology, Center for Women's Health, University of Tübingen, Tübingen, Germany, [10]Oncology, Novartis Pharma AG, Basel, Switzerland, [11]Oncology, Novartis Institutes for BioMedical Research, Cambridge, MA, USA, [12]Oncology, Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA, [13]Internal Medicine, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, Republic of Korea

Background: In the Phase III MONALEESA-3 study (NCT02422615), RIB + FUL significantly improved progression-free survival (PFS) vs placebo (PBO) + FUL in patients with HR+, HER2– ABC who received no or up to 1 line of prior endocrine therapy for ABC (hazard ratio 0.593; 95% confidence interval 0.480–0.732). Here we present PFS data by baseline tumor Ki67, total Rb, and p16 protein expression, and CCND1, CDKN2A, and ESR1 messenger RNA (mRNA) levels.

Methods: Postmenopausal women (N = 726) with HR+, HER2– ABC were randomized 2:1 to RIB (600 mg/day; 3 weeks on/1 week off) + FUL (500 mg) or PBO + FUL. The primary endpoint was PFS. PFS by biomarker expression was an exploratory endpoint. Baseline tumor tissue was evaluated for protein expression (immunohistochemistry) and gene expression (NanoString® nCounter Customized Panel). To assess correlations between protein/gene expression and PFS, patients were classified into prespecified low vs high expression subgroups; 14% of positively stained cells was used as a cutoff for Ki67, 10th percentile was used as a cutoff for total Rb, and median expression was used as a cutoff for all other proteins/genes.

Results: PFS hazard ratios for all biomarker subgroups favored RIB + FUL vs PBO + FUL (Table). Consistent RIB + FUL treatment benefit was seen regardless of Ki67 protein expression or CCND1 gene expression. A numerically greater PFS benefit was observed with RIB + FUL in patients with low vs high p16 protein expression and low vs high CDKN2A mRNA expression; a similar trend was observed in patients with low vs high ESR1 mRNA expression.

Conclusions: RIB + FUL significantly prolonged PFS vs PBO + FUL, with consistent treatment effects observed regardless of biomarker expression. There was a trend towards greater PFS benefit with RIB + FUL in patients with low vs high expression of p16 protein, and low vs high CDKN2A and ESR1 mRNA levels.

Clinical trial identification: NCT02422615 April 21, 2015.

347P Potential survival gains from first-line (1L) systemic therapy advances in metastatic triple-negative breast cancer (mTNBC)

P. Bajaj[1], J.A. Roth[2], S.D. Sullivan[3], A. Stein[1], R. Mahtani[4], S.D. Ramsey[2]
[1]U.S. Medical Affairs, Genentech Inc. - Roche, South San Francisco, CA, USA, [2]Hutchinson Institute for Cancer Outcomes Research, Fred Hutchinson Cancer Research Center, Seattle, WA, USA, [3]School of Pharmacy, University of Washington, Seattle, WA, USA, [4]Sylvester Comprehensive Cancer Center, University of Miami Health System, Deerfield Beach, FL, USA

Background: Approximately 15% of the 67,000 women diagnosed with metastatic breast cancer (mBC) annually in the U.S. have mTNBC. Few effective treatment options for mTNBC patients have been identified in the past decade & outcomes are poor vs. other mBC subtypes. The objectives of this study were to quantify overall survival (OS) gains in mTNBC from 2010-2015 & project the potential magnitude of OS gains from new therapies approved by 2020.

Methods: We created a simulation model to estimate OS in mTNBC cohorts diagnosed from 2010-2020. OS data were derived from mTNBC clinical trials & were extrapolated to a lifetime horizon by fitting parametric curves. The distribution of 1L regimens used in each diagnosis year came from the IPSOS Global Oncology Monitor - a commercial registry. We projected 2020 OS assuming that 50% of patients receive newly approved therapies (e.g. immunotherapy) & those therapies have an average OS hazard ratio (HR) of 0.7 vs. docetaxel. Scenarios explored alternative HRs of 0.6 & 0.8. We estimated 5-year OS, mean OS & population life year (LY) gains assuming static mTNBC incidence (10,050 cases/year).

Results: From 2010-2015, 5-year OS increased by 2.2% & mean OS increased 1.6 months. If new treatments meet projections for efficacy & market adoption, 5-year mTNBC OS could triple from 5.2% in 2010 to 15.6% in 2020. Over a lifetime horizon, mean per-patient OS could improve by 10.2 months (8,543 population LYs). The population survival gains from 2015-2020 (7,203 LYs) would be ~5-fold greater vs. gains from 2010-2015 (1,340 LYs). Scenarios with average new treatment HRs of 0.6 & 0.8 resulted in population survival gains of 10,902 LYs & 6,763 LYs vs. 2010.

Table: 347P

Diagnosis Year	5-Year OS (%)	Mean OS (Months)	Population LYs
2010	5.2	22.9	19,179
2015	7.4	24.5	20,519
2020 (Projected)	15.6	33.1	27,721

Conclusions: We report modest mTNBC survival gains from 2010 to 2015, but show that clinically meaningful gains could be achieved if new treatments in development achieve realistic levels of effectiveness & are widely adopted. There is high unmet need in mTNBC & these new treatments offer hope for improved future outcomes.

348P Economic evaluation of eribulin in the treatment of triple negative breast cancer in the United Kingdom

J. Wex[1], C. Bodnar[2], C. Simon[3], F. Fernandes[4], N. Tanova[1]
[1]HEMA, Amaris, London, UK, [2]Global Value and Access, Eisai Europe, Hatfield, UK, [3]Market Access, Eisai, Hatfield, UK, [4]Health Economics, Eisai, Hatfield, UK

Background: Eribulin is indicated in the European Union for patients with locally advanced or metastatic breast cancer after ≥1 prior chemotherapy for advanced disease, including an anthracycline and a taxane. The license is based on clinical trials which included patients with triple negative breast cancer (TNBC). We sought to evaluate clinical and cost-effectiveness of eribulin in this population using decision analytic modelling.

Methods: Data on OS, PFS and TTD from TNBC patients from two randomized open label studies of eribulin, 305 (NCT00388726) and 301 (NCT00337103), were pooled (N = 352). The comparators were TPC (any single-agent chemotherapy, hormonal or biological treatment; radiotherapy; or symptomatic treatment alone) (305) and capecitabine (301). A partitioned survival model developed for the National Institute for Health and Clinical Excellence submission based on pooled Kaplan-Meier data, accounting for tumour objective response and adverse events with health-state specific utilities mapped from QLQC30 data from study 301 was used. Lifetime horizon with discount rate of 3.5% for costs and quality-adjusted life years (QALYs) was applied. Threshold analysis was based on 2017 UK costs and reimbursement decision criteria.

Results: Use of eribulin versus the pooled comparator of capecitabine or TPC was associated with greater mean overall survival (16.00 vs 12.38 months) and progression-free survival (4.4 vs 3.6 months) with 0.3 life years (LYs) gained and 0.2 incremental QALYs. 77% of LYs and 75% of QALYs were gained in progressive disease. Using UK end of life criteria and considering the patient access scheme price, eribulin falls well within the cost-effectiveness threshold of £50,000/QALY and would be considered cost-effective in the UK setting. The results were sensitive to price of eribulin, utility in the progressive disease state, discount rates and drug administration costs.

Conclusions: Eribulin is cost-effective in the treatment of patients with TNBC after ≥1 prior chemotherapy for advanced disease, including an anthracycline and a taxane in the UK.

349P Use of bone-modifying agents (BMA) and osteonecrosis of the jaw (ONJ) among older patients with metastatic breast cancer (BC)

M. Chavez Mac Gregor[1], X. Lei[2], H. Zhao[2], C. van Poznak[3], S.H. Giordano[1]

[1]Breast Medical Oncology, Health Services Research, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [2]Health Services Research, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [3]Breast Medical Oncology, The University of Michigan, Ann Arbor, MI, USA

Background: BC patients who have evidence of bone metastases should be treated with BMAs in order to reduce skeletal related events. ONJ is a serious complication associated the use of BMAs. In this large population-based study we evaluate the patterns of use of BMAs and ONJ rates in a cohort of older BC patients.

Methods: Patients diagnosed with de novo metastatic BC between 2007-2013 were identified in the SEER-Medicare database. We identified the presence of bone metastases using specific PEDSF variables and claims. All patients were required to receive systemic anticancer therapy within one year of diagnosis. HCPCS codes were used to identify the use of BMAs within 1 year of cancer diagnosis, ONJ was identified using an established ICD-9 codes. Descriptive statistics and regression models were used.

Results: A total of 1,528 patients were included. The median age of the cohort was 74 yo. Within one year of diagnosis of bone metastases 71.1% of the patients received BMAs (68% bisphosphonates, 27% denosumab, 5% both). Older patients (OR = 0.64; 95%CI 0.46-0.89), those with more comorbidities (OR = 0.61; 95%CI 0.43-0.85) or with full/partial state buy-in (OR = 0.65; 95%CI 0.49-0.87) -surrogate for poverty- were less likely to receive BMAs. Nineteen cases of ONJ were identified, all of them occurred among BMAs-treated patients (1.7%), the 2-year and 4-year cumulative rates were 1.4% and 4.0%, respectively. Similar rates of ONJ were observed between patients treated with bisphosphonates and denosumab. Median duration of BMA therapy among patients who developed ONJ was 20 months (IQR 10-43). No clinical predictors of ONJ were identified.

Conclusions: In this large, nationally-representative cohort, the majority of the BC patients with evidence of bone metastases received treatment with BMA according to current guidelines. Similar rates of ONJ were observed among bisphosphonates and denosumab users. ONJ occurred in approximately 2% of this SEER-Medicare population of patients with BC and bone metastases treated with BMA. Our findings are of significant value since they reflect the patterns of care and complications associated with these commonly used agents in the general population.

350P Liver surgery of breast cancer liver metastases: Rapid surgical decision after diagnosis does not negatively impact long-term results

V. Lucidi[1], G. Liberale[2], D. Germanova[3], M. Bez[1], V. Donckier[4]

[1]Digestive Surgery, Hepatobiliary Surgery & Liver Transplantation, Erasme University Hospital-(Universite Libre de Bruxelles), Brussels, Belgium, [2]Surgery, Institut Jules Bordet, Brussels, Belgium, [3]Digestive Surgery, Erasme University Hospital ULB, Brussels, Belgium, [4]Surgery, Institute Jules Bordet, Brussels, Belgium

Background: Surgery could be indicated in selected patients with breast cancer liver metastases (BCLM) but accurate identification of the candidates for surgery remains a challenge. We investigated if an observational period of time after the diagnosis of BCLM could improve the selection for surgery.

Methods: We performed a retrospective analysis of 72 consecutive patients operated for BCLM between 2000 and 2015. Clinicopathologic and outcome data were compared between 2 groups: Early surgery (ES), including patients operated for BCLM ≤12 months after liver metastases (LM) diagnosis, and late surgery (LS), including patients operated >12 months after diagnosis.

Results: Mean age was 48 years (28-74) at time of liver surgery. Median time between primary and LM diagnosis was 35 months (0-211) and median time between LM diagnosis and surgery was 12 months (0-134). Clinicopathologic characteristics were similar in ES (n = 37) and LS (n = 35) patients. In the whole population, 1, 3 and 5-years progression free (PFS) and overall (OS) survivals were respectively of 70%, 43%, 30% and 93%, 66%, 43%. In multivariate analysis, neither PFS nor OS differences were observed between ES and LS groups (PFS - HR = 1,13 p = 0,72 and OS - HR = 1,06, p = 0,85 for LS), only primary tumor estrogen receptor positivity had a positive impact for OS (HR = 0,48 p = 0,05).

Conclusions: No difference in survival was observed between patients operated rapidly for BCLM as compared with patients operated after observational period, suggesting that it is not necessary to postpone the surgery in patients with resectable LM.

Background: Metastatic breast cancer (MBC) behavior differs depending on the molecular subtype based on hormone receptors (HR) and HER2 statuses. We aimed at evaluating the kinetics of central nervous system metastases (CNSM) occurrence, and the prognosis after CNSM, according to the molecular subtype.

Methods: Retrospective analysis of 16703 MBC patients from the French Epidemiological Strategy and Medical Economics (ESME) database involving 18 specialized cancer centers (NCT03275311) (2008-2014 database). The time between stage IV and CNSM diagnosis (CNSM-free survival CNSMFS) and between CNSM diagnosis and death from any cause (overall survival OS) were estimated with the Kaplan-Meier method and compared with the log-rank test.

Results: Median follow-up was 42.8 months. Among the selected patients, 64.1% of patients had HR+/HER2-, 11.0% HER2+/HR+, 7.5% HER2+/HR- and 17.4% triple negative (TN, HR-/HER2-) MBC. Median age at MBC diagnosis was 61.2. 4118 patients (24.6%) were diagnosed with CNSM at initial diagnosis of primary tumor or during their MBC follow-up: 18.7%, 34.9%, 49.2% and 38.0% of patients with HR+/HER2-, HER2+/HR+, HER2+/HR- and TN tumors, respectively. Median age at CNSM diagnosis was 58.1 overall, 54.1 for TN patients and 59.9 for HER2+ patients ($p < 0.0001$). 1200 patients (7.2%) had CNSM at the time of stage IV diagnosis, while 2918 developed CNSM during the course of MBC, with a median CNSMFS of 17.0 months (95% CI 16.5-17.9). The molecular subtype was independently associated with CNSMFS: HER2-/HR+ NE (95%CI 91.1NE), HER2+/HR+ 61.7 (95%CI 51.7-74.1), HER2+/HR- 24.9 (95%CI 22.7-28.9) and TN 29.9 months (95%CI 27.0-33.1) ($p < 0.001$). With a 30 months median follow-up, median OS after CNSM diagnosis was 7.9 months (95% CI 7.2-8.4): 7.1 months for HR+/HER2-, 18.9 months for HER2+/HR+, 13.1 months for HER2+/HR- and 4.4 months for TN ($p < 0.0001$). These differences were significant when assessed in multivariate analysis ($p < 0.0001$ for HER2+/HR+, HER2+/HR- and TN tumors compared with HER2/ HR+ tumors).

Conclusions: We found that the breast cancer molecular subtype strongly impacts the occurrence, kinetics and prognosis of CNSM in MBC patients.

352P Features associated with long-term survival in metastatic breast cancer

N. Klar[1], M. Rosenzweig[2], B. Diergaarde[3], A.M. Brufsky[4]

[1]Department of Medicine, UPMC Presbyterian Hospital, Pittsburgh, PA, USA, [2]School of Nursing, University of Pittsburgh, Pittsburgh, PA, USA, [3]Graduate School of Public Health, University of Pittsburgh, Pittsburgh, PA, USA, [4]Division of Hematology/ Oncology, Magee-Womens Hospital of UPMC, Pittsburgh, PA, USA

Background: 5-10% of women with metastatic breast cancer (MBC) survive ≥5 years. Predictors of long-term survival are not clearly elucidated. We used data from 122 long-term MBC survivors (≥5-year survival from date of MBC diagnosis) and 191 short-term MBC survivors (≤2-year survival from date from MBC diagnosis) to identify clinico-pathologic and socioeconomic features associated with MBC survival.

Methods: Women initially diagnosed with breast cancer (BC) in or after 1999, and diagnosed with MBC at Magee Women's Cancer Program of UPMC were included (N = 313). Data abstracted from medical records included: stage at initial BC diagnosis, body mass index (BMI), Charlson Comorbidity Index (CCI), age, menopausal status at initial BC diagnosis, tumor receptor status at initial BC diagnosis, site of initial metastases, time between initial diagnosis and MBC, household income, race, employment status, and partner status. Differences between groups were assessed using t-tests and

Chi-square or Fisher's exact tests. Odds ratios (OR) and 95% confidence intervals (CI) were calculated using multivariate logistic regression models.

Results: Long-term survivors were significantly ($P < 0.05$) younger, had more ER positive, PR positive, and Her2 positive disease, lower CCI, more often premenopausal at initial diagnosis, lower rates of visceral metastases, higher household income, and more often partnered than short-term survivors. Long-term term survivors were also significantly more often diagnosed with de novo MBC compared to short-term survivors. The association with long-term survival remained significant after adjustment for age, tumor receptor status, and CCI (OR: 3.0, 95% CI 1.6-5.4). Time interval between initial diagnosis and MBC, BMI, race, and employment status were not associated with survival.

Conclusions: Diagnosis of de novo MBC, ER-, PR- and/or Her2-positive primary tumor, higher household income, younger age, lower CCI, premenopausal status, and having a partner are associated with long-term survival after diagnosis of MBC. This is one of the first studies to show a survival benefit in MBC for patients with de novo MBC, positive partner status and higher household income.

353P Physical activity and lifestyle in women with metastatic breast cancer: The ABLE study

B. Fervers[1], L. Delrieu[1], O. Pérol[1], O. Febvey-Combes[2], A. Dufresne[3], T. Bachelot[3], P. Heudel[4], O. Tredan[3], M. Touillaud[1], V. Pialoux[5]

[1]Cancer Environnement, Centre Léon Bérard, Lyon, France, [2]Département de la Recherche Clinique et de l'Innovation, Centre Léon Bérard, Lyon, France, [3]Département d'Oncologie Médicale, Centre Léon Bérard, Lyon, France, [4]Centre Léon Bérard, Lyon, France, [5]Laboratoire Inter-Universitaire de Biologie de la Motricité, Université Claude Bernard Lyon, Villeurbanne, France

Background: About 5% of breast cancers are metastatic (MBC) at diagnosis and 20-30% of localized breast cancer become secondarily metastatic. Patients suffer from many detrimental symptoms related to metastasis and treatments. Only four intervention studies worldwide have focused on physical activity (PA) interventions in MBC patients. The ABLE study is designed to assess the feasibility of a 6-month PA intervention in MBC patients and the effects of PA on physical, biological, psychological and clinical parameters.

Methods: A cohort of 50 newly diagnosed MBC patients have been recruited in an unsupervised and personalized 6-month PA program. At baseline and 6 months, we assessed anthropometrics, functional tests, biological parameters (inflammation, oxidative stress), questionnaires-based PA, quality of life, & fatigue, and tumor progression. Patients have worn a PA tracker which served both as a tool to record their own behaviour and maintain exercise adherence.

Results: The recruitment rate was at 94%. At baseline, participants' age was 54.7 years (SD 10.4), BMI was 25.9kg/m^2 (5.7). Significant increase in distance during 6MWT (10.0%), extension force of the quadriceps (20.3%) and significant decrease of weight (2.0%), BMI (2.3%) and hip circumference (2.4%) were observed after the completion of the program. Mean walking steps during 6 months were 4799 per day.

Conclusions: The high recruitment rate shows the willingness of MBC patients to participate in this type of program. Preliminary data confirmed the need and desire of a PA intervention in the MBC population. This unsupervised PA program may encourage patients to maintain a long term physically active lifestyle.

Clinical trial identification: NCT03148886.

355P Establishment and validation of M1 stage subdivisions for patients with de novo metastatic breast cancer: A population-based study

C. Lin, J. Wu, L. Zhu

Comprehensive Breast Health Center, Shanghai Ruijin Hospital, Shanghai Jiao Tong University, College of Medicine, Shanghai, China

Background: Patients with metastatic breast cancer (MBC) is a heterogeneous group with different survival outcomes. The current "catch-all" M1 category of breast cancer cannot be used for accurate prognosis prediction.

Methods: Patients with de novo MBC were identified using the Surveillance, Epidemiology, and End Results (SEER) database and divided randomly into the training and validation sets. The Fine and Gray's competing risks model was developed to identify the variables associated with increased breast cancer-specific death (BCSD) in the training set. Cumulative incidence curves were estimated and compared using Gray's test. And the M1 subdivisions system was established based on the independent prognostic factors for BCSD.

Results: Multivariate analysis showed the involvement of brain or liver and the number of metastatic organs were independent prognostic factors for BCSD. Therefore, we subdivided the M1 stage into three categories: M1a, involvement of single organ but no brain or liver; M1b, liver metastasis only or involvement of multiple organs but no brain or liver; M1c, involvement of multiple organs including liver but no brain, or brain involvement with or without liver, irrespective of the number of metastatic organs (M1b vs M1a, subdistribution hazard ratio [SHR] 1.45, 95% CI 1.28 - 1.65; M1c vs M1a, SHR 2.47, 95% CI 2.22 - 2.75; M1c vs M1b, SHR 1.67, 95% CI 1.47 - 1.90). The dose-response risk estimation was also observed in the validation and whole sets. Primary tumor surgery decreased from 43.2% in 2010 to 29.8% in 2014, with similar patterns seen in all M1 subdivisions. And patients of M1a benefited most from primary tumor surgery (M1a: SHR 0.55, 95% CI 0.49 - 0.60; M1b: SHR 0.71, 95% CI 0.60 - 0.82; M1c: SHR 0.63, 95% CI 0.55 - 0.72) in the adjusted competing risks model. Three-year cancer-specific mortality cumulative rates.

Table: 355P

	Training set		Validation set		Whole set	
M1 subdivision	Incidence rate (%)	95% CI (%)	Incidence rate (%)	95% CI (%)	Incidence rate (%)	95% CI (%)
M1a	42.4	39.8 - 44.9	44.1	41.6 - 46.7	43.2	41.4 - 45.1
M1b	53.7	49.1 - 58.0	50.6	46.3 - 54.8	52.1	48.9 - 55.1
M1c	72.1	68.3 - 75.6	70.4	66.4 - 74.0	71.3	68.6 - 73.8
P	< .001		< .001		< .001	

Conclusions: The M1 subdivisions system can better guide the prognosis prediction and treatment planning in patients with de novo MBC.

356P A prospective observational study of mobile application-based patient-reported outcomes (PRO) in advanced breast cancer: Interim baseline data from the MADELINE study

D. Odom[1], D. Mitra[2], K. Hollis[3], D. Richardson[3], J.A. Kaye[4], L. McRoy[5]

[1]Biostatistics, RTI Health Solutions, Research Triangle Park, NC, USA, [2]Patient Health & Impact, Pfizer Inc, New York, NY, USA, [3]Surveys and Observational Studies, RTI Health Solutions, Research Triangle Park, NC, USA, [4]Pharmacoepidemiology and Risk Management, RTI Health Solutions, Research Triangle Park, NC, USA, [5]US Medical Affairs, Pfizer Inc, New York, NY, USA

Background: MADELINE is a multicenter study enrolling women with advanced/metastatic breast cancer (ABC/MBC) receiving palbociclib in combination with an aromatase inhibitor (AI) as initial endocrine therapy or fulvestrant after progression on prior endocrine therapy according to the FDA-approved indication for palbociclib (Group 1) or approved therapies for ABC/MBC other than palbociclib (Group 2). A novel mobile application was developed to collect real-time PRO data to assess patient (pt) functioning and quality of life through daily, weekly, and monthly questionnaires for 6 months. Patient demographic and clinical information was recorded in an electronic case report form at baseline and for the planned 6-month follow-up.

Methods: Patients were administered the 12-Item Short Form Health Survey (SF-12) and the Center for Epidemiologic Studies Depression Scale (CES-D-10) at baseline. An analysis of baseline data as of March 1, 2018, on Group 1 pts with baseline mobile app and electronic case report form data was performed.

Results: Thirteen sites contributed 50 pts for this baseline analysis. Mean (SD) age was 58.6 (11.48); 86% were white. The most common metastatic sites were bone (54%) and lymph nodes (32%). ECOG performance status was 0, 1, and 2 in 61%, 24%, and 2% of pts, respectively. At enrollment, 27 pts (54%) initiated palbociclib plus AI, and 23 (46%) initiated palbociclib plus fulvestrant. There were no substantial differences between these palbociclib subgroups on SF-12 domain scores or CES-D-10 score; overall cohort scores are shown in the table.

Conclusions: This initial analysis describes the current population of palbociclib-treated pts in the MADELINE study. Recruitment and data collection are ongoing with plans for 30 total sites and up to 250 patients, with final results expected August 2019.

Table: 356P

Measure Mean (SD)	Group 1 (N = 50)
SF-12	
General Health	46.7 (9.51)
Physical Functioning	45.4 (11.07)
Role Physical	44.3 (11.46)
Bodily Pain	45.1 (12.96)
Vitality	45.3 (10.06)
Social Functioning	47.2 (10.83)
Role Emotional	47.3 (9.76)
Mental Health	48.8 (10.73)
Physical Component Summary	44.4 (11.65)
Mental Component Summary	48.7 (10.53)

357P Stereotactic radiosurgery (SRS) for brain metastases (BM) from breast cancer (BC): A single centre experience of factors influencing survival

T. Wilson[1], T. Robinson[1], C. Macfarlane[2], T. Spencer[3], C. Herbert[3], J. Braybrooke[1]

[1]Medical Oncology, University Hospitals Bristol NHS Trust Bristol Haematology and Oncology Centre, Bristol, UK, [2]Oncology, University Hospital Southampton NHS Foundation Trust, Southampton, UK, [3]Clinical Oncology, University Hospitals Bristol NHS Trust Bristol Haematology and Oncology Centre, Bristol, UK

Background: BM occur in up to 30% of patients with BC. SRS can be considered as an alternative to surgery or whole brain radiotherapy for control of single or multiple metastases. Factors that could predict overall survival (OS) and guide treatment choice have not been clearly defined.

Methods: Data for consecutive patients with BC treated with SRS between November 2013 and August 2017 in a single tertiary referral centre were collected to assess factors that might predict survival. T-tests, Kaplan Meier and log-rank methods were used for statistical analysis.

Results: 93 patients (pts) received SRS, of whom 32 were alive when data was censored on 1/2/18. The median overall survival (OS) post SRS was 14.0 mths (95% C.I +/- 2.4mths) with a significant correlation between age and OS (53 pts $\leq$60yr, OS = 18.1mths; 43pts >60y OS = 10.3mths, r=-0.21, p = 0.04). There were 31 ER+/HER2- pts (OS 15.2mths), 14 ER+/HER2+ pts (OS 31.9mths), 30 ER-/HER2+ pts (OS 22.8mths) and 16 Triple negative (TN) pts (OS 8.5mths). OS was significantly better for pts with HER2+ disease (p = 0.0018) with the poorest survival in pts with TN cancer (p = <0.0001). 39pts had 1 lesion treated (OS 16.2mths), 35pts had 2-5 lesions treated (OS 9.7mths), 19 pts had $\geq$6 lesions (OS 19.2mths). Whilst the number of lesions treated did not correlate with OS (r=-0.095, p = 0.37) a larger volume of tumour treated (>10cm^3) was associated with worse survival (r=-0.253, p = 0.01). At the time of SRS 17pts had no other systemic disease (OS 13.7mths). When present, control of systemic disease outside the brain was associated with improved OS (36 pts stable systemic disease OS = 20mths, 32 pts progressive systemic disease (PSD) OS = 9.7mths; p = 0.0013). 49 pts had known disease status at death, 17 had PSD, 16 had progressive CNS disease (PCD), 13 had PSD + PCD and 3 had no progression.

Conclusions: Age, receptor status, control of systemic disease, total tumour volume treated, but not the number of lesions appears to influence survival following SRS treatment of BM in BC. Our results are consistent with other series with worse outcomes seen in older patients and those with TN cancers. In addition to treating BM, control of systemic disease outside the brain remains important in prolonging survival.

358P Prolonged overall survival for patients with bone-only metastases at presentation of metastatic breast cancer

E. Curtit[1], F. Bazan[1], L. Chaigneau[1], G. Mouillet[1], E. Dobi[1], L. Mansi[1], N. Meneveau[1], M-J. Paillard[1], G. Meynard[1], E. Klajer[1], C. Villanueva[2], P. Montcuquet[1], X. Pivot[3], L. Cals[4]

[1]Medical Oncology, CHU Besançon, Hôpital Jean Minjoz, Besançon, France, [2]Medical Oncology, Centre de Cancérologie du Grand Montpellier, Montpellier, France, [3]Medical Oncology, Centre Paul Strauss Centre de Lutte contre le Cancer, Strasbourg, France, [4]Medical Oncology, CH Mende, Mende, France

Background: More than 50% of metastatic breast cancer patients experience bone metastases over the course of disease and around 15% of cases have metastases confined to the skeleton at metastatic presentation. The aim of this study was to access the overall survival of breast cancer patients with bone-only metastases at presentation.

Methods: Among 907 patients, we identified from our prospective computerized database 123 patients with bone-only metastases at diagnosis of metastatic breast cancer. We retrospectively collected data from the patients' files.

Results: The median overall survival was 8,3 years (CI 95% 6,7-10,3) and 73% and 41% of patients were alive at 5 and 10 years, respectively. No multivariate model with factors identified at presentation was able to predict overall survival length. Sixty per cent of patients developed visceral metastases over the time and the median interval between the diagnosis of bone metastases and the occurrence of visceral metastases was 28 months (4 - 193). In multivariate analysis, negative progesterone receptor status was associated with the occurrence of visceral metastasis (HR = 2,4; p = 0,03). Eleven per cent of patients had a solitary bone metastasis; 67% of patients developed axial metastases and 41% long bone metastases.

Conclusions: Breast cancer patients with bone-only metastases at presentation of metastatic disease might form a distinct clinical entity among metastatic breast cancer patients with a favorable prognosis and a prolonged overall survival. No prognostic factors identified at the presentation of the disease were able to predict very long survivors. Further investigations on these tumors biology and clinical trials dedicated to this population are required.

359P Surgery of the primary tumor for de novo metastatic breast cancer: The controversy continues

B. López de San Vicente, E. Galve Calvo, A. Zumarraga, F. Pikab ea, J.F. Arango Arteaga, M. López Santillan, C. Figaredo, M.A. Sala Gonzalez, M. Nuño Escolastico, P. Novas Vidal, J. Legaspi, P. Martinez del Prado

Medical Oncology, Hospital Universitario Basurto, Bilbao, Spain

Background: De novo metastatic breast cancer (dnMBC) represents 6–10% of breast cancer. Due to its incurability, dnMBC is generally treated with systemic therapies to achieve disease control and reduce tumor-related symptoms. The need for radical locoregional treatment and its consequent benefit in this setting remains still controversial. Meta-analysis of retrospective studies and prospective randomized studies did not report a clear survival benefit. The aim of this study was to analyze the impact of surgery to primary tumor (PT) in patients (pts) presenting with dnMBC.

Methods: Between Feb 2006-Oct 2015 we performed a retrospective chart review to 129 consecutive pts who attended our hospital with dnMBC. Descriptive, Kaplan-Meier and Cox regression analyses were carried out using SPSS version 23.0.

Results: A total of 129 pts. were analyzed. Median age was 68 years (range: 20-95), 59 pts (46%) had single organ metastasis, and their distribution according to the predominant site of disease was: skin/soft tissue 42 pts (33%), bone 87 pts (67%) and visceral 85 pts (66%). Surgery (S) of the PT was done in 32 pts (25%), 24 was radical procedures, 8 palliative and besides, 27 pts underwent axillary dissection. Initial S treatment was the choice for 29 pts. In the S group single organ disease was present in 66% vs 39% non-S group. Metastatic sites were: 50% vs 71% visceral, 44% vs 21% with bone metastasis in the S vs non-S group respectively. With a median follow-up of 2 years (SD 2.20), the 5-yr overall survival (OS) was 11.64% in the entire de novo MBC population, with a median OS of 36 m in the S-group vs 21 m. in the non-S-group (HR 1.46 p = 0.081). Subgroup analyses did not show a benefit of PT surgery in OS regardless of the number of metastasis and site of disease, and BC subtypes. The multi-adjusted HR for surgery was 0.14 (p = 0.188). The multivariate Cox regression analysis model included the site of disease (p = 0.971), the histopathologic grade (p = 0.876) and the hormone receptor status (p = 0.003).

Conclusions: In our series, surgical treatment of the primary tumor in patients with de novo metastatic breast cancer did not show a benefit in overall survival. Results of ongoing randomized trials are needed.

Background: Systemic chemotherapy with anti-HER2 therapy is the standard of care for HER2-positive advanced breast cancer. Patient outcomes have improved remarkably with the use of novel anti-HER2 drugs, including trastuzumab (H), pertuzumab (P), and trastuzumab emtansine (T-DM1). The combination treatment comprising H, P, and docetaxel (D) (HPD) is highly recommended as the 1st-line treatment for patients with HER2-positive advanced breast cancer. In contrast, for elderly patients over 65 years of age, this regimen seems to be intolerable mentally and physically, and impairs their quality of life. A new standard treatment with less toxicity and non-inferior efficacy for elderly patients is needed.

Trial design: We have planned a randomized, multicenter, open-label, phase III trial to confirm the non-inferiority of T-DM1 compared to HPD in terms of overall survival (OS) in elderly patients with HER2-positive advanced breast cancer. The eligibility criteria are as follows: 1) histologically proven HER2-positive breast cancer with metastatic disease 2) age 65-74 years with a performance status (PS) score 0-2, or 75-79 years with a PS score 0-1, and 3) no anti-HER2 therapy with chemotherapy for breast cancer, excluding peri-operative adjuvant therapy. Patients will be randomized to receive either HPD (H 6 mg/kg, P 420 mg/body, and D 60 mg/m^2) or T-DM1 3.6 mg/kg every 3 weeks. The dose up of D (75 mg/m^2) from the second cycle is defined based on the data regarding safety during the first cycle. The primary endpoint is OS. The secondary endpoints are progression-free survival, response rate, adverse events, breast cancer-related death, and deterioration of activities of daily living. The trial has been designed to achieve 70% power to confirm non-inferiority of T-DM1 compared with HPD at a one-sided alpha of 5% with a non-inferiority margin of 1.3 in terms of hazard ratio. With a median OS of 30 months in both arms, 6 years of accrual, and 5 years of follow up, 312 pts are required, and the planned sample size is 330. The study commenced in January 2018.Clinical trial information: UMIN000030783.

Clinical trial identification: UMIN000030783.

362TiP ATTAIN: Phase III study of etirinotecan pegol (EP) vs treatment of physician's choice (TPC) in patients (pts) with metastatic breast cancer (MBC) who have stable brain metastases (BM) previously treated with an anthracycline, a taxane, and capecitabine (ATC)

D. Tripathy[1], S.M. Tolaney[2], A.D. Seidman[3], C.K. Anders[4], N.K. Ibrahim[1], H.S. Rugo[5], C.J. Twelves[6], V. Dieras[7], V. Müller[8], A.L. Hannah[9], M.A. Tagliaferri[10], J. Cortes Castan[11]

[1]Department of Breast Medical Oncology, Division of Cancer Medicine, MD Anderson Cancer Center, Houston, TX, USA, [2]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, USA, [3]Medical Oncology, Memorial Sloan-Kettering Cancer Center, New York, NY, USA, [4]UNC Breast Center, University of North Carolina, Chapel Hill, NC, USA, [5]Breast Cancer Center, UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA, USA, [6]Oncology and Clinical Research, St. James's University Hospital Leeds, Leeds, UK, [7]Department of Medical Oncology, Institut Curie, Paris, Paris, France, [8]Department of Gynecology, Hamburg-Eppendorf University Medical Center, Hamburg, Germany, [9]Consultant, Consultant, Sebastapol, CA, USA, [10]Clinical Development, Nektar Therapeutics, San Francisco, CA, USA, [11]Breast Cancer Program, Vall d'Hebron University Hospital, Barcelona, Spain

Background: EP is a next-generation topoisomerase I inhibitor-polymer conjugate that provides continuous exposure to SN-38, the active metabolite of irinotecan. A BM mouse model showed high penetration and retention of SN-38 in CNS lesions, resulting in decreased size of CNS lesions and improved survival at concentrations achieved at the recommended dose in pts (Adkins BMC Cancer 2015). Although a phase 3 trial (BEACON) of EP vs TPC in 852 pts with advanced BC did not meet its primary endpoint of overall survival (OS) (HR 0.87; $P = 0.08$), a pre-planned subset analysis of 67 pts with stable BM showed improved OS (HR 0.51 [95% CI 0.30-0.86]; $P < 0.01$) (Perez Lancet Oncol 2015). The current phase 3 trial (ATTAIN) was designed to further study this subpopulation of pts.

Trial design: Pts with MBC with locally treated stable BM will be randomized 1:1 to EP or TPC in an open-label phase 3 study. Eligibility includes: ECOG PS 0 or 1; adequate organ function; prior ATC therapy (any setting); $\geq$1 prior cytotoxic regimen for pts with triple negative MBC; $\geq$2 prior cytotoxic regimens for pts with HR+ or HER2+ BC (pts with HR+/HER2+ BC must have received prior hormone therapy/HER2 targeted therapy); prior definitive local therapy of BM (whole brain radiation [RT], stereotactic RT or surgical resection as single-agent or combination); and stable signs/symptoms of BM with steroids (ie, unchanged or decreasing $\geq$7 days prior to randomization). Primary endpoint is OS. Key secondary endpoints are ORR and PFS by RECIST v1.1 and RANO-BM, CBR (ORR+SD $\geq$ 6 months) and QoL. Pts randomized to TPC will receive 1 of 7 IV agents. Pts are stratified by region, PS and receptor status. An independent data monitoring committee will assess interim data and determine final number of events needed to provide 80% conditional power to detect a statistically significant improvement in OS based on the promising zone adaptive design (Mehta & Pocock, 2011). Up to 220 pts will be randomized. PK sampling and UGT1A1 testing will be performed in the EP arm; plasma ctDNA will be assessed for predictive markers of efficacy.

Clinical trial identification: NCT02915744.

363TiP Phase Ib/IIa study of RX-5902, a novel orally bioavailable inhibitor of phosphorylated P68, which prevents nuclear β-catenin translocation in patients with triple negative breast cancer

J.R. Diamond[1], E. Andreopoulou[2], A.M. Favret[3], R. Nanda[4], C. Peterson[5], E. Benaim[5]
[1]Medical Oncology, University of Colorado Cancer Center Anschutz Cancer Pavilion, Aurora, CO, USA, [2]Medical Oncology, Weill Cornell Medicine/New York Presbyterian Hospital, New York, NY, USA, [3]Oncology, Virginia Cancer Specialists, Fairfax, VA, USA, [4]Oncology, University of Chicago, Chicago, IL, USA, [5]Clinical Operations, Rexahn Pharmaceuticals, Inc, Rockville, MD, USA

Background: RX5902 is an oral anti-tumor and immune modulating drug targeting the phosphorylated form of p68 (also known as DDX5), a member of the DEAD box family of RNA helicases. Phosphorylated p68 may play a vital role in cell proliferation and tumor/cancer progression by affecting elements in the Wnt Canonical pathway.

Trial design: This study is conducted as a phase 1b/2a with a 2-stage design. In stage 2 of the phase 2a study, eligible subjects (aged $\geq$ 18 years) are those diagnosed with triple negative breast cancer, refractory intolerant or ineligible to receive approved standard therapies. There is no limit on the number of prior therapies. Subjects need to have measurable or evaluable disease per RECIST ver 1.1, ECOG performance of 0 or 1 and normal organ function. Use of potent inhibitors or inducers of CYP3A4/3A5, within 14 days of planned study treatment, are excluded. Eligible subjects, who have been fasting, will receive oral RX-5902 at 250 mg administered 5 times per week followed by 2 days off for 4 weeks in each cycle. Treatment will continue for 6 or more cycles, or until confirmed disease progression, unacceptable toxicity, withdrawal of consent, or decision to discontinue. Primary endpoint is progression free survival (by RECIST v1.1); secondary end points include safety, overall response rate, time to progression and duration of response (by RECIST v1.1), duration of response. adverse events will be graded per NCI CTCAE v4.0. Response will be assessed every 8 weeks. Exploratory endpoints include biochemical levels of drug targets. Approximately 40 evaluable subjects will be enrolled in stage 2 of the phase 2.

Clinical trial identification: NCT02003092.

Legal entity responsible for the study: Rexahn Pharmaceuticals Inc.

Funding: Rexahn Pharmaceuticals, Inc.

Disclosure: C. Peterson, E. Benaim: Employee: Rexahn Pharmaceuticals. All other authors have declared no conflicts of interest.

364TiP Anti-hormonal maintenance treatment with or without the CDK4/6 inhibitor ribociclib after first line chemotherapy in hormone receptor positive/HER2 negative metastatic breast cancer: A phase II trial (AMICA) GBG 97

T. Decker[1], C. Denkert[2], K. Lübbe[3], V. Müller[4], C. Mundhenke[5], J. Furlanetto[6], M. Schmidt[7], M. Thill[8], V. Tierbach[9], F. Seither[10], S. Loibl[6]
[1]Hämatologie, Onkologie, Ravensburg, Germany, [2]Institute of Pathology, Charite Berlin Mitte, Berlin, Germany, [3]Onkologie, Diakovere gGmbH, Hannover, Germany, [4]Department of Gynecology, Hamburg-Eppendorf University Medical Center, Hamburg, Germany, [5]Klinik für Gynäkologie und Geburtshilfe, Universität Kiel, Kiel, Germany, [6]Department of Medicine and Research, German Breast Group (GBG) Forschungs GmbH, Neu-Isenburg, Germany, [7]Johannes Gutenberg-Universität Mainz, Mainz, Germany, [8]Gynäkologie, Kliniken Markus-Krankenhaus, Agaplesion, Frankfurt am Main, Germany, [9]Project Management, German Breast Group (GBG) Forschungs GmbH, Neu-Isenburg, Germany, [10]Statistic, German Breast Group (GBG) Forschungs GmbH, Neu-Isenburg, Germany

Background: Although longer duration of chemotherapy (CT) is associated with longer progression-free survival (PFS) and overall survival (OS) in patients with metastatic breast cancer (MBC), the duration of CT is usually dictated by toxicities and patients and physicians preferences, resulting in treatment durations of less than 6 months. Therefore, well tolerated maintenance treatments with the potential to prolong PFS and OS are needed.

Trial design: AMICA is a multicentre, prospectively, randomized, open-label, controlled phase II study. Patients with hormone receptor (HR)+/HER2- MBC achieving stable disease or tumor response after at least 4 cycles of first-line CT at the discretion of the investigator (e.g. taxanes, capecitabine, vinorelbine, anthracyclines) will be eligible to be randomized 2:1 to receive maintenance endocrine therapy (ET) per investigator's choice either with or without the CDK4/6 inhibitor ribociclib. Patients might have received up to one prior line of ET. Maintenance ET could have already been started up to 6 weeks before randomization, but after achievement of stable disease or tumor response. Life-expectacy of $>$ 6 months is required. In both study arms, treatment will be given until disease progression, unacceptable toxicity, or withdrawal of consent. Primary objective is to evaluate the impact of a maintenance ET after first-line CT with or without ribociclib on PFS. Secondary objectives are OS, clinical benefit rate, safety, compliance and patient reported outcomes. Biomarkers predicting response to CDK inhibition and ET in formalin-fixed paraffin-embedded metastatic tissue and blood as well as the role of mutations in ctDNA will be analysed. Overall, 150 patients will be recruited. The study is conducted in 20-30 sites in Germany. One patient has been recruited so far.

365TiP SAMANTHA: A European registry study to prospectively observe treatment patterns and outcomes in participants with HER2-positive unresectable locally advanced (LA) or metastatic breast cancer (mBC)

G.G. Steger[1], F. Puglisi[2], C. Timcheva[3], L. Costa[4], M. Casa-Nova[5], D. Hitzl[6], B. Dampier[7], N. Lindegger[8]
[1]Department of Internal Medicine I, Division of Oncology and Hematology, Medizinische Universität Wien, Vienna, Austria, [2]Department of Clinical Oncology, IRCCS CRO di Aviano, National Cancer Institute, Aviano, Italy, [3]Clinic of Medical Oncology, MHAT for Women Health Nadezhda OOD, Sofia, Bulgaria, [4]Oncology Division, Hospital de Santa Maria, Centro Hospitalar de Lisboa Norte, Lissabon, Portugal, [5]Medical Oncology, Hospital Beatriz Angelo-Loures, Loures, Portugal, [6]Medical Affairs, Roche Austria GmbH, Vienna, Austria, [7]Medical Affairs, Clinical Research Consulting, Vienna, Austria, [8]Global Product Development, F. Hoffmann-La Roche AG - Switzerland, Basel, Switzerland

Background: Numerous treatment options are available to patients with HER2-positive (HER2+) breast cancer. The used drugs as well as the sequence in which they are used may vary between countries. Frequently used in unresectable LA/mBC is trastuzumab, usually proposed in various combinations, as well as pertuzumab, trastuzumab-emtasine, and lapatinib. Only limited data are available on the treatment patterns used in clinical practice. This study is part of a global umbrella study and will meet the need for real world data on treatment patterns and outcomes in HER2+ unresectable LA or mBC. A descriptive analysis may identify possible associations between patient characteristics, treatments and outcomes. The study will collect data for up to 8 years, thus as new treatments become available, the study will also offer a unique opportunity to gain insight into evolving treatment options.

Trial design: SAMANTHA is a prospective, multicenter non-interventional post authorization safety study designed to observe anti-cancer treatment regimens and clinical outcomes in participants with HER2+ unresectable LA/mBC for up to 8 years. Diagnosis of unresectable LA or mBC can be up to 6 months old prior to registry enrollment. Enrolled participants will receive treatment and clinical assessments for their HER2+ unresectable LA/mBC as determined by their treating physician, according to the standard of care and routine clinical practice at each site. Primary outcome measures are progression-free survival per anti-cancer treatment regimens assessed according to site-/country-specific medical practice and percentage of participants by different anti-cancer treatment regimens and treatment sequences. Secondary outcome measures include overall survival, duration of response per anti-cancer treatment regimens, percentage of participants with best overall response of complete response or partial response per anti-cancer treatment and total number of treatment regimens received by participants.

Background: Navebine is an antineplastic agent that has shown afficacy in the treatment of a variety of solid tumors, including breast cancer. The drug can be given intriavenously, but also as oral tablet treatment. Preclinical studies, as well as clinical observations, suggest that the administration of small, frequent doses of chemotherapy (metronomic dosing) has an effect, not only on cancer cells, but also on endothelialcells in the tumor vasculature. By giving smaller, but more frekvent doses of the drug, higher dose intensity, without corresponding side effects, is optained. Whether treatment under the metronomic principle is superior to conventional treatment, has not yet been validated in the clinic, so this study is hoped to clarify this.

Trial design: This is a investigator-initated, prospective randomized fase II, non-blinded multinational, multicentre study running in Denmark and Norway. 200 women diagnosed with HER2 neg metastatic breast cancer will be enroled. Patients are randomized to either: Arm A Clasical treatment: Navelbine Oral: Navelbine Oral[a]: 60 mg/m^2 day 1, day 8 (and day 15), every three weeks for the first cycle. Hereafter 80 mg/m^2 day 1 and day 8, every three weeks for de following cycles. Or Arm B Metronomic treatment: Navelbine Oral[a]: with 3 week cycles of daily doses of 30 mg. (Patients with body surface $\leq$ 1,54 m^2 or 65 Years or more start on 20 mg daily.) Treatment is given first or second line (chemotherapy). The primary Objectives is to evaluate the Disease Control Rate (CR + PR + SD, SD > 3 months) in the two arms. Secondary Objectives are to compare the duration of Disease Control, TTP, RR, DR and OS and side effects for the two regimens. Also Evaluation of the Global Health Status/QoL, on the basis of the EORTC QOL C30 questionnaire is made. Finally a translational study to explore the potential of biomarkers during metronomic therapy is performed.The patients will be treated until progression or to high toxicity, or until the patient wishes discontinuation.

Clinical trial identification: EudraCT: 2016-002165-63. Health Board no: 2017040059. Approved by Research Ethics Commitee and Data Protection Agency June 2017.

Legal entity responsible for the study: Sven Tyge Langkjer.

Funding: The study is an investigator-initiated study, but financially supported by the pharmaceutical company Pierre Fabre.

Disclosure: All authors have declared no conflicts of interest.

367TiP LUCY: A phase IIIb, real-world study of olaparib in HER2-negative metastatic breast cancer patients with a BRCA mutation

K.A. Gelmon[1], G.P. Walker[2], G.V. Fisher[2], S.C. McCutcheon[2]

[1]British Columbia Cancer Agency, Vancouver, BC, Canada, [2]AstraZeneca, Cambridge, UK

Background: The Phase III OlympiAD trial (NCT02000622) showed a significant improvement in progression-free survival (PFS) in favour of olaparib vs physician's choice chemotherapy in patients with HER2-negative metastatic breast cancer (mBC) and a germline BRCA mutation (gBRCAm). In January 2018, the US FDA expanded the approved use of olaparib to treat patients with HER2-negative mBC and a gBRCAm. LUCY (NCT03286842) has been initiated to evaluate the clinical effectiveness of olaparib in these patients in a real-world setting, and has been expanded to include a cohort of patients with somatic BRCA mutations (sBRCAm).

Trial design: LUCY is an open-label, single-arm, multicentre, international Phase IIIb trial. Patients with HER2-negative mBC and a deleterious BRCAm (gBRCAm or sBRCAm), who have received treatment with taxane or anthracycline in either the adjuvant or metastatic setting, and $\leq$2 prior lines of chemotherapy for metastatic disease, will be enrolled. Patients will be treated with open-label olaparib tablets (300 mg twice daily) until disease progression, unacceptable toxicity, or other discontinuation criteria. For gBRCAm patients (Cohort 1), the primary objective is to evaluate the clinical effectiveness of olaparib via investigator-assessed PFS (radiological, symptomatic, or clear progression of non-measurable disease); secondary objectives include overall survival, time to second progression, and clinical response rate. These primary and secondary objectives will be exploratory in sBRCAm patients (Cohort 2), and PFS will be assessed by RECIST 1.1.

An additional key exploratory objective will be 24-week disease control rate in the subset of all patients with adequately treated, stable brain metastases at baseline. Safety and tolerability will be described. Initial screening across ~170 sites in 16 countries will be conducted to identify a target sample of 250 patients with gBRCAm and 20 patients with sBRCAm. The first subject was enrolled in Q1 2018.

Clinical trial identification: NCT03286842.

Editorial acknowledgement: Stephen Paterson, Mudskipper Business Ltd.

368TiP START: A randomized phase II study in patients with triple negative, androgen receptor positive locally recurrent (unresectable) or metastatic breast cancer treated with darolutamide or capecitabine (UCBG-306)

H. Bonnefoi[1], C. Levy[2], G. MacGrogan[3], T. Grellety[4], B. Asselain[5], M. Pulido[6], S. Everhard[7], J. Lemonnier[8], A. Gonçalves[9]

[1]Medical Oncology, Institute Bergonié, Bordeaux, France, [2]Department of Medical Oncology, Centre Francois Baclesse, Caen, France, [3]Department of Pathology, Institute Bergonié, Bordeaux, France, [4]Medical Oncology, Institute Bergonié, Bordeaux, France, [5]UCBG, UNICANCER, Paris, France, [6]Epidemiological and Clinical Research Unit and INSERM CIC1401, Institute Bergonié, Bordeaux, France, [7]R&D, UCBG, UNICANCER, Paris, France, [8]R&D, UCBG, UNICANCER, Paris, France, [9]Department of Medical Oncology, Institute Paoli Calmettes, Marseille, France

Background: Up to 36% of triple-negative breast cancer (TNBC) are androgen receptor (AR)-positive ($\geq$ 10% by immuno-histochemistry, IHC). When these tumours metastasise, several clinical trials assessing antagonists of the AR or androgen synthesis suppressor showed promising clinical benefit rates (CBR). Darolutamide is a novel, effective and well tolerated AR antagonist tested in prostate cancer clinical trials. Thus we aim to assess clinical activity and safety of darolutamide in AR-positive TNBC.

Trial design: This is an open-label, multicenter, randomized, two-arm non-comparative phase II trial (NCT03383679). Women with locally recurrent (unresectable) or metastatic and centrally confirmed AR-positive TNBC are eligible. Patients should be chemotherapy naïve or have received a maximum of one line of chemotherapy for advanced disease. Eligible patients are randomized (2:1) between darolutamide experimental arm (600 mg twice daily) and capecitabine control arm (according to each center policy, minimum 1000 mg/m2 twice daily, 2 weeks on and 1 week off). Randomization (minimization) is stratified by number of previous lines of chemotherapy (0 versus 1). In each arm, the primary endpoint is the clinical benefit rate (CBR) at 16 weeks, defined as complete response, partial response or stable disease as per RECIST 1.1 criteria. Tumour biopsies and sequential circulating tumour DNA are collected as part of a translational research program. A total of 90 patients will be randomized.The first patient was included in March 2018. As of May 2018, 3 patients have been screened and 1 patient has been randomized.

Clinical trial identification: NCT03383679.

Legal entity responsible for the study: UNICANCER.

Funding: Bayer.

Disclosure: All authors have declared no conflicts of interest.

369TiP PATINA: A randomized, open label, phase III trial to evaluate the efficacy and safety of palbociclib + Anti-HER2 therapy + endocrine therapy (ET) vs. anti-HER2 therapy + ET after induction treatment for hormone receptor positive (HR+)/HER2-positive metastatic breast cancer (MBC)

Background: Pre-clinical data showed the role of CDK 4/6 inhibition in HER2+ disease. Results from phase 2 clinical trials point to synergistic antitumor activity and potential efficacy of palbociclib when given in combination with anti-HER2 therapy (tx), particularly in HR+/HER2+ breast cancer. The aim of PATINA is to evaluate the efficacy and safety of the addition of palbociclib to anti-HER2 tx and ET maintenance after induction tx in the 1st line setting for HR+/HER2+ MBC.

Trial design: The PATINA trial (AFT-38/NCT02947685) is a pivotal, open-label, international, phase III study. The trial is open to patients (pts) with histologically confirmed HR+/HER2+ MBC provided they are without evidence of disease progression by local assessment after induction tx. Following 4-8 cycles of chemotherapy (taxane or vinorelbine) with anti-HER2 tx for MBC, pts will be randomized 1:1 to standard anti-HER2 tx (trastuzumab +/- pertuzumab) in combination with ET with or without palbociclib until disease progression. ET options are either an aromatase inhibitor or fulvestrant. Premenopausal women must receive LHRH agonist. Total planned accrual is 496 pts. Primary objective is to demonstrate that the combination of palbociclib with anti-HER2 tx plus ET is superior to anti-HER2 tx plus ET alone in prolonging progression-free survival (PFS). Key secondary objectives are measures of tumor control, overall survival, safety and quality of life. The main translational science objective is to compare PFS estimates according to PIK3CA mutation status. All pts approached to participate in PATINA will be asked to share remaining biospecimens with the Mastering Breast Cancer Initiative. This initiative was created in order to understand the natural history of MBC and how it envolves over time with the aim to develop new treatments for this patient population. Recruitment has started in 07/2017 and is expected to take place across approximately 130 sites in Australia, Germany, Italy, New Zealand, Spain, and the US.

370TiP A phase Ib, multicenter, open-label study of the antibody-drug conjugate trastuzumab deruxtecan (DS-8201a) combination with nivolumab for advanced HER2-expressing breast or urothelial cancer

S.A. Hurvitz[1], M.D. Galsky[2], J. Shahidi[3], G. Zhang[4], S. Raza[3], A. Necchi[5]

[1]Department of Medicine, UCLA Medical Center, Los Angeles, CA, USA, [2]Department of Medicine, Icahn School of Medicine at Mount Sinai, New York, NY, USA, [3]Clinical Development, Daiichi Sankyo Inc., Basking Ridge, NJ, USA, [4]Biostatistics and Data Management, Daiichi Sankyo Inc., Basking Ridge, NJ, USA, [5]Medical Oncology, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

Background: DS-8201a is a novel antibody-drug conjugate comprised of a humanized HER2 antibody attached by a cleavable peptide-based linker to a topoisomerase I inhibitor; characterized by a high drug-to-antibody ratio of about 8. In an ongoing phase 1 trial, DS-8201a showed high and durable responses across multiple tumors, with a confirmed objective response rate (ORR) of 61.4% in previously T-DM1-treated HER2-positive (IHC 3+ or IHC2+ and ISH+) breast cancer (BC) and 31.6% in HER2 low-expressing (IHC 2+/1+ and ISH–) BC (Oct 2017 cutoff; Modi et al, SABCS 2017). Nivolumab, an anti-PD-1 antibody, is FDA-approved for metastatic urothelial carcinoma (UC) after platinum failure. A xenograft model of HER2-expressing cancer showed significantly increased survival with the combination of DS-8201a with an anti-PD-1 antibody vs either treatment alone (Iwata et al, ASCO 2017).

Trial design: This phase 1b, multicenter, open-label study will assess the combination of DS-8201a with nivolumab in previously chemotherapy-treated HER2-expressing advanced BC or UC. Previous treatment with anti-PD-1/PD-L1 therapy is an exclusion criterion. A dose escalation (part 1) will identify the recommended dose for expansion (RDE), and dose expansion (part 2) will evaluate efficacy and safety/tolerability of the DS-8201a RDE combination with nivolumab (360 mg IV; q3wk). Part 1 is a 3 + 3+3 design with 3 dose cohorts of DS-8201a (3.2, 5.4, and 6.4 mg/kg q3wk); enrollment will start at 3.2 mg/kg. Following RDE determination, enrollment in part 2 will open (Table); estimated total enrollment is 99–117. ORR is the primary efficacy endpoint; secondary endpoints include overall survival, disease control rate, duration of response, progression-free survival, time to response based on central review, and safety/tolerability. The study is open for enrollment as of May 2018.

Table: 370TiP

Part 2 Cohorts

Cohort	Cancer Type	HER2 Status	Approximate Enrollment
1	BC	HER2-positive (IHC 3+ or ISH+)	30
2	BC	HER2 low-expressing (IHC 2+/1+ and ISH–)	15
3	UC	HER2 high-expressing (IHC 3+/2+)	30
4	UC	HER2 low-expressing (IHC 1+)	15

Clinical trial identification: NCT03523572.

383P Worldwide trends in survival from adult glioma 2000-2014 (CONCORD-3): Impact of morphology

F. Girardi, V. Di Carlo, A. Bonaventure, C. Allemani, M.P. Coleman, CONCORD Working Group

Non-communicable Disease Epidemiology, London School of Hygiene and Tropical Medicine, London, UK

Background: The CONCORD programme initiated world-wide surveillance of trends in population-based cancer survival in 2015. The third cycle (CONCORD-3) covered 18 cancers, including brain tumours. Data for 656,659 adults (15-99 years) diagnosed with a brain tumour were provided by 286 registries in 59 countries. For adults diagnosed during 2010-2014, 5-year net survival from all brain tumours combined varied between 15% and 42%. We will present detailed comparison of survival trends for gliomas defined by anatomic location, morphology and WHO grade.

Methods: We will present the numbers of adults diagnosed with a glioma and the subtype distribution by continent. We will estimate net survival up to 5 years, using the unbiased Pohar Perme estimator. Net survival is the probability that patients survive their cancer until a given time since diagnosis, after controlling for competing risks of death (background mortality) by age, sex, country and calendar year.

Results: Data were obtained for 545,184 adults. Glioblastoma was the most common morphology (57%). Astrocytic, oligodendroglial and oligo-astrocytic tumours specified as WHO grade I-III made up 21% of all gliomas, while glioma not otherwise specified (NOS) and astrocytoma NOS made up 15%. Rarer tumours, such as oligodendroglioma, fibrillary astrocytoma, pilocytic astrocytoma, mixed glioma, anaplastic oligodendroglioma and anaplastic astrocytoma made up less than 10% of gliomas in all continents. The frequency of glioblastoma was 58% or higher in Europe, North America and Oceania, 53% in Africa and around 45% in Asia and Central and South America. The frequency of astrocytoma NOS was lowest in Europe, North America and Oceania (below 9%) and highest in Central and South America (22%).

Conclusions: The distribution of gliomas varies around the world. The differential was the frequency of unspecified morphologies, which may be partly attributable to diagnostic capacity. We will assess the extent to which disparities in morphology contribute to worldwide variation in survival from adult brain tumours. When comprehensive survival analyses are available, this project is expected to become the reference for international comparison of brain tumour survival, to help inform national cancer control plans.

384P Clinical characteristics of 3,030 glioblastoma multiforme (GBM) patients in high, upper middle and lower middle economic regions based on real-world data (RWD)

L.M. Mitrofan[1], M.R. Krukas-Hampel[2], L.A. Mendoza[3]

[1]Real World Evidence Solutions, Oncology, IQVIA, Paris, France, [2]Consulting Services, IQVIA Global Consulting Services, New York, NY, USA, [3]Medical Strategy & Science, Oncology-Hematology, IQVIA, Prague, Czech Republic

Background: GBM is the most common and aggressive primary brain tumor in adults. This study investigated RWD-based differences among 3,030 GBM patients stratified by three economic regions.

Methods: The analysis was based on IQVIA syndicated cross-sectional surveys, collecting anonymized patient-level data between January 2016 and September 2017 in different countries, grouped into three economically different regions. Region 1 (high): EU5 (France, Germany, Italy, UK, Spain), Canada, Australia; Region 2 (upper middle): Korea, China, Taiwan; Region 3 (lower middle): Brazil, Mexico.

Results: The percentage of patients aged >65 years was 23.9 % for region 1, 6.33 % for region 2 and 13.62 % for region 3, confirming younger GBM population in region 2. The age difference among the regions was statistically significant ($P < 0.0001$). The incidence of male (65 %) and female (35 %) patients was homogenous across all regions. Region 1 showed the highest testing rate (60 %) for MGMT promoter methylation and region 3 the lowest (33 %). EGFR mutation was not studied in more than 50 % of patients across the regions. However, in overall tested population, the EGFR VIII mutations varied: 39 %, 90 %, and 73 % for regions 1, 2 and 3, respectively. Concerning drug treatment options, temozolomide was the leading therapy (> 90 %) in all three regions, regardless of MGMT and EGFR status. The highest percentage (35 %) for cognitive impairment studied by MMSE (Mini Mental State Examination) was found in region 2, followed by 25 % and 22 % in regions 1 and 3, respectively. We did not find any differences in Performance Status or comorbidities among the regions, with no reported comorbidities in > 60 % of patients.

Conclusions: This multi-variable analysis from RWD shows differences in clinical characteristics (i.e., age, biomarkers and MMSE), which may be taken into consideration in the design of GBM global studies. To our best knowledge, this study was based on the largest GBM database ever published.

385P Radiotherapy versus combined radiochemotherapy for unresectable glioblastoma: A SEER based analysis

M.H. Osman

Faculty of Medicine, Zagazig University, Zagazig, Egypt

Background: Glioblastoma (GBM) is the most common type of malignant primary brain tumors originating from glial cells. GBM is an aggressive and extremely invasive tumor with a very poor prognosis and median survival of 12.1-14.6 months. Surgery is a corner stone in the treatment of GBM. However, resection may be inapplicable for lesions located in eloquent gray matter such as brainstem, basal ganglia or thalamus. For unresectable tumors, treatment varies from short-course radiotherapy to extended-course radiotherapy and even combined radiochemotherapy. In this study, we compare radiotherapy alone with combined radiochemotherapy to determine patients' survival with both treatments.

Methods: To identify patients with unresectable GBM, the Surveillance, Epidemiology and End Results database (SEER) of the National Cancer Institute was searched. Patients with an initial diagnosis of GBM between 2004 and 2013 were identified and their clinical characteristics were extracted from records for analysis.

Results: A total number of 2562 patients with unresectable GBM was identified with a median age of 63 years and a median survival of 6 months. The most common sites for tumor was frontal lobe (23.2%) and overlapping lesion of brain (21.1%). Out of total, 548 (21.4%) with a median age of 69 years received radiotherapy alone and 2014 (78.6%) with a median age of 61 years received combined radiochemotherapy. Survival analysis showed that patients who received combined radiochemotherapy had better survival compared to whom received radiotherapy alone with 1-year relative survival of 32.3% and 11.5% and 2-year relative survival of 11.1% and 3.5% for combined radiochemotherapy group and radiotherapy alone group, respectively (p-value < 0.001).

Conclusions: The prognosis of patients with unresectable GBM is still very poor. Combined radiochemotherapy showed a significant better survival compared to radiotherapy alone.

386P Clinical characteristics of glioblastoma multiforme (GBM) patients who reached 400 days post diagnostic from a retrospective real-world data

L.M. Mitrofan[1], M.R. Krukas-Hampel[2], L.A. Mendoza[3]

[1]Real World Evidence Solutions, Oncology, IQVIA, Paris, France, [2]Consulting Services, IQVIA Global Consulting Services, New York, NY, USA, [3]Medical Strategy & Science, Oncology-Hematology, IQVIA, Prague, Czech Republic

Background: GBM is the most common and aggressive primary CNS malignancy with a median survival of 12-14 months. Less than 3% of GBM patients survive three years. Understanding the clinical profile along with the predictors for Long Term Survivors is of outstanding importance.

Methods: This study used IQVIA syndicated cross sectional surveys analysing retrospectively anonymized live patient-level data between January 2016 and September 2017 from EU5, Canada, Australia, Korea, China, Taiwan, Brazil and Mexico. We characterized patients who achieved at least 400 days (group 400) between their diagnosis and the start date of their latest therapy at the time they were surveyed. 370 patients correspond to group 400 from the collected population of 3,036. Due to methodological limitations for data collection, we will mainly focus our analysis on the clinical profile of group 400 without fully comparing them with the rest of the population.

Results: Majority of patients in group 400 are relapsed (92.4%) with a mean of 791.7 $\pm$780.6 days from diagnosis to relapse date ($N = 342$). 38% of patients are having an ECOG more than 2 at the moment of their current therapy and 67% have no comorbidities. The time to first chemotherapy has a mean value of 293.3 $\pm$795.1 days) and the time to first surgery is 33.7 $\pm$250.5 days. 57.0% of patients had one surgery with 70.8% of these patients having a total resection for their last surgery. In addition, the age of the patients was below 45 years for 33% for group 400 versus 20% for the bellow 400, which indicate a higher number of young patients in the group 400. We identified that Ratio male/female is relatively homogenous across both groups. The expression of mutant EGFRvIII was significantly lower (4.59%) in the 400 group compared with 16.84% in the bellow 400 group ($P<.0001$). MGMT promoter methylation was not significantly different ($P = 0.3711$).

Conclusions: GBM patients who reach 400 days between their diagnosis and the start date of last therapy are in majority patients who had relapsed and more likely to be younger, and show a lower percentage of non-mutated EGFRvIII. Of outmost clinical interest, it would be to predict what patients would pass from below 400 group to 400 days group.

387P Corticosteroids administration as a prognostic factor in glioblastoma patients: An Egyptian experience

K. Abdel Karim, M.R. Kelany, O. Abdelrahman, A.M. El-Adawy

Clinical Oncology Department, Ain Shams University, Faculty of Medicine, Cairo, Egypt

Background: Glioblastoma multiform (GBM) is the most common primary malignant brain tumors. Standard management is maximal safe resection followed by concurrent chemoradiotherapy then adjuvant chemotherapy with temozolomide TMZ. Management of GBM patients also involves medical treatment containing corticosteroids that might have direct effects on tumor cell proliferation and apoptosis. We aimed at discussing the clinical relation between corticosteroids usage in GBM patients, overall survival OS, and progression free survival PFS, according to the records from Clinical Oncology Department, Ain Shams University, Cairo, Egypt.

Methods: Retrospective analysis was performed on 66 adult patients diagnosed with GBM by surgery or imaging criteria between January 2014 and December 2016. Data analysis was performed on October 2017 to assess the relation between corticosteroid dependence (defined as the failure to withdraw the corticosteroids after their initiation during the treatment with radiotherapy and TMZ) with OS and PFS. Patients were arranged in 2 arms according to steroid dependency. Arm (A) was steroid dependent (34 patients) and arm (B) was steroid non-dependent (32 patients).

Results: The median age of the entire cohort was 52.8 years (Range 25-72) with male predominance (68.1%) and 72.7 % of the patients received radiotherapy as their main treatment. 59.1 % of the whole cohort were treated by standard radiotherapy regimen of 60 Gy, while 13.6 % were treated by hypo-fractionation radiotherapy with total dose of 45 Gy. 62.1 % of the patients received TMZ concurrently with radiotherapy. Corticosteroids dependency was statistically significantly correlated to both OS with a median of 2.5 months in the corticosteroids dependent group vs. 13.1 months in the corticosteroids non-dependent group ($p < 0.001$), and also to PFS with a median of 2.3 in the corticosteroids dependent group vs. 9.4 months in the corticosteroid non-dependent group ($p = 0.035$).

Conclusions: This study from an Egyptian center shows that dependence on corticosteroids during the course of treatment of GBM patients may affect survival. Larger multicentric studies are needed to elaborate the influence of corticosteroids on the disease course.

388P Impaired survival in resected glioblastoma multiforme patients treated with early chemoradiation

L.P. del Carpio[1], P. Gomila[1], S.D. Camacho[1], S. Moron[1], M. Riudavets[1], C. Molto[1], A. Bujosa[1], M. Borrell[1], R. Teres[1], B. Martin[1], P. Gallardo[1], E. Acosta[2], L. Tilea[2], A. Soto[2], C. De Quintana[3], J. Craven-Bartle[2], A. Gallardo[4], B. Gomez[5], S. Bonilla[5], O. Gallego[1]

[1]Medical Oncology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [2]Radiation Oncology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [3]Neurosurgery, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [4]Pathology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [5]Neuroradiology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background: The best time to initiate concurrent chemoradioation (ChRT) with temozolamide after surgery in glioblastoma multiform (GBM) patients has not been clearly established. Our aim was to investigate whether survival is influenced by the time to ChRT in patients with different types of surgery.

Methods: We conducted a retrospective study of all the patients treated in our centre from January 2005 to December 2017, with a histological diagnosed GBM, which underwent surgery and completed concurrent ChRT with temozolamide. The time to ChRT was grouped in 4 quartiles, and early ChRT was defined as happening during the first quartile. Surgery type was divided into resection (R) and biopsy (B). Survival at 12 months (OS12m), median progression free survival (mPFS) and overall survival (mOS) were calculated. Other relevant clinical factors were also analyzed.

Results: From a total of 160 patients, 119 who completed ChRT were included. The median time to ChRT was 37 days, (Q1=26, Q2=37, Q3=45); 35 (30%) received early ChRT (≤26 days). Patients who underwent R were 101 (85%) and 18 (15%) B. The mean age was 62y, 94 patients (79%) had PS 0-1, MGMT methylation was positive in 23 (19%). There were no significant differences between groups regarding Age, PS and MGMT status; but more patients treated with B received early ChRT (31% vs 8%). The OS12m was shorter for patients who underwent R and received early vs no-early ChRT (35% vs 73%, p = 0.002). No differences in OS12m were found for B patients (0% vs 18%, p = 0.4) according to time to ChRT. For patients who received early ChRT, the mOS was similar despite surgery type (9.9, 95% CI 9.6 – 11 vs 12.9, 95% CI 6.5 – 19.3, p = 0.8, for R and B, respectively). But for patients who did not receive early ChRT, longer survival was achieved in the R vs B subgroup (16.2, 95%CI 14.1 – 17.8 vs 11.1, 95% CI 4.5 – 17.7, p = 0.024, for R and B, respectively) and resection type remained significant in the multivariate analysis (HR = 1.2, p = 0.02).

Conclusions: We have found that patients with GBM who underwent resection had a worse prognosis if they received early chemoradiation (≤ 26 days). No differences were found for biopsied patients. A no-early chemoradation approach for patients who underwent resection may be safe. Prospective studies are encouraged.

389P Bevacizumab-induced hypertension correlation with survival in recurrent glioblastoma multiforme

N.T. Tavares, J. Simões, C. Borges, S. Meireles, A. Costa, C. Fernandes, C. Caeiro, M. Damasceno

Serviço de Oncologia Médica, Centro Hospitalar de São João, EPE, Porto, Portugal

Background: Patients with Glioblastoma multiforme (GBM) have a poor prognosis and therapeutic options are scarce after recurrence. Bevacizumab (Bv) is approved for use in this setting with proven benefits in progression-free survival (PFS) but not in overall survival (OS). Arterial hypertension (HT), a well described side effect of Bv, has been proposed as a predictive marker of clinical response in GBM as well as in other neoplasms, though conflicting data is available. This study tried to evaluate the prognostic impact of HT and other factors in recurrent GBM.

Methods: Retrospective cohort of adult patients with recurrent GBM treated with a combination of Bv + Irinotecan (BvI) or Lomustine (BvL) between 01/01/2009 and 31/12/2017. Clinical records were analysed. Bv-induced HT was defined as a single evaluation ≥140/90 mmHg during first 3 months of treatment or the need to initiate or increase dose of antihypertensive drugs. OS and PFS were estimated by Kaplan-Meier method and multivariate analysis according to Cox regression; a significant level of 0.05 was chosen to assess the statistical significance.

Results: 120 patients were included with male gender predominance (64.2%) and a median age at Bv onsent of 58.7 (27-78 yo). All patients were treated in first line with surgery (complete resection: 61.7%; partial resection: 38.3%) and Stupp protocol. BvI was used in 70.8% (n = 85) and BvL in 29.2% (n = 35) patients. Bv-induced HT was found in 29% of patients (n = 29) and proteinuria (PU) in 15% (n = 18). Median PFS was 4.4 months (mo) (CI 95% 3.5-5.4) and median OS was 7.8 mo (CI 95% 6.8-87). In multivariate analysis (Table), both HT and PU had an impact in PFS. OS was significantly prolonged in patients with HT and in those without corticosteroids (CCS) at Bv.

Table: 389P

		PFS (mo)	HR (CI 95%)	OS (mo)	HR (CI 95%)
HT	Yes	9.1	HR 1.825	14	HR 2.726
	No	4.1	(1.136-2.931), p = 0.013	7.8	(1.325-5.608), p = 0.006
PU	Yes	6.1	HR 2.341	-	-
	No	3.9	(1.282-4.275), p = 0.006	-	
CCS at Bv onset	Yes	-	-	6.9	HR 2.022
	No	-		13.4	(1.059-3.860), p = 0.033

Conclusions: In recurrent GBM patients treated with Bv combinations, HT was significantly related with prolonged PFS and OS. PU and the need for CCS also showed a significant prognostic impact.

390P +405C>G polymorphism of VEGF in randomly selected GBM patients

I. Djan[1], M. Djan[2], N. Vucinic[3], B. Nikolin[4], S. Salma[4], S. Lucic[5], N. Vuckovic[6], M. Lucic[7]

[1]Department of Radiotherapy, Oncology Institute of Vojvodina, Sremska Kamenica, Serbia, [2]Department of Biology and Ecology, University of Novi Sad Faculty of Sciences, Novi Sad, Serbia, [3]Department of Pharmacy, University of Novi Sad Faculty of Medicine, Novi Sad, Serbia, [4]Department of Medical Oncology, Oncology Institute of Vojvodina, Sremska Kamenica, Serbia, [5]Department of Nuclear Medicine, Oncology Institute of Vojvodina, Sremska Kamenica, Serbia, [6]Department of Pathology, University of Novi Sad Faculty of Medicine, Novi Sad, Serbia, [7]Diagnostic Imaging Center, Oncology Institute of Vojvodina, Sremska Kamenica, Serbia

Background: Vascular endothelial growth factor (VEGF) is a glycoprotein growth factor specific for vascular endothelial cells, responsible for angiogenesis. So far, 44 SNPs with clinical relevance have been detected (ClinVar NCBI database) and the majority of those are associated with cancers of colon and others solid tumors. The aim of this study was to assess the distribution of + 405C>G VEGF gene polymorphism in patients diagnosed with glioblastoma and to test association with the overall survival.

Methods: Tissue paraffin-embedded samples were subjected to molecular analyses and VEGF polymorphism detection retrieved from 66 patients diagnosed for glioblastoma. VEGF genotypes at position <G405C were detected using allele-specific PCR, followed by RFLP-PCR with 2U of BsmFI (Fermentas, Lithuania). The results were analyzed using SPSS Statistics 17.0 software.

Results: The most frequent allele (SNP variant) was G (72.58%) (Table). No statistically significant differences were observed in a pairwise genotype groups comparison for overall survival (OS). Between-group variance is negative (-3,840), indicating no differences in mean OS among genotypes. ANOVA also did not show any statistically significant variance among groups (F = 0.124; p = 0.879).

Table: 390P Descriptive statistics for overall survival in three genotypes of VEGF gene

Genotype	N	Mean OS	SD	SE	CI (95%)	
					lower	upper
CC	9	10.56	8.918	2.973	3.70	17.41
CG	32	11.00	9.449	1.670	7.59	14.41
GG	21	12.10	8.420	1.837	8.26	15.93
Total	62	11.31	8.910	1.132	9.04	13.57

N – number of patients; OS – overall survival in months; SD – standard deviation; SE – standard error; CI – confidence interval; min – minimum in months; max – maximum in month

Conclusions: Even though no significant difference in overall survival in GBM patients regarding the examined polymorphism of VEGF gene was found, it was also shown that genotype GG has one month longer overall survival in the examined patients group. It

is probable that random selection of patients regardless of applied treatment, or without treatment, and ECOG 1-4 requires larger number of patients to be included in order to provide final proof whether this polymorphism has any effect on overall survival.

391P Expression and clinical prognostic role of ZWINT in glioma: Analysis based on data-mining and integration of gene databases

Z. Mengxian

Cancer Center, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

Background: Human ZW10 interacting kinetochore protein (ZWINT) gene plays critical roles in mitotic cycle maintenance and is known to be linked with poor clinical prognosis in various tumors. However, the clinical significance of ZWINT in glioma has not yet been understood. The purpose of this study was to determine the expression profile and functions of ZWINT in glioma, to confirm its prognostic value.

Methods: The gene expression and clinical information profile were downloaded from The Cancer Genome Atlas (TCGA) dataset and a statistical analysis was made. We probed the edgeR and gplots packages in the R language to identify differentially expressed genes (DEGs). The Kaplan–Meier plotter online tool was used to study the association of ZWINT expression and overall survival (OS) of glioma patients. Immunohistochemistry (IHC) and quantitative RT-PCR were performed to evaluate protein and mRNA expression levels of ZWINT. ZWINT-siRNA was transfected into U251 and U87 glioma cells to inhibit the expression of ZWINT. Then, the effects of ZWINT silencing on glioma cell lines proliferation, invasion and apoptosis were determined by the Celigo assay, MTT assay, transwell assay, Annexin V FACS assay and Caspase-3/7 assay in vitro. Functional and pathway enrichment analysis were performed for DEGs using the DAVID database. Protein–protein interaction (PPI) network analysis was established by STRING and visualized by Cytoscape.

Results: Integrated analysis revealed that ZWINT protein and mRNA expression were significantly upregulated in glioma versus normal tissues, its expression was positively correlated with the patient age, poor pathological grade, and conferred poor prognosis. Knockdown of ZWINT expression inhibited the proliferation and invasion of U251 and U87 cells, and apoptosis was distinctly increased following ZWINT-siRNA infection. 20 hub genes and a significant module showed that the DEGs were principally related to cell division, and mitotic cell cycle.

Conclusions: Our preliminary study highlighted that the expression of ZWINT is upregulated in glioma, which is correlated with poor prognosis. ZWINT silencing can effectively inhibit proliferation, induce apoptosis and suppress migration and invasion during human glioma development, which may provide a new promising tumor-specific therapeutic combination hub genes target for anti-mitosis agents.

392P Lipid peroxidation and cognitive impairment in patients with brain cancers

S. Kim[1], S. Kim[2]

[1]College of Nrusing, Keimyung University, Daegu, Republic of Korea, [2]Public Health Center, Uijeongbu City Hall, Uijeongbu City, Republic of Korea

Background: The prevalence of cognitive impairment is known to be high, but the knowledge of its correlates with lipid peroxidation is limited. The mechanisms responsible for the development of cognitive impairment have been discussed widely, and emerging evidence suggests a significant role of lipid peroxidation as well as vascular inflammation as main contributors to cognitive impairment. We aimed to explore the relationship between lipid peroxidation and the presence of cognitive impairment in patients with brain cancers during cancer-related therapy.

Methods: 58 first-ever brain cancer patients without previous cognitive impairment were consecutively enrolled in the current study. The levels of lipid peroxidation were evaluated by looking at the total cholesterol (TC) to high-density lipoprotein (HDL)-cholesterol (TC/HDL-c), low-density lipoprotein (LDL)-cholesterol to HDL-cholesterol (LDL-c/HDL-c), and triglycerides to HDL-cholesterol (TG/HDL-c) at the same time as performing a cognitive impairment test. The lipid peroxidation was measured at two times, within 24 h after admission and 3 months after recieving cancer-related therapy. Cognition function was evaluated by the Mini-Mental State Examination (MMSE) at the same time as lipid peroxidation evaluation.

Results: In this study, all patients were homogeneous in terms of general characteristics, tumor histology types, severity, and location. The patients were classified as cognitively impaired (n = 15, 25.9%) or non-cognitively impaired (n = 43, 74.1%) at 3 month after recieving cancer-related therapy. At admission time, the serum levels of lipid peroxidation were normal values in all patients but the levels were increased at 3 months after brain cancer onset in cognitively impaired groups. The level of lipid peroxidation was significantly different both with and without cognitive impairment groups at 3 months after brain cancer onset ($p < 0.001$). There was no significant difference between the two groups in tumor histology types, severity, and location.

Conclusions: Lipid peroxidation will need to be considered as a potential indicator for the management of cognitive impairment in early brain cancer stages.

393P FAT1 on YAP1-TEAD1 interaction augments oncogenic potential of GBM cells

Y. Gupta[1], S.S. Shivajirao[1], K. Irshad[1], B. Dikshit[1], T. Srivastava[2], P.P. Chattopadhyay[1], S. Sinha[1], K. Chosdol[1]

[1]Biochemistry, AIIMS, New Delhi, India, [2]Genetics, University of Delhi, New Delhi, India

Background: Glioblastoma (GBM) is a lethal brain tumor arising from supporting cells of the brain. We have recognized the oncogenic role of FAT1 gene in GBM, regulating inflammatory and hypoxic microenvironment of the tumor as well as migratory/invasive properties of tumor cells. In *Drosophila*, fat, the ortholog of FAT1, is known to regulate the Salvador-Warts-Hippo (SWH) pathway, but its role in human is not clear. Here, we have analyzed the effect of FAT1 on SWH pathway in glioma.

Methods: Glioma cell lines (U87MG, U373, A172, GOS3 and SW1088) were transfected with FAT1 specific siRNA/control siRNA and the expression of SWH pathway molecules was analysed by qPCR/western blot. Protein-protein interactions were analyzed by co-immunoprecipitation (Co-IP) after over-expression of YAP1 (wild-type and mutated) and TEAD1 with and without FAT1 knockdown.

Results: The mRNA expression of FAT1 and SWH pathway molecules (MST1, LATS1, LATS2, YAP1 and TEAD1) was highest in U87MG cells followed by A172, U373MG and GOS3. After FAT1 knockdown, the mRNA expression of MST1 and BIRC2 were significantly decreased with no change in the levels of LATS1, LATS2, YAP1, TEAD1 and BIRC5. At protein level, increased YAP1 and phospho-YAP1 was observed after FAT1 knockdown with increased total as well as phospho-YAP1 in the cytoplasmic extract as compared to the nuclear extract. There was significant reduction in the interaction between YAP1 and TEAD1 in siFAT1 treated cells compared with siControl treated cells.

Conclusions: On FAT1 knockdown, we found (i) increased YAP1 protein level, which could be by increasing the protein stability as no change was observed at the mRNA level, (ii) increased phospho-YAP1 level as it relieves the inhibitory effect on YAP1 phosphorylation, (iii) it affects the sub-cellular localization of YAP1 by retaining YAP1 in the cytosol and thereby, (iv) decrease in the YAP1:TEAD1 interaction with decreased expression of their target gene, Birc2. This finding of the effect of FAT1 on YAP1 in GBM is novel with features pointing towards the oncogenic role of FAT1 by regulating YAP1 sub-cellular localization and co-transcriptional activity independent of SWH pathway.

394P Extracts of *Cerbera manghas L.* effectively inhibit the growth of glioblastoma cells and their stemloids

Y-J. Lai, J-C. Tsai, W-S. Liu, H-I. Lam

Department of Life Science, National Taiwan Normal University, Taipei, Taiwan

Background: Glioblastoma multiforme (GBM) is the grade IV glioma and the most common adult primary brain tumor. It is notorious for its heterogeneity, invasiveness and resistance to chemo- and radiotherapies. These characteristics make it a highly recurrent malignant disease with poor prognosis. The potential new target for intervention in GBM is its cancer stem cells (GSCs).

Methods: To identify an improved treatment by targeting GSCs, we screened 400 botanical extracts for their effects on cytotoxicity and colony formation ability in GBM cell lines and tumorspheres.

Results: We identified the extracts of *Cerbera manghas* L. as being effective inhibitors of the growth and migration of GBM cell lines and its tumorspheres. We further demonstrated that neriifolin was one of the active principles. Neriifolin effectively inhibits the growth of $CD133^+$-GBM tumorspheres and their colony formation. The extracts of *Cerbera* and neriifolin both reduced AKT activation and caused cell cycle G1 arrest while reducing the protein level of the stem cell marker Sox2. Furthermore, higher doses of these treatments induced apoptosis of tumorspheres. In the mouse

xenotransplantation model, neriifolin inhibited the growth of $CD133^{+}$-GBM tumorsphere-derived tumors in vivo.

Conclusions: In summary, neriifolin obtained from extracts of *C. manghas* may serve as a drug lead compound for GBM therapies.

395P Contrast enhancement in low grade gliomas: A classic prognostic factor in the molecular age

F. Castet[1], E. Alanya[2], M. Gil-Gil[1], N. Vidal[3], C. Izquierdo[4], C. Mesia[1], J. Bruna[5]

[1]Medical Oncology, Institut Català d'Oncologia Hospital Duran i Reynals, Barcelona, Spain, [2]Medical Oncology and Radiotherapy, Edgardo Rebagliati Martins National Hospital - EsSalud, Lima, Peru, [3]Anatomia Patològica, Hospital Universitari de Bellvitge, Hospitalet De Llobregat, Spain, [4]Service de Neuro-Oncologie, Hospices Civils de Lyon, Groupe Hospitalier Est, Lyon, France, [5]Neurology, Hospital Universitari de Bellvitge, Hospitalet De Llobregat, Spain

Background: Contrast enhancement (CE) is described in 10-60% of low grade gliomas (LGG). Its prognostic significance is controversial, and its correlation with IDH mutations and 1p/19q codeletion is unknown. The aim of this study is to investigate whether CE is associated with molecular characteristics of LGG and elucidate its prognostic value.

Methods: All confirmed histological cases of LGG diagnosed in a single institution between years 2000-2016 were retrospectively reviewed (n = 104). Clinical, radiological and molecular factors were collected. Spinal and brainstem localization, only-biopsied tumours with ring-like enhancement and incomplete medical records were excluded. 1p/19 codeletion analysis was performed by FISH, IDH was performed by immunohistochemistry. IDH wild-type tumours were confirmed with qPCR. Overall survival (OS) was estimated by Kaplan-Meier method.

Results: We included 89 patients, with a median follow-up of 73.3 months. Mean age was 41.6 years, and 65.2% were male. CE was present on 25.8% of preoperative MRI, and 25.3% of patients were considered high-risk according to Pignatti score. Most were astrocytomas (67.4%) and 84.4% were surgically removed. IDH mutation was found in 66.7% of tumour samples, and 17.9% had a 1p/19q codeletion. No differences were observed amongst CE and non-CE groups, apart from age (46.6 vs 39.9 years, respectively; $p = 0.041$). IDH mutation ($p = 0.776$) and 1p/19q codeletion ($p = 0.512$) were evenly distributed. On univariate analysis, size >6cm ($p = 0.002$), CE ($p = 0.026$), extent of resection ($p = 0.008$), Pignatti score ($p = 0.002$) and IDH mutation ($p = 0.003$) were significantly associated to OS. On multivariate analysis, only CE ($p = 0.009$) and IDH status ($p = 0.005$) were independently associated to OS.

Conclusions: CE in LGG provides complementary and independent prognostic information to IDH and 1p/19q codeletion. Its contribution to treatment decisions requires further exploration in larger prospective cohort studies.

396P Can diffusion tensor MR imaging identify glioma IDH mutation status?

S. Bisdas[1], J. Yuan[2], L. Mancini[2], D. Roettger[3]

[1]Institute of Neurology, University College London, London, UK, [2]Department of Neuroradiology, University College London Hospitals NHS Trust, London, UK, [3]R&D, Image Analysis Ltd, London, UK

Background: The isocitrate dehydrogenase (IDH) mutation status is a recognized molecular biomarker for glioma stratification. In addition, glioma clinical management benefits from advanced MRI sequences including diffusion tensor imaging (DTI). For first time, we investigated the diagnostic power of DTI to characterize gliomas with respect to IDH mutation status.

Methods: This retrospective study examines the accuracy of DTI for staging of IDH mutant (98) and wild-type (67) gliomas in a treatment-naïve setting. The tumour was manually segmented in the MRI and two DTI-derived parameters, namely fractional anisotropy (FA) and mean diffusivity (MD) values were calculated and plotted as histograms. Thresholds for the optimal diagnostic performance in terms of IDH mutation were sought in selected histogram parameters of FA and MD maps using parametric and non-parametric tests as well as receiver operating characteristic curve analysis.

Results: Significantly higher MD median values and significantly lower FA median values were observed in the IDH mutant compared with the wild-type group. As follows, the median MD value was defined as a robust predictor for IDH mutation status [area under the curve (AUC) = 0.82]. The developed logistic regression model included the top 5 correlating histogram parameters and the patient age. The assessment using the parameter combination reached better performance (AUC=0.85) compared with the prediction using parameter of the median MD value alone.

Conclusions: MR imaging DTI-derived metrics (MD and FA values) in combination with demographic information has the potential to non-invasively predict molecular stratification of gliomas.

397P Comparative assessment of orthotopic brain tumor growth using bioluminescence and magnetic resonance imaging

Y. Tsvetkova[1], C. Green[2], G. Schuetz[2], J. Hoffmann[3], D. Zopf[1], P. Lejeune[1]

[1]Drug Discovery, Oncology, Bayer AG, Berlin, Germany, [2]MR & CT Contrast Media Research, Bayer AG, Berlin, Germany, [3]Experimental Pharmacology & Oncology, EPO Berlin-Buch GmbH, Berlin, Germany

Background: Small-animal tumor models are essential for developing translational therapeutic strategies in oncology research. Intracranial brain tumor models are of high clinical relevance, since they closely resemble the tumorigenesis in humans. The use of such models, however, requires the application of imaging methods to quantitatively assess tumor growth and therapy efficacy. The objective of this study was to evaluate intracranial tumor growth and treatment response in mouse models using magnetic resonance imaging (MRI) and bioluminescence imaging (BLI). Further aim was to establish correlation between tumor volume and bioluminescence signal and compare the imaging modalities in terms of accuracy and efficiency.

Methods: Three groups (untreated, vehicle and Temozolomide-treated group) of ten mice each were implanted intracranially using stereotactic device with U87 glioma cells expressing firefly luciferase. Two cycles of temozolomide at 50 mg/kg 5days on/9days off were administered orally by gavage. The mice were imaged using bioluminescence and MR (preclinical 4.7 T MR scanner) once per week.

Results: The data showed that both imaging methods can efficiently measure tumor growth and therapy response but significantly differ in their throughput and type of information. MRI offers detailed tumor localization and 3D volumetric measurements, but has limited capacity to assess early tumor growth. BLI identifies tumors early but not tumor localization, precluding discrimination of intraventricular and extracranial tumor growth. Tumor volume determined with MRI and BLI signal intensity showed a strong linear correlation (r = 0.918).

Conclusions: BLI appears a reliable technique to evaluate intracranial tumor growth in mouse models. Adding MR scans to longitudinal BLI improves assessment of tumor properties such as volume, location, hemorrhage and necrosis. Other intracranial tumor xenografts, with varying characteristics, i.e. diffuse growth, are being analyzed to improve assessment of both imaging modalities.

398P Radiologically evident treatment effects in patients with glioblastoma (GBM) and its clinical implications

H.K. Gan[1], C. Murone[1], M. Wong[2], G. Fitt[3], E. Kennedy[4], D. Maag[4], K. Aldape[5]

[1]Medical Oncology, Olivia Newton-John Cancer Research Institute/ Austin Health, Heidelberg, Australia, [2]Medicine, Sydney Medical School, The University of Sydney, Sydney, Australia, [3]Radiology, Austin Health and Olivia Newton-John Cancer Research Institute, Austin Hospital, Heidelberg, Melbourne, Australia, [4]Oncology Development, AbbVie Inc USA, North Chicago, IL, USA, [5]Department of Pathology, Toronto General Hospital/Research Institute (UHN), Toronto, ON, Canada

Background: GBM is the most common primary brain tumor. Survival is poor with standard surgery followed by radiotherapy (RT) and temozolomide (TMZ). Pseudoprogression on MRI is well described post-RT, particularly within the first 3 months, and confounds response assessment. Whilst not previously described for drug treatment alone, anecdotal cases were described in a Phase 1 study of depatuxizumab mafodotin (depatux-m). Depatux-m is an antibody-drug conjugate, comprised of a tumor-specific anti-EGFR antibody linked to a microtubule cytotoxin, monomethyl auristatin F, that demonstrated promising antitumor activity in adult GBM pts with EGFR-amplified tumors. This exploratory study will determine if depatux-m exhibits radiologically evident treatment effects in pts with GBM, i.e. drug induced pseudoprogression.

Methods: This non-interventional study enrolls pts with GBM who underwent tumor debulking surgery after MRI evidence suggested treatment failure in Phase 1-3 depatux-m trials. Pts had received depatux-m alone or in combination with TMZ. Resected tumor tissue is formalin-fixed, paraffin-embedded and centrally reviewed. Radiographic assessments were collected per original study protocol (typically q8 wks), or as clinically indicated, and centrally reviewed. Clinical response is evaluated by RANO criteria. This study will assess correlation between radiographic and histologic evidence of disease progression after depatux-m treatment. Exploratory endpoints are progression-free survival and overall survival.

Results: As of April 2018, 7 pts with recurrent GBM were enrolled at 2 sites in Australia. All pts completed RT at a minimum of 11 months (range 11-26) prior to re-resection. 4 pts had histological confirmation of recurrence prior to treatment.

Conclusions: Histology showed that 57% (4/7) of pts with disease progression by RANO criteria after depatux-m, with or without TMZ, had predominantly treatment effect per local pathologist assessment. Central review indicated that of these 4 pts, 2 pts were ≥75% necrotic and 2 showed complete absence of tumour. 2 pts had histological confirmation of recurrence prior to treatment. Cases and associated clinical impact are presented.

399P Melanoma with brain metastases: Experience of immunotherapy in a single center

D.R. Naskhletashvili[1], L.V. Demidov[2], A.H. Bekyashev[1], V.A. Aloshin[1], E.V. Prozorenko[1]

[1]Neurooncology, N. N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation, [2]Biotherapy, N. N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation

Background: The effectiveness of conventional chemotherapy (temozolomide, fotemustine, lomustine) alone and its combinations with radiation therapy in patients with melanoma with cerebral metastases does not exceed 7-10%, There is no significant impact on overall survival, which is 2-4 month. Research of immunotherapy (nivolumab, ipilimumab, pembrolizumab) is relevant in melanoma patients with brain metastases in the absence of mutations of the BRAF, or in the case of the progression of the disease while therapy BRAF inhibitors in patients with mutations of the BRAF.

Methods: The effect of the various schemes immunotherapy was evaluated in 22 patients with melanoma with brain metastases in Russian N.N. Blokhin Cancer Research Center. Patients received the following treatment options: nivolumab (6 patients), ipilimumab (11 patients), nivolumab + ipilimumab (2 patients), pembrolizumab (3 patients). The immunotherapy was combined with whole brain irradiation in 1 patient (4,5%), in 11 patients (50,0%) – in combination with stereotactic radiotherapy/radiosurgery.

Results: Complete regression of brain metastases was achieved in 3 patients (13,6%), partial regression in 2 (9,1%), stabilization in 11 (50,0%). Thus, the tumor control in the brain was observed in 16 patients (72,7%). In 22 patients (100,0%) were also established metastases in other sites (extracranial lesions). Complete regression of metastases in extracranial lesions was achieved in 4 patients (18,2%), partial regression – in 2 (9,1%), stabilization in 13 (59,1%). The median time to disease progression was 5,0 months. The median survival of patients was 10,0 months.

Conclusions: The preliminary results of our study show that the application of immunotherapy, including the combination with local control of metastases in the brain in patients with melanoma with brain metastases provides control over the disease in most patients and has a significant advantage with a group of historical control (chemotherapy ± whole brain irradiation).

400P Systemic management of malignant meningioma: A comparative survival and molecular marker analysis between ocreotide in combination with everolimus compared to sunitinib

A.F. Cardona Zorrilla[1], A. Ruiz-Patiño[1], O. Arrieta[2], L. Zatarain-Barron[2], F. Hakim[3], E. Jimenez[3], J.A. Mejia[3], F. Ramon[3], N. Useche[4], S. Bermudez[4], D. Pineda[5], H. Cifuentes[5], L.L. Rojas[6], L.E. Pino Villareal[7], C. Balana[8]

[1]Translational Research, Foundation for Clinical and Applied Cancer Research, Bogotá, Colombia, [2]Thoracic Oncology, Instituto Nacional de Cancerologia, Mexico City, Mexico, [3]Neurosurgery, Fundacion Santa Fe de Bogotá, Bogotá, Colombia, [4]Neuroradiology, Fundacion Santa Fe de Bogotá, Bogotá, Colombia, [5]Neuroradiology, Clinica Del Country, Bogotá, Colombia, [6]Clinical Oncology, Clinica Colsanitas, Bogotá, Colombia, [7]Clinical Oncology, Fundacion Santa Fe de Bogotá, Bogotá, Colombia, [8]Neuro-Oncology Section, Oncology Department, Catalan Institute of Oncology (ICO Badalona), Hospital Germans Trias i Pujol, Badalona, Spain

Background: Anaplastic and atypical recurrent meningioma constitute a rare pathology with very few available effective systemic treatments.

Methods: A comprehensive analysis of 31 patients with atypical (WHO II) or anaplastic meningiomas (WHO III) that were recurrent and refractory to radiotherapy was conducted in two reference centers of Colombia. Only patients who had received some systemic treatment (sunitinib, everolimus/octeotride and bevacizumab) and had a complete follow-up were included. Overall survival (OS), progression free survival and toxicities were evaluated. Additionally, tissue samples were examined for PDGFRa and VEGFR2 and its expression was correlated with outcomes.

Results: Twenty two patients (72%) were females with a median age of 55 years (SD ± 15.3). The most prevalent histology was anaplastic meningioma in 20 patients (65%) with 48% of patients suffering from three previous relapses before the start of systemic treatment. A total of 14 patients received combination therapy with octeotride/everolimus, 11 received sunitinib and the remaining 6 other second line agents. Median OS was 37.3 months (95%CI 28.5-42.1) and the PFS during the treatment with everolimus/octeotride (EO) and sunitinib (Su) was 12.1 months (95%CI 9.2-21.1) and 9.1 months (95%CI 6.8-16.8); $p = 0.43$), respectively. The OS of the group treated with the EO→Su→Bev sequence ($1^{st}/2^{nd}/3^{rd}$ line) was 6.5 months longer than the Su→EO→Bev sequence, a finding that was not significant (36.0 vs. 29.5 months; $p = 0.349$). When analyzing molecular markers, the positive PDGFRa and negative VEGFR2 expression were associated with longer survival both in OS and PFS.

Conclusions: Sunitinib and ocreotide/everolimus have similar efficacy and safety in the systemic management of refractory meningioma. VEGFR2 and PDGFRa expression are strongly associated with major survival endpoints.

401P Impact of postoperative residual tumor and meningeal dissemination in adult medulloblastoma: A retrospective analysis

R. Barreto, P.A.H. Viveiros, M.C. Mesquita, V.M. Santos, O. Feher

Oncologia Clínica, ICESP - Instituto do Câncer do Estado de São Paulo, São Paulo, Brazil

Background: Medulloblastoma (MB) is the most common central nervous system (CNS) malignant tumor in children and reaches its peak in the first decade of life. In adults, MB is very rare, comprising less the 1% of total CNS tumors. Although molecular subtypes are well defined, the impact of other prognostic variables, such as postoperative residual tumor (PRT) and the presence of neuroaxis dissemination (NAD) are controversial.

Methods: We performed a retrospective analysis in consecutive adult patients with MB treated at Instituto do Câncer do Estado de São Paulo from 2008 to 2016. Patients data on tumor histology, ECOG-PS at diagnosis, low/high-risk clinical classification (according to tumor size, metastasis, NAD and PRT) and adjuvant radiotherapy (RT) or chemotherapy (CT) were reviewed through medical records.

Results: Thirty-eight patients were included. Median age was 28,8 years-old (18,3 to 40,8) and patients were followed-up for a median of 5,28 years. Five patients died during follow-up, all cancer related, and 8 had progression events. All patients were submitted to surgical resection; 15 were considered high-risk patients; 34 were submitted to RT and 23 to CT in addition to RT. The most common RT regimen was 36Gy on neuroaxis and 18Gy boost on the posterior fossa (67%) and the most common CT protocol was a combination of lomustine, vincristine and cisplatin (39%). The two most common histological subtypes were classical (19), followed by desmoplastic (14). Fifteen patients were considered high-risk. On univariate analysis, the presence of PRT ($p < 0,0001$) and NAD ($p = 0,008$) had a negative impact on survival. Cox proportional-hazards regression for multivariate analysis confirmed the detrimental impact of PRT, while NAD had a marginal effect.

Conclusions: Medulloblastoma seems to bear a general favorable prognosis among adults. The presence of postoperative residual tumor, and perhaps neuroaxis dissemination, seem to impact negatively survival.

402P Adult medulloblastoma: An oncology radiation therapy department experience with 22 cases

M. Kallel[1], Z. Fessi[1], W. Siala[1], W. mnejja[1], N. Fourati[1], H. daoud[1], T. Boudawara[2], Z. Boudawara[1], M. Frikha[3], J. Daoud[1]

[1]Radiation Oncology, Habib Bourguiba Hospital Institute - Sfax, Sfax, Tunisia, [2]Pathology, Hopital Habib Bourguiba - Sfax University, Sfax, Tunisia, [3]Medical Oncology, Habib Bourguiba Hospital Insitute - Sfax, Sfax, Tunisia

Background: Medulloblastoma is the most common central nervous system tumor in children. However, the occurrence in adults is rare and accounts for about 1% - 2%. The objective of this study is to define the clinical characteristic of this entity and therapeutic results.

Methods: We retrospectively evaluated the treatment data of 22 adult patients (≥18 years) treated for medulloblatoma from 1993 to 2013 in our department. Median follow up was 161.5 months [58; 296 months].

Results: Male female ratio was 2.14 :1. Median age was 25 years [18 ; 57]. Eight patients (36%) had cerebellar hemispheric tumors, nine cases (41%) occur in the vermis and five patients (23%) had an hemispheric-vermian localisation. Twenty one patients (95%) underwent macroscopically total exicision. Sixteen patients (73%) had classic form; five patients had desmoplastic (23%) type and one patient had extensive nodularity type. Patients were stratified into standard and high risk in 14 and 5 cases respectively. The risk couldn't be identified for 3 patients. Among patients in the high-risk group, four received a cisplatin/etoposide chemotherapy before radiation. All patients had craniospinal radiotherapy. The mean interval between surgery and the begining of radiation therapy was 107 days. Craniospinal dose range between 30Gy and 36Gy. The dose in the posterior fossa was respectively 54Gy and 64Gy in 18 (82%) and 4 (18%) cases. The 5 year overall survival was 63%.

Conclusions: There are differences between pediatric and adult patients with medulloblastoma in terms of clinical and pathological characteristic. Ultimately, prospective trials including adult patient with medulloblastoma are needed to optimize the management of this rare and complex disease.

403P Pineal parenchymal tumors: Patterns of care from a tertiary cancer centre in India

B. Devnani[1], S. Gupta[1], H. Kp[1], P.K. Julka[2], G.K. Rath[3]

[1]Radiation Oncology, All India Institute of Medical Sciences, Delhi, India, [2]Radiotherapy and Oncology, All India Institute of Medical Sciences, Delhi, India, [3]Radiation Oncology, B.R. Ambedkar Institute Rotary Cancer Hospital (AIMS), New Delhi, India

Background: The aim of this study is to report clinical features and treatment outcome of pineal parenchymal tumors (PPTs).

Methods: Between 2006-2017, medical records of 34 patients of PPTs were analyzed to study patterns of care of patients who received adjuvant radiotherapy (RT) with or without chemotherapy (CT) following surgery. Overall survival (OS) and progression-free survival (PFS) were analyzed by Kaplan- Meier method.

Results: According to WHO classification, the study comprises of 19 pineoblastomas (PB), 11 pineal parenchymal tumors of intermediate differentiation (PPTID) and 4 pineocytomas (PC). Median age at presentation was 10, 26 and 30 years, respectively. Headache was commonest symptom (77%) followed by visual disturbance. 59% underwent surgical resection and 41% had biopsy only. Median MIB labelling index of PPTIDs was 6%, whereas it was 35% in PB and 2% in PC. Spinal drop metastasis was present in 8 patients with PB and 3 patients with PPTIDs. All PBs and PPTIDs with spinal drop metastasis (2) received cranio-spinal irradiation (CSI) and adjuvant CT. The rest of the PPTIDs and PC received focal RT to the brain. The commonest regimen was a combination of carboplatin and etoposide (CE), used in 6 (32 %) PB. CE with vincristine and IT-MTX was given in patients who developed drop metastasis subsequently. At a median follow-up of 16 months, 9 (47%) patients of PB and 3 (27%) of PPTID developed recurrence in cranio-spinal axis. 5 year progression-free survival was 41%, 62% and 75%, respectively. Median overall survival (OS) was 27, 50, 18 months, and 5 year OS was 38%, 47% and 75%, respectively.

Conclusions: PPTs reflect a broad spectrum of malignant potential and prognosis. PB is an aggressive tumor and requires adjuvant CSI and CT following surgery. PPTIDs are relatively rare and require meticulous pretreatment evaluation of neuraxis and knowledge of pathological factors for management. Multi-institutional cooperation in the form of prospective studies is recommended in view of rarity of tumor.

404P Advantages of next-generation sequencing in revealing low-level somatic mosaicism in blood samples of retinoblastoma patients

E.A. Alekseeva[1], V.M. Kozlova[2], T.L. Ushakova[2], A.S. Tanas[1], O.V. Babenko[1], T.P. Kazubskaya[2], V.V. Strelnikov[1], D.V. Zaletaev[3]

[1]Laboratory of Epigenetics, Research Centre for Medical Genetics, Moscow, Russian Federation, [2]Institute of Pediatric Oncology, N. N. Blokhin Science Medical Research Center of Oncology, Moscow, Russian Federation, [3]Laboratory of Medical Genetics, Sechenov First Moscow State Medical University, Moscow, Russian Federation

Background: Retinoblastoma (RB) is an embryonic malignant tumor of retina caused by inactivation of both alleles of the RB1 tumor suppressor gene. Identifying low-level mosaic mutations in RB1 gene in blood samples is challenging. Mosaic mutations arise in early embryogenesis and require high-resolution techniques for detection. In approximately 10% of families, the initial RB1 mutation is mosaic. The ability to identify RB1 mosaicism is important for genetic counseling because mosaicism increases the risk for developing RB in the other eye, second cancers and transmitting the mutation to progeny.

Methods: Using NGS we have evaluated the spectrum and frequency of RB1 mutations mosaicism in peripheral blood of 120 patients with sporadic RB (82 unilateral and 38 bilateral).

Results: In 5,8% (7/120) of patients a low-level mosaic mutation was found. The spectrum of identified mosaic RB1 mutations, the degree of mosaicism and clinical characteristics are shown in the table. Additionally, we analyzed the Sanger sequencing data from 72 blood samples from patients with sporadic RB (48 unilateral and 24 bilateral), performed earlier in our laboratory, and have not identified mosaic cases.

Table: 404P The spectrum of identified mosaic RB1 mutations

Sample	Form (uni/bi-lateral)	Age of onset	Mosaic mutation	Degree of mosaicism,%	Mutation in relatives
RB1	Uni-	6 mo	c.C1363T (14ex)	C:80, T:20	Negative
RB2	Uni-	1yr 8 mo	c.C1363T (14ex)	C:74, T:26	Negative
RB3	Bi-	3 weeks	c.2326delC (23ex)	wt:80, del:20	Negative
RB4	Uni-	3 yr	c.C958T (10ex)	C:80, T:20	Negative
RB5	Uni-	3 mo	c.C751T (8ex)	C:84, T:16	Negative
RB6	Uni-	1 yr 8 mo	c.1215 + 1G-A (12ex)	G:87, A:13	Negative
RB7	Uni-	8 mo	c.C1735T (18ex)	C:79, T:21	Negative
RB8	No symptoms	No	c.887delT (9ex)	wt:85, del:15	Positive bilateral daughter

Conclusions: NGS is an efficient method for detecting low-level mosaic mutations in blood samples from RB patients. Clinically, RB1 mosaicism is variable, it can manifest as a bilateral or a unilateral form with early or late onset, or without disease, which make the diagnosis even more difficult.

405TiP Avelumab in newly diagnosed glioblastoma multiforme: The SEJ study

F.H. Jacques[1], G. Nicholas[2], I. Lorimer[3]

[1]Neurology, Clinique Neuro-Outaouais, Gatineau, QC, Canada, [2]Oncology, Ottawa Hospital General campus, Ottawa, ON, Canada, [3]Cancer Therapeutics Program, Ottawa Hospital Research Institute, Ottawa, ON, Canada

Background: Patients with Glioblastoma Multiforme (GBM) despite standard therapy have a dismal prognosis and thus represent a significant unmet medical need. GBM has well documented systemic and local immunosuppressive mechanisms to escape immune surveillance and grow. GBM tumor cells as well as the microglia within it have a high incidence of PD-L1 surface expression which makes it more susceptible to anti-PD-L1 antagonism and ADCC through avelumab therapy. Combination of avelumab with other anticancer therapies have been shown safe and perhaps synergistic. A clinical trial looking at adding avelumab to standard therapy in patients with GBM is therefore indicated.

Trial design: This is a single center, phase 2, open label, open-ended add-on, single dose study of 52 weeks duration in patients receiving standard therapy for newly diagnosed GBM. In total 30 patients who meet the entry criteria will be entered into the study within 3 weeks of finishing their last day of combined radiotherapy/temozolomide. Avelumab will be initiated concurrently with the initiation of the first 5 day, monthly cycle of temozolomide and continued for a total of 52 weeks. The study will consist of 3 different phases: Combination Phase a Monotherapy Phase and an Extended Safety Follow-up Phase.

Clinical trial identification: NCT03047473.

Legal entity responsible for the study: Clinique Neuro-Outaouais.

Funding: Study is funded by an unrestricted grant from Merck Serono.

Disclosure: All authors have declared no conflicts of interest.

406TiP Phase I/IIa study of concomitant radiotherapy with olaparib and temozolomide in unresectable high-grade gliomas patients: OLA-TMZ-RTE-01

Background: The Stupp protocol is the standard treatment of glioblastoma multiform (GBM). The non-dividing nature of normal brain cells is an opportunity to enhance the therapeutic ratio by combining radiation with inhibitors of replication-specific DNA repair pathways such PARP inhibitors as olaparib. PARP inhibition also increases cellular sensitivity to radiation and may be higher in tumor than in normal tissue. Progress in technical imaging and intensity-modulated-radiotherapy (IMRT) techniques provide new possibilities for sparing healthy tissues. We propose a phase 1/2a trial to assess the safety and efficacy of Olaparib combined with TMZ plus fractionated IMRT as a first line treatment in unresectable GBM patients (pts).

Trial design: Based on the Stupp phase 2 design, 2 treatment periods are considered. The radiotherapy (RT) period occurs after the last surgery: the pt receives IMRT, daily TMZ during IMRT and olaparib, given at the same dose until 4 weeks after the end of IMRT. For the maintenance (MT) period, the pt receives TMZ (days 1-5 every 28 days, for 6 cycles) plus olaparib (at the MT dose level up to disease progression or unacceptable toxicity). The phase 1 includes 2 consecutive dose escalations to separate both periods for DLT (Dose Limiting Toxicities) assessment. First 15 pts will receive olaparib only during the RT period to determine the MTD1 (Maximum-Tolerated Dose) among 7 dose levels, by assessing DLT on this period. Next 15 pts will all receive MTD1 during the RT period, and a new dose-escalation will determine MTD2 ($\leq$MTD1) during the MT period, assessing DLT from the first 2 cycles. For phase 2a, IMRT and TMZ are given according to the Stupp protocol. Olaparib is given at the MTD1 during the RT period and at the MTD2 during the MT period. Brain disease is assessed using RANO criteria. The trial includes ancillary studies on tumor biopsies, spectro-MRI and neurocognitive and quality of life assessment. Up to 79 pts will be enrolled: 30 pts in the phase 1 and 49 pts in the phase 2a (Case&Morgan two-stage design). This trial (NCT03212742) is granted by the French Cancer Institute and Health Ministry (PHRC-K15-135) and Astra-Zeneca for olaparib provision. First pt was enrolled on Oct 2017.

Background: Activation of the MAPK pathway via the BRAF V600 mutation has been observed in several tumors. This mutation is observed in a subset of pediatric brain tumors, including HGG and LGG for which limited therapeutic options are currently available. In a phase I/II clinical trial of pediatric patients (pts) with recurrent or refractory BRAF V600–mutant relapsed tumors, the BRAF inhibitor dabrafenib demonstrated its efficacy, including complete responses, in pediatric pts with HGG and LGG. As the combination of dabrafenib plus the MEK inhibitor trametinib has resulted in improved efficacy in multiple adult BRAF V600–mutant tumors, including melanoma and non-small cell lung cancer, this combination warrants further investigation in pediatric pts with gliomas bearing the same mutation.

Trial design: This global, open-label, phase II study (NCT02684058) will evaluate the anti-tumor activity of the combination of dabrafenib plus trametinib in 2 pediatric glioma cohorts recruiting from up to 70 sites across 17 countries. The single-arm BRAF V600–mutated HGG cohort of approximately 40 pts (aged $\geq$ 6 and $<$ 18 y) with relapsed or refractory disease will be treated with dabrafenib twice daily (BID) plus trametinib once daily (QD) based on age and weight. The primary endpoint for this cohort is overall response rate (ORR) per investigator's assessment according to Response Assessment in Neuro-Oncology (RANO) criteria. The BRAF V600–mutated LGG cohort of approximately 102 chemotherapy-naive pts (aged $\geq$ 6 and $<$ 18 y) with unresectable disease will be randomized 2:1 to receive either dabrafenib (BID) plus trametinib (QD) or carboplatin plus vincristine. The primary endpoint for the LGG cohort is ORR per independent assessment according to RANO criteria. Pt crossover from the chemotherapy arm to the experimental arm will be allowed after independent confirmation of radiologic disease progression. Key secondary endpoints for both cohorts include duration of response, progression-free survival, time to response, clinical benefit rate, overall survival, and safety/tolerability.

Clinical trial identification: NCT02684058.

419P Double blind concordance study of colo-rectal cancer treatment recommendations between artificial intelligence advisory programme watson for oncology (WFO) & multidisciplinary tumor board (MDT)

S. Sampige Prasannakumar[1], M. Sepulveda[2], C. Rohit Kumar[1], A. Rauthan[3], P. Patil[4], Y. Ramya[1]

[1]Surgical Oncology, Manipal Comprehensive Cancer Centre Manipal Hospital, Bangalore, India, [2]Clinical Research, IBM Health, Florida, NY, USA, [3]Medical Oncology, Manipal Comprehensive Cancer Center Manipal Hospital, Bangalore, India, [4]Medical Oncology, Manipal Comprehensive Cancer Center Manipal Hospital, Bangalore, India

Background: In this era of personalized medicine there is outburst of information and plethora of new treatment strategy. Data Tsunami overwhelms human cognitive capacity. Artificial intelligence is being used for information-intensive decision making. We present here an experience with this technology in cancer treatment decision support.

Methods: WFO was used to obtain treatment recommendations of cases that were previously evaluated by a MDT at a major cancer center in India between 2014 and 2016. A comparison was made between the oncology advisor's recommended treatment and that of the tumor board. Treatment concordance was defined as a tumor board recommendation falling into the oncology advisor's categories of "recommended" or "for consideration" treatments. All non-concordant cases (n = 33) were re-presented to the tumor board in a blinded fashion in 2016 to address time of evaluation differences between the tumor board and the oncology advisor. Results are presented as the proportion of concordant cases.

Results: From 2014-2016 we had 126 colon cancers & 124 rectal cancers. Of colon 62 & 64 were non-metastatic & metastatic respectively, whereas in rectal cancer it was 93 & 31 respectively. Mean age of the patient was 55 years. The overall concordance at first analysis was 87%. At sub group analysis in colon (85% vs 77%) & rectum (97%vs81%) & Overall (92% vs78%) non-metastatic cases had higher concordance level than metastatic cases (Table1). There were 31 cases which were non-concordant that were re-challenged to MDT. After second review the overall concordance level improved from 87% to 95%.

Conclusions: Artificial intelligence treatment recommendations with Watson for Oncology showed high levels of concordance with a multidisciplinary tumor board. This cognitive computing technology holds much promise in helping oncologists make information intensive, evidence based treatment decisions.These findings are encouraging for the use of this technology. Additional investigations are needed to understand concordance in settings where cancer expertise and treatment options may differ.

[1]Comprehensive Cancer Center, Helsinki University Central Hospital, Helsinki, Finland, [2]DITEP, Gustave Roussy Institut de Cancérologie, Villejuif, France, [3]Trial Unit, Helsinki University Central Hospital, Helsinki, Finland, [4]Molecular Therapeutics Research Unit, Department of Medical Oncology, Vall d'Hebron University Hospital, Barcelona, Spain, [5]Early Phase Trials Unit, Institute Bergonié, Bordeaux, France, [6]Academic Department of Oncology, UCL Cancer Institute, University College London, London, UK, [7]Department of Oncology, Phase 1 Unit, Copenhagen University Hospital - Rigshospitalet, Copenhagen, Denmark, [8]SCRI, Sarah Cannon Research Institute SCRI UK, London, UK, [9]Orion Corporation, Orion Pharma, Espoo, Finland, [10]Early Drug Development, Vall d'Hebron University Hospital, Barcelona, Spain

Background: ODM-203 is an orally available small molecule with balanced inhibitory effects on FGFR 1-4 and VEGFR 1-3 subtypes. We present here results of the phase 1/2 KIDES study.

Methods: The KIDES study is an open-label, non-randomized, multicentre phase 1/2 first-in-man study of ODM-203 in patients with advanced solid tumors. In the Part 1 dose escalation (3 + 3), ODM-203 was evaluated in 31 patients between 50-800mg daily with food to identify the maximum tolerated dose (MTD). Part 2 expansion included 53 patients to evaluate a new formulation, the recommended phase 2 dose and the dose schedule. Patients continued ODM-203 treatment until disease progression or dose limiting toxicity.

Results: 84 patients (median 57 years, range 28-80), with the most common tumor types being cholangio, breast, colorectal, endometrium, ovarian and thyroid carcinoma, were included, with most patients in Part 2 having FGFR alterations. Six patients remain on treatment. In the dose-escalation Part 1, 800mg/day was considered the highest dose that could not be tolerated although MTD was not formally identified. This was because of a general adverse event (AE) burden and increased bilirubin in most patients. Bilirubin increase was due to UGT1A1 inhibition by ODM-203 and resolved in all cases upon dose reduction/interruption. In Part 2, the optimal dose was determined to be 400mg/day with food. Most AE's were grade 1-2, the most common ones being increased bilirubin (76%), fatigue and asthenia (68%), diarrhoea (60%), stomatitis (41%), arthralgia (41%) and decreased apetite (41%). Most common grade >3 AE's were bilirubin increase (45%), fatigue (6%) and diarrhoea (6%). There were 6 (9%) partial responses (PR) and additionally 24 (35%) patients achieved target lesion reduction. In total, 30 (44%) patients had disease stabilisation (SD) with median of 21 weeks on the study. The clinical benefit rate (CR + PR + SD) was 36/69 (52%).

Conclusions: Patients treated with ODM-203, especially those with FGFR-aberrant or VEGFR sensitive tumours, had preliminary promising anti-tumour response and on-target effects.

Clinical trial identification: NCT02264418.

Background: DNA damage caused by TMZ can sensitize tumors to the effects of PARP inhibitors. Pamiparib is a selective PARP1/2 inhibitor with potent PARP trapping that can cross the blood-brain barrier and has shown synergistic cytotoxicity with TMZ in nonclinical experiments. In Phase 1 studies (NCT02361723; NCT03333915), pamiparib was generally well tolerated and showed preliminary antitumor activity; single-agent RP2D was defined as 60 mg PO BID.

Methods: This dose-escalation/expansion study (NCT03150810) is enrolling pts using a modified 3 + 3 design to establish the safety and MTD of pamiparib plus TMZ. During dose escalation, pts receive pamiparib 60 mg PO BID plus escalating doses of TMZ QD on Days 1–7 (Arm A) or continuously (Arm B) for each 28-day cycle. The primary endpoint is safety/tolerability, including estimation of MTD and RP2D. Key secondary endpoints are PK profiles of TMZ and pamiparib and antitumor activity (RECIST v1.1) of combination treatment; biomarker (eg, gBRCA) assessment is exploratory.

Results: As of 16 Feb 2018, 16 pts (Arm A, n = 4, 40 mg TMZ; n = 4, 80 mg TMZ; n = 3, 120 mg TMZ; Arm B, n = 4, 20 mg TMZ; n = 1, 40 mg TMZ) with a median age of 69.5 yr (range 50–85) have enrolled; 8 remain on treatment. Prostate and small cell lung cancers (n = 4 each) were the most common tumors; most pts (n = 14) had received ≥3 prior treatments. Most common pamiparib-related AEs were nausea (n = 6), and nausea and thrombocytopenia (n = 5 each) for TMZ. In Arm A, 2 pts at 120 mg TMZ reported a DLT of grade 4 neutropenia >7 days. Neutropenia and thrombocytopenia (n = 4 each) were the only ≥grade 3 AEs occurring in > 2 pts. No AE led to treatment discontinuation or death. Plasma exposure for pamiparib and TMZ were consistent with single-agent trials. One pt with peritoneal cancer in Arm A had a 99.5% decrease in CA125 by wk 12. In the 7 pts with ≥1 post-baseline tumor assessment, 2 pts in Arm A (kidney, n = 1; SCLC, n = 1) achieved unconfirmed PRs.

Conclusions: In pts with solid tumors, pamiparib 60 mg PO BID combined with pulsed or continuous flat dosed TMZ showed preliminary antitumor activity and was generally well tolerated with the expected toxicity of bone marrow suppression.

Clinical trial identification: NCT03150810.

422P First-in-human study of the monopolar spindle 1 (Mps1) kinase inhibitor BAY 1161909 in combination with paclitaxel in subjects with advanced malignancies

P. Lorusso[1], S.P. Chawla[2], J. Bendell[3], A.F. Shields[4], G. Shapiro[5], P. Rajagopalan[6], C. Cyris[7], I. Bruns[8], J. Mei[8], F. Souza[8], D. Rasco[9], J.P. Eder[1], A.W. Tolcher[10]

[1]Yale Cancer Center, Yale University School of Medicine, New Haven, CT, USA, [2]Oncology, Sarcoma Oncology Research Center, Santa Monica, CA, USA, [3]GI Oncology Research, Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN, USA, [4]Department of Medicine, Karmanos Cancer Institute, Detroit, MI, USA, [5]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, USA, [6]Clinical Pharmacology, Bayer HealthCare Pharmaceuticals Inc, New York, NY, USA, [7]Clinical Statistics, Bayer HealthCare Pharmaceuticals Inc, New York, NY, USA, [8]Translational Medicine Oncology, Bayer HealthCare Pharmaceuticals Inc, New York, NY, USA, [9]Medical Oncology, START, San Antonio, TX, USA, [10]Clinical Research, South Texas Accelerated Research Therapeutics (START); NEXT OncologyTM, San Antonio, TX, USA

Background: Mps1 is a serine threonine kinase and a core component of the spindle assembly checkpoint. Two potent, selective, and orally active Mps1 inhibitors – BAY 1161909 (BAY; lead compound) and BAY 1217389 – have shown improved efficacy in combination with paclitaxel (Pac) in xenograft models, including Pac-insensitive and acquired resistance models. We report here on the safety, tolerability, and maximum tolerated dose (MTD) of the lead compound BAY in combination with Pac.

Methods: Subjects with advanced malignancies (solid tumors) and refractory to standard therapy were eligible. BAY was administered twice daily (BID) in a 2-days on/5-days off dosing schedule in combination with weekly IV Pac starting at 75 mg/m^2 (Pac-75), and then at 90 mg/m^2 (Pac-90). The dose of BAY was doubled in sequential cohorts until the MTD was reached. Pharmacokinetic analyses were done to determine exposure of BAY and Pac.

Results: A total of 37 patients were enrolled and treated in the Pac-75 cohort and 32 in the Pac-90 cohort, with median age 60 in both groups. Breast, NSCLC, and ovarian adenocarcinomas were the most common cancers. The majority of patients (53.6%) had >3 prior lines of anticancer therapy. BAY exposure generally increased in a dose proportional manner and did not affect Pac exposure. In BAY plus Pac-75 cohorts, 16% of patients had grade (G) 3 BAY-related adverse events (AEs), with no G4/G5 events. In the Pac-90 cohorts, 28% of patients had G3 events, one G4 and no G5 BAY-related events. The most common treatment emergent AEs were fatigue (44.9%), anemia (39.1%), alopecia (37.7%), diarrhea (34.8%) and nausea (33.3%). In 35 evaluable patients from the BAY plus Pac-75 group, there were 5 (14%) PRs, 11 SD,17 PD, and 2 patients not determined. In 28 evaluable patients in the BAY plus Pac-90 group, there were 4 (14%) PRs, 13 SD, and 11 PD. Six of 9 patients with a PR had prior Pac. One dose limiting toxicity (ALT increased) was reported in the BAY 180 mg BID plus Pac-90 dose cohort. The MTD was determined as BAY 90 mg BID plus Pac-90.

Conclusions: BAY in combination with Pac demonstrated good tolerability with manageable AEs and preliminary evidence of efficacy. Study with the follow-up compound BAY 1217389 is ongoing.

Clinical trial identification: NCT02138812.

423P Phase I study of IDO1 inhibitor navoximod (GDC-0919) as monotherapy and in combination with atezolizumab in Japanese patients with advanced solid tumors

N. Yamamoto[1], Y. Fujiwara[1], S. Kondo[1], S. Iwasa[1], K. Yonemori[1], A. Shimomura[1], S. Kitano[1], T. Shimizu[1], T. Koyama[1], T. Ebata[1], N. Sato[2], K. Nakai[3], M. Inatani[4], K. Tamura[1]

[1]Department of Experimental Therapeutics, National Cancer Center Hospital, Tokyo, Japan, [2]Clinical Study Management Department, Chugai Pharmaceutical Co., Ltd., Tokyo, Japan, [3]Clinical Pharmacology Department, Chugai Pharmaceutical Co., Ltd., Tokyo, Japan, [4]Clinical Science & Strategy Department, Chugai Pharmaceutical Co., Ltd., Tokyo, Japan

Background: Navoximod is a small molecule inhibitor of indoleamine-2,3-dioxygenase 1 (IDO1) which catalyzes the oxidation of L-tryptophan (Trp) into kynurenine (Kyn). This study aimed to investigate maximum tolerated dose (MTD), safety, pharmacokinetics (PK) and pharmacodynamics of navoximod as monotherapy and in combination with atezolizumab, an anti-PD-L1 antibody, in Japanese patients (pts) with advanced solid tumors.

Methods: Phase 1, open-label, 3 + 3 dose-escalation study. Primary endpoints were safety, tolerability, and PK. Pts received navoximod (400, 600 or 1000 mg orally twice daily [BID], for 21 days/cycle) monotherapy (Stage 1) or navoximod (200, 400, 600 or 1000 mg orally BID, for 21 days/cycle) in combination with atezolizumab (1200 mg IV, every 21 days) (Stage 2).

Results: Twenty pts were enrolled in the 400 mg (n = 3), 600 mg (n = 4) and 1000 mg (n = 3) cohorts of Stage 1, and in the 200 mg (n = 3), 400 mg (n = 3), 600 mg (n = 3) and 1000 mg (n = 1) cohorts of Stage 2. Across all cohorts, no DLT was observed and MTD was not reached in either stages. In Stage 1, treatment related adverse events (TRAEs) of any grade occurring in ≥ 20% of pts were chromaturia (50%) and

maculopapular rash (20%). Grade ≥ 3 TRAEs were reported in 2 pts (20%), including maculopapular rash and lipase increased. In Stage 2, TRAEs ≥ 20% were fatigue (20%), chromaturia (60%), decreased appetite (40%), hyponatremia (20%), AST increased (20%), ALT increased (20%) and lymphopenia (20%). Grade ≥ 3 TRAEs were reported in 3 pts (30%), including hyponatremia, AST increased, ALT increased, lymphopenia and neutropenia. C_{max} and AUC of navoximod as monotherapy were dose-proportional from 400 to 1000 mg and PK profile was similar in combination with atezolizumab. Reduction of Kyn in plasma was observed in accordance with concentration of navoximod. Stable disease (SD) was observed in 5 pts including 2 pts with SD > 4months in Stage 1, and in 8 pts including 4 pts with SD > 4months in Stage 2, respectively.

Conclusions: Navoximod as monotherapy and in combination with atezolizumab was generally well-tolerated in Japanese pts with linear PK and evidence of systemic inhibition of IDO1.

Clinical trial identification: JapicCTI-163330.

425P SPIRE: A phase Ib/ randomised IIa open label clinical trial combining guadecitabine with cisplatin and gemcitabine chemotherapy for solid malignancies including bladder cancer

S.J. Crabb[1], S.J. Danson[2], D. Dunkley[3], M. Kalevras[3], A. Whitehead[3], S. Hill[3], K. Fines[3], C. Robb[3], J. Bennett[1], L. Ksiazek[1], S.L. Brown[2], L. Evans[4], M. Serra[5], K. Jones[6], C. McDowell[7], J.W. Catto[8], R. Huddart[5], G. Griffiths[3]

[1]Southampton Experimental Cancer Medicine Centre, University of Southampton, Southampton, UK, [2]Sheffield Experimental Cancer Medicine Centre, University of Sheffield, Sheffield, UK, [3]Southampton Clinical Trials Unit, University of Southampton, Southampton, UK, [4]Department of Oncology, Weston Park Hospital, Sheffield, UK, [5]Division of Radiotherapy and Imaging, Institute of Cancer Research and Royal Marsden, Sutton, UK, [6]Bob Champion Unit, Institute of Cancer Research and Royal Marsden Hospital, Sutton, UK, [7]Combinations Alliance, Cancer Research UK, London, UK, [8]Academic Urology Unit, The Medical School, University of Sheffield, Sheffield, UK

Background: Cisplatin resistance derives, in part, via tumour suppressor gene promotor methylation. In Vitro this reverses on co-administration of a DNA hypomethylating agent. Guadecitabine is a DNA methyltransferase inhibitor developed for optimised delivery of the active metabolite decitabine. SPIRE is an ECMC Combinations Alliance phase Ib/IIa clinical trial to establish a safe dose and schedule to combine guadecitabine with cisplatin/gemcitabine chemotherapy (GC). We report the phase Ib component.

Methods: Patients (pts) with incurable metastatic solid cancer, received GC (G: 1000 mg/m^2, IV, day (D) 8 + 15; C: 70 mg/m^2, IV, D8), and guadecitabine (SC, D1-5) for up to 6 x 21D cycles. Maximum tolerated dose (MTD) was determined with predefined criteria for dose limiting toxicity (DLT; CTCAE v4.03) in cohorts of 3-6 (rolling 6 design). The recommended phase II dose/schedule (RP2D) was expanded to include 6 bladder cancer pts. Subsequent cohorts incorporated GCSF (filgrastim, 300 µg SC, D15-21) if DLTs occurred due to neutropenia. Primary endpoint: guadecitabine MTD. Secondary endpoints: pharmacodynamic (PD) and pharmacokinetic (PK) parameters. Coordination: CRUK Southampton Clinical Trials Unit. Sponsor: University Hospital Southampton NHS Foundation Trust. Funding: Cancer Research UK (C9317/A19903) and Astex Pharmaceuticals.

Results: DLT occurred in 3 of 4 pts (thromboembolism; G4 neutropenia ≥7 days; febrile neutropenia) in cohort 1 (guadecitabine 20 mg/m^2 D1-5), in 1 of 8 pts (febrile neutropenia) in cohort 2 (guadecitabine 20 mg/m^2 D1-5 + GCSF) and 3 of 5 pts (febrile neutropenia; G3 diarrhoea + hypokalaemia; G4 neutropenia/thrombocytopenia ≥7 days + G3 tooth infection) in cohort 3 (guadecitabine 30 mg/m^2 D1-5 + GCSF). PD endpoints of mean plasma LINE-1 methylation depletion and haemoglobin F re-expression were consistent with guadecitabine target effect and PK parameters consistent with guadecitabine single agent data.

Conclusions: Guadecitabine 20 mg/m^2, day 1-5, with GCSF prophylaxis, is the RP2D in combination with GC. A randomised dose expansion is proceeding as neoadjuvant treatment for bladder cancer.

426P Zirconium-89 (89Zr)-labeled bispecific T-cell engager (BiTE®) AMG 211 PET imaging to determine AMG 211 biodistribution in patients with gastrointestinal (GI) adenocarcinomas

K.L. Moek[1], S.J.H. Waaijer[1], I.C. Kok[1], F.V. Suurs[1], A. Brouwers[2], C.W. Menke-van der Houven van Oordt[3], T.T. Wind[1], J.A. Gietema[1], C.P. Schroder[1], S.V.K. Mahesh[2], A. Jorritsma-Smit[4], M.N. Lub-De Hooge[4], R.S.N. Fehrmann[1], D.J. de Groot[1], E.G.E. de Vries[1]

[1]Medical Oncology, University Medical Center Groningen, Groningen, Netherlands, [2]Radiology, Nuclear Medicine and Molecular Imaging, University Medical Center Groningen, Groningen, Netherlands, [3]Medical Oncology, VUMC Cancer Center Amsterdam, Amsterdam, Netherlands, [4]Clinical Pharmacy and Pharmacology, University Medical Center Groningen, Groningen, Netherlands

Background: AMG 211 is a ~55 kDa BiTE® antibody construct directed against carcinoembryonic antigen (CEA, CEACAM5) on tumor cells and cluster of differentiation 3 (CD3) on cytotoxic T-cells. Biodistribution of bispecific antibodies in humans is largely unknown. Therefore, we performed a first-in-human feasibility study with ^{89}Zr-AMG 211 as PET tracer to explore AMG 211 biodistribution in normal and tumor tissues.

Methods: Nine patients with advanced GI adenocarcinomas underwent ^{89}Zr-AMG 211 PET imaging before (n = 7), during (n = 1) or before and during (n = 1) AMG 211 treatment. Before AMG 211 treatment, a fixed dose of 37 MBq 200 µg ^{89}Zr-AMG 211 alone (n = 2), or in combination with 1,800 µg (n = 4) or 4,800 µg (n = 2) cold AMG 211 was administered over 3 hours (h) followed by PET scans at 3, 6, and 24 h. ^{89}Zr-AMG 211 uptake was measured as standardized uptake value (SUV). ^{89}Zr-AMG 211 integrity in plasma and urine was analyzed with gel electrophoresis and binding of ^{89}Zr-AMG 211 to immune cells by counting Ficoll separated whole blood fractions.

Results: Before AMG 211 treatment, the optimal imaging dose was 200 µg ^{89}Zr-AMG 211 + 1,800 µg cold AMG 211. At 3 h the highest blood pool SUV_{mean} was 4.0, and tracer serum half-life was 3.3 h. Uptake in CD3-rich lymphoid tissues such as the spleen and bone marrow was SUV_{mean} 3.2 and 1.8, respectively. Uptake in these tissues decreased slower than in other normal tissues. ^{89}Zr-AMG 211 remained intact in plasma and was excreted predominantly via the kidneys in degraded forms. Of 43 visible tumor lesions, 37 were PET quantifiable, with a SUV_{max} of 4.0 (interquartile range 2.7 – 4.4) at 3 h using the optimal imaging dose. The maximum tracer uptake differed between tumor lesions 5-fold within and 9-fold between patients. During AMG 211 treatment (n = 2) more tracer was present in the blood pool, while tumor lesions were not visualized, possibly reflecting target saturation.

Conclusions: In this first-in-human study high specific ^{89}Zr-AMG 211 accumulation was observed in CD3-rich lymphoid tissues. In addition, a clear, inter- and intra-individual heterogeneous tumor uptake was seen.

427P Phase I study of AMG 211/MEDI-565 administered as continuous intravenous infusion (cIV) for relapsed/refractory gastrointestinal (GI) adenocarcinoma

K.L. Moek[1], W.M. Fiedler[2], J.C. von Einem[3], H.M. Verheul[4], T. Seufferlein[5], D.J. de Groot[1], V. Heinemann[3], M. Kebenko[2], C.W. Menke-van der Houven van Oordt[4], T.J. Ettrich[5], E. Rasmussen[6], P. Bogner[7], B. Sable[6], S. Stienen[7], E.G.E. de Vries[1]

[1]Medical Oncology, University Medical Center Groningen, Groningen, Netherlands, [2]Department of Internal Medicine II, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [3]Department of Medical Oncology and Comprehensive Cancer Center, University Hospital Grosshadern, LMU Munich, Munich, Germany, [4]Medical Oncology, Vrije University Medical Center (VUMC), Amsterdam, Netherlands, [5]Department of Internal Medicine I, University of Ulm, Ulm, Germany, [6]Medical Oncology, Amgen Inc, Thousand Oaks, CA, USA, [7]Medical Oncology, Amgen Research (Munich) GmbH, Munich, Germany

Background: AMG 211 is a bispecific CEA-directed CD3 T-cell engager (BiTE$^{(R)}$) that inhibits growth of CEA-expressing cancer cells in various cancer models. It was explored as intermittent 3-hour infusion for 5 subsequent days in a Ph 1 study (Pishvaian et al, 2016). The present study used cIV administration suggesting an improved therapeutic index versus an intermittent infusion by reduction of adverse events attributable to high C_{max} and steady state exposure levels maintained above a threshold required for anti-tumor activity.

Methods: To evaluate safety, pharmacokinetics (PK), pharmacodynamics (PD), and efficacy, patients (pts) with relapsed/refractory GI adenocarcinomas were treated with cIV AMG 211 for 7, 14 or 28 days at 0.2-12.8 mg/day in repeated cycles until confirmed

disease progression, occurrence of a dose-limiting toxicity (DLT) or discontinuation for other reasons. A Bayesian logistic regression model was intended to guide dose escalation after a first DLT.

Results: 44 pts (median age 64.5 (range 57, 70), Karnofsky > 70%) were dosed in up to 7 cycles (median 2) in 8 dose cohorts without observing a DLT. The majority (N = 32) were pts with CRC, 6 had pancreatic cancer, 4 cholangiocarcinoma and one each esophageal and appendix adenocarcinoma. AMG 211 was discontinued due to disease progression in 33 pts (73%), adverse event in 7 pts (16%), pts request and due to other reason in 2 pts (4%) each. Adverse events reported in > 20% of pts were fatigue (54%), nausea, abdominal pain, pyrexia (39% each) and diarrhea (32%). PK steady-state concentrations of AMG 211 were reached within 2 days of dosing and maintained throughout the treatment. In general, exposure, assessed by Cmax, Css, and AUC, was increasing with dose. Initial changes in inflammatory and tumor markers were seen. The study was discontinued after observation of anti-AMG 211 antibodies in all pts treated at high doses of > 3.2 mg and drop in exposure with high titers.

Conclusions: PD markers confirmed BiTE® mechanism of action. However, despite an acceptable safety profile immunogenicity leading to insufficient exposure for objective responses precluded the definition of a therapeutic window for AMG 211.

Clinical trial identification: NCT02291614.

428P Interim results from a phase I trial of SL-801: A novel XPO-1 inhibitor, in patients with advanced solid tumors

T.M. Bauer[1], M. Barve[2], E.G. Chiorean[3], P. Lorusso[4], K. Courtney[5], D. Qi[6], A. Olguin[7], J. Bullington[6], M. Sardone[8], V. Dunn[8], S. Shemesh[8], J. Chen[7], C. Brooks[7], J. Wang[9]

[1]Oncology, Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN, USA, [2]Oncology, Mary Crowley Cancer Research, Dallas, TX, USA, [3]Oncology, University of Washington, Seattle, WA, USA, [4]Yale Cancer Center, Yale University School of Medicine, New Haven, CT, USA, [5]Medical Oncology, UT Southwestern Medical Center, Dallas, TX, USA, [6]Clinical, Stemline Therapeutics, New York, NY, USA, [7]R&D, Stemline Therapeutics, New York, NY, USA, [8]Clinical Operations, Stemline Therapeutics, New York, NY, USA, [9]Drug Development Unit, Sarah Cannon Research Institute at Florida Cancer Specialists, Sarasota, FL, USA

Background: SL-801 is a novel, oral, small molecule reversible inhibitor of Exportin-1 (XPO-1), a critical nuclear export protein overexpressed in many cancers. SL-801 has demonstrated potent in vitro and in vivo anti-tumor activity against a broad range of hematologic and solid cancers. SL-801's reversible inhibition of XPO-1 may translate to selective activity and potential safety benefits. Interim results from the dose-escalation study are reported.

Methods: STML-801-0115 is a first-in-human, multicenter Phase 1 3x3 dose escalation study in patients with localized unresectable, or metastatic solid tumors resistant to or relapsed following standard therapy. Objectives are to evaluate safety, tolerability, identify maximum tolerated dose (MTD) or optimal dose/regimen, and assess pharmacokinetics, pharmacodynamics, and preliminary anti-tumor activity. SL-801 is orally administered on days 1-4 and 8-11 of a 21-day cycle. Starting dose was 5 mg; Currently enrolling 60 mg (escalation ongoing).

Results: As of 4/27/18, 35 patients received SL-801 (median age 64 years [range: 39-76, 18 females, range: 1-11 prior therapies; 69% ≥3rd line). No dose limiting toxicity (DLT) has been identified, and a MTD has not been reached. Median follow-up was 1.4 months (range: 0.2-10.8). Dose-dependent increases in C_{max} and AUC have been observed. The most frequent treatment-related grade 1-2 adverse events (TRAEs) were nausea (46%), vomiting (34%), fatigue (29%), decreased appetite (20%), and diarrhea (17%). Grade 3 TRAEs included nausea (n = 3; 40, 45, 50 mg), vomiting (n = 1; 45 mg), diarrhea (n = 2; 10, 50 mg), acute renal injury (n = 1; 30 mg), and neutropenia (n = 1; 10 mg). No grade 4 or 5 TRAEs reported. Eight patients (23%) had stable disease (SD) and remained on study for 3-15+ cycles. Six patients, with mucinous adenocarcinoma, GE junction, colon, neuroendocrine, basal cell, and breast cancer, had SD for ≥2.5 months; notably, the basal cell carcinoma patient had a SD response >9 months. Radiographic tumor shrinkage >10% noted in 3 patients.

Conclusions: SL-801 appears to be well tolerated in advanced solid tumor patients, and to date 23% of heavily pre-treated patients have achieved SD as best response. Enrollment and dose escalation continue.

Clinical trial identification: NCT02667873.

429P NEO2734: A novel potent oral dual BET and P300/CBP inhibitor

F. Giles[1], M. Witcher[2], B. Brown[3]

[1]Developmental Therapeutics, DTC, Chicago, IL, USA, [2]Oncology, McGill University, Montreal, QC, Canada, [3]Oncology, NEOMED Therapeutics 1 Inc, Montreal, QC, Canada

Background: The Bromodomain (BRD) and Extra-Terminal domain (BET) family of proteins are key regulators of epigenetic control. Modulation of the BET family is a developmental therapeutics priority. Cyclic AMP response element binding protein (CREB)-binding protein (CBP) and E1A interacting protein of 300 kDa (EP300 or P300) are highly homologous BRD-containing transcriptional co-activators and are validated oncology targets. We have developed a series of potent dual inhibititors of BET-CBP/P300 with NEO2734 and NEO1132 as lead clinical candidates.

Methods: NEO2734 was profiled against the BET inhibitor iBET762 in cellular assays and in multiple human cancer xenograft models including castrate resistant prostate cancer (CRPC) (Vcap) and colon cancer (MC38).

Results: NEO2734 antiproliferative activity against a variety of solid tumor cell lines (Table). In a MDA-MB-231 Triple negative breast cancer cell line NEO2734 was more efficient at killing the cancer cells (85%) than a range of non-dual BET inhibitors which killed up to 50% of the cancer cells. NEO2734 has major activity at 10mg/kg (p.o.) in both CRPC and a colon cancer xenograft model whereas iBET762 has minimal activity at 30mg/kg (p.o.) both dosed once daily for 18 days. In the CRPC (Vcap) xenograft, mice were treated by oral gavage with NEO2734 (10mg/kg, and 15mg/kg) and the reference compound iBET762 (30mg/kg) for 18 days. In this model, NEO2734 led to potent tumor regression in a dose dependent manner. Much weaker activity was observed for iBET-762 at either 30 mg/kg. The antitumor activity correlated well with the reduction of PSA. The colon cancer xenograft was carried out in Syngeneic mice and the activity was compared with iBET762, anti-CTLA4 and anti-PDL1. NEO2734 was active at 10mg/kg (p.o.), as seen with the anti-PDL1 and superior to the anti-CTLA4 and iBET762.

Table: 429P

Cell line	Tissue Type	IC50 (μM) (72h)		
		NEO2734	iBET762	Cisplatin

430P Phase I study: Safety and tolerability of varlitinib (VAR) in combination with oxaliplatin and capecitabine (COX) or oxaliplatin and 5-FU (FOL) in advanced solid tumours

A. Seet[1], S.P. Choo[2], D.W.M. Tai[3], Y.C.J. Lam[1], W.T. Teng[4], C. Lim[5], T.K.H. Lim[6], I.B. Tan[3], E. Petricoin[7], M. Ng[8]

[1]Medical Oncology, National Cancer Centre Singapore, Singapore, [2]Medical Oncology, National Cancer Center, Singapore, [3]Division of Medical Oncology, National Cancer Centre Singapore, [4]CTE, National Cancer Centre Singapore, [5]Biostatistics, CTE, National Cancer Centre Singapore, Singapore, [6]Department of Pathology, Singapore General Hospital, Singapore, [7]Applied Proteomics and Molecular Medicine, Institute of Biomedical Innovation, George Mason University, Manassas, VA, USA, [8]Division of Medical Oncology, National Cancer Centre (NCC), Singapore

Background: Varlitinib (VAR, ASLAN001) is a potent pan-HER oral tyrosine kinase inhibitor, with efficacy in EGFR mutant and HER2 over-expressing tumours. We evaluated the safety, tolerability and maximum tolerated dose (MTD) of VAR with CAPOX (COX) and mFolfox6 (FOL), in pts with advanced solid tumours.

Methods: Eligible pts had advanced solid tumours, ECOG performance status (PS) 0-1 and adequate organ function. Colorectal cancer (CRC) with RAS/RAF mutations were excluded. COX (Capecitabine 850mg/m^2 BID D1-D14 with oxaliplatin (OX) 130mg/m2 IV D1, Q21 days) or mFolfox6 (5-FU 400mg/m^2 IV bolus D1 and 2400mg/m^2 over 46 hrs with OX 85mg/m^2 IV D1, Leucovorin 400mg/m^2 IV D1, Q14 days) was given with VAR 200-400mg BID. Maximum 6 cycles COX or 9 cycles FOL, followed by VAR alone. Dose-limiting toxicity (DLT) period was 2 cycles.

Results: 30 pts were enrolled, 9 COX and 21 FOL arm. 15 (52%) CRC (all prior OX), 6 (21%) cholangiocarcinoma (CC), 3 (10%) gallbladder cancer and 6 (20%) others. Sex M/F 13/17, median age (range), PS, lines of prior chemo was 62yrs (36-71), 1(0-1) and 3.5(0-7) respectively. 28 pts were evaluable for MTD. MTD of VAR was 300mg/BID when given with FOL or COX.

Table: 430P

Dose	Pt enrolled/ evaluable	DLT
COX + VAR 400mg/BID	3/2	G3 Fatigue x2
COX + VAR 300mg/BID	6/6	G3 Fatigue
FOL + VAR 400mg/BID	4/4	G4 Transaminitis, G3 Raised Bilirubin
FOL + VAR 300mg/BID	11/9	G4 Encephalopathy, G3 Rash
FOL + VAR 200mg/BID	6/6	G3 Encephalopathy

Grade 3/4 AEs (occurring $\geq$ 5%): neutropenia 5 (17%), fatigue 3(10%), transaminitis 2(7%), diarrhoea 2(7%), febrile neutropenia 2(7%), transient metabolic encephalopathy 2(7%). Of 28 pts evaluable for response, 3 (11%) had PR and 16 (57%) SD. Disease control rate (PR+SD) for $\geq$ 12wks was 13 (46%). 5 (18%) had long PFS (223-645 days), comprising a gallbladder and CRC (both HER2-overexpressing, prior platinum), CC, bladder and CRC (prior OX and cetuximab). PK analysis did not show VAR accumulation. Plasma cell free DNA and HER pathway inhibition results will be presented later.

Conclusions: MTD for VAR with COX and FOL was 300mg/BID. Durable efficacy was seen in biliary cancers and CRC. ASLAN pharmaceuticals and the Singapore National Medical Research Council supported this study.

Clinical trial identification: NCT02435927.

431P Phase Ib study of safety and tolerability of selinexor in Asian patients with advanced solid cancers

V.Y.M. Heong[1], M.L. Goh[2], W.P. Yong[1], R.A. Soo[2], C.E. Chee[1], S. Raghav[1], B-C. Goh[1], S.C. Lee[1], J. Lim[1], A. Wong[1], D.S.P. Tan[3]

[1]Haematology-Oncology, National University Cancer Institute Singapore (NCIS), Singapore, [2]Haematology-Oncology, National University Hospital, Singapore, [3]Hematology-Oncology, National University Hospital (NUH), National University Cancer Institute, Singapore (NCIS), National University Hospital (NUH), Singapore, Singapore

Background: Selinexor (SEL) is a potent Exportin 1 inhibitor that forces nuclear retention and activation of multiple tumour suppressor proteins resulting in tumour cell death. The safety, tolerability and pharmacokinetics were previously evaluated in the Asian population with preliminary evidence suggesting improved outcomes in tumors driven by the PI3K/AKT and Raf1/MEK/ERK pathway, thymic, NPC and refractory lymphoma.

Methods: SEL was administered orally to patients with advance solid tumour malignancy with PI3K/AKT/RAS mutations, thymic carcinoma, NPC or double expressor/transformed B cell lymphoma or cutaneous T-cell lymphoma in a phase Ib dose expansion study. Patients (pts) were treated using the established RP2D for Asian population of 60mg twice a week for 2 weeks in a 21-day cycle. Response was evaluated every two cycles (RECIST v1.1).

Results: 47 pts (17 M/ 16 F) received 60mg oral SEL. 28, 1 and 4 pts with solid tumours with PI3K/AKT/RAS mutation, NPC and refractory lymphoma respectively were enrolled. 1 lung, 14 colorectal (CRC), 5 gynecological (1 cervix; 4 ovarian), 6 pancreatic and 2 breast respectively had mutations in the PI3K/AKT/RAS pathway. Median PFS for patients with solid malignancy with mutations in the PI3K/AKT/RAS pathway and refractory lymphoma was 40d and 81d respectively, with 1 lymphoma pt still ongoing after 441 days. Median PFS for pts with KRAS mutant CRC and pancreatic cancer was 42 and 31 days respectively. Dose reductions occurred in 7 (14.9%) pts and dose interruptions occurred in 29.8% of pts.

Conclusions: The RP2D dose of SEL is tolerable and safe in the Asian population. This dose will be used in the phase 2 study for further efficacy analysis.

432P Population pharmacokinetic analyses for talazoparib (TALA) in cancer patients

Y. Yu[1], C. Durairaj[1], H. Shi[2], D.D. Wang[1]

[1]Oncology, Pfizer, Inc., San Diego, CA, USA, [2]Oncology, Pfizer, Inc., Groton, CT, USA

Background: This analysis described the population pharmacokinetics (popPK) of TALA in cancer patients to identify significant covariates, evaluate the PK comparability of 4 x 0.25 mg capsules and 1 x 1 mg capsule as a 1 mg dose, and provide individual PK predictions for PK/pharmacodynamic analysis.

Methods: The data used for the analysis included 6207 PK observations from 490 patients treated with TALA in 4 studies (PRP-001, PRP-002, ABRAZO, and EMBRACA); the detailed PK data will be disclosed in the poster. TALA concentration-time data were analyzed by using a nonlinear mixed-effects modeling approach with NONMEM. Inclusion of covariates was conducted by visual inspection of ETAs vs covariates of interest followed by statistical test (stepwise covariate modeling).

Results: A 2-compartment model with 1st-order absorption best described the PK of TALA. The estimated population-typical value for apparent oral clearance (CL/F) was 6.37 L/h, apparent volume of central compartment (V_2/F) 162 L, and absorption rate constant (k_a) 1.22 1/hour. While food and formulation were significant covariates on k_a, they had no impact on bioavailability (F). Coadministration with strong P-gp inhibitors increased the relative bioavailability by 44.7%. Baseline creatinine clearance was significant for CL/F with a 14.4% and 37.1% decrease in CL/F for patients with mild and moderate renal impairment, respectively. Asian (23.7% higher CL/F), age (on CL/F), and baseline body weight (BWT) (on V_2/F) are significant covariates but not considered clinically relevant. Other covariates tested (sex, liver enzymes, acid-reducing agents) were not significant on relevant PK parameters.

Conclusions: The population PK model adequately described the observed PK data of TALA. Results suggest that no dose adjustment is necessary based on a patient's age, BWT, race, or sex or for patients with mild renal or hepatic impairment or for patients taking acid-reducing agents. TALA can be taken without regard of food. The PK of 1 x 1 mg capsule and 4 x 0.25 mg capsules as 1 mg dose was comparable. The dose of TALA should be reduced to 0.75 mg for patients taking strong P-gp inhibitors or for patients with moderate renal impairment.

Clinical trial identification: NCT01945775, NCT02034916, NCT01286987, NCT01399840.

433P An open-label, phase I, dose escalating study evaluating safety, tolerability and pharmacokinetics of oral administration of irinotecan in adult patients with solid tumors

J.A. Palshof[1], I. Kümler[1], P.G. Sørensen[1], B.V. Jensen[2], D.L. Nielsen[2],
[1]Department of Oncology, Herlev Hospital, Herlev, Denmark, [2]Department of Oncology, Herlev and Gentofte Hospital, Herlev, Denmark

Background: Oral drug formulations have several advantages compared to intravenous formulation. Apart from patient convenience and favorable pharmaco-economics they offer the possibility of frequent drug administration at home. In this study, we present a new oral irinotecan formulation designed as an enteric coated immediate release tablet which in pre-clinical studies has shown good exposure with low variability.

Methods: A phase I, dose escalating study to assess safety, tolerability, pharmacokinetics and efficacy of an oral irinotecan formulation and to establish the maximum tolerated dose (MTD). Each treatment cycle was once-daily irinotecan for 14 days followed by one week rest.

Results: 25 patients were included across four cohorts; 3 patients were included in cohort 1 (20 mg/m^2), 7 patients were included in cohort 2 (30 mg/m^2), 3 patients were included in cohort 3 (25 mg/m^2) and 12 patients were included in cohort 4 (21 mg/m^2). Median age was 67 years, 52% were performance status (PS) 0 while 48% were PS 1. Median number of prior therapies was 3 (range1 to 6). MTD was established at 21 mg/m^2. No responses were observed. Nine patients (36%) had stable disease (SD), lasting median 19 weeks (range 7-45 weeks). Among these 5 patients had previously received irinotecan.No grade 3/4 hematologic toxicities were reported. Totally 6 patients experienced grade 1/2 anemia, 3 patients had grade 1/2 leucopenia and 1 patient had grade 1 trombocytopenia. Most common non-hematological grade 1 and 2 adverse events were nausea, fatigue, diarrhea, vomiting and cholinergic syndrome. Grade 3 toxicities included diarrhea, fatigue, nausea and vomiting, no grade 4 events were reported. PK data showed consistent daily exposures during treatment at days 1 and 14 and no drug accumulation. SN-38 interpatient variability was in the same range as after infusion.

Conclusions: Oral irinotecan was generally well tolerated; side effects were manageable and similar in type to those observed with intravenous irinotecan. Hematological toxicities were few and only grade 1/2. In this heavily pre-treated patient population oral irinotecan demonstrated activity even among patients previously treated with irinotecan.

Clinical trial identification: EudraCT: 2014-005584-32; NCT03295084.

434P Biomarker-driven access to crizotinib in ALK, MET or ROS1 positive (+) malignancies in adults and children: The French national AcSé program

G. Vassal[1], N. Cozic[2], R. Houot[3], L. Brugières[4], T. Aparicio[5], J-Y. Blay[6], M. Perol[6], P. Brice[7], E. Meriaux[8], B. Geoerger[4], M.R. El Bejjani[9], S. Moalla[9], I. Bièche[10], S. Lantuejoul[11], C. Mahier Ait Oukhatar[12], N. Hoog Labouret[13], D. Moro-Sibilot[14]
[1]Clinical Research Department, Gustave Roussy Cancer Campus, Villejuif, France, [2]Oncostat, Gustave Roussy Cancer Campus, Villejuif, France, [3]Hematology, Hôpital Pontchaillou, Rennes, France, [4]Department of Pediatric and Adolescent Oncology, Gustave Roussy Cancer Campus Grand Paris, Villejuif, France, [5]Gastroenterology and Digestive Oncology, Hôpital Saint Louis, Paris, France, [6]Medical Oncology, Centre Léon Bérard, Lyon, France, [7]Hematology and Oncology, Hôpital St. Louis, Paris, France, [8]Medical Oncology, ICO Institut de Cancerologie de l'Ouest René Gauducheau, Saint-Herblain, France, [9]Radiology, Gustave Roussy Cancer Campus, Villejuif, France, [10]Pharmacogenomics Unit, Institut Curie, Paris, France, [11]Department of Biopathology, Centre Léon Bérard, Lyon, France, [12]Research and Development, UNICANCER, Paris, France, [13]Biology, Transfert and Innovation Department, Institut National du Cancer, Boulogne Billancourt, France, [14]Thoracic Pneumology, Hôpital Michallon, Grenoble, France

Background: Crizotinib (czb) was registered for ALK+ NSCLC in 2013 and recently for ROS1+ stage IV NSCLC. Czb targets (ALK, MET, ROS1) are also altered (translocation [tlc], amplification [amp], mutation [mut]) in a wide range of malignancies (malg.) in adults and children. To generate high evidenced-based knowledge and to prevent off-label use, the French National Cancer Institute (INCa) launched the AcSé Program: equal access to tumor molecular diagnosis including an exploratory phase II trial.

Methods: Biomarker testing was proposed to patients (pts) $\geq$ 1 year old (yo) with an advanced disease among more than 15 malg. known to harbor a czb target alteration. If not eligible for any other trial, pts may enter one of the 22 cohorts defined by the type of tumor and target. Tumor response was evaluated every 2 months (mo) using RECIST v1.1. The primary endpoint is the objective response rate (ORR) at 2 mo [complete + partial response]. A two-stage Simon design is applied to each cohort.

Results: From 08/2013 to 03/2018, 13179 pts from 186 centers have entered the biomarker program. Tumor alterations found in pts were: ALK tlc, mut, amp in 14/2070, 8/313, 10/1858; MET amp ($\geq$6 copies/diploid genome) in 395/7932 [251/4171 NSCLC, 60/1232 glioblastomas, 28/939 colon, 35/570 esogastric, 7/640 ovarian cancers]; MET mut in 102/2836; ROS1 tlc in 82/4755 [NSCLC, cholangiocarcinoma, inflammatory myofibroblastic tumor (IMT)]. Overall, 237 pts (median age, 57 [1–92]) received czb (adult 250 mg bid; child 280 mg/m^2 bid).

Table: 434P

Positive cohorts	Pts analyzed	CR/PR at 2 mo	ORR % [IC95%]
ALCL ALK tlc	24	12	54 [34-75]
NSCLC MET amp	25 37 28*	7 20 5**	28 [10 - 46] 54 [38 - 70]
ROS1 tlc MET mut			18 [4 -32]
Esogastric MET amp	9	3	33 [7-70]
IMT ALK tlc / ROS1 tlc	8	3	38 [9-76]

*including 4 pts wIth MET mut on other exon than exon 14
**pts with MET mut exon 14 195 grade $\geq$3 adverse events (AEs) or SAE were reported in 83/237 pts. Grade $\geq$3 AEs were: ALT increased (6%), neutropenia (5%) and lymphopenia (5%).

Conclusions: Czb displayed a wide antitumor activity in several MET, ALK and ROS1+ malg. Equal and safe access across France to molecular testing and targeted therapies outside their approved indication is feasible.

Clinical trial identification: NCT02034981.

435P Preliminary results of PROCLAIM-CX-072: The first-in-human, dose-finding trial of PD-L1 probody therapeutic CX-072 as monotherapy in patients (pts) with advanced solid tumors

V. Boni[1], J. Garcia-Corbacho[2], P.A. Ott[3], D.C. Cho[4], K.A. Autio[5], N. Uboha[6], A.I. Spira[7], R. Humphrey[8], M. Will[8], A. Naing[9], F. Thistlethwaite[10], E.G.E. de Vries[11], H-T. Arkenau[12]
[1]Medical Oncology, START Madrid-CIOCC HM Hospital Sanchinarro, Madrid, Spain, [2]Medical Oncology, Hospital Clinic Barcelona, Barcelona, Spain, [3]Center for Immuno-Oncology, Dana-Farber Cancer Institute, Boston, MA, USA, [4]Department of Medicine, New York University Langone Medical Center, New York, NY, USA, [5]Medical Oncology, Memorial Sloan Kettering Cancer Center, New York, NY, USA, [6]Carbone Cancer Center, University of Wisconsin, Madison, WI, USA, [7]Virginia Cancer Specialists, Fairfax, VA, USA, [8]Medical Oncology, CytomX Therapeutics, South San Francisco, CA, USA, [9]Oncology, MD Anderson Cancer Center, Houston, TX, USA, [10]Medical Oncology, The Christie NHS Foundation Trust, Manchester, UK, [11]Medical Oncology, University Medical Center Groningen, Groningen, Netherlands, [12]Sarah Cannon Research Institute SCRI UK, London, UK

Background: Antibodies (Abs) against programmed cell death ligand-1 (PD-L1) have improved survival in many types of cancer when used as monotherapy. However, anti–PD-L1 agents can be associated with high-grade immune-related adverse events (irAEs), particularly when used in combination with other anticancer agents. CX-072 is an anti–PD-L1 Probody™ therapeutic (Pb-Tx) designed to be preferentially activated by proteases in the tumor microenvironment and not in healthy tissue. Preclinically, Pb-Tx exhibited anticancer activity of the parent Ab with reduced toxicities in models of autoimmunity.

Methods: In parts A and A2 of the ongoing phase 1/2 Probody Clinical Assessment In Man (PROCLAIM)-CX-072 study (NCT03013491), CX-072 monotherapy is evaluated in a dose-escalation cohort of pts with advanced, heavily pretreated solid tumors. Part A2 required PD-L1-positive tumors and paired biopsies. Eligible pts were PD-1, PD-L1, and CTLA-4 inhibitor naive, with immunotherapy (IMT) unavailable as a standard of care. CX-072 is given every 14 days in cohorts of intravenous doses ranging from 0.03-30 mg/kg.

Results: As of April 20, 2018, part A/A2 had enrolled 37 pts. Pts had a median (range) of 3 (1-13) prior anticancer treatments. 14 (37.8%) pts are still on treatment at time of data cut. Median (range) time on treatment was 2.1 months (1-10). One DLT was observed (grade 3 febrile neutropenia; 3 mg/kg); MTD was not reached. Grade 3-4 treatment-related events were observed in 4 (10.8%) pts. irAEs with reversible grade 3 events occurred in 3 patients: thrombocytopenia, aminotransferase increases, and dyspnea. Two subjects discontinued CX-072 due to AEs. Across all dose levels, best response based on investigators' assessment in 23 evaluable pts included 2 partial response (thymoma, 3 mg/kg; TNBC, 10 mg/kg), 10 stable disease, and 11 progressive disease.

Conclusions: Preliminary data suggest that CX-072 demonstrates the characteristics of an antibody prodrug with antitumor activity and an acceptable safety profile in heavily pretreated pts with IMT-naive solid tumors. These data warrant further exploration of CX-072 as monotherapy and in combination with other anti-cancer agents.

Clinical trial identification: NCT03013491.

Background: Combination treatment with PD-1 + CTLA-4 checkpoint inhibitors shows improvement in breadth, depth, and durability of response, coupled with a disproportionate increase in immune-related adverse events (irAE). CX-072, a Probody™ therapeutic (Pb-Tx) directed against PD-L1, is designed to be preferentially activated by tumor-associated proteases and not in healthy tissue. Preclinically, anti–PD-1 Pb-Tx + anti–CTLA-4 showed comparable efficacy with improved safety compared to the non–Pb-Tx combination control. This dose-escalation cohort examines safety and tolerability of CX-072 (anti-PD-L1 Pb-Tx) + the CTLA-4 inhibitor ipi in pts with advanced solid tumors.

Methods: In this ongoing phase 1/2 study (NCT03013491), PD-1, PD-L1, and CTLA-4 inhibitor-naive pts receive combination CX-072 + ipi (part B1). Planned doses of CX-072 (0.3, 1, 3, or 10 mg/kg) are administered in combination with ipi (3, 6, or 10 mg/kg) every 21 days for 4 cycles, followed by CX-072 monotherapy every 14 days.

Results: As of April 20, 2018, part B1 enrolled 16 pts. Median age (range) and number of prior anticancer treatments was 60 years (28-70) and 3 (1-12), respectively. 6 pts were still on treatment at time of data cut. Median number (range) of CX-072 (0.3, 1, 3, or 10 mg/kg) and ipi (3 mg/kg) doses were 3 (1-20) and 3 (1-4), respectively. All cohorts through 10 mg/kg CX-072 (dose selected for monotherapy cohort expansion) are now enrolled without reaching the MTD. 1 DLT (grade 3 dyspnea, 0.3 mg/kg CX-072 + ipi) occurred. Grade 3 treatment-related (TR) irAEs occurred in 2 pts (12.5%; colitis and dyspnea/pneumonitis). No subject discontinued due to TR irAEs. Best response in 10 evaluable pts included 1 complete response (anal SCC, 0.3 mg/kg CX-072 + ipi), 2 partial response (non-seminoma testicular, 1 mg/kg CX-072 + ipi; small bowel, 3 mg/kg CX-072 + ipi), 1 stable disease, and 6 progressive disease.

Conclusions: Despite small pt numbers and limited follow up, early data suggest manageable safety profiles at all doses and antitumor activity with CX-072 + ipi in tumor types not approved for checkpoint inhibitors. The study is ongoing and escalation of ipi to 10 mg/kg is pending.

Clinical trial identification: NCT03013491.

437P PT-112: A well-tolerated novel immunogenic cell death (ICD) inducer with activity in advanced solid tumors

D.D. Karp[1], D.R. Camidge[2], J.R. Infante[3], T.D. Ames[4], J.M. Jimeno[5], A.H. Bryce[6]

[1]Department of Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [2]Department of Medicine, University of Colorado Cancer Center, Aurora, CO, USA, [3]Department of Drug Development, Sarah Cannon Research Institute, Nashville, TN, USA, [4]Department of Research and Development, Phosplatin Therapeutics LLC, New York, NY, USA, [5]Department of Clinical Development, Phosplatin Therapeutics LLC, New York, NY, USA, [6]Department of Internal Medicine, Mayo Clinic Cancer Center, Phoenix, AZ, USA

Background: PT-112, a novel platinum pyrophosphate agent under development in solid tumors and hematological malignancies, is a potent inducer of damage associated molecular patterns (DAMPs) characteristic of ICD. It also affects G1/S cell cycle transition independent of DNA damage or repair pathways. Here we present a clinical update and analysis of single-agent activity in heavily pre-treated pts.

Methods: We treated 62 pts in an all-comer 3x3 Phase I dose escalation study. PT-112 was given IV for 1hr on days 1,8,15 (28d cycle) at dose levels 12 – 420 mg/m^2.

Results: All dose levels completed were deemed safe, with dose-linear pharmacokinetics, and MTD was not reached. Fatigue was the most common side effect. No significant acute neurotoxicity was reported in 533 infusions. Grade 1-2 peripheral neuropathy was seen in 8/62 pts (13%), and Grade 3 in 2 pts (3%) with cumulative doses of 3.1 and 4.3 g/m^2. Neutropenia (6 pts) and thrombocytopenia (8 pts) were limited with no infections or bleeding. Median prior lines of therapy = 5. Tumor control, metabolic and biomarker responses were observed at doses at / above 125 mg/m^2, with PSA reduction in 4 / 8 prostate pts. A non small cell lung cancer pt previously unresponsive to anti-PD-1 immunotherapy achieved a 6+ month RECIST PR at 250 mg/m^2 and complete PET response in liver / bone sites. A small cell lung pt who rapidly progressed on CTLA4 + PD-1 immunotherapy achieved PR at 360mg/m^2, progression free at 7.5 months. Marked tumor reduction at 360 mg/m^2 is ongoing after 6 mos. in a malignant thymoma pt with bulky thoracic disease. Time to response was 5-8 wks in all 3 pts. PFS at 6 mos. was reached in 8 / 46 evaluable pts at / above 125 mg/m^2 (17.4%). The ORR in 28 evaluable pts at / above 250mg/m^2 was 10.7%. At the provisional RP2D, now under confirmation (360 mg/m^2), 2 of 3 pts experienced durable tumor shrinkage.

Conclusions: PT-112 is a novel ICD inducing agent that is safe and well tolerated. Single-agent activity occurred in heavily pre-treated pts. Neither acute neurotoxicity nor kidney damage occurred. Fatigue was the most common side effect. Beneficial activity was observed at a range of doses, indicative of a broad therapeutic index, lack of cross-resistance with standard agents and feasibility for combinations.

Clinical trial identification: NCT: 2266745 IND: 118577.

Background: ABBV-181 is a humanized, recombinant, IgG1 monoclonal antibody targeting programmed cell death 1 (PD-1), incorporating an Fc mutation to limit FcgR-mediated effector function. Here we present preliminary ABBV-181 monotherapy data.

Methods: Patients (pts) with previously treated advanced solid tumors received ABBV-181 to progression at 1, 3, or 10 mg/kg IV Q2W (3 + 3 dose finding phase). Following dose finding, multi-histology, non-small cell lung cancer (NSCLC) and head and neck squamous cell cancer (HNSCC) cohorts were opened. Dose limiting toxicities (DLTs) were assessed on days 1-28 of dose finding focused on immune mediated (IM) events, hemolysis, and cytopenia. Response is assessed Q8W per response evaluation criteria in solid tumors (RECIST v.1.1) and immune RECIST.

Results: As of January 15, 2018, 53 pts were treated with ABBV-181: 25 in dose finding, 17, 6, and 5 in multi-histology, HNSCC and NSCLC cohorts, respectively. Median age was 61 (range 27-84) years, 41% male, most frequent diagnoses in dose finding and multi-histology: cholangio, ovarian, breast and cervical carcinoma. Median days on study were 43 (range 1-379), 42 (79%) pts had $\geq$ 1 adverse event (AE), 22 pts (42%) had grade $\geq$ 3 AEs and 8 (15%) pts had IM AEs. The most frequent AEs of any grade were: fatigue (18 pts), constipation and vomiting (9 pts each). No DLTs were reported. ABBV-181 was discontinued in 33 (62%) pts, 27 for progression and 1 each for AEs of diabetic ketoacidosis, progression and small intestinal obstruction. PD-L1 was expressed on 7/21 (33%) available pretreatment samples (Dako 28-8 assay with 1% threshold). By investigator assessment, 4/34 (12%) pts with post baseline assessment responded (all in dose finding, all partial responses). Sustained PD-1 saturation on circulating CD4 T cells was observed at all doses. ABBV-181 pharmacokinetics (PK) were approximately dose-proportional in dose finding.

Conclusions: ABBV-181 monotherapy demonstrates target engagement and encouraging efficacy without unexpected safety signals. PK and pharmacodynamic data from dose finding support flat doses of 250 mg Q2W, 375 mg Q3W or 500 mg Q4W for expansion. Enrollment in the expansion cohorts continues.

439P Prospective validation of prognostic scores to improve patient selection for immuno-oncology trials

C. Massard[1], N.H. Segal[2], D.C. Cho[3], V.A. Papadimitrakopoulou[4], N.A. Rizvi[5], B.C. Cho[6], L. Yu[7], H. Yang[7], H-J. Hsieh[7], J. Zhang[7], W. Zhao[7], G. Gao[7], X. Guo[7], S. Abdullah[8], J. Englert[8], J-C. Soria[8], M. Dar[8], L. Roskos[9], C. Ferte[8], S.J. Antonia[10]

[1]Drug Development Department, Institut Gustave Roussy Cancer Campus, Villejuif, France, [2]Gastrointestinal Oncology Service, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY, USA, [3]Department of Medicine, New York University School of Medicine, New York, NY, USA, [4]Department of Thoracic Head and Neck Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA, [5]Thoracic Oncology, Memorial Sloan Kettering Cancer Center and Columbia University Medical Center, New York, NY, USA, [6]Medical Oncology, Yonsei University College of Medicine, Seoul, Republic of Korea, [7]Biostatistics, MedImmune, Gaithersburg, MD, USA, [8]Medical Oncology, MedImmune, Gaithersburg, MD, USA, [9]Clinical Pharmacology & DMPK, MedImmune, Gaithersburg, MD, USA, [10]Thoracic Oncology, Moffitt Cancer Center, Tampa, FL, USA

Background: Life expectancy estimation is critical to select patients in clinical trials, notably in the phase I setting. However, most protocols use subjective criteria to meet this goal. Several scores have been developed from retrospective studies, but their utility in the immuno-oncology (IO) context remains unknown. The recent recognition of fast progressors under IO treatment further underscores the need for more objective prediction.

Methods: NSCLC and UBC patients (n = 972) prospectively enrolled in 3 phase I trials investigating durvalumab (anti-PDL1) ± tremelimumab (anti-CTLA4) across 160 centers were analyzed. We assessed the variability in the 8- and 12-week life expectancy rate across centers. Clinicopathological variables were used to train (n = 648) and validate (n = 324) a tool (FastProgIO) predicting 12-week life expectancy using a multivariate regression method. We compared FastProgIO to existing published scores (RMH, GRIM, LIPI). The performance was assessed by time dependent true positive rate (TPR) and false positive rate (FPR).

Results: Substantial variability was observed across sites with 26% and 65% of centers having enrolled > 15% of patients with life expectancy < = 8 and 12 weeks, respectively. FastProgIO includes neutrophils, AST, alkaline phosphatase and hemoglobin as the predictive markers. Overall, the TPR of FastProgIO was superior across a 4 to 12 weeks range to RMH, GRIM and LIPI. At 12 weeks, the TPR for FastProgIO was 73%, (90% CI: 67-80%) versus 69%, 65% and 41% for RMH, GRIM and LIPI, respectively. Furthermore, the FPR of FastProgIO (11%, 90%CI: 9.3-13%) was comparable to LIPI (10%), but better controlled than RMH and GRIM (20%, 17%).

Conclusions: The use of subjective criteria to estimate the 12-week life expectancy of patients enrolled in IO trials is clearly suboptimal and can lead to ethical, scientific, medical, and public health conundrums. In this large cohort of patients, FastProgIO appears superior to RMH, GRIM and LIPI to define life expectancy of patients based on easily available baseline clinical characteristics, and can be used to better select patients for IO clinical trials. An extended validation of this model in other tumor types is ongoing and will be presented.

440P Intratumoral administration of pro-inflammatory allogeneic, "off-the-shelf", dendritic cells in combination with anti-PD-1 or anti-CD137 has a synergistic anti-tumor effect

A. Karlsson-Parra, G. Fotaki, D. Yu, M. Essand

Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden

Background: Activated NK-cells are known to play immune-regulatory "helper" functions, being able to recruit and activate "bystander" DCs and to promote cross-presentation of cell-associated antigens to $CD8^+$ T cells by producing IFN-γ and TNF-α. We have recently shown that intratumoral administration of pro-inflammatory allogeneic mouse DCs (alloDCs) induce NK-cell recruitment and that human GMP-produced human alloDCs (ilixadencel) used in clinical trials (NCT00625755, NCT01974661, NCT02686944, NCT02432846), promote enhanced cytotoxicity and strong IFN-γ production in allogeneic NK-cells in vitro. Furthermore, co-culture of ilixadencel with allogeneic PBMCs leads to a pro-inflammatory environment inducing maturation and strongly enhanced cross-presentation in "bystander" DCs. Here we investigated the anti-tumor effect of intratumorally administered pro-inflammatory mouse alloDCs as monotherapy and in combination with anti-PD-1 or anti-CD137.

Methods: AlloDCs were produced from C57BL/6 mice and activated with a cocktail consisting of polyI:C, R848 and IFN-γ. After cryopreservation and subsequent thawing the cells were injected intratumorally 2 or 3 times starting at day 14 post subcutaneous CT-26 tumor cell inoculation in Balb/C mice. AlloDCs were given as monotherapy or

in combination with anti-PD-1 or anti-CD137. The studies were conducted at Charles River Laboratories, Morrisville, NC, USA.

Results: AlloDCs did not significantly delay tumor progression, likewise did not anti-PD-1. Combined treatment with alloDCs/anti-PD-1 significantly delayed tumor progression, while treatment with intratumoral administrations of polyI:C combined with anti-PD-1 showed no significant delay. Anti-CD137 treatment significantly delayed tumor progression and also induced one complete (10%) tumor response. Notably, the combination of alloDCs with anti-CD137 induced a highly significant anti-tumor synergy, including complete tumor eradication in 3 out of 9 mice (33%).

Conclusions: Intratumoral administration of allogeneic pro-inflammatory DCs induces a synergistic anti-tumor response when combined with systemic anti-PD-1 or anti-CD137 treatment.

441P OT-1096: A first-in-class immunoactivating small molecule that targets the thioredoxin reductase/thioredoxin axis causes strong tumor growth inhibition by downregulating intratumoral tregs in a humanized TNBC-PDX model

O. Orwar, I. Lowstedt, K. Andersson, G. Gannedahl, G. Willman, M. Davidsson, W. Stafford, C. Trkulja

Oblique Therapeutics AB, Gothenburg, Sweden

Background: Triple-negative breast cancer is an aggressive subtype associated with poor prognosis and limited treatment options, and new effective medicines are needed. We have developed a novel class of SecTRAP- forming small molecules that lead to a change-of-function of thioredoxin reductase that is cytotoxic to cancer cells (Staffort et al. Sci Transl Med, 2018). However, the immunomodulatory effects of OT-1096 are unknown. This study examined the efficacy of OT-1096 in humanized CD34+ NSG mice bearing patient-derived TNBC xenografts and compared the efficacy of OT-1096 to pembrolizumab. Additionally, the immunoactivating effects of OT-1096 were analyzed.

Methods: NSG mice, humanized with CD34+ stem cells from 3 different human donors were engrafted with TNBC invasive ductal carcinoma patient-derived xenografts. The mice were treated with OT-1096 (10mg/kg IV) tiwk and was compared to treatment with pembrolizumab (10mg/kg initial dose, thereafter 5mg/kg IP) biwk, single agent and in combination with OT-1096. Tumor volume was measured using calipers for 31 days and xenografts were analyzed with FACS to determine immune cell infiltration at day 41(sacrifice).

Results: OT-1096 showed statistically significant tumor growth inhibition (TGI: 63%) when comparing treatments arms with all three donors combined. OT-1096 also presented improved tumor growth control compared to pembrolizumab. FACs analysis of xenografts showed OT-1096-treated tumors to have a lower fraction of Tregs within the TIL population as compared to controls. OT-1096 treatment was both safe and well tolerated.

Conclusions: OT-1096 shows promising results in a humanized mouse TNBC PDX model with improved tumor growth inhibition compared to pembrolizumab. The results suggest that OT-1096 possesses both redox system modulation and beneficial immunomodulatory potential, and warrants further investigations of OT-1096 in TNBC and other malignancies.

Background: The anti-cancer activity of 5-FU, and its other forms: floxuridine and capecitabine, is largely attributable to its active metabolite, fluorodeoxyuridine-monophosphate (FUDR-MP) that inhibits the enzyme thymidylate synthase (TS) and depletes the dTMP pool essential for cancer cell replication. Although 5-FU based agents remain the cornerstone of treatment for many tumour types, key cellular resistance mechanisms of breakdown, activation and transport limit their effectiveness. NUC-3373 is a phosphoramidate transformation of FUDR-MP designed to bypass these resistance pathways. It efficiently inhibits TS and depletes the dTMP pool within 2-4 hours. NUC-3373 is resistant to dihydropyrimidine dehydrogenase-mediated degradation and does not generate the toxic metabolite dhFU. NUC3373 has an advantageous PK/PD profile compared to 5-FU, with plasma $t_{1/2}$=9.7 h vs 8-14 mins, enabling the study of a more convenient alternate weekly dose-scheduling (Ghazaly et al ESMO, 2017).

Trial design: The primary study objective is to determine the RP2D and schedule of NUC3373 in patients with advanced cancers. Secondary objectives include safety, anti-tumour activity and PK/PD. In Part I, NUC-3373 was administered as an IV infusion on days 1, 8, 15 and 22 of a 28-day cycle. In Part II, NUC-3373 was administered on days 1 and 15 of a 28-day cycle. For PK analyses, blood samples were collected at 12 timepoints up to 48 h post-dose during cycle 1. Plasma and intracellular metabolites were measured by UPLC-MS/MS. Levels of free and bound TS were measured in PBMCs by western blotting. To date, thirty-six patients have been enrolled: Part I n = 29; Part II n = 7. Dose escalation is ongoing to establish the RP2D. Cohorts in Part I received NUC-3373 at 125, 250, 500, 750, 1125 and 1500 mg/m^2 and cohorts in Part II at 1500 and 1875 mg/m^2.

Clinical trial identification: NCT02723240.

Background: IGF-1R is over-expressed by neoplastic cells in many human cancers, associated with tumorigenesis, metastasis and treatment resistance. W0101 is a First-in-Class Antibody Drug Conjugate (ADC), designed for treatment of patients with tumors overexpressing membrane IGF-1R. Preclinically, internalization and anti-tumor activity of W0101 was shown in models expressing membrane IGF-1R (AACR 2018). To select potential responders to W0101 we developed a prototype immuno-histochemistry assay using a proprietary monoclonal antibody detecting a specific epitope on human IGF-1R, different from that of W0101. Using this test, we evaluated the membrane expression of IGF-1R in samples of squamous non-small-cell lung cancer (sqNSCLC), head-and-neck cancer and ER+ HER2- invasive breast cancer. This assay is currently used for retrospective assessment of patients included in this study. Here we present the design of a phase I/II international, multicentre, open label dose escalation and dose expansion study of intravenous infusion of W0101 in patients with advanced or metastatic solid tumors.

Trial design: This phase I/II consists of 2 parts: an initial dose escalation phase (I) followed by an expansion cohort (s) phase (II). In the dose escalation phase, 2 schedules of administration in 2 successive cohorts of patients will be assessed: Q2W schedule (A1) and a Q3W or Q4W schedule (A2). The first dose and the schedule of administration in cohort A2 will be determined using all safety and pharmacokinetics data generated in cohort A1 and using a PK/PD model. The phase I will allow to determine the Maximum Tolerated Dose and Schedule (MTDS) and to characterize dose-limiting toxicities (DLTs). The dose-toxicity relationships established via a Bayesian Logistic Regression Model will support the dose escalation process and will be used to assess the MTDS and recommended doses for expansion. Following completion of the dose escalation phase, the expansion phase will enroll up to 4 cohorts of patients prospectively tested for overexpression of IGF-1R to assess preliminary efficacy. A Simon design will be used for futility analysis.

Clinical trial identification: NCT03316638.

444TiP Phase I/II study investigating safety, tolerability, pharmacokinetics, and preliminary antitumor activity of anti-PD-L1 monoclonal antibody BGB-A333 alone and in combination with anti-PD-1 monoclonal antibody tislelizumab in patients with advanced solid tumors

J. Desai[1], M. Voskoboynik[2], B. Markman[3], J. Hou[4], D. Zeng[5], T. Meniawy[6]

[1]Oncology, Peter MacCallum Cancer Centre and Royal Melbourne Hospital, Melbourne, Australia, [2]Oncology, Nucleus Network, Melbourne, Australia, [3]Medical Oncology, Monash Health and Monash University, Melbourne, Australia, [4]Immuno-Oncology, BeiGene USA, Inc., Emeryville, CA, USA, [5]Clinical Science, BeiGene USA, Inc., Emeryville, CA, USA, [6]Linear Clinical Research and Sir Charles Gairdner Hospital, University of Western Australia, Nedlands, Australia

Background: PD-1 and its ligand, PD-L1, play critical roles in immune modulation of tumor progression. Tislelizumab is a humanized IgG4 monoclonal antibody against PD-1. A first-in-human, phase 1A/1B study (NCT02407990) demonstrated that single-agent tislelizumab was generally well tolerated and showed evidence of antitumor activity in patients with advanced solid tumors at the recommended phase 2 dose (RP2D) of 200 mg administered every 3 weeks (Q3W). BGB-A333 is a humanized IgG1 monoclonal antibody against PD-L1 that increased functional activities of human T cells in in vitro studies, and showed antitumor activity in various cancer xenograft models. BGB-A333 blocks the interaction between PD-L1 and CD80 (B7-1), which in turn releases inhibitory signals to T cells, enhances T-cell expansion, and prevents T-cell anergy induction. Therefore, the combination of anti-PD-1 and anti-PD-L1 can potentially elicit stronger antitumor immunity through blockade of multiple complementary immune-suppressive signals in tumor microenvironments.

Trial design: This open-label study (NCT03379259) consists of two phases, each phase consisting of two parts. Phase 1 will investigate the safety and tolerability of the BGB-A333 alone and in combination with tislelizumab. Phase 1A (BGB-A333 dose escalation) will follow a 3 + 3 design to establish the RP2D of BGB-A333. Phase 1B (combination dose confirmation) explores the safety and tolerability of IV BGB-A333 (dose determined from dose escalation) in combination with IV tislelizumab (200 mg Q3W). Phase 2 will evaluate the antitumor activity of BGB-A333 alone and in combination with tislelizumab. Phase 2A (BGB-A333 dose expansion) has two cohorts: non-small cell lung cancer and urothelial carcinoma. Phase 2B (combination dose expansion) will enroll patients with specific tumor types, which will be chosen based on data from phase 2A and other studies. The primary endpoint of the phase 2 study is overall response rate. A total of 156 patients are estimated to be enrolled; as of 11 April 2018, 9 patients have been enrolled.

Clinical trial identification: NCT03379259.

445TiP Comprehensive profiling and molecularly guided therapy (MGT) for carcinomas of unknown primary (CUP): CUPISCO: A phase II, randomised, multicentre study comparing targeted therapy or immunotherapy with standard platinum-based chemotherapy

A. Krämer[1], F. Losa[2], L.M. Gay[3], D.R. Page[4], S. Foser[4], T.I. Mughal[5], J.S. Ross[3], G. Baciarello[6], L.R. Mileshkin[7], S. Osborne[8], H. Moch[9]

[1]Clinical Cooperation Unit Molecular Hematology/Oncology, German Cancer Research Center (DKFZ) and Department of Internal Medicine V, University of Heidelberg, Heidelberg, Germany, [2]Medical Oncology Department, Hospital Sant Joan Despí – Moises Broggi, Barcelona, Spain, [3]Pathology Group, Foundation Medicine, Inc., Cambridge, MA, USA, [4]Personalised Healthcare, F. Hoffmann-La Roche Ltd, Basel, Switzerland, [5]Hematology and Oncology, Tufts University Medical Center, Boston, MA, USA, [6]Department of Medical Oncology, Gustave Roussy, Villejuif, France, [7]Medical Oncology, Peter MacCallum Cancer Centre, Melbourne, Australia, [8]PDMA Operations (Biometrics), F. Hoffmann-La Roche Ltd, Basel, Switzerland, [9]Department of Pathology and Molecular Pathology, University Hospital Zurich, Zurich, Switzerland

Background: CUPs are heterogeneous tumours of diverse origins that often have poor prognoses and high unmet clinical need. Their heterogeneity makes the conduct of clinical trials difficult. The CUPISCO study aims to compare the overall efficacy and safety of MGT with standard platinum-based chemotherapy for patients (pts) with CUP.

Trial design: Eligible pts have a histological diagnosis of adeno- or poorly differentiated carcinoma without detectable primary tumour according to ESMO diagnostic guidelines (nonspecific CUP subset per ESMO definition only); Eastern Cooperative Oncology Group performance status 0–1; ≥1 measurable lesion; and are naive to systemic therapy. All pts receive hybrid capture-based comprehensive genomic profiling (FoundationOne®, FoundationACT®) to assess tumour genomic alterations, microsatellite instability and tumour mutational burden. Pts who achieve complete response [CR], partial response [PR] or stable disease [SD] after 3 induction chemotherapy cycles of carboplatin/paclitaxel, carboplatin/gemcitabine or cisplatin/gemcitabine are randomised (3:1) to investigator's choice (IC) from 9 MGT regimens (7 targeted therapy regimens, 2 immunotherapy regimens) or 3 further chemotherapy cycles. Randomisation is stratified by gender and response during the induction period (CR + PR vs SD). A key element of the trial design is a 'Molecular Tumour Board (MTB)', comprising the investigator, reference pathologist, reference oncologist and cancer genomics consultant (when needed), who advise investigators on MGT choice based on tumour genomic profiles. Pts with progressive disease during the induction period will be assigned to IC of MGT regimens with advice from the MTB. The primary efficacy endpoint is investigator-assessed progression-free survival (time from randomisation to first occurrence of disease progression per Response Evaluation Criteria in Solid Tumors v1.1, or death from any cause). Enrolment of 790 pts is planned across 23 countries and ~101 sites. Recruitment is ongoing; 5 pts have been screened to date (NCT03498521).

Clinical trial identification: NCT03498521.

446TiP REVEAL: A phase I/II, open-label, multicenter, dose escalation and dose expansion study of NKTR-262 [TLR 7/8 agonist] plus NKTR-214 [CD122-biased agonist] with or without nivolumab (nivo) in patients (pts) with locally advanced or metastatic solid tumor malignancies

A. Diab[1], M. Marcondes[2], M.A. Tagliaferri[3], U. Hoch[4], J. Zhang[3], W. Rubas[5], S. Kivimae[5], J. Zalevsky[6], A.P. Conley[1], E. Borazanci[7], S.P. D'Angelo[8]

[1]Department of Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA, [2]Oncology Clinical Development, Nektar Therapeutics, San Francisco, CA, USA, [3]Clinical Development, Nektar Therapeutics, San Francisco, CA, USA, [4]Oncology, Nektar Therapeutics, San Francisco, CA, USA, [5]Oncology, Nektar Therapeutics, San Francisco, CA, USA, [6]Biology, Nektar Therapeutics, San Francisco, CA, USA, [7]Oncology, Honor Health/TGen, Scottsdale, AZ, USA, [8]Medical Oncology, Memorial Sloan-Kettering Cancer Center, New York, NY, USA

Background: Cancer treatments that couple pharmacological activation of tumor antigen presentation with activation and expansion of $CD8^+$ T and NK cells in the tumor environment have the potential to induce an effective anti-tumor immune response in pts. NKTR-262 is a small molecule agonist of toll-like receptors (TLRs) 7/8 designed to be retained in the tumor micro-environment to activate antigen-presenting cells (eg, dendritic cells) to create new antigen-specific cytotoxic T cells. As a CD122-biased agonist, NKTR-214 monotherapy increases newly proliferative $CD8^+$ T cells in tumors. NKTR-262 + NKTR-214 is expected to increase expansion of antigen-specific $CD8^+$ T cells. In preclinical studies, a single intratumoral (IT) injection of NKTR-262 + IV NKTR-214 resulted in complete abscopal effects in tumor models (Kivimae, SITC '17). Preliminary clinical data show NKTR-214 + nivo enhances immune-stimulatory responses (Diab, SITC '17). The REVEAL trial will assess safety and anti-tumor activity of NKTR-262 + NKTR-214 with or without nivo for the treatment of selected cancers.

Trial design: Primary objectives of the phase 1 dose escalation are to identify the recommended phase 2 dose of the doublet, NKTR-262 + NKTR-214 and of the triplet, NKTR-262 + NKTR-214 + nivo. Secondary objectives include antitumor activity including ORR, PFS and OS. Pts will receive IT NKTR-262 at escalating doses q3w until

biological response. The study will enroll eligible pts with advanced and/or metastatic melanoma, Merkel cell carcinoma, triple-negative breast cancer, ovarian carcinoma, renal cell carcinoma, colorectal cancer, urothelial carcinoma, or sarcoma. Eligibility includes measurable disease per RECIST 1.1 with at least 2 lesions (1 amenable to IT injection and biopsy collection). ~48 pts will be enrolled in phase 1 and ~345 pts in phase 2. Pts in the NKTR-262 + NKTR-214 cohorts will have progressed on prior approved therapies and pts in the NKTR-262 + NKTR-214 + nivo cohorts will be naïve to immunotherapy treatment. Trial is open and recruiting.

Clinical trial identification: NCT03435640.

447TiP The cancer molecular screening and therapeutics program (MoST): A molecular screening platform with multiple, parallel, signal-seeking therapeutic substudies

S. Thavaneswaran[1], L. Sebastian[2], M. Ballinger[1], M. Cowley[3], J. Grady[3], A. Joshua[4], C. Lee[2], K. Sjoquist[2], W. Hague[2], J. Simes[2], D. Thomas[1]

[1]Genomic Cancer Medicine, The Garvan Institute of Medical Research, Darlinghurst, Australia, [2]Clinical Trials Research, The NHMRC Clinical Trials Centre, Camperdown, Australia, [3]Bioinformatics, The Garvan Institute of Medical Research, Darlinghurst, Australia, [4]Medical Oncology, The Kinghorn Cancer Centre, Darlinghurst, Australia

Background: Innovative approaches are needed to translate molecular opportunities into clinical care. MoST tests a novel paradigm for evaluation of biomarker-driven treatments (tx) for patients (pts) with advanced cancer, with a particular focus on rare or neglected cancers.

Trial design: Tx-refractory pts (N = 1000) undergo molecular screening using archival tumour tissue. Results are reviewed by the Molecular Tumor Board (MTB) to identify actionable variants and eligibility for substudies. A master protocol allows expedited addition of ≥ 12 open-label, phase Ib/IIa, single-arm substudies, with 16 pts per module deemed reasonable for signal-seeking purposes. The primary objectives are to identify potential clinical activity for biomarker-driven tx, biomarkers that predict for response, and to evaluate the MoST study design. Three substudies are active: 1) palbociclib - molecular eligibility includes amplification/activating mutations in cyclin D pathway genes, or loss of function mutations in CDKN2A; 2) olaparib+durvalumab (ola+durva) – molecular eligibility is a homologous recombination repair gene defect; 3) durvalumab+tremelimumab (durva+treme) offers a tx in the absence of actionable findings. Further substudies planned include vismodegib and eribulin for tumours with PTCH1 or SMO mutations, and CD31 positivity respectively. Since September 2016, recruitment to screening has exceeded targets. Of the 571 pts enrolled to April 2018, 474 MTB reports have been issued, 57 are in progress, 31 had insufficient tissue and 43 died prior to issue of a MTB report. Median time to MTB report issue was 44 days over latest quarter (n = 89). Rare cancers comprise at least 44%; an actionable mutation to inform therapy reported in > 40%. Palbociclib (n = 16) and durva+treme (n = 4x16, 64 pts) substudies have completed recruitment; ola+durva (n = 3x16 pts) is currently recruiting. The distribution of actionable mutations across cancers, and in particular rare cancers will be informative, as it comprises the essential first steps to gaining access to novel, personalized treatments for pts.

Clinical trial identification: Framework protocol Trial ID ACTRN12616000908437. Registered 08 July 2016. Therapeutic substudy 1 (palbociclib) Trial ID ACTRN12616000931471. Registered 13 July 2016. Therapeutic substudy 2-5 (durvalumab plus tremelimumab) Trial ID ACTRN12616001019493. Registered 02 August 2016. Therapeutic substudy 6-8 (olaparib plus durvalumab) Trial ID ACTRN12617001000392. Registered 11 July 2017.

448TiP MEDIOLA: A phase I/II trial of olaparib (PARP inhibitor) in combination with durvalumab (anti-PD-L1 antibody) in pts with advanced solid tumours – new ovarian cancer cohorts

R.T. Penson[1], Y. Drew[2], M.J.A. de Jonge[3], S-H. Hong[4], Y.H. Park[5], A. Wolfer[6], J. Brown[7], M. Ferguson[8], M.E. Gore[9], R.H. Alvarez[10], B. Kaufman[11], C. Gresty[12], H.K. Angell[12], K. Meyer[13], M. Lanasa[13], P. Herbolsheimer[13], S. Domchek[14]

[1]Massachusetts General Hospital, Boston, MA, USA, [2]Northern Centre for Cancer Care, Newcastle Upon Tyne, UK, [3]Erasmus MC Daniel den Hoed Cancer Center, Rotterdam, Netherlands, [4]Seoul St Mary's Hospital, Catholic University of Korea, Seoul, Republic of Korea, [5]Samsung Medical Center, Seoul, Republic of Korea, [6]Lausanne University Hospital, Lausanne, Switzerland, [7]Beatson West of Scotland Cancer Centre, Glasgow, UK, [8]NHS Tayside, Dundee, UK, [9]The Royal Marsden Hospital NHS Foundation Trust, London, UK, [10]Cancer Treatment Centers of America, Augusta University, Augusta, GA, USA, [11]Sheba Medical Center, Ramat Gan, Israel, [12]AstraZeneca, Cambridge, UK, [13]AstraZeneca, Gaithersburg, MD, USA, [14]Hospital of the University of Pennsylvania, Philadelphia, PA, USA

Background: Olaparib (Lynparza®) is a poly(ADP-ribose) polymerase (PARP) inhibitor that prevents the repair of single-strand DNA breaks. Durvalumab (Imfinzi®) is a programmed cell death ligand 1 (anti-PD-L1) inhibitor, which functions by promoting antitumour immune responses. Inhibition of vascular endothelial growth factor (VEGF) has been reported to enhance PARP inhibitor activity. Combinations of immune checkpoint inhibitors and bevacizumab have shown promising results in other tumour types. Here, the efficacy and safety of bevacizumab (anti-VEGF-A antibody) is investigated in combination with olaparib + durvalumab in platinum-sensitive relapsed (PSR) non-gBRCAm ovarian cancer (OC) pts (NCT02734004).

Trial design: Initially, 148 pts were enrolled across several tumour types (small-cell lung cancer, gastric cancer, germline BRCA-mutated [gBRCAm] breast cancer, or PSR gBRCAm OC). Pts received olaparib 300 mg po bid for a 4-wk run-in, followed by olaparib 300 mg po bid and durvalumab 1.5 g IV q4w. Primary endpoints were disease control rate (DCR) at 12 wks, safety and tolerability. Secondary endpoints: pharmacokinetics (PK), DCR at 28 wks, objective response rate (ORR), progression-free survival (PFS), and overall survival (OS). Tumours were assessed at baseline, 4 wks and every 8 wks thereafter. Enrolment was completed for these initial cohorts, and new PSR OC cohorts (Table) have been added, based on the preliminary results. These cohorts have no olaparib run-in, tumour assessments are performed at baseline and every 8 wks thereafter, bevacizumab 10 mg/kg is given q 2 weeks, and pts with 1–2 prior chemotherapy lines are allowed.

Table: 448TiP New MEDIOLA cohorts

OC cohort name	Drugs	Population	Primary endpoint
Expansion (N = 80)	Olaparib+Durvalumab	gBRCAm	ORR
Doublet (N = 30)	Olaparib+Durvalumab	non-gBRCAm	DCR 24 wks
Triplet (N = 30)	Olaparib+Durvalumab+ Bevacizumab	non-gBRCAm	DCR 24 wks

Other endpoints: Safety and tolerability, PK, DCR at 56 wks, ORR, PFS, and OS. Biomarker endpoints: Analysis of tumour-infiltrating lymphocytes and PD-L1 expression.

Clinical trial identification: NCT02734004.

449TiP MASTER KEY project: A basket/umbrella trial for rare cancers in Japan

S. Noda[1], K. Yonemori[2], N. Shirakawa[3], H.S. Okuma[1], T. Shimizu[4], A. Hirakawa[5], T. Shibata[6], T. Sukigara[1], N. Okita[1], A. Kawai[7], N. Yamamoto[4], K. Nakamura[1], H. Mano[8], T. Nishida[9], Y. Fujiwara[1]

[1]Clinical Research Support Office, National Cancer Center Hospital, Tokyo, Japan, [2]Department of Breast and Medical Oncology, National Cancer Center Hospital, Tokyo, Japan, [3]Department of Pediatric Oncology, National Cancer Center Hospital, Tokyo, Japan, [4]Department of Experimental Therapeutics, National Cancer Center Hospital, Tokyo, Japan, [5]Department of Biostatistics and Bioinformatics, The University of Tokyo, Tokyo, Japan, [6]Center for Research Administration and Support, National Cancer Center, Tokyo, Japan, [7]Department of Musculoskeletal Oncology and Rehabilitation, National Cancer Center Hospital, Tokyo, Japan, [8]Division of Cellular Signaling, National Cancer Center Research Institute, Tokyo, Japan, [9]Department of Gastric Surgery, National Cancer Center Hospital, Tokyo, Japan

Background: Rare cancers have had a challenge in establishing standard therapies for patients compared to major cancers, due to the lack of basis for clinical studies and investigations. We started a biomarker driven basket/umbrella trial using a "master protocol", called the MASTER KEY Project, which aims to find more efficient ways to evaluate treatments for rare cancers and to build a treatment development infrastructure by collaborating with industries. Similar studies including NCI-MATCH trial are ongoing; however, MASTER KEY Project is the first to be reported for such large scale trials that focuses only on rare cancers.

Trial design: The project consists of two main parts: the prospective registry study part and the multiple clinical trials (sub-study) part. Patients with advanced rare cancers (annual incidence less than 6 cases per 100,000 population)/cancers of unknown primary/rare pathological subtypes of major cancers, who have priorly been evaluated by a molecular diagnostic testing, such as a validated next generation sequencing assay, are enrolled into the registry study. The primary objective of the registry study is to collect consecutive data on biomarker, patient background, and prognosis to build a large-scale database highly reliable for use as historical control data in future clinical trials. In the sub-studies, drugs are provided by various industries, who are collaborators. Sub-studies are placed under a "master protocol", allowing new sub-studies to be added at any time. Each sub-study is ordinarily a single arm study and will enroll 5-20 patients with the appropriate biomarker of interest, regardless of histopathologic tumor type. A biomarker-negative sub-study will also be available so that all patients have a chance to be enrolled in a sub-study. The project opened in May 2017. As of April 2018, more than 200 of a planned 100 patients/year have been enrolled in the project. There are three ongoing sub-studies. Two of them are biomarker related studies, which enroll patients harboring BRAF mutation and mismatch repair deficiency, respectively. In addition, three sub-studies are under planning and they will open by fall of 2018.

Background: Association between mitotane and platinum-etoposide chemotherapy is the front-line treatment in metastatic adrenocortical carcinoma (ACC), although this regimen shows limited efficacy. Drug-drug interaction between mitotane -which is a strong pharmacokinetic inductor of CYP3A4 and BRCP- and etoposide –which is a substrate of CYP3A4 and BRCP- may contribute to chemoresistance in ACC. The aim of this study was to evaluate the pharmacokinetic interaction between mitotane and etoposide.

Methods: From December 2016 to October 2017, this observational study included 5 consecutive ACC patients treated with platinum-etoposide (120 to 150 mg/m^2 J1-J2-J3 at cycle 1) chemotherapy in referral center for rare adrenal diseases and oncology department of Cochin hospital, Paris. Plasma etoposide concentrations were measured using liquid chromatography at 0, 4 and 24h after each etoposide infusion. In the absence of dose-limiting toxicity, a dose escalation of etoposide was proposed from cycle 2.

Results: Patients received a median of 3 [2 to 6] chemotherapy cycles, in association with mitotane (4 patients, median mitotane plasma concentration of 14.2 mg/L) or after mitotane discontinuation (1 patient, plasma concentration 1 mg/L). Etoposide clearance was higher in association with mitotane (4.95 L/h [2.67 to 6.20]) than after discontinuation (2.53 L/h [2.02 to 2.78], Wilcoxon p = 0.014) or in a reference population not treated with mitotane (1.81 L/h)[1]. Etoposide dose escalation was performed in 4 patients treated with mitotane, resulting in 2 minor tumor response at 300mg/m^2 and 1 febrile neutropenia.

Conclusions: Drug-drug interaction between mitotane and etoposide may partly explain the low efficacy of platinum-etoposide chemotherapy in ACC. Given the elimination half-life of mitotane is extremely long (18-159 days), this observation suggests further a potential benefit of increasing etoposide dosage in patients receiving mitotane than stopping mitotane before chemotherapy initiation in ACC patients.

Background: REG 160 mg/day 3 weeks on/1 week off is approved for the treatment of patients with treatment-refractory mCRC. This final analysis of the prospective, observational CORRELATE study describes REG real-world dosing in mCRC.

Methods: CORRELATE (NCT02042144) was conducted in 13 countries across Europe, Latin American, and Asia and enrolled patients with mCRC for whom the decision to treat with REG was made by the treating physician. The primary aim was to assess safety.

Results: Of 1037 patients, 57% started treatment at 160 mg, 30% at 120 mg, and 13% at $\leq$ 80 mg. The mean and median percent of the approved dose was 75%. At baseline, median age was 65 years, most patients were ECOG performance status (PS) 0–1 (87%), and 56% had KRAS mutations; age and ECOG PS was similar between dose groups (160 vs 120 mg; Table). Dose reductions were more frequent in the 160 versus 120 mg group, while the proportion of patients having an interruption/delay or treatment modification was similar. Treatment modifications were most commonly due to treatment-emergent adverse events (TEAEs) (66%). Overall, most discontinuations (49%) were due to radiologic disease progression, whereas 19% were due to REG-related TEAEs. Overall, TEAEs of any grade occurred in 95% of patients, and were deemed REG related in 80%. Grade $\geq$3 TEAEs occurred in 62% of patients, and were attributed to REG in 36%. The most common REG-related grade $\geq$3 TEAEs were fatigue (9%), hand–foot skin reaction (7%), and hypertension (6%). Grade 5 TEAEs occurred in 17% of patients and were considered REG related in 1%. Median overall survival (OS) was 7.6 months (95% CI 7.1–8.2) and the estimated 1-year OS was 34%.

Table: 463P

%	Starting dose 160 mg (N = 591)	Starting dose 120 mg (N = 315)	Total (N = 1037)
Median age*	64 (24–85)	65 (33–89)	65 (24–93)
Sex, male/female	58/42	66/34	61/39
ECOG PS 0–1/2–4	89/4	85/9	87/6
Metastatic site at study entry, liver/lung	73/57	69/57	72/57
Median treatment duration†	2.6 (0.03–29.5)	2.4 (0.03–20.6)	2.5 (0.03–29.5)
Treatment modification	65	63	65
Dose reduction	47	34	40
Treatment interruption/delay	50	47	48
Treatment modification due to AEs	76	58	66

*years (range);
†months (range)

Conclusions: In this real-world, observational study, the starting dose of REG for nearly half of patients was less than 160 mg/day. Common TEAEs were generally consistent with the known safety profile of REG in mCRC.

Clinical trial identification: NCT02042144.

464P Safety and efficacy of trifluridine/tipiracil (FTD/TPI) in metastatic colorectal cancer (mCRC) patients according to previous treatment with regorafenib in the international phase IIIb PRECONNECT study

J. Taieb[1], A. Falcone[2], S. Lonardi[3], T.J. Price[4], J-B. Bachet[5], L. Wyrwicz[6], F. Ciardiello[7], M. Becquart[8], N. Mounedji[8], E. Van Cutsem[9]

M. Sklodowskiej Curie, Warszawa, Poland, [7]Dipartimento di Medicina di Precisione, Università degli Studi della Campania Luigi Vanvitelli, Naples, Italy, [8]Global Medical Affairs Oncology, Servier, Suresnes, France, [9]Digestive Oncology, University Hospitals Gasthuisberg/Leuven and KULeuven, Leuven, Belgium

Background: The oral chemotherapy trifluridine/tipiracil (FTD/TPI or TAS-102) is approved for treatment of previously treated mCRC patients (pts) beyond the second line, in the same setting as regorafenib. Optimal treatment sequencing between the two at this stage is not established. Here, a descriptive post hoc sub-group analysis assessed safety and efficacy of FTD/TPI in mCRC pts according to previous treatment with regorafenib in a preliminary analysis of the phase 3b PRECONNECT study (NCT03306394).

Methods: PRECONNECT is enrolling pts with histologically confirmed mCRC previously treated with available therapies, with an Eastern Cooperative Oncology Group (ECOG) performance status (PS) of 0/1. Pts receive oral FTD/TPI (35 mg/m^2 bid) on days 1–5 and 8–12 of each 28-day cycle. Of the 462 patients who received at least one dose at cutoff (1 Nov 2017), 166 (36%) were pretreated with regorafenib.

Results: Patient subgroups pretreated (n = 166) and non-pretreated (n = 296) with regorafenib were broadly similar, with a slight imbalance for RAS mutant status (61% vs 47%), left-sided tumour (58% vs 65%) and treatment line (12% vs 36% receiving FTD/TPI third line), respectively. There was no difference in rate of emergent or drug-related any grade adverse events (AEs), or drug-related grade ≥3 AEs in pts treated with FTD/TPI between the regorafenib pretreated and regorafenib non-pretreated subgroups (98% vs 96%; 77% vs 79%; and 54% vs 51%, respectively). The most common drug-related grade ≥3 AEs were neutropenia (43% vs 40%) and anemia (8% vs 7%). Median FTD/TPI treatment duration were 2.7 and 3.1 months, with a median PFS of 2.7 (95% CI 2.2-3.3) and 3.3 months (95% CI 2.8-3.7), disease control rate was 38% (95% CI 30–46) and 43% (95% CI 37-49) and median time to ECOG-PS ≥2 was 8.5 and 8.7 months in the regorafenib pretreated and regorafenib non-pretreated, respectively.

Conclusions: FTD/TPI may be used either before or after regorafenib with similar efficacy results making treatment safety profile and patient quality of life major points to determine treatment option in third-line for mCRC patients.

Background: Randomized phase 3 trials, RECOURSE and TERRA, established trifluridine/tipiracil (FTD/TPI) as a salvage-line therapy for patients with metastatic colorectal cancer (mCRC). This retrospective, large cohort study, JFMC50, aims to assess the treatment pattern and outcomes of FTD/TPI for mCRC in routine clinical practice.

Methods: We collected data of patients with mCRC who received FTD/TPI during July 2014-September 2016 in Japanese institutions. However, we examined patients who fulfilled the eligibility criteria, through their backgrounds, treatment course, clinical outcomes, including the OS, time to treatment failure (TTF), disease control rate (DCR), and safety. The main eligibility criteria were the ECOG performance status (PS) 0-2 and the starting dose of FTD/TPI close to the standard dose.

Results: From 127 Japanese institutions, we collected data of 2030 patients and assessed 1770 patients. Patients' backgrounds were the median age [67 (23-92) years], males (60.1%), ECOG PS 0/1/2 (33.7%/56.7%/9.5%), right-sided tumor (25.4%), and prior regorafenib treatment (23.3%). The median OS and TTF were 8.1 and 2.7 months, respectively; the DCR was 21.0%. Major grade 3 or 4 adverse events were leukopenia, neutropenia, and anemia (25.9%, 39.3%, and 17.7%, respectively). At the data cutoff date, 1756 patients discontinued FTD/TPI therapy. The median OS because of treatment termination due to disease progression was 11.6 months in the progression after progressive disease (PD) by RECIST (n = 122), 9.2 months in PD by RECIST (n = 930), 7.8 months in the elevation of tumor marker (n = 109), and 4.9 months in clinical PD (n = 206).

Conclusions: Both efficacy and safety of FTD/TPI in the clinical practice were compatible with clinical trials. The continuous use of FTD/TPI after PD by RECIST could contribute to longer survival; however, further investigation is warranted.

Background: Regorafenib (REG) significantly increases overall survival (OS) in previously treated mCRC pts. However, no prospective trial specific to elderly population including geriatric parameter evaluation has evaluated the safety and efficacy of REG in its registered indication.

Methods: Multicenter one-arm phase II that enrolled pts $\geq$70 years, ECOG performance status $\leq$1, with mCRC after failure of fluoropyrimidine-based chemotherapy, anti-VEGF and anti-EGFR treatment. Primary endpoint was tumor control rate 2 months after initiation of REG administered at 160mg/day (3weeks on/1 week off).

Results: 43 pts were enrolled from January 2016 to April 2017, median age 77 (range 70 – 91), ECOG 0: 37.2%, ECOG 1: 60.5%, altered activities of daily living (ADL) in 37.5%. Median time from diagnosis of metastases to enrolment: 27.7 months, median number of previous lines: 3. At the time of analysis, the median follow-up was 13.3 months and 62.8% pts had died. One patient never started treatment. The median duration of REG treatment was 45.0 days [5 to 440]. 8 patients were not evaluable for the primary endpoint. Tumor control rate at 2 months in the 35 evaluable pts was 31.4% [18.7% – 46.6%]. Among the 11 pts with tumor control, 9 (81.8%) were $<$ 80 yrs. In the 42 treated pts, median progression free survival (PFS) and OS were 2.2 [1.9-3.3] and 7.5 [5.5-14.6] months, respectively. Modification of the initial dose was performed in 54.3% of the 116 cycles delivered. A grade 3-4 adverse event was observed in 37 (88.1%) pts notably: asthenia (45.2%), hand foot syndrome (21.4%), arterial hypertension (21.4%), and diarrhea (7.1%). Treatment was stopped for toxicity without progression in 12 (28.6%) pts. Among them, 10 (83.3%) pts were ECOG 1, 6 (50%) were over 80 years and 6 (50%) had abnormal baseline ADL. No toxic death was observed.

Conclusions: Treatment with REG in heavily pretreated elderly pts gives a tumor control at 2 months in around 30% of pts. The median PFS and OS are comparable to those observed in the pivotal study. With caution due to small number, drop-out rate for treatment toxicity seems higher in pts with ECOG 1, age over 80 yrs and abnormal ADL.

Background: Regorafenib is the first small-molecule multikinase inhibitor with survival benefit as a salvage line therapy for metastatic colorectal cancer (mCRC). However, severe toxicities often occur early and require dose reduction and/or interruption. To improve dose intensity and treatment outcome, we investigated regorafenib dose escalation strategy with low starting dose. The association between systemic exposure and tolerability was also analyzed.

Methods: In this phase II, single arm, multicenter study, we enrolled patients with refractory mCRC. Regorafenib was initiated at 120 mg/day. In patients who experienced neither hand-foot skin reaction nor grade $\geq$2 adverse reactions without dose reduction or interruption until day 15 in the first cycle, the dose of regorafenib was escalated to standard dose of 160 mg/day at day 15. The primary endpoint was disease control rate (DCR). With power of 80% and two-sided alpha of 5%, 67 patients were required to reject 30% of DCR expecting 45% of DCR. Serum concentrations of regorafenib and its active metabolites (M-2, N-oxide metabolite; M-5, N-oxide/N-desmethyl metabolite) at days 8, 15 and 22 in the first cycle were assessed.

Results: From September 2016 to December 2017, 68 patients were enrolled. The DCR was 32.4% (95% CI, 21.5-44.8) with no patients achieving complete or partial response. The dose of regorafenib was escalated to 160 mg at day 15 in only six patients of 39 patients without dose reduction or interruption until day 15. In 55 patients without dose reduction or interruption due to adverse reactions until day8, the serum concentrations of regorafenib at day 8 in the six patients whose dose was escalated to 160 mg were significantly lower than those in the other 49 patients (median, 3978 nM; range, 2487-13614 nM vs. 6951 nM; 2822-17621 nM; $P = 0.028$). The serum concentrations of sum of regorafenib and active metabolites (M-2 and M-5) at day 8 showed similar tendency (6582 nM; 2913-21388 nM vs. 11730 nM; 4596-33211 nM; $P = 0.064$).

Conclusions: This dose escalation strategy with low starting dose for regorafenib did not improve DCR. Lower systemic exposure was associated with better tolerability.

468P Regorafenib for metastatic colorectal carcinoma: A registry-based analysis

K. Kopeckova[1], R. Chloupkova[2], B. Melichar[3], Z. Linke[1], L.B. Petruzelka[4], J. Finek[5], O. Fiala[5], J. Tomasek[6], I. Kiss[7], J. Prausova[1], T. Buchler[8]

[1]Oncology, Second Faculty of Medicine, Charles University and Motol University Hospital, Prague, Czech Republic, [2]Institute of Biostatistics and Analyses, Masaryk University Brno, Brno, Czech Republic, [3]Oncology, Palacky University Medical School and Teaching Hospital, Olomouc, Czech Republic, [4]Oncology, First Faculty of Medicine, Charles University and General University Hospital, Prague, Czech Republic, [5]Oncology, University Hospital Plzen, Plzen, Czech Republic, [6]Department of Comprehensive Cancer Care, Masaryk Memorial Cancer Institute, Brno, Czech Republic, [7]Department of Comprehensive Cancer Care, Masaryk Memorial Cancer Institute, Brno, South Moravian, Czech Republic, [8]Oncology, First Faculty of Medicine, Charles University and Thomayer Hospital, Prague, Czech Republic

Background: Regorafenib is a multikinase inhibitor approved for the therapy of patients with metastatic colorectal carcinoma (mCRC) previously treated with a fluoropyrimidine, oxaliplatin, irinotecan, anti-VEGF therapy, and (in wild-type RAS

tumours) anti-EGFR therapy. The aim of the present study was to analyse the outcomes of treatment with regorafenib in real-world clinical practice based on data from a national registry.

Methods: The CORECT registry (http://corect.registry.cz) is a non-interventional database of patients with colorectal cancer treated with targeted agents. The analysis included 451 evaluable patients treated with regorafenib for mCRC.

Results: The median age at diagnosis was 61.1 years. The primary tumor was in the left colon or rectum in 343 patients (76.1%), right colon in 81 patients (18.0%), data on location were not available for 27 patients (6.0%). KRAS mutation was detected in 202 patients (44.8%) and NRAS mutation in 40 patients (8.9%). The median duration of treatment was 2.7 months (range 0.0-23.4 months). Partial response was seen in 12 patients (3.2%). Progression of the disease was reported in 170 patients (44.7%) and disease stabilisation for at least 6 weeks in 110 patients (28.9%). Progression-free and overall survival data are shown in the table. Improved outcomes were observed in patients with longer interval from diagnosis of mCRC and in those without liver metastases. Age, tumor sidedness, and RAS status were not associated with outcome of regorafenib therapy. The main cause of treatment discontinuation was disease progression (71.3%) followed by general deterioration in the absence of radiological progression in 93 patients (24.5%), and adverse events related to regorafenib in (4.2%).

Table: 468P Progression-free survival and overall survival of patients treated with regorafenib

	Median (95% CI)	3-month survival (95% CI)	6-month survival (95% CI)
Progression-free survival	3.5 months (3.2–3.7)	57.6% (52.5–62.4)	25.2% (20.9–29.9)
Overall survival	9.3 months (7.9–10.7)	88.8% (85.2–91.5)	68.7% (63.6–73.3)

Conclusions: Overall survival of patients treated with regorafenib in real-world clinical practice exceeded that achieved in randomised trials.

[1]Coloproctological Surgery, Juntendo University School of Medicine, Tokyo, Japan, [2]Gastroenterological Surgery, Fukuoka University School of Medicine, Fukuoka, Japan, [3]Gastroenterological Surgery, Nippon Medical School, Tokyo, Japan, [4]Surgery, Teikyo University Chiba Medical Center, Ichihara, Chiba, Japan, [5]Digestive Tract and General Surgery, Saitama Medical University, Saitama, Japan, [6]Surgical Oncology, Dokkyo Medical University, Tochigi, Japan, [7]Department of Chemotherapy, Tokyo Women's Medical University Yachiyo Medical Center, Yachiyo, Japan, [8]Surgery, Iwata City Hospital, Shizuoka, Japan, [9]Gastroenterological Surgery, Shiga Medical University, Shiga, Japan, [10]Surgery, Tokyo Women's Medical University, Tokyo, Japan, [11]Surgery, Nippon Medical School Chiba Hokusoh Hospital, Inzai, Chiba, Japan

Background: TAS-102 improved overall survival of refractory colorectal cancer patients with median progression free survival (PFS) of 2.0 months (RECOURSE trial). Subsequently, the combination of TAS-102 and Bevacizumab has been shown to extend median PFS with 3.7 months (C-TASK FORCE). However, this study included patients with 2nd line and 3rd line chemotherapy. Our study was planned exclusively for patients receiving this combination as the 3rd line chemotherapy to investigate clinical impact of this combination beyond cytotoxic doublet.

Methods: This phase II study was conducted in investigator-initiated, open-label, single-arm, multicentered manner in Japan. Eligible patients were 20-80 years old, and had to have an Eastern Cooperative Oncology Group performance status of 0 or 1; had confirmed unresectable metastatic colorectal cancer (mCRC) with histologically diagnosed adenocarcinoma; were refractory or intolerant to fluoropyrimidine, irinotecan, and oxaliplatin in the 1st and the 2nd line chemotherapy; and had no previous treatment with regorafenib. TAS-102 (35 mg/ m^2) was given orally twice daily on days 1–5 and 8–12 in a 4-weeks cycle, and bevacizumab (5 mg/ kg) was administered by intravenous infusion for 30 minutes in every 2 weeks. The primary endpoint was progression free survival (PFS), and the secondary endpoints were time to treatment failure (TTF), response rate (RR), overall survival (OS), and safety.

Results: Between June 1, 2016, and August 31, 2017, 32 patients with mCRC were enrolled in this study. The median PFS was 4.5 months. Partial response was observed in 2 patients. The most common adverse events above grade 3 were neutropenia (15 patients) followed by thrombocytopenia (4 patients). Treatment-related serious adverse events were reported in one patient. There were no non-hematologic adverse events above grade 3. No treatment-related deaths occurred.

Conclusions: This is the first study which involves the combination of TAS-102 and Bevacizumab as the 3rd line chemotherapy in the setting beyond cytotoxic doublet, and showed to improve PFS for the patients with mCRC. This combination has a potential to be one of therapeutic options of the 3rd line chemotherapy for mCRC.

Rossi, AOUI and University of Verona, Verona, Italy, [10]Oncology Medical Division, Servier France, Suresnes, France, [11]Oncology Medical Division, Servier, Suresnes, France, [12]Medical Oncology, Vall d'Hebron University Hospital, Barcelona, Spain

Background: The addition of the monoclonal antibody bevacizumab to chemotherapy has shown survival benefits in pts with mCRC. Another potential strategy is to combine chemotherapy with immunotherapies to enhance antitumor effect of the immune system. In vivo studies have shown an increase in anti-tumor activity when combining FTD/TPI with oxaliplatin or bevacizumab; and an increase in tumor immunogenicity after treatment with FTD/TPI and oxaliplatin, leading to a better tumor response to anti-PD-1 exposure.

Methods: Further to the dose-escalation part (24 pts), the recommended dose (RD) was defined as FTD/TPI 35 mg/m^2 bid, days 1–5 q14, together with oxaliplatin 85 mg/m^2 (day 1). Safety data were collected during expansion part from 12 evaluable pts treated with the doublet at the RD with either nivolumab 3 mg/kg (n = 6) or bevacizumab 5 mg/kg (n = 6) administered at day 1. Pts were monitored for safety for the first 2 months of treatment before allowing further enrollment. Eligibility criteria included measurable disease, performance status (PS) 0-1, normal organ function, and progression after >1 prior anti-tumor therapy (excluding oxaliplatin).

Results: Baseline characteristics were median age of 67 years (range 52 to 75 years); PS 0/1 (3/9 pts), male/female (8/4 pts); and colon/rectum (5/7 pts). Drugrelated adverse events (AEs) reported in $\geq$ 2 pts were neutropenia, diarrhoea, asthenia, and nausea; mainly (93%) grade 1-2. The most common grade 3 or 4 drugrelated event was neutropenia. Grade 1 neurotoxicity attributed to oxaliplatin was observed in 2 pts. No immune-related AE due to nivolumab were reported. Best overall response included 2 partial responses after 2 months of treatment (1 pt in bevacizumab cohort, 1 MSI-H pt in nivolumab cohort). Pharmacokinetics parameters for FTD/TPI were aligned with historical data.

Conclusions: The safety data showed that the two triplets were well tolerated. Expansion enrollment is continuing in both cohorts to confirm preliminary evidence of activity in a larger number of patients.

Clinical trial identification: NCT02848443.

471P A phase I study to determine the maximum tolerated dose of trifluridine/tipiracil and oxaliplatin in patients with refractory metastatic colorectal cancer: LUPIN study

M. Suenaga[1], T. Wakatsuki[1], M. Ogura[1], T. Ichimura[1], E. Shinozaki[1], I. Nakayama[1], H. Osumi[1], Y. Ota[1], K. Chin[1], T. Mashima[2], H. Seimiya[2], D. Takahari[1], K. Yamaguchi[1]

[1]Department of Gastroenterology, Cancer Institute Hospital of JFCR, Tokyo, Japan, [2]Molecular Biotherapy, Cancer Chemotherapy Center of JFCR, Tokyo, Japan

Background: The effectiveness of reintroduction of oxaliplatin for metastatic colorectal cancer (mCRC) refractory to both oxaliplatin and irinotecan was previously reported in a single arm, open-label phase II study (RE-OPEN, Suenaga, 2015). We conducted a phase I study to determine the maximum tolerated dose (MTD) and the safety of oxaliplatin plus trifluridine/tipiracil (FTD/TPI, also known as TAS-102) in patients with refractory mCRC (UMIN000015764).

Methods: Three dosages of intravenous oxaliplatin (50, 65 and 85 mg/m^2) on days 1 and 15 and a fixed dose of FTD/TPI 35 mg/m^2 bid on days 1–5, 15–19 every 4 weeks were investigated in patients with refractory mCRC by using a 3 + 3 design. Eligible patients had received prior oxaliplatin-based treatment that achieved a response or stable disease followed by confirmed disease progression at least 6 months before entering the study.

Results: 12 patients were enrolled in the study. Characteristics of patients were as follows: median age, 62 (range, 47–68) years; male/female, 6/6; ECOG PS 0, 75%; number of prior regimens ≥3, 33.3%; and median oxaliplatin-free interval, 24.3 (range, 6.2–71.4) months. 3 of 6 patients of the oxaliplatin 85mg/m^2 cohort had dose-limiting toxicities (DLTs): treatment delay on 2nd cycle ≥8 days due to grade ≥2 neutropenia or grade 2 AST/ALT increased. No DLTs were observed in the other cohorts. The median number of treatment cycles was 3 (range, 1–9): 9 patients continued the treatment until disease progression; and 3 patients discontinued due to toxicity or patient's refusal. In safety, grade ≥3 adverse events were neutropenia (n = 3), thrombocytopenia (n = 1), anorexia (n = 1) and nausea (n = 1). There was no evidence of allergic reaction to oxaliplatin and severe peripheral sensory neuropathy.

Conclusions: According to the results of this phase I study, a combination of trifluridine/tipiracil 35 mg/m^2 bid on days 1–5, 15–19 and oxaliplatin 85 mg/m^2 on days 1 and 15 every 4 weeks could be a candidate for recommended dose of the trifluridine/tipiracil+oxaliplatin regimen in patients with refractory mCRC.

Clinical trial identification: UMIN000015764 (release date, 1/12/2014).

472P Sidedness of the primary tumor on the effect of TAS-102 for refractory metastatic colorectal cancer

S. Ueda[1], Y. Tsuboguchi[2], Y. Nakatani[2], A. Tsuya[3], S-I. Nishina[4], K. Akiyoshi[2], S. Okazaki[5], S. Tokunaga[2], H. Daga[2]

[1]Medical Oncology, Osaka City General Hospital, Nara, Japan, [2]Medical Oncology, Osaka City General Hospital, Osaka, Japan, [3]Clinical Oncology, Osaka City General Hospital, Osaka, Japan, [4]Medical Oncology, Ako Central Hospital, Ako-city, Japan, [5]Medical Oncology, Kyoto Medical Center, Kyoto, Fushimi-ku, Japan

Background: TAS-102 study was shown to have clinical activity in a large population of Japanese and Western patientswith heavily pretreated metastatic colorectal cancer, including those whose disease was refractory to fluorouracil.But we know few date of TAS-102 in daily medical practice. So we assessed efficacy and safety of TAS-102 for refractory metastatic colorectal cancer.

Methods: We retrospectively reviewed the data of 86 patientswho received TAS-102 treatment in our institution between June2014 and October2017.TAS-102 (with each dose consisting of 35 mg per square meter) was administered twice daily, 5 days on and 2 days off for 2 weeks, followed by 2 weeksrest period. The regimen was repeated every 4 weeks.

Results: The median age was 69 years (range, 27–87). Performance status of 1 and 2 were 39 and 47 patients. RAS wild and mutant were 39 and 47 patients. Primary tumor site of right and left were 25 and 61 patients. All patients had received prior chemotherapy regimens containing a fluoropyrimidine, oxaliplatin, and irinotecan. 41 patients received 4 or more prior chemotherapy. Response rate and disease control rate of all were 1% and 24%. Right and left-sided of response rate were 4% and 0%. Right and left-sided of disease control rate were 32% and 19%. Median PFS was 62 days, right and left-sided were 55 and 64 days. Median OS was 216 days, right and left-sided were 262 and 200 days. OS was longer than previously reported. 40 patientsreceived subsequent chemotherapy. Adverse events were mild with 18% of Grade 4 neutropenia and 4% of Grade 3 febrile neutropenia.

Conclusions: TAS-102 was active and tolerable for heavily treated refractory metastatic colorectal cancer. There were no significant difference of PFS and OS in primary tumor site.

473P Influence of the proton pump inhibitor esomeprazole on the bioavailability of regorafenib

F.M. de Man[1], K.G.A.M. Hussaarts[1], M. de With[1], E. Oomen-De Hoop[1], H.K. van Halteren[2], N.C.H.P. van der Burg-De Graauw[3], F.A.L.M. Eskens[1], T. van Gelder[4], R.W.F. van Leeuwen[4], R.H.J. Mathijssen[1]

[1]Medical Oncology, Erasmus MC Cancer Institute, Rotterdam, Netherlands, [2]Internal Medicine, Admiraal de Ruijter Hospital, Vlissingen, Netherlands, [3]Internal Medicine, Bravis Hospital, Roosendaal, Netherlands, [4]Hospital Pharmacy, Erasmus University Medical Center, Rotterdam, Netherlands

Background: The multikinase inhibitor regorafenib (REG) is currently registered for the treatment of colorectal cancer (CRC), gastrointestinal stromal tumors (GIST), and hepatocellular carcinoma. REG exhibits a pH-dependent solubility, and therefore acid reducing drugs such as proton pump inhibitors (PPIs, e.g. esomeprazole) might reduce REG absorption by increasing the stomach pH as was shown for many other kinase inhibitors (van Leeuwen, Lancet Oncol, 2014). We performed a randomized, 3-phase, cross-over trial to compare the exposure of REG alone to REG with esomeprazole (concomitantly or 3 hours prior to REG intake) in CRC and GIST patients.

Methods: Patients were randomized into 2 sequence groups consisting of 3 phases: REG intake alone, REG with concomitant esomeprazole (for 5 days), and REG 3 hours preceded by esomeprazole (for 5 days). Pharmacokinetic (PK) blood sampling was performed at the 21th, 49th and 77th day of the trial. All patients were treated with REG 120 mg at steady-state. Primary endpoint was the relative difference (RD) in geometric means for REG $AUC_{0\text{-}24h}$. A linear mixed model was used to analyze log-transformed area under the curve (AUC). For multiple testing a Bonferroni correction was applied.

Results: A total of 14 patients were evaluable for the primary endpoint. Exposure ($AUC_{0\text{-}24h}$) to REG alone was: 55.9 μg*h/mL (CV: 40.3%). For REG with concomitant esomeprazole or with esomeprazole 3 hours prior $AUC_{0\text{-}24h}$ was: 53.7 μg*h/mL (CV: 33.5%) and 53.6 μg*h/mL (CV: 42.6%) respectively. No significant differences were identified when REG alone was compared to REG with concomitant esomeprazole (RD: -3.9%, 95% CI: -20.5-16.1%, p = 1.0) or REG with esomeprazole 3 hours prior (RD: -4.1%, 95% CI: -22.8-19.2%, p = 1.0). Furthermore, no significant differences were observed in other PK parameters of REG and its active metabolites M-2 and M-5 (i.e. C_{max}, T_{max}). Most common adverse events ≥ grade 2 were hypertension (71%), fatigue (43%) and hand foot skin reaction (36%).

Conclusions: The use of esomeprazole concomitantly or 3 hours prior to REG intake did not alter REG pharmacokinetics. Our results indicate that PPIs like esomeprazole can be combined with REG without the appearance of a significant drug interaction.

Clinical trial identification: NCT02800330, 01-05-2016.

Abteilung, Asklepios Klinik Altona, Hamburg, Germany, [14]Institute for Medical Systems Biology, Ulm University, Ulm, Germany

Background: Antiangiogenic agents are frequently used in the systemic treatment of metastatic colorectal cancer (mCRC). Since these strategies target not the tumor but the tumor associated endothelium establishing positive or negative predictive biomarkers is challenging. Recent research indicated a potentially predictive value of cytokines and angiogenic factors (CAF) for early detection of progression during treatment with chemotherapy and bevacizumab. The PERMAD trial is a two-phase trial with the primary objective to evaluate of the impact of a personalized, marker-driven treatment approach with early detection of progression and modification of treatment. The aim of the first phase is to establish a combination of CAFs that allows early detection/prediction of disease progression (PD) under a treatment with FOLFOX plus bevacizumab (Bev). The second phase is a randomized part with marker-driven switch of anti-angiogenic agent and maintenance of the chemotherapy backbone until definite radiological PD compared to a conventional treatment approach of changing chemotherapy and antiangiogenic agent at time of radiologic PD. Here we report the results from the first phase examining samples of 50 patients.

Methods: During the run-in phase 102 CAFs were established in blood samples taken prior to treatment and q2w thereafter until PD. Using machine learning we aimed at establishing a combination of 5 out of the 102 CAFs that fulfilled these criteria: cytokines should be affected by PD, but not by treatment itself and should indicate PD at least 2 months prior to the time of PD as determined by MD-CT which was performed every 2 months.

Results: Using our machine learning approach we could establish a combination of markers from 30 patients that is associated with $>$ 80% accuracy with PD 2 months prior to radiological PD under a treatment with FOLFOX plus Bev. This combination will be corroborated in another 20 patients (data presented at the meeting) and used for the second, randomized part of the trial.

Conclusions: Using advanced bioinformatics we have identified a biomarker combination that is associated with subsequent PD with a high accuracy under a treatment with FOLFOX plus Bev.

Background: The TRICOLORE trial previously demonstrated that S-1 and irinotecan (IRI) plus bevacizumab (Bmab) was non-inferior to mFOLFOX6 or CapeOX plus Bmab in terms of progression-free survival (PFS) as first-line treatment for metastatic colorectal cancer (mCRC), irrespective of RAS status (Komatsu Y, et al. ESMO 2017, and Yamada Y, et al. Ann Oncol. 2018). We now report the final overall survival (OS) after a median follow-up of more than 3 years. The results of this trial were subjected to an exploratory analysis to determine if primary tumor location (TL) influenced the response to S-1 and IRI plus Bmab.

Methods: This trial was a randomized, open-label, phase 3 trial. Chemotherapy-naïve patients with mCRC were randomly assigned to receive either mFOLFOX6 or CapeOX plus Bmab (arm A) or S-1 and IRI plus Bmab (arm B, given as a 3-week regimen [7.5 mg/kg Bmab, 150 mg/m^2 IRI on day 1, and 40 − 60 mg S-1 twice daily for 2 weeks, followed by a 1-week rest] or a 4-week regimen [5 mg/kg Bmab, 100 mg/m^2, IRI on days 1 and 15, and 40 − 60 mg S-1 twice daily for 2 weeks, followed by a 2-week rest). Patients' data were finally updated in September 2017.

Results: At this final analysis, the median overall survival (mOS) was 32.6 months with arm A and 34.3 months with arm B (median follow-up, 48.7 months). The hazard ratio (HR) for OS was 0.89 (95% CI: 0.72 − 1.10). Median progression-free survival (mPFS) in arm A/B were 10.8/14.0 months (HR 0.86, 95% CI: 0.71–1.04, $p < 0.0001$ for non-inferiority). In right-sided TL, mOS and mPFS in arm A/B were 25.6/28.1 months (HR 0.82, 95% CI 0.56-1.21) and 9.6 /11.4 months (HR 0.85, 95% CI 0.60-1.22), respectively. In left-sided TL, mOS and mPFS in arm A/B were 35.5/36.8 months (HR 0.89, 95% CI 0.68-1.15) and 11.3/15.0 months (HR 0.82, 95% CI 0.66-1.03), respectively.

Conclusions: Our updated analysis reconfirmed that S-1 and IRI plus Bmab is non-inferior to mFOLFOX6 or CapeOX plus Bmab in terms of PFS. S-1 and IRI plus Bmab is now recommended as a 1st-line treatment for mCRC irrespective of primary TL and RAS status.

Background: FOLFIRI (5FU/leucovorin/irinotecan) + aflibercept significantly improves median overall survival (OS), progression-free survival (PFS) and objective response rate (ORR) in patients (pts) with previously treated metastatic colorectal cancer (mCRC). The aim of this study was to investigate efficacy and tolerability of adding aflibercept to FOLFIRI in the first line setting.

Methods: Pts with untreated documented mCRC received aflibercept plus FOLFIRI every 14 days until progression or unacceptable toxicity in an open, phase II single arm, multicenter trial. The primary endpoint was the 6-months PFS rate. Secondary endpoints were overall PFS, OS and tolerability. A two- steps Simon design was used with H_0: 55% and H_1= 75%, respectively (one-sided $\alpha = 5\%$, 1-β=90%). Data were analyzed in intention to treat population. The study was stopped at the first stage.

Results: 41 patients were included and 40 analyzed (1 consent withdrawal) in 9 French centers between 10/2014 and 02/2017. Median age was 65 y (46-81), 42% were men, 53% had two or more metastatic sites. Eighteen patients (54.5%, IC [38.940; 69.509]) were alive and non-progressive at 6 months. Treatment with FOLFIRI plus aflibercept was therefore considered ineffective, inclusions were stopped. Median follow-up was 20.5 months (95% CI (15,11 ; 27,86)). ORR was 54% and disease control rate was 80%. Median duration of treatment was 5.2 months, median PFS and OS were 8,3 and 21.9 months respectively. Grade 3-4 adverse events were mainly gastrointestinal (18 pts, 45% : mucositis (15%), diarrhea (12,5%), abdominal pain (10%)) and vascular (13 pts, 32,5% : hypertension (17,5%) and venous thromboembolism (15%)). Severe hematological toxicities occurred in 7,5% of pts. 87.5% of patients had at least one dose modification during treatment. 37 pts received a second line therapy.

Conclusions: First line FOLFIRI+ aflibercept for mCRC pts is feasible but with significant toxicities leading to dose reduction in the majority of patients. Median PFS and OS were close to those reported with classical doublet and targeted agents in this setting.

477P Folfiri-aflibercept vs folfiri-bevacizumab as second line treatment of RAS mutated metastatic colorectal cancer in real practice

A. Ottaiano[1], M. Capozzi[2], C. De Divitiis[2], A. Cassata[2], A. De Stefano[2], S. Tafuto[2], A. Avallone[2], G. Nasti[1]

[1]SSD Innovative Therapies for Abdominal Metastases - Abdominal Oncology, Istituto Nazionale Tumori, IRCCS, Fondazione "G. Pascale", Naples, Italy, [2]Abdominal Oncology, Istituto Nazionale Tumori, IRCCS, Fondazione "G. Pascale", Naples, Italy

Background: To date the treatment of RAS mutated (-M) metastatic colorectal cancer (mCRC) patients (pts) relies on the administration of oxaliplatin-based chemotherapy and bevacizumab as first line. Intensive debate is open about second-line treatments.

Methods: This is a real practice study; consecutive RAS-M unresectable mCRC were treated at the oncologist discretion at progression to FOLFOX/BEVA (fluorouracil, folinic acid, oxaliplatin, bevacizumab) with FOLFIRI/BEVA (fluorouracil, folinic acid, irinotecan, bevacizumab) (arm A) or FOLFIRI/AFLI (FOLFIRI, aflibercept) (arm B). We have analyzed differences in outcome and response between the two therapy sequences.

Results: Seventy-four patients were treated from January 2014 to January 2018; 31 treated with arm A, 43 with arm B. Among clinical factors there was a predominance of more extended disease (>two metastatic sites) in arm B (25/31 [51.2%] vs 40/43 [32.3 %] arm A; $p = 0.0414$). Fifty-nine pts were evaluable for response through RECIST: arm A, 5 PR, 15 SD, 8 PD; arm B, 5 PR, 16 SD, 10 PD. Second-line chemotherapy doses were reduced in 32.3% of pts in arm A and 38.1% in arm B. There were no grade 4 toxic events (NCI-CTC v4.0). The mean distance from first-line discontinuation to second-line start was 0.8 months in arm A and 2.4 months in arm B. Duration of first-line chemotherapy was significantly shorter in pts treated in arm B (12 pts < 6 months arm B vs 1 pt in arm A; $p = 0.0278$). Analysis of overall survival (OS) was done excluding these 13 pts to avoid prognostic interferences. Median OS were 22.7 in arm A vs 25.5 months in arm B (+ 2.8 months; $P = 0.6855$, HR: 1.12; 95% CI: 0.62 to 2.03). No maintenance treatment was done in arm B while in arm A BEVA with or without fluorouracil and folinic acid was done; censoring the analysis of OS at the end of the induction phase of both arms favored arm B ($P = 0.0425$; HR: 0.42; 95% CI: 0.15 to 1.15).

Conclusions: In our real practice, oncologists tend to administer FOLFIRI/AFLI in more extended RAS-M mCRC and to delay start of therapy. FOLFIRI/BEVA and FOLFIRI/AFLI are equally effective second-lines albeit FOLFIRI/AFLI, during the induction phase (6 months), is associated with a lower risk of death.

Background: VELOUR trial compared FOLFIRI+/-aflibercept in 1226 mCRC patients after progression to oxaliplatin-based treatment, regardless of biological previous therapies. mOS (13.50 vs 12.06 months) and mPFS (6.90 vs 4.67 months) were increased, which led to aflibercept approval. We do not have yet enough information on aflibercept after anti-EGFR treatment. Our goal was to analyze efficacy and safety data of aflibercept in this specific context.

Methods: Retrospective analysis of clinical, therapeutic, and survival data collected from 120 consecutive RASwt mCRC patients treated from 2012 to 2017 with FOLFIRI-aflibercept after progression to standard chemotherapy + anti-EGFR in 12 Spanish hospitals.

Results: Median age was 60, 62.5% male, 37.5% female. 24% were right-sided tumours and 76% left-sided, with primary tumour resection in 41%. 100% RASwt, 5% BRAFmt. All patients received prior anti-EGFR therapy and 96% had ECOG 0/1. Median of FOLFIRI-Aflibercept cycles was 12, with 33% ORR. mPFS was 6.9 months (95% CI 6.0-7.7). BRAF, ECOG, primary tumour resection and n° of metastatic sites had statistical significance in univariate analysis; and primary tumour resection was also significant in multivariate analysis. mOS was 14.5 months (95% CI 9.7-19.3), with statistical significance in univariate for primary tumour resection, ECOG, and n° of metastatic sites. ECOG and n° of metastatic sites reached significance in multivariate analysis. As for toxicity, only 18.3% needed aflibercept dose reduction. 2nd line treatment was discontinued in 71.8% (mostly due to progression: 51.7%, 6.7% toxicity,1.7% surgery). 37% reached G3-4 toxicity (16.6% hematologic, 7.5% HTN, 5.9% asthenia, 2.5% perforation) 59% received a 3rd line therapy: 23% TAS-102, 18% regorafenib, 9% capecitabine.

Conclusions: RASwt mCRC patients reached similar results to those reported in VELOUR trial. The efficacy of subsequent aflibercept-containing 2nd line was maintained regardless of prior anti-EGFR. The efficacy of subsequent aflibercept-containing 2nd line was maintained regardless of prior anti-EGFR. Our results suggest that FOLFIRI-aflibercept, after 1st line with anti-EGFR, is a good treatment strategy for RASwt mCRC.

479P A phase II study of bevacizumab and irinotecan plus alternate-day S-1 as a second-line therapy for colorectal cancer: The AIRS study

M. Honda[1], C. Matsuda[2], C. Tanaka[3], K. Kondo[4], T. Takahashi[5], C. Kosugi[6], Y. Tokunaga[7], H. Takemoto[8], H.M. Kim[9], J. Sakamoto[10], K. Oba[11], H. Mishima[12]

[1]Minimally Invasive Surgical and Medical Oncology, Fukushima Medical University, Fukushima, Japan, [2]Gastroenterological Surgery, Osaka University, Osaka, Japan, [3]Surgery, Gifu Prefectural General Medical Center, Gifu, Japan, [4]Surgery, National Hospital Organization, Nagoya Medical Center, Nagoya, Japan, [5]Surgical Oncology, Gifu University Graduate School of Medicine, Gifu, Japan, [6]Department of Surgery, Teikyo University Chiba Medical Center, Ichihara, Chiba, Japan, [7]Surgery, Kyoto Japan Post Hospital, Kyoto, Japan, [8]Surgery, Kinki Central Hospital, Osaka, Japan, [9]Surgery, Rinku General Medical Center, Izumisano, Japan, [10]Surgery, Tokai Central Hospital, Kakamigahara, Japan, [11]Biostatistics, The University of Tokyo School of Public Health, Tokyo, Japan, [12]Surgery, Aichi Medical University, Nagakute, Japan

Background: The aim of this single-arm phase II clinical trial was to evaluate whether the alternate-day administration of S-1 plus irinotecan would reduce the incidence of severe diarrhea in comparison to consecutive-day S-1 administration (standard IRIS regimen) in second-line treatment in patients with metastatic colorectal cancer.

Methods: Patients with metastatic colorectal cancer after failure with first-line treatment of oxaliplatin and fluoropyrimidine were enrolled. Irinotecan (150 mg/m2) and bevacizumab (5mg/kg) were given intravenously on day 1. Oral S-1 was administered on alternate-days at a dose of 40-60mg twice a day. Cycles were repeated every two weeks. The primary endpoint was the incidence of grade $\geq$3 diarrhea. Our hypothesis set the 21% as a threshold incidence and 10% as an expected incidence from previous studies with one-sided alpha = 0.05. The secondary endpoints included the relative dose intensity, progression free survival, overall survival and other adverse events.

Results: A total of 51 patients were enrolled. The incidence of grade $\geq$3 diarrhea was 15.7% (8/51). Other common grade $\geq$3 adverse events were neutropenia, anemia, thrombocytopenia and fatigue were 13.7% (7/51), 5.9% (3/51), 2.0% (1/51) and 5.9% (3/51), respectively. The relative dose intensities of irinotecan, bevacizumab, and S-1 were 80.0%, 86.8%, and 77.7%, respectively. The median progression free survival and overall survival were 8.4 months (5.8 - 9.8) and 17.1 months (11.8 - 22.3).

Conclusions: The alternate day S-1 administration doesn't have significant effectiveness to reduce diarrhea in patients who received second line treatment for metastatic colorectal cancer.

Clinical trial identification: UMIN000008947.

480P The safety and efficacy of FOLFOXIRI plus molecular target therapy as a first-line treatment for metastatic colorectal cancer: A multicentre retrospective study

T. Ogata[1], H. Satake[2], M. Ogata[1], Y. Hatachi[1], M. Hamada[3], H. Yasui[1]

[1]Department of Medical Oncology, Kobe City Medical Center General Hospital, Kobe, Japan, [2]Cancer Treatment Center, Kansai Medical University Hospital, Hirakata, Japan, [3]Department of Surgery, Kansai Medical University Hospital, Hirakata, Japan

Background: The TRIBE study showed that FOLFOXIRI plus bevacizumab therapy is an effective treatment for metastatic colorectal cancer (mCRC). This study aimed to determine the safety and effectiveness of FOLFOXIRI therapy as a first-line treatment.

Methods: We retrospectively collected data of patients with mCRC treated with FOLFOXIRI from March 2014 to December 2017 in two centres.

Results: Fifty-five patients were enrolled in this study (median age, 60 years; males 25, females 30). The tumour location was classified as right and left in 15 and 40 patients, respectively. Twenty-nine and twenty-six patients had RAS wild-type disease and mutation-type disease, respectively. Anti-VEGF and anti-EGFR antibodies were used in 38 and 17 patients, respectively. The most common grade 3 or 4 adverse event was neutropenia (51%). Skin toxicities and hypomagnesaemia showed a statistically higher frequency among patients with anti-EGFR antibodies ($P < 0.001$ and $P = 0.039$, respectively). The overall response rate (ORR) was 67% (complete response [CR], 7 patients; partial response [PR], 30 patients; not evaluated [NE], 1 patient), and the disease control rate was 96% (stable disease, 16 patients). The median progression free survival (mPFS) was 11.0 (0.43 − 45.3) months and the median overall survival (mOS) was 41.9 (1.00 − 45.3) months. In FOLFOXIRI plus anti-VEGF antibodies, the ORR was 55% (CR, 5 patients; PR 16 patients), and in FOLFOXIRI plus anti-EGFR antibodies, the ORR was 94% (CR, 2 patients; PR, 14 patients; NE, 1 patient) ($P = 0.271$). With a median follow up of 18.4 months, mPFS and mOS were not significantly different in patients with anti-EGFR antibodies or anti-VEGF antibodies (hazard ratio [HR], 3.12 [0.883 − 11.0]; $P = 0.143$ and $P = 0.063$, respectively). Twelve patients had progressive disease (PD) during the induction phase. In these patients, mOS was significantly poorer (13.2 months versus 41.9 months; HR, 23.3 [6.77 − 80.1]; $P < 0.001$).

Conclusions: FOLFOXIRI plus molecular target therapy showed impressive results for patients with mCRC. The response rate was significantly higher in patients with anti-EGFR antibodies, although skin toxicities and hypomagnesaemia tend to occur in these patients.

Background: Several previous reports indicated that cetuximab (Cmab) rechallenge may be efficacious in patients for whom Cmab was previously effective. On the other hand, some reports did not support this. Considering the plasticity of sensitive clone, we assumed that an anti-EGFR antibody-free interval (aEFI) and efficacy may be correlated. This current study investigates the efficacy and safety of Cmab rechallenge as a salvage chemotherapy.

Methods: The E-Rechallenge tiral is a multicenter phase II study in mCRC patients who have become refractory to fluoropyrimidines, L-OHP, CPT-11, Cmab and bevacizumab, and in whom previous treatment with Cmab was effective in any earlier line (achieving CR, PR, or SD that persisted for $\geq$6 months). The other main eligibility criteria are; RAS wild-type, measurable disease, aEFI $\geq$16 weeks between the last dose of Cmab during previous treatment and the start of Cmab rechallenge. Protocol treatment is the combination of weekly Cmab with biweekly CPT-11. The primary endpoint is response rate (RR). Secondary endpoints are progression free survival (PFS), overall survival (OS), association between the aEFI and efficacy, and safety. Using a single-stage binominal design, 45 patients were required; a RR of $\geq$ 20% was considered promising, and a RR of $\leq$ 5% unacceptable (one-sided $\alpha = 2.5\%$, $\beta = 10\%$). Additional research of ctDNA was conducted optionally.

Results: Between Dec 2014 and Oct 2017, 33 patients were enrolled. Patients' characteristics were as follows; mean age 64.4, male/female 84.8%/15.2%, primary location right/left 12.1%/87.9% and the efficacy in previous Cmab, CR/PR/SD $\geq$6 months 3%/78.8%/18.2%, respectively. The primary endpoint; the rates of PR/SD/PD (95%CI) were PR 15.6% (5.3-32.7%)/SD 40.6% (23.6-57.6%)/ PD 43.8% (26.4-62.3%). Secondary endpoint; median PFS and OS (95%CI) were 88 days (62-113days) and 262 days (195-307days). There were no statistical significant difference of PFS stratified by median aEFI. New signals of adverse events were not identified.

Conclusions: Cmab rechallenge showed some activity in the salvage setting, in patients for whom Cmab was previously effective. The additional research of ctDNA may contribute to identify patients with benefit from Cmab rechallenge.

Clinical trial identification: UMIN 000016439.

Background: RET rearrangements (RETr) are uncommon yet emerging oncogenic targets found in RAS/BRAF wild-type colorectal cancers (CRCs), particularly right-sided, MSI-high tumors. We describe the molecular landscape of metastatic CRCs harboring a somatic RETr detected by next generation sequencing (NGS) of cell-free DNA (cfDNA). cfDNA data complement previous descriptions of RETr in tissue, which are limited by small series of patients (pts) and cfDNA also provides a summary of genomic alterations (alts) across multiple metastatic sites in pts typically exposed to one or more lines of therapy.

Methods: Between 2/2015-3/2018, somatic RETr were identified among 4,234 consecutive metastatic CRC pts with tumor DNA detected on a 68-73 gene cfDNA assay (Guardant360®, Redwood City, CA). This validated NGS assay evaluates single nucleotide variants, and select indels, fusions, and copy number gains with high sensitivity and analytic specificity. Relevant clinicopathologic correlates were obtained from clinicians.

Results: Seventeen RETr were detected in 16 pts (0.4%). Functionally significant alts in other cancer genes were found in 88% of samples with a RETr (median 9.5 additional alts, max 23). There was a high co-occurrence of canonical KRAS alts (14 alts in 7/16 pts), 5 of whom also had alts in NRAS (n = 4pts), the EGFR extracellular domain (ECD, n = 4), and/or BRAF V600E (n = 3). For 4 pts with available comprehensive tissue NGS results, the RETr was detected in cfDNA only. Two also had KRAS, NRAS, and EGFR ECD alts, one had an EGFR activating alt, and the fourth had a FGFR3 fusion, all detected only in cfDNA. Prior to cfDNA collection, all 4 had progressed on anti-EGFR therapy after a median of 12mo (range 8-16mo) of treatment. Four additional RETr/KRAS+ pts had either a KRAS alt that was not detected in tissue (n = 2) or co-occurred with an ALK fusion and/or BRAF V600E in pts who had prior anti-EGFR therapy (n = 2).

Conclusions: RETr commonly co-occur with RAS/RAF alts in cfDNA, a novel observation. The alt pattern and clinicopatholgoic history suggest RETr contribute to acquired resistance to anti-EGFR therapy in metastatic CRC. Our data also raise the question of whether driver RETr may be associated with primary resistance to anti-EGFR therapy.

[1]Clinical Oncology, St. Marianna University School of Medicine, Kawasaki, Japan, [2]Medical Oncology, Ludwig Maximilians University - Grosshadern, Munich, Germany, [3]Preventive Medicine, University of Southern California, Norris Comprehensive Cancer Center, Los Angeles, CA, USA, [4]Biostatistics and Bioinformatics, HTG Molecular Diagnostics Inc., Tucson, AZ, USA, [5]R&D and Pharmaceutical Services, Cancer Genetics, Inc., Los Angeles, CA, USA, [6]Kite, Santa Monica, CA, USA, [7]Medical Oncology, University of Southern California, Norris Comprehensive Cancer Center, Los Angeles, CA, USA, [8]Clinical Oncology, Kagawa University Hospital, Kagawa, Japan, [9]Medical Oncology, Showa University Fujigaoka Hospital, Yokohama, Japan, [10]Gastroenterology, Chiba Cancer Center, Chiba, Japan, [11]Medical Oncology, Showa University Koto Toyosu Hospital, Tokyo, Japan, [12]Digestive Surgery, Nihon University School of Medicine, Tokyo, Japan, [13]Clinical Medicine (Biostatistics), Kitasato University, Tokyo, Japan, [14] Department of Medical Oncology and Comprehensive Cancer Center, Ludwig Maximilians University - Grosshadern, Munich, Germany

Background: We conducted a biomarker study to identify significant genes to predict efficacy of cetuximab (cet) based treatment using tumor samples from mCRC patients (pts) enrolled in JACCRO CC-05/06AR (UMIN000010635) and FIRE-3 (NCT00433927), which evaluated 1st-line doublet plus cet therapy. There are no established predictive biomarkers beyond RAS mutations. We reported recently CDX2 gene expression levels as a promising biomarker for cet treatment in KRAS wild-type mCRC pts of the JACCRO trial (ASCO 2016, abst3592). Therefore, we performed the validation study using tumor samples from pts enrolled in the FIRE-3 trial.

Methods: We analyzed tissue samples of 77 pts of the JACCRO trial for discovery set and 250 pts of cet arm in the FIRE-3 trial for validation set. Gene expression levels were measured by HTG EdgeSeq Oncology Biomarker Panel, which is comprised of probes targeting 2560 genes implicated in numbers of pathways, using next generation sequencing for quantitative analysis of targeted RNAs. Univariate Cox regression analysis was conducted for all genes that passed QC filtering.

Results: Seventy-one pts (male/female, 39/32; median age, 63 yrs) and 102 pts (male/female, 75/27; median age, 63 yrs) were successful for gene expression analysis in the JACCRO and FIRE-3 set, respectively. The Cox regression analysis identified 24 genes for overall survival (OS) and 8 genes for progression-free survival (PFS), which all were significant ($p < 0.005$) in the JACCRO set. Among those genes, LYZ and RNF43 genes were found to be significantly associated with OS (coefficients, 0.21; $p = 0.013$) and PFS (coefficients, -0.20; $p = 0.037$), respectively, in the FIRE-3 set. In the JACCRO set, high expression ($\log2 > 9.07$) of CDX2 predicted a significantly longer PFS ($p = 0.002$). The same effect was found in the FIRE-3 set when applied the same cutoff value (median PFS 10.9 vs. 6.9 months, HR 0.39, 95%CI 0.22-0.72, $p = 0.002$).

Conclusions: Our biomarker study validated CDX2 as a novel predictor for clinical outcome of 1st-line cet based chemotherapy in mCRC. These data warrant further exploration of CDX2 as a biomarker or as a potential target for drug development.

Clinical trial identification: UMIN000010635.

484P Retrospective RAS analysis of the EPIC trial: Cetuximab plus irinotecan vs irinotecan in patients (pts) with second-line metastatic colorectal cancer (mCRC)

A. Sobrero[1], H-J. Lenz[2], C. Eng[3], W. Scheithauer[4], G. Middleton[5], W. Chen[6], R. Esser[7], J. Nippgen[8], H. Burris[9]

[1]*Medical Oncology, Policlinico San Martino IRCCS, Genoa, Italy,* [2]*Medical Oncology, University of Southern California, Los Angeles, CA, USA,* [3]*Department of Gastrointestinal Medical Oncology, M. D. Anderson Cancer Center, Houston, TX, USA,* [4]*Clinical Department of Oncology, Medical University of Vienna, Vienna, Austria,* [5]*Institute of Immunology and Immunotherapy, University of Birmingham, Birmingham, UK,* [6]*R&D Global Biostatistics & Epidemiology, EMD Serono, Beijing, China,* [7]*Global Medical Affairs Oncology, Merck KGaA, Darmstadt, Germany,* [8]*Medical Oncology, Merck KGaA, Darmstadt, Germany,* [9]*Drug Development, Tennessee Oncology, Nashville, TN, USA*

Background: The multicenter, open-label, randomized, phase 3 EPIC study (EMR 062202-025) investigated the addition of cetuximab to irinotecan vs irinotecan in pts with EGFR-expressing mCRC who had previously progressed on first-line fluoropyrimidine- and oxaliplatin-based chemotherapy. The primary endpoint was overall survival (OS). We present the extended RAS analysis (KRAS/NRAS exons 2, 3, and 4) for the EPIC study population.

Methods: 1298 RAS-unselected pts were enrolled from May 2003 to February 2006. Existing DNA samples were reanalyzed using BEAMing (beads, emulsion, amplification, magnetics) technology. RAS wild-type (wt) status was defined as having all alleles be analyzable and a sum of RAS mutations of $\leq 5\%$. Baseline characteristics, efficacy, safety, and post-study therapy were assessed. 10.3% had no RAS data available.

Results: Among the 452 (231 in the cetuximab + irinotecan arm and 221 in the irinotecan arm) pts with RAS wt mCRC, baseline characteristics were comparable to those of the unselected population. 67.5% had 1 prior line of therapy. In the cetuximab + irinotecan vs irinotecan arms, median progression-free survival (PFS) was 5.4 vs 2.6 months (HR, 0.57 [95% CI, 0.46-0.69]; $P < .0001$), median OS was 12.3 vs 12.0 months (HR, 0.91 [95% CI, 0.71-1.17; $P = .4645$]), and overall response rate (ORR) was 29.4% vs 5.0% (OR, 8.12 [95% CI, 4.04-17.40]; $P < .0001$), respectively. 76.4% and 61.8% of pts in the cetuximab + irinotecan vs irinotecan arms, respectively, experienced a grade ≥ 3 adverse event. 47.1% of pts in the irinotecan arm received cetuximab in a subsequent line of therapy vs 11.3% in the cetuximab + irinotecan arm.

Conclusions: This retrospective analysis confirms that cetuximab-based therapy is suitable as a standard, second-line treatment for pts with RAS wt mCRC. Specifically, the addition of cetuximab to irinotecan significantly improved PFS and ORR in this population. A large proportion of pts in the irinotecan arm crossed over to receive post-study cetuximab, potentially masking any OS benefit of the addition of cetuximab to irinotecan in this study. Benefits appear clinically relevantly higher than for pts with RAS-unselected or KRAS wt mCRC.

Background: Two phases III studies (FIRE-3 and CALGB/SWOG80405) suggested higher response rate (RR) for doublet chemotherapy with an anti-EGFR (Epidermal Growth Factor Receptor) compared to an anti-VEGF (Vascular Endothelial Growth Factor), in first line RAS/BRAF wild-type (WT) unresectable metastatic colorectal cancer (mCRC). Unfortunately, in clinical practice the delay to obtain RAS/BRAF status may delay the chemotherapy start. No study has evaluated the impact of a delayed introduction of the anti-EGFR.

Methods: This retrospective multicentric AGEO (Association Gastro-Entérologues Oncologues) study included mCRC RAS/BRAF WT patients who received a doublet chemotherapy either with an anti-VEGF introduced immediately (control arm) or with an anti-EGFR introduced at cycle 2 or 3 (delayed group) between 2013 and 2016. The primary endpoint was the Progression Free Survival (PFS). The Overall Survival (OS) and the RR were secondary endpoints. Given different characteristics between the two groups, a propensity score was developed.

Results: A total of 262 patients were included: 129 in the control group and 133 in the delayed group. Compared to the delayed group, patients treated in the control group were more likely descendant mCRC (60% vs 44%) and had more metastatic sites (>1 site: 57% vs 40%). In the delayed anti-EGFR group, the time to obtain RAS status was 20.7 days $\pm$18.9. The anti-EGFR was introduced in 70% of cases at C2 and in 30% at C3. Using the propensity score, there was no more difference between the two groups. The median follow-up was 37.9 months. PFS and RR were significantly longer and higher in the delayed anti-EGFR group compared to the control anti-VEGF group (PFS: 13.8 vs 10.8 months, $p = 0.03$; RR: 67% vs 46%, $p = 0.0007$). Meantime, no difference was observed concerning OS (30.4 months vs 30.0 months, $p = 0.23$).

Conclusions: There is no deleterious effect of delayed anti-EGFR introduction at cycle 2 or 3 compared to the immediate introduction of anti-VEGF in patients with RAS/BRAF WT mCRC. Therefore, in current clinical practice, if the response rate is an important goal, it is possible to wait for RAS status and to initially start chemotherapy without targeted therapy.

Background: RAS testing is used to select patients sensitive to anti-EGFR therapies in metastatic colorectal cancer (mCRC) but other biomarkers such as BRAF, PIK3CA/PTEN and p-IGF-1R+/MMP7 + (DP phenotype) have not prospectively assessed to predict anti-EGFR resistance.

Methods: We designed a multicenter prospective trial (NCT01276379) to evaluate if the following biomarkers BRAF mutation, PIK3CA mutation/PTEN loss and DP phenotype can improve the prediction of 12-months progression-free survival (PFS) over the use of only clinical variables in patients with RAS WT mCRC treated with standard chemotherapy plus biweekly Cetuximab as first-line therapy. The planned sample size was 170 RAS WT patients to detect a 20% difference in 12-month PFR based on analysis of clinical and selected biomarkers (alpha=.05, beta=.2). The discriminatory capacity of the biomarkers was evaluated using ROC curves.

Results: We included 181 RAS WT patients. The biomarker distribution was: BRAF mutant 20 patients (11%), PIK3CA mutated/PTEN loss 98 patients (58%) and DP 23 patients (12.7%). Median PFS: BRAF WT 11.4 vs BRAF mutant 5.9 months ($p = 0.004$). PIK3CA/PTEN pathway and DP phenotype did not discriminate PFR (p=NS). Baseline clinical variables with good prognosis in a multivariable model were PS = 0, left sided tumor and resectable liver metastases (i.e. liver only metastases (<3 nodules and <5cm)).

Conclusions: A clinical score discriminates between two groups of patients who benefitted differently from chemotherapy plus cetuximab. The addition of BRAF, PIK3CA/PTEN and DP to the clinical score does not improve the prediction of 12m PFS.

Clinical trial identification: EudraCT: 2010-019236-12.

487P Patient selection for targeting integrin with abituzumab in patients with metastatic colorectal cancer (mCRC): A retrospective analysis of the randomized phase I/II Poseidon study

R. Laeufle[1], D. Arnold[2], S. Kopetz[3], J. Straub[4], R. Bruns[5], G. Massimini[6], R. Debenedetto[7], R. Linke[7], E. Elez Fernandez[8], J. Tabernero[9]

[1]Clinical Development and Medical Affairs, SFJ Pharmaceuticals, Pleasanton, CA, USA, [2]Med. Abteilung, Asklepios Klinik Altona, Hamburg, Germany, [3]Department of Gastrointestinal Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA, [4]Global Early Development, Merck KGaA, Darmstadt, Germany, [5]Biostatistics, Merck KGaA, Darmstadt, Germany, [6]Global Research and Development, Merck KGaA, Darmstadt, Germany, [7]Clinical Development and Medical Affairs, SFJ-Pharmaceuticals, Pleasanton, CA, USA, [8]Gastrointestinal Cancer and Drug Development, Vall d'Hebron University Hospital, Barcelona, Spain, [9]Medical Oncology, Vall d'Hebron University Hospital, Barcelona, Spain

Background: Adding abituzumab (EMD 525797) a humanized monoclonal IgG2 antibody, targeting αv integrin subunit to the control arm (irinotecan+cetuximab) failed to demonstrate a statistically significant PFS benefit in a phase I/II in second line KRAS wild-type (KRAS wt exon-2) mCRC. A pre-planned explorative biomarker analysis suggested that high integrin αvβ6 expression may be negatively prognostic for OS in the control arm and predictive for prolonged OS with abituzumab treatment. {Elez et al Annals of Oncology, Volume 26, Issue 1, 1 January 2015, Pages 132–140}.

Methods: Further retrospective analysis of Poseidon study data were performed (n = 98 patients with high and n = 99 low αvβ6 expression) to correlate the impact of location of tumor (left n = 152 versus right n = 44, and one patient had both right and left colorectal cancer) and integrin αvβ6 expression (low versus high) on overall survival (OS), progression free survival (PFS) and objective response rate (ORR) of abituzumab added to irinotecan+cetuximab.

Results: This retrospective explorative analysis suggest that patients with left sided KRAS wt mCRC and high expression of αvβ6 showed the most benefit for median OS of 25.6 months versus 10.2 months (HR 0.36 [95% CI 0.17; 0.75]; median PFS of 8.6 months versus 4.2 months (HR 0.61 [95% CI 0.31; 1.22]); ORR. 9/20 (45.0%) versus 5/22 (22.7%), when treated with abituzumab 1000 mg + irinotecan+cetuximab versus irinotecan+cetuximab alone. No treatment benefit was observed in right sided mCRC with high expression of αvβ6 and in all mCRC with low expression of αvβ6.

Conclusions: Although the sample size is small, patients with left sided KRAS wt mCRC and high expression of αvβ6 integrin in their tumor seem to benefit most from the addition of abituzumab to irinotecan+cetuximab compared to irinotecan+cetuximab alone. A prospective study in 1L left sided RAS wild-type mCRC with high expression of αvβ6 is planned with the addition of abituzumab 1000mg to SOC.

Clinical trial identification: Explorative, retrospective data analysis of study NCT01008475; first release October 19, 2009.

[1]Surgery, Saiseikai Fukuoka General Hospital, Fukuoka, Japan, [2]Department of Biostatistics, Yokohama City University Hospital, Yokohama, Japan, [3]Department of Clinical Oncology, Aichi Cancer Center Hospital, Nagoya, Aichi, Japan, [4]Specialized Surgeries, Tokyo Medical and Dental University, Tokyo, Japan, [5]Department of Surgery and Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan, [6]Surgical Oncology, Gifu University Hospital, Gifu, Japan, [7]Surgery, Tohoku Rosai Hospital, Sendai, Japan, [8]Pathology, Keio University School of Medicine, Tokyo, Japan, [9]Pathology and Microbiology, Saga University, Saga, Japan, [10]Molecular Diagnostic Pathology, Iwate Medical University, Morioka, Japan, [11]Diagnostic Pathology, University of Toyama, Toyama, Japan, [12]Surgery, Tohoku University Hospital, Sendai, Miyagi, Japan, [13]Department of Gastroenterology, University of Tsukuba, Tsukuba, Japan, [14]Surgery, Hyogo College of Medicine, Nishinomiya, Japan

Background: We previously reported the results of a randomized phase II controlled trial comparing mFOLFOX6 plus bevacizumab (Bmab) with mFOLFOX6 plus cetuximab (Cmab) for KRAS wild-type (wt) colorectal cancer (CRC) with liver-limited metastases that were not optimally resectable. The current study is the first to examine the role of histopathologic response based on the study data of anti-VEGF versus anti-EGFR antibody.

Methods: In the ATOM trial, KRAS wild-type CRC patients with liver-limited metastases were eligible if the number of lesions was more than 5 and/or the size of lesions was more than 5cm in the maximum diameter. The primary endpoint was progression-free survival (PFS). Of 116 eligible patients, patients who underwent liver metastasectomy were evaluated for histopathologic response in this study. Resected liver specimens were assessed by the independent pathological review committee. Preplanned pathological assessments included tumor regression grade (TRG), dangerous halo, and sinusoidal obstruction of resected liver specimens. Patients were categorized into major histopathologic response (MjHR) if they had TRG of 1 (viable tumor cells = 0%) or 2 (< 25%), partial histopathologic response (PHR) if they had TRG of 3 (< 50%), or no histopathologic response (NHR) if they had TRG of 4 (< 75%) or 5 (> 75%).

Results: A total of 59 patients had TRG evaluation based on resected specimens by liver metastasectomy. Of those, 55 (28 in Bmab arm, 27 in Cmab arm) were eligible for analysis. In the Bmab arm, the number of patients with MjHR/PHR/NHR was 12/1/15 (43/4/54%); in the Cmab arm, 13/10/4 (48/37/15%). Median PFS of patients with a MjHR or PHR/NHR was 8.3 or 4.4 months in the Bmab arm and Not Reached or 5.4 months in the Cmab arm. Patients with a MjHR had a longer PFS than those with a PHR/NHR in both the Bmab arm (hazard ratio [HR], 0.50 (95%CI, 0.19-1.28)) and the Cmab arm (HR, 0.17 (95%CI, 0.05-0.58)).

Conclusions: In the TRG assessment, the proportion of MjHR was similar between the two arms. The impact of MjHR on PFS as compared to PHR/NHR was observed in both arms. Further results regarding other assessments will be presented.

489P Verification of guideline conform mCRC treatment with EGFR inhibitors with real-world evidence data from EU5 countries

L. Hoyer, N. Schmidt

BU Oncology, Real World Insights, IQVIA Commercial GmbH & Co. OHG, Frankfurt am Main, Germany

Background: The EGFR inhibitors cetuximab and panitumumab are indicated for patients suffering from metastatic colorectal cancer (mCRC), which are RAS wild-type. The aim of this analysis is to verify with real-world data whether the drug usage of those EGFR inhibitors reflects clinical guidelines with regards to their genomic profile.

Methods: Anonymized patients-level data collected through a large web-based survey between April 2017 and March 2018 was used. The study reported patient case history information across all cancer types in 5EU (France, Germany, Italy, Spain & UK). Treatment information and biomarker testing information on 5248 mCRC drug treated patients were analyzed.

Results: Evaluating KRAS and NRAS biomarkers status, real-world data analysis showed that 18,9% of mCRC patients were not tested for N-RAS mutation and 11,4% were not tested for K-RAS mutation. 16% of the mCRC population were RAS mutant. However, 3,2% of these patients received cetuximab and panitumumab even though they did not qualify for this treatment, due to their RAS mutation. Among all mCRC patients who were RAS wildtype, 49,4% of them received cetuximab or panitumumab.

Conclusions: This analysis of real-word data showed that biomarkers testing is not carried out in all mCRC patients. Secondly, the use of EGFR inhibitors in the RAS mutant mCRC patient population demonstrates a misalignment with clinical guidelines. Howver, most of patients receiving EGFR inhibitors are RAS wildtype, which implies that the majority of mCRC patients receiving EGFR inhibitors is treated according to medical guidelines regarding their genomic profile.

491P Impact of delayed addition of anti-EGFR monoclonal antibodies on the outcome of first-line therapy in metastatic colorectal cancer patients: A retrospective registry-based analysis

T. Buchler[1], O. Fiala[2], V. Veskrnova[1], R. Chloupkova[3], A. Poprach[4], I. Kiss[4], K. Kopeckova[5], L. Dusek[3], L. Slavicek[6], M. Kohoutek[7], J. Finek[2], M. Svoboda[4], J. Dvorak[1], L.B. Petruzelka[8], B. Melichar[9]

[1]Oncology, First Faculty of Medicine, Charles University and Thomayer Hospital, Prague, Czech Republic, [2]Oncology, University Hospital Plzen, Plzen, Czech Republic, [3]Institute of Biostatistic and Analyses, Masaryk University Brno, Brno, Czech Republic, [4]Department of Comprehensive Cancer Care, Masaryk Memorial Cancer Institute, Brno, Czech Republic, [5]Oncology, Second Faculty of Medicine, Charles University and Motol University Hospital, Prague, Czech Republic, [6]Oncology, Hospital Jihlava, Jihlava, Czech Republic, [7]Oncology, T Bata's Regional Hospital, Zlin, Czech Republic, [8]Oncology, First Faculty of Medicine, Charles University and General University Hospital, Prague, Czech Republic, [9]Oncology, Palacky University Medical School and Teaching Hospital, Olomouc, Czech Republic

Background: The addition of monoclonal antibodies against epidermal growth factor receptor (anti-EGFR Abs) to chemotherapy is commonly delayed in the real-world clinical practice, usually because of delays in obtaining RAS testing results. The aim of this retrospective registry-based analysis was to determine whether the delayed addition of anti-EGFR mAbs up to the fourth cycle of backbone chemotherapy adversely affects outcomes of mCRC patients treated with first-line regimens.

Methods: Clinical data of patients with RAS wild-type mCRC treated with first-line systemic therapy regimens containing anti-EGFR mAbs from a national database were analysed retrospectively. Patients were divided into three groups according to the timing of anti-EGFR mAbs addition to the chemotherapy backbone. Cohort A (n = 401) included patients with anti-EGFR mAbs added to chemotherapy from the first cycle, cohort B (n = 71) patients with anti-EGFR mAbs added to chemotherapy from the second cycle, and cohort C (n = 101) patients who had anti-EGFR mAbs added to chemotherapy from the third or fourth cycle. The chemotherapy backbone regimens consisted of FOLFOX or FOLFIRI regimens.

Results: 336 (58.6%) patients received panitumumab and 237 (41.4%) patients received cetuximab. The median progression-free survival (PFS) of the whole cohort was 12.2 months (95% confidence interval [CI] 10.9–13.5), and the median overall survival (OS) was 33.5 months (95% CI 27.6–39.4). Survival results for the cohorts defined by the time of addition of anti-EGFR MoAbs to chemotherapy are shown in the table. In a multivariate test, ECOG performance status and chemotherapy regimen were associated with PFS, whereas the site of primary tumour and chemotherapy regimen were associated with OS.

Table: 491P

Cohort	PFS (95% CI), months	Log-rank p-value	OS (95% CI), months	Log-rank p-value
A (n = 401)	12.9 (11.5–14.3)		30.6 months (25.2–36.1)	
B (n = 71)	9.7 (9.1–10.3)	A vs. B p = 0.185	Not reached	A vs. B p = 0.645
C (n = 101)	11.5 (9.8–13.2)	A vs. C p = 0.826	37.9 months (28.6–47.3)	A vs. C p = 0.052

Conclusions: Delayed addition of anti-EGFR mAbs up to the fourth cycle of first-line chemotherapy was not associated with inferior survival or response rates.

Background: Hepatic resection is known to be the standard treatment for patients with colorectal liver metastasis (CRLM). The recent advancement in chemotherapy has led to the extended surgical indication and better outcome in patients with advanced CRLM. This phase II trial was designed to prospectively evaluate the validity of induction chemotherapy using mFOLFOX with cetuximab for advanced CRLM, which has been reported to provide early tumor shrinkage in CRLM with KRAS wild type.

Methods: Patients having advanced CRLM (tumor number > =5 and/or technically unresectbale) with KRAS wild type were included to this study. The induction of mFOLFOX with cetuximab was followed by the evaluation of surgical indication every 4 cycles (2 months). If all the tumors were regarded as technically resectable, we performed surgical resection after the waiting period of 1 month and postoperative chemotherapy was added until 12 cycles in total. If they were unresectable, we continued the regimen within the upper limit of 12 cycles. The primary endpoint was R0 resection rate. The secondary endpoints included recurrence free survival (RFS), progression free survival (PFS), and overall survival (OS).

Results: Between May 2012 and May 2015, total 50 patients were enrolled to this trial in 14 centers. The induction was not done in 2 patients, who were excluded. The median age of the 48 patients was 62.5 (range: 45 to 79) including 36 men and 12 women. The median tumor number detected by CT before the induction was 12 (1 to 57). R0 and R1 resections were performed in 26 and 5 patients, respectively (R0 resection rate: 54.2%), and there was no mortality. Under the median follow-up of 2.5 years, the 3-year RFS was 14.4%, 3-year PFS was 8.2%, 3-year OS was 60.0%, and median survival time was 3.4year.

Conclusions: For advanced CRLM with KRAS wild type, mFOLFOX with cetuximab induction therapy provided the sufficient R0 resection rate and favorable outcome.

Background: Combination therapy with oral fluoropyrimidine and irinotecan with cetuximab has not yet been established as first-line treatment of metastatic colorectal cancer (mCRC). This study was designed to assess the tolerability of different doses of tri-weekly intravenous infusion of irinotecan in combination with S-1 (IRIS) and weekly cetuximab (phase I) and explore the efficacy and safety of the IRIS in combination with cetuximab in patients with mCRC (phase II).

Methods: Main eligibility was RAS (exon 2) wild-type mCRC and without any prior chemotherapy except for adjuvant therapy. S-1 was given orally at a dose of 40 mg/m^2 (40-60mg) twice for 2 weeks, followed by a 1-week rest. Irinotecan (150mg/m^2) was given on days 1. Cetuximab was administered on days 1 (400 mg/ m^2), 8 (250 mg/ m^2) and 15 (250 mg/ m^2), followed by every week (250 mg/ m^2) thereafter. A standard 3 + 3 phase I dose de-escalation design was utilized to decide maximum tolerant dose (MTD) and recommend dose (RD) of irinotecan. Primary endpoint of Phase II part was overall response rate (ORR). We set the expected and threshold RRs at 60% and 40%, respectively. ORR was assessed by central office according to RECIST version 1.1 criteria.

Results: Between December 2014 and September 2017, 58 patients were enrolled. Seven patients were excluded owing to ineligibility. No dose limiting toxicity was observed in phase I part and RD irinotecan was decided at 150mg/m^2. In phase II part, the treatment response with confirmation was complete response (CR) in 1, and partial response (PR) in 28, stable disease (SD) in 15, progressive disease (PD) in 6, not evaluated (NE) in 1, final response rate was 56.9% (90 %; CI 44.4 – 68.7 %, p = 0.011). The safety profile revealed the common Grade 3/4 adverse events to be neutropenia (31.4%), appetite loss (27.5%), hypokalemia (11.8%) and diarrhea (11.8%). Grade 3/4 HFS occurred in 9 patients (9.8%).

Conclusions: This study showed the efficacy and safely was comparable to other first line treatment regimens. The results support IRIS/cetuximab is more convenient and provide treatment flexibility in first line treatment with metastatic colorectal cancers.

494P A multi-institutional randomized phase II study on the timing of oxaliplatin plus 5-fluorouracil (FOLFOX) for patients (pts) with operable stage III rectal cancer: The KIR study

P. Kavan[1], I. Barrera[1], L. Azoulay[1], A-G. Martin[2], C. Vasilevsky[1], M. Boutros[1], E. Ferland[3], G. Batist[1], T. Vuong[1]

[1]Oncology, Jewish General Hospital McGill University, Montreal, QC, Canada, [2]Oncology, CHU de Quebec Laval, Montreal, QC, Canada, [3]Oncology, CHUM, Montreal, QC, Canada

Background: Recent randomized studies have shown low compliance to adjuvant chemotherapy in stage III rectal cancer pts who received preoperative combined chemotherapy and external beam radiation (CT/EBRT) with total mesorectal excision (TME surgery). We examined whether giving part of the chemotherapy prior to radiotherapy (delivered by brachytherapy (HDRBT)) and surgery (instead of chemotherapy after RT and surgery, which is the current standard of care) for pts with node positive operable rectal cancer, would result in higher pt compliance to chemotherapy.

Methods: Between 2010-2017, 180 eligible pts were randomly assigned (2:1) to two arms, 6 cycles of FOLFOX prior to radiotherapy and surgery following by 6 cycles of FOLFOX in adjuvant (Arm A, (AA)), or 12 cycles of FOLFOX in adjuvant (Arm B, (AB)). The primary end point was compliance to chemotherapy (pts receiving at least 85% of full-dose CT prescribed at each cycle (x 12 cycles), 1 yr post-diagnosis); secondary end points were disease free survival rate (DFS), pT0N0, local recurrence rate and overall survival (OS), 5 yrs post-surgery.

Results: All pts were randomly assigned to either AA (n = 120; 84 pts were male (M), median age (MA) was 65 years) or AB (n = 60; 35 pts were M, MA was 63.5 years). Compliance on AA was 78% and 51.9% on AB. Levels of G3/G4 toxicity were 30.8% in AA and 28.3% in AB respectively. 174 of 178 pts completed HDRBT as planned (97.7%). In AA, 3 pts progressed locally under CT. 1 pt refused HDRBT after randomization in AB. pT0N0 for AA and AB were 35pts (30.1%) and 15 pts (25%). The 3-year DFS was 80% with AA and 76% with AB (p = 0.6511). The 3-year OS for AA and AB were 94% and 85%, respectively (p = 0.8219).

Conclusions: The safety and improved compliance to neoadjuvant CT is confirmed in this study using HDRBT as a neoadjuvant modality for rectal cancer. There is no statistical difference in pT0N0 rate, local recurrence, and DFS between the two arms in the early result analysis, but favorable oncological outcomes are observed. At the time of this reporting, pelvic nodal recurrence is seldom isolated, asymptomatic and preceded by systemic failure.

Clinical trial identification: NCT01274962.

495P Tumor regression grading after preoperative hyperfractionated radiotherapy/chemoradiotherapy for locally advanced rectal cancers: A phase III clinical study

A. Idasiak[1], K. Galwas-Kliber[1], K. Behrendt[1], I. Wziętek[2], M. Zeman[3], E. Stobiecka[4], E. Chmielik[4], T. Dworzecki[2], R. Suwiński[1]

[1]Radiotherapy and Chemotherapy Clinic and Teaching Hospital, Maria Sklodowska Curie MSC Memorial Cancer Institute in Gliwice, Gliwice, Poland, [2]Radiotherapy Department, Maria Sklodowska Curie MSC Memorial Cancer Institute in Gliwice, Gliwice, Poland, [3]Department of Surgery, Maria Sklodowska Curie MSC Memorial Cancer Institute in Gliwice, Gliwice, Poland, [4]Department of Pathology, Maria Sklodowska Curie MSC Memorial Cancer Institute in Gliwice, Gliwice, Poland

Background: We investigated tumor regression grading (TRG) as a prognostic marker for disease-free survival (DFS) in patients with advanced rectal cancer treated within phase III randomized study. The study was prospective trial of preoperative hyperfractionated radiotherapy (HART) compared with concomitant hyperfractionated radiotherapy with co-administration of chemotherapy based on 5FU (HART-CT) in patients with T2/N+ or T3/any N resectable mid-low primary rectal cancer.

Methods: The 136 patients were randomly assigned to HART (n = 69) and HART-CT (n = 67). The pelvis was irradiated twice a day (28 fractions of 1.5 Gy), with a minimal interfraction interval of 8 hrs to total dose 42 Gy over 18 days (HART) or mentioned scheme with concurrent chemotherapy: 5FU-325mg/m^2 (bolus) on days 1-3 and days 16-18 (HART-CT). Surgery was performed 5-6 weeks after HART/HART-CT. The TRG was recorded using 4-point scale: TRG0 (pCR) denoted no cancer cells; TRG1 - cancer cells less than 10% of a tumor mass; TRG2 cancer cells in 10-50% or TRG3 - cancer cells in more than 50% of tumor mass. Multivariable analysis was performed using Cox regression models adjusted for treatment arm, resection status and pathologic stage. Cox proportional hazard model was used in survival analysis.

Results: The crude rate of patients with any serious adverse events during the follow-up was 12% vs. 17% for HART and HART-CT. Anterior resection was performed in 52% vs. 62% for HART and HART-CT respectively (p = 0.06). Of the 136 patients evaluable for pathologic response there were 3(4%) vs. 9(13%), 16(23%) vs. 24(36%), 40(58%) vs. 30(45%), and 10 (15%) vs. 4(6%) patients with TRG 0, 1, 2 and 3, respectively in HART vs. HART-CT, the difference was statistically significant p = 0.002. The actuarial 2-year cumulative loco-regional relapse free survival control rates (LRC) for HART vs.

HART-CT were 86% vs. 91% and actuarial DFS control rates were 70% vs. 76%, respectively.

Conclusions: Significant differences in the tumor regression grading (TRG) were found. Both LRC and DFS of rectal cancer patients treated with HART vs. HART-CT had favorable outcomes in those allocated to HART-CT. Also the sphincter preservation rate tended to favor HART-CT.

Clinical trial identification: NCT01814969.

Background: At present, distant metastasis remains the main cause of failure for locally advanced rectal cancer (LARC), efficient short-course radiotherapy (SCRT) combined with neoadjuvant chemotherapy is an attempt of optimizing pre-operative treatment.

Methods: We did this randomized, phase III study in multiple centers in China. Patients with middle or lower rectal adenocarcinomas, staged cT_{3-4} and/or N_{1-2} by MRI, were randomly assigned to receive 5Gy × 5 and 4 courses of CAPOX (experimental group) or 50 Gy in 25 fractions concurrently with capecitabine (control group). TME in both groups was performed 6-8 weeks later, then two or six courses of CAPOX as postoperative chemotherapy was prescribed in experimental or control group, respectively. The purpose of this interim analysis was focusing on the compararison of primary enrolled 100 patients.

Results: Initially enrolled 100 patients, 51 in experimental group and 49 in control group were analyzed, with MRF+ 27.5% vs. 30.6%, MRI based T_{3-4} 92.2% vs. 98.0%, N_{1-2} 74.5% vs. 77.6%, and EMVI $scores_{3-4}$ 52.9% vs. 65.3% in each group. The completion rates of neoadjuvant treatment were 98.0% vs. 100% ($p = 0.325$), with incidences of grade III-IV toxicity 17.6% vs. 4.1% ($p = 0.076$) in each group, respectively. 80 patients completed surgery and 7 patients (all in experimental group) chose "watch-and-wait" policy due to clinical complete remission (cCR) after neoadjuvant treatment. 92.9% and 89.5% of patients in experimental and control group had R_0 resection ($p = 0.593$), while 26.2% and 5.3% of them achieved $_{yp}T_0N_0$ ($p = 0.011$), respectively. The completion rates of adjuvant chemotherapy were 76.2% vs. 65.8% ($p = 0.305$) in each group, respectively. On the whole, the patients who had received 6 cycles of chemotherapy accounted for 62.7% vs. 49.0% ($p = 0.000$) in experimental and control group, and there were 76.5% and 49.0% of patients who could complete all planned treatments in each group, respectively.

Conclusions: The interim analysis revealed the acute toxicity and surgical complication were acceptable and comparable in both groups, however, the people in experimental group showed better treatment completion.

Clinical trial identification: NCT02533271.

497P mFOLFOXIRI versus mFOLFOX6 as neoadjuvant chemotherapy in locally advanced rectal cancer: A propensity score analysis from two prospective trials

J. Zhang, Y. Deng, Z. Wu, H. Hu, Y. Cai, J. Ling

Medical Oncology, The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background: Neoadjuvant chemoradiotherapy (CRT) is the standard of treatment for locally advanced rectal cancer, but it delays administration of systemic chemotherapy, leading to high incidence of distant metastases. To enhance systemic chemotherapy and avoid the damage of radiation, full dose of neoadjuvant chemotherapy regimens with mFOLFOXIRI or mFOLFOX6 were both under investigation. Here, we aimed to compare the safety and efficacy of preoperative chemotherapy with mFOLFOXIRI versus mFOLFOX6 in locally advanced rectal cancer.

Methods: Prospectively maintained databases of patients from two clinical trials (NCT01211210 and NCT02217020) underwent preoperative treatment for locally advanced rectal cancer in a single center were included. Those had received mFOLFOXIRI or mFOLFOX6 chemotherapy alone preoperatively was selected for this study, including 90 patients with mFOLFOXIRI and 119 patients with mFOLFOX6. All patients had undergone total mesorectal excision. A comparative analysis was performed after the implementation of propensity score matching on the 2 main cohorts (mFOLFOXIRI and mFOLFOX6).

Results: A total of 209 patients were enrolled in the study. After propensity score matching, 180 patients were selected. 90 patients were comparable in the two groups. Higher pathologic complete response rate was observed in mFOLFOXIRI group than that of mFOLFOX6 group (16.7% vs. 5.6%, $p = 0.03$), although the tumor downstaging (ypT0-2N0M0) rate was comparable in this two group (41.1% vs. 37.8%, $P = 0.76$). The anal preservation rate was similar between the two groups (87.8% vs. 89.2%). Higher incidence of grade 3/4neutropenia (42.2% vs. 10%, $P < 0.001$) was shown in mFOLFOXIRI group than that of mFOLFOX6 group.

Conclusions: Preoperative mFOLFOXIRI chemotherapy showed higher pCR rate than that of mFOLFOX6. The tumor downstaging rate was comparable between the two regimens. But the adverse events were more common in mFOLFOXIRI group. Whether the intensive regimen would improve the survival is unknown. Further follow-up is needed.

Clinical trial identification: NCT01211210 and NCT02217020.

Pascale", Naples, Italy, [7]Radiotherapy, Istituto Nazionale Tumori – I.R.C.C.S - Fondazione Pascale, Naples, Italy, [8]Translational Research, Istituto Nazionale Tumori – I.R.C.C.S - Fondazione Pascale, Naples, Italy, [9]Abdominal Oncology, Istituto Nazionale Tumori, IRCCS, Fondazione "G. Pascale", Naples, Italy

Background: Recurrence with distant metastases is the predominant pattern of failure in locally advanced rectal cancer (LARC), thus the integration of new agents into preoperative fluoropyrimidine-based chemo-radiotherapy represents a clinical challenge to intensify the therapeutic strategy. We have recently reported synergistic antitumor interaction between valproic acid (VPA), an histone-deacetylase inhibitor, capecitabine (CAP) and radiotherapy in colorectal cancer preclinical models.

Methods: We planned two parallel phase-1 studies in low-moderate risk LARC patients (pts) to assess the safety of preoperative short-course radiotherapy (SCRT) (5 Gy/day on days 1 to 5 days) combined with (a) CAP alone (4 increasing dose levels: 500 to 825 mg/m2/bid, on days -1 to 20), or (b) CAP as above plus VPA (orally on days -14 to 21, with an intra-patient titration for a target serum level of 50-100 μg/ml), followed by surgery 8 weeks after the end of SCRT. Within each of the two phase-1 trials, maximum tolerated dose (MTD) was defined as the dose level that produces a dose-limiting toxicity (DLT) occurring within 5 weeks from day 1 of treatment in more than one-third of pts. Correlative studies on pharmacokinetic and pharmacodynamics biomarkers on both tumor and peripheral blood samples as well as FDG-PET were also planned.

Results: From Apr 2013 and Oct 2018, 28 pts were enrolled in the two phase-1 studies. Median age was 61 (range 46-71), 100% were PS 0. No DLT occurred with CAP alone, but a symptomatic angina occurred in a patient at the first dose level of CAP plus VPA. However, no DLT was observed within the further 3 pts enrolled at the same level, nor

at the following dose levels. All but one pts underwent R0 resection. TRG1 was obtained in 6 pts, TRG2 in 11 pts, TRG3 in 8 pts and TRG4 in 3 pts.

Conclusions: The addition of CAP to preoperative SCRT +/- VPA is feasible and 825 mg/m2/bid is the recommended dose that will be used in an ongoing phase-2 trial, aimed to explore whether the addition of VPA and/or CAP to preoperative SCRT might increase TRG1 rate in low-moderate risk LARC pts.

Clinical trial identification: NCT01898104.

499P A classifier of 53BP1, immune score and texture analysis of MRI images can predict pathological response to chemoradiotherapy in locally advanced rectal cancer

H. Ma, J. Yao, A. Huang, Y. Xiao, L. Fan

Cancer Center, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

Background: Preoperative chemoradiotherapy is the standard care for advanced rectal cancer. Yet, predicting the response remains a challenge. Our previous studies found that 53BP1 protein deletion leaded to chemoradiotherapy resistance.53BP1 deficiency played pivotal role in inducing lymphocyte mature. As the development of functional imaging, texture analysis can predict response to chemoradiotherapy. Our study aims to explore the relationship among 53BP1 protein, immune score, texture analysis and radiation sensitivity, then set a new classifier to predict response in advanced rectal cancer.

Methods: We enrolled 57 advanced rectal cancer patients who received neoadjuvant chemoradiotherapy in Wuhan Union hospital from January 2015 to January 2018. The expression of 53BP1, CD3, CD8, CD45RO was detected by immunohistochemistry. Immune score were calculated, which are based on the combination of two lymphocyte populations (CD3/CD45RO, CD3/CD8 or CD8/CD45RO) both in the center (CT) and the invasive margin (IM) of tumors. T2W MRI images studies obtained in 34 patients before treatments, texture analysis by manually delineating a region of interest. The response rate, anus preservation rate were collected. The relationship among 53BP1 protein, immune score, texture analysis parameters and radiation sensitivity were explored by t-test. A new classifier was set to predict pathological response.

Results: The results indicated that the response rate in 53BP1 deletion group was significantly lower than that in 53BP1 high expression group (25.00% vs.84.44%, $P < 0.005$). "CD3+CD8" is the most reasonable immune score, the patients of 53BP1 deletion had lower immune score. The response rate in lower immune score group was lower than higher immune score group (54.54% vs.88.57%, $P < 0.005$). Texture analysis parameters were related with response rate. We set a new classifier to predict response in advanced rectal cancer, we randomly selected 10 patients as training group, others were selected as predict group, the accuracy is 83.33%.

Conclusions: A classifier of 53BP1, immune score and texture analysis of MRI can predict response in advanced rectal cancer.

500P Mismatch repair deficient rectal cancer is resistant to induction combination chemotherapy

A. Cercek[1], G. Dos Santos Fernandes[2], C. Roxburgh[3], S. Ng[4], R. Yaeger[1], N. Segal[1], K. Ganesh[1], D. Reidy[1], J.J. Smith[5], G. Nash[5], J. Guillem[5], P. Paty[5], J. Shia[6], J. Garcia-Aguilar[5], L. Diaz[1], C. Crane[4], K. Goodman[4], L. Saltz[7], M. Weiser[5], Z. Stadler[2]

[1]Medicine, Memorial Sloan Kettering Cancer Center, New York, NY, USA, [2]GI Medical Oncology, Memorial Sloan Kettering Cancer Center, New York, NY, USA, [3]Surgical Oncology, MSKCC, New York, NY, USA, [4]Radiation Oncology, Memorial Sloan Kettering Cancer Center, New York, NY, USA, [5]Surgery, MSKCC, New York, NY, USA, [6]Pathology, Memorial Sloan-Kettering Cancer Center, New York, NY, USA, [7]Gastrointestinal Oncology Service, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY, USA

Background: Although most rectal cancers are responsive to combination induction chemotherapy, the sensitivity of mismatch repair deficient (MMR-D) rectal cancers to chemotherapy remains uncertain.

Methods: MMR-D rectal tumor cases were retrospectively reviewed with tabulation of baseline characteristics, treatment modalities and clinical outcomes. Prevalence of germline mutations in the MMR genes, diagnostic of Lynch syndrome (LS), was compared to LS-associated colon cancer patients. We also assessed somatic mutational status for a subset of these patients.

Results: Twenty of the 49 patients received induction chemotherapy with 5FU and oxaliplatin, 15 received standard neoadjuvant chemoradiation, and 14 proceeded directly to surgery. Of the 15 patients treated with induction chemoradiation, 93% ($n = 14$) experienced radiographic response and tumor downstaging; and none of these patients showed evidence of disease progression. In contrast, of the 18 patients treated with induction chemotherapy alone, only 61% ($n = 11$) experienced tumor response and 28% ($n = 5$) of patients demonstrated progressive disease while on therapy. The majority of these cases, 82% (41/50) harbored germline mutations in the MMR genes and the observed prevalence of germline MSH2 and MSH6 mutations was significantly higher in the rectal ($n = 41$) versus colon ($n = 244$) cancer patients (rectal vs colon: MSH2: 57% vs 37%; MSH6: 20% vs 11%; p-value <0.0005).

Conclusions: Patients with MMR-D rectal tumors appear to have a high chance of disease progression on induction chemotherapy. As opposed to LS-associated colon cancers, LS-associated rectal cancers are more likely to harbor MSH2 or MSH6 germline mutations. Upfront testing for MMR status and initial treatment with chemoradiation in MMR-D rectal tumors should be undertaken until better therapies are available.

501P Outcomes of chemoradiotherapy plus local excision in patients with clinical T1 or T2, N0 rectal cancer

T. Suzuki, S. Sadahiro, T. Ogimi, H. Miyakita, G. Saito, K. Okada, A. Tanaka

Surgery, Tokai University School of Medicine, Isehara, Japan

Background: NCCN guidelines recommend local excision (LE) as a standard treatment for selected patients with cT1/T2,N0,M0 rectal cancer. However, the rates of local recurrence after LE alone were 12.5% in cT1 disease and 22.1% in cT2 disease and those after total mesorectal excision (TME) were 6.9% and 15.1%, respectively. In pathological T1 disease, adding (chemo)radiotherapy (CRT) to LE decreased the rate of local recurrence to 5%, which was comparable to the rate after TME (4%). In pT2 disease who underwent LE, the local recurrence rate decreased slightly but remained high (14%) even after CRT.

Methods: In our institution, patients with cT1, N0 disease with a tumor diameter of less than 30 mm underwent transanal full thickness LE and additionally receive CRT (40/45Gy plus UFT or S-1). Patients with poorly differentiated adenocarcinoma or mucinous carcinoma should additionally undergo TME. Patients with cT2, N0 disease underwent transanal LE after CRT. Patients whose tumors include poorly differentiated adenocarcinoma or mucinous carcinoma should receive TME.

Results: In accordance with these treatment policy, LE was performed in 65 patients with cT1, N0 disease, 50 of whom additionally received CRT. The median follow-up was 71 months. Local recurrence occurred in 1 patient (2%), and distant metastasis occurred in 3 patients (6%). The 5-year disease-free survival rate (5y DFS) was 86%, and the 5-year overall survival rate (5y OS) was 92%. Patients with pT1 disease who had local nodal recurrence underwent abdominoperineal resection and are still alive with no recurrence. In 53 patients with cT2, N0 disease, LE was performed after CRT. Four patients had pT3 disease and additionally underwent TME. In the other 49 patients, six patients (12%) had local recurrence at the anastomotic site, and 7 (14%) had distant metastasis. The 5y DFS was 70%, and the 5y OS was 87%.

Conclusions: These results suggested that multidisciplinary treatment combining chemoradiotherapy with local excision is a treatment option in some patients with a preoperative diagnosis of clinical T1, N0 or T2, N0 rectal cancer. However, further studies are needed to determine the optimal treatment for patients with clinical T2, N0 rectal cancer.

502P Comparison of immune microenvironment between different neoadjuvant radiotherapy regimens for rectal cancer

J. Wu, Q. Peng, J. Li, L. Tang, Y. Huang, X. Zhang

Department of Radiation Oncology, Fujian Medical University Cancer Hospital, Fujian Cancer Hospital, Fuzhou, China

Background: Conventionally neoadjuvant radiotherapy regimens for rectal cancer are long-course radiotherapy in combination with chemotherapy (LCRT) and short-course radiotherapy (SCRT). We aimed to compare the different immune microenvironment in patients between two the different radiotherapy regimens.

Methods: The expression of LAG-3, CD8 and CD3 was detected by immunohistochemistry on specimen of 76 rectal cancer patients following neoadjuvant treatment. The expression of proteins was assessed as the percentage of positive cells (PP). The variation of proteins expression was compared by Mann-Whitney U test analysis.

Results: LCRT was given in 40 (52.6%) patients and the rest 36 (47.4%) patients were SCRT. The median PP of immune cells LAG-3 expression was 15% (range, 0% - 80%) in all patients. The expression of CD8 and CD3 were 10% (range, 0 - 80%) and 30% (range, 0 - 90%), respectively. The LAG-3 expression was high in patients with SCRT

compared to LCRT (22.5% vs. 8.0%, P = 0.0440). On the contrary, CD8+ cells were high in LCRT (15% vs. 8%, P = 0.0146). No difference was observed in CD3+ cells.

Conclusions: Tumor microenvironment might be modified by different fractions and dose. Immune cells LAG-3 expression were high with respect to SCRT. The diverse expression pattern of LAG-3 between SCRT and LCRT supporting the different combination strategies of immune checkpoint blockade and neoadjuvant radiotherapy.

Blokhin National Medical Research Center of Oncology» of the Ministry of Health of the Russian Federation, Moscow, Russian Federation

Background: We decided to evaluate preoperative clinical factors associated with progression free survival, overall survival and tumor regression in patients with locally-advanced rectal cancer after chemo-radiotherapy.

Methods: we analyzed prospective database of patients with locally-advancded rectal cancer (cT3-4N0-2M0) who received preoperative chemo-radiotherapy followed by surgery in our center from 2004 to 2013. Multivariate regression analyses was performed to evaluate odds of absent morphological response (Dworak tumo regression rate system 0-2) and hazards of progression and deaths. Statistical analyses was performed with SPSS v.20.

Results: Chemo-radiotherapy followed by surgery was performed in 457 patients with locally-advanced rectal cancer. The median f.-up was 46 months (2-141), 3-year progression free survival and overall survival were 79% and 91%, respectively. Multivariate regression analyses revealed factors associated with tumor regression rate 0-2 as high level (above normal range) CEA (carcinoembryonic antigen) before chemo-radiotherapy (OR 1.49 95%CI 1.11-2.02, p = 0.008), neutrophils count ≥ 7,000/µl (OR 2.29, 95%CI 1.0-5.2, p=0.05) and cT4 (OR 3.73, 95%CI 2.03-6.86, p < 0.001). Independent negative prognostic factors for progression free survival were perineural invasion (HR 3.1, 95% CI 1.43-6.89, p<0,001), neutrophil/lymphocyte ratio before surgery ≥ 3 (HR 1.8, 95%CI 1.37-2.42, p=0.01) and ypT3-4 or/and N + (HR 1.82, 95%CI 0.45-0.92, p<0.01). For overall survival: ypT3-4 or/and N + (HR 1.9, 95%CI 1.3-2.65, p<0.01), lymphatic vessel invasion (HR 2.4, 95%CI 1.27-4.59, p<0.01) and leucocytes count before surgery ≥11,000/µl (HR 3.1, 95%CI 1.33-7.33, p<0.01).

Conclusions: ypTNM after preoperative chemo-radiotherapy more effective than cTNM predicts progression free and overall survival in patients with localy-advanced rectal cancer.

504P Association of systemic and local inflammation with prognosis in rectal cancer treated with neoadjuvant radiotherapy

J. Li[1], X. Zhang[2], Y. Huang[2], L. Tang[2], Q. Peng[2], J. Wu[1]

[1]Department of Radiation Oncology, Fujian Cancer Hospital, Fujian Medical University Cancer Hospital, Fuzhou, Fujian, China, [2]Department of Radiation Oncology, Fujian Medical University Cancer Hospital, Fuzhou,Fujian, China

Background: To explore the characteristics of cancer-associated systemic and local inflammation and its impact on overall survival (OS) in locally advanced rectal cancer (LARC) treated with neoadjuvant radiotherapy (RT).

Methods: A consecutive cohort of 76 LARC patients underwent neoadjuvant RT were retrospectively analyzed from February 2012 to September 2015. Peripheral neutrophil to lymphocyte ratio (NLR) was calculated at diagnosis, and tumor-infiltrating lymphocyte was examined in postoperative tumor tissue by immunohistochemistry. The association between clinicopathological features and inflammation was explored through chi-square test. The prognostic factors in terms of OS were investigated through uni- and multivariate Cox regression. SPSS 22.0 was used for statistical analyses.

Results: The median follow-up time was 29.0 months (range, 2-59). The 1-, 3- and 5-year OS rates were 93.4% (95%CI 87.91-98.89), 80.0% (95%CI 69.81-90.19) and 68.6% (95%CI 46.06-91.14), respectively. High NLR (≥2.0) and low CD8+ T-cells (<9%) were more common in 76 patients (53.9% and 59.2%, respectively). For patients with high NLR and low CD8+ T-cells, 5-year OS was significantly worse than those with low NLR and high CD8+ T-cells (P = 0.005). Also, NLR ≥ 2.0 was associated with poor tumor regression after neoadjuvant RT (P = 0.039), while no significant association was found between CD8+ T-cells and tumor regression. In addition, NLR was related to lymphovascular invasion (P = 0.031). CD8+ T-cell was related to neural invasion (P = 0.048) and mucinous adenocarcinoma (P = 0.045). Furthermore, NLR (HR 7.71, 95%CI 1.30-45.71, P = 0.025), CD8+ T-cells (HR 0.09, 95%CI 0.01-0.67, P = 0.018) , age (HR 16.1, 95%CI 1.56-167.15, P = 0.020), lymphovascular invasion (HR 7.17, 95%CI 1.12-46.05, P = 0.038) and T stage (HR 0.03, 95%CI 0.00-0.45, P = 0.011) were independent risk factors for prognosis according to multivariate Cox regression.

Conclusions: High NLR and low CD8+ T-cells were significantly associated with dismal survival. Systemic combined with local inflammation might help to predict prognosis of LARC with neoadjuvant RT.

505P Early prediction of histopathological response by PET/CT after two weeks of neoadjuvant chemoradiotherapy for rectal cancer: Wishful thinking or reality?

Y. Kundel[1], G. Natalia[2], H. Berenshtain[2], J. Prus[3], B. Brenner[3]

[1]Radiation Oncology, Rabin Medical Center Davidoff Cancer Centre, Beilinson Campus, Petah Tikva, Israel, [2]Radiology, Rabin Medical Center Beilinson Campus, Petah Tikva, Israel, [3]Oncology, Institute of Oncology, Davidoff Cancer Center, Rabin Medical Center, Beilinson Hospital, Petach Tiqva, Israel

Background: Neoadjuvant chemoradiotherapy (CRT) is standard in locally advanced rectal cancer (LARC). Current data on the predictive value of early PET/CT, i.e. the correlation between the tumor's early metabolic response, manifested by the reduction of its ^{18}F-FDG uptake after two weeks of CRT compared with baseline, and histopathological response, are conflicting.

Methods: Patients (pts) with histologically confirmed LARC who were planned to receive standard CRT regimen of 50.4 Gray radiotherapy with concurrent fluoropyrimidine–based chemotherapy followed by radical surgery were eligible for the study. Baseline PET/CT was done within 4 weeks prior to CRT and the investigational scan was done two weeks+/-two days after its initiation. Maximum standardized uptake value (SUV-MAX) and the changes in FDG uptake between the two scans (ΔSUV-MAX) were compared with the histopathological response at surgery. Response was classified by tumor regression grade (TRG) and presence of pathological complete response (pCR).

Results: Twenty pts were included in the study, 65% with clinical stage II and 35% with stage III. Ninety percents of tumors were located at least 5 cm from the anal verge. Pts underwent surgery within a median of 8.6 weeks (4.5-12.8) after the completion of CRT. Six pts (30%) achieved pCR and 7 (35%) had TRG I-II. Absolute SUV-MAX values at both time points did not correlate with pCR (p = 0.099) nor with TRG (p = 0.670). Histopathological response also did not correlate with ΔSUV-MAX: pts who achieved pCR had median ΔSUV-MAX of -45%, while those who did not had median ΔSUV-MAX of -41% (p = 0.617). Similarly, pts with TRG I-II and those with TRG III-IV had the same median ΔSUV-MAX of -42% (p = 0.882). In addition, using ROC analysis we did not find any cutoff of any the PET-CT parameters that will predict pCR or TRG I-II.

Conclusions: In the current study, early PET/CT done after two weeks of neoadjuvant CRT for LARC, failed to predict histopathological response to treatment.

506P Association between obesity and efficacy of chemoradiotherapy in rectal cancer patients

C. Diaz Romero[1], R.G. Calderillo[1], M. Herrera-Martínez[2], R.G. Erika[1], J.M. Flores Castro[1]

[1]Oncology, Instituto Nacional de Cancerologia - Mexico, Mexico City, Mexico, [2]Medical Oncology, Instituto Nacional de Cancerologia - Mexico, Mexico City, Mexico

Background: Obesity is a major public health problem, in Mexico there is a high prevalence of obesity. However, there have been few studies that have reported association between obesity and rectal cancer outcomes in the Mexican population. Many studies have recently revealed the relationship between obesity and cancer. Controversy remains as to whether obesity has a harmful prognostic effect in advanced stage rectal cancer patients. There is a report that obesity was associated with lower pathologic complete response rates in rectal cancer patients after neoadjuvant chemoradiotherapy. In their study, complete response was associated with better disease-free survival.

Therefore, we hypothesized that obesity influenced the local treatment outcomes in patients with rectal cancer after surgery and RT.

Methods: A total of 312 eligible patients were retrospectively analyzed; from 1999 to 2014 at National Cancer Institute Mexico, they received chemo-radiotherapy concomitant before surgery for rectal cancer.

The patients were categorized as obese, overweight, normal weight, or underweight based on BMI according to World Health Organization (WHO) criteria. Pathological complete response (pCR) was defined as no invasive cancer in the rectal or lymph tissue. Chi-squared tests were used for detecting the predictors of pCR and determining the relationship between BMI category and pCR rate in the subgroup analysis with respect to other variables.

Results: Median age was 54 years (18-82), 24% of patients were obese, 31% were overweight, and 45% normal or underweight. 22% (n = 68) of patients were pCR. In multivariate analysis, there was statistical trend in pCR between treatment groups: pCR for obese 16/75 patients, overweight 21/97 and normal or underweight was 31/140 patients (p = 0.057). Nevertheless, obese patients compared with normal weight patients (OR = 0.81; 95% CI, 0.69 to 1.33 p = 0.039) were significantly less likely to have a pCR.

Conclusions: These results show an association between obesity and a poor pathological response in rectal cancer patients. This analysis suggests that higher BMI should be considered, and the mechanism of influence of BMI and obesity, on treatment response in patients with rectal cancer.

507P Treatment outcomes of patients with localized anal squamous cell carcinoma and HIV infection: Systematic review and meta-analysis

M. Camandaroba[1], R. Riechelmann[1], V. Silva[1], C. Mello[1], R. Araujo[2]

[1]*Oncology, A. C. Camargo Cancer Center, Sao Paulo, Brazil,* [2]*Upper GI and HPB Surgery, Barretos Cancer Hospital, São Paulo, Brazil*

Background: Definitive chemoradiation (CRT) is the standard treatment for localized squamous cell carcinoma of the anus (SCCA). Because most phase III trials in SCCA have excluded patients with HIV, the evidence on treatment outcomes of these patients is lacking. We performed a systematic review and meta-analysis on the efficacy and toxicity profiles of HIV-positive SCCA patients treated with definitive CRT.

Methods: The systematic search was conducted Embase, Medline, Cochrane Libary, Scopus, Lilacs and Opengrey, from inception until September 2017. Eligible studies were clinical trials, prospective or retrospective cohorts studies. The main outcome variables were 3-year disease-free (DFS) and overall survival (OS) rates and frequency of grade 3 or 4 (G3/4) treatment-related toxicities, according to HIV status. Meta-analyses using pooled risk ratios were performed for binary outcomes from comparative studies from the antiretroviral therapy era with random and fixed effects models.

Results: Out of 3,951 studies, 40 were deemed eligible, with a total of 3,720 patients. One third (N = 1,298; 34%) were HIV-positive and their median pre CRT CD4 count was 347 um/L. HIV-positive patients presented trends for higher risk of G3/4 cutaneous toxicities (Risk Ratio [RR]: 1.56,95% [CI] 0.98-2.48;p0.061; I2= 77%), G3/4 leukopenia (RR: 1.28, 95% [CI] 0.96-1.70; p = 0.088; I2= 0%) and inferior 3-year DFS rate (RR: 1.52, 95% [CI] 0.99-2.33, p = 0.057; I2= 52.19%), and significantly worse 3-year OS rate (RR: 1.64, 95% [CI] 1.27-2.11,p< 0.001; I2= 0%).

Conclusions: Patients with localized SCCA and HIV infection treated with CRT tend to experience higher risk of toxicities and worse DFS and OS rates. Our findings suggest that future trials should be tailored to HIV-positive patients.

508P p16 and PD-L1 expression in locoregional squamous cell carcinoma of the anal canal: A single center retrospective analysis in Japan

R. Takahashi[1], T. Wakatsuki[1], N. Yamamoto[2], S. Taguchi[3], E. Shinozaki[1], H. Osumi[1], M. Ogura[1], T. Ichimura[1], D. Takahari[1], M. Suenaga[1], K. Chin[1], M. Oguchi[3], M. Ueno[1], K. Yamaguchi[1]

[1]*Department of Gastroenterology, Cancer Institute Hospital of JFCR, Tokyo, Japan,* [2]*Department of Pathology, Cancer Institute Hospital of JFCR, Tokyo, Japan,* [3]*Department of Radiotherapy, Cancer Institute Hospital of JFCR, Tokyo, Japan*

Background: Squamous cell carcinoma of the anal canal (SCCA) is a rare malignancy especially in Asia. It is widely known that SCCA is linked to prior infection with human papillomavirus (HPV) in western countries. However, it is unclear whether HPV is associated with SCCA in Japan. In addition, expression of PD-L1, potential predictive marker for anti-PD-1 antibody, and its prognostic impact on locoregional SCCA remain to be elucidated. The aim of this study is to examine expression rates and prognostic impact of p16 and PD-L1 in Japanese patients with SCCA.

Methods: 34 patients with locoregional SCCA were treated by concurrent CRT at the Cancer Institute Hospital between 2007 and 2017. Among them, 28 patients whose biopsy specimens were available were enrolled. Radiation consisted of 45.0-59.4 Gy. Chemotherapy was given during radiation: 1000mg/m^2 daily fluorouracil on day 1-4 and 29-32, and a single dose of mitomycin C 10mg/m^2 administered on day 1 and 29. Data on relapse and death were obtained until March 2018. p16 positive was defined as p16 was stained on tumor nuclei. PD-L1 positive was also defined as PD-L1 was overexpressed on tumor membrane with more than 2+ score and the area was more than 5%.

Results: Of 28 patients, the median age was 59 (range 35-82) years. Male to female sex ratio was 1:6. 6 (21.4%) were clinically staged as I, 4 (14.3%) as II, 5 (17.9%) as IIIA, and 13 (46.4%) as IIIB. SCCA remained or recurred in 1 with cStage II, 1 with cStage IIIA and 7 with cStage IIIB. 3-year disease free survival (DFS) was 65.8% (95%CI, 44.3-80.6%), and 3-year overall survival (OS) was 79.2% (95%CI, 53.4-91.7%). Of 28 cases, 27 (96.4%) were positive for p16, and 6 (21.4%) were positive for PD-L1. In univariate analysis for DFS and OS, lymph node metastasis was significantly related to poor outcomes (DFS, p = 0.0289; OS, p < 0.0001). T factor (p < 0.0001) and tumor stage (p = 0.0035) significantly influenced OS. No significantly difference was found in terms of PD-L1 expression (DFS, p = 0.595; OS, p = 0.544).

Conclusions: High expression rate of p16 was observed in Japanese patients with locoregional SCCA. Lymph node metastasis, advanced T factor and tumor stage were negative prognostic factors for CRT, but no prognostic impact of PD-L1 was found.

Radiologie, Charite, Berlin, Germany,* [5]*Chirugie, Charite, Berlin, Germany,* [6]*Chirugie, Uniklinik Mainz, Mainz, Germany,* [7]*Chirurgie, Maastricht University Medical Center (MUMC), Maastricht, Netherlands,* [8]*Klinik f. Allgemeine-, Viszeral-, Thorax-, Transplantations- und Kinderchirurgie, Uniklinikum Schleswig-Holstein, Kiel, Germany,* [9]*Chirurgie, LMU Großhadern, Munich, Germany,* [10]*Chirugie, Uniklinik Leipzig, Leipzig, Germany,* [11]*Chirurgie, Uniklinik Köln, Cologne, Germany,* [12]*Radiologie, Charite, Berlin, Germany,* [13]*Statistik, Clinassess, Leverkusen, Germany,* [14]*Chirurgie, Universitaetsklinikum Aachen (UKA), Aachen, Germany,* [15]*Biometrie, IBE München, Munich, Germany*

Background: Paired tumor evaluations before randomization and at best response (nadir) of 270 patients with RAS WT tumors treated with first-line therapy with cetuximab (cet) vs. bevacizumab (bev)- in combination with FOLFIRI were reviewed for resectability of metastates. We assessed parameters influencing resectability, conversion to resectability and survival after nadir.

Methods: Baseline information and resectability were correlated with Fisher's exact tests. Conversion to resectability was defined as unresectable disease before randomization and resectable disease at nadir. Univariate and multivariate logistic models were fitted with resectability at nadir as response variable. A Cox model comparing the survival from nadir was used to measure the influence of treatment, resectability at nadir and resection (time dependent variable). Interaction of resection and treatment arm on survival was tested by likelihood ratio test.

Results: Initial Lung metastases (OR = 0.35 95% CI = (0.19 - 0.63), p = 0.001), BRAF mutation (OR = 0.33 95% CI = (0.12-0.82), p = 0.03) and high alkaline phosphatase (OR = 0.51, 95% CI = (0.31-0.81), p = 0.006) were associated with less chance of conversion to resectability and in case of lung metastases also of being resected if resectability at nadir was observed (OR = 0.33, 95% CI = (0.08-1.04) p = 0.046). Early tumor shrinkage (=ETS: -20% tumor diameter after 6 weeks therapy) and depth of response (DpR) were associated with conversion to resectability (ETS: OR = 1.86, 95% CI = (1.06-3.3), p = 0.034, DpR: OR = 1.02, 95% CI = (1.01-1.03), p < 0.001). Metastatic resection improved post-nadir survival (HR = 0.53, 95% CI = (0.29- 0.97), p = 0.04). This was pronounced in cet-treated patients as compared to bev-treated patients (HR (cet)=0.17, 95% CI = (0.04-0.69), p = 0.01; HR (bev)=0.89, 95% CI = (0.47-1.69), p = 0.73; interaction test p = 0.02).

Conclusions: Conversion to resectability is associated with baseline characteristics like lung metastases and BRAF mutation as well as with early efficacy parameters (ETS, DpR). In FIRE-3, resection of metastases was associated with improved post-nadir survival, this effect originated predominantly from the cetuximab-based study arm.

510P Targeted therapies in conversion therapy in mCRC: A systematic review and meta-analysis

B. Xing[1], B. Cui[2], Z. Gu[3], H. Peng[4]

[1]Department of Gastrointestinal Surgery, Xiangya Hospital of Central South University, Changsha, China, [2]Oncology, Third Affiliated Hospital of Harbin Medical University, Harbin, China, [3]Merck Serono Co. Ltd, Darmstadt, Germany, [4]Hepatopancreatobiliary Surgery, Peking University Cancer Hospital, Beijing, China

Background: Chemotherapy (CT) plays a vital role as conversion treatment for initially unresectable or borderline resectable colorectal cancer (CRC). Targeted therapies are recommended with CT for conversion therapy; however, their role in conversion of initially unresectable tumours has not been elucidated. This meta-analysis evaluated the role of targeted therapies for conversion aimed at R0 resection in KRAS WT mCRC.

Methods: We conducted a literature search for randomized controlled trials (RCTs) in PubMed, Embase and Cochrane library evaluating the role of anti EGFR and anti VEGF as conversion therapies. A comparison was performed for anti-EGFR + CT vs. anti-VEGF + CT (Gp. A) and anti-EGFR + CT vs. CT (Gp. B). R0 resection rate and objective response rate (ORR) were the primary outcomes; with overall survival (OS), progression free survival (PFS) and safety evaluated as the secondary outcomes. Primary outcomes and safety were presented as relative risk (RR) and 95% confidence interval (CI), whereas survival was presented as hazard ratio (HR) and 95%CI.

Results: We identified 8 RCTs from the potential 81 studies. In Gp. A, a fixed effects model was used for analysis; and showed that although non-significant, anti EGFR + CT had better R0 resection rate (RR 1.44, 95% CI 0.91,2.27; $p = 0.1156$; $I^2 = 0\%$) and ORR (RR 1.05, 95% CI 0.88, 1.24; $p = 0.6039$; $I^2 = 0\%$) compared with anti VEGF + CT. OS with anti EGFR + CT was significantly longer than anti VEGF + CT (HR: 0.64; CI 0.47, 0.86; $p = 0.0036$; $I^2 = 0\%$); however, PFS was numerically better in anti EGFR + CT. Compared with CT alone, anti EGFR + CT resulted in significantly higher R0 resection rate (RR 1.85, 95% CI 1.15,2.98; $p = 0.0107$; $I^2 = 57.16\%$) and ORR (RR 1.19, 95% CI 1.11, 1.28; $p < 0.0001$; $I^2 = 0\%$). In Gp. B, only PFS was significantly longer with anti EGFR + CT vs. CT (HR: 0.85; 95% CI 0.74, 0.98; $p = 0.0015$; $I^2 = 45.60\%$), and not OS. Safety evaluation showed anti EGFR + CT with significantly greater adverse events than CT alone (RR: 1.26; 95% CI: 1.18, 1.35; $p < 0.0001$).

Conclusions: In conclusion, anti EGFR + CT was an effective conversion therapy compared with anti VEGF + CT and CT in patients with initially unresectable mCRC; however, frequency of AEs was more with targeted therapy.

Background: The phase III WJOG4407G study showed non-inferiority of FOLFIRI plus bevacizumab to mFOLFOX6 plus bevacizumab in progression-free survival, as the first-line chemotherapy for patients with metastatic colorectal cancer. The aim of this study was to evaluate the predictive and prognostic value of morphologic response to first-line chemotherapy containing bevacizumab in patients with CLM.

Methods: This study is a post hoc analysis of patients from the WJOG4407G study. Morphologic response was assessed with the comparison of baseline and week 8 contrast-enhanced CT images. Three blinded radiologists evaluated CT images and classified as optimal, incomplete or none response according to the morphologic criteria. RECIST response, early tumor shrinkage (ETS) and depth of response (DpR) were also evaluated. The Cox proportional hazards model was used to investigate the association between radiological variables and progression-free survival (PFS) and overall survival (OS).

Results: Of 395 patients who were eligible for efficacy analysis in the WJOG4407G study, 70 patients had liver-limited disease. Enhanced CT images of 57 of these patients from 22 participating centers were collected. Two patients were excluded from this analysis because their post-chemotherapy metastases were too small. Optimal morphologic response was identified in 19 of 55 patients (34.5%). The median PFS was 10.7 months for patients with optimal response and 10.1 months in those with incomplete/no response (log-rank $p = 0.96$). The median OS was 26.2 and 35.5 months, respectively (log-rank $p = 0.062$). According to univariate analysis, morphologic response was not associated with PFS or OS, whereas RECIST response was significantly associated with both PFS and OS, with ETS and DpR being associated with significantly longer PFS.

Conclusions: Morphologic response might be neither predictive nor prognostic factor in patients with CLM undergoing chemotherapy containing bevacizumab, whereas RECIST response was significantly associated with both PFS and OS.

512P KRAS mutations as a prognostic factor after metastasectomy in colorectal cancer patients

M. Domenech Viñolas[1], C. Santos[1], J. Pérez[2], M. Varela[3], M. Martinez Villacampa[1], A. Teule[1], J.C. Ruffinelli Rodriguez[1], N. Mulet Margalef[1], G. Soler[1], A. Ortega[1], M.S. Bergamino[1], X. SanJuan[3], J. Torras[4], E. Ramos[4], R. Salazar[1]

[1]Medical Oncology, Catalan Institute of Oncology, Hospitalet de Llobregat, Spain, [2]Research Unit, Catalan Institute of Oncology, Hospitalet de Llobregat, Spain, [3]Pathology, Hospital Universitari de Bellvitge, Hospitalet de Llobregat, Spain, [4]Surgical, Hospital Universitari de Bellvitge, Hospitalet de Llobregat, Spain

Background: Different clinicopathological factors have been associated with survival after liver metastasis resection in metastatic colorectal cancer (mCRC) patients. However, there is a need to better identify those patients who may benefit from metastasis resection. In this retrospective study we aimed to analyse clinical outcomes according to KRAS mutational status in a prospective collected series of mCRC patients.

Methods: We evaluated mCRC patients with exon 2 KRAS mutational status assessed between 2010 and 2014. Exon 2 KRAS mutational analysis was performed by therascreen® or cobas® assays. We excluded patients (pts) with no clinical data available. Disease-free survival (DFS) and overall survival (OS) were calculated using the Kaplan-Meier method.

Results: KRAS mutational status was assessed in 395 mCRC patients, but clinical data were only available in 348 patients. Median age was 66 years old. Two hundred and twenty-six patients were male (65%) and 210 pts (60%) had synchronous metastases at diagnosis. KRAS mutations were detected in 175 tumours (51%). Liver was the most common site of metastasis (210 pts, 60%), followed by lung (133 pts, 33%), lymph nodes (56 pts, 16%) and peritoneum (44 pts, 11%). Lung metastases at diagnosis were more frequent in KRAS mutant tumours (38% vs 27%, p-value = 0.022). We observed different metastasis spread pattern between pts with KRAS mutant and KRAS wt tumours. Risk of lung metastasis after 50 months of follow-up was higher in KRAS mutant tumours (77% vs 60%, p=.023). Risk of brain metastasis was also higher (18% vs 2%, p=.012). Median OS was 37 months, with no differences observed between KRAS mutant and KRAS wt tumours (34 vs 41 months, p-value = .70). One hundred thirty-nine patients underwent metastases resection (39.9%). In this subgroup of patients, KRAS mutations were associated with worse DFS (13.3 vs 24.5 months, p-value=.024).

Conclusions: KRAS mutations were associated with lung metastasis in CRC patients and different pattern spread. Although KRAS mutations were not a prognostic biomarker in the metastatic setting, patients with KRAS mutant tumours had a shorter DFS after metastasis resection.

Background: The benefit of preoperative chemotherapy (pre-CT) and metastasectomy for pulmonary metastasis (PM) from colorectal cancer (CRC) (PM-CRC) are unclear due to a lack of enough studies. However, there are some patients who receive chemotherapy after PM detection and subsequently undergo metastasectomy in clinical practice. The aim of this study was to investigate the impact of response to pre-CT on the outcome of pulmonary metastasectomy for PM-CRC.

Methods: The subjects were 92 patients, who received pre-CT before metastasectomy for PM-CRC, identified from the 1237 patients whose PM-CRC were curatively resected at 46 institutions in Japan between 2004 and 2008.

Results: Twenty-six (28%) patients initially judged to have inoperable PM underwent chemotherapy leading to conversion to be resectable and subsequently received metastasectomy. The remaining 66 patients initially judged to have operable PM received pre-CT and subsequently underwent metastasectomy. Fifty-six (61%) patients received fluoropyrimidine based regimens combined with oxaliplatin or irinotecan, and most of the remaining 26 received tegafur/uracil. Pre-CT yielded partial response (PR), stable disease (SD) and progressive disease (PD) in 28 (30%), 26 (28%) and 38 (42%) patients, respectively. At metastasectomy, the proportions of patients with extrathoracic lesion, multiple PMs, and abnormal carcinoembryonic antigen level were 34, 58, and 40%, respectively. Wedge resection was the most frequent (62%) surgical procedure. The five-year disease-free (DFS) and overall survival (OS) rate of the all 92 patients were 25.1% (95% CI 16.4-34.7) and 45.4% (33.4-56.7). The five-year DFS rates of the patients with PR/SD and PD during pre-CT were 28.2% (16.5-41.1) and 20.6% (9.2-35.2), and those of OS were 58.1% (40.8-71.9) and 27.5% (12.9-44.3), respectively. By multivariate analysis, independent prognosticators were two or less PMs (HR = 0.56, 95% CI 0.33-0.94; p = 0.029) for DFS, and performance status 0 (0.44, 0.22-0.90; 0.024) and PR/SD during pre-CT (0.33, 0.18-0.61; < 0.001) for OS.

Conclusions: Response to Pre-CT had some impacts on OS after metastasectomy for PM-CRC: better in the patients with PR/SD compared to PD.

514P Long-term outcomes with cytoreductive surgery (CRS) and hyperthermic intraperitoneal chemotherapy (HIPEC) in peritoneal carcinomatosis: 10-year experience in a developing country

F. Arias[1], E. Londoño-Schimmer[1], J. Otero[2], C.E. Cétares[1], G.E. Herrera[1], M. Mora[1], P. Rodriguez[3], M. Mejía[3], J.D. Guerra[4], A. Ruiz-Patiño[5], A.F. Cardona Zorrilla[5]

[1]Department of Surgery, Peritoneal Neoplasms Clinical Care Center, Fundacion Santa Fe de Bogotá, Bogotá, Colombia, [2]Clinical Oncology Group, Institute of Oncology, Fundacion Santa Fe de Bogotá, Bogotá, Colombia, [3]Department of Pathology, Fundacion Santa Fe de Bogotá, Bogotá, Colombia, [4]Facultad de Medicina, Universidad de Los Andes, Bogotá, Colombia, [5]Translational Research, Foundation for Clinical and Applied Cancer Research, Bogotá, Colombia

Background: Cytoreductive surgery (CRS) plus hyperthermic intraperitoneal chemotherapy (HIPEC) has emerged as a comprehensive treatment of peritoneal malignancies and it is currently a viable option in the increasing number of specialized centers all around the world.

Methods: A review of 119 CRS/HIPEC patients operated between 2007-2017 in a tertiary referral center of Bogotá, Colombia was performed. Patient characteristics, surgical variables, and postoperative outcomes were prospectively collected and analyzed.

Results: Median age at diagnosis was 51-yo (r, 22-78) and 73% (n = 87) were female. Primary origin of the peritoneal carcinomatosis was the appendix in 64%, advanced ovarian and primary peritoneal carcinomas (PC) in 17%, colorectal cancer (CRC) in 10.1%, peritoneal mesothelioma (PM) in 9%, and others in 1.6%. Prior surgical Peritoneal Cancer Index (PCI) was 19 (r, 2-39) and 25.2% were exposed to preoperative chemotherapy. Complete cytoreduction rate (CCR) was 81.5% (75% appendiceal tumors, 94% OC, 83% CRC, and 100% PM [p = 0.81]). Grade III, IV, and V complications were reported in 10%, 12%, and 4% of patients, respectively. Progression-free survival (PFS) was 38.4 months (95%CI 12.6-64.3) and 5-year PFS was 64%. PFS was positively influenced by appendiceal and mesothelioma histology (p = 0.035) as well as complete cytoreduction (p = 0.0001). At 42-month median follow-up 26 patients have died and the median overall survival (OS) was 108.5 months (95%CI 77.5-139.5). OS of patients with t relapse was 78.6 months (95% CI 36.1-121.1) and NR (p = 0.002), respectively, and only this variable adversely affected the multivariate analysis (RR 3.7, 95% CI 1.4-9.5; p = 0.007).

Conclusions: CRS/HIPEC is an effective treatment for patients with PC providing long-term survival and should be considered as standard of care. Our results, from a specialized center in a developing Latin-American country, are comparable to those from first-world centers, implying the importance of group experience in providing high-quality outcomes. Results showed that patients without relapse at the 5th year follow-up could be considered cured, but should always resume observation.

515P Clinical impact of 18F-FDG-PET/CT (PET) in patients (P) with oligometastatic disease (OMD) at a skin and gastrointestinal tumour section

J.J. Garcia-Mosquera, L. Layos Romero, C. Buges, S. España Fernandez, S. Chen, J.M. Velarde, E. Felip, C. Erasun Lecuona, L. Angelats, M. Cucurull Salamero, J.L. Manzano

Medical Oncology, Catalan Institute of Oncology (ICO Badalona), Hospital Germans Trias i Pujol, Badalona, Barcelona, Spain

Background: Is important to avoid aggressive treatments in P with OMD with undetected metastasis. Previous data demonstrated that PET can have a significant clinical impact, especially in colorectal cancer.

Methods: Retrospectively, we review the history of P studied with PET at our unit, from October 2013 to December 2017. We included only P with OMD with a PET done to complete disease extension study in addition to conventional imaging and previously to undergo a potential curative management. Baseline data (age, sex, primary and stage), disease extension and initial strategy before PET were collected. After PET, disease extension, definitive strategy and overall survival (OS) was determined.

Results: Overall, 93 P met the inclusion criteria: 72 (77%) colorectal (CRC), 13 (14%) melanoma, 4 (4%) biliary tract, 2 (2%) oesophageal and 2 (2%) other primaries. The mean age was 64 years (range: 24-83) and 58 (62%) P were male. At debut, 64 (79%) P were non-metastatic, and PET was done at the recurrence. After PET, 47 (51%) P were restaged: 35 (38%) were upstaged and 12 (13%) were downstaged. Final strategy was changed in 43 (46%) P, leading to a non-radical plan in 32 (34%) P. On the radical plan group there was 2 (2.2%) p with no malignant disease after surgery (pulmonary

tuberculosis and aspergillosis). Median OS after PET in CRC cohort with changed strategy was significantly lower (28m, CI 95% 23-32) versus cohort without changes (47m, CI 95% 29-65); p-value 0.03.

Conclusions: After PET approximately half of P were restaged, consequently avoiding aggressive strategies in one-third of P. PET seems to be effective in selecting P with poor overall survival outcomes that need a palliative rather than a radical management. PET has relevant advantages compared with conventional imaging in the selection of P with OMD disease who may be eligible for surgery or local techniques.

516P Simultaneous resection of colorectal primary tumor and liver metastasis after neoadjuvant therapy: A propensity score matching analysis

Y. Xu

Department of Colorectal Cancer, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Considering the surgical safety and presentation of perioperative complications, simultaneous resection of colorectal cancer and liver metastasis after neoadjuvant treatment is not regularly conducted in many centers. Herein, we assessed and compared the surgical safety and incidences of postoperative complications in patients with and without neoadjuvant treatment.

Methods: A total of 257 patients who underwent simultaneous resection were included in this single-center, retrospective study. Comparison of the short-term outcomes was performed after propensity score adjustment.

Results: No postoperative death occurred. After matching, the differences from colorectal cancer and liver metastasis were well-balanced. The median operative time, and blood loss and intraoperative transfusion rates did not differ between Group A (without neoadjuvant treatment) and Group B. The morbidity (Group A vs. Group B, 15.4% vs. 19.2%, $p = 0.420$), and Clavien-Dindo grade of complications ($p = 0.632$) were also similar. No difference was found when the complications were divided according to the origin (general, colorectal and hepatic). The length of the hospital stays also did not differ between the groups. Ratios of patients with the elevation of some important blood indices related to liver function did not differ, and there was no increase in the number of patients with delayed adjuvant treatment after surgery in Group B.

Conclusions: Simultaneous resection after neoadjuvant treatment was found to be comparably safe. It did not increase morbidity and influence subsequent adjuvant treatment, and may be a treatment option for patients with synchronous liver metastasis.

517P Clinical factors are unable to accurately predict the absence of benefit of surgery in patients operated for resection of colorectal liver metastasis

A. Bohlok[1], H. Tessely[2], E. Naets[2], F. Bouazza[1], D. Germanova[3], J.L. Van Laethem[3], A. Hendlisz[4], V. Lucidi[3], V. Donckier[1]

[1]Surgery, Institute Jules Bordet, Brussels, Belgium, [2]Chirurgie, Institut Jules Bordet, Bruxelles, Belgium, [3]Digestive Surgery, Erasme University Hospital ULB, Brussels, Belgium, [4]Medical Oncology Clinic, Institut Jules Bordet, Université Libre de Bruxelles, Brussels, Belgium

Background: A substantial proportion of patients operated of resection for colorectal liver metastases (CRLM) with curative-intent will rapidly recur after surgery, emphasizing the need to improve the current selection process for surgery. The aim of the study is to analyze clinicopathologic prognostic factors that could better identify patients that wouldn't benefit of surgery.

Methods: A prospective database including patients operated of hepatectomy for CRLM between 2005 and 2017 was analyzed. Within this population, we selected and compared 2 groups: early relapsers (ER), defined as patients with unresectable recurrence $\leq$1 year postoperatively considered as having not benefited of surgery and long-term survivors (LTS), defined as patients without recurrence $\geq$5 years after first hepatectomy. In the entire population and in the 2 subgroups, we analyzed potential predictive factors, using uni- and multivariate analysis.

Results: In total population ($N = 357$), 5 and 10-year disease-free survival (DFS) and overall survival (OS) are 26 and 21.5% and 44 and 25% respectively. In univariate analysis, Fong's Clinical Risk Score (CRS) >2, mutated-KRAS, major hepatectomy and positive resection margins are significant poor prognostic factors for DFS and OS. In multivariate analysis only mutated-KRAS remains a significant poor prognostic factor for DFS (HR = 1,5 Ci:1,06-2,12 p = 0,02) and OS (HR = 1,8 Ci:1,19-2,70 p = 0,005). Comparing the 2 subgroups ER-group (77 patients) and LTS-group (64 patients), representing respectively 21 and 18% of entire population the univariate analysis showed significantly more synchronous CRLM, multiple metastases, mutated-KRAS and CRS>2 in the ER group. Of note, 25% of LTS had CRS>2. In multivariate analysis, only multiple metastases remain significantly increased in ER ($p = 0.016$).

Conclusions: Clinical factors are unable to discriminate preoperatively the patients who will benefit of surgery for CRLM from those in whom surgery will be futile. This strongly underlines the need to identify other markers of tumor biology for better individualization of the therapeutic decision.

518P Hepatic arterial infusion (HAI) of oxaliplatin with capecitabine in first line treatment of patients (pts) with liver limited metastases from colorectal cancer (LLmCRC)

B.V. Vittrup[1], H.H. Nørgaard[2], M. Bergenfeldt[3], F.O. Larsen[1], E. Høgdall[4], J.S. Johansen[1], J.S. Sidenius Johansen[1], H.K. Hermann[2], D.L. Nielsen[1]

[1]Oncology, Herlev and Gentofte Hospital, Herlev, Denmark, [2]Radiology, Herlev and Gentofte Hospital, Herlev, Denmark, [3]Surgery, Herlev Hospital and Skåne Hospital, Herlev, Denmark, [4]Pathology, Herlev and Gentofte Hospital, Copenhagen, Denmark

Background: The hepatic artery accounts for the primary blood supply of liver metastases from CRC.

Methods: First-line therapy with up to 12 series of HAI with oxaliplatin 100 mg/m^2 day 1 and capecitabine 3500 mg/m^2 day 1-7 every second week. When the hepatic arterial anatomy did not permit a permanent catheter pts had intravenous oxaliplatin 130 mg/m^2 day 1 every third week combined with capecitabine 2000 mg/m^2 day 1-14 (CAPOX). RAS mutations were retrospectively determined by next generation sequencing of KRAS Exon (E) 2, codon (C) 12 and 13, E3C59 and 61, E4C117 and 146 and NRAS E2C12 and 13, E3C59 and 61, E4C117 and 146. Pts had a baseline PET/CT scan and was evaluated by liver surgeons for resectability.

Results: Included were 93 pts, 66 had HAI and 27 CAPOX. The groups were comparable with an equal distribution of RAS wildtype (RAS-W) and mutants (RAS-M) tumours. Follow-up was 95-154 mths. Overall response rate (ORR) with complete (CR) and partial remission (PR) was 89% vs 59% in the HAI vs. CAPOX group ($P = 0.0008$). Progression-free survival (PFS) was independent of RAS status and treatment. Median overall survival (OS) was 6 mths. longer in the HAI vs CAPOX group (HR 1.62, 95% Confidence Interval (CI) 1.0-2.6, $P = 0.05$). OS was independent of RAS status in the CAPOX group and equal to OS in the HAI RAS-M group. Pts with RAS-W tumours treated with HAI survived double that of all the other groups (HAI-RAS-W vs HAI-RAS-M: HR 1.88, 95%CI 1.1-3.2, $P = 0.023$, HAI-RAS-W vs. CAPOX-RAS-W: HR 1.60 95%CI 1.12-2.27, $P = 0.009$). Toxicity of HAI was comparable to CAPOX with abdominal pain, neuropathy, and hand foot syndrome as the most common adverse events.

Table: 518P

	HAI-CAPOX			Systemic-CAPOX		
	All	RAS-W	RAS-M	All	RAS-W	RAS-M
No	66	31	35	27	14	13
NA	2		2	3	1	2
CR	8 (12%)	6	2	0		
PR	51 (77%)	25	26	16 (59%)	10	6
SD	4		4	6 (22%)	3	3
PD	1		1	2		2
mOS [1]	36 (28-44)	64 (45-81)	29 (24-35)	30 (24-35)	30 (20-41)	22 (16-29)
mPFS [1]	12 (10-15)	14 (11-17)	11 (8-15)	11 (9-13)	12 (7-17)	10 (8-13)

Mths with 95%CI in brackets. NA=not applicable, SD =stable disease and PD=progressive disease.

Conclusions: ORR and OS was significantly higher when pts with LLmCRC was treated with Capecitabine and HAI with oxaliplatin compared to CAPOX. Survival benefit is limited to pts with RAS-W tumours treated with HAI.

Background: High microsatellite instability (MSI-H) is a prognostic marker in early colon cancer (CC) identified in retrospective analysis of many trials. However, broad validation in real-life cohorts and its association with clinical and molecular markers is lacking.

Methods: In Sep 2013 the molecular registry trial Colopredict Plus was intiatied in 70 German community cancer centers recruiting patients with UICC stage II and III CC. MSI was tested by immunohistochemistry (IHC) of mismatch repair proteins MLH1, MSH2, MSH6 and PMS2. In case of any loss of protein expression fragment length analysis (FLA) was performed, defining MSI high tumors (MSI-H) and MS stable tumors (MSS). Moreover, mutations in known prognostic factors in CC such as RAS, BRAF, PI3K and others were determined by next generation sequencing (NGS).

Results: By April 2018, 2102 patients have been recruited: median age 72 yrs., stage II/III: 1108/994 pts. So far, tissue was analysed in 1342 pts. Of these, 377 pts. were IHC neg with 290 pts. subsequently tested MSI-H upon FLA (21.6%). Median age was 73 yrs. female/male: 677/665 pts., stage II/III: 736/606 pts. Association of MS status with clinical and molecular factors is shown in the table. Upon NGS analysis we found 18.9% BRAF mutations, 41.5% KRAS mutations, 3.2% NRAS mutations and 25.1% PI3K mutations. MSI-H status was significantly associated with BRAF mutation and wild-type status of RAS.

Conclusions: MSI-H was more frequent in this community based registry compared to randomised trials, possibly related to a higher median age in our cohort. MSI-H was associated with female sex, right-sided primary tumor and BRAF mutations representing a heterogeneous subgroup of CC. First survival data will be presented at the meeting. Table: Association of clinical features with MSI-H in patients with CC (MS status determined by FLA).

Table: 519P

	All	MSI-H (%)	MSS (%)
	1342	290 (21,6)	1052 (78,4)
Median age	73	76	73
Male	677	78 (11,5)	599 (88,5)
Female	665	212 (31,9)	453 (68,1)
Stage II	736	181 (24,6)	555 (75,4)
Stage III	606	109 (18)	497 (82)
Right Colon	793	242 (30,5)	551 (69,5)
Left Colon	536	47 (8,8)	489 (91,2)

[1]Department of Specialized Surgeries, Tokyo Medical and Dental University, Tokyo, Japan, [2]Department of Translational Oncology, Tokyo Medical and Dental University, Tokyo, Japan, [3]Division of Medical Statistics, Translational Research Informatics Center, Foundation for Biomedical Research and Innovation at Kobe, Hyogo, Japan, [4]Department of Surgery, National Defense Medical College, Saitama, Japan, [5]Specialized Surgeries, Tokyo Medical and Dental University, Tokyo, Japan, [6]Biostatistics Center, Kurume University, Graduate School of Medicine, Fukuoka, Japan, [7]Department of Biostatistics, Nagoya University, Aichi, Japan, [8]Division of Lower GI Surgery, Department of Surgery, Hyogo College of Medicine, Hyogo, Japan, [9]Division of Clinical Oncology, Kochi Health Sciences Center, Kochi, Japan, [10]Deparment of Surgery, Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Tokyo, Japan, [11]Department of Surgery, Tochigi Cancer Center, Tochigi, Japan, [12]Department of Surgery, Kitasato University School of Medicine, Kanagawa, Japan, [13]Deparment of Surgery, National Defense Medical College, Saitama, Japan, [14]Department of Biostatistics, Kyoto Prefectural University of Medicine, Kyoto, Japan, [15]Deparment of Surgery, Tokyo Medical and Dental University, Tokyo, Japan

Background: The SACURA trial is a phase III study to evaluate the superiority of 1-year adjuvant treatment with oral tegafur-uracil (UFT) to surgery alone in stage II colon cancer, in which survival benefit of 1-year UFT was not demonstrated (Eur J Cancer 96:54-63, 2018). In an additional biomarker study, we studied MSI status and 18qLOH of cancer tissues and evaluated their clinical value in stage II colon cancer patients.

Methods: A total of 1026 samples were collected from patients enrolled in the SACURA trial. MSI was evaluated by 5 markers; BAT25, BAT26, D2S123, D5S346, and D17S250. MSI-high (MSI-H) was defined as the presence of instability in more than 20% of the markers. 18qLOH was evaluated by 3 markers; D18S69, D18S74E, and D18S851. 18qLOH positivity was defined as the presence of LOH in any of the 18q markers. 18q LOH negativity was strictly defined as the presence of at least one informative markers and the absence of LOH.

Results: MSI-H was observed in 74 (7.2%) patients. The 18q LOH was present in 526 patients (51.3%) and LOH negativity was observed in 354 (34.5%). Informative LOH data was not available in 146 patients (14.2%). Relapse free survival (RFS) in MSI-H patients was better than that in non MSI-H (HR: 0.40, 95%CI: 0.17-0.98, p = 0.045). RFS in 18qLOH positive patients was significantly worse than in 18qLOH negative patients (hazard ratio: 1.44, 95%CI: 1.01-2.07, p = 0.047). When the patients were divided into 3 groups using MSI status and 18qLOH, approximately 5% differences of RFS were observed among the subgroups (Table). In the group 1 and 2, 5-year RFS rates were favorable and there were no differences in RFS between the treatment arms. In the group 3, 5-year RFS rate in the UFT group was +3% better than in the surgery-alone group although the difference was not significant.

Table: 520P

5yRFS in the subgroups divided by MSI status and 18qLOH

Subgroup divided by MSI status and 18qLOH	5yRFS		
	Overall	Surgery-alone group	UFT group
group 1: MSI-H	92.9% (N = 74)	94.3% (N = 36)	91.7% (N = 38)
group 2: non MSI-H and 18qLOH negative	87.2% (N = 327)	87.5% (N = 153)	87.0% (N = 174)
group 3: non MSI-H and 18qLOH positive/non-informative	82.5% (N = 625)	81.0% (N = 320)	84.0% (N = 305)

Conclusions: In stage II colon cancer, adjuvant chemotherapy might be unnecessary for MSI-H or 18qLOH negative patients. MSI status and 18qLOH might be useful biomarkers in stage II colon cancers.

Clinical trial identification: NCT00392899.

521P miR-31 as a prognostic and predictive marker of disease-free survival (DFS) in resected stage III colon cancer: A retrospective analysis of the PETACC-8 trial

Y. Gaston Mathe[1], S. Martin-Lannerée[2], C. Vazart[2], K. Fontaine[2], C. Mulot[3], A. Caumont[4], F. Montestruc[4], K. Le Malicot[5], C. Lepage[6], J. Taieb[7], P. Laurent-Puig[8]

[1]Molecular Diagnostics, IntegraGen SA, Évry, France, [2]R&D, IntegraGen, Évry, France, [3]U1147, INSERM, Paris, France, [4]Biostatistics, EXYSTAT, Malakoff, France, [5]Biostatistics, FFCD-, Dijon, France, [6]Clinical Oncology, CHU Dijon, Dijon, France, [7]Department of Gastroenterology and Digestive Oncology, Hopital European George Pompidou, Paris, France, [8]UMR1147, Paris Descartes University, Paris, France

Background: In RAS wild type metastatic colorectal cancer patients (pts), high tumor expression of microRNA miR-31-3p and miR-31-5p has been associated with poorer benefit of anti-EGFR therapy. miR-31-3p expression has been shown to be predictive of treatment effect in the FIRE-3 trial. The PETACC-8 phase III trial assessed the efficacy of cetux addition to FOLFOX compared to FOLFOX only in pts with resected stage III colon cancer (CC). The primary end point was negative, but a trend towards benefit of cetux on disease free survival (DFS) was observed in pts with RAS/BRAF wild type (WT) tumors. The current study aimed at assessing miR-31-3p and 5p tumor levels as prognostic and predictive biomarkers of adjuvant cetux benefit in these pts.

Methods: miR-31-3p and 5p levels were measured by RT-qPCR from 477 WT pts tumor RNA. The primary objective was to demonstrate a benefit of cetux on DFS for low miR-31-3p expressers. Cox regression model was used for univariate and multivariate analyses. Optimal cut-off values for low and high expressers were determined post hoc.

Results: In the studied population, cetux benefit was significant for DFS (HR = 0.71 [0.50;1.00] p = 0.05) but not for Overall Survival (OS) (HR = 0.79 [0.53;1.18] p = 0.25). Expression of miR-31-3p and miR-31-5p were highly correlated (R > 0.9). Higher miR-31-3p and 5p expression were associated with shorter DFS and OS (p < 0.01). Pts with low miR-31-3p levels (n = 218/435, 50%) had a non-significant benefit from cetux on DFS (HR 0.61 [0.33; 1.11] p = 0.10) and OS (HR = 0.67 [0.33; 1.35] p = 0.26). Pts with low miR-31-5p levels (n = 233/477, 49%) benefited from cetux on DFS (HR = 0.46 [0.25; 0.84] p = 0.01) and OS (HR = 0.50 [0.25; 0.99], p = 0.047) whereas high expressers did not (DFS: HR = 0.87 [0.56; 1.34] ; OS: HR = 1.01 [0.61; 1.67]). miR-31-5p was predictive of treatment effect on DFS at the 10% level (interaction tests: p = 0.09 for DFS and p = 0.103 for OS). Results were still significant after adjustment for clinical covariates.

Conclusions: In pts with resected stage III WT CC, miR-31-3p and 5p were prognostic of DFS and OS. Pts with low miR-31 expression benefited from cetux addition to FOLFOX for adjuvant therapy, and miR-31-5p was predictive of cetux efficacy.

Background: Prognostic factors in resected colon cancer (CC) guide adjuvant therapy and intensity of follow up. Inflammation parameters as C-reactive protein and neutrophil counts in relation to lymphocyte number (neutrophil/lymphocyte ratio: NLR) have been correlated with poor prognosis in advanced tumors. To confirm the prognostic value of a prechemoterapy NLR in adjuvant setting, we performed a retrospective analysis of high risk stage II and stage III resected CC patients randomized into the TOSCA phase 3 trial comparing 3 or 6 months of adjuvant chemotherapy.

Methods: patients randomized in TOSCA trial with data available for NLR analysis before chemotherapy were included. A recursive partitioning analysis was performed to identify the best cut-off that better discriminates patients in terms of relapse-free survival (RFS). According to this cut-off, RFS and overall survival (OS) hazard ratios (HR) for NLR were calculated and adjusted for age, sex, treatment type (XELOX vs FOLFOX) and duration (3 vs 6 months), grade, stage, performance status (PS), site and CEA level.

Results: Out of 3759 subjects randomized in the TOSCA trial, 1590 were included in the efficacy analysis. Mean NLR was 2.1 (median 1.8; range 0.3-24.0). Among patients analysed, 17.4% relapsed and 12.2% died. The best NLR cut off detect in this analysis population is 2.33. However, only age, PS, stage III and CEA levels were associated with RFS and OS in multivariate analysis, but not NLR>2.33 (RFS: HR = 1.17, 95%CI 0.90-1.51; P = 0.24, OS: HR = 1.16 95%CI 0.84-1.61; P = 0.38). Site was also correlated with poor OS.

Conclusions: Prechemotherapy NLR is not significantly associated with poor prognosis in patients with CC undergoing adjuvant chemotherapy. Resection of primary tumor and the associated reduced inflammatory stimulus may explain the lack of correlation with prognosis of NLR. Baseline evaluation, before surgery, likely represents the better timing to collect this information in cancer patients.

523P Distribution of lymph node metastases can have an impact on survival benefit of oxaliplatin-containing chemotherapy in stage III colon cancer

Y. Chae[1], J.G. Kim[2], J.H. Baek[3], S.J. Lee[2], D.W. Baek[2], B.W. Kang[2]

[1]Oncology, Kyungpook National University Medical Center, Daegu, Republic of Korea, [2]Oncology, Kyungpook National University Hospital, Daegu, Republic of Korea, [3]Oncology, Ulsan University Hospital, Ulsan, Republic of Korea

Background: This study investigated the effect of oxaliplatin-containing adjuvant chemotherapy according to the distribution of lymph node (LN) metastases for patients with stage III colon cancer (CC).

Methods: Among 1554 patients with CRC who underwent surgical resection between 2010 and 2014, 254 patients were diagnosed with stage III CC, and adjuvant chemotherapy was administered. Patients were treated with either oxaliplatin-containing chemotherapy or non-oxaliplatin-containing chemotherapy according to each investigator decision. LN distribution was classified on the basis of the Japanese classification of colorectal carcinoma. The patients were grouped into two categories: pericolic LN-positive and extrapericolic LN-positive.

Results: Among the 254 patients enrolled in this study, 175 belonged to the PLN group, whereas the remaining 79 patients to the ELN group. The PLN group was also divided into two groups based on the regimen: 79 patients were included in the non-oxaliplatin-containing chemotherapy group, while 96 in the oxaliplatin-containing chemotherapy group. The characteristics were similar between two groups, except for age and body mass index. During the median follow-up duration of 48.5 months

(range 4.7-94.0), 39 (15.4%) patients died and 47 (30.5%) patients experienced recurrence and the estimated DFS and OS at 3 years was 82.8% and 90.1%, respectively. In the univariate analysis, oxaliplatin chemotherapy was not significantly associated with DFS (p = 0.457) and OS (p = 0.147). In the multivariate analysis, the addition of oxaliplatin showed no prognostic significance on DFS (p = 0.073) and OS (p = 0.594).

Conclusions: In conclusion, oxaliplatin-containing adjuvant chemotherapy was not found to have a significant effect on survival for stage III CC patients with only PLN. Accordingly, the current study can provide a novel strategy for subgroups with limited LNs distribution, considering that the state of the LN distribution is a critical factor for therapeutic success.

524P Implications of thymidylate synthase gene polymorphisms, KRAS and BRAF mutations in the survival of patients with colorectal cancer treated with adjuvant chemotherapy

A. Ntavatzikos[1], A. Spathis[2], P. Patapis[3], G. Peros[4], I. Panayiotides[5], I. Papadopoulos[4], A. Koumarianou[1]

[1]Hematology Oncology Unit, Fourth Department of Internal Medicine, Athens Greece, Attikon University Hospital, Athens, Greece, [2]Department of Cytopathology, Attikon University Hospital, Athens, Greece, [3]Third Department of Surgery, Attikon University Hospital, Athens, Greece, [4]Fourth Department of Surgery, Attikon University Hospital, Athens, Greece, [5]Pathology, Attikon University Hospital, Athens, Greece

Background: Fluoropyrimidine-based adjuvant chemotherapy in colorectal cancer (CRC) is associated with a reduction of recurrence in only 25% of patients (pts) with stage III disease. The aim of this study was to investigate thymidylate synthase (TYMS) gene polymorphisms, KRAS and BRAF as possible factors affecting therapeutic outcome in pts with stage III CRC.

Methods: Formalin-fixed paraffin-embedded tissues of 130 consecutive pts treated with FABC between 2005-2007 were analysed with PCR for the detection of TYMS polymorphisms, mKRAS and mBRAF. Patients were classified into three groups of 5'UTR TYMS polymorphisms according to the predicted expression profile (high, medium and low). Based on the presence or absence of the 3'UTR polymorphism ins/LOH pts were allocated into two groups (high and low risk). Cox regression models examined factors associated with survival outcome.

Results: The 5-year DFS and OS rate was 61.6% and 73.9% respectively. Patients who had tumors with 5'UTR polymorphisms of intermediate TYMS expression profile (2RG/3RG, 2RG/LOH, 3RC/LOH) when compared to those with low (2RG/2RG, 2RG/3RC, 3RC/3RC) or high expression (3RG/3RG, 3RG/LOH, 3RG/3RC) had lower risk for relapse (HR 0.320, p = 0.02 and HR 0.343, p = 0.013 respectively) and death (HR 0.368, p = 0.031 and HR 0.394, p = 0.029 respectively). The 3'UTR polymorphism ins/LOH was independently associated with increased risk for disease recurrence (p = 0.001) and death (p = 0.005). Presence of mBRAF (3.8% pts) was associated with an increased risk of death (HR 4.500, p = 0.022), whereas mKRAS (39% of pts) was not found to correlate with survival.

Conclusions: The group of TYMS polymorphisms 2RG/3RG, 2RG/LOH, 3RC/LOH, the absence of ins/LOH and absence of mBRAF were associated with better prognosis of pts with early stage CRC. Mutated KRAS was not found to affect relapse or risk of death in the adjuvant setting. Further prospective studies investigating the role of TYMS polymorphisms and mBRAF are warranted to identify pts who could benefit from 5FU-based cytotoxic chemotherapy.

526P Results of the national organised colorectal cancer screening program with FIT in Paris

A. Pellat[1], R. Coriat[2], S. Chaussade[2]

[1]Medical Oncology, Hôpital Saint-Antoine, Paris, France, [2]Gastroenterology and Digestive Oncology, Hôpital Cochin, Paris, France

Background: In France, colorectal cancer (CRC) benefits from a nationwide screening program. The faecal immunochemical test (FIT) is being used since April 2015. The test is recommended in asymptomatic patients followed by a colonoscopy if positive for identification and treatment of colorectal lesions. We investigate the CRC national organised screening program using FIT in Paris.

Methods: We performed a retrospective observational study, collecting data from the screening program in Paris using the ADECA75 database. Rates of participation, numbers of positive FIT, detection rates and positive predictive values (PPV) for advanced adenomas (AA) and/or CRC were determined.

Results: Between 01/01/2016 and 30/06/2017, 620.227 Parisians were eligible and 409.340 were invited to participate to the program. A total of 88.796 participants (23%) performed the test with 3.839 positive tests (4.3%). In the positive test population, 2.706 out of 3.839 individuals (70.5%) performed the required colonoscopy with available reports. Histology reports were only available for 2.401 participants (88,7%). Regarding lesions, 733 (30,5%) and 205 patients (8.5%) had AA and CRC, respectively.

Conclusions: Over 18 months of screening with FIT in Paris, the PPV is in line with expected results while the participation rate is below European recommendations.

527P Screening strategy of Lynch syndrome for Chinese colorectal cancer patients with MLH1-immunoloss

W. Wang, L. Dong, S. Zou, N. Lu

Pathology Department, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences, Peking Union Medical College, Beijing, China

Background: Inactivation of MLH1 due to promoter hypermethylation strongly suggests a sporadic origin, and nearly half sporadic colorectal cancer patients harbor BRAF mutation, providing exclusion criteria for Lynch syndrome (LS). However, there was little evidence from Chinese population. The aim of this study was to compare the utility of two tests, and explore the possibility of substituting BRAF immunohistochemical staining (IHC) for real-time PCR.

Methods: We reviewed MMR expression status of consecutive patients who had undergone surgery for colorectal cancer between 2012.1.1 and 2014.12.30 in Chinese National Cancer Center. Among 317 patients who were identified as dMMR, 170 patients with MLH1 immunoloss were taken into final analysis. MLH1 methylation status was evaluated by MS-PCR(methylation – specific PCR) ,BRAF mutation was tested by IHC and real-time PCR.

Results: 52.9%patients display MLH1 promoter hypermethylation. As for BRAF status, the mutation rate tested by IHC and real-time PCR was 14.1% and17.1%, respectively, and the concordance rate was 92.1%. BRAF mutation did better on ruling out patients whose relatives had CRC history. Although patients who had unmethylated CRCs had a notably stronger family history of CRC, there were still 13.3% patients in the hypermethylation group having family history of CRC, indicating a likelihood of LS.

Table: 527P

Feature	MLH1 methylated n = 90	MLH1 unmethylated n = 80	P	BRAF mutation n = 24	BRAF wild-type n = 146	p
Median age	62y	50y		64y	54y	
Synchronic CRC	3(3.3)	8(10.0)	0.078	1(4.2)	10(6.8)	0.962
FDR or SDR with LS-related tumor	17(18.9)	14(17.5)	0.815	3(12.5)	28(19.2)	0.617
FDR or SDR with CRC	12(13.3)	32(40)	0.000	0	44(30.1)	0.002
FDR with CRC	9(10.0)	27(35.0)	0.000	0	36(24.7)	0.016
Revised Bethesda guidelines	43(47.8)	69(86.3)	0.000	8(33.3)	104(71.2)	0.000

Conclusions: The mutation rate of BRAF in Chinese population with MSI CRCs was significantly lower than that in western countries, leading to a decreased specificity. Thus, BRAF mutation alone was not efficient to be a negative predictor of LS. Due to the high specificity of MLH1 methylation test and the high concordance rate of IHC and real-time PCR for BRAF mutation, patients who have MLH1 hypermethylation, BRAF wild-type tested by IHC and family history of CRC should be recommended for germline mutation test additional to those with MLH1 unmethylated CRCs.

528P Early detection of colorectal cancer using breath biomarkers: Preliminary study

G. Woodfield[1], I. Belluomo[1], H. Panesar[1], G.P. Lin[1], P. Boshier[1], A. Romano[1], J. Martin[2], C. Groves[3], B. Saunders[4], W. Atkin[1], G.B. Hanna[1]

[1]Department of Surgery and Cancer, Imperial College London, London, UK, [2]Gastroenterology, Imperial College Healthcare NHS Trust, London, UK, [3]Gastroenterology, St George's Healthcare NHS Trust, London, UK, [4]Gastroenterology, St Mark's Hospital, London, UK

Background: Colorectal cancer (CRC) is the 2nd most common UK cause of cancer death. The bowel cancer screening programme (BCSP) has saved lifes through early cancer diagnosis. However, it only targets those aged 60-74, and leads to many potentially unnecessary colonoscopies. A breath test could be used as a more specific non-invasive screening tool, or to triage/reassure symptomatic patients. Prior studies have shown promising results using exhaled propanal for detecting CRC (96% sensitivity/76% specificity). The Colorectal BReath Analysis (COBRA) study aims to determine the diagnostic accuracy of breath volatile organic compounds for detecting CRC, first by analysing breath of known colorectal cancer patients, then by testing the resultant diagnostic model on a prospective BCSP population, target 2000 patients.

Methods: Clinical data was collected from patients attending for colonoscopies or CRC surgery across 4 London centres July 2017 to May 2018. Exhaled breath (500mls) was collected using the ReCIVA™ breath sampling device, onto thermal desorption tubes. Analysis by gas chromatography mass spectrometry and proton transfer reaction (PTR) mass spectrometry identified and quantified breath compounds.

Results: 426 patients were recruited for this preliminary dataset. 80 samples were excluded due to inadequate colonoscopies, instrument faults or inadequate quality measures. This left 346 patients; 20 with known CR adenocarcinoma were sampled pre-operatively, the rest from endoscopy units pre-colonoscopy. All were nil by mouth having had bowel preparation. Colonoscopy results showed: 29 CR adenocarcinoma, 84 normal, 35 benign pathology, 31 IBD, 83, 20 and 57 with low, intermediate and high risk polyps, and 7 with polyposis syndromes. PTR data analysis so far indicates that there are discriminatory breath compounds between pathology groups, but analysis is ongoing to investigate potential confounders.

Conclusions: Further analysis of this preliminary dataset is expected to reveal compounds of interest for colorectal cancer diagnosis. The true diagnostic accuracy of breath testing is expected to be revealed once these compounds are tested on the larger population dataset for COBRA (recruitment ongoing since January 2018).

529P Survival of stage IV colorectal cancer: Interaction of cancer location, microsatellite instability and KRAS mutation

J. Uhlig[1], S. Stein[2], J. Lacy[3], C.S. Fuchs[3], H.S. Kim[1]

[1]Section of Interventional Radiology, Yale School of Medicine - Interventional Radiology Yale Cancer Center, New Haven, CT, USA, [2]Medical Oncology, Yale School of Medicine, New Haven, CT, USA, [3]Yale Cancer Center, Yale University, New Haven, CT, USA,

Background: The current literature on stage IV colorectal cancer (CRC) indicates a survival advantage for left-sided CRC. Still, the biological basis remains unclear. We assessed the interaction of cancer location with microsatellite instability (MSI) and KRAS mutation to elaborate how key molecular features modify the effect of cancer location on overall survival.

Methods: The 2010-2015 United States National Cancer Database was searched for stage IV colorectal adenocarcinomas. Overall survival (OS) was assessed via Cox models, implementing 2/3-way interaction terms.

Results: A total of 73,685 patients were included, of which n = 11,720/n=25,433 had data on microsatellite and KRAS status. Left-sided CRC was an independent predictor of improved OS (vs. right: HR = 0.75, $p < 0.001$). Rectal cancer had highest OS (2/5-year OS: 43%/10%) compared to cancers of the rectosigmoid junction (HR = 1.07), sigmoid (HR = 1.12), descending colon (HR = 1.19), transverse colon (HR = 1.41), ascending colon (HR = 1.45) or cecum/appendix (HR = 1.45, $p < 0.001$ respectively). Patients with stable microsatellites (MSS) had improved OS versus MSI (HR = 0.93, $p = 0.027$); KRAS wildtype showed superior OS over KRAS mutation (HR = 0.88, $p < 0.001$). CRC location interacted with microsatellite status and KRAS mutation: the prognostic impact of MSS was more pronounced in rectal cancers versus other locations (interaction $p < 0.001$); the prognostic impact of KRAS wildtype was larger in rectal cancers (interaction $p < 0.001$). In a 3-way interaction model, the largest prognostic impact of MSS and KRAS wildtype was noted for rectal cancer (interaction term $p < 0.05$). The table summarizes 2/4-year OS rates.

Table: 529P Adjusted 2-year and 4-year OS rates by cancer location and mutational status

Location / mutational status	Two year OS	Four year OS
rectal CRC, MSS, KRAS wildtype	68%	38%
rectal CRC, MSS, KRAS mutation	56%	29%
rectal CRC, MSI, KRAS wildtype	66%	39%
rectal CRC, MSI, KRAS mutation	43%	18%
other CRC, MSS, KRAS wildtype	60%	31%
other CRC, MSS, KRAS mutation	52%	24%
other CRC, MSI, KRAS wildtype	47%	25%
other CRC, MSI, KRAS mutation	48%	20%

Conclusions: Survival for stage IV CRC shows marked variation depending on location, MSI and KRAS mutation. The prognostic effects of molecular features varies by CRC location, demonstrating largest impact in rectal cancers.

530P Influence of primary tumour sidedness on survival after upfront primary tumour resection (PTR) in synchronous metastatic colon cancer (mCC)

K.L. van Rooijen[1], S.A. Kurk[1], D.E.W. van der Kruijssen[1], S. Elias[2], A.M. May[3], A. Cats[4], G-J.M. Creemers[5], F.L.G. Erdkamp[6], O.J. Loosveld[7], C.J. Rodenburg[8], P.J. Tanis[9], G.R. Vink[10], J.H.W. de Wilt[11], C.J.A. Punt[12], M. Koopman[1]

[1]Medical Oncology, University Hospital Utrecht, Utrecht, Netherlands, [2]Epidemiolgy, Julius Center of Health Academy, Utrecht, Netherlands, [3]Julius Center, University Hospital Utrecht, Utrecht, Netherlands, [4]GI Oncology, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, [5]Department of Medical Oncology, Catharina Hospital, Eindhoven, Netherlands, [6]Medical Oncology, Zuyderland Medical Center-Sittard-Geleen, Sittard, Netherlands, [7]Medical Oncology, Amphia Ziekenhuis-location Molengracht, Breda, Netherlands, [8]Medical Oncology, Meander Medical Center, Amersfoort, Netherlands, [9]Surgical Oncology, Academic Medical Center, Amsterdam, Netherlands, [10]General Oncology, Netherlands Comprehensive Cancer Organisation, Utrecht, Netherlands, [11]Surgical Oncology, University Medical Center St Radboud, Nijmegen, Netherlands, [12]Medical Oncology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands

Background: Retrospective data suggest a survival benefit for PTR in synchronous mCC, which is the topic of ongoing prospective trials. Whether outcome after PTR varies by primary tumour sidedness, an important prognostic factor in colorectal cancer (CRC), is currently unknown. We investigated the impact of upfront PTR followed by systemic treatment in synchronous mCC according to sidedness within two randomized phase 3 trials (CAIRO and CAIRO2).

Methods: A total of 408 synchronous mCC patients, with available data on both PTR status and sidedness, were included (CAIRO n = 279; CAIRO2 n = 129, excluding patients treated with both bevacizumab and cetuximab). We used mixed effect Cox regression models to study the association between PTR and overall survival (OS) and to estimate hazard ratios (HR). Models were adjusted for age, treatment arm, WHO performance status (PS), serum lactate dehydrogenase (LDH) and year of enrollment as potential confounders. To analyze whether PTR effect was modified by sidedness, we tested the interaction term of PTR status and sidedness.

Results: A total of 191 patients (46.8%) had right-sided mCC and 217 patients (53.2%) had left-sided mCC. The rate of PTR was comparable in right-sided (69.1%) and left-sided (65.0%) mCC. Patients who underwent PTR had better PS and LDH level compared to patients without PTR. Univariable and multivariable analyses demonstrated significant and comparable ($p_{interaction} > 0.05$) survival benefits after upfront PTR for both right-sided and left-sided mCC (Table).

Table: 530P

HR (95%CI) for OS after PTR versus no PTR

	Right-sided mCC (n = 191)	Left-sided mCC (n = 217)	pinteraction	Overall effect (n = 408)
Univariable	0.53 (0.38-0.73)	0.66 (0.49-0.87)	0.31	0.61 (0.50-0.76)
Multivariable	0.60 (0.42-0.84)	0.72 (0.53-0.96)	0.43	0.69 (0.55-0.87)

Conclusions: The previously reported better survival after PTR among synchronous mCRC patients included in the CAIRO and CAIRO2 trials was significant for all mCC patients in our analysis, independent of sidedness. Prospective randomized trials on the prognostic effect of PTR in synchronous mCC, i.e. the CAIRO4 trial, remain valid for mCC patients with both right- and left-sided primary tumours.

531P The clinical features and genomic landscape of elevated microsatellite alterations at selected tetranucleotide repeats (EMAST) in patients with colorectal cancer

M-H. Chen[1], S-C. Chang[2], P-C. Lin[3], S-H. Yang[4], C-C. Lin[4], Y-T. Lan[4], H-H. Lin[4], C-H. Lin[5], W-Y. Liang[6], W-S. Chen[4], J-K. Jiang[7], J-K. Lin[7]

[1]Department of Oncology, Taipei Veterans General Hospital, Taipei, Taiwan, [2]Department of Surgery, Faculty of Medicine, National Yang-Ming University, Taipei, Taiwan, [3]Department of Health and Welfare, University of Taipei, Taipei, Taiwan, [4]Surgery, Taipei Veterans General Hospital, Taipei, Taiwan, [5]Division of Genomic Medicine, National Health Research Institutes, Taipei, Taiwan, [6]Pathology, Taipei Veterans General Hospital, Taipei, Taiwan, [7]Taipei Veterans General Hospital, Department of Surgery, Taipei, Taiwan

Background: The form of microsatellite instability (MSI) affecting tetranucleotide repeats known as EMAST (elevated microsatellite alterations at selected tetranucleotide repeats) has emerged as a new potential biomarker in multiple cancers. In colorectal cancer (CRC), the clinical implications and mutation spectrum of EMAST mutations remain inconclusive.

Methods: We evaluated 1,505 CRC cases using five EMAST markers (D20S82, D20S85, D8S321, D9S242 and MYCL1) and the Bethesda panel of MSI markers. Most commonly mutations involved in CRCs were identified by MassArray Assay and DNA repair genes were analyzed by Next-Generation Sequencing (NGS). Clinical characteristics and prognostic relevance were correlated with EMAST. SPSS software (version 16.0) was used to perform all statistical analyses.

Results: Tumors with EMAST-positivity were detected in 159 (10.6%) out of 1,505 CRC cases and associated with unique clinical features including female predominance ($p = 0.017$), higher prevalence of proximal colon tumors ($p < 0.001$), early stage tumors ($p = 0.002$), poorly differentiated tumors ($p < 0.001$), mucinous histology ($p = 0.001$), and MSI ($p < 0.001$) and higher incidence of mutations in PI3KCA ($p = 0.003$), BRAF ($p < 0.001$), TGFßR ($p < 0.001$), PTEN ($p = 0.001$), and AKT1 ($p = 0.04$) compared with EMAST-negative tumors. Compared with EMAST-positive alone or MSI-H alone tumors, EMAST-positive MSI-H tumors had higher rates of MSH6, MSH3, PMS2, and EXO1 gene mutation ($p < 0.001$, $p = 0.005$, $p = 0.001$, and $p = 0.027$) and MLH1, MSH6, and EXO1 gene mutation ($p = 0.019$, $p = 0.005$, and $p = 0.046$), respectively. Finally, EMAST-positivity was a good prognostic indicator in early stage CRC ($p = 0.002$) but not in late CRC ($p = 0.920$).

Conclusions: The EMAST defines a unique molecular subtype of CRC.

532P Identification of positively and negatively selected driver gene mutations associated with colorectal cancer with microsatellite instability

V. Jonchere[1], L. Marisa[2], M. Greene[3], A. Guilloux[4], A. Collura[1], A. De Reynies[2], A. Duval[1]

[1]Centre De Rercherche (CdR) Saint-Antoine INSERM - UMR S 938, Hôpital Saint-Antoine, Paris, France, [2]Programme 'Cartes d'Identité des Tumeurs', Ligue Nationale Contre le Cancer, Paris, France, [3]UMRS 938, INSERM, Paris, France, [4]UMR 8071, Évry University, Évry, France

Background: Recent studies have shown that cancers arise due to the positive selection of driver somatic events in tumor DNA, with negative selection playing only a minor role. However, these investigations were concerned with alterations at non-repetitive sequences and did not take into account mutations in repetitive sequences that have very high pathophysiological relevance in the tumors displaying Microsatellite Instability (MSI) due to mismatch repair deficiency investigated in the present study.

Methods: We performed whole exome sequencing of 47 MSI CRC and confirmed results in an independent cohort of 53 MSI CRC. We used probabilistic model of mutational events within microsatellites, while adapting preexisting models to analyze non-repetitive DNA sequences. Negatively selected coding alterations in MSI CRC were investigated for their functional and clinical impact in CRC cell lines and in a third cohort of 164 MSI CRC patients.

Results: Both positive and negative selection of somatic mutations in DNA repeats was observed, leading us to identify the expected driver genes associated with the MSI-driven tumorigenic process. Several Coding negatively selected, MSI-related mutational events (n = 5) were demonstrated to have deleterious effects on tumor cells. In the tumors in which deleterious MSI mutations are observed despite the negative selection, they were associated with worse survival in MSI CRC patients (hazard ratio [HR], 3; 95% confidence interval, 1.1-7.9; $p = 0.03$), suggesting their anticancer impact should be offset by other as yet unknown oncogenic processes that contribute to poor prognosis.

Conclusions: The present results shed new light on the main driver somatic mutations acting in MSI-driven tumorigenesis, suggesting that genomic instability in MSI CRC plays a dual role in achieving tumor cell transformation.

533P Distinct clinico-pathological features of hypermutant colorectal cancers with POLE pathogenic mutations, Lynch syndrome and sporadic MSI analyzed over 1,000 colorectal cancer patients

T. Nagasaka[1], A. Nyuya[1], H. Tanioka[1], Y. Katata[1], M. Yokota[2], F. Taniguchi[3], T. Kawai[4], Y. Mori[4], K. Shigeyasu[4], M. Okawaki[1], M. Yamamura[1], Y. Umeda[4], A. Tsuruta[5], T. Ueno[5], Y. Yamaguchi[1]

[1]Medical Oncology, Kawasaki Medical School Hospital, Kurashiki, Japan, [2]General Surgery, Kurashiki Central Hospital, Kurashiki, Japan, [3]Surgery, Iwakuni Clinical Hospital, Iwakuni, Japan, [4]Gastroenterological Surgery, Okayama University Hospital, Okayama, Japan, [5]Digestive Surgery, Kawasaki Medical School Hospital, Kurashiki, Japan

Background: POLE proofreading mutations cause ultrahypermutant-phenotype in colorectal cancer (CRC) but the characters of POLE mutations are still obscure in contrast to Lynch syndrome or sporadic microsatellite instability (MSI). Herein, we examined mutation profiles of POLE in 1,039 CRC Japanese patients, and tried to clarify clinico-pathological features of hypermutant CRC patients with respect to POLE mutations, Lynch syndrome and sporadic MSI.

Methods: We analyzed POLE pathogenic hotspot (exon9, 13 and 14), BRAF codon 600 and KRAS exon 2 mutations by Sanger sequencing. MSI status was confirmed by a multiplex PCR assay. MSI positive cases were confirmed the four mismatch repair (MMR) proteins (MLH1, MSH2, PMS2, and MSH6) expression. Germline mutations were analyzed by Sanger sequencing and a TruSight One Sequencing Panel using a next generation sequencer.

Results: Of 1,039 CRC patients, only four cases showed POLE pathogenic mutations (two P286R, one V411L and one S459F). The four POLE-mutant CRCs showed no MSI. CRC with MMR deficient (=MSI) were observed in 58 cases (5.6%). Of CRCs with MSI, Lynch syndrome was found in 17 cases and the rest of 41 cases were sporadic MSI. Therefore, we divided 1,039 CRCs into the four subsets; POLE-mutant (POLE; n = 4, 0.4%), Lynch syndrome (LS; n = 17, 1.6%), sporadic MSI (MSI; n = 41, 4.0%), and non-hypermutant CRCs (NH; n = 997, 94.0%). Mean age at diagnosis in POLE/LS/MSI/NH was 52.5/55.7/73.6/65.9 years, respectively ($P < .0001$). Frequency of female in POLE/LS/MSI/NH was 50/23.5/61/41% ($P = 0.03$). The primary tumor located at the right colon was observed in 100/35/80.5/30% of POLE/LS/MSI/NH ($P < .0001$). BRAF mutation was observed in 49% of MSI and 4% of NH while KRAS mutation was in 35% of LS and 32% of NH ($P < .0001$). Interestingly, 100/82/78% of POLE/LS/MSI tumors were diagnosed at the earlier stage, I or II, while 46% of NH ($P < .0001$). The recurrence free survival rate at 5-years was better in POLE (100%)/LS (86%)/MSI (94%) compared with that in NH (74%).

Conclusions: POLE-mutant CRC was rare, observed in the younger without family history, located at the right colon, and diagnosed at the earlier stage.

534P Patterns of germline and somatic mutations in 16 mismatch repair associated genes analyzed with next generation sequencing (NGS) in colorectal cancer with EMAST (+) and/or MSI-high

S-C. Chang[1], P-C. Lin[2], C-C. Lin[1], J-K. Lin[3], Y-T. Lan[1], J-K. Jiang[3], S-H. Yang[1], C-H. Lin[4], W-S. Chen[1]

[1]Surgery, Taipei Veterans General Hospital, Taipei, Taiwan, [2]Department of Clinical Pathology, Taipei City Hospital, Taipei, Taiwan, [3]Taipei Veterans General Hospital, Department of Surgery, Taipei, Taiwan, [4]Division of Genomic Medicine, National Health Research Institutes, Taipei, Taiwan

Background: We assume that besides mismatch repair (MMR) genes, next generation sequencing (NGS) of MMR associated genes could improve detection of driver mutattors and clarify the somatic mutation patterns of subtypes CRC classfied by EMAST and MSI-high.

Methods: Extracted from a 1505 CRC cases database,81 cases with MSI-high and EMAST+,78 cases with EMAST+ and MSS, and 72 cases with MSI-high but EMAST- were identified. The tumor and WBC DNA were applied and got from Biobank of Taipei-Veteran General Hospital afer approval of IRB. The germline and somatic mutations were analyzied with 16- genes NGS (illumina HiSeq2500 system).

Results: Totally 284 pathological germline mutations were identified in 161 patients with MSI-high or EMAST+. The most common gene mutations were EPCAM (17.3%), MSH6 (16.9%), followed by MLH1 (15.2%), and AXIN2(15.2%). Majority of EMAST and MSI resulted from not only MMR dysfunction, but also germline mutations of AXIN2, POLD1 and TGFBR2. After deduction of 284 germline mutations, there were 1,090 somatic mutations in 161 cases with germline mutations, 445 mutations in 70 cases without germline mutations. Tumors with EMAST+ and MSI-high had signifcantly higher mutation number than those of tumors with only EMAST+ or only MSI-high. Besides germline mutations of AXIN2, germline mutations of other genes were similar. With AXIN2 germline mutations, somatic mutation rate was 187.7 ± 97.8 mut/MB significantly higher than those of without germline mutations (137.8± 84.5 mut/MB $p = 0.002$). Besides five major MMR genes, Eleven Axin2, eight POLE and six TGFbR2 germline mutations resulted in following MSI-high or EMAST (+) genotype without other accompany germline mutation. Clinically, patients with germline mutation had significantly higher frequency of proximal tumor location and early stage disease.

Conclusions: Our result showed that NGS could enhance detection of familial CRC. Somatic mutation burden might be through MSI or EMAST but not only germline mutation genes themselves. Several genes with germline mutations could explain origin of the familiar CRC. AXIN2 gene deserved to do futher experiment to confirm its role in WNT pathway and as a hypermutator.

535P Lower tumor mutational burden (TMB) and hepatic metastases may predict for lack of response to PD-1 blockade in MSI-H metastatic colorectal cancer (MCRC)

I. Amanam[1], J. Chao[1], D. Lim[1], S. Rahmanuddin[1], A.B. Schrock[2], S.M. Ali[2], C. Lau[1], D. Chevalier[1], E. Harris[1], J. Saluja[1], C. Wang[1], M. Fakih[1]

[1]Department of Medical Oncology and Therapeutics, City of Hope, Duarte, CA, USA, [2]Genetics, Foundation Medicine, Cambridge, MA, USA

Background: MCRC with microsatellite instability (MSI-H) are associated with cytotoxic lymphocytic infiltration that is counterbalanced by multiple checkpoints. Several prospective clinical trials in chemotherapy-resistant MSI-H MCRC have demonstrated a high rate of disease control and a favorable progression free survival (PFS) with PD-1 inhibitors. However, there is a significant discrepancy in response rates (RR) with pembrolizumab and nivolumab (28% to 52%), likely reflecting patient heterogeneity. We sought to determine the RR to PD-1/PD-L1 targeting in a single center setting.

Methods: All MCRC patients (pts) with MSI-H tumors (by CLIA certified PCR, IHC, or NGS assays) who were treated at City of Hope with PD-1 or PD-L1 inhibitors starting Jan 2016 were identified. RR and PFS were determined by RECIST 1.1. BRAF status, primary tumor location, and metastatic sites were collected on all pts. TMB as determined by FoundationOne® on 0.83-1.1 megabases (Mb) of sequenced DNA was collected, when available.

Results: 17 pts with MSI-H tumors were identified (16 treated with pembrolizumab and 1 with darvulumab). Pts characteristics were: males (10, 59%), age (median 53.7 years, range 33-78), BRAF mutant (6, 35%), right sided (11, 65%), and liver-sparing (8, 47%). 7 (41%) had an objective response, 2 (12%) had stable disease. The median PFS was 9.97 months (mo), and the 6 and 12 mo PFS rates were 53% and 35%, respectively. TMB was available for 9 MSI-H cases (range 8 – 73 mutations/Mb): 1 CR (TMB 73), 1 PR (TMB 71), and 1 SD (TMB 31), and 6 PD (TMB: 6, 13, 16, 18, 25, 36). We categorized our patients based on the lowest 10% (TMB < 23.5) and 25% (TMB < 33.06) TMB cut points identified from a large Foundation Medicine database of MSI-H MCRC. All 4/4 patients in the lowest TMB decile and 5/6 in the lowest TMB quartile experienced PD. On univariate analysis, only hepatic metastases ($p = 0.01$) and low TMB ($p = 0.02$) were associated with poor PFS.

Conclusions: A substantial percentage of pts with MSI-H tumors will progress with PD-1/PD-L1 inhibitors; these patients appear to be enriched for a low TMB status and hepatic metastases. Additional studies should explore TMB as a predictive marker of response to checkpoint inhibition in MSI-H CRC.

536P Comparison of microsatellite status detections in colorectal carcinoma

M. Chen, L. Yu, B. Liu, X. Qian, M. Yang

The Comprehensive Cancer Center of Drum Tower Hospital, Medical School of Nanjing University& Clinical Cancer Institute of Nanjing University, Nanjing, China

Background: There are two commonly accepted methods for detecting microsatellite status: the one is to detect amplified microsatellite loci by polymerase chain reaction (PCR), and the other is to detect mismatch repair gene (MMR) proteins expression by immunohistochemistry(IHC). The PCR detection is considered to have accuracy in clinic, while the IHC is widely used because of its easier operation and cheaper expense.

Methods: In order to compare IHC with PCR in detecting the microsatellite status in colorectal carcinoma, A total of 569 samples of colorectal carcinoma resection were collected in Department of Pathology, Nanjing Drum Tower Hospital between June 2014 and June 2017, all samples were used IHC and PCR to detect microsatellite status, the consistency of results between the two methods was compared.

Results: We found that 48 cases of microsatellite instability (MSI) were detected by PCR, including 37 cases of microsatellite instability high (MSI-H), 11 cases of microsatellite instability low (MSI-L) and 521 cases of MSS. MSI accounted for 8.44% of all cases, of which the MSI-H accounted for 6.50%.The IHC results of 569 patients showed that 69 cases were deficient mismatch repair (dMMR), 500 cases were proficient mismatch repair (pMMR), dMMR accounted for 12.13% of all cases. The loss expression of PMS2 protein was the most common while the MSH6 was rare. The coincidence rate of the two methods for detecting microsatellite states was 91.92%.

Conclusions: IHC and PCR method had high consistency in microsatellite status. Compared with PCR, IHC method is more economical, convenient for clinical operations. When the 4 repair proteins were without missing detected by IHC, it can be diagnosed as MSS / MSI-L, further PCR was not necessary, and when any repair protein is found to be deficient, PCR detection was needed to determine whether there existed MSI. Our conclusion will save a lot of time and cost for clinical work.

537P Assessment of local clinical practice for testing of mismatch repair deficiency in metastatic colorectal cancer: The need for new diagnostic guidelines prior to immunotherapy

R. Cohen[1], E. Hain[2], O. Buhard[2], A. Guilloux[3], A. Bardier[4], R. Kaci[5], P. Bertheau[6], F. Renaud[7], F. Bibeau[8], J-F. Fléjou[9], T. André[1], M. Svrcek[9], A. Duval[2]

[1]Medical Oncology, Sorbonne Université, AP-HP, Hôpital Saint-Antoine, Paris, France, [2]Centre de Recherche Saint-Antoine, Equipe Instabilité des Microsatellites et Cancer, Equipe Labellisée par la Ligue Nationale Contre le Cancer, Sorbonne Université, INSERM, Unité Mixte de Recherche Scientifique 938 and SIRIC CURAMUS, Paris, France, [3]UMR 8071, Évry University, Évry, France, [4]Pathology, AP-HP, Hôpital Pitié Salpétrière, Paris, France, [5]Pathology, AP-HP, Hôpital Lariboisière, Paris, France, [6]Pathology, AP-HP, Hôpital Saint-Louis, Paris, France, [7]Pathology, CHU Lille, Lille, France, [8]Service d'Anatomie Pathologique, CHU de Caen, Caen, France, [9]Pathology, Sorbonne Université, AP-HP, Hôpital Saint-Antoine, Paris, France

Background: Immune checkpoint inhibitors (ICKi) have been approved for patients with metastatic colorectal cancer (mCRC) displaying MSI/dMMR (microsatellite instability, defective mismatch repair). We aimed to evaluate the accuracy of standard immunohistochemistry and PCR methods for the detection of MSI/dMMR in mCRC in routine clinical practice.

Methods: The study was performed on a multicenter retrospective cohort of mCRCs previously determined as MSI and/or dMMR by local assessment and on a prospective, single center cohort of patients included in ICKi trials based on positive MSI and/or dMMR status previously determined by the originating institutes. We re-assessed dMMR and MSI status in our specialized diagnostic center using immunohistochemistry (antibodies directed against MLH1, MSH2, MSH6 and PMS2), and pentaplex PCR (BAT-25, BAT-26, NR-21, NR-24 and NR-27). The positive predictive value (PPV) of local assessment was the primary objective of the study. Detection rate (i.e. conclusive result) and sensitivity of immunohistochemistry and PCR by central review were evaluated.

Results: Nine false-positives (9.8%) were found in the retrospective cohort (N = 92). These were initially diagnosed as MSI and/or dMMR by the originating institute but were reclassified as MMR proficient /microsatellite stable in our laboratory (PPV=90.2%; 95%CI, 82.2-95.0). The PPV in the prospective cohort (N = 39) was 92.3% (95%CI, 79.0-98.1), with the 3 false-positive patients experiencing progressive disease with ICKi treatment. Amongst the 119 true-positive mCRCs, the detection rate and sensitivity were respectively 100% and 95.8% for immunohistochemistry, while for pentaplex PCR these were 81.5% and 95.9%. Only the combination of immunohistochemistry and pentaplex PCR methods resulted in 100% detection rate and 100% sensitivity.

Conclusions: Local assessment of MSI/dMMR status in mCRC resulted in misdiagnosis of 9.1% of cases as false positive and subsequently incorrect treatment with ICKi. We recommend new guidelines that mandate dual testing of mCRC samples in experienced diagnostic centers using both PCR and immunohistochemistry.

538P The prognostic role of PD L1 expression according to MSI status in stage III colon cancer after curative resection

S-H. Cho[1], H-J. Shim[1], J.E. Hwang[1], W-K. Bae[1], I.J. Chung[2]

[1]Hemato-Oncology, Chonnam National University Medical School & Chonnam National University Hwasun Hospital, Hwasun, Republic of Korea, [2]Hemato-Oncology, Chonnam National University Hwasun Hospital, Hwasun, Republic of Korea

Background: Tumors expressing programmed death ligand 1 (PD-L1) can render immune inactivated via triggering of PD-1 receptor on T cells with various pathways. Based on this mechanism, the blockade PD-1/PD-L1 pathway has been used as a therapeutic target for metastatic CRC. In the present study, we evaluated the prognostic role of PD-L1 expression associated with microsatellite status in surgically resected stage III colon cancer patients.

Methods: PD-L1 expression was performed by immunohistochemistry from 182 stage III colon cancer patients after curative resection. The percentage of PD-L1 positive tumor cells and staining intensity were evaluated and categorized as 'strong' or 'weak' positive group. Clinical and histopathologic parameters including of MSI status and survival outcomes were analyzed with IDO expression which stands for the suppressive immune environment.

Results: Strong PD-L1 expression was observed in 29% of all patients. Perineural invasion and lymphocyte response were more frequently shown in strong expression of PD-L1 grop. Among resected patients, MSI was shown in 23 patients (12%). Although there was no significant difference between microsatellite status and PD-L1 expression, strong PD-L1 tended to better overall survival in microsatellite stable (MSS) colon cancer ($P = 0.056$). In contrast, strong PD-L1 expression was significantly correlated with worse DFS ($P = 0.001$) and OS ($P < 0.001$) than weak PD-L1 expression group in microsatellite instability (MSI) patients, regardless of adjuvant chemotherapy. Also, the strong IDO expression was tended to be more frequently shown in strong PD-L1 expression (36.4%) group than weak PD-L1 expression (14.3%) group in MSI patients.

Conclusions: The expression of PD-L1 is differently affected on the survival outcomes according to the status of microsatellite. There is no significant relationship between the expression of PD-L1 and prognosis in MSS stage III colon cancer patients. However, in MSI colon cancer which has been well known as a highly immunogenic property, strong PD-L1 expression is significantly associated with poor prognosis on survival outcomes reflecting the immunosuppressive microenvironment in curative resected stage III colon cancer patient.

539P Pre-diagnostic anthropometry, sex, and risk of colorectal cancer according to tumor-infiltrating immune cell composition

J. Berntsson, J. Eberhard, B. Nodin, A.H. Larsson, K. Jirstrom

Department of Clinical Sciences, Division of Oncology and Pathology, Lund University, Lund, Sweden

Background: Obesity is a well-established risk factor for colorectal cancer (CRC), but whether this risk differs according to CRC subtype defined by the tumor immune microenvironment has been sparsely described. Herein, we examined the relationship between pre-diagnostic anthropometry and CRC risk according to tumor-infiltrating immune cell composition, with particular reference to potential sex differences.

Methods: The density of immune cells expressing PD1, PD-L1 (PD-L1/IC), CD3, CD8, FoxP3, CD20, CD68, CD163, and tumor cells expressing PD-L1 (PD-L1/TC) was assessed by immunohistochemistry in tissue microarrays with tumors from 584 incident CRC cases in the Malmö Diet and Cancer Study (n = 28098). Multivariable Cox regression models, adjusted for age, smoking and alcohol intake, were applied to calculate hazard ratios (HR) for CRC risk according to height, weight, bodyfat %, waist- and hip circumference, waist-hip ratio (WHR), body mass index (BMI), and different immune cell subsets.

Results: Obesity, measured as several anthropometric factors, was significantly associated with PD-L1$^+$/TC low, CD8$^+$ high, FoxP3$^+$ low, CD20$^+$ low, and CD163$^+$ low tumors in both sexes, and with PD1$^+$ low tumors in women. A contrasting risk between sexes was seen for PD-L1/IC$^+$ tumors, in that obesity was significantly associated with risk of PD-L1/IC$^+$ high tumors in women (p_{trend} for weight = 0.008, p_{trend} for BMI = 0.039), but with risk of PD-L1/IC$^+$ low tumors in men (p_{trend} for weight = 0.005, p_{trend} for bodyfat % = 0.003, p_{trend} for waist <0.001, p_{trend} for hip = 0.012, p_{trend} for BMI = 0.001, p_{trend} for WHR <0.001). Furthermore, obesity was associated with risk of any CD3$^+$ high or low and any CD68$^+$ high or low tumors in both sexes, and with any PD1$^+$ high or low tumors in men. In age and BMI-adjusted survival analysis, PD1$^+$, CD8$^+$, CD20$^+$, and CD68$^+$ high were favorable prognostic factors only in women, and FoxP3$^+$ high only in men. High PD-L1$^+$ and CD3$^+$ expression was prognostic in both sexes.

Conclusions: Anthropometric factors may influence the immune landscape of colorectal cancer, possibly in a sex-dependent manner. Thus, obesity and sex may be important factors to take into account when stratifying patients for immunotherapy.

540P Monocyte-to-lymphocyte ratio in metastatic colorectal cancer: Prognostic role evaluation and cut-off definition

D. Basile[1], S.K. Garattini[1], G. Pelizzari[1], F. Cortiula[1], L. Gerratana[1], M. Cattaneo[1], C. Corvaja[1], A. Parnofiello[1], V.J. Andreotti[1], E. Bertoli[1], C. Lisanti[1], D. Iacono[2], M. Casagrande[2], G.G. Cardellino[2], G. Miolo[3], N. Pella[2], G. Aprile[4], A. Buonadonna[3], G. Fasola[2], F. Puglisi[5]

[1]Department of Medicine (DAME), University of Udine, Udine, Italy, [2]Oncology, ASUIUD Azienda Ospedaliero-Universitaria di Udine, Udine, Italy, [3]Department of Medical Oncology and Cancer Prevention, CRO National Cancer Institute, Aviano, Italy, [4]Medical Oncology, ULSS 8 Berica, Vicenza, Italy, [5]University of Udine, Udine, Department of Medical Oncology and Cancer Prevention, CRO National Cancer Institute, Aviano, Italy

Background: Changes in peripheral blood cells composition may reflect tumor immune microenvironment and its role in cancer growth control. High monocyte-to-lymphocyte ratio (MLR) could be a sign of tumor's recruitment of suppressive cells, showing a prognostic role in many cancer types. This study aimed to evaluate the prognostic role of MLR in metastatic colorectal cancer (MCRC).

Methods: This retrospective study analyzed a consecutive cohort of 392 patients (pts) with MCRC treated in 2004-2017 at the Oncology Departments of Aviano and Udine (Italy). The prognostic impact of MLR on overall survival (OS) was evaluated with uni and multivariate Cox regression analyses. The best cut-off value to predict survival was defined through ROC analysis.

Results: Before first line therapy, 269 pts (69%) were aged <70, 120 pts (31%) had a right tumor, 150 pts (38%) a left tumor and 117 pts (30%) a rectal one. Of note, 105 pts (27%) received metastasectomy and 142 pts had >1 metastasis. Metastasis were more frequent in liver (40%), lung (20%) and peritoneum (20%) Overall, 57% had a KRAS mutation (m) and 11% had a BRAFm. At median follow-up of 60 months, median OS was 26 months. At univariate analysis, older age (HR 1.61, $p < 0.001$), nodes (pN2 HR 1.48, $p = 0.036$; pN3 HR 2.52, $p = 0.001$), KRASm (HR 1.36, $p = 0.020$) and MLR (HR 3.32, $p < 0.001$) were associated with worse OS. Conversely, sidedness (left HR 0.65, $p = 0.003$; rectum HR 0.73, $p = 0.042$), metastasectomy (HR 0.36, $p < 0.001$) and adjuvant chemotherapy (HR 0.66, $p = 0.008$) were associated with better OS. By multivariate analysis, sidedness and metastasectomy confirmed a better OS, while MLR (HR 3.20, $p < 0.001$), nodes (pN2 HR 1.89, $p = 0.006$; pN3 HR 2.25, $p = 0.014$), and KRASm (HR 1.50, $p < 0.001$) were associated with worse OS. The adoption of the cut-off value for MLR (i.e. 0.44) predicted worse OS both in univariate (HR 2.23, $p < 0.001$) and multivariate (HR 2.41; $p < 0.001$) analyses. Moreover, MLR was associated with number of metastatic sites ($p < 0.001$), type of sites ($p < 0.001$), sidedness ($p = 0.001$) and LDH level ($p < 0.001$).

Conclusions: High MLR is an independent prognostic factor associated with worse OS and pathological features of MCRC. Further studies are needed to confirm these data.

541P Clinical relevance of circulating tumor DNA using amplicon-based deep sequencing panel in colorectal cancer patients with liver metastasis

H. Osumi[1], E. Shinozaki[1], H. Zembutsu[2], Y. Takeda[3], T. Wakatsuki[1], T. Ichimura[1], Y. Ota[1], I. Nakayama[1], M. Ogura[1], M. Suenaga[1], D. Takahari[1], K. Chin[1], A. Saiura[3], S. Takahashi[4], T. Noda[2], K. Yamaguchi[1]

[1]Department of Gastroenterology, Cancer Institute Hospital of JFCR, Tokyo, Japan, [2]Cancer Precision Medicine Center, Cancer Institute, Japanese Foundation for Cancer Research, Tokyo, Japan, [3]Department of Surgery, Cancer Institute Hospital of JFCR, Tokyo, Japan, [4]Department of Medical Oncology, Cancer Institute Hospital of JFCR, Tokyo, Japan

Background: Liquid biopsy system using the detection of circulating tumor DNA (ctDNA) is expected to provide the utility as a novel diagnostic tool for cancers.

Methods: We prospectively enrolled a total of 101 metastatic colorectal cancer(mCRC) patients with liver metastasis. We investigated frequency of detectable mutations in cell-free DNA (cfDNA), concordance rate of RAS mutation between tissue and cfDNA, and relationship between the mutant allele frequencies (MAFs) and clinicopathological factors. We further investigated the relationship between time course of ctDNA and chemoresponse. Amplicon-based deep sequencing with molecular barcode (including hotspots of 14 genes) was performed to detect the ctDNA.

Results: Mutation(s) in plasma cfDNA were detected in 87.1% (88/101) of patients. The frequencies of plasma cfDNA mutation at TP53, KRAS, APC, and PIK3CA were 68.3%, 38.6%, 23.7%, and 14.8%, respectively. RAS mutational concordance rate between tissues and cfDNA was 76.2% (77/101). MAFs were significantly associated with CEA ($P < 0.0001$), CA19-9 ($P = 0.006$), LDH ($P < 0.0001$) levels and the number of metastatic organs ($P < 0.0001$). Patients with liver or lymph node metastasis had significantly higher MAF compared with those without metastases ($P < 0.0001$, $P = 0.008$, respectively). The patients with lower MAF at 8 weeks after initiation of chemotherapy showed significantly longer survival than those with higher MAF (>median vs $\leq$ median, PFS, $P = 0.001$, OS, $P = 0.049$). Increase of MAF had been observed earlier than tumor markers before disease progression were confirmed by computed tomography ($P = 0.01$).

Conclusions: Our results suggested that this cfDNA assay could detect mutations at a high rate of mCRC patients, and could be a useful tool for early detection of chemoresistance as well as a prognostic marker in the clinic.

Background: Circulating tumour DNA (ctDNA) provides a non-invasive approach for gene mutation detection. The aim of this study is to evaluate the concordance of RAS/BRAF mutational status in tumour tissue and plasma in metastatic colorectal cancer (mCRC) patients.

Methods: Plasma samples were collected prospectively from previously untreated mCRC patients (TASCO1 NCT02743221) and analysed centrally by droplet digital PCR (ddPCR) with sensitivity down to 0.2% for KRAS exon 2, 0.5% for NRAS exon 2 and BRAF. Tumour RAS/BRAF status was determined locally from primary or metastatic tumours according to routine practice.

Results: Out of the 153 patients included, 121 had tissue and plasma mutation status available for KRAS exon 2, 129 patients for NRAS exon 2 and 70 patients for BRAF V600E. In these subgroups, the prevalence of KRAS exon 2, NRAS exon 2 and BRAF mutations detected in plasma was 30.6%, 0.8% and 11.4%, respectively vs. 47.1%, 1.6% and 12.9%, respectively in tumours. For KRAS, the concordance was 81.8% with a Kappa coefficient of 0.63. KRAS mutation was detected in tumour tissue and not in plasma for 21 patients (17.4%), potentially explained by low tumour burden or low tumour DNA shedding. KRAS mutation was detected in plasma but not in tumour tissue for just one patient. For NRAS, a concordance of 99.2% (kappa = 0.66) was observed between plasma and tumour tissue. One discordant case (0.8%) was observed for which NRAS was detected only in tissue. This case also presented KRAS mutation both in plasma and tumour tissue excluding an explanation related to tumour DNA shedding. For BRAF, a concordance of 95.7% (kappa = 0.80) was observed between plasma and tumour tissue: BRAF mutation was detected only in plasma in one case (1.4%) and only in tumour tissue in 2 cases (2.9%). One of the two cases displaying BRAF V600E in tumour but not in plasma also had an NRAS mutation in plasma and unknown NRAS status in tumours.

Conclusions: This study showed that RAS/BRAF mutations can be detected in plasma samples from mCRC patients by ddPCR. However, in the context of the study, analysis of the ctDNA did not allow detection of RAS/BRAF mutations in all patients where these mutations were present in the tumour.

Background: We have conducted a phase II trial of 1st-line modified (m)-FOLFOXIRI plus bev for RAS mutant mCRC, which included a biomarker study using liquid biopsies [Oncotarget 2018]. There are few reports on monitoring changes in gene mutation (mt) status in mCRC harboring RAS mt. Therefore, the pre-planned analysis was performed to investigate a number of genes in ctDNA during therapy that might be determinants of therapeutic efficacy.

Methods: Sixty-two patients (pts) with unresectable/measurable tumors received protocol treatment with m-FOLFOXIRI (irinotecan 150 mg/m^2, oxaliplatin 85 mg/m^2, levofolinate [LV] 200 mg/m^2, and fluorouracil 2400 mg/m^2 repeated biweekly) plus bev. The phase II trial included objective response rate (ORR) for primary endpoint and progression-free survival (PFS), overall survival, early tumor shrinkage, depth of response (DpR), and safety for secondary endpoints. In 53 pts who enrolled in the biomarker study, plasma samples for extraction of ctDNA were collected at 3 points (pre-, 8wks, and progression) and analyzed for specific KRAS and NRAS variants with real-time PCR assays.

Results: Fifty-three pts had the following clinical data: median age of 61yrs, 57% male, 91% PS0, 28% right-sided tumors, ORR of 72%, median DpR of 49%, and median PFS of 10.8 months. RAS mt was detected in pre-treatment plasma in 79% (42/53) of pts. Among pts with mt in ctDNA at pre-treatment, 76% changed to mt-negative 8wks after treatment. ORR and DpR were higher in pts of mt-negative at 8wks compared to pts of mt-positive (81% vs. 50% and 55% vs. 34%, respectively). Median PFS was 11.9 and 8.8 months in pts who were mt-negative and mt-positive, respectively (HR 0.58, 95%CI 0.25-1.33, $P = 0.20$). Interestingly, in 26 pts who experienced progressive disease (PD)

and were evaluable for ctDNA analysis, 52% (11/21) of pts with mt at pre-treatment still had no mt in plasma at PD. Pts of mt-negative at PD had longer survival time from PD compared to pts of mt-positive (9.3 vs. 7.0 months).

Conclusions: Gene mt status in ctDNA during therapy may predict clinical outcome of triplet plus bev treatment in RAS mutant mCRC. Our study suggests that pts with no mt in plasma at PD may have more favorable post-treatment.

544P ctDNA assays identify alterations in RAS, EGFR, and cMET that are unique to RAS-WT patients progressing on anti-EGFR therapy

R. Gupta, D. Chevalier, J. Saluja, C. Lau, C. Wang, M. Fakih

Department of Medical Oncology and Therapeutics, City of Hope, Duarte, CA, USA

Background: Circulating tumor DNA (ctDNA) assays and tumor sequencing provide insight to tumor heterogeneity and mechanism of resistance in patients with MCRC. Direct comparisons between Guardant360® (G360) ctDNA panel and the comprehensive Foundation One® NGS (FO) panel in MCRC patients (pts) are limited.

Methods: We identified MCRC pts with FO at diagnosis and subsequent G360 ctDNA assays. Pts were divided into 3 categories based on ctDNA collection date: 1) ctDNA testing prior to any treatment, 2) ctDNA following non-anti-EGFR therapy and 3) ctDNA following anti-EGFR progression (PD). We compared genomic alterations by FO and G360 within the same pts to characterize clonal evolution and its impact on outcome.

Results: 43 pts with MCRC with FO had at least one ctDNA assay. High concordance between ctDNA and FO was noted in untreated pts ($n = 11$) for common oncogenic drivers, including RAS and BRAF. In 2/11 cases, 2 RAS mutations were identified on G360 only: NRAS E31D (unknown significance), and a low frequency G12D (0.3%) which may have been below the reporting limits for FO. Concordance was also noted in pts pre-treated with non-anti-EGFR therapy ($n = 11$). In contrast, ctDNA assays of RAS-wild type pts with PD following anti-EGFR ($n = 19$) showed a high rate of emergent activating KRAS [Q61H (3/19 cfDNA 0.08% -9.8%) and L19F (1/19 cfDNA 1.1%)], EGFR V441G (3/19 cfDNA 0.4%-7.9%), and FGFR2 mutations (2/19 cfDNA 1.8%-2.1%), suggesting that these are common mechanisms of resistance[VR1] . 1 pt had emergence of EGFR V441G mutation without any KRAS or NRAS mutations. Only 3 pts had serial ctDNA assays. 1 pt with BRAF V600E mutation developed cMET amplification after progressing following 6 months of response on BRAF + MEK + EGFR inhibitors. Upon withdrawal of targeted therapy, his cMET amplification resolved and he responded again to BRAF + EGFR inhibitors (5 months and ongoing), confirming clonal evolution in response to BRAF inhibitors and their withdrawal.

Conclusions: In untreated and progressing anti-EGFR naïve pts, ctDNA provides an accurate assessment of oncogenic RAS and BRAF status. Clonal evolution is captured on ctDNA in response to anti-EGFR therapy and extends beyond emerging RAS mutations to EGFR mutations and cMET amplification.

Background: To evaluate RAS and BRAF mutation testing in circulating tumor (ct) DNA for prediction of chemotherapy plus anti-EGFR benefit and acquisition of resistance in metastatic colorectal cancer (mCRC) patients (pts).

Methods: RAS and BRAF mutational status, were assessed by Idylla™ system (Biocartis) ctDNA methodology in a baseline plasma sample and a serum sample collected at the time of the last available determination from KRAS exon 2 wild-type (WT) mCRC patients treated with first-line antiEGFR therapy within two first-line prospective biomarker-designed clinical trials (PULSE; NCT01288339 and POSIBA; NCT01276379).

Results: Analysis of extended RAS and BRAF in tissue and plasma from 178 KRAS exon 2 wild-type mCRC pts showed a sensitivity of 59% and a specificity of 90%. Patients with baseline RAS and BRAF ($n = 36$) mutant ctDNA had a median Progression Free Survival (mPFS) of 8.2 months (CI 95% 6.3-10 months) and 6.7 months (CI 95% 4.3-9.1 months) respectively, whereas double wild-type (2WT) pts had a mPFS of 13.6 months (CI 95% 11.7-15.4 months; $p < 0.0001$). Analogously the median overall survival (mOS) of baseline RAS and BRAF ctDNA mutant pts was 22.3 months (CI 95% 15.6-29 months) and 8.9 months (CI 95% 6.3-11.4 months) respectively, which were significantly inferior to the mOS of 40.4 months (CI 95% 35.9-44.9 months) in 2WT pts ($p < 0.0001$). Acquisition of RAS/BRAF mutations was 9/63 (14%) in pts with progressive disease (PD) (i.e, blood draw within 1 month before PD or after PD) (median 24.8 days (-29 to 484 days)) compared to 6/73 (8%) in pts with no PD or blood extraction for ctDNA analysis before 1 month of PD (median -265.6 days (-31 to -1126 days) ($p = 0.47$). Median OS in patients with RAS/BRAF acquisition was 23.9 months (CI 95% 19.7-27.9 months) compared to 40.6 months (CI 95% NR-NR months) in pts who remained free of mutations ($p = 0.016$).

Conclusions: Our results confirm that baseline RAS and BRAF testing in ctDNA discriminates PFS and OS. The emergence of RAS/BRAF mutations has limited impact on the time to progression to antiEGFR therapy and confers poor prognosis.

Background: Tumour-tissue biopsy testing is the standard of care (SOC) to assess RAS mutation in mCRC pts. However, the analysis of circulating cell-free DNA (cfDNA) has the added advantage of being able to evidence genetic tumour heterogeneity. We explored the correlation of the RAS mutational status assessed in plasma samples with first-line (1L) treatment outcomes in SOC RAS wild type (wt) mCRC pts.

Methods: Prospective, observational, multi-centre study in mCRC pts with RASwt according to tumour-tissue biopsy and treated following standard clinical practice. Plasma samples were collected before starting 1L treatment and sent to Sysmex Inostics GmbH for BEAMing analysis. The lower threshold limit was a mutant allele fraction (MAF) $\geq$ 0.02%. Tumour response (TR) was evaluated approximately every 3 months based on RECIST criteria.

Results: 119 pts were included (61% male; median age: 65 y). 113 received chemotherapy (CT) + anti-EGFR, 4 CT + anti-VEGF and 2 CT alone. Overall response rate (ORR) was 68.1% (95%CI: 58.9-76.3) for all pts and 75% (95%CI: 65.8-82.8) in the108 pts with TR data. In pts treated with panitumumab (n = 92), the most homogeneous group, 76.1% (n = 70) presented left-sided tumours and 19.6% (n = 18) right-sided; overall ORR was 78.3% (95%CI: 68.4-86.2); 81.4% (95%CI: 70.3-89.7) for left and 72.2% (95%CI: 46.5-90.3) for right-sided pts. ORR in the panitumumab subgroup according to RAS mutational status analysed in cfDNA for the three MAF (cut-offs) considered is presented in the table.

Table: 546P

	ORR (not confirmed) % (95% CI)	ORR (not confirmed) % (95% CI)	Odds Ratio (95% CI); P-value*
Mutant allele fraction, cut-off (n)	RASwt	RASmt	
≥1% (90 wt/2 mt)	78.9 (69.0 – 86.8)	50.0 (1.3 - 98.7)	3.7 (0.2 – 62.6) 0.389
≥0.1% (87 wt/5 mt)	79.3 (69.3 – 87.3)	60.0 (14.7 - 94.7)	2.6 (0.4 – 16.5) 0.297
≥0.02% (80 wt/12 mt)	80.0 (69.6- 88.1)	66.7 (34.9-90.1)	2.0 (0.5 – 7.5) 0.285

*Fisher Test; CI=confidence interval; ORR: Overall Response Rate.

Conclusions: A high ORR was observed in pts treated with panitumumab independently of the localization. ORR in panitumumab treated patients tends to be higher in plasma RASwt. ORR in pts with plasma RASmt increases when a lower MAF cut-off is used. Further investigation is needed to find the optimal clinical cut-off. Study supported by Amgen.

547P Serial monitoring of circulating tumor DNA in patients with metastatic colorectal cancer to predict the therapeutic response

J. Zhou[1], C. Bai[2], Z. Sun[2], Y. Cheng[2], N. JIA[3], Y. Zhou[2]

[1]Department of Medical Oncology, PUMCH, Beijing, China, [2]Medical Oncology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China, [3]Medical Oncology, PUMCH, Beijing, China

Background: Early biomarkers of therapeutic responses could help optimize the treatment of metastatic colorectal cancer (mCRC). This prospective exploratory study was designed to explore the serial changes in plasma-circulating tumor DNA (ctDNA) as an early marker of therapeutic response to systemic treatment in mCRC.

Methods: Forty-seven mCRC patients receiving standard first-line therapy every two weeks were enrolled. Somatic mutations in plasma ctDNA were detected serially before each of the first four cycles via next-generation sequencing, and the mutation of maximal frequency in pretreatment ctDNA was selected as the candidate mutation for analysis. Radiologic responses were assessed after the fourth cycle.

Results: The results indicated that mutations in pretreatment ctDNA could be detected in 45 (95.7%) patients. Among the 41 patients monitored serially, imaging after four cycles of treatment showed 17 PR, 18 SD, and 6 PD cases. Changes in ctDNA could differentiate patients with progressive disease two cycles (approximately four weeks) earlier than the changes in CEA and CA19-9 levels could, and changes in ctDNA levels as early as prior to cycle 2 predicted the radiologic responses after cycle 4. A log2 value of fold-change in ctDNA after cycle 1 (log2 (C1/C0)) > -0.832 predicted progressive disease, with a sensitivity and specificity of 100.0% (95%CI: 54.1-100.0%) cand 85.7% (95%CI: 69.7-95.2%), respectively, and an accuracy of 87.8% (95%CI: 73.8-95.9%). Patients with ctDNA log2 (C1/C0) > -0.832 showed significantly worse progression-free survival than did those with log2 (C1/C0) $\leq$ -0.832 (median 2.5 versus 9.0 months; P = 0.016).

Conclusions: The present exploratory study suggests that early changes in ctDNA that are detected via targeted sequencing might potentially predict later radiologic responses in mCRC.

548P Cross-platform comparison of NGS and MALDI-TOF for detecting RAS/RAF/PIK3CA mutations in circulating tumor DNA from metastatic colorectal cancer patient plasma

L. Liang[1], B-L. Wang[2], Q. Yu[2], T-S. Liu[1], W. Guo[2]

[1]Medical Oncology, Zhongshan Hospital, Fudan University, Shanghai, China, [2]Laboratory Medicine, Zhongshan Hospital, Fudan University, Shanghai, China

Background: Evaluating tumor RAS/RAF status is essential for treatment selection and prognosis evaluation in metastatic colorectal cancer (mCRC) patients. Analyzing ctDNA in mCRC patients has many advantages because of its non-invasive nature. However, since the signal of ctDNA is generally low, detection of ctDNA from different platforms need to be carefully interpreted before adapting new technology into routine clinical application.

Methods: 60 mCRC patients under different treatment status were recruited. A cross-platform comparison between MALDI-TOF (UltraSEEK) and next-generation sequencing (NGS) was done by examining KRAS/NRAS/BRAF/PIK3CA mutations frequency in plasma from patients. Inconsistent results between two platforms were examined by droplet digital polymerase chain reaction (ddPCR). All results were compared to the mutation status in tissue retrospectively.

Results: In the comparison between NGS and MALDI-TOF, we focused on 65 hotspots, 53.57% and 60.71% of the samples were reported to be positive by NGS and MALDI-TOF respectively. Concordance rate between two platforms was 73.21%. Discrepancy between two platforms was examined by ddPCR, and a reproducible result was then treated as a true positive. The PPA of NGS and MALDI-TOF was 93.94%, 90.91 %; NPA of NGS and MALDI-TOF was 99.97%, 99.63 %, respectively. After establishing a ground truth for plasma result, 56 patients were found to have comparable ARMS result from tissue. Apart from 10 patients undertaking chemotherapy or Cetuximab, 95.6% (44/46) patients have their plasma result consistent with that from tissue. For 10 patients undergoing treatment at the time of plasma acquisition, ctDNA status detected by NGS was showed to be an effective biomarker to monitor the response to treatment: 90% (9/10) of patients had a ctDNA status that were consistent with their progression status.

Conclusions: ctDNA detected by NGS was showed to be a reliable signal that reflects tumor burden and informs treatment response. Even challenge exists in detecting variants in low frequency in plasma, appropriate selection of technology allows reliable examination of clinical utility in upcoming clinical studies.

549P Second line EGFR-inhibitors in RAS mutant metastatic colorectal cancer: The plasma RAS wild type "window of opportunity"

P. Gazzaniga[1], C. Raimondi[2], F. Urbano[3], E. Cortesi[3]

[1]Molecular Medicine, Sapienza University of Rome, Rome, Italy, [2]Radiology, Oncology and Pathology, Sapienza Univeristy of Rome, Rome, Italy, [3]Radiology, Oncology and Pathology, Policlinico Umberto I, Rome, Italy

Background: RAS mutations are found in 30-50% of metastatic colorectal cancer (mCRC) and determine the ineligibility for EGFR-targeted therapies. Recent studies have demonstrated that the analysis of circulating tumor DNA (ctDNA) is a surrogate of tumor biopsy for mutations detection. To date, studies have been focused on the appearance of RAS-mutant clones in patients with RAS-wild type mCRC, as biomarkers of anti-EGFR therapy resistance. We here describe a population of RAS mutant

mCRC who converted to wt -RAS status in blood over the course of first-line treatments. As proof of concept, the absence of any clinically relevant mutation of RAS genes in blood has been used as a therapeutically exploitable window. To this purpose five patients received second-line treatment with anti-EGFR, achieving a durable clinical benefit.

Methods: Blood samples from 20 patients with mutant RAS status were prospectively collected before initiating first- line therapies. RAS mutational status was assessed on tumor tissue and plasma samples at baseline. In all cases with plasma-tissue concordance at baseline (n. 15), RAS mutations were serially monitored every 3 months. Idylla™(Biocartis) was used to investigate RAS mutational profile from plasma. Specifically, Idylla™ ctKRAS Mutation Assay and Idylla™ ctNRAS/BRAF/EGFR Mutation Assay were used.

Results: 15 mCRC patients harboring any RAS mutation in tumor tissue and plasma at the time of diagnosis were serially monitored through plasma ctDNA analysis. Eleven patients (73%) switched to a wild- type RAS status in blood during the course of first line treatments. At disease progression in the first-line setting, 5 of them have received EGFR inhibitors as a second-line treatment, achieving a durable clinical benefit.

Conclusions: ctDNA analysis might reveal a therapeutically exploitable window of opportunity, characterized by the prevalence of wt -RAS clones, which can be converted in a clinically meaningful benefit for patients. Our planned KAIROS trial might determine whether the response to EGFR inhibition, in patients with RAS mutant cancers converted to RAS wild-type in course of treatments, might become the rule rather than the exception.

550P Evaluation of the sensitivity of RAS mutation detection of the Idylla platform in comparison to the OncoBEAM RAS CRC assay

A. Vivancos[1], E. Aranda Aguilar[2], M. Benavides[3], E. Elez Fernandez[4], M. Toledano[2], M. Alvarez[5], E. Diaz Rubio[6], A. Gómez-España[2], V. Garcia-Barberan[6], M.R. Chica-Parrao[7]

[1]Genomics, Vall d'Hebron University Hospital, Barcelona, Spain, [2]Oncology, University Hospital Reina Sofia, Cordoba, Spain, [3]Oncology, Hospital Regional Universitario Carlos Haya, Malaga, Spain, [4]Oncology, Vall d'Hebron University Hospital, Barcelona, Spain, [5]Pathology, Hospital Regional Universitario Carlos Haya, Malaga, Spain, [6]Oncology, Hospital Clinico Universitario San Carlos, Madrid, Spain, [7]Oncology, Hospital Universitario Virgen de la Victoria, Malaga, Spain

Background: Accurate detection of RAS mutations in metastatic colorectal cancer (mCRC) patients is of high clinical importance for therapy selection as RAS detection methods lacking sensitivity may lead to poor patient outcomes. Liquid biopsy has emerged as a viable alternative to individualize the management and treatment of mCRC patients. The objective of this study was to provide a head-to-head comparison of the sensitivity of two tests for KRAS mutation detection in plasma from mCRC patients: dPCR-based OncoBEAM and qPCR Idylla.

Methods: Plasma samples from mCRC patients determined to be KRAS-positive using OncoBEAM were re-tested using Idylla. 116 samples with mutant allelic fractions (MAF) below 5% were selected for analysis. The positive percent agreement (PPA) of KRAS mutation results was compared for replicate samples analyzed by OncoBEAM and Idylla.

Results: Idylla detected KRAS mutations in 81 out of 116 (69.8%, $p < 0.0001$) OncoBEAM KRAS-positive plasma samples. Categorization of results based on MAF% revealed distinct differences in sensitivity between the two technologies.

Table: 550P

MAF% Range	PPA Idylla vs OncoBEAM
1-5%	89.1% (33/37) ($p = 0.1336$)
0.1-1%	65.1% (41/63) ($p < 0.0001$)
0.02%-0.1%	43.8% (7/16) ($p = 0.0077$)

Significant differences have been observed in patients with liver and other metastases, except lung, 41/51 (80.4%, $p = 0.0044$) and patients with lung and other metastases, except liver, 16/24 (66.7%, $p = 0.0133$).

Conclusions: OncoBEAM demonstrated significantly greater sensitivity for plasma detection of RAS mutations than Idylla. Moreover, these data identify a "gray zone" below 1% MAF where Idylla fails to identify RAS-positivity in patient plasma samples. These findings show that liquid biopsy assays with diminished sensitivity may lack the dynamic range to provide accurate and timely RAS mutational status information to properly guide highly individualized anti-EGFR therapy and chemotherapy treatment decisions that may benefit patient outcomes.

551P Non-invasive genotyping and monitoring of tumor evolution in locally advanced rectal cancer (LARC) patients using circulating tumor DNA (ctDNA)

S. Toomey[1], A. Sartori[2], D. Irwin[3], S. Hummel[4], A. Carr[1], C.L. Lee[5], P. Armstrong[1], A. Farrelly[6], S. El-Masry[7], D. McNamara[8], P.G. Morris[9], L. Grogan[9], O.S. Breathnach[9], L. O'Sullivan[10], S. Bradshaw[11], A.N.A.M. Rashed[12], R. Smyth[1], J. Workman[1], B. O'Neill[13], B. Hennessy[9]

[1]Molecular Medicine, Royal College of Surgeons in Ireland, Dublin, Ireland, [2]Scientific Affairs, Agena Biosciences, Hamburg, Germany, [3]Agena Bioscience, Brisbane, Australia, [4]Agena Bioscience, San Diego, CA, USA, [5]Medical Oncology, St Vincents University Hospital, Dublin, Ireland, [6]Oncology Molecular Medicine, Royal College of Surgeons in Ireland, Beaumont Hospital, Dublin, Ireland, [7]Surgery, Our Lady of Lourdes Hospital, Drogheda, Ireland, [8]Surgery, Beaumont Hospital, Dublin, Ireland, [9]Medical Oncology, Beaumont Hospital, Dublin, Ireland, [10]Cancer Trials Ireland, Dublin, Ireland, [11]Radiation Oncology, St Luke's Radiation Oncology Network, Dublin, Ireland, [12]Oncology, Our Lady of Lourdes Hospital, Drogheda, Co. Louth, Ireland, [13]Radiation Oncology, St. Luke's Radiation Oncology Network, Dublin, Ireland

Background: There is limited information on the feasibility and clinical potential of ctDNA analysis in non-metastatic rectal cancer. We assessed whether detection and analysis of plasma ctDNA could help monitor tumor evolution during neoadjuvant chemoradiotherapy (NACRT) treatment for LARC.

Methods: 27 LARC patients who were enrolled on the CTRIAL-IE (ICORG) 12-38 TRI-LARC clinical trial (NCT02151019) and received NACRT prior to surgery, had samples for ctDNA analysis taken at baseline pre-NACRT, during week 3 of radiotherapy (RT), during the final week of RT, prior to surgery, and 3-12 months post-surgery. DNA from baseline biopsy samples was genotyped for 86 hotspot mutations in BRAF, EGFR, KRAS, NRAS and PIK3CA using the iPLEX™ HS Colon Panel on the MassARRAY® System (Agena Bioscience). The UltraSEEK™ Colon Panel (Agena Bioscience) was used to track 107 hotspot mutations in serial ctDNA samples.

Results: At least one mutation was identified in 67% (18/27) of baseline biopsy samples. 15 patients (56%) had a KRAS mutation. Identical mutations were found in baseline ctDNA of 11/15 patients (73%). The median KRAS mutant allele frequency (MAF) in baseline ctDNA samples was 0.9% (range 0.1-2%). This significantly decreased over treatment (0.15% week 3 RT, 0.35% final week RT, 0.1% prior to surgery) ($p < 0.05$). 10 patients had a KRAS mutation in their baseline ctDNA that was not detected in their biopsy, with a median MAF of 0.3% (range 0.1-1.3%). Mutations in NRAS and PIK3CA were identified in 3/27 (11%) and 2/27 (7%) of patients, respectively. NRAS and PIK3CA mutations were identified in the ctDNA of 2/3 (67%) and 1/2 (50%) patients. Post-operative ctDNA samples were available for 13 patients and residual mutations were detected in 10 patients (77%), 3 of whom (30%) had recurrence at median follow up of 20.1 months. There was no recurrence in any patient with negative ctDNA post-surgery.

Conclusions: ctDNA can identify clinically relevant biomarkers and could be used as a minimally invasive alternative to repeated tumor biopsies to monitor tumor evolution. ctDNA detection after resection may provide evidence of residual disease and could identify patients at high risk of recurrence.

Clinical trial identification: NCT02151019.

552P Circulating tumor DNA by next generation sequencing as a prognostic and predictive biomarker in metastatic colorectal cancer

N. Jia[1], L. Chang[2], X. Dou[1], M. Guan[1], Y. Shao[1], N. Li[1], Y. Cheng[1], H. Ying[1], Z. Sun[1], Y. Zhou[1], L. Zhao[1], J. Zhou[1], C. Bai[1]

[1]Medical Oncology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China, [2]Medical Science, Geneplus-Beijing, Beijing, China

Background: Biomarkers of prognosis and efficacy in patients with metastatic colorectal cancer (mCRC) are crucial for optimizing therapeutic strategies. The aim of our study was to explore the applicability of circulating tumor DNA (ctDNA) as a prognostic and predictive marker in mCRC.

Methods: Sequential Patients with mCRC were included. Both plasma ctDNA and serum CEA were assessed in samples obtained before treatment and after 4 cycles of chemotherapy (C4). Target-capture deep sequencing with a panel covering 1021 genes was performed to detected somatic mutations in ctDNA. Clonal population structures were identified based on variations from ctDNA using Bayesian cluster with Pyclone. Molecular tumor burden index (mTBI) was calculated with the mean variant allele frequency of mutations in trunk clonal population. Cox regression analysis, Spearman's

rank correlation, Receiver operating characteristic (ROC) curves and Kaplan-Meier plots were used for statistical analyses.

Results: A total of 20 patients were prospectively included and treated with FOLFOX (15/20) or FOLFIRI (5/20) from Sep 2015 to Aug 2016. Median follow-up was 6.9 months (range 1.6-26.6). Somatic mutations for baseline ctDNA analysis were identified in 17/20 (85%) of the patients. In a multivariable analysis, a high baseline mTBI was associated with the risk of disease progression (HR, 1.091; 95% CI, 1.032–1.153; P = 0.002). The optimal baseline mTBI for predicting progression-free survival (PFS), as determined by the ROC curves (ROC area = 0.83, P = 0.0126), was 6.81%. Patients with baseline mTBI below 6.81% had longer PFS compared to those above (median 9.9 versus 4.35 months; HR, 2.966; 95% CI: 1.075-8.184; P = 0.0115). Fold reductions of mTBI from baseline to post-C4 were obtained in 16/20 (80%) of the patients. In a bivariate correlations analysis, fold reduction of mTBI was related to tumor response (r = -0.661, P = 0.005). In contrast, serum CEA level and its variation did not correlate with PFS and tumor response, respectively.

Conclusions: High baseline mTBI and inferior PFS were correlated in mCRC, so were fold reduction of mTBI and tumor response. Therefore, ctDNA could be potentially a biomarker for prognosis and efficacy.

553P Dynamic monitoring of KRAS, NRAS, BRAF and PIK3CA mutations in circulating cell-free DNA for metastatic colorectal cancer patients treated with cetuximab

L.L. Liu, Z. Tong, C. Yan, H. Zhang, W. Jiang, Y. Zheng, P. Zhao, W. Fang

Medical Oncology, First Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou, China

Background: Genomic heterogeneity affects response to targeted agents. Liquid biopsy is a promising approach to detect genetic mutations in circulating cellfree DNA (cfDNA) and allows the tracking of treatment-induced genetic evolution in metastatic colorectal cancer (mCRC) patients.

Methods: Longitudinal plasma samples (n = 92) were collected from 15 mCRC patients receiving cetuximab contained regimen therapy. KRAS, NRAS, BRAF and PIK3CA mutational status relevant to cetuximab resistance were monitored by next-generation sequencing in plasma, which could be reflected by variant allele frequency (VAF). We also included 11 healthy controls to differentiate total cfDNA levels from mCRC patients.

Results: Of these 15 mCRC patients, baseline plasmas were collected in 8 patients. The average cfDNA level in treatment naive patients was significantly higher than healthy cohort (p = 0.0004). Moreover, cfDNA levels correlate with the tumor burden before systemic therapy (R^2=0.544). Dynamics of KRAS/NRAS/BRAF/PIK3CA VAF mirrored disease evolution, showing the same trend with partial response, disease progression and relapse. In addition, KRAS/NRAS/BRAF/PIK3CA VAF gradually declined upon cetuximab withdrawal for more than 2 months, and partial response was again achieved when cetuximab was re-used on 1 patient. This provided a molecular explanation for the efficacy of rechallenge therapies based on EGFR blockade.

Conclusions: Dynamic monitoring of KRAS/NRAS/BRAF/PIK3CA mutations in cfDNA is feasible and appears to be useful in early detection of drug resistance to cetuximab in mCRC patients.

554P KRAS-dependent and independent mechanisms of progressive disease (PD) in colorectal cancer (CRC) patients (pts) with liver metastases (LM) while monitoring on circulating cell free DNA (cfDNA)

A. Kirov[1], Z. Mihaylova[2], V. Petrova[2], T. Todorov[3], D. Petkova[2], A. Garev[2], A. Todorova-Georgieva[4]

[1]Human Genetics, Independent Medico-Diagnostic Laboratory Genome Centre Bulgaria, Sofia, Bulgaria, [2]Department of Medical Oncology, Military Medical Academy, Sofia, Bulgaria, [3]Human Genetics, Genetic Medico-Diagnostic Laboratory Genica, Sofia, Bulgaria, [4]Medical Chemistry and Biochemistry, Medical University Sofia, Sofia, Bulgaria

Background: KRAS mutational analysis (MA) in plasma (P) cfDNA is an alternative to tissue (T) analysis with concordance rate (ConR) from 30 to 90%. The emergence of KRAS mutation (M) during the course of anti-EGFR therapy is responsible for acquired resistance (AR). We aimed to evaluate the RAS ConR between T and cfDNA in mCRC pts, and to monitor changes in RAS M status.

Methods: All blood samples were collected in cfDNA Preservative Tubes (Norgen Biotek Corp., Canada). ctDNA was extracted within 3 days after sampling, the extraction was performed by commercial kit (P/Serum cfDNA Purification Mini Kit, Norgen Biotek). KRAS (ex 2) M on P cfDNA and tumor T were detected by real-time PCR kits TheraScreen: K-RAS Mutation Kit. The other M were detected by Sanger sequencing (BigDye Terminator v3.1 Cycle Sequencing Kit - Thermo Fisher Scientific).

Results: In the ConR evaluation were enrolled prospectively 63 mCRC pts. Only LM had 52,4% (33) pts, from whom - 27,3% (9) pts had primary resectable LM. The median time from T biopsy (primary -97%) to P collection was 275, 7 days (range 26 - 1560). TMA revealed 58,7% (37) M pts from whom 78,4% (29) pts had KRAS ex.2 M. cfDNA evaluation showed the distribution of M to wild (W) - 81%/19% with KRAS ConR of 58,7%. To reduce time between T and P samples MA in the monitoring analysis were included only 31 pts who had primary unresectable LM, with baseline (b) P collection. In 5 pts with KRAS M after converting treatment, LM resection resulted in W type on consecutive cfDNAs. In responding pts (10) with W disease on bcfDNA, there was no change in MA consequently. In non-responders with W type the appearance of KRAS M was noted in 6 pts, while in the rest 3 pts PD was not correlated to KRAS M. In non-responders with KRAS M on bcfDNA (6 pts), monitoring of cfDNA revealed disappearance of KRAS M contemporary with mainly LM PD.

Conclusions: The estimated ConR between primary tumor and cfDNA KRAS MA was 58%. The emergence of KRAS M in W type pts reveled AR to anti-EGFR therapy. In pts with M KRAS on bcfDNA, liver resection in responders and LM PD in non-responders correlated with loss of KRAS M as a mechanism of AR to anti-angiogenesis treatment in the later.

555P Correlation between ctDNA methylation and CEA in colorectal cancer

W-W. Tang[1,2], H-X. An[3,1], D. Zhou[3], M-Q. Cai[1], R. Zeng[1], X-J. Lv[4,1], L-L. Chen[1], F. Ye[1], Y. Zhang[5]

[1]Department of Medical Oncology, Xiamen Cancer Hospital, The First Affiliated Hospital of Xiamen University, Xiamen, China, [2]Oncology, Fujian Medical University, Fuzhou, China, [3]Department of Medical Oncology, Xiang'an Hospital of Xiamen University, Xiamen, China, [4]Xiamen Cancer Hospital, The First Affiliated Hospital of Xiamen University; Xiamen Humanity Hospital, Xiamen, China, [5]Key Laboratory of Design and Assembly of Functional Nanostructures, Fujian Provincial Key Laboratory of Nanomaterials, Fujian Institute of Research on the Structure of Matter, Chinese Academy of Sciences, Xiamen, China

Background: Compared with the classical tumor markers, ctDNA has higher accuracy and specificity while being noninvasive. Based on the prophase work, we explore the role of ctDNA methylation in the detection of PCDH18 as a new tumor marker compared with CEA in the clinical diagnosis and progressive evaluation of colorectal cancer (CRC).

Methods: We collected peripheral blood from 60 patients with advanced primary CRC before and after two courses of treatment, as well as from 60 healthy individuals, and the clinicopathologic characteristics were analyzed. The changes of CEA levels before and after treatment were dynamically monitored by electrochemiluminescence (ECL). The methylation status of PCDH18 was detected by qMSP, the correlation between them was also statistically analyzed, and the value of different indexes in the diagnosis and monitoring of tumor progression of CRC were compared.

Results: We found that the percentage of methylation of PCDH18 in plasma of CRC before treatment was significantly higher than that of normal plasma samples. The difference ($p < 0.01$) suggests that PCDH18 methylation may be involved in the carcinogenesis of CRC. PCDH18 methylation was not significantly correlated with sex, tumor location, histological type, tumor differentiation, TNM or CEA($P > 0.05$). To further explore the relationship between the methylation of PCDH18 and the risk of CRC, the results showed that with the increase of methylation level of PCDH18, the risk of CRC and tumor progression increased significantly, while in CEA group, the OR > 1 only in the group with CEA elevation as the dividing point, but the P value was not statistically significant. The sensitivity and specificity of PCDH18 ctDNA methylation combined with CEA in the diagnosis of progression of CRC were 90.0% and 67.6%, respectively. The area under the curve (AUC) reached 0.861. Further analysis showed that PCDH18 ctDNA methylation was 67.86% while CEA was negative in CRC progression patients, indicating that PCDH18 ctDNA methylation could significantly increase the detection of progression in comparison with CEA.

Conclusions: The methylation of PCDH18 ctDNA may play an important role in the diagnosis and prediction of tumor progression in CRC as a new tumor marker and can significantly increase the detection of tumor progression in CEA-negative patients. W-W. Tang, H-X. An and D. Zhou contributed equally to this work.

556P Cell free DNA and hepatic arterial infusion of oxaliplatin plus systemic capecitabine for patients with colorectal cancer liver metastases

A.K. Boysen[1], J.V. Schou[2], B.V. Jensen[2], D.L. Nielsen[2], B.S. Sørensen[3], J.S. Johansen[2], K-L.G. Spindler[3]

[1]Oncology, Aarhus University Hospital, Aarhus, Denmark, [2]Department of Oncology, Herlev and Gentofte Hospital, Herlev, Denmark, [3]Experimental Clinical Oncology, Aarhus University Hospital, Aarhus, Denmark

Background: Hepatic Arterial Infusion (HAI) where the cytotoxic agents are administered intrahepatic is an experimental treatment option for patients with colorectal cancer liver metastases (CRCLM). We aimed to investigate the level of cell free DNA (cfDNA) in patients with CRCLM receiving HAI with oxaliplatin and systemic capecitabine.

Methods: Patients were treated according to a single arm phase II study including patients with liver limited mCRC from November 2004 to May 2010, who were not eligible for any other standard local treatment. Therapy comprised intrahepatic infusion of oxaliplatin 100 mg/m2 every second week with concomitant oral capecitabine 3500 mg/m2 every second week for up to 12 cycles. A pre-treatment plasma sample was used for quantification of cfDNA by a modified fluorescent assay. Survival was analyzed by the Kaplan-Meier method and Cox multiple regression analysis.

Results: Baseline plasma samples were available from 62 patients. The majority of patients were males (61%), the median age 61.3 years (range 40.8-74.8) and distribution of colonic/rectal cancers 68%/32%. The median level of cfDNA was 0.92 ng/µL (95% CI 0.84-1.00) with no significant differences according to pre-treatment patients characteristics apart from significantly higher cfDNA levels with poor PS ($p < 0.001$). Plasma cfDNA was significantly lower (0.91 ng/µL, 95% CI 0.76-0.98) in patients who achieved an objective response compared to non-responders (1.79 ng/µL, 95% CI 0.99-2.57, $p = 0.02$). Patients with a baseline value of cfDNA above the 75th quartile had a median overall survival of 2.4 years (95% CI 0.7-2.8), compared to 3.9 years (95% CI 2.8-5.9) for patients below the 75th quartile ($p = 0.02$). In multivariate analysis, only increasing baseline level of cfDNA, (HR 1.90, 95% CI 1.07-3.38, $p = 0.03$), and mutated KRAS status, (HR 3.17, 95%CI 1.67-6.03, $p < 0.001$), remained associated with short survival.

Conclusions: Patients with a low baseline level of plasma cfDNA had a favorable outcome from treatment with HAI and capecitabine for CRCLM. Consequently, cfDNA could hold clinically relevant predictive and prognostic information, which needs validation in this setting.

Background: Metastatic colorectal signet ring cell carcinoma (mSRCRC) is a rare entity and data are limited, concerning small number of patients. Chemosensitivity for metastatic disease has never been assessed. This study analyzes their chemosensitivity and investigates their clinicopathological, molecular and prognostic characteristics.

Methods: This nationwide retrospective study included patients with mSRCRC from 2003 to 2017 in 31 french centers. They were divided into three groups: curative care (group 1), palliative chemotherapy (group 2) and best supportive care (group 3).

Results: Data on 204 patients were collected. Median age was 63 years. Tumors were more frequent in proximal colon (46%) and rectum (29%), were T4 (71%) and poorly differenciated (86%). Sites for metastases were mainly peritoneum (69%), lymph nodes (28%) and liver (23%). Microsatellite instability (MSI) and BRAF V600E mutation were found in 19% (21/108) and 9% (9/103) of patients, and were mainly right sided (respectively 27% and 12% respectively). BRAF mutation was found in 19% of MSI tumors. RAS mutation was found in 23% (29/127) and did not vary with side. Median overall survival (mOS) was 10,1 months ($_{95\%}$CI = [7.9;12.8]). mOS for group 1 (n = 38), group 2 (n = 112) and group 3 (n = 54) were 45,1 months, 10,9 months and 1,8 months. No difference in mOS was found between tumor location, signet ring cell's percentage and MSI status ($p = 0,13$; $p = 0,40$ and $p = 0,82$). In group 2, first-line treatment (1L) was antiVEGF-based in 28,4% and antiEGFr-based in 22% of cases. Response and control rates were 13,2% and 50% respectively in 1L. Progression-free survival (PFS) was 5 months with biotherapy and 3,9 months with cytotoxics alone ($p = 0,016$). There was no difference in PFS between antiVEGF and antiEGFr ($p = 0,8$) in 1L, and between right-sided ($p = 0,275$) and left-sided ($p = 0,265$) tumors.

Conclusions: This large cohort of mSRCRC shows poor prognosis, specific location and molecular alterations which provides low chemosensitivity. Microsatellite analysis should be done regarding promising results of immunotherapy in MSI-high tumors.

558P The combination of trifluridine/tipiracil and oxaliplatin induces immunogenic cell death in microsatellite stable colorectal cancer

F. Ghiringhelli[1], E. Limagne[2], M. Thibaudin[2], L. Nuttin[2], A. Spill[2], V. Derangere[2], V. Cattan[3], E. Peranzoni[4], N. Amellal[3]

[1]Medical Oncology Unit, Centre Georges-François Leclerc, Dijon, France, [2]Plateform of Cancer Biology, Centre Georges-François Leclerc, Dijon, France, [3]Servier Oncology, Instut de Recherches Internationales Servier, Suresnes, France, [4]Servier Oncology, Instut de Recherches Servier, Croissy, France

Background: Patients with microsatellite-stable (MSS) colorectal cancer have limited clinical benefit with PD-1 blockade [1, 2]. These tumors are poorly immunogenic and highly infiltrated by immunosuppressive populations [3]. In this context, identification of drug combinations both inducing immunogenicity and modulating tolerogenicity is crucial for the sensitization of MSS colorectal cancer to immune-checkpoint inhibitors. The aim of this study was to evaluate the immunological properties of the trifluridine/tipiracil and oxaliplatin combination in the murine MSS colorectal cancer CT26 model.

Methods: Immunogenic cell death was evaluated both in vitro and in vivo (HMGB1/ATP release, calreticulin and EIF2α endoplasmic reticulum stress marker). Both antitumor CD8 (IFNγ, Granzyme B, PD-1) and tolerogenic (including Treg, polymorphonuclear-granulocytic/monocytic myeloid-derived suppressor cells and tumor-associated macrophages [TAM]) responses were analyzed by immunochemistry and flow cytometry.

Results: Combined therapy induced all immunogenic cell death markers in vitro. In tumor tissue, HMGB1 nuclear delocalization and EIF2α phosphorylation were significantly increased after trifluridine/tipiracil and oxaliplatin exposure as compared to each single agent; no effect was seen with the single agents. These immunogenic signals allow the recruitment of PD-1$^+$ CD8 cells with high capacity for production of IFNγ, TNFα and granzyme B production capacities. Furthermore, the trifluridine/tipiracil and oxaliplatin combination was seen to markedly deplete TAM, in particular TAM2.

Conclusions: The trifluridine/tipiracil and oxaliplatin combination induces immunogenic cell death and antitumor CD8 activation as well as depletion of immunosuppressive TAM2 in MSS colorectal cancer. This chemotherapy combination could therefore be considered as a potential new therapeutic option for immune checkpoint inhibitor sensitization in MSS colorectal cancer. 1. 559P Distribution of endocrine tumor marker-positive cells in adenocarcinoma tissue between right-sided and left-sided colon cancer

T. Ogimi[1], S. Sadahiro[1], H. Miyakita[1], G. Saito[1], K. Okada[1], A. Tanaka[1], T. Suzuki[1], H. Kajiwara[2]

[1]Surgery, Tokai University School of Medicine, Isehara, Japan, [2]Pathology, Tokai University School of Medicine, Isehara, Japan

Background: Neuroendocrine carcinoma (NEC) is a rare disease accounting for 0.03% to 0.2% of all colorectal cancers and has been reported to occur significantly more frequently in the right-sided colon. Tumors consisting of both adenocarcinoma and NEC components or mixtures of these components have been reported. Some cases of adenocarcinoma diagnosed on H-E staining include neuroendocrine tumor

components. We tested the hypothesis that distribution of endocrine tumor marker-positive cells in cancer tissue differ between right-sided and left-sided colon cancer.

Methods: The study group comprised 354 patients with stage II or III colon cancer who underwent curative resection from 2007 to 2012. Immunostaining was performed using chromogranin A (cgA), synaptophysin, and CD56 as gastrointestinal endocrine tumor markers. Cases in which positive cells were seen in some part of the cancer tissue were evaluated to be positive.

Results: Tumors were located in the right-sided colon in 181 patients (51.1%) and the left-sided colon in 173 patients (48.8%). Immunohistochemical staining was positive for cgA in 66 patients (18.6%), positive for synaptophysin in 102 patients (28.8%), and positive for CD56 in 55 patients (15.5%). Immunohistochemical staining was positive for at least one of these markers in 118 patients (33.3%) and for all of the markers in 27 patients (7.6%). The rate of positive staining for cgA was 23.7% (43/181) in right-sided colon cancer and 13.2% (23/173) in left-sided colon cancer. The rate of positive staining for synaptophysin was 35.3% (64/181) in right-sided colon cancer and 21.9% (38/173) in left-sided colon cancer. The rate of positive staining for CD56 was 22.6% (41/181) in right-sided colon cancer and 8.0% (14/173) in left-sided colon cancer. The rates of positive staining for cgA, synaptophysin, or CD56 were significantly higher in right-sided colon cancer ($p = 0.0115$, $p = 0.0054$, and $p = 0.0062$).

Conclusions: Overall, 33.3% of patients with adenocarcinoma of the colon had endocrine tumor components in cancer tissue. The rates of positive staining for endocrine tumor markers were significantly higher in right-sided colon cancer, which may be associated with the high incidence of NEC in the right side of the colon.

560P Prospective DPYD testing in colorectal cancer patients in a realworld UK population

B.K. Eccles[1], A.S. Harle[1], S. Pullinger[2], C. Holling[1], A. Ingram[3], S. Stark[2], M. Bunce[2], G. Melville[1], J. Gibbins[3], N. Calcutt[3], T. Hickish[4], M. Flubacher[1], T. Marinaki[5]

[1]Oncology, Poole Hospital NHS Foundation Trust, Poole, UK, [2]Surgical Oncology, Royal Bournemouth Hospital, Bournemouth, UK, [3]Oncology, Dorchester County Hospital, Dorchester, UK, [4]Oncology, Royal Bournemouth Hospital and University, Bournemouth, UK, [5]Purine Research Laboratory, St. Thomas Hospital, London, UK

Background: Polymorphisms within the DPYD gene are present in 7% of Europeans but account for 23% of life-threatening toxicity from fluoropyrimidine (FP) chemotherapy. Four DPYD variants have an adjusted relative risk for toxicity of 1.59 - 4.4. Upfront genotyping is safe and cost effective but not mandated by ESMO guidelines. To reduce the risk of life-threatening toxicity we implemented prospective DPYD testing as standard practice.

Methods: Consecutive colorectal cancer (CRC) patients in a UK cancer centre due to receive FP chemotherapy were genotyped by real time PCR for known clinically relevant DPYD mutations: c.1905+G>A 2*, c.2846A>T, c.1679T>G and c.1605 G>A and from March 2017, c.1236G>A/HapB. We followed published recommendations for dose reduction or alternative drug. Demographics, dose, toxicity and survival data were collected.

Results: Between 1/1/16-31/12/2017, 230 patients were tested. 72% had capecitabine, 24% 5-fluorouracil, and 4% raltitrexed combinations. After dose reduction or alternative therapy, grade 3/4 diarrhoea was similar in wildtype and mutations (10 vs 13%) and any toxicity admissions were not significantly different ($p = 0.284$). There were no treatment deaths.

Conclusions: To our knowledge, we are the only UK centre to implement prospective DPYD testing in routine clinical practice for CRC patients. In published data of unselected CRC patients the G3/4 GI toxicity is 15%, but if 2* variant is present this increases to 73%. In the latter population, genotype guided dosing reduces the risk to 28%. Our rate for all variants was 10% but limited by small numbers. Pharmacokinetics in another study showed adequate 5FU exposure with a 50% dose reduction, alleviating underdosing concerns. The growing evidence supports prospective DPYD testing. We have shown it is practical and may mitigate serious toxicities.

Total 58% adjuvant 27% neoadjuvant 24% palliative		230 (100%)	92%	49 (21%)	23 (10%)

561P Standard fluoropyrimidine dosages in chemoradiation therapy result in an increased risk of severe toxicity in DPYD variant allele carriers

C.A.T.C. Lunenburg[1], L.M. Henricks[2], E. Dreussi[3], F.P. Peters[4], M. Fiocco[5], D. Meulendijks[6], G. Toffoli[3], H-J. Guchelaar[7], J.J. Swen[7], E. Cecchin[3], J.H.M. Schellens[2], H. Gelderblom[1]

[1]Department of Medical Oncology, Leiden University Medical Center (LUMC), Leiden, Netherlands, [2]Department of Clinical Pharmacology, Division of Medical Oncology, The Netherlands Cancer Institute, Amsterdam, Netherlands, [3]Experimental and Clinical Pharmacology Unit, National Cancer Institute, Aviano, Italy, [4]Department of Radiotherapy, Leiden University Medical Center (LUMC), Leiden, Netherlands, [5]Medical Statistics, Department of Biomedical Data Sciences, Leiden University Medical Centre, Leiden, Netherlands, [6]Dutch Medicines Evaluation Board, CBG-MEB, Utrecht, Netherlands, [7]Department of Clinical Pharmacy and Toxicology, Leiden University Medical Center, Leiden, Netherlands

Background: Prospective DPYD genotyping prevents severe fluoropyrimidine-induced toxicity by decreasing initial dosages in DPYD variant allele carriers. However, fluoropyrimidine dosages in chemoradiation therapy are already lower compared to other fluoropyrimidine-containing regimens. It is unknown if recommended dose reductions of pharmacogenetic guidelines are valid for DPYD variant allele carriers receiving fluoropyrimidines in chemoradiation therapy. The aim of this study was to investigate severe toxicity in DPYD variant allele carriers receiving chemoradiation therapy.

Methods: Three databases were used, containing data on patients who received fluoropyrimidine-based chemoradiation therapy. Frequencies of severe (grade $\geq$3) toxicity in DPYD variant allele carriers (DPYD*2A, DPYD*13, c.2846A>T or c.1236G>A) receiving upfront fluoropyrimidine dose reductions according to current pharmacogenetic dosing guidelines (50 or 75% depending on the variant), and DPYD variant allele carriers receiving full-dose were compared to DPYD wild-type patients receiving standard dose fluoropyrimidines in chemoradiation therapy.

Results: DPYD variant allele carriers treated with standard dosages ($N = 34$) showed an increased risk of severe gastrointestinal (adjusted OR = 2.58, 95% CI = 1.02-6.53, $P = 0.045$) or severe haematological (adjusted OR = 4.19, 95% CI = 1.32-13.25, $P = 0.015$) toxicity compared to wild-type patients ($N = 771$). DPYD variant allele carriers who received dose reductions ($N = 22$) showed a comparable frequency of severe gastrointestinal toxicity, but a higher frequency of severe haematological toxicity, compared to wild-type patients. The mean duration of hospitalisation was significantly shorter in DPYD variant allele carriers who received dose reductions compared to DPYD variant allele carriers treated with standard dosages (4 versus 23 days, $P = 0.010$).

Conclusions: Standard fluoropyrimidine dosages in chemoradiation therapy resulted in an increased risk of severe toxicity in DPYD variant allele carriers. Fluoropyrimidine dose reductions for DPYD variant allele carriers should also be applied in patients receiving chemoradiation therapy.

562P Determination of DPYD polymorphisms before treatment with chemotherapy with a pyrimidine: Should we continue doing it?

C. Avila Andrade[1], A.J. Cunquero Tomas[1], A.B. Fernandez Diaz[1], M. Meri Abad[1], L.D. Condori Farfan[1], I. Shaheen[1], S. Cervantes Garcia[2], M.J. Safont Aguilera[1], V. Iranzo Gonzalez-Cruz[1], V. Sforza[3], C. Caballero[4], M.C. Godes de Bremond[1], M. Gil[1], F.D.A. Aparisi Aparisi[5], A. Blasco Cordellat[6], A. Berrocal Jaime[6], I. Ferrer Bolufer[2], M. Lobo de Mena[6], G. Marcaida Benito[2], C. Camps[7]

[1]*Medical Oncology Service, Hospital General Universitario Valencia, Valencia, Spain,* [2]*Clinical Analysis, Hospital General Universitario Valencia, Valencia, Spain,* [3]*Department of Medical Oncology, Università degli Studi della Campania Luigi Vanvitelli, Naples, Italy,* [4]*Medical Oncology, Hospital General, Valencia, Spain,* [5]*Oncology, Fundación de Investigación Hospital General Universitario de Valencia, Valencia, Spain,* [6]*Medical Oncology, Hospital General Universitario Valencia, Valencia, Spain,* [7]*Medical Oncology, Consorcio Hospital General Universitario de Valencia, Valencia, Spain*

Background: The toxicity produced by chemotherapy worsens in the presence of mutations in certain enzymes of metabolism or degradation. Such is the case of dihydropyrimidine dehydrogenase (DPYD) in the treatment with fluoropyrimidines. Detection prior to the start of treatment could be beneficial to prevent this increase in toxicity.

Methods: A prospective study in which the DPYD polymorphisms are analyzed, after the first visit in Oncology of patients with a diagnosis of colorectal cancer (CRC), gastroesophageal cancer (CGE) or cancer in the head and neck, that can be treated with fluoropyrimidine-based chemotherapy. After DNA extraction from the peripheral blood sample the methodology used was: 1. Directed genotyping of variant * 2A, * 13 and rs67376798 of the DPYD gene, by analysis of allelic discrimination polymorphisms with TAQMAN probes, previous amplification in an ABI Prism 7900 (Applied Biosystems).

Results: We included 374 patients, with an average age of 67a, 62% men, with PS 0 or 1 in 97% of the cases. Localization of the primary tumor was: CRC 85%, GEC 12%, H&N (3%). 97% were adenocarcinomas and 3% squamous carcinoma. The intention of adjuvant treatment in 46%, neoadjuvant 17%, a first line of metastatic disease 33%, the second line of metastatic disease 3%. Schemes used: combinations of 5FU with oxaliplatin (58%), capecitabine in monotherapy or radiotherapy in neoadjuvant (33%). Toxicities G3-4: diarrhea 1.3%, neutropenia 0.8%, rash, 1.3% and mucositis 0.3% Four patients with DPYD deficit (1.1%) were found. two patients with a complete deficit that started capecitabine adjuvant at 50%, increasing to 75% in the 2nd cycle with G1 diarrhea as a relevant toxicity. Another two patients with DPYP heterozygous deficit decided to change treatment scheme to ralitrexed every 3 weeks.

Conclusions: In our study, we observed that the enzymatic deficit in the metabolic pathways related to 5FU are rare, and probably do not influence the initiation of chemotherapy treatment.

These results will not influence the usual clinical practice, but we think are very important to avoid toxicity to the patient if these are present.

Background: DS-8201a is a HER2-targeting antibody-drug conjugate with a novel peptide-based cleavable linker, a topoisomerase I inhibitor payload, and a high drug-to-antibody ratio (7 to 8). In preclinical studies, DS-8201a showed a broad antitumor activity in a wide range of tumors, including colorectal cancer (CRC) regardless of KRAS status. The ongoing phase 1 trial has a dose-escalation (part 1) and -expansion (part 2) and includes subjects (sbj) with advanced breast cancer, gastric cancer, and other HER2-expressing/mutated solid tumors. Here, we present updated results for HER2-expressing CRC.

Methods: Sbj with advanced HER2-expressing (defined as IHC $\geq$1+) CRC were eligible to enroll. HER2 expression was assessed using archival tissue. Objective response rate (ORR), disease control rate (DCR; CR + PR + SD), duration of response (DOR), and adverse events (AEs) were assessed.

Results: As of Apr 18, 2018, 19 HER2-expressing CRC sbj received $\geq$1 dose of DS-8201a at 6.4 mg/kg. Median age was 59 y with median of 4 prior regimens (range: 1 to 8). Sixteen of 19 sbj had prior treatment (tx) with irinotecan, another topoisomerase -I inhibitor. At the data cutoff, 7 of 19 (36.8%) sbj remain on treatment. Median duration of tx was 2.76 months (range 0.69, 15.44). Two sbj were known to have KRAS mutations. Overall, confirmed ORR and DCR in the efficacy evaluable sbj was 3 of 12 (25.0%) and 10 of 12 (83.3%), respectively. All responses were observed in KRAS wild-type sbj. One sbj with a KRAS mutation had SD with reduction in tumor markers. Median DOR has not been reached (NR, range 2.76, 5.52+ mo). Nine of 15 (60.0%) sbj with $\geq$1 post baseline scan experienced tumor shrinkage. Major reason for tx discontinuation was progressive disease (9/12; 75.0%). As for the safety outcomes, 12/19 (63.2%) experienced a grade $\geq$3 AE. Common AEs included nausea 57.9% (0.0% grade $\geq$3), platelet count decreased 52.6% (26.3% grade $\geq$3), anemia 47.4% (26.3% grade $\geq$3), vomiting 42.1% (0% grade $\geq$3), and diarrhea 42.1% (0% grade $\geq$3).

Conclusions: DS-8201a demonstrated antitumor activity with manageable safety profile in heavily pretreated subjects with HER2-expressing CRC and warrants further investigation in a phase 2 trial.

Clinical trial identification: NCT02564900.

Background: Anti-VEGF agents in combination with chemotherapy improve PFS of patients with mCRC in the 1st- and 2nd-line-setting. During anti-VEGF treatment tumour angiogenesis is driven by other factors but VEGF. Nintedanib is a triple angiokinase inhibitor of human VEGFR-1-3, FGFR-1/-3 and PDGFR-α/-β thereby additionally targets angiogenic escape mechanisms upon resistance to anti-VEGF treatment. The TRICC-C trial evaluates the combination of mFOLFOX6 plus Nintedanib. Final results of the randomized phase II trial are presented.

Methods: Patients with mCRC having received one line of non-oxaliplatin containing palliative chemotherapy, with an ECOG-PS of 0 or 1 were randomized 1:1 in a double-blind design to receive: mFOLFOX6 plus Nintedanib (2 x 200 mg p.o./d, d1-d14) or placebo, respectively, repeated every 14 days. Primary endpoint was PFS. Secondary endpoints were ORR, OS and safety. Patients who received at least one dose of trial medication were included in the efficacy and safety analyses.

Results: From 12/2012 to 5/2016 53 patients (scheduled n = 180) were randomized. The trial was terminated prematurely due to slow accrual. Compared to mFOLFOX6 plus

placebo (F+P), the combination of mFOLFOX6 plus Nintedanib (F+N) improved mPFS (F+P: 4.6 vs F+N: 8.1 mo.; HR 0.65; 95% CI 0.32-1.30; p = 0.2156), mOS (F+P: 9.9 vs. F+N: 17.1 mo.; HR 1.03, 95% CI 0.48-2.23; p = 0.9387) and DCR (F+P: 50 vs. F+N: 66,7%; p = 0.2709). ORR was comparable in both arms (F+N: 3.8 vs. F+P: 3.7%). Toxicity was low to moderate without major differences between both arms except G 3/4 neutropenia (F+N: 19%, F+P: 12%) and GI disorders (F+N: 23%, F+P: 15%).

Conclusions: Final results suggest a PFS, OS and DCR benefit for mFOLFOX6 + Nintedanib vs. mFOLFOX6 + placebo in the 2nd-line therapy of mCRC. Due to the premature termination of the trial there was no statistical significance demonstrable. Showing no clinically significant PFS-benefit in the 1st-line situation (mFOLFOX6 plus Nintedanib/Bevacizumab, Ann Oncol. 2015) or the last line as single agent, respectively (ESMO 2016) the TRICC-C results suggests that Nintedanib could be an interesting therapeutic option for the 2nd-line situation in combination with mFOLFOX6.

565P Dose finding and safety study of reovirus (Reo) with irinotecan/ fluorouracil/ leucovorin/ bevacizumab (FOLFIRI/B) in patients with KRAS mutant metastatic colorectal cancer (mCRC): Final results

S. Goel[1], A. Ocean[2], R. Parakrama[1], M.H. Ghalib[1], I. Chaudhary[1], U. Shah[1], M. Coffey[3], E. Kaledzi[1], R. Maitra[1]

[1]Medical Oncology, Montefiore Medical Center (East campus) - Medical Park at Eastchester Albert Einstein Cancer Center, Bronx, NY, USA, [2]Solid Tumor Division, New York Presbyterian-Weill Cornell Medical College, New York, NY, USA, [3]Oncology, Oncolytics, Calgary, AB, Canada

Background: KRAS mutation is a biomarker of exclusion of anti-EGFR agents in patients with mCRC, who have limited options once they progress on oxaliplatin and irinotecan-based regimens. Reo is a naturally occurring, ubiquitous, non-enveloped double stranded RNA virus that selectively replicates in tumor cells harboring KRAS mutations. Reo is synergistic with irinotecan (IRI) in in vitro and in vivo models.

Methods: This was a phase I dose escalation study of FOLFIRI/B and Reo to determine maximum tolerated dose (MTD) and recommended phase two dose (RPTD). Eligible pts were adults with oxaliplatin refractory KRAS-mutant mCRC. Both, IRI (150-180 mg/m^2) and Reo (1x10^{10} $TCID_{50}$ to 3x10^{10} $TCID_{50}$) were escalated. Reo was given intravenously over 1 hour on days 1-5 every 4 weeks (wk). FOLFIRI/B was delivered every 2 wk as per standard protocol. Pharmacokinetics (PK), on study tumor biopsies, and immune response was studied.

Results: 36 pts enrolled; 23 females (64%), median age 63 years, FOLFIRI naïve (24) and pre-treated (12). At the highest dose of 180 mg/m^2 of IRI, among FOLFIRI pre-treated pts, 2 had dose-limiting toxicity (DLT) in cycle 1; one suffered from grade 4 thrombocytopenia, and another developed febrile neutropenia and urosepsis. However, in FOLFIRI naïve patients, none/6 had a DLT. Common (>10%) toxicities included neutropenia, anemia, thrombocytopenia, fatigue, and diarrhea. One patient died of acute renal failure. The MTD was the highest individual dose of FOLFIRI/B (180 mg/m^2 IRI) and reovirus (3x10^{10} $TCID_{50}$), and is the RPTD. At this dose, 3 of 6 patients (50%) had a PR and the median progression free survival (PFS) and overall survival (OS) were 65.6 wk and > 98.3 wk (as of May 9, 2018), respectively. There was no PK interaction noted. Immunogold staining against viral capsid protein σ demonstrated viral "homing" in the tumor cells. Flow cytometry revealed rapid dendritic cell maturation with subsequent activation of cytotoxic T cells.

Conclusions: The combination of reovirus with FOLFIRI/B is safe, and well tolerated. The PFS and OS is superior to historic data and this combination deserves further exploration.

Clinical trial identification: NCT01274624.

Background: GC1118 is a novel anti-EGFR monoclonal antibody and has unique binding epitopes and different ligand binding inhibitory activity compared to cetuximab and panitumumab. In dose escalation part of a first-in-human phase 1 study, RP2D were determined as 4 mg/kg, in weekly dosing schedule (NCT02352571). DLT was skin toxicity. Here we report efficacy and safety data of GC1118 in patients (pts) with colorectal cancer (CRC) and gastric cancer (GC) tested in dose expansion part.

Methods: Cohort 1 (C1) recruited pts with metastatic CRC with no prior EGFR antibody treatment who have failed to 5-FU, oxaliplatin and irinotecan. Cohort 2 (C2) enrolled pts with metastatic CRC with resistance to prior EGFR antibody. Cohort 3 (C3) enrolled pts with EGFR over-expressing (2+,3+) metastatic GC cancer who have failed to standard treatment. GC1118 was administrated on days 1, 8, 15 and 22 every 4 weeks.

Results: A total of 39 pts were enrolled (C1: 14, C2:12, C3:13). Evaluable pts were 12 in each cohort. In C1, SD was observed in 58.33% (7/12) and there was no CR/PR case. In C2, 2 patients (16.67%) obtained PR, 1 SD (8.33%), and 9 PD (75.0%). In C3, PR was 8.33% (1/12), SD 16.67% (2/12), and PD 75.0%. The progression-free survival (PFS) were 14 weeks (95% CI: 7.1-30.1), 6.93 weeks (95% CI: 4.2-14.8), and 6.7 weeks (95% CI: 5.0-11.0), respectively Adverse event (AE) was observed in 97.4% of patients and treatment-related AE (TRAE) occurred in 92.3% of patients. Skin toxicity (all grade) was observed in 89.7% of patients (35/39), stomatitis 20.51%(all grade 1/2), and diarrhea 17.95% (all grade 1/2). Dose reduction due to AE was required in 23.08% of patients (9/39), and dose interruption due to AE was needed in 58.9% of patients (23/39). TRAE higher than grade 3 was observed in 20.5% of patients (8/39). Among them, skin toxicity was most common (12.8%, 5/39 patients) There was no treatment-related death.

Conclusions: GC1118 showed promising anti-tumor activity, especially in CRC with resistance to prior EGFR antibody with 16.7% PR, even in heavily treated population. GC1118 was generally well tolerated, and skin toxicities were by far the most common AEs.

Background: Matrix metalloproteinase-9 (MMP-9) is highly expressed in metastatic colorectal cancer (mCRC) and other advanced cancers and confers an adverse prognosis. In a preclinical CRC model, inhibition of MMP-9 was associated with reduced tumor growth. Andecaliximab (ADX) is a chimeric antibody directed against MMP-9, engineered to remove T cell epitopes and reduce risk of human anti-mouse antibodies. In this phase I

multi-cohort study, we evaluated the combination of ADX with standard chemotherapy in patients with previously untreated mCRC. (Clinicaltrials.gov NCT# 01803282).

Methods: The study enrolled 45 eligible patients (19 female) with measurable disease and previously untreated mCRC. The median age was 62 years (range 34-78) and 18% (8/45) of patients had received prior adjuvant chemotherapy. Patients were treated with 800 mg ADX IV every two weeks plus standard doses mFOLFOX6 and bevacizumab. Safety and efficacy were assessed. Primary endpoints were safety and tolerability. Exploratory endpoints were investigator-assessed objective response rate (ORR), progression-free survival (PFS), and overall survival (OS). Molecular analysis of archival tumor samples was performed.

Results: As of March 5, 2018, the median duration of ADX treatment was 8.8 months. Median PFS follow up time was 13.5 months. The most common adverse events were fatigue (78%), nausea (71%), diarrhea (56%), peripheral sensory neuropathy (49%), decreased appetite (40%), and neutropenia (40%). 38% of patients reported serious adverse events (SAEs). Acute respiratory failure and sepsis (both 4%) were the most common SAEs. Median PFS was 10 months (90% CI 9.0-12.0 months), median duration of response was 8.1 months (90% CI 6.1, 10.4). Overall response rate was 62% (90% CI 49 – 74%) with 4% complete response rate. The response rate was 50% for mutated BRAF, 67% for mutated RAS, 67% for right-sided disease. The median OS was not reached. Study treatment continues in 7% of patients.

Conclusions: Combination of ADX with mFOLFOX6 and bevacizumab was safe and shows response and PFS similar to historical data with FOLFOX-bevacizumab in first-line treatment of patients with previously untreated mCRC.

568P A phase II study of pemetrexed and erlotinib for metastatic colorectal cancer refractory to standard chemotherapy

S-H. Beom[1], K-W. Lee[2], S-H. Cho[3], Y.S. Park[4], T.W. Kim[5], K.H. Lee[6], M. Jung[1], S.J. Shin[1], J.B. Ahn[1]

[1]Department of Internal Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, Republic of Korea, [2]Internal Medicine, Seoul National University Bundang Hospital, Seoul, Republic of Korea, [3]Hemato-Oncology, Chonnam National University Medical School & Chonnam National University Hwasun Hospital, Hwasun, Jeollanam-do, Republic of Korea, [4]Hematology-Oncology, Samsung Medical Center Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [5]Asan Medical Center, University of Ulsan, Seoul, Republic of Korea, [6]Yeungnam University College of Medicine, Department of Internal Medicine, Daegu, Republic of Korea

Background: There are very limited treatment options in metastatic colorectal cancer (mCRC) after progression on chemotherapy including fluoropyrimidine, oxaliplatin and irinotecan. This open label, multi-center, phase II study was conducted to investigate the combination of pemetrexed and erlotinib in patients who were refractory to previous chemotherapy for mCRC.

Methods: Patients were eligible if they had metastatic colorectal cancer that progressed to standard chemotherapy including fluoropyrimidine, oxaliplatin, and irinotecan. Each 21-day cycle consisted of intravenous pemetrexed at 500 mg/m^2 on day 1 and daily oral erlotinib at 150 mg (reduced to 100 mg after the first 29 patients).

Results: Fifty patients were enrolled onto this phase II study. Twenty-seven patients (54%) had KRAS wild type tumors and 23 patients (46%) did KRAS mutant tumors. Forty-six patients were evaluable for response; twenty-seven patients (59%) had stable disease (SD) and 4 patients (9%) achieved prolonged SD for >6 months. No complete or partial responses were seen. The median progression-free survival was 2.5 months and the median overall survival was 7.3 months. Clinically significant grade 3 to 4 toxicities included diarrhea (6%), fatigue (6%), ileus (4%), skin rash (2%), and myalgia (2%); grade 3 or 4 toxicities were reduced with a lower starting dose of erlotinib.

Conclusions: The combination of pemetrexed and erlotinib seems to have limited activity in refractory mCRC patients. Further research for the regimen is not warranted without understanding predictive biomarkers.

Clinical trial identification: NCT02723578.

569P ISO-CC-005; A phase I/II study of arfolitixorin (MTHF) in combination with 5-FU, irinotecan, and oxaliplatin ± bevacizumab in patients with metastasizing colorectal cancer

G.U. Carlsson[1], T.K. Guren[2], J. Haux[3], P. Pfeiffer[4], H. Taflin[1], D. Mavroudis[5], V. Georgoulias[6], C. Papadimitriou[7], N. Kentepozidis[8], D. Boumpas[9], L. Skintemo[10], K.M.E. Ganlöv[11], B. Gustavsson[12]

[1]Department of Surgery, Sahlgrenska University Hospital, Gothenburg, Sweden, [2]The Norwegian Radium Hospital, Oslo University Hospital, Oslo, Norway, [3]Department of Surgery, Skaraborg Hospital, Skövde, Sweden, [4]Experimental Research in Medical Cancer Therapy, Odense University Hospital, Odense, Denmark, [5]Medical Oncology, University General Hospital, Heraklion, Greece, [6]Oncology, IASO General Hospital, Cholargos Athens, Greece, [7]Oncology, Alexandra Hospital, Athens, Attiki, Greece, [8]Oncology, 251 Hellenic Airforce General Hospital, Athens, Greece, [9]Oncology, University Hospital Attikon, Chaidari Athens, Greece, [10]Clinical Reserach, Isofol Medical AB, Gothenburg, Sweden, [11]Medical, Isofol Medical AB, Gothenburg, Sweden, [12]Surgical Oncology Lab, University of Gothenburg, Goteborg, Sweden

Background: Chemotherapy treatment of Colorectal Cancer, often include 5-Fluorouracil (5- FU). 5-FU inhibits the enzyme thymidylate synthase (TS), stopping the supply of thymidine for DNA synthesis. 5-FU is always combined with a folate, which enhances the 5-FU effect. Marketed folates such as LV/L-LV are prodrugs needing enzymatic conversion. Arfolitixorin (formerly Modufolin®) is the natural, biologically active form of the folates and is expected to be efficacious in a larger proportion of patients with less inter- and intra-individual variability.

Methods: ISO-CC-005 is a multi-center, phase I/II study in mCRC patients eligible for 5-FU/folate therapy alone or in combination with irinotecan or oxaliplatin ± bevacizumab. The study investigates safety and tolerability of arfolitixorin at 4 dose levels by analysing the number and severity of AEs, SAEs and DLTs. Efficacy is evaluated as ORR after 4 cycles of chemotherapy. Gene expression, deoxyuridine levels as an indirect marker of TS inhibition and time to death is also investigated. 3-6 patients per cohort are included. All receives arfolitixorin twice every two weeks during at least 4 cycles of chemotherapy.

Results: Today, 67 patients have been enrolled and 59 have initiated treatment. 13 are 1st line patients, 16 are in 2nd line, 10 are in 3rd line and 1 is in 5th treatment line. 27 SAEs have been reported in 13 patients, 6 of these were judged as at least possibly related to arfolitixorin. No SAE were judged as solely related to arfolitixorin. 49 patients have today been evaluated for efficacy. ORR 1st line patients (n = 14) at 8 weeks All 43% (6 PR, 7 SD, 1PD) Patients with arfolitixorin dose ≥60 mg/m^2 56% (5 PR, 3 SD, 1 PD) Patients with arfolitixorin dose ≥60 mg/m^2 + oxaliplatin 60% (3 PR, 1 SD, 1 PD).

Conclusions: The lack of need for metabolic activation makes arfolitixorin a better candidate than LV/L-LV for improved outcome of 5-FU-based chemotherapy regimens in mCRC. The ISO-CC-005 study evaluates arfolitixorin in combination with 5-FU, irinotecan, oxaliplatin ± bevacizumab in mCRC patients in 4 countries in Europe. The results, so far, for both safety and efficacy seems promising.

570P Detection of frailty in elderly colorectal càncer patients: Is G8 a good screening tool?

G. Soler, J.C. Ruffinelli Rodriguez, R. Legido, M. Martinez Villacampa, F.J. Perez, B. Pardo-Burdalo, J.A. Marín, I. Morilla Ruiz, L. Heras Lopez, S. Vazquez, S. Recalde, M. Plana Serrahima, C. Santos, N. Mulet Margalef, A. Teule, R. Salazar, M.C. Galan, J. Saldaña

Medical Oncology, Institut Català d'Oncologia Hospital Duran i Reynals, Barcelona, Spain

Background: Colorectal cancer (CRC) is one of the most commonly diagnosed cancers. About one half of cases are diagnosed in patients over 70 years of age. A multidimensional geriatric assessment is recommended in older patients but requires considerable time and resources. The aim of this study was to explore whether the G8 questionnaire to identify frailty may be helpful in decision-making in older CCR patients.

Methods: From October 2015 to July 2017, 142 patients over 75 years old were included prospectively. All the patients were assessed on four scales: G8, Pfeiffer, Barthel and TIRS scale, in addition to assessing age, comorbidity and functional status. Positive screening was performed for those older than 85 years, and those younger than 85 with 2 criteria (G8 $\leq$14, Pfeiffer $>$ 2, Barthel $<$ 90 and TIRS +).

Results: The median age was 80.4 years (75.1 – 88.9). 45% had metastatic disease. 82% had G8 score$\leq$14; 38% decided not to be treated with chemotherapy. 62% were treated with chemotherapy (47% capecitabine, 11% FOLFOX6 and 4% in a clinical trial). 43 % of the patients with G8$\leq$14 started treatment with adapted doses and 39% at subsequent cycles. Of the G8$>$ 14, only 28% were reduced at the beginning and 14% at subsequent cycles. Grade 3/4 toxicities in the G8$\leq$14 versus G8$>$14. were: plantar palmar syndrome 14.3% vs 0%; hematological 15% vs 0%; gastrointestinal 18% vs 14%; mucositis 3.6% vs 0%; asthenia 11% vs 0%; and renal failure 4% vs 0%.

Conclusions: The G8 questionnaire helps to discriminate which patients are candidates for chemotherapy. If the G8 score is $\leq$ 14, it supports the decision to reduce the dose and it predicts toxicity. This suggests that G8 could be an instrument that detects frailty in older patients with CRC with the intention of undergoing systemic treatment. After analyzing these results, it is recommended to perform a complete geriatric assesment in these patients to validate our conclusions.

[1]Group and Project Development, EuropaColon UK, Salisbury, UK, [2]Hospitalet de Llobregat, Hospital Duran i Reynals, Barcelona, Spain, [3]Unidad de Cirugía de Colon y Recto, Hospital Valle de Hebron, Universitat Autonoma de Barcelona, Barcelona, Spain, [4]Onkoradiológia, Egyesített Szent István és Szent László Kórház, Budapest, Hungary, [5]Department of Physiotherapy, Semmelweis University Faculty of Health Sciences, Budapest, Hungary, [6]Modeling and Simulation, Evidera, Budapest, Hungary, [7]Modelling and Simulations, Evidera, London, UK

Background: With increasing emphasis on patients' voices, EuropaColon, a European CRC patient organization, conducted a cross-sectional European survey on unmet needs in mCRC, in 12 countries. The aim was to better understand the challenges, needs and the health-related quality of life (HRQoL). The objective of this work is to report the preliminary results for Hungary (HU), Poland (PL), Serbia (RS) and Spain (ES).

Methods: IRB approval was obtained. Clinicians, and nurses with partner organizations of EuropaColon recruited patients. The survey had two sections: treatment-related information and HRQoL. The former comprised questions on timing of diagnosis/treatment, multidisciplinary team discussion (MDT), type of treatments received, and information on treatments and side-effects. Both paper-based and online completion were available. Single data entry was done by EuropaColon. Descriptive analyses were carried out in Excel. No imputation of missing data was done.

Results: 548 surveys were analyzed. Completion rates were high. Most responders were treated in public hospitals and 85-92% in HU, ES and PL and 57% in RS were undergoing treatment at the time. Most patients (82%) received treatments within 3 months after diagnosis with CRC, 16% within first 2 weeks. 60% underwent MDT discussion and were informed about the outcome. Proportions however varied between countries, with lowest for PL (46%) and highest for RS (74%). Proportion of patients feeling their views were considered prior starting treatment varied (from 30% in RS to 83% in HU). Most patients had surgery and chemotherapy (83% and 91%), 21% radio- and 9% targeted therapy. Specific therapies however were not given in 13-23% of cases. Patients were relatively informed about side effects (73%). A fifth of patients received molecular test, from a low 6% in RS up to 34% in PL.

Conclusions: Among mCRC patients in HU, ES, RS and PL the degree of information varies. Patients know about MDT and are informed about potential side effects. However, the specific treatment is not well known, and molecular testing is rare. Variations across countries need to be investigated further. Study limitations include cross-sectional design and single data entry.

572P Socioeconomic discrepancies in survival of stage IV colorectal cancer

H.S. Kim[1], J. Uhlig[2], S. Stein[3], L. Jill[3], C.S. Fuchs[4]

[1]Section of Interventional Radiology, Yale School of Medicine - Interventional Radiology Yale Cancer Center, New Haven, CT, USA, [2]Section of Interventional Radiology, Yale School of Medicine, New Haven, CT, USA, [3]Medical Oncology, Yale School of Medicine, New Haven, CT, USA, [4]Yale Cancer Center, Yale University, New Haven, CT, USA

Background: To evaluate the impact of socioeconomic factors on survival in stage IV colorectal cancer (CRC).

Methods: The United States National Cancer Database was searched for stage IV colorectal adenocarcinomas diagnosed between 2010 and 2015. Overall survival (OS) was assessed via multivariable Cox proportional Hazards models, adjusting socioeconomic factors for potential confounders.

Results: A total of 73,685 patients with median age of 64 years were included. 54.5% of patients were male. After adjustment for potential confounders, improved OS was seen for female patients (vs. male HR = 0.95, $p < 0.001$), Caucasians (vs. African Americans HR = 0.95, $p < 0.001$) and those with higher income (63.000 vs. $<$ 38.000 USD HR = 0.92, $p < 0.001$). Independently, insurance status impacted survival with higher OS seen for patients with private insurance (vs. Medicaid HR = 0.89, $p < 0.001$; vs. Medicare HR = 0.85, $p < 0.001$). Further, OS correlated with type and location of the treating center: improved OS was evident for patients treated at academic/research centers (vs. other centers HR = 0.84, $p < 0.001$). Highest survival rates were observed in the Middle Atlantic and West South Central US state regions compared to other regions (HR = 1.18 to HR = 1.35, $p < 0.001$). The table summarizes adjusted 2-year and 5-year overall survival rates by US state region.

Table: 572P Adjusted survival rates for stage IV CRC by US state region

location	Adjusted Two-year OS	Adjusted Five-year OS
Middle Atlantic	43%	13%
West South Central	43%	15%
Mountain	38%	8%
South Atlantic	36%	8%
New England	35%	5%
Pacific	35%	8%
East North Central	34%	6%
East South Central	32%	7%
West North Central	32%	5%

Conclusions: Socioeconomic factors independently impacted survival in stage IV CRC. Improved outcomes were observed for female Caucasians with high socioeconomic status and access to academic treatment centers in certain US state regions.

573P Influence of not having children on mortality in patients with metastatic (mCRC) colorectal cancer

S. Ahmed[1], T. Baig[2], A. Zaidi[1], H. Chalchal[3], K. Haider[1], T. Asif[1], N. Iqbal[1]

[1]Oncology, Saskatoon Cancer Centre University of Saskatchewan, Saskatoon, SK, Canada, [2]Microbiology, University of Saskatchewan, Saskatoon, SK, Canada, [3]Oncology, Allan Blair Cancer Center, Regina, SK, Canada

Background: Although there is evidence that parents live longer than non-parents, prognostic effect of parenthood in cancer patients is not well established. We previously noted that palliative use of chemotherapy in patients with mCRC significantly varied in those with and without children and use of chemotherapy was 3-fold lower in patients with no children (2018 GI Cancers Symposium). In this study we examined if childless individual with mCRC have higher mortality than patients with children.

Methods: Patients with mCRC diagnosed in 2006-2010 in Saskatchewan were assessed. Cox proportional hazard multivariate analyses were performed to determine correlation between not having children and mortality.

Results: 569 patients with median age 69 yrs (IQR 59-77) and M:F was 59:41 were identified. Of 569 patients, 461 (81%) had children. Significant differences were noted between the group with children and the group with no children with respect to being married/partnered (74 vs. 32%, $p < 0.001$), performance status $\geq$2 (33 vs. 45%, $p = 0.02$), distance to travel to cancer center $>$ 100 km (45 vs. 60%, $p = 0.007$), low

albumin (70 vs. 85%, p = 0.001), anemia (68 vs. 87%, p < 0.001), and use of chemotherapy (64 vs. 31, p < 0.001 respectively. On Cox proportional multivariate analysis after adjustment for other variables, not having children (HR 1.4; 95%CI: 1.10-1.90), not having chemotherapy (3.6, 2.8-4.6), no metastasectomy (2.15, 1.60-2.91), intact primary tumor (1.91, 1.56-2.33), leukocytosis (1.35, 1.07-1.70), elevated alkaline phosphatase (1.32, 1.07-1.62), performance status ≥2 (1.30, 1.10-1.60), right colon cancer (1.28, 1.04-1.57), grade III cancer (1.28, 1.05-1.56) and stage IVb disease (1.25, 1.04-1.50) were correlated with poor survival.

Conclusions: The present study demonstrated that not having children was independently associated with an increased risk of mortality in patients with metastatic colorectal cancer. Future studies are warranted to confirm the finding and to determine underlying etiology.

574P Interim quality of life results from a real world European survey on the unmet needs of patients living with metastatic colorectal cancer (mCRC)

Z. Maravic[1], L. Wyrwicz[2], B. Karczmarek-Borowska[3], A. Horvath[4], A. Ruiz Casado[5], A. Carrato Mena[6], N. Muszbek[7], P. Rakonczai[8]

[1]Group and Project Development, EuropaColon UK, Salisbury, UK, [2]Medical Oncology, Centrum Onkologii-Instytut im. M. Sklodowskiej Curie, Warszawa, Poland, [3]Medical Oncology, Provincial Specialized Hospital in Rzeszów, Rzeszow, Poland, [4]Medical Oncology, Semmelweis University Kutvolgyi Clinical Center, Budapest, Hungary, [5]Medical Oncology, Hospital Puerta de Hierro, Majadahonda, Spain, [6]Medical Oncology, Hospital Universitario Ramon y Cajal, Madrid, Spain, [7]Modelling and Simulations, Evidera (European Headquarter), London, UK, [8]Modeling and Simulation, Evidera, Budapest, Hungary

Background: With increasing emphasis on health-related quality of life (HRQoL), EuropaColon, a European CRC patient organization, conducted a European survey on experience and HRQoL in mCRC in 12 countries. The aim is to report the interim results with the European Organization for Research and Treatment of Cancer (EORTC) quality of life questionnaire (QLQ) for Hungary (HU), Poland (PL), Serbia (RS) and Spain (ES).

Methods: After IRB approval, clinicians, nurses with partner organizations of EuropaColon recruited patients. In addition to demographics, diagnosis and treatment (reported elsewhere), the survey assessed HRQoL using EORTC QLQ-C30. Single data entry was done by EuropaColon. The QLQ-C30 global score, function- and symptom-specific scores, and the financial difficulties item were summarized by country using the "QoLR" package in R .

Results: 548 surveys were analyzed. Completion rates were high in RS, PL and HU (>95%), and lower in ES (77-79%). Place in treatment pathway varied (e.g. in HU 92.2% were undergoing, while in RS 25.6% completed treatment). Scores were consistently higher in HU and ES, with emotional function affected the most.

Table: 574P

Country	Mean score (SD)					
	Global Quality of Life	Functions				
		Physical	Role	Emotional	Cognitive	Social
HU	69.4 (20.7)	82.9 (16.3)	81.4 (23.7)	73.9 (22.5)	87.9 (19.1)	80.9 (24.6)
PL	56.1 (18.1)	70.1 (20.5)	71.9 (28.2)	67.1 (22.7)	76.7 (22.3)	67.2 (27.5)
RS	55.9 (21.1)	69.7 (19.5)	63.6 (25.7)	53.5 (28.4)	71.3 (24.6)	53.9 (26)
ES	68.1 (21.6)	84.3 (17.9)	81.8 (25.4)	76.4 (24.1)	85.4 (19.4)	77.7 (24.1)

Mean fatigue and pain symptom scores were lower in HU/ES and higher in RS/PL. This was maintained in nausea, insomnia, appetite loss, constipation, but not in dyspnea, diarrhea. Differences could be affected by the patients' place in the treatment pathway. Global health scores for RS and PL were lower, and symptom scores were higher than reported in mCRC trials.

Conclusions: mCRC has an important effect on HRQoL, which can differ among real-world mCRC patients and those in clinical trials. Variations across countries and comparisons to HRQoL in trials require further analysis.

575P Interim analysis of the non-interventional study QoLiTrap (AIO-LQ-0113) in patients with metastatic colorectal cancer (mCRC) treated with aflibercept (AFL) + FOLFIRI: Efficacy according to age group ≤65 and >65 years

R.D. Hofheinz[1], H-G. Derigs[2], G. Piringer[3], R. von Moos[4]

[1]Interdisciplinary Tumor Center, Universitätsklinikum Mannheim, Mannheim, Germany, [2]Clinic of Internal Medicine, Klinikum Frankfurt Höchst, Frankfurt A. M., Germany, [3]Palliative Medicine, Klinikum Wels-Grieskirchen GmbH, Wels, Austria, [4]Department of Oncology/Hematology, Kantonsspital Graubünden, Chur, Switzerland

Background: AFL targets VEGF-A, VEGF-B and PlGF. It is approved in combination with FOLFIRI for treatment of mCRC that is resistant to or has progressed after oxaliplatin-containing therapy.

Methods: QoLiTrap is an ongoing non-interventional study conducted in DACH region to evaluate Quality-of-life (QoL) in 1500 mCRC patients treated with AFL+FOLFIRI using the EORTC-QLQ C30 questionnaire at baseline and before every cycle.

Results: For this interim analysis according to age groups (≤ 65 and > 65 years / cut-off: 05 Dec 2017) 702 patients (mean age: 64.8 ± 9.9 yrs; 65.0% male, 50.9% with RAS mutation) who completed the baseline and at least 2 additional questionnaires were evaluated. 50% of patients each were ≤65 and >65 yrs old at therapy start. 86.3% and 85.8% of younger and older patients, respectively, had an ECOG of ≤ 1. A median of 7 cycles (range 1 – 65) was given to patients aged ≤65, patients >65 yrs received a median of 6 cycles (range 1 - 54). Mean global health scores at baseline was 55.6 for patients aged ≤65 yrs and 59.1 for patients aged >65 yrs. Mean score decreased slightly in both age groups. 48.4% of younger and 46.7% of older patients received study treatment as second line. More than 75% of patients in both age groups received prior anti-EGFR and / or bevacizumab (BEV) treatment. 89.5% of younger and 92.3% of older patients received prior palliative therapies or prior therapies during metastatic stage. Median PFS of patients pretreated with anti-EGFR or BEV only was 7.6 months (95% CI 3.7-) and 7.0 months (95% CI 5.6- 8.5), respectively, for younger patients, and 9.4 months (95% CI 5.9-) and 7.6 months (95% CI 5.8- 9.0), respectively, for older patients. Regarding evaluable patients pretreated with anti-EGFR and/or BEV 11.2% and 10.4% of age group ≤65 and >65 yrs, respectively, exhibited CR+PR.

Conclusions: This interim analysis showed that there are no obvious differences between age groups regarding previous treatment and efficacy in mCRC patients treated with AFL+FOLFIRI under routine conditions. Toxicity was in line with the known safety profile of the study medication. Supported by Sanofi-Aventis Deutschland GmbH.

576P Inhibitory effect of a synthetic bioresorbable adhesion membrane on small bowel obstruction (SBO) in patients undergoing elective surgery for colon cancer: A randomized controlled trial

G. Saito, S. Sadahiro, H. Miyakita, K. Okada, A. Tanaka, T. Suzuki

Surgery, Tokai University School of Medicine, Isehara, Japan

Background: Intraabdominal adhesion may occur in about 70% to 100% after abdominal surgery and is one of the most common causes of SBO. Seprafilm®, a synthetic bioresorbable adhesion membrane, has been reported not to decrease the incidence of SBO, but to significantly decrease the reoperation in patients with inflammatory bowel disease. However, the inhibitory effect of Seprafilm® on SBO in colon cancer remains unclear. We therefore conducted a randomized study to investigate the inhibitory effect of Seprafilm® on SBO in patients with colon cancer.

Methods: The study group comprised 345 patients (pts) with colon cancer who underwent curative surgery electively from 2006 through 2013. Seprafilm® were placed under the midline incision before closing the abdomen in 166 pts (Seprafilm® group), and no sheet of Seprafilm® was placed in the remaining 179 pts (control group). We compared the incidence of SBO and adhesive findings at the time of reoperation. SBO was defined as bowel obstruction which need decompression after readmission. The median follow-up period in the surviving patients was 66.3 months.

Results: Patient characteristics did not differ between the groups. SBO developed in 13 pts (7.8%) in the Seprafilm® group and 19 pts (10.6%) in the control group. SBO occurred within 30 days after surgery in 3 pts (23.1%) in the Seprafilm® group and 8 pts (42.1%) in the control group. The incidences tended to be higher in the control group, but the difference was not significant. Reoperation was required by 5 pts (38.5%) in the Seprafilm® group and 7 pts (36.8%) in the control group, with no

significant difference. Among the pts who required surgery, SBO was caused by adhesion to the midline incision in 1 patient (7.7%) in the Seprafilm® group and in 2 pts (10.5%) in the control group. This difference was also not significant. Multivariate analysis showed that a history of laparotomy was only an independent risk factor for SBO and the use of Seprafilm® was unrelated to the incidence of SBO.

Conclusions: A midline incision was an infrequent cause of SBO in pts who underwent surgery for colon cancer. It was unclear whether the placement of Seprafilm® under the midline incision can decrease SBO.

577P Short- and long-term outcomes of high tie versus low tie with lymph node dissection around the inferior mesenteric artery in sigmoid colon or rectal cancer surgery

X. Li

Colorectal Surgery, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Controversy is ongoing on the level of inferior mesenteric artery (IMA) ligation in sigmoid colon or rectal cancer surgery. In the present study, we aimed to reevaluate the mortality and morbidity especially for anastomotic leakage of low tie combined with lymph node dissection (LT+LND) around the inferior mesenteric artery compared with high tie (HT) in sigmoid colon or rectal cancer surgery using propensity score matching (PSM) analyses.

Methods: A total of 1895 patients with sigmoid colon or rectal cancer who underwent curative surgery from 2012 to 2017 in Fudan University Shanghai Cancer Center were recruited into this study. After PSM, LT+LND-and HT-matched patients were comparable. Ultimately, 277 patients were ligated at the origin of IMA and 277 patients experienced the preservation of left colic artery plus lymph node dissection around IMA. The survival outcomes and clinicopathological characteristics were reviewed from the database retrospectively.

Results: The median follow-up period was 13.7 months (range from 1 to 69 months). There were no differences in terms of postoperative complication rate and overall survival (OS) as well as disease-free survival (DFS). In the HT group and LT+LND group, the 3-year OS rates were 90.8% and 90.0%, respectively, whereas the 3-year DFS rates were 78.7% and 73.9%, respectively. Further, LT+LND was associated with prolonged operation time and less blood loss.

Conclusions: LT+LND seems to be less invasive and is not inferior to HT from the point of oncological safety. Further prospective studies and long-term follow-up data are needed.

578P Mesenteric vs. antimesenteric colorectal cancer: A single center study

K.H. Lee[1], W.R. Kim[2], J.W. Kim[3]

[1]Department of Surgery, Bundang Cha Medical Center, Seongnam, Republic of Korea, [2]Surgery, CHA Bundang Medical Center, Seongnam, Republic of Korea, [3]Surgery, Cha University, Gyunggi, Republic of Korea

Background: We investigated the possible correlation between the prognosis and circumferential location of the tumor according to the cancer involvement on the mesenteric side. This study is based on the hypothesis that mesenteric tumors, which are closer to blood and lymphatic vessels, could spread more aggressively and rapidly compared to the antimesenteric tumors.

Methods: We reviewed the retrospectively collected data of 251 patients treated during the period of October 2008 to May 2012. 162 patients with mesenteric side involving tumors were included in the mesenteric group, and 89 patients with antimesenteric tumors were included in the antimesenteric group. The analyzed information included age, gender, location, size of the main lesion, extent of lymph node metastasis, pathologic features, metastasis, complication, TNM stage, recurrence and 5-year survival. We retrospectively studied the survival of patients by examining of our 5-year follow-up archive. Data were analyzed using Pearson-Chi square test and Kaplan-Meier curve analysis.

Results: There was no statistical difference between the two groups regarding age, gender, location, extent of lymph node metastasis, pathologic features, complication, and TNM stage. The size of the main tumor was statistically larger in the mesenteric group compared to the antimesenteric group. (P value = 0.03) The mesenteric group showed statistically higher rate of distant metastasis and carcinomatosis than the antimesenteric group. (P value = 0.02) In addition, the mesenteric group showed lower 5-year survival rate than the antimesenteric group.

Conclusions: In conclusion, mesenteric tumors have significantly larger size of main tumor, higher rate of distant metastasis and worse 5-year survival than antimesenteric tumors. This difference implies that colorectal cancers should be regarded differently according to the circumferential location and more careful follow up is necessary with mesenteric side involving colorectal cancer patients.

579P The SLICE study: The prognostic role of visceral fat in metastatic colorectal cancer

D. Basile[1], C. Lisanti[1], M. Borghi[2], M. Bartoletti[1], L. Gerratana[1], L. Bortot[1], G. Pelizzari[1], C. Corvaja[1], E. Ongaro[1], S.K. Garattini[1], V. Fanotto[1], A. Parnofiello[1], F. Cortiula[1], M. Cattaneo[1], V.J. Andreotti[1], E. Bertoli[1], M. Guardascione[3], G. Miolo[4], F. Puglisi[5], A. Buonadonna[4]

[1]Department of Medicine (DAME), University of Udine, Udine, Italy, [2]Intensive Care Unit, CRO National Cancer Institute, Aviano, Italy, [3]Clinical and Experimental Pharmacology, CRO National Cancer Institute, Aviano, Italy, [4]Department of Medical Oncology and Cancer Prevention, CRO National Cancer Institute, Aviano, Italy, [5]University of Udine, Udine, Department of Medical Oncology and Cancer Prevention, CRO National Cancer Institute, Aviano, Italy

Background: Body composition, more specially the excess of body weight, was established as a risk factor of the colorectal cancer initiation and progression. Aim of this study was to investigate the prognostic role of adiposity, especially visceral fat (VAT), in metastatic colorectal cancer (MCRC).

Methods: This retrospective study analyzed a consecutive cohort of 71 patients (pts) with MCRC treated between 2013 and 2017 at the Oncology Department of Aviano National Cancer Institute (Italy). VAT area was measured as cross-sectional (cm^2) area at the L3 level divided by the square of the height (m^2). A ROC analysis was performed to define a threshold capable to identify distinct prognostic categories of patients according to VAT. Subsequently, the value of VAT in predicting overall survival (OS) and progression free survival (PFS) was evaluated with uni- and multivariate Cox regression analyses. Survival outcomes were estimated with Kaplan-Meier curves.

Results: Before first line therapy, 19 pts (27%) were aged>70, 14 pts (20%) had a right tumor, 21 pts (30%) a left tumor and 35 pts (50%) a rectal one. Of note, 59 pts (83%) underwent primitive tumor resection and 24 pts (33%) received metastasectomy. Interestingly, 40 pts (56%) had a body mass index (BMI)>25 and 42 (59%) had median VAT of 51.94. LDH level > =480 UI/L was recorded in 12 pts (27%) reflecting the inflammatory response. The obtained cut-off for VAT was 44. Median OS was 30.97 months. At univariate analysis, older age (HR 2.46, p = 0.013), primary tumor resection (HR 0.40, p = 0.029), VAT>44 (HR 2.85, p = 0.011), metastasectomy (HR 0.22, p = 0.005), were significantly associated with OS. By multivariate analysis, only VAT>44 (HR2.64; p = 0.030) was significantly associated with OS. Conversely, VAT showed no prognostic impact in terms of PFS.

Conclusions: This exploratory study supported the prognostic role of adiposity evaluation in patients with MCRC. In particular, high values of VAT were predictors of worse outcome. These encouraging preliminary data merit to be validated through prospective investigations.

580P Safety and outcomes of self-expandable metal stents (SEMS) versus emergency surgery for acute colonic obstruction in metastatic colon cancer patients treated with bevacizumab (BV)

V.E. Pacheco-Barcia[1], R. Mondéjar Solís[2], O. Martínez-Sáez[3], F. Longo[4], E. Bermejo[5], J.A. Moreno[6], C. Marin[5], A. Correa[5], R. Maqueda[5], J. Rogado[1], A. García de Paredes[7], E. Rodriguez de Santiago[7], V. Pachón Olmos[3], R. Ferreiro Monteagudo[3], M. Rodriguez Garrote[3], A. Carrato Mena[4], O. Donnay[1], E. Martin Perez[5], C. Santander[6], R. Colomer Bosch[1]

[1]Medical Oncology- Instituto de Investigación Sanitaria La Princesa, Hospital Universitario de La Princesa, Madrid, Spain, [2]Medical Oncology, Hospital Universitario de La Princesa, Madrid, Spain, [3]Medical Oncology, Hospital Universitario Ramón y Cajal, Madrid, Spain, [4]Medical Oncology, Hospital Universitario Ramon y Cajal, Madrid, Spain, [5]Surgical Oncology, Hospital Universitario La Princesa, Madrid, Spain, [6]Gastroenterology, Hospital Universitario de La Princesa, Madrid, Spain, [7]Gastroenterology, Hospital Universitario Ramon y Cajal, Madrid, Spain

Background: Colorectal cancer presents with malignant bowel obstruction in about 10% of cases. SEMS can be an alternative for immediate surgery but long-term data is limited regarding clinical outcomes and safety of BV in this subset of patients.

Methods: We performed a retrospective review of 2850 cases of colon cancer from January 2012 to October 2017, and identified metastatic patients with malignant bowel obstruction initially treated with SEMS or emergency surgery. Differences in procedure-related morbidity and overall survival (OS) were assessed.

Results: We selected 119 cases, 79 treated with SEMS and 40 with surgery. Median age: 76. Median follow-up time: 11 months. No differences in sidedness or RAS status between

cohorts. SEMS and surgery had a similar rate of complications (35.5% vs 32.5%, p = 0.45) and showed longer time to complications (18m vs 1m, p = 0.004). In patients treated with BV, complications were similar in SEMS and surgery (40% vs 31%, RR 1.28, p = 0.5) and perforation was also similar (13% vs 19%, RR 1.46, p = 0.4). The incidence of perforation in the SEMS group was similar between BV and chemotherapy alone (13% vs 9%, p = 0.2). In patients without systemic therapy, complications were higher in the surgery group compared to SEMS (50% vs 25%, RR 1.34, p = 0.1), also the incidence of perforation (20% vs 6%, RR 1.57, p = 0.2), but not statistically significant. SEMS and surgery showed similar OS (14m vs 15m, p = 0.5). Treatment with BV increased OS in SEMS group (18 months vs 7 months, p = 0.001) and surgery group (20 months vs 4 months, p = 0.001) compared to patients without subsequent medical treatment. In the multivariate analysis, patients treated with subsequent medical treatment showed a statistically significant longer OS [HR 0.43, CI95% 0.19-0.94, p = 0.02] and patients who had complications, showed a shorter OS (HR 2.45, CI95% 1.17-5.12, p = 0.01).

Conclusions: Bevacizumab-based therapy increased survival in metastatic colon cancer and, was not associated with a higher risk of perforation in patients with SEMS. Emergency surgery and SEMS showed a similar incidence of complications and perforations, with no differences between both strategies in patients treated with BV.

581P Metronomic capecitabine plus cyclophosphamide in unresectable or relapsed pseudomyxoma peritonei

A. Raimondi[1], S. Corallo[1], M. Niger[1], M. Antista[1], G. Randon[1], F. Morano[1], C. Cremolini[2], M. Di Bartolomeo[1], F.G.M. de Braud[1], F. Pietrantonio[1]

[1]Medical Oncology Department, Istituto Nazionale dei Tumori di Milano - Fondazione IRCCS, Milan, Italy, [2]Polo Oncologico, Azienda Ospedaliera Universitaria S. Chiara, Pisa, Italy

Background: The standard treatment of Pseudomyxoma Peritonei (PMP) is cytoreductive surgery (CRS) with hyperthermic intraperitoneal chemotherapy (HIPEC). No consensus was reached on treatment of unresectable or recurrent disease. PMP is considered chemoresistant for its low mitotic index but non-randomized series showed promising results with regimens for gastrointestinal tumors. Metronomic schedules may be preferred for their antiangiogenic and immunomodulatory activity.

Methods: We conducted a single center prospective single arm trial. Inclusion criteria were histologically confirmed PMP, unresectable or relapsed after CRS/HIPEC, in progression to surgery or previous treatments. Patients received continuous metronomic capecitabine (625 mg/sqm b.i.d.) plus cyclophosphamide (50 mg/day) until progressive disease, unacceptable toxicity or consent withdrawal. The primary endpoint was progression free survival (PFS); secondary endpoints were disease control rate (DCR), overall survival (OS) and safety profile. Ion Torrent® next generation sequencing technology (Hot-spot Cancer Panel) was used to characterize molecular profile.

Results: 23 consecutive patients were enrolled from April 2015 to October 2017. At a median follow up of 13.5 months, median PFS was 9.5 months and 1-year OS rate 73.7% (95% CI 47.3% - 88.3%). No partial or complete responses were observed but DCR was 74% and 22% patients achieved a prolonged disease stability (>13 months). A significant tumor markers reduction (>20%) was seen in 43% patients for CA19.9, 22% for CA125 and 39% for CEA. The safety profile was manageable: 78% patients reported G1/2 drug related adverse events, only 17% G3 and none G4/5. As expected, the main toxicities were anemia, neutropenia, nausea, diarrhea, fatigue and hand foot syndrome. Only 17% patients required capecitabine dose reduction. Molecular profile was available in 15/23 cases: KRAS mutations were found in all cases and GNAS mutations in 47%.

Conclusions: Metronomic capecitabine plus cyclophosphamide is an active and well tolerated regimen in unresectable or recurrent PMP, with a safety profile comparing favorably with historical data. Further studies are needed to identify predictive biomarkers for novel treatment strategies.

582P Utility of carcinoembryonic antigen (CEA) in appendiceal carcinoma

A. Karippot[1], S. Groover[2], J. Ai[3], S. Nambiar[4]

[1]Hematology/Oncology, Cancer Treatment Centers of America, Tulsa, OK, USA, [2]Biochemistry & Microbiology, Oklahoma State University Center for Health Sciences, Tulsa, OK, USA, [3]Oncology, Cancer Treatment Centers of America, Tulsa, OK, USA, [4]Hematology/Oncology, Cancer Treatment Centers of America, Tulsa, OK, USA

Background: Primary cancers of the appendix are rare and are frequently diagnosed after surgery for appendicitis. There is no designated staging system or evidence-based guideline for treatment. The staging and treatment of appendiceal adenocarcinoma mirror that of colon cancer. Elevated serum carcinoembryonic antigen (CEA) has been strongly associated with poor prognosis in colorectal cancer, so our study aims to first compare appendiceal cancers with tumors of the ascending colon, and then evaluate the prognostic value of CEA in appendiceal cancers.

Methods: We performed a retrospective analysis of all patients (n = 2,614) diagnosed with appendiceal adenocarcinoma from 2004 to 2014 in the National Cancer Institute's Surveillance, Epidemiology and End Results database. All appendiceal cancer patients were designated as either elevated (C1) or normal (C0) based on the pretreatment serum CEA level. We performed univariate and multivariate analyses to compare appendiceal cancer characteristics to tumors of the ascending colon (n = 73,057), then identified independent factors associated with CEA elevation in appendiceal cancers.

Results: Upon multivariate analysis, compared to tumors of the ascending colon, appendiceal cancers are significantly more likely (P < 0.05) to have higher stage at diagnosis (OR 2.95, 1.19, 6.56 for stage 2, 3, and 4). They are less likely to have the CEA test ordered (OR 0.31). Appendiceal cancers are being diagnosed more in recent years (OR 1.90, 2.11, 1.86 for years 2012, 2013, and 2014) while colon cancer incidence is remaining the same. Compared to C0 appendiceal cancers, C1 cancers are more likely to have higher tumor grade (OR 6.56 and 5.50 for grade 2 and 3) and higher overall stage (OR 1.96, 2.44, 9.60 for stage 2, 3, and 4).

Conclusions: Though appendiceal cancers are rare, they are increasing in incidence. They are less likely than colorectal cancers to have the CEA test ordered despite CEA elevation odds ratio having no significant difference between the two cancers. Elevated CEA in appendiceal cancers is associated with later stage and higher grade. CEA levels should be checked in all appendiceal cancer patients to assist in the development of treatment strategies.

Background: The risk of venous thromboembolic events (VTE) during adjuvant chemotherapy for colorectal cancer (CRC) is unknown. We aim to evaluate if the Khorana score (KS) can predict this risk of VTEs and overall survival (OS) in a randomised phase III, noninferiority, open-label trial of different durations of adjuvant chemotherapy in resected stage II-III CRC.

Methods: Data were obtained using a TOSCA ['Randomised trial investigating the role of FOLFOX-4 or XELOX (three versus six months) regimen duration as adjuvant therapy for patients with stage II/III colon cancer'] study. A logistic regression model was used to test the associations between the risk of VTEs and the KS. The results are expressed as odds ratios (OR) with 95% confidence intervals (95% CI). To assess the effect of the KS on OS, multivariate analyses using Cox regression models was performed. The results are expressed as hazard ratios (HR) with 95% CI.

Results: Among n = 1,380 CRC patients with available data, the VTE risk (n = 72 events: 5.2%) was similar in the three- and six-month duration arms (5.5% vs. 4.9%) with 0.2% of patients belonging to the high-risk KS group. Rates of VTE were similar in the low- and intermediate-risk groups (4.8% vs. 6.4%). KS did not represent an independent predictive factor for VTE risk, with a low positive predictive value and accuracy (6.4% and 74.1%). Chemotherapy duration was not associated with VTE risk. Also, KS was not associated with OS in multivariate analysis (HR = 0.92, 95% CI, 0.63–1.36; P = 0.68).

Conclusions: The use of the KS was not a predictor of VTEs in a low–moderate thromboembolic risk population as CRC. These data did not support the use of KS to estimate the occurrence of VTE during adjuvant chemotherapy and suggest that other assessment risk tools must be evaluated.

584P The clinical utility of early follow-up computed tomography in patients with stage II-III colorectal cancer receiving oxaliplatin-based chemotherapy

Y. Lee, S.Y. Kim, J.E. Kim, Y.S. Hong, T.W. Kim

Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea

Background: Surveillance after curative resection for colorectal cancer with computed tomography (CT) of abdomen, pelvis and chest is a standard practice, but the optimal interval of surveillance CT is unclear. Usually recommended interval is 6 to 12 months, but in South Korea, earlier follow-up CT during adjuvant chemotherapy for stage II or III disease is a common practice. This study aimed to show clinical utility of early follow-up CT (EFCT) within 6 months after surgery.

Methods: The medical records of patients with stage II or III colorectal cancer who received oxaliplatin-based adjuvant chemotherapy between January 2011 and December 2014 in Asan Medical Center were retrospectively reviewed. Those who started adjuvant chemotherapy beyond 3 months after surgery and who were dead or lost to follow-up before 6 months after surgery were excluded. Information on the results of EFCT and subsequent treatment was obtained.

Results: In a total of 678 patients, 597 (88%) underwent EFCT. EFCT was associated with advanced stage: 78% (74/95) of stage II, 88% (317/359) of low-risk stage III (pT1-3 and N1), and 92% (206/224) of high-risk stage III (pT4 or N2) checked EFCT ($p = 0.002$). EFCT revealed recurrence in 6 (1%); 0 of stage II, 1 (0.3%) of low-risk stage III, and 5 (2.4%) of high-risk stage III ($p = 0.132$). Only 1 of 6 patients with recurrence underwent surgical resection of curative intent. There were no differences in overall survival (OS), disease-free survival (DFS), and cumulative occurrence of local treatment for DFS events according to undergoing EFCT with adjustment to age, gender, and stage.

Conclusions: Early recurrence within 6 months after surgery occurred in 1% of patients who were treated with oxaliplatin-based adjuvant chemotherapy, mostly in high-risk stage III disease. The practice of EFCT was associated with advanced stage but did not affect OS, DFS, or cumulative occurrence of local treatment. Clinical utility of EFCT seems to be low and should be discouraged especially in stage II or low-risk stage III disease.

585P Clinical benefit of whole genome and transcriptome analysis (WGTA) in metastatic colorectal cancer (MCRC): Results from the personalized oncogenomics program (POG)

S.L. Liu[1], J. Loree[1], D. Renouf[1], M. Jones[2], S. Yip[2], M. Marra[3], S. Jones[3], J. Nelson[3], J. Laskin[1], H. Lim[1], S. Gill[1]

[1]Medical Oncology, British Columbia Cancer Agency, Vancouver, BC, Canada, [2]Genomics, BC Genome Science Centre, Vancouver, BC, Canada, [3]Genome Science Centre, BC Cancer Agency, Vancouver, BC, Canada

Background: Standard guidelines recommend mutation testing for KRAS, NRAS and BRAF in MCRC. POG at BC Cancer is an investigational project that performs WGTA to identify potential hypothetical actionable biomarkers. We aimed to determine its clinical significance compared to standard sequencing panels by analyzing the prevalence of actionable variants and their impact on treatment decisions.

Methods: We analyzed 69 POG MCRC patients (pts) and summarized their WGTA results to identify germline and somatic coding variants, copy number alterations, structural alterations and gene expression outliers. Actionable items were defined as variants that could direct therapy with an investigational or approved agent, and were classified as either standard (found in local sequencing panel- BC Oncopanel) or expanded (not in Oncopanel).

Results: 74% of pts received 2 or more prior lines of chemotherapy. 1 pt died before biopsy was made available and 1 pt had an unsuccessful biopsy. Remaining analysis of 67 pts revealed 49 (73%) pts with actionable alterations, of which 43% consisted of mutation changes, 40% expression changes, 14% copy number variants, and 3% high mutational burden or HRD. Most common standard alterations (54%) were mutations in TP53, KRAS, BRAF, PIK3CA and most common expanded items (46%) were high expression of FGFR1/3, FLT1/3, and VEGFA/B. Among these, 13 (27%) pts had alterations that led to standard chemotherapy or anti-EGFR based treatment, and 7 (14%) pts had a variant that resulted in non-standard therapies. Of those, only irbesartan, targeting the FOS-JUN pathway, resulted in a meaningful response duration of 28 months, while the remaining had an average PFS of 1.7 month. 29 (59%) pts did not receive therapy outlined in POG analysis due to lack of access for the target drug ($n = 15$), poor performance status ($n = 7$), and patient or physician preference ($n = 7$).

Conclusions: WGTA in MCRC provided additional understanding of tumor biology, with high rates of expression changes not otherwise captured in standard sequencing panel. However, at the present time, there is limited additional clinical therapeutic benefit in comparison. Future development is needed and ongoing.

586P Sequencing of KRAS and NRAS in 1501 colorectal carcinomas reveals significant share of mutations, which are not included in common diagnostic kits

E.N. Imyanitov[1], N.V. Mitiushkina[1], E.S. Kuligina[1], M. Holmatov[1], G.A. Yanus[1], I. Demidova[2], T. Kekeeva[3], M. Gordiev[4], E. Kharitonova[5], I. Tsimafeyeu[5], S. Tjulandin[6]

[1]Department of Tumor Growth Biology, N.N. Petrov Institute of Oncology, St. Petersburg, Russian Federation, [2]Laboratory of Molecular Genetics, Moscow City Oncology Hospital No. 62, Moscow, Russian Federation, [3]Laboratory of Epigenetics, Research Centre for Medical Genetics, Moscow, Russian Federation, [4]Laboratory of Molecular Genetics, Tatarstan Cancer Center, Kazan, Russian Federation, [5]Head Office, Russian Society of Clinical Oncology, Moscow, Russian Federation, [6]Department of Clinical Pharmacology and Chemotherapy, N. N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation

Background: KRAS and NRAS mutations render resistance to EGFR therapeutic antibodies. Some data indicate that erroneous administration of cetuximab or panitumumab to patients with RAS-mutated colorectal cancer (CRC) may even accelerate tumour growth.

Methods: 1501 CRC patients were included in the analysis. High-resolution melting (HRM) was performed for the initial screening of KRAS and NRAS mutations in exons 2, 3 and 4. Common RAS mutations were detected by allele-specific PCR, then the remaining samples were analysed by pyrosequencing.

Results: RAS mutations were identified in 756 (50.4%) CRCs. KRAS and NRAS alterations were generally mutually exclusive, with the exception of 2 CRCs carrying lesions in both oncogenes. Distribution or RAS mutations did not show correlation with age or gender. Significant number of the revealed mutations are not included in the spectrum of substitutions covered by commercial kits. For 681 identified KRAS mutations, the following coverage is expected according to manufacturer's brochures: Therascreen (Qiagen): 592 (86.9%); cobas® (Roche, US version): 615 (90.3%); AmoyDx: 665 (97.7%); KRAS StripAssay® (ViennaLab): 600 (88.1%); KRAS XL StripAssay® (ViennaLab): 671 (98.5%). For 77 detected NRAS mutations, these estimates would be 73 (94.8%) for AmoyDx and 75 (97.4%) for NRAS XL StripAssay® (ViennaLab).

Conclusions: Clinically significant share of KRAS and NRAS mutations is likely to be missed by conventional mutation-specific diagnostic kits. This limitation has to be considered while defining diagnostic standards for CRC therapy.

587P Patterns of care and of biomolecular characterization of right, transverse, and left colorectal cancer from real-life evidence in Asia Pacific and European countries

E. Mari[1], S. Mpima[2], F. Guglielmetti[1], P. Nasuti[2]

[1]Oncology Medical Strategy and Science, IQVIA Milan, Italy, [2]Real World and Analytics Solutions, IQVIA, London, UK

Background: Colorectal cancer (CRC) is biologically heterogeneous with 4 distinct consensus molecular subtypes (CMSs) leading to different prognosis and different response to anti-VEGF and anti-EGFR agents, and different CMSs profiles in Right, Transverse (Trv), and Left location of primary CRC. We aim at describing the patterns of care by the location of primary CRC to provide the baseline reference for future research.

Methods: Anonymized CRC patients-level data collected through a large web-based survey between 9217 patients in EU5 (France, Germany, Italy, Spain & UK) and APAC (China, Japan & S. Korea) collected between January – December 2017.

Results: Data from overall 9217 (5041 advanced) pts from EU5 and APAC was analyzed. Left, Right, and Trv CRC location proportion was similar across regions (Left: 52% all pts, 53% EU5, 50% APAC; Right: 39% all pts, 39% EU5, 40% APAC; Trv: 9% all pts, 8% EU5, 10% APAC). Slightly more pts with liver metastases was reported for Left location of CRC (42% all pts, 44% EU5, 38% APAC) than Right (40% all pts, 43% EU5, 31% APAC) or Trv (37% all pts, 40% EU5, 31% APAC). The incidence of biomolecular alterations was: KRAS mutant: Left 38%, Right 45%, Trv 43%; NRAS mutant: Left 27%, Right 32%, Trv 32%; BRAF mutant: Left 7%, Right 12%, Trv 12%; High MSI: Left 16%, Right 22%, Trv 25%; PD-1/PDL-1/2 positive: Left 17%, Right 13%, Trv 25% (PD-1/PDL-1/2 testing on 225/9217 pts, 2,4%). More Bevacizumab based treatments are used for primary Right location, and more anti-EGFR based therapy for

primary Left location. The use of Immunotherapy was minimal, with these pts tested for either MSI or PD-1/L1 expressed.

Table: 587P

Treatments	LEFT			RIGHT			TRANSVERSE		
	Total %	EU5 %	APAC %	Total %	EU5 %	APAC %	Total %	EU5 %	APAC %
Bevacizumab based	17	17	18	22	22	20	16	16	19
Anti EGFR based	14	16	7	8	9	6	11	12	5
Immunotherapy based	0,04	0,03	0,10	0,03	0,04	–	0,12	0,17	–

Conclusions: This real-world data currently highlights slight but not marked differences in the management of disease in the Left, Right, and Transverse primary location of CRC. Over time we anticipate that differences will arise with primary location of CRC being increasingly considered for the clinical management of CRC.

588P The role of primary tumour location in the recurrence rate of metachronous metastasis of colon cancer

M. Rimini[1], C. Bardasi[2], F. Gelsomino[3], K. Andrikou[3], C. Santini[2], G. Orsi[4], M. Salati[5], M.L. Riggi[4], S. Pipitone[6], S. Cascinu[7], A. Spallanzani[3]

[1]Modena Cancer Center, Department of Oncology/Hematology, University of Modena, Azienda Ospedaliero - Universitaria Policlinico di Modena, Modena, Italy, [2]Modena Cancer Center, Department of Oncology/Hematology, University of Modena and Reggio Emilia, Modena, Italy, [3]Medical Oncology, University Hospital of Modena, Modena, Italy, [4]Department of Oncology/Hematology, University of Modena and Reggio Emilia, Modena Cancer Center, Modena, Italy, [5]Modena Cancer Center, Department of Oncology/Hematology, Azienda Ospedaliero - Universitaria Policlinico di Modena, Modena, Italy, [6]Dipartimento di Oncologia ed Ematologia, Azienda Ospedaliero - Universitaria Policlinico di Modena, Modena, Italy, [7]Oncology, Azienda Ospedaliero - Universitaria Policlinico di Modena, Modena, Italy

Background: Recent studies suggest that primary tumour location (PTL) has a prognostic value in patients (pts) with metastatic colorectal cancer (CRC), while its role in early stage disease remains unclear. The aim of this analysis is to investigate the relationship between PTL and the development of metachronous metastasis.

Methods: We performed a population-based study from Modena Cancer Registry collecting data of patients (pts) with early stage disease (stage I, II, III) who underwent surgery from 1995 to 2010. We hypothesized a potential impact of PTL on the postoperative recurrence rate. Fisher's exact test, univariate and multivariate Cox regression analysis were performed.

Results: During the study period, 1570 pts with left-sided colon cancer (LCC) and 841 pts with right-sided colon cancer (RCC) were registered. In the entire cohort, 268 of 1576 pts (17%) with LCC and 100 of 841 pts (11.2 %) with RCC developed metachronous metastasis, for a total of 368 of 2411 pts (15%). Comparing LCC and RCC clinical and pathological status we found no statistically difference in lymph-node status ($p = 0.737$) but an increasing rate of G3 cancers in RCC vs LCC ($p = 0.010$). Median overall survival (OS) from early stage disease diagnosis for LCC patients was 45 months versus 35 months for RCC patients, with no significant difference in relapse free survival between the two groups (23.8 Vs 23.0 months). When relapsed, time to death resulted to be significantly longer in LCC group than in RCC group (14.7 vs 6.3 months; HR 1.46, 95% C.I. 1,16-1,86; p 0,001). In the multivariate Cox regression analysis adjusted for grading and stage at diagnosis, we confirmed a statistically significant impact of the primary tumour sidedness on OS in the relapsed setting (HR 1.48, 95% C.I: 1.15-1.89, $p = 0.001$).

Conclusions: In accordance to literature, our registry data confirm the prognostic role of PTL in advanced colorectal cancers: in particular, right-sided tumours have low recurrence rate but poor prognosis once relapsed. Other investigations are necessary to better understand the substantial heterogeneity within the molecular biology of RCC and LCC in order to provide a better post-operative surveillance and to select the most effective treatment strategies after relapse.

589P The prognostic value of KRAS, NRAS, BRAF and DNA mismatch repair (MMR) status in left- and right-sided metastatic colorectal cancer (mCRC): A Belgian population-based study

K. Janssens[1], G. van Camp[2], K. Op de Beeck[3], E. Fransen[4], F. Calay[5], N. van Damme[5], M. Peeters[6]

[1]Internal Medicine, University of Antwerp, Antwerp, Belgium, [2]Medical Genetics, U.Z.A. University Hospital Antwerp, Edegem, Belgium, [3]Center of Oncological Research (CORE), University of Antwerp, Edegem, Belgium, [4]StatUa, University of Antwerp, Edegem, Belgium, [5]Belgian Cancer Registry, Sint-Joost-ten-Node, Belgium, [6]Medical Oncology, U.Z.A. University Hospital Antwerp, Edegem, Belgium

Background: In recent years, various studies have convincingly shown that mCRC patients with left-sided primaries have a significantly better prognosis than those with right-sided tumors. More research is required to identify the biomarkers that cause this difference in survival. Furthermore, these conclusions are mostly based on data of clinical trials and therefore selected patients. Confirmation in population-based studies is necessary. Therefore, the aim of current study is to compare the impact of biomarkers on survival rates in left- and right-sided mCRC in the (non-selected) Belgian population.

Methods: In Belgium, data on patient and tumor characteristics of all new diagnosed cancers are collected in the Belgian Cancer Registry. A random sample of 1035 patients diagnosed with mCRC in 2014 was included in our analysis. We obtained information on age, sex, primary tumor location, biomarker data (MMR status and BRAF, KRAS and NRAS mutational status) and survival. We constructed a logistic regression model, using location, age, gender and biomarkers as independent variables and survival as dependent variable.

Results: After exclusion of 177 patients with a second tumor, the study included 858 mCRC patients: 268 (31.24%) with right-sided mCRC, 352 (41.03%) with left-sided mCRC, 212 (24.71%) with rectal cancer and 26 (2.03%) with an overlapping lesion or unknown localization. KRAS and BRAF mutations were more frequently observed in right-sided tumors compared to left-sided tumors, whereas NRAS mutations were more frequently observed in left-sided CRC compared to right-sided CRC. Microsatellite instability (MSI)-high tumors were more frequently observed on the right side of the colon. Detailed overall survival data according to tumor location and biomarker status will be available at the congress.

Conclusions: We present the survival data of 1035 Belgian mCRC patients according to age, sex, tumor location and biomarker status. Currently, we can conclude that in Belgian patients left-sided mCRC has a better prognosis than right-sided mCRC, regardless of biomarkers status.

590P Increase in tumor-infiltrating FoxP3-positive regulatory T cells in left-sided colorectal cancer tissues after preoperative oral uracil and tegafur/leucovorin chemotherapy

S. Sadahiro[1], T. Suzuki[1], A. Tanaka[1], K. Okada[1], G. Saito[1], H. Miyakita[1], H. Kajiwara[2], H. Nagase[3]

[1]Surgery, Tokai University School of Medicine, Isehara, Japan, [2]Pathology, Tokai University School of Medicine, Isehara, Japan, [3]Applied Pharmacology Lab., Taiho Pharmaceutical Co., Ltd, Tokushima, Japan

Background: Oral uracil and tegafur (UFT)/leucovorin (LV) are widely used as a standard adjuvant chemotherapy (CT) for colorectal cancer (CRC). Immunotherapy (IT) such as pembrolizumab are being approved and developed for the treatment of CRC with high microsatellite instability which is specific to right-sided CRC. We previously showed that the increases in the gene expressions of the IT targets, CTLA4 and LAG3, after UFT/LV CT were specific to left-sided CRC (ESMO2017). In this study, we examined the amount of tumor infiltrating lymphocytes (TILs) and the subtype of TILs in tumor tissues after and without UFT/LV CT.

Methods: In 90 patients with CRC, UFT (300 mg/m^2/day) and LV (75 mg/day) were administered for 2 weeks before surgery (UFT/LV group), and in the other 170 patients with CRC, no CT was treated before surgery (control group). The amounts of TILs were quantitatively evaluated using HE-stained tumor tissue. The subtypes of TILs were evaluated by immunohistochemical analyses (IHA) of the surface markers of lymphocytes (CD3, CD4, CD8 and FoxP3). The patients were divided into low and high groups of the expressions of the markers using the appropriate cutoff values.

Results: The rate of TIL-high patients in UFT/LV group was significantly higher than in control group (34.4% vs. 15.3%, $p = 0.0008$). In IHA of TILs, the rate of FoxP3-high patients in UFT/LV group was significantly higher than in control group (41.1% vs. 22.4%, $p = 0.0024$). No differences were observed in other lymphocytic markers, CD3, CD4, and CD8. In left-sided tumors, the rates of TIL- and FoxP3-high patients in UFT/LV group were significantly higher than in control group (45.8% vs. 14.3%, $p < 0.0001$ and 43.8% vs. 20.9%, $p = 0.0060$, respectively). In right-sided tumors, there were no differences in both groups.

Conclusions: The increases in TILs, especially FoxP3-positive regulatory T cells, after UFT/LV CT may be specific to left-sided CRC, suggesting that the combination therapy of UFT/LV and immune checkpoint inhibitors or the sequential therapy of immune

checkpoint inhibitors followed by UFT/LV can be useful for patients with left-sided CRC.

591P Comparing metastatic (M) young onset (YO) colorectal cancer (CRC) with average onset (AO): Do they differ clinically and genetically?

G. Dos Santos Fernandes[1], W. Chatila[1], R. Yaeger[1], R. Mendelsohn[1], Z. Stadler[1], N.H. Segal[2], A. Varghese[3], D. Reidy[3], L. Diaz[3], J. Shia[4], E. Vakiani[4], J. Hechtman[4], N. Schultz[5], M. Berger[4], D. Hyman[3], D. Solit[3], L. Saltz[2], J. Garcia Aguilar[6], A. Cercek[3]

[1]GI Medical Oncology, Memorial Sloan-Kettering Cancer Center, New York, NY, USA, [2]Gastrointestinal Oncology Service, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY, USA, [3]Medicine, Memorial Sloan Kettering Cancer Center, New York, NY, USA, [4]Pathology, Memorial Sloan-Kettering Cancer Center, New York, NY, USA, [5]The Nikolaus Schultz Lab, Memorial Sloan-Kettering Cancer Center, New York, NY, USA, [6]Surgery, Memorial Sloan-Kettering Cancer Center, New York, NY, USA

Background: The incidence of colorectal cancer in patients(pts) under the age of 50 has been steadily on rising over the last two decades. This is in sharp contrast to average onset CRC where there has been a decline. Little is known about clinical behavior and biology of metastatic CRC in the growing YO population.

Methods: We defined YO as < 45 yo and AO as > 50 yo. To better understand the differences in biology of early onset rectal tumors, we tabulated the clinical characteristics, genomics using next generation sequencing(MSK-IMPACT), treatments and outcomes in 175 metastatic pts with EO CRC, treated at Memorial Sloan Kettering Cancer Center between 2014 and 2017 and compared these cases to a cohort of AO M CRC cases ($n = 413$) with CRC related hereditary syndromes such as Lynch Syndrome and inflammatory bowel disease were excluded.

Results: We analyzed 175 in the YO cohort. Age at diagnosis was between 17-35yo in 46 and between 36-45 in 129 pts. Among YO patients, there were 50.2% males, 27.7% smokers and the median BMI was 25.5. Comparing to AO, YO pts have significantly less right sided tumors (22.8% vs 33%; $p = 0.01$). Treatment choices did not differ among YO vs AO groups; systemic chemotherapy (46.7% vs 42.6%; $p = 0.40$) and metastasectomy (54.6 vs 49.4; $p = 0.33$). Overall survival was 59months in the YO vs 63.9 for the AO ($p = 0.194$). Among genetic characteristics mutational burden and copy number comparison showed no significant differences between the groups.

Conclusions: Our series describes a comprehensive clinical and genomic profile of EO mCRC. In contrast to prior reports YO does not appear to be associated with more aggressive disease and there was no difference in treatment modalities. Detailed genomic and clinical characteristics will be presented.

592P Impact of Charlson comorbidity index on survival of octogenarian patients with colorectal cancer

E.D. Inga Saavedra[1], J.R. Rodriguez[1], E. Casaut Lora[2], A. Gonzalez-Haba[1], V. Serrano Pecos[1], M.F. Martinez Barragan[1], E. Blanco[1], J. Gomez-Ulla[1]

[1]Medical Oncology Service, Hospital Infanta Cristina, Badajoz, Spain, [2]Oncology, Hospital Perpetuo Socorro, Badajoz, Spain

Background: Octogenarians have higher rates of comorbidity that are associated with a poor prognosis. Few studies have identified prognostic factors of elderly patients (pts) with colorectal cancer (CRC), so their optimized care strategies remain controversial. Charlson comorbidity index (CCI) is the most widely used clinical scoring system to predict the survival of patients with malignancies. The aim of this study was to investigate the prevalence of comorbidity and the prognostic impact of the CCI score for survival among octogenarian pts with CRC in our center.

Methods: We reviewed 151 pts referred to Medical Oncology between January 2012 and March 2017. Data on demographics, staging, treatment and survival were collected and analysed. CCI score was independent variable. OS rates was estimated by the Kaplan–Meier method, with differences in survival between groups compared by the log-rank test.

Results: We reviewed 151 pts with CRC referred to Medical Oncology between January 2012 and March 2017. Data on demographics, staging, treatment and survival was collected and analysed. CCI score was the independent variable. OS rates was estimated by the Kaplan–Meier method, with differences in survival between groups compared by the log-rank test. Results Octogenarians were a 19% of all pts, 82 (54%) men and 69 (46%) women. The median age was 84 years. There was no difference in performance status (PS) between genders with PS 0-1 in 76%, PS 2 in 26% and PS 3-4 in 10%. Pts were divided into high CCI score (CCI ≥ 3; $n = 52$) and low CCI score (CCI < 3; $n = 99$) groups for comparative analyses of differences in their short- and long-term outcomes. The overall survival (OS) in pts with a Low CCI Score was longer than that in high CCI score (46 versus 25 months; $p < 0.01$). High CCI score significantly relates to poorer survival outcome for all stages ($p < 0.001$).

Table: 592P

Characteristics	Low CCI group (n = 99)	High CCI group (n = 52)	p value
Sex (male/female)	46/53	23/29	0.74
Stage at diagnosis I II III IV	10 21 39 29	6 7 16 23	0.003
Primary tumor location Right Left Rectum	38 44 17	24 17 11	0.24

Conclusions: In our study CCI score (low or high) showed be independent factor in prognosis and survival in octogenarian patients with colorectal cancer.

Funding: Has not received any funding.

593P The SENECA study: Prognostic role of serum biomarkers in elderly metastatic colorectal cancer patients

C. Lisanti[1], D. Basile[1], S.K. Garattini[1], G. Pelizzari[1], A. Parnofiello[1], F. Cortiula[1], E. Ongaro[1], M. Cattaneo[1], C. Corvaja[1], V.J. Andreotti[1], M. Bartoletti[1], M. Casagrande[2], D. Iacono[2], M. Bonotto[2], P. Ermacora[2], N. Pella[2], A. Buonadonna[3], F. Puglisi[4], G. Fasola[2], G. Miolo[3]

[1]Department of Medicine (DAME), University of Udine, Udine, Italy, [2]Department of Oncology, ASUIUD Santa Maria della Misericordia, Udine, Italy, [3]Department of Medical Oncology and Cancer Prevention, CRO National Cancer Institute, Aviano, Italy, [4]University of Udine, Department of Medical Oncology and Cancer Prevention, CRO National Cancer Institute, Aviano, Italy

Background: Aging induces meaningful changes in immune system and inflammation response with increase in monocyte-lymphocyte ratio (MLR) and serum lactate dehydrogenase (LDH) levels. Notably, high levels of these serum biomarkers are associated with poor prognosis in many tumors. We aim to explore the prognostic role of baseline (i.e. before first line chemotherapy) MLR and LDH levels in elderly patients (pts) with metastatic colorectal cancer (MCRC).

Methods: A retrospective analysis of a consecutive cohort of 120 elderly (>70 years) pts treated for MCRC between 2004 and 2017 at the Oncology Department of Aviano National Cancer Institute and University Hospital of Udine (Italy), was conducted. The prognostic role of MLR and LDH levels on overall survival (OS) was investigated through uni- and multivariate Cox regression analyses.

Results: At a median follow-up of 50.83 months, median OS was 19.96 months. Overall, 46 pts (38%) presented a right cancer, 43 pts (36%) a left cancer and 30 pts (25%) a rectal one. In 8 (8%) and 47 (50%) pts a mutation of BRAF or KRAS was detected, respectively. Liver (36%), lymph-nodes (22%), peritoneum (22%) and lung (17%) were the most frequent sites of metastasis. Noteworthy, 22 pts (18%) had undergone a metastasectomy. High levels of LDH (>480 U/L) and MLR (>0.45, obtained with ROC curve) were discovered in 23 (32%) and 51 (42%) patients respectively. By univariate analysis, high levels of LDH (HR 2.81, $p = 0.001$), MLR (HR 2.26, $p < 0.001$) or both (HR 6.42, $p < 0.001$) and node involvement at diagnosis (pN2 vs. pN0 HR 2.15, $p = 0.019$; pN3 vs. pN0 HR 2.69, $p = 0.052$) were associated with worse OS. Metastasectomy (HR 0.47, $p = 0.009$), tumor resection (HR 0.50, $p = 0.010$) and left sidedness (HR 0.53, $p = 0.01$) were associated with better OS. By multivariate analysis, high levels of LDH (HR 2.64, $p = 0.004$), MLR (HR 2.21, $p = 0.009$) or both (HR 4.19, $p = 0.019$) were independently associated with worse OS.

Conclusions: High baseline levels of LDH, MLR or both are unfavorable independent prognostic factors in elderly pts treated with first line chemotherapy for MCRC. These preliminary results emphasize the need of prospective studies to validate these cost-effectiveness biomarkers in this subgroup of pts.

594P Determinants of oncologist's choice in offering drug holidays during first line therapy for patients with metastatic colorectal cancer

S.K.K. Garattini[1], M. Bonotto[1], L. Porcu[2], E. Ongaro[1], D. Basile[3], F. Cortiula[1], G. Pelizzari[3], M. Cattaneo[1], A. Parnofiello[1], V.J. Andreotti[1], C. Corvaja[3], G.G. Cardellino[1], P. Ermacora[1], M. Casagrande[1], D. Iacono[1], N. Pella[1], A. Buonadonna[3], A.M. Minisini[1], F. Puglisi[3], G. Fasola[1]

[1]Oncology, ASUIUD Azienda Ospedaliero-Universitaria di Udine, Udine, Italy, [2]Laboratory of Methodology for Clinical Research-Oncology, IRCCS Istituto di Ricerche Farmacologiche Mario Negri, Milan, Italy, [3]Oncology, CRO di Aviano, Aviano, Italy

Background: Overall survival of patients (pts) with metastatic colorectal cancer (mCRC) has been increasing over the last decades. "Drug holiday" strategies were introduced by the oncologists to reduce toxicity. We aimed at studying what are the

clinico-pathological and treatment factors that drive the decision to propose a "drug holiday" in first line.

Methods: This is a retrospective series of consecutive pts affected by mCRC treated with first line chemotherapy. The pts included were treated from 1/1/2005 to 15/03/2017 at University Hospital of Udine and IRCCS CRO of Aviano, Italy. A "drug Holiday" was defined as 56 or more consecutive days without chemotherapy during first-line. Upfront metastasectomy were excluded. Logistic regression was used to find association between predictors and "holiday offer" in univariate and multivariate analysis.

Results: A total of 648 pts were included. In detail, 215 received a drug holiday (33.2%) while 433 (66.8%) received continuous treatment. In univariate analysis, the variables associated with holiday were: non-upfront metastasectomy (OR 11.8, IC 95% 6.62-22.6, $p < 0.001$), thermoablation (OR 6.08, IC 95% 3.19-11.58, $p < 0.001$), primary tumor (OR 2.79, IC 95% 1.79-4.34, $p < 0.001$), G3-G4 pathological grade (OR 1.49, IC 95% 1.01-2.19, $p = 0.046$), adjuvant CT (OR 1.54,IC 95% 1.06-2.33, $p = 0.023$). Adjuvant RT (OR 1.62, IC 95% 0.99-2.62, $p = 0.051$) showed a trend towards association. More than one metastatic site at diagnosis (OR 0.59, IC 95% 0.42-0.83, $p = 0.003$) and nodal involvement (OR 0.57, IC 95%, 0.34-0.95, $p = 0.032$) were associated to continuous treatment. In multivariate analysis, only first line non-upfront metastasectomy (OR 9.89, IC95% 4.38-22.33, $p < 0.001$), thermoablation (OR 4.48, IC95% 1.97-10.19, $p < 0.001$) and primary tumor resection (OR 2.43, IC95% 1.14-5.19, $p = 0.022$) were independently associated with drug-holiday.

Conclusions: In our cohort, clinicians were more prone to propose a drug holiday in pts who had received non-upfront metastasectomy or thermo-ablation or were treated on their primary tumor. Having more than one site of metastasis at the beginning of 1st line and nodal involvement favored continuous therapy.

596P Combined inhibition of MEK and PI3KCA pathway induces synergic antitumor activity in HER2 amplified human colorectal cancer models

V. Belli[1], N. Matrone[1], S. Napolitano[1], E. Martinelli[1], M.D. Castellone[2], L. Trusolino[3], E.F. Giunta[1], V. De Falco[1], N. Zanaletti[1], P.P. Vitiello[1], D. Ciardiello[1], M. Terminiello[1], F. Ciardiello[4], T. Troiani[1]

[1]Medicina di Precisione, Università degli Studi della Campania Luigi Vanvitelli, Naples, Italy, [2]Università degli Studi dell Istitute of Experimental Endocrinology and Oncology, CNR, Naples, Italy, [3]IRCCS, Istituto di Candiolo, Candiolo, Italy, [4]Dipartimento di Medicina di Precisione, Università degli Studi della Campania Luigi Vanvitelli, Naples, Italy

Background: Cetuximab and panitumumab, monoclonal antibodies direct against the epidermal growth factor receptor (EGFR) are a therapeutic option for mCRC patients wild type for KRAS and NRAS genes. However, only a subset of mCRC patients receives clinical benefit from these therapies due to the development of resistance mechanisms. HER2 gene amplification or HER2 activating mutations have been implicated as resistance mechanisms to anti-EGFR therapies. However, little is known about the role of HER2 in cancer resistance to anti-EGFR antibodies.

Methods: We transfected colon cancer cells sensitive to anti-EGFR antibodies (LIM1215 and SW48) with HER2 vector in order to obtain stable clones overexpressing HER2 protein. LIM1215-HER2 and SW48-HER2 cells were characterized by their morphological and molecular profile through cell migration and WB assays. Moreover, different drugs sensitivity was evaluated by MTT and colony formation. Furthermore, HER2 amplified cells were engrafted into nude mice and treated with different drugs.

Results: HER2 amplified cells show an overexpression and activation of the HER family receptors coupled by an intracellular downstream activation pathway of AKT, MAPK, and MEK proteins compared to parental cells. HER2 amplified cells were treated with several combinations of drugs directed against HER receptors, such as anti-EGFR antibodies of first, second and third generation (cetuximab, SYM004 and MM151); trastuzumab, pertuzumab and lapatinib directed against HER2 receptor; and duligotuzumab direct against HER3. Subsequently, both cells were treated with drugs directed against MEK and PI3KCA proteins, such as refametinib and pictilisib. Among these therapeutic options, the combination of refametinib and pictilisib have shown the most synergist anti-proliferative activity. The in vivo xenograft CRC models have confirmed the synergistic antitumor activity of this combined treatment. Moreover, PDTX HER amplified CRC models will be used to validate the previous results.

Conclusions: These results suggest that the treatment with refamentinib and pictilisib could be a strategy for patients with HER2 amplification that do not receive clinical benefit from standard anti-EGFR therapies.

597P Predictive value of in-vitro testing anti-cancer therapy sensitivity on 3D micro-tumors (tumoroids) from patients with metastatic colorectal cancer: A feasibility study

L.H. Jensen[1], C. Dam[1], G. Hagel[2], C. Hansen[1], H. Harling[3], B.M. Havelund[1], A. Jakobsen[1], J. Lindebjerg[1], S. Rafaelsen[1], O. Thastrup[4], T.F. Hansen[1]

[1]Danish Colorectal Cancer Center South, Center of Clinical Excellence, Vejle Hospital, Institute of Regional Health Research, University of Southern Denmark, Vejle, Denmark, [2]Laboratory, 2cureX, Copenhagen, Denmark, [3]Surgery, Bispebjerg Hospital, Copenhagen, Denmark, [4]2cureX, University of Copenhagen - Department of Drug Design and Pharmacology, Copenhagen, Denmark

Background: The treatment of cancer may be improved by testing the chemo sensitivity of cancer cells obtained from the patient's tumor. 3D culture represents a promising method for modeling of patient tumors in vitro. The purpose of this study was to test the feasibility of a clinical trial offering patients with metastatic colorectal cancer treatment based on in-vitro testing anti-cancer therapy sensitivity.

Methods: Main inclusion criteria were stage IV colorectal cancer, PS 0-1, previous exposure to 5FU, oxaliplatin, irinotecan, bevacizumab and, if RAS/RAF wild-type, an EGFR inhibitor. Fresh cancer tissues from metastases were cultivated as tumoroids. The culturing protocol which was originally developed for resected tissue was optimized for the smaller tissue amounts received from needle biopsies. Ten patients were to be included and at least five of them to have clinically applicable results in order for the procedure to be feasible.

Results: Ten patients were included from September to December 2017 in one institution. Biopsies were from liver (6), peritoneum (2), retroperitoneum (1) and lung (1). Rebiopsies were allowed and a total of 19 biopsy sessions were performed with ultrasound (14), CT (3) or sigmoidoscopy (2). In seven cases, the biopsy, tumorsphere formation and sensitivity testing was successful. Median time from biopsy to result was 34 days (range 19-50). A notable challenge was obtaining sufficient viable tumor tissue resulting in increased culture times or the need for re-biopsies.

Conclusions: This is the first clinical study of its kind. The method of selecting last-line treatment of colorectal cancer based on fresh biopsies was feasible as results were obtained in seven out of ten cases. The trial is now extended to a phase II trial with PFS as the primary endpoint.

Clinical trial identification: NCT03251612.

598P Macrophage migration inhibitory factor overexpression is a mechanism of acquired resistance to anti-EGFR inhibitor cetuximab in human colorectal cancer cell line

N. Matrone[1], A. Chambery[2], R. Russo[2], P.V. Pedone[2], V. Belli[1], S. Napolitano[1], E. Martinelli[1], E.F. Giunta[1], V. De Falco[1], N. Zanaletti[1], P. Vitale[1], M. Terminiello[1], C. Cardone[1], F. Ciardiello[1], T. Troiani[1]

[1]Precision Medicine, Università degli Studi della Campania Luigi Vanvitelli, Naples, Italy, [2]Dipartimento di Scienze e Tecnologie Ambientali, Biologiche e Farmaceutiche, Università degli Studi della Campania Luigi Vanvitelli, Naples, Italy

Background: The anti-epidermal growth factor receptor (EGFR) monoclonal antibodies (mAbs) cetuximab and panitumumab are effective in a subset of RAS/BRAF wild-type (WT) metastatic colorectal cancers (mCRCs) patients. Despite an accurate RAS-driven selection, not all patients will respond to EGFR inhibitors and the onset of secondary resistance limits their clinical benefit.

Methods: With the aim of developing effective preclinical models for testing possible strategies to overcome acquired resistance to EGFR blockade, we have generated a series of human colon cancer cell lines with in vitro and in vivo acquired resistance to anti-EGFR inhibitors. To better investigate the differentially expressed proteins involved in EGFR resistance, we applied an advanced quantitative proteomic approach based on TMT isobaric labeling and nano-liquid chromatography coupled with high resolution tandem mass spectrometry (MS/MS).

Results: To evaluate changes in protein expression we have used human CRC cell line cetuximab-sensitive GEO, as well as its derived cell line with acquired resistance to cetuximab GEO-CR. By MS/MS, we have identified and quantified 2455 proteins; 53 proteins were found to be differentially expressed in GEO-CR compared to GEO cells. Only 11 proteins were found to be high regulated in GEO-CR, among these we focused our attention on the inhibition factor of macrophage migration (MIF) for its relevance in CRC tumorigenesis. To explore its involvement in resistance to cetuximab in CRC cell line, we have performed an MTT assay with two MIF-antagonists, ISO1 a cell-permeable inhibitor of MIF tautomerase and 4-IPP, a selective MIF inhibitor that blocks MIF and its receptor, CD74, internalization. GEO-CR cell line was treated with two MIF antagonists alone and in combination with cetuximab. Only the combined treatment with cetuximab and 4-IPP induced a synergistic antiproliferative and apoptotic effects.

Conclusions: These results suggest that MIF overexpression is involved in acquired resistance to cetuximab and the inhibition of EGFR and MIF could be a strategy for overcoming anti-EGFR resistance in patients with CRC.

Background: OIPN is a common adverse event leading to early discontinuation of oxaliplatin. This was the first exploratory trial for proof of concept of whether ART-123 prevented OIPN.

Methods: Patients with pStage II or III colon cancer who planned adjuvant chemotherapy with mFOLFOX6 were randomly allocated to the following 3 groups in a double-blind manner; placebo group (placebo saline on day 1-3), 1-day ART-123 group (ART-123 380U/kg on day 1 and placebo on day 2-3), and 3-day ART-123 group (ART-123 on day 1-3). Study drug was given intravenously for 30 min immediately before oxaliplatin. The severity of OIPN was evaluated using NCI-CTCAE by physicians and FACT/GOG-NTX-12 (score range 0-48, lower values more severe) by patients. NCI-CTCAE was assessed at baseline, day 1-3 of every cycle, and 14 and 42 days after the last treatment with oxaliplatin. FACT/GOG-NTX-12 was assessed at baseline, day 1 and 8 of every cycle, and 14 and 42 days after the last treatment with oxaliplatin.

Results: Eighty patients were randomized, and 79 (28 placebo, 27 1-day ART-123, and 24 3-day ART-123) patients were analyzed. Both 1-day and 3-day ART-123 tended to reduce the cumulative incidence of NCI-CTCAE grade 2 or higher OIPN and prevent worsening of FACT/GOG-NTX-12 scores, compared to placebo (Table). No substantial differences in other adverse events were noted.

Table: 599P

		Placebo (n = 28)	1-day ART-123 (n = 27)	3-day ART-123 (n = 24)
Sensory neuropathy NCI-CTCAE (% grade 2 or higher)	Baseline	0%	0%	0%
	at 6th cycle	39%	19%	17%
	at 12th cycle	64%	41%	46%
Overall scores in FACT/GOG-NTX-12 (the least square mean (SE))	Baseline	46 (0.4)	47 (0.5)	46 (0.5)
	at 6th cycle	35 (1.6)	39 (1.6)	38 (1.6)
	at 12th cycle	29 (1.9)	36 (1.9)	32 (2.0)
Median total dose of oxaliplatin (mg/m^2)(range)		819 (84-1000)	849 (331-1037)	921 (255-1012)

Conclusions: ART-123 showed promising efficacy in delaying and reducing OIPN without serious safety concerns.

Clinical trial identification: NCT02792842.

600P Development of a nomogram for predicting survival in microsatellite stable patients with resected colorectal cancer

Y. Li[1], J. Peng[1], T. Hou[2], H. Han-Zhang[3], H. Liu[3], J. Xiang[3], L. Zhang[3], X. Ma[1], D. Huang[4], S. Cai[1]

[1]Department of Colorectal Surgery, Fudan University Shanghai Cancer Center, Shanghai, China, [2]Bioinfo, Burning Rock Biotech, Guangzhou, China, [3]Medicine, Burning Rock Biotech, Guangzhou, China, [4]Department of Pathology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: The benefits of adjuvant chemotherapy remain controversial in microsatellite stable (MSS) stage II resected colorectal cancer (CRC) patients. In this study, we constructed an overall survival (OS) prediction model for this subgroup, integrating a combination of molecular and clinical predictors.

Methods: Variables with p-values < 0.05 were entered into multivariate analyses using Cox stepwise regression model to select independent predictors as input for OS prediction nomogram. A final model was selected using a backward step-down process, which used Akaike Information Criterion as a stopping rule. The probability of 3-year and 5-year survival can be obtained by summing up the total score and locating it on the total point scale.

Results: We performed targeted sequencing on surgically resected tumor tissue of 122 stage II MSS patients, defined as having less than 15% length-instable loci, using a panel which allows for simultaneous detection of MSI status and mutation in 41 CRC-related genes. Among them, 23, 30 and 69 patients were diagnosed with proximal, distal and rectal cancer, respectively. To predict the probability of 3-year and 5-year survival, we constructed a nomogram incorporating the significant prognostic factors, including APC, ATM, BRAF, PTEN, TP53 (LOF), mutation count (high: >3, low: <=3), age, CEA, and the location of the tumor. The actual and predicted survivals were in an excellent agreement, reflected by a C-index of 0.887 (95% CI: 0.816-0.957). Furthermore, Kaplan-Meier curves for survival outcomes showed significant distinction ($p < 0.001$) after stratifying our cohort into low, median and high risk groups according to total score obtained from our nomogram. Our data also demonstrated high risk patients who received adjuvant chemotherapy are associated with a better OS ($p = 0.004$). Low and median risk patients did not benefit from adjuvant chemotherapy, reflected by comparable OS.

Conclusions: We developed a nomogram model for predicting survival of MSS patients with stage II resected CRC. It can potentially serve as complementary method for clinicians to identify subgroups necessitating adjuvant therapy.

Background: Mismatch repair deficiency (dMMR) due to germline mutations in DNA repair genes including MLH1, MSH2, MSH6 and PMS2, or somatic aberrant silencing of MLH1, is a well-established feature for Lynch syndrome, a major type of hereditary colorectal cancer (CRC). The purpose of this study is to derive prevalence of germline MMR gene mutations in Chinese population with dMMR CRC.

Methods: ColonCore panel is designed for simultaneous detection of microsatellite instabiligy (MSI) status of 22 regions and mutations in 38 CRC-related genes. Whole exons of the 38 genes were covered by the panel. The MSI phenotype detection method was a read-count-distribution-based approach. It utilized the coverage ratio of a specific set of repeat lengths as the main characteristic of each microsatellite locus, and categorized a locus as unstable if the coverage ratio was less than a given threshold. The MSI status of a sample was determined by the percentage of unstable loci in the given sample.

Results: Among 1394 postsurgical CRC patients whose MMR status were detected by immunohistochemistry (IHC), 99 patients were dMMR, accounting for 7.1%. The concordance rate was 92.3% between MSI and IHC. Next, we investigated the germline mutation spectrum of dMMR patients. About 26.3% patients harbored pathogenic germline MMR gene mutations, with 13%, 6%, 5% and 2% of patients carrying pathogenic MLH1, MSH2, MSH6 and PMS2 mutations, respectively. Specially, about 30% pathogenic MLH1 mutation occured in splice region. Among patients with pathogenic MMR gene mutations, their first cancer was diagnosed ranging from 22 to 69 years old

with median age at diagnosis was 50, and only 57% have a family history of ≥ 1 relative with Lynch syndrome related cancers. Furthermore, 3% harbored pathogenic mutations in other genes. Approximately, 17% of patients harbored MMR gene variants of unknown significance (VUS) and 26% harbored other VUS. The remaining 28% of patients had no pathogenic or VUS mutations from this panel.

Conclusions: The prevalence rate of germline pathogenic mutations is 26% in dMMR CRC patients, accounting for 1.8% of all resectable CRC patients. Median age at diagnosis of Lynch syndrome related cancers is 50 years old and nearly 40% Lynch syndrome patients have no family history.

602P Kynurenine 3-monooxygenase as a potential biomarker for colorectal cancer

C-Y. Liu[1], C-H. Lee[1], J-L. Chen[1], T-T. Huang[1], S-H. Yang[2], J-K. Jiang[2], W-S. Chen[2], K-D. Lee[3], H-W. Teng[1]

[1]Oncology, Taipei Veterans General Hospital, Taipei, Taiwan, [2]Surgery, Taipei Veterans General Hospital, Taipei, Taiwan, [3]Internal Medicine, Taipei Medical University Hospital, Taipei, Taiwan

Background: Colorectal cancer (CRC) is the third most common cancer and the cause of cancer-related deaths worldwide. Due to the lack of highly sensitive and specific biomarkers, colorectal cancer often identified at the late stages in most patients when diagnosed. Identifying the potential cancer marker and understanding the mechanisms of metastasis and progression behind colorectal cancer is crucial for human CRC. Kynurenine 3-monooxygenase (KMO) is a monooxygenase participating in tryptophan metabolism. Previous studies showed that KMO related to metastasis and proliferation in hepatocellular carcinoma. However, the biological role of KMO in human CRC is still unclear.

Methods: The expression level of KMO in patients with CRC was examined using immunohistochemistry (IHC). The correlation between KMO expression and patient survival rate was analyzed using The Cancer Genome Atlas (TCGA) database. CRC cell lines were used to perform functional assays. UPF 648, a potent KMO inhibitor, and RNAi against KMO and luciferase were used for in vitro studies. Cell viability was analyzed by MTT assay. Cells motility was examined by transwell assay. Stemness properties were assessed by sphere assay and the expression of cancer stem cells markers.

Results: IHC data showed that the expression of KMO was upregulated in CRC tumor tissues compared with normal counterparts of CRC. Furthermore, higher level of KMO transcript was associated with worse overall survival in CRC patients in TCGA database. Knockdown of KMO inhibited the expression of cancer stem cells markers, including CD44 and Nanog, as well as abilities of migration and invasion of CRC cells. Furthermore, the effect of KMO activity inhibition in cell viability was cell lines specific whereas the abilities of cell migration, invasion and sphere formation in CRC cells were significantly suppressed by UPF 648 treatment.

Conclusions: Our data suggests that KMO may serve as a potential biomarker and play tumor-promoting role in CRC.

603TiP Induction chemotherapy plus chemoradiotherapy with or without aspirin in high risk rectal cancer (ICAR)

J.C.E.S.O.D. Souza[1], R. Araujo[2], M. Valadão[2], C. Carrara[3], M.Á. Barbosa[3], R. Guimarães[4], J. Carvalho[4], G. Kovaleski[5], I. Small[6], A. Marins[5], A.P. Victorino[1], R. Gil[1], J.P. Jesus[2], L.H. de Araujo[1], A.C. de Melo[5]

[1]Oncology Department, INCA - Instituto Nacional de Cancer, Rio de Janeiro, Brazil, [2]Surgery Department, INCA - Instituto Nacional de Cancer, Rio de Janeiro, Brazil, [3]Radiology Department, INCA - Instituto Nacional de Cancer, Rio de Janeiro, Brazil, [4]Radiotherapy Department, INCA - Instituto Nacional de Cancer, Rio de Janeiro, Brazil, [5]Clinical Research Department, INCA - Instituto Nacional de Cancer, Rio de Janeiro, Brazil, [6]Biostatiscs Department, INCA - Instituto Nacional de Cancer, Rio de Janeiro, Brazil

Background: Induction chemotherapy followed by chemoradiation is an attractive approach, with more favorable compliance and toxicity profiles. Furthermore, the benefit of aspirin in cancer of the colon and rectum is already known. Recently, it was described its potential activity during chemoradiotherapy. The aim is to evaluate the efficacy of total neoadjuvant treatment and the aspirin use during chemoradiotherapy for high-risk rectal cancer.

Trial design: Randomized trial to evaluate induction treatment with XELOX and Capecitabine-based chemoradiotherapy with or without aspirin in a high risk population selected by MRI. High-risk will be defined by presence of at least one of the following criteria on high-resolution thin-slice MRI: tumors within 1 mm of or beyond the mesorectal fascia; tumor extending 5 mm or more into perirectal fat; resectable cT4 tumors; lower third; nodal involvement; extramural vascular invasion. Primary objective is to evaluate the tumor downstaging after total neoadjuvant treatment with or without aspirin. All the patients enrolled in the study will receive XELOX every 21 days for four cycles, unless unacceptable toxicity or progression is detected. After this treatment, patients will be randomized to receive Capecitabine-based chemoradiotherapy with aspirin or placebo (Capecitabine 850 mg/m^2 5 days per week combined with radiotherapy with total dose of 50.4 Gy in 28 days). Random assignment of treatment will be stratified by MRI tumour regression grade. After 8-10 weeks, they will be evaluated by MRI. Patients with complete clinical response will be managed with "watch and wait" approach. The sample size was calculated according to Simon's optimal two-stage design. Accordingly, 11 patients must be included in each group during the first stage. If 3 patients or fewer show downstaging, the trial will be stopped (interim efficacy analysis). Inclusion of patients will continue until 31 patients are included, in order to detect a difference of 26% or greater in downstaging. A treatment regimen will be considered effective if more than 10 patients of the total 31 show downstaging (final analysis), reaching 90% power with an alpha of 0.05 level of significance.

Clinical trial identification: NCT03170115.

604TiP Phase II study of surgery after S-1 + oxaliplatin +bevacizumab therapy for unresectable rectal cancer by organ-preserved TME

T. Yoshida[1], T. Miura[1], Y. Sakamoto[1], H. Morohashi[1], H. Fujita[2], K. Sato[1], K. Hakamada[1]

[1]Gastroenterological Surgery, Hirosaki University Hospital, Hirosaki, Japan, [2]Radiology, Hirosaki University Hospital, Hirosaki, Japan

Background: For unresectable locally advanced rectal cancer (ULARC), long-course preoperative neoadjuvant chemoradiotherapy (NACRT) was recommended by ESMO guideline. However, ULARC had the risk of not only local recurrence but also subsequent metastatic disease. In these circumstances, preoperative neoadjuvant intense chemotherapy without radiotherapy (NAC) are being investigated in multiple trials. The recent trials suggested equivalent local down staging and pCR rates of NAC using doublet therapy + bevacizumab as compared with standard NACRT. On the other hands, the addition of bevacizumab could be associated with anastomotic insufficiency or rectal perforation. Therefore, the strategy of the safe and sufficient introduction of preoperative doublet therapy + bevacizumab has been required for ULARC.

Trial design: Primary end point: T down-staging rate (The rate of pT0, pTis, pT1 and pT2) Inclusion criteria: 1. Clinical stage T3 or T4, any N without distant metastases. 2. Unresectable rectal cancer by organ-sparing TME which was judged by high resolution MRI. The features include CRM < =1mm, T4b, and lateral lymph node metastasis. Exclusion criteria: 1. Over 75 years old. 2. The patients had thromboembolism or significant abnormal electrocardiogram or cardiovascular disease. Protocol: S-1 is administered orally at 80mg/m2/day for 14 consecutive days followed by a 7 day rest. L-OHP is given intravenously on days 1, at a dose of 130mg/m2/day. Bevacizumab is given intravenously on days 1, at a dose of 7.5mg/kg/day. 21 days are assumed 1 course, and chemotherapy consisted of 4 courses. Surgery is carried out in 8 to 12 weeks after the end of chemotherapy. The type of surgery was defined by high resolution MRI after preoperative chemotherapy within 2 weeks before the date of surgery. Target sample: 32 patients Features of this trial: Paying attention to the safety and efficacy of bevacizumab compared with prior trials according to the following points; 1. long interval between surgery and the administration of bevacizumab. 2. The transverse loop colostomy is required before NAC in case of stenosis. 3. The diverting stoma are necessary after intestinal reconstruction.

605TiP Phase II study of resection of primary colorectal cancer and synchronous liver metastasis after S-1 + oxaliplatin (SOX) + bevacizumab (Bmab) therapy and adjuvant S-1 chemotherapy

T. Miura, H. Morohashi, Y. Sakamoto, T. Yoshida, K. Sato, K. Ishido, D. Kudo, N. Kimura, K. Hakamada

Gastroenterological Surgery, Hirosaki University Hospital, Hirosaki, Japan

Background: For resectable colorectal liver metastasis, perioperative adjuvant chemotherapy was suggested to prolong disease-free survival. However, the relapse rate was still high even after doublet therapy. To decrease the relapse rate, doublet + targetted therapy was tried but the efficacy and perioperative safety of the targetted therapy have not been significantly shown. These failures might be caused by inappropriate indication, timing of preoperative chemotherapy and short interval between chemotherapy

and surgery. In these circumstances, we designed a preoperative doublet + bevacizumab therapy in high-risk patients such as synchronous liver metastasis before simultaneous resection of primary and liver metastasis.

Trial design: Primary end point: Disease-free survival. Inclusion criteria: 1. Clinical any T and any N with only liver metastases. Exclusion criteria: 1. Over 75 years old. 2. The patients had thromboembolism or significant abnormal electrocardiogram or cardiovascular disease. Protocol: S-1 is administered orally at 80mg/m^2/day for 14 consecutive days followed by a 7-day rest. Oxaliplatin (L-OHP) was given intravenously on days 1, at a dose of 130mg/m^2/day. Bevacizumab is given intravenously on days 1, at a dose of 7.5mg/kg/day. 21 days were assumed 1 course, and chemotherapy consisted of 4 courses. Surgery was carried out 8 to 12 weeks after the end of chemotherapy. Adjuvant chemotherapy of S-1 at 80mg/m^2/day for 14 consecutive days followed by a 7-day rest was initiated within 6-8 weeks after surgery. Target sample: 28 patients. Features of this trial: Paying attention to the safety and efficacy of bevacizumab compared with prior trials according to the following points; 1. Long interval between surgery and the administration of bevacizumab. 2. Preoperative chemotherapy was administered prior to resection of primary colorectal cancer in order to increase the intensity of chemotherapy. 3. The loop ostomy is required before neoadjuvant chemotherapy in case of stenosis.

Background: Rmab, an anti-VEGFR-2 antibody, inhibits VEGF-A, -C, -D binding and endothelial cell proliferation, while bevacizumab (Bmab) binds to and blocks circulating VEGF-A. The RAISE trial showed the survival benefit of FOLFIRI plus Rmab compared with FOLFIRI plus placebo as second-line treatment for patients with mCRC. The TRIBE trial demonstrated that FOLFOXIRI plus Bmab improved overall response rate (ORR), progression-free survival and overall survival compared with FOLFIRI plus Bmab as induction therapy followed by maintenance therapy with fluorouracil (5-FU), l-leucovorin (l-LV) and Bmab. However, little is known about the role of Rmab in first-line setting and the comparison of induction followed by maintenance therapy with continuous therapy continued until progressive disease (PD) or unacceptable toxicity.

Trial design: WJOG9216G is an open-label, randomized phase II study evaluating FOLFIRI plus Rmab until PD (arm A) versus FOLFOXIRI plus Rmab for 8 to 12 cycles followed by maintenance therapy with 5-FU, l-LV and Rmab (arm B) for patients with mCRC. Eligibility criteria include histologically confirmed unresectable colorectal adenocarcinoma, age of 20-75 years, ECOG PS of 0 or 1, without UGT1A1 *6/ *6, *28/ *28 or *6/ *28, no history of prior chemotherapy for mCRC, and adequate organ function. Stratification criteria are institution, RAS status, history of adjuvant chemotherapy, and primary tumor location. Arm A comprises Rmab 8 mg/kg, irinotecan (IRI) 180 mg/m^2, l-LV 200 mg/m^2, and bolus 5-FU 400 mg/m^2 followed by a 46-hour continuous infusion (ci) of 5-FU 2400 mg/m^2 every 2 weeks until PD. Arm B consists of 8 to 12 cycles of FOLFOXIRI plus Rmab (Rmab 8 mg/kg, IRI 165 mg/m^2, oxaliplatin 85 mg/m^2, l-LV 200 mg/m^2, and 5-FU ci 3200 mg/m^2) as induction therapy followed by 5-FU/l-LV plus Rmab until PD. Primary endpoint is ORR, and main secondary endpoints are PFS, PFS2, OS and safety. Sample size was calculated to be 120 (60 patients per arm), with a one-sided alpha of 10% and a power of 80%, assuming ORR of 50% in arm A and of 70% in arm B. This study has enrolled 23 patients as of April 28th, 2018.

Clinical trial identification: UMIN000026527 (Release date: March 13th, 2017).

Background: While BRAF mutations occur in 10-15% of metastatic colorectal cancer (mCRC), BRAF Non-V600E mutations was recently reported with ranging 2.2 - 5.2%. We have reported that BRAF Non-V600E could be a negative impact on survival outcome as well as anti-EGFR antibody treatment for pretreated mCRC patients (Shinozaki E, et al. Br J Cancer 2017). In addition, simultaneous inhibitions of MEK, BRAF and EGFR exhibited most potent anti-tumor activities in BRAF Non-V600E mutant cell lines and xenografted models (unpublished data).

Trial design: BIG BANG study is a multicenter phase II study to assess efficacy, safety and proof-of-concept of the triple combinations of binimetinib (BINI) + encorafenib (ENCO) + cetuximab (CETUX) in patients with BRAF Non-V600E mutated mCRC, identified by either tumor tissue-based analysis (primary analysis cohort) or circulating tumor DNA (ctDNA) analysis (liquid biopsy cohort). Key eligibility criteria includes ECOG PS $\leq$ 1; mCRC with BRAF Non-V600E mutant and RAS wild-type; refractory or intolerant to at least one fluoropyrimidine-based regimen (including irinotecan or oxaliplatin) and no prior history of anti-EGFR antibody and regorafenib. Enrolled patients receive BINI (45 mg, BID), ENCO (300 mg, QD), and CETUX (initially 400 mg/m^2, and subsequently 250 mg/m^2, QW), which are same recommended doses as the BEACON CRC trial (NCT02928224). In addition, the natural history data of patients with BRAF Non-V600E mutations who do not meet the eligibility criteria are collected as a historical control. The primary endpoint is the objective response rate (ORR) for primary analysis cohort. A sample size of the primary analysis cohort is calculated to be 21 on the hypothesis that the threshold ORR is 6% and expected ORR is 30%, with a significant level of 2.5% (one-sided) and power of 80%. Furthermore, paired tissue and blood samples will be obtained for pharmacodynamics analysis before study treatment, pre-dose of second cycle, and after disease progression. To our best knowledge, this is the first study targeting BRAF Non-V600E mutated mCRC.

[1]Department of Clinical Oncology, Aichi Cancer Center Hospital, Nagoya, Aichi, Japan, [2]Department of Clinical Oncology, Aichi Cancer Center Hospital, Nagoya, Japan, [3]Department of Gastroenterology and Gastrointestinal Oncology, National Cancer Center Hospital East, Kashiwa, Japan, [4]Department of Cancer Chemotherapy, Hokkaido University Hospital Cancer Center, Sapporo, Japan, [5]Department of Gastrointestinal Oncology, Cancer Institute Hospital of JFCR, Tokyo, Japan, [6]Department of Clinical Oncology, St Marianna University School of Medicine, Kawasaki City, Japan, [7]Department of Frontier Science for Cancer and Chemotherapy, Osaka University, Osaka, Japan, [8]Department of Gastrointestinal Medical Oncology, National Hospital Organization Shikoku Cancer Center, Matsuyama, Japan, [9]Department of Gastrointestinal and Medical Oncology, National Kyushu Cancer Center, Fukuoka, Japan, [10]Clinical Research Support Office, National Cancer Center Hospital East, Kashiwa, Japan

Background: BRAF V600E mutations are present in 5-10% of metastatic colorectal cancer (mCRC) patients, associated with aggressive biology and limited response to standard chemotherapy, especially in second line and beyond. BRAF V600E mutant CRCs have different patterns of gene expression from the BRAF wild-type, and preclinical evidence suggests that microtubule inhibitors have a potential antitumor effect on xenograft models of BRAF V600E mutant CRC; among them, eribulin has greater growth inhibitory activity than either vinblastine or paclitaxel in vitro. In addition, we have experienced a hint of activity for BRAF V600E mutant CRC patients with tumor shrinkage following eribulin treatment (Masuishi T, et al. Ann Oncol, 2018).

Trial design: BRAVERY study is a multicenter phase II study to evaluate the efficacy and safety of eribulin in patients with BRAF V600E mutant mCRC detected in either tumor tissue (primary analysis cohort) or circulating tumor DNA (ctDNA) assay (liquid biopsy cohort). Key eligibility criteria are refractory or intolerant to at least one regimen (including irinotecan or oxaliplatin) containing fluoropyrimidine, an age of 20 years or older, and ECOG performance status of 0–1. Eribulin is administered intravenously at a dose of 1.4 mg/m^2 on Days 1 and 8, repeated every 21 days. Primary endpoint is confirmed objective response rate (ORR) by investigator's assessment. A sample size of the primary analysis cohort is calculated 27 using two-stage design with ORR of 25% deemed promising and 5% unacceptable (one-sided α, 0.05; β, 0.1). Secondary endpoints include progression-free survival, time to treatment failure, disease control rate, overall survival and adverse events. Furthermore, pretreated tissue and serial blood samples are collected for biomarker analysis; especially focused on gene expression associated with BRAF mutant-like CRC as a predictive marker, BRAF mutant allele frequency in ctDNA as early detection of efficacy, and acquired gene alteration as resistant mechanism to eribulin. At the end of April 2018, four patients have been enrolled in primary analysis cohort since March 2018. Clinical trial information: UMIN000031221 and 000031552.

Clinical trial identification: UMIN000031221 and 000031552. 26/March/2018.

Pascale", Naples, Italy

Background: Anti-EGFR treatment demonstrated a clinical benefit limited to RAS-wt mCRC pts. In the FIRE-3 trial the depth of response was significantly associated with survival and the median time to tumor nadir was of 3.6months in the FOLFIRI plus anti-EGFR arm. These data suggest that further exposure to combined treatment may not result in an outcome improvement, but only in an increase of side effects. Therefore, a drug holiday strategy could increase adherence to therapy and quality of life. The feasibility of intermittent use of FOLFIRI in first line was showed by the GISCAD study, but no data are available on the optimal duration of anti-EGFR monoclonal antibodies (moAbs). This issue is of particular interest given the dermatologic toxicities of anti-EGFR moAbs and the emergence of drug resistant clones. In mCRC pts recent data suggest a molecular adaptation of tumor to an intermittent drug schedule with anti-EGFR moAbs. On this basis, we designed a multicenter phase II randomized two arms study with intermittent PAN plus FOLFIRI compared to the same regimen given continuously until disease progression (PD) in the first line treatment of pts with WT RAS and BRAF unresectable mCRC, with a prospective genetic analysis of both tumor tissue and cfDNA.

Trial design: PFS on treatment (PFS_{OT}) at 12months is the primary endpoint. Assuming a p0=30% (corresponding to a median PFS of 7months), and a p1=43% (corresponding to a median PFS of 10months), setting the significance level at 10% with a power of 80% a total of 68 pts will be enrolled in each arm. At the time of enrollment, pts will be immediately randomized to one of the two arms: standard continuous or exploratory intermittent treatment. All pts will receive an induction treatment with 8 cycles of PAN plus FOLFIRI, given every two weeks, at the standard dosage. After the induction treatment, non-progressing pts will receive continuous PAN plus FOLFIRI until PD, unacceptable toxicity or informed consent withdrawal (Standard ARM) or observe a treatment free interval until PD followed by up to 8 cycles of PAN plus FOLFIRI (Experimental ARM). Treatment cycling will continue till any PD on treatment.

Background: Colorectal cancer (CRC) is one of the most common malignancies, and a leading cause of cancer death worldwide. Surgery is the only curative therapy available for locally advanced colon cancer (LACC), however, the disease is associated with a significant recurrence rate and even with adjuvant therapy its prognosis is far from satisfactory. Preoperative treatment strategy is an attractive concept in LACC because it has the theoretical advantages to eradicate micrometastases, to reduce tumor cell shedding during surgery, to allow the assessment of initial tumor response and could be better tolerated than adjuvant treatment. The results of the recently reported FOxTROT trial has shown that preoperative chemotherapy in LACC is feasible with no increase in surgical morbidity or mortality. The immune contexture of solid tumors has become an emerging hallmark of cancers. Recent evidences indicate that immune infiltrate (immunoscore) is an informative prognostic indicator in LACC. Moreover, it was demonstrated that immunoscore is also a stronger predictor of patient survival than microsatellite instability. Based on these considerations, we designed a window of opportunity study to determine the feasibility of nivolumab in the preoperative setting in pts with LACC.

Trial design: Pts will receive nivolumab at a flat dosage of 240 mgs every two weeks on Day -28 and Day-14 (+/- one day) prior to planned surgery on Day 0 or up to + 7 days. An initial 6-pts safety run-in cohort will be followed by an expansion cohort, with a planned accrual of 16 pts. Postoperatively, standard adjuvant chemotherapy will be administered as recommended by guidelines. Primary objective is to determine the safety and feasibility of Nivolumab in the preoperative setting. The exploratory primary objective is the rate of pathological complete tumor regression, as well as correlative studies to determine molecular and immunophenotypic changes in tumor and peripheral blood samples as potential biomarkers of toxicity/efficacy. Secondary objective are tumor response rate defined by RECIST, postoperative complications, relapse-free survival, overall survival and metabolic response changes evaluated by FDG-PET-CT scan prior to surgery.

Chan School of Public Health, Boston, MA, USA, [15]Medical Oncology, Hospital Clínic of Barcelona, Barcelona, Spain

Background: Monoclonal antibodies against checkpoint inhibitors (CHKPNT) such as pembrolizumab showed clinical benefit in patients with microsatellite instability (MSI) in mCRC but not in MSS patients. Cancer vaccines with ADC could be a complementary therapeutic approach to CHKPNT. We previously conducted a negative randomized phase II trial in mCRC patients refractory to standard therapy, with ADC compared to the best supportive (Eur J Cancer 64:167-74, 2016). A phase I-II multicentric trial with avelumab (anti-PD-L1) plus ADC vaccine in pre-treated MSS mCRC patients began in April 2018 (NCT03152565).

Trial design: The study is designed to evaluate the safety, tolerability, pharmacodynamics and anti-tumour effects of the combination in pre-treated MSS mCRC patients. In the phase I, patients are assigned using a standard 3x3 de-escalation criteria (level -1 if dose limiting toxicity (DLT) with avelumab 3 mg/kg every 2 weeks) to received avelumab at a dose of 10 mg/kg every 2 weeks combined to ADC vaccine at days 1, 14, 28, 42 and 56, and thereafter every 6 months until disease progression (maximum of 6 additional doses) or unacceptable toxicity. Biopsies to prepare tumour lysate will be obtained from primary tumour or metastatic disease. The primary objective is to determine the maximum tolerated dose (MTD) and the efficacy of the combination. To detect at least a 20% difference in PFS at 6 months (from 20% to 40%), 33 patients are needed (80% power, alpha equals 5%, two sided). An interim analysis (Simon's two stage) when the first 18 patients are accrued is planned. Secondary objective includes pharmacodynamics (a) NanoString 360 gene immune-signature from archival biopsy, at study entry and at 2 months therapy (b) cytokine and chemokine determination (at study entry and at 2 months therapy) and (c) Autologous tumour mixed leucocyte reaction to test the polarisation of the immune response against the combination (at study entry and at 2 months therapy).

612TiP Phase I studies assessing the safety and clinical activity of multiple doses of a NKG2D-based CAR-T therapy, CYAD-01, in metastatic colorectal cancer

A. Flament[1], A. Hendlisz[2], L. Shaza[2], S. Aspeslagh[2], M. Vouche[3], V. Donckier[3], A. Awada[2], J-P. Machiels[4], M. van den Eynde[4], J-L. Canon[5], J. Carrasco[6], C. Lonez[1], F.F. Lehmann[1]

[1]Clinical Development, Celyad SA, Mont Saint Guibert, Belgium, [2]Medical Oncology Clinic, Institut Jules Bordet, Université Libre de Bruxelles, Brussels, Belgium, [3]Department of Radiology, Institut Jules Bordet, Université Libre de Bruxelles, Brussels, Belgium, [4]Oncology, Cliniques Universitaires St. Luc, Brussels, Belgium, [5] Service d'Oncologie-Hématologie, Grand Hopital de Charleroi Site Notre Dame, Charleroi, Belgium, [6]Medical Oncology, Grand Hopital de Charleroi Site Notre Dame, Charleroi, Belgium

Background: Chimeric antigen receptor T-cell (CAR-Ts) therapies have yet to demonstrate positive results in the context of solid tumors likely because of the inability of classical CAR-Ts to infiltrate into the tumor and overcome the hostile immune suppressive tumor microenvironment (TME). CYAD-01, a NKG2D receptor-based CAR-T, is currently evaluated in the ongoing THINK study (NCT03018405) without preconditioning therapy in both hematologic and solid indications, and demonstrated encouraging signs of clinical stabilization in refractory metastatic colorectal (mCRC) and ovarian cancer patients. These preliminary results prompted us to design a clinical development plan evaluating CYAD-01 in multiple settings.

Trial design: To improve the likeliness to observe clinical activity of CYAD-01 in metastatic solid tumors, the SHRINK (NCT03310008) and the LINK (NCT03370198) trials have been designed to address, respectively, the challenge related to the immunosuppressive TME and difficulty of CAR-T cells to access the site of metastases. The SHRINK trial is evaluating the multiple infusion CYAD-01 treatment i.v. administered concurrently to a standard-of-care FOLFOX neoadjuvant treatment for the treatment of mCRC disease with potentially resectable liver metastases, with the aim to (i) favor infiltration into the immunosuppressive TME but also (ii) provide an opportunity for the CYAD-01 cells to better engraft due to the lymphodepletion induced by the FOLFOX, and likely (iii) increase the NKG2D ligand expression in tumor tissues targeted by CYAD-01. The LINK trial is evaluating multiple hepatic transarterial administrations of CYAD-01 in mCRC patients with unresectable liver metastases with the potential advantage of a lower systemic toxicity and higher and more persistent concentration of the infused cells on the TME compared to systemic administration and difference in blood supply between uninvolved liver parenchyma and metastases. Finally, the boosting of the adaptive immune response by CYAD-01 might control distant lesions due to a possible abscopal effect. Both studies were initiated in 2018 and the first patients were successfully enrolled.

Clinical trial identification: NCT03310008, EudraCT: 2017-000616-41; NCT03370198, EudraCT 2017-000959-11.

613TiP Serum levels of interleukin 8 (IL-8) and other cytokines as predictors of the efficacy of aflibercept in combination with FOLFIRI in metastatic colo-rectal cancer patients: The FLIBER study

C. Buonerba[1], S. Vecchiarelli[2], F. Cappuzzo[2]

[1]Dipartimento di Medicina Clinica e Chirurgia, Università Federico II, Naples, Italy, [2]UOC Oncologia Medica, Ospedale Civile di Ravenna - S.ta Maria delle Croci, Ravenna, Italy

Background: The VELOUR study (Van Cutsem, et al. 2012) showed that the addition of aflibercept to irinotecan-based chemotherapy (FOLFIRI) in patients with metastatic colorectal cancer (mCRC) refractory to oxaliplatin-based chemotherapy was associated with improved progression-free and overall survival. IL-8 enhances cell proliferation and survival and promotes tumor angiogenesis (Lee, et al. 2012). In the randomized phase II AFFIRM study, conducted in mCRC patients treated with oxaliplatin-based chemotherapy with or without aflibercept, high serum levels of circulating IL-8 were significantly associated with reduced PFS (Lambrechts, et al. 2015). While in patients treated without aflibercept, PFS was independent on IL-8 levels, patients treated with aflibercept with IL-8 levels $\leq$ vs. $>$ 19 pg ml−1 presented a median progression free survival of 9.3 (7.52–11.10) vs. 4.1 (2.33–8.54) months. The FLIBER trial aims to explore the predictive value of serum levels of IL-8 and other cytokines in a population of mCRC patients receiving aflibercept plus FOLFIRI.

Trial design: The FLIBER trial is a phase IV single arm study which plans to enroll 124 patients with mCRC resistant to or progressed after an oxaliplatin-containing regimen who are planned to start aflibercept in combination with FOLFIRI as per standard clinical practice and decision by their treating oncologist. Patients will be assessed for a serum cytokine panel at baseline, after 2 months of treatment and at radiologic progression. The primary end point is progression free survival (PFS), with the objective to estimate the difference in PFS between the two groups defined on the basis of their baseline IL-8 levels ($>=$ vs. $<$ than median). The secondary endpoints are Radiologic Response Rate (rRR), Overall Survival (OS) and Safety profile and their relationship with IL-8 levels and the other cytokines assessed. Assessed cytokines include PDGF, IL-1b, IP10, IL-1ra, IL-2, IL-4, IL-5, IL-6, IL-7, IL-8, IL-9, IL-10, IL-12, IL-13, IL-15, IL-17, Eotaxin, bFGF, GCSF, GMCSF, IFNg, MCP1, MIP1a, MIP1b, RANTES, TNFa and VEGF, VEGFA, T-cad, VEGFR3, SAP, VDBP, neuropilin1, CRP, endoglin, PlGF.

Clinical trial identification: EudraCT: 2017-003509-16.

Background: A majority of patients with mCRC are not suitable for potentially curative resection and their management consists in palliative-intended chemotherapy (CT). Nevertheless, it is described that in patients who achieve complete response (CR) with CT alone or after multimodality treatment, median overall survival is significantly longer than in other patients. In combination with CT, anti-EGFR antibodies appear to be the biological agents of choice in order to reach the best response rate as long as tumors are RAS wild-type.To determine RAS and BRAF mutational status, we have already demonstrated the clinical validity and utility of circulating DNA (ctDNA) analysis using IntPlex® method. Selecting patients with this technology, we aim to investigate response rate and outcomes reached with panitumumab in combination with a standard (mFOLFOX6) or an intensified CT regimen (FOLFIRINOX) in RAS and BRAF wild-type (WT) metastatic patients.

Trial design: This is a national multicentric open-label randomized phase II trial. Key inclusion criteria are age between 18 and 75 years, ECOG PS 0 and 1, untreated synchronous or metachronous metastatic disease deemed unresectable with curative intent, RAS and BRAF WT tumor according to analysis of ctDNA by Intplex® technology. 209 patients will be randomized 2:1 to either FOLFIRINOX-panitumumab ($N = 139$) or mFOLFOX6-panitumumab ($N = 70$)(12 planned cycles in each arm). For each arm, two strata are planned according to disease-extent (non/liver limited disease). Primary endpoint is the CR rate defined as complete disappearance of metastatic lesions and CEA level normalization. It can be reached with CT alone or with a multimodal approach. Secondary endpoints are progression-free and overall survival, secondary resection rate, early tumor shrinkage, depth of response, safety, diagnostic performance of ctDNA analysis. On-treatment, an ancillary study assesses appearance of RAS mutations in ctDNA detected by Intplex® technology. The first patient was enrolled in October 2017 and $>$ 20 sites are planned to recruit patients.

Clinical trial identification: NCT02980510.

Background: We have conducted the Nationwide Cancer Genome Screening Project in Japan since April 2015 using Next Generation Sequencing in advanced non-colorectal gastrointestinal (GI) cancer (aNon-CRC), called as the SCRUM-Japan GI-SCREEN. The objective is to evaluate the frequency of cancer genome alterations and to identify patients who are candidate for clinical trial for corresponding targeting agents.

Methods: This study is ongoing with the participation of 23 major cancer centers. Patients with aNon-CRC, including advanced esophageal cancer (aEC), who plan to or receive chemotherapy were eligible. DNA and RNA were extracted from formalin-fixed paraffin embedded (FFPE) tumor samples and were analyzed by the Oncomine Cancer Research Panel (OCP) which allows to detect mutations, copy number variant (CNV) and fusion genes in a CLIA certified CAP accredited lab. The detected genomic variant data were classified according to genetic drivers of cancer, including gain- and loss-of-function or single nucleotide variant based on the Oncomine Knowledgebase.

Results: By the end of March 2017, a total of 220 aEC samples were analyzed. The sequence with the OCP was successfully performed in 144 (65.5%). Out of 144 patients, the proportion of sample and histology type is followed; surgical specimen 52.1%, squamous cell carcinoma 92.4%. The frequently detected mutations were TP53(76.4%), NFE2L2 (38.2%), CDKN2A (9.7%), PIK3CA (6.3%), RB1 (5.6%), and CNVs were CCND1 (38.2%), EGFR (7.6%), ATP11B (6.9%), SOX2 (6.9%). ERBB2 amplification was identified in 3 cases (2.1%) and FGFR3-TACC3 fusion was identified in one case (0.7%). Five patients with druggable genomic alterations (PIK3CA($n = 2$), EGFR($n = 2$), FGFR3-TACC fusion($n = 1$)) were enrolled for clinical trials of targeting therapies.

Conclusions: This nationwide screening system is efficient to detect rare gene alterations in aEC. This novel knowledge provides an intriguing background to investigate new target approaches in these patients and to progress precision medicine. Clinical trial information: UMIN000016344 (Non-CRC).

Clinical trial identification: UMIN000016344.

628P Signal transduction pathway activity during neoadjuvant treatment in esophageal adenocarcinomas

A. Creemers[1], S.L. Meijer[2], M. Stoffels[3], G.K.J. Hooijer[2], L. Holtzer[3], H. van Ooijen[3], A. Van Brussel[3], E.M.G. Aussems-Custers[3], M. van Berge Henegouwen[4], M.C.C.M. Hulshof[5], K.K. Krishnadath[6], A. van de Stolpe[7], M.F. Bijlsma[8], H.W.M. van Laarhoven[1]

[1]Medical Oncology, Academic Medical Center (AMC), Amsterdam, Netherlands, [2]Pathology, Academic Medical Center (AMC), Amsterdam, Netherlands, [3]Precision and Decentralized Diagnostics, Philips Research, Eindhoven, Netherlands, [4]Surgery, Academic Medical Center, Amsterdam, Netherlands, [5]Radiotherapy, Academic Medical Center (AMC), Amsterdam, Netherlands, [6]Gastroenterology, Academic Medical Center (AMC), Amsterdam, Netherlands, [7]Research, Philips, Eindhoven, Netherlands, [8]LEXOR, Academic Medical Center (AMC), Amsterdam, Netherlands

Background: Little is known about signaling pathway activity in esophageal adenocarcinomas. Using a new methodology we have delineated the activity of key pathways involved in tumor growth during neoadjuvant treatment. The aim is to use this knowledge to personalize, and thereby improve, treatment strategies.

Methods: We included all patients with esophageal adenocarcinomas between 2004 and May 2013 in the AMC. Paired tumor samples were obtained before start of neoadjuvant chemoradiation therapy according to the CROSS regimen and at surgical resection of the esophagus. Using a custom-built device, digital annotations of whole slide H&E scans were transferred to a hematoxylin-stained slide, which was subsequently deparaffinized. Marked tumor areas were scraped for RNA extraction and qPCR. qPCR data were subjected to stringent QC prior to determining the signaling pathway activity scores of the AR-, ER-, FOXO/PI3K-, HH-, TGF-β- and WNT pathway, using a combined mRNA-Bayesian model-based method (Verhaegh et al, Cancer Res, 2014). Pathway activity scores were correlated to pathological response to treatment (Mandard score).

Results: Based on a test set of esophageal tumor tissue samples, we determined that tumor areas of $\geq 2mm^2$ were eligible for RNA isolation and pathway activity analysis. We provide a analysis of 288 currently processed samples. FOXO activity was significantly higher in post-treatment resection specimen compared to matched pre-treatment biopsies ($p < 0.001$). Patients with high FOXO activity in post-treatment resection specimen showed better response to treatment ($p = 0.019$).

Conclusions: The assessment of pathway activity is feasible on small amounts of tumor. Marked dynamics in FOXO activity are observed during nCRT in esophageal adenocarcinomas. Patients with high FOXO activity post-nCRT show better response to treatment. An active PI3K pathway blocks FOXO transcriptional activity. To increase FOXO transcriptional activity, patients might benefit from the addition of PI3K-inhibitors to the nCRT regimen.

629P Hypoxia gene expression defines a poor prognostic sub-group in oesophageal adenocarcinoma

R.V. Douglas, C. McKinney, L. Stevenson, L. Cairns, R.D. Kennedy, J.K. Blayney, R.C. Turkington

Queen's University Belfast, Health Science Building, Belfast, UK

Background: The incidence of Oesophageal Adenocarcinoma (OAC) has risen 6-fold in the western world in the last forty years but survival is poor. Increased molecular understanding of this heterogeneous disease is needed to improve treatment selection and develop novel therapies. This study uses gene expression data to perform unbiased molecular subtyping and identify prognostic subgroups in OAC.

Methods: Transcriptional profiling of 274 treatment naïve OAC biopsies was performed using the Almac Diagnostics Xcel array™. All patients received platinum-based neo-adjuvant chemotherapy prior to surgical resection at four United Kingdom centres between 2004-2012. Iterative semi-supervised clustering based on gene expression level variability was performed followed by functional enrichment using DAVID. Cluster membership was assessed for independence of known prognostic factors using Cox proportional hazards regression for relapse-free (RFS) and overall survival (OS). Clustering was repeated with a published 51-gene hypoxia signature with validation in the TGCA OAC ($n = 65$) and oesophageal squamous cell carcinoma ($n = 45$) cohorts.

Results: Patients were clustered into two groups with significantly different RFS ($HR = 0.54$, $p = 0.05$) and OS ($HR = 0.52$, $p = 0.04$). There were no significant differences in known prognostic factors such as pathological response, lymphovascular invasion and resection margin. Pathway analysis revealed the PI3K-AKT, p53, Tumour Necrosis Factor and Hypoxia Inducible Factor 1 (HIF-1) signalling pathway to be upregulated in the poor prognostic group. To further investigate the role of the HIF-1 pathway, a hypoxia 51-gene signature was applied. Patients were stratified into hypoxia low and high groups with improved RFS (HR 0.64, 95% CI 0.42-0.97; $p = 0.04$) and OS (HR 0.67, 95% CI 0.44-1.02; $p = 0.06$) in the hypoxia-low group. Increased OS for the hypoxia-low group was also observed in the TCGA cohort (HR 0.49, 95% CI 0.24-0.97; $p = 0.04$). There was a significant association between membership of the poor prognostic and hypoxia-low cluster groups ($p < 0.001$).

Conclusions: Molecular stratification and application of a hypoxia gene signature identifies a poor prognostic group of OAC patients characterised by upregulation of hypoxia signalling.

630P Neoadjuvant radio-chemotherapy for esophageal cancer: A multicenter European study comparing paclitaxel/carboplatin, 5FU/cisplatin and FOLFOX

P. Allemann[1], S. Mantziari[1], M. Winiker[1], A.D. Wagner[2], A. Digklia[2], M. van Berge Henegouwen[3], S.S. Gisbertz[3], A. Slaman[3], R. van Hillegersberg[4], J.P. Ruurda[4], H. Brenkman[4], M. Nilsson[5], K. Satoshi[5], G. Piessen[6], D. Collet[7], C. Gronnier[7], N. Carrere[8], A. Marinho[8], N. Demartines[1], M. Schafer[1]

[1]Visceral Surgery, Centre Hospitalier Universitaire Vaudois - CHUV, Lausanne, Switzerland, [2]Medical Oncology, Centre Hospitalier Universitaire Vaudois - CHUV, Lausanne, Switzerland, [3]Surgery, Academic Medical Center, Amsterdam, Netherlands, [4]Surgery, University Medical Center Utrecht, Utrecht, Netherlands, [5]Surgical Gastroenterology, Karolinska Institute, Huddinge, Sweden, [6]Chirurgie Digestive, C.H.U. Claude Huriez, Lille, France, [7]Digestive Surgery, University Hospital Bordeaux, Bordeaux, France, [8]Oncological Surgery, CHU Toulouse, Toulouse, France

Background: Different regimens of neoadjuvant radio-chemotherapy are concurrently used prior to surgery for resectable, locally advanced esophageal cancer. Comparative data are scarce and to some extent conflicting, regarding toxicity and long-term outcomes when treating different subtypes. This study aimed to assess clinical tolerances and long-term survival of three commonly used combinations of neoadjuvant therapies.

Methods: Patients operated from January 2004 to December 2014 who underwent neoadjuvant radio-chemotherapy with Paclitaxel/Carboplatin, or 5FU/Cisplatin, or FOLFOX for adenocarcinoma or squamous cell carcinoma were included. Seven European centers colligated data of 1188 patients. Cases with missing data ($n = 147$) or death <30 days postoperative ($n = 51$) were excluded. The primary outcome was the overall survival; secondary outcomes were the completeness and toxicity of neoadjuvant treatment, the disease free survival and the recurrence timing and pattern.

Results: Of the 990 eligible patients, Paclitaxel/Carboplatin was used in 598 patients (60%), 5FU/Cisplatin in 331 (33%) and Folfox in 61 (7%). The groups received a median radiation dose of 41.4 Gy, 45 Gy and 45 Gy ($p = 0.65$). Adenocarcinoma was the most frequent subtype (69%). No differences were detected in median overall survival (41 months, 34 months and 46 months, $p = 0.251$). Comparing the overall survival of the three regimens for adenocarcinoma vs squamous cell carcinoma, no difference was observed as well. There were no differences in chemotherapy-related morbidity (13%, 11% and 9%, $p = 0.57$), chemotherapy completeness (85%, 88% and 90%, $p = 0.542$) and radiotherapy completeness (98%, 99% and 96%, $p = 0.9$) between the three groups. Recurrence rates were similar (42%, 46% and 34%, $p = 0.169$), but median disease-free survival was improved in the 5FU/Cisplatin group (10 months, 18 months and 13 months, $p < 0.001$).

Conclusions: The overall survival did not differ between different neoadjuvant treatments. Moreover, no advantage of one regimen for specific cancer subtypes was observed. At most, a modest clinical advantage of 5-FU/Cisplatin was observed for disease-free survival.

Clinical trial identification: Research Registry number: 2157.

631P Neoadjuvant therapy for esophageal adenocarcinoma: A propensity score-matched comparison of paclitaxel and carboplatin chemoradiotherapy with cisplatin and 5-fluoruracil-based chemo- or chemoradiotherapy

A.P. Barbour[1], S. Brosda[1], B. Wijnhoven[2], S. van Hootgem[2], J.J.B. Lanschot[3], S. Barbour[4], S. Lagarde[2], L. Krause[1], D. Pryor[5], J. Thomas[6], E.T. Walpole[7], A. van der Gaast[8], M. Smithers[6]

[1]Diamantina Institute, The University of Queensland, Woolloongabba, Australia, [2]Department of Surgery, Erasmus Medical Center, Rotterdam, Netherlands, [3]Department of General Surgery, Erasmus Medical Center, Rotterdam, Netherlands, [4]Radiation Oncology Centre, Greenslopes Private Hospital, Greenslopes, Australia, [5]Radiation Oncology, Princess Alexandra Hospital, Woolloongabba, Australia, [6]Department of Surgery, Princess Alexandra Hospital, Woolloongabba, Australia, [7]Medical Oncology, Princess Alexandra Hospital, Woolloongabba, Australia, [8]Medical Oncology, Erasmus University Medical Center, Rotterdam, Netherlands

Background: Multimodality treatments of patients with esophageal adenocarcinoma (EAC) improve survival, but the optimal treatment strategy remains undetermined. This study aimed to compare response, local recurrence and survival outcomes in patients undergoing neoadjuvant paclitaxel and carboplatin chemoradiotherapy with 41Gy (CROSS) with neoadjuvant cisplatin and 5-fluoruracil (CF)-based chemoradiotherapy with 45Gy (CFRT) or CF chemotherapy followed by oesophagectomy for EAC.

Methods: Patients who underwent CROSS, CFRT or CF followed by surgery for EAC were identified from two single institution prospective databases from Australia and the Netherlands (2000-2018) and included in this study. After pair-wise propensity score matching (caliper 0.2) using pre-treatment variables (age, gender, year of treatment, tumor length and site, and clinical T stage), we compared the impact of the treatments on pathological outcomes, patterns of recurrence and overall survival.

Results: Of the 637 eligible patients, 429 patients were analysed following propensity score matching. This resulted in 143 patients in each group with median follow up 61 months. CROSS and CFRT demonstrated significantly higher pathological complete response rates ($p < 0.001$), lower ypT stage ($p < 0.001$) and lower ypN stage ($p < 0.001$) compared with CF. There were no statistically significant differences in 5-year local recurrence-free survival between the three treatment groups: CROSS 76% (95%CI: 68-85); CFRT 71% (95%CI: 64-81); and CF 66% (95%CI: 65-76). Similarly, there were no significant differences in 5-year overall survival rates between groups: CROSS 52% (95%CI: 44-62); CFRT 40% (95%CI: 32-49); and 46% (95%CI: 38-55)($p = 0.18$, log rank). Median overall survival for CROSS was 69 months (95%CI: 47-139), for CFRT 32 months (95%CI: 26-52), and for CF 47 months (95%CI: 33-66) ($p = 0.33$, log rank).

Conclusions: In this study, there were higher pathological response rates and lower pathological stage associated with CROSS and CFRT. However, overall survival and local recurrence was similar for CROSS, CF and CFRT.

632P Induction chemotherapy for locally advanced esophageal cancer

G. Harada, R.R.D.C.C. Bonadio, F.C.C. de Araújo, C.R. Victor, F.R. Takeda, R.A.A. Sallum, U.R. Junior, I. Cecconello, T.B. de Castria

Medical Oncology, ICESP - Instituto do Câncer do Estado de São Paulo, São Paulo, Brazil

Background: The concurrent chemoradiotherapy followed by surgery is the standard treatment for locally advanced esophageal cancer (LAEC) and the role of induction chemotherapy (IC) remains unclear. We aimed to study if the addition of IC to standard treatment increases the rate of pathologic complete response (pCR).

Methods: We assembled a retrospective analysis of patients (pts) diagnosed with LAEC and treated with preoperative chemoradiotherapy followed by esophagectomy (CRT+S), preceded or not by IC, between 2009 and 2017. Patients' characteristics, tumor variables and treatment outcomes were evaluated. Kaplan-Meier method was used to estimate overall survival and Cox proportional hazard model to evaluate prognostic factors.

Results: 103 pts were studied, with a median age of 62 years (range 37-84). Seventy-five pts (73%) were male, 67 (65%) had squamous cell carcinoma and 31 (30%) adenocarcinoma. Forty-three pts (41,7%) received IC followed by CRT+S (IC+CRT+S). The most frequent IC consisted of paclitaxel and platinum (38 pts – 90%) and the median number of cycles was 2 (range 1-6). All pts received CRT+S. Concurrent chemotherapy was a combination of paclitaxel and platinum in 94 pts (91%). The median radiation dose was 41.4 Gy (range 39.6-50.4). There was no statistically significant difference in pCR between the IC group and the standard CRT+S group. The pCR was 41.9% and 46.7% in the IC+CRT+S and CRT+S group ($p = 0,628$), respectively. In the multivariate analysis, pCR was an independent prognostic factor for failure free survival (FFS) (HR 0.35, 95% CI 0.14-0.85, $p = 0.021$), but not for overall survival (OS) ($p = 0.863$). The factor that significantly affected OS in the multivariate analysis was positive lymph node (HR 5.9, 95% CI 1.23-28.27, $p = 0.026$). IC, histology, histologic grade, radiation dose, T stage were not identified as independent prognostic factors for neither OS nor FFS.

Conclusions: Our data suggest that the addition of IC to standard CRT+S does not increase the pCR rate in LAEC. No difference in OS was observed between pts that received or not IC. Regardless of the treatment received, pts achieving a pCR presented improved FFS.

633P The role of comprehensive evaluation for clinical complete response in predicting pathologic complete response in patients treated with neoadjuvant chemoradiation for esophageal squamous cell carcinoma (ESCC)

H-S. Im[1], J. Kang[2], Y-H. Kim[3], H.R. Kim[3], J.H. Kim[4], H-Y. Jung[5], G-H. Lee[5], H.J. Song[5], D.H. Kim[5], K.D. Choi[5], J.H. Lee[5], J.Y. Ahn[5], J-S. Ryu[6], K-J. Cho[7], S-B. Kim[8], S.R. Park[8]

[1]Department of Internal Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [2]Department of Oncology, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [3]Department of Thoracic Surgery, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [4]Department of Radiation Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [5]Department of Gastroenterology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [6]Department of Nuclear Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [7]Department of Pathology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [8]Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea

Background: Neoadjuvant chemoradiation (nCRT) followed by surgery is the preferred treatment for locally advanced ESCC. But a recent trial suggested close observation might be a reasonable option in patients achieving clinical complete response (CR) to nCRT. For this strategy, accurate clinical assessment for predicting pathologic CR (pCR) is essential. In NCCN guidelines PET/CT is recommend as response assessment, whereas endoscopy is optional after nCRT.

Methods: In 234 patients who received nCRT (46–50.4Gy) plus surgery for locally advanced ESCC at Asan Medical Center from 2007 to 2014, the performance of endoscopy and PET/CT which were done 4-8 weeks after nCRT for predicting pCR was evaluated. Metabolic CR (mCR) was defined as complete resolution of FDG uptake within all lesions, making them indistinguishable from surrounding tissue, and endoscopic CR (eCR) as no residual mucosal lesions except for scar change.

Results: pCR (ypT0N0) was achieved in 108 patients (46.2%), and ypT0N+ in 17 (7.3%). Among patients who underwent PET/CT ($n = 231$), mCR was obtained in 102 (44.2%), and non-mCR in 81 (35.1%), whereas metabolic response could not be assessed due to diffuse esophagitis in 48 (20.8%). The sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) of mCR for pCR was 56.6%, 46.4%, 58.8%, and 71.6%, respectively. Among patients who underwent endoscopy ($n = 229$), eCR was obtained in 42 (18.3%), and the sensitivity, specificity, PPV, and NPV of eCR for pCR only in primary tumor site (ypT0N+/-) was 29.5%, 94.4%, 85.7%, and 54.0%, respectively. When adding endoscopic response to metabolic response, the sensitivity, specificity, PPV, and NPV of clinical CR for pCR was 27.9%, 94.3%, 80.6%, and 60.5%, respectively, and the positive likelihood ratio for pCR was 4.9 (95% CI 2.2–10.6).

Conclusions: The addition of endoscopic evaluation to metabolic response after nCRT improved specificity and PPV for pCR compared to metabolic response alone, which could help in applying surveillance strategy without immediate surgery in patients achieving clinical CR after nCRT for ESCC.

634P Prognostic impact of inflammation-based scores in esophageal cancer patients achieving pathologic complete response after neoadjuvant chemoradiotherapy followed by surgery

J. Kang[1], H-S. Im[2], Y-H. Kim[3], H.R. Kim[3], J.H. Kim[4], H-Y. Jung[5], G-H. Lee[5], H.J. Song[5], D.H. Kim[5], K.D. Choi[5], J.H. Lee[5], J.Y. Ahn[5], J-S. Ryu[6], K-J. Cho[7], S-B. Kim[8], S.R. Park[2]

[1]Division of Hematology/Oncology, Department of Internal Medicine, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [2]Department of Oncology, Asan Medical Center, Seoul, Republic of Korea, [3]Department of Thoracic Surgery, Asan Medical Center, Seoul, Republic of Korea, [4]Department of Radiation Oncology, Asan Medical Center, Seoul, Republic of Korea, [5]Department of Gastroenterology, Asan Medical Center, Seoul, Republic of Korea, [6]Department of Nuclear Medicine, Asan Medical Center, Seoul, Republic of Korea, [7]Department of Pathology, Asan Medical Center, Seoul, Republic of Korea, [8]Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea

Background: Patients achieving pathologic complete response (pCR) after neoadjuvant chemoradiotherapy (NCRT) followed by surgery for locally advanced esophageal squamous cell carcinoma (ESCC) have a favorable prognosis. However, about 20–30% of the patients still suffer recurrences, and there are few studies evaluating prognostic factors in these patients. This retrospective analysis was performed to identify the prognostic factors in ESCC patients with pCR after NCRT followed by surgery.

Methods: Among 234 patients with ESCC who were treated with NCRT followed by surgery between 2007 and 2014 at Asan Medical Center in South Korea, 108 patients who achieved pCR ($n = 108$, 46.2%) were included in this analysis. Clinical, pathologic, treatment, and laboratory factors including inflammation-based scores such as neutrophil-lymphocyte ratio (NLR), platelet-lymphocyte ratio (PLR) and modified Glasgow prognostic score (mGPS) were included in univariate and multivariate analysis using the Cox-proportional hazards model.

Results: With the median follow-up duration of 84.5 months (range, 1.3–139.9), 10 patients (9.2%) had recurrent disease. The 5-year overall survival (OS) and relapse-free survival (RFS) rates were 71.9% and 71.5%, respectively. In multivariate analysis, advanced clinical T stage (T3/4 vs.1/2: HR = 2.7; 95% CI, 1.37–5.16; $p = 0.004$), higher post-NCRT PLR ($\geq$167.4: HR = 2.0; 95% CI, 1.01–3.78; $p = 0.048$), and age $\geq$65 years (HR = 2.4; 95% CI, 1.25–4.71; $p = 0.009$) were independent poor prognostic factors for OS. Advanced clinical T stage (T3/4 vs.1/2: HR = 2.7; 95% CI, 1.31–5.65; $p = 0.007$), higher post-NCRT PLR ($\geq$167.4: HR = 2.1; 95% CI, 1.00–4.20; $p = 0.049$), and age $\geq$65 years (HR = 2.1; 95% CI, 1.02–4.21; $p = 0.044$) were also significant adverse prognostic factors for RFS. The 5-year OS rates according to number of risk factors (0/1 vs. 2 vs. 3) were 84.9%, 59.1%, and 43.6%, respectively.

Conclusions: Post-NCRT PLR together with age and pretreatment clinical T stage might be useful in identifying patients with a poor prognosis even after achieving pCR with NCRT plus surgery.

635P Association of sarcopenia with dose-limiting toxicities and survival in oesophageal adenocarcinoma treated with neoadjuvant chemotherapy

J.M.J. Weaver[1], C. Cipriano[1], A. McWilliam[2], Z. Kordatou[3], M. Abraham[3], T. Germetaki[4], G. Papaxoinis[5], W. Mansoor[1]

[1]Medical Oncology, The Christie NHS Foundation Trust, Manchester, UK, [2]Department of Cancer Sciences, University of Manchester, Manchester, UK, [3]Nutrition & Dietetics, The Christie NHS Foundation Trust, Manchester, UK, [4]Medical & Clinical Oncology, The Christie NHS Foundation Trust, Manchester, UK, [5]Medical Oncology, Laiko General Hospital of Athens, Athens, Greece

Background: Despite several recent studies the association of sarcopenia with outcomes in oesophageal adenocarcinoma (OAC); in particular overall survival and dose limiting toxicity (DLT), remains unclear likely due to the heterogeneity of the populations included. There is therefore a need for studies of sarcopenia utilising large homogenously treated cohorts.

Methods: We retrospectively collected data on DLT from 197 OAC patients treated with neoadjuvant chemotherapy at a single institution between August 2009 and September 2016. CT scans were visualised using the Worldmatch software package skeletal muscle at the L3 level was manually segmented. Published sex-specific cut-offs for skeletal muscle index (SMI) were used to classify patients as sarcopenic. Patients were further classified as sarcopenically obese if they had both sarcopenia and a BMI $\geq$ 30. Statistical analysis was completed using RStudio, Kaplan-Meier curves were plotted and differences in survival between sarcopenic and non-sarcopenic patients was analysed using a cox proportional hazards model. The Chi-squared test was used to analyse differences in toxicity between groups.

Results: Sarcopenia was observed in 81% of patients. There was no correlation with age and SMI ($r = -0.1$). Average SMI was greater in men than women (44.2 cm^2/m^2 versus 33.7 cm^2/m^2, male versus female). Sarcopenic patients had a worse overall survival than non-sarcopenic patients (median OS, 28.0 months versus 19.3 months, $p = 0.0225$). In contrast patients with sarcopenic obesity showed no difference in OS, in keeping with

previous data. There was no significant difference between rates of DLT in patients with sarcopenia and those without (16.4% and 13.2% respectively, $p > 0.05$). There was a non-significant trend towards increasing rates of completion of 6 cycles of perioperative chemotherapy in non-sarcopenic patients (47% Vs 37%).

Conclusions: In our large homogenously treated cohort of patients undergoing neoadjuvant chemotherapy for OAC sarcopenia was associated with poorer OS confirming recent studies of smaller mixed populations.

636P Survival benefit of re-irradiation in esophageal cancer patients with locoregional recurrence: A propensity score matched analysis

K. Xiangquan, Y. Huang, B. Zheng, Q. Zhuang, X. Zhang, L. Tang, J. Li, J. Wu

Department of Radiation Oncology, Fujian Cancer Hospital, Fujian Medical University Cancer Hospital, Fuzhou, Fujian, China

Background: To investigate the prognostic factors of esophageal squamous cell carcinoma (ESCC) with locoregional recurrence and to explore whether re-irradiation(re-RT) improves outcomes.

Methods: We retrospectively analyzed 87 ESCC patients with locoregional recurrence. All patients received radiotherapy in the initial treatment. The failure patterns were classified into regional lymph node recurrence only (LN) and local failure with/without regional lymph node recurrence (LF). A propensity score model was utilized to balance baseline covariates: RT group ($n = 33$) comprising patients who underwent re-RT and non-RT group ($n = 33$) without re-RT. Outcomes measure including overall survival (OS) and toxicities.

Results: Median follow-up was 87 months (range 2-206). Of the 87 included patients, 39 received re-RT. Failure pattern and re-RT were the independent prognostic factors of OS ($P = 0.040$ and 0.015) by Cox multivariate analysis. Further subgroup analysis did not demonstrate a survival benefit with re-RT combined with chemotherapy as compared to re-RT alone ($P = 0.70$). After propensity score matching, no differences were found between two groups' characteristics by Chi-square tests. Similarly, Cox model demonstrated failure pattern and re-RT as the prognostic factors, with hazard ratio (HR) 0.319 (95% confidence interval [CI] 0.117–0.869, $P = 0.025$) and HR 0.375 (95% CI 0.201–0.701, $P = 0.002$) in the matched chort. Also, significant differences in OS ($P = 0.004$) were presented in failure pattern (LN vs. LF, $P = 0.004$) and re-RT (RT vs. non-RT, $P < 0.001$). In terms of toxicities, there were 9.09% and 3.03% of tracheoesophageal fistulas, 15.15% and 3.03% of pericardial/pleural effusion in the RT and non-RT group, respectively ($P > 0.05$). The RT group had a higher rate of radiation pneumonitis (24.24% vs. 6.06%, $P = 0.039$), but no pneumonia related deaths occurred.

Conclusions: Re-irradiation might improve the long-term prognosis of locoregional recurrent ESCC with a radiation history. Though the radiation pneumonitis is more frequent, re-irradiation is well tolerated.

637P Magnetic resonance imaging in oesophageal (oes) cancer: Results from the STO3 MRI substudy

M. Davidson[1], M. Nankivell[2], D. Cunningham[1], N. Starling[1], D-M. Koh[3], G. Brown[3], W. Allum[1], A. Wotherspoon[4], E. Smyth[1], L. Ly[2], N. Kleovoulou[2], R. Langley[2], A. Riddell[3]

[1]Gastrointestinal Research, Royal Marsden Hospital NHS Foundation Trust, London, UK, [2]Medical Research Council Clinical Trials Unit at UCL, University College London, London, UK, [3]Radiology Department, Royal Marsden Hospital NHS Foundation Trust, London, UK, [4]Histopathology Department, Royal Marsden Hospital NHS Foundation Trust, London, UK

Background: A key aim of neoadjuvant therapy in oes cancer is to increase the chance of complete R0 resection. Microscopic residual disease after surgery is reported in around 30% cases, mainly involving the circumferential resection margin (CRM), with current staging techniques unable to accurately identify pts at risk of residual tumour at the CRM. Previous small single site studies have shown that high res T2-weighted MRI achieves detailed imaging of oes anatomy and has the potential to serve as an additional non-invasive staging modality.

Methods: As part of the UK STO3 trial pts from participating centres with operable lower oes and type I/II OGJ adenoca were enrolled in the MRI observational sub-study. All pts underwent standard staging investigations, with additional MRI scans pre and post neoadjuvant chemo, followed by surgery. MRI parameters were consistent across sites and included CRM, T/N staging and apparent diffusion coefficient (ADC) assessment. Scans were reviewed locally and centrally to assess interobserver variability. Chemo response and association with pathological outcome were recorded.

Results: Between Aug 2011 and Mar 2015 57 pts were recruited from 11 sites. Of these 32 had matched pre and post chemo scans and 28 had corresponding pathological outcome data available. Negative CRM status was correctly identified on post chemo MRI in 17/19 (89%) cases; positive CRM in 3/9 (33%) cases. When compared to pathological staging there was concordance between MRI T staging in 36% cases, with overstaging in 43% and understaging in 21%. Concordance between MRI and CT for T/N staging was 66% and 77% respectively. Tumour size reductions and ADC increases were observed during chemo. Local sites predicted significantly more CRM involvement than central review (48 vs 19%).

Conclusions: This represents the first prospective, multi-centre, national trial of MRI in oes cancer and is the first report of interobserver variability between treatment centres. Although limited by small numbers, MRI showed promising specificity to identify negative surgical margins and reasonable correlation with pathological outcome. Discrepancy between local and central review was observed, suggesting that more standardised methods of MRI assessment in oes cancer are required.

638P Prognostic value of pretreatment diffusion weighted magnetic resonance imaging based texture in concurrent chemo-radiotherapy of esophageal squamous cell cancer

B. Li[1], Z. Li[2], C. Han[3]

[1]Radiation Oncology, Cancer Hospital and Institute of Shandong, Jinan, China, [2]Radiation Oncology, Shandong Cancer Hospital, Jinan, China, [3]Radiation Oncology, Hebe Cancer Hospital, Shijiazhuang, China

Background: The aim of this study was to explore the prognostic value of diffusion-weighted magnetic resonance imaging (DWI) 3D texture features in esophageal squamous cell carcinoma (ESCC) patients undergoing concurrent chemo-radiotherapy (CRT).

Methods: We prospectively enrolled 82 cases with ESCC into a cohort study which underwent DWI before CRT. All MR examinations included axial T2WI, T1WI and diffusion-weighted sequences ($b = 0$, $b = 600$ s/mm^2). Two groups of tumor features were examined: (1) clinical features (eg, TNM stage, age and gender) and demographics; (2) spatial texture features of apparent diffusion coefficient (ADC), which characterize tumor intensity range, spatial patterns and distribution and associated changes resulting from CRT. A reproducible and no redundant feature set was statistically filtered and validated. The prognostic value of each parameter for overall survival was investigated using Kaplan-Meier and Cox regression models for univariate and multivariate analyses, respectively.

Results: Both univariate and multivariate Cox model analyses showed that the radiation dose; IHIST_energy, m_contrast_1, m_clustershade_2, Diff_ClusetrTendency_2, Diff_homogeneity_2, m_Inversevariance_2, high intensity small zone emphasis (HISE) and low intensity large zone emphasis (LILE) associated significantly with survival. Our study showed seven 3D texture parameters extracted from ADC maps could distinguish high, median and low risk groups (Log-rank $c^2 = 9.7$, $P = 0.00773$).

Conclusions: The ADC 3D texture features can be useful biomarkers to predict the survival of ESCC patients who received CRT. The combination of DWI texture and conventional prognostic factors can be used to generate robust predictive models for survival rate.

639P Volume reduction rate of the primary tumor of esophageal squamous cell carcinoma after neoadjuvant chemotherapy: Could this measurement be a surrogate end point for survival before surgery?

S. Nagasawa[1], T. Ogata[1], K. Hara[1], Y. Shimoda[1], M. Nakazono[1], Y. Kumazu[1], T. Hayashi[1], T. Yamada[1], Y. Rino[2], M. Masuda[2], T. Yoshikawa[3], T. Oshima[1]

[1]Gastrointestinal Surgery, Kanagawa Cancer Center, Yokohama, Japan, [2]Surgery, Yokohama City University, Yokohama, Japan, [3]Gastric Surgery Division, National Cancer Center Hospital, Tokyo, Japan

Background: Neoadjuvant chemotherapy (NAC) followed by surgery is regarded as a standard treatment for Stage II and III resectable thoracic esophageal squamous cell carcinoma (ESCC) in Japan. In general, therapeutic effect of NAC against the primary tumor is estimated microscopically with resected specimen after surgery. Then, this microscopic assessment is validated as surrogating survival. However, as this assessment needs resected specimen, therapeutic effect could not be evaluated before surgery. The aim of this study was to investigate whether therapeutic effects in imaging findings obtained by calculating tumor volume reduction could be a surrogating survival or not.

Methods: This retrospective study examined the patients who fulfilled the following criteria; (1) thoracic ESCC, (2) underwent esophagectomy following NAC between

January 2011 and December 2015, and (3) clinical Stage II or III. Tumor volume was calculated by multiplying length and thickness in the lateral view of esophagography. The reduction rate of tumor volume was calculated as follow; (pre NAC tumor volume – post NAC tumor volume) / pre NAC tumor volume . The cut off value of volume reduction ratio was determined as 50%, 60%, and 70% respectively. Patients were divided into an effective group and an ineffective group in each cut off value, and examined relationship with 3-year relapse-free survival (3yRFS). The hazard ratio (HR) for 3yRFS in each cut off value was estimated for selecting optimal cut off surrogating survival.

Results: In total, 93 patients were included in this study. 3yRFS of the effective group / ineffective group and HR of ineffective group for effective group in each cut off were 70.2% / 39.4% (HR = 0.469 [95% CI = 0.253 - 0.868], p = 0.0136) in 50%, 73.5% / 40.3% (HR = 0.418 [95% CI = 0.216 - 0.809] , p = 0.00752) in 60%, and 80.4% / 42.8% (HR = 0.427 [95% CI = 0.199 - 0.916], p = 0.0243) in 70%.

Conclusions: Therapeutic effect of NAC evaluated by imaging finding was reflected in 3-year relapse free survival. Especially for optimal surrogate of 3yRFS, the optimal cut off point was 60% volume reduction after NAC.

640P A model using computed tomography-based compactness to predict prognosis after multimodal treatment for esophageal squamous cell carcinoma

Q. Wang[1], B. Cao[1], J. Chen[2], T. Li[3], J. Lang[3], Z. Xiao[4]

[1]Radiation Oncology, Sichuan Cancer Hospital & Institution, Sichuan Cancer Center, School of Medicine, University of Electronic, Chengdu, China, [2]Radiation Oncology, Fujian Cancer Hospital & Fujian Medical University Cancer Hospital, Fuzhou, China, [3]Department of Radiotherapy, Sichuan Cancer Hospital & Institute, Chengdu, China, [4]Radiation Oncology, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: We aimed to establish a risk model using computed tomography-based compactness to predict overall survival (OS) and progression-free survival (PFS) after multimodal treatment for esophageal squamous cell carcinoma (ESCC).

Methods: We extracted pre-treatment CT-based tumor data (volume, surface area, and compactness) for 512 cases of ESCC that were treated at 3 centers. A risk model based on compactness was trained using Cox regression analyses of 83 cases, and then the model was validated using two independent cohorts (98 patients and 283 patients). The largest cohort (283 patients) was then evaluated using the risk model to predict response to radiotherapy with or without chemotherapy.

Results: In the three datasets, the pre-treatment compactness risk model provided good accuracy for predicting OS (P = 0.012, P = 0.022, and P = 0.003) and PFS (P < 0.001, P = 0.003, and P = 0.005). Patients in the low-risk group did not experience a significant OS benefit from concurrent chemoradiotherapy (P = 0.099). Furthermore, after pre-operation concurrent chemoradiotherapy, the OS outcomes were similar among patients in the low-risk group who did and did not achieve a pathological complete response (P = 0.127). Compactness was correlated with clinical T stage but was more accurate for predicting prognosis after treatment for ESCC, based on higher C-index values in all three datasets.

Conclusions: Our compactness-based risk model was effective for predicting OS and PFS after multimodal treatment for ESCC. Therefore, it may be useful for guiding personalized treatment.

641P Clinical significance of 18F-fluorodeoxyglucose-positron emission tomography-positive lymph nodes to outcomes of trimodal therapy for esophageal squamous cell carcinoma

Y. Hamai[1], M. Emi[1], Y. Ibuki[1], M. Okada[2]

[1]Surgical Oncology, Institute of Biomedical & Health Sciences, Hiroshima University, Hiroshima, Japan, [2]Surgical Oncology, Hiroshima University, Hiroshima, Japan

Background: The clinical significance of lymph node (LN) status determined by preoperative ^{18}F-fluorodeoxyglucose-positron emission tomography (FDG-PET) has not been investigated in patients with locally advanced esophageal squamous cell carcinoma (ESCC) treated with neoadjuvant chemoradiotherapy (NCRT) followed by surgery (trimodal therapy).

Methods: We reviewed 132 consecutive patients with ESCC who were preoperatively evaluated using FDG-PET before and after NCRT to analyze associations among LN status according to PET findings, pathological LN metastasis and the prognosis of ESCC after trimodal therapy.

Results: PET-positive LN both before and after NCRT comprised significant predictive markers of pathological LN metastasis (sensitivity, specificity and accuracy: 84.5%; 40.5%; 59.8% [p = 0.002] before, and 27.6%, 87.8% and 61.4% [p = 0.02] after NCRT, respectively). The numbers of LN evaluated using PET before and after NCRT and of pathological metastatic LN were significantly associated. Univariate and multivariable analyses selected LN status determined by PET before NCRT as a significant independent predictor of both recurrence-free (LN negative vs. positive: hazard ratio [HR], 1.90; 95% confidence interval [CI], 1.02 – 3.23; p = 0.045) and overall survival (HR, 2.62; 95% CI, 1.29 – 5.30, p = 0.01).

Conclusions: The status of LN determined by preoperative FDG-PET is significantly associated with pathological LN status and the prognosis of ESCC with trimodal therapy. Thus, FDG-PET is a useful diagnostic tool with which to preoperatively predict pathological LN metastasis and survival among patients with ESCC.

642P Phase I study results from an esophageal squamous cell carcinoma (ESCC) cohort treated with M7824 (MSB0011359C), a bifunctional fusion protein targeting transforming growth factor β (TGF-β) and PD-L1

C-C. Lin[1], T. Doi[2], K. Muro[3], M-M. Hou[4], T. Esaki[5], H. Hara[6], H-C. Chung[7], M. Osada[8], C. Helwig[9], S. Kondo[10]

[1]Department of Oncology, National Taiwan University Hospital, Taipei City, Taiwan, [2]Division of Endoscopy and Gastrointestinal Oncology, National Cancer Center Hospital East, Kashiwa, Chiba, Japan, [3]Department of Endoscopy, Aichi Cancer Center Hospital, Nagoya, Japan, [4]Division of Hematology-Oncology, Chang Gung Memorial Hospital-Linkou, Taoyuan, Taiwan, [5]Department of Gastrointestinal and Medical Oncology, National Kyushu Cancer Center, Fukuoka, Japan, [6]Department of Gastroenterology, Saitama Cancer Center, Saitama, Japan, [7]Medical Oncology, Severance Hospital, Seoul, Republic of Korea, [8]Medical Oncology, Merck Serono, Tokyo, Japan, [9]Medical Oncology, Merck KGaA, Darmstadt, Germany, [10]Department of Hepatobiliary and Pancreatic Oncology, National Cancer Center Hospital, Tokyo, Japan

Background: Inhibition of the TGF-β pathway, which promotes tumor immunosuppression, may enhance the clinical response to PD-(L)1 monoclonal antibodies (mAbs). M7824 is an innovative first-in-class bifunctional fusion protein composed of a human anti–PD-L1 IgG1 mAb fused with 2 extracellular domains of the TGFβ receptor II to function as a TGF-β "trap". We report on the safety and efficacy of M7824 in a cohort of Asian patients (pts) with ESCC. Esophageal cancer is the sixth most common type of cancer in Eastern Asia, with ESCC accounting for ≈90% of cases. ESCC represents an area of high unmet need. Additionally, no immunotherapies have been yet approved for this patient population, and monochemotherapy with a taxane or irinotecan remains the 2L standard of care (ORRs, ≤16%).

Methods: In this expansion cohort of the ongoing, phase 1 trial NCT02699515, Asian pts with ESCC unselected for PD-L1 expression, for which no standard therapy exists or has failed, received M7824 1,200 mg q2w until disease progression, unacceptable toxicity, or trial withdrawal. The primary objective is safety and tolerability; secondary objectives include best overall response per RECIST v1.1.

Results: As of January 4, 2018, 30 pts received M7824 for a median of 6.1 (range, 2.0–44.1) weeks; 4 pts remained on treatment. 76.7% of patients had received ≥2 prior lines of treatment. The most common TRAEs were hypothyroidism, maculopapular rash (both 16.7%), rash (13.3%), and interstitial lung disease (ILD; 10.0%). Grade 3 TRAEs occurred in 4 pts (13.3%; eczema, increased amylase, lip SCC, maculopapular rash, rash); 2 grade 4 TRAEs were observed (6.7%; ILD, increased blood creatine phosphokinase). 3 treatment discontinuations, but no deaths, due to TRAEs occurred. 6 pts (confirmed ORR, 20.0%; unconfirmed ORR, 26.7%) had a partial response (duration of response, 1.4+, 2.8+, 4.2+, 4.2+, 5.8, and 7.0 months); 5 pts had stable disease (disease control rate, 36.7%) by investigator read.

Conclusions: M7824 had a manageable safety profile and promising preliminary efficacy in heavily pretreated Asian pts with ESCC and no/limited treatment options.

Clinical trial identification: NCT02699515.

643P M7824 (MSB0011359C), a bifunctional fusion protein targeting PD-L1 and TGF-*β*, in patients with post-platinum esophageal adenocarcinoma (EAC): Preliminary results from a phase I cohort

B. Tan[1], A. Khattak[2], E. Felip[3], K. Kelly[4], P. Rich[5], D. Wang[6], C. Helwig[7], I. Dussault[8], L. Ojalvo[9], N. Isambert[10]

[1]Medical Oncology, Washington University School of Medicine, Saint Louis, MO, USA, [2]Medical Oncology, Fiona Stanley Hospital, Murdoch, Australia, [3]Medical Oncology Service (Lung Cancer Unit), Vall d'Hebron University Hospital, Barcelona, Spain, [4]Hematology Oncology, University of California Davis Cancer Center, Sacramento, CA, USA, [5]Medical Oncology, Cancer Treatment Centers of America, Newnan, GA, USA, [6]Medical Oncology, Henry Ford Hospital, Detroit, MI, USA, [7]Biostatistics, Merck KGaA, Darmstadt, Germany, [8]Clinical Biomarkers, Immuno-Oncology, EMD Serono, Billerica, MA, USA, [9]Immuno-Oncology, EMD Serono, Billerica, MA, USA, [10]Medical Oncology, Centre Georges-François Leclerc, Dijon, France

Background: TGF-β and PD-(L)1 are 2 mechanisms of immune suppression in the tumor microenvironment; blocking both may enhance antitumor activity. M7824 is an innovative first-in-class bifunctional fusion protein composed of an anti–PD-L1 mAb fused with 2 extracellular domains of TGF-βRII (a TGF-β "trap"). Advanced EAC is treated per gastric cancer guidelines, with ORRs ≤14% with 2L SoC taxane monotherapy. We report results in patients (pts) with EAC that progressed on ≥ 1 platinum-based therapy. Emerging data with immunotherapies show clinical activity in advanced EAC, though none are currently approved in these pts.

Methods: In the ongoing trial NCT02517398, pts with advanced, post-platinum EAC received M7824 1200 mg q2w until confirmed PD per RECIST v1.1, unacceptable toxicity or trial withdrawal. The primary endpoint is BOR per RECIST; secondary endpoints include safety/tolerability. Biomarker analysis included tumor cell PD-L1 expression (antibody clone 73-10).

Results: As of August 23, 2017 (median follow-up, 14.4 [range, 1.3–43.3] weeks), 30 pts with advanced EAC (80% had ≥2 prior lines of therapy) received M7824. The median therapy duration was 6.1 (range, 2.0–40.0) weeks; treatment was ongoing in 4 pts (13.3%). 19 pts (63.3%) had TRAEs; 7 pts (23.3%) experienced grade 3 TRAEs (anemia [2 pts], Bowen's disease, cancer pain, generalized rash, hemorrhagic gastritis, hypophysitis, hypopituitarism, and skin SCC [1 pt each]). No grade 4 TRAEs, study discontinuations, or deaths due to a TRAE were observed. 6 pts (confirmed ORR 20.0%) had a PR with 3 responses ongoing per RECIST (DOR, 1.4+, 2.0, 2.8, 2.9+, 3.6, 6.5+ months), and 4 pts (13.3%) had SD per RECIST by independent committee read. 9 pts (31.0% of 29 evaluable) had PD-L1 + (≥1%) tumors. ORR was 22.2% in pts with PD-L1+ and 20.0% in pts with PD-L1– tumors.

Conclusions: These preliminary data show that M7824 resulted in a manageable safety profile in pts with advanced EAC. Early signs of clinical efficacy in this heavily pretreated population are encouraging, with an ORR of 20%, irrespective of PD-L1 expression. Updated efficacy data and biomarker analysis will be presented.

Clinical trial identification: NCT02517398.

Background: We initiated the Nationwide Cancer Genome Screening Project in Japan since February 2014. From October 2015, we have introduced the Next Generation Sequencing to detect cancer genome alterations in advanced pancreatic cancer (aPC), called as the SCRUM-Japan GI-SCREEN.

Methods: This study is ongoing with 20 major cancer centers. Patients with aPC who plan to or receive chemotherapy were eligible. DNA and RNA were extracted from formalin-fixed paraffin embedded (FFPE) tumor samples and were analyzed by the Oncomine Cancer Research Panel (OCP) which allows to detect mutations, copy number variant (CNV) and fusion genes in a CLIA certified CAP accredited lab. The detected genomic variant data were classified according to genetic drivers of cancer, including gain- and loss-of-function or single nucleotide variant based on the Oncomine Knowledgebase.

Results: As of March 31st in 2017, total of 270 aPC patients were enrolled and 209 samples were analyzed. The sequence was successfully performed in 136 tumors (65.1%). The origin of samples included the primary site of 65.4%, metastatic site of 34.6%. The tissue samples were obtained by surgical resection 32.4%, needle biopsy 33.8%, EUS-FNA 27.9%, and other 5.9%. Rate for success sequence of EUS-FNA was 56.7%. The frequently detected mutations (≥ 2%) in 136 samples of which results were available were KRAS (91.9%), TP53 (62.5%), CDKN2A (14.0%), SMAD4 (10.3%), GNAS (4.4%), TET2(4.4%), PIK3CA(3.7%), ATM (2.9%), STK11 (2.9%), BRCA2 (2.2%). Most frequently detected CNVs (≥ 7copies) was MYC (2.9%), and no gene fusion was detected. We will show the clinical outcome based on certain key cancer genome alterations.

Conclusions: This nationwide screening system is efficient to detect rare gene alterations in aPC. This novel knowledge provides an intriguing background to investigate new targeted approaches in these patients and to progress precision medicine.

Clinical trial identification: UMIN000016344.

645P Spatial genomic heterogeneity from multi-region endoscopic biopsies in primary gastric cancer: Implications for precision therapy

S.J. Klempner[1], J. Chao[2], K. Kim[3], K-M. Kim[4], S-T. Kim[3], J. Lee[3], H. Lee[5]

[1]Medical Oncology, The Angeles Clinic and Research Institute, Los Angeles, CA, USA, [2]Department of Medical Oncology and Therapeutics, City of Hope, Duarte, CA, USA, [3]Medicine, Samsung Medical Center, Seoul, Republic of Korea, [4]Pathology, Samsung Medical Center, Seoul, Republic of Korea, [5]Gastroenterology, Samsung Medical Center, Seoul, Republic of Korea

Background: The responses and benefit from targeted therapies in gastric cancer (GC) remain limited and improved biologic understanding is needed. Both inter-tumoral and intra-tumoral heterogeneity for HER2 and EGFR has been observed in small datasets and may limit efficacy of targeted therapies. Broader heterogeneity assessment has not been studied. We sought to explore intra-tumoral heterogeneity in GC by multi-region sampling of primary gastric tumors with subsequent interrogation of mutational differences via next generation sequencing (NGS) and cell-free DNA (cfDNA) analyses.

Methods: Patients with newly diagnosed advanced GC underwent endoscopic mapping and pre-determined 8-region biopsy of the primary with concurrent plasma cfDNA sampling. Biopsy samples were subjected to NGS using a 32-gene custom panel and plasma cfDNA analyzed via 28-gene cfDNA assay. Clinicopathologic features and genomic alterations (GA) were abstracted and descriptive statistics were used to compare samples.

Results: All six initial patients underwent multi-region biopsy and NGS. Within a given patient the average number of GA observed in all biopsies (shared GA) was 3.3 with an average of 12.8 non-shared alterations ($p = < 0.05$). There was no significant difference in the average mutant allele frequency (MAF) or MAF variability between shared and non-shared GA in the primary tumor ($p = > 0.05$). Cell free DNA analyses identified GA not found in each respective case's multi-region primary tumor analysis, likely reflective of GA derived from metastatic sites. An updated cohort will be presented.

Conclusions: Endoscopic multi-region biopsy of GC is feasible and significant genomic heterogeneity existed within the primary in all patients. Paired cfDNA analyses should also be included to complement studies of intra-tumoral heterogeneity. Standardized methods to determine intra and inter-tumoral heterogeneity are needed and stratification by heterogeneity score in prospective trials may inform optimal patient selection, particularly in targeted therapies.

646P EGFR amplification (amp) and survival in the REAL-3 trial

E. Smyth[1], K. Kouvelakis[2], D. Cunningham[1], J.C. Hahne[3], C. Peckitt[2], G. Vlachogiannis[3], D. Watkins[1], S. Rao[1], N. Starling[1], S.H. Wilson[3], T.S. Waddell[4], A. Okines[1], T. Crosby[5], W. Mansoor[4], J. Wadsley[6], G. Middleton[7], A. Wotherspoon[8], I. Chau[9], N. Valeri[3]

[1]Gastrointestinal Oncology, Royal Marsden Hospital NHS Foundation Trust, London, UK, [2]R&D, Royal Marsden Hospital NHS Foundation Trust, London, UK, [3]Molecular Pathology, The Institute of Cancer Research/Royal Marsden NHS Foundation Trust, Sutton, UK, [4]Medical Oncology, The Christie NHS Foundation Trust, Manchester, UK, [5]Oncology, Velindre Cancer Centre, Cardiff, UK, [6]Oncology, Weston Park Hospital Cancer Research Centre, Sheffield, South Yorkshire, UK, [7]Institute of Immunology and Immunotherapy, University of Birmingham, Birmingham, UK, [8]Histopathology, Royal Marsden Hospital NHS Foundation Trust, Sutton, UK, [9]Department of Medicine, The Institute of Cancer Research/Royal Marsden NHS Foundation Trust, Sutton, UK

Background: EGFR amp occurs in 6-10% of gastroesophageal adenocarcinomas (OGA). The effect of EGFR amp on survival in advanced chemotherapy treated OGA is unknown. We evaluated EGFR amp in tissue and plasma in patients (pts) treated in the REAL3 trial.

Methods: REAL3 was a randomised, open-label phase 3 trial in treatment naïve, advanced OGA pts assessing the addition of panitumumab (P) to epirubicin, oxaliplatin and capecitabine (EOX) (HR 1.37 (95% CI 1.07-1.76) $p = 0.013$; EOX-P vs EOX). DNA was extracted from pre-treatment biopsies and plasma. EGFR copy number was assessed by ddPCR using probes for EGFR and reference probe CNTNAP2 (Ch7). EGFR:CNTNAP2 copy number assessment allowed detection of EGFR amp and exclusion of Ch7 polysomy. The association between EGFR amp and progression free and overall survival (PFS/OS) was assessed by the Kaplan-Meier method and Cox regression.

Results: 271 pts (of a total 553 pts treated) had tissue analysed. EGFR ratio was ≥2 in 19/271 (7.0%); 14/271 (5.2%) had ratio ≥5. Plasma was analysed in 370 pts; 23/370 (6.2%) had EGFR ratio ≥2 and 10/370 (2.7%) had ratio ≥5. EGFR amp pts were balanced according to clinicopathological variables. Of 14 EGFR amp tissue samples 7 plasma samples (50%) were concordant; all had EGFR ratio ≥ 5. OS and PFS by EGFR amp are shown in the table. Results were similar for ratio ≥5. Multivariate analysis adjusted for age, gender, PS and histology demonstrated a similar prognostic trend in each arm.

Table: 646P OS and PFS by arm and EGFR amp

	EGFR	n	Median OS (95% C.I.)	HR (95% C.I.)
EOX OS				
Tissue	<2	120	12.5 (9.5-15.7)	Ref
	≥2	7	11.5 (na)	1.2 (0.5-2.8)
Plasma	<2	163	11.8 (10.5-14.6)	Ref
	≥2	4	11.5 (na)	1.6 (0.5-5.0)
EOX PFS				
Tissue	<2	120	7.6 (6.4-8.9)	Ref
	≥2	7	6.6 (na)	1.4 (0.6-3.2)
Plasma	<2	163	7.1 (6.2-8.6)	Ref
	≥2	4	6.5(na)	1.2 (0.4-3.2)
EOX-P OS				
Tissue	<2	113	8.5 (7.0-9.7)	Ref
	≥2	10	5.7 (1.7-12.9)	1.3 (0.7-2.4)
Plasma	<2	169	9.7 (8.5-11.8)	Ref
	≥2	18	7.8 (3.9-12.9)	1.6 (0.8-3.1)
EOX-P PFS				
Tissue	<2	113	5.7 (4.5-6.3)	Ref
	≥2	10	2.7 (1.6-12.2)	1.2 (0.6-2.3)
Plasma	<2	169	6.9 (6.0-8.6)	Ref
	≥2	18	5.3 (2.6-10.0)	1.28 (0.8-2.1)

Conclusions: Liquid biopsy using ddPCR can detect EGFR amp in advanced OGA patients; higher levels of EGFR tissue amp may predict plasma status. EGFR amp appears to be negatively prognostic, however due to low biomarker prevalence this difference was not significant.

Clinical trial identification: NCT00824785.

Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Warsaw, Poland, [6]Preclinical Development Departament, Celon Pharma, Lomianki, Poland, [7]Celon Pharma S.A., Lomianki, Poland

Background: Fibroblast growth factors (FGF) and their receptors are complex intracellular pathway that controls cellular proliferation and tumour growth and invasion. FGFR alterations have been shown to be associated with the initiation and progression of gastric cancer (GC). We investigated the correlations of the FGFR2 amplification and expression with clinicopathological characteristics and outcomes in advanced/ metastatic gastric cancer patients who received systemic chemotherapy based on fluoropyrimidine.

Methods: FFPE tumor samples were obtained from patients with advanced/ metastatic gastric cancer who received systemic chemotherapy based on fluoropyrimidine diagnosed at 2 cancer centers between 2010 and 2016. FGFR2 gene copy number was assessed by FISH method using probes specific for the 10q26 locus and the chromosome 10 centromere (CEN10). FGFR2 amplification was defined as FGFR2/CEN10 $\geq$2.0. FGFR2 protein expression was determined by immunohistochemistry. Overexpression was defined as complete membrane staining intensity $\geq$2 + (graded from 0 to 3+) in cancer cells.

Results: From the cohort consists of 186 GC patients, FFPEs were available from 123 pts. FGFR2 amplification was found in 4/123 (3,3%) patients with FGFR2/CEN10 median 1,16 +1,77 and range 0,8-20,0. FGFR2 overexpression was observed in 5/123 (4,1%) patients. FGFR2 amplification had no significantly impact on overall survival (OS) and progression free survival (PFS) in compare those without FGFR2 amplification (respectively, HR = 1.43, 95% CI 0.54 to 4.04, p = 0.4426 and HR = 3.06, 95%CI 0.94 to 9.97, p = 0.0628). There was no prognostic significance observed for FGFR2 overexpression on OS and PFS (respectively, HR = 1.27, 95%CI 0.52 to 3.15, p = 0.5961 and HR = 2.44, 95%CI 0.88 to 6.78, p = 0.0863).

Conclusions: The rate of GC patients with tumors positive for FGFR2 amplification or expression was consistent with the data published in the literature. However FGFR2 amplification and overexpression has no prognostic significance in advanced/ metastatic gastric cancer patients who received systemic chemotherapy based on fluoropyrimidine. Therefore, further investigation on a larger population is required.

648P Changes in CpG methylation of APC, CDH13, MLH1, MGMT, P16 and RASSF1A in gastric adenocarcinoma

N.N. Timoshkina[1], O.I. Kit[2], D.I. Vodolazhskiy[1], N.V. Soldatkina[2], Y.A. Gevorkyan[2], N.S. Samoylenko[2], D.A. Kharagezov[2], M.N. Duritskiy[3], A.V. Dashkov[2], D.O. Kaymakchi[2], D.S. Petrov[2], S.A. Ilchenko[2], V.A. Sustretov[3], L.Y. Vladimirova[4]

[1]Laboratory of Molecular Oncology, Rostov Research Institute of Oncology, Rostov-on-Don, Russian Federation, [2]Department of Surgical Oncology, Rostov Research Institute of Oncology, Rostov-on-Don, Russian Federation, [3]Clinical Diagnostic Department, Rostov Research Institute of Oncology, Rostov-on-Don, Russian Federation, [4]Medical Department, Rostov Research Institute of Oncology, Rostov-on-Don, Russian Federation

Background: Stomach cancer (SC) is one of the most common cancers and the third leading cause of cancer-related deaths; however, it is often diagnosed at later stages. Literature data on epigenetic changes in stomach cancer and precancer, in particular on hypermethylation of tumor suppressor genes, indicate its important role in gastric tissue malignization.

Methods: Bisulfite pyrosequencing was used to study the CpG methylation in promoter sites of 6 tumor suppressor genes (APC, CDH13, MLH1, MGMT, P16 and RASSF1A). The study included paired bioptates of tumors and intact tissues obtained from 35 patients (25 men, 10 women, median age 67 years) with stomach cancer (G2-3 adenocarcinoma, T3-4N0-2M0).

Results: The rates of hypermethylation of the MGMT, P16 and RASSF1A genes amounted to 23%, 14% and 11% respectively. Increased methylation in the promoter site of the MLH1 gene was observed in one case only (11% vs 4%). Regulatory sites of CDH13 and APC genes in intact tissues were atypically hypermethylated in 80% of cases, which was obviously associated with functional characteristics of the gastric mucosa. However, the methylation of the promoter site of the CDH13 gene in non-tumor tissue was 2 times lower compared to the local tumor (p = 0.002) and 1.5 times lower compared to the tumor with lymph node metastases (p = 0.012). An association between the methylation of the P16 and RASSF1A genes and higher tumor grade G (p = 0.046) and increasing tumor sizes (T-classification, p = 0.028) was registered.

Conclusions: We observed hypermethylation of the promoter sites of the MGMT, P16 (CDKN2A) and RASSF1A genes in malignant stomach tissues compared to intact tissues which demonstrated the importance of disorders of repair processes (MGMT and RASSF1A) and mechanisms of regulation of the cell cycle (CDKN2A) in the malignization of stomach tissues. The methylation status of these genes can be a useful biomarker for early diagnosis of stomach cancer or possible therapeutic targets.

649P The level of somatic mutations as an indicator of overall survival in gastric cancer

T. Kekeeva[1], A.S. Tanas[2], L. Khashimov[3], V. Lyadov[4], Y. Andreeva[5], G. Frank[5], L. Zavalishina[5], D.V. Zaletaev[6], V.V. Strelnikov[7]

[1]Laboratory of Epigenetics, Research Centre for Medical Genetics, Moscow, Russian Federation, [2]Epigenetics, Research Centre for Medical Genetics, Moscow, Russian Federation, [3]Pathology, Russian Medical Academy of Postgraduate Education, Moscow, Russian Federation, [4]Surgery, Treatment and Rehabilitation Center, Moscow, Russian Federation, [5]Pathology Department, Russian Medical Academy of Continuous Professional Education, Moscow, Russian Federation, [6]Laboratory of Medical Genetics, Sechenov First Moscow State Medical University, Moscow, Russian Federation, [7]Epigenetics, Institute of Molecular Medicine, Moscow, Russian Federation

Background: Gastric cancer (GC) is a leading cause of cancer deaths. Tumor staging has been conceived as the best predictor of patient survival. Nevertheless, TNM classification has limited power to fully reflect the complicated progression events. Prognosis varies from individual to individual even though the two patients stay in a similar tumor stage, therefore the molecular biology of the individual tumor might be the key point to better understand the nature of GC. The identification of somatic mutations (SM) has the potential to offer diagnostic and prognostic information. The present study is focusing on implementation of clinical exome sequencing for SM identification.

Methods: 18 gastric cancer specimens and 18 corresponding adjacent normal gastric specimens were obtained from GC patients with stages from Ia to IV. Paired-ended sequencing was performed using Trusight one sequencing panel (Illumina) on a NEXTSEQ500 platform. 94,5% of the target regions were represented with an average sequencing depth of 20-fold. A somatic variant list was generated for each patient by using MuTect.

Results: Tumor and normal library targeted 4,813 genes associated with known clinical phenotypes were sequenced with mean coverage of 99x. Mean number of detected variations was 7613 per sample. After MuTect filtration the amount of SM was varied from 2 to 414 per sample. We found 692 SM: 5 pathogenic mutations in TP53, ARID1A and HER2 genes, 40 were described in COSMIC and dbSNP database, the rest were novel mutations. By the time of 2 years follow-up, 5 patients (27.8%) died, all of them had intermediate grade adenocarcinoma. Importantly, all of them had dramatic number of SM (from 37 to 414). At the operation moment 3 of them had III stage, 2 of them had 1b and IIa stages. For patients with overall survival (OS) > 2 years the number of SM increases with disease stage: I-II stage from 2 to 12, III stage – from 2 to 20, IV stage – from 12 to 43. For patients with OS < 2 years the number of SM was high nevertheless stage.

Conclusions: We found more than 600 novel mutations, from them 18 mutations were localized in genes previously associated with gastric cancer pathogenesis. In the current moment of the investigation patients with high level of SM have unfavorable prognosis (OS less than 2 year) regardless of stage.

650P Mechanisms of G9a on promoting tumor invasion and metastasis of gastric cancer

B. Liu[1], L. Hu[2]

[1]Surgery, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China, [2]Surgery, Shanghai Ruijin Hospital, Shanghai Jiao Tong University, College of Medicine, Shanghai, China

Background: Histone methyltransferase G9a is up-regulated in a wide variety of human tumors. The aims of this study are to clarify G9a expression in tumor tissues and its adjacent normal tissues of gastric cancer, to investigate the effect of G9a on tumor invasion and metastasis of gastric cancer by up-regulating and down-regulating the expression of G9a in gastric cancer cells, and to validate it in animal model.

Methods: IHC was used to detect the expression of G9a in gastric cancer tissues and its adjacent non-tumor tissues and to analyze the relationship between G9a and

clinicopathological parameters. After overexpressing or knock-down G9a stable gastric cancer cell lines were constructed, the effect of G9a on tumor invasion and metastasis of gastric cancer cells was detected by transwell assay, ankylosis resistance assay, soft agar formation assay and adhesion assay, nude mice model of cell peritoneal transplantation used to validate the in vitro results. The expression of related pathway gene was detected by WB, the interaction between the protein and the promoter region was detected by double luciferase reporter assay and ChIP and Co-IP was used to detect the interaction between proteins.

Results: G9a highly expressed in GC tissues. G9a expression level was correlated with advanced stage and shorter overall survival. Silencing G9a attenuate the peritoneal metastasis-relevant traits activities of GC cells, ectopic overexpression of G9A contributes to promote tumor metastasis. G9a expression can be induced by Reg IV via p-erk/p-SP1 pathway. SP1 directly binds to G9A promoter and promote its expression. G9a can form a transcriptional activator complex with P300 and GR to participate in ITGB3 expression induced by DEX. G9a participates in ITGB3 expression induced by DEX was independent on the SET domain and methyltransferase activity of G9a.

Conclusions: The expression of G9a in gastric cancer was significantly up-regulated. Overexpression of G9a in gastric cancer cells promoted tumor invasion and metastasis behavior of cancer cells and vise versa. G9a was involved in the process of tumor invasion and metastasis of gastric cancer through the regulation of ITGB3.

651P Prospective observation: Clinicopathological features and clinical utility of plasma Epstein-Barr virus DNA load of Epstein-Barr virus-associated gastric carcinoma

M-Z. Qiu

Medical Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: EBV associated gastric carcinomas (EBVaGC) accounts for 8-9% of all gastric cancer (GC) patients. All previous reports on EBVaGC were retrospective. The value of plasma EBV-DNA load in relation to EBVaGC is under researched.

Methods: From October 2014 to September 2017, we prospectively collected GC patients with EBER examination (N = 2,760) from Sun Yat-sen University Cancer Center. We compared the EBER status in paired biopsy and resection samples of 69 metastatic GC patients. The relationship between Helicobacter pylori (HP) infection and EBER was analyzed in 148 GC patients. Plasma EBV-DNA load was dynamic monitored in EBVaGC patients. All statistical analyses were performed using the Stata 13.0. All statistical tests were two-sided.

Results: The incidence rate of EBVaGC in China was 5.07% (140/2760). EBVaGC patients were male predominant, younger, and had better histologic differentiation, earlier Tumor-Node-Metastasis stage than EBV negative GC (EBVnGC) patients. The 3-year survival was 76.84% (95% CI: 60.48-87.27%) vs 58.18% (95% CI: 55.89-60.39%) for EBVaGC and EBVnGC patients, P = 0.0001. Hp infection rate was 16.22% (23/148). There was no significant difference between EBVaGC (14.93%) and EBVnGC (17.28%) patients, P = 0.698. The consistent rate between biopsy and surgical resection samples was 98.6% (68/69). Only one patient was EBER negative in the biopsy and positive in the resection sample. The mean concentration of plasma EBV-DNA was 155.69 copies per milliliter in EBVnGC patients and 11109.6 copies per milliliter in EBVaGC patients, P < 0.001. Positive identifications of plasma EBV-DNA was associated with unfavorable prognosis. EBV-DNA load decreased when patients got PR/SD, while it increased when disease progressed.

Conclusions: This is the largest population prospective analysis of theclinicalpathological clinicopathological features and prognostic values of EBVaGC patients. The incidence rate of EBVaGC wais around 5%. Plasma EBV-DNA is a good marker in predicting recurrence and chemotherapy response for EBVaGC patients.

652P Is standard adjuvant chemotherapy effective in patients with Epstein-Barr virus associated gastric cancer?

J.G. Kim[1], Y. Chae[2], J.H. Baek[3], B.W. Kang[1]

[1]Oncology, Kyungpook National University Hospital, Daegu, Republic of Korea, [2]Oncology, Kyungpook National University Medical Center, Daegu, Republic of Korea, [3]Oncology, Ulsan University Hospital, Ulsan, Republic of Korea

Background: Based on a comprehensive molecular characterization of gastric cancer, Epstein-Barr virus (EBV)-associated gastric cancer (EBVaGC) can be classified as one of the four subtypes of gastric cancer (GC). Several studies have shown significantly better prognosis of EBVaGC compared with EBV-negative GC (EBVnGC). However, no published study has yet investigated the clinical significance of standard adjuvant chemotherapy in patients with resected EBVaGC. Accordingly, the present study analyzed the prognostic differences between EBVaGC and EBVnGC, and their survival impacts on standard adjuvant chemotherapy.

Methods: This study retrospectively reviewed 773 patients with gastric cancer who underwent surgical resection at Kyungpook National University Chilgok Hospital, between January 2011 and December 2017. The patients were enrolled according to the following criteria: 1) pathologically diagnosed with primary gastric adenocarcinoma, 2) the presence of test using EBV-encoded RNA in situ hybridization, 3) stage II/III according to the seventh edition of the UICC/AJCC for the stomach, and 4) postoperative adjuvant chemotherapy.

Results: Among 276 eligible patients, 59 (21.4%) and 217 patients (78.6%) were determined as EBVaGC and EBVnGC, respectively. One hundred twenty-nine (46.7%) patients were classified as stage II and 147 (53.3%) were as stage III. As for adjuvant chemotherapy, 87 patients (31.5%) received capecitabine and oxaliplatin (XELOX), while 189 (68.5%) received S-1, respectively. With a median follow-up duration of 21.3 months (2.4-89.0), the estimated 3-year disease-free survival (DFS) and overall survival (OS) rates were 74.8% and 83.0%, respectively. In a univariate analysis and multivariate analysis using a Cox proportional hazard model, EBV-positivity was not significantly associated with disease-free survival (p = 0.630) for all patients and XELOX or S-1 group.

Conclusions: In conclusion, EBV-positivity was not found to be associated with prognosis in patients with curatively respective gastric cancer who received standard adjuvant chemotherapy. Accordingly, the standard adjuvant chemotherapy can be used for patients with EBVaGC.

653P PD-L1 expression and T-cell inflamed gene expression profile (GEP) in Korean and US patients (pts) with advanced gastric cancer (GC)

S.Y. Rha[1], G.Y. Ku[2], H.S. Kim[3], H.C. Chung[1], F.G. Amlashi[4], D.M. Maru[5], C. Fein[2], L. Tang[6], M.J. Savage[7], W. Zhou[7], T. Wu[7], S.A. Peter[7], D.P. Kelsen[8], J.A. Ajani[4]

[1]Internal Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, Republic of Korea, [2]Medical Oncology, Memorial Sloan Kettering Cancer Center, New York, NY, USA, [3]Medical Oncology and Internal Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, Republic of Korea, [4]Gastrointestinal Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [5]Pathology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [6]Pathology, Memorial Sloan Kettering Cancer Center, New York, NY, USA, [7]Medical Oncology, Merck & Co., Inc., Kenilworth, NJ, USA, [8]Medical Oncology, Merck & Co., Inc., New York, NY, USA

Background: PD-L1 expression and GEP have been associated with response to anti–PD-1/PD-L1 therapy. We studied PD-L1 expression and GEP in pts receiving standard therapy for GC in South Korea and the US in an observational study.

Methods: Tumor samples were collected from 2003-2017 from the Yonsei Cancer Center (South Korea), MD Anderson Cancer Center (US), and Memorial Sloan Kettering Cancer Center (US). PD-L1 expression was assessed by PD-L1 IHC 22C3 pharmDx assay (Agilent Technologies); PD-L1+ was defined as combined positive score (CPS) ≥1. GEP was analyzed only in Korean pts. GEP score was derived from an 18-gene signature measured using extracted tumor RNA analyzed by NanoString nCounter platform. High/low GEP was based on a cutoff of –0.318. PD-L1 expression was analyzed using chi-squared and multiple logistic regression; survival was estimated using the Kaplan-Meier method, log-rank test, and Cox proportional hazards models.

Results: 574 tumor samples (73% biopsy, 27% surgical resection) from pts with GC (median [range] age 61 [21-90] years) were analyzed. Of the 574 pts, 49% (277/567) had stage IV disease; 43% (249/574) had operable disease (half of whom received adjuvant chemotherapy), and 57% (325/574) had inoperable disease (74% received chemotherapy, 18% received chemoradiation). The prevalence of PD-L1+ expression was 67% overall, 69% in Korean pts, 66% in US pts, 68% in biopsy samples, and 67% in surgical resection samples. Greater PD-L1+ expression was seen in older (≥65 years) vs younger pts (P = 0.011) and in pts with inoperable vs operable disease (P < 0.0001). PD-L1 expression was not associated with overall survival (OS) (log-rank test P = 0.25). 85% (243/286) of Korean pts had high GEP. High GEP was associated with tumor grade (P < 0.001) and clinical stage (P < 0.0001). High GEP may be associated with longer OS (adjusted hazard ratio 0.46 [95% CI 0.32-0.66]). GEP was mildly correlated with PD-L1 CPS (Spearman r = 0.24 [P < 0.0001]).

Conclusions: PD-L1 expression was similar in Korean and US pts with GC and in biopsy and surgical resection samples. GEP was associated with OS while PD-L1 expression was not. Further investigation of GEP with anti–PD-1/PD-L1 therapy is warranted.

654P Relationship between immune related molecules and chemosensitivity and prognosis in gastric cancer

T. Hagi, Y. Kurokawa, T. Hashimoto, Y. Miyazaki, T. Takahashi, K. Tanaka, T. Makino, M. Yamasaki, K. Nakajima, M. Mori, Y. Doki

Gastroenterological Surgery, Osaka University Graduate School of Medicine, Suita, Japan

Background: Microsatellite instability (MSI), mainly caused by dysfunction of mutL homolog 1 (MLH1), was classified as one of distinctive molecular subtype of gastric cancer. MSI was also reported to be associated with high PD-L1 expression and high Immunoscore (IS), a density analysis of tumor-infiltrating lymphocytes. This study aimed to investigate the association between MLH1, PD-L1 expression, and IS and chemosensitivity and prognosis in gastric cancer.

Methods: A total of 271 patients who underwent gastrectomy (R0/1) for gastric cancer between 2008 and 2016 in our institution were retrospectively analyzed. Immunohistochemistry was performed to evaluate MLH1 and PD-L1 expression. IS was evaluated by the density of CD3+ and CD8+ lymphocytes in the center and invasive margin of tumor and classified into two groups; IS-High or IS-Low. The relationship between these markers and the pathological effect of neoadjuvant chemotherapy (NAC) was examined in patients with NAC, and recurrence-free survival (RFS) was compared separately with and without NAC.

Results: Low MLH1, high PD-L1 expression, and IS-High was observed in 29 (11%), 70 (26%), and 114 (42%) patients, respectively. Low MLH1 expression was significantly associated with high PD-L1 expression ($P = 0.006$) and IS-high ($P = 0.04$). In patients with NAC ($n = 114$), low MLH1 expression was significantly associated with low chemosensitivity (lower proportion of pathological effect Grade≥1b, $P = 0.006$), although PD-L1 expression and IS were not associated with chemosensitivity ($P = 0.99$, $P = 0.08$). In patients without NAC ($n = 157$), low MLH1 expression and IS-High were significantly associated with better RFS ($P = 0.02$, $P < 0.001$), however not associated in patients with NAC ($P = 0.70$, $P = 0.07$). While, PD-L1 expression was not associated with RFS in both patients with and without NAC ($P = 0.20$, $P = 0.51$). Multivariate analysis revealed that high MLH1 expression and IS-low were one of the independent risk factors for RFS (HR: 2.9 [1.3-6.9] $P = 0.014$, HR:1.9 [1.2-3.0] $P < 0.001$).

Conclusions: Although low MLH1 expression and IS-high may be associated with better prognosis, low MLH1 expression may be also associated with low chemosensitivity.

655P Prognostic significance of lymphocyte-activation gene-3 expression in chemoradiotherapy-naïve esophageal and gastric adenocarcinoma

C. Siesing, M.C. Svensson, C. Hedner, B. Nodin, D. Borg, K. Jirstrom

Department of Clinical Sciences, Oncology and Pathology, Lund University, Faculty of Medicine, Lund, Sweden

Background: Neoadjuvant and/or adjuvant treatment has led to an improved survival in patients with resectable gastroesophageal adenocarcinoma (GEAC). Nevertheless, survival rates remain poor and, hence, there is a great need to identify novel treatment strategies and relevant complementary diagnostics. Immunotherapies targeting the PD-1/PD-L1 checkpoints have shown promising results, but simultaneous inhibition of other fundamental checkpoints, such as lymphocyte-activation gene-3 (LAG-3), may further improve clinical outcome. The expression and prognostic significance of LAG-3 in GEAC has however not yet been described. Herein, we examined the expression of LAG-3 in tumour-infiltrating immune cells (TIC) in chemoradiotherapy-naïve GEAC and paired lymph node metastases, with particular reference to its relationship with PD-1 and PD-L1 expression, mismatch repair (MMR) status, and survival.

Methods: Immunohistochemical LAG-3 expression was analysed in tissue microarrays with 165 primary tumours and 72 paired lymph node metastases from a retrospective consecutive cohort of patients with chemoradiotherapy-naïve resected GEAC. LAG-3 expression was denoted in categories of negative (0), low (1-10) and high (>10). PD-1, PD-L1 expression and MMR status had been previously analysed.

Results: The distribution of LAG-3 expression in primary tumours was 55.8% negative, 28.5% low, and 15.8% high. The corresponding figures in lymph node metastases were 48.6% negative, 37.5% low, and 13.9% high. LAG-3 expression did not differ by tumour location. Positive LAG-3 expression in primary tumours was an independent factor for prolonged overall survival in the entire cohort (HR = 0.64, 95% CI 0.43-0.96), and in gastric cancer (HR = 0.35, 95% CI 0.17-0.74). LAG-3 expression in primary tumours was significantly associated with PD-L1 expression in both tumour cells and TIC, and with PD-1 expression in TIC, but not with MMR status.

Conclusions: LAG-3 is expressed in a considerable proportion of GEAC, with a similar distribution in primary tumours and lymph node metastases. Positive LAG-3 expression is an independent favourable prognostic factor, particularly in gastric cancer.

[1]JCOG Data Center/ Operations Office, National Cancer Center, Tokyo, Japan, [2]Department of Surgery, Teikyo University Hospital, Tokyo, Japan, [3]Gastric Surgery Division, National Cancer Center Hospital, Tokyo, Japan, [4]Department of Gastroenterological Surgery, Toranomon Hospital, Tokyo, Japan, [5]Department of Surgery, Gifu Municipal Hospital, Gifu, Japan, [6]Department of Gastroenterological Surgery, Shizuoka General Hospital, Shizuoka, Japan, [7]Surgery Division, Yao Municipal Hospital, Osaka, Japan, [8]Department of Digestive Surgery, Tenri Hospital, Nara, Japan, [9]Department of Surgery, Tochigi Cancer Center, Tochigi, Japan, [10]Department of Surgery, Hiroshima City Asa Hospital, Hiroshima, Japan, [11]Department of Surgery, Tokyo Metropolitan Bokutoh Hospital, Tokyo, Japan, [12]Department of Gastroenterological Surgery, Nagoya University Graduate School of Medicine, Nagoya, Japan, [13]Gastric Surgery Division, National Cancer Center Hospital East, Chiba, Japan, [14]Gastrointesitnal Medical Onclogy, National Cancer Center Hospital, Tokyo, Japan, [15]Department of Gastroenterological Surgery, Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, Japan, [16]Department of Surgery, Yodogawa Chrisitan Hospital, Osaka, Hyogo, Japan, [17]Department of Gastric Surgery, Shizuoka Cancer Center, Shizuoka, Japan

Background: Neoadjuvant chemotherapy (NAC) has been increasingly used for gastric cancer. JCOG1302A investigated whether cT3-4/ N1-3 was a suitable criterion for NAC minimizing the contamination of pStage I. In that study, 77.2% of tumors diagnosed as cT3-4 by a combination of endoscopy and computed tomography (CT) were pT3-4. The role of endoscopic ultrasonography (EUS) or additional options in diagnosis of invasion depth was unclear.

Methods: Using data of JCOG1302A, we evaluated accuracy of endoscopic or CT diagnosis of cT3-4 to detect pT3-4, by comparing positive predictive value (PPV), negative predictive value (NPV), and kappa index (KI) between conventional endoscopy (CE) with and without EUS, CT of 5 mm and 1 mm slice, and CT with and without foaming agent (FA).

Results: Data from 1232 patients enrolled in 53 institutions were analyzed (Table). Overall, there is no remarkable difference in any comparison. More specifically, PPV and KI were slightly higher in CE alone rather than in CE combined with EUS. Although NPV was higher in 1 mm slice CT and CT with FA, PPV was higher in 5 mm slice CT and CT without FA. Table 1 Comparison of PPV, NPV, and KI between CE alone and CE combined with EUS, between 5 mm slice CT and 1 mm slice CT, and between CT without FA and CT with FA.

Table: 656P

	CE alone (n = 1232)	CE combined with EUS (n = 91)
PPV	79.2% (76.2-81.9)	73.7% (60.3-84.5)
NPV	59.2% (54.3-63.9)	58.8% (40.7-75.4)
KI	0.38 (0.33-0.44)	0.32 (0.12-0.52)
	5 mm slice CT (n = 1042)	1 mm slice CT (n = 255)
PPV	77.8% (74.6-80.7)	75.5% (68.9-81.4)
NPV	62.9% (57.1-68.5)	71.2% (57.9-82.2)
KI	0.38 (0.32-0.44)	0.39 (0.28-0.51)
	CT without FA (n = 840)	CT with FA (n = 368)
PPV	78.6% (75.1-81.8)	75.1% (69.5-80.1)
NPV	60.9% (54.4-67.3)	69.7% (59.7-78.5)
