Results: Currently 17 patients have been included. Of these, 2 patients showed PD upon treatment and did not proceed to surgery. In 14/15 (93%) patients resection was possible after neoadjuvant treatment, of which 13 (93%) were R0 resections. Median follow-up time is 22 months with a median recurrence free survival of 9 months in patients undergoing surgery. The 1-year overall survival (OS) was 88% and 2-year OS 59%. Median OS was not reached. Metabolic response rates (RR) on PET/CT at 8 weeks were: 4 (24%) CR, 11 (65%) PR, 0 (0%) SD, 2 (12%) PD. Pathologic RR differed: 6 (35%) CR, 5 (29%) PR, 3 (19%) SD, 0 (0%) PD and in 3 patients (18%) no pathologic response was measured, since no resection was performed. Most patients (82%) experienced any toxicity, of which the majority (64%) was grade 1 and the most common reported toxicity was fever. Grade 3 toxicity occurred in 2 patients (12%).

Conclusions: Neoadjuvant dabrafenib and trametinib shows to be a potent cytoreductive treatment, allowing radical resection of metastases in 13/17 (76%) patients with prior unresectable locally advanced melanoma. Patients with no recurrence remained disease-free for a prolonged period of time. If there was recurrent disease, this usually occurred within months after surgery and this may present an opportunity for further tailored adjuvant therapy.

1255P Impact of intralesional interleukin 2 (IL2) for in-transit melanoma in two Canadian centres

D.S. Ernst[1], V. Hayward[2], H. McConkey[3], X. Teng[4], E. Saettler[5], T. Cheng[6], C. Temple-Oberle[7], F. Gwadry-Sridhar[8]

[1]Department of Oncology, London Regional Cancer Program, London, ON, Canada, [2]Department of Surgery, University of British Columbia, Kelowna, BC, Canada, [3]Global Melanoma Research Network, London, ON, Canada, [4]Data Science, Pulse Infoframe Inc., London, ON, Canada, [5]Department of Surgery, Western University, London, ON, Canada, [6]Departemnt of Oncology, University of Calgary, Calgary, AB, Canada, [7]Department of Surgery, University of Calgary, Calgary, AB, Canada, [8]Department Computer Science, Western University, London, ON, Canada

Background: In-transit (IT) melanoma is a form of metastatic disease that is associated with high morbidity and is often refractory to treatment. Intralesional (IAL) IL2 has been increasingly utilized to obtain loco-regional control. This study utilizes a national

registry to evaluate response and duration of response of standardized IAL therapy at tertiary centres in 2 provinces.

Methods: Patients (pts) receiving IAL IL2 between 2000 and 2017 were included. Data regarding patient demographics, stage, extent of disease, and all treatments were collected. All pts received a median IL2 dose of 12 million IU given as an IAL injection every 2 to 4 weeks repeated 2 to 8 times to complete a session.

Results: A total of 87 pts aged 21 to 94 (mean: 69 yrs) were included. IT disease was located in the following areas: limbs in 68 pts (79%), head and neck in 13 pts (15%) and trunk in 5 pts (6%). 20% of pts developed IT within 3 months of primary diagnosis, 69% developed IT after 6 months and 11% after 3 years. IT lesions per individual ranged from 1 to 40+; 45% had >10 lesions. Patients had a complete response rate of 32% (28 pts) and a partial response rate of 38% (33 pts). 27 (31%) pts experienced a recurrence after their 1st IL2 session, with a mean of 225 days (median: 204). Of these pts, 15 (56%) pts developed loco-regional recurrences, while 6 (22%) developed distant metastases and 6 (22%) had both distant and loco-regional recurrences. 27 pts (31%) received systemic treatment for metastatic disease. 18 (21%) pts died of disease, while 3% died of other causes while disease was present. 7 (8%) died of other causes with disease status unknown, and 25 (29%) and 34 (39%) are recorded alive with more than a year (1 to 11 yrs) or less than a year follow up, respectively. No grade 3 or 4 toxicity was experienced by pts who received IL2 therapy. On multi-variant analysis, age, extent of disease and prior systemic therapy did not impact overall response (X^2 test, $p > 0.05$).

Conclusions: IAL IL2 appears to be an effective therapeutic option for pts with advanced melanoma and IT disease, with an overall response rate of 70%. With further long-term follow up of these pts, the impact on overall survival can be determined.

1256P Combined ipilimumab and nivolumab first-line and after BRAF-directed targeted therapies in advanced melanoma patients

H.C. Dearden[1], R. Mason[2], B. Nguyen[3], J.A. Soon[4], J.L. Smith[5], M. Randhawa[6], A. Mant[7], L. Warburton[3], S. Lo[1], T. Meniawy[3], A. Guminski[1], P. Parente[7], S. Ali[6], A. Haydon[4], G.V. Long[1], M.S. Carlino[5], M. Millward[3], V.G. Atkinson[2], A.M. Menzies[1]

[1]Medical Oncology, Melanoma Institute Australia, University of Sydney, North Sydney, Australia, [2]Medical Oncology, Princess Alexandra Hospital, Woolloongabba, Australia, [3]Medical Oncology, Sir Charles Gairdner Hospital, Perth, Australia, [4]Medical Oncology, The Alfred Hospital, Melbourne, Australia, [5]Medical Oncology, Westmead Hospital, Westmead, Australia, [6]Medical Oncology, The Canberra Hospital, Garran, Australia, [7]Medical Oncology, Box Hill Hospital-Eastern health, Box Hill, Australia

Background: Combination ipilimumab and nivolumab is a highly active systemic therapy for metastatic melanoma but can cause significant toxicity. How best to integrate this combination into clinical practice, in real-world patients, and in the setting of BRAF targeted therapy, is not clear. We sought to explore the safety and efficacy of combination ipilimumab and nivolumab in such a population.

Methods: Consecutive patients with unresectable stage IIIC/IV melanoma commenced on ipilimumab and nivolumab via an early access scheme across 10 tertiary melanoma institutions in Australia were identified retrospectively. Data collected included demographics, prior and subsequent systemic treatments, toxicity, RECIST response and survival outcomes.

Results: 152 patients were included for analysis, including 60 (39%) treatment-naïve and 33 (22%) who had failed first-line BRAF/MEK inhibitors and then treated with combination therapy second-line. In the whole cohort, most patients had a high AJCC M stage (63% M1c, 26% M1d) and elevated LDH (55%), with similar distribution of adverse features in the treatment naïve and BRAF/MEK failure subgroups. Treatment-related adverse events occurred in 102 (67%) patients, grade 3-5 in 38% (1 death from immune myocarditis). The objective response rate was 41% in the whole cohort, 57% (17% complete) in treatment naïve, and only 21% (3% complete) in BRAF/MEK failure patients. Median progression-free survival was 4.0 months (95% CI, 3.0 to 6.0) in the whole cohort, 11.0 months (95% CI, 6.0 - NR) in treatment-naïve patients, and 2.0 months (95% CI, 1.4 - 4.6) in BRAF/MEK failure patients.

Conclusions: Combination ipilumumab and nivolumab can be used safely and effectively in a real-world population, including in patients that are heavily pre-treated and those with adverse disease characteristics. While first-line efficacy appears comparable to that seen in trial populations, BRAF-mutant patients who have failed prior BRAF/MEK inhibitors are less likely to respond, supporting first-line use of combination immunotherapy in the majority of newly diagnosed poor prognosis metastatic melanoma patients.

1257P KEYNOTE-151: A phase Ib study of second-line pembrolizumab (Pembro) for Chinese patients (pts) with advanced or metastatic melanoma

L. Si[1], X. Zhang[2], Y. Shu[3], H. Pan[4], D. Wu[5], J. Liu[6], F. Lou[4], X. Wang[7], X. Wen[2], Y. Gu[3], L. Zhu[3], S. Lan[3], X. Cai[6], Y. Zhou[8], J. Ge[9], J. Li[9], H. Wu[9], J. Guo[7]

[1]Department of Renal Cancer and Melanoma, Peking University Cancer Hospital-Beijing Cancer Hospital, Beijing, China, [2]Biotherapy Centre, Sun Yat-sen University Cancer Centre, Guangzhou, China, [3]Oncology Department, Jiangsu Province Hospital, NanJing, China, [4]Oncology, Sir Run Run Shaw Hospital, Zhejiang University School of Medicine, Hangzhou, China, [5]Cancer Center, The First Hospital of Jilin University, Jilin, China, [6]Oncology, The First Affiliated Hospital of Dalian Medical University, Liaoning Sheng, China, [7]Urology and Melanoma, Beijing Cancer Hospital, Beijing, China, [8]Medical Oncology, MSD China, Shanghai, China, [9]Medical Oncology, MSD China, Beijing, China

Background: Pembro shows robust antitumor activity and a avourable safety profile in metastatic melanoma. Checkpoint inhibition has not been well characterized in Chinese pts. We present the first results of KEYNOTE-151 (NCT02821000), which was conducted to evaluate the safety and efficacy of second-line pembro in Chinese pts with advanced melanoma.

Methods: Chinese pts aged ≥18 y with previously treated advanced melanoma and measurable disease per RECIST v1.1 as assessed by blinded independent central review (BICR) received pembro 2 mg/kg Q3W for 35 cycles (~2 y) or until confirmed disease progression, intolerable toxicity, or pt/investigator decision to discontinue. Primary end points were ORR per RECIST v1.1 assessed by BICR and safety. Objective response was confirmed by repeat radiographic assessment ≥4 wk from first response. Key secondary end points included DOR and PFS per RECIST v1.1 assessed by BICR and OS. Data cutoff was Dec 27, 2017.

Results: 103 pts were enrolled; median age was 52.0 y (range, 22.0-77.0); 42.7% were male; 51.5% had PD-L1–positive tumors; 37.9% had acral melanoma; 14.6% had mucosal melanoma. Median follow-up was 7.9 mo (range, 5.6-13.1). Confirmed CR and PR were achieved in 1 pt and 16 pts, for an ORR of 16.7% (95% CI, 10.0-25.3). 22 (21.6%) pts had SD. DCR was 38.2% (95% CI, 28.8-48.4). ORR was 15.8% (95% CI, 6.0-31.3%) for the acral subtype and 13.3% (95% CI, 1.7-40.5%) for the mucosal subtype. Median DOR for responders was 8.4 mo; 5 (65.6%) pts had a response duration ≥6 mo at data cutoff. Median OS was 12.1 mo (95% CI, 9.6-NR). Estimated OS was 75.7% at 6 mo and 50.6% at 12 mo. Median PFS was 2.8 mo (95% CI, 2.7-3.5). Estimated PFS was 20.4% at 6 mo and 11.9% at 12 mo. Treatment-related AEs (TRAEs) were reported in 87 (84.5%) pts; 9 (8.7%) experienced a grade 3-5 TRAE; 2 (1.9%) discontinued due to a TRAE; no pts died due to a TRAE.

Conclusions: Results demonstrate pembro was well tolerated, with clinically meaningful antitumor activity in Chinese pts with advanced melanoma who were treated in the second-line setting where there is no standard regimen available. The extended Kaplan-Meier curve tail indicates that treatment with pembro can provide long-term survival benefit.

Arrigo, Alessandria, Italy, [11]Melanoma Cancer Immunotherapy and Innovative Therapy Unit, AOU Policlinico Federico II, Naples, Italy, [12]U.O Oncologia Medica, Struttura Ospedaliera S. Chiara, Trento, Italy, [13]Oncologia Medica, Ospedale "Fabrizio Spaziani", Sora, Italy

Background: AntiPD1 Nivolumab (N) or Pembrolizumab (P) are an option for first line treatment in metastatic melanoma (MM) but predictive factors of efficacy are needed to choose between them or other treatment (antiPd1+AntiCTLA4, BRAF+MEK inhibitors (BMEi) for BRAF mutated melanoma). Many studies suggest that LDH, ECOG PS, tumor burden can identify BRAF mutated MM patients (pt) in which BMEi show better outcome. Similar data are not available for N or P in first line. We evaluate pt treated with N or P in first line in order to verify if these factors or other factors can be applyed also to antiPD1.

Methods: A retrospective multicenter study was conducted in 13 Italian Oncology Centers, evaluating MM pt treated with N or P in first line from 2016. Endpoints were OS and PFS, Kaplan Mayer and Cox regression were applied for survival analysis.

Results: 236 pt were analyzed (51% treated with N, 7% BRAF mutated). ECOG PS was 0 in 169 pt, number of metastatic sites (Nu) was less then 3 in 135 pt, in 88 pt there were not visceral metastasis (Vi), LDH was normal in 141 pt, ratio between baseline neutrophils and total leukocytes count (Fr) was less then 0.7 in 152 pt: in univariate analysis, all this factors resulted significantly associated with better OS (all $p < 0.0003$) and PFS (all $p < 0.003$), the only exeption were pt with Nu less then 3 that resulted not signficantly different in PFS then pt with higher Nu (p 0.13). In multivariate analysis all these factors were confirmed as significantly associated with better PFS and OS (all $p < 0.03$), with the exeption of Nu (p 0.22) A score was counted for every pt considering the number of favorable baseline factors present (normal LDH, ECOG PS 0, Vi 0, Fr < 0.7) 18 months-PFS was 69% in pt with all 4 favorable factors vs 41% in pt without favorables factors (p value 0.0029). 18 months-OS was 90% in pt with all four favoreble factors vs 48% in pt without favorables factors (p value<0.0001).

Conclusions: ECOG PS 0, normal LDH, Fr < 0.7, absent Vi are indipendent baseline factors associated with favorable PFS and OS of MM pt treated with N or P in first line (instead of Nu – that was found relevant for BMEi in other study). Subgroup with all these factors has a better prognosis. These data can help first line treatment choice and should be evaluated prospectively.

1259P Switch to checkpoint inhibition (CPI) after targeted therapy (TT) at time of progression or during ongoing response: A retrospective analysis of patients with advanced BRAF mutated melanoma

I.L.M. Reijers, E.A. Rozeman, H. Mallo, W. Uyterlinde, S. Adriaansz, J. Lijnsvelt, S. Wilgenhof, J.V. van Thienen, J.B.A.G. Haanen, C.U. Blank

Medical Oncology, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands

Background: The outcome of patients (pts) with BRAFV600 mutated advanced melanoma has dramatically improved by the introduction of TT and CPI. Pts responding on CPI have a high chance of long-term benefit. Pts with fast progressive disease (PD), high LDH and/or symptomatic (brain) metastasis often start with TT to induce a fast response, although most pts will relapse. Short-term TT increases intratumoral T-cell infiltration, which is diminished at PD. In addition, LDH level normalization and improvement of performance status (PS) during response to TT, might also argue for an earlier switch to CPI before PD.

Methods: We retrospectively identified pts that started treatment with TT and switched to subsequent CPI (either anti-PD-1 or anti-PD-1 plus anti-CTLA-4) at our institute. Progression was defined as radiological PD according to RECIST 1.1 or clinical PD defined by treating physician. Progression free survival (PFS) from start CPI (PFS-CPI), start TT (PFS-total) and overall survival (OS) were analyzed by Kaplan Meier methods and hazard ratio's (HR) were calculated by Cox regression analysis.

Results: In total 74 pts were included; 37 pts switched to CPI prior to PD (noPD-switch) and 37 pts switched at PD (PD-switch); 32 vs 51% had brain metastases and 41 vs 49% had an elevated LDH. Median time on TT in the noPD-switch and the PD-switch group was 3.2 and 4.5 months, respectively. PFS-CPI was 2.5 months in the noPD-switch group vs 1.2 months in the PD-switch group ($p = 0.11$). OS was superior in the noPD-switch group with a median of 30.6 vs 14.1 months ($p = 0.01$). After correcting for previous treatment, LDH, PS, brain metastasis and number of metastatic sites, HR for OS was 0.48 (95% CI 0.22–1.01). Subgroup analysis revealed that pts with brain metastasis seem to benefit most from switch prior to PD. In pts that had reinduction of TT after CPI failure, the noPD-switch group benefitted longer from this subsequent TT line, although total time of benefit on TT (before and after CPI) was the same in both groups.

Conclusions: Pts that switch to CPI prior to PD upon TT have an increased OS, which can be attributed to the benefit from CPI and not the total time on TT.

Background: Regimens combining BRAF and MEK inhibitors have revolutionized the treatment of patients with unresectable (stage III) or distant metastatic (stage IV) BRAF V600-mutant cutaneous melanoma. As only dabrafenib (D) was available in France, the objective of this study was to provide access to T and to assess, in the French population, the benefits of the combination of T (D+T) previously reported.

Methods: This single arm, open label, multicenter, non-randomized study included patients with histologically confirmed stage III unresectable or IV BRAF V600-mutant melanoma, with or without brain metastases (BM). Patients received D (150 mg twice/day) combined with T (2 mg once/day). Outcomes were overall response rate (ORR), progression-free survival (PFS), and frequencies of adverse events (AEs). Median PFS was estimated using the Kaplan-Meier method.

Results: Between March 2015 and November 2016, 914 patients were screened in 40 French centers and 856 received at least one dose of D+T. The table presents baseline characteristics. Median followup was 5.63 months. ORR was 50.2% in the overall population and 41.5% in patients with BM. Median PFS was 8.02 months (95% CI, [7.33-8.77]) in the overall population and 5.68 months (95% CI, [5.29-6.87]) in patients with BM. The safety profile was consistent with previous reports. Among AEs of special interest, pyrexia/hyperthermia was the most frequent: 38.2% (327/856) all grades; grade (G) 1 29.0%, G2 14.8%, G3 4.0% and G4 0.5%.

1261P Loss of HLA class I expression and T-cell infiltration or PD-L1 expression are associated with different response patterns to pembrolizumab in melanoma

A. Degraeuwe[1], N. van Baren[2], F. Cornelis[3], P. van Eeckhout[4], J-F. Baurain[5]

[1]Medical Oncology, Université Catholique Louvain, Bruxelles, Belgium, [2]Institut de Duve, Université Catholique Louvain, Bruxelles, Belgium, [3]Medical Oncology, Cliniques Universitaires St. Luc, Brussels, Belgium, [4]Anatomopathologie, Cliniques Universitaires St. Luc, Bruxelles, Belgium, [5]King Albert 2 Cancer Institute, Cliniques Universitaires St. Luc, Brussels, Belgium

Background: PD-1 blockade monoclonal antibodies, nivolumab and pembrolizumab, increase quality of life and overall survival of metastatic melanoma and are today's first-line treatment of metastatic melanoma. Nevertheless, only 40% of the patients will respond to anti-PD-1 monotherapy. In the era of personalized medicine, an important stake is to identify the patients who will benefit from these treatments, which are also responsible for scare but serious side effects. We have tested several biomarkers to discriminate between responders and non-responders.

Methods: We have retrospectively analysed 18 patients treated by pembrolizumab for metastatic melanoma. Immunohistochemical staining was performed on pre-treatment metastatic tissue for antigens such as MELANA, TYR, GP100, PD-L1, CD3, CD8, IDO1, HLA class I heavy chain and β_2-microglobulin. Two reviewers assessed the staining independently. For PD-L1 testing, the MEL-score was used. For T-cell infiltration, we have quoted the presence of CD3 CD8 T cell and their location.

Results: We found that only PD-L1 expression and the presence of T-cell infiltration were associated with a better response to pembrolizumab: PD-L1 expression ($p = 0,043$), T-cell infiltration ($p = 0,025$) and T-cell location at the periphery of the tumoral nodules ($p = 0,025$). PD-L1 expression and the presence of T lymphocytes were also associated with a longer survival. The median overall survival was 31,5 months for the T-cell rich metastasis and PD-L1 high expression versus 4 months for non T-cell infiltrated tumours and 7 months for PD-L1 negative tumours. Furthermore, 50% of the metastases showed reduced or absent HLA class I expression by the tumour cells. The role of tumoral HLA loss in response and resistance to PD-1 blockade has still to be defined.

Conclusions: Although significant correlations were observed between some biomarkers and the response to anti-PD-1 therapy as described in larger studies, no predictive biomarker has currently been identified in our small series. Recent and future technical progresses will enable new studies aiming to find reliable biomarkers and to clarify the complex mechanisms of response and resistance to immune checkpoint inhibitors.

1262P Soluble PD-L1 as a prognostic factor in advanced acral and mucosal melanoma

X. Wang, C. Cui, J. Yu, Y. Kong, L. Si, Z. Chi, X. Sheng, L. Mao, B. Lian, B. Tang, X. Yan, J. Guo

Renal Cancer and Melanoma, Beijing Cancer Hospital, Beijing, China

Background: Elevated levels of soluble PD-L1 (sPD-L1) have been associated with worse prognosis in renal cell carcinoma and multiple myeloma. However, the regulatory roles and function of sPD-L1 in advanced melanoma are not fully understood. This study was designed to evaluate the association between circulating sPD-L1 expression and prognosis in patients with advanced acral and mucosal melanoma.

Methods: Totally 102 untreated advanced acral and mucosal melanoma patients from Peking University Cancer Hospital between Jan 2012 and Dec 2015 were enrolled in the present study. Peripheral blood samples were obtained from 40 healthy donors as control. Circulating sPD-L1 expression was tested by enzymelinked immunosorbent assay (ELISA).

Results: The advanced melanoma cohort includes 58 acral melanoma and 44 mucosal melanoma. Concentrations of sPD-L1 (2.91ng/mL) were elevated in the plasma of prior to treatment advanced melanoma patients in comparison with healthy donors (0.59ng/mL). The expression of sPD-L1 in serum was found to be highly up-regulated in 39 (38.2%) of 102 cases. The sPD-L1 concentration appeared to be significantly related with subtype (arcal 3.14 vs. mucosal 2.60 ng/mL P = 0.004). No significant association was observed between serum sPD-L1 level and other clinicopathological variables as: BRAF mutation, LDH level, tumor burden and peripheral blood CD4+/CD8+. There were no associations between sPD-L1 and chemotherapy clinical responses in our cohort. But the overall survival rates were statistically estimated with the expression of sPD-L1. The OS in this cohort with high and low up-regulated sPD-L1 expression levels was 8.50 months and 11.64 months, respectively (p = 0.022).

Conclusions: sPD-L1 was elevated in advance acral and mucosal melanoma patients and may play an important role in patients prognosis.

1263P The analysis of treatment sequencing and clinical outcomes in BRAF-positive and BRAF-negative unresectable/metastatic melanoma patients treated with systemic therapies in routine practice

A.M. Czarnecka, P. Teterycz, I. Lugowska, P. Rogala, T. Switaj, P.L. Rutkowski

Department of Soft Tissue, Bone Sarcoma and Melanoma, Maria Sklodowska-Curie Institute - Oncology Center, Warsaw, Poland

Background: BRAF V600 mutation was considered as a negative prognostic factor in metastatic (stage IV) melanoma patients (pts). Nowadays, two effective systemic treatment modalities - targeted therapy with BRAF+MEK inhibitors and immunotherapy are available for this group of pts contrary to BRAF-wild-type patients where only immunotherapy is used. It is unclear what is the outcome of therapy and treatment sequence in advanced melanoma patients with BRAF-positive and negative patients in the routine practice.

Methods: In this retrospective one-center study, we included 276 (134, 48.6% BRAF V600 mutated) consecutive pts with unresectable/metastatic stage III/IV melanoma treated between 01/2016 and 02/2018. Kaplan-Meier survival probability estimation and Cox's proportional hazards model were used for analysis.

Results: The first line treatment comprised of anti-PD1 antibodies (in 167 cases, i.e. all BRAF-negative and 25 BRAF-mutant pts) and BRAF/MEK inhibitors (in 109 cases BRAF+ pts). The 1-year overall survival (OS) rates were 61.6% (95% confidence interval, CI: 53.4-71.1) in BRAF-negative pts, 61.1% (95%CI: 51.8-72.1) and 77.3% (95%CI: 61.6-97.1) in BRAF-mutated pts who started BRAF/MEK inhibitors or anty-PD1 antibodies as the first line treatment, respectively. In the multivariable model adjusted for age, sex and LDH level BRAF-mutated pts who received anti-PD1 as 1st line treatment had slightly worse first line progression-free survival (HR: 1.91, 95%CI: 1.00-3.63, p = 0.05), but there were no differences in the multivariable model for OS (HR: 0.67, 95%CI: 0.28-1.58, p = 0.35).

Conclusions: The short-term outcomes of advanced melanoma patients treated with modern systemic therapies are similar independently of BRAF V600 mutation status. Numerically, the best survival rates were reached in BRAF-positive pts who received anti-PD1 antibodies as the 1st line treatment, but this effect needs to be confirmed in a larger population study.

1264P Long-term survivors among patients with metastatic melanoma treated with targeted agents and/or checkpoint inhibitors

H. Linardou, A. Laskarakis, A. Molfeta, K. Sakellariou, A. Tarampikou, E. Soroli, K. Gkiati, D. Bafaloukos

Oncology Department, Metropolitan Hospital, Athens, Greece

Background: Long-term survival for patients with metastatic melanoma (MM) was very rare until the advent of targeted and checkpoint inhibitor therapy. Today clinical trial data provide evidence of encouraging 3-year and even 5-year survival rates, while real-world data are lacking.

Methods: Patient and disease characteristics were collected among MM patients treated in a reference oncology center since 2012 with targeted and/or checkpoint inhibitor agents. We defined long-term survivors as patients with survival >2years from MM diagnosis; biological material was collected for genomic analyses.

Results: From 130 MM patients treated with BRAF/MEK inhibitors and/or anti-CTLA4, anti-PD1 agents in any line, 25 long-term survivors were identified (19,2%), 15 men/ 10 women. Long-term survival was characterized by good prognosis features at initial diagnosis: median PS 0, normal LDH (60%), low disease burden (≤3 metastatic sites, 88%), median Distant Metastasis Free Interval (DMFI) 3 years (range 0-23+ years), 16/25 BRAF mutant MM. All long-term survivors had achieved an objective response (complete/partial) to targeted or immuno- therapy. Objective response was associated with long-term survival regardless of treatment line. Complete responses to targeted or immunotherapy are still ongoing (2 to immunotherapy >3 years, 2 to BRAF/MEKi >5 years). Most patients are alive today (21/25, 84%): 9 patients (36%) survive >5 years from MM diagnosis, with 8 of them (32%) surviving >5 years from new therapy initiation (targeted or immuno). The majority of patients (22/25, 88%) survive >3 years from initial MM diagnosis and 76% survive >3 years from therapy initiation (targeted or immuno-), suggesting that the long-term survival benefit is due to the new therapy. Genomic analysis will complement the clinical characteristics of long-term survival.

Conclusions: A significant number of patients with MM treated in a reference center achieved long-term survival with targeted or immuno-therapy. The specific clinical and genomic characteristics of these long-term survivors can improve our understanding of the biological behaviour of the disease but also assist the optimal choice and use of new therapies.

Background: SD-101 is a synthetic CpG-ODN agonist of TLR9. Pembrolizumab is an antibody to PD-1. DV3-MEL-01 (SYNERGY-001) assesses the safety and preliminary efficacy of the combination of SD-101 and pembrolizumab in stage IIIC-IV melanoma.

Methods: Phase 1b evaluated SD-101 at multiple doses injected in a single tumor Q1W x 4 then Q3W x 7 in combination with a fixed dose of pembrolizumab (200 mg IV Q3W). Phase 2 is evaluating SD-101 at 8 mg in 1 lesion and 2 mg/lesion in 1-4 lesions. Patients were eligible if their tumor progressed on or after prior anti-PD-1 therapy. Scans are performed every 64 days. Per-protocol overall responses (ORR) were assessed per investigator using RECIST v1.1/irRECIST. The modified intent-to-treat (mITT) population included all patients except those on study who had not reached the Day 64 scan. PFS rate was calculated using the mITT population. The per-protocol population comprised patients who received at least 1 dose of each drug and had ≥1 post baseline scan.

Results: 38 patients enrolled: median age 64 years; male 74%; ECOG PS 0 58%; Stage IIIC 32%, IVM1a/b 13%, Stage IVM1c/d 50%; LDH > ULN 39%. SD-101 safety profile consists of transient, mild-to-moderate flu-like symptoms and injection-site reactions. Grade 3-4 treatment-related AEs = 32%. Immune-related AEs (irAEs) = 5%. ORR (mITT) = 16% (6/37) (CR 3%/PR 14%/SD 30% [DCR = 46%]/PD 38%/NE 16%). Evaluable ORR =19% (6/31). 7 pts were not evaluable: on study but no Day 64 scan yet (n = 1), AE (n = 1), clinical PD (n = 2), withdrew consent/unknown (n = 3). 2 of 8 patients who began combination therapy within 3 months of starting anti-PD-1 therapy had responses including 1 CR. Median DOR not reached (range 9 weeks, 45 weeks). Median follow up = 13 weeks (range 6, 45 weeks). 6 month PFS rate = 16%. One third

of the patients currently have biomarker assessments demonstrating a broad increase in TILs in patients with responses with ≥ 3 fold increase in T cells.

Conclusions: The combination of SD-101 and pembrolizumab induced responses in some patients who developed progressive disease on or after prior anti-PD-1 therapy. The combination is well tolerated with no evidence of an increased rate of irAEs.

Clinical trial identification: NCT02521870.

1266P Update on the randomised phase Ib/II study of the selective small molecule AXL inhibitor bemcentinib (BGB324) in combination with either dabrafenib/trametinib or pembrolizumab in patients with metastatic melanoma

C. Schuster[1], G. Gausdal[2], B.T. Gjertsen[3], J. Lorens[4], O. Straume[5]

[1]Department of Clinical Science, Centre for Cancer Biomarkers, University of Bergen, Bergen, Norway, [2]BerGenBio ASA, BerGenBio ASA, Bergen, Norway, [3]Department of Internal Medicine, Helse Bergen Haukeland University Hospital, Bergen, Norway, [4]Department of Biomedicine, Centre for Cancer Biomarkers, University of Bergen, Bergen, Norway, [5]Oncology and Medical Physics, Haukeland Universitetssykehus, Bergen, Norway

Background: Upregulation of the receptor tyrosine kinase AXL has been linked with both minor treatment effect of PD-1 blockade and acquired resistance to BRAF inhibitors in melanoma. Bemcentinib is a first-in-class orally bioavailable selective inhibitor of AXL which is currently investigated in several phase II clinical trials. BGBIL006 (NCT02872259) is an open label phase Ib/II trial designed to explore whether combination with bemcentinib improves overall response rates to standard of care therapies in patients (pts) with metastatic melanoma (MM).

Methods: Dose escalation of bemcentinib in combination with 150mg twice daily/2mg daily dabrafenib/trametinib (D/T) in newly diagnosed, BRAF+, MM with high tumour load followed a 3 + 3 design (part 1). In part 2, pts were randomised 2:1 to receive D/T or pembro +/- bemcentinib at RP2D, respectively, based on mutation status and tumour load. Pts were allowed to switch D/T with pembrolizumab and vice versa upon progression (part 3). Tumour responses were assessed per investigator using RECIST v1.1. Plasma protein biomarker levels were measured using the DiscoveryMap v3.3 panel (Myriad RBM) in pts pre-dose and at C2D1.

Results: In part 1, 6 pts were enrolled first line (age 34-71, LDH > 1 x ULN 50%). There was 1 dose limiting toxicity (G3 rash) and an RP2D of bemcentinib in combination with D/T of 200mg daily bemcentinib with full dose D/T was confirmed. As of 2 May 18, a further 17 pts have been enrolled into part 2 of the study and four had progressed to part 3. Grade 3 treatment-related adverse events (AEs) were observed in 7 pts (30%). No G4 AEs or treatment related deaths occurred. Biomarkers candidates predicting treatment benefit were explored. Pre/post treatment changes of soluble proteins will be presented.

Conclusions: Bemcentinib RP2D (200 mg daily) is well tolerated in combination with both D/T and pembro without increased toxicity compared to either therapeutic approach alone. Further investigation of safety and efficacy as well as biomarker candidates is ongoing.

Clinical trial identification: NCT02872259.

Background: Canerpaturev (C-REV, formerly HF10) is an oncolytic, spontaneous mutant of HSV-1, and is one of immunotherapies that combine direct tumor cell killing with immune modulation. We report the safety and antitumor activity data of Phase II multicenter trial of C-REV in combination with ipilimumab (ipi) in melanoma.

Methods: The Phase II was to determine the efficacy and safety of i.t. C-REV and i.v. ipi. Key entry criteria: age ≥ 20 yrs, ECOG PS ≤ 2, Stage IIIB, IIIC or IV unresectable melanoma, who received prior therapies and had measurable non-visceral lesion(s) suitable for injection. C-REV was injected into each tumor (1×10^7 $TCID_{50}$/mL/dose, up to 5mL); 4 injections q1wk; then up to 15 injections q3wk. Four ipi infusions (3 mg/kg) were administered at q3wk. AEs were graded per CTCAE 4.0. Tumor responses were assessed per irRC and mWHO at 6, 12, 18 and 24 wks. Primary endpoint was Best Overall Response Rate (BORR) by irRC at 24 wks.

Results: Of 28 pts enrolled and treated as of the data cut-off 04 May 2018: 43% men, 31 to 81 yrs, disease stage 7% IIIB, 29% IIIC and 64% IV, and disease type 39% acral lentiginous and 21% mucosal melanoma. All pts were received prior cancer therapies: 89% PD-1 monotherapy, 7% DAVFeron and 11% DTIC. 12% had ≥G3 drug-related AEs; Hepatic function disorder, Malaise, Hyponatraemia, Constipation, Nausea, Toxicoderma, Adrenal insufficiency, and Muscle weakness lower limb. Of 27 efficacy evaluable pts, BORR by irRC at 24 wks was 7% and disease stability rate was 56%. One patient had PR in injected lesions and systemic lesions also showed the response after 6 wks of the combo therapy.

Conclusions: The combination of C-REV with ipi did not show the exacerbate ipi toxicity, and had a favorable benefit/risk profile. The encouraging antitumor activity was observed in Japanese pts who had received prior therapies such as PD-1. It is recently well-known that the response to ipi after anti-PD-1 therapy was unsatisfactory and associated with a high frequency of severe irAEs, in particular Asian populations. From this study, C-REV+ipi therapy has potential to become a new 2nd line treatment for melanoma.

1268P NCI 9922: Phase II study of ibrutinib in treatment-refractory distant metastatic cutaneous melanoma (DMCM)

S.J. Moschos[1], Z. Eroglu[2], N.I. Khushalani[2], K.L. Kendra[3], G. Ansstas[4], G.K. In[5], P. Wang[6], G. Liu[7], F.A. Collichio[8], C.C. Arrowood[9], J.E. Reed[1], N. Garrett-Mead[9], N.E. Thomas[8], D.W. Ollila[8], S.P. Ivy[10], A. Ivanova[8], E.C. Dees[8], J.L. Abbruzzese[11]

[1]Medicine, Lineberger Comprehensive Cancer Center, Chapel Hill, NC, USA, [2]Cutaneous Oncology Program, Moffitt Cancer Center, Tampa, FL, USA, [3]Cutaneous Oncology Program, Ohio State University Comprehensive Cancer Center - James, Columbus, OH, USA, [4]Medicine, Washington University School of Medicine in St. Louis, St. Louis, MO, USA, [5]Medicine, Keck School of Medicine at University of Southern California, Los Angeles, CA, USA, [6]Medicine, UK Markey Cancer Center, Lexington, KY, USA, [7]Medicine, University of Wisconsin, Madison, WI, USA, [8]Medicine, Lineberger Comprehensive Cancer Center, Chapel Hill, NC, USA, [9]Clinical Trials Unit, Duke Cancer Institute, Durham, NC, USA, [10]Cancer Therapy Evaluation Program, National Cancer Institute, Bethesda, MD, USA, [11]Medicine, Duke Cancer Institute, Durham, NC, USA

Background: The IL-2 inducible kinase (ITK) is highly expressed in metastatic melanomas and molecular targeting and/or pharmacologic inhibition of ITK in preclinical melanoma models suppresses cell proliferation without inducing cell death (Carson CCR 2015). Ibrutinib suppresses proliferation of melanoma cell lines in low nM concentrations (Moschos ASCO 2017, TPS9592). We hypothesize that targeting DMCM with ibrutinib will induce antitumor responses, especially in high ITK-expressing melanomas.

Methods: This is an open-label, single-arm, Simon's 2-stage design, multicenter, phase II study for patients (pts) with DMCM refractory to or ineligible for PD-1 and MAPK inhibitors, if BRAFV600-mutant. Given that the IC50 of ibrutinib for ITK is > 10 times than Bruton's tyrosine kinase's, we administered ibrutinib at 840mg qd. We hypothesized that an ineffective drug will have a = <5% response rate and = <18% 6-month PFS rate. We present the results of the first stage.

Results: 18 pts (13 males; median age 63.5, range 37-82; 14 with M1c disease; 4 with BRAFV600 mutation; 12 with performance status 1 or 2; 4 with resistance to 4 treatments; 5 with resistance to = >5 treatments) were enrolled. Median exposure to ibrutinib was 27.5 days (range 4-155). The most frequent all-grade side effects were fatigue (55%), anorexia (50%), gastrointestinal upset (44%), and anemia (39%). 4 grade IV (hyponatremia, sepsis, cytokine release syndrome, and constipation occurred 6% each) and 9 grade III events [hyponatremia (17%); pneumonia, hypertension, anemia, hypoalbuminemia, dehydration, lymphopenia occurred 6% each] were seen. No antitumor responses were seen. At a median follow-up of 5 months, all pts had progressed (median PFS was 1.3 months, range 0.2-5.5). 15 pts were discontinued from study due to progression and 14 pts had died from melanoma. Median OS was 5 months (range 0.3-10.4 months) in pts who died.

Conclusions: In this treatment-refractory DMCM, high-dose ibrutinib did not induce any meaningful clinical benefit; therefore the study will not proceed to stage 2. Correlation between PFS and expression of ITK by melanoma cells and density of tumor-infiltrating T- and B-cells in pretreatment tumor specimens will be reported at the time of the meeting.

Clinical trial identification: NCT03427398.

1269P Initial cohort expansion results of sustained arginine depletion with pegzilarginase in melanoma patients in a phase I advanced solid tumor trial

B. Chmielowski[1], M. Gordon[2], E.I. Buchbinder[3], R.J. Sullivan[4], J.V. Cohen[4], B.D. Curti[5], D. Davar[6], J. Homsi[7], K.M. Komatsubara[8], H. Lara-Guerra[9], S.E. Alters[10], S. Ferrati[10], S. Eckert[11], S.W. Rowlinson[10], J.E. Wooldridge[9], A. Ribas[1], R.D. Carvajal[8]

[1]Department of Medicine, Jonsson Comprehensive Cancer Center at UCLA, Los Angeles, CA, USA, [2]Medical Oncology, HonorHealth Virginia G Piper Cancer Care Network, Scottsdale, AZ, USA, [3]Melanoma, Dana-Farber Cancer Institute, Boston, MA, USA, [4]Hematology/Oncology, Massachusetts General Hospital, Boston, MA, USA, [5]Oncology and Hematology, Providence Cancer Institute, Portland, OR, USA, [6]Medicine, University of Pittsburgh, Pittsburgh, PA, USA, [7]Internal Medicine, UT Southwestern Medical Center, Dallas, TX, USA, [8]Hematology/Oncology, Herbert Irving Comprehensive Cancer Center, New York, NY, USA, [9]Medical, Aeglea Biotherapeutics, Austin, TX, USA, [10]Translational Research, Aeglea Biotherapeutics, Austin, TX, USA, [11]Biometrics, Aeglea Biotherapeutics, Austin, TX, USA

Background: Tumors with low argininosuccinate synthetase 1 (ASS1) expression have impaired arginine synthesis and are dependent on extracellular arginine for survival. Pegzilarginase (AEB1102) is a pegylated, recombinant, cobalt-substituted human arginase I that depletes plasma arginine. MTD was previously reported as 0.33 mg/kg weekly (AACR 2018). Here we update the preliminary safety and activity of monotherapy pegzilarginase in uveal (UM) and cutaneous (CM) melanoma cohorts of an ongoing Phase 1 study (NCT02561234).

Methods: Adult patients (pts) with metastatic UM or CM were eligible after prior standard treatments. IV pegzilarginase was administered at the MTD. Primary objective was safety (CTCAE v4.03); additional endpoints included PK, PD, tumor ASS1 expression, and preliminary anti-tumor activity (RECIST 1.1).

Results: At analysis, 16 pts with melanoma (11 UM, 5 CM) received pegzilarginase in cohort expansions. 5 dose-escalation pts with UM (3) or CM (2) were also treated at MTD. For the 21 pts with UM or CM treated at MTD, treatment-related AEs (TRAE) in > 10% pts included fatigue, nausea, diarrhea, vomiting, decreased appetite, dizziness, gait disturbance, muscular weakness, and tremor. No Grade ≥4 TRAEs were observed, and Grade 3 TRAEs were reported by one pt each: asthenia, failure to thrive, and hypophosphatemia. Median weeks on pegzilarginase was 5.9 (range 0 [1 dose] to 17.1 weeks). Pegzilarginase depleted plasma arginine from a median of 58 μM at baseline to a median of 4 μM at 72 hours post-dose (n = 12). In 13 pts with week 8 response assessment, 6 had stable disease. 13 pts with UM or CM had prior IO therapy; 7 had PD as best response to last prior therapy. 10/16 tumors showed no or low ASS1 expression.

Conclusions: The safety, PD, and activity profile of pegzilarginase at the MTD continues to support weekly administration with a margin for dose adjustment. Given very poor outcomes in pts with advanced UM and CM, pre-clinical data showing enhanced effects of pegzilarginase when combined with PD-L1 inhibition, and the observation of stable disease this trial, further development of pegzilarginase in combination with anti-PD-L(1) therapy is warranted for these tumors.

Clinical trial identification: NCT02561234.

Background: Only few studies on limited series of patients have evaluated the efficacy of immunotherapy in patients with metastatic mucosal melanoma (MM) or uveal melanoma (UM). The aim of the study was to assess the objective response rate and survival of patients with metastatic MM or UM treated with anti-CTLA-4 or anti-PD-1.

Methods: A multicenter retrospective study was performed in 25 Dermatology Departments in France. All patients with stage IIIC to IV MM or UM who were treated with anti-CTLA-4 or anti-PD-1 between 2008 and 2016 were included. Tumor response was evaluated according to RECISTv1.1 criteria at Week 12, and compared with a second cohort of patients treated with chemotherapy from 2000 to 2016. Overall survival (OS) was evaluated using Kaplan Meier method, and adjusted for main prognostic factors. UM or MM were analysed separately.

Results: A total of 439 patients were included, 229 with MM (151 treated with immunotherapy and 78 treated with chemotherapy) and 210 with UM (100 treated with immunotherapy and 110 treated with chemotherapy). Objective response rates of MM to anti-CTLA-4 and anti-PD-1 were 3/76 (3.9%, 95%CI=0.5%-8.3%) and 15/75 (20%, 95%CI=0.9%-29.1%) respectively, versus 11/78 (14.1%, 95%CI=6.4%-21.8%) in patients treated with chemotherapy ($p = 0.047$ and $p = 0.4$). No tumor response was observed in UM patients treated with immunotherapy, versus 4/110 responses (3.6%, 95%CI=0.2-7.4%) in patients treated with chemotherapy ($p = 0.12$). The OS of MM patients treated with immunotherapy was longer than that of patients treated with chemotherapy ($p = 0.002$), with a median OS of 15.97 [interquartile range (IQR)=6.89-27.12] and 8.82 months [IQR=5.2-14.9], respectively. After adjusting for main prognostic factors, the OS of MM patients treated with immunotherapy remained longer than that of patients treated with chemotherapy (HR = 0.61 [0.4; 0.95], $p = 0.028$). The adjusted and non-adjusted OS of UM patients treated with immunotherapy was not different from that of patients treated with chemotherapy (HR = 1.06 [0.70; 1.61], $p = 0.78$) with median of 13.38 months [IQR=6.03-29.57] and 11.02 months [IQR=5.8-23.9], respectively.

Conclusions: Anti-PD-1 should be considered for the treatment of patients with advanced MM. The prognosis of metastatic UM remains poor.

1271P Retrospective analysis of the treatment of metastatic uveal melanoma comparing systemic chemotherapy and transarterial chemoembolization

C.A. Peuker[1], L. Polzin[2], S. Ochsenreither[3], M. De Bucourt[4], S. Leyvraz[1], U. Keilholz[5], A. Joussen[6], J. Eucker[7]

[1]Medical Oncology, Haematology and Tumor Immunology, Charité Comprehensive Cancer Center, Berlin, Germany, [2]Department of Haematology and Medical Oncology, Campus Benjamin Franklin, Berlin, Germany, Charité - University Medicine Berlin, Berlin, Germany, [3]Charité Comprehensive Cancer Center, Charité University of Medicine, Berlin, Germany, [4]Department of Radiology, Campus Benjamin Franklin, Berlin, Germany, Charité - University Medicine Berlin, Berlin, Germany, [5]Oncology, Charite Comprehensive Cancer Center, Berlin, Germany, [6]Department of Ophthalmology, Campus Benjamin Franklin, Berlin, Germany, Charité - University Medicine Berlin, Berlin, Germany, [7]Medizinische Klinik M. S. Hämatologie und Onkologie, Charite, Campus Benjamin Franklin Medizinische Klinik III, Berlin, Germany

Background: Metastatic uveal melanoma (mUM) is a rare disease with poor prognosis, hardly responding to systemic treatment. As the liver is the most common and prognostic relevant metastatic site, liver-directed therapies have come into focus.

Methods: A retrospective analysis was carried out in patients who were treated at our center between 2008 and 2017 receiving chemotherapy (1000 mg/m^2 gemcitabine + 3500 mg/m^2 treosulfan (GeT) on days 1 + 8, 4-week cycles) or transarterial chemoembolization (TACE, EmboCept® S microspheres + 50 mg cisplatin, every 4-6 weeks) as 1st-line therapy for mUM.

Results: 287 patients were treated for mUM in the time period, 93 received TACE and 82 GeT as 1st-line therapy. Patient characteristics differed in the metastatic pattern: patients receiving GeT having a significant higher rate of non-liver dominant metastatic disease compared to the TACE group ($p < 0.001$), whereas there was no difference in age, sex, DFI, laboratory values and percentage of liver involvement. Median overall survival (OS) in the GeT group was 11.3 vs. 8.4 months in the TACE group ($p = 0.089$), with a median progression-free survival (PFS) of 2.7 and 2.8 months respectively (ns). Overall response rate for GeT was 6.8% and disease control rate was 41.1%, for TACE 10.2% and 47.7% respectively (both ns). Age, sex, baseline laboratory values, PFS and percentage of liver involvement were significantly associated with OS in univariate analysis. Multivariate Cox regression analysis identified male sex, elevated bilirubin, GGT, ALP, percentage of liver involvement >50% and PFS ≤2.7 months as significant independent prognostic factors for shorter survival. The metastatic pattern and the type of treatment did not show to be significant prognostic factors.

Conclusions: Liver-directed therapies can improve response rates compared to systemic therapies and should be preferred in patients with liver-dominant metastatic pattern. However, PFS and OS remain poor and not significantly different between intrahepatic and systemic therapies. Further research should focus on developing new therapies based on a better understanding of the biology of these tumors.

1272P Outcome of an active surveillance programme for patients (pts) with uveal melanoma (UM) after primary curative therapy (PTx): Single institution 10-year experience

C.L. Lee[1], G. Gullo[1], N. Horgan[2], D. Smith[1], M. Moran[1], J.P. Crown[1]

[1]Medical Oncology, St Vincents University Hospital, Dublin, Ireland, [2]Surgery, Royal Victoria Eye & Ear Hospital, Dublin, Ireland

Background: About 30% of pts with UM develop metastatic disease (MUM) despite PTx. MUM has poor prognosis and no systemic treatment (STx) has been proven to improve overall survival (OS). The role of active surveillance after PTx is still controversial.

Methods: We performed an outcome analysis of all UM pts prospectively registered onto our active surveillance programme after PTx. All pts had systemic staging at diagnosis and then 6-monthly liver imaging (CT triple-phase, MRI, ultrasound) and clinical review for the first 5 years and 12-monthly afterwards. Progression-free survival (PFS) was calculated from time of first systemic relapse to first disease progression, OS from time of first systemic relapse to death or latest FU.

Results: Out of 169 pts registered between April 2008 and April 2018, 32 (19%) developed MUM during surveillance: 14 pts (44%) relapsed <2 yrs, 14 (44%) >2 and <5 yrs, 4 (12%) >5 yrs from PTx. Median FU is 46.8 mos. MUM pts characteristics: males 17 (53%); median age 59yrs (range 31-86); median tumour thickness at diagnosis 9mm (range 3-22); sites of metastases: liver only 10 (31%), liver + other sites 19 (60%), extrahepatic only 3 (9%). Relapses were asymptomatic and detected on surveillance imaging in 25 (78%) pts. Median duration to relapse after PTx is 27.4 mos. Eight pts (25%) were upfront resectable (PRx) and underwent radical hepatic metastasectomies, 24 pts (75%) were non-resectable (NRx) and underwent immunotherapy (n = 12), other systemic therapies (n = 5) [4 chemotherapy, 1 BRAF inhibitor], locoregional Tx (n = 3) [2 Delcath, 1 RFA], best supportive care (n = 4). At median FU of 46.8 mos (0-120 mos), 27 pts have died and the median OS is 13.5mos. PFS was longer in PRx pts compared to NRx pts (PFS: 9.8 vs 4.4 mos / OS: 20.7 vs 39.3 mos). All 8 resectable pts developed further disease relapse [median time to hepatic relapse 9.8 mons (range 5.2 -13.1)].

Conclusions: Our data indicate that active surveillance after PTx of UM can allow detection of asymptomatic potentially resectable liver metastases, especially in pts with high risk UM (i.e. thickness >5mm). Although durable remission after hepatic metastasectomy is rare, PFS and OS may be meaningfully prolonged.

1273P Activation of non-canonical NFκB (NC-NFκB) pathway in inflammatory environment of uveal melanoma

M.K. Singh[1], R. Meel[2], N. Pushker[2], S. Sen[1], K. Chodsol[3], S. Bakhshi[4], S. Kashyap[1]

[1]Ocular Pathology, All India Institute of Medical Sciences, New Delhi, India, [2]Ophthalmology, All India Institute of Medical Sciences, New Delhi, India, [3]Biochemistry, All India Institute of Medical Sciences, New Delhi, India, [4]Medical Oncology, All India Institute of Medical Sciences, New Delhi, India

Background: Uveal melanomas are considered as malignant phenotype having a high density of macrophages, blood vessels, and T-lymphocytes. Presence of epithelioid cells with high melanin pigmentation leads to worse patient's prognosis. Non-canonical NFκB (NC-NFκB) pathway plays an important role in inflammation which promotes cancer initiation and progression. p52 and RelB are the dimer proteins of the NC-NFκB pathway. The aim of the study is to detect the expression of p52/RelB protein dimer in the inflammatory microenvironment of uveal melanoma and its prognostic significance.

Methods: Evaluation of p52/RelB dimer was assessed by using immunohistochemistry and western blotting in 75 formalin fixed uveal melanoma tissues and transcriptional analysis was done on 58 fresh frozen tissues by real-time PCR. Immunopositive expression of both proteins was taken as a positive expression of the dimer ($p52^+/RelB^+$) and immunonegative of both proteins taken as ($p52^-/RelB^-$) negative expression of the dimer. Results were then correlated with clinicopathological parameters and disease-free survival.

Results: Immunoexpression of $p52^+/RelB^+$ protein showed both nuclear and cytoplasmic expression in 35 cases whereas 15 showed cytoplasmic only. qRT-PCR showed upregulation of $p52^+/RelB^+$ gene in 65.51% cases at the transcriptional level. Expression of both cytoplasmic and nuclear $p52^+/RelB^+$ dimers showed significant correlation with cases having high tumor infiltrated lymphocytes, macrophages (CD68+) and presence of blood vessels (CD34+). There was a statistically significant difference in the disease-free survival of patients with nuclear/cytoplasmic $p52^+/RelB^+$ immunopositivity ($p < 0.05$).

Conclusions: This preliminary data suggests that p52/RelB protein dimer plays an important role in the inflammatory microenvironment of uveal melanoma which might be responsible for the pathogenesis of this disease. Further translational studies are required to explore the nature of NC-NFκB pathway in the tumor microenvironment of uveal melanoma.

1274P The use of PD-1 inhibitors for the advanced melanoma of esophagus

L. Mao, X. Wang, L. Si, Y. Kong, Z. Chi, X. Sheng, C. Cui, B. Lian, B. Tang, X. Yan, J. Guo
Renal Cancer and Melanoma, Beijing Cancer Hospital, Beijing, China

Background: Melanoma of esophagus (ME) is a rare type of melanoma, accounting for <3% of cases. Patients with advanced melanoma of esophagus origin, tend to have lower response rates on traditional therapies. Thus, we report our experience with 11 patients with advanced esophageal melanoma who received PD-1 inhibitors.

Methods: A retrospective analysis of 77 patients with advanced ME were conducted from the database of Peking University Cancer Hospital between Jan 2008 and Sep 2017. We collected the clinical data and assessed objective response rates (ORR) and progression–free survival (PFS). The data cutoff date was Jan 1st 2018.

Results: We identified the 77 patients were unresectable or metastatic esophageal melanomas. The Median age was 57, with 67.5% being male. 78% patients had history of esophagectomy and 64 patients had received prior systemic therapy. There were 8 (10.4%) patients harbored C-KIT mutations and 5 (6.5%) harbored BRAF. We divided the patients into 3 cohorts according to different treatments: Chemotherapy (C: 8 DTIC/26 TMZ/ 23 PTX; 57 cases), Targeted therapy (T: 6 imatinib/3 vemurafenib; 9 cases) or PD-1 inhibitors (P, 11 cases). The PFS were 3.0 and 4.2 months with limited ORR of 5.7% and 25.0% respectively for C and T cohort. In the P cohort, 7/11 patients (63.6%) achieved PR and other 3 remained SD > 4+ months. The PFS for the P cohort was 13.0+ months. Toxicities were as expected and were usually grade 1or 2.

Conclusions: Although this cohort of patients was small, it was the largest report for now. To our knowledge this is also the first report of outcomes of PD-1 inhibitors in advanced esophageal melanomas. The dramatic response appears to be an available option for patients with advanced esophageal melanomas.

1275P Phase II trial on nivolumab in patients with unresectable or metastatic mucosal melanoma

M. Nomura[1], M. Andoh[2], T. Yokota[3], T. Miyazaki[4], H. Satake[5], S. Iwasawa[6], A. Sonoda[7], K. Kato[8], M. Muto[1]

[1]Medical Oncology, Kyoto University-Graduate School of Medicine, Kyoto, Japan, [2]Clinical Oncology, Aichi Cancer Center Hospital, Nagoya, Japan, [3]Gastrointestinal Oncology, Shizuoka Cancer Center, Shizuoka, Japan, [4]Head and Neck Surgery, Kurashiki Central Hospital, Kurashiki, Japan, [5]Medical Oncology, Kobe City Medical Center General Hospital, Kobe, Japan, [6]Respirology, Chiba University Graduate School of Medicine, Chiba, Japan, [7]Gastroenterology, Shiga University of Medical Science, Otsu, Japan, [8]Gastrointestinal Medical Oncology, National Cancer Center Hospital, Tokyo, Japan

Background: Mucosal melanoma is rare and an aggressive malignancy with poor response compared with cutaneous melanoma. The prospective trial on immune-checkpoint inhibitors in unresectable or metastatic mucosal melanoma has not been reported except pooled analysis. The aim of this phase II trial was to assess the efficacy and safety of nivolumab monotherapy for unresectable or metastatic mucosal melanoma.

Methods: Eligibility criteria were as follows: histological diagnosis of unresectable or metastatic mucosal melanoma; age ≧ 20 years; ECOG performance status 0 or 1; and with measurable lesions. Patients received nivolumab 2 mg/kg every 3 weeks. The primary endpoint was response rate (RR) according to Response Evaluation Criteria in Solid Tumors version 1.1(≧ 20%). The secondary endpoints were overall survival, progression-free survival, disease control rate, and toxicity.

Results: A total of 20 patients were enrolled between December 2014 and July 2017. Two patients without measurable lesion were excluded from analysis of efficacy. The RR was 22%, suggesting that the primary endpoint was met. One patient achieved a complete response, three patients achieved partial response, and six patients achieved stable disease as their best response. The median progression-free survival was 1.4 months (95% CI, 1.15 to 5.47). The median overall survival was 12.03 months (95% CI, 3.50 to not reach). The 1-year overall survival data was 52.6% (95% CI, 28.5 to 72.0). Treatment-related adverse events of grade 3 or 4 occurred in 15% (3/20) of the patients. Grade 3 diarrhea was observed in two patients and grade 3 adrenal insufficiency was observed in one patient. They were resolved by corticosteroid.

Conclusions: Although this trial met the primary endpoint, the RR was still unsatisfactory. Therefore, the further treatment development is required.

Background: Anti-PD1 antibodies (aPD1s) for advanced melanoma have proven their superiority over chemotherapy and ipilimumab in phase III trials. However, in real-world many patients were not represented in these trials. We report real-world outcomes of aPD1 for advanced melanoma.

Methods: Pts with advanced (non-uveal) melanoma from 2014 to 2016 who received 1st line aPD1 were selected from the Dutch Melanoma Treatment Registry - a population based registry in the Netherlands. Outcomes of pts normally eligible (ELI) for trial participation (ECOG PS of 0-1, no brain metastasis, auto-immune disease, HIV, psychiatric disorder or corticosteroid use) were compared to pts normally non-eligible (N-ELI) for trial participation. Time to event was estimated with Kaplan-Meier method and overall survival (OS) with cox regression analysis.

Results: In total 552 patients with advanced melanoma received 1st line aPD1. Median age was 65yrs (range 21-94). At baseline 28% had elevated LDH, 90% ECOG PS of 0-1, 19% brain metastases, 65% stage IV-M1c disease and 41% had a BRAF mutation. Toxicity grade 3-4 occurred in 68 pts (12.3%). Median follow-up estimated with reverse Kaplan-Meier method was 18.8 mo (95%CI: 18-20). 1- and 2-yr OS (95%CI) was 72% (68-76%) and 59% (55-65%) and median OS was not reached. Median time to next treatment (TTNT) for ELI pts was not reached and TTNT for N-ELI pts was 10.6 mo (95%CI: 8.3-14.7). Median time of treatment duration was 8.8 mo (95%CI: 6.9-10.5) for ELI pts and 5.3 mo (95%CI: 4.1-7.1) for N-ELI pts. 1- and 2-yr OS were respectively 76% (72-81%) and 63% (57-70%) versus 65% (95%CI: 59-72%) and 53 (95%CI: 45-61% (log-rank test p-value: 0.003). Unadjusted hazard ratio (HR) for OS was 1.57 (95%CI: 1.17-2.09) for N-ELI compared to ELI pts and adjusted HR was 1.28 (95%CI: 0.94-1.73). HR for LDH >500 UI/L was 2.10 (95%CI: 1.23-3.58) and HR for BRAF neg. pts 1.74 (95%CI: 1.26-2.41).

Conclusions: Real-world outcomes of 1st line aPD1s in patients with advanced melanoma seem to be in accordance to results observed in phase III trials. These data support that N-ELI pts normally not represented in phase III trials may benefit from aPD1 treatment. LDH >500 UI/L and BRAF neg. status were associated with poorer survival.

1277P Stereotactic radiation therapy in melanoma brain metastasis: A European, multicentric cohort

A. Paix[1], F. Thillays[2], F. Courtault-Deslandes[3], I. Popp[4], H. Herrscher[5], J. Biau[6], O. Briard[7], A-L. Grosu[8], G. Noël[9]

[1]Radiation Oncology, Centre Paul Strauss Centre de Lutte Contre le Cancer, Strasbourg, France, [2]Radiotherapy, Institut Cancérologique de l'Ouest, Saint Herblain, France, [3]Radiotherapy, Centre Georges-Francois Leclerc, Dijon, France, [4]Klinik für Strahlenheilkunde, Universitätsklinikum Freiburg, Freiburg, Germany, [5]Medical Oncology, University Hospital Strasbourg, Strasbourg, France, [6]Radiotherapy, Centre Jean Perrin, Clermont-Ferrand, France, [7]Radiotherapy, Centre Henry Kaplan – Centre Hospitalier Universitaire de Tours, Tours, France, [8]Radiation Oncology, Univeristy of Freiburg, Freiburg, Germany, [9]Radiotherapy, Centre Paul Strauss, Strasbourg, France

Background: Brain metastases are frequent in patients with melanoma and stereotactic radiotherapy is one of the main treatment options. We report the efficacy and safety of hypofractionated stereotactic radiation therapy (HFSRT) and stereotactic radiosurgery (SRS), and its role in melanoma brain metastasis management.

Methods: On behalf of the French-speaking neuro-oncologist association (ANOCEF), we retrospectively collected clinical data of 150 patients and 299 brain metastases from melanoma treated with SRS or HFRSRT in 6 radiation oncology departments in France and in Germany. The primary endpoint was the response to the treatment according to RANO criteria. Secondary endpoints were overall survival (OS).

Results: We conducted a Bayesian multivariate logistic regression for treatment response probability. Age, control of disease and stereotactic radiosurgery have an odds ratio (OR) of 1.02 [1.00 – 1.05], 4.61 [1.15 – 13.24] and 4.33 [0.94 – 13.38] respectively and a probability of being > 1 of 94%, 99% and 97% respectively. BRAF mutation, time between dosimetric MRI and treatment, Ipilimumab administration, multiple brain metastases and WHO performans status have an OR of 0.559 [0.21 – 1.33], [0.79 – 0.94], 0.57 [0.17 – 1.39], 0.41 [0.11 – 1.04] and 0.63 [0.25 – 1.28] respectively and a probability of being < 1 of 91%, 100%, 91%, 97% and 91% respectively. Median OS was 11 months [8 – 20] and the multivariate Cox analysis estimated a Hazard ratio of 0.37 ($p = 0.007$) and 0.8 ($p = 3.7E-6$) for the control of the disease and the brain progression-free survival respectively.

Conclusions: We report the results of one of the largest cohort of patients treated with SRS and HFSRT for melanoma brain metastases. Our analysis suggests that the age of the patient, the control of the disease and SRS are associated with higher response probability while BRAF mutation, the time between dosimetric MRI and treatment, Ipilimumab administration, multiple brain metastases and poor WHO PS are associated with lower response probability.

Background: The EORTC 1325-MG/Keynote 054 trial demonstrated prolonged recurrence-free survival with adjuvant pembrolizumab compared to placebo (hazard ratio = 0.57; $P < 0.001$. Eggermont et al, NEJM, 2018). Incidence of adverse events grades 3 or higher related to treatment were higher in the pembrolizumab arm (14.7%) than the placebo arm (3.4%). Here we report results from the health-related quality of life (HRQoL) exploratory endpoint.

Methods: A total of 1019 patients with histologically confirmed, cutaneous melanoma metastatic to a lymph node, classified as stage IIIA, IIIB or IIIC were randomized after complete resection to receive 200 mg pembrolizumab (514 patients) or placebo (505 patients). Treatment was administered every 3 weeks for 1 year, or until disease recurrence or unacceptable toxicity. All enrolled patients were required to complete a HRQoL questionnaire at baseline and every 12 weeks (during 2 years after randomization). The primary HRQoL outcome was global health/QoL (GHQ) as measured by the EORTC QLQ-C30. All other scales from this questionnaire were secondary. Scores were compared according to the average score per patient overall, during treatment and after treatment.

Results: HRQoL compliance was >90% at baseline, >70% during the first year and >60% thereafter for both arms. Data attrition limited the analyses to week 84 (19 months). Baseline GHQ scores were similar between arms at 77 points and remained stable over time. The average GHQ score was 2.2 points (95% CI: 4.3-0.2), 1.1 points (95% CI: 3.2 - -0.9) and 2.2 points (95% CI: 4.8 - -0.4) lower in the pembrolizumab arm compared to placebo for the average overall, during and after treatment respectively. These differences are within 5 point clinical relevance threshold for the QLQ-C30. Results from the secondary scales revealed a similar pattern with scores stable over time and treatment differences never reaching the 5 point threshold.

Conclusions: Pembrolizumab maintains health-related quality of life compared to placebo, when given as adjuvant therapy for patients with resected high-risk stage III melanoma.

Clinical trial identification: EudraCT: 2014-004944-37; NCT02362594.

1279P The real-world impact of modern treatments on the survival of patients with metastatic melanoma

M. Donia[1], E. Ellebaek[2], T.H. Øllegaard[3], L. Duval[3], J.B. Aaby[4], L. Højberg[4], U.H. Køhler[5], H. Schmidt[3], L. Bastholt[4], I-M. Svane[1]

[1]*Center for Cancer Immune Therapy and Department of Oncology, Herlev and Gentofte Hospital, University of Copenhagen, Herlev, Denmark,* [2]*Department of Oncology, Herlev and Gentofte Hospital, Herlev, Denmark,* [3]*Department of Oncology, Aarhus University Hospital, Aarhus, Denmark,* [4]*Medical Oncology, Odense University Hospital, Odense, Denmark,* [5]*Braintrust Consult, Braintrust Consult, Odense, Denmark*

Background: Phase III trials with strict enrolment criteria led to the approval of several new treatments for unresectable or metastatic melanoma (MM) between 2010 and 2015. The impact of modern treatments on the overall survival of the whole "real world" population of MM is unknown.

Methods: The Danish MM database contains data on the entire, unselected population diagnosed with MM within a nationwide area. To evaluate the impact of novel treatments, all MM cases diagnosed in three non-consecutive years marked by major changes in the availability of 1st line treatments (2012: i.v. IL-2 and BRAFi; 2014: anti-CTLA-4; 2016: anti-PD-1 and MEKi) were retrieved. Patients were grouped into "trial-like" and "trial-excluded" based on seven predefined eligibility criteria used in all MM registration immunotherapy clinical trials, including CNS metastases and PS ≥ 2. The database was locked on February 1st 2018.

Results: We retrieved the data of all 838 patients diagnosed with MM (excluding ocular melanoma) in Denmark during 2012, 2014 and 2016. The baseline characteristics of patients diagnosed in 2012, 2014 and 2016 were similar. In the "trial-like" population (39% of all MM), which met all seven eligibility criteria for trial participation, the median overall survival (OS) was not yet reached in the 2016 group versus 20.1 months in 2014 (hazard ratio [HR] for death 0.57, 95% CI 0.38-0.84; $p = 0.0049$) and 16.5 months in 2012 (HR 0.47, 95% CI 0.30-0.73; $p = 0.0008$). No major survival differences were observed in 2014 versus 2012 (HR 0.77, 95% CI 0.55-1.08; $p = 0.1354$). In the "trial-excluded" population (61% of all MM), 75% of patients had known CNS metastases and/or PS ≥ 2. Here, the median OS was improved to 6.8 months in the 2016 group versus 5.2 months in 2014 (HR 0.67, 95% CI 0.52-0.86; $p = 0.0013$) and 4.3 months in 2012 (HR 0.67, 95% CI 0.53-0.86; $p = 0.0016$), with no difference between 2012 and 2014 ($p = 0.65$).

Conclusions: "Trial-like" patients represent only 39% of the total MM population in the real world. Our data show that the introduction of modern treatments led to an improved survival of real world patients with MM, regardless of their clinical trial eligibility.

1280P Treatment patterns of melanoma by BRAF mutation status in the US in 2011-2017: A retrospective cohort study

L. Raskin[1], S. Shah[2], M. Braunlin[1], J. Buchanan[2], D. Cohan[3]

[1]*Global Center for Observational Research, AMGEN (Headquarters), Thousand Oaks, CA, USA,* [2]*Global Health Economics, AMGEN (Headquarters), Thousand Oaks, CA, USA,* [3]*Medical Affairs, AMGEN (Headquarters), Thousand Oaks, CA, USA*

Background: New therapies have changed melanoma treatment after 2011; however, these changes have not been studied well, especially in $BRAF^{Mut}$ melanomas.

Methods: We studied 4197 melanoma patients who received systemic therapy in 2011-17 in the US electronic medical record database OSCER. Among these, 1687 (40%) were studied for treatments by line of therapy (LOT) and biomarkers from 2011-16.

Results: Therapies included: 64% checkpoint inhibitors (CPI), 19% BRAF/MEK inhibitors (BRAF/MEKi), 17% chemotherapy, 16% cytokines, and 1% oncolytic viral therapy. In 2011-17, overall CPI use increased from 23% to 81% (pembrolizumab 32%,

nivolumab 23%, ipilimumab/nivolumab 21%) but ipilimumab use decreased to 13%. BRAF/MEKi use did not change (20-21%) but vemurafenib (2% in 2017) was replaced by dabrafenib/trametinib and cobimetinib/vemurafenib (14% and 4%). Cytokine and chemotherapy use declined (43% to 3% and 35% to 7%, respectively). During 2011-17, CPI and BRAF/MEKi were used more in LOT 1-4 (60% and 25%) than as adjuvant (30% and 2%), whereas cytokines were used as adjuvant only (64%). CPI were used most in $NRAS^{Mut}$ (85%) and less in $BRAF^{Mut}$, $BRAF^{wt}$, or $NRAS^{wt}$ (57-66%). In $BRAF^{Mut}$, CPI use was higher in stage III (62%) than IV (52%) unlike in $BRAF^{wt}$ (52% stage III vs. 90% stage IV). BRAFi were used in 65% of $BRAF^{Mut}$, more in stage IV than III (79% vs. 34%). $BRAF^{Mut}$ and $NRAS^{Mut}$ received less adjuvant therapy than wild-type (20-22% vs. 28-31%) but more LOT ($BRAF^{Mut}$ had 89% LOT 1, 37% LOT 2, 13% LOT 3, 5% LOT 4+). The table compares treatment changes in $BRAF^{Mut}$ melanoma between 2011-14 and 2015-16.

Table: 1280P Treatment changes in $BRAF^{mut}$ melanoma between 2011-14 and 2015-16

Therapy	2011-14			2015-16		
	Adjuvant	LOT 1	LOT 2	Adjuvant	LOT 1	LOT 2
BRAF/MEKi						
Vemurafenib	12%	28%	12%	0	5%	5%
Dabrafenib/Trametinib	4%	21%	26%	9%	43%	38%
Cobimetinib/Vemurafenib	0	<1%	2%	0	4%	10%
Dabrafenib	0	4%	8%	0	4%	2%
Trametinib	0	2%	4%	0	1%	2%
CPI						
Ipilimumab	14%	23%	20%	35%	8%	5%
Pembrolizumab	1%	7%	11%	7%	13%	21%
Nivolumab	0	7%	12%	9%	10%	21%
Ipilimumab/Nivolumab	1%	6%	7%	7%	15%	12%
Cytokines	60%	7%	1%	33%	3%	0
Chemotherapy	2%	4%	7%	0	3%	0

Conclusions: Checkpoint inhibitors have replaced other advanced melanoma therapies, providing more treatment options to patients with $BRAF^{Mut}$ melanoma.

1281P Assessment of real-world effectiveness of first-line (1L) nivolumab (NIVO) plus ipilimumab (IPI) or NIVO monotherapy for advanced melanoma: A retrospective cohort study

M. Freeman[1], K. Gupte-Singh[2], M. You[3], T.K. Le[3], C. Ritchings[4], S. Rao[2], S. Jang[5]

[1]Department of Medical Oncology & Therapeutics Research, City of Hope, Duarte, CA, USA, [2]Health Economics Outcomes Research, Bristol-Myers Squibb, Princeton, NJ, USA, [3]Center for Observational Research & Data Sciences, Bristol-Myers Squibb, Princeton, NJ, USA, [4]Melanoma, Bristol-Myers Squibb, Princeton, NJ, USA, [5]Hematology Oncology, Inova Melanoma and Skin Cancer Center, Fairfax, VI, USA

Background: NIVO+IPI and NIVO are approved for 1L treatment of patients with unresectable or metastatic (advanced) melanoma. This study assessed real-world outcomes (objective response rate [ORR], progression-free survival [PFS], and overall survival [OS]) with NIVO+IPI or NIVO alone in patients with advanced melanoma using the US Flatiron Health electronic health record database from January 2011 to June 2017.

Methods: Eligible patients were aged ≥18 years, diagnosed with advanced melanoma, and treated with 1L NIVO+IPI or NIVO (index date). Outcomes were assessed based on an in-depth review of patient charts. Patients were followed until death, database discontinuation, or end of the study period. Factors associated with ORR, PFS, and OS were evaluated using logistic and Cox proportional hazards regression models. An evaluation of safety outcomes is ongoing.

Results: 463 patients were eligible (NIVO+IPI, n = 254; NIVO, n = 209), with a mean follow-up of 9.2 months (range 1.0-31.6). Of those with data available, 39% of patients had elevated LDH, 35% had ECOG PS 1, and 33% were BRAF mutant. Compared with NIVO patients, NIVO+IPI patients were younger (71 vs 61 years) and a higher proportion were treated in academic centers (7.7% vs 18.9%). For NIVO+IPI and NIVO, ORR was 51% and 41%, median PFS was 12.2 and 5.4 months (1-year PFS rate 51% and 37%), and median OS was not reached and 20.1 months (1-year OS rate 71% and 60%), respectively. After adjusting for patient characteristics, NIVO+IPI patients were twice as likely to respond within 3 months, had a 35% lower likelihood of progression, and had a 35% lower likelihood of death compared with NIVO (Table).

Table: 1281P

Factor	Model value vs reference value	Hazard/odds ratio (95% CI)	P value
PFS			
Treatment	NIVO+IPI vs NIVO	0.65 (0.50, 0.83)	0.0006
LDH	≤ULN vs >ULN	0.56 (0.41, 0.77)	0.0003
OS			
Treatment	NIVO+IPI vs NIVO	0.65 (0.47, 0.90)	0.0354
LDH	≤ULN vs >ULN	0.44 (0.29, 0.67)	<0.0001
ECOG PS	0–1 vs 2–5	0.48 (0.31, 0.75)	0.0016
Response			
Treatment	NIVO+IPI vs NIVO	2.13 (1.27, 3.56)	0.0039

Conclusions: In this real-world clinical practice database, 1L NIVO+IPI was associated with improved efficacy outcomes compared with NIVO alone in patients with advanced melanoma.

1282P Responder analysis based on patient-reported outcomes (PROs) and clinical endpoints (CEPs) in patients (pts) with metastatic Merkel cell carcinoma (mMCC) treated with avelumab

S.P. D'Angelo[1], F. Fofana[2], M. Schlichting[3], M. Henry-Szatkowski[4], M. Hennessy[5], M. Bharmal[6]

[1]Medical Oncology, Memorial Sloan Kettering Cancer Center & Weill Cornell Medical College, New York, NY, USA, [2]Patient-Centered Outcomes, Mapi Group, Leiden, Netherlands, [3]BioStatistics, Merck KGaA, Darmstadt, Germany, [4]Patient-Centered Outcomes, Mapi Group, Lyon, France, [5]Medical Oncology, EMD Serono, Billerica, MA, USA, [6]Global Evidence & Value Development, Merck KGaA, Darmstadt, Germany

Background: To better understand the impact of the anti–PD-L1 antibody avelumab, clinical outcomes and PROs in chemotherapy-refractory pts with mMCC enrolled in a single-arm, international phase 2 trial (NCT02155647) were analysed. Here we explore the proportion of pts categorised as responders based on these outcome measures.

Methods: PROs were assessed at baseline (BL), at week 7, thereafter Q6W until disease progression, and at end of treatment using EQ-5D, a generic health-related quality of life (HRQoL) tool, and FACT-M, a cancer-specific HRQoL tool. Pts were categorised as meaningfully improved/stable or as meaningfully worsened. HRQoL deterioration-free survival (QFS) was defined as the time from BL to either a meaningful worsening from BL with no further improvement in HRQoL or death. QFS rates of PRO endpoints were computed at specific time points. Responders based on PRO meaningfully improved/stable and QFS analyses were described along with the best overall response (BOR) and progression-free survival (PFS) analyses assessed by IERC per RECIST v1.1.

Results: As of Sept 26, 2017, 88 pts had been followed for a minimum of 24 months (mo; median, 29.2 [range, 24.8-38.1]). The table presents responders based on PROs and CEPs at 6, 12, 18, and 24 mo. In addition, PRO-based, 2-year rates of improved/stable endpoints tended to be higher than the BOR rate of 33%, ranging from 41% for FACT-M physical well-being to 58% for FACT-M melanoma surgery scale.

Table: 1282P

		6 mo	12 mo	18 mo	24 mo
CEPs					
PFS rate, %		40	29	29	26
PRO endpoints					
QFS rate, %	EQ-5D VAS	52	52	49	38
	FACT-M total	45	40	36	32
	FACT-M physical well-being	44	37	33	33
	FACT-M social/family well-being	40	40	31	26
	FACT-M emotional well-being	45	40	33	33
	FACT-M functional well-being	41	34	31	27
	FACT-M melanoma subscale	53	42	39	39
	FACT-M melanoma surgery scale	46	43	38	38
	FACT-G total	41	39	35	31

Conclusions: The findings show similarity in the proportion of responders based on clinical and PRO endpoints, reiterating the potential association of both outcome measures in this mMCC population. This confirms the interest in using PROs in trials to contribute to the interpretation of objective CEPs.

Clinical trial identification: NCT02155647.

1283P Treatment pattern and clinical outcomes of patients with locally advanced and metastatic melanoma in a real-world setting in China

C. Cui[1], X. Yan[1], S. Liu[2], A. Deitz[3], L. Si[4], Z. Chi[1], X. Sheng[1], B. Lian[1], J. Li[2], J. Ge[2], X. Wang[1], L. Mao[1], B. Tang[1], L. Zhou[1], X. Bai[1], S. Li[1], B. Li[2], H. Wu[2], J. Guo[1]

[1]Urology and Melanoma, Beijing Cancer Hospital, Beijing, China, [2]Medical Oncology, MSD China, Beijing, China, [3]Medical Oncology, Merck & Co., Inc., Kenilworth, NJ, USA, [4]Department of Renal Cancer and Melanoma, Peking University Cancer Hospital-Beijing Cancer Hospital, Beijing, China

Background: In China, treatment options for late-stage melanoma, particularly for second-line (2L) therapy, are limited. This retrospective, observational study used electronic medical records (EMRs) of patients (pts) with melanoma treated at Beijing Cancer Hospital (BCH) to describe the treatment pattern and real-world clinical outcomes in locally advanced, metastatic melanoma in China.

Methods: All adult pts with unresectable stage III or IV melanoma who initiated treatment between Jan 1, 2014, and Dec 31, 2015, were eligible. Pts were treated and followed up with regular imaging (every 3 mo). Trained researchers performed additional medical chart reviews to supplement data captured in the EMR database. Complete or partial responses, per RECIST v1.1 were adjudicated case by case. Survival analysis involved the Kaplan-Meier method, pts were censored at last known date alive before Dec 31, 2017.

Results: Of 248 pts included in the study, 40.7% and 30.6% had acral and mucosal histology, respectively; almost all (~95%) had stage IV melanoma; 221 received first-line (1L) therapy and 116 received 2L therapy (89 received both at BCH within the treatment period). The most common 1L regimens were dacarbazine + cisplatin + recombinant human endostatin (RHE) (36.7%) and paclitaxel + carboplatin + bevacizumab (22.2%). The most common 2L regimens were paclitaxel albumin + carboplatin + bevacizumab (22.4%), paclitaxel + carboplatin + RHE (15.5%) and paclitaxel albumin + cisplatin + RHE (12.1%). Clinical outcomes in pts with advanced melanoma are summarized in the table and are generally unfavorable: ORR <10%; median PFS <4 months; median OS < 1 year. Median DOR was 9.1 mo for 1L and 7.5 mo for 2L therapy.

Table: 1283P

	1L Therapy (N = 221)	2L Therapy (N = 116)
Response		
CR, n	2	0
PR, n	12	4
ORR, % (95% CI)	6.3% (3.5-10.4)	3.4% (0.9-8.6)
Median DOR (range), months	9.1 (1.7-28.4+)	7.5 (4.6-24.2+)
Median PFS (95% CI), months	3.5 (2.9-4.2)	2.3 (2.0-3.0)
12-month PFS rate	10.6%	5.2%
Deaths, n (%)	171 (77.4)	101 (87.1)
Median OS (95% CI), months	10.5 (9.2-12.1)	7.5 (6.5-8.7)
12-month OS rate	43.5%	30.5%

CI, confidence interval; CR, complete response; DOR, duration of response; 1L, first-line therapy; 2L, second-line therapy; ORR, objective response rate; OS, overall survival; PR, partial response; PFS, progression-free survival.

Conclusions: The poor outcomes observed in this study suggest a high degree of unmet medical need for advanced melanoma in China in both the 1L and 2L settings.

1284P Real life costs associated with the management of unresectable metastatic melanoma (uMM)

D. Strens[1], M. Peeters[2], P.M.C. Specenier[3]

[1]Realidad, Grimbergen, Belgium, [2]Oncology, U.Z.A. University Hospital Antwerp, Edegem, Belgium, [3]Oncology, Antwerp University Hospital, Grimbergen, Belgium

Background: Cancer care costs are a major concern for patients and society. We aimed to assess real life costs for the medical management of uMM.

Methods: We performed a retrospective patient chart review collecting data on demographics, disease characteristics and management. A complete registry of patients diagnosed with melanoma at the Antwerp University Hospital between 2007 and 12/2017 was compiled. Eligible for this chart review were all patients with uMM with sufficient data available and who either had an observation period of > 1 year at the time of this review or who deceased before December 31, 2017. Direct costs were calculated by multiplying each item of resource use, obtained from each individual patient chart, with its unit cost (2018, €) using the Belgian public health care payer's perspective (PHCP) and patient's perspective. A Kaplan–Meier sample average (KMSA) estimator was used to weight expected costs by the probability of survival and to adjust for censored data.

Results: 89 patients fulfilled all eligibility criteria for this chart review. Ten of the patients (11%) are still alive. 9 patients (10%) received best supportive care (BSC) only. 40 patients (45%) received > 1 immunotherapy or targeted agent. Mean overall monthly cost/patient for the entire cohort was € 7,244, of which € 7,153 was covered by the public health care payer. The cost was driven by systemic treatment costs (69% of cost). Median overall survival (OS) was 8.18 months (95 % CI: 6.0-10.3). Mean monthly overall cost was € 9,269 for patients (n = 40) with potential access to anti-PD1, anti-CTLA-4, BRAFi, and MEKi; median OS in this cohort was 13.83 months (95 % CI: 8.6-19.0). Mean monthly overall cost was € 3,258 for patients (n = 33) treated with chemotherapy/BSC only. Median OS in this cohort was 3.91 months (95 % CI: 2.2-5.6). Mean monthly overall cost was € 5,398 for patients (n = 16) who had access to anti-CTLA-4 and/or BRAFi but not to MEKi and anti-PD1. Median OS in these patients was 11.0 months (95 % CI 7.5-14.6).

Conclusions: Management of uMM results in considerable costs for the PHCP, mainly driven by systemic treatment costs. Also in a real-life setting, the introduction of immunotherapy and targeted agents substantially improved survival. However, mean monthly cost has nearly tripled.

1285P Drug treatment in melanoma: A real-world analysis across Europe and Japan

A. Martinez de Pinillos, P. Nasuti, C. Anger

Real World & Analytics Solutions, IQVIA, London, UK

Background: Incidence/prevalence of melanoma in Asia are both 3% of that in Europe. However, westernization of the Asian population (increase in UV exposure and sun-seeking), is impacting these traditionally low figures. Local drug regulatory agencies have anticipated a shift in treatment from standard to novel molecular targeted and immunotherapeutic products. This study examines treatment differences in melanoma patients in EU5 and Japan, considering dissimilarities between populations.

Methods: A large sample of 4,209 drug treated melanoma cases were collected January 2017-March 2018 through a cross sectional survey in EU5 (France, Germany, Spain, Italy, UK), and Japan. Testing for genetic mutations and drug use were analysed for 3,997 advanced/metastatic (adv/met) patients.

Results: When specified, Acral Lentiginous Melanoma (ALM) and Nodular Melanoma were the most common histology in Japan (25%) during the investigated period, while being only 4% in EU5, where nodular melanoma (23%) and superficial spreading melanoma (21%) were the most frequent. Anti PD1/CTLA4 lead the adv/met melanoma setting in EU5 (58%), followed by BRAF (35%) and MEK inhibitors (19%). In Japan, although anti PD1/CTLA4 play an important role in adv/met melanoma (57%), BRAF and MEK inhibitors are uncommon (up to 2% use) and other standard drugs (Interferons, Anthracyclines, Platinum-based, other chemotherapy) which are uncommon in EU5 (4% use at most), are used in up to 21% of Japanese patients. BRAF mutations were tested in 96% in EU5 vs. 52% in Japan for adv/met patients, with 48% and 26% positive cases respectively. PD1 testing was higher in Japan (40%), also presenting a larger PD1 positive population (17%) than the European counterpart.

Conclusions: We have demonstrated penetration of novel immuno-oncology drugs both in Europe and Japan. Existing differences in melanoma treatment between both regions provide insights on Asian populations, which are not as well documented. Although these might be influenced by ethnic and genetic factors, maturity of the region should be considered and further analyses would provide an interesting observation on the trend of both regions.

1286P EUMelaReg: A European platform for outcome research on real world treatment data of patients with advanced melanoma

M. Weichenthal[1], A.C.J. van Akkooi[2], P. Mohr[3], E. Ellebaek[4], I-M. Svane[4], S. Ugurel-Becker[5], U. Leiter[6], L. Hoejberg[7], J.B.A.G. Haanen[8], H. Schmidt[9], T.H. Oellegaard[10], M.W.J.M. Wouters[2], D. Schadendorf[11], L. Bastholt[12]

[1]Dermatology, University of Kiel, Kiel, Germany, [2]Surgical Oncology, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, [3]Skin Cancer Center, Dermatologic Center Buxtehude, Buxtehude, Germany, [4]Department of Oncology, Herlev and Gentofte Hospital, Herlev, Denmark, [5]Dermatology, University Hospital Essen, Essen, Germany, [6]Dermatooncology, Department of Dermatology, University Hospital Tuebingen, Tuebingen, Germany, [7]Oncology, Odense University Hospital, Odense, Denmark, [8]Medical Oncology, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, [9]Department of Oncology, Aarhus University Hospital, Aarhus, Denmark, [10]Oncology, Aarhus University Hospital, Aarhus, Denmark, [11]Department of Dermatology, University Hospital Essen Westdeutsches Tumorzentrum, Essen, Germany, [12]Medical Oncology, Odense University Hospital, Odense, Denmark

Background: During the past ten years several fundamental breakthroughs have radically changed the treatment options in metastatic melanoma. Both targeted therapies (TT) and immunotherapies (IT) randomized clinical trials have shown significant benefit in relapse free and overall survival. Since the underlying clinical trials represent selected patient populations who had to meet several inclusion and exclusion criteria, the EuMelaReg consortium sought to evaluate "real world" melanoma cases presenting for initial treatment decision with stage IV or unresectable stage III disease.

Methods: Data sources from Denmark (Danish metastatic melanoma database), Germany (ADOReg Registry) or The Netherlands (Dutch Melanoma Treatment Registry) were merged in a stepwise procedure into a standardized data representation format. The harmonized database for the current analysis included subgroups of patients presenting in 2014 for treatment of non-resectable stage III or metastatic stage IV disease on a regular basis. Criteria used to validate the process of data harmonization contained primary demographic data as well as data concerning the advanced disease status (ECOG status, serum LDH, and baseline tumor burden including the presence of brain metastasis), and the different treatment strategies and regimens.

Results: It could be shown that more than 30 percent of the cases included would not have qualified for common inclusion and/or exclusion criteria of clinical phase III trials in advanced melanoma. Moreover, the distribution of prognostic and predicive factors varied substancially between the real-world populations and published study populations.

Conclusions: Final endpoints of the ongoing data collection and analysis will contain among other parameters progression free survival, overall survival, and tolerability of treatment. Collaboration is sought to a range of other European registries and countries.

Background: In 2016, all licensed single agent and combination BRAF-targeted therapies (BT) and checkpoint inhibitors (CI) were approved for advanced melanoma in the UK. An evaluation of treatment choices in routine clinical practice was undertaken.

Methods: A retrospective chart review was conducted in 7 UK cancer centres, which included patients ≥18 years old with advanced melanoma who started 1st-line (1L) therapy and received at least 1 dose between July 2016 and June 2017. Patients taking part in clinical trials were not eligible. Patient demographics, disease characteristics, and 1L and subsequent therapy lines were recorded. Interim analyses were descriptive.

Results: 280 patients were followed for median 9 (range: <1-19) months; 80%, 19%, and 1% patients received 1, 2, or 3 therapy lines. 92% of patients had BRAF testing, 26% had NRAS testing, and <1% of tumours were tested for PDL1. BRAF and NRAS mutation rates were 41% and 7%, respectively. 73% of patients received CIs 1L: 46% pembrolizumab (Pem), 26% nivolumab+ipilimumab (N+I), 1% ipilimumab (Ipi), <1% nivolumab (N); 27% patients received BT 1L: 20% dabrafenib+trametinib (D+T), 7% dabrafenib (D). 38% of BRAF mutant patients received 1L CI. Most common reasons for therapy selection were biomarker status (42%) and perceived benefit (27%). Two-thirds of patients discontinued 1L therapy (BT: 76%, CI: 62%), 79% within 6 months of starting. Most common reasons for stopping were adverse events for N+I (59%) and progressive disease for BT and Pem (54% each). 40% of patients who discontinued BT received 2nd-line (2L) therapy 71% N+I, 29% Pem, <1% vemurafenib. 17% of patients who discontinued Pem received 2L therapy: 57% Ipi, 21% BT (7% D+T, 14% D), 14% other, and 7% trial agents. 41% of patients who discontinued N+I received 2L therapy: 63% BT (58% D+T, 5% D), 21% Pem, 8% other, and 8% trial agents.

Conclusions: The most common 1L therapy was CI. BRAF mutation status, however, influenced treatment choice, with two-thirds of BRAF mutant melanoma patients receiving BT 1L. More than double the number of patients receiving BT and N+I 1L received 2L therapy compared with patients receiving Pem 1L. Further exploration of these data will be presented.

1288P The national melanoma research registry: A fundamental for disease characterization and epidemiology

F. Gwadry-Sridhar[1], H. McConkey[2], X. Teng[3], D.S. Ernst[4]

[1]Informatics, Pulse infoframe Inc., London, ON, Canada, [2]Research Coordinator, Global Melanoma Research Network, London, ON, Canada, [3]Data Science, Pulse Infoframe Inc., London, ON, Canada, [4]Dept of Oncology, London Regional Cancer Program, London, ON, Canada

Background: Approximately 7200 Canadians are diagnosed with primary melanoma each year resulting in 1240 deaths. While the advent of new treatment provides hope, the emergence of precision medicine requires genomic data and clinical trials benefit from real-world data. To avail of these advances, a better understanding of both disease characterization and the impact of treatment on both clinical endpoints and patient reported outcomes is necessary to assess morbidity and mortality. We initiated a Pan-Canadian Melanoma Research Network (CMRN) in 2010 to collect both clinical and patient reported data.

Methods: The CMRN collects data retrospectively and prospectively from ten cancer centers in Ontario, Alberta and Quebec. The data dictionary includes 250 disease specific variables collected to produce structured data, including stage, pathology, tumour mutation types, time from primary diagnosis to recurrence, sites of metastases, and lines of treatment. Outcomes such as metastasis free interval, quality of life and survival and performance status are collected.

Results: 3016 patients (pts) have consented to this registry. 11% pts are $<$ 50 years; 42% pts are 41-70 years; whereas 47% pts are $>$ 71 years. 58% are male and 42% are female. 67% of pts presented with Stage I or II melanoma, and 33% presented with Stage III or IV. Of pts with known primary histology, 73% were classified as superficial spreading or nodular (36.5% each). Of the 589 pts who received mutation testing, 51% were found to have a BRAF mutation. Interferon treatment accounted for 80% of adjuvant therapies, whereas $<$ 3% were checkpoint inhibitors or targeted therapies. 931 pts received metastatic systemic treatment. 14% of 1st line treatments were targeted therapies, whereas 18% were checkpoint inhibitors. 49% of metastatic patients received a 2nd line treatment, with checkpoint inhibitors and targeted therapies accounting for 65% and 10%, respectively.

Conclusions: This CMRN allows for detailed analysis of both patient and disease characteristics, providing a key tool for future research. This network is still expanding to include additional provinces and continues to conduct real-world research to advance care and improve outcomes.

Background: Significant advances were recently observed in the treatment of metastatic melanoma (MM). With 60% of patients now reaching a second line of treatment (trt) and a significant improvement in survival, the assessment of quality of life (QoL) during whole disease is necessary. The objective of this work is to describe the evolution of QoL of patients (pts) over trt lines until death.

Methods: QoL is collected through MelBase, a prospective French multicentric cohort dedicated to the follow-up of adults with MM. It is assessed using the EQ-5D (called utility, with range 0-1) and the FACT-M (score range 0-172) questionnaires, at inclusion (i.e. at MM diagnosis) and then every 3 months or at each trt change, until death. Evolution of QoL as compared to the beginning of the 1st line is described at the beginning of the 2nd line, at progression and one month before death.

Results: QoL is assessed on 1183 pts included between 2013 and 2017. Median follow-up is 12 months and 605 patients died during follow-up. At inclusion, the mean score is 0.831 [CI$_{95\%}$: 0.817; 0.843] for utility and 128.487 [CI$_{95\%}$: 127.047; 129.924] for FACT-M scores. Between baseline and 6 months of 1st trt line, QoL decreased of 0.008 [CI$_{95\%}$: -0.010; 0.030] (-0.8%) for utility score and of 1.62 [CI$_{95\%}$: -0.770; 4.010] (-0.9%) for the FACT-M scores compared to baseline, whereas it evolves of -0.003 [CI$_{95\%}$: -0.030; 0.010] (-0.3%) for utility score and of 0.256 [CI$_{95\%}$: -2.550; 3.060] (0.2%) for the FACT-M at the beginning of 2nd line. At progression, QoL evolves of -0.015 [CI$_{95\%}$: -0.03; 0.01] (-1.5%) for utility score and of -2.640 [CI$_{95\%}$: -1.420; 3.450] (1.5%) for the FACT-M. The greatest QoL deterioration was observed one month before death by -0.129 [CI$_{95\%}$: -0.170; -0.090] (-13%) for utility score and by 18.961 [CI$_{95\%}$: -22.880; -15.040] (11%) for the FACT-M score.

Conclusions: In Melbase cohort, patient's QoL with MM seems to be fairly stable through trt lines and disease progression. The QoL of pts appears to be mainly degraded during the "pre-death" period. Complementary analyses are ongoing to evaluate the impact on prognostic factors, treatments and time on the evolution of QoL.

1290P Avelumab in European patients (pts) with metastatic Merkel cell carcinoma (mMCC): Experience from an ad-hoc expanded access program (EAP)

P. Nathan[1], V. Kasturi[2], L. Dirix[3], E. Fenig[4], P.A. Ascierto[5], M. Hennessy[6], J. Reed[6], A. Engelsberg[7], S. Hariharan[8], C. Lebbé[9]

[1]Department of Medical Oncology, Mount Vernon Cancer Centre, Northwood, Middlesex, UK, [2]Medical Affairs, EMD Serono USA, Rockland, MA, USA, [3]Medical Oncology, GZA Ziekenhuizen Campus Sint-Augustinus University of Antwerp, Antwerp, Belgium, [4]Medical Oncology, University of Tel Aviv, Tel Aviv, Israel, [5]Melanoma, Cancer Immunotherapy and Development Therapeutics Unit, Istituto Nazionale Tumori – I.R.C.C.S - Fondazione Pascale, Naples, Italy, [6]Medical Oncology, EMD Serono, Billerica, MA, USA, [7]Medical Oncology, Pfizer Pharma GmbH, Berlin, Germany, [8]Medical Oncology, Pfizer, New York, NY, USA, [9]CIC and Dermatology, Saint-Louis Hospital, Paris, France

Background: Avelumab—a human anti–PD-L1 IgG1 monoclonal antibody—showed favorable efficacy and safety in pts with mMCC in the phase 2 JAVELIN Merkel 200 trial (NCT02155647), leading to its approval in multiple countries. Here, we describe real-world experience with avelumab in European pts with mMCC.

Methods: European pts participating in the EAP (NCT03089658) had stage IV mMCC and progressive disease (PD) on/after chemotherapy or were ineligible for either chemotherapy or participation in clinical trials. In contrast to JAVELIN Merkel 200, pts could have ECOG PS $\geq$ 2, treated brain metastases, or immunosuppressive conditions. Pts received a 3-mo supply of avelumab (administered 10 mg/kg IV Q2W until PD or unacceptable toxicity); resupply was allowed for pts with complete response (CR), partial response (PR), stable disease, or clinical benefit per physician assessment. No central imaging was obtained.

Results: As of April 30, 2018, of 521 requests for avelumab across 37 countries, 343 were received in Europe: 305 were approved (including 20 for immunocompromised [IC] pts), 29 were medically rejected, and 9 were withdrawn. Most requests were from France (n = 96) and Italy (n = 87). 275 European pts received avelumab. Median age was 73 y (range, 28-95 y), and 69% of pts were male. Of 250 pts on treatment $>$3 mo, 145 (58%) had either unevaluable tumors or no data reported (including 11 IC pts). Of 105 evaluable pts, physician-assessed objective responses were observed in 54.3% (57 pts; including 3 IC pts [2 CR and 1 PR]) with 25.7% CR (27 pts) and 28.6% PR (30 pts). Median duration of treatment in pts with response was 195 d (range, 30-570 d). The disease control rate in evaluable pts was 75%. No new safety signals were reported. The EAP is ongoing but closing in 2018 as required postapproval.

Conclusions: The avelumab EAP provides an alternative treatment option for pts with mMCC with PD on/after chemotherapy or who are ineligible for either chemotherapy or clinical trials. In a real-world setting, avelumab showed efficacy and safety consistent with JAVELIN Merkel 200.

1291P Cost-effectiveness (CE) of avelumab vs standard care (SC) for the treatment of patients (pts) with metastatic Merkel cell carcinoma (mMCC)

M. Bharmal[1], A. Amin[2], C. Stapelkamp[2], C. Pescott[1], A. Hatswell[3], C. Lilley[4], A. Bullement[4], A. Willis[4]

[1]Global Evidence & Value Development, Merck KGaA, Darmstadt, Germany, [2]Global Evidence & Value Development, Merck Serono Ltd, Feltham, UK, [3]Department of Statistical Science, University College London and Delta Hat Limited, London, UK, [4]Health Economics, BresMed Health Solutions, Sheffield, UK

Background: mMCC is a rare, aggressive skin cancer with limited response to chemotherapy and a poor prognosis. Avelumab, an anti–PD-L1 IgG1 monoclonal antibody, provides a new treatment option with demonstrated durable responses and promising survival outcomes in the only registrational, prospective study of mMCC, JAVELIN Merkel 200 (JM 200; NCT02155647). This analysis assesses the CE of avelumab vs SC in pts with mMCC.

Methods: A 3-state partitioned-survival model was generated to assess the lifetime costs and effects of avelumab and SC from a UK National Health Service (NHS) perspective. Survival and health-related quality-of-life data were taken from JM 200 and observational studies to inform estimates of life-years (LYs) and quality-adjusted LYs (QALYs). Published literature and NHS reference costs were sought to quantify costs within the model, with other parameters sourced from JM 200, literature, or clinical opinion. Overall costs and QALYs were used to calculate the incremental CE ratio (ICER [cost per QALY gained]). Treatment-experienced (TE) pts had a minimum follow-up of 24 months, while data were extrapolated using hazard ratios for treatment-naive (TN) pts due to data immaturity.

Results: When costs and QALYs were discounted at 3.5% per annum, avelumab was associated with ICERs of £32,612 (TE) and £36,635 (TN) per QALY gained. Probabilistic sensitivity analysis demonstrated that avelumab was associated with a 93.3% (TE) and 76.4% (TN) probability of being CE at a willingness-to-pay threshold of £50,000 per QALY gained.

Table: 1291P

Population	Incremental		ICER
	Costs	QALYs	
TE	£78,558	2.41	£32,612
TN	£77,434	2.11	£36,635

Conclusions: This CE analysis from JM 200 demonstrates that avelumab is a CE treatment option for pts with mMCC vs SC. The UK National Institute for Health and Care Excellence recommended avelumab for TE and TN pts; hence, an effective treatment is now available to all UK pts with mMCC. A confirmatory analysis will be conducted with more-mature TN data.

Background: Cemiplimab (REGN2810) demonstrated a positive risk/benefit profile and produced antitumour activity in patients (pts) with advanced CSCC in the primary analysis, by independent central review, of a phase 1 CSCC expansion cohorts (ECs). We now report longer follow-up data from the CSCC ECs of the phase 1 study (NCT02383212).

Methods: Pts with distantly metastatic or unresectable locally/regionally advanced CSCC were enrolled in ECs 7 and 8, respectively. All pts received cemiplimab 3 mg/kg every 2 weeks over 30 minutes by intravenous infusion for up to 48 weeks. Tumour measurements were performed by RECIST 1.1 every 8 weeks to determine overall response rate (ORR; complete response [CR] + partial response [PR]) according to intention to treat. The data cut-off date was 20 Jan, 2018. Tumour response in this report was by investigator assessment.

Results: A total of 26 pts were enrolled (21 M/ 5 F; 10 in EC 7, 16 in EC 8; median age: 72.5 years [range: 55–88]; ECOG performance status was 1 in 16 pts and 0 in 10 pts). Median duration of follow-up was 11.9 months (range: 1.1–18.2). Median duration of cemiplimab exposure was 36.0 weeks. The most common treatment-emergent adverse event (TEAE) of any grade was fatigue (26.9%). The only TEAEs of grade $\geq$3 that occurred in more than one pt were hypercalcaemia and skin infection (each 7.7%). ORR was 50.0% (95% CI: 29.9–70.1), with 2 CRs and 11 PRs; 5 patients had stable disease (SD), 6 had progressive disease, and 2 were not evaluable for response. Durable disease control rate (SD or response for $\geq$105 days) was 57.7% (95% CI: 36.9–76.6). Median time to response was 1.9 months (range: 1.7–7.5). The median duration of response has not been reached, and as of the data cut-off date, for pts with CR or PR, the observed duration of response exceeded 6 months in 9 pts and 12 months in 5 pts.

Conclusions: The increasing duration of response in this analysis provides further evidence of a positive risk/benefit profile for cemiplimab in pts with advanced CSCC.

Clinical trial identification: NCT02383212.

Background: Approximately 20-30% of non-melanoma skin cancers are squamous cell carcinomas of the skin (SCCS). SCCS incidence is increasing and they often occur in elderly or immunosuppressed patients (pts). SCCS can progress to stages impossible to treat by surgical excision or radiotherapy. Cisplatin-based combinations show efficacy but are too toxic for elderly pts. Cetuximab (Ce) demonstrates 69% disease control rate (DCR) at 6 weeks but in few, highly selected pts. This study aims to evaluate the efficacy of Ce in non-selected pts with SCCS.

Methods: This retrospective study included pts with relapsing unresectable or metastatic SCCS treated with Ce monotherapy (weekly loading dose 400 and 250 mg/m^2). The primary objective was DCR at 6 weeks. 60 pts (38 male) with local relapses of metastatic CSCC (100%), were treated between 30/05/2007 and 07/04/2017 in 13 centers. Median age was 83.1 yrs (min 47.4, max 96.1 yrs). Two-thirds of pts had one or two comorbidities, including 13% (n = 8) with immune disorder. 54% had local relapse. Main metastatic locations were nodes (n = 15), lung (n = 8) and skin (n = 5). 90% were chemotherapy-naïve, 57% had previous radiotherapy, and all were primarily resected. Mean time between previous treatment and Ce was 20.1 months (min 0, max 300). Mean Ce injection number was 24.8 (min 4, max 60).

Results: Complete response, partial response, stabilization (S) and progression were 7%, 48%, 32% and 13%, respectively, at 6 weeks and 2%, 42%, 29% and 27% at 3 months. 90% of pts experienced at least a disease S as best overall response. Ce was discontinued in 1 patient after first injection due to grade III infusion-related toxicity. All other grade III toxicities were cutaneous (n = 8) with 5 discontinuations. No toxic deaths were reported. Median follow-up, progression-free survival and overall survival were 11.7 months [95% CI: 9.6-30.1], 9.7 months [95% CI: 4.8-43.4] and 17.5 months [95% CI: 9.4-43.1] respectively.

Conclusions: Cetuximab is a safe and efficient treatment for patients, even very old, with SCCS. The toxicity profile of Ce compares very favorably with cisplatine-based protocols. These results indicate that Ce is a promising platform to test new combinations.

1294P Sonidegib preplanned subgroups analyses of objective response rates: Final 42-month results from the BOLT study

R. Dummer

Dermatology, University Hospital Zürich-Dermatology, Zurich, Switzerland

Background: Based on results of the phase 2 BOLT study (NCT01327053), sonidegib 200 mg once daily (QD) was approved in the US for patients with locally advanced basal cell carcinoma (laBCC) not amenable to curative surgery or radiotherapy and in Switzerland and Australia also for metastatic BCC (mBCC). Here we report the final 42-month results—the longest follow-up data available from a hedgehog inhibitor (HHI) clinical trial—for a preplanned prespecified subgroup analysis for the primary endpoint, the objective response rate (ORR), in patients receiving 200 mg.

Methods: BOLT was a double-blind phase 2 study where HHI treatment–naïve patients with laBCC not amenable to curative surgery/radiotherapy, or with metastatic BCC (mBCC) were randomized 1:2 to sonidegib 200 or 800 mg QD, respectively. The primary endpoint was ORR. Analyses were performed at 12, 30, and 42 months after the last patient was randomized.

Results: For prespecified groups at 42 months, the ORRs for 200 mg QD were consistent for laBCC aggressive (59.5%; n = 37) and laBCC nonaggressive (51.7%; n = 29) histologies; male (43.8%; n = 48) and female (54.8%; n = 31); patients aged <65 years (59.4%; n = 32) and those aged ≥65 years (40.4%; n = 47); white (49.3%; n = 71) and nonwhite patients (37.5%; n = 8); and for patients not receiving (51.8%; n = 56) and those receiving (39.1%; n = 23) gastric pH agents. Subgroup analyses by disease strata (laBCC [56.1%; n = 66] vs mBCC [7.7%; n = 13]) and Eastern Cooperative Oncology Group performance status (0 [60%; n = 50] vs ≥ 1 [29.6%; n = 27;]) for the primary ORR endpoint showed heterogeneous results like those reported at 30 months. The safety/tolerability profile was consistent across 42 months with no new AEs emerging.

Conclusions: These results confirmed the consistency of treatment effect for sonidegib 200 mg QD at 42 months across several preplanned subgroups, including age, disease histology, gender, race, and use of gastric pH agents.

Clinical trial identification: NCT01327053.

1295P Treatment of advanced basal cell carcinoma with sonidegib: Duration of response and quality of life evaluation from BOLT

M.R. Migden

Dermatology and Head and Neck Surgery, The University of Texas M. D. Anderson Cancer Center, Houston, TX, USA

Background: For patients with advanced basal cell carcinoma (BCC), including those with locally advanced BCC (laBCC) and metastatic BCC (mBCC), hedgehog pathway inhibitors (HPIs) are a treatment option. Sonidegib is an HPI approved for use in patients with advanced BCC (Switzerland and Australia) and laBCC (USA and EU), based on data from the BOLT study (NCT01327053). Here we report the duration of response (DOR) at 42 months and quality of life (QoL) results at the 12- and 30-month analyses from BOLT.

Methods: BOLT was a multicenter, randomized, double-blind, phase 2 trial that evaluated sonidegib in treatment-naïve patients with mBCC (n = 36) or laBCC (n = 194) who were not amenable to curative surgery or radiation therapy. Patients were randomized 1:2 to either 200 mg or 800 mg PO QD, and data analyses were performed at 6, 12, 18, 30, and 42 months. The primary endpoint was objective response rate (ORR) and a key secondary endpoint included DOR as assessed by central review. QoL was assessed using the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire C30 (EORTC QLQ-C30) and the associated Head and Neck Cancer Module 35 (EORTC H&N35).

Results: At the 42-month analysis, the median DOR was 26.1 months in laBCC patients treated with sonidegib 200 mg vs 23.3 months in patients treated with 800 mg. The ORR was higher in the 200 mg group vs the 800 mg group (Table). In mBCC patients, the median DOR was 24 months for sonidegib 200 mg and not estimable for the 800 mg group. The ORR was lower in the 200 mg group vs the 800 mg group (Table). During the course of treatment, the QoL for these patients was analyzed, and the majority of patients in both dosage groups had maintenance of or improvement in QoL relative to baseline.

Table: 1295P ORR in sonidegib-treated patients with advanced BCC

	laBCC		mBCC	
	200 mg n = 66	800 mg n = 128	200 mg n = 13	800 mg n = 23
ORR %	56	46	8	17
Complete Response, n (%)	3 (4.5)	2 (1.6)	0	0
Partial Response, n (%)	34 (51.5)	57 (44.5)	1 (7.7)	4 (17.4)

Conclusions: Data from the 42-months analysis demonstrated that patients receiving sonidegib had a long duration of response. Results from the 12- and 30-month analyses show maintenance and improvement in QoL consistent with that of the primary data observed in BOLT.

Clinical trial identification: NCT01327053 CLDE225A2201.

1296P Discovery of novel germline genetic biomarkers of melanoma recurrence impacting exonic and long non-coding RNA (lncRNA) transcripts

T. Kirchhoff[1], D. Simpson[2], T. Hekal[2], R. Ferguson[2], E. Kazlow[2], U. Moran[2], Y. Lee[3], A. Izsak[3], M.A. Wilson[4], R. Shapiro[4], A. Pavlick[4], I. Osman[3]

[1]Perlmutter Cancer Center, New York University, New York, NY, USA, [2]Perlmutter Cancer Center, New York University Medical Center, New York, NY, USA, [3]Dermatology, New York University Medical Center, New York, NY, USA, [4]Department of Medicine, New York University - Perlmutter Cancer Center - Langone Medical Center, New York, NY, USA

Background: One challenge in clinical management of cutaneous melanoma (CM) is the limited predictability of recurrence and hence the progression to advanced stages that associate with less favorable outcomes. Aggressive follow-up care and novel adjuvant therapy strategies in early-stage patients with high-risk of recurrence would likely improve CM-specific survival and reduce mortality. We developed a genome-wide approach to identify germline genetic determinants of melanoma prognosis as putative personalized biomarkers for patients at risk of CM recurrence.

Methods: Exploring both the coding and non-coding transcribed genome we performed germline whole genome sequencing (WGS) and tumor RNA-seq on 96 CM patients with tumor/blood matched specimens. All patients were of primary stages I-IIB and of Ashkenazi Jewish ancestry to reduce genetic heterogeneity. We compared 48 patients that recurred in < 4 years versus 48 patients with recurrence in > 6 years. Univariate and multivariate logistic regression, gene-burden analysis (SKAT), and differential expression analyses of both mRNA and lncRNAs were used to identify germline regions associated with melanoma recurrence.

Results: Several gene regions were associated with melanoma recurrence, with NEGR1 and MGST3 both passing SKAT levels of significance ($p < 1e-05$), and logistic regression analysis on common WGS variants found over 100 variants with significance $p < 1e-03$. In addition, we found 200 differentially expressed putative lncRNAs ($p < 0.05$). The analysis of germline WGS found rs199818927, a 1bp insertion previously associated with both NEGR1 and lncRNA LINC01360, among our top 5 most significant regression results ($OR = 9.107$ $p = 2.31e-05$).

Conclusions: This initial phase of our large scale whole genome scan has uncovered germline variants in several coding loci and putative lncRNAs that associate with melanoma recurrence. Most notably, we identified germline variation in a lncRNA near NEGR1, a putative tumor suppressor that has been shown to be under-expressed in advanced cancers, indicating its putative role in cancer progression to metastatic stages. We are currently expanding the patient cohorts and validating these results.

1297P Pilot study: Localizing target lymph node using a magnetic marker allows reliable and representative judgement of pathological responses after neo-adjuvant ipilimumab (IPI) + nivolumab (NIVO) in macroscopic stage III melanoma

A.C.J. van Akkooi[1], B. Schermers[2], V. Franke[1], M. Wouters[1], C.L. Zuur[3], W.M.C. Klop[3], E.A. Rozeman[4], B.A. van de Wiel[5], T.J.M. Ruers[1], C.U. Blank[6]

[1]Surgical Oncology, Netherlands Cancer Institute/Antoni van Leeuwenhoek hospital (NKI-AVL), Amsterdam, Netherlands, [2]Surgical Oncology, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, [3]Head and Neck Surgery and Oncology, Netherlands Cancer Institute/Antoni van Leeuwenhoek hospital (NKI-AVL), Amsterdam, Netherlands, [4]Medical Oncology, The Netherlands Cancer Institute, Amsterdam, Netherlands, [5]Pathology, Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital (NKI-AVL), Amsterdam, Netherlands, [6]Medical Oncology, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands

Background: The outcome of high risk stage III melanoma patients (pts) is poor, with a 5-year overall survival (OS) rate of $< 50\%$. Adjuvant (adj) high dose IPI , adj NIVO and pembrolizumab improved RFS. Neo-adjuvant (neoadj) treatment may be an even more favorable approach as immune checkpoint inhibition is of greatest value at the moment of TCR triggering and therefore dependent on the amount of antigen present. In our previous phase Ib OpACIN study the pathological RR (pRR) was 78% in the neoadj arm, and to date after 25 months of median follow-up none of the responders has relapsed. This raises the question whether such pts need to undergo complete lymph node dissection (CLND). A prerequisite for such an approach would be an analysis method that reliably indicates pathological response within the whole lymph node bed, without the need for CLND.

Methods: To address this question an in-house developed magnetic marker was placed ultrasound-guided at baseline into the largest regional lymph node metastasis of pts participating in OpACIN-neo, (NCT02977052), a phase 2 trial aiming at identification of the optimal neoadj combination scheme of IPI and NIVO in stage IIIB/C melanoma pts followed by CLND.

Results: So far, 11 pts participated in this side trial of OpACIN-neo. No complications from marker placing were observed, and all magnetic markers were retrieved during the CLND after 6 weeks of neoadj IPI+NIVO. 10/11 marked lymph-nodes (LN were representative in their response for the whole CLND specimen, i.e. index node showed a complete or partial response (PR), all others on CLND showed the same or better responses. Only 1 case was incongruent, as the index LN had 60% vital tumor (no response) compared to another LN (40% vital tumor, PR).

Conclusions: Our early exploratory data from this pilot study indicate that marked LN in stage III melanoma could serve as response indicators for the outcome of the whole CLND after neoadj IPI+NIVO. If confirmed, our data can open the path towards response-driven extent of lymph-node dissection in macroscopic stage III melanoma.

Clinical trial identification: NCT02977052.

1298P Discovery of KIRREL as a biomarker for prognostic stratification of patients with thin melanoma

S. Lundgren, H. Fagerström-Vahman, L. Ben-Dror, B. Nodin, K. Jirstrom

Department of Clinical Sciences, Oncology and Pathology, Lund University, Faculty of Medicine, Lund, Sweden

Background: There is a great unmet clinical need to identify patients with thin primary cutaneous melanomas (T1, Breslow thickness ≤ 1 mm) who have a high risk for tumor recurrence and death from melanoma. Kin of IRRE-like protein 1 (KIRREL/NEPH1) is expressed in podocytes and involved in glomerular filtration, but its expression in human cancer has not yet been reported. Screening in the Human Protein Atlas portal revealed a particularly high expression of KIRREL in melanoma, both at the mRNA and protein levels. In this study, we followed up on these findings and examined the prognostic value of KIRREL in a population-based cohort of melanoma.

Methods: Immunohistochemical analysis of KIRREL was performed on tissue microarrays with a subset of primary tumors and paired lymph node metastases from an original cohort of 268 incident cases of melanoma in the Malmö Diet and Cancer study. Kaplan Meier analysis and Cox proportional hazards modelling were used to assess the relationship between KIRREL expression and time to recurrence (TTR) and melanoma-specific survival (MSS). The prognostic value of KIRREL mRNA expression was examined in 102 melanoma cases in The Cancer Genome Atlas (TCGA).

Results: Membranous/cytoplasmic expression of KIRREL was detected in 158/185 (85.4%) primary tumours and 18/19 (94.7%) metastases, in various fractions and intensities. High expression of KIRREL was significantly associated with several unfavourable clinicopathological factors. KIRREL expression was not prognostic in tumours >1 mm thickness, but in T1 tumours ($n = 106$, median thickness 0.58, range 0.08-1.00), high expression of KIRREL was significantly associated with a reduced TTR, independent of and outperforming absolute thickness in mm and ulceration ($HR = 4.54$, 95% CI 1.01-20.45), and borderline significantly associated with MSS. High mRNA levels of KIRREL were associated with a significantly reduced overall survival in the TCGA ($p = 0.028$).

Conclusions: KIRREL is not only a novel potential diagnostic marker for melanoma, but may also be a useful prognostic biomarker for improved stratification of patients with thin melanoma. These findings may be of high clinical relevance and therefore merit further validation.

1299P BRAF V600E mutation in melanoma sustains IFN-gamma inducible PD-L1 expression by coactivating STAT1 and increasing protein translation

M.M. Wasylecka-Juszczyńska, P. Górniak, M. Szydłowski, A. Polak, P. Juszczyński

Department of Experimental Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, Poland

Background: Approximately 40-60% of melanoma patients have activating BRAF mutations. Targeting BRAF inhibits proliferation of melanoma cells and increases their immunogenicity. PD-1 immune checkpoint blockade is another breakthrough in melanoma therapy, shown to effectively restore T cell function. These observations indicate that combinatorial use of BRAF inhibitors and immunotherapy might be a rational therapeutic strategy. Herein, we studied the role of BRAF V600E in regulating the expression of PD-L1 in melanoma cells.

Methods: CD274 gene transcript abundance and PD-L1 protein level was measured with qPCR, Western-blot and FACS. Identification of signaling pathways responsible for regulation of PD-L1 expression was performed using western blot, FACS and

reporter assays. Azide-alkyne cycloaddition ("Click-it" chemistry) was used to analyze de novo protein synthesis.

Results: BRAF-mutant melanoma cell lines exhibited low basal expression of PD-L1 that was markedly induced by IFN-γ, pointing to an adaptive mechanism of PD-L1 expression. BRAF inhibitor significantly reduced IFN-γ-induced PD-L1 levels. In cell lines treated with IFN-γ, vemurafenib decreased STAT1 S727 phosphorylation and expression of PD-L1, suggesting direct regulation of STAT1 by ERK. In A375 cells with constitutively active MEK kinase, vemurafenib had no effect on STAT1 phosphorylation and CD274 transcript level. These results indicate that RAS/RAF/MEK/ERK axis is crucial for maintaining IFN-γ-induced CD274 gene transcription. In addition, vemurafenib decreased activity of proteins responsible for translation regulation (pS6, p4E-BP1), suggesting that inhibition of protein synthesis could be another mechanisms leading to PD-L1 decrease. To test this hypothesis, we measured de novo PD-L1 synthesis following BRAF inhibition, and found markedly reduced PD-L1 translation. Importantly, we also noted decreased translation of other immunoregulatory proteins, such as galectin-1.

Conclusions: BRAF mutations influence PD-L1 expression by modulating its transcription and translation. BRAF inhibition has a potential immunomodulatory effect, at least in part by decreasing IFN-γ induced PD-L1 expression.

Background: BRAF and MEK inhibitor (BRAF+MEKi) combination therapy has helped extend median life expectancy of BRAF mutant advanced melanoma patients to over 2 years. Acquired resistance limits duration of benefit and treatment-related toxicity can be a problem. Clinical reports suggest that intermittent dosing to manage side-effects does not compromise efficacy and can help patients to remain on treatment longer. In a mouse model, tumour cells resistant to the BRAF inhibitor vemurafenib appear to suffer a fitness deficit in the absence of drug, so that intermittent dosing could delay or prevent the emergence of resistant tumours. We hypothesise that intermittent dosing with BRAF+MEKi will sustain patients on treatment for longer, delay disease progression and improve quality of life (QoL). However, patient and investigator acceptance of randomisation and compliance with less treatment is uncertain.

Trial design: INTERIM is a UK national portfolio multi-centre feasibility trial developed by the NCRI Skin Cancer Clinical Studies Group. Patients with $BRAF^{V600}$ mutant stage 3 unresectable or metastatic melanoma with ECOG performance status (PS) 0-2 due to start BRAF+MEKi are randomised to receive dabrafenib (150mg bid) and trametinib (2mg od) either continuously or intermittently (dabrafenib days 1-21 and trametinib days 1 – 14) on a 28 day cycle. Concomitant immunotherapy is not allowed. Randomisation is stratified for brain metastases, PS, stage and lactate dehydrogenase level. We will recruit 150 patients (75 patients per arm) in 18 months at 20 UK sites to provide reliable information on recruitment, treatment compliance, progression-free survival and overall QoL (composite primary endpoint). Secondary endpoints include safety, health-economic evaluation, patient reported outcomes focusing on skin toxicity and patient experience. In addition we will explore ctDNA as a predictive biomarker and in tracking evolution of patients' tumours. Pharmacokinetic sampling will be performed in a subset of patients to help refine the intermittent schedule. From November 2017 until April 2018, 11 patients have been randomised at 9 sites.

Clinical trial identification: EudraCT: 2016-005228-27.

1301TiP A phase I/Ib study of concurrent intravenous (IV) and intrathecal (IT) nivolumab (Nivo) for melanoma patients (pts) with leptomeningeal disease (LMD)

I.C. Glitza, M.L. Rohlfs, M. Iqbal, J. Richard, E. Burton, S. Duncan, C. Brown, J. Anderson, P. Hwu, W-J. Hwu, M. Wong, C. Yee, S. Patel, S. Woodman, R. Amaria, A. Diab, H. Tawbi, M. Davies

Melanoma Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA

Background: Although advances in treatment with immune checkpoint inhibitors (CPI) have greatly improved the survival for pts with metastatic melanoma (MM), many still progress and ultimately die from this disease. Metastases to the Central Nervous System (CNS) are one of the most common and devastating complications of MM, occurring in up to 60% of pts and those with LMD have the worst prognosis (overall survival only weeks) and limited treatment options. Our program has demonstrated that IT administration of interleukin-2 (IL2) induces durable disease control and prolonged survival in pts with LMD, with 1, 2, 5- year survival rates of 36%, 26%, and 13% respectively. Given the favorable clinical activity and safety compared to systemic IL2 and supported by pre-clinical data, we hypothesize that IT administration of nivo is safe and will induce CNS immune responses in pts with LMD.

Trial design: This single center Phase I/Ib trial (NCT03025256) will treat MM LMD pts with concurrent IT (via Ommaya) and IV nivo. The initial dose escalation phase (up to 18pts) will determine the safety and recommended dose (primary objective) followed by an expansion cohort (12 pts) at the recommended dose to assess overall survival (secondary objective). Cycle 1 will consist of IT nivo only at a starting flat dose of 5mg. In subsequent cycles, IT nivo will be followed the next day by IV nivo 240mg Q2W. Pts will be hospitalized overnight for the IT dosing and monitored for neurotoxicity, including signs of elevated intracranial pressure. We will use the Bayesian mTPI method to determine the recommended dose. Pts must have radiographic and/or CSF cytopathologic (CSF) confirmed LMD. Prior therapy with systemic CPI and steroid use ($\leq$ 4 mg / 24 hrs of dexamethasone or equivalent) to control CNS symptoms is allowed. Exploratory objectives include the evaluation of immunological effects of this treatment on immune cells in the CSF versus peripheral blood and non-LMD tumors. This is the first in human study for LMD pts to receive CPI via IT and systemic administration concurrently. This approach has great potential to be a safe and more efficacious therapy in MM patients with LMD for which there is an urgent unmet need.

Background: Immune checkpoint inhibitors targeting the programmed death receptor1 (PD1) and cytotoxic Tlymphocyte antigen 4 (CTLA4) pathways have provided significant clinical benefit for patients with unresectable or metastatic melanoma. However, a proportion of patients may not respond or may progress with current

therapies. Lymphocyteactivation gene 3 (LAG3) is an additional immune checkpoint pathway that negatively regulates effector Tcell function and is a marker of Tcell exhaustion. Dual checkpoint inhibition of the LAG3 and PD1 pathways, by relatlimab and nivolumab, respectively, showed clinical activity in patients with previously treated metastatic or unresectable melanoma whose disease progressed during prior anti–PD(L)1 therapy, with a safety profile similar to nivolumab monotherapy (Ascierto P, et al. Presented at the ESMO 2017 Congress; September 8–12, 2017; Madrid, Spain. Oral LBA18). CA224047 will assess the clinical efficacy and safety of relatlimab in combination with nivolumab versus nivolumab alone in previously untreated metastatic or unresectable melanoma.

Trial design: This is a randomized, multicenter, doubleblind, phase 2/3 study of relatlimab in combination with nivolumab versus nivolumab alone, in previously untreated metastatic or unresectable melanoma. Approximately 700 patients aged ≥12 years, with no prior systemic anticancer therapy for histologically confirmed stage III (unresectable) or stage IV (metastatic) melanoma and biopsy tissue available for biomarker analyses, are being randomized. Patients with active brain metastases or leptomeningeal metastases, or ocular melanoma are excluded. The primary endpoint for the phase 2 component is objective response rate, and for phase 3 is progressionfree survival. Other endpoints include overall survival, duration of response, disease control rate, and safety and tolerability. This study has started to enroll patients.

Background: Less than a decade ago, the prognosis of advanced melanoma was extremely poor, with a 5-year overall survival (OS) of only 9-28%. Introduction of targeted therapies and immunotherapies have significantly improved the outcome of these patients. Ipilimumab, an anti-CTLA-4 antibody, was the first to show clinical benefit in advanced melanoma patients and 20% achieved long-term survival. The PD-1-blocking agents pembrolizumab and nivolumab further increased objective response rates (ORR) up to 40% and are now often used as first-line therapy. However, a large group of patients still does not benefit from this treatment. Adoptive cell therapy with tumor infiltrating lymphocytes (TIL) has shown promising clinical ORR of 40-70% in patients with advanced melanoma in several phase I/II trials, with durable responses in a substantial group of patients. TIL treatment consists of infusion of ex vivo expanded tumor resident T cells following non-myeloablative (NMA) chemotherapy and subsequent high-dose interleukine-2 (HD IL-2).

Trial design: In this international, multicenter, open-label phase III trial, 168 patients with irresectable stage IIIc or IV melanoma, between 18 and 75 years of age, with resectable metastatic lesion(s) of at least 2-3 cm diameter and sufficient organ function, will be randomized 1:1 to either ipilimumab or TIL treatment. Patients will be stratified for $BRAF^{V600}$ mutation status, treatment line (1^{st} or 2^{nd}) and treatment center. Patients randomized to ipilimumab (3 mg/kg i.v.) receive this once every 3 weeks, maximum of 4 doses. Patients randomized to TIL will undergo resection of a metastatic lesion for the outgrowth of TIL. Subsequently, NMA chemotherapy with cyclophosphamide (60 mg/kg/day for 2 days i.v.) and fludarabine (25 mg/m^2/day for 5 days i.v.) is administered prior to infusion of $> 5x10^9$ TIL followed by HD IL-2 (600.000 IU/kg/dose every 8 hours, maximum of 15 doses). The primary endpoint is progression free survival at 6 months. Secondary endpoints are ORR, complete response rate, OS and safety. Enrollment started in September 2014.

Clinical trial identification: NCT02278887.

[1]Laura and Isaac Perlmutter Cancer Center, NYU Langone Health, New York, NY, USA, [2]Department of Medical Oncology, Melanoma Institute Australia, The University of Sydney, Royal North Shore and Mater Hospitals, Sydney, Australia, [3]Department of Medical Oncology, Netherlands Cancer Institute, Amsterdam, Netherlands, [4]Department of Medical Oncology, Hospital Clinic of Barcelona, Barcelona, Spain, [5]Department of Dermatology, University Hospital Zürich Skin Cancer Center, Zurich, Switzerland, [6]Mount Vernon Cancer Centre, East and North NHS Trust, Northwood, UK, [7]David Geffen School of Medicine, the Jonsson Comprehensive Cancer Center, University of California, Los Angeles, CA, USA, [8]Cancer Immunotherapy and Innovative Therapies, Istituto Nazionale Tumori-IRCCS Fondazione "G. Pascale", Naples, Italy, [9]Department of Medicine, Institute Gustave Roussy, Paris, France, [10]Global Clinical Program, Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA, [11]Biostatistics, Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA, [12]Global Clinical Program, Novartis Pharma AG, Basel, Switzerland, [13]Oncology Precision Medicine, Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA, [14]Department of Dermatology, University Hospital Essen, Essen, Germany

Background: Significant advancements, including development of immune checkpoint inhibitors and targeted therapies, have transformed outcomes for patients (pts) with unresectable or metastatic melanoma. However, pts who do not respond or who progress while receiving these regimens have limited options. Spartalizumab (PDR001) is a high-affinity, humanized monoclonal antibody blocking the programmed cell death 1 (PD-1) receptor. This study is evaluating combinations of spartalizumab with novel compounds to restore antitumor T-cell activity in pts with melanoma progressing after prior PD-1 blockade therapy.

Trial design: This randomized, open-label, 2-part, multicenter, open platform, phase II study (NCT03484923; PLATforM) will evaluate safety and efficacy of spartalizumab combination treatment in pts with unresectable or metastatic melanoma progressing after prior anti–PD-1/L1 therapy and a BRAF inhibitor if the tumor harbors a BRAF V600 mutation. The primary endpoint will be objective response rate per RECIST v1.1, with duration of response and assessment of paired tumor biopsies for biomarkers of antitumor T-cell activity as part of the secondary endpoints. The first "selection" part of the study will begin with 3 combination arms: (1) spartalizumab + LAG525 (LAG-3 antibody), (2) spartalizumab + capmatinib (c-MET inhibitor), and (3) spartalizumab + canakinumab (IL-1β antagonist). For the selection part, the PLATforM study uses an adaptive design that, during the selection phase, allows dropping arms for futility, adding new arms, and selecting 1 or multiple arms for further expansion. Bayesian methodology is used with specific probability criteria for futility and efficacy assessments at each interim analysis. Pts (≈ 60-85) will be stratified by baseline lactate dehydrogenase level and randomized equally to all open arms during the selection part. In the second "expansion" part, efficacy and safety of treatment combination(s) selected during part one will be further investigated. Sample size for part two will be adaptive and based on predictive power calculations considering the results from the selection part.

1305TiP Phase I dose-escalation and expansion study of intratumoral CV8102, a RNA-based TLR- and RIG-1 agonist in patients with advanced solid tumors

P. Terheyden[1], C. Weishaupt[2], L. Heinzerling[3], U. Klinkhardt[4], J. Krauss[5], P. Mohr[6], F. Kiecker[7], J.C. Becker[8], A.) Dähling (Submitter[4], F. Döner[9], R. Heidenreich[9], B. Scheel[4], O. Schönborn-Kellenberger[10], T. Seibel[4], U. Gnad-Vogt[4]

[1]Klinik für Dermatologie, Allergologie zund Venerologie, Universitätsklinikum Schleswig-Holstein, Lübeck, Germany, [2]Haut- und Geschlechtskrankheiten, Universitätsklinikum Münster (UKM), Münster, Germany, [3]Dermatologie, Universitätsklinikum Erlangen, Erlangen, Germany, [4]Clinical Development, CureVac AG, Frankfurt am Main, Germany, [5]Onkologie, Universitätsklinikum Heidelberg (NCT), Heidelberg, Germany, [6]Dermatologie, Elbe Klinikum Buxtehude, Buxtehude, Germany, [7]Dermatologie, Charité Universitätsmedizin Berlin, Berlin, Germany, [8]Dermatologie, Universitätsklinikum Essen, Essen, Germany, [9]Research, CureVac AG, Tübingen, Germany, [10]Statistical Consulting, Cogitars GmbH, Heidelberg, Germany

Background: Local activation of innate immune signaling pathways, such as Toll-like Receptors (TLRs) or RIG-I-like Receptors (RLRs), is a promising cancer immunotherapeutic approach to overcome the tumor immunosuppressive microenvironment and to induce/restore anti-tumor immunity. CV8102 consists of a single-stranded, non-coding RNA complexed with a cationic peptide and acts as an agonist to human TLR-7, -8 and RLRs. Local administration of CV8102 was shown to induce upregulation of inflammatory cytokines, chemokines and IFN-γ related genes at the injection site followed by activation of T, NK, NKT cells and migratory dendritic cells in the draining lymph node (Heidenreich 2015; Ziegler 2017). In a syngeneic murine model, intratumoral (IT) delivery of CV8102 induced dose-dependent anti-tumor activity and synergized with systemic anti-PD1 antibody treatment.

Trial design: This phase I study is evaluating IT injection of CV8102 alone or in combination with a systemic anti-PD-1 antibody in patients with advanced solid tumors. Patients with advanced inoperable melanoma, cutaneous/head and neck squamous cell or adenoid cystic carcinoma and at least one lesion accessible for IT injection are eligible. After determination of the maximum tolerated/ recommended dose of CV8102 alone and in combination with an anti-PD1 antibody, expansion cohorts are planned in different indications. A Bayesian logistic regression model with overdose control will be used to guide the dose escalation. Patients in each cohort will receive up to 8 injections into a single tumor lesion over a 12 weeks period. The primary objective is to determine safety and tolerability, secondary/explorative objectives are to evaluate tumor response and changes in tumor tissue and blood-based biomarkers. The study has been initiated and enrollment is ongoing.

Background: IMO-2125 (tilsotolimod) is a TLR9 agonist with potent immunostimulating activity. An ongoing Phase 1/2 clinical study of intratumoral tilsotolimod + ipi (NCT02644967) shows the combination to be well-tolerated over the range of tilsotolimod doses tested, with evidence of dendritic cell activation and infiltration of tumor-specific immune cells in subject samples. Clinical responses (including durable CR > 21 months) have been seen in anti-PD-1-refractory subjects. Because no therapy has been shown to prolong survival after failure of first-line anti-PD-1 immunotherapy, this study is designed to show superiority of tilsotolimod + ipi over ipi alone.

Trial design: This is a randomized phase 3 global, multi-center, open-label comparison of ipi (3 mg/kg) +/- intratumoral tilsotolimod (8mg) in subjects with advanced cutaneous or mucosal melanoma with disease progression while on anti-PD-1 therapy. Eligible subjects are age ≥18 years with histologically confirmed Stage III or IV melanoma, ≥1 measurable lesion accessible for injection, ECOG ≤1, adequate organ function, and excluding those with previous TLR agonist treatment, prior ipi (except adjuvant), or CNS disease other than stable (≥4 wks) brain mets. Subjects will be randomized 1:1 to either ipi alone (Arm A) or tilsotolimod + ipi (Arm B) and stratified on the duration of prior antiPD-1 therapy (≥12 weeks/<12 weeks), stage (M1c/other), BRAF status and prior targeted therapy (TT) (BRAF wt/BRAF mut+ with TT/BRAF mut+ no TT). Primary endpoints comprise RECIST v1.1 ORR by independent central review and OS. Secondary endpoints include DRR, TTR, PFS, PRO, and safety. Treatment duration is 10 weeks (4 ipi doses) for subjects in Arm A and 24 weeks (9 tilsotolimod + 4 ipi doses) in Arm B. Final analysis (ORR and OS) will occur when 219 death events have occurred, estimated at 36 months after the first randomization. After 110 deaths, an interim analysis will be done for OS. Enrollment is planned as 308 subjects at around 80 centers in 10 countries. It is currently recruiting in the US and Australia with study initiation ongoing in EU and Canada.

1314P Efficacy and safety of telotristat ethyl (TE) in combination with lanreotide (LAN) in patients with a neuroendocrine tumour and carcinoid syndrome (CS) diarrhoea (CSD): Meta-analysis of phase III double-blind placebo (PBO)-controlled TELESTAR and TELECAST studies

D. Hörsch[1], R. Garcia-Carbonero[2], J.W. Valle[3], P. Perros[4], S. Welin[5], L. Keeber[6], A. Houchard[7], P. Lapuerta[8]

[1]Department of Gastroenterology/Endocrinology, ENETS Center of Excellence, Zentralklinik Bad Berka, Bad Berka, Germany, [2]Medical Oncology, University Hospital 12 de Octubre, Madrid, Spain, [3]Department of Medical Oncology, The Christie NHS Foundation Trust, Manchester, UK, [4]Department of Endocrinology, Royal Victoria Infirmary, Newcastle Upon Tyne, UK, [5]Department of Endocrine Oncology, Uppsala University Hospital, Uppsala, Sweden, [6]Rare Diseases, Ipsen Ltd, Slough, UK, [7]Clinical Statistics, Ipsen Pharma France, Boulogne-Billancourt, France, [8]Clinical Development, Lexicon Pharmaceuticals, Princeton, NJ, USA

Background: LAN 120 mg, a somatostatin analogue (SSA), is approved in the EU and recently in the USA for CS. In two phase 3 trials in CS, TE 250 mg or 500 mg three-times daily (tid) combined with SSA therapy (LAN or octreotide) demonstrated reduced bowel movement (BM) frequency and urinary 5-hydroxyindole acetic acid (u5-HIAA) levels vs. PBO. TE 250 mg is approved by the FDA and EMA for CSD inadequately controlled by SSAs. This post hoc meta-analysis used patient-level data from the two phase 3 studies to further examine the efficacy and safety of TE + LAN.

Methods: In the TELESTAR (NCT01677910) and TELECAST (NCT02063659) studies, patients using and continuing stable-dose SSAs were randomly assigned 1:1:1 to PBO, TE 250 mg or TE 500 mg tid for a 12-week double-blind (DB) period. Here, only data for patients using LAN during the run-in periods were included. Endpoints included descriptive changes from baseline in 24-hour u5-HIAA, BMs/day, flushing episodes and incidence of adverse events (AEs).

Results: Of 211 patients in the studies, 54 receiving LAN were included in the analysis (44% women, mean [SD] age 61.8 [10.5] years, mean [SD] BMI 25.7 [5.0] kg/m^2; 34 [63%] used LAN 4-weekly, 20 [37%] used LAN 3-weekly). One patient received octreotide instead of LAN during the DB period. Randomization of this cohort is shown with efficacy and safety data in the table.

Table: 1314P

	PBO tid	TE 250 mg tid	TE 500 mg tid
Number of LAN patients randomly allocated	n = 29	n = 10	n = 15
u5-HIAA (mg/24 hour)			
Patients with levels > upper limit of normal (at randomization): n (%)	15 (51.7)	6 (60.0)	9 (60.0)
Baseline: median [95% CI]	24.9 [12.2; 80.9]	57.6 [12.9; 159.8]	31.0 [19.0; 259.2]
Week-12 change from baseline: median [95% CI]	1.6 [–6.7; 5.0]	–12.4 [–86.4; 77.2]	–24.6 [–134.6; –10.0]
BMs/day: median [95% CI]			
Baseline	3.5 [2.4; 4.4]	3.1 [1.3; 5.6]	5.3 [3.6; 6.1]
Week-12 change from baseline	–0.2 [–1.1; 0.2]	–0.9 [–2.6; –0.0]	–1.29 [–3.3; –0.0]
Flushing (counts/day): median [95% CI]			
Baseline	3.5 [1.5; 5.1]	2.8 [0.5; 4.9]	2.9 [0.8; 4.3]
Week-12 change from baseline	0.00 [–1.1; 0.4]	–0.5 [–1.2; 0.7]	–0.5 [–2.0; 0.4]
Safety: n (%) patients			
Any AE	26 (90)	9 (90)	14 (93)
Treatment-related AEs	8 (28)	6 (60)	12 (80)
Serious AEs	3 (10)	1 (10)	4 (27)
Treatment-related serious AEs	1 (3)	0	0
Deaths	1 (3)	0	0

Conclusions: Changes from baseline in u5-HIAA, BMs and flushing suggest a trend towards meaningful efficacy of TE + LAN in CSD, in a population with moderately elevated baseline BM frequency. The combination TE + LAN was generally well tolerated. No power calculation was performed for this exploratory post hoc analysis; imbalanced groups and low patient numbers preclude any formal comparison with PBO. Evaluation of this TE + LAN regimen as first-line therapy in patients with CSD may be warranted.

Background: Treatment with somatostatin analogs (SSA) in monotherapy is the most attractive first-line option for most patients with well-differentiated stage IV unresectable gastroenteropancreatic neuroendocrine tumors (GEP-NETs). The objective is to develop and internally validate tool for predicting progression-free survival (PFS) during treatment with SSA.

Methods: The GETNE-TRASGU study is a subanalysis of the Spanish Group of NETs registry (R-GETNE). The cohort contains 309 patients treated between 2000-2017 with SSA in the first-line of advanced disease. PFS data were evaluated using Cox proportional risk regression and graphically represented as a nomogram. Missing data were controlled by multiple imputation. Bootstrap Harrell's c-index with 150 replications was used to assess discrimination.

Results: The median PFS was 25.5 months (95% CI, 20.8-30.8). The nomogram contains 5 covariates significantly associated with PFS: Ki67% index, neutrophil-lymphocyte ratio (NLR), extrahepatic metastases, liver tumor burden and primary tumor location. The median PFS was 3.7 (95% CI, 2.5-not computable) in poor prognosis group, 8.3 (95% CI, 6.0-30.0) in intermediate-bad, 18.4 (95% CI, 14.3-23.6) in intermediate-good, and 37.1 months (95% CI, 30.8-53.5) in good prognosis group. Ki67% (continuous variable) predicted PFS with HR 1.03 (95% CI, 1.01-1.06), RNL (continuous variable) with HR 1.08 (95%CI, 1.01-1.16), extrahepatic metastases with HR 1.70 (I95% CI 1.23-2.32), liver tumor burden >50% with HR 2.07 (95% CI, 1.28-3.34); compared with intestinal (reference), pancreatic with HR 2.18 (95%CI, 1.56-3.04), rectal with HR 1.99 (95% CI, 1.11-3.58), unknown origin with HR 1.71 (95% CI, 1.02-2.85), and other tumors with HR 2.58 (95% CI, 1.22-5.43). This model shows adequate calibration, with acceptable discrimination capability [c-index of 0.641 (95% CI, 0.60-0.68)].

Conclusions: The GETNE-TRASGU nomogram allows stratification of patients with advanced and well-differentiated GEP-NETs into four prognostic groups, with potential implications for treatment selection.

Background: The aim of this study was to assess Progression Free Survival (PFS), Safety and Quality of Life (QoL) in subgroups of varying hepatic burden in the NETTER-1 study population.

Methods: Patients (pts) were randomized to receive either ^{177}Lu-DOTATATE (Lu)(n = 117) or high-dose octreotide (Oct) (n = 114). The liver tumor burden (LTB) was defined as tumor volume/total liver volume by CT, and categorized as low (<25%), moderate (25-50%), and high (>50%). PFS, QoL and hepatotoxicity were assessed based on baseline LTB. QoL was analysed using EQRTC QLQC 30 and G.I. NET 21 questionnaires completed at baseline and every 12 weeks thereafter for low and moderate/high LTB subgroups. Deterioriation was defined if the score decreased by $\geq$ 10 points at any time point after baseline. Time to deterioration (TTD) was defined as the time from randomization to the first QoL deterioration.

Results: Median PFS (months) in Lu vs Oct was 28.35 vs 11.04 in low (HR = 0.218, 95% CI 0.120 to 0.394); Not Reached (NR) vs 8.67 in moderate (HR = 0.202, 95% CI 0.077 to 0.525); 19.38 vs 5.52 in high LTB (HR = 0.193, 95% CI 0.079 to 0.474), respectively. Median TTD (months) for Global Health Status was 28.81 vs 6.11 in low (HR = 0.376, 95% CI 0.196 to 0.720); NR vs 5.98 in moderate/high LTB (HR = 0.453, 95% CI 0.178 to 1.152). In Lu arm, Grade 3/4 (CTCAE v 4.03) AST and ALT toxicities occurred in the low LTB in 2 and 3 patients, and in the high LTB group in 3 and 1 patients, respectively. Grade 3/4 hyperbilirubinemia occurred in one patient from the low LTB and one from the moderate LTB group. All liver function tests abnormalities were resolved without sequela. There were no high grade ALT, AST and Biliriubin toxicities in Oct arm.

Conclusions: ^{177}Lu-DOTATATE treatment demonstrated significant PFS improvement regardless of the extent of baseline liver tumor burden in patients with well-differentiated, metastatic midgut NET. Clinically significant liver function test abnormalities were rare, were not associated with high liver tumor burden, and resolved without sequela. The analysis shows that ^{177}Lu-DOTATATE treatment also provides quality of life benefit regardless of baseline liver tumor burden.

Clinical trial identification: NCT01578239.

1317P Treatment outcomes for well differentiated grade 3 neuroendocrine tumors (NET G3)

L. Apostolidis, D. Jäger, E.C. Winkler

Department of Medical Oncology, National Center for Tumor Diseases, University Hospital Heidelberg, Heidelberg, Germany

Background: In the most current WHO classification for tumors of the endocrine organs, well differentiated grade 3 neuroendocrine tumors (NET G3) have been distinguished from poorly differentiated grade 3 neuroendocrine carcinomas (NEC G3).

Retrospective data suggest that commonly applied first-line chemotherapy protocols with cisplatin or carboplatin in combination with etoposide (PE) are less effective in NET G3 than NEC G3. Therefore current treatment guidelines suggest alternative first-line treatment with protocols like temozolomide-based (TEM) which have only been evaluated in second-line so far. The aim of this study was to evaluate treatment outcomes for NET G3 with a focus on efficacy of different first-line regimens.

Methods: Retrospective analysis of all patients with NET G3 in the NEN database of our center. All histopathological findings were reviewed by the investigators in order to comply with the most current WHO classification.

Results: A total of 89 patients could be identified. Primary tumors were mainly located in the pancreas. Median overall survival (OS) was not reach during a median follow-up of 18.4 months. 79 patients received palliative first-line therapy: PE 34, FOLFOX 17, TEM 12, other (including streptozotocin-based regimens, targeted agents, peptide receptor radionuclide therapy, somatostatin analogues) 16. Overall response (ORR) and disease control rate (DCR) was 38.2 % and 70.6 % for PE, 64.7 % and 82.4 % for FOLFOX, 12 % and 58.3 % for TEM, 25 % and 62.5 % for other respectively. Median progression-free survial for PE was 6.7 months. Compared to PE, the other treatment groups showed a trend towards a prolonged PFS (FOLFOX 8.6 months, $p = 0.151$; TEM 10.8 months; $p = 0.333$, other 12.0 months, $p = 0.085$). All non-PE patients combined showed a significantly prolonged PFS vs. PE (10.8 months; $p = 0.039$).

Conclusions: In this first comparative analysis of first-line treatments for NET G3, patients treated with non-PE regimens show a significantly prolonged PFS. Regarding ORR, FOLFOX seems to be the most active therapeutic regimen. Further prospective evaluation of the optimal therapeutic strategy for this newly defined tumor entity is needed.

Clinical trial identification: The trial was approved by the institutional research ethics committee (approval S-428/2014).

Legal entity responsible for the study: National Center for Tumor Diseases (NCT) Heidelberg.

Funding: Has not received any funding.

1318P Carboplatin (CB) combined with oral or intravenous (IV) etoposide (ET) for advanced extra-pulmonary (EP) poorly differentiated (PD) neuroendocrine carcinoma (NEC): Real-world findings from two European neuroendocrine tumour society centres of excellence

M. Frizziero[1], F. Spada[2], A. Lamarca[3], Z. Kordatou[3], J. Barriuso[4], C. Nuttall[3], M.G. McNamara[4], R. Hubner[3], W. Mansoor[3], P. Manoharan[5], N. Fazio[2], J.W. Valle[4]

[1]Medical Oncology, The Christie NHS Foundation Trust, Manchester, UK, [2]Gastrointestinal and Neuroendocrine Tumors Unit, Medical Oncology, Istituto Europeo di Oncologia, Milan, Italy, [3]Medical Oncology, The Christie NHS Foundation Trust, Manchester, UK, [4]Medical Oncology/Division of Cancer Sciences, The Christie NHS Foundation Trust/Univeristy of Manchester, Manchester, UK, [5]Radiology and Nuclear Medicine, The Christie NHS Foundation Trust, Manchester, UK

Background: Carboplatin-Etoposide is a 1st-line (1L) option for patients (pts) with advanced EP-PD-NEC. Schedules with oral or IV ET are used in clinical practice. Data from randomised trials are lacking.

Methods: Records of pts diagnosed with advanced EP-PD-NEC and treated with CB/oral-ET and CB/IV-ET were reviewed retrospectively (09/96-02/17). First-line survival/activity/toxicity data are reported.

Results: One-hundred-thirteen pts were identified: median (med) follow-up was 11.5 months (m); med age was 65.8 years (range 24-88); male=64%; ECOG performance status 0-1=81%; no/mild comorbidities=81%; gastro-entero-pancreatic origin=54%; stage IV = 90% (53% liver metastases). Median Ki-67=70% (95%CI 60-80%), Ki-67>55%=59%. A total of 123 courses of CB-ET were administered: 106 (86%) 1L, 16 (13%) 2nd-line (2L) and 1 (1%) 3rd-line; med cycles/line=4; oral-ET 45%, IV-ET 55%. Median CB-ET dose-intensity (available for 82 courses): 96% (1L), 90% (2L). Median 1L-progression free survival (PFS) was 5.9m (95%CI 5.0-7.1): oral-ET 5.6m, IV-ET 6.2m, hazard ratio (HR)=0.76 (95%CI 0.51-1.14). Median 1L-overall survival (OS) was 11.5m (95%CI 8.9-13.6): oral-ET 8.9m, IV-ET 12.1m, HR = 0.68 (95%CI 0.45-1.03), $p = 0.07$. Radiological response (assessed for 95 pts), 1L-disease control rate was 75.8% (95%CI 67.1-84.6): oral-ET 69.8% (95%CI 55.5-84.1), IV-ET 80.8% (95%CI 69.7-91.8). Liver metastases were the only independent factor related to worse 1L-PFS on multivariable analysis, HR = 1.71 (95%CI 1.11-2.63). Commonest 1L-grade 3-4 adverse event (AE) was myelosuppression (47.2%); no significant differences between oral-ET and IV-ET AEs, except for venous thromboembolism; oral-ET 12.5%, IV-ET 1.7% ($p = 0.04$).

Conclusions: This is one of the largest series of pts with advanced EP-PD-NEC treated with CB-ET in the current literature. Oral-ET and IV-ET schedules are associated with comparable 1L-PFS/activity/toxicity data. There is a trend towards better 1L-OS for IV-ET schedules; this, however, may be driven by differences in patient selection between the two subgroups.

1319P Post-hoc analysis of CLARINET phase III study to investigate the influence of diabetic status on progression-free survival (PFS) of patients with neuroendocrine tumours (NETs) treated with lanreotide (LAN) or placebo (PBO)

S. Pusceddu[1], C. Vernieri[1], M. Di Maio[2], N. Prinzi[3], M. Torchio[1], R. Buzzoni[1], X-M. Truong-Thanh[4], V. Mazzaferro[5], F.G.M. de Braud[6]

[1]Medical Oncology, ENETS Center of Excellence, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [2]Division of Medical Oncology, "Ordine Mauriziano" Hospital, Turin, Italy, [3]Medical Oncology ENETS Center of Excellence, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [4]Global Medical Affairs, Ipsen Pharma France, Boulogne-Billancourt, France, [5]Gastrointestinal Surgery and Liver Transplantation Department, ENETS Center of Excellence, University of Milan, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [6]Medical Oncology, ENETS Center of Excellence, University of Milan, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy

Background: Diabetes mellitus (DM) is a risk factor for pancreatic NETs, but its prognostic role in stage IV NETs is less defined. We evaluated the impact of diabetes on PFS in patients with advanced, non-functioning GEP-NETs.

Methods: Post hoc analysis of data from the phase III double-blind, placebo-controlled CLARINET study (NCT00353496) to investigate association between DM (any of: medical history of type 1 or 2; use of antihyperglycemic medication; HbA1c ≥6.5%, fasting plasma glucose ≥7mmol/L; non-fasting plasma glucose ≥11.11mmol/L [at baseline or during study]) and PFS (Kaplan-Meier). Multivariate Cox analysis including treatment (LAN vs PBO), DM at baseline, previous therapy and progression at baseline was used to test interaction between DM and LAN efficacy.

Results: The overall population (total, n = 204; LAN, n = 101; PBO, n = 103) had well-differentiated (Ki-67 <10%) foregut (45%), midgut (36%), or hindgut (7%) and unknown (13%) NET. 79 patients had DM, 125 did not (N-DM); 24 received metformin in combination with LAN (n = 14) or PBO (n = 10). Median PFS (mPFS) was 96.0 months (mo) [95% CI: 70.4; not reached (NR)] for DM vs 98.0 mo [72.1;NR] for N-DM (HR 1.20 [0.79;1.82], $p = 0.38$). For DM, mPFS with LAN (n = 42) was NR [95.9;NR] vs 60.0 mo [48.0;74.4] with PBO (n = 37) (HR 0.27, [0.13-0.57], $p = 0.0002$). For N-DM, mPFS with LAN (n = 59) was NR [96.0;NR] vs 72.1 mo [52.0;NA] with PBO (n = 66) (HR 0.64 [0.35-1.15], $p = 0.04$). In multivariate analysis, DM at baseline was not significantly associated with PFS (HR 1.64 [0.95;2.84], $p = 0.08$). Significant impact of LAN on PFS was confirmed (HR 0.53 [0.31;0.89], $p = 0.02$), without significant interaction between LAN efficacy and DM ($p = 0.62$).

Conclusions: DM did not emerge as a negative prognostic factor in advanced stage IV NETs. Efficacy of LAN in DM and N-DM was confirmed. Although LAN–DM interaction was not significant, LAN efficacy seemed particularly favorable in DM compared to N-DM patients, in terms of HR. These findings, along with a potential favorable association with hypoglycemic drugs such as metformin, should be evaluated and validated in prospective biomarker studies.

Clinical trial identification: Post hoc analisys of phase III double-blind, placebo-controlled CLARINET study (NCT00353496).

1320P The prognostic role of morphology and Ki67 in grade 3 gastroenteropancreatic (GEP) neuroendocrine neoplasms (NEN)

A.R. Hayes[1], M. Furnace[1], C. Rundell[2], R. Shah[2], G. Muller[2], C. Thirlwell[1], T.V. Luong[1], C. Toumpanakis[1], M. Caplin[1], D. Mandair[1]

[1]Neuroendocrine Tumour Unit, Royal Free Hospital, London, UK, [2]School of Medicine, University College of London, London, UK

Background: GEP NEN are classified according to morphology and proliferation index. According to the WHO 2010 classification, grade 3 (G3) GEP NEN are defined as having a Ki67 >20%. However, G3 well-differentiated NETs (WD-NETs) and poorly-differentiated neuroendocrine carcinomas (PD-NECs) may overlap in their proliferation index leading to prognostic and therapeutic uncertainties. Recently, WHO 2017, defined a new subgroup of G3 pancreatic NETs (PNET); G3a for WD-NETs and G3b for PD-NECs.

Methods: We retrospectively identified patients with G3 GEP NEN and divided them into WD-NETs and PD-NECs according to histological reports. The relationship between baseline characteristics and OS was analysed using the Kaplan Meier logrank

test. Univariate and multivariate analyses were performed using the Cox proportional hazards model. Optimal Ki67 cut-points were explored using R version 2.15.0.

Results: 145 patients with G3 GEP NENs had median follow-up 17 mo (59% male, 50% PD-NEC, 37% PNEN). There was a trend in improved survival in the WD-NET cohort (median Ki67 30%) compared to PD-NECs (median Ki67 60%); 29 vs 22 months ($p = 0.1$) more marked in the non-PNET cohort (median OS WD-NET 44 mo vs PD-NEC 20 mo; $p = 0.1$). Of the entire cohort, an independent effect of Ki67 was demonstrated on risk of mortality ($p = 0.02$). A Ki67 cutoff of 50% was found to have the highest logrank statistic. Ki67 $\geq$50% was associated with poorer OS compared to lower Ki67 index (median OS 38 mo vs 20 mo; $p = 0.005$). Somatostatin receptor imaging (SRI) was positive in 81% of WD-NETs compared to 45% of PD-NECs.

Conclusions: Our findings suggest that morphology and proliferative index are important factors in the prognostic evaluation of G3 GEP NEN of pancreatic and non-pancreatic origin. Ki67 remains the most reliable prognostic factor and further work is required to refine optimal Ki67 cutoffs in the G3 GEP NEN cohort to guide prognosis and treatment.

1321P Surgical resection of primary tumor is prolonged survival in metastatic pancreatic neuroendocrine carcinoma

T. Feng

Abdominal Medical Oncology, Zhejiang Cancer Hospital, Hangzhou, China

Background: Most of pancreatic neuroendocrine carcinoma (PanNEC) present with distant metastases. Removal of the primary tumor is not recommended for metastatic PanNEC patients considering the limited survival benefit compared to well differentiated grade patients. However, published data to support these recommendations regarding PanNEC are scarce. The aim of this study was to assess whether resection of the primary tumor in patients with stage IV PanNEC has an impact on survival.

Methods: Patients with stage IV PanNEC registered in the Surveillance, Epidemiology, and End Results database between 1973 and 2014 were identified. The specific criteria are as follows:1 The histologic subtypes and their ICD-O-3: large cell neuroendocrine carcinoma(8013), small cell carcinoma(8041) and neuroendocrine carcinoma (8246); 2 histologic differentiation grade: poorly differentiated and undifferentiated; 3 Diagnostic confirmation is "Positive histology"; 4 the age $\geq$ 18 years and $\leq$ 85 years; 5 "SEER historic stage" variable is"distant"or AJCC stage IV;6.Survival months flag is "Complete dates are available and there are more than 0 days of survival". Overall (OS) and cancer-specific survival (CSS) of patients who did and did not undergo resection of their primary tumor were compared by means of risk-adjusted Cox proportional hazard regression analysis and propensity score matched analysis.

Results: We identified 461 patients with metastatic PanNEC and survival data. 15.8% (73/461) of patients had surgical removal of their primary tumor. Median survival of patients undergoing primary tumor resection was 28 (95% CI: 4.751-51.249) versus 6 (95% CI: 4.672-7.328) months for those without resection ($p < 0.0001$). Patients underwent primary tumor resection showed a significant benefit in both OS (HR of death=0.296, 95%CI 0.206–0.424, $p < 0.001$) and CSS (HR of death=0.329, 95 % CI 0.219–0.493, $p < 0.001$) in unadjusted multivariate Cox regression analysis; the benefit persisted after propensity score adjustment.

Conclusions: The recent recommendations judging resection of the primary as inadvisable and the accompanying trend towards fewer palliative resections of the primary tumor in IV stage PanNEC have to be contested.

Lee Moffitt Cancer Center University of South Florida, Tampa, FL, USA, [17]Odette Cancer Center, Sunnybrook Health Sciences Centre, Toronto, ON, Canada, [18]Oncology, University of Alabama-Birmingham Medical Centre, Birmingham, AL, USA

Background: Despite LNETs increasing in incidence and prevalence, little data exists about natural history and response to various therapies. Management is often based on expert opinion and extrapolation from other NETS. CommNETS and NANETS undertook a rigorous consensus process to endorse and update the 2015 ENETS guidelines (1).

Methods: An endorsement approach based on the AGREE II processes (2) was undertaken by a 4 nation, 22 member CommNETS/NANETS panel, including experts from: surgery, pulmonology, medical and radiation oncology, nuclear medicine, pathology, pharmacy and patients/advocates. Two members assessed content and quality of the 52 ENETS statements using the Rigour of Development subscale. A systematic literature and abstract search since 2013 was conducted. Topic experts reviewed relevant ENETS statements and new data, using a patient-centered care perspective and a LNET-specific focus, to provide justification for endorsement or modification and to define a single important unanswered question. Statements were subsequently discussed by the entire panel at a face-to-face meeting and graded using Oxford criteria (3).

Results: 230 relevant new studies were identified. Of the 20 ENETS statements relating to management strategies, 4 were endorsed, 16 modified and 3 added (see table). A set of important unanswered questions will inform future studies.

Table: 1322P

Therapy	Main change
Surgery	updated techniques for localized disease modified followup protocol expanded indication for liver cytoreduction
Adjuvant	not recommended
Locoregional	optional for slow growing disease
Hormone	prophylaxis of carcinoid crisis added
PRRT	broadened to all SSTR-expressing tumours
Chemotherapy	newer data on temozolomide-based regimens included
Targeted	evidence for everolimus upgraded new statement, not supporting use of anti-angiogenics
Radiotherapy	palliative use for local symptoms added

Conclusions: Through the consensus process, guidelines for LNETS were updated to include recent evidence and practice changes. The guidelines provide clear, evidenced based statements to harmonise treatment of LNETS internationally. 1323P Diffuse idiopathic pulmonary neuroendocrine cell hyperplasia (DIPNECH) in patients with pulmonary carcinoid tumours: Prevalence and prognosis of an under-recognised disease

A.R. Hayes[1], J. Banks[2], H. Shah[2], T.V. Luong[1], S. Navalkissoor[1], A. Grossman[1], D. Mandair[1], C. Toumpanakis[1], M. Caplin[1]

[1]Neuroendocrine Tumour Unit, Royal Free Hospital, London, UK, [2]Medical School, University College of London, London, UK

Background: DIPNECH is considered a rare condition and the natural history is poorly described. Its prevalence is likely underestimated given the absence of routine reporting on histopathology and often insufficient background lung parenchyma in the setting of lung biopsy. It is thought to give rise to pulmonary carcinoids (PCs) (>5 mm) or tumourlets (≤5 mm). We aimed to assess the prevalence and characteristics of DIPNECH in the PC population and to investigate predictors of progression-free (PFS) and overall survival (OS).

Methods: We identified patients with PCs plus histologically-proven DIPNECH and/or high suspicion of DIPNECH on imaging. The relationship between baseline characteristics and PFS and OS was analysed using the Kaplan-Meier method and curves were compared using the logrank test.

Results: 46/233 (20%) patients with well-differentiated PCs and DIPNECH were identified (91% female, 52% never smokers, 50% cough and/or dyspnoea at time of diagnosis, 76% typical carcinoids (TC), 24% atypical carcinoids (AC), 9% both TC and AC) had median follow-up 37 mo (range 2-138 mo). Multicentric carcinoids were demonstrated in 11 (24%) patients on histopathology and a further 26 (57%) patients had synchronous carcinoids suggested on enhanced CT (multiple nodules >5 mm). Median PFS was 10.4 years. Six (13%) patients developed regional or distant metastases after a median of 25 months (8-125 mo) and most patients had higher proliferative indices on biopsy of metastases compared to histopathology at diagnosis. Atypical carcinoid morphology (PFS p-value 0.0006, OS p-value 0.03) and carcinoid TNM stage (PFS p-value $p < 0.0001$, OS p-value 0.006) was associated with shorter PFS and poorer OS. Of the entire cohort, ten year survival rate was 87%. Median OS was not reached.

Conclusions: DIPNECH may be more prevalent in the PC population than previously appreciated, especially in women. Whilst our results confirm DIPNECH is predominantly an indolent disease associated with TCs, up to one quarter of patients may develop ACs and these patients may warrant closer observation. Median PFS is long and lifelong follow-up is recommended.

1324P The role of modulation of somatostatin analogues (SSAs) in association to peptide receptor radionuclide therapy (PRRT) after SSAs progression disease (PD) in advanced well-differentiated (WD) entero-pancreatic neuroendocrine tumours (EP-NETs)

N. Prinzi[1], E. Seregni[2], A. Raimondi[1], M. Maccauro[2], F. Corti[1], G. Lo Russo[1], F. Nichetti[1], M. Torchio[1], J. Coppa[3], G. Peverelli[1], F. Pagani[1], M. Di Bartolomeo[1], V. Mazzaferro[3], F. de Braud[1], S. Pusceddu[1]

[1]Medical Oncology Department, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [2]Nuclear Medicine Department, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [3]Gastrointestinal Surgery and Liver Transplantation Department, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy

Background: The NETTER-1 trial has recently shown the efficacy of ^{177}Lu-DOTATATE in association with Octreotide (OCT) in somatostatin receptor positive midgut NETs, progressing to OCT. The aim of this analysis was to evaluate the role of SSA in association to PRRT beyond PD or after switch to other SSA at PD.

Methods: Out of 107 WD EP-NETs, treated with PRRT (^{90}Y-DOTATOC/DOTATATE and/or ^{177}Lu-DOTATOC/DOTATATE) at the Istituto Nazionale Tumori of Milan, from 2008 to 2017, 69 patients (pts) treated with the combination of PRRT and SSA (OCT or Lanreotide, LAN) after SSA treatment failure, were evaluated for present analysis. We identified 2 groups: S1, pts who kept the same SSA treatment beyond first PD; S2, pts who switched the SSA with another SSA after first PD. Median Progression Free Survival (mPFS) (from the start of first SSA) and Overall Survival (OS) have been evaluated using the Kaplan-Maier method.

Results: In S1 ($n = 47$) and S2 ($n = 22$) groups median age and sex were 58 ys (range 29-78) and 59.5% males vs 52.5 ys (range 35-78) and 45.4% males, respectively. We had a P-NETs percentage of 34% vs 40.9% in the S1 vs S2 groups, respectively. The most of pts (82.9% in S1 and 86.3% in S2) received PRRT with alternate radionuclides (^{90}Y/^{177}Lu). Overall the median number of PRRT cycles was 4.2 in S1 and 4.8 in S2 ($p = 0.09$). In the S1 (SSA beyond PD) group PRRT was associated with OCT in 74.5% and LAN in 25.5% of pts. In the S2 group (SSA switched with other SSA) PRRT was associated with OCT in 27.3% and LAN in 72.7% of pts. In the overall population the mPFS and OS were 70 (CI95% 52.8-87.1) and 82 (CI95% 66.7-97.2) months (mo), respectively. The difference on mPFS was 53 and 127 mo in S1 and S2, respectively ($p = 0.001$; HR: 0.31; CI95% 0.15-0.63). In S1 group the OS was 69 mo vs 150 mo in S2 ($p = 0.004$; HR: 0.32; CI95% 0.14-0.71).

Conclusions: Despite the retrospective nature of the analysis and the low number of pts, we found a significant difference on mPFS and OS between S1 and S2 groups. In pts with advanced WD EP-NETs treated with PRRT plus SSA after SSA failure, the "switch" strategy of SSA after PD, might improve PFS and/or OS.

1325P Prognostic importance of lymph node (LN) yield after curative resection of gastroenteropancreatic neuroendocrinetumours (GEP NETs)

J. Chiramel[1], R. Almond[2], A.E. Slagter[3], A. Khan[1], K.H.J. Lim[1], B. Chakrabarty[4], A. Minicozzi[5], A. Lamarca[6], W. Mansoor[1], R. Hubner[1], J.W. Valle[6], M.G. McNamara[1]

[1]Medial Oncology, The Christie NHS Foundation Trust, Manchester, UK, [2]Analytics and Development, The Christie NHS Foundation Trust, Manchester, UK, [3]Radiation Oncology, NKI-AVL, Amsterdam, Netherlands, [4]Pathology, The Christie NHS Foundation Trust, Manchester, UK, [5]Surgery, The Christie Hospital NHS Foundation Trust, Manchester, UK, [6]Medical Oncology, The Christie NHS Foundation Trust, Manchester, UK

Background: Surgery is the main stay of treatment for GEP NETs, but there is no consensus on optimal number of resected LNs. The effect of LN status and yield on relapse-free (RFS) and overall survival (OS) in patients (pts) with resected GEP NETs were evaluated.

Methods: Data on pts who underwent curative resection for GEP-NETs (Jan 02-Mar 17) were retrospectively analysed. Grade III tumours (Ki67>20%) were excluded. Kaplan-Meier and univariate/multivariable Cox-proportional hazard analyses were performed. Cut-point analysis was assessed to distinguish a binary categorisation of total LNs retrieved associated with RFS.

Results: Of 217 pts, median (med) age was 59 yrs: 51% male. Primary tumour sites: small bowel (42%), pancreas (25%), appendix (18%), rectum (7%), colon (3%), gastric (2%), others (2%); grade 1 (G1): 77%, G2: 23%. LN cut-point value associated with RFS was 8; ≥8 LNs were retrieved in 106 pts, <8 in 45, and 0 or no record/documentation of LN retrieval in 66. Relapse was reported in 50 pts; 35 deaths. Med follow up times for all pts were 41 months (95% CI 36-51) and 71 months (95% CI 63–76) for RFS and OS respectively. On univariate analysis, there was no effect of LN ratio (number involved/number retrieved) on RFS: $p = 0.1$ or OS: $p = 0.75$. On univariate analysis, tumour necrosis ($p = 0.021$) and perineural infiltration ($p = 0.016$) were the only two variables significantly associated with OS; G ($p = 1$), TNM staging ($p = 0.19$) and surgical margin ($p = 0.69$) were not significantly associated with OS. Multivariable analysis for RFS included 4 variables of interest: perineural infiltration, LNs retrieved, positive LNs and localisation (Table).

Table: 1325P

Variable	Hazard Ratio	(95% CI)	p
Perineural infiltration	1.46	(0.74 - 2.69)	0.277
≥8 lymph nodes retrieved	2.70	(1.07 - 6.84)	0.036
Any lymph nodes positive	2.71	(0.88 - 8.30)	0.081
Pancreas (relative to 'other')	27.33	(2.54 - 294.08)	0.006
Small Bowel (relative to 'other')	32.44	(2.92 - 360.58)	0.005

Conclusions: Removal of ≥ 8 LNs is associated with greater risk of relapse in G1 & G2 GEP NETs; localisation also has a significant association with RFS, necessitating stricter surveillance. Larger prospective studies are required to validate these findings.

[1]Hematology Oncology Unit, Fourth Department of Internal Medicine, Athens Greece, Attikon University Hospital, Athens, Greece, [2]Oncology Unit, Henry Dynan General Hospital, Athens, Greece, [3]Data Office, Hellenic Cooperative Oncology Group (HeCOG), Athens, Greece, [4]Oncology Clinic, Papageorgiou Hospital Aristotle University of Thessaloniki, Thessaloniki, Greece, [5]1st Department of Propaedeutic Internal Medicine, National and Kapodistrian University of Athens, Athens, Greece, [6]Radiology, Vioiatriki, Athens, Greece, [7]Oncology Clinic, General Oncological Hospital of Kifisia "Agioi Anargyroi", Kifisia, Attica, Greece, [8]Oncology Clinic, University Hospital of Ioannina, Ioannina, Greece

Background: The purpose of this study was to explore the efficacy and safety of everolimus administered as first-line treatment in newly diagnosed patients (pts) with metastatic or inoperable gastroenteropancreatic neuroendocrine tumors (GEPNETs).

Methods: This phase II, multicenter, single-arm clinical trial, included pts with advanced GEPNET of well or moderate differentiation and a Ki67<20%. Everolimus 10mg/day was administered until disease progression. All pts' tumors were non-functioning; 18 pts (72%) received concomitantly octreotide long-acting release (LAR) 30mg/month. Endpoints of the study included progression-free survival (PFS), objective response to treatment (RECIST 1.1) and safety.

Results: After a median follow-up of 53 months, twenty-five pts (G1:11 pts, G2:14 pts; Ki67≤2%:11 pts, Ki67=3-19%:14 pts; pancreas:10 pts, GI:15 pts) received a median of 5 treatment cycles per patient. Centrally assessed radiographic responses in 23 evaluable patients included 43% PR, 48% SD and 9% PD. Of the 18 pts receiving octreotide LAR and everolimus, 9 patients had SD and 9 PR. The median PFS was 14.6 months, while the 15-months PFS rate was 48%. No fatal reaction occurred. Twenty-three grade 3-4 events were recorded (14 pts; 56%). Among them, 19 events were assessed as related to treatment and included stomatitis (G3: 3 pts; 12%), diarrhea (G3: 2 pts; 8%), CPK increase (2 pts; 8%), GGT increase (2 pts; 8%), hypokalemia/hypomagnesemia (1 pt; 4%), neutropenia (G3:1 pt; 4%), anemia (G3: 1 pt; 4%), and hyperglycemia (G3:1 pt; 4%). 8 serious adverse reactions to everolimus (6 pts; 24%) occurred. 6 (5 pts; 20%) were grade 3-4, namely mucositis G3/ bacteremia G3 (1 pt; 4%), pneumonia G3 (1 pt; 4%), diarrhea G3 (1 pt; 4%), and CPK G3 (1 pt; 4%) and G4 (1 pt; 4%). Baseline chromogranin A < 4x ULN was found to be associated with improved PFS as compared to higher values (HR = 0.34, 95% CI 0.11-1.02, Wald's p = 0.055).

Conclusions: This prospective phase II study confirms everolimus's efficacy as upfront therapy and provides for the first time high rates of partial responses in advanced GEPNETs attributed to the combined effect of everolimus and octreotide LAR.

Clinical trial identification: NCT01648465.

1327P Improved quality of life in patients with GEP-NETs treated with 177Lu-dotatate

B. Saravana-Bawan[1], M. Wieler[2], T. McMullen[1], A. McEwan[2]

[1]Department of Surgery, University of Alberta, Edmonton, AB, Canada, [2]Department of Oncology, University of Alberta Cross Cancer Institute, Edmonton, AB, Canada

Background: The incidence of gastroenteropancreatic neuroendocrine tumors (GEP-NETs) has been increasing over recent decades. Lutetium therapy is now established as a treatment with benefit towards progression-free survival (PFS) in patients with metastatic GEP-NETs with median PFS of up to 36 months. However, the effect of ^{177}Lu-DOTATATE on quality of life (QoL) is not yet well understood with few studies evaluating the impact on symptom control and patient function. Our study sought to evaluate the change in QoL for patients with progressive GEP-NETs treated with ^{177}Lu-DOTATATE.

Methods: Our study was conducted as a part of the Phase II open label clinical trial at the Cross Cancer Institute in Edmonton. Patient enrollment started in March of 2014 and is ongoing. Treatment consisted of induction phase of 5.55 GBq administered at four treatments, 10 weeks apart. For patients without toxicity or progression on treatment, a maintenance phase was entered consisting of 2.78 GBq every 6 months for up to 4 years and maximum of 12 total treatments. QoL over ^{177}Lu-DOTATATE treatment was assessed with EORTC QLQ-C30 and QLQ-GI.NET 21 QoL questionnaires at baseline and subsequent to each treatment. Planned interim analysis of QoL was completed in all patients having completed induction therapy. Repeated measures ANOVA was performed. A p value of < 0.05 was considered significant and change in EORTC score of ≥ 5 points was considered to be clinically significant.

Results: In total 85 patients met inclusion criteria for interim analysis: tumor of gastroenteric or pancreatic origin and completion of four ^{177}Lu-DOTATATE treatments. Primary analysis revealed statistically significant change and clinically significant improvement in mean insomnia (36.43 to 25.58), endocrine symptom (20.37 to 14.81) and GI symptom scores (22.28 to 16.67) from baseline to post fourth treatment. Overall global health status was maintained over treatment course with no improvement but also no statistically significant deterioration in QoL.

Conclusions: ^{177}Lu-DOTATATE is not only effective in improving PFS for patients with metastatic GEP-NETs but also maintains overall quality of life and importantly provides patients with improvement in specific symptoms such as insomnia, endocrine and GI symptoms.

Clinical trial identification: NCT01876771.

Lawrence[13], S. Leyden[14], Y. Majima[15], D. Metz[16], D. O'Toole[17], P. Ruszniewski[18], B. Wiedenmann[19]

[1]NET Patient Foundation, NET Patient Foundation, Leamington Spa, UK, [2]Neuroendocrine Tumour Unit, Royal Free Hospital School of Medicine, London, UK, [3]Unicorn Foundation, Auckland, New Zealand, [4]Neuroendocrine Tumour Unit, Royal Free London NHS Foundation Trust, London, UK, [5]Nuclear Medicine, Fortis Memorial Research Institute, Gurgaon, India, [6]Department of Surgery, IRCCS San Raffaele, Milan, Italy, [7]Umbria Regional Cancer Network, Perugia, Italy, [8]Medical Oncology, Stanford University Medical Center, Stanford, CA, USA, [9]The Carcinoid Cancer Foundation, New York, NY, USA, [10]Nuclear Medicine, Peter MacCallum Cancer Center, Melbourne, Australia, [11]Neuroendocrine Tumor Research Foundation NET, Boston, MA, USA, [12]International Neuroendocrine Cancer Alliance (INCA), Boston, MA, USA, [13]Faculty of Medical & Health Sciences, University of Auckland Faculty of Medical & Health Sciences, Auckland, New Zealand, [14]Unicorn Foundation, Blairgowrie, Australia, [15]NPO PanCAN Japan, Tokyo, Japan, [16]Division of Gastroenterology, University of Pennsylvania, Philadelphia, PA, USA, [17]Neuroendocrine Tumour Clinic, St Vincents University Hospital, Dublin, Ireland, [18]Division of Gastroenterology and Pancreatology, Hôpital Beaujon, Clichy, France, [19]Division of Hepatology and Gastroenterology, Universitätsklinik Charité, Campus Virchow Klinikum, Berlin, Germany

Background: The International Neuroendocrine Cancer Alliance (INCA) supports NET patients (and their families) by advocating on their behalf to improve diagnosis, care and research. The current survey was undertaken to identify and describe unmet needs in good quality care for NET patients.

Methods: Patients and family, healthcare professionals (HCPs) and patient advocates were surveyed online (Feb-Mar 2017) completing 35 questions covering: Information; Standards of care; Diagnostics and treatment; Research.

Results: 443 responses from 26 countries were collected: 338 patient/family; 70 HCPs; 35 advocates. Patients reported several information gaps at diagnosis, which were not perceived by HCPs (Table). 46% of patients felt their needs about treatment options were fully/mostly met, compared with 88% of HCPs. Many patients (70%) sought information via patient association websites, with 62% feeling this fully/mostly met their needs. 32% of patient advocates felt appropriate standards of care are not met, particularly in terms of psychological (76%) and mental health (71%) care and holistic support (e.g. diet, exercise; 65%). While 90% of HCPs stated MDT care was always/sometime provided, only 66% of patients reported seeing a MDT. Access to Gallium-68-DOTATATE/DOTATOC PET/CT (patients 72%; HCPs 86%; advocates 85%) and PRRT (42%; 77%; 95%) were the major unmet diagnostic and treatment needs. More involvement by patients in research was desired (patients 53%; HCPs 57%; advocates: 82%), particularly in clinical trials and in raising the profile of NET research. The research priority for patients and advocates was in earlier, more accurate diagnosis, while HCPs prioritised clinical trials to improve treatment.

Table: 1328P Informational needs not met at diagnosis

	Patient	HCP
Relevant clinical trials	53%	6%
NETs research	53%	6%
Psychological care	48%	13%
Signposting to patient associations	44%	4%
Advice on how to manage the condition	34%	1%

Conclusions: The INCA survey has highlighted areas for improvement related to information provision, access to gold standard care and attention, focus and patient involvement in research.

Background: Vandetanib has demonstrated efficacy in advanced MTC in a large phase III trial (ZETA trial, JCO 2012). However, the study had several limitations that impact in the daily clinical practice, such as the efficacy in patients (pts) with documented disease progression or beyond first-line therapy who have a worse prognosis.

Methods: Pts with advanced unresectable MTC with previous radiologically documented disease progression were included in the Spanish National Database of the Rare Cancer Working Group (GETHI). Pts started treatment with vandetanib 300mg qd as initial dose, with dose reductions allowed as per toxicity. Baseline characteristics, progression free survival (PFS), response rate (RR), correlation with biomarkers and toxicity data were reviewed retrospectively in first, second and third line setting. The program was validated by regulatory authorities and all patients signed and informed consent form.

Results: 59 pts (med age:48y; male 61%) were included. 14% had RET mutations. Vandetanib was given as first line in 61%, second-line in 22% and third-line therapy in 17% of pts. RR and median PFS in first, second and third-lines were 47%, 53% and 40% (p 0.85%) and 16.8, 13.6 and 11.5 months (p 0.94) respectively. No correlation was found between calcitonin or CEA reduction and RR. However, CEA level decrease (30% versus baseline) appeared to predict PFS longer than 11 months (p 0.028). Treatment was well tolerated and dose reduction was needed in 23% to handle toxicity. Main side effects were grade 1-2 including fatigue (22%), skin rash (19%), hypertension (14%) and diarrhea (14%). Most frequent grade 3 toxicity was oral mucositis (3%).

Conclusions: Probability of tumor shrinkage with vandetanib is maintained throughout treatment lines despite of a trend of reduced benefit in PFS beyond first-line in a cohort of pts with a worse prognosis. CEA reduction may predict longer PFS. Safety is maintained regardless prognosis and prior therapies.

1330P Development and validation of neuroendocrine tumor marker panel in small biopsies using multiplexed mass spectrometry

S. Thyparambil[1], E. An[1], S. Sellappan[1], E.R. Wertheimer[1], S. Landolfi[2], J. Capdevila[2], F. Cecchi[1], P.G. Nuciforo[3], R. Heaton[1], T. Hembrough[1]

[1]R&D, NantOmics, LLC, Rockville, MD, USA, [2]Gastrointestinal and Endocrine Tumor Unit, Vall d'Hebron University Hospital, Barcelona, Spain, [3]Molecular Oncology, Vall d'Hebron University Hospital, Barcelona, Spain

Background: Neuroendocrine tumors (NET) occur throughout the body but are not commonly suspected in breast, prostate or colorectal cancers. Morphologic evidence of neuroendocrine differentiation may prompt testing for neuroendocrine markers, but such testing is not routine. Now that NET-specific therapies can increase patient survival, distinction of NET from non-NET is essential. We developed a multiplexed mass spectrometry-based screening tool to measure tumor expression of 3 common neuroendocrine (NE) proteins. We tested and validated this NET panel in clinical biopsies of NET and non-NET.

Methods: Formalin-fixed-paraffin-embedded (FFPE) NET were microdissected and solubilized to tryptic peptides for mass spectrometric analysis using selected reaction monitoring. Synthetic versions of chromogranin A (CHGA), synaptophysin (SYP) and CD56 peptides were used to develop the assay. Using mass spectrometry with stable isotope labeled internal standards, these 3 NE proteins were quantitated in FFPE tumor biopsies of NET and non-NET.

Results: In the test set, 20 of 20 previously diagnosed NET (of the lung and gastroenteropancreatic tract) expressed $\geq$2 of the 3 NE protein markers (positive predictive value=100%), and 47 of 50 non-NET (non-small cell lung cancer) expressed none of the markers, with only one sample expressing $\geq$2 markers (negative predictive value=98%.). NET positivity was therefore defined as expression of $\geq$ 2 markers. In a validation set of 16 NET, the proteomic panel confirmed 13 cases. Of the 3 discordant cases, one of these was a small-cell lung cancer with mixed NE and squamous histology. When used to screen 614 consecutive clinical samples of multiple tumor types, the panel found 16 tumors that unexpectedly expressed $\geq$2 NE markers. Upon pathology review, 5 of these were confirmed as NET, thus revealing new treatment options for 5 patients.

Conclusions: A mass spectrometry-based screening tool can identify NET with sensitivity and specificity similar to that of immunohistochemistry. Such proteomic testing can identify NE proteins simultaneously with dozens of therapeutically relevant biomarkers (eg, HER2, EGFR) to inform treatment decision making without the need for additional FFPE sections.

Isar, Technical University Muenchen, Munich, Germany, [9]Institut de Cancérologie, Gustave Roussy, Villejuif, France, [10]Global Medical Affairs, Ipsen Pharma France, Boulogne-Billancourt, France, [11]Clinical Statistics, Ipsen Pharma France, Boulogne-Billancourt, France, [12]Nuclear Medicine, Memorial Sloan-Kettering Cancer Center, New York, NY, USA

Background: ^{177}Lu-DOTATATE is licensed for gastroenteropancreatic (GEP-)NETs. PRELUDE is an international retrospective study (NCT02788578) to describe LAN use with ^{177}Lu-PRRT (LAN–PRRT) in advanced NETs. Here we report effectiveness results, including a post hoc TGR analysis to complement RECIST-based progression measures.

Methods: Analysis of patients (pts) receiving LAN with ^{177}Lu-DOTATATE/DOTATOC followed by LAN only. Key inclusion criteria: metastatic/locally advanced, grade 1/2, somatostatin receptor-positive GEP-/lung NET, progressive disease (PD) within 12 mo and within 6 mo before LAN–PRRT start (assessed locally), $\geq$1 LAN injection 8 wks before LAN–PRRT start, continuous LAN use during LAN–PRRT, cumulative PRRT activity $\geq$500 mCi. Primary endpoint: progression-free survival (PFS) rate at end of last LAN–PRRT cycle (RECIST v1.1, central review). Key secondary endpoints: PFS rate at last available follow-up (RECIST v1.1 central review), best overall response (OR; RECIST v1.1 central review). Post hoc analysis: TGR (% variation of tumour volume/mo) calculated from sum of longest diameter of target lesions between two MRI/CT scans during: prebaseline/baseline (within 12 mo and within 6 mo before baseline), baseline/end of last LAN–PRRT cycle (within 6 mo before baseline and end of last LAN–PRRT cycle), and end of last LAN–PRRT cycle/last available follow-up visit.

Results: Enrolment terminated early (insufficient recruitment): 40 pts (GEP n = 39; lung n = 1) (full analysis set: GEP n = 23, lung n = 1). LAN exposure and effectiveness results in GEP-NETs are shown in the table. Waterfall plots of prebaseline/baseline TGR showed individual progressions and regressions, with a mean of 0 [–1.4; 1.5].

Table: 1331P

	Patients with GEP-NETs (n = 23)
Median (range) LAN exposure, mo Overall Prior to LAN–PRRT During LAN–PRRT During LAN only follow-up	37.0 (16.7–90.0) 10.5 (0.7–61.7) 14.2 (7.0–24.0) 12.6 (6.1–32.5)
PFS rate [95% CI] at end of last LAN–PRRT cycle	91.7% [53.9; 98.8]
PFS rate [95% CI] at last available follow-up (up to 12 mo post-treatment)	95.0% [69.5; 99.3]
Best OR [95% CI] RECIST v1.1	Partial response (PR): 34.8% [18.8; 55.1] Stable disease: 60.9% [40.8; 77.8] PD: 4.3% [0.8; 21.0]
Mean [95% CI] TGR: Prebaseline/baseline Baseline/end of last LAN–PRRT cycle End of last LAN–PRRT cycle/last available follow-up visit	0.0% [−1.4; 1.5] −1.6% [−2.7; −0.4] −0.2% [−1.3; 0.9]

Conclusions: Effectiveness data were encouraging in this small selected population. TGR suggested tumour regression during LAN–PRRT. Despite low baseline TGR, 35% pts had RECIST PR on central assessment.

1332P Detection of mutations and copy number alterations in circulating DNA from pancreatic neuroendocrine tumor patients

G. Boons[1], K. Op de Beeck[1], T. Vandamme[1], M. Beyens[2], G. Roeyen[3], K. Janssens[2], K. Zwaenepoel[1], G. van Camp[2], M. Peeters[1]

[1]MIPRO, University of Antwerp/Antwerp University Hospital, Edegem, Belgium, [2]MEDGEN, University of Antwerp/Antwerp University Hospital, Edegem, Belgium, [3]Hepatobiliary, Transplantation and Endocrine Surgery, Antwerp University Hospital, Edegem, Belgium

Background: Chromogranin A, the most frequently used circulating biomarker for diagnosis and follow-up of pancreatic neuroendocrine tumor (PNET) patients, has several limitations. Research in other tumor types has indicated the biomarker potential of circulating tumor DNA (ctDNA). However, ctDNA remains unexplored in PNETs. In this study, we aimed to detect and profile ctDNA in plasma of PNET patients.

Methods: Tumor tissue, perioperative blood samples and clinicopathological data were prospectively collected from 10 PNET patients undergoing surgery for their primary tumor at the Antwerp University Hospital. An additional blood sample was collected from one case during follow-up, when patient had disease progression. Whole exome sequencing was performed on tumor and germline DNA to identify somatic variants and copy number alterations (CNAs). For every patient a somatic single nucleotide variant (SNV) was selected and a digital droplet PCR assay was developed to detect this SNV in DNA isolated from plasma. Shallow whole genome sequencing (sWGS) was performed on plasma DNA to identify CNAs.

Results: In two patients, the somatic SNV could be detected in the perioperative plasma sample at variant allele fractions (VAFs) of 19% and 21%. Interestingly, both patients had metastatic disease and succumbed within two years after surgery, while the other eight patients presented with localized disease and are currently disease-free. The follow-up plasma sample of one of the positive cases showed an increase in VAF to 57%. Next, sWGS was performed on ctDNA-positive plasma to detect CNAs. A significant correlation ($p < 0.01$) was found between CNAs in primary tumor and CNAs in perioperative plasma sample. The CNA profile of the follow-up sample showed increased genetic instability.

Conclusions: We provide evidence for the presence of ctDNA in patients with a metastatic PNET. Non-metastatic cases were ctDNA-negative. An increase in VAF and genetic instability were found in the follow-up sample of one of the metastatic cases, suggesting potential for ctDNA as follow-up marker. Furthermore, CNAs in primary tumor and plasma sample were significantly correlated, proposing ctDNA as an alternative for molecular profiling of tissue in metastatic patients.

Background: Patients with metastatic or locally advanced, non-resectable, grade 3 neuroendocrine carcinoma (NEC) of the lung or gastroenteropancreatic system (GEP NEC) are usually treated with first-line platinum-based chemotherapy. There is no standard second-line treatment when progression occurs. Different second-line chemotherapy combinations have been evaluated retrospectively, but with poor results. FOLFIRI was evaluated in a retrospective monocentric study, showing a disease control rate (DCR) of 62%. In another retrospective study, temozolomide-based chemotherapy obtained a DCR of 71%. There is growing evidence that the current grading system for NECs has a number of inconsistencies, highlighting the need for more accurate biomarkers to better understand the natural history of this very aggressive disease.

Trial design: SENECA study is a randomized, non-comparative, multicenter phase II trial designed to evaluate the efficacy and safety of FOLFIRI or capecitabine plus temozolomide (CAPTEM) after failure of first-line treatment in lung and GEP NECs. Primary aim is to assess DCR of the regimens, with safety as a co-primary. Secondary aims are the evaluation of overall survival (OS), progression-free survival (PFS) and quality of life. It is also planned to assess Gallium-PET/CT and tissue and circulating biomarkers as prognostic and predictive factors. Eligibility criteria are age $\geq$18 years, metastatic or locally advanced, non-resectable, lung or GEP NEC, and documented evidence of progressive disease during or after first-line platinum-based chemotherapy (cisplatin/carboplatin and etoposide; FOLFOX4 or CAPOX). Each patient is randomized to receive FOLFIRI or CAPTEM, considering Ki-67 (21-55 % vs > 55%) and primary tumor site (lung vs. GEP) as stratification factors. The randomized study design allows for two active treatments to be evaluated in a comparable patient population. Analysis will be performed for each regimen separately. 56 patients will be enrolled in each arm of the study (total of 112 patients). Sixteen centers are taking part in the study and recruitment is ongoing. The first patient was randomized on March 6, 2017.

1334TiP A phase I study of oncolytic immunotherapy of metastatic neuroendocrine tumours using intralesional rose bengal disodium

T.J. Price[1], G. Cehic[2], I. Kirkwood[3], G. Maddern[4], E.A. Wachter[5], D. Sarson[6], R. Sebben[7], L. Leopardi[4], J. Reid[4], S.J. Neuhaus[8]

[1]Medical Oncology, The Queen Elizabeth Hospital and University of Adelaide, Woodville, Australia, [2]Nuclear Medicine, The Queen Elizabeth Hospital, Woodville, Australia, [3]Nuclear Medicine, Royal Adelaide Hospital, Adelaide, Australia, [4]Surgery, The Queen Elizabeth Hospital, Woodville, SA, Australia, [5]Development, Provectus Pharmaceuticals, Knoxville, TN, USA, [6]Development, Provectus Biopharmaceuticals, Sydney, Australia, [7]Radiology, The Queen Elizabeth Hospital, Woodville, Australia, [8]Surgical Oncology, University of Adelaide, Woodville, Australia

Background: Neuroendocrine tumours (NET) associated with the gastrointestinal tract are frequently indolent but problematic as a result of potential endocrine secretory properties and metastasis often to the liver. Metastases (mNET) located in the midgut and liver often secrete vasoactive products, giving rise to the "carcinoid Syndrome,"; flushing, diarrhoea, wheezing, abdominal cramps and peripheral oedema. Treatment options for mNET include surgical resection, chemoablation, and use somatostatin analogues (e.g. octreotide, lantreotide) or radio-labelled analogues (e.g. Lutate/Lutathera, ^{177}Lu DOTA-octreotate). However there is a need for additional options for mNET patients. There has been a paradigm shift in anti-cancer therapy over the last decade with the introduction of immunotherapy treatments. Intralesional rose bengal disodium (PV-10) is undergoing clinical development as an oncolytic immunotherapy and is the subject of this phase 1 study examining potential use of PV-10 for treatment of symptomatic mNET of the liver (NCT02693067).

Trial design: This phase 1 study is evaluating the safety, tolerability and reduction of biochemical markers and symptoms resulting from image guided percutaneous administration of PV-10 in up to 12 participants with mNET of the liver not amenable to resection or other potentially curative therapy. The Target Lesion(s) as defined by the interventional radiologist must be a uni-dimensionally measurable lesion with longest diameter between 1.0cm and 3.9cm as measured. The primary endpoint is safety. Secondary endpoints include objective response rate (ORR), target lesion SSTR and biochemical response. ORR is assessed by contrast enhanced CT and ^{68}Ga-DOTATATE PET standardised uptake value (SUV) allows SSTR expression to be used as a surrogate for tumour viability. In addition to characterizing direct effect of PV-10 in injected lesions, response of uninjected bystander lesions is evaluated by CT and PET to characterize potential systemic benefit. Integration of patient-reported outcome (QLQ-GI.NET21), serum biomarker (CgA) and objective response (PET) data will allow testing of concordance between independent indicators of clinical benefit.

Clinical trial identification: NCT02693067.

Funding: Provectus Biopharmaceuticals.

Disclosure: E.A. Wachter, D. Sarson: Employment: Provectus Biopharmaceuticals. All other authors have declared no conflicts of interest.

1335TiP COMPETE trial: Peptide receptor radionuclide therapy (PRRT) with 177Lu-edotreotide vs. everolimus in progressive GEP-NET

M.E. Pavel[1], A. Rinke[2], R.P. Baum[3]

[1]Gastroenterology and Hepatology, Endocrinology & Metabolic Diseases, Universitätsklinik Erlangen, Erlangen, Germany, [2]Klinik für Gastroenterologie und Endokrinologie, University Hospital of Marburg Klinik für Innere Medizin, Marburg, Germany, [3]Theranostics Center for Molecular Radiotherapy and Molecular Imaging, Zentralklinik Bad Berka GmbH, Bad Berka, Germany

Background: There are only limited treatment options for metastasized gastroenteropancreatic neuroendocrine tumors (GEP-NETs). Current standard therapies include somatostatin analogs and targeted drugs such as everolimus and sunitinib. While these treatments rarely induce objective tumor remission, disease stabilization may be achieved for limited periods of time. Median PFS with everolimus in prospective phase III trials is 11 months. A subset of patients may have a benefit of systemic chemotherapy. PRRT has recently emerged as a promising option providing more durable response and potentially higher objective response rates. This therapy uses IV-infused radiolabeled somatostatin analogues to deliver radioactivity directly to metastases, destroying tumor cells but sparing most of the surrounding tissue. A first retrospective study on ^{177}LuEdotreotide PRRT in metastasized GEP-NET reported a median PFS of 34.5 months in patients who received $\geq$2 treatment cycles.

Trial design: COMPETE is a prospective, randomised, controlled, open-label, multicentre phase III study to evaluate the efficacy and safety of ^{177}Lu-Edotreotide PRRT in comparison with everolimus in patients with inoperable, progressive, somatostatin receptor-positive (SSTR^{+}) GEP-NET. The study is ongoing in 11 countries & 40 centres worldwide, and currently recruiting patients. 300 patients will be randomized with progressive GEP-NET: 200 will receive max. 4 cycles of ^{177}Lu-Edotreotide PRRT (7.5 GBq/cycle) every 3 months or until diagnosis of progression; 100 will receive 10 mg everolimus daily for 24 months, or until diagnosis of progression. Study duration per patient will be 24 months. The primary endpoint is PFS. Diagnosis of progression and hepatic tumor burden will be established based on radiological information from morphological imaging (MRI and/or CT) according to RECIST 1.1. Key secondary endpoints are objective response rate (ORR), defined as % of patients achieving partial or complete response (PR/CR) as best outcome, and median duration of disease control (mDDC). Other secondary variables include safety and tolerability, dosimetry measures, overall survival, and quality of life.

Clinical trial identification: NCT03049189.

1337P Predictive models for CEUS of the breast: Is it feasible in improved performance of BI-RADS evaluation of critical breast lesions?

L. Jun[1], Q. Chen[1], L. Tang[2], L. Yang[3], E. Han[4], Y. Chen[5], L. Yuan[6]

[1]Ultrasound Department, Sichuan Provincial People's Hospital, Chengdu, China, [2]Ultrasound Department, Fujian Provincial Cancer Hospital, Fuzhou, China, [3]Ultrasound Department, Yunnan Tumor Hospital Third Affiliated Hospital of Kunming Medical University, Kunming, China, [4]Ultrasound Department, Huangshi Central Hospital, Huangshi, China, [5]Ultrasound Department, Chengdu First People's Hospital, Chengdu, China, [6]Ultrasound Department, Tangdu Hospital, Xian, China

Background: This prospective study is to determine whether predictive model for contrast-enhanced ultrasound (CEUS) of the breast can improve the precision of BI-RADS.

Methods: A total of 1060 breast lesions classified as BI-RADS 4 or 5 on ultrasound were evaluated. CEUS was performed before core needle biopsy or surgical resection and a revised BI-RADS classification was assigned based on 6 predictive models for CEUS of malignant and benign breast lesions as follows: malignant predictive models : (1) hyper-enhancement with enlarged size; (2) hyper-enhancement with perfusion defect; (3) hyper- or iso-enhancement, present penetrating vessels or crab claw-like pattern. Benign predictive models: (4) rapid wash-in with hyper-enhancement, clear margin after enhancement without enlarged size; (5) synchronous or slow wash-in with iso-enhancement, and cannot distinguish margin and shape after enhancement; and (6) synchronous or slow wash-in with hypo-enhancement, with equal or smaller size after enhancement. To evaluate the diagnostic performance of CEUS-based BI-RADS assignment with pathological examination as reference criteria.

Results: The CEUS-based BI-RADS evaluation classified 287/1060 (27.08%) lesions into category 3, 195 (18.40%), 124 (11.7%) and 144 (13.58%) lesions into categories 4A, 4B and 4C, respectively, and 310 (29.24%) into category 5, compared with 423/1060(39.91%), 348(32.83%), 150(14.15%) and 139(13.11%) in BI-RADS 4A, 4B, 4C. and 5 based on conventional ultrasound and mammography. Selecting CEUS- based BI-RADS category 3 as an appropriate cut-off gave accuracy, sensitivity, specificity, positive and negative predictive values of 69.25%, 98.06%, 49.47%, 58.99% and 96.86%, respectively for the diagnosis of malignant disease. The cancer-to-biopsy yield was 60.16% with CEUS-based BI-RADS 3 selected as the biopsy threshold compared with 43.86% otherwise, while the biopsy rate was only 72.92% compared with 100% otherwise (Figure 2). Overall, only 1.94% of invasive cancers were misdiagnosed as BI-RADS 3 we use nowadays.

Conclusions: This study suggests that evaluation of BI-RADS 4 or 5 breast lesions with CEUS result in reduced biopsy rates and increased cancer-to-biopsy yields.

1338P Tracking VSV-IFNβ-NIS oncolytic virus (OV) activity in patients (pts) with advanced solid tumors: The iodide symporter gene (NIS) as a pharmacodynamic (PD) marker using SPECT/CT imaging of OV therapy

J. Merchan[1], M.R. Patel[2], S.F. Powell[3], J. Strauss[4], T.P. Cripe[5], M.O. Old[6], R.M. Diaz[7], S.J. Russell[8], A.S. Bexon[9], L. Suksanpaisan[10], M.K. O'Connor[11], K.W. Peng[12]

[1]Oncology, Miami School of Medicine, Miami, FL, USA, [2]Hematology, Oncology and Transplantation, Minnesota Medical School, Minneapolis, MN, USA, [3]Hematology and Oncology, Sanford Health, Sioux Falls, SD, USA, [4]Oncology, Mary Crowley Medical Research Center, Dallas, TX, USA, [5]Hematology/Oncology/BMT, Nationwide Children's Hospital, Columbus, OH, USA, [6]Arthur James Cancer Hospital, The Ohio State University, Columbus, OH, USA, [7]Regulatory and Clinical Affairs, Vyriad, Rochester, MN, USA, [8]Vyriad, Rochester, NY, USA, [9]Vyriad, Rochester, NY, USA, [10]Diagnostics, Imanis Life Sciences, Rochester, NY, USA, [11]Nuclear Medicine, Mayo Clinic, Rochester, MN, USA, [12]CTO, Vyriad, Rochester, NY, USA

Background: VSV-IFNβ-NIS (Voyager V1; VV1) is a VSV-derived OV with low human seroprevalence. In addition to its tumor-selective and immune-stimulatory properties, VV1 encodes the human thyroidal sodium iodide symporter NIS to allow imaging of virus-infected tumors with IV ^{99m}Tc pertechnetate. Preclinical studies show increasing ^{99m}Tc uptake correlates with virus dose and allows spatial and temporal tracking of virus.

Methods: Single-photon emission computerized tomography (SPECT/CT) is used to assess virus replication and spread. In a phase 1 study, VV1 is given intratumorally into 1 target lesion on Day 1 (D1). SPECT/CT imaging is performed 45 minutes after 20 mCi IV ^{99m}Tc at baseline and D3. If there is uptake in injected tumor on D3, SPECT/CTs are also done D8 and D15. Imaging requirements include: gamma camera, low energy high resolution collimators with standard acquisition protocols and iterative image reconstruction. All images are read locally and centrally.

Results: SPECT/CT has been performed on 12 patients at 4 VV1 dose levels (DL). ^{99m}Tc uptake was not detected at the first 2 DLs but was seen in injected lesions of 2/4 pts at DL 3 (3e7 $TCID_{50}$) in pts with metastatic colorectal and pancreas cancer, and 1/2 to date at DL 4. PD analysis revealed SPECT/CT-positive pts had peak uptake in injected lesions between D3 and D8. Tumor biopsy samples are being analyzed to correlate SPECT/CT with viral RNA. Spread to uninjected lesions was not yet visualized, but viral RNA was recovered in cystic fluid from the lesion with the strongest signal in a pancreas cancer pt.

Conclusions: This novel therapeutic and diagnostic approach allows PD visualization of the investigational oncolytic virotherapy, VV1, replicating within the injected lesion. Positive images at dose levels 3-4 indicate we have reached a viral dose that allows sufficient viral replication for potential clinical activity. Further objectives include correlation of SPECT/CT positivity with clinical response, viremia, immune infiltrates, and genetic markers of susceptibility to OV therapy.

Background: Central immunohistochemistry (IHC) is the clinical gold standard for assessing ER, PR, HER2 and Ki67 in FFPE breast cancers, however limitations still exist concerning (pre) analytic validity. mRNA expression assays provide an alternative approach to measuring these biomarkers. Xpert® Breast Cancer STRAT4 is a CE-IVD, cartridge-based test performed on the GeneXpert platform which semi-automates sample preparation and RT-qPCR detection of ESR1, PGR, ERBB2 and MKi67 mRNA in FFPE tissues. Here we demonstrate the concordance of STRAT4 mRNA in comparison to central IHC in women treated within the phase III ABCSG-6 adjuvant endocrine therapy trial.

Methods: We evaluated ESR1, PGR, ERBB2 and MKi67 mRNA expression by STRAT4 and ER, PR, HER2 and Ki67 by IHC (FISH for HER2 IHC 2+) in 525 surgical FFPE specimens from ABCSG-6. All STRAT4 and IHC/FISH testing was performed by a central academic reference laboratory. Concordance (overall percent agreement) between STRAT4 and IHC for each marker was the predetermined primary objective. The effect of binary parameters (positive vs negative) obtained by IHC and by STRAT4 on distant recurrence free interval (DRFI) was analyzed by Cox models and described by hazard ratios (HR).

Results: In this study, concordance between STRAT4 and IHC was 98.6% for ER, 92.6% for PR, 98.4% for HER2, and 88.7% for Ki67 (excluding intermediate IHC 10-20% staining). In univariate Cox regression analyses, PR (HR 0.29, $P < 0.001$), HER2 (HR 2.62, $P = 0.005$), and Ki67 (HR 3.45, $P = 0.001$) tested by central IHC and PGR (HR 0.48,$P = 0.007$), ERBB2 (HR 2.29, $P = 0.037$) and MKi67 (HR 3.87, $P < 0.001$) tested by STRAT4 were all significantly associated with DRFI whereas neither ER by IHC, (HR 0.35, $P = 0.077$, nor ESR1 by STRAT4 (HR 0.73, $P = 0.597$), was associated with DRFI.

Conclusions: We demonstrate high concordance between centrally assessed IHC and mRNA measurements of the four main biomarkers routinely assessed in early breast cancer. This was corroborated by the similar prognostic values observed for protein versus mRNA assessments for each marker. Future investigations of the clinical utility of mRNA based measurements by STRAT4 in breast cancer cohorts are warranted.

Background: Precision medicine using multi-platform profiling of metastatic cancers is becoming increasingly used. However, its clinical utility in guiding patients' treatment remains unknown.

Methods: Here we assessed whether molecular profiling helps physicians in their treatment decision by analysing the molecular profile of 1657 advanced cancer patient samples who had failed at least one standard of care treatment using a combination of next generation sequencing (NGS), immunohistochemistry (IHC) and other specific tests. The results were interpreted, and personalized treatments for each patient were suggested. After a minimum of three months, using internet surveys, we investigated how our recommendations influenced treatment choice of the oncologist.

Results: Our data showed that NGS alone provided the oncologist with useful information in 10-50% of cases (depending on cancer type), whereas the addition of IHC/other tests extensively increased the usefulness of the information provided. For patients who were still alive after the provision of the molecular information (76.8%), 60.4% of their oncologists followed our recommendations. Most decisions (93.4%) were made based on the combination of NGS and IHC/other tests, and an approved drug -rather than clinical trial enrolment- was the main treatment choice. Most common reasons given by physicians to explain the non-adherence to recommendations were drug availability and cost, which remain barriers to precision medicine. Finally, we observed that 27% of patients treated with the suggested therapies had an overall survival >12 months.

Conclusions: Our study demonstrates that the combination of NGS and IHC/other tests provides the most useful information in aiding treatment decisions by oncologists in routine clinical practice. However, barriers to full implementation of this approach remain, and include drug availability, cost and low participation in clinical trials.

1341P Comparison of tissue-based and liquid biopsy genomic tests to guide lung cancer therapy: Asian experience

M-L. Nairismägi[1], K-C. Tung[2], Y-T. Yang[2], Y-J. Lu[2], R-S. Jhou[2], P-N. Yu[2], Y-T. Liu[2], Y-L. Hsieh[2], S.L. Poon[1], S-J. Chen[2], K.T. Tan[2]

[1]Medical Affairs, ACT Genomics (Singapore) Pte. Ltd., Singapore, [2]Medical Informatics, ACT Genomics Co., Ltd., Taipei, Taiwan

Background: Liquid biopsies are rapidly changing the diagnostics in oncology; however, their usability to guide treatment selection remains unknown. Here we explored the differences between liquid biopsy and tissue-based genomic tests in Asian lung cancer patients.

Methods: 226 formalin-fixed, paraffin-embedded (FFPE) and 274 plasma clinical samples were subjected to next-generation sequencing using the Ion Torrent Proton System with mean sequencing depth $\geq 700\times$ and $7{,}000\times$, respectively. FFPE samples were profiled using a 35-gene and circulating tumor DNA samples a 11-gene hotspot panel for base substitutions (single nucleotide variants/small indels) and copy number variants (CNV; for FFPE only).

Results: Actionable variants were identified in 47% (129/274) of liquid biopsies. Actionability was higher in tissue-based tests – 76% (172/226) – with 64% (111/172) derived from base substitutions, 9% (15/172) from CNVs and 27% (46/172) from both. EGFR mutations, indicating the use of tyrosine kinase inhibitors (TKI), were detected in 38% (105/274) and 49% (110/226) of liquid biopsy and tissue-based tests, respectively. Identification of TKI resistance mechanisms via EGFR T790M/C797S or the downstream KRAS, BRAF, PIK3CA, ERBB2 and MET mutations was also higher for tissue testing – alterations were discovered in 38% (86/226) and 27% (75/274) of samples, affecting a total of 35% (78/226) and 24% (65/274) patients, respectively, for tissue and liquid biopsy tests. Tissue testing detected additional CNV-originating TKI

resistance mechanisms (EGFR, MET and HER2 amplifications) in 24% (53/226) samples affecting an additional 13% (30/226) patients on top of those harboring mutation-based resistance mechanisms. RAF and MEK inhibitor indications were identified in 12% (28/226) and 3% (8/274), and mTOR blockade indications in 8% (19/226) and 7% (19/274) of tissue and liquid biopsy tests, respectively.

Conclusions: Although liquid biopsy tests are able to identity a large proportion of lung cancer patients with indications for targeted therapy, tissue-based testing outperforms liquid biopsies for most therapeutic indications. Inclusion of CNV analysis could potentially increase the detection rate in liquid biopsies.

1342P 68Ga-PSMA-PET/CT imaging for locally advanced, recurrent and metastatic adenoid cystic carcinoma and salivary duct carcinoma

W. van Boxtel[1], S. Lütje[2], I. van Engen- van Grunsven[3], G. Verhaegh[4], J. Schalken[4], M. Janssen[2], J. Nagarajah[2], M. Gotthardt[2], C.M.L. van Herpen[1]

[1]Medical Oncology, Radboud University Medical Center, Nijmegen, Netherlands, [2]Radiology and Nuclear Medicine, Radboud University Medical Center, Nijmegen, Netherlands, [3]Pathology, Radboud University Medical Center, Nijmegen, Netherlands, [4]Urology, Radboud University Medical Center, Nijmegen, Netherlands

Background: Salivary gland cancer (SGC) is a rare cancer with few treatment options. Adenoid cystic carcinoma (ACC) and salivary duct carcinoma (SDC) are major subtypes of SGC which often show immunohistochemical expression of prostate-specific membrane antigen (PSMA). In prostate cancer, PSMA ligands labeled with radioisotopes such as ^{68}Ga or ^{177}Lu, are used for imaging or therapy. The aim of this study was to evaluate ^{68}Ga-PSMA ligand uptake in patients with locally recurrent and/or metastatic ACC and SDC and to establish the diagnostic value of ^{68}Ga-PSMA-PET/CT imaging compared to full-dose CT imaging.

Methods: ^{68}Ga-PSMA-HBED-CC PET/CT scans were performed in 14 ACC patients and 10 SDC patients including a full-dose CT scan of the neck, chest and abdomen. ^{68}Ga-PSMA ligand uptake was evaluated in local recurrences and metastatic lesions. Detected lesions were compared to CT results. Maximum standardized uptake values (SUV_{max}) were determined. The study protocol was approved by the local medical ethical committee and a written informed consent was obtained from all patients.

Results: Moderate to intense PSMA ligand uptake was observed in local recurrences and distant metastases in all ACC patients and 40% of SDC patients. In addition, PSMA-PET imaging detected additional bone metastases in 2 ACC patients and additional lymph node metastases in 1 ACC patient which were not detected on a full-dose CT scan. In 1 ACC patient a local recurrence of a vulvar ACC was suspected on CT but PSMA-PET imaging was negative, which turned out to be scar tissue, eventually.

Conclusions: PSMA-PET imaging showed moderate to intense ligand uptake in local recurrences and distant metastases of all ACC patients and 40% of SDC patients. Based on the high uptake, these patients may be promising candidates for ^{177}Lu-PSMA radioligand therapy in future. Moreover, PSMA-PET imaging has added diagnostic value compared to full-dose CT imaging.

Clinical trial identification: NCT03319641.

1343P Histology and detectability on ring-type dedicated breast PET in breast cancer

Y. Kimura[1], S. Sasada[1], N. Goda[1], K. Kajitani[1], A. Emi[1], N. Masumoto[1], T. Kadoya[1], R. Haruta[1], T. Kataoka[1], M. Okada[2]

[1]Breast Surgery, Hiroshima University Hospital, Hiroshima, Japan, [2]Surgical Oncology, Hiroshima University, Hiroshima, Japan

Background: Although dedicated breast PET (DbPET) visualizes sub-centimeter breast cancer lesions and intratumoral heterogeneity, the impact of histology on the detectability of DbPET remains unknown.

Methods: This study included 455 patients with breast cancer, who underwent whole-body PET (WBPET) and ring-type DbPET between January 2016 and March 2018. The relationship of histology and sensitivities of WBPET and DbPET for breast cancer was assessed.

Results: The median patient age was 57 years and histology was as follows: 82 (18.0%) noninvasive carcinoma, 18 (4.0%) microinvasive carcinoma, 305 (67.0%) invasive carcinoma with no special type, 9 (2.0%) invasive lobular carcinoma, and 41 (9.0%) other types. The sensitivity of WBPET and DbPET was 74.5% and 93.2%, respectively. The sensitivities of each histology on WBPET/DbPET were 41.5%/78.0%, 72.2%/100%, 83.9%/96.7%, 44.4%/88.9%, and 78.0%/95.1%, respectively (Table). The sensitivity was low on WBPET in noninvasive, microinvasive, invasive lobular, mucinous and tubular carcinomas. Lobular carcinoma in situ had low sensitivity on both WBPET and DbPET imaging. In the multivariate analysis, undetectable tumor factors on WBPET were sub-centimeter tumor size (Odds ratio [OR] = 6.04, P < 0.001) and histology (OR = 1.69, P = 0.08); for DbPET, Ki-67 labeling index was an undetectable tumor factor (OR = 4.32, P = 0.039).

Table: 1343P Sensitivities of whole-body and dedicated breast PET according to histology

	N	Sensitivity (%)		P
		WbPET	DbPET	
Total	455	339 (74.5)	424 (93.2)	< 0.001
Noninvasive carcinoma	82	34 (41.5)	64 (78.0)	< 0.001
Ductal carcinoma in situ	72	32 (44.4)	61 (84.7)	< 0.001
Lobular carcinoma in situ	8	1 (12.5)	2 (25.0)	1
Others	2	1 (50.0)	1 (50.0)	1
Microinvasive carcinoma	18	13 (72.2)	18 (100)	0.046
Invasive carcinoma of no special type	305	256 (83.9)	295 (96.7)	< 0.001
Invasive lobular carcinoma	9	4 (44.4)	8 (88.9)	0.131
Others	41	32 (78.0)	39 (95.1)	0.048
Mucinous carcinoma	19	13 (68.4)	18 (94.7)	0.09
Tubular carcinoma	5	3 (60.0)	4 (80.0)	0.444
Carcinoma with apocrine differentiation	5	5 (100)	5 (100)	1
Invasive micropapillary carcinoma	5	5 (100)	5 (100)	1
Others	7	6 (85.7)	7 (100)	1

Conclusions: Breast cancers with the specific histological subtypes are hard to detect on WBPET. DbPET can overcome the factors for weak WBPET detectability, such as tumor size and histology, and might prevent the overdiagnosis of lobular carcinoma in situ.

1344P Thermal liquid biopsy as a new tool for lung cancer patients diagnostic: Pilot study

A. Rodrigo[1], O. Abian[2], A. Velazquez-Campoy[3], A. Callejo[4], S. Vega[5], A. Fernandez[6], O. Sánchez-Gracia[2], P. Iranzo Gomez[6], M. Cruellas[6], E. Quilez Bielsa[6], D. Isla[6]

[1]Medical Oncology, Hospital Arnau de Vilanova, Lleida, Spain, [2]Research, IACS-ISS Aragón, Zaragoza, Spain, [3]Research, ARAID Foundation, Zaragoza, Spain, [4]Oncology Department, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [5]Research, BIFI institute-University of Zaragoza, Zaragoza, Spain, [6]Medical Oncology, Hospital Clinico Universitario Lozano Blesa, Zaragoza, Spain

Background: Thermal Liquid Biopsy (TLB) is based on Differential Scanning Calorimetry (DSC, calorimetric thermogram analysis of serum samples) as a new clinical approach for diagnostic assessment of lung cancer patients. DSC is highly sensitive and it studies the unfolding transitions in proteins by thermal denaturation. The DSC profile of blood serum has been previously proposed as a novel approach for diagnosis and monitoring several diseases. Our main objective is to determine the TLB capacity to differentiate between Healthy Controls (HC) and Lung Cancer Patients (LCP).

Methods: Blood samples from HC and LCP were analyzed with a high sensitivity microcalorimeter VP-DSC (MicroCal-Malvern). The data were processed by Origin 7 software. Thermograms acquired were analyzed with a multiparametric method developed by our research group, procuring some indicators to interpret the results. The Area Under the Curve (AUC) was analyzed and the Youden's Index obtained from ROC curves, allowing to construct the contingency tables. Odds Ratio (OR) was also calculated by binary logistic regression.

Results: 117 samples from LCP (Average age 64.6±8.7, 83.0% men) stage distribution (II: 5.2%, III: 25.9%; IV: 69.0%), smoking status (63.8% smoking, 6.5% non-smoking) histology distribution (37.1% Adenocarcinoma, 28.4% Squamous, 30.2% small cell) compared to 123 HC from a blood bank with homogeneous distribution. 10 out of 28 parameters of our multiparametric method showed statistical differences between HC and LCP. After developing ROC curves, AUC higher than 0.75 were observed in these 10 parameters, exceeding 0.85 in 3 of them. The Youden's index was calculated for all, finding sensitivity and specificity values higher than 75.0-90.0% (for the best parameter

both were more than 85.0%). Comparing HC to LCP, we calculated OR obtaining 10 parameters over 10, showing a high positive association between clinical parameters and DSC results.

Conclusions: High positive association between clinical groups and TLB parameters offers advantages over current diagnosis techniques (CT imaging), providing a powerful diagnostic approach with a minimally-invasive, low-risk, low-cost clinical test for LCP. Future promising applications, such as screening programs, could be developed from TLB.

1345P Data-mining of 110 172 electronic patient records with the ConSoRe tool: An analysis of second primary cancer in a comprehensive cancer center

P. Heudel[1], T. Durand[1], B. Fervers[1], F. Gomez[1], M. Rivoire[1], T. Bachelot[2], L. Claude[1], C. Chassagne-Clement[1], F. Pilleul[1], T. Mognetti[1], Y. Devaux[1], J-L. Soubirou[1], C. Lasset[1], D. Perol[1], G. Chvetzoff[1], C. Pezet[1], S. Beaupere[1], P. Zrounba[1], J-Y. Blay[2]

[1]Centre Léon Bérard, Lyon, France, [2]Medical oncology, Centre Léon Bérard, Lyon, France

Background: We report a data-mining analysis of 110,172 electronic patient records (EPR) of the Leon Berard Comprehensive Cancer Center (CLB) over a 10 years period to identify characteristics of second primary cancers (SPC).

Methods: ConSoRe is a new generation data analytics solution using natural language processing to search aggregated data and perform advanced data mining. It was used for data extraction from EPR of 110,172 patients (pts), 47,257 men (M) and 62,915 women (W), treated at the CLB from 2007 to 2017. Patient characteristics, treatment and survival were extracted.

Results: Data extraction identified 88,622 pts with at least one cancer. Among them 7,430 (8.4%) had a SPC: 9% (3,475/38,554) in M and 7.9% (3955/50068) in W ($p = 3\ 10^{-9}$). Of interest, only 4,296 SPC (57%) were already documented manually by the physicians in the dedicated forms. Mean age at diagnosis of first cancer (FC) is 55.1 years (y) in M and 51.8 y in W. Mean interval (MI) from diagnosis of FC to SPC is 5.3 years (4.4 in M, 6.1 in W; T test $p = 4\ 10^{-23}$). Proportions of SPC among specific localization FC are: For M, head & neck cancer (n = 484/5,277, MI: 3.4 y), lymphoma (n = 336/5,611, MI: 5.1 y), prostate cancer (n = 334/4,643, MI: 6.1 y);for W, breast cancer (n = 1,502/21,447, MI: 8.6 y), soft tissue sarcoma (n = 321/3,683, MI: 4.5 y), lymphoma (n = 293/4,432, MI: 6.3 y). Time to SPC differ significantly depending on FC (Anova: $p = 2\ 10^{-18}$).Pts with SPC were more likely to have received chemotherapy (31.1%) for their FC treatment compared to pts without SPC (20.8%; $p = 1.6\ 10^{-94}$). Also, pts with SPC treated by chemotherapy for their FC had shorter MI than pts who did not (3.2 y versus 5.6 y). In multivariate analysis, time from diagnosis of FC to SPC is significantly linked to FC site and shorter when FC was treated with chemotherapy. SPC was significantly correlated to a worth survival: 19% of death with FC at the time of analysis, versus 27.6% of those with SPC ($p = 9.7\ 10^{-57}$).

Conclusions: Screening over 100,000 EPR with ConSoRe enabled to retrieve SPC more exhaustively than the physician forms. ConSoRe will be validated in a broader series of 300,000 EPR and used to study SPC risk factors to enable prevention and early detection.

1346P Real world cfDNA collection in EGFR-mutant NSCLC

N. Marcoux[1], L.V. Sequist[1], A. Hata[1], M. Banwait[1], I. Dagogo-Jack[1], R. Nagy[2], R.B. Lanman[2], A. Muzikansky[3], S.R. Digumarthy[4], Z. Piotrowska[1]

[1]Hematology/Oncology, Massachusetts General Hospital, Boston, MA, USA, [2]Medical Affairs, Guardant Health, Redwood City, CA, USA, [3]Biostatistics, Massachusetts General Hospital, Boston, MA, USA, [4]Thoracic Radiology, Massachusetts General Hospital, Boston, MA, USA

Background: Plasma cell-free DNA (cfDNA) assays are increasingly used in clinic. Despite their rapid adoption, best practices for use and interpretation need better definition. We assessed key clinically-relevant questions using a prospectively collected cohort of EGFR-mutant pts.

Methods: Starting in 2015, serial cfDNA testing via Guardant360 NGS was obtained from MGH pts with advanced EGFR-mutant NSCLC across multiple lines of therapy in an IRB-approved project. Medical records were analyzed retrospectively, tissue was genotyped by institutional NGS (SNaPshot), scans were assessed by RECIST. Correlations were tested by Wilcoxon Rank-Sum.

Results: 372 plasma samples were collected from 89 pts, covering 150 therapy regimens including 26 drugs (targeted, immune, cytotoxic). To assess genotype correlation, we examined matched cfDNA and tissue biopsies at clinical progression for 60 regimens (51 pts). cfDNA-tissue concordance was 73% for founder EGFR mutations (n = 60), 72% for T790M (n = 60) and 89% for MET amp (n = 53). Excluding 15 samples without detectable founder mutation (presumed "non-shedders"), concordance for T790M=89% and MET=90%. To assess if relative change in cfDNA allelic fraction (AF) correlates with radiographic response, we examined 21 regimens (19 pts) with cfDNA samples at baseline and $\leq$ 30 days, and 3 aspects of the Guardant360 report. 12/21 regimens yielded PR by scans. Decrease in cfDNA AF in the 1st month of therapy correlated with ultimate PR whether assessing the change in AF of founder EGFR ($p = 0.03$), largest AF regardless of gene ($p = 0.02$) or sum of all detected AFs ($p = 0.02$).

Conclusions: CommercialcfDNA assays are readily available, facilitate serial AF monitoring and provide clinically-relevant data at acquired resistance. Among EGFR pts, we found real world cfDNA-tissue correlation of founder mutations and T790M was high and resistance mutation (T790M, MET) results in cfDNA may be most reliable when founder EGFR mutations are detected. Importantly, MET amp had high cfDNA-tissue concordance, which was unexpected. Early AF decrease (within 1st month of therapy) significantly correlates with radiographic response regardless of which aspect of the Guardant360 report is considered. Further investigation is needed to inform optimal use and interpretation of cfDNA assays.

1347TiP Proof-of-concept study evaluating a new tool for standardising radiological assessment of tumour response to treatment in routine clinical practice

C. Mastier[1], C. de la Fouchardière[2], J. Fayette[2], M. Sarabi[2], P. Heudel[2], A. Coulon[1], N. Banaste[1], E. Mercier-Bischoff[1], M. Barma[1], M. Brahmi[2], P. Cassier[2], S. Couchon Thaunat[1], L. Eberst[2], G. Fournier-Garin[3], P. Metral[3], F. Pilleul[1], J-Y. Blay[2]

[1]Department of Radiology, Centre Léon Bérard, Lyon, France, [2]Department of Medical Oncology, Centre Léon Bérard, Lyon, France, [3]Department of Clinical Research and Innovation, Centre Léon Bérard, Lyon, France

Background: Accurate and timely radiological assessment of solid tumour response to treatment is essential to optimise patient outcomes in oncology. Evaluation of tumour response according to Response Evaluation Criteria In Solid Tumors (RECIST) is constantly performed in clinical trials and more occasionally in routine clinical practice. Radiological reporting is not usually standardised. MIRIO (ON'COHUB), a newly developed tool, streamlines interactions between oncologists and radiologists to optimise and ease response evaluation according to RECIST in routine practice. It applies to reading computed tomography scans and magnetic resonance imaging, and allows switching between evaluation criteria (RECIST 1.1, iRECIST and modified RECIST). MIRIO also provides a standardised radiological report, improving communication between oncology and radiology teams to guide treatment decisions. An ongoing proof-of-concept study is evaluating the feasibility of using MIRIO to assess tumour response according to RECIST in routine clinical practice and identify the benefits it may provide to clinical oncology teams and patients.

Trial design: Oncologists specialised in sarcomas, breast, lung, colorectal and head and neck cancers, plus radiologists, will use MIRIO to assess tumours at baseline and tumour response according to RECIST for all new patients seen at Centre Léon Bérard, Lyon, France during the study period. Approximately 80 patients in clinical trials and 320 patients in routine clinical practice will be included. Study duration will be 6 months, with the first patients included in March 2018. All investigators will receive training on MIRIO before including patients in the study. A sample of 20 patient records will be peer-reviewed to determine if MIRIO can improve concordance of assessments made by the radiologist and the oncologist. Other outcome measures include assessments of the quality of data in radiology reports with MIRIO versus standard practice, user satisfaction, integration of the tool into routine practice and improvements in therapeutic follow-up for patients.

1351P Impact of the 8th edition AJCC classification in early stage lung cancer

A.S. Cortegoso Mosquera[1], M. Vieito Villar[2], C. Rodriguez Lopez[1], V. Varela Pose[1], V. Cebey Lopez[1], J. Alvarez Fernandez[1], M. Perez Martelo[1], S. Aguin Losada[1], U. Anido Herranz[1], L. Leon Mateos[1], F.J. Baron Duarte[3], J.J. Garcia Gonzalez[1]

[1]Medical Oncology, Complejo Hospitalario Universitario de Santiago de Compostela SERGAS, Santiago de Compostela, Spain, [2]Oncology, Vall dHebron Institute of Oncology (VHIO), Barcelona, Spain, [3]Medical Oncology, Complejo Hospitalario Universitario A Coruña, A Coruña, Spain

Background: Lung cancer is the main cause of cancer death worldwide. Even in early stages the cancer-specific survival is poor due to disease relapse. The TNM classification is the strongest prognostic tool. The 8th AJCC edition has changed the cutpoints for stage, leading to a "stage shift" or a "stage decrease", mainly reflecting changes in the prognostic score attributed to the tumor diameter. We have reviewed a cohort of patients that were treated before the benefit of adjuvant chemotherapy was proved, in order to corroborate which of the two classifications represents better the risk of recurrence.

Methods: Retrospective analysis of a cohort of 182 patients with lung cancer treated with complete resection and no adyuvant chemotherapy, between 1999 and 2006. Evaluation criteria: overall survival.

Results: 1. Patient characteristics: median diagnostic age 68 years (39-86), 90% males, 48% current and 42% former smokers, 37% diagnosed of COPD. 2. Tumor characteristics:

- Histology: squamous 57%, adenocarcinoma 36%.

- Grade: 47% moderately differentiated, 33% undifferentiated. - Pathological staging by TNM edition.

Table: 1351P

7th edition n (%)		8th edition n (%)	
IA	44 (24)	IA1	5 (2.7)
		IA2	23 (12.6)
		IA3	26 (14.3)
IB	69 (38)	IB	30 (16)
IIA	20 (11)	IIA	27 (15)
IIB	49 (26)	IIB	46 (25)
IIIA	0	IIIA	25 (14)

3. median OS in our cohort of patients = 79 months (IC95% = 58-100) log Rank test p=NS me OS by pathological stage defined by 8th ed. AJCC: IA1 97 m (IC95% 37-158) IA2 108 m (IC95% 54-162) IA3 139 m (IC95% 13-266) IB 71 m (IC95% 45-96) IIA 35 m (IC95% 19-51) IIB 62 m (IC95% 34-90) IIIA 56 m (IC95% 0-141) 4. OS stage I vs II - by 7th edition: 93 vs 66 m, log Rank test, p = 0.016 - by 8th edition: 97 vs 70 m, log Rank test, p = 0.026 5. COPD as an adverse prognostic factor: meOS = 111 vs 55 months, log Rank test, p = 0.002

Conclusions: In our cohort of patients, the 8th edition of AJCC classification identifies better than the previous edition a group of patients with worse prognosis regarding to a higher size of the tumour and shiftening their pathological stage. Due to the small sample, we couldn't prove a more accurate prognostic information for the new stage I

categories in the 8th edition. COPD is confirmed in our serie as an adverse prognostic clinical factor.

1352P A serum miRNA biomarker panel for the detection of early stage non-small cell lung cancer

L. Ying[1], R. Zou[2], L. Du[3], L. Shi[4], N. Zhang[1], J. Jin[1], J. Wu[1], F. Zhang[1], K. Chen[1], M. Huang[1], Y. Zhang[5], A. Lin[6], H. Yu[7], L. Zhou[2], W. Mao[8], D. Su[9]

[1]Zhejiang Cancer Hospital, Zhejiang Cancer Research Institution, Hangzhou, China, [2]MIRXES (hangzhou) Biotechnology Co, MIRXES (hangzhou) Biotechnology Co, Hangzhou, China, [3]Zhejiang Cancer Hospital, Zhejiang Cancer Center, Hangzhou, China, [4]Zhejiang Cancer Hospital, Radiology Department, Hangzhou, China, [5]Zhejiang Cancer Hospital, Department of Clinical Laboratory, Hangzhou, China, [6]Taizhou Hospital of Zhejiang Province, Human Tissue Bank/Medical Research Center, Taizhou, China, [7]University of Hawaii Cancer Center, University of Hawaii Cancer Center, Hawaii, USA, [8]Zhejiang Cancer Hospital, Department of Thoracic Surgery, Hangzhou, China, [9]Zhejiang Cancer Hospital, Department of Pathology, Hangzhou, China

Background: Non-small cell lung cancer is the most prevalent cancer and leading cause of cancer death worldwide. Low-dose spiral computed tomography (LDCT) scan is being recommended as a screening test for smokers in the US. However, the poor specificity of LDCT has raised significant concerns about its high chance of false positive results. This study aimed to develop a blood miRNA based molecular diagnostic test for the detection of early stage lung cancer.

Methods: The three-phase study was designed with a total of 948 cancer-free controls, and 768 patients with NSCLC. In the discovery phase, more than 400 miRNAs were profiled with MiRXES's qPCR based high throughput assay platform through a highly defined Chinese male smoker case-control cohort (n = 424) where the cases were collected from Zhejiang Cancer Hospital and the controls were collected form the LDCT screening program in Zhejiang province, China. Differentially expressed miRNAs were further validated in another Chinese case-control cohort (n = 432) collected from similar sources and a white case-control cohort (n = 218) collected from the EU and US. Finally, the identified miRNAs were further assessed in three additional Asian cohorts: a Chinese cohort collected from the similar sources (n = 237), a Chinese cohort collected from independent sources (n = 340), and a Singaporean cohort (Chinese, Malay and Indian population) (n = 65).

Results: 29 miRNA biomarkers with p-value (FDR) <0.01 and more than one z-score (standardized score) difference were identified in the discovery phase. With multiple time of two-fold cross-validation, 5 miRNAs were found to be minimally required to form the biomarker panel for the accurate prediction of early stage lung cancer and the panel gives 0.936 (95% CI, 0.912-0.957) AUC for the Chinese validation cohort and 0.970 (95% CI, 0.939-0.986) AUC for the white validation cohort. The 5-miRNA biomarker panel were then further validated in three additional Asian cohorts, giving 0.973 (95% CI 0.950-0.986) AUC for similarly sourced Chinese cohort, 0.916 (95% CI, 0.852-0.949) AUC for the independently sourced Chinese cohort, and 0.911 (95% CI, 0.822-0.963) AUC for the Singaporean cohort, respectively.

Conclusions: The five-miRNA panel in serum may serve as a potential non-invasive biomarker in detecting early stage NSCLC.

1353P Split-lobe resections versus lobectomy for stage IA-IB peripheral non-small cell lung cancer

A. Levitckii[1], D. Chichevatov[2], M. Ter-Ovanesov[1], E. Sinev[2]

[1]Thoracic Oncology, City Clinical Hospital, Moscow, Russian Federation, [2]Thoracic Oncology, Regional Cancer Center, Penza, Russian Federation

Background: To compare left-upper, right and left inferior split-lobe procedures with the same lobectomies for surgical treatment of peripheral non-small cell lung cancer of stage IA-IB, originating from the large pulmonary lobes.

Methods: We analyzed the results of the treatment of 116 patients, who underwent surgical procedures for clinical stage IA-IB non-small cell lung cancer. Patients were divided into two groups, based on the type of procedure performed. Lobectomies were performed in 78 (67,2%) patients, split-lobe resections of the large pulmonary lobes in 38 (32,8%): upper left trisegmentectomy (S1,2,3) in 14 patients, resection of the lingula (S4,5) in 7, anatomical segmentectomy S6 in 15, resection of basal segments in 2 patients. Radical mediastinal lymph node dissection was performed in all cases. The primary end-points of the analysis were relapse-free survival (RFS), overall survival (OS) and rate of recurrence (RR).

Results: There were no significant differences in morbidity between lobectomy and split-lobe resection groups (7,7% vs. 5,3%; p=NS). RR was registered in 9 patients in the lobectomy group vs 7 patients from split-lobe group (11,5% vs. 18,4%; p=NS). Regional recurrence in hilar lymph nodes was confirmed only in one patient from split-lobe group 28 months after right anatomical segmentectomy S6. Survival analysis did not show significant differences between lobectomy and split-lobe groups. Overall 5-year survival was 82,0% (95% confidence interval, 70,3-93,7%) in lobectomy group versus 74,8% (95% confidence interval, 57,5-97,1%) in split-lobe group (p = 0,369). Relapse-free 5-year survival was 85,2% (95% confidence interval, 76,8-94,6%) in lobectomy group versus 76,2% (95% confidence interval, 59,6-92,8%) in split-lobe group (p = 0,353). Cox regression analysis with multiple factors demonstrated statistical significance for overall (p = 0,03) and relapse-free (p = 0,025) survival only for pT1-T2 tumour descriptors.

Conclusions: Split-lobe procedures and lobectomy have equivalent in-hospital morbidity and long-term results for patients with clinical stage IA-IB peripheral non-small cell LC. In the future split-lobe resection can be recommended as a standard procedure for early stage peripheral non-small cell LC.

1354P Patient reported outcomes after the treatment of early stage non-small cell lung cancer by stereotactic body radiotherapy compared to surgery

L. Alberts[1], H.B. Wolff[2], E.A. Kastelijn[1], F.J. Lagerwaard[3], S. Senan[3], S.Y. El Sharouni[4], F.M.N.H. Schramel[1], V.M.H. Coupe[2]

[1]Pulmonology, St. Antonius Ziekenhuis, Nieuwegein, Netherlands, [2]Epidemiology and Biostatistics, Vrije University Medical Centre (VUMC), Amsterdam, Netherlands, [3]Radiation Oncology, Vrije University Medical Centre (VUMC), Amsterdam, Netherlands, [4]Radiotherapy, University Medical Center Utrecht, Utrecht, Netherlands

Background: As survival seems to be equal after either stereotactic body radiotherapy (SBRT) or surgery for patients with stage I non-small cell lung cancer (NSCLC), treatment impact on the quality of life (QoL) after is essential for well-informed decision making. After a surgical resection, deterioration of QoL is often observed in the early post-treatment period, whereas QoL is reported to be maintained after SBRT. The aim of this study is to compare QoL in the first year after SBRT and surgery.

Methods: QoL was assessed by using the European Organisation for Research and Treatment of Cancer (EORTC) Quality of Life Questionnaire (QLQ-C30) and the lung cancer-specific supplementary questionnaire (QLQ-LC13) at baseline and 3, 6 and 12 months after treatment. Two prospectively collected databases of patients with clinically proven stage I NSCLC, from two large hospitals in the Netherlands, were pooled (n = 306; 256 patients were treated with SBRT and 41 patients with surgery). This observational study design is susceptible to selection bias. To correct for confounding, propensity-scores were calculated using forward stepwise logistic regression, to be selected for surgical treatment. For the final model, age, dichotomized ECOG score and FEV1% predicted scores were selected.

Results: The 41 surgical patients were matched to 41 SBRT patients on propensity score with a 1:1 ratio. At baseline, patients in the surgery group report a lower health related-QoL compared to patients in the SBRT group. However, during the first year after treatment, no clinical meaningful differences in social-, role, physical, emotional and cognitive domains were observed between patients treated using either modality. Furthermore, no clinical meaningful differences in QLQ-LC13 scores (dyspnea, pain, fatigue) after treatment were observed.

Conclusions: This study comparing a matched cohort, revealed no clinical significant differences in QoL following either SBRT or surgery for an early stage NSCLC.

1355P miR-200s in operated NSCLC: Main drivers of epithelial to mesenchymal transition and independent prognostic factors

A. Legras

Thoracic Surgery, Assistance Publique - Hopitaux De Paris, Paris, France

Background: Epithelial-to-mesenchymal transition (EMT) plays essential roles in non-small cell lung cancer (NSCLC) progression and was related to TWIST1 reactivation. Among regulators of EMT, microRNAs are extensively studied. This work aimed at identifying microRNAs that might be important regulators of TWIST1 and EMT in NSCLC.

Methods: We performed miRSeq in a series of EGFR-mutated lung adenocarcinomas (n = 24, series A) and identified a set of miRNAs (n = 12) associated to TWIST1 reactivation. These miRNAs and additional EMT-related miRNAs selected from the

literature and from TCGA public data were reanalysed by Fluidigm® technology on the same series. Two miRNAs were significantly associated with TWIST1 reactivation. We then quantified these two miRNAs in a series of 176 consecutive operated NSCLC (series B), in addition to E-cadherin, Jup, N-cadherin, Zeb1, Snai1, Twist1, Vimentin, TCF3 and CD44 using qPCR. Results were validated using TCGA public data.

Results: MiR-200a-3p and miR-429 were significantly associated with TWIST1 reactivation ($p = 0.018$) in series A, not confirmed by the 16 EGFR-mutated lung adenocarcinomas of series B, but by TCGA analysis ($p = 0.03$). In series B, miR-200a-3p and miR-429 expression levels were highly correlated ($p < 0.001$) together and associated to Twist1 up-regulation ($p = 0.02$ and $p = 0.07$, respectively), EMT ($p = 0.003$) and stem cell features ($p < 0.05$). Low miR-200a-3p and miR-429 expression levels were significantly associated with overall survival in multivariate analyses (Cox; $p = 0.008$ and $p = 0.01$, respectively), thus identified as independent prognostic factors. TCGA overall survival multivariate analyses confirmed this finding ($p < 0.02$).

Conclusions: This study provides new insights on the clinical impact of miR-200 family members down-regulation in localized NSCLC. EMT targeting should be considered as a therapeutic option for a subset of NSCLC patients.

Bourgogne Franche-Comté, INSERM, EFS BFC, UMR1098, Interactions Hôte-Greffon-Tumeur/Ingénierie Cellulaire et Génique, LabEx LipSTIC,, Besançon, France, [2]INSERM CIC-1431 Clinical Investigation Center in Biotherapies, Plateforme de Biomonitoring, Besançon, France, [3]CIC-1431, University Hospital of Besançon, Besançon, France, [4]University Hospital of Besançon, Department of Pneumology, Besançon, France, [5]Service de Chirurgie Thoracique, AP-HP, Hôpital Européen Georges Pompidou, Paris, France, [6]Service d'Oncologie Médicale, AP-HP, Hôpital Européen Georges Pompidou, Paris, France

Background: Natural killer (NK) cells are innate effector lymphocytes involved in cancer immunosurveillance. Here we investigated the distribution, function and prognosis role of circulating NK cell subsets in non-small cell lung cancer (NSCLC).

Methods: Blood samples from 176 NSCLC patients were collected before any treatment and from 41 healthy donors (HD) as control. The phenotype and cytotoxic functions of NK cells were performed by multicolor flow cytometry. Kaplan–Meier method was used to estimate survival.

Results: NSCLC patients exhibited three distinct NK cell subsets in blood such as $CD56^{dim}$ $CD16^{+}$, $CD56^{dim}$ $CD16^{-}$ and $CD56^{bright}$ NK cells. However, a lower rate of $CD56^{dim}$ $CD16^{+}$ NK cells and a higher rate of $CD56^{dim}$ $CD16^{-}$ NK cells were found in patients as compared to HD. Unsupervised clustering analysis of activating receptors expression such as NKG2D, NKp30, NKp44, and NKp46 identified four groups of patients with distinct circulating NK cell profiles. We showed that the rate of circulating $NKp46^{+}$ NK cells was inversely correlated with overall survival (OS). Consistently, the median OS in high versus low level $NKp46^{+}$ NK cell group was 16 and 27 months respectively ($P = 0.04$). This effect was mainly driven by $NKp46^{+}$ $CD56^{dim}$ $CD16^{+}$ NK cells subset ($P = 0.02$). Finally, blocking NKp46 receptor in vitro was able to restore antitumor T cell immunity suggesting an inhibitory role of $NKp46^{+}$ NK cells.

Conclusions: Altogether, our results show a distinct pattern of circulating NK cell subsets in NSCLC and also support the immune regulatory property of $NKp46^{+}$ NK cell subsets. This study provides important insights on circulating $Nkp46^{+}$ NK cell subsets as potential prognosis factor in lung cancer.

1357P A positive correlation between the EZH2 and PD-L1 expression in patients with resected lung adenocarcinoma

G. Toyokawa[1], K. Takada[2], R. Hamamoto[3], Y. Yamada[4], T. Tagawa[2], F. Shoji[1], K. Yamazaki[1], Y. Oda[4], S. Takeo[1]

[1]Department of Thoracic Surgery, National Hospital Organization, Kyushu Medical Center, Fukuoka, Japan, [2]Department of Surgery and Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan, [3]National Cancer Center, Division of Molecular Modification and Cancer Biology, Tokyo, Japan, [4]Department of Anatomic Pathology, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan

Background: Enhancer of zeste homolog 2 (EZH2) is reported to be involved in lung cancer pathogenesis via the epigenetic regulation of various genes. Recently, EZH2 was shown to control mechanisms of adaptive resistance to immunotherapy in melanoma; however, the association between EZH2 and programmed death-ligand 1 (PD-L1), which reflects the tumor microenvironment, remains poorly understood.

Methods: A total of 428 patients with resected lung adenocarcinoma were analyzed for their EZH2 and PD-L1 expression by immunohistochemistry and evaluated to determine the association between the EZH2 and PD-L1 expression.

Results: Among 428 patients, the EZH2 expression was identified in 219 (51.2%), while the PD-L1 expression was observed in 88 (20.6%). The recurrence-free and overall survival (RFS and OS, respectively) were significantly shorter in patients with the EZH2 expression than in those without it. A multivariate analysis showed that EZH2 remained an independent prognosticator for the RFS and OS. Patients with the EZH2-positive lung adenocarcinoma exhibited a significantly higher expression of PD-L1 than those without it. A logistic regression analysis with backward elimination revealed that the presence of lymphatic and vessel invasion and PD-L1 positivity were independently associated with the EZH2 expression, while age over 70, the presence of vessel invasion, wild-type epidermal growth factor receptor, and EZH2 positivity were significantly associated with the PD-L1 expression.

Conclusions: EZH2-expressing lung adenocarcinomas were shown to express PD-L1 protein more frequently than non-expressing lesions. This study provides the first evidence of a possible association between the EZH2 and PD-L1 expression in patients with resected lung adenocarcinoma.

1358P Comprehensive analysis for immune profiles of tumor microenvironment in non-small cell lung cancers: Prognostic effect of immunomodulatory molecules

K. Takamochi[1], M. Hosoya[2], K. Mogushi[2], T. Hayashi[3], M. Ito[4], H. Kawaji[4], Y. Hayashizaki[4], K. Suzuki[1]

[1]Department of General Thoracic Surgery, Juntendo University School of Medicine, Tokyo, Japan, [2]Intractable Disease Research Center, Juntendo University Graduate School of Medicine, Tokyo, Japan, [3]Department of Human Pathology, Juntendo University School of Medicine, Tokyo, Japan, [4]Preventive Medicine and Applied Genomics Unit, Riken Advanced Center for Computing and Communication, Yokohama, Japan

Background: Therapies targeting immune checkpoints have recently shown promising activity in non-small cell lung cancer (NSCLC) patients. T-cell activation is controlled by the balance of co-stimulatory molecules and co-inhibitory molecules (immune checkpoint molecules).

Methods: A comprehensive analysis was performed for immune profiles of tumor microenvironment in NSCLCs using cap analysis of gene expression (CAGE). CAGE is a method used to quantify promoter activities across the whole genome by determining the 5' ends of capped RNA molecules with next-generation sequencing. Gene expressions of PD-L1, PD-L2, co-inhibitory molecules (CTLA-4, PD-1, TIM-3, BTLA, VISTA, and LAG-3), co-stimulatory molecules (CD28, OX40, GITR, CD317, CD27, and HVEM), and markers of immune cells (CD4, CD8, CD25, Foxp3, CD68, and CD204) were quantified using RNA extracted from frozen tumor tissue samples of 100 surgically resected NSCLCs (71 adenocarcinomas (AD), 22 squamous cell carcinomas (SQ), and 7 other histologic types).

Results: NSCLCs in this study were classified into two groups: tumors with high expression of almost all immunomodulatory targets (immunoreactive) and tumors with intermediate or low expression (non-immunoreactive). Co-stimulatory and co-inhibitory molecules were simultaneously highly expressed in immunoreactive tumors. The prognosis of immunoreactive ADs was worse than that of non-immunoreactive ADs regardless of histologic grade or EGFR mutation status ($P = 0.002$). However, an opposite trend was observed in SQs ($P = 0.789$). In ADs, high expression of CD137, TIM-3, and HVEM was an unfavorable prognostic factor. In SQs, high expression of CTLA-4 and LAG-3 was a favorable prognostic factor, and whereas HVEM expression was unfavorable.

Conclusions: NSCLCs can be classified into immunogenic and non-immunogenic tumors. The prognostic effect of immunomodulatory molecules differs according to histologic types and gene expression profiles of immune cells.

1359P Association between PD-L1 expression and survival in early stage non-small cell carcinoma

E. Gálvez[1], C. Gálvez Muñoz[2], A. Cotes Sanchís[1], A. Gonzaga López[1], M.M. Llorente Ostiategui[1], M. Montero Gómez[1], I. Aranda López[3], C. Llorca Ferrandiz[1]
[1]Oncología, Hospital General de Elda, Elda, Spain, [2]Cirugía Torácica, Hospital General de Alicante, Alicante, Spain, [3]Anatomía Patológica, Hospital General de Alicante, Alicante, Spain

Background: Programmed death-ligand 1 (PD-L1) is used to predict response to immunotherapy. Temporal variability in the expression of PD-L1 in tumor cells has been reported; we wanted to assess the prevalence and prognostic role of PD-L1 expression in patients with resected non-small cell lung carcinoma (NSCLC) in initial stages with negative ganglia.

Methods: We analyzed tumor tissue of 170 patients with NSCLC stages I and II (pN0), no adjuvant or neoadjuvant therapy. Immunohistochemical staining of PD-L1 (Dako PD-L1 IHC 22C3 pharmDx) was performed on sections of tissue microarrays (TMAs), being able to be carried out in 165 cases (97%). The results were correlated (Ji Square and Fisher test) with clinicopathological variables (gender, age, smoking, pathological stage, histological type, nuclear grade, Ki67). For the analysis of survival (disease-free (DFS) and overall (OS) survival), the curves of Kaplan-Meier were used with the test of the logarithmic ranges (log rank test), and the proportional method of Cox taking the negative values as reference.

Results: The median age was 66 years (IQR 60-73), 135 men and 35 women. Eighty-eight per cent of them were smokers. The median follow-up was 64 months (range 1-163). The distribution by stages was: 51% of pathological stage IA, 31% of IB stage and 18% corresponded to stage II with pN0. Regarding histology there were 57% adenocarcinomas, 34% squamous cell carcinomas and 7% large cell carcinomas. PD-L1 expression was detected in 28.8% of the cases: 19.8% of the adenocarcinoma tumours and 41.3% of the squamous subtypes. We found a PD-L1 expression greater than 5% in 24.7% of cases and 11.8% of the total showed a PD-L1 expression $\geq$ 50%. The median DFS was 59.6 months (IQR 27-85) and OS 64.2 months (IQR 39.9-94.9). A statistically significant association was observed between expression of PD-L1 and younger age (inverse relationship, p = 0,033) and histologic subtype (lower expression in squamous type, p = 0,029). Kaplan-Meier analysis showed less DFS in positive PD-L1 patients. No significant differences were observed in relation to overall survival.

Conclusions: The expression of PD-L1 is associated with morphological data of greater aggressiveness and is a risk factor for relapse in NSCLC in early stages without positive ganglia.

1360P Neoadjuvant pembrolizumab (Pembro) for early stage non-small cell lung cancer (NSCLC): Initial report of a phase I study, MK3475-223

A. Ben Nun[1], N. Golan[1], E. Ofek[2], D. Urban[3], I. Kamer[3], D. Simansky[1], A. Onn[4], A. Ackerstein[3], S.P. Raskin[3], T. Shulimzon[4], N. Zeitlin[1], I. Redinsky[3], S. Halperin[3], M. Jurkowicz[3], J. Bar[3]
[1]Department of Thoracic Surgery, Chaim Sheba Medical Center, Ramat Gan, Israel, [2]Department of Pathology, Chaim Sheba Medical Center, Ramat Gan, Israel, [3]Institute of Oncology, Chaim Sheba Medical Center, Ramat Gan, Israel, [4]Institute of Pulmonology, Chaim Sheba Medical Center, Ramat Gan, Israel

Background: NSCLC is the most common cause of cancer-related death. Even clinical stage I or II tumors that are completely resected harbor a 5-year survival of only 30-50%. Immunotherapy is being investigated now as adjuvant therapy and might improve those results. We hypothesize that neo-adjuvant immunotherapy is a feasible, safe and effective treatment for early stage NSCLC.

Methods: MK3475-223 is a phase I study, testing neoadjuvant Pembro for stage I and II NSCLC. Study design is based on a classical 3 + 3 cohort, but the differences between cohorts are not drug dose but number of treatments (1st cohort 1 treatment, 2nd and 3rd cohorts 2 treatments with a 3 weeks (wk) interval between them) prior to surgery, and interval from last dose to surgery (1st cohort 3 wks, 2nd cohort 2 wks, 3rd cohort 1 wk). All Pembro treatments are 200mg. Primary objectives are to determine safety, recommended phase 2 dose/schedule, pathological and radiological response. Dose limiting toxicities (DLT) were defined as significant surgical complications (bleeding, delayed wound healing, acute respiratory distress syndrome, prolonged air-leak) or a significant delay of surgery. DLT period was defined as 30 days post-surgery.

Results: To date, two cohorts (6 patients (pts)) have been fully recruited and completed the DLT period. No DLT has occurred. Adverse events (AEs) are within the recognized AE profile of Pembro and of thoracic surgical procedures. No significant responses were seen in the 1st cohort (1 Pembro treatment, 3 wks later surgery). Out of 3 pts on the 2nd cohort (2 Pembro treatments, 2 wks later surgery), 2 pts (66.6%) demonstrate near complete pathologic response, with less than 1% of tumor cells left estimated. The study is ongoing and continuing to recruit, currently recruiting the final cohort (2 pembro treatments, 1 wk later surgery), to be followed by an expansion cohort.

Conclusions: Neoadjuvant Pembro is a promising option for early stage NSCLC. Initial data suggest the safety of this approach. The trial will provide initial evidence as well as correlative studies regarding the efficacy of this approach.

1361P Neoadjuvant chemotherapy with bevacizumab followed by surgery for clinical stage II/IIIA non-squamous non-small cell lung cancer: Survival results from a phase II feasibility study (NAVAL)

Y. Tsutani[1], Y. Miyata[1], K. Suzuki[2], K. Takamochi[2], F. Tanaka[3], H. Nakayama[4], Y. Yamashita[5], M. Oda[6], M. Tsuboi[7], M. Okada[1]
[1]Surgical Oncology, Hiroshima University, Hiroshima, Japan, [2]Thoracic Surgery, Juntendo University, Tokyo, Japan, [3]Thoracic Surgery, University of Occupational and Environmental Health, Kokura, Japan, [4]Thoracic Surgery, Kanagawa Cancer Center, Yokohama, Japan, [5]Thoracic Surgery, Kure Medical Center, Kure, Japan, [6]Thoracic Surgery, Kanazawa University, Kanazawa, Japan, [7]Thoracic Surgery and Oncology, National Cancer Center Hospital East, Kashiwa, Japan

Background: We previously reported that neoadjuvant cisplatin, pemetrexed, and bevacizumab followed by surgery is safe and feasible in patients with clinical stage II/IIIA non-squamous non-small cell lung cancer (NSCLC) (NAVAL study). The purpose of this study is to evaluate survival results, which are secondary endpoints of NAVAL study.

Methods: In a phase II feasibility study of neoadjuvant chemotherapy with cisplatin (75 mg/m^2), pemetrexed (500 mg/m^2), and bevacizumab (15 mg/kg) followed by surgery for resectable clinical stage II/IIIA non-squamous NSCLC, progression-free survival (PFS) and overall survival (OS) were analyzed. Patients who had less than 33% residual viable primary tumor after neoadjuvant chemotherapy were defined as pathologic responders. Others were defined as non-responders.

Results: Among all 30 patients, 25 underwent surgical resection after 3 cycle of neoadjuvant chemotherapy with bevacizumab, and 3 underwent off protocol surgical resection. Two-year PFS rate and 5-year PFS rate were 41.5% and 34.6%, respectively. Two-year OS rate and 5-year OS rate were 70.0% and 60.0%, respectively. Six (20%) patients were classified as pathologic responders, whereas 24 (80%) as non-responders. There was significant difference in PFS between pathologic responders (5-year PFS rate, 100%) and non-responders (5-year PFS rate, 17.5%; P = 0.002). Also, there was significant difference in OS between pathologic responders (5-year OS rate, 100%) and non-responders (5-year OS rate, 43.5%; P = 0.006).

Conclusions: Neoadjuvant cisplatin, pemetrexed, and bevacizumab followed by surgery is effective for clinical stage II/IIIA non-squamous NSCLC. Long-term survival after surgery is expected for pathologic responders, whereas additional therapy will be needed for non-responders.

1362P Clinical outcomes and treatment strategies of sarcomatoid carcinoma of the lung

Y. Wang
Thoracic Surgery, Hebei Provincial Tumor Hospital, Shijiazhuang, China

Background: Sarcomatoid carcinoma of the lung is characterized by worse prognosis, and generally felt to be chemo-refractory compared with other non-small cell lung cancer. We conduct this retrospective study to investigate the clinical characteristics of patients with sarcomatoid carcinoma of the lung and determine the optimal treatment strategies.

Methods: We reviewed the medical records of 8176 patients with resected lung cancer in a single high-volume institution between 2008 and 2015. All patients with pathologically diagnosed sarcomatoid carcinoma were evaluated. Clinicopathologic data were analyzed using Kaplan-Meier analysis and Cox regression analysis. Subgroups stratified by pathological stage were analysed to determine the optimal treatment modality. We also conducted subgroup analysis of overall survival among pulmonary sarcomatoid carcinoma and other NSCLC patients.

Results: Kaplan-Meier and Cox regression analyses showed pathological stage (8th edition) is the independent prognostic factor (P = 0.001, HR = 2.601, 95%CI(1.447-4.675)) for pulmonary sarcomatoid carcinoma. Overall survival favored other NSCLC over PSC across subgroups. Male (HR = 0.695, 95%CI(0.505-0.955)), age above 60

years (HR = 0.622, 95%CI(0.417-0.928)), never-smoker (HR = 0.583, 95%CI(0.383-0.888)), patients who had no alcohol abuse history (HR = 0.597, 95%CI(0.416-0.856)), tumor size >5cm (HR = 0.700, 95%CI(0.492-0.995)), tumor stage T1 (HR = 0.383, 95%CI(0.167-0.877)), tumor location in peripheral (HR = 0.577, 95%CI(0.367-0.906)), or in both peripheral and central (HR = 0.626, 95%CI(0.424-0.923)), node stage N0 (HR = 0.599, 95%CI(0.403-0.891)), stage Ia(HR = 0.362, 95%CI(0.131-1.000)), stage Ib(HR = 0.450, 95%CI(0.278-0.729)), surgery alone (HR = 0.712, 95%CI(0.507-0.999)).

Conclusions: Pathological stage (8th edition) is independent prognostic factor for sarcomatoid carcinoma of the lung. Surgery followed by adjuvant chemotherapy should be considered for stage I pulmonary sarcomatoid carcinoma. Further prospective studies are needed to confirm these results.

1366P The impact of the new TNM classification on survival of patients in stage III non-small cell lung cancer

M. Vrankar, K. Stanic

Radiotherapy, Institute of Oncology Ljubljana, Ljubljana, Slovenia

Background: In the new 8th TNM classification, stage III non-small cell lung cancer (NSCLC) is divided into three subgroups. Stage IIIA includes T4 N0 M0 and T3/4 N1 M0 tumours as well as T1/T2 N2 M0 tumours. Stage IIIB tumours are either T3/T4 N2 M0 or T1/T2 N3 M0. Stage IIIC involves T3/T4 N3 M0 tumours. Beside new IIIC stage, the greatest change is reclassification of T category based on dimension. Tumours larger than 7 cm that were previously T3 are now staged T4. The anatomic extent of disease is the base of the TNM classification with impact on survival. The aim of this analysis was to determine applicability of the new 8th TNM edition on survival of stage III NSCLC treated with combined radiochemotherapy between 2005 and 2010 in our institution.

Methods: A total of 101 patient with stage III NSCLC treated between September 2005 and November 2010 with induction chemotherapy and radiochemotherapy were included in long term survival analysis of TNM restaging. Results of survival are presented for the 7^{th} and 8^{th} edition in view of the revised T stage.

Results: After a median follow up of 117.5 months, median overall survival (mOS) of stage IIIA patients according to the 7th TNM classification was significantly longer than those of stage IIIB patients (30.8 months and 19.0 months, $p = 0.005$). Redefinition of the stages according to the new 8th TNM classification showed similar mOS for patients in stage IIIA and stage IIIB (21.6 months and 24.9 months), but much shorter mOS for stage IIIC patients with 6.6 months ($p = 0.885$). Of 101 patient 13 were up-graded from T3 to T4 according to new TNM classification. In the 7th TNM classification T3N2 was in stage IIIA and T4N2 in stage IIIB, while in 8th TNM classification both are in stage IIIB. According to 7th TNM classification, mOS of patients in stage T3N2 was significantly longer with 60.0 months than in stage T4N2 with 19.2 months ($p = 0.004$). After the revision there is no difference, mOS of patients with T3N2 was 28.4 months and with T4N2 was 31.4 months ($p = 0.478$).

Conclusions: The statistical difference in survival between subgroups of stage III shown in the old TNM classification did not appear in the new classification. Other factors could affect prognosis that are patient, tumour and treatment related.

1367P Survival in never-smokers with non-small cell lung cancer: A population-based study from Sweden

L. Löfling[1], S. Bahmanyar[1], A. Karimi[2], H. Kieler[1], M. Lambe[3], K. Lamberg Lundström[2], F. Sandin[3], G. Wagenius[4]

[1]Centre for Pharmacoepidemiology, Medicine Solna, Karolinska Institute, Stockholm, Sweden, [2]Pulmonary Medicine, University Hospital Uppsala, Uppsala, Sweden, [3]Regional Oncologic Centre, Uppsala, Sweden, [4]Oncology, Karolinska University Hospital, Solna, Sweden

Background: Tobacco smoking is the major risk factor for lung cancer. However, approximately 10% of patients diagnosed with lung cancer have never smoked and knowledge of their characteristics and survival remain limited. Specific genetic alterations, e.g. ALK (anaplastic lymphoma kinase) rearrangements and EGFR (epidermal growth factor receptor) mutations, are more common in never-smoking lung cancer patients than in current or former smokers. We aimed to investigate characteristics of patients with different smoking history and estimate their lung cancer-specific survival.

Methods: This study was based on data from the Lung Cancer Database Sweden generated by record linkage between the Swedish National Lung Cancer Register and other population-based registers. Patients diagnosed with primary non-small cell lung cancer between 2002 and 2016 were included. The Kaplan-Meier method was used to estimate lung cancer-specific survival by smoking history (never-smokers, former smokers, and current smokers).

Results: In total, 41,262 patients with lung cancer were included, of those 4,624 (11.2%) had never smoked. Never-smokers were older at time of the diagnosis (median: 73 years, Inter Quartile Range (IQR)=63-80) than current smokers (median: 67 years, IQR=61-73) and former smokers (median: 72 years, IQR=66-78). Women were overrepresented among never-smokers (66%) than among current (49%) and former smokers (43%). Adenocarcinoma was the most frequent histological subtype in all groups, but was proportionally more frequent in never-smokers (77%) compared to current smokers (52%) and former smokers (57%). The estimated overall (all stages) 2-year cause specific lung cancer survival was higher in never-smokers (35.9%, 95% CI 34.4 - 37.5) than among current smokers (29.4%, 95% CI 28.7 - 30.2) and former smokers (30.7%, 95% CI 30.0 -31.4).

Conclusions: The observed longer survival and the difference in histopathology suggest that tumours in never-smokers have a different pathogenesis and a different behaviour than tobacco-associated lung cancer. In further analyses, we will examine observed differences in outcomes in more detail, including the modifying role of other prognostic factors.

1368P Clinical features and prognosis of eighty-five patients with primary pulmonary lymphoepithelioma-like carcinoma

Q.Y. Yin, G.Y. Gao, C.Z. Zhou, Z. Zhu, Y.Q. Liu, X.H. Xie, X.Q. Lin, Z.H. Xie, J.X. Zhang, O.Y. Ming, S.Y. Li, R.C. Chen

State Key Laboratory of Respiratory Disease, National Clinical Research Center of Respiratory Disease, Guangzhou Institute of the Respiratory Disease, The 1st Affiliated Hospital of Guangzhou Medical University, Guangzhou, China

Background: Pulmonary lymphoepithelioma-like carcinoma (PLELC) is a rare subtype of lung cancer that is less reported and not well understood around the world.

Methods: A retrospective analysis of clinical features for 85 patients was conducted to determine the prognostic factors in terms of age, gender, radiographic features, serum tumor markers, TNM stages, pathological features, treatment and prognosis.

Results: PLELC preferentially affects the young (< 60 years old: 71.8%) nonsmokers (72.9%), without significant difference in gender. The median follow-up time was 15 months (1-37 months) for the whole group and most patients were in the early stage with opportunity of operation (50.6%). For the advanced stage group, patients mainly received chemotherapies and radiotherapies, the 0.5-year and 1.5-year PFS rates were 61% and 29%, respectively. The TNM stage ($P = 0.014$) and performance status (PS) ($P = 0.040$) were associated with PFS significantly in the univariate analysis, while TNM stage was an independent prognostic factor in multivariate analysis ($P = 0.026$). In the subtype analysis, patients in the advanced stage receiving Gemcitabine plus platinum (GP group) or Paclitaxel plus platinum (TP group) had better PFS than Pemetrexed plus platinum (PP group) ($P = 0.005$).

Conclusions: PLELC had a better prognosis compared with other types of non-small cell lung cancer (NSCLC) and was sensitive to radiotherapy and chemotherapy. The current results recommended that the GP and TP should be used as first-line treatment of PLELC. The TNM stage and PS were predictive in prognosis of PLELC patients.

1369P Meta-analysis of prognostic factors of completely resected pathologic N2 stage IIIA non-small cell lung cancer including 11,384 patients

X. Zhan, N. Li
Key Laboratory of Cancer Proteomics of Chinese Ministry of Health, Xiangya Hospital, Central South University, Changsha, China

Background: Patients with IIIA-pN2 non-small cell lung cancer (NSCLC) are a heterogeneous group, So this meta-analysis aimed to determine prognostic factors and compare different postoperative adjuvant therapies on survival.

Methods: MEDLINE, Embase, Web of Science were searched to identify relevant trials up to May 2017. Datas of univariate and multivariate analyses of prognostic factors for overall survival (OS) were extracted and calculated by hazard ratios (HR) and 95% confience intervals (95% CI). Pooled survival curves were constructed by Engauge Digitizer and RStudio.

Results: Overall 26 trials comprising 11,384 patients were included. The subgroup analysis for OS indicated that increased age (HR 1.02, 95%CI 1.02-1.02, $P < 0.00001$), male (HR 1.37, 95%CI 1.25–1.49, $P < 0.00001$), increased pathologic T stage (HR 1.27, 95%CI 1.12–1.45, $P = 0.0003$), multiple N2 metastases (HR 1.53, 95%CI 1.34–1.74, $P < 0.0001$), positive of skip matestasis (HR 2.07, 95%CI 1.25–3.42, $P < 0.0001$), involvement of N1 nodal station (HR 1.42, 95%CI 1.13–1.70, $P = 0.003$), pneumonectomy (HR 1.42, 95%CI 1.16–1.73, $P = 0.0007$), increasing clinical T classification (HR 1.48, 95%CI 1.09–2.02, $P = 0.01$), increasing clinical N classification (HR 1.75, 95%CI 1.23–1.48, $P = 0.002$) were significantly associated with poor OS and N downstaging (HR 0.46, 95%CI 0.37–0.68, $P < 0.0001$), PORT (HR 0.76, 95%CI 0.64–0.72, $P = 0.004$), adjuvant chemotherapy (HR 0.69, 95%CI 0.56–0.85, $P = 0.007$) were significantly associated with better OS. The 5-year disease-free survival rate was 38.9% in postoperative chemoradiotherapy group and 29.5% in postoperative chemotherapy group ($p = 0.001$). Survival was improved in patients with pN2 disease who received postoperative radiotherapy, both in the chemotherapy (5-year survival rate, 65.3% vs. 49.3%) and observation arm (5-year survival rate, 53.3% vs. 32.3%).

Conclusions: The main prognostic factors were age, gender, clinical T stage, pathologic T stage, operation procedure, clinical N status, involved N2 stations, N1 nodes involved, N2 Skip metastasis, N downstaging, postoperative radiotherapy as well as adjuvant chemotherapy. And these should be considered as stratification factors for further trials.

1370P The results of treatment of non-small cell lung cancer stage III with a preoperative vinorelbine/carboplatin and personalized adjuvant chemotherapy

E.O. Rodionov[1], S.V. Miller[1], S.A. Tuzikov[1], M.M. Tsyganov[2], N.V. Litviakov[2], L.A. Efteev[1], I.V. Deriusheva[2]
[1]Thoracic and Abdominal Department, Cancer Research Institute, Tomsk National Research Medical Center, Russian Academy of Sciences, Tomsk, Russian Federation, [2]Laboratory of Viral Oncology, Cancer Research Institute, Tomsk National Research Medical Center, Russian Academy of Sciences, Tomsk, Russian Federation

Background: Individual chemotherapy based on the determination of molecular biomarkers of chemosensitivity is a new way to treat patients with NSCLC. Promising markers for chemosensitivity are monoresistance genes such as BRCA1, RRM1, ERCC1, TOP1, TOP2α, TUBB3, TYMS, and ABCC5.

Methods: We enrolled and analyzed 62 patients with stage III NSCLC. All the patients have received 2 courses of neoadjuvant chemotherapy vinorelbine/carboplatin and surgery. Then patients were randomly assigned (1:1 ratio) to either the personalized adjuvant chemotherapy arm (main group) or the adjuvant chemotherapy vinorelbine/carboplatin arm (control group). In the main group, carboplatin-containing doublets were assigned based on monoresistance gene expression levels ABCC5, RRM1, ERCC1, BRCA1, TOP1, TOP2α, TUBB3 and TYMS. RNA was extracted from tumor after neoadjuvant chemotherapy using "RNeasy Plus Mini Kit" (QIAGEN, Germany). The analysis of monoresistance genes expression was done by qRT-PCR method. A χ^2 test was used to analyze gene expression in relation to clinicopathological parameters. The survival rates were calculated by the Kaplan-Meier method.

Results: The follow-up period was 4 - 76 months. In the main group, the disease progression was observed in 6 patients (19.4%), in the control group - 15 patients (48.4%). Three-year disease-free survival in the main group was 80.7% (median DFS not achieved), in the control group - 51.6%, median DFS - 34 months (HR: 2.56, 95% CI: 1.09 - 6,03); differences are statistically significant: Log-Rank test $\chi 2=4.196$, $p = 0.041$. There was no difference in three-year overall survival (main group: 87.1%, control group: 67.7%, HR: 2.27, 95% CI: 0.79 - 6,47).

Conclusions: Personalized postoperative chemotherapy based on the determination of monoresistance gene expression after neoadjuvant chemotherapy allows significant increase of patients 3-year disease-free survival by 29.1%.

Clínico Zaragoza, Zaragoza, Spain

Background: This study aims to compare efficacy and safety of two widely used combinations of cisplatin (P) in this setting: as etoposide (E) and vinorelbine. This last, in its oral formulation (oV) which has achieved comparable results as the IV formulation and patients (pts) prefer it.

Methods: Pts between 18-75years, with histologically proven untreated and unresectable locally-advanced NSCLC (LA-NSCLC), adequate respiratory function, V20≤35% and ECOG-PS 0-1, were randomized 1:1 to oV-P arm: 2 induction cycles (cy) of oV-P followed by 2 cy more with RT; or to E-P arm: 2 cy of E-P concomitants to RT. Both arms with a total radiation dose of 66Gy administered 2 Gys daily. Primary endpoint was progression free survival (PFS) by RECIST 1.1. Secondary endpoints: overall response rate (ORR), overall survival (OS) and safety. With α-error of 0.05 (one-tailed test) and 0.1 β-error, median PFS unacceptable for the oV-P arm of 10 months (m) (p0) and a very acceptable of 15 m (p1), 122 eligible pts were required.

Results: 140 pts from 23 institutions of SLCG were randomized between 08/2011-12/2014. 134 pts were treated (66 in oV-P and 68 in E-P arms). Results based on this 134 pts are presented. Median age 62 years [39-76]; PS 0/1, 45%/55%; current smoker 51%; squamous cell 51%; stage IIIB 54%. 244 and 131 cy were given in the oV-P and E-P arms, respectively. All irradiated pts in oV-P arm received at least 60Gy, 7 pts in the E-P arm received less than 60Gy (4 due to toxicity). 1 pt (1.5%) in oV-P arm and 12 pts (17.6%) in E-P arm presented esophagitis G3/4 ($p = 0.002$). ORR were 39 (61.9%) and 41 pts (65.1%) in the oV-P and E-P arms, respectively ($p = 0.711$). After 26.3 m [0.03-61] of follow-up, 77.9% pts progressed and 58.6% pts died. Median PFS was 10.8 m (CI95%; 7.5-14) in oV-P arm and 9.1 m (CI95%; 5.5-12.7) in E-P arm ($p = 0.389$). Median OS was 38 m (CI95%; 21.3-58.8) in oV-P and 27.1 m (CI95%; 19.3-34.9) in E-P arm ($p = 0.547$).

Conclusions: Clearly both regimens achieve similar efficacy however oV-P has less toxicity, especially esophagitis G3/4.

Background: Treatment with an immune checkpoint inhibitor (ICI) on completion of concurrent chemoradiotherapy (CCRT) for pts with inoperable stage III NSCLC significantly prolongs the PFS; however the best chemotherapy regimen in CCRT has not been established. This study was conducted to evaluate whether SP or DP, both with concurrent thoracic radiotherapy, in pts with inoperable stage III NSCLC showed a favorable 2-year OS rate with less toxicity in the SP arm as presented previously (J Clin Oncol 2017; 35, suppl; abstr 8534). An update of survival, relapsed sites and post-treatment information with prolonged follow-up has been awaited.

Methods: Pts with inoperable stage III NSCLC were randomized to SP (S-1 40 mg/m^2 bid on days 1-14 and 29-42 plus cisplatin 60 mg/m^2 on days 1 and 29) or DP (docetaxel 50 mg/m^2 and cisplatin 80 mg/m^2 on days 1 and 29), with concurrent radiotherapy beginning on day 1 (60 Gy/30 fr) followed by two additional cycles of the chemotherapy. Primary endpoint was 2-year OS rate, and secondary endpoints included OS, PFS and safety.

Results: Among 110 pts enrolled, 106 (53 in each arm) were evaluable, with male/female 83/23; median age 65 (range 42-74); performance status 0/1 59/47; IIIA/IIIB 59/47. With a median follow-up of 48.1 months, 2-year survival and median OS were 79% (95% CI: 68-90%) and 55.2 months in the SP and 69% (95% CI: 57-82%) and 50.8 months in the DP arm, respectively. 5-year PFS rates in SP and DP arms were 23.2 (95% CI: 11-35) and 23.6% (95% CI: 11-36), and 5-year OS rates were 48.8 (95% CI: 34-64) and 42.3% (95%CI: 24-61), respectively. Hematological and non-hematological toxicities were less in the SP arm. Relapsed site in the RT field and in the CNS were similar between the two arms. Post-treatment chemotherapy for pts with progression was delivered in 92.5% and 71.1% pts in SP and DP arms, respectively.

Conclusions: Because of favorable 2-year OS with less toxicity, we choose SP in CCRT as a future reference regimen. High 5-year PFS and OS rates shown here should be considered in designing further studies where CCRT is followed by ICI.

1373P Identification of subjects with locally advanced lung cancer who are likely to respond to standard-of-care chemoradiotherapy by a longitudinal monitoring of circulating tumor DNA (ctDNA) using a comprehensive ultra-sensitive NGS assay

P. Vitazka[1], N. Tikoo[2], A. Balasubramanyam[2], L. Xi[3], S. Yaung[3], E. Kwok[4], A. Lovejoy[5], D. Klass[5], M. Heibeck[6], K. Probst[7], A. Rehfeldt[7], E. Meldgaard[8], A. Madsen[9], M. Clement[9], J. Palma[10], B. Sorensen[9], P. Meldgaard[8]

[1]Clinical Science, Roche Sequencing Solutions, Inc., Pleasanton, CA, USA, [2]Biometrics, Roche Sequencing Solutions, Inc., Pleasanton, CA, USA, [3]Bioinformatics, Roche Sequencing Solutions, Inc., Pleasanton, CA, USA, [4]Clinical Operations, Roche Sequencing Solutions, Inc., Pleasanton, CA, USA, [5]Development, Roche Sequencing Solutions, Inc., Pleasanton, CA, USA, [6]Biometrics, Roche Sequencing Solutions, Inc., Potsdam, Germany, [7]Clinical Operations, Roche Sequencing Solutions, Inc., Potsdam, Germany, [8]Department of Oncology, Aarhus University Hospital, Aarhus, Denmark, [9]Clinical-Biochemistry, Aarhus University Hospital, Aarhus, Denmark, [10]Medical Scientific Affairs, Roche Sequencing Solutions, Inc., Pleasanton, CA, USA

Background: Only ~20% of patients with locally advanced non-small cell lung cancer (NSCLC) have long term benefit from chemoradiation treatment. Analysis of ctDNA may be superior to other conventional approaches (e.g. CT imaging) in early detection of recurrent disease and can facilitate personalization of treatment strategies. Here we evaluate association between ctDNA levels and survival in subjects with locally advanced NSCLC using an ultra-sensitive next-generation sequencing (NGS) assay.

Methods: Treatment naive tumor and longitudinally collected plasma specimens were analyzed using a 197-gene NGS assay (AVENIO ctDNA Surveillance Kit and AVENIO Tumor Tissue Surveillance Kit prototype, Research Use Only). Mutations detected in pre-chemotherapy tumor specimens and in pre-chemotherapy or pre-radiation therapy plasma specimens were monitored in post-treatment plasma samples by measuring the number of Mutant Molecules Per Milliliter-of-plasma (MMPM). MMPM values were correlated with disease control (as evaluated by RECIST1.1). Kaplan-Meier curves and Cox proportional hazards models were used to assess association of tumor burden with subject survival.

Results: We sequenced 36 tumor and 160 plasma specimens from 40 subjects. At least one mutation reporter was identified in 92% (n = 27/33) of tumor and in 100% (n = 31/31) of pre-chemo or 100% (n = 37/37) of pre-radiation plasma specimens. The best predictive performance of the assay was observed using tumor pre-treatment reporters and MMPM cutoff of 8 in plasma samples collected at completion of the scheduled chemoradiation regimen. Subjects with MMPM below the cutoff had a mean overall survival (OS) benefit of 18.5 months (n = 27, Tarone p-value=0.013, HR = 3.73, 95%CI = 1.37-10.12). A similar trend was observed using plasma pre-chemo reporters (n = 31, Tarone p-value=0.024, HR = 2.08, 95%CI = 0.91-4.74).

Conclusions: Circulating tumor DNA monitoring with an ultra-sensitive NGS-based assay identifies subjects with a locally advanced NSCLC who will have a more favorable outcome when treated with a stand-of-care chemoradiation therapy.

1374P Correlations between Ape1/Ref-1, ICAM-1 and IL-17A levels in serum and radiation pneumonitis for local advanced non-small cell lung cancer patients

L. Guo

Radiotherapy Department, Henan Cancer Hospital, Zhengzhou, China

Background: The main manifestations of radiation pneumonitis are injury of alveolar epithelial and endothelial cells, abnormal expression of cytokines, abnormal proliferation of fibroblasts and synthesis of fibrous matrix. The occurrence of radiation pneumonitis is associated with multiplecytokine level abnormality. These cytokines can also be used as bio-markers to predict the occurrence of radiation pneumonitis.

Methods: NSCLC patients (68 cases) were treated with concurrent radiotherapy and chemotherapy, every patient's normal tissue were controlled with a same radation dose. 68 local advanced NSCLC patients with concurrent chemoradiotherapy were detected the levels of Ape1/Ref-1, ICAM-1 and IL-17A in serum by ELISA before radiotherapy and in the 14th week after radiotherapy. Acute and advanced radiation pulmonary injury was graded according to RTOG/EORTC diagnostic and grading criteria. Grade 2 or more radiation pneumonitis was taken as the main end point.

Results: Eighteen cases out of 68 developed radiation pneumonitis, 50 of 68 cases have no radiation pneumonia development. There was no significant change of Ape1/Ref-1 levels before and after radiotherapy in radiation pneumonitis group ($P > 0.05$). There was no significant change of Ape1/Ref-1 concentration in serum after radiotherapy between radiation pneumonitis group and non- radiation pneumonitis group ($P > 0.05$). Compared with before radiotherapy, upregulation degree of ICAM-1 levels in radiation pneumonitis group was higher than that in non- radiation pneumonitis group ($P < 0.05$). There was no significant change of IL-17A concentration before and after radiotherapy in radiation pneumonitis group, but after radiotherapy IL-17A concentration in serum were higher than that in non-radiation pneumonitis group ($P < 0.05$). Correlation analysis found that the change of ICAM-1 before and after radiotherapy has no obvious correlation with the incidence of radiation pneumonitis, and IL–17A change has obvious correlation with the incidence of radiation pneumonitis.

Conclusions: IL-17A in serum could be the predictive factors of radiation pneumonitis for local advanced NSCLC patients with concurrent chemoradiotherapy.

1375P Programmed cell death ligand 1 expression and CD8 positive lymphocytes in stage III non-small cell lung cancer after neo adjuvant concurrent chemoradiotherapy and their relation with prognosis

E. Choe[1], C. Yoon-Jin[2], H-S. Shim[3], C-Y. Lee[4], B.C. Cho[5], H-R. Kim[1]

[1]Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Seoul, Republic of Korea, [2]Department of Pathology, Yonsei University College of Medicine, Gangnam Severance Hospital, Seoul, Republic of Korea, [3]Department of Pathology, Yonsei University College of Medicine, Seoul, Republic of Korea, [4]Department of Thoracic and Cardiovascular Surgery, Yonsei University College of Medicine, Seoul, Republic of Korea, [5]Medical Oncology, Yonsei Cancer Center Yonsei University, Seoul, Republic of Korea

Background: Previous studies in non-small cell lung cancer (NSCLC) on programmed cell death ligand 1 (PD-L1) expression and its role in prognosis led to conflicting results. For treatment plan after CCRT, we sought to analyze PD-L1 expression and CD8+ lymphocyte and their relation with prognosis in stage III NSCLC patients treated with neo adjuvant CCRT followed by surgery with curative aim.

Methods: We retrospectively enrolled 43 patients with stage III NSCLC treated with neo adjuvant CCRT followed by surgery at Yonsei Cancer Center Severance hospital, between June 2008 and October 2010. Immunohistochemistry (IHC) was performed on tissue sections of PD-L1 expression and presence of stromal CD8+ lymphocytes in NSCLC specimens. Weekly standard chemotherapy based on platinum was included in CCRT.

Results: The median age of patients at diagnosis was 62 years. Thirty patients (70%) were males and 13 patients (30%) were females. Never smokers were 17 patients (40%). Twenty-five patients had squamous cell carcinoma (58%). The post-CCRT PD-L1-positive group exhibited a tendency of poorer recurrence free survival (RFS) compared to post CCRT PD-L1-negative group ($p = 0.108$). The overall survival (OS) also showed a similar trend ($p = 0.215$). In the survival analysis with pre-CCRT specimens, both RFS and OS analyses showed no statistically significant differences ($p = 0.423$). Although it was not statistically significant, in a group showed increase in PD-L1 expression after CCRT resulted in the steepest curve in OS analysis ($p = 0.220$). Increase in stromal CD8+ lymphocytes after CCRT exhibited better survival than other groups (decrease or no change) ($p = 0.017$).

Conclusions: Increase in CD8+ lymphocyte density improved OS. Because this study was performed with small number of patients, prognostic value of PD-L1 in this group of patients should be considered for future treatment planning or study design although it was not statistically significant in this study.

Background: Concurrent Chemo-Radiotherapy (cCRT) is standard treatment in "fit patients" (pts) affected with locally advanced (LA) NSCLC, with surgery limited to few selected cases. Despite some improvements, outcomes are still unsatisfactory, with only 15-25% of pts alive at 5 years. Recently, encouraging results were obtained with the addition of immunotherapy (IT) to cCRT. Survey was conducted to evaluate the pattern of care of LA-NSCLC treatment among Italian Thoracic Oncologists (TO) involving pneumologists, thoracic surgeons, radiation and medical oncologists.

Methods: In February 2018, all Italian TO were invited to participate to a "web-based" survey consisting in 15 multiple-choice questions about staging procedures and most appropriate multimodal approach to manage LA-NSCLC. Questions were also focused on diagnostic imaging and histopathological modalities.

Results: 421 responses were analyzed;69% of responders had more than 5 years experience in thoracic oncology. In 72% of Centers, TO regularly attend a weekly multidisciplinary Team (MDT) meeting, while in 28% MDT is not regularly planned. About pathology, cytological/histological morphologic diagnosis of malignancy were considered enough to define a therapeutic approach in 63% of responders. In N2, Stage IIIA, "minimal" pts upfront surgery was considered the preferred option from 43% of responders, while in N2, multi-nodal and/or bulky pts cCRT was recommended. For this latter group ("unresectable") only 54% considered cCRT the most appropriate choice, while 46% preferred a sequential chemo-RT, even in fit pts due to better pts compliance and lower toxicity profiles.

Conclusions: Our analysis showed an inhomogeneous scenario between different specialists regarding the appropriate therapeutic choices for LA-NSCLC treatment. Additionally, some discrepancies were found about a correct selection of pts fit for cCRT. Many efforts have to be put towards the increase of a true multidisciplinarity, since in many Institutions lack of MDT was described. Future investigations and trials are necessary to optimize treatment approaches in LA-NSCLC, in particular considering recent clinical results on combination of cCRT and IT.

Background: In the primary analysis of this study (EudraCT: 2007-005792-34), D dosed to a 12.0-g/dL Hb ceiling was noninferior to P for overall survival (OS) and progression-free survival (PFS) and superior to P for transfusion (TN) or Hb ≤ 8.0 g/dL in anemic pts with advanced NSCLC (screening Hb ≤ 11.0 g/dL).

Methods: Adults with stage IV NSCLC expected to receive ≥2 cycles of myelosuppressive chemotherapy, life expectancy >6 mo, ECOG 0–1, and Hb ≤ 11.0 g/dL were randomized 2:1 to D (500 μg SC) or P Q3W. Pts were stratified by region, histology, and Hb. This ad hoc analysis assessed key study endpoints in pts with baseline Hb ≤ 10.0 g/dL and in subgroups with Hb 9.0–10.0 and <9.0 g/dL. Primary endpoint of the parent study was OS; a Cox proportional hazards model, stratified by randomization factors, was used to evaluate noninferiority (upper confidence limit for hazard ratio [HR] <1.15). Secondary endpoints were PFS (noninferiority) and incidence of TN or Hb ≤ 8.0 g/dL from wk 5 to end of efficacy treatment period (EOETP).

Results: Of 2549 pts enrolled in the trial, 1183 had baseline Hb ≤ 10.0 g/dL (735, Hb 9.0–10.0; 448, Hb < 9.0 g/dL). Pts were well matched between arms for sex, race, and age. Among pts with Hb ≤ 10.0 g/dL, the HRs for OS and PFS were close to 1.0; results were consistent in the subgroups. Odds ratios for TN or Hb ≤ 8.0 g/dL from wk 5 to EOETP were <1.0 and were consistent in the subgroups (Table). TN was more frequent in pts with lower baseline Hb. Safety findings were consistent with previous studies; thrombovascular events were more frequent with D than P (Table).

Conclusions: The results presented here appear mostly consistent with the primary study results, but this ad hoc analysis was not powered to demonstrate noninferiority or superiority, so the results should be interpreted in that context.

Clinical trial identification: NCT00858364; July 17, 2009.

1388P Incidence of cardiac toxicities in patients with advanced non-small cell lung cancer treated with osimertinib: A combined analysis of two phase III randomized controlled trials

K.Z. Thein[1], S. Swarup[1], S. Ball[2], M. Quirch[2], Y. Vorakunthada[2], K.K. Htwe[3], N. D'Cunha[1], F. Hardwicke[1], S. Awasthi[1], L. Tijani[1]

[1]Hematology Oncology, Texas Tech University Health Sciences Center, Lubbock, TX, USA, [2]Internal Medicine, Texas Tech University Health Sciences Center, Lubbock, TX, USA, [3]Internal Medicine, Kingsbrook Jewish Medical Center, Brooklyn, NY, USA

Background: Osimertinib is an oral, irreversible epidermal growth factor receptor tyrosine kinase inhibitor (EGFR-TKI). In both EGFR-TKI sensitizing and EGFR T790M resistance mutations in advanced non-small-cell lung cancer (NSCLC), osimertinib has shown to improve survival. Nevertheless, cardiac toxicities remain a safety concern. We undertook a systematic review and meta-analysis of randomized controlled trials (RCT) to determine the incidence of cardiac toxicities.

Methods: MEDLINE, EMBASE databases and meeting abstracts from inception through March 2018 were queried. Phase III RCTs that mentioned cardiac failure (CF), decrease in ejection fraction (EF) and ECG QT prolongation as adverse effects were incorporated in the analysis. Mantel-Haenszel (MH) method was used to calculate the estimated pooled risk ratio (RR) and absolute risk difference (RD) with 95% confidence interval (CI). A fixed effects model was applied.

Results: 971 patients with advanced NSCLC from two phase III RCTs were included. Studies compared osimertinib vs carboplatin/cisplatin + pemetrexed and osimertinib vs gefitinib/erlotinib. The I^2 statistic for heterogeneity was 0, and the heterogeneity X^2 (Cochran's Q) was 1 (P = 0.787), suggesting homogeneity among RCTs. The CF incidence was 21 (3.763%) in the osimertinib group vs 6 (1.453%) in control group. The RR for CF was 2.719 (95% CI: 1.094 – 6.755, P = 0.031) and RD was 0.026 (95% CI: 0.006 – 0.046, P = 0.012). The decrease in EF was noted in 16 (2.867%) in study arm vs 5 (1.211%) in control arm. The RR for decrease in EF was 2.502 (95% CI: 0.927 –6.753, P = 0.070) and RD was 0.019 (95% CI: - 0.001 – 0.037, P = 0.037). The QT prolongation was reported in 35 (6.272%) vs 12 (2.906%) in control group with the RR of 2.623 (95% CI: 1.374 –5.007, P = 0.003) and RD of 0.04 (95% CI: - 0.017 – 0.071, P = 0.002).

Conclusions: Chemotherapy-induced cardiotoxicity, a major cause of morbidity and mortality, is one of the most feared complications and affects patients' quality of life and adds financial burden. Our study showed that osimertinib notably increased the risk of cardiac toxicities with a RR of 2.71 for CF and 2.62 for QT prolongation. Prompt monitoring and early intervention is warranted.

1389P Impact of early steroids use on clinical outcomes of patients with advanced NSCLC treated with immune checkpoint inhibitors

G. Fucà, M. Poggi, G. Galli, M. Imbimbo, G. Lo Russo, D. Signorelli, M. Vitali, M. Ganzinelli, N. Zilembo, F. de Braud, M.C. Garassino, C. Proto

Medical Oncology Department, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

Background: In advanced non-small cell lung cancer (NSCLC), immune checkpoint inhibitors (ICIs) significantly improved patients (pts) prognosis, even if many factors could impair their efficacy. The impact of steroids (well below the immunosuppressant dose) on ICIs outcomes is debatable, although a quite number of pts starts immunotherapy while on, or early recurs to steroids as supportive care medications or for mild AEs. Here, we aimed at assessing the impact of early steroids use on clinical outcomes of ICIs treatment in a series of pts with advanced NSCLC.

Methods: All consecutive pts with advanced NSCLC who started ICIs at our institution from Apr 2013 to Dec 2017 were retrospectively reviewed. Pts with at least one instrumental response assessment were included. Early use of steroids was defined as the use of a daily prednisone-equivalent dose ≥ 10 mg for at least 1 day within 28 days from ICIs initiation. Chi-square test or Fisher's exact test were used to analyze the association of early use of steroids with pts' characteristics. The Kaplan-Meier method and the Cox proportional-hazards model were used for survival analyses.

Results: Out of 151 pts included, 35 (23 %) made early use of steroids. Most of the pts (96%) received single agent anti PD-1/PD-L1, while 6 pts (4%) received combinatorial PD-L1+CTLA-4 blockade. Early use of steroids was negatively associated with disease control (OR 0,32; 95% CI 0.14-0.71, P = .006) and positively associated with ≥2 metastatic sites (OR 3,08, 95% CI 1.33-7.89; P = .01) and ECOG PS ^{3} 2 (OR 4.57; 95% CI 1.10-20.37; P = .03). With a median follow-up of 32.7 months, early use of steroids conferred a worse median progression-free survival (PFS) (1.98 vs 3.94 months; HR 1.80; 95% CI 1.20-2.80; P = .003). In the multivariable model including other covariates significantly associated with PFS (i.e. ECOG PS and PD-L1 status), the early use of steroids was confirmed to be independently associated with poorer PFS (HR 1.88; 95% CI 1.08-3.28; P = .03).

Conclusions: We found that the early use of steroids independently affects clinical outcomes in patients with advanced NSCLC treated with ICIs. If these findings will be further validated, such use in this setting should be carefully evaluated and avoided when not strictly needed.

Background: Anlotinib is an oral tyrosine kinase inhibitor targeting VEGFR, FGFR, PDGFR and c-kit. Anlotinib showed significantly improvement in overall survival in ALTER0303 trial for refractory NSCLC, a randomized, double-blind, placebo-controlled phase III trial in China. This study reported the tolerance of anlotinib in the ALTER0303.

Methods: The adverse events (AEs), dose modification, and therapy interruption were collected from anlotinib group (n = 294) and placebo group (n = 143) that were enrolled in ALTER0303. AEs were graded using Common Terminology Criteria.

Results: The anlotinb related grade ≥3 AEs reported in ≥ 1% patients were hypertension (13.3%), hyponatremia (4.8%), hand-foot syndrome (HFS) (3.7%), hemoptysis (3.1%), GGT elevation (2.7%), hypertriglyceridemia (2.4%), QT interval prolongation (2.4%), lipase elevation (2.4%), proteinuria (2.4%), oral mucositis (1.0%), diarrhea (1.0%), and hyperbilirubinemia (1.0%). Grade ≥3 hypertension, HFS, and hypertriglyceridemia were significantly more frequent in the anlotinib group than in the control group. Dose reduction and drug interruption were required in 24 (8.16%) (Table) and 31 (10.54%) patients in anlotinib group, respectively. The most common anlotinib-related AEs causing interruption were hemoptysis (2.3%), venous thromboembolism (1.0%), proteinuria (0.7%), interstitial lung disease (0.7%), and pneumothorax (0.7%).

Table: 1390P Dose modification due to anlotinib-related adverse events

Adverse events	No. (%)	Dose modification
Hand-foot syndrome	7 (2.3)	12mg→10mg
Hypertension	3 (1.0)	12mg→10mg
Hypertriglyceridemia	2 (<1)	12mg→10mg
Diarrhea	1 (<1) 1 (<1)	12mg→10mg 12mg→10mg→8mg
Liver dysfunction	1 (<1) 1 (<1)	12mg→10mg 12mg→10mg→8mg
Anorexia	2 (<1)	12mg→10mg
Oral mucositis	2 (<1)	12mg→10mg
Arrhythmia	2 (<1)	12mg→10mg
Fatigue	1 (<1)	12mg→10mg
Dyspnea	1 (<1)	12mg→10mg

Conclusions: It was important to manage hand-foot syndrome, hypertension, diarrhea and hemoptysis, so that patients could benefit from anlotinib.

Clinical trial identification: NCT02388919.

1391P Immune-related adverse events (irAEs) and survival (OS) in metastatic non-small cell lung cancer (mNSCLC) patients (pts) treated with immunotherapy

M. Meliàn Sosa, C. Puchades, J.A. Mendez, A. Torres, C. Rodrigo, G. Gimeno, E. Rama, A. Martínez-Castillo, J. Caballero Daroqui, J. Gomez Codina, O. Juan-Vidal, D. Lorente
Medical Oncology, Hospital Universitari i Politècnic La Fe, Valencia, Spain

Background: Immunotherapy represents a new standard of care in first and second line treatment of advanced NSCLC. Immune related adverse events (irAEs) have been proposed as an indicator of treatment efficacy.

Methods: Retrospective analysis of mNSCLC patients treated with anti-PD/anti-PDL1 with or without anti-CTLA4 therapy. Electronic patient records were reviewed; irAEs were identified and graded according to CTC AE v4.03 criteria. The association with survival was evaluated in uni- (UV) and multivariable (MV) Cox-regression models.

Results: 64 pts were identified; 41 (64.1%) were adenocarcinomas and 27 (42.2%) received immunotherapy in first-line. 44 pts (68.8%) received antiPD1/PDL1 monotherapy, and 20 pts (31.2%) received antiPDL1 + antiCTLA4. 15 pts (25%) developed irAEs: gastrointestinal (17.6%), endocrine (11.8%), cutaneous (17.6%), other (33.3%). Treatment was interrupted in 8 (53.3%) and suspended in 5 (33.3%) pts. 7 (50%) pts received high dose corticosteroids. No toxic deaths occurred. iRAEs were not significantly increased in pts receiving combination therapy (30% vs 20%, p = 0.377). Median OS was 6.5 m (95%CI: 0.24-12.7). Pts experiencing irAEs had a significantly higher OS (HR: 0.2; 95%CI: 0.07-0.58; p = 0.003) in UV analysis, and was independent of other prognostic factors in MV analysis (Table).

Table: 1391P MV Cox-regression survival model

Factor	HR (95%CI)	p-value
irAE (yes vs no)	0.18 (0.06 – 0.53)	0.002
Histology	1.11 (0.99 – 1.24)	0.061
ECOG PS	0.82 (0.42 – 1.59)	0.551
Treatment line (first line vs second or further)	1.06 (0.52 – 2.18)	0.868
Treatment type (monotherapy vs combination)	2.25 (1.02 – 4.99)	0.045

Conclusions: The development of irAEs may identify pts with a higher likelihood of benefitting from immunotherapy in NSCLC. These findings will require prospective validation in well-designed clinical trials.

1392P Dose-determination results from a phase Ib/II study of ceritinib (CER) + ribociclib (RIB) in ALK-positive (ALK+) non-small cell lung cancer (NSCLC)

A. Santoro[1], W-C. Su[2], A. Navarro[3], M. Simonelli[4], J.C-H. Yang[5], A. Ardizzoni[6], F. Barlesi[7], J.H. Kang[8], S. Didominick[9], A. Abdelhady[10], B. Goswami[10], A. Crystal[9], E. Felip[3]
[1]Humanitas University and Humanitas Cancer Center, Milan, Italy, [2]National Cheng Kung University Hospital, Tainan, Taiwan, [3]Vall d'Hebron University Hospital, Barcelona, Spain, [4]Department of Biomedical Sciences, Humanitas University and Humanitas Cancer Center, Milan, (MI), Italy, [5]National Taiwan University Hospital, Taipei, Taiwan, [6]University Hospital Bologna, Bologna, Italy, [7]Aix-Marseille University, Assistance Publique Hopitaux de Marseille, Marseille, France, [8]Catholic University of Korea, Seoul, Republic of Korea, [9]Oncology, Novartis Pharmaceutical Corporations, Cambridge, MA, USA, [10]Oncology, Novartis Pharmaceutical Corporations, Hyderabad, India

Background: Preclinical data suggest cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) may improve ALK inhibitor (ALKi) efficacy in ALK+ NSCLC. A Phase Ib/II study (NCT02292550) is assessing CER (ALKi) + RIB (CDK4/6i) in patients (pts) with ALK+ NSCLC; here we report data from the Phase Ib dose-escalation.

Methods: Pts with Stage IIIB/IV ALK+ NSCLC (≥1 prior therapy for advanced NSCLC; no prior CDK4/6i) received escalating doses of CER (starting dose 300 mg once daily [QD]; continuous [cont]) + RIB (starting dose 100 mg QD; 3 weeks [wks] on/1 wk off) under fed conditions. Primary objective: maximum tolerated dose/recommended Phase II dose (RP2D); secondary objectives: safety, pharmacokinetics, and efficacy.

Results: As of Jan 8, 2018, 27 pts were enrolled into 5 dose cohorts (Table); 8 were ALKi naive, 14 had prior crizotinib; 5 had prior 3rd-generation (gen) ALKi. Treatment was ongoing in n = 4; the most common reason for discontinuation was disease progression (n/n; 10/27). One dose-limiting toxicity occurred (CER 450 mg + RIB 100 mg; Grade [G] 2 increased blood creatinine for ≥7 consecutive days); RP2D was CER 300 mg QD (cont) + RIB 200 mg QD (3 wks on/1 wk off). At steady state, CER and RIB exposure (AUC_{0-24h}) each increased by ~1.5–2 fold compared with CER and RIB single-agent exposures under fasting conditions, with considerable variability in the setting of limited pt numbers. G3/4 treatment-related adverse events occurred in 15 pts; the most common (≥10% of pts) were decreased neutrophil count, increased ALT, and

Table: 1392P

	CER 300 mg + RIB 100 mg	CER 450 mg + RIB 100 mg	CER 300 mg + RIB 200 mg	CER 450 mg + RIB 200 mg	CER 450 mg + RIB 300 mg	All

1393P Safety profile and effectiveness of alectinib in the real-world surveillance study of 1251 Japanese patients with ALK-positive non-small cell lung cancer

Y. Ohe[1], N. Yamamoto[2], A. Gemma[3], M. Kusumoto[4], I. Yamada[5], T. Ishii[6], N. Masuda[7]

[1]Department of Thoracic Oncology, National Cancer Center Hospital, Tokyo, Japan, [2]Third Department of Internal Medicine, Wakayama Medical University, Wakayama, Japan, [3]Division of Pulmonary Medicine and Oncology, Nippon Medical School, Tokyo, Japan, [4]Department of Diagnostic Radiology, National Cancer Center Hospital East, Kashiwa, Japan, [5]Department of Pharmacovigilance, Chugai Pharmaceutical Co.,Ltd., Chuo-Ku, Tokyo, Japan, [6]Department of Real World Data Science, Chugai Pharmaceutical Co., Ltd., Tokyo, Japan, [7]Division of Clinical Research Center, Izumi City General Hospital, Osaka, Japan

Background: Alectinib is a CNS penetrant and highly selective ALK inhibitor. The Japanese Risk Management Plan based on the phase I/II studies highlighted interstitial lung disease (ILD), liver function disorder, decreased neutrophil cell and white blood cell counts as identified risk in Japanese patients (pts). To investigate the safety and effectiveness of alectinib, including adverse drug reactions (ADR) of particular concern in the real world setting, a large scale surveillance funded by Chugai Pharmaceuticals has been implemented. This study is registered with the UMIN, number UMIN000014989.

Methods: From Sep 2014 to June 2015 all pts with ALK-positive recurrent/advanced NSCLC treated with alectinib, were enrolled in the study. The observation period was 18 months, ADR were collected. Overall survival (OS) was also assessed.

Results: By Jun 2015, a total of 1251 pts were registered. We analysed 1221 pts as the safety population. Baseline characteristics included: female (54% of population), median age (62 years), ECOG PS 3-4 (n = 89) (7%), pts who received first line (18%), second line (32%) or third line or more (50%) treatments, pts who received crizotinib (63%), brain metastases (41%). The overall incidence of ADRs was 53.6% (mostly grade 1/2), the most common were laboratory tests abnormality (27.7%). ILD events were reported in 47 pts (3.8% of population), including grade 3 events in 8 pts and grade 4 events in 1 pt, in which the rate of recovery or improvement was 92%. Events of liver function disorder were reported in 242 pts (19.8%), including grade 3 events in 24 pts, and events of neutrophil cell and white blood cell decrease were reported in 93 pts (7.6%), including grade 3 events in 12 pts and grade 4 events in 2 pts, in which the rates of recovery or improvement were 83% and 93%, respectively. Median OS was not reached. Overall survival rate at 12 months and 18 months were 82.4% and 76.2%, respectively.

Conclusions: These final data from this study in Japanese ALK-positive NSCLC pts provide an acceptable safety and effectiveness profile in the real-world setting. Alectinib was primarily one of the effective therapies for the treatment of ALK-positive NSCLC.

1394P A multicenter study of mutational profiling of Chinese ALK+ non-small cell lung cancer patients with acquired resistance to crizotinib using next generation sequencing

C. Xu[1], W. Wang[2], W. Zhuang[3], Z. Song[2], Y. Zhu[4], G. Chen[1], M. Fang[2], T. Lv[5], Y. Song[5]

[1]Pathology, Fujian Cancer Hospital, Fuzhou, China, [2]Chemotherapy, Zhejiang Cancer Hospital, Hangzhou, China, [3]Medical Thoracic Oncology, Fujian Cancer Hospital, Fuzhou, China, [4]Thoracic Disease Center, Zhejiang Rongjun Hospital, Jiaxing, China, [5]Respiratory Medicine, Jinling Hospital, Nanjing, China

Background: Anaplastic lymphoma kinase (ALK) rearrangements define a distinct molecular subtype of non-small cell lung cancer. Recently, the therapeutic landscape for advanced ALK+ NSCLC has been transformed by the development of increasingly potent and selective ALK inhibitors. Crizotinib was the first ALK inhibitor to enter clinical development. The mechanism of acquired resistance to crizotinib for the patients with ALK+ NSCLC is not yet fully identified. In this study, we performed mutational profiling in a cohort of 42 ALK+NSCLC patients at diagnosis and following acquired resistance to crizotinib using targeted NGS.

Methods: A total of 42 patients with stage IIIb-IV ALK+ NSCLC underwent tumor biopsies or blood withdrawal by the time of acquiring resistance to crizotinib, including 19 formalin-fixed paraffin-embedded (FFPE) samples, 12 serum samples and 11 serous effusions. We used targeted NGS to detect the gene status of patients.

Results: In total, we identified 92 genetic alterations with a median of 2.2 mutations per patient. 83% of patients still exhibit fusions, and 29% of patients acquired ALK point mutations. Besides other known resistance mechanisms, we identified KRAS mutations in 14% of patients, and EGFR mutations in 12%. Interestingly, we also observed IGF1R, GPR133, CDH18and HSD17B3 mutations in ALK point mutation-negative patients, which were restricted to crizotinib resistance.

Conclusions: Our study uncovered mutational profiles of ALK+NSCLC patients with crizotinib resistance with potential therapeutic implications, and this study also comprehensively depicted the genetic landscape in a Chinese ALK+NSCLC population resistant to crizotinib. Our analysis demonstrates new perspectives for further study of resistance and suggests corresponding relevant tactics against the challenge of disease progression.

1395P Lung cancers carrying distinct ALK fusion variants demonstrate similar responsiveness to ALK tyrosine kinase inhibitors

E.N. Imyanitov[1], N.V. Mitiushkina[1], V.I. Tiurin[1], A.G. Iyevleva[1], M. Holmatov[1], E. Filippova[2], F. Moiseyenko[3], N. Levchenko[4], S. Odintsova[2], A. Lozhkina[2], A.V. Togo[1], N. Karaseva[5], V.M. Moiseyenko[3], S. Orlov[2]

[1]Department of Tumor Growth Biology, N.N. Petrov Institute of Oncology, St. Petersburg, Russian Federation, [2]Department of Oncology, Pavlov State Medical University, St. Petersburg, Russian Federation, [3]Department of Chemotherapy, St. Petersburg City Cancer Center, St. Petersburg, Russian Federation, [4]Department of Thoracic Oncology, N.N. Petrov Institute of Oncology, St. Petersburg, Russian Federation, [5]Department fo Thoracic Oncology, City Clinical Oncology Dispensary, St. Petersburg, Russian Federation

Background: Multiple laboratory evidences indicate that distinct variants of ALK translocations differ in their biochemical properties and responsiveness to ALK tyrosine kinase inhibitors (TKI). These data are supported by some Asian clinical studies, which showed improved responses to crizotinib in non-small cell lung cancer (NSCLC) patients carrying particular variants of ALK translocation.

Methods: This study retrospectively considered 64 Russian patients with ALK-rearranged NSCLC, who were treated by crizotinib (n = 23), ceritinib (n = 39) or alectinib (n = 2). ALK fusion variants were genotyped by PCR.

Results: Median progression-free survival (PFS) approached to 18 and 21 months in subjects with "short" (v.3a/b, v.5a/b) vs. "long" (TAPE-domain containing) fusion variants (p = 0.783), respectively; similar data were obtained while comparing EML4/ALK variant 1 vs. other ALK translocations (19 and 21 months, respectively; p = 0.604). Objective response rates were also strikingly similar in the above groups ("short": 88%, "long": 77%, p = 0.479; variant 1: 76%, other translocations: 81%, p = 0.753). Furthermore, ALK variants did not influence the disease outcomes when patients treated by crizotinib and ceritinib were analyzed separately. Overall, PFS on ALK TKI did not depend on whether the drug was administered upfront or after chemotherapy. Ceritinib produced significantly longer PFS than crizotinib (p = 0.022).

Conclusions: This is the first non-Asian study evaluating the relationship between ALK fusion variants and response to ALK TKI. Although being larger in size as compared to published data sets, it failed to confirm the role of the type of ALK translocation in determining the treatment outcome.

1396P Efficacy and safety of crizotinib in previously treated patients (Pts) with ALK+ advanced non-small cell lung cancer (NSCLC) aged ≥65 years (y)

D. Moro-Sibilot[1], M-J. Ahn[2], B. Halmos[3], D-W. Kim[4], G.J. Riely[5], A.T. Shaw[6], P-C. Yang[7], S. Lanzalone[8], A. Polli[8], K.D. Wilner[9], J. De Castro Carpeño[10]

[1]Pneumologie, CHU Grenoble-Alpes, Grenoble, France, [2]Samsung Medical Center, Seoul, Republic of Korea, [3]Montefiore Medical Center, Albert Einstein College of Medicine, New York, NY, USA, [4]Department of Internal Medicine, Seoul National University Hospital, Seoul, Republic of Korea, [5]Memorial Sloan Kettering Cancer Center, New York, NY, USA, [6]Massachusetts General Hospital, Boston, MA, USA, [7]Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan, [8]Pfizer Oncology, Milan, Italy, [9]Pfizer Oncology, La Jolla, CA, USA, [10]Medical Oncology Service, Hospital Universitario La Paz, Madrid, Spain

Background: Crizotinib is an oral tyrosine kinase inhibitor (TKI) approved for treatment of ALK+ advanced NSCLC. We report efficacy and safety from subgroups of pts aged ≥65 y included in PROFILE 1005, the largest clinical trial to date of an ALK TKI in ALK+ NSCLC.

Methods: PROFILE 1005 (NCT00932451) was a multicenter, single-arm phase 2 trial of crizotinib (250 mg twice daily; continuously) in pts with ALK+ NSCLC who had failed ≥1 line of systemic treatment for advanced/metastatic disease. Co-primary endpoints were objective response rate (ORR) per RECIST v1.1 and adverse events (AEs). Other efficacy endpoints included duration of response (DOR), progression-free survival (PFS) and overall survival (OS).

Results: Of 1066 treated pts, 93 (54 female/39 male) and 79 pts (49 female/30 male) were aged 65–70 y and >70 y, respectively, at baseline (overall safety population). 908 out of 1066 pts, including 74 pts in the 65–70 y subgroup and 57 in the >70 y subgroup, were ALK+ by central FISH testing; all were evaluable for response. The table shows investigator-assessed efficacy endpoints for these pts. Most common TRAEs in the 65–70 (n = 93) and >70 y (n = 79) subgroups, respectively, were vision disorder (54.8% & 45.6%), nausea (50.5% & 57.0%), edema (43.0% & 57.0%), vomiting (41.9% & 51.9%) and diarrhea (39.8 % & 48.1%), mostly Grade 1/2, comparable to the safety profile of the overall safety population (n = 1066), but with some higher frequencies seen in the >70 y subgroup. In the 65–70 y and >70 y subgroups, respectively, 24.7% and 27.8% of pts had TRAEs leading to dose reductions (overall safety population, 18.3%), and 9.7% and 13.9% had TRAEs requiring permanent treatment discontinuation (overall safety population, 5.6%).

Conclusions: Efficacy and safety profiles in ALK+ NSCLC pts aged 65–70 or > 70 y were comparable to those previously reported for PROFILE 1005, with some TRAEs occurring at higher frequencies in pts >70 y.

Background: The oral tyrosine kinase inhibitor (TKI) crizotinib is approved for the treatment of pts with anaplastic lymphoma kinase (ALK)+ advanced NSCLC. Here we report safety results for pts who were treated with crizotinib for longer than 1 year (y) in PROFILE 1005, the largest clinical trial to date of an ALK TKI in ALK+ advanced NSCLC.

Methods: The PROFILE 1005 study (NCT00932451) was a single-arm phase 2 trial of crizotinib (250 mg twice daily; continuously) conducted at multiple centers. The study enrolled pts with ALK+ NSCLC who had failed ≥1 line of systemic treatment for locally advanced/metastatic disease. The co-primary endpoints were safety and objective response rate.

Results: A total of 1066 pts were treated; 240 and 248 pts were treated for 1–2 y and >2 y, respectively. Treatment-related adverse events (TRAEs) are summarized by treatment duration subgroup in the table. Most common TRAEs of any grade in the 1–2 y and >2 y subgroups, respectively, were vision disorder (65.8% and 69.4%), nausea (57.5% and 58.1%), diarrhea (54.2% and 61.3%), vomiting (49.6% and 46.4%) and edema (47.1% and 60.1%). The most common grade 3/4 TRAE in both subgroups was neutropenia (17.1% and 23.0%). Two grade 5 TRAEs (interstitial lung disease [n = 1] and cardiac arrest [n = 1; for which other factors could not be excluded]) were reported in the >2 y subgroup; no grade 5 TRAEs were reported in the 1–2 y subgroup. Selected TRAEs of interest based on prior experience with crizotinib included the following, reported in the 1–2 y and >2 y subgroups, respectively: elevated transaminases (35.4% and 37.1%), hepatotoxicity (1.3% and 1.2%), interstitial lung disease (2.1% and 2.4%), ECG QT prolonged (2.5% and 4.8%), bradycardia (13.3% and 16.5%), and renal cysts (2.1% and 7.7%).

Table: 1397P

n (%)	Treatment duration subgroup		
	1–2 y (n = 240)	>2y (n = 248)	Overall (n = 1066)
Pts with TRAEs	239 (99.6)	247 (99.6)	1022 (95.9)
Pts with serious TRAEs	23 (9.6)	34 (13.7)	119 (11.2)
Pts with grade 3 or 4 TRAEs	104 (43.3)	114 (46.0)	425 (39.9)
Pts with temporary discontinuation due to TRAEs	87 (36.3)	103 (41.5)	332 (31.1)
Pts with dose reductions due to TRAEs	54 (22.5)	56 (22.6)	195 (18.3)
Pts permanently discontinued treatment due to TRAEs	2 (0.8)	4 (1.6)	60 (5.6)

Table: 1396P

	Patients With ALK+ NSCLC by Central FISH Testing		
	65–70 y (n = 74)	>70 y (n = 57)	PROFILE 1005 Total (n = 908)
Mean age, years (range)	67 (65–70)	76 (71–84)	52 (19–84)
ORR, % (95% CI)[a]	54.1 (42.1, 65.7)	47.4 (34.0, 61.0)	54.1 (50.8, 57.4)
Median DOR (Kaplan–Meier), months (95% CI)[a]	11.4 (8.3, 16.6)	12.4 (9.6, 14.1)	11.8 (10.4, 12.8)
Median PFS (Kaplan–Meier), months (95% CI)[b]	9.6 (5.5, 16.8)	11.6 (6.9, 15.1)	8.4 (7.1, 9.7)
Median PFS (Kaplan–Meier), months (95% CI)[b]	23.2 (17.6, 31.2)	17.0 (12.2, 22.4)	21.8 (19.4, 24.0)

[a]Calculated using the exact method based on the F distribution

[b]Based on Brookmeyer and Crowley method

Conclusions: No new major safety signals were observed. The long-term safety profile was consistent with the known safety profile of crizotinib.

1398P Real-world progression-free survival of patients on anaplastic lymphoma kinase (ALK) tyrosine kinase inhibitors (TKIs) for ALK+ non-small cell lung cancer (NSCLC)

M. Jahanzeb[1], H.M. Lin[2], X. Pan[2], Y. Yin[3], P. Hou[3], B.L. Nordstrom[4], A. Desai[5], M.A. Socinski[6]

[1]Sylvester Comprehensive Cancer Center, University of Miami, Deerfield Beach, FL, USA, [2]Global Outcomes Research, Millennium Pharmaceuticals, Inc., Cambridge, MA, USA, [3]Safety and Observational Statistics, Millennium Pharmaceuticals, Inc., Cambridge, MA, USA, [4]Real World Evidence, Evidera, Waltham, MA, USA, [5]Global Medical Affairs, Millennium Pharmaceuticals, Inc., Cambridge, MA, USA, [6]Florida Hospital Cancer Institute, Orlando, FL, USA

Background: Patients with NSCLC characterized by ALK rearrangements may benefit from ALK TKI therapies. Although ALK TKIs have shown improved efficacy relative to conventional chemotherapy, the prognosis for patients with ALK+ NSCLC remains suboptimal. The present study uses real-world evidence to examine progression-free survival (PFS) among patients with ALK+ NSCLC treated with an ALK TKI.

Methods: Patients with advanced ALK+ NSCLC diagnosed and treated with an ALK TKI in 2011-2017 were identified from the Flatiron Health Electronic Health Record (EHR)-derived database. Real-world PFS (rwPFS) was estimated as the time from treatment line start to progression or death, where progression was abstracted from clinician notes and radiology/pathology reports by trained medical reviewers. Analyses examined rwPFS following the patient's first line containing ALK TKI. For patients who received crizotinib as their first TKI followed by a second ALK TKI, a similar analysis examined rwPFS following their second ALK TKI line. Data were censored at end of follow-up for patients without progression or death. The median and 95% confidence interval (CI) of rwPFS following first and second ALK TKI were obtained from Kaplan-Meier methods.

Results: Of 409 ALK TKI-treated patients with advanced ALK+ NSCLC, mean age was 60.4 years and 51.6% were female. Most patients (n = 379; 92.7%) received crizotinib as their first ALK TKI; of these, 180 (47.5%) were later treated with a second ALK TKI (e.g. ceritinib, alectinib). Median (95% CI) rwPFS was 7.5 (6.6-8.6) months following first ALK TKI; and 6.4 (5.2-8.2) months following second ALK TKI post-crizotinib (including 6.3 [4.3-8.4] months for ceritinib (n = 99) and 7.6 [5.2-13.6] months for alectinib (n = 64)).

Conclusions: In this real-world analysis of patients with advanced ALK+ NSCLC treated with earlier approved ALK TKIs, rwPFS remains short, indicating a clear need for more effective treatments of ALK+ NSCLC.

Background: Lorlatinib is a selective, potent, brain-penetrant, third-generation ALK/ROS1 tyrosine kinase inhibitor with robust clinical activity in pts with ALK-positive (ALK+) or ROS1-positive (ROS1+) advanced NSCLC. The phase 1/2 study (NCT01970865) assessed lorlatinib in pts with ALK+ or ROS1+ NSCLC based on prior treatment. Phase 2 efficacy/safety was previously reported. Here, we present PRO results.

Methods: In this ongoing open-label, multicenter study, pts received lorlatinib 100 mg once daily. Global quality of life (QoL), pt functioning and symptoms were assessed with the European Organisation for Research and Treatment of Cancer QoL Questionnaire Core 30 (QLQ-C30) and the Lung Cancer 13 module (QLQ-LC13) at baseline (BL) and on day 1 of each cycle. Higher scores indicated higher functioning/QoL or greater symptom severity. Change from BL (ΔBL) was summarized; a ≥ 10-point ΔBL (improved or worsened) was considered clinically meaningful. An average of mean ΔBL was calculated for each pt across cycles to determine the proportion of pts with a clinically meaningful change.

Results: Median treatment duration was 8.3 months. Interim PRO data were analyzed through cycle 24; the completion rate was ≥94%. Clinically meaningful improvements from BL were seen for global QoL; most pts had improved (43%) or stable (neither improved nor worsened) scores (40%). Clinically meaningful improvements occurred in functioning domains and symptoms; further details will be presented. The highest proportion of pts improved in emotional (38%), role (38%) and social (34%) functioning domains. Proportions of pts with improved/stable/worse cognitive functioning were 24%/51%/24%. Most pts had improved or stable symptom scores; the greatest proportions of pts improved for symptoms of fatigue (49%), insomnia (45%) and appetite loss (42%) on QLQ-C30 and cough (44%), pain in other parts (33%) and pain in chest (30%) on QLQ-LC13. The symptom with the greatest proportion of pts with clinically meaningful worsening was peripheral neuropathy (38%).

Conclusions: Lorlatinib showed favorable clinical benefit and improvements in global QoL, functioning and key NSCLC symptoms in pts with ALK+ or ROS1+ NSCLC.

Clinical trial identification: Clinical trial registration: NCT01970865.

Background: ROS1 mutation occurs in approximately 1-2% of patients with NSCLC. There are limited data on the efficacy of crizotinib therapy in the treatment of ROS1-positive advanced stage NSCLC. The survival results of two studies evaluating the efficacy of crizotinib in these patients are contradictory. In the study, we aimed to evaluate real life data of the patients with ROS1 positive advanced stage NSCLC treated with crizotinib in Turkey.

Methods: In this multicenter study, patients with ROS1-positive NSCLC treated with crizotinib were retrospectively analyzed. Clinical and demographic characteristics of the disease, response rates median PFS and side effects with crizotinib were evaluated in 42 patients.

Results: Twenty-two of the patients (52.4%) were female, and 23 (54.8%) were non-smoker. The median age at the time of diagnosis was 51 (20-80) years. The most common histology was adenocarcinoma (n ve %). At baseline, 12 (28.6%) patients had pleural effusion, 11 (26.2%) had brain metastasis, and 17 (40.5%) had bone metastasis. The baseline ECOG performance score was "0" in 28.6% and "1" in 64.3%. Crizotinib was used in 45.2% of patients at the first line, 42.9% at the second line, and 12.0% in the next steps. The most common side effect was fatigue (43%). In 4 patients vascular event developed (3 thromboemboli, 1 acute MI). Brain metastasis developed in 31% of the patients at the follow-up. The overall response rate with crizotinib was 59.5% with 9.5% complete remission and 50.0% partial remission. The disease control rate was 83.3%. The median PFS was 13.2 months and the 12-month PFS was 53%. Twelve-month OS was 62%, the median OS was 25 months. Two patients who developed progression were treated with lorlatinib and one patient was treated with ceritinib and and then alectinib. Overall survival in these patients were 24 months, 28 months and 13.7 months, respectively.

Conclusions: In 2 published studies, median PFS in patients with ROS1-positive NSCLC with treated crizotinib were reported as 9.1 and 19.2 months independently of the treatment step. In our study, the median PFS was 13.2 months in patients as a result of real-life data of patients in Turkey. The clinical features of the disease are compatible with the literature.

1402P Docetaxel plus ramucirumab with primary prophylactic pegylated-granulocyte-colony stimulating factor for pretreated non-small cell lung cancer

D. Harada[1], A. Hata[2], C. Okuda[2], R. Kaji[2], Y. Masuda[3], Y. Takechi[4], T. Kozuki[1], N. Nogami[1], N. Katakami[2]

[1]Department of Thoracic Oncology, National Hospital Organization Shikoku Cancer Center, Matsuyama, Japan, [2]Department of Medical Oncology, Kobe City Medical Center General Hospital, Kobe, Japan, [3]Department of Pharmacy, Kobe City Medical Center General Hospital, Kobe, Japan, [4]Department of Pharmacy, National Hospital Organization Shikoku Cancer Center, Matsuyama, Japan

Background: A Japanese randomized phase II trial comparing docetaxel plus ramucirumab with docetaxel monotherapy (JVCG) showed that effectiveness of additional ramucirumab was comparable to that of a randomized phase III trial (REVEL). However, in the JVCG study, febrile neutropenia (FN) was confirmed in 34% of the patients in the combination arm. It was assumed that the high frequency of FN was related to the fact that preventive prophylactic pegylated (PEG)-granulocyte-colony stimulating factor (G-CSF) was administered to only 6% of the patients. The aim of our study was to evaluate the efficacy and safety of docetaxel plus ramucirumab with primary prophylactic PEG-G-CSF for Japanese pretreated non-small cell lung cancer (NSCLC).

Methods: We retrospectively reviewed medical records of pretreated NSCLC cases who had received docetaxel plus ramucirumab in our departments.

Results: Sixty-one pretreated NSCLC patients underwent docetaxel plus ramucirumab. Primary prophylactic PEG-G-CSF was performed in 52 (85%) patients (prophylactic group). No FN (0%) was confirmed in 52 prophylactic group patients, whereas FN was observed in 3 (33%) of 9 non-prophylactic group patients. Among prophylactic group, median lines of prior therapy was 2 (range, 1-9). Median cycles of docetaxel plus ramucirumab was 3 (range, 1-25) (9 and 3 cases moved to ramucirumab and docetaxel monotherapies, respectively). Response rate and disease control rate were 30.8% and 73.1%, respectively. Median progression-free survival was 4.5 (95% confidence interval [CI], 3.0-6.6) months. Median overall survival was 11.4 (95% CI, 8.0-13.9) months. Six (11.5%) patients had grade 3/4 neutropenia. Observed grade 3 (incidence $\geq$10%) adverse event (AE) was oral mucositis (13.5%). There were no grade 4/5 non-hematological AEs.

Conclusions: Our study demonstrated the efficacy and safety of docetaxel plus ramucirumab with PEG-G-CSF. Primary prophylactic PEG-G-CSF could markedly reduce incidence of FN in Japanese clinical practice.

Editorial acknowledgement: We thank Ayami Asakawa, Mizuho Awaki, Suemi Minamihara, Hiroko Ishikawa and Mamiya Atagi for their assistance, and Mr. David Martin for writing support.

Background: The addition of bevacizumab (B) to platinum doublets prolongs the survival for non-squamous (NSQ) NSCLC. The role of monotherapy with B is unclear for elderly NSQ NSCLC patients (pts). We presented the comparable efficacy data in a previous meeting. Here, we present the survival and quality of life analyses of TORG1323.

Methods: Pts were pathologically diagnosed untreated elderly (≥75 years old) NSQ NSCLC, who were stage IIIB, IV, or recurrent disease, and PS 0-1. EGFR mutation or ALKrearranged pts were allowed after receiving each tyrosine kinase inhibitor. Pts were randomized 1:1 to receiving either docetaxel (D) or pemetrexed (P) with B. The primary endpoint was progression-free survival (PFS) assessed by independent review committee. B was administered 15 mg/kg, D was 50 mg/m^2, or P was 500 mg/m^2 every 3 weeks until disease progression or unacceptable toxicity based on our previous studies. Selection design was adopted for this study. The planned sample size was 120 pts to yield 80% power to select an optimal regimen correctly and PB is chosen for the further evaluation if the point estimate of hazard ratio (HR) for PFS was ≤1.20.

Results: Enrollment was terminated early at the end of March 2017 because of slow accrual. A total of 103 pts (DB/PB= 51/52 pts) were enrolled and 99 pts (49/50 pts) comprise the full analysis set. Patient characteristics were well balanced between the two arms. Median age was 78 (range: 75-88) in DB and 79 (75-94) in PB. EGFR mutation+/ALK translocation+/wild type/unknown= 13/0/34/2 in DB and 13/2/33/2 in PB. A total of 77 events occurred at data cut-off, which corresponded to 77.7% power. The median PFS of DB and PB were 6.1 months (mo) and 4.6 mo (HR 1.03, 95%C.I. 0.66-1.61: p = 0.901). The median OS of DB and PB were 18.7 mo and 26.6 mo (HR 0.69, 95% C.I. 0.36-1.30; p = 0.2465). The mean change from baseline of Functional Assessment of Cancer Therapy - Lung (FACT-L) total was -8.4 in DB and -2.7 in PB (p = 0.0096).

Conclusions: PB results in less deterioration of QoL. The efficacy is comparable between the two arms for elderly (≥75 years old) advanced NSQ NSCLC.

Clinical trial identification: UMIN000012786 01-Jan-2014.

Background: The SENECA trial, a phase IIb, open label, multicentre study, aimed to investigate in the real life efficacy and safety of nintedanib plus docetaxel, used weekly (T1) or q3wks (T2), in pretreated nsNSCLC patients, stratified for relapse-timing (within or over 3 months from end of first-line therapy). Preliminary efficacy data have been previously presented: no difference in median Progression Free-Survival and a similar trend in Overall Survival between T1 and T2 were showed. Weekly docetaxel has better tolerability than q3wks administration: aim of this study is to evaluate two different docetaxel schedules combined with nintedanib, in order to potentially maximize their use.

Methods: Baseline characteristics have been already presented. Incidence and severity of treatment-related Adverse Events (AEs) were evaluated from beginning of treatment until 28 days after its completion, according to Common Terminology Criteria for Adverse Events (CTCAE) version 3, in 167 patients (receiving at least one dose of study drugs) enrolled in 18 Italian oncologic centres, between January 2016 and March 2018.

Results: Incidence of any grades AEs was numerically higher in T2 compared to T1 (484 vs 450 events, respectively); a complete overview of AEs (≥ 5% incidence in either group) is reassumed in Table1. Docetaxel was reduced in 14.4% patients, more frequently in T2 vs T1 (18.8% vs 9.7%). Nintedanib reduction was needed in 19.8% of patients, 23.2% in T1 and 15.3% in T2, mainly for diarrhea. Thirty-one (18.6%) patients permanently discontinued study drugs (11 in T1 vs 20 in T2) due to hypersensitivity reactions and pain.

Table: 1404P Main AEs observed in the SENECA trial according to docetaxel schedule and CTCAE grade

AEs	N = 167					
	T1 (N = 82)	T2 (N = 85)	p-value	T1 (N = 82)	T2 (N = 85)	p-value
	Any Grades			Grade ≥ 3		
Fatigue	44(53.6%)	56(65.9%)	0.10	5(6.1%)	10(11.7%)	0.20
Diarrhea	41(50%)	40(47%)	0.70	4(4.8%)	4(4.7%)	0.95
ALT elevation	24(29.3%)	17(20%)	0.16	4(4.8%)	5(5.9%)	0.77
Afebrile Neutropenia	11(13.4%)	45(52.9%)	<0.0001	3(3.6%)	17(20%)	<0.0001
Pain	19(23.2%)	21(24.7%)	0.81	3(3.6%)	2(2.3%)	0.62
Anemia	18(21.9%)	16(18.8%)	0.61	1(1.2%)	1(1.2%)	0.30
Nausea	17(20.7%)	14(16.5%)	0.47	3(3.6%)	3(3.5%)	0.96
Dyspnea	16(19.5%)	18(21.2%)	0.78	2(2.4%)	2(2.3%)	0.97
Fever	15(18.3%)	9(10.6%)	0.15	2(2.4%)	0(0%)	0.14
Cough	13(15.8%)	14(16.5%)	0.91	0(0%)	0(0%)	NE
Decreased Platelets	11(13.4%)	2(2.3%)	0.007	0(0%)	0(0%)	NE
Skin Toxicity	11(13.4%)	9(10.6%)	0.57	0(0%)	1(1.2%)	0.32
Oral Mucositis	10(12.2%)	19(22.3%)	0.08	3(3.6%)	1(1.2%)	0.29
GGT elevation	9(11%)	10(11.8%)	0.87	3(3.6%)	5(5.9%)	0.50
Vomiting	7(8.5%)	15(17.6%)	0.08	0(0%)	1(1.2%)	0.32
Decreased leukocytes	5(6.1%)	10(11.8%)	0.20	0(0%)	2(2.3%)	0.16
AST elevation	6(7.3%)	6(7%)	0.94	2(2.4%)	1(1.2%)	0.53
Dysgeusia	6(7.3%)	5(5.9%)	0.70	0(0%)	0(0%)	NE
Parestesie	4(4.9%)	1(1.2%)	0.38	7(8.5%)	0(0%)	0.97

ALT: alanine aminotrasferase; NE: not evaluable; AST: aspartate aminotransferase; GGT: gamma-glutamyltransferase.

Conclusions: Preliminary safety data of SENECA trial show statistically significant differences only in a few of the items explored (particularly afebrile neutropenia), but underline a clear trend of higher tolerability for weekly docetaxel combination treatment in second line nsNSCLC patients.

Background: Lung cancer is one of the most common non-AIDS-defined malignancies. Its prognosis has been considered to be poorer in HIV-positive patients (pts) than is the general population. Circulating tumor DNA (ctDNA) has been shown to be a prognostic marker in HIV-undetermined pts. Our goal was to assess its prognosis value in HIV-positive pts.

Methods: 61 HIV-positive pts with advanced non-squamous NSCLC were included in IFCT phase II trial evaluating carboplatin AUC5 pemetrexed 500 mg/m^2 every 3 weeks, as first-line of treatment. Baseline blood samples were collected in all pts; ctDNA was assessed by ultra-deep targeted NGS using a dedicated variant caller algorithm.

Results: 55 (90%) samples were available. They were from 42 males (76.4%), 53 ± 7 years (mean ± SD), smokers (92.7%), stage III (9%) or IV (91%) and performance status (PS) 0-1 (83.6%). 18 pts were AIDS (32.7%) and 49 received HAART (89%). Mean (±SD) CD4 counts were 223/μL±222 and viral load of 39.5 [0-95499]. Disease control rate at 4 cycles was 32.7% (n = 18). PFS was 3.5 months (IC95% 2.6-4.7). OS was 8.8 months (IC95% 5.9-13.7). ctDNA was detected in 35 pts (64%) with 22 and 13 pts having high [2-49%] or low ctDNA [0.7-2%] loads, respectively. Among positive samples, 77% had a TP53 mutation and 43% had more than one alteration. Alterations in oncogene drivers were identified in KRAS, NRAS, EGFR, BRAF and MET and were mutually exclusive. ctDNA positivity was not related to clinical parameters. In multivariate analysis, AIDS status (HR 2.17 (1.09-4.32), p = 0.03) and positive ctDNA (HR 4.31 (2.06-8.99), <0.0001) were significantly associated to PFS and, PS 2 vs. 0-1 (HR 4.10 (1.62-10.36), p=.003) and positive ctDNA (HR 3.52 (1.72-7.19), p = 0.0006) to OS. Similar results were found when groups were analyzed according to ctDNA quantification, low versus high versus null.

Conclusions: ctDNA detection and quantification using ultra-deep targeted NGS is an independent prognostic factor of OS and PFS in advanced NSCLC from HIV-infected pts.

Clinical trial identification: NCT01296113.

1406P Final results of the concordance analysis of PD-L1 immunohistochemistry (IHC) assays and polymerase chain reaction (PCR) in non-small lung cancer (NSCLC) patients

I. Tsimafeyeu[1], E.N. Imyanitov[2], L. Zavalishina[3], G. Raskin[4], P. Povilaitite[5], N. Savelov[6], E. Kharitonova[1], A. Rumyantsev[7], I. Pugach[1], Y. Andreeva[3], A. Petrov[5], G. Frank[3], S. Tjulandin[7]

[1]Russian Society of Clinical Oncology, Moscow, Russian Federation, [2]Laboratory of Molecular Oncology, N.N.Petrov Research Inst. of Oncology, Saint Petersburg, Russian Federation, [3]Pathology Department, Russian Medical Academy of Continuous Professional Education, Moscow, Russian Federation, [4]Pathology, A.M. Granov Russian Scientific Centre of Radiology and Surgical Technologies, Saint-Petersburg, Russian Federation, [5]Dept. of Pathology, Rostov Regional Bureau of Pathology, Rostov-on-Don, Russian Federation, [6]Lab. of Pathology, Moscow City Oncology Hospital No. 62, Moscow, Russian Federation, [7]Dept. of Clinical Pharmacology and Chemotherapy, N.N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation

Background: The goal of the CLOVER study is to perform a pairwise comparison of 4 tests based on the same patient population: 3 validated PD-L1 IHC assays [Ventana SP142 (atezolizumab), Ventana SP263 (durvalumab), Dako 22C3 (pembrolizumab) and one PCR test.

Methods: 473 NSCLC samples (including 81 EGFR+, 36 ALK+, 131 squamous cell carcinoma) were stained with PD-L1 IHC assays. Four pathologists independently evaluated the percentages of tumor (TC) and tumor infiltrating immune cells (IC) staining positive at any intensity. PD-L1 transcripts were quantified by Taqman RT-PCR assay using SDHA as a gene-referee; dCT = 2 was chosen as a threshold between positive and negative RNA expression. The concordance analysis was performed to assess (1) correlation of IC and TC between different assays, (2) the predictive properties of one test of another. One test-specific cutoff rule for each assay was pre-specified as: for first-line TC or IC ≥ 5% for SP142, TC ≥ 25% for SP263, TC ≥ 50% for 22C3, and for second-line TC ≥ 50% or IC ≥ 10% for SP142, TC ≥ 25% for SP263, TC ≥ 1% for 22C3.

Results: Pearson Correlation Coefficients (PCC) for TC were: 0.71, 0.87 and 0.75 between SP142/22C3, SP263/22C3 and SP142/SP263, respectively. PCC for IC were: 0.45, 0.61 and 0.68 for the same pairs. Low correlation was observed between PCR test and any of the IHC assays for TC and IC. Table represents how well one assay can predictthe same outcome (positivity or negativity) of another assay using recommended individual cutoffs for each test. Among patients who were negative by PCR, 92%-99% of the patients were negative by any of the three IHC assays using corresponding recommended cutoff. Among patients who were positive by PCR, 9-45% of them were positive by IHC assays.

Table: 1406P Probability of negative test B, given negative test A

Test A	Test B					
	SP142		SP263		22C3	
	First-line	Second-line	First-line	Second-line	First-line	Second-line
SP142	-	-	92%	85%	97%	65%
SP263	91%	98%	-	-	99%	76%
22C3	88%	99%	91%	99%	-	-
Probability of Positive Test B, given Positive Test A						
SP142	-	-	65%	76%	48%	94%
SP263	68%	28%	-	-	57%	98%
22C3	82%	17%	93%	49%	-	-

Conclusions: PCR should not be recommended as a substitute for a PD-L1 IHC assay due to high probability of false positive prediction and low PCC. 22C3 could be considered as a substitute for SP263 in first-line.

Background: Baseline dNLR is associated with ICI outcomes in advanced NSCLC; we previously reported that the early dNLR change during ICI was correlated to benefit in 292 advanced NSCLC patients. We aimed to confirm the impact of dNLR monitoring in a larger cohort.

Methods: 1225 patients with advanced NSCLC treated with ICI (PD1/PDL1 +/- CTLA4) from 10 European/US centers were identified between Nov. 2012 and Mar. 2018. dNLR at baseline and before cycle 2 were retrospectively collected. dNLR was defined as neutrophils/(leucocytes-neutrophils). dNLR monitoring, combining dNLR at baseline (B) et before cycle 2 (C2) stratified the 3 groups: good (if dNLR$\leq$3 remained low at B and C2), intermediate (if dNLR status increased $\leq$3 at B and >3 at C2 or decreased >3 at B and $\leq$3 at C2), poor (dNLR>3 at B and C2).

Results: 689 (56%) were males, 1058 (87%) smokers, 1066 (87%) with PS $\leq$ 1, with median age 65 years; 926 (76%) had nonsquamous; 108 were KRASm. PDL1 was known in 403/1225 (33%) and was $\geq$1% in 270 (67%). The median PFS and OS were 3.1m [95% CI 3-4] and 12m [10-13.7]. dNLR was >3 at B in 416 (34%) and before C2 in 417 pts (34%). At C2, the dNLR status changed in 267 pts, with 133 (11%) dNLR decreased and 134 (11%) dNLR increased. The median OS was 18.6m [16-21] for the good group when dNLR remained low (n = 675, 55%), 9.2m [8-13.9] for the intermediate when dNLR changed (n = 267, 22%) and 5m [4-6.3] for the poor group when dNLR remained high (dNLR>3, n = 283, 23%) (P < 0.0001). The median PFS was 5m [4-5.5] for the good group, 2.6m [2-4] for the intermediate and 2m [2-2.6] for the poor group (P < 0.0001). The poor group was associated with radiological disease progression (OR 2.22, CI 1.33-3.7, P = 0.002).

Conclusions: Baseline and 2nd cycle dNLR monitoring can early discriminate the benefit to ICI in advanced NSCLC patients on treatment. dNLR should be prospectively studied in clinical trials.

Background: Brain metastases (BM) are frequent in NSCLC. Unfortunately, pts with (untreated) BM are often excluded from ICI trials and prognostic factors in ICI treated BM pts are largely unknown.

Methods: Retrospective data collection of all consecutive advanced ICI treated NSCLC pts in 6 centers (5 French, 1 Dutch) (nov 2012 – March 2018). All BM pts were selected; (intracranial) overall response rate (investigator assessed), progression free survival (PFS), overall survival (OS) data were collected. Active BM: non-irradiated new and/or growing lesions on brain imaging < 6 weeks before ICI start.

Results: 241/945 (26%) pts had BM: 61% male, 76% WHO PS 0-1, median age 61 years, 75% nonsquamous, 4% driver mutation, 31% known PD-L1 (61% $\geq$1% expression). ICI treatment was median 2nd line (range 1-8), 95% had monotherapy ICI. Median time BM diagnosis till ICI start: 184 days. >5 BM: 30%, active BM: 40%, symptomatic: 14%, steroid use: 26%, known disease specific Graded Prognostic Assessment (ds-GPA) at start of ICI: 94% (36% 0-1, 58% 1.5-2.5, 6% 3), previous cranial irradiation (RT): 68% (56% stereotactic, 44% whole brain), median time RT to ICI start: 109 days. Median follow-up: 14 months. 78% had PD on ICI: 12% BM only, 28% extracranial, 50% both, 10% no imaging (clinical PD). At PD, 23% of BM only PD pts had extracranial response and 21% of extracranial only PD pts had cranial response. Median (95% CI) PFS and OS were 2 (1-2) and 9 (7-13) months, respectively. In multivariate analysis, > 2 metastatic organs and symptomatic BM at ICI start were associated with a worse PFS and OS; higher ds-GPA with superior PFS and OS (Table). In univariate analysis, active BM vs stable BM and brain RT vs no brain RT were not associated with outcome (HR PFS 0.98 (p = 0.66)/ HR OS 0.93 (p = 0.92) and HR PFS 0.82 (p = 0.19) / HR OS 0.82 (p = 0.27)).

Conclusions: Number of metastatic organs, symptomatic BM and ds-GPA are associated with outcome in BM pts treated with ICI.

1409P Association of efficacy and immune-related adverse events (irAEs) in patients with NSCLC receiving immune-checkpoint inhibitors (ICIs)

M. Riudavets Melia[1], I. Gabriela Sullivan[1], A. Barba Joaquín[1], G. Anguera Palacios[1], L.P. del Carpio[1], C. Molto Valiente[1], S.D. Camacho Arellano[1], S. Moron Asensio[1], P. Gomila Pons[1], M. Andres Granyó[1], D. Castillo Villegas[2], C. Facundo Molas[3], E. Garcia Planella[4], C. González Blanco[5], A. Barnadas Molins[1], I. Gich Saladich[6], M. Majem Tarruella[1]

[1]Medical Oncology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [2]Pneumology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [3]Nephrology, Puigvert Foundation, Barcelona, Spain, [4]Gastroenterology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [5]Endocrinology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [6]Epidemiology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background: ICIs are a standard treatment in advanced NSCLC. However, ICIs can induce irAEs that may interrupt treatment. Here we report the incidence of irAEs and its correlation with efficacy.

Methods: We retrospectively analyzed 101 patients (pts) with advanced NSCLC receiving ICIs in our institution from March 2014 to January 2018. IrAEs were graded following CTCAE v4.0. Kaplan Meier and log-rank tests were used to evaluate progression-free (PFS) and overall survival (OS). Analyses were performed using SPSS v24 package.

Results: Median age was 66.4 [37-85] years, 74.3% were male. 33 (32.7%) pts presented squamous and 68 (67.3%) non-squamous histology. Most frequent ICIs were nivolumab (50%), pembrolizumab (31%) and atezolizumab (16%), used as monotherapy (79.2%) or in combination with chemotherapy (20.8%). Median duration of treatment was 2.7 [0.6-26.2] months. 61 (60.4%) pts developed 106 irAEs, with a mean of 1.02 [0-4] irAEs/pts. Most frequent irAEs were rash (24.5%), pruritus (22.6%), diarrhea (21%), thyroid dysfuncion (10.5%), arthritis (8.5%), hepatitis (2.9%) and pneumonitis (2%). 8 (7.5%) patients experienced grade (G) 3-4 irAEs: 1 G3 pneumonitis, 4 G3 diarrhea, 1 G3 mucositis, 1 G3 nephritis and 1 G3 haemolytic anemia. There was one treatment-related death due to pneumonitis. 47 (46.5%) pts received systemic corticosteroids during immunotherapy, 29.8% for irAEs management. 11 (10.9%) pts discontinued treatment due to irAEs. At the time of data analysis, 86.8% of irAEs had improved. With a median follow-up of 8.9 [0.6-48.2] months, median OS was superior in pts experiencing irAEs: not reached (NR) vs 7.8 [95%CI, 5.2-10.5] months (p 0.001). Similarly, PFS was significantly longer: 6.2 [95%CI, 2.3-10.1] vs 2.7 [95%CI, 1.8-3.5] months ($p < 0.0001$). OS was higher in pts who didn't receive steroids during ICIs: NR vs 9.9 [95%CI, 6.8-13.0] months (p 0.024). No association was found between efficacy and the use of antibiotics in the 3 months before first ICIs injection or during treatment.

Conclusions: Development of irAEs was associated with efficacy of ICIs in pts with advanced NSCLC. A negative correlation between the use of systemic corticosteroids and outcomes was found.

1410P Tumor mutation burden (TMB) estimation using small-sized targeted next-generation sequencing (NGS) to predict efficacy of immune checkpoint inhibitors (ICIs) for non-small cell lung cancer (NSCLC)

T. Ikeda[1], K. Ohashi[2], A. Sekine[3], Y. Ohe[4], T. Tsuda[5], Y. Kataoka[6], S. Hara[7], N. Okamoto[8], M. Kodani[9], S. Matsumoto[10], K. Goto[11]

Background: TMB is promising as a biomarker for the treatment with ICIs. However, because it is difficult to apply whole exon-based TMB analysis into the current practice, clinically applicable simple methods for estimating TMB are needed. The aim of this study was to evaluate TMB based on a small-sized targeted NGS as a biomarker for ICIs.

Methods: Since March 2015 to April 2017, a total of 2243 NSCLC patients (pts) from 244 institutions were enrolled in our large-scale nationwide genome screening network (LC-SCRUM-Japan). Tumor samples were subjected to a 260 kb-sized NGS assay, Oncomine Comprehensive Assay (OCA) ver.1, targeting 143 cancer-related genes. TMB, number of somatic mutations/Mb, was assessed from the results of OCA ver.1 assay, and a cut-off point of TMB to predict response to ICIs was determined by ROC curve. Clinico-genomic database of LC-SCRUM-Japan was utilized for this analysis.

Results: 470 NSCLCs, consisting of 359 adenocarcinomas, 73 squamous cell carcinomas and 38 others, were evaluated in this study. The median number of mutations was 11.5/Mb (range, 0-130.8/Mb). We defined number of mutations ≧15.4/Mb as high TMB and <15.4/Mb as low TMB. High TMB was observed 34.3% (123/359) in adenocarcinoma and 41.1% (30/73) in squamous cell carcinoma. The response rate was higher in pts with high TMB than in those with low TMB (13.3% [23/173] vs. 5.7% [17/297], $p = 0.0059$). The durable clinical benefit (DCB; complete response, partial response or stable disease that lasted >6 months) rate also tended to be higher in pts with high TMB than in those with low TMB (17.3% [30/173] vs. 11.8% [35/297], $p = 0.0980$). The progression-free survival (PFS) was not significantly different between the high and low TMB pts (median PFS, 4.4 vs. 3.3 months, $p = 0.1401$).

Conclusions: TMB estimated by OCA ver.1 seemed to be correlated with response rate and DCB but not PFS in NSCLC pts treated with ICIs, suggesting a limitation of TMB estimation by this small-sized targeted NGS as a biomarker of ICIs. Optimal TMB estimation to predict the efficacy of ICIs are warranted.

1411P Identification of genomic markers of sensitivity and resistance to checkpoint inhibitors in non-small cell lung cancer in a real world clinico-genomic database

K. Murugesan, G. Li, G. Kaushik, G. Singal, V.A. Miller, G.M. Frampton, L.A. Albacker

Cancer Genomics, Foundation Medicine, Inc., Cambridge, MA, USA

Background: Treatment of non-small cell lung cancer (NSCLC) with checkpoint inhibitors (CI) that block the PD-L1 pathway has resulted in profound responses but only in a subset of patients. Our aim was to examine biomarkers associated with response and resistance to CI in advanced NSCLC to help inform patient stratification.

Methods: We examined 820 lung adenocarcinoma (LUAD) samples that had matched PD-L1 staining and received genomic profiling to measure tumor mutational burden (TMB) and genomic alterations in 315 genes (FM cohort). We also examined progression free survival (PFS) of 1310 CI treated patients in a HIPAA compliant, real world clinicogenomic database (CGDB). These patients received the FoundationOne assay as part of routine care and had electronic health record data available in the Flatiron Health Database (Singal, ASCO 2017).

Results: In the CGDB, we observed known associations between likelihood of PFS and TMB, loss of STK11. TMB correlated with median PFS in months (mPFS): TMB > 20 mutations per MB (N = 164) – 6 mo vs TMB < =20 (N = 1146) – 2.8 mo, P = 1e-07). Patients with STK11 loss had reduced mPFS (wt 3.1 mo vs mut 2.5 mo, P = 0.01). We analyzed PDL1 staining for driver alterations in LUADs in the FM cohort. EGFR mutant samples were enriched for PDL1 negative staining (FM cohort: P = 6.3e-5) and the EGFR cohort had reduced mPFS (CGDB: wt 3 mo vs mut 2.4 mo, P = 0.003). Samples with MET exon 14 skipping mutations were enriched for PDL1 high positive staining (FM: P = 2.3e-5), but the MET cohort had similar mPFS (CGDB: wt 3 mo vs mut 2.7 mo, P = 0.8). Samples with BRAF alterations trended towards both PDL1 high positive staining (FM: P = 0.06) and increased mPFS (CGDB: wt 2.9 mo vs mut 4.6 mo, P = 0.2).

Conclusions: We examined PFS of NSCLC patients on CI therapies in a clinicogenomic database and observed known associations with TMB, STK11 and EGFR alterations. We found that, at a population level, MET altered patients did not have enhanced mPFS despite increased PDL1 HP staining, suggesting dual or targeted therapies. Real-world datasets such as the CGDB hold promise in prioritizing therapies and identifying biomarkers of response and resistance.

1412P HLA-DrbB1 heterozygosis and early auto-antibody rise predict prolonged survival in metastatic NSCLC patients undergoing PD-1 blockade

P. Correale[1], R. Giannicola[1], C. Botta[2], P.S. Tagliaferri[2], P. Pastina[3], M. Monoriti[4], R. Saladino[4], A. Falzea[1], V. Barbieri[2], G. D'Arrigo[5], G. Tripepi[5], P. Tassone[2], L. Pirtoli[3]

[1]Onco-Hematology and Radiotherapy, Grande Ospedale Metropolitano, Reggio Calabria, Italy, [2]Magna Grecia University, Medical Oncology Unit, AUO Mater Domini, Catanzaro, Italy, [3]Radiotherapy Unit, University Hospital of Siena, Istituto Toscano Tumori, Siena, Italy, [4]Patologia Clinica, Grande Ospedale Metropolitano, Reggio Calabria, Italy, [5]CNR IFC, Reggio Calabria, Italy

Background: PD-1/PDL-1-blockade by nivolumab is a promising and efficacious treatment for mNSCLC patients. It acts by rescuing PD-1-inactivated tumor-infiltrating-lymphocytes, an event indispensable for a short-term antitumor response. Nevertheless, continuous immune-priming is needed to avoid clonal-T-cell exhaustion and to prolong patient survival. We have investigated, whether class-I/II HLA homo/heterozygosis, antigen cascade and cross-priming measured as auto-antibody (AAbs) rise may predict patient outcomes with nivolumab treatment.

Methods: This is a retrospective study including ninety-eight mNSCLC patients who received nivolumab (3mg/kg every 15 days) between September 2015 and March 2018 as a second line of treatment. Log-rank test and Mantel-Cox analysis were carried out to correlate PFS and OS with homo/heterozygosis HLA status, respectively, for locus A, B, C and DrB1 and baseline and post-treatment levels of AAbs [anti-nuclear antibodies (ANA), extractable nuclear antigen (ENA), anti-smooth cell antigen (ASMA), anti-neutrophil cytoplasmic antigens (ANCA)].

Results: A PFS and OS of 13.68 (95%CI:10.85 -16.5) and 16.41 (95%CI:13.48- 19.34) months, were, respectively, recorded. They were not correlated with histology, sex or previous radiotherapy. HLA-DrB1 heterozygosis showed a significant advantage in OS (HR = 0.18, 95%CI:0.036-0.902; p = 0.037). A prolonged survival was also found in patients who showed early rise (within thirty days) of one (score 1, HR = 0.235, 95% CI: 0.084-0.654. P = 0.018) or more AAbs (score 2, HR = 0.22, 95% CI: 0.081-0.624, P = 0.001). Finally, Cox analysis revealed a predictive role for treatment-related early increase in eosinophil cell counts (OS, HR: 0.68, 95% CI: 0.57-0.81, P = 0.031).

Conclusions: Heterozygosis in the HLA-DrB1 locus and early rise in ANA, ENA and/or ASMA is predictive of longer OS in nivolumab-treated mNSCLC patients. These data support the hypothesis that continuous and efficient tumor antigen-release and cross-priming during PD1/PDL-1 blockade is critical for long-term patient survival. These results offer a strong rationale to design future immunotherapy trials in NSCLC patients.

1413P Neutrophil-platelet score (NPS), a predictive systemic inflammation score for PD-1 immune checkpoint inhibitors (ICI) in pretreated advanced non-small cell lung cancer (NSCLC) patients

X. Mielgo Rubio[1], M. Sereno Moyano[2], L.E. Chara[3], R. López-Castro[4], J. Rubio-Martínez[5], A. Velastegui[6], C. Olier-Garate[1], S. Falagán[2], I. Gómez-Barreda[3], A. Riquelme[7], J. Silva-Ruiz[1], J. Moreno-Rubio[8], C. López[3], C. Bueno[7], A. Cardeña[9], E. Pérez-Fernández[10], M.P. Martí-Castelló[11], M.J. Sotelo-Lezama[7]

[1]Oncology Unit, Hospital Universitario Fundación Alcorcón, Alcorcón, Spain, [2]Medical Oncology, Hospital Infanta Sofia, Ss De Los Reyes, Spain, [3]Medical Oncology, Hospital Universitario Guadalajara, Guadalajara, Spain, [4]Medical Oncology, Hospital Universitario Clínico de Valladolid, Valladolid, Spain, [5]Medical Oncology, Hospital Universitario Móstoles, Móstoles, Spain, [6]Medical Oncology, Hospital Universitario Rey Juan Carlos, Móstoles, Spain, [7]Medical Oncology, Hospital Infanta Cristina, Parla, Spain, [8]Medical Oncology, Hospital Infanta Sofia, Madrid, Spain, [9]Oncology, Hospital Universitario Fundación Alcorcón, Madrid, Spain, [10]Research Unit, Statistical Support, Hospital Universitario Fundación Alcorcón, Alcorcón, Spain, [11]Medicine, Universidad Rey Juan Carlos, Alcorcón, Spain

Background: Systemic inflammation response can be characterized by changes of peripheral blood cell amounts. Several blood cell-based scores have been found to have prognostic value in some tumors treated with ICI. Neutrophil-platelet score (NPS) is a systemic inflammation-based score characterizing 3 prognostic groups: good (0), neutrophils < =7500 and platelets < =400000; intermediate (1), neutrophils >7500 or platelets >400000; poor (2), neutrophils >7500 and platelets >400000). It has never been evaluated as prognostic biomarker in NSCLC patients treated with ICI.

Methods: This is a multicenter retrospective study with the aim to evaluate prognostic value of NPS in patients with pretreated advanced NSCLC treated with PD-1 ICI between March 2015 and April 2018. Clinical data were contributed by 7 medical centers in Spain. Primary endpoint was association of NPS with overall survival (OS).

Results: 168 patients were included. Median age 65 years (39-85). 134(79,8%) were male and 121(72%) were PS > =1. Predominant histologies were adenocarcinoma (50%) and squamous-cell carcinoma (42,9%). 92,3% received nivolumab and 7,7% pembrolizumab. 2,3% had EGFR mutations, and 0,6% ALK rearrangement. PD-L1 IHC was available in 25% (<1%: 36,6%; 1-49%: 39%; > =50%: 24,4%). Median number of prior lines was 1 (1-5). Median number of cycles 11 (1-68). Median follow-up time 6,3m. Response rate (RR) was 30,4% and disease control rate (DCR) 52%. Median PFS and OS were 5,6 months (m) (3,9-7,3) and 11,4 m (9,4-13,5). According to NPS, median OS for good, intermediate, and poor prognostic groups was 11,9m (9,4-14,4), 6,8m (3,3-10,2), and 3m (1,4-4,6), respectively (p = 0,003). Higher NPS was associated with poor OS: NPS1 HR 1,73 (95%CI,1,13-2,65),p=0,01; NPS2 HR 2,89 (95%CI,1,31-6,39), p = 0,009). No significant association between NPS and PFS was found. NPS was associated with DCR, NPS2 had more patients with progression disease as best response to ICI than NPS1 and 0 (86 vs 57 vs 42%, p = 0,039).

Conclusions: NPS predicted OS and DCR in pretreated advanced NSCLC patients who received treatment with PD-1 ICI nivolumab or pembrolizumab. These results need to be validated in prospective studies.

1414P Prediction of PD-1 immunotherapy (IO) response for KRAS mutated non-small cell lung cancer (NSCLC) based on co-mutations using a computational biological model

H. Wakelee[1], J. Aredo[2], S. Vali[3], N.K. Singh[4], S.V. Vasista[4], U. Mitra[4], T. Abbasi[3], S.K. Padda[5]

[1]Medicine/Oncology, Stanford Advanced Medicine Center, Stanford, CA, USA, [2]School of Medicine, Stanford University, Stanford, CA, USA, [3]Research, Cellworks Group, San Jose, CA, USA, [4]Research, Cellworks Research India Pvt. Ltd, Bangalore, India, [5]Medicine/Oncology, Stanford University, Stanford, CA, USA

Background: KRAS mutated NSCLC is a heterogeneous disease due to the impact of co-mutations (co-mut). In preclinical models, KRASco-mut differentially activate downstream pathways and affect the tumor immune microenvironment in diverse ways. Data suggest KRASco-mut may affect sensitivity to PD-1 axis IO.

Methods: Genomic information of 2974 NSCLC patients was input into computational biological model (CBM) software (Cellworks Group, San Jose, CA). Computational protein network maps of disease characteristics were generated for each patient. CBM was used to predict sensitivity to PD-1 axis IO in KRASco-mut subsets including: KRAS/TP53, KRAS/CDKN2A, KRAS/STK11, KRAS/KEAP1, KRAS/STK11/KEAP1, KRAS/PIK3CA, and KRAS without co-mut. The 3 key metrics used to predict sensitivity included PD-L1 expression; Dendritic Cell Infiltration Index (9 chemokine markers); and Immunosuppressive Biomarker Expression (14 markers). Correlation of CBM prediction of IO sensitivity was examined in a clinical cohort of 36 KRASmutated NSCLC patients with available overall survival (OS) data from Stanford University treated with PD-1 axis IO during their treatment course.

Results: In the overall cohort, withregards to prediction of sensitivity to PD-1 axis IO, CBM predicted the majority of patients with KRAS/KEAP1and KRAS/STK11/KEAP1 to not benefit from IO, whereas CBM predicted the majority of patients with KRAS/TP53, KRAS/PI3KCA, and KRAS without co-mut to benefit. No definitive predictions could be made for KRAS/STK11and KRAS/CDKN2A. In the clinical cohort of 36 patients treated with PD-1 axis IO during their treatment course, CBM was able to assess 27 of these patients, identifying patients with OS > 12 months, with 82.8% positive predictive value, 42.9% negative predictive value, and 75% concordance.

Conclusions: CBM predicted certain subsets of KRASmutated NSCLC based on co-mut are more likely to be sensitive to PD-1 axis IO. In a small clinical cohort of KRASmutated NSCLC treated with PD-1 axis IO, in light of existing biomarkers, CBM identified patients with improved prognosis with good positive predictive value.

1415P Association between early immune-related adverse events and clinical outcomes in patients with advanced non-small cell lung cancer treated with pembrolizumab as first-line therapy: A retrospective multicenter cohort study

K. Hosoya[1], D. Fujimoto[1], M. Tamiya[2], A. Tamiya[3], H. Suzuki[4], K. Hirano[5], T. Yokoyama[6], M. Morita[7], Y. Fukuda[8], M. Kanazu[9], T. Makio[10]

[1]Respiratory Medicine, Kobe City Medical Center General Hospital, Kobe, Japan, [2]Thoracic Oncology, Osaka International Cancer Institute, Osaka, Japan, [3]Internal Medicine, National Hospital Organization Kinki-Chuo Chest Medical Center, Sakai, Japan, [4]Thoracic Oncology, Osaka Habikino Medical Center, Osaka, Japan, [5]Respiratory Medicine, Hyogo Prefectural Amagasaki General Medical Center, Amagasaki, Japan, [6]Respiratory Medicine, Kurashiki Central Hospital, Kurashiki, Japan, [7]Respiratory Medicine, Kobe City Medical Center West Hospital, Kobe, Japan, [8]Respiratory Medicine, Himeji Medical Center, Himeji, Japan, [9]Thoracic Oncology, National Hospital Organization Toneyama National Hospital, Toyonaka, Japan, [10]Respiratory Medicine, Itami City Hospital, Itami, Japan

Background: Previous studies have shown that early immune-related adverse events (irAEs) are associated with better outcomes in patients with advanced non-small cell lung cancer (NSCLC) who received nivolumab, and the associations differ among various types of early irAEs. However, these previous studies included patients regardless of their PD-L1 status and lines of therapy.

Methods: We retrospectively analyzed patients with advanced NSCLC and PD-L1 TPS of ≥ 50% who received pembrolizumab as the first line therapy at 10 institutions between February 2017 and January 2018. Patients were excluded if they were treated with systemic glucocorticoids or other immunosuppressive agents. Early irAEs were defined as irAEs that occurred within 3 weeks after commencing pembrolizumab therapy.

Results: In total, 145 patients were included; their median age was 71 (range: 39-87) years. Of the 145 patients, 122 (84%) were men, 119 (82%) had PS 0-1, and 5 (3%) had EGFR-mutations or ALK-rearrangements. In all patients, the objective response and disease control rates were 55% and 77%, respectively. Common early irAEs included rash, pyrexia, and interstitial lung disease. The objective response and disease control rates were significantly higher in patients with early irAEs than in those without (79% versus 46% and 95% versus 71% [both $p < 0.01$]), respectively. Similarly, the median PFS was significantly longer in patients with early irAEs than those without (not reached versus 7.0 months, $p = 0.04$). When we analyzed the association between types of early irAEs and clinical outcomes, rash and/or pyrexia was strongly associated with longer PFS than those without rash or pyrexia (not reached vs. 6.9 months, $p = 0.01$). The follow-up is ongoing.

Conclusions: In patients with advanced NSCLC and PD-L1 TPS of ≥ 50% who received first-line pembrolizumab, early irAEs were associated with better clinical outcomes. Moreover, early development of rash and pyrexia was strongly associated with better clinical outcomes.

Clinical trial identification: UMIN000032470.

1416P Immunosenescence (iSenescence) correlates with disease progression in advanced non-small cell lung cancer (aNSCLC) patients treated with PD-(L)1 inhibitors (IO)

R. Ferrara[1], M. Naigeon[1], E. Auclin[2], B. Duchemann[1], L. Cassard[1], J. Medhi[1], L. Boselli[1], J. Grivel[1], A. Desnoyer[1], L. Mezquita[3], F. Aboubakar[3], L. Hendriks[3], D. Planchard[3], C. Caramella[4], J. Remon[3], M. Ngocamus[5], C. Nicotra[5], B. Besse[3], N. Chaput[1]

[1]Laboratory of Immune Oncology, Institut Gustave Roussy, Villejuif, France, [2]Oncology, Hopital European George Pompidou, Paris, France, [3]Department of Medical Oncology, Gustave Roussy Institute, Villejuif, France, [4]Radiology, Institut Gustave Roussy, Villejuif, France, [5]Drug Development Department, Institut Gustave Roussy, Villejuif, France

Background: iSenescence is a progressive remodeling of immune functions with a multifactorial etiology (i.e. aging, chronic inflammation, cancer). Although the absence of CD28 and the expression of CD57 and Killer-cell lectin-like receptor G1 (KLRG1) on peripheral T-lymphocytes are potential hallmarks of iSenescence, the characterization of such phenotype in IO-treated aNSCLC patients and the correlation with clinical characteristics and benefit from immunotherapy are currently unknown.

Methods: A senescent immune phenotype (SIP) defined as a percentage of circulating $CD8^+CD28^-CD57^+KLRG1^+$ T-lymphocytes was assessed by flow cytometry (FC) on fresh blood from aNSCLC patients treated with IO in a single institution (03/2017–04/2018). A log-rank maximization method was used to identify a SIP cut-off level and dichotomize patients accordingly. The objective was to correlate SIP with clinical characteristics and RECIST response by univariate logistic regression analysis.

Results: 39 aNSCLC patients were evaluable for SIP before IO: 38% ≥ 65 years, 87% non-squamous, 38% KRAS mutated, 54% with PD-L1 expression ≥1%, 13% chemotherapy naïve. Among 30 patients evaluable for IO response, 53% had progression (PD), 27% stability (SD), 20% partial response (PR). Median PFS was 1.9 months (95% CI 1.5; 2.5). OS was not calculated due to the short follow-up [6 months (95% CI 4-11)]. SIP (% $CD28^-CD57^+KLRG1^+$) median value on circulating $CD8^+$ lymphocytes was 15.26% (min 1.87%, max 56.28%). Overall, 13 (33%) of 39 patients had >22.25% $CD8^+$ lymphocytes with a $CD28^-CD57^+KLRG1^+$ phenotype, being classified as SIP^+. SIP status did not significantly correlate with age, IO-baseline patients' characteristics or previous chemotherapy exposure. Among patients evaluable for IO response, only 1 (10%) of 10 SIP^+ experienced disease control (PR/SD), compared to 13 (65%) of 20 SIP^- patients; similarly, PD rate was significantly higher in SIP^+ compared to SIP^- patients (90% vs 35%, $p = 0.007$).

Conclusions: iSenescence, monitored by FC measurement of 3 surface molecules on circulating $CD8^+$ lymphocytes, is observed in 33% of aNSCLC patients, is independent of age and correlates with lower disease control rate upon IO.

1417P Preliminary results of PRINCiPe (predictors of resistance to immunotherapy with nivolumab [NIV]) study in advanced pretreated non-small cell lung cancer (APNSCLC), investigating the role of an immune genomic signature (IGS) including JAK2, JAK3, PIAS4, PTPN2, STAT3, IFNAR2 alterations

S. Pilotto[1], G. Grizzi[1], I. Sperduti[2], M. Simbolo[3], C. Vicentini[3], A. Caliò[3], M. Caccese[1], A. Mafficini[3], L. Carbognin[1], V. Corbo[3], A. Gkountakos[3], A. Santo[1], M. Infante[4], M. Brunelli[3], A. Scarpa[5], G. Tortora[1], E. Bria[6]

[1]Medical Oncology, University of Verona, AOUI Verona, Verona, Italy, [2]Biostatistics, Regina Elena National Cancer Institute, Rome, Italy, [3]Department of Diagnostics and Public Health, Section of Anatomical Pathology, University and Hospital Trust of Verona, Verona, Italy, [4]Thoracic Surgery, AOUI Verona, Verona, Italy, [5]ARC-Net Research Centre and Department of Diagnostics and Public Health, AOU Verona, Verona, Italy, [6]UOC Oncologia Medica, Università Cattolica del Sacro Cuore - Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy

Background: Although immunotherapy impressively improved the outcome of APNSCLC, many patients (pts) rapidly progress. The mechanism of resistance may be influenced by genomic abnormalities in immune-escape/editing genes.

Methods: FFPE-tumor blocks of APNSCLC pts undergone NIV were retrospectively sequenced for Somatic Mutations/Copy Number Variations (SM/CNV) (Ampliseq 17-genes customized panel: APLNR, B2M, IFNAR1, IFNAR2, IFNGR1, IFNGR2, IRF9, JAK1, JAK2, JAK3, PIAS4, PTPN2, SOCS1, STAT1, STAT2, STAT3, TYK2). End-points of PRINCiPe study: overall-, progression-free-survival (OS/PFS) and objective response rate (ORR).

Results: 24 APNSCLC pts were gathered (median age 69.5 yrs, median number of previous lines 3 [2-5], 2nd line NIV [70.8%], male/female 79.2/20.8%, squamous/non-squamous 41.7/58.3%, EGFR mutant 5 [20.8%], median follow-up 6.8 months [range 1-23], deaths 14 [58.3%]). JAK3/JAK2 (6/3 pts, 25/12.5%) CNV, and IFNAR2/STAT3 SM (2 pts, 8.3%) were the most frequent abnormalities. Pts (12) with JAK3, PIAS4, PTPN2, STAT3, IFNAR2 SM and/or JAK2/3 CNV (IGS+) had a significantly lower OS/PFS than those without (IGS-). At multivariate analysis, IGS+ was independently associated with shorter OS (HR 4.90, 95% CI 1.40-16.5, $p = 0.01$) and PFS (HR 6.10, 95% CI 2.0-18.7, $p = 0.001$); the (previous) surgery was significantly associated

with longer PFS (HR 4.20, 95% CI 1.1-11.4, p = 0.03). IGS+ pts were significantly more associated with the presence of liver metastases (p = 0.04). A trend towards lower activity of NIV in EGFR+ pts was found.

Table: 1417P

	IGS+	IGS-	p-value
ORR (%, 95% CI)	-	16.6% (2-31)	0.09
Median OS (months, 95% CI)	4 (1-8)	13 (n.e.)	0.046
Median PFS (months, 95% CI)	3 (2-3.5)	6 (5-9)	0.002

Conclusions: The derived IGS appears to identify APNSCLC pts with a lower chance to benefit from NIV, supporting intrinsic resistance. Given the small sample, a prospective larger and external validation is ongoing.

1418P The need of re-biopsy: Increase in PD-L1 expression from initial stage to recurrence of non-small cell lung cancer

M. Lacour[1], S.Y. Lee[2], U. Rulle[3], A. Soltermann[3], E.J. Rushing[4], D. Soldini[3], S. Hiltbrunner[2], W. Weder[1], A. Curioni-Fontecedro[2]

[1]Thoracic Surgery, University Hospital Zurich, Zurich, Switzerland, [2]Medical Oncology / Haematology, University Hospital Zurich, Zurich, Switzerland, [3]Surgical Pathology, University Hospital Zurich, Zurich, Switzerland, [4]Neuropathology, University Hospital Zurich, Zurich, Switzerland

Background: Non-small cell lung cancer (NSCLC) has the highest mortality rate of all cancers worldwide. Developments in oncological therapy have led to new therapeutic guidelines including immunotherapy such as PD-1/ PD-L1 inhibitors. However, PD-L1 expression in tumor cells might be a dynamic process explaining variability in PD-L1 expression. To test the hypothesis of PD-L1 conversion in patients presenting with NSCLC we evaluated PD-L1 expression in initial tumor samples as well as at recurrence.

Methods: We retrospectively examined PD-L1 expression in resected specimens of patients with NSCLC as well as in biopsies at recurrence by immunohistochemistry (IHC). Patients presenting NSCLC recurrence after adjuvant chemotherapy and with no adjuvant chemotherapy were included. IHC score was defined as the proportion of tumor cells with stained cell membrane. Migration of IHC group was considered as a significant change in PD-L1. Four IHC score groups were defined: TC0 <1%, TC1 ≥1 <5%, TC2 ≥5 <50% and TC3 ≥50%

Results: In total, 36 patients were included. All patients presented adenocarcinoma. 20 patients (56%) underwent adjuvant chemotherapy after surgical resection and 16 patients (44%) had no adjuvant chemotherapy. Initial PD-L1 expression was present in 10 out of 36 patients corresponding to 28%. Out of 20 patients receiving adjuvant chemotherapy 7 patients (35%) showed significant upregulation in PD-L1 expression at recurrence. In comparison to patients with no adjuvant therapy, where only 2 out of 16 (12.5%) showed significant change in PD-L1 expression. Furthermore, 6 out of 36 patients (17%) were PD-L1 negative and had become positive at NSCLC recurrence.

Conclusions: Progress in immunotherapy has led to new therapeutic guidelines. We demonstrated that chemotherapy might increase PD-L1 expression in NSCLC specimens. These findings suggest that chemotherapy in combination with immunotherapy might constitute a new therapeutic strategy for locally advanced NSCLC. Furthermore, in about 17% of our patients, the initial tumor sample proved PD-L1 negative, but a significant change in PD-L1 expression at tumor recurrence was demonstrated. This might suggest the use of PD-L1 inhibitors in first line therapy, even if PD-L1 expression is not present at time of diagnosis.

1419P Basal lymphopenia as a potential predictor of benefit from immunotherapy in metastatic non-small cell lung cancer

G. Galli[1], M. Poggi[1], G. Fucà[1], G. Lo Russo[1], C. Proto[1], D. Signorelli[1], M. Vitali[1], M. Ganzinelli[1], N. Zilembo[1], F. de Braud[1], M.C. Garassino[2], M. Imbimbo[1]

[1]Medical Oncology Department, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy, [2]Thoracic Unit, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy

Background: Immunotherapy (IO) is an established treatment (tx) option for metastatic non-small cell lung cancer (mNSCLC). Nonetheless, as only a minority of pts shows tumor response, research is focusing on identification of predictive factors to improve pts' selection. The potential role of blood cell count alterations has been proposed, but evidence is contradictory. We aimed at studying the role of lymphopenia in a cohort of mNSCLC pts treated with IO.

Methods: We retrospectively collected data about all mNSCLC pts treated with IO at Istituto Nazionale dei Tumori, Milan, Italy, from 04/2013 to 01/2018. Basal lymphopenia (Lp) was defined as a lymphocyte count (LC)≤900/mL at the first administration of IO and was considered as a categorical variable. Survival was estimated with Kaplan-Meier method; log-rank test was used to compare curves. Multivariate analyses were performed with Cox proportional model.

Results: We identified 150 pts, with a median age of 66.5 years. IO was an antiPD1 in 64.0% of cases, an antiPDL1 in 31.3% of cases, and a combination antiPDL1/CTLA4 in 4.7% of cases. IO was administered as a first line tx in 23 pts, as a second line tx in 66 cases, as a more advanced line of tx in 61 cases. Median progression free survival (PFS) and overall survival (OS) of the global population were 3.2 and 11.2 months (mos), respectively. Though non-statistically significant, there was a tendency towards a lower response rate (RR) for cases with basal Lp (10.0% vs 25.0%, p.0881); disease control rate (DCR) for the same group was significantly worse (30.0% vs 58.4%, p.0074) than for cases without Lp. Pts with Lp also showed shorter PFS and OS than cases with normal LC (PFS 1.9 vs 3.0 mos, p.0010; OS 4.5 vs 13.5 mos, p<.0001). The impact of LC on OS retained significance after correction for the effects of performance status, which was the only other variable influencing this endpoint.

Conclusions: The presence of Lp at the beginning of IO was related to inferior disease control and shorter survival in the analyzed cohort. Given the limitations of a retrospective study, these results need confirmation in larger case series. Nonetheless, the suggestion that Lp may predict poor benefit from IO in mNSCLC warrants further investigation.

Background: Anti-PD1 antibodies has become the standard second line treatment for advanced Non-Small-Cell Lung Cancer (NSCLC). The efficacy of these treatments seems to be higher in tumors expressing PDL1. However, the difficulty to achieve tumour samples for the analysis of PDL1 is a barrier for precise oncology. The aim of this study was to evaluate the utility of circulating biomarkers such as sPDL1, sPDL2, sCD80 and sHVEM as predictors of response to PD1 blockers in NSCLC.

Methods: Blood samples were collected before treatment from 34 NSCLC pts who received anti-PD1 therapy (second line). Plasma levels of four immune-markers were measured through ELISA and Multiplex bead-based assays. When needed, continuous variables were categorized using the median or quartiles as a cut-off. Non parametric test were used for correlations between analytical variables and clinical-pathological parameters, response rate. For survival analysis (progression free- PFS or overall survival - OS) Kaplan Meier curves and long-rank test were performed.

Results: Median age of the pts included in the study was 64y, 73% were males and 67% adenocarcinomas. Median plasma levels of PDL1, PDL2, CD80 and HVEM were 1.31, 1.12, 0.197 and 0.451 ng/ml, respectively. No relevant association between clinic-pathological parameters and the plasma markers analyzed were found. Interestingly, response rate in patients with sPDL1 in the first quartile (Q1) was 11%, whereas for those in the Q2 and Q3 were 44% and 40%, respectively and the percentage raises to 50% in the Q4. Patients with higher plasma levels of CD80 had a significant increase in PFS compared to those with sCD80 below the median (14.50 vs 1.70 months, p = 0.026, respectively).

Conclusions: In conclusion, circulating immune markers can be reliable detected in plasma of advanced NSCLC pts. In pts treated with anti-PD1 antibodies, sPDL1 and sCD80 seem to be related to the degree of response or PFS. Further investigations to assess the role of these biomarkers in the context of immunotherapy are needed.

1421P Clinical characterization of rare EGFR mutations in non-small cell lung cancer and in silico prediction of drug sensitivity

S. Ikemura[1], H. Yasuda[2], S. Matsumoto[3], M. Kamada[4], T. Betsuyaku[2], Y. Okuno[4], K. Goto[5], K. Tsuchihara[6], K. Soejima[7]

[1]Cancer Center, Keio University School of Medicine, Tokyo, Japan, [2]Department of Pulmonary Medicine, Keio University School of Medicine, Tokyo, Japan, [3]Department of Thoracic Oncology, National Cancer Center Hospital East, Kashiwa, Japan, [4]Graduate School of Medicine, Kyoto University, Kyoto, Japan, [5]Department of Thoracic Oncology, National Cancer Center Hospital East, Kashiwa, Japan, [6]Division of Translational Genomics, Group of Translational Research, National Cancer Center Hospital, Tokyo, Japan, [7]Clinical and Translational Research Center, Translational Research Division, Keio University Hospital, Tokyo, Japan

Background: Recent genome scale characterization of cancers identified overwhelming numbers of novel, rare and uncharacterized somatic mutations, variance of unknown significance (VUS), in non-small cell lung cancer (NSCLC). In order to make these VUS data clinically useful, further functional and biological characterization of each mutation is mandatory. In addition, development of novel strategies to overcome mutation diversity of lung cancer is needed.

Methods: Using the large-scale prospective cohort data of the LC-SCRUM-Japan, nationwide lung cancer clinical and the genomic characterization network in Japan, we characterized the frequency and distribution of rare EGFR mutations in NSCLC and the clinical course of the patients harboring these mutations. In addition, to perform functional and biological characterization of each mutation, we created a Ba/F3 EGFR minor mutation library. Furthermore, the in silico sensitivity prediction model has been developed to demonstrate binding affinity of protein and drug compound and applied to EGFR tyrosine kinase inhibitor with mutated EGFR.

Results: Of the 2164 NSCLC patients examined by LC-SCRUM-Japan, 113 (5.2%) harbored rare EGFR mutations. We found the diverse distribution of EGFR mutations throughout the gene, the most frequent group included EGFR exon 20 insertion mutations (52 cases). We clarified the sensitivity profile of the VUS to EGFR tyrosine kinase inhibitors. Binding affinities calculated by the in silico sensitivity prediction model showed statistically significant correlation (R2: 0.7425, $p < 0.05$) with the experimentally observed IC50 values.

Conclusions: These data may help in choosing or predicting the appropriate inhibitor for lung cancer with VUS in EGFR, thereby contributing to the further development of precision medicine. Here, we clarified the diversity of VUS in EGFR and provide novel insights, via supercomputer utilized drug sensitivity prediction, in the cancer field.

Background: BELIEF, a single-arm, phase 2 trial, showed a median (med) progression-free survival (PFS) of 13.2 months (m) with erlotinib and bevacizumab in patients (pts) with advanced EGFR mutated NSCLC (Rosell et al 2017). We prospectively and longitudinally examined the evolution of sensitizing EGFR and p.T790M mutations, in circulating free DNA (cfDNA).

Methods: Blood samples were collected at baseline (BaS), at time of response (6w) and at progression (PD) and sent to a central laboratory. cfDNA was purified, and EGFR mutations were analyzed with real-time PCR assay. The fully validated assay is highly specific (>99%) and sensitive (76%) for EGFR sensitizing mutations.

Results: As of 12 March 2018, at a med follow-up of 47m (IQR: 42, 59), 2 pts (2%) are still on full protocol treatment, while 95 PFS events (87%) and 70 deaths (64%) have occurred. The med PFS is 13.2m (95% CI: 10.3, 15.5), the med overall survival (OS) is 30.2m (95% CI: 23.1, 39.6) and the 2-year OS is 58.4% (95% CI: 48.2-67.2%). cfDNA are available at BaS for 91 pts, at 6w for 72 pts and at PD for 58 pts. EGFR mutations identified in blood were also originally found in tissue. 69 pts had cfDNA assessment both at BaS and 6w. Med PFS was 19.1m for 24 pts without EGFR mutations in cfDNA at BaS and at 6w, versus 12.6m for 43 pts with EGFR mutations detected in cfDNA at BaS, but not at 6w ($p = 0.019$). 46 pts had the 3-pronged assessments (BaS, 6w, PD). The med PFS for the BaS negative group that remained negative at PD was 17.4m (12 pts), while for the BaS positive group that converted to negative at 6w and remained negative at PD was 13.1m (7pts; $p = 0.72$). For those BaS positive who converted to negative at 6w, but later became positive again at PD, the med PFS was 10.6m ($p = 0.20$). At PD, 41% of pts harbored T790M. For pts with BaS EGFR mutations, the med PFS was 13.4m (16 pts) in those without T790M, and 9m (17 pts) for the T790M mutated at PD ($p = 0.14$).

Conclusions: These data suggest the absence of sensitizing EGFR mutations in cfDNA at BaS confers significantly better PFS than in pts with EGFR mutant cfDNA. A trend of shorter PFS is seen in the subgroup of pts with BaS EGFR mutant cfDNA, from whom, at PD, EGFR mutations were again detected. EGFR mutant cfDNA could be an indicator for co-occurring oncogenic events and the use of cfDNA exome platforms should be encouraged.

Clinical trial identification: NCT01562028.

1423P Pre-treatment EGFR-T790M subclones in lung adenocarcinoma harboring activating mutation of EGFR: A positive prognostic factor for survival?

I. Prediletto[1], E. Vasile[1], R. Bruno[2], E. Macerola[2], G. Pasquini[1], G. Fontanini[2], A. Falcone[1]

[1]Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy, [2]Department of Surgical, Medical, Molecular Pathology and Critical Area, University of Pisa, Pisa, Italy

Background: In lung adenocarcinoma, activating mutation of EGFR (aEGFR) and EGFR-T790M can coexist. T790M confers resistance to 1st and 2nd generation TKIs, the standard 1st line treatment. T790M may also be observed at diagnosis (preT790M+) in 0,5-3% cases using standard techniques and up to 30% with highly sensitive ones. FDA and EMA approved osimertinib, a 3rd generation TKI overcoming T790M resistance, for 2nd-line in patients T790M+. Recently FDA approved it for 1st-line of aEGFR+ metastatic disease. Current guidelines make no distinction in aEGFR patients with or without preT790M+. In the osimertinib era it becomes important to detect properly T790M at diagnosis and to define the best strategy for preT790M+. The aim of this study was to find differences in terms of survival and response rate between preT790M+ and wild-type for T790M (WT), detecting T790M with a highly sensitive technique.

Methods: We selected aEGFR+ lung adenocarcinoma who received 1st or 2nd generation TKI in 1st line treatment in our Institution. We reanalyzed the tumor samples of the diagnosis with RainDrop Digital PCR. For statistical analysis we used Kaplan-Meyer method and log-rank test.

Results: We analyzed tumor samples of 28 subjects. At diagnosis, all were wild-type for T790M with standard techniques. With RainDrop Digital PCR, preT790M+ were 28,6% ($n = 8$). In $\geq 2^{nd}$ lines 50% of preT790M+ and 30% of WT received osimertinib,

according to T790M detection after progression. 1-yr and 2-yr survival were, respectively, 100% and 89% for preT790M+; 68% and 60% for WT. Median OS (mOS) of preT790M+ was not reached at the end of followup and 32.7 months for WT ($p = 0.098$). There were no differences in mOS stratifying by osimertinib use the study population ($p = 0.792$) and preT790M+ subgroup ($p = 1.000$). RR was 87,5% for preT790M+, 60% for WT ($p = 0.241$). Median PFS was 10,4 months for preT790M+, 13.3 months for WT ($p = 0.721$).

Conclusions: Our data, with the limits of the small sample size, show that the coexistence at diagnosis of aEGFR and T790M is not negligible. PreT790M+ tumors could represent a more indolent disease. Further studies are needed to define the optimal timing for osimertinib in these patients.

Background: Approximately 60% of EGFR mutant non-small cell lung cancer (NSCLC) patients treated with first/second generation EGFR-TKIs will acquire resistance by the T790M mutation. Since osimertinib, a third generation EGFR-TKI, is active for NSCLC with T790M, re-biopsy to examine the T790M status at the disease progression is necessary to administer osimertinib adequately. T790M monitoring in patients receiving EGFR-TKIs by plasma ctDNA could give valuable clinical information.

Methods: Patients with advanced or post-operative recurrent NSCLC with the sensitive EGFR mutations who receive the first EGFR-TKI treatment are eligible. Plasma samples at the baseline and the several timings of the disease are analyzed for EGFR mutation status using Cobas EGFR Mutation Test®.

Results: Between September 2016 and March 2017, 122 patients at 15 institutions in Japan were enrolled. Total 1291 plasma samples from 121 patients were analyzed for EGFR mutation status at March 2018. At the baseline, the sensitive EGFR mutation (Ex19 del 14, L858R 15) was detected in 29 (23.9%) of 121 patients and the resistant EGFR mutation T790M was detected in 3 (2.5%) patients. During the follow up period, 63 (52.1%) patients experienced disease progression and 62 (51.2%) stopped the first EGFR-TKI treatment. Twenty-one (17.5%) patients showed T790M in plasma ctDNA. Median time from the first EGFR-TKI treatment to the detection of T790M in plasma ctDNA was 441 days. Although 30 patients received re-biopsy to examine the EGFR mutation status at the disease progression, T790M was detected in only eight (22.2%) of the 36 re-biopsied materials. Seven (87.5%) of the eight patients who showed T790M in the re-biopsied materials received osimertinib, whereas 12 (57.1%) of the 21 patients with T790M detection in plasma received osimertinib, 4 (19.0%) continued the first EGFR-TKI, and 4 (19.0%) received platinum-based chemotherapy.

Conclusions: Although ctDNA monitoring during the EGFR-TKI treatment is useful, further investigation is necessary to elucidate the efficacy of osimertinib treatment based on the T790M detection in plasma ctDNA.

Background: We conducted a trial evaluating the efficacy of low-dose erlotinib (ERL) in frail patients with EGFR-mt non-small cell lung cancer (NSCLC). The primary endpoint was met, with the objective response rate (ORR) of 60% (2018 ASCO Abstr. 9063). Previously, it has been reported that ABCB1 genetic polymorphisms affect pharmacokinetics (PK) of ERL and associated adverse events. We investigated ERL plasma concentration and efficacy, as well as the effects of ABCB1 genetic polymorphisms in the patients who participated in this trial.

Methods: Frail patients with EGFR-mt NSCLC who had not undergone chemotherapy were enrolled and administered 50 mg of ERL. Blood samples were collected prior to treatment for ABCB1 genetic polymorphism testing and at 15 days ($\pm$7 days) after initiating ERL administration to measure steady-state trough values. The samples were analyzed at the central laboratory. Plasma concentration was measured with a high-performance liquid chromatograph-tandem mass spectrometery and ABCB1 gene polymorphism analysis using the i-densy™ genetic testing platform.

Results: Of the patients who participated in the trial between December 2014 and April 2017 ($n = 80$), ERL plasma concentration could be measured in 48 patients (males/females 17/31; median age 80 (range 49-90); PS 0-1/2/3-4 35/7/6) and genetic analysis in 45 patients. The ORR for low-dose ERL in the 48 patients was 62.5% (CR/PR/SD/PD/NE 1/29/12/3/3), and the median plasma concentration was 685 ng/ml (range 153-1950). ABCB genetic polymorphism analysis results were: C3435T; TT/non-TT 7/38, G2677T/A; TT/non-TT 7/38, C1236T; TT/non-TT 17/28, with all-TT/others: 5/40. The plasma ERL concentrations did not differ according to response: median plasma concentrations (ng/ml) of CR+PR/SD/PD cases were 701/737/590, $p = 0.435$. Genetic polymorphisms were not correlated with ERL PK, nor were they associated with diarrhea ($p = 0.202$) or rash ($p = 0.29$) by Mann-Whitney tests.

Conclusions: In this trial, no clear correlation was observed between ERL PK and efficacy. In frail patients, low-dose ERL administration of 50 mg is effective and safe, regardless of ABCB genetic polymorphisms.

Background: Targeted therapy (EGFR tyrosine kinase inhibitors, EGFR-TKIs) has been proven effective in NSCLC patients with activating EGFR mutations. Despite the initial response, most patients progress. Several acquired-resistance mutations have been described, including the EGFR T790M mutation. Here we use longitudinal plasma monitoring to identify different mechanisms of acquired resistance to EGFR-TKIs and demonstrate that tumor heterogeneity and clonal evolution may play a role in the outcome of subjects treated with osimertinib.

Methods: Tumor and plasma were collected from 13 subjects with metastatic lung adenocarcinoma treated with erlotinib followed by osimertinib, upon the development of resistance (T790M positive). Overall, 10 FFPE tumor and 115 longitudinally collected plasma specimens were analyzed with either the FDA-approved cobas® EGFR Mutation Test v2 or a 197-gene NGS assay (AVENIO ctDNA Surveillance Kit and AVENIO Tumor Tissue Surveillance Kit prototype, Research Use Only). Detected EGFR and non-EGFR mutations were correlated with disease control (evaluated by RECIST1.1).

Results: The concordance of EGFR mutations (L858R, T790M, Ex19Del) detected by cobas® and AVENIO assay in pre-osimertinib plasma samples was 92.31% (n = 12/13). The AVENIO assay detected additional mutations in ~6 non-EGFR genes. Some of these mutations were already present in pre-erlotinib plasma samples. Not all mutations showed directional change in allelic fraction (AF) after treatment with osimertinib, i.e. some subjects had a complete loss of T790M mutation, whereas other mutations remained unchanged or their AF increased, suggesting clonal heterogeneity. In general, subjects with more than 5 non-EGFR mutations (median count = 5) had a significantly lower median overall survival (OS) benefit of 30.5 months (n = 13, log-rank p-value=0.0048, HR = 12, 95% CI (1.5, 104)).

Conclusions: Longitudinal ctDNA monitoring of subjects treated with EGFR-TKIs with a multi-gene NGS panel enables identification of different resistance mechanisms and can potentially guide a selection of optimal treatment combination and sequencing strategies.

1427P Applicability of lung-molGPA index in non-small cell lung cancer patients with various gene alterations and brain metastases

K. Chen[1], Y. Fan[2], Z. Huang[2], Y. Xu[3], X. Yu[1], H. Wang[1]

[1]Chemotherapy Department, Zhejiang Cancer Hospital, Hangzhou, China, [2]Key laboratory on Diagnosis and Treatment Technology on Thoracic Cancer, Zhejiang Cancer Hospital, Hangzhou, China, [3]Key Laboratory on Diagnosis and Treatment Technology on Thoracic Cancer, Zhejiang Cancer Hospital, Hangzhou, Zhejiang, China

Background: The Lung-molGPA index is based on the original Diagnosis-Specific Graded Prognostic Assessment (DS-GPA) by incorporating recently reported gene alteration data for non-small cell lung cancer (NSCLC) patients with brain metastases (BM). However, the prognostic prediction value of DS-GPA and Lung-molGPA models remains undetermined, especially in patients with different molecule types.

Methods: A total of 1184 NSCLC patients with BM analyses for clinical factors and outcomes were identified at Zhejiang Cancer Hospital, China. All prognostic factors were weighted for significance by hazard ratios. The applicability of DS-GPA and Lung-molGPA were reappraised in NSCLC patients with BM and various genetic profiles. Additionally, a modified Lung-molGPA, was newly developed for mutant NSCLC patients.

Results: The NSCLC patients in the present study had a median survival of 14.0 months from the time of BM diagnosis. Both DS-GPA and Lung-molGPA models could predict the outcomes ($P < 0.001$), while Lung-molGPA model appeared to exhibit better accurate prediction. Furthermore, Lung-molGPA scores exhibited a discrimination capability in patients with gene variations (3.5-4.0 vs 2.5-3.0 vs 1.5-2.0 vs 0-1.0=62.0 vs 32.0 vs 17.7 vs 3.2 months, $P < 0.001$). However, no significant difference was reached in wild-type patients ($P = 0.133$). Regarding the oncogene-positive NSCLC patients with BM, a modified Lung-molGPA index had been established derived from the prognostic factors with the C-index of 0.73 (95% CI: 0.73-0.80) to accurately calculate the survival probability ($P < 0.001$).

Conclusions: In an era of precision medicine, the Lung-molGPA could precisely predict the prognosis of mutant NSCLC patients with BM, while not working in wild-type patients.

Background: Several therapies targeting molecular alterations in subgroups of NSCLC patients (pts) have been approved and require pts to be tested for these targets. Thorough knowledge of the diagnostic and therapeutic algorithm in routine practice is crucial to evaluate and improve the quality of care.

Methods: The prospective, national clinical research platform CRISP recruits pts in currently 149 representative cancer centres in all therapeutic sectors in Germany. Up to 8000 pts will be recruited and followed until death or up to a maximum of 3 years, respectively. Data from 823 pts recruited by 89 centers by June 30th, 2017 was analysed regarding molecular testing. An update with data cut June 30th, 2018 including at least 2.000 pts by 130 centres will be presented at the conference.

Results: Median age was 67 years and 61% of pts were male. 12% of pts were never smokers. 79% of pts had non-squamous carcinoma (nsqc), 21% squamous carcinoma (sqc). Overall 84% (nsqc 92%, sqc 52%) of pts were tested with at least one test method at the start of treatment. Median turn around time was 2 weeks for next generation sequencing (NGS), 10 days for FISH and one week for other sequencing and IHC. In pts with nsqc (n = 653) 32% of pts were tested by NGS, 45% by other sequencing and 49% by IHC and 38% by FISH. Molecular test rates for EGFR, ALK , and ROS-1 were 73%, 70%, and 53% respectively. In pts with sqc (n = 170) 12% of pts were tested by NGS, 11% by other sequencing, 34% by IHC and 10% by FISH. Molecular test rates for EGFR, ALK, and ROS-1 were 23%, 21%, and 15%, respectively. Test rates for PD-L1 increased from 23% in 2016 to 48% in the first half of 2017. For pts with nsqc for whom test results were available at time of analysis, an EGFR alteration was detected in 15% (n = 71), an ALK alteration in 8% (n = 37), and a ROS-1 alteration in 3% (n = 10) of pts. 24% (n = 65) of pts for whom PD-L1 tumour proportion score (TPS) results were available had a TPS ≥50%.

Conclusions: CRISP presents current real life data on molecular testing from all treatment sectors in Germany. Pts are frequently tested for molecular alterations. NGS is used in one third of nsqc pts. Reasons for testing / non-testing and changes over time will be discussed based on the 2018 data cut.

Clinical trial identification: NCT02622581.

Background: Recent studies demonstrated profound clinical activity of osimertinib in epidermal growth factor receptor (EGFR)-mutant non-small cell lung cancer (NSCLC) patients. However, the emergence of resistance limits the clinical benefit inevitably, demanding dissection of its underlying mechanisms. Here, we provide the molecular landscape of osimertinib resistance investigated by clinical sample sequencing and patient-derived cancer models.

Methods: The paired tumor tissue (n = 10) and plasma samples (n = 8) were collected from 12 EGFR-mutant NSCLC patients before and after osimertinib treatment in the ASTRIS trial (NCT02474355). The tissue and plasma DNAs were analyzed by targeted next-generation sequencing (NGS) of 112 cancer-related genes (AZ100 panel). The patient-derived cancer cell lines (PDC) and tumor xenografts (PDTX) were established from osimertinib-treated patients. Osimertinib resistant cell line (PC9-GR/AR) was also established by chronic drug administration. The preclinical resistance models were investigated by whole-exome sequencing (WES) and RNA-seq.

Results: The paired baseline and progression sample analysis identified the emergence of acquired mutations, EGFR C797S (n = 1), KRAS G12D (n = 1), and PIK3CA E545K mutations (n = 2), in the progression samples. One of these progression tissue samples with an acquired PIK3CA mutation also lost EGFR. A preexisting KRAS G12D mutation and PTEN loss were also identified in two patients who showed primary resistance to osimertinib. The WES of osimertinib-resistant PDC revealed amplification of GLI1, CDK4, and CCND1. The osimertinib-resistant PDTXs harboring PIK3CA H1047R mutation and MET amplification were established, and PI3K inhibitors and MET inhibitors will be tested. The RNA-seq analysis showed upregulation of epithelial-mesenchymal transition signatures in PC9-GR/AR cells compared to PC9-GR cells that are potentially related to epigenetic resistance mechanisms.

Conclusions: Our multi-layered molecular analysis of osimertinib-resistant patients' clinical samples and patient-derived cancer models demonstrates a diverse spectrum of osimertinib resistance mechanisms.

1430P Cell-free circulating tumour DNA (ctDNA) in the management of patients with non-biopsiable advanced non-small cell lung cancer (NSCLC)

M. Kushnir[1], H. Winter[1], C. Murias[1], P. Bains[1], C.Z. Abbosh[2], D. Papadatos-Pastos[3], T. Newsome-Davis[4], T. Ahmed[3], C. Swanton[5], M.D. Forster[6], D. Moore[7], P. Bennett[8], I. Faull[9], R.B. Lanman[10], H-T. Arkenau[11]

[1]Early Phase Trials, Sarah Cannon Research Institute, London, UK, [2]Oncology, St. James's University Hospital Leeds, Leeds, UK, [3]Medical Oncology, University College Hospital, London, UK, [4]Medical Oncology, Chelsea and Westminster, London, UK, [5]Translational Cancer Therapeutics, The Francis Crick Institute, London, UK, [6]Medical Oncology, University College London Cancer Institute, London, UK, [7]Medical Oncology, University College London Cancer Institute, London, UK, [8]Genomics, Sarah Cannon Molecular Diagnostics, London, UK, [9]Business Development & Medical Affairs, Guardant Health, Barcelona, Spain, [10]Medical Affairs, Guardant Health, Redwood City, CA, USA, [11]SCRI, Sarah Cannon Research Institute SCRI UK, London, UK

Background: Genomic profiling of cell-free ctDNA is a non-invasive method to guide personalised medicine. We assessed the utility of ctDNA in routine clinical practice where tumor biopsy were impossible to obtain, tissue insufficient or clinically contraindicated.

Methods: A 73-gene panel using ctDNA NGS (Guardant360®) was offered to consecutive stage 4 NSCLC patients - results were discussed in our Genomics Review Board to assess potential actionable alterations and enrolment into clinical trials.

Results: 50 pts (37F:13M; median 64 yrs) participated. ctDNA was obtained in 6 treatment (Tx) naïve patients (pts), in 22pts post 1st-line, in 7pts post 2nd-line, in 5 pts post 3rd-line and in 5 pts with > 4 Tx – in 5 pts prior Tx was unknown. EGFR status at Dx was known in 40 (23mt/17wt) and unknown in 10 pts. Of the pts with known EGFRmt, 6 pts progressed on gefitinib, 7 pts on afatinib, 8 pts on erlotinib, and 2 pts did not receive prior anti-EGFR Tx. ctDNA testing confirmed EGFRmt in 14 pts. In 9 pts with previously Bx-proven EGFRmt ctDNA did not detect an EGFRmt - the lag time between Bx and ctDNA was a median of 18 months (range 1-94 months). New EGFRmt were found in 3 pts with unknown EGFR status allowing access to anti-EGFR Tx. Acquired T790M were found in 4 pts progressing on prior anti-EGFR Tx, those pts received osimertinib. In 1 pt with ctDNA T790M+, a concomitant solid Bx was T790M-. Other alterations were, TP53 (n = 23), KRAS (n = 7), ERBB2 (n = 1), NTRK1 (n = 2), NF1 (n = 12), MET (n = 7), BRAF (n = 5), PIK3CA (n = 5), ALK (n = 2), BRCA1 (n = 1), BRCA2 (n = 2), PDGFRA (n = 3), AR (n = 4), TERT (n = 3), CDK4 (n = 3), CDK6 (n = 3), FGFR2 (n = 2), STK11 (n = 2), KIT (n = 2), SMAD4 (n = 3), CDH1 (n = 1), NOTCH1 (n = 2), RB1 (n = 3), TSC1 (n = 1), ERBB1(n = 1), MTOR (n = 3), MYC (n = 3), ARAF (n = 1), GNAS (n = 1), AKT1(n = 1), CDKN2A (n = 2), ARID1A (n = 2), CTNNB1 (n = 1), CCNE1 (n = 1). Critical review in the GRB meeting was fundamental in interpreting the genetic alterations of significance.

Conclusions: We confirm the feasibility and clinical utility of ctDNA testing in NSCLC patients where tumor biopsies were insufficient, impossible or contraindicated and identified 7 pts (14%) who based on their ctDNA results received 1st/2nd-line anti-EGFR treatment, several more were recommended for clinical trials.

1431P TP53 mutations impair overall survival of TKI-treated patients with oncogene-driven NSCLC

P. Christopoulos[1], M. Kirchner[2], F. Bozorgmehr[1], V. Endris[2], M. Elsayed[1], N. Magios[1], A-L. Volckmar[2], R. Penzel[2], F.J.F. Herth[3], C.P. Heussel[4], H. Winter[5], T. Muley[6], M. Meister[6], J.R. Fischer[7], S. Rieken[8], F. Lasitschka[2], H. Bischoff[1], P. Schirmacher[2], M. Thomas[1], A. Stenzinger[2]

[1]Department of Oncology, Thoraxklinik at Heidelberg University Hospital, Heidelberg, Germany, [2]Institute of Pathology, Heidelberg University Hospital, Heidelberg, Germany, [3]Department of Pulmology, Thoraxklinik at Heidelberg University Hospital, Heidelberg, Germany, [4]Diagnostic and Interventional Radiology with Nuclear Medicine, Thoraxklinik at Heidelberg University Hospital, Heidelberg, Germany, [5]Department of Thoracic Surgery, Thoraxklinik at Heidelberg University Hospital, Heidelberg, Germany, [6]Translational Research Unit, Thoraxklinik at Heidelberg University Hospital, Heidelberg, Germany, [7]Department of Oncology, Lungenklinik Loewenstein, Loewenstein, Germany, [8]Department of Radiation Oncology, Heidelberg University Hospital, Heidelberg, Germany

Background: Tyrosine kinase inhibitors (TKI) have considerably improved survival of patients with oncogene-driven non-small cell lung cancer (NSCLC). However, prognosis varies widely, and identification of molecular factors with a critical role for adverse outcome could facilitate further advances in management.

Methods: We retrospectively studied the clinical course of patients with metastatic epidermal growth factor receptor (EGFR)- or anaplastic lymphoma kinase (ALK)-driven NSCLC and known baseline TP53 status that received TKI at our institutions. Overall survival (OS) from the start of treatment for metastatic disease was analyzed according to Kaplan-Meier or by Cox regression.

Results: A total of n = 149 $EGFR^+$ and n = 76 ALK^+ patients were included with a median age of 62 years (interquartile range [IQR] 19), a median ECOG performance status of 0.5 (IQR 1) and a predominance of female (136/225=60%) never-/light-smokers (median number of pack-years 9, IQR 16). Median OS was 36 months for $EGFR^+$ and 44 months for ALK^+ NSCLC patients. TP53 mutations were present at diagnosis in 34% (51/149) of $EGFR^+$ and 19% (15/76) of ALK^+ patients, and they were associated with inferior OS in both $EGFR^+$ (24 vs. 40 months in median, $p = 0.027$) and ALK^+ NSCLC (24 vs. 53 months, $p = 0.001$). Their adverse effect was comparable to that of a worse initial clinical condition as reflected by an ECOG performance status of 1 compared to 0 (HR = 1.8 for ECOG vs. 1.8 for TP53 mutations in $EGFR^+$ patients, and HR = 4.1 for ECOG vs. 3.7 for TP53 mutations in ALK^+ patients, all $p < 0.05$ in bivariable analyses), and it was independent from that of the oncogene variant in both patient groups (HR = 1.9 for other EGFR alterations vs. exon 19 indels, and HR = 1.8 for TP53 mutations vs. wild-type in $EGFR^+$ patients; HR = 2.3 for EML4-ALK V3 vs. V1/V2, and HR = 4.7 for TP53 mutations vs. wild-type in ALK^+ patients, all $p < 0.05$ in bivariable analyses).

Conclusions: TP53 mutations impair overall survival of TKI-treated patients with EGFR- and ALK-driven NCSLC independent of baseline clinical status and oncogene variant. Their detection could assist selection of cases for more aggressive management. Preclinical exploration of their role in acquired TKI resistance could guide novel therapeutic strategies.

1432P Hybrid capture NGS reliably detects a spectrum of clinically significant genetic aberrations in both, primary diagnostics and the relapse scenario

S. Schatz[1], M. Falk[2], R. Menon[3], L.C. Heukamp[3], J. Roeper[4], F. Griesinger[5], M. Tiemann[1]
[1]Hematopathology Hamburg, Hamburg, Germany, [2]Hematopathology Hamburg, Hamburg, Germany, [3]NEO New Oncology, Cologne, Germany, [4]Pius Hospital Oldenburg, University of Oldenburg, Oldenburg, Germany, [5]Pius Hospital Oldenburg, Oldenburg, Germany

Background: The purpose of this study was to analyze the frequency and type of genetic alterations in tyrosine kinase inhibitor (TKI)-naïve vs. TKI-treated NSCLC patients. We report a spectrum of resistance mechanisms upon TKI treatment in liquid biopsies using a comprehensive hybrid capture NGS test (HC-NGS).

Methods: We retrospectively collected mutational data of 200 solid NSCLC biopsies of treatment-naïve patients that were routinely tested for clinically relevant mutations by HC-NGS at our institution. In addition, we analyzed mutational data from 367 liquid biopsies of NSCLC patients whose disease progressed under treatment. Solid tumor biopsies and liquid biopsies were tested using a 39-gene HC-NGS panel including 39 clinically relevant genes (NEOselect, LOD 3.0%; NEOliquid, LOD 0.1%; NEO New Oncology GmbH, Cologne).

Results: Primary HC-NGS diagnostics in TKI -aïve patients revealed 12% (24/200) TKI-sensitive EGFR mutations, 5.0% (10/200) Alk/ROS/RET translocations, 0.5% (1/200) BRAF V600E, and in one patient a MET Exon 14 skipping mutation (0.5%, 1/200). Further, a variety of clinically relevant mutations were detected, among others, prognostically relevant TP53 mutations at a frequency of 52.0% (104/200). In addition, we tested 367 liquid biopsies from relapse patients. 30.9% (113/367) pts had an activating EGFR mutation and therefore presumably received EGFR TKI treatment. Of the 113 pts, 39.8% (45/113) developed a T790M resistance mutation and 1.8% (2/113) an additional MET amplification.

Conclusions: HC-NGS allows for comprehensive analysis of somatic tumor aberrations in the primary diagnostic setting as well as in the relapse scenario. Mechanisms of primary oncogenic activation as well as mechanisms of resistance are heterogeneous and include point mutations, translocations and gene amplifications. Therefore, HC-NGS should be used for diagnosis in both, the primary and the relapse setting.

1433P Prognostic value of the neutrophil-to-lymphocyte ratio (NLR) in advanced non-small cell lung cancer

K. Adamowicz[1], A. Romanowska[2], R.E. Zaucha[3]
[1]Regional Oncology Centre, Gdansk, Poland, [2]Clinical Oncology and Radiotherapy, University Clinical Center, Gdansk, Poland, [3]Radiotherapy and Clinical Oncology, Medical University of Gdansk, Gdansk, Poland

Background: Metastatic non-small cell lung cancer (NSCLC) represents one of the biggest therapeutic challenges. Palliative chemotherapy (CT) is the first-choice treatment in patients without targetable mutations. Unfortunately, reliable markers predicting response to CT have not been found yet. Most of NSCLC cases arise and develop in a background of smoking-related chronic inflammation. Since neutrophils are the most prevalent immune cell type in NSCLC microenvironment we hypothesized that the revelator of the inflammatory process such as the neutrophil to lymphocyte ratio (NLR) could have a prognostic or predictive value.

Methods: To evaluate the predictive and prognostic value of pretreatment NLR in NSCLC we analyzed data of the group of consecutive patients treated systemically for NSCLC at two institutions between January 2011 and December 2014. NLR was retrospectively calculated from the peripheral blood counts collected before therapy. Multivariate Cox logistic regression was used to assess the relationship between NLR and treatment results after adjusting for age, gender, ECOG, and cigarette smoking. Based on available data we chose NLR=3 as the cut-off level discriminating high (NLR >3) and low values.

Results: In the whole cohort ($N = 204$) with 184 patients (90%) being current or former smokers, 131 (64%) were male, 188 (92%) had a performance status (PS) 0 to 1, 93 patients (46%) had squamous cell cancer, 85 (42%) adenocarcinoma, and 26 (12%) other subtypes. Median age at diagnosis was 65 years (range 41 to 71.7 years). Platinum-based CT was administered in 92% of patients: cisplatin in 155 (76%), and carboplatin in 33 (16%) patients. NLR ranged from 2.04 to 4.62 (median = 3.02). Study groups created according to the NLR value were well balanced. There were 54 objective responses (26,5%) including 2 complete remissions. NLR was a significant and independent factor predicting response to treatment (OR 0.048; 95% CI 0.015-0.152; $p < 0.001$). Median overall survival in all patients was 12 months: 9.6 vs 13.2 months, respectively in NLR>3 vs ≤ 3 ($p < 0.001$).

Conclusions: NLR>3 was correlated with worse outcomes, therefore might be useful for identifying patients unlikely to benefit from CT.

1434P A phase II study of nedaplatin and nab-paclitaxel for patients with previously untreated advanced squamous cell lung cancer (KRSG1302)

T. Sugiyama[1], T. Kasai[1], N. Koyama[2], K. Kobayashi[3], E. Hoshi[4], M. Nakayama[5], K. Mori[6]
[1]Department of Medical Oncology, Tochigi Cancer Center, Utsunomiya, Japan, [2]Department of Clinical Oncology, Tokyo Medical University Hachioji Medical Center, Tokyo, Japan, [3]Respiratory Medicine, Saitama Medical University Internatl Medical Centre, Saitama, Japan, [4]Thorcic Surgery, Saitama Cardiovascular and Respiratory Center, Kumagaya, Japan, [5]Thorcic Surgery, Saitama Medical Center, Kawagoe, Japan, [6]Respiratory Medicine, Tsuboi Cancer Center Hospital, Koriyama, Japan

Background: Nedaplatin (N) and nab-paclitaxel (nab-P) are efficacious in the treatment of non-small cell lung cancer (NSCLC), especially squamous cell lung cancer. Although a combination of N and nab-P was expected in the treatment of squamous cell lung cancer, there was no sufficient data.

Methods: The eligibility criteria were no prior chemotherapy; stage IIIB or stage IV squamous cell lung cancer; a performance status (PS) of 0–1; $75 >$ age > 20 years; and adequate hematologic, hepatic, and renal function. Patients (pts) received escalating doses of nab-P under a fixed dose of N (100 mg/m^2, day 1) every 3 weeks in the phase I part. The initial dose of nab-P was 100 mg/m^2 of day 1, 8 (level 1), and that of the next dose was 100 mg/m^2 of day 1, 8, 15 (level 2). In the phase II part, pts received the recommended dose (RD) of N/nab-P. The primary endpoint was tumor response, which was measured using Response Evaluation Criteria in Solid Tumors 1.1.

Results: Five pts were enrolled in the phase I part. Three pts of level 1 have experienced no dose-limiting toxicities (DLTs). Two pts of level 2 have experienced DLTs, which were febrile neutropenia and the down of PS, respectively. Therefore, level 1 was determined to RD. 23 pts were enrolled in phase II part. Three pts in level 1 and 23 pts in phase II were evaluable, together. Partial response, stable disease, and progressive disease were noted in 21, 0, and 2 pts, respectively, yielding a response rate of 91.3% (95%confidence interval [CI]: 72.0–98.9). The median progression-free survival was 223 days (95%CI: 144–330), and the median survival time was 358 days (95%CI: 255–950). The grade 3 and 4 toxicities observed during all cycles were neutropenia (5 and 9 pts), anemia (6 and 2 pts), thrombocytopenia (5 and 3 pts). Grade 3 febrile neutropenia, pneumonia, and acute coronary syndrome were observed in 1, 2, and 1 pts, respectively. However, there was no treatment related death.

Conclusions: A combination of N (100 mg/m^2, day 1) and nab-P (100 mg/m^2, day 1, 8) every 3 weeks was the recommended dose. N/nab-P in this recommended dose appears to be efficacious and torerable in patients with untreated advanced squamous cell lung cancer.

1435P Bevacizumab as first-line treatment in advanced non-squamous non-small cell lung cancer (NSCLC) in patients aged over 65 years in France: Final results of the AVANTAGE study

F. Lionel[1], D. Perol[2], P-J. Souquet[3], H. Le Caer[4], E. Dansin[5], C. Audigier Valette[6], J-L. Mouysset[7], M.L. Uffredi[8], M. Ionescu-Goga[9], K. Veerabudun[10], Y. Lelarge[11], E. Fabre-Guillevin[12]

[1]Service de Pneumologie et Cancérologie Thoracique, L'Hopital Nord Ouest, Villefranche Sur Saone, France, [2]Centre Léon Bérard, Lyon, France, [3]Service de Pneumologie et Cancérologie Thoracique, Centre Hospitalier Lyon Sud, Pierre Bénite, France, [4]Pneumologie, Centre Hospitalier, Saint Brieuc, France, [5]Service de Pneumologie, Centre Oscar Lambret, Lille, France, [6]Service de Pneumologie, Hospital Sainte Musse, Toulon, France, [7]Medical Oncology, Clinique Rambot-Provençale, Aix-en-Provence, France, [8]Medical, Roche S.A.S., Boulogne-Billancourt, France, [9]Pharmaco-Vigilance, Roche S.A.S., Boulaogne-Billancourt, France, [10]Statistics, Aixial, Boulogne-Billancourt, France, [11]Operation Clinique, Hays, Paris, France, [12]Service de Pneumologie, La Défense, France

Background: NSCLC is frequent in elderly patients (pts), however there is limited information on the treatment of this population. This study describes the first-line treatment with bevacizumab (bev) of NSCLC elderly pts in real life in France.

Methods: AVANTAGE is a non-interventional, prospective, multicenter French study conducted in pts with advanced NSCLC starting first-line chemotherapy (CT) with bev. It includes 2 cohorts, pts aged 65-70 (C1), or $\geq$ 70 (C2) . Data were collected at inclusion and every 3 months subsequently for 18 months. The primary objective was to describe CT used with bev in first-line in routine clinical practice.

Results: A total of 249 pts were eligible (277 included) in 68 centers: 108 (43%) in C1 & 141 (57%) in C2. They were predominantly men (75%), ECOG PS 0-1 (85%) PS 2 (15%), G8 questionnaire score >14 (35%), stage IV (96%), Charlson comorbidity index unadjusted $\leq$2 (63%), and brain metastases identified in 18% of pts overall, 20% of pts in C2. Platinum-based doublet CT and pemetrexed (pem) was the most used combination with bev in 186 (75%) pts overall: - 81% of pts in C1 (62% cisplatin-pem and 18% carboplatin-pem) - 70% of pts in C2 (26% cisplatin-pem and 44% carboplatin-pem). The initial dose of bev with CT was 7.5 mg/kg/3 weeks in 70% of pts. Overall, maintenance treatment was administered to 61% pts, including 53% with bev (24% in monotherapy and 29% with pem). Maintenance was 64% in C1and 62% in C2. Median PFS was 7.1 months, and median OS was 12.3 months (14.9 months in C1, 11.3 months in C2). Overall, 92% of pts presented at least 1 AE. Pts with grade $\geq$ 3 AEs related to bev were 12% in C1 and 24% in C2. In the safety population (260), 148 pts died during the study. 3 pts (all in C2) died due to SAEs related to treatment (intestinal perforation; febrile neutropenia/septic shock/ thrombocytopenia; unknown cause).

Conclusions: AVANTAGE is the 1st prospective cohort conducted in routine clinical practice in France in elderly pts eligible for 1st-line CT with bev. The most frequently used treatment was the combination of platinum-pem doublet (75% of pts). Bev effectiveness as 1st line treatment in NSCLC was consistent with the efficacy observed in clinical trials in the elderly as was the safety profile.

Clinical trial identification: Clincial Trial Gov: NCT01893268.

Background: Bevacizumab (Bev) combined with platinum-based chemotherapy is a standard treatment for advanced non-squamous non-small-cell lung cancer (non-Sq NSCLC). Cisplatin + pemetrexed (CisPem) is suggested as the most promising chemotherapy regimen combined with Bev. However, no study has been conducted to evaluate the efficacy and safety of CisPemBev compared with carboplatin + paclitaxel + bevacizumab (CarPacBev) for advanced non-Sq NSCLC.

Methods: Treatment-naïve patients with advanced or recurrent EGFR/ALK-negative non-Sq NSCLC from 55 sites across Japan were randomly assigned in a 2:1 ratio to either CisPemBev (4 cycles of Cis [75 mg/m^2] + Pem [500 mg/m^2] + Bev [15 mg/kg] q3wk, followed by maintenance Pem + Bev q3wk until progression) or CarPacBev (4 cycles of Car [AUC 6] + Pac [200 mg/m^2] + Bev q3wk, followed by maintenance Bev q3wk until progression). The primary endpoint was progression-free survival (PFS) by central review. The secondary endpoints were overall survival (OS), overall response rate (ORR) and safety profile. The target numbers of patients and events were determined to be 210 and 170, respectively, to observe a point estimate of HR for PFS (CisPemBev/CarPacBev) <0.83 with a high probability (80%) when the true HR was 0.72. The data were cutoff in July, 2017. OS data were updated for this presentation in April, 2018.

Results: Between May 2014 and May 2016, 199 patients were randomly assigned to receive CisPemBev (N = 132) or CarPacBev (N = 67). In the primary analysis, PFS events occurred in 171 patients. The HR for PFS by central review (CisPemBev/CarPacBev) was 0.825 (95% CI 0.600-1.134, median PFS, 7.6 vs 7.0 months), and the ORR was 57% for CisPemBev and 55% for CarPacBev. OS events occurred in 119 patients. The median survival follow-up duration was 28.3 months. The median OS was 23.4 months for CisPemBev and 21.6 months for CarPacBev (HR 0.845, 95% CI 0.583-1.242).

Conclusions: PFS was prolonged with CisPemBev compared with CarPacBev. However, there was no difference in OS between two arms. CisPem is the most effective chemotherapy regimen combined with Bev for advanced non-Sq NSCLC.

Background: Ataxia telangiectasia and Rad3-related protein (ATR) is an essential DNA damage response regulator, and is required for proliferating cell survival. DNA-damaging agents often induce replicative stress leading to activation and reliance on ATR; inhibition of ATR signalling is an attractive strategy to sensitize tumors to DNA-damaging chemotherapy. M6620 is a potent, selective inhibitor of ATR with preclinical anticancer activity in combination with DNA-damaging chemotherapy. Here, we report dose expansion cohort data for a phase I trial of M6620 plus Gem in pts with advanced NSCLC (NCT02157792).

Methods: Eligible pts had measurable (RECIST 1.1) advanced NSCLC with up to 2 lines of prior therapy, with one including a platinum analog. Of 40 pts planned for enrollment, ≥20 had to have a TP53 mutation (TP53+), ≤10 ATM loss of expression (ATM–) (both alterations associated with ATR inhibitor sensitivity in preclinical studies), and ≈10 neither TP53+ nor ATM–; status was determined from fresh or archival tissue. Pts received Gem 1000 mg/m^2 on days 1 + 8 and M6620 210 mg/m^2 on days 2 + 9 of each 21-day cycle. Pharmacokinetics was assessed on day 2 of cycle 1. Primary endpoints were safety and overall response rate (ORR).

Results: The safety set included 33 pts who received combination therapy (median age, 62.0 years [range 36–76]; TP53+, 19; WHO PS 0/1, 9/23). 31/33 pts had a treatment-emergent adverse event (TEAE), with 19 (57.6%) having grade ≥3 TEAEs: fatigue (n = 6), neutropenia (4), anemia (3), thrombocytopenia (3), malaise (2), vomiting (2), ALT increase (2), AST increase (2), pneumonia (2), sepsis (2) (grade ≥3 TEAES occurring in ≥ 2 pts). Of the 24 treated pts with baseline and on-treatment assessments, 3 pts had a partial response (PR; ORR 12.5%) and 18 pts (75%) had stable disease (SD). Four pts had PR or SD ≥ 6 months (clinical benefit rate 16.7%). Updated efficacy and PK data will be presented from an upcoming analysis.

Conclusions: The ATR inhibitor M6620 combined with Gem showed signs of activity in advanced NSCLC; tolerability was acceptable.

Clinical trial identification: NCT02157792.

Background: The prognosis of non-small cell lung cancer (NSCLC) patients with interstitial lung disease (ILD) has been reported to be poor, and 10-20% of those receiving chemotherapy experienced exacerbation of ILD induced by chemotherapy. To evaluate the safety and efficacy of nab-paclitaxel (nab-P)/ carboplatin (C) for NSCLC patients with ILD, this multicenter phase II study was conducted.

Methods: Chemotherapy-naive patients with pathologically confirmed advanced NSCLC and ILD received 4 cycles of nab-P (100 mg/m^2, d1, 8, 15) + C (AUC=6 d1) every 3 weeks. ILDs were diagnosed based on the fibrosing ILD criteria and categorized to three patterns by investigators; usual interstitial pneumonia (UIP), possible UIP, inconsistent UIP. Primary endpoint was exacerbation-free rate (EFR) of ILD at 28 days after protocol treatment. Secondary endpoints were response rate, progression-free survival (PFS), overall survival (OS), EFR of ILD, toxicities.

Results: From 06/2014 to 12/2016, 94 patients were enrolled in this study, and 92 patients received protocol treatment. Median age was 70 years, 89% were male, 45/55% were PS 0/1, and 58% had non-squamous histology. In the primary analysis, EFR of ILD at 28 days after protocol treatment was 95.7% (88/92, 90%CI; 90.3-98.6). In the subgroup of patients with UIP pattern, EFR of ILD at 28 days was 94% (47/50). Response rate was 51% (90%CI; 40-62). At the time of data cutoff, median PFS was 6.1 months, and median OS was 15.1 months. The most common grade 3 or 4 adverse events were neutropenia (75%), leukopenia (53%), anemia (48%), thrombocytopenia (20%), hyponatremia (17%), febrile neutropenia (9%) and infection (7%). Two treatment-related deaths (one each of pulmonary infection and ILD exacerbation) were observed.

Conclusions: This study demonstrated that nab-P/C was well tolerated in NSCLC patients with ILD in terms of safety including risk of exacerbation of ILD, even if of UIP pattern. Although this study was a single arm, nab-P/C might be more effective compared with other regimens of previous reports.

1439P HALO 107-201: A phase Ib, open-label, multicenter study of pegvorhyaluronidase alfa (PEGPH20) + docetaxel in patients (pts) with recurrent locally advanced or metastatic non-small cell lung cancer (NSCLC)

M. Baumgart[1], M. Muhsin[2], W. Wu[2], N. Gabrail[3]

[1]Department of Medicine, University of Rochester Medical Center, Rochester, NY, USA, [2]Clinical Development, Halozyme Therapeutics, Inc., San Diego, CA, USA, [3]Cancer and Research Facility, Gabrail Cancer Center, Canton, OH, USA

Background: Hyaluronan (HA) accumulation in solid tumors impedes drug access. PEGPH20 degrades tumor HA and may increase access and efficacy of therapies to the tumor. This study (NCT02346370) assessed PEGPH20 + docetaxel safety and tolerability in pts with Stage IIIB/IV squamous and nonsquamous NSCLC who have failed 1 platinum-based chemotherapy regimen and ≤3 systemic anticancer regimens.

Methods: This study was planned as dose escalation (standard 3 + 3 design) and dose expansion (in HAhigh patients). During dose escalation, eligible pts received PEGPH20 (1.6, 3.0 and 2.2 μg/kg) as an IV infusion on D1 and docetaxel 75 mg/m^2 IV on D2 of each 21-day cycle. Pts continued study treatment until disease progression or unacceptable toxicity in longterm follow-up. Primary objectives were PEGPH20 + docetaxel safety and tolerability and determination of the RP2D of PEGPH20. Secondary objectives included PEGPH20 + docetaxel efficacy and pharmacokinetics.

Results: The study discontinued early due to treatment landscape changes, including the introduction of immune checkpoint inhibitors and in standard of care for NSCLC, ie docetaxel became later-line therapy. Thus, R2PD was not determined but the highest tolerated dose was 2.2 μg/kg. Prior to discontinuation, 15 pts were treated (1.6 μg/kg n = 7; 3.0 μg/kg n = 4; 2.2 μg/kg n = 4). Most were female (66.7%) and had adenocarcinoma (66.7%); mean age was 62.6 years. ECOG PS was 0 or 1 in 46.7% and 53.3% of pts, respectively. Safety findings are summarized in the table. All TEs and all but one MSE reported were considered related to PEGPH20.

Conclusions: PEGPH20 + docetaxel safety and tolerability were acceptable. Given the observed rates of TEs and MSEs, more effective methods for management of these AEs with this drug combination should be explored in future studies.

Clinical trial identification: NCT02346370.

Background: The doublets OV+P and GEM+P are among standard treatment options in NSCLC. The study aims to assess efficacy, safety of OV+P (Arm A) and GEM+P (Arm B), followed by maintenance with OV or GEM respectively.

Methods: Pts were randomised to receive (every 3-week cycles): OV at 80 mg/m^2 D1 and D8 (60 mg/m^2 Cycle 1) + P 80 mg/m^2 D1 or GEM 1250 mg/m^2 (D1 and D8) + P 75 mg/m^2 D1. After 4 cycles of combination, pts without progressive disease received single agent OV or GEM respectively as maintenance until progression or unacceptable toxicity. Primary endpoint: Disease Control Rate (DCR) on study treatment period (combination, maintenance). Secondary endpoints: safety, efficacy, quality of life.

Results: 113 pts were included between 2013-2015 in intent-to-treat population (ITT). Baseline: 57 pts (Arm A)/ 56 pts (Arm B), median age of 61 and 64.5 years, stage IV 96.5% and 91.1% respectively. In Arm A/ B, 57 pts and 56 were treated in combination period; in maintenance, 29 and 28 pts were treated with OV or Gem. Final results (ITT) for study treatment period in Arm A/ B: DCR 73.7% [95%, CI (62.4; 100.0)] and 75% [95%, CI (63.7; 100.0)]. Median duration of treatment 12.1 and 13.2 weeks; objective response 24.6% [14.1; 37.8] and 30.4% [18.8; 44.1]; median [95% CI] duration of disease control in months (mo) 4.8 [4.1-5.7] and 5.2 [4.3-6.6]; median PFS: 4.2 (2.8-4.9) and 4.3 (3.1-5.5) mo; median survival: 10.2 (6.9-12.9) and 8.4 (5.3-11.9) mo. Total of any grades (Gr) of related adverse events (r-AEs) arm A/ B respectively: 87.7% and 92.9%. Any grade of related infections: 1.8% vs 8.9%.Gr 3-4 of selected r-AEs: nausea/ vomiting 1.8%/3.5% vs 8.9%/ 5.4%, peripheral neuropathy 0% vs1.8%, renal failure

Table: 1439P

	PEGPH20 1.6 μg/kg + docetaxel (n = 7)	PEGPH20 3.0 μg/kg + docetaxel (n = 4)	PEGPH20 2.2 μg/kg + docetaxel (n = 4)	Total (N = 15)
AE category				
Any AE, n (%)	7 (100)	4 (100)	4 (100)	15 (100)
Any Grade ≥3 AE, n (%)	5 (71.4)	4 (100)	3 (75.0)	12 (80.0)
Serious AEs (SAEs), n (%)[†]	3 (42.9)	3 (75.0)	1 (25.0)	7 (46.7)
AEs leading to discontinuation, n (%)	1 (14.3)	1 (25.0)	2 (50.0)	4 (26.7)
AEs with outcome of death, n (%)	0 (0)	0 (0)	0 (0)	0 (0)
AEs (≥50% of the total population), n (%)				
Fatigue	6 (85.7)	3 (75.0)	4 (100)	13 (86.7)
Muscle spasms	4 (57.1)	2 (50.0)	3 (75.0)	9 (60.0)
Myalgia	4 (57.1)[‡]	3 (75.0)	1 (25.0)	8 (53.3)
Thromboembolic events (TEs), n (%)[§]	0 (0)	1 (25.0)[¶]	3 (75.0)	4 (26.7)
Musculoskeletal events (MSEs), n (%)	6 (85.7)[‡]	4 (100)	4 (100)	14 (93.3)

[†]With the exception of two Grade 4 SAEs (gastroenteritis/Escherichia coli sepsis), and one Grade 2 SAE, most SAEs were Grade 3;
[‡]One event of Grade 2 myalgia was also considered a SAE;
[§]All thromboembolic events were considered related to PEGPH20;
[¶]One event of Grade 3 deep vein thrombosis was also considered to be a SAE

1.8% vs 3.6%, septic shock 0 vs 1.8%. Grade 1-2 related alopecia (8.8% vs 21.4%). One toxic death in each arm. Biological toxicities of gr 3-4 neutropenia 43.9%/37.5%, anaemia 17.5%/10.7%, thrombocytopenia 1.8%/10.7%. Full results to be presented at the meeting.

Conclusions: This study confirms efficacy, safety of OV+P in sq NSCLC with a trend for a better median survival for OV+P.

Department of Internal Medicine, Iwate Medical University School of Medicine, Morioka, Japan

Background: Combinations of EGFR-TKIs and VEGF inhibitors are one of the candidates for next strategy for EGFR-mutated lung cancer. We conducted a phase III study comparing BE to E in pts with untreated non-small-cell lung cancer (NSCLC). This study includes the pts with central nervous system (CNS) metastases (mets).

Methods: Chemotherapy-naïve pts with advanced non-squamous NSCLC harboring EGFR-mutation were randomly assigned to receive either combination with erlotinib (150 mg daily) plus bevacizumab (15 mg/kg iv q3w) or erlotinib (150 mg daily). Pts with asymptomatic stable CNS mets that did not require corticosteroids were allowed to enroll. The primary endpoint was PFS. Secondary endpoints were OS, RR, safety, and QoL. This study was planned to enroll 214 pts in total.

Results: Between Jun 3, 2015, and Aug 31, 2016, 228 pts with EGFR mutations were enrolled. There were one cessation prior to the study treatment and one withdrawal of consent; the remaining 226 pts were assigned to BE (n = 112) and E (n = 114). Pts were followed up for a median of 12.4 months. The interim analysis showed that the study met its primary endpoint. At data cutoff (Sept 21, 2017), median PFS was 16.9 months (95% CI 14.2-21.0) in BE and 13.3 months (11.1-15.3) in E ($p = 0.0157$) (HR 0.605, 95% CI 0.417-0.877). The number of pts with CNS mets at the enrollment was 72 (32.1%). In pts without CNS mets, median PFS was 18.0 months (95% CI 15.4- not reached) in BE and 15.1 months (11.1-16.1) in E ($p = 0.0141$). In pts with CNS mets, median PFS was 12.7 months (95% CI 9.8- 18.1) in BE and 11.2months (8.8-14.7) in E ($p = 0.413$). Although some toxicities such as hemorrhage, proteinuria, and hypertension significantly increased in BE compared to in E, there was no significant difference among other toxicities between BE and E. Five cases had low-grade pneumonitis in E but no pneumonitis in BE. There was no treatment-related death.

Conclusions: In this study, BE as a combination of EGFR-TKIs and VEGF inhibitors achieved durable response, especially absence of CNS mets. BE is a promising regimen for EGFR-mutated NSCLC.

KG, Vienna, Austria, [14]Medical Oncology, Boehringer Ingelheim Pharmaceuticals Inc., Ridgefield, CT, USA, [15]Medical Oncology, Vall d'Hebron University Hospital, Barcelona, Spain

Background: Primary LL8 data showed significantly improved PFS and OS with afatinib compared with erlotinib as second-line treatment in pts with lung SCC, leading to the approval of afatinib in this setting. As previously reported (data cut-off: Apr 2015), PFS (2.6 vs 1.9 months; HR 0.81 [95% CI 0.69–0.96]; $p = 0.01$), objective response rate (ORR; 5.5 vs 2.8%; $p = 0.06$) and disease control rate (DCR; 50.5 vs 39.5%; $p = 0.002$) were higher with afatinib vs erlotinib. PFS and OS benefits on afatinib appeared even greater for pts with ErbB mutation-positive tumours vs ErbB wild-type tumours. Here we present the final analysis of OS and safety data. Other efficacy endpoints were not updated; as of Apr 2015, only 9 (1%) pts remained on treatment, so minimal changes would be expected.

Methods: This open-label, multicentre, Phase III trial enrolled pts with stage IIIB/IV lung SCC who had progressed on $\geq$ 4 cycles of platinum-based chemotherapy. Pts were randomised 1:1 to receive afatinib (40 mg/day) or erlotinib (150 mg/day) until progression. Primary endpoint was PFS by independent radiological review. The key secondary endpoint was OS; other endpoints included ORR, DCR and safety.

Results: 795 patients were included (398 on afatinib; 397 on erlotinib). Baseline characteristics were well balanced between arms. Updated OS (data cut-off: Mar 2018) was significantly longer for afatinib than erlotinib (7.8 vs 6.8 months; HR 0.84 [95% CI 0.73–0.97]; $p = 0.019$). Overall AE profile was comparable between arms: 57.4% of afatinib and 57.5% of erlotinib pts reported AEs $\geq$grade 3 (G3); serious AEs were reported for 44.4% and 44.3% of pts, respectively. A higher incidence of drug-related $\geq$G3 diarrhoea (10.5 vs 2.5%) and G3 stomatitis (4.1 vs 0%) was reported on afatinib, and a higher incidence of G3 rash/acne was reported on erlotinib (5.9 vs 10.4%). AEs leading to treatment discontinuation were comparable across arms (20.4 vs 16.7%). Updated data on pts with long-term disease control (treatment $\geq$1 year) will be presented.

Conclusions: Results are consistent with those previously reported for LL8. Updated OS was significantly greater for afatinib than erlotinib. The AE profile was comparable across arms and manageable.

Clinical trial identification: NCT01523587.

Background: More than 40% of non-small cell lung cancer (NSCLC) patients develop CNS metastasis in their lifetime. Clinical studies have shown superior efficacy of osimertinib in CNS compared to platinum chemotherapy. Treatment efficacy in patients with or without CNS metastasis were observed within the second interim analysis of ASTRIS (NCT02474355). Data cut-off (DCO) was 20 October 2017.

Methods: In ASTRIS, advanced NSCLC patients with locally confirmed T790M mutation, prior EGFR-TKI therapy were enrolled. Patients with stable CNS metastases were allowed. The primary endpoint was overall survival (OS); other endpoints included investigator-assessed response rate (RR), progression-free survival (PFS), time to treatment discontinuation (TTD) and safety. These endpoints were also analyzed according to presence of CNS metastasis.

Results: In 466 Korean patients, CNS metastasis was evaluated in 310 patients and was present in 211 (68.1%) patients (CNS-met) and not present in 99 (31.9%) patients (CNS-no). 155 patients were not evaluated for CNS metastasis (CNS-ne). At DCO, 236 patients (50.6%) were ongoing and median duration of exposure was 11.2 (0–19) months. In patients evaluable for response, defined as at least one dose of osimertinib and one response assessment, RR was 71.0% (320/451; 95% CI, 66.5–75.1): Patients with (N = 211), without (N = 99), and not-evaluated CNS metastasis (N = 155) had RR of 68% (134/197), 79.6% (78/98), and 69.7% (108/155), respectively. Median PFS was 12.4 months (95% CI, 11.1-13.6); 10.8 months in CNS-met, 11.0 months in CNS-no, and 15.1 months in CNS-ne. Median TTD was 16.5 months (95% CI, 14.1-NC); 11.2 months in CNS-met, 14.7 months in CNS-no, and NC (95% CI, 15.5-NC) in CNS-ne. OS was not reached (data maturity: 19.7%). Serious adverse events (AE) regardless of causality were reported in 116 patients (24.9%) and AEs leading to death in 13 patients (2.8%). ILD/pneumonitis-like events were reported in 8 patients (1.7%), and QTc prolongation in 7 patients (1.5%).

Conclusions: In the ASTRIS Korean subset, patients with or without CNS metastasis had comparable efficacy outcomes. These data continue to support osimertinib's clinical benefit on EGFRm T790M NSCLC patients with CNS metastasis.

Clinical trial identification: NCT02474355.

1444P A randomized phase II trial of erlotinib or erlotinib and bevacizumab in patients with advanced EGFR mutant non-small cell lung cancer (NSCLC)

T.E. Stinchcombe[1], P.A. Janne[2], X. Wang[3], E.M. Bertino[4], J.M. Weiss[5], L. Bazhenova[6], L. Gu[3], C.J. Lau[2], C.P. Paweletz[2], A.J. Jaslowski[7], G.J. Gerstner[8], M.Q. Baggstrom[9], S.L. Graziano[10], J. BeardenIII,[11], E.E. Vokes[12]

[1]Medical Oncology, Duke Cancer Center, Durham, NC, USA, [2]Medical Oncology, Dana Farber Cancer Institute, Boston, MA, USA, [3]Department of Biostatistics and Bioinformatics, Duke University, Durham, NC, USA, [4]Medical Oncology, The Ohio State University James Cancer Hospital, Columbus, OH, USA, [5]Hematology/Oncology, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA, [6]Medicine, Moores UCSD Cancer Center, La Jolla, CA, USA, [7]Medical Oncology, St. Mary's Hospital, Green Bay, WI, USA, [8]Medical Oncology, Illinois CancerCare, P.C., Peoria, IL, USA, [9]Medical Oncology, Washington University School of Medicine, St. Louis, MO, USA, [10]Medical Oncology, SUNY Upstate Medical University, Syracuse, NY, USA, [11]Medical Oncology, Palmetto Hematology Oncology Associates, Spartanburg, SC, USA, [12]Medical Oncology, The University of Chicago Medical Centre, Chicago, IL, USA

Background: A retrospective subset analysis from a phase 3 trial, and preclinical data supported prospective study of elrotinib and bevacizumab in patients (pts) with EGFR mutant NSCLC.

Methods: Pts were required to have an EGFR exon 19 deletion or exon 21 L858R mutation based on local testing. Pts were assigned to erlotinib 150 mg daily (E) or erlotinib 150 mg daily and bevacizumab 15 mg/kg IV every 3 weeks (EB). The primary objective was progression-free survival (PFS); secondary objectives were objective response rate (ORR), and overall survival (OS). cfDNA samples were collected at baseline, at time of imaging, and disease progression. The study was designed to detect a hazard ratio (HR) of 0.667 in favor of EB, with a power of 81% at one-sided significance level of 0.20; under exponential hazards. HR corresponds to an improvement in median PFS from 10 to 15 months.

Results: From 11/2012 to 8/2016 88 pts were enrolled. The median age was 63 years (range 31 to 84), the majority were women (70%), had a history of never smoking (55%), performance status (PS) of 1 (51%), and EGFR exon 19 deletion (67%). With a median follow-up of 23 months, 69 PFS events have been observed. A statistically significant difference in PFS in pts assigned to EB compared to E was not observed (HR of 0.87, 95 CI: 0.54-1.43; p = 0.59; median PFS 17.9 and 13.5 months, respectively). The ORR in the EB and E arms were 83% vs 81% (p = 1.0). 33 OS events have been observed. The OS analysis of pts assigned to EB compared to E revealed a HR of 1.54, 95% CI: 0.74-3.19, p = 0.25; median OS 29.9 months and not evaluable, respectively. Grade $\geq$ 3 adverse events (rate $\geq$ 10%) in the EB and E arms were: rash (26% and 18%), diarrhea (9% and 13%), hypertension (40% and 22%), and proteinuria (12% and 0%). In EB and E arms 23 and 21 pts received subsequent therapies; in the EB and E arms osimertinib was a subsequent therapy in 10 and 13 pts, respectively. cfDNA were available for 36/69 pts with progressive disease; exon 19 deletion or exon 21 L858R detected in 12 samples and T790M in 5 samples.

Conclusions: Treatment with EB compared to E did not result in a statistically significant improvement in PFS in pts with EGFR mutant NSCLC. OS data are immature. A review of subsequent therapies and additional cfDNA analyses are ongoing.

Clinical trial identification: NCT01532089.

Background: The aim of this study was to assess the efficacy and safety of afatinib, an epidermal growth factor receptor (EGFR) tyrosin kinase inhibitor (TKI), for elderly Japanese patients with EGFR mutation-positive advanced non-small cell lung cancer (NSCLC).

Methods: NEJ027 was single-arm, multicenter, open-label phase II study of first-line afatinib monotherapy. Patients aged 75 or older with stage IIIB/IV or recurrent non-squamous NSCLC harboring EGFR mutations were enrolled. The patients received afatinib at a start dose of 40mg/day until disease progression or unacceptable toxicity. The primary endpoint was overall response rate (ORR), and the secondary endpoints were disease control rate (DCR), progression-free survival (PFS), overall survival (OS) and safety profile.

Results: Between January 28, 2016, and September 14, 2017, a total of 38 patients with a median age of 77 years (range, 75-91) were enrolled (15 males; 21 Eastern Cooperative Oncology Group performance status 0; all adenocarcinoma; 23 EGFR exon 19 deletion mutation) in safety analysis and 37 in the full analysis set. The ORR was 75.7% (95% confidence interval: CI 61.9-89.5) and DCR was 89.2%. The median PFS was 14.3 months (95% CI 9.9-not reached). The common grade 3 or 4 adverse events were diarrhea (10 [26.3%]), stomatitis (5 [13.2%]), rash (2 [5.3%]), appetite loss (5 [13.2%]), nail abnormality (4 [10.5%]) and pneumonitis (2 [5.3%]). 30 patients (78.9%) required 1 step or more dose reduction.

Conclusions: Although the percentage of patients requiring dose reduction seemed relatively higher than that in previous studies, first-line afatinib at a start dose of 40mg/day was found to be well-tolerated by dose adjustment and effective in elderly patients with advanced non-squamous NSCLC harboring EGFR mutations.

1446P Management of leptomeningeal metastases in EGFR mutated non-small cell lung cancer: Analysis of tyrosine kinase inhibitors sequence

R. Flippot[1], E. Auclin[2], P. Biondani[3], E. Le Rhun[4], J. Adam[5], D. Planchard[6], C. Caramella[7], C. Le Pechoux[8], L. Lacroix[9], A. Gazzah[10], L. Mezquita[6], B. Besse[11]

[1]Medical Oncology, Gustave Roussy, Villejuif, France, [2]Oncology, Hopital European George Pompidou, Paris, France, [3]Oncology, Hôpital Paul Brousse, Villejuif, France, [4]Neuro-oncology, Neurosurgery Department, Roger Salengro Hospital, Lille, France, [5]Pathology, Institut Gustave Roussy, Villejuif, France, [6]Medical Oncology, Institut Gustave Roussy, Villejuif, France, [7]Radiology, Gustave Roussy, Villejuif, France, [8]Radiation Therapy, Institut Gustave Roussy, Villejuif, France, [9]Biology, Institut Gustave Roussy, Villejuif, France, [10]Drug Development Department, Institut Gustave Roussy, Villejuif, France, [11]Department of Cancer Medicine, Institut Gustave Roussy, Villejuif, France

Background: Non-small cell lung carcinomas (NSCLC) with leptomeningeal metastases are associated with poor outcomes. Tyrosine kinase inhibitors (TKI) in EGFR-mutated (EGFRm) tumors might have substantial activity. Impact of TKI sequence on survival and clinical benefit is unknown.

Methods: Consecutive patients (pts) from 2 institutions with EGFRm NSCLC and LM were included. Retrospective collection of clinical, pathological and radiological data was performed. Overall survival (OS), Progression-free survival (PFS), clinical response rate (CRR) and disease control rate (DCR; stable disease $>$ 2 months or clinical response) were assessed. Evaluation of TKI sequence and dose modifications in pts who had LM progression with first-line TKI was performed.

Results: Seventy pts were enrolled from Apr. 2003 to Feb. 2018. Median age was 54 [26-79], 73% were female and 85% non-smokers. Median time from initial diagnosis to LM onset was 17.5 months (m) [0-106], and pts received a median of 2 [1-7] prior therapies before LM onset. Median OS from LM onset was 7m [95% CI 6-9]. After LM diagnosis, pts received a median of 2 [1-6] lines of systemic therapy. Forty pts received 2nd-line TKI after LM progression under TKI, with a 2nd-line median PFS of 3m [95% CI 2-not reached], CRR 38%, DCR 73%. In pts who switched treatment at LM progression (N = 36), 21 switched from any TKI to erlotinib ("E",53%), 10 maintained erlotinib with either dose increase or concurrent bevacizumab ("HD-E", 22%), 2 switched from erlotinib to afatinib or gefitinib ("A/G", 6%), and 4 with T790M mutation switched from any TKI to osimertinib ("O", 11%). Pts with E had 6-months PFS of 41%, median OS of 6 months [95% CI 3-7], and DCR of 62%. Both pts with A/G had absolute OS $<$ 2m. Pts with HD-E had a median OS of 3 months [2-6] and a DCR of 80%. In T790M-mutated pts, O provided a median OS of 10 months [6-10] and a DCR of 100%.

Conclusions: TKIs in LM from EGFRm NSCLC provide disease control in most pts. Switch from afatinib/gefitinib to erlotinib provided extended survival for patients who progressed with first-line TKI. A higher dose of erlotinib might rescue resistance to erlotinib in subsets of pts.

1447P Risk of not receiving second-line therapy is high in EGFR mt+ pts: Real world data of certified lung cancer centers on treatment sequence in EGFR mt+ pts

J. Roeper[1], M. Falk[2], S. Schatz[3], M. Tiemann[3], C. Wesseler[4], G. Wiest[4], S. Sackmann[5], D. Ukena[5], L.C. Heukamp[6], F. Griesinger[7]

[1]University Department Internal-Medicine-Oncology, Pius Hospital Oldenburg, University of Oldenburg, Oldenburg, Germany, [2]Molecular Pathology, Hematopathology Hamburg, Hamburg, Germany, [3]Molecular Pathology, Hematopathology Hamburg, Hamburg, Germany, [4]Department of Oncology, Asklepios Klinik Harburg, Hamburg, Germany, [5]Department of Pneumology, Klinikum Bremen-Ost, Bremen, Germany, [6]Molecular Pathology, NEO New Oncology, Cologne, Germany, [7]University Department Internal Medicine-Oncology, Pius Hospital Oldenburg, University of Oldenburg, Oldenburg, Germany

Background: Recently FLAURA study demonstrated significant PFS and numeric OS benefit for Osimertinib 1st line vs. 1st gen. TKI's Erlotinib/Gefitinib. The number of pts switching from 1st gen. to 3rd gen. TKI (30%) appeared to be low and it is questionable whether these data represent real world sequencing treatment patterns. Therefore, we investigated the sequence pattern, i.e. the percentage of 2nd line therapy in EGFR mt+ pts in 3 certified lung cancer centers in Germany.

Methods: Data of 912 of 1477 pts tested for EGFR mutations were analyzed between 2009-2017. 140/144 pts with an activating EGFR mt + (16%) and treated with systemic therapy (4 pts received no therapy) were identified and their treatments were captured as well as their outcome. 36 pts were treated before accessibility to 3rd generation TKI and 104 pts after accessibility to 3rd generation TKI.

Results: 130/140 pts were treated with 1st line TKI and 10 received 1st line chemotherapy. 17 pts are still on 1st line TKI, 8 pts were lost to follow-up, 3 pts died while on 1st line TKI. 112 pts were candidates for 2nd line therapy. 34/112 (30%) of these pts did not receive 2nd line therapy. Causes for not receiving 2nd line therapy were pts refusal (n = 2), bad PS (n = 26) frequently due to CNS metastases, fast progression and death (n = 6). After accessibility of 3rd gen. TKI, 20 of 66 (30%) pts did not receive 2nd line therapy. Median OS of the overall cohort was 27 months (n = 140), median OS of pts receiving 2nd line (n = 78) vs. no 2nd line (n = 62) was 36 vs. 14 months ($p < 0.0001$). After accessibility of 3rd gen. TKI 30/104 pts (29%) receive a 3rd gen. TKI after 1st line or 2nd line therapy. Median OS of pts receiving (n = 30) and not receiving 3rd gen. TKI (n = 110) was 55 months vs. 22 months ($p < 0.0001$).

Conclusions: In real world, a significant number of pts treated with 1st or 2nd gen. TKI do not reach 2nd line therapy even when 3rd gen. TKI were accessible. Reasons for not receiving 2nd line therapy are in most cases deterioration of PS and lack of possibility to test for T790M in the minority of cases (n = 28/66, 42% were not tested). These data, although favorable for the small and very selected cohort of pts treated with Osimertinib, might argue for the most effective therapy in 1st line for pts with EGFR mt+ tumors.

1448P Patterns of recurrence to Osimertinib in T790m positive NSCLC: A Swiss cohort study

S. Schmid[1], D. Klingbiel[2], S. Aeppli[1], C. Britschgi[3], O. Gautschi[4], M. Pless[5], S.I. Rothschild[6], L. Wannesson De Nicola[7], W-D. Janthur[8], D. Foerbs[9], I. Demmer[9], W. Jochum[9], M. Früh[1]

[1]Department of Oncology / Hematology, Cantonal Hospital St. Gallen, St. Gallen, Switzerland, [2]Swiss Group for Clinical Cancer Research Coordinating Center, SAKK, Bern, Switzerland, [3]Department of Hematology and Oncology, Universitätsspital Zürich, Zurich, Switzerland, [4]Medical Oncology, Cantonal Hospital Lucerne, Lucern, Switzerland, [5]Oncology/Hematology, Kantonsspital Winterthur, Winterthur, Switzerland, [6]Onkologie, Universitätsspital Basel, Basel, Switzerland, [7]Oncology, IOSI - Ospedale Regionale Bellinzona e Valli, Bellinzona, Switzerland, [8]Onkologie, Kantonsspital Aarau ZOHT, Aarau, Switzerland, [9]Pathology, Kantonsspital St. Gallen, St. Gallen, Switzerland

Background: Osimertinib (Osi) is an EGFR-TKI that potently inhibits both EGFR-sensitizing and EGFR T790M resistance mutations in non-small cell lung cancer (NSCLC). Identification of oligo-progression (PD) on Osi may allow local treatment and continuation of Osi. Metastatic patterns at the time of acquired resistance to Osi are poorly understood.

Methods: We retrospectively analyzed 50 pre-treated T790M+ NSCLC patients who received Osi at 7 Swiss centers. Oligo-PD was defined as PD in $\leq$ 5 lesions. Archived pre-treatment and fresh biopsies at PD were analyzed for mutational profiling.

Results: Median age was 62 years (range: 37-89), 64% females, 86% had a PS ≤ 1, 54%/13% were never/current smokers. Patients had one (44%), two (34%) or more (22%) prior treatment lines. At diagnosis, patients had EGFR exon 19 deletion (74%), L858R exon 21 mutation (24%) and concomitant exon 18/ exon 20 mutation (2%). Before Osi start, T790M was detected in blood (28%) or tumor tissue (72%). Median follow-up was 15.3 (IQR: 8.6-21.6) months. Overall response rate was 83%, median progression-free survival 15.1 months (IQR: 6.4-20.1), median overall survival 25.1 months (IQR: 16.7-not reached [NR]) and median treatment duration 18.1 months (IQR: 10.1-23.5). At data cut off, PD had occurred in 26 patients (52%). There were 73% oligo- vs. 27% systemic PD. Median treatment duration in patients with oligo-PD was 19.6 vs 6.5 months if systemic PD. The number of progressive lesions in oligo-PD patients were 1 (32%), 2 (37%), 3 (26%), and 5 (5%). Main sites of PD were lung (n = 14), bone (n = 10), lymph nodes (n = 6), liver and pleura (n = 5 each), and brain (n = 4). 12 patients with oligo-PD continued treatment with Osi beyond progression, ten of them after local therapy (8x radiotherapy, 2x surgery). Median time of treatment beyond PD was 10.7 months in patients with oligo-PD (IQR: 5.7-NR). Analyses of pretreatment and post-PD tumor tissue from a subset of patients will be presented.

Conclusions: In patients with acquired resistance to Osi, we observed a high rate of extracranial oligo-PD. Outcomes of patients with oligo-PD were favorable with the majority continuing Osi in addition to local therapy, supporting the concept of Osi treatment beyond progression in combination with local therapy of progressing lesions.

Pulmonology, Florence-Nightingale-Hospital, Düsseldorf, Germany, [10]Dept. of Pneumology, Krankenhaus München Bogenhausen Med. II Abteilung, Munich, Germany, [11]Department of Internal Medicine III, Division of Pulmonary and Respiratory Medicine, RoMed Clinical Centre, Rosenheim, Germany, [12]Boehringer Ingelheim Pharma GmbH & Co. KG, Germany, Ingelheim Am Rhein, Germany

Background: Afatinib is an irreversible ErbB family blocker, which is approved as monotherapy for the treatment of advanced non-small cell lung cancer (NSCLC) patients with activating EGFR mutations. Here we report the first interim analysis of the NIS GIDEON, which was initiated to investigate the efficacy and tolerability of Afatinib in first line treatment in the daily clinical routine in Germany.

Methods: EGFR-mutated NSCLC patients were treated with Afatinib according to label until progression, death or discontinuation due to patients' or physicians' decision. Efficacy (objective response rate, ORR; disease control rate, DCR and progression-free survival, PFS) was prospectively assessed by investigators and additional data about tolerability under everyday treatment conditions were documented.

Results: A total of 151 pat. were enrolled in the study and received Afatinib treatment. EGFR mutations comprised exon 19 deletions (Del19, 56.6 %), L858R point mutations (21.9 %) and uncommon mutations (18.5 %). Median age was 67 years (38-89) with 91 Pat. ≥65 years (60.3%). Pat. started treatment on 40mg/d (72.8 %) Afatinib or < 40mg/d (25.8 %). Dose reductions during the course of therapy were frequent, 61.8 % with 40mg/d starting dose and 53.8% with <40mg/d. ORR for the total treated population was 73% with a DCR of 90 %. ORR was similar according to different subgroups, e.g. mutation type and age. mPFS at the time of analysis was 12.9 Mon. and in the group of pat. ≥65 years 13.7 Mon. OS date are not mature yet. The most frequent documented AEs were diarrhea and rash/acne, with 11.6 % of pat. discontinued treatment due to drug related AEs.

Conclusions: Afatinib is a standard therapy for patients with activating EGFR mutations in Germany. The first results of this prospective NIS confirm the robust clinical data for Afatinib in the clinical routine setting, especially in the elderly population, which is underrepresented in clinical trials. A starting dose of < 40 mg Afatinib in selected pat. does not seem to be inferior in terms of efficacy.

Clinical trial identification: NCT02047903.

1450P Osimertinib treatment for patients with EGFR exon 20 insertion positive non-small cell lung cancer

B. van Veggel[1], A. van der Wekken[2], S. Hashemi[3], R. Cornelissen[4], K. Monkhorst[5], D. Heideman[6], T. Radonic[6], E.F. Smit[7], E. Schuuring[8], J. De Langen[1]

[1]Thoracic Oncology, Netherlands Cancer Institute/Antoni van Leeuwenhoek hospital (NKI-AVL), Amsterdam, Netherlands, [2]Pulmonary Diseases, University of Groningen, Groningen, Netherlands, [3]Pulmonary Diseases, VU University Medical Center, Amsterdam, Netherlands, [4]Pulmonary Diseases, Erasmus MC, Rotterdam, Netherlands, [5]Pathology, Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital (NKI-AVL), Amsterdam, Netherlands, [6]Pathology, VU University Medical Center, Amsterdam, Netherlands, [7]Pulmonary Diseases, The Netherlands Cancer Institute, Amsterdam, Netherlands, [8]Pathology, University Hospital Groningen (UMCG), Groningen, Netherlands

Background: Epidermal growth factor receptor (EGFR) exon 20 insertions are identified in 4-10% of al EGFR mutations in non-small cell lung cancer (NSCLC) and are generally associated with primary resistance to first and second generation EGFR tyrosine kinase inhibitors (TKIs). In vitro and preclinical animal studies have shown that osimertinib exerts antitumor activity in EGFR exon 20 insertion positive NSCLC cell lines. We report on a cohort of advanced stage NSCLC patients, harboring an EGFR exon 20 insertion, that was treated with osimertinib.

Methods: 17 patients with advanced NSCLC harboring an EGFR exon 20 insertion were treated with osimertinib 80 mg once daily, in four institutions in the Netherlands. Data were obtained retrospectively. EGFR mutation status was assessed by next-generation sequencing. Progression free survival (PFS), disease control rate (DCR) and objective response rate (ORR) were assessed using RECIST v1.1.

Results: Median age was 63 years (range 35 – 81), 71% was female and median number of prior systemic treatments was 1 (range 0 – 3). Ten patients (59%) received prior platinum-based chemotherapy, and 2 patients afatinib, one patient experienced stable disease for 11 months, the other patient showed progression. Among all patients treated with osimertinib, we observed 1 partial response, 13 patients with stable diseases and 3 with progressive disease as best response (ORR 6%). Two patients were still on osimertinib treatment at the cut-off date. Median PFS was 3.7 months (95% CI: 2.3 – 5.4 months). Six of seventeen patients (35%) achieved DCR at five months.

Table: 1450P

Patient	Number of prior treatments	Prior platinum based chemotherapy	Prior EGFR TKI	Best RECIST response	PFS (months)
1	2	Yes	no	SD	4.0
2	1	Yes	no	SD	1.6
3	2	Yes	no	PR	0.7
4	1	Yes	no	PR	0.7
5	2	Yes	no	SD	3.8
6	1	Yes	no	SD	3.0
7	3	Yes	no	SD	9.3
8	1	Yes	no	SD	17.0
9	1	No	no	SD	3.7
10	1	Yes	no	SD	17.2
11	0	No	no	PR	3.1
12	0	No	no	SD	2.6
13	0	No	no	SD	6.5
14	3	Yes	afatinib (SD)	SD	7.9
15	1	No	afatinib (PD)	PD	1.7
16	0	no	no	SD	8.3
17	0	no	no	SD	1.4

EGFR, epidermal growth factor receptor; RECIST: Response Evaluation Criteria in Solid Tumors; PR, partial response; SD, stable disease; PD, progressive disease; PFS, progression free survival

Conclusions: Osimertinib has limited antitumor activity in patients with EGFR exon 20 mutated NSCLC, with an ORR of 6%. A subset of patients (35%) seems to derive benefit from osimertinib treatment with durable disease control for more than five months.

1451P The characteristics and clinical outcome of metastatic NSCLC harboring uncommon EGFR mutation at Thailand's tertiary referral center

J. Chantharasamee[1], N. Poungvarin[2], P. Danchaivijitr[1], S. Techawatanawanna[1]

[1]Medicine, Siriraj Hospital, Mahidol University, Bangkok, Thailand, [2]Clinical Pathology, Siriraj Hospital, Mahidol University, Bangkok, Thailand

Background: An uncommon EGFR-mutant NSCLC is a rare subset of NSCLC. Prevalence and clinical outcome of this entity remain unclear. Several studies have reported the benefit of EGFR-tyrosine kinase inhibitor in patients harboring complex or uncommon EGFR mutations but there are insufficient data to determine the advantage of EGFR-TKI over chemotherapy. This study aimed to review the prevalence and clinical outcome of treatment of uncommon EGFR-mutant patients in real-world practice.

Methods: We retrospectively reviewed medical records of 681 patients tested for EGFR mutation NSCLC during 2014-2018 to collect the mutational status and to compare the survival outcomes between the patients treated with EGFR-TKI and chemotherapy.

Results: At a median follow-up of 19.1 months, 317 (47%) patients were identified with EGFR-mutant NSCLC. Twenty-eight patients (8.8%) harbored uncommon EGFR mutations. Of those 28 patients, the most frequent single mutation was exon20 insertion (21%, n = 6); 5 were L861Q and 4 were G719X. 13 (46%) patients had compound mutations: 4 were G719X plus S768I; 4 were de novo T790M plus either L858R or deletion(del)19; 2 were L858R plus del19; 1 was L858R plus Ex20Ins; 1 was del19 plus KRAS mutation, and 1 with G719X plus E709A was found in squamous cell carcinoma. History of tobacco use was found in 50% of patients. 100% of male patients with G719X mutation were smokers. 57% of the 28 patients were treated with EGFR-TKI, mostly 1st generation, and 29% were treated with chemotherapy alone. The objective response rate was 56% in the TKI group. Median progression-free survival (PFS) in the TKI group was 10.2 months. 5-year overall survival (OS) rate was 34%. Patients treated with TKI had significantly better 5-year OS rate than those who had never received TKI (54% vs. 17%, 95%CI 1.23-14.66, p log-rank= 0.02). The longest OS was 73.6 months in a patient with del19 plus de novo T790M.

Conclusions: This study demonstrated the benefit of 1st generation EGFR-TKI was greater than with chemotherapy alone in the patients with uncommon or compound EGFR mutation NSCLC. Rare EGFR mutations can be detected in squamous cell carcinoma. There was a high prevalence of smoking among the male patients with G719X-mutant NSCLC.

Background: EGFR T790M mutation is the most common acquired mechanism of resistance in NSCLC patients treated with EGFR-TKI. Alternative mechanisms include activation of the receptor tyrosine kinases MET or AXL. S49076 is a multi-target inhibitor and a potent ATP-competitive TKI that targets MET, AXL and FGFR1/2/3. Here we report phase 1 molecular and safety data of resistant patients without the EGFR T790M mutation that were treated with S49076 combined with gefitinib.

Methods: A dose-escalation of S49076 in combination with gefitinib 250 mg once daily was conducted using a modified Bayesian Continual Reassessment Method. Toxicity was evaluated according to Common Terminology Criteria for Adverse Events (AEs), v4.0. Resistant patients were selected according to a tumor molecular profile including presence of the activating EGFR mutation, absence of T790M and with at least one of the following: MET amplification, or MET or AXL overexpression.

Results: The molecular profile screening has been performed in 46 EGFR/T790M-negative tumour samples. In total, 23/46 met the molecular eligibility criteria: 21 with MET dysregulation (11 MET amplification, 20 MET overexpression and 4 both MET / AXL dysregulations), and 2 with AXL overexpression only. Fourteen patients were treated: 4 received the 500 mg dose and 10 received the 600 mg dose, which was considered as the recommended dose. Related AEs included diarrhoea, paronychia, asthenia, nausea, vomiting, ALAT and ASAT increase, anaemia, peripheral oedema and yellow skin, mostly grade 1-2. One patient experienced a DLT at 600 mg (grade 3 stomatitis); 2 patients experienced 3 serious related AEs (asthenia, atrial fibrillation and diarrhoea). No grade 4-5 AEs were reported. Concomitant intake of gefitinib did not appear to modify the S49076 PK profile as compared to previous data. Limited anti-tumour activity was observed in the 12 evaluable patients: 1 partial response and 9 stable diseases.

Conclusions: S49076 combined with gefitinib is well tolerated and data are consistent with the overall safety profile of each drug. The observed frequency of MET dysregulation was comparable to those reported in the literature whereas AXL overexpression was lower than expected.

1453P Afatinib dose intensity and clinical efficacy in advanced EGFR-mutated non-small cell lung cancer: UK multicentre real-life data

C. Escriu[1], M. Sallam[2], L.P. del Carpio[3], N. Tokaca[4], L. Solway[5], R. Shah[6], A. Fouzia[7], Q. Ghafoor[5], S. Popat[8], P.E. Postmus[9]

[1]Medical Oncology, The Clatterbridge Cancer Center, Merseyside, Merseyside, UK, [2]School of Medicine, University of Liverpool, Liverpool, UK, [3]Medical Oncology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [4]Medical Oncology, The Royal Marsden NHS Foundation Trust, London, UK, [5]Oncology, University Hospitals Birmingham NHS Foundation Trust, Birmingham, UK, [6]Medical Oncology, Maidstone and Tumbridge Wells NHS Trust, Maidstone, UK, [7]Medical Oncology, The Clatterbridge Cancer Center, Merseyside, UK, [8]Medicine, The Francis Crick Institute, London, UK, [9]Respiratory Diseases, Leiden University Medical Center (LUMC), Leiden, Netherlands

Background: The second-generation afatinib has shown longer Progression-Free Survival (PFS) than gefitinib in the first line treatment of advanced EGFR mutated lung cancer, and has excellent penetration into the central nervous system. It is licensed at a starting dose of 40mg/day, but in real-life practice dose reductions due to toxicity are common. As for other targeted agents, it is questionable if dose selection should be based on biological active dose instead of maximum tolerable dose. Here we aimed to identify the frequency of afatinib dose reductions and analyse their impact in survival outcomes in the UK real-life population.

Methods: Patients with EGFR-mutated lung cancer treated with afatinib between April 2014 and December 2017 in four UK centres were retrospectively identified. The frequency of dose reductions and response rates was quantified. Dose Intensity (DI; average daily dose over the total treatment period) was calculated and patients were grouped into DI $>$ 30mg/day and DI $\leq$ 30mg/day; PFS and Overall Survival (OS) curves were plotted.

Results: 98 patients were identified. The median treatment duration was 8.5 months (range 01.-42.7), and mean DI 30.6mg/day. 85 patients started at 40mg/day and 13 at 30mg/day. They required dose reductions in 65% (n = 55) and 46% (n = 6), respectively. The starting dose did not influence response rates. 50 patients (51%) received a DI $\leq$ 30 and 48 patients (49%) received a DI $>$ 30. A lower DI did not significantly influence PFS (HR 0.65(0.37-1.14); p = 0.127) or OS (HR 0.58(0.28-1.20); p = 0.14), but showed a trend to better outcomes. Patients with brain metastasis (n = 11(22%) DI $\leq$ 30 and n = 14(29%) DI $>$ 30) had similar clinical outcomes regardless of DI, and patients that required a reduction to the lowest dose of 20mg/day (n = 28) achieved similar PFS (HR 0.58(0.3-1.14); p = 0.113) and OS (HR 0.41 (0.16-1.08); p = 0.062) as the rest (n = 70).

Conclusions: Our results suggest equal clinical efficacy in patients treated with a lower DI of afatinib, and a reduced need for dose reductions in patients starting at 30mg/day. Prospective tolerability and efficacy of afatinib starting at 30mg/day will be quantified in a phase II UK study.

1454P EGFR tyrosine kinase inhibitors in non-small cell lung cancer: Nationwide register-based cohort study in Sweden

S. Bergström[1], H. Nordahl Christensen[2], F. Wiklund[3], M. Bergqvist[4]

[1]Oncology, Gävle Hospital, Gävle, Sweden, [2]Nordic-Baltic, AstraZeneca, Södertälje, Sweden, [3]Stockholm, Statisticon AB, Stockholm, Sweden, [4]Radiation Sciences, Umeå University, Umeå, Sweden

Background: Epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs) are recommended as first-line treatment for EGFR mutation-positive NSCLC by international and Swedish clinical guidelines. However, knowledge on treatment patterns of TKIs in a real life clinical setting is limited. The aim was to describe disease characteristics and comorbidities of stage IIIB/IV NSCLC patients receiving first line TKI, and treatment patterns related to switch, re-challenge, and discontinuation.

Methods: All patients with stage IIIB/IV NSCLC during 2010-2015 were identified in the national Swedish Cancer Registry, and linked with data on dispensed EGFR-TKI drugs and comorbidity from Swedish national health registries. First line TKI treatment was defined from date of first dispensed EGFR-TKI drug (gefitinib, erlotinib, afatinib) until a treatment gap of minimum 90 days or switch to another EGFR-TKI drug within the same drug class.

Results: Of 9,992 stage IIIB/IV NSCLC patients (mean age 70 years, female 49%), 1419 (14%) received first-line TKI treatment. Overall, 59% of TKI treated patients (median age 68 years) were female, 44% had at least one comorbidity, 85% had adenocarcinoma, and 89% were stage IV. TKI treatment patterns changed during the observation period. Initiation of TKI treatment declined from 23% to 9% in 2010 and 2015, respectively. However, median time from diagnosis to treatment initiation was shorter (from 7 to 2 months) at the end of observation, and the median treatment length was prolonged particularly for patients diagnosed in later years (from about 2 to 6 months in 2013 and 2015, respectively). Switching and re-challenge patterns were more common at the end of the observation period.

Conclusions: This is the first large nationwide study on patients receiving first-line TKIs in routine clinical practice in Sweden. Changes in TKI treatment patterns, such as shorter time to treatment initiation, prolonged treatment length, and more TKI switching and re-challenging during the observation period, may reflect extension of EGFR testing. Correctly targeted patients according to clinical guidelines, may contribute to an extended survival of this patient population.

Background: We constructed a data set of EGFR-mutant NSCLC patients (pts) and compared the overall survival of first-generation (1G) and second-generation (2G) EGFR-TKIs in clinical practice using propensity score.

Methods: We reviewed the available data of all EGFR-mutated NSCLC pts who received EGFR-TKI therapy between Jan 2008 and Aug 2017 in the 11 institutions in Japan. The primary endpoint was OS. When comparing OS between 1G and 2G EGFR-TKIs, the propensity scoring was performed using two methods; matching and IPTW with adjusted factors (age, sex, smoking history, histology, EGFR mutational subtype, clinical stage, ECOG PS, line of treatment, brain metastasis) which were previously described in the statistical plan. The statistical plan had been opened prior to statistical analysis. (Clinical Trial information: UMIN000030121)

Results: A total of 1400 pts from 11 institutions were enrolled in this study, and the data from the 1354 pts who received EGFR-TKI alone was analyzed (gefitinib, N = 726; erlotinib, N = 413; afatinib, N = 215). Median age was 70, [range, 28-99] and 61.3% were female. The mutational status was exon 19 deletion in 671 pts, L858R in 571 pts, and minor or compound mutation in 112 pts. 95.1% were histologically diagnosed with adenocarcinoma, and 81.1% were with 0 to 1 of ECOG PS. Median OS (months [95%CI]) were 30.9 [27.7-33.9] in 1G (gefitinib, 32.2 [28.4-36.4]; erlotinib, 28.1 [24.9-33.4]), and 38.6 [32.2-NR] in 2G (afatinib), respectively. The trend of longer OS for afatinib against first-generation EGFR-TKIs remained even after adjusted by propensity score. (unadjusted, HR 0.682, p = 0.0031; adjusted by IPTW, HR 0.783 p $<$ 0.0001; adjusted by matching [1:2], HR 0.747, p = 0.0629) Subgroup analysis showed that the patients with exon 19 deletion had significantly longer overall survival benefit from afatinib therapy than 1G EGFR-TKI. (vs. gefitinib, p = 0.0016; vs. erlotinib, p = 0.0135).

Conclusions: From this analysis of 1354 data records, using propensity scoring, afatinib had a trend of longer OS compared with gefitinib and erlotinib.

Background: The irreversible ErbB family blocker, afatinib, is approved for first-line treatment of metastatic NSCLC harbouring non-resistant EGFR mutations. While afatinib has demonstrated a predictable and manageable safety profile in pts with EGFR mutation-positive (EGFRm+) NSCLC, elderly pts are often under-represented in clinical trials. Here, we summarise the current status of, and preliminary data from, an ongoing Phase IV trial of afatinib in elderly pts with Del19/L858R EGFRm+ NSCLC (NCT02514174).

Methods: Pts aged ≥70 yrs with Stage IV/recurrent Del19/L858R EGFRm+ NSCLC naïve to prior systemic therapy have been enrolled to sites in the USA. Pts receive afatinib QD (starting dose 30 mg/day) until disease progression/intolerable AEs. Dose reduction to 20 mg/day is permitted in the case of select Grade 2/≥3 AEs. The primary endpoint is the occurrence of AEs leading to dose reduction. Secondary endpoints include occurrence of Grade ≥3 diarrhoea and Grade ≥3 rash/acne, stomatitis and paronychia (grouped terms). Other endpoints are AEs by NCI CTCAE grade, objective response (OR), PFS and overall survival. Preliminary safety data are reported here.

Results: As of 7 Feb 2018, 26 pts have been enrolled across 9 sites, and 24 pts have entered into the trial. Twenty-three pts have been treated: 57% female; 30% Asian; 26%/74% ECOG PS 0/1; median age (range) 79 (71–93) yrs. Thirteen (57%) pts remain on treatment. Reasons for treatment discontinuation were progressive disease (26%), AEs (9%), refusal to continue study medication (4%), and other (4%). All pts have had at least one AE of any cause (Grade 3/4: 52%/0%), most commonly (preferred term [PT]) diarrhoea (87%), rash (61%) and fatigue (48%). The most common treatment-related AEs (PTs) reported are diarrhoea (83%), rash (57%) and dry skin (39%), and the most common serious AEs (PTs) reported are vomiting and dehydration (both 9%). Ten (43%) pts have achieved confirmed OR (complete/partial response: 1 [4%]/9 [39%]) and 10 (43%) pts have had stable disease.

Conclusions: In this preliminary analysis, afatinib (30 mg/day) demonstrated a predictable safety profile in pts aged ≥70 yrs with Del19/L858R EGFRm+ NSCLC. Updated data will be presented.

Clinical trial identification: NCT02514174.

1457P Is there a difference in PFS or OS of T790M-mutated NSCLC patients treated with osimertinib either after chemotherapy or immediately after previous target therapy?

C.H. Lai, M-C. Lin, Y-H. Tsai, C-C. Wang

Division of Pulmonary and Critical Care Medicine, Chang Gung Memorial Hospital-Kaohsiung, Kaohsiung City, Taiwan

Background: Osimertinib (Tagresso) is recommended as an option for treating patients with locally advanced or metastatic EGFR T790M mutation-positive NSCLC whose disease has progressed after first-line TKIs. We compared OS and PFS in patients who received osimertinib treatment immediately after previous treatment with TKIs, and those who received osimertinib after their last cycle of chemotherapy.

Methods: This study enrolled a total of 2605 patients who were diagnosed with lung cancer between January 2013 and April 2017. Among these patients, there were 779 patients with inoperable EGFR-mutated NSCLC who had received TKIs as first-line therapy. Furthermore, 166 of these 779 patients who were resistant to TKIs had received re-biopsy. There were 71 patients who received osimertinib therapy for at least 2 weeks since March 2016.

Results: Demographics and clinical characteristics of the 71 patients are described in the table. Among these cases, 26 (36.6%) patients received osimertinib as 2nd-line therapy after first-line TKI therapy. Seventeen (23.9%) patients received osimertinib as 3rd-line therapy, and 28 (39.4%) patients received osimertinib in >= 4th-line setting. The median PFS in patients as 2nd-line therapy was 11.9 months and that was 17.3 months as 3rd-line therapy. The median PFS in patients as >= 4th-line therapy was 9.3 months. Among the 71 patients, there were 34 (47.9%) patients who received it after previous chemotherapy (Group A), and 37 patients (52.1%) who received osimertinib immediately after previous TKI therapy (Group B). The median PFS for Group A and Group B patients was 12.8 months and 11.0 months, respectively ($p = 0.306$). A higher percentage of patients in Group B had progressive disease (8 cases, 21.6%) compared to Group A (2 case, 5.9% ; $\chi^2 = 0.08$). Besides, obesity patients (BMI >= 27) had trend of shorter PFS with osimertinib therapy. (8.4 months vs. 12.6 months, $P = 0.05$).

Conclusions: Our data suggested that T790M-mutated NSCLC patients may have a better response, and longer PFS when treated with osimertinib therapy after previous chemotherapy compared to after previous TKI treatment. Due to the small sample size, our data need to be updated and need further re-analysis.

1458P Bone metastasis reduces responsiveness to EGFR-TKIs in patients with EGFR-mutated advanced lung adenocarcinoma

X. Zheng, C. Huang, G. Lin

Department of Thoracic Oncology, Fujian Cancer Hospital, Fuzhou, China

Background: The impact of bone metastasis on the patient's response to EGFR-TKI therapy is yet to be determined in lung adenocarcinoma (LUAD) patients harboring EGFR mutations.

Methods: This is a retrospective analysis of the efficacy of EGFR-TKIs for LUAD patients with EGFR mutations, comparing patients with bone metastases (BM) and those with no bone metastases (NBM). Regular imaging that evaluated the bone metastasis response was required for patients with BM. Overall response, median progression-free survival (mPFS), and progression patterns were calculated.

Results: Of the 502 patients reviewed, 175 were evaluated (BM 96, NBM 79). Clinical characteristics were balanced between the groups. Median PFS was 11.0 months in the NBM group versus 7.0 months in the BM group, $P = 0.013$. The mPFS was significantly decreased in patients with multiple BM (≥4) compared with those having oligometastases (1-3) or NBM (7.0 months vs. 10.0 months vs. 11.0 months, $P = 0.003$). Multivariate analysis confirmed that bone metastasis was an independent negative predictive factor of PFS, hazard ratio 1.87, $P = 0.003$. The response rate was higher in the NBM group than in the BM group (70.9% vs. 56.3%), $P = 0.046$. Bone was one of the frequent sites of EGFR-TKIs failure, accounting for 52 of 125 (41.6%). Patients with NBM had a remarkably lower rate of bone failure compared to patients with BM, 11.8% vs. 62.2%, $P < 0.001$.

Conclusions: Bone metastasis and multiple metastases in particular, reduce the responsiveness to EGFR-TKIs for LUAD patients with EGFR mutations. Monitoring of bone metastases should be a routine clinical practice in patients with BM.

1459P Which of afatinib and gefitinib/erlotinib is the better EGFR-TKI to be followed by osimertinib?

M. Tamiya[1], A. Tamiya[2], H. Suzuki[3], K. Nakahama[2], Y. Taniguchi[2], K. Kunimasa[1], M. Kimura[1], T. Inoue[1], K. Nishino[1], T. Hirashima[3], S. Atagi[2], F. Imamura[1], T. Kumagai[1]

[1]Thoracic Oncology, Osaka International Cnacer Institute, Osaka, Japan, [2]Internal Medicine, National Hospital Organization Kinki-Chuo Chest Medical Center, Sakai, Japan, [3]Thoracic Malignancy, Osaka Habikino Medical Center, Habikino, Japan

Background: In epidermal growth factor receptor (EGFR) mutation-positive non-small cell lung cancer (NSCLC), there are various treatment challenges. Most patients develop resistance and relaps within 1-1.5 years after first-line EGFR- tyrosine kinase inhibitor (TKI) treatment [1st- and 2nd- generation (G) TKIs]. Some studies suggest that afatinib may overcome the tumor heterogeneity.

Methods: We conducted the multi-center retrospective study in patients with EGFR-mutant NSCLC after acquired resistance to EGFR-TKIs appeared at any line of therapy. The outcomes between afatinib followed by osimertinib and 1st-G EGFR TKIs followed by osimertinib (3rd-G EGFR TKI) were evaluated.

Results: We enrolled 111 T790M mutation-positive patients treated with osimertinib. The median age was 69 (range: 39-88) year old. Among them, 33 (29.7%) were male, 100 (90%) were with PS 0-1, and 35 (31.5%) were treated with afatinib followed by osimertinib. The median treatment line with afatinib or 1st-G EGFR TKI followed by osimertinib was 5 or 4. In all patients, the objective response and disease control rates were 63.1% and 77.5%, respectively. The objective response and disease control rates were significantly higher in patients with afatinib followed by osimertinib than in those with 1st-G EGFR TKI followed by osimertinib [82.9% vs 53.9% ($p = 0.0065$) and 91.4% vs 71.1% ($p = 0.032$)], respectively. The median PFS (with <60% events) was longer and in favor of afatinib followed by osimertinib compared with 1st-G EGFR TKI followed by osimertinib (15.7 vs 8.9 months, $p = 0.195$). The follow-up is still ongoing.

Conclusions: Afatinib followed by osimertinib may provide better clinical benefit for NSCLC patients harboring T790M mutation compared with 1st-G EGFR TKIs. Afatinib followed by osimertinib is one of the first line sequential options even if osimertinib can be used as a first line therapy.

1460P Biopsy on progression in EGFR mutation positive (EGFRm) advanced non-small cell lung cancer (aNSCLC) patients (pts): A Canadian experience

Q.S-C. Chu[1], A. Agha[2], N.C. Devost[3], R. Walton[3], S. Ghosh[4], C. Ho[5]

[1]Oncology, University of Alberta Cross Cancer Institute, Edmonton, AB, Canada, [2]Medicine, University of British Columbia, Vancouver, BC, Canada, [3]Oncology, AstraZeneca, Toronto, ON, Canada, [4]BioStatistics, University of Alberta Cross Cancer Institute, Edmonton, AB, Canada, [5]Medical oncology, British Columbia Cancer Agency, Vancouver, BC, Canada

Background: EGFR tyrosine kinase inhibitors (EGFR-TKIs) are standard therapy for EGFRm aNSCLC. Upon progression, 50-60% will develop the secondary T790M mutation. Recent trials demonstrated improvement in outcomes with osimertinib over standard platinum-based chemotherapy as 2L therapy for T790M-positive EGFRm aNSCLC. To identify T790M, tumour biopsy or plasma testing is necessary. This study aimed to evaluate biopsy procedures and mutational analysis at two Canadian cancer centres.

Methods: BC Cancer-Vancouver and Cross Cancer Institute performed a retrospective review of pts who signed consent to enroll to the AURA2, AURA3 or ASTRIS studies. Pt characteristics, biopsy method, rebiopsy methods/complications, number of rebiopsies performed, and incidence of the T790M mutation were collected.

Results: 84 pts were considered for trial enrolment. 80 signed consent with M:F 32:68%; ECOG 0/1/2: 11/66/23%; smoker/ex-smoker/never smoker: 6/21/73%; exon 19/L858R/other: 60/36/4%; prior curative intent treatment in 18%. 78 pts underwent biopsy, most commonly CT/US-guided biopsy (50%), bronchoscope/EBUS (32%), thoracentesis/surgical biopsy (12%). 3 pts had plasma testing. Type of biopsies were cores (47%), fine needle biopsy (18%), transbronchial biopsy (14%), other (21%). The most common sites for biopsy were lung or nodes (64%). The median number of biopsies performed was 2. Only 8% of pts experienced complications after biopsy. 77% of samples were adequate for T790M testing: 35% performed locally, 65% centrally. Overall, 47 pts were found to have T790M; of which, 44 were enrolled in a trial. Among 40 pts who were ineligible for trials, reasons included: T790M negative (72.5%), decline in performance status/death (15%), inadequate tissue (5%), biopsy refusal, unable to biopsy, and symptomatic brain metastases requiring radiation (2.5% each). Additional data on practice pattern will be presented.

Conclusions: Patients and physicians were amenable to re-biopsy at progression for further tumor characterization and treatment selection. The incidence of complications was low despite the majority being pulmonary biopsies. 23% of the samples were not adequate for molecular analysis.

Background: Osimertinib is a third-generation, CNS-active EGFR-TKI that potently and selectively inhibits both EGFR-TKI sensitising and EGFR T790M resistance mutations. We report results from the European subset of the ongoing global ASTRIS study (NCT02474355).

Methods: Eligible pts receive osimertinib 80 mg once daily. Inclusion criteria: Stage IIIB/IV T790M-positive NSCLC; T790M status confirmed locally by validated test, not restricted by sample type; prior EGFR-TKI therapy received; WHO performance status (PS) 0 – 2; acceptable organ and bone marrow function and no history of interstitial lung disease (ILD) or QTc prolongation. Asymptomatic, stable CNS metastases are permitted. The primary efficacy outcome is overall survival (OS). Second interim data cut-off (DCO) 20 Oct 2017.

Results: From Sept 18 2015, 759 pts were enrolled across 8 European countries and received ≥1 dose of osimertinib: median follow-up 10.9 months (mo) (range <1 – 24), median age 66 yrs (32–92), 24% ≥75 yrs, 69% female, 97% White, 14% WHO PS 2, 44% prior chemotherapy. T790M-positive status was identified from tissue in 290 pts (38%), plasma ctDNA in 415 pts (55%) and from other sources in 53 pts (7%). At DCO, 545 pts (72%) had discontinued treatment (214 [28%] ongoing); 442 pts (58%) had withdrawn from the study, including 268 deaths (35%); median duration of exposure 9.7 mo (<1–25). In pts evaluable for response, investigator-assessed clinical response rate was 55.3% (381/689; 95% CI 51.5, 59.1). Estimated median progression-free survival (PFS) was 9.7 mo (95% CI 8.5, 10.8), with 470 (62%) progressions/deaths. OS data are not mature (OS at 12 mo was 67.4%; 95% CI 63.7, 70.8). Adverse events (AEs) leading to dose modification and treatment discontinuation were reported in 149 pts (20%) and 53 pts (7%), respectively. Serious AEs were reported in 147 pts (19%). ILD / pneumonitis-like events were reported in 22 pts (3%), and QTc prolongation in 7 pts (1%).

Conclusions: In this European dataset from ASTRIS, clinical activity (response and PFS) with osimertinib in patients with T790M-positive NSCLC is similar to that observed in the global ASTRIS population and the wider osimertinib clinical trial programme with no new safety signals.

Clinical trial identification: NCT02474355.

1462P Impact of blood-based biomarkers on survival outcomes with pembrolizumab in pre-treated advanced non-small cell lung cancer (NSCLC) patients (pts)

R.Y. Tay, J. Chiramel, E. Montague, F. Wilson, Y. Summers, F.H. Blackhall, R. Califano
Department of Medical Oncology, The Christie NHS Foundation Trust, Manchester, UK

Background: Elevated neutrophil-lymphocyte ratio (NLR), derived NLR (dNLR) and lactate dehydrogenase (LDH) have been identified as potential prognostic/predictive biomarkers to immune checkpoint inhibitors (ICI). The Lung Immune Prognostic Index (LIPI) utilises dNLR and LDH to define prognostic subgroups associated with overall survival (OS) and overall response rate (ORR) to ICI. The objective of this study was to assess progression free survival (PFS) and OS in pre-treated advanced NSCLC pts who received pembrolizumab and to perform a comparative analysis of pre-treatment NLR, dNLR, LDH, LIPI score and PD-L1 tumour proportion score (TPS) on survival, ORR and toxicity.

Methods: Pre-treated advanced NSCLC pts who received pembrolizumab (Jan '17-Jan '18) at The Christie were identified. Baseline demographics, PD-L1 TPS, NLR, dNLR and LDH were collected. Elevated NLR, dNLR and LDH was defined as ≥ 5, ≥ 3 and $\geq$ upper limit normal (ULN), respectively. LIPI score was calculated (Table). Survival analysis was performed using Kaplan-Meier method. Univariate logistic regression models were used to assess patient characteristics on PFS.

Table: 1462P Lung immune prognostic index (LIPI)

Good	dNLR <3 AND LDH <ULN
Intermediate	dNLR ≥3 OR LDH ≥ULN
Poor	dNLR ≥3 AND LDH ≥ULN

Results: 58 pts were analysed; median age: 67, males 66%, non-squamous 64%, 53% had PD-L1 TPS 1-49%. After median follow up of 5.2 months, 38/58 (66%) pts progressed. Median PFS and OS was 3.7m (95% CI 2.52-9.54) and 11.2m (95% CI 6.3-NR), respectively. ORR was 22.4%. A non-significant trend towards longer PFS was observed between LDH <ULN vs ≥ULN (5.5 vs 2.8m; p = 0.4), NLR <5 vs ≥ 5 (5.51 vs 3.7m; p = 0.99), dNLR <3 vs ≥ 3 (5.51 vs 2.66; p = 0.31), PD-L1 TPS ≥50 vs 1-49% (9.54 vs 2.82m, p = 0.29) and LIPI good/int/poor subgroups (5.8 vs 3.02 vs 1.89m; p = 0.23). Impact of blood-based markers on ORR and toxicity will be presented.

Conclusions: Our cohort demonstrated similar survival outcomes to KEYNOTE-010. Baseline NLR, dNLR, LDH, PD-L1 TPS and LIPI score were not significantly prognostic of survival.

Background: 2L+ overall response rates (ORRs) with PD-(L)1 inhibitors in patients (pts) with advanced NSCLC range from 12% to 19% (PD-L1 unselected), and median PFS ranges from 2.3 to 4.0 mo. Inhibiting the transforming growth factor β (TGF-β) pathway, which promotes tumor immunosuppression, may enhance the response to PD-(L)1 therapy. M7824 is an innovative first-in-class bifunctional fusion protein composed of a human IgG1 monoclonal antibody against PD-L1 fused with 2 extracellular domains of TGF-βRII (a TGF-β "trap").

Methods: Pts with advanced NSCLC unselected for PD-L1 who progressed after 1L standard treatment (no prior immunotherapy) were randomized to receive M7824 500 or 1200 mg (n = 40 each) q2w until disease progression, unacceptable toxicity or trial withdrawal in this expansion cohort of the ongoing, phase 1 trial NCT02517398. The primary objective is to assess BOR per RECIST v1.1; other objectives are dose exploration and safety/tolerability. Tumor cell PD-L1 expression (Ab clone 73-10 [≥80% is comparable to ≥ 50% with 22C3]) was evaluable in 75 pts.

Results: As of March 12, 2018, 80 pts received M7824 for a median of 11.9 (range, 2-66.1) wk, with a median follow-up of 51.1 wk; 10 pts remain on treatment. Investigator-assessed confirmed ORR was 27.5% at 1200 mg and 20% at 500 mg. Clinical activity was observed across PD-L1 subgroups (Table); ORR was 40.7% in PD-L1 + (≥1%) and 71.4% in PD-L1–high (≥80%) pts at 1200 mg. The most common treatment-related adverse events (TRAEs) were pruritus (20%), maculopapular rash (18.8%), decreased appetite (12.5%) and asthenia (11.3%). Grade ≥3 TRAEs occurred in 23 pts (28.8%); 8 pts (500 mg, n = 2; 1200 mg, n = 6) discontinued treatment due to TRAEs. No treatment-related deaths occurred.

Table: 1463P

ORR, n/N; %	500 mg	1200 mg	Total
All PD-L1+	8/40; 20.0 6/31;	11/40; 27.5 11/27;	19/80; 23.8 17/58;
PD-L1 high	19.4 2/6; 33.3	40.7 5/7; 71.4	29.3 7/13; 53.8
Median PFS; OS, mo			
All PD-L1+	1.4; 10.9 1.6;	2.7; NR 6.8;	2.1; 12.2 2.7;
PD-L1 high	10.3 1.5; NR	NR NR; NR	NR 8.1; NR

NR, not reached.

Conclusions: M7824 had promising efficacy, with encouraging PFS and OS, and ORRs at the RP2D of 1200 mg of 40.7% and 71.4% in PD-L1+ and PD-L1 high pts, respectively. Treatment was well tolerated.

Clinical trial identification: NCT02517398.

Background: In KEYNOTE-189 (NCT02578680), pembro plus pem and platinum provided superior OS (HR 0.49, P < .00001) and PFS (HR 0.52, P < .00001) and had manageable safety vs placebo plus pem and platinum as first-line therapy for metastatic nonsquamous NSCLC. In an exploratory analysis, we assessed outcomes by investigator's choice of carboplatin (carbo) or cisplatin (cis).

Methods: 616 patients (pts) with untreated metastatic nonsquamous NSCLC regardless of PD-L1 TPS without sensitizing EGFR or ALK alteration were randomized 2:1 to 4 Q3W cycles of pembro 200 mg or placebo + pem 500 mg/m^2 + carbo AUC 5 or cis

75 mg/m^2 followed by maintenance pembro or placebo + pem. Randomization was stratified by TPS (<1% vs ≥ 1%), platinum (carbo vs cis), and smoking status (current/former vs never). Primary end points were OS and PFS; ORR and safety were secondary.

Results: Carbo was chosen for 72% of pts in both arms. OS, PFS, and ORR were improved in the pembro plus pem and platinum arm in both carbo and cis recipients (Table). In the pembro vs placebo arm, 83% vs 72% received 4 carbo doses and 81% vs 79% received 4 cis doses. 76% vs 65% and 78% vs 72%, respectively, received ≥5 pem doses. Grade 3-5 AE rates for pembro vs placebo were 70% vs 66% with carbo and 59% vs 65% with cis. Rates of the most common any-grade AEs were generally similar for carbo and cis: nausea 54% with pembro vs 48% with placebo for carbo and 60% vs 63% for cis, anemia 45% vs 48% and 50% vs 44%, and fatigue 44% vs 43% and 33% vs 26%. Rates of acute kidney injury in the pembro arm were 5.1% with carbo and 5.4% with cis.

Conclusions: Pembro plus pem and platinum improved efficacy and was generally tolerable compared with placebo plus pem and platinum regardless of the chosen platinum. These data support the use of both carbo and cis in combination with pembro and pem as first-line therapy for metastatic nonsquamous NSCLC.

Clinical trial identification: NCT02578680, originally posted October 19, 2015.

1465P Phase I dose escalation of pembrolizumab given concurrently with palliative thoracic radiotherapy (RT) for NSCLC

R. Kumar[1], D.P. Walder[1], A. Pejanaute[2], R. Gunapala[3], J. Bhosle[3], N. Yousef[3], S. Popat[3], F. McDonald[3], I. Locke[3], K. Harrington[4], A. Tree[5], S. Lalondrelle[6], R. Huddart[5], M.E.R. O'Brien[1], M. Ahmed[1]

[1]Lung Cancer Unit, The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, London, UK, [2]Clinical Trials Unit, The Royal Marsden NHS Foundation Trust, London, UK, [3]Lung Cancer Unit, The Royal Marsden NHS Foundation Trust, London, UK, [4]Head and Neck Unit, The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, London, UK, [5]Urology Unit, The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, London, UK, [6]Gynaecology Unit, The Royal Marsden NHS Foundation Trust, London, UK

Background: Pembrolizumab is used routinely in advanced NSCLC. Combination strategies, such as with RT are of great interest. We report on safety and tolerability of an open-label phase 1 trial for cohort 1 of pembrolizumab with 2 schedules of palliative RT.

Methods: All cohort 1 patients started with a pembrolizumab dose of 100mg given 2 weeks prior to RT, and then received pembrolizumab 100mg 2-weekly concurrently with RT, followed by maintenance dose 200mg pembrolizumab 3-weekly. The RT was either 20 Gy/5# (low dose RT - LD) or 36 Gy/12# (high dose RT - HD). Cohort 2 pembrolizumab dose will be 200mg, for all doses, with the same RT schedules. Dose limiting toxicity (DLT) period, 2 months from completing RT, is defined as grade (G) 2 pneumonitis, G4 oesophagitis or G2 myelitis.

Results: 3/6 pts in the LD and 6/8 pts in the HD were evaluable for DLTs. Mean age was 61 years, 64% were female, 71% were smokers, ECOG performance status was 1 in 100%. 57% were of non-squamous histology with no driver mutations, and 64% were PD-L1 positive (TPS ≥1%). All pts had adverse events (AEs); G3–4 AEs were seen in 66.7% in the LD and 37.5% in the HD. There were no DLTs. In the LD, G3 AEs included: anaemia (n = 1), back pain (n = 1), bronchitis (n = 1), dyspnoea (n = 1), fatigue (n = 1), hypokalaemia (n = 1), hypophosphataemia (n = 1), and syncope (n = 2). In the HD, 1 pt had drug induced liver injury (G1 ALT, G3 ALP, G2 AST, G1 bilirubin, G4 GGT), and so the cohort was expanded by a further 3 pts. No DLTs were seen. G3 AEs included: pneumonia (n = 1), back pain (n = 1), dehydration (n = 1), radiation dermatitis (n = 1), diarrhoea (n = 1), hyperglycaemia (n = 1), and hypokalaemia (n = 2). 1 pt had G4 urosepsis. In the LD and HD, pts also had RT dermatitis (G1 n = 11, G2 n = 2), RT esophagitis (G1 n = 10, G2 n = 4), and RT pneumonitis (G1 n = 6). With a median follow-up of 7.9 months, median PFS was 1.3 months in the LD and 3.7 months in the HD (HR 0.28, P = 0.056). Median OS was 5.2 months in the LD and 8.3 months in the HD (HR 0.59, P = 0.441). Disease control rate (DCR) was 37.5% in the LD (3 SD) and 62.5% in the HD (3 PR, 2 SD; P = 0.592). DCR did not correlate with PD-L1 status (P = 1.00).

Conclusions: Combining pembrolizumab and palliative thoracic RT appears to be safe and tolerable with both RT doses. This trial continues to recruit to cohort 2.

Clinical trial identification: NCT NCT02587455.

1466P Effects of antibiotic use during immunotherapy in metastatic non-small cell lung cancer

G. Galli[1], M. Poggi[1], G. Fucà1, M. Imbimbo[1], C. Proto[1], D. Signorelli[1], M. Vitali[1], N. Zilembo[1], M. Ganzinelli[1], F. de Braud[1], M.C. Garassino[2], G. Lo Russo[1]

[1]Medical Oncology, Istituto Nazionale dei Tumori di Milano - Fondazione IRCCS, Milan, Italy, [2]Thoracic Unit, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy

Background: Immunotherapy (IO) has improved the outcome of metastatic non-small cell lung cancer (mNSCLC), but only a minority of patients (pts) derives a benefit from treatment (tx). Recent evidences supported a role of gut flora in influencing systemic response against tumors. The use of antibiotics (Abs) may impair the balance of microbiota and negatively affect the efficacy of IO. We aimed at analyzing this topic in a cohort of mNSCLC pts.

Methods: Data about all consecutive mNSCLC pts treated with IO at Istituto Nazionale dei Tumori, Milan, Italy, from 04/2013 to 01/2018 were retrospectively collected. We considered relevant for the analysis the use of Abs between 1 month (mo) before and 3 mos after the beginning of IO. We also evaluated the variable "Ab exposure" (AE), defined as the % "days of ab tx/days of IO". Survival was estimated with Kaplan-Meier method; curves were compared with log-rank test. Cox proportional model was used for multivariate analyses.

Results: We identified 157 cases. Most pts had a performance status (PS) ECOG $\geq$1 (52.2%) and $\geq$2 sites of metastatic disease (86.0%). IO was either an anti-PD1 (62.4%), an anti-PDL1 (32.5%), or a combination anti-PDL1/CTLA4 (5.1%); it was prescribed in first line in 25 pts, in second line in 66 pts, in a more advanced lines in 66 pts. Abs were administered to 27 pts, mostly for pneumonia. The most common were levofloxacin (55.6%), amoxi-clavulanate (25.9%) and ceftriaxone (14.8%). Progression free survival (PFS) and overall survival (OS) did not differ between Ab-treated and Ab-untreated pts (p.18; p.24, respectively). Median AE of the Ab-treated pts was 4.3% (range 0.6%-42.9%). Both PFS and OS were significantly lower in pts with a higher AE than the median one (2.2 vs 7.7 mos, p<.0001; 4.9 vs 16.3 mos, p.0004, respectively). At multivariate analysis with the other significant variables (PS and IO line), the impact of AE on PFS and OS retained significance (p.0003; p.0002, respectively).

Conclusions: These results suggest that the length of Ab tx, rather than their simple use in a defined time frame, may impair the efficacy of IO. Further research is needed to support this evidence. However, it may be advisable to carefully evaluate the prescription of long Ab cycles to mNSCLC pts receiving IO.

1467P Efficacy and safety of nivolumab for cytotoxic chemotherapy unfit patients with advanced non-small cell lung cancer: A phase II study

Y. Okuma[1], S. Kitano[2], K. Watanabe[1], M. Yomota[1], Y. Hosomi[3], Y. Zenke[4], N. Yamamoto[5]

[1]Department of Thoracic Oncology and Respiratory Medicine, Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Tokyo, Japan, [2]Experimental Therapeutics, National Cancer Center Hospital, Tokyo, Japan, [3]Department of Thoracic Oncology & Respiratory Medicine, Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Tokyo, Japan, [4]Department of Thoracic Oncology, National Cancer Center Hospital East, Kashiwa, Chiba, Japan, [5]Developmental Therapeutics, National Cancer Center Hospital, Tokyo, Japan

Background: This single-center phase II study aimed to examine the efficacy and feasibility of nivolumab for patients with advanced non-small cell lung cancer (NSCLC) who were unsuitable for single-agent chemotherapy or targeted agents because of their poor performance status (PS).

Methods: In this study, we enrolled previously treated patients with advanced NSCLC with poor PS of 2–4 without any indication of cytotoxic chemotherapy or targeted therapies. All enrolled patients received nivolumab (3 mg/kg, every 2 weeks) until progression or unacceptable toxicities. In addition, we prospectively obtained peripheral blood mononuclear cells (PBMC) and plasma from patients after obtaining their informed consent before treatment.

Results: Between April 2016 and December 2017, we enrolled 33 patients with NSCLC and poor PS, including 23 patients with PS 3–4. In this study, the response rate was 29.0% (90% confidence interval (CI), 17.7%–43.7%), and the disease control rate was 41.9% in 31 evaluable patients. PS improvement rate was 29.0%. In addition, the median progression-free survival (mPFS), median overall survival (mOS), and 1-year survival rates were 1.5 (95% CI, 1.0–2.7) months, 3.8 (95% CI, 2.4–16.3) months, and 37.6%, respectively. Among patients harboring EGFR-mutations (mut), the mPFS was 2.6 and 1.1 months in EGFR-wild type (wt) and EGFR-mut ($p = 0.015$), respectively, and the mOS was 9.3 and 1.9 months in EGFR-wt and EGFR-mut ($p = 0.029$), respectively. During the study period, treatment-related deaths were observed in 2 patients (6.1%). We obtained blood samples from 75% of the enrolled patients (data will be updated in the meeting).

Conclusions: To the best of our knowledge, this is the first trial to investigate the efficacy of immune checkpoints in patients with advanced NSCLC with poor PS. Although the response rate was similar to those with good PS, shorter survival was observed. Excluding patients harboring driver mutations may enhance treatment efficacy to show a survival benefit even for poor PS patients. Nevertheless, the biomarker investigation warrants focus on the PBMC analysis.

Background: Nivolumab is a standard treatment for second line in patients (pts) with advanced NSCLC. Real world data about toxicity and efficacy of nivolumab is lacking.

Methods: We have analyzed 665 pts from the Expanded Access Program, which included pts with pretreated NSCLC who received $\geq$1dose of nivolumab 3mg/kg q2w from 01/2015 for squamous (Sq) and 06/2015 for non-Sq NSCLC, to 11/2017.

Results: Median age was 61 (32-85) years, 73% were men, 85% had ECOG 0-1, 88% were current/former smokers and 15% had brain M1. 128 (19.2%) pts presented Sq and 537 (80.8%) Non-Sq NSCLC. 7% of pts presented EGFR mutation. PD-L1 was $\geq$1% in 33% of analyzed pts. Nivolumab was administered as 2nd/$\geq$3rd line in 33% and 67% of pts. Post-nivolumab treatment was administered to 25% pts that received nivolumab in 2nd line and to 23% that received nivolumab in 3rd line. After a median follow-up of 8.2 months, the median OS was 8-97 (95% CI 7.69-10.24) months, and the median PFS was 3.23 (95% CI 2.77-3.70) months. Estimated 1-year OS was 42.4% (95%CI 38.5-42.8%) and estimated 1-year PFS was 22.2% (95% CI 19.1-25.3%). No differences in OS or PFS were observed according to histologies. Among pts that received nivolumab in 2nd line, the median OS was 9.8 (95% CI 7.3-12.0) months and the median PFS was 3.3 (95%CI 2.4-4.2) months. Among pts that received nivolumab in $\geq$ 3rd line the median OS was 8.6 (95% CI 7.2-10.0) months and the median PFS was 3.1 (95% CI 2.6-3.7) months. Median OS for pts that received post-nivolumab treatment in 3rd line was 9.3 (95 CI% 7.0-11.6) months. 296 (44.5%) pts presented toxicity to nivolumab, which was grade $\geq$3 in 69 (10.4%) pts. According to the presence of grade $\geq$3 toxicity, the median OS was 14.57 (CI 95% 8.45-20.68) months for pts with and 8.73 (CI 95% 7.50-9.96) months for pts without grade$\geq$3 toxicity ($p = 0.074$). Additional efficacy and safety data, including PS2, brain M1, response to first line, or post-nivolumab treatment will be presented.

Conclusions: Efficacy and safety of nivolumab was in line with previously shown data. There was a trend to a better OS for those pts experiencing grade$\geq$3 toxicity.

Clinical trial identification: NCT03132493.

1469P EVIDENS: An observational study of nivolumab-treated patients in advanced non-small cell lung cancer (NSCLC) in a real-world setting: Initial results on 1394 patients

A. Dixmier[1], D. Debieuvre[2], C. Raspaud[3], J.B. Auliac[4], N. Benoit[5], P. Bombaron[6], B. Asselain[7], A. Dumont[8], P. Lamoureux[9], N. Goyard[10], D. Moro-Sibilot[11], M. Perol[12], F. Barlesi[13], C. Audigier Valette[14]

[1]Pneumologie et Oncologie Thoracique, C.H.R. Orleans - La Source, Orleans, France, [2]Service de Pneumologie, Hôpital Emile Muller, GHRMSA, Mulhouse, France, [3]Pneumologie, Clinique Pasteur, Toulouse, France, [4]Pneumologie, CH François Quesnay, Mantes La Jolie, France, [5]Pneumologie, Clinique de l'Europe, Amiens, France, [6]Pneumologie-Cancérologie, Hôpital privé Jean Mermoz, Lyon, France, [7]Biostatistics, Institut Curie, Paris, France, [8]Immuno-Oncology Lung Medical Affairs, Bristol-Myers Squibb, Rueil-Malmaison, France, [9]Excellence Opérationnelle Médicale, Bristol-Myers Squibb, Vandoeuvre les Nancy, France, [10]Global Clinical Trial Strategy and Operations, Bristol-Myers Squibb, Rueil-Malmaison, France, [11]Pneumologie, Centre Hospitalier Universitaire de Grenoble Alpes, Grenoble, France, [12]Cancérologie Médicale, Centre Léon Bérard, Lyon, France, [13]Service d'Oncologie Multidisciplinaire et Innovations Thérapeutiques, Aix-Marseille Université; Assistance Publique Hôpitaux de Marseille, Marseille, France, [14]Pneumology, Hospital Sainte Musse, Toulon, France

Background: Nivolumab demonstrated efficacy and safety in patients previously treated for advanced NSCLC in two phase 3 trials: CheckMate 017 and 057. Real-world data in a large unselected population are needed to support these results. EVIDENS aims to describe clinical characteristics of NSCLC patients treated with nivolumab in real-life in France and to assess its efficacy and safety.

Methods: EVIDENS is an observational, multicenter, longitudinal cohort study of adult NSCLC patients treated with nivolumab in a representative sample of general hospitals, university hospitals and private clinics in France. From Dec 2016 to Nov 2017, 186 sites participated in the study. We report here a pre-planned analysis including patients with confirmed NSCLC treated with at least one dose of nivolumab with a minimum of 6 months of follow-up. Kaplan-Meier estimates were derived for PFS and medians with their 95% confidence intervals.

Results: At data cut off April 20, 2018, 1394 NSCLC patients received nivolumab, including 434 (31.1%) with Squamous (Sq)-NSCLC and 960 (68.9%) with non-Sq-NSCLC. Baseline patient characteristics were representative of a standard advanced NSCLC population: median age 66.0 years (range 35-91), 69.2% men, 89.6% current and former smokers, 83.2% PS 0-1. 279 (20.0%) patients had brain metastases and 41 (2.9%) patients had active autoimmune disease. PD-L1 was tested in 187 patients and expressed ($\geq$1%) in 121 (64.7%) patients. Of the 828 non-Sq NSCLC patients tested, 46 (5,5%) had EGFR mutations. Nivolumab was administered in 2nd and $\geq$3rd line for 74.4% and 25.3% of patients respectively. Median PFS since inclusion was 3 months (95%CI 2.96-3.61). Adverse events occurred in 885 (63.5%) patients, including 145 (10.4%) grade 3/4 events.

Conclusions: These preliminary results of EVIDENS confirm both the activity and safety profile of nivolumab in the $\geq$2nd line setting in usual clinical practice, including patient populations under-represented in pivotal clinical trials. Outcomes over a longer follow-up period (minimum potential 12 months) and OS data will be presented during the congress.

CrI, Credible interval; SUCRA, surface under the cumulative ranking curve; q3w, every 3 weeks; qw, once a week.

(NMA) of time-to-event data, to address challenges in evaluating overall survival (OS) and switching with CIT.

Methods: A systematic literature review identified randomized, controlled, Phase II-IV trials of US- or EU-approved 2L+ treatments for advanced/metastatic NSCLC that enrolled ≥ 10 adult patients (pts) per treatment arm. An FP-NMA was used to estimate time-to-event outcomes: OS (5-y horizon) and progression-free survival (PFS; 2.5-y horizon). Expected survival time reflected the area under the curve over the time horizon. Adjusted analyses accounted for treatment switching. Expected OS times were ranked by median ranking with 95% credible intervals and by surface under the cumulative ranking curve (SUCRA).

Results: Of 25,115 screened publications, 35 studies of chemotherapy (chemo), PD-(L)1 inhibitors, targeted and other non-chemo agents, and placebo were included in the FP-NMA. In this model, all CIT PD-(L)1 inhibitors (nivolumab [nivo], atezolizumab [atezo] and pembrolizumab [pembro] in rank order) had similar estimated 5-year OS and ranked above all other treatments (Table). When adjusted for switching, all 3 CITs remained the highest-ranking treatments, with atezo ranked highest, followed by nivo and pembro. PFS and PD-(L)1 inhibitors' population subgroup results will be shown.

Conclusions: This FP-NMA showed that PD-(L)1 inhibitors had the highest expected 5-year OS amongst 2L treatments and that factors such as switching affected OS benefit. These results, which vary from prior models, suggest that FP-NMA may be a more relevant and viable method for assessing LT clinical benefit in pts treated with CIT.

1471P Prior or concurrent radiotherapy and nivolumab immunotherapy in non-small cell lung cancer

G. Ratnayake[1], M. Shankar[2], K. Roberts[3], R. Mason[4], B.G.M. Hughes[1], Z. Lwin[1], V. Jain[3], K.J. O'Byrne[5], B. Chua[1]

Background: Preclinical and retrospective clinical studies suggest that combining radiotherapy (RT) with programmed cell death protein 1 (PD-1) blockade may elicit a synergistic anti-tumour response. We aimed to assess whether prior or concurrent RT was associated with improved disease control in patients with metastatic non-small cell lung cancer (NSCLC) treated with nivolumab.

Methods: We conducted a retrospective study of patients receiving nivolumab as second or subsequent line therapy for metastatic NSCLC across four tertiary oncology centers. All patients received nivolumab at a dose of 3mg/kg every 2 weeks intravenously. Survival and toxicity data were collected prospectively. Patients were categorized into those who received any RT for NSCLC (with curative or palliative intent, thoracic or otherwise) prior to or during nivolumab therapy, and those with no history of RT for NSCLC. Kaplan-Meier survival analysis was performed for progression-free survival (PFS) and overall survival (OS) following commencement of nivolumab.

Results: 85 patients (32 female, 53 male) received nivolumab between July 2015 and December 2016. Patients had a median age of 67 years (range 42-84) at commencement of nivolumab and were followed up for a median of 15 months. 65 patients (76.4%) received RT prior to or during nivolumab and 20 patients (23.6%) received nivolumab alone. Baseline characteristics of age, performance status, histology, smoking status, sites of metastatic disease and previous therapy were similar between the two groups. Prior or concurrent RT was associated with prolongation of PFS, median 2.8 months with RT versus 1.3 months without RT ($P = 0.02$, HR = 0.494, 95% CI 0.279-0.873). The median OS of the group receiving RT was 6.4 months vs 4.2 months for the no RT group but the difference did not reach statistical significance ($p = 0.20$). RT was not associated with an increase in toxicity and Grade 2 or greater pneumonitis rates were low in both groups (RT 4.6% vs no RT 5%).

Conclusions: RT prior to or concurrent with nivolumab for metastatic NSCLC was associated with superior PFS over nivolumab alone with no evidence of increase in adverse effects. RT may potentiate the effect of anti-PD-1 immunotherapy in NSCLC.

Background: Immunotherapy with anti PD-1 antibodies (mAbs) is the standard of care for the treatment of advanced Non-Small-Cell Lung Cancer (NSCLC). A conspicuous group of patients with advanced NSCLC are more than 75 years old. However, no randomized controlled trial exploring anti PD-1 therapy in older individuals has been published until now and few experiences in clinical practice have been reported. We therefore performed a multicenter retrospective analysis on NSCLC elderly patients treated with anti PD-1 therapy.

Methods: We collected data from seven centers. Inclusion criteria were a diagnosis of advanced NSCLC, age ≥75 years, and treatment with anti-PD-1mAbs (pembrolizumab or nivolumab) in first or following lines. Primary end-points of the study were efficacy, in terms of Disease Control Rate (DCR), Overall Response Rate (ORR), Progression-Free Survival (PFS), and safety, by means of immune-related adverse events (irAEs).

Results: The Clinical records of 72 patients followed since 2015 were analyzed. Median age was 77 years (75-86), males ware more frequently represented (60/72, 83%). A current or previous smoking history was found in 67/72 (93%) patients. Very old individuals (> 80 years old) were 21/72 (29%) and ECOG PS was 0-1 for 49/72 patients (63%). Non-squamous histology was prevalent 45/72, (62%). Brain metastases were found in 6/72 (8%) patients. Most of the patients (58/72, 81%) received nivolumab. For 68 patients, data on DCR, ORR were available. 39/68 (54%) had a DCR, while 17/68 (24%) had an ORR. Less than 10% of the patients had oligoprogression or pseudoprogression (8,3 and 9,7 % respectively). Overall immune-related adverse events occurred in 9/72 (14%) of individuals, 4/10 (40%) of them grade 3/4, being hematological and liver toxicities the most frequent ones (4 and 3%, respectively). At time of analysis, median PFS was 4,4 months (0.5-25 SD 5,53). In the Cox regression analysis, PFS was significantly influenced by DCR and smoking status ($p = 0{,}0001$, OR 17 95% CI 5,4 - 52,3 and $p = 0{,}001$, OR 11 95% CI 2,6-45, respectively).

Conclusions: In our cohort of elderly patients, anti PD-1 agents demonstrated to have a good toxicity profile and an efficacy comparable with the younger population.

Background: Immune checkpoint inhibitors (ICIs) offer longer survival than chemotherapy in advanced non-small cell lung cancer (NSCLC). In subset analyses, ICIs extended survival compared to chemotherapy in patients aged ≥65 years, but the effects in patients aged ≥75 years are controversial. We performed multicenter, collaborative, and retrospective analyses of ICI efficacy and safety in NSCLC patients aged ≥75 years.

Methods: We retrospectively studied 434 advanced NSCLC patients who received ICIs from December 2015 to December 2017 at seven centers, and retrospectively applied the G8 screening tool from medical records.

Results: Of 434 patients who received ICIs, 100 were aged ≥75 years (median: 79 years; range: 75–90 years). Five patients with PS 3 were omitted. The histological diagnoses were non-squamous cell carcinoma in 55 (57.9%), squamous cell carcinoma in 40 (42.1%). ICIs were given as a first-line treatment to 20 patients, and as a second- or later-line treatment to 75; 67 (70.5%) patients received nivolumab, and 28 (29.5%) pembrolizumab. The PD-L1 tumor proportion scores (TPS) were <1% in 4 (4.2%), 1-

49% in 10 (10.5%), and ≥50% in 26 (27.4%) and unknown in 55 (57.9%). The objective response rate (ORR) was 35.0% (CR: 0, PR: 7, SD: 6, PD: 5, NE: 2), the median progression-free survival (PFS) was 6.1 months [95% confidence interval (CI): 1.6–7.7], and the median survival time (MST) was 8.7 months [95% CI: 7.9–not reached (NR)] for first-line treatment in patients with TPS ≥50%. The ORR was 20.0% (CR: 0, PR: 15, SD: 18, PD: 31, and NE: 11), the PFS was 2.9 months [95% CI: 1.9–4.6], and the MST was 15.5 months [95% CI: 5.5–NR] for second- or later-line treatment. The median G8 score was 11.5 (range: 5.5–15.5). The MST was longer in the G8 high (>11.5) group than the low (≤11.5) group (NR vs. 8.2 months) ($p = 0.02$). Likewise, the MST was 17.8 months (PS 0–1) vs. 3.1 months (PS 2) ($p < 0.01$). The grade ≥2 immune-related adverse events incidence was 23.3% (thyroid disease: 4.2%; interstitial lung disease: 10.5%).

Conclusions: Although the observation period is short and the data is immature, ICIs were effective and tolerable for patients aged ≥75 years. PS is a simple and exact parameter, but G8 screening is also useful in judging ICI adequacy for the elderly.

Brest - Hôpital Morvan, Brest, France, [8]Division of Medical and Scientific Affairs, ESMO - European Society for Medical Oncology, Lugano - Viganello, Switzerland, [9]Pneumology, Centre Hospitalier Du Mans, Le Mans, France, [10]IAE, Université de Nantes, Nantes, France, [11]IAE, University of Nantes, Nantes, France, [12]Cancer Observatory, CHRU Brest, Brest, France

Background: In 2016, nivolumab could be prescribed according to French registration in stage IIIB/IV NSCLC after disease progression with prior platinum-based chemotherapy and TKI therapy for patients with EGFR mutation. The Observatory of Drugs, Medical Devices and Therapeutic Innovations (OMEDIT), a network from the Health Ministry has evaluated the use, current practices and medico-economic approach in the Bretagne and Pays de la Loire areas.

Methods: All consenting adult patients with stage IIIB/IV NSCLC who initiated nivolumab (3 mg/kg every 2 weeks) in 2016 were included. Minimum follow-up for survival was 12 months. Sex, age, mutation profile, toxicities, Clinic Benefit (CB: pts with complete/partial response/stable disease as the best response), progression-free survival (PFS) and overall survival (OS) have been studied for ECOG PS 0-1 pts (according to registration).

Results: 377 pts with squamous (113 pts), non-squamous (197) and undifferentiated (67) NSCLC have been included. The median number of courses was 8 (1-54). 140 pts (37%) had 1 to 4 courses, 67 pts (18%) 5 to 8 courses and 170 pts (45%) more than 8. 247 pts were treated in 2nd line, 98 in 3rd line. All lines combined, CB was experienced by 212 pts (56%). For these pts, median course was 17 (1-54), mPFS and mOS were 4.6 months and 15.0 months, respectively. No difference on survival has been noticed according to histology, treatment line, age (cut-off 70 y), grade III/IV toxicity. However, mPFS and mOS were lower in ECOG PS ≥ 2 pts than in PS0-1 pts: 2.4 months vs 4.6 m ($p < 0.01$) for PFS and 3.7 m vs 15.0 m ($p < 0.001$) for OS. 20% of pts presented grade III/IV toxicities. These pts presented a better CB (74% vs 56%, $p = 0.002$). In 2016-2017, this treatment, for pts initiated in 2016 only, cost 15.8 million euros (drug, hospitalisation and transportation). 86% of these costs were dedicated to pts who experienced CB.

Conclusions: In a real-life setting, survival outcomes and toxicities with nivolumab in advanced NSCLC are comparable to literature data. ECOG PS ≥ 2 pts presented shorter survival than PS0-1 pts. Interestingly, 86% of the cost incurred for these treatments was to pts with CB. Updated data will be shown at the meeting.

1475P Radiological identification of rapid progressions in advanced NSCLC patients treated with nivolumab

P.F. Simões da Rocha[1], E. Ripoll[2], A. Corbera[1], M. Hardy-Werbin[1], A.F. Fernandez-Alarza[2], M. Orrillo[1], À. Taus[1], E. Arriola[1]

[1]Medical Oncology, Hospital del Mar, Barcelona, Spain, [2]Radiology Department, Hospital del Mar, Barcelona, Spain

Background: With the wide introduction of anti-PD-1 agents in the treatment of NSCLC, the unusual patterns of response are now observed more frequently in the clinical setting. One of the major concerns for clinicians is hyperprogression, perceived as a reality by many but for which there is still discussion and has no standard definition. The aim of our work was to analyse the patterns of response to nivolumab in a homogeneously treated population of patients with NSCLC and identify cases with hyperprogression.

Methods: Between December 2015 and August 2017, 42 patients with NSCLC were treated with Nivolumab at 3mg/kg every 2 weeks. A retrospective evaluation of the CT scans (previous to baseline, baseline before nivolumab, subsequent scans after nivolumab) was performed by a thoracic radiologist. Tumour growth rate was defined as the percentage of variation by RECIST1.1 over time. It was calculated for the pre and post-nivolumab period (RECIST%/time (days)). We defined hyperprogressors as those patients whose tumour growth was 2 times greater on nivolumab than in the pre-nivolumab period.

Results: RECIST 1.1 evaluation was feasible in 40 patients. Best response was a partial response in 17.5% patients, including 4 cases (10%) of pseudoprogression and 2 cases with delayed response (after 1st scan). Thirty percent and 52.5% of patients showed stable disease and progressive disease, respectively. Among the 20 patients who developed progression by RECIST 1.1 on nivolumab, 16 experienced a more rapid progression in the post-nivolumab period (median % of change/t 0.6 Vs 0.3 in the pre-nivolumab period; $p = 0.02$)). Sixty percent (12/20) of progressing patients were hyperprogressors according to our definition (30% of the total population). No differences between hyperprogressors vs rest of progressors according to age, performance status, treatment line, gender or histology was observed.

Conclusions: Rare patterns of response (pseudoprogression, hyperprogression) must be considered in the evaluation of patients treated with immunotherapy. Unexpectedly rapid progressions are observed on immunotherapy. Standardized definitions and mechanisms for these events warrant further investigation.

1476P Role of immunotherapy (I) for advanced, pre-treated, non-squamous NSCLC (APNS-NSCLC): Preliminary data of a pooled analysis with network meta-analysis

C. Cherubini[1], M. Papi[1], L. Gianni[2], C. Gianni[2], S.V.L. Nicoletti[1], M. Fantini[1], L.A. Lazzari Agli[1], D. Tassinari[1]

[1]Oncology, Ospedale Infermi, Rimini, Italy, [2]Oncology and Haematology, Ospedale Infermi, Rimini, Italy

Background: To assess the role of I for second line treatment of APNS-NSCLC.

Methods: A pooled analysis of the final data of the CA209057, the KEYNOTE-010 and the OAK trial was performed. Overall Survival (OS) was the primary end point of the trial. The outcomes of patients with PD-L1 expression of 1%-49% (PD-L1 1%-49%), PD-L1 expression <1% (PD-L1<1%) or mutated-EGFR (EGFR+) were analyzed comparing any checkpoint inhibitor with standard chemotherapy. An indirect comparison with network meta-analysis was performed between the different checkpoint inhibitors whenever a significant difference was observed in the pooled analysis. Direct and indirect comparisons were performed using a random effect model.

Results: The outcome of 1720 patients was analyzed. 313 patients had been treated with Atezolizumab (A), 292 with Nivolumab (N), 270 with Pembrolizumab (P), and 845

with Docetaxel (D). The preliminary results were detailed in the table (Legend. CI95%: 95% Confidence Interval; *: Pooled Analysis; **: Network Meta-Analysis).

Table: 1476P

	OS Hazard Ratio	CI95%	
A vs D (PD-L1 1%-49%)	0.571	0.423-0.771	P < 0.001
N vs D (PD-L1 1%-49%)	0.62	0.467-0.882	P = 0.001
P vs D (PD-L1 1%-49%)	0.76	0.604-0.956	P = 0.019
I vs D (PD-L1 1%-49%)*	0.66	0.555-0.786	P < 0.001
A vs N (PD-L1 1%-49%)**	0.921	0.609-1.392	P = 0.696
A vs P (PD-L1 1%-49%)**	0.751	0.541-1.043	P = 0.087
N vs P (PD-L1 1%-49%)**	0.816	0.597-1.116	P = 0.491
N vs D (PD-L1<1%)	0.9	0.66-1.214	P = 0.491
A vs D (PD-L1<1%)	1.04	0.619-1.747	P = 0.882
I vs D (PD-L1<1%)*	0.933	0.72-1.21	P = 0.601
P vs D (EGFR+)	0.88	0.453-1.71	P = 0.706
N vs D (EGFR+)	1.18	0.693-2.004	P = 0.542
I vs S (EGFR+)*	1.052	0.695-1.594	P = 0.81

Conclusions: Our data seem to confirm the role of I for APNS-NSCLC with PD-L1 1%-49%. On the contrary, not-significant benefits in terms of OS seem to emerge for patients with PD-L1<1% or EGFR+ expression. Likewise, no significant differences seem to emerge from the indirect comparisons between A, N and P for patients with a PD-L1 1%-49% expression. Although all these data need to be analyzed with caution, as expression of indirect comparisons, waiting further conformations from clinical trials they can support clinicians for daily clinical practice.

Medical Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: The advent of IO has led to greater availability of effective subsequent treatments and extended survival of patients, increasingly complicating the evaluation of overall survival (OS) in adNSCLC trials. To expedite drug developments and allow timely approvals of potentially effective agents for previously treated adNSCLC, we assessed the validity of PFS and 1y survival as SE in 2nd-line adNSCLC trials, especially in those containing immunotherapies.

Methods: We conducted a systemic literature search of 2nd-line adNSCLC trials. A weighted linear regression analysis between post 2nd-line treatments and OS was performed to establish the necessity of SE in 2nd-line trials. Adopting Buyse's criteria for surrogacy, a two-stage meta-analytic validation model was used to assess associations between SE and OS at patient-level and trial-level. The strength of association was quantified by the coefficient of determination (R^2). R^2 >0.6 was defined a priori as clinically relevant. Results were validated with leave-one-out cross validation methods.

Results: Of 1680 studies identified, 85 trials with 146 arms and 25,698 patients were included. Data of 22,804 patients from 50 trials (103 arms) were used for surrogacy assessment. A significant correlation between percentages of post 2nd-line treatments and OS improvements was identified (R^2 [95% confidence interval] =0.347 [0.345-0.351], $P_{Pearson}$ <0.0001, $P_{Spearman}$ <0.0001). PFS showed weak patient-level (0.100 [0.098-0.101]) and trial-level (0.064 [0.059-0.069]) associations with OS, while 1y survival strongly correlated with OS at both levels ($R^2_{patient}$=0.707 [0.704-0.708]; R^2_{trial}=0.829 [0.828-0.831]). Subgroup analysis of IO trials yielded similar results (PFS: $R^2_{patient}$=0.177 [0.128-0.200], R^2_{trial}=0.835 [0.791-0.918]; 1y survival: $R^2_{patient}$=0.965 [0.960-0.968], R^2_{trial}=0.778 [0.734-0.856]).

Conclusions: A valid SE is needed in 2nd-line adNSCLC trials in the era of IO. PFS poorly correlated with OS at both patient-level and trial-level, while 1y survival showed the potential of being a valid SE in future 2nd-line adNSCLC trials.

1478P Efficacy of second-line nivolumab after early time to progression on first-line cytotoxic chemotherapy in patients with advanced non-small cell lung cancer (NSCLC)

T. Ota, K. Kirita, H. Udagawa, S. Umemura, S. Matsumoto, K. Yoh, S. Niho, K. Goto

Thoracic Oncology, National Cancer Center Hospital East, Kashiwa, Japan

Background: Some previous studies showed chemo-resistance was associated with upregulation of programmed cell death ligand 1 (PD-L1) and mutation burden in NSCLC. Recently, immune checkpoint inhibitors are available to treat NSCLC, whereas efficacy of immune checkpoint inhibitor in patients showing early progression to first-line cytotoxic chemotherapy remains unknown.

Methods: We retrospectively collected medical records of advanced NSCLC patients who received second-line nivolumab treatment after cytotoxic chemotherapy in our hospital. Early progression was defined as exacerbation less than 16 weeks from the initiation of first-line chemotherapy. The patients were divided according to time to progression (TTP) of first-line therapy for <16, and ≥16weeks and were evaluated efficacy of second-line nivolumab.

Results: Fifty-one patients were received nivolumab treatment as second-line therapy after first-line line cytotoxic chemotherapy failure from February 2016 to April 2017, 22 patients were in the TTP <16 weeks group and 29 patients were in the TTP ≥16 weeks group. The median TTP of first-line cytotoxic chemotherapy was 17.0 weeks (95% CI 8.0-23.1 weeks). The median progression-free survival (PFS) of second-line nivolumab was 6.7 months (95% CI 3.2 -11.2 months). The median PFS was 11.3 months in the TTP <16 weeks group versus 3.7 months in the TTP ≥16 weeks group (hazard ratio, 0.44; 95% CI, 0.21–0.88, P = 0.019). The objective response rate was 55% versus 18% (P = 0.005) and the complete response rate was 5% vs 0%. The median overall survival was not reached and 11.3 months, respectively (hazard ratio, 0.68; 95% CI, 0.30–1.46, p = 0.32). On multivariate analysis, TTP <16 weeks (hazard ratio, 0.39; 95% CI, 0.17-0.83, p = 0.015) and non-sq histology (hazard ratio, 0.33; 95% CI, 0.16-0.69, p = 0.004) were significantly favorable factors for PFS.

Conclusions: Among patients with advanced NSCLC that had early progressed during or after primary cytotoxic chemotherapy, nivolumab was effective as second-line therapy.

Background: In September 2016, the SLCG began a RTT in 53 Spanish hospitals. In this study, we present data on patients with NSCLC with advanced disease.

Methods: The study comprises all the patients included in the RTT since September 2016 with stage IV disease. Progressionfree survival (PFS) and overall survival (OS) were evaluated with the Kaplan-Meier curves and the groups were compared using the Log-rank test. The variables related with the patients that were analyzed included: age, gender, smoking habit, comorbidities, performance status (PS) by ECOG and histology of the tumor. The molecular tests performed in the group of patients with advanced disease were also analyzed. We also analyzed the treatment received in this patient cohort.

Results: Out of the total of 2361 patients included, diagnosed between July 1991 and April 2018, 1194 had stage IV NSCLC. Mean age was 63.2 years, 824 (69%) were males, 473 (39.6%) active smokers and 475 (39.8%) ex-smokers. The most frequent histology

was adenocarcinoma, in 894 patients (74.9%), and squamous cell, in 220 patients (18.4%). A total of 78.6% (938) of the patients had some type of comorbidity: HBP (38.5%), dyslipidemia (28.1%), diabetes mellitus (16.3%) and COPD (14.7%). A total of 978 patients (81.9%) underwent some type of molecular test. The EGFR analysis was performed in 900 patients (75.4%), and was positive in 25.6%. ALP was analyzed in 763 patients (63.9%), mostly by IHC (44.7%), 5.2% being positive by this method. Of the total, 158 patients (13.2%) did not receive any treatment, 530 patients (44.4%) received 1 treatment line, 295 patients (24.7%) two lines, 128 patients (10.7%) three lines, and 30 patients (2.5%) 4 or more lines. A total of 60.9% of the patients received a platinum doublet in first line, the most commonly used being the combination of platinum with pemetrexed (34%). 1171 patients are evaluable for overall survival, with a median survival of 17.4 m (95% CI 14.6-20.2 m).

Conclusions: In this cohort of patients, the clinical characteristics are those expected for this group of patients with advanced disease. However, a greater percentage than that expected of the EGFR mutations appears, perhaps due to a population supraselection.

1481P Extra-cost of brain metastases in patients with non-squamous non-small cell lung cancer (NSCLC): A French national hospital database analysis

N. Girard[1], D. Cozzone[2], L. de Léotoing[3], C. Tournier[3], A. Vainchtock[3], B. Tehard[2], A. Cortot[4]

[1]Oncology, Institut Curie, Paris, France, [2]National Access & Pricing, Roche S.A.S - France, Boulogne-Billancourt, France, [3]Consultancy, HEVA, Lyon, France, [4]Oncology, CHRU de Lille, Lille, France

Background: To assess the incremental cost associated with the management of patients with primary non-squamous non-small cell lung cancer (NSCLC) with brain metastases (BM) at the time of diagnosis

Methods: A retrospective database analysis was performed using the French exhaustive Hospital medical information database (PMSI). Patients with metastatic lung cancer were identified through a combination of ICD-10 diagnosis codes: C34* for lung cancer combined with at least one metastasis code (C77*, C78*, C79*). All such patients hospitalised with metastatic lung cancer for the first time in 2013 were eligible. Those with at least one prescription of bevacizumab or pemetrexed at the index stay or during the 24-month following period were considered to have non-squamous NSCLC. Two cohorts were identified, one with BM and one with metastases at other sites. For each patient, total in-hospital medical resource consumption associated with the initial stay in 2013 and with any follow-up stays in the following 24 months was documented. Costs were attributed from official French national tariffs and expressed in 2017 Euros.

Results: The study included 1,529 patients with other metastases (62.6 ± 9.8 years old; 69.0% of men) and 971 patients with BM (58.6 ± 9.1 years old; 59.3% of men). The mean number of hospitalisations in the 24-month follow-up period was 17 per patient with other metastases and 21 per patient with BM. >99% of patients in both groups received chemotherapy. 57.7% patients with BM and 12.9% patients with other metastases were managed by radiotherapy. 37.2% patients with BM and 23.5% patients with other metastases received palliative care. 942 patients with other metastases and 695 with BM died during hospitalisation within two years (61.6% vs 71.6%). The associated cost was € 2,979 per patient-month for those with BM and € 2,426 for those with other metastases, representing a differential cost of € 553 per month. Radiotherapy (+€164/month) and palliative care (+€130/month) were the principal drivers of the incremental cost).

Conclusions: The presence of BM at the time of diagnosis of non-squamous NSCLC carries a significant burden, and ways of lowering it are needed.

1482P Localablative treatment for synchronous oligometastatic lung cancer: A propensity score analysis of 180 patients

N. Frost[1], A. Tessmer[2], A. Schmittel[3], V. van Laak[4], S. Ochsenreither[5], B. Temmesfeld-Wollbrück[1], B. Schmidt[4], N. Suttorp[1], M. Witzenrath[1], C. Grohe[2]

[1]Department of Infectious Diseases and Pulmonary Medicine, Charité – Universitätsmedizin Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Berlin, Germany, [2]Department of Pulmonary Medicine, Evangelische Lungenklinik Berlin-Buch, Berlin, Germany, [3]Onkologie Seestrasse, Schwerpunkt Hamatologie und Onkologie, Berlin, Germany, [4]Department of Pulmonary Medicine, DRK-Klinikum Berlin-Mitte, Berlin, Germany, [5]Charité Comprehensive Cancer Center, Charité – Universitätsmedizin Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Berlin, Germany

Background: Localablative treatment (LAT) improves outcome in lung cancer with oligometastatic disease (OMD) and potentially leads to long term survival. The aim of this retrospective study was to evaluate and quantify the additional benefit of LAT in synchronous OMD and to further identify prognostic factors for outcome and survival.

Methods: A propensity score matched pairs analysis was performed on a set of patient and disease variables in 180 patients, treated for synchronous OMD (including non-small cell and neuroendocrine lung cancer) with ≤4 metastatic lesions between 2000 and 2016 in 3 specified lung cancer centers in Berlin, Germany. Patients had either received LAT for all sites of disease (intervention group) by surgery or stereotactic ablative body radiation, or standard chemotherapy, if necessary combined with a palliative-intended local treatment (control group).

Results: Median follow-up time was 32.2 and 18.8 months for the intervention and control group, respectively. Substantial benefits in median progression free survival (PFS, 25.1 vs. 8.2 months; HR, 0.30; 95% CI, 0.21-0.43; $p < 0.001$) and overall survival (OS, 60.4 vs. 22.5 months; HR, 0.42; 95% CI, 0.28-0.62; $p < 0.001$) were associated to LAT. Histology of adenocarcinoma (PFS: HR, 0.58; 95% CI, 0.37-0.91; $p = 0.02$; OS: HR, 0.53; 95% CI,0.33-0.86; $p = 0.01$) and small primaries (T1a; PFS: HR, 0.36; 95% CI, 0.18-0.70, $p = 0.003$; OS: HR, 0.39; 95% CI, 0.18-0.84; $p = 0.02$) also predicted a favorable prognosis concerning PFS and OS. Nodal stage (N0-2 vs. 3; HR, 0.49; 95% CI, 0.25-0.97; $p = 0.04$) and number of metastases (1 vs. 2-4; HR, 0.63; 95% CI, 0.41-0.96; $p = 0.03$) were associated with an extended PFS, whereas initial ECOG-PS (0-1 vs. 2; HR, 0.42; 95% CI, 0.20-0.91; $p = 0.03$) predicted OS.

Conclusions: LAT was the strongest predictor for PFS and OS in patients with OMD and ≤4 metastases. Survival observed in the control group identifies OMD as a subset of lung cancer with a generally more favorable prognosis.

1483P Initial treatment in patients (pts) diagnosed with non-small cell lung cancer (NSCLC) in Denmark from 2005-2015: The SCAN-LEAF study

J.B. Sørensen[1], S. Ekman[2], P. Horvat[3], D. Layton[4], J. Kim[4], M. Rosenlund[4], A. Juarez-Garcia[5], M. Daumont[6], H.C. Jacobs[5], L. Lacoin[6], O.T. Brustugun[7], M. Planck[8]

[1]Department of Oncology, Rigshospitalet, Copenhagen, Denmark, [2]Department of Oncology, Karolinska University Hospital-Solna, Stockholm, Sweden, [3]Real World Evidence Solutions, IQVIA, London, UK, [4]Data Science, IQVIA, London, UK, [5]Worldwide Health Economics & Outcomes Research, Bristol-Myers Squibb, Uxbridge, UK, [6]Worldwide Health Economics & Outcomes Research, Bristol-Myers Squibb, Braine-L'Alleud, Belgium, [7]Department of Oncology, Radiumhospitalet, Oslo, Norway, [8]Division of Oncology and Pathology, Skane University Hospital-Lund, Lund, Sweden

Background: Describing initial treatment (tx) post-NSCLC diagnosis is important in order to understand clinicians' intent in routine care, based on pt/disease characteristics and disease stage at diagnosis. The SCAN-LEAF project aims to describe the epidemiology, clinical care and outcomes of NSCLC pts in Scandinavia. Here, we report initial tx and outcomes among pts with incident NSCLC in Denmark from 2005-2015.

Table: 1483P

	Stage I (N = 4138)	Stage II (N = 2322)	Stage IIIA (N = 3594)	Stage IIIB (N = 3735)	Stage IV (N = 16,486)
Initial treatment, %					
Surgery	68.6	64.9	30.9	5.9	2.8
Surgery with neoadjuvant or adjuvant SACT	7.8	29.4	18.0	3.5	1.5
Radiotherapy only	20.2	14.2	16.7	18.7	19.2
SACT and radiotherapy	1.8	7.1	24.4	25.1	19.6
SACT only	2.5	5.9	18.6	35.7	34.3
Untreated (ie, none of the above)	6.9	8.0	9.5	14.5	24.1
SACT regimen in initial treatment, %	12.1	42.4	61.0	64.3	55.4
No SACT in initial treatment, %	87.9	57.6	39.0	35.7	44.6

Methods: The Danish cohort, established by linkage of Danish national registries, includes all adult pts with incident NSCLC from 2005-2015 (follow-up until Dec 2016). Initial tx includes lung surgery, radiotherapy (RT) and systemic anticancer therapy (SACT) captured through procedure codes (no drug names); it is defined as the first tx received at any time after diagnosis associated with any other tx received within 12 wks of this first tx start. Further analyses will assess the changes in initial tx patterns and overall survival over time, using the Kaplan–Meier method.

Results: Of the 31,939 pts with incident NSCLC, mean age was 68.4 yrs (13.3% ≥80 yrs) and 48.0% were women. TNM stage distribution (stage I, II, IIIA, IIIB, IV, missing) was 12.9%, 7.3%, 11.2%, 11.7%, 51.6% and 5.2%, respectively. 54.4% had non-squamous cell carcinoma and 26.5% squamous cell carcinoma. Initial tx is shown in the table. The proportion of pts receiving SACT (alone or with surgery/RT) was 12.1%, 42.4%, 61.0%, 64.3% and 55.4% in stages I–IV, respectively. The proportion of untreated pts increased from 6.9% in stage I to 24.1% in stage IV.

Conclusions: From 2005-2015, half of NSCLC pts were diagnosed at stage IV. Most pts at stage I and II were treated with surgery, adjuvant/neoadjuvant SACT being relatively uncommon. At stage III, most pts received SACT either as adjuvant/neoadjuvant tx (1/5 of stage IIIA), associated with RT (1/4 of stage IIIA/B) or alone (1/5 of stage IIIA; 1/3 of stage IIIB). Only half of metastatic pts received SACT, highlighting a significant unmet treatment need in NSCLC.

1484P Treatment patterns in patients (pts) with stage IIIB-IV non-small cell lung cancer (NSCLC) in Sweden: The SCAN-LEAF study

S. Ekman[1], M. Planck[2], J.B. Sørensen[3], P. Horvat[4], D. Layton[5], J. Kim[5], M. Rosenlund[5], A. Juarez-Garcia[6], M. Daumont[7], H.C. Jacobs[6], L. Lacoin[7], O.T. Brustugun[8]

[1]Department of Oncology, Karolinska University Hospital-Solna, Stockholm, Sweden, [2]Division of Oncology and Pathology, Skane University Hospital-Lund, Lund, Sweden, [3]Department of Oncology, Rigshospitalet, Copenhagen, Denmark, [4]Real World Evidence Solutions, IQVIA, London, UK, [5]Data Science, IQVIA, London, UK, [6]Worldwide Health Economics & Outcomes Research, Bristol-Myers Squibb, Uxbridge, UK, [7]Worldwide Health Economics & Outcomes Research, Bristol-Myers Squibb, Braine-L'Alleud, Belgium, [8]Department of Oncology, Radiumhospitalet, Oslo, Norway

Background: A better understanding of real-world treatment (tx) patterns and associated clinical outcomes in the rapidly changing landscape of NSCLC is critical for informing clinical decision-making and maximising pt benefits. The SCAN-LEAF project aims to describe epidemiology, clinical care and outcomes of NSCLC pts in Scandinavia. Here, we report tx patterns and outcomes in pts with incident stage IIIB-IV NSCLC in 2 university hospitals in Sweden.

Methods: This retrospective cohort study includes all adult pts diagnosed with stage IIIB-IV NSCLC from 2012–2015, and followed in Uppsala and Stockholm University hospitals (follow-up until end of 2016). Electronic medical records were extracted and linked with national registries. Lines of therapy (LoTs) were defined using an algorithm based on systemic anticancer therapy (SACT). Descriptive results are shown by histology. Ongoing analyses will assess LoTs by mutation status, time to next LoT and overall survival using the Kaplan–Meier method.

Results: 1625 pts diagnosed at stage IIIB-IV were identified (58.5% of all incident NSCLC). Mean age was 69.1 yrs (13.6% ≥80 yrs) and 49.5% were male. Histology distribution was: 70.9% non-squamous cell carcinoma (NSQ), 17.7% squamous-cell carcinoma (SQ), 10.3% not otherwise specified (NOS) and 3.4% other NSCLC. Of 831 EGFR-tested pts (51.1%), 21.2% had mutant EGFR; of 612 ALK-tested pts (37.7%), 10.0% had ALK translocations; of 33 PD-L1-tested pts (2.0%), 45.5% had PD-L1 expression ≥1%. Overall, 888 pts (54.7%) received a 1st LoT, of whom, 276 received a 2nd LoT (31.1%). SACT regimens are shown in the table.

Table: 1484P

SACT regimens in stage IIIB-IV NSCLC (used in ≥ 5 patients)	All NSCLC	NSQ	SQ	NOS
1st line of therapy, %	(N = 888)	(N = 638)	(N = 119)	(N = 99)
Platinum-based chemotherapy	80.3	77.4	88.2	87.9
Non-platinum single agent	5.2	4.4	6.7	6.1
Tyrosine kinase inhibitor (mainly erlotinib)	14.4	18.0	5.0	6.1
2nd line of therapy, %	(N = 276)	(N = 201)	(N = 40)	(N = 24)
Platinum-based chemotherapy	23.6	19.9	30.0	25.0
Non-platinum single agent	56.5	55.7	62.5	66.7
> Docetaxel	39.5	37.3	47.5	54.2
> Pemetrexed	8.7	10.9	2.5	4.2
> Vinorelbine	8.0	7.5	12.5	8.3
Tyrosine kinase inhibitor	19.6	24.4	5.0	8.3
> Erlotinib	8.4	10.0	5.0	0.0
> Crizotinib	6.9	9.5	0.0	0.0
> Afatinib	2.9	3.5	0.0	4.2

Conclusions: During the 2012-2016 period (mainly prior to immunotherapy reimbursement), approximately half of incident stage IIIB-IV pts received a 1st LoT and only one-third of those received a 2nd LoT, mostly with non-platinum chemotherapy or tyrosine kinase inhibitors. Almost half of stage IIIB-IV NSCLC pts remained untreated after diagnosis (no SACT regimen).

1485P NSCLC with well controlled extra-cranial disease but uncontrolled brain metastases

H.A. Jung[1], K. Park[2], J-M. Sun[3], S.H. Lee[4], J.S. Ahn[5], M-J. Ahn[6], S. Park[7]

[1]Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [2]Div. of Heamatology/Oncology, Medicine, Samsung Medical Center Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [3]Hematology/Oncology, Samsung Medical Center, Seoul, Republic of Korea, [4]Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Seoul, Republic of Korea, [5]Hematology & Oncology, Samsung Medical Center, Seoul, Republic of Korea, [6]Hematology and Oncology, Samsung Medical Center, Seoul, Republic of Korea, [7]Hematology-oncology, Samsung Medical Center Sungkyunkwan University School of Medicine, Seoul, Republic of Korea

Background: Brain metastases are currently both common in clinical oncology and a critical problem, since they negatively affect patients' quality of life as well as survival. In the era of targeted therapy, survival for metastatic, recurrent lung cancer has improved. However, improved systemic treatment modalities have led to prolonged disease courses and subsequently to an increased incidence of brain metastases.

Methods: We recruited patients who were diagnosed with non-small cell lung cancer at a Samsung Medical Center from 2008 to 2017. We collected clinical characteristics and treatment pattern by medical chart review and analyzed their mutation status by NGS (ampliseq and cancer scan).

Results: Among 12918 patients who were diagnosed with non-small cell lung cancer and received chemotherapy, 1566 patients received gamma knife surgery and 1209 patients received whole brain radiotherapy. 3922 were EGFR mutant non-small cell lung cancers and received EGFR tyrosine kinase inhibitors (erlotinib: 1424; gefitinib: 2210; afatinib: 606; dacomitinib: 24). Among EGFR-mutant patients, 663 (16.9%) patients received whole brain radiation therap (WBRT) and 765 (19.5%) received gamma-knife surgery. 320 patients who were diagnosed with ALK-positive non-small cell lung cancer received ALK inhibitors (crizotinib: 308; alectinib 54). Among them 51 (15.9%) received WBRT and 81 (25.3%) patients received gamma-knife surgery. 268 patients received gamma-knife surgery three times or more. 51 patients received gamma-knife surgery five times or more (maximum 14 of gamma-knife surgery). Among them, 27 (52.9%) patients were EGFR mutant and 11 (21.6%) patients were ALK-rearrangement non-small cell lung cancer.

Conclusions: In patients with EGFR-mutant or ALK-rearrangement non-small cell lung cancer, local treatment for brain metastasis was performed frequently. A minority of patients have well controlled extracranial disease but poorly controlled intracranial disease, and in these cases strategies to maintain systemic chemotherapy and persistent topical treatments for brain lesions are also helpful. Further research is needed to find out the unique tumor biology of patients with uncontrolled brain metastases.

1486P Risk assessment in brain-only oligometastatic non-small cell lung cancer (BOO-NSCLC) patients (pts): Recursive partioning analysis (RPA) model modification

C. Salvador Coloma[1], D. Lorente[2], C. Escoin[3], J.A. Mendez[1], O. Juan-Vidal[4]

[1]Medical Oncology, Hospital Universitari i Politècnic La Fe, Valencia, Spain, [2]Medical Oncologist, HULa Fe, Valencia, Spain, [3]Medical Oncology, Hospital La Ribera, Valencia, Spain, [4]Medical Oncology, Hospital Universitari i Politécnic La Fe, Valencia, Spain

Background: Brain metastases (BM) have traditionally been associated with adverse outcome. BOO-NSCLC, however, may represent a distinct population subtype in whom a radical therapeutic approach may be feasible. We aimed to assess the impact of the RPA group classification in this population subtype.

Methods: Retrospective analysis of pts with BOO-NSCLC (1-5 BMs as only metastatic site) treated between 2010-2018 at a single institution. RPA classification and other clinical variables was derived from electronic patient records. Survival analyses were performed with Kaplan Meier and uni- (UV) and multivariable (MV) Cox-regression models. Performance of the survival models was assessed by ROC AUCs and weighted c-indices.

Results: 67 pts were identified. Median age: 59 years. The majority were men (71.6%) with adenocarcinoma histology (73.1%). Median-overall survival (mOS) was 20.2 months (95CI%:11.5-28.9). RPA group score was significantly associated with OS: not reached (NR) vs 16.2m vs 4.5m for RPA group I, II and III pts respectively (HR: 5.7; 95%CI: 3-10.8; $p < 0.001$). The model based on RPA only had a ROC AUC of 79.6% and a c-index of 0.743. T-stage (T1-2 vs T3-4), N-stage (N0-N1 vs N2-N3) and histology were associated with OS in UV cox-regression models, and were included in the MV model (Table). The addition of these variables to the RPA model increased the ROC AUC to 92.3% ($p = 0.008$) and c-index to 0.854.

Table: 1486P UV and MV Cox-Regression survival analysis

	UNIVARIABLE		MULTIVARIABLE	
	HR (95%CI)	p-value	HR (95%CI)	p-value
RPA Group	5.7 (3-10.8)	<0.001	10 (4.5-22.6)	<0.001
T-Stage	2.8 (1.4-5.7)	0.004	6.2 (2.7-14.7)	<0.001
N-Stage	2.2 (1.1-4.4)	0.031	1.8 (0.8-3.8)	0.134
Histology	1.2 (1.1-1.4)	0.003	1.4 (1.1-1.6)	<0.001

Conclusions: RPA group classification may adequately stratify BOO-NSCLC pts into favorable, intermediate and adverse prognostic groups. The addition of histology, T-stage and N-stage of the primary tumor may improve the prognostic accuracy of the model. These findings require prospective validation.

1487P LURET: Final survival results of the phase II trial of vandetanib in patients with advanced RET-rearranged non-small cell lung cancer

K. Yoh[1], T. Seto[2], M. Satouchi[3], M. Nishio[4], N. Yamamoto[5], H. Murakami[6], N. Nogami[7], S. Kuroda[8], S. Nomura[8], A. Sato[8], K. Tsuchihara[9], T. Kohno[10], S. Matsumoto[1], K. Goto[1]

[1]Department of Thoracic Oncology, National Cancer Center Hospital East, Kashiwa, Japan, [2]Department of Thoracic Oncology, National Kyushu Cancer Center, Fukuoka, Japan, [3]Department of Thoracic Oncology, Hyogo Cancer Center, Hyogo, Japan, [4]Thoracic Oncology Center, The Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, Japan, [5]Department of Thoracic Oncology, National Cancer Center Hospital, Tokyo, Japan, [6]Division of Thoracic Oncology, Shizuoka Cancer Center, Shizuoka, Japan, [7]Department of Thoracic Oncology, Shikoku Cancer Center, Matsuyama, Japan, [8]Office of Clinical Research Support, Hospital East, National Cancer Center, Kashiwa, Japan, [9]Division of Translational Informatics, Exploratory Oncology Research and Clinical Trial Center, National Cancer Center, Kashiwa, Japan, [10]Division of Genome Biology, National Cancer Center Research Institute, Tokyo, Japan

Background: The LURET phase II trial evaluated the efficacy and safety of vandetanib in patients with advanced RET-rearranged non-small cell lung cancer (NSCLC). Among eligible patients included in primary analysis, objective response rate (ORR) met the primary endpoint (53% [90% CI 31-74]). Here, we report a final analysis of survival outcomes in LURET.

Methods: In all, 19 patients with advanced RET-rearranged NSCLC continuously received 300 mg of oral vandetanib daily. The variant types of RET fusion included 10 KIF5B-RET, 6 CCDC6-RET, and 3 unknown. The data cutoff date was Aug 31, 2017, for a final analysis. In this final analysis, the data on progression-free survival (PFS), overall survival (OS) and safety were updated.

Results: At the final data cutoff, 1 patient was still receiving vandetanib without disease progression. Among all 19 patients in the intention-to-treat population, median PFS was 6.5 months (95% CI, 2.8-8.5) as determined by the independent radiology review committee. Median OS was 13.5 months (95% CI, 9.8-28.1) and the overall survival rate at 12 months was 52.6% (95% CI 28.7-71.9). In the subgroup analysis according to the type of RET fusion, median PFS and OS were 2.9 months (95% CI 1.1-15.7) and 10.5 months (95% CI 3.0-18.1) in patients with KIF5B-RET whereas 8.4 (95% CI 4.7-not reached [NR]) and NR (95% CI 9.9-NR) in those with CCDC6-RET. No new adverse events were observed compared with previous studies in unselected NSCLC.

Conclusions: Our results found that vandetanib to be effective in patients with advanced RET-rearranged NSCLC, and that RET rearrangement may be a favorable molecular subgroup of NSCLC suitable for targeted therapy.

Clinical trial identification: This study is registered with UMIN-CTR, number UMIN000010095.

Background: BRAF mutations are found in 2-3% of NSCLC. BRAF inhibitors reportedly have antitumor activity. The French National Cancer Institute (INCa) launched a program giving nationwide access to vemurafenib for cancer pts with BRAF-mutated tumors and supporting molecular screening. We report here the results of the NSCLC cohort.

Methods: BRAF mutational status was assessed on INCa molecular genetic centers by direct sequencing or NGS. Pts with BRAF V600E mutation, progressing after $\geq$1 standard treatment were proposed vemurafenib 960 mg BID. Objective Response Rate

(ORR) was assessed using RECIST v1.1 every 8 weeks. A sequential Bayesian approach was planned to allow early stopping using an inefficacy boundary for ORR of 10%. If no early stopping occurred, the treatment was considered worthy for further evaluation if there was a 90% probability that the estimated ORR is ≥ 30%, the efficacy boundary.

Results: From 10/2014 to 10/2017, 101 NSCLC pts harboring BRAF V600E were enrolled. Median age: 68 years (range 41–85), 68% smokers, 50% females, 100% non-squamous histology and 19% with ECOG PS 2. Most frequent grade ≥3 adverse events (AEs) were asthenia (10% of pts), epidermoid carcinoma (7%), dermatitis (6%) and increased GGT (6%). Three toxic deaths were reported: 1 nausea and vomiting leading to dehydration, 1 pneumonia and 1 neutropenic sepsis. Among the enrolled pts, 100 BRAF V600E NSCLC pts evaluable for the best overall response (BOR), 43 PR, 21 SD, 16 PD, 12 deaths before assessment and 8 not evaluable (no tumor assessment) were observed. The mean objective response rate was 44.9% (95% CI: 35.2; 54.8), the efficacy boundary was reached with a predictive probability greater than 90%. Median duration of response was 6.5 months (5.1-7.3). Median progression-free survival (PFS) was 5.2 months (3.8-6.9) and median OS was 9.3 months. Nine pts were still on treatment at the cut-off date, 91 have stopped vemurafenib (55 PD, 23 AEs, 3 deaths, 1 doctor's decision, 9 patient's decisions).

Conclusions: Vemurafenib provided reasonable response rate and prolonged PFS in BRAF V600E pretreated NSCLC. These results confirm the activity of BRAF inhibitors in these pts and underline the need of integrating BRAF V600E in biomarkers routine screening.

1489P Treatment patterns and overall survival in patients with BRAF-mutated metastatic non-small cell lung cancer

R.K. Goyal[1], A. Kron[2], J. Wolf[2], J. Mazieres[3], C. Chouaid[4], K.L. Davis[5], M. Perrinjaquet[6], S. Knoll[7]

[1]Health Economics, RTI Health Solutions, Research Triangle Park, NC, USA, [2]Center for Integrated Oncology Cologne Bonn, University Hospital Cologne, Kerpener, Germany, [3]Thoracic Oncology, Hospital Larrey, Toulouse, France, [4]Chest Department, Centre Hospitalier Intercommunal Créteil, Créteil, France, [5]Health Economics, RTI Health Solutions, Research Triangle Park, NC, USA, [6]Life Sciences, Navigant, London, UK, [7]Global Oncology Value and Access (GVA), Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA

Background: BRAF mutations are observed in 2% – 4% of all non-small cell lung cancer (NSCLC) patients, but few targeted therapies are available, with limited practice level data on utilization and outcomes. This study therefore aims to document, from a "real-world" perspective, treatment patterns, testing characteristics, and overall survival (OS) in patients with BRAF-positive (BRAF+) metastatic NSCLC (mNSCLC).

Methods: This was a multinational, retrospective medical record review of patients with BRAF+ mNSCLC (diagnosed 2005-2016) in EU, Canada and S Korea. Patients were ≥18 years of age at mNSCLC diagnosis ("index") and had ≥12 months of post-index follow-up time, except for patients who died sooner. Study measures included baseline patient characteristics, timing of mutational testing, systemic therapies for mNSCLC, and OS. Kaplan-Meier analyses were conducted to descriptively analyze OS dependent on treatment with a BRAF inhibitor (BRAFi).

Results: Of all patients (n = 76; median age = 64 years), 24% had been tested for BRAF mutation at index; 61% had been tested before initiating the first line of therapy (LOT-1), 79% before LOT-2 and 85% before LOT-3. Chemotherapy was the most common first (76%), second (46%), and third (38%) LOT. BRAFi (+/- a MEK inhibitor) was received by 53% of all patients initiating a systemic therapy (n = 66) in any LOT. Median OS from index was 19.4 months (95% CI = 13.3-22.8) in all patients, 23.4 months (95% CI = 18.5-98.4) in patients treated with BRAFi, and 11.8 months (95% CI = 4.5-20.0) in patients not treated with BRAFi, in any LOT. Three-year OS rates from LOT initiation are summarized in the table.

Conclusions: The majority of confirmed BRAF+ mNSCLC patients were tested for BRAF mutation before initiation of LOT-1. Chemotherapy was the predominant front-line therapy and BRAFi was utilized mainly in second and later LOTs. Median OS was numerically higher in patients treated with BRAFi versus patients not treated with BRAFi in any LOT.

Background: About 5% of NSCLCs have overexpression and amplification of HER2 or its mutations, mostly exon 20 insertions. There are still few data available on roles of HER2 alterations in NSCLCs.

Methods: To determine the frequency and characteristics of HER2 alterations in NSCLCs and to identify patients (pts) eligible for clinical trial of trastuzumab (HOT1303-B), we conducted a prospective observational study of HER2 alterations in pts with advanced NSCLCs without EGFR or ALK mutations. We determined HER2 overexpression by IHC, amplification by dual color in situ hybridization (DISH), and mutation of exons 8, 19, 20 and 21 by direct sequence and that of all the exons by NGS. We also analyzed 48 cancer-related genes by NGS using targeted sequencing kits.

Table: 1489P OS rate from start of LOTs

	LOT-1		LOT-2		LOT-3	
	BRAFi (n = 34)	No BRAFi (n = 28)	BRAFi (n = 28)	No BRAFi (n = 16)	BRAFi (n = 18)	No BRAFi (n = 13)
3-year OS rate (standard error)	33.9% (0.09)	17.1% (0.09)	37.5% (0.10)	22.9% (0.12)	49.5% (0.13)	9.0% (0.09)

Results: Until completion of enrollment of HOT1303-B, 129 eligible pts with advanced NSCLCs including 108 adenocarcinoma pts were enrolled to this study. IHC3+ was observed in 6 pts (4.6%), all of whom showed DISH+. IHC2+/DISH+ were also observed in 6 pts (4.6%). Hotspot mutations (5 exon 20 YVMA insertions and 2 S310F mutations) were detected in 7 pts (5.4%), and non-hotspot mutations including a previously unknown L755_N758delinsPST mutation were detected in 12 pts (9.3%). Amplifications and hotspot mutations were mutually exclusive except a case with IHC2+/DISH+ and S310F. When we defined amplifications and hotspot mutations narrowly as HER2 alterations (18 pts, 14%), they correlated with smoking inversely ($p = 0.03$), but not with age, sex, chemotherapy response or overall survival from 1st line therapy. The 48 gene NGS analysis was conducted in 91 pts. Number of mutated genes per pt (median, 2; range, 0-23) did not correlate with HER2 alterations. The most frequently mutated gene was TP53, mutations of which tended to correlate with HER2 alterations (11/14, 79% vs. 41/77, 53%; $p = 0.08$). Although there were no genes mutations of which were significantly associated with HER2 alterations, HER2 altered tumors had no oncogenic driver mutations including K-RAS and B-RAF.

Conclusions: HER2 alterations were relatively frequently observed. Hotspot mutations and amplifications were almost mutually exclusive and tended to be associated with TP53 mutations. Precise roles of distinct HER2 alterations should be determined in larger cohorts.

1491P A phase II study of trastuzumab monotherapy in pretreated patients with non-small cell lung cancers (NSCLCs) harboring HER2 alterations: HOT1303-B trial

I. Kinoshita[1], T. Goda[1], K. Watanabe[2], M. Maemondo[3], S. Oizumi[4], T. Amano[5], Y. Hatanaka[6], Y. Matsuno[7], H. Nishihara[8], H. Asahina[9], T. Harada[10], K. Goto[11], H. Isobe[12], M. Nishimura[13], H. Dosaka-Akita[1]

[1]Department of Medical Oncology, Faculty of Medicine and Graduate School of Medicine, Hokkaido University, Sapporo, Japan, [2]Department of Respiratory Medicine, Miyagi Cancer Center, Natori, Japan, [3]Division of Respiratory Medicine, Allergy, and Rheumatology., Iwate Medical University School of Medicine, Morioka, Japan, [4]Department of Respiratory Medicine, National Hospital Organization Hokkaido Cancer Center, Sapporo, Japan, [5]Clinical Research and Medical Innovation Center, Hokkaido University Hospital, Sapporo, Japan, [6]Research Division of Genome Companion Diagnostics, Hokkaido University Hospital, Sapporo, Japan, [7]Department of Surgical Pathology, Hokkaido University Hospital, Sapporo, Japan, [8]Genomics Unit, Keio Cancer Center, Keio University School of Medicine, Sapporo, Japan, [9]First Department of Medicine, Hokkaido University Hospital, Sapporo, Japan, [10]Department of Respiratory Medicine, JCHO Hokkaido Hospital, Sapporo, Japan, [11]Department of Thoracic Oncology, National Cancer Center Hospital East, Kashiwa, Japan, [12]Department of Medical Oncology, KKR Sapporo Medical Center, Sapporo, Japan, [13]Department of Respiratory Medicine, Faculty of Medicine and Graduate School of Medicine, Hokkaido University, Sapporo, Japan

Background: About 5% of NSCLCs have high level of overexpression and/or amplification of HER2 or its mutations, mostly exon 20 insertions. Retrospective studies suggest some activity of a Her2-targeted antibody, trastuzumab, for HER2-altered NSCLCs. However, no clinical trial data of trastuzumab monotherapy for HER2-altered NSCLCs are available so far.

Methods: HOT1303-B was a multicenter, single-arm phase II study of trastuzumab for NSCLC patients who were pretreated with two or more regimens and had HER2-altered tumors (IHC 3+ or IHC 2+/dual color in situ hybridization [DISH] +, and/or presence of mutations) identified by a HER2 screening study HOT1303-A and a nationwide genomic screening study LC-SCRUM-Japan. Eligible patients (pts) were treated with trastuzumab 6 mg/kg every 3 weeks (loading dose 8 mg/kg). The primary endpoint was the overall response rate (ORR) using RECIST v1.1. This study required ten pts, with ORR of 10% considered non-promising and 40% promising (one-sided alpha = 0.10; beta = 0.2).

Results: Ten pts were recruited in this trial. The median age was 59 (range 44-74), three pts were female, three pts were never smokers, nine pts had performance status 0-1, and all had adenocarcinomas. The median lines of prior systemic therapy were 3 (range 2-6). There were two pts with IHC 3+, one pt with IHC 2+/DISH +, five pts with exon 20 insertions (four A755_G776insYVMA and one G776>VC) and two pts with S310F mutations without overlapping cases. ORR was 0% (95% CI, 0-26%). Disease control ratio (DCR) was 70% (95% CI, 39-91%). Median progression-free survival was 5.2 months (95% CI, 1.4-6.3). Grade ≥ 3 adverse events occurred only in a patient with grade 3 pneumonitis, which was judged as organizing pneumonia related with tumor progression. OS data will be presented at the meeting.

Conclusions: Trastuzumab monotherapy did not produce response for HER2-altered NSCLCs in this cohort, although DCR and PFS seemed favorable for the heavily treated pts. Additional approaches including combination therapy are required for HER2-targeted therapy using trastuzumab.

1492P BPI-9016M, a novel c-Met inhibitor, in pretreated advanced solid tumor: Results from a first-in-human, phase I, dose-escalation study

X. Hu[1], X. Zheng[2], H. Mo[1], X. Cui[2], L. Ding[3], F. Tan[4], P. Hu[2], Y. Shi[1]

[1]Department of Medical Oncology, Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College; Beijing Key Laboratory of Clinical Study on Anticancer Molecular Targeted Drugs, Beijing, China, [2]Clinical Pharmacology Research Center, Peking Union Medical College Hospital, Beijing, China, [3]Headquarter, Bettapharma Pharmaceuticals Co.Ltd, Hangzhou, China, [4]R&D center, Bettapharma Pharmaceuticals Co.Ltd, Beijing, China

Background: BPI-9016M (Betta Pharmaceuticals Co, Ltd, Hangzhou, China) is a potent targeted therapy that inhibits MET and Axl. This first-in-human study is to assess the safety, tolerability, and pharmacokinetics (PK) of BPI-9016M in patients with advanced solid tumor, and to determine the maximum tolerated dose (MTD) and recommended phase 2 dose (RP2D) for the phase Ib/II study.

Methods: Method: Eligible patients were enrolled into sequential dose-escalating cohorts from 100 mg to 1000 mg given orally once per day continually following the conventional 3 + 3 design. The primary endpoint was safety and tolerability. MTD was defined as the highest dose level resulting in < 1 of 3 dose limiting toxicities (DLTs). Blood levels of BPI-9016M were evaluated after single and multiple administration (NCT02478866).

Results: Twenty patients were enrolled and treated in 6 of 7 predefined dose cohorts (100 mg n = 4, 200 mg n = 3, 300 mg n = 3, 450 mg n = 4, 600 mg n = 3, 800 mg n = 3), dose escalation stopped at 800 mg due to saturation. All had stage IV non-small cell lung cancer (NSCLC) progressed on previous systemic therapy (including previous EGFR TKI in 16 patients). BPI-9016M was well-tolerated in all dose cohorts without DLT. The incidence of overall and grade 3/4 TRAEs was 85% and 45%, respectively. Common TRAEs included elevated ALT (45%), constipation (30%), elevated bilirubin (25%), and oral paresthesia (25%). Tumor response was seen in 1 patients in the 800 mg dose cohort. Systemic exposure to BPI-9016M (maximum plasma concentration and AUC) increased with increasing dose. Mean time to maximum plasma concentration and half-life were 2 to 5.33 hours and 8.09 to 22.3 hours, respectively. Two metabolites (M1, M2-2) were detected.

Conclusions: BPI-9016M was well tolerated in patients with advanced solid tumor. A phase Ib study is ongoing to investigate the safety and activity of BPI-9016M in patients with c-Met-dysregulated advanced NSCLC (NCT02929290).

Clinical trial identification: NCT02478866.

1493P Clinical characteristics and outcomes of non-small cell lung cancer (NSCLC) patients harboring MET exon 14 splice sites mutations

P. JAMME[1], F. Escande[2], C. Descarpentries[2], M.C. Copin[2], E. Dansin[3], T. Vanparis[4], D. Tulasne[5], S. Baldacci[6], Z. Kherrouche[1], A. Cortot[6]

[1]Institut Pasteur de Lille, Lille, France, [2]Haut de France, Centre Biologie et Pathologie, CHRU Lille, Lille, France, [3] Centre Oscar Lambret, Lille, France, [4]Centre Hospitalier de Boulogne-sur-Mer, Boulogne-sur-Mer, France, [5]Institut Pasteur de Lille, Lille, France, [6]Hopital Calmette, CHRU Lille, Lille, France

Background: MET exon 14 splice sites mutations define a unique subset of NSCLC patients who may benefit from MET inhibitors. Patterns of disease spread and response to chemotherapy in these patients are still poorly known.

Methods: Clinicopathologic characteristics and outcome of patients harboring MET exon 14 splice sites mutations identified in a single molecular center were retrospectively collected.

Results: We identified 39 patients from 12 french institutions between July 2009 and February 2018. Median age was 75 (range 55-91), sex ratio was 1.16 (M/W), 15 patients (38%) were never smokers. histologic type was adenocarcinoma in 31 tumors (79%) pulmonary sarcomatoid carcinoma in 3 tumors (8%) and NOS NSCLC in 5 tumors (13%). MET exon 14 alterations were deletions in 21 patients (54%), point mutations in 14 patients (36%) and delins in 4 patients (10%). Ten patients had a concurrent TP53 mutation, 3 patients had a RAS mutation, and 1 patient had a PIK3CA mutation. Among the 14 patients tested for PDL1 expression, 9 (64%) were PDL1 high ($\geq$50%). The disease was diagnosed at stage IIIB/IV in 24 patients (62%) . Among those, the most frequent metastatic sites at diagnosis were bones (61%), lung (43%), pleura (39%) and brain (13%). 17 patients received at least one line of chemotherapy. Objective response rate for 1st line chemotherapy was 44%. Anti-PD1 agent was initiated in 6 patients, 1 patient (16%) achieved an objective response. MET TKI was initiated in 7 patients. Median overall survival for stage IIIB/IV patients was 8.5 months.

Conclusions: NSCLC patients harboring a MET exon 14 splice sites mutation are characterized by older age, never smoking status in half of the cases, and metastatic spread to bones. Future efforts should focus on identifying predictive markers of response to MET TKIs.

1494P Risk of lung cancer following pulmonary tuberculosis: A nationwide population-based cohort study, South Korea

S-S. Han[1], J. Heo[2], S-J. Lee[1]

[1]Internal Medicine, Kangwon National University, Chuncheon, Republic of Korea, [2]Internal Medicine, Kangwon National University Hospital, Chuncheon, Republic of Korea

Background: Some epidemiologic studies on lung cancer have reported findings that suggest the possibility of association between lung disease and lung cancer. The association of pulmonary tuberculosis (TB) and lung cancer has attracted attention for several years and has remained controversial. Therefore, we investigated that the relationship between pulmonary TB and lung cancer by considering the time of TB diagnosis in this study.

Methods: This study was used the National Health Insurance Service – National Sample Cohort in South Korea. Patients with pulmonary TB diagnostic codes and treated with anti-tuberculosis in adults over 20 years of age were defined as pulmonary TB patients. It was monitored the incidence of lung cancer after diagnosis of active pulmonary TB. We compared 3,776 patients with pulmonary TB and 18,880 controls matched for sex and age from 2003 to 2013. Multivariate Cox proportional hazard model was used to calculate the adjusted hazard ratio of lung cancer after adjusting for sex, age, house income, smoking status. The incidences of lung cancer were compared according to duration time after TB infection by calculating the incidence rates ratio (IRR).

Results: During the study period, 194 patients were diagnosed with lung cancer. A total of 86 lung cancer patients were diagnosed in 3,776 pulmonary TB patients and 108 patients were diagnosed in 18,880 control group. The IRR in TB group was the higher at 12.26 within 1 year and 3.33 at 1 year to less than 4 years after TB infection compared with the control group. There was a higher risk of lung cancer in pulmonary TB patients compared to control group (HR, 4.18; 95% CI, 3.15-5.56). The risk of lung cancer after pulmonary TB was HR 9.85 (95% CI, 4.57-21.23), 7.14 (95% CI, 3.63-14.05), 3.32 (95% CI, 2.12-5.19) and 2.57(95% CI, 1.40-4.72) respectively under 50s, 50s, 60s and 70s above. As the age increased, HR of lung cancer decreased after diagnosis of pulmonary TB, gradually.

Conclusions: Pulmonary tuberculosis is a risk factor for lung cancer. In patients with pulmonary TB, it may be considered the co-existence of lung cancer and be necessary to carefully observe the occurrence of lung cancer for a certain period of time after diagnosis of pulmonary TB, especially in younger patients.

1495P Analysis of the relationship between heading N / L and survival in patients treated with immunotherapy in lung cancer

N. De Dios Alvare, M. Costa Rivas, S. Agraso Busto, A. Alonso Herrero, M.J. Villanueva Silva, D. Pereiro Corbacho, C. García Benito

Oncology, Hospital Universitario Alvaro Cunqueiro, Vigo, Spain

Background: The neutrophil-lymphocyte (N / L) ratio is a marker of general immune response in different stress situations, having shown a relationship between the quotient and the evolution of patients treated with immunotherapy (IT), emphasizing the importance of inflammation in these patients.

Methods: In order to evaluate this relationship in a context of usual clinical practice, a retrospective review of patients with pulmonary neoplasia who received IT treatment in the first line or successive, between November 2015 and December 2017. Data were collected from the clinical history, with attention to baseline neutrophil and lymphocyte numbers, objective response by criteria iRECIST 1.1 and overall survival (OS) defined from the beginning of treatment until death.

Results: Sixty-six patients (22 women and 44 men) with a mean age of 64 years (44-78) were analyzed. 9.1%, 9 patients (p) received immunotherapy as first line treatment, 69.7% (46p) received it as 2nd line and 21.2% (14p) as 3rd line treatment. Regarding the type of IT, 49p (74.2%) received treatment with Nivolumab and 17p (25.8%) were treated with Pembrolizumab. Two stretches of baseline N / L ratios $<=5$ (low) and>5 (high) were defined. Low ratio N / L ($<=5$) was identified in 47p (71.2%) of the patients treated with IT and high ratio N/L (>5) in 19p (20.8%). Of the 47 patients with a low ratio: 22p (46.8%) had some type of response or stabilization of their disease, 15p (31.9%) had progression and 10p (21.3%) received less than months of treatment, 5p for PS reorientation and the other 5p continue with the treatment and are pending reevaluation. Among the 19p patients with high N / L quotient: 4p (21.1%) presented response or stabilization of the disease, 15p (78.9%) presented progression or treatment was interrupted due to deterioration of the ECOG. The average survival in the group with a low N / L ratio ($<=5$) was 87.85 weeks compared to the group with a high N / L ratio (>5) 25.74 weeks ($p<0.05$).

Conclusions: The N / L ratio has been identified in some studies as an adverse prognostic factor in patients treated with IT. Our data from the usual clinical practice support this theory. If these findings are confirmed in future studies, it could be used as a response biomarker for better patient selection.

Chiles Research Institute, Providence Cancer Institute, Portland, OR, USA, [10]Washington University Medical School, St. Louis, MO, USA, [11]Medical Oncology, Walter Reed National Military Medical Center, Bathesda, MD, USA, [12]Xcovery Holdings, Inc., Palm Beach Gardens, USA, [13]Clinical Operations, Xcovery Holding Company, LLC, Palm Beach Gardens, FL, USA, [14]CSO, Xcovery Holdings, Inc., Palm Beach Gardens, FL, USA, [15]Xcovery Holdings, Inc., Palm Beach Gardens, FL, USA, [16]Vanderbilt Ingram Cancer Center, Nashville, TN, USA

Background: Ensartinib is a potent ALK small molecule tyrosine kinase inhibitor (TKI). It has shown efficacy in intracranial tumor models. The activity of ensartinib is being evaluated in an ongoing phase 2 study of ALK positive NSCLC patients (pts). As progression due to growth of pre-existing brain metastases (BrM) or development of new BrM is a common mechanism of treatment resistance, we examined the clinical intracranial activity of ensartinib in pts with known BrM (target and/or non-target) at baseline or subsequent central nervous system (CNS) progression.

Methods: Pts who were either ALK TKI naïve (1st line), had received prior crizotinib and no other ALK TKI (2nd line), or had received prior crizotinib and a 2nd generation ALK TKI (3rd line) received ensartinib 225mg QD until disease progression (PD),

unacceptable toxicity or investigator discretion. Tumor assessments were performed locally every 8 weeks. Pts with asymptomatic BrM at baseline were allowed to enroll. To be considered a CNS target lesion, it had to be > 3 mm in diameter and, if previously treated, must have been at least 4 weeks post whole brain radiation therapy with demonstrated tumor growth and may not have been treated by stereotactic radiosurgery.

Results: As of the data cut-off (May 1, 2018), 77 ALK evaluable pts (ALK+ NSCLC pts at > 200mg QD with a post baseline response assessment) were assessed. Overall, 23 pts (30%) had BrM progression (new or existing lesions). For 41 pts who had no BrM at baseline and received ensartinib as 1st line (10 pts), 2nd line (18 pts) or 3rd line (13 pts), only 2 pts (5%) progressed due to the development of BrM. For 36 pts who had BrM at baseline (5 as 1st line, 19 as 2nd line, 12 as 3rd line), 21 pts (58 %) had BrM progression, some at the time of systemic progression. For patients with baseline CNS target lesions, the CNS objective response rate was 100% (n = 3) for 1st line pts, 54% (n = 13) for 2nd line pts, and 33% (n = 3) for 3rd line pts; with a CNS disease control rate of 100% for all pts. Complete CNS responses were observed in 3 pts with target CNS lesions and in 3 pts with only non-target lesions.

Conclusions: The data indicate that ensartinib has promising CNS activity.

Clinical trial identification: NCT01625234.

Lee Moffitt Cancer Center, Tampa, FL, USA, [6]Department of Internal Medicine, Chungbuk National University Hospital, Cheongju, Republic of Korea, [7]Department of Medicine, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, USA, [8]Earle A. Chiles Research Institute, Providence Cancer Institute, Portland, OR, USA, [9]Clinical Oncology, Janssen Research & Development, Raritan, NJ, USA, [10]Department of Medicine, Samsung Medical Center, Seoul, Republic of Korea

Background: JNJ-372 has demonstrated activity in EGFR and cMET-driven tumor models. In an ongoing phase 1 study of JNJ-372 in patients (pts) with advanced NSCLC, 1050 mg was identified as a recommended phase 2 dose in dose escalation (Part 1) and is being explored in the dose expansion of pts with EGFR-mutated (mut) NSCLC (Part 2).

Methods: Pts were treated with JNJ-372 IV weekly x 4W for cycle 1, then biweekly thereafter. Pharmacokinetic (PK) sampling was taken at multiple time points for all pts in Part 1 and for the first 6 pts in Part 2. Disease evaluations were performed every 8 weeks. Tumors were characterized at baseline through next-generation sequencing of ctDNA and/or tumor tissue.

Results: As of April 13th, 2018, 55 pts received JNJ-372 in Part 1 (n = 30) or Part 2 (n = 25), with 21 pts (38%) continuing therapy. Median age was 63y, 40% were male, 96% were Asian, and median prior systemic therapies was 2. The most frequent (≥15%) adverse events (AEs) were infusion-related reaction (56%), rash/acneiform dermatitis (53%), dyspnea (20%), paronychia (24%), nausea (22%), constipation (18%), stomatitis (18%), decreased appetite (18%), pruritus (16%), fatigue (16%), and peripheral edema (16%). AEs were mostly grade 1-2, with 3 ≥grade 3 treatment-related AEs (myalgia, neutropenia, and peripheral edema, all grade 3). PK was linear and dose proportional at doses ≥350 mg, with faster clearance PK at the 140-mg dose. Of the 30 response-evaluable pts with EGFRmut disease, treated at doses ≥700 mg, there are 8 partial responses (PRs; 4 confirmed PRs). This includes 6 pts with L858R or Exon19del primary mutations, and acquired resistance to first and/or third-generation EGFR tyrosine kinase inhibitors (TKIs), and 2 pts with primary Exon20ins disease. Activity was also observed in 2 pts with EGFRwt disease (squamous cell carcinoma and pleomorphic adenocarcinoma), each with -20% change in sum of largest diameter. The longest duration of treatment was 13.6 months.

Conclusions: JNJ-372 is a novel EGFR-cMET bispecific antibody with a manageable safety profile consistent with EGFR and cMET inhibition. Preliminary evidence suggests JNJ-372 can have activity in EGFR-driven NSCLC, including pts resistant to EGFR TKIs.

1498P Optimal interval from preceding radiotherapy (RT) to enhance efficacy of immune check point inhibitors (ICIs): Consecutive analysis of 294 patients with non-small cell lung cancer (NSCLC)

H. Horinouchi[1], Y. Matsumoto[1], S. Murakami[1], Y. Goto[1], S. Kanda[1], Y. Fujiwara[1], N. Yamamoto[1], Y. Nakayama[2], Y. Ohe[1]

[1]Department of Thoracic Oncology, National Cancer Center Hospital, Tokyo, Japan, [2]Department of Radiation Oncology, National Cancer Center Hospital, Tokyo, Japan

Background: Based on the preclinical findings, preceding RT enhances efficacy of ICIs. Phase III trial (PACIFIC) evaluating efficacy of durvalumab as consolidation after chemo-RT showed significant improvement in progression-free survival (PFS) in patients with stage III NSCLC (Antonia et al., NEJM 2017). Retrospective analysis showed previous RT resulted longer PFS by ICIs (Shaverdian et al., Lancet Oncol 2017). However, the optimal interval between preceding RT and ICIs has not been clarified.

Methods: Between Dec 2015 and Apr 2018, we analyzed consecutive NSCLC patients received ICIs. Patients' characteristics, driver oncogene alteration (EGFR, ALK and ROS1), RT before ICIs (no RT, definitive or palliative thoracic radiotherapy [TRT] and palliative RT for other sites [other RT]) and PFS were investigated. The interval between the initial day of ICIs and the start date of RT (in patients with RT) or first line chemotherapy (in patients without RT) was classified as follows; within 6 months [<6], 6 to 12 months [6-12] and 12 months or longer [>12].

Results: A total of 294 patients with NSCLC received ICIs; male / female: 186 / 108, median age: 66 (range, 32-85), squamous (Sq) / non-Sq: 60 / 234, driver oncogene alteration (positive / negative or unknown): 47 / 247, regimen (nivolumab / pembrolizumab): 235 / 59, RT (no RT / TRT / other RT): 131 / 83 / 80 and interval time categories (<6 / 6-12 / >12): 91 / 74 / 129. Significantly better PFS of ICIs was demonstrated in patients after TRT (HR 0.71, 95% CI: 0.52-0.97). According to the interval time from preceding RT, efficacy of ICIs was especially enhanced with 6-12 month interval from TRT, even after adjusting by PS, sex, age, histology, tobacco history, ICI regimen and driver oncogene status (adjusted HR 0.37, 95% CI: 0.18-0.76).

Table: 1498P PFS of ICIs according to interval from preceding TRT or other RT in comparison with patients without RT

	Total n = 294 HR [95%CI]	Within 6 mo n = 91 HR [95%CI]	6 to 12 mo n = 74 HR [95%CI]	12 mo or longer n = 129 HR [95%CI]
No RT	1	1	1	1
TRT	0.71 [0.52-0.97]	0.98 [0.49-1.98]	0.35 [0.17-0.71]	0.92 [0.59-1.43]
No RT	1	1	1	1
Other RT	1.02 [0.75-1.39]	0.96 [0.56-1.66]	1.22 [0.66-2.27]	0.89 [0.53-1.48]

Conclusions: Efficacy of ICIs was significantly better in patients after TRT especially between 6 to 12 months from preceding RT.

1499TiP Tumor treating fields concurrent with standard of care for stage 4 non-small cell lung cancer (NSCLC) following platinum failure: Phase III LUNAR study

U. Weinberg[1], O. Farber[2], M. Giladi[3], Z. Bomzon[4], E. Kirson[2]

[1]R&D, Novocure, Luzern, Switzerland, [2]R&D, Novocure, Haifa, Israel, [3]Preclinical Research, Novocure, Haifa, Israel, [4]Physics, Novocure, Haifa, Israel

Background: Tumor Treating Fields (TTFields) is a non-invasive, anti-mitotic treatment approved for glioblastoma based on significantly improved survival outcomes in a Phase 3 trial. Efficacy of TTFields in NSCLC has been shown preclinically and the safety confirmed in a phase I/II pilot study combined with pemetrexed. We hypothesize that adding TTFields to immune checkpoint inhibitors or docetaxel following platinum doublet failure will increase overall survival (OS) in stage 4 NSCLC.

Trial design: The LUNAR trial [NCT02973789] is enrolling patients (N = 534), with squamous or non-squamous NSCLC who are stratified per selected standard therapy (immune checkpoint inhibitors or docetaxel), histology (squamous vs. non-squamous) and geographical region. Key inclusion criteria include disease progression while on/after platinum-based therapy, ECOG 0-2, no electronic medical devices in the upper torso, and absence of brain metastasis. Docetaxel or immune checkpoint inhibitors are given at standard doses. TTFields are applied to the upper torso for >18 hours/day, allowing patients to maintain daily activities. TTFields are continued until progression in the thorax and/or liver. Follow-up is performed once q6 weeks using CT scans of the chest and abdomen. On progression in the thorax and/or liver, patients have 3 post-progression follow-up visits and are then followed monthly for survival. The primary endpoint is superiority in OS with TTFields in combination with the standard of care treatments versus (vs) standard of care treatments alone. Key secondary endpoints compare the OS in patients treated with TTFields and docetaxel vs docetaxel alone, and patients treated with TTFields and immune checkpoint inhibitors vs those treated with immune checkpoint inhibitors alone. An exploratory analysis will test non-inferiority of TTFields with docetaxel compared to checkpoint inhibitors alone. Secondary endpoints include progression-free survival, radiological response rate, quality of life based on the EORTC QLQ C30 questionnaire and severity and frequency of adverse events. The sample size is powered to detect a HR of 0.75 in TTFields-treated patients versus control group.

Clinical trial identification: NCT02973789.

1500TiP eXalt3: Phase III randomized study comparing ensartinib to crizotinib in anaplastic lymphoma kinase positive non-small cell lung cancer patients

L. Horn[1], Y-L. Wu[2], M. Reck[3], H. Wakelee[4], C. Liang[5], K. Harrow[6], V. Oertel[7], T. Mok[8]

[1]Vanderbilt Ingram Cancer Center, Nashville, TN, USA, [2]Guangdong Lung Cancer Institute, Guangdong General Hospital, Guangzhou, Guangdong, China, [3]Thoracic Oncology, Krankenhaus Grosshansdorf, Grosshansdorf, Germany, [4]Medicine/Oncology, Stanford Advanced Medicine Center, Stanford, CA, USA, [5]CSO, Xcovery Holdings, Inc., Palm Beach Gardens, FL, USA, [6]Clinical Operations, Xcovery Holding Company, LLC, Palm Beach Gardens, FL, USA, [7]Xcovery Holdings, Inc., Palm Beach Gardens, FL, USA, [8]Clinical Oncology, Chinese University of Hong Kong, Shatin, China

Background: Ensartinib (X-396) is a novel, potent ALK small molecule tyrosine kinase inhibitor (TKI). It is well-tolerated and has shown promising activity in NSCLC patients in a phase 1/2 study in patients that were both ALK TKI naïve and patients that received prior crizotinib, as well as those with CNS metastases. The safety profile of ensartinib appears to be different from other ALK TKIs.

Trial design: In this global, phase 3, open-label, randomized study, approximately 270 patients with ALK+ NSCLC who have received no prior ALK TKI and up to one prior chemotherapy regimen will be randomized with stratification by prior chemotherapy (0/1), performance status (0-1/2), brain metastases at screening (absence/presence), and geographic region (Asia /other), to receive oral ensartinib (225 mg, once daily) or crizotinib (250mg, twice daily) until disease progression or intolerable toxicity. Eligibility also includes patients ≥ 18 years of age, stage IIIB or IV ALK+ NSCLC. Patients are required to have measurable disease per RECIST 1.1, adequate organ function, and an ECOG PS of ≤ 2. Adequate tumor tissue (archival or fresh biopsy) must be available for central testing. The primary endpoint is progression-free survival assessed by independent radiology review based on RECIST v. 1.1 criteria. Secondary efficacy endpoints include overall survival, response rates (overall and central nervous system [CNS]), PFS by investigator assessment, time to response, duration of response, and time to CNS progression. The study has > 80% power to detect a superior effect of ensartinib over crizotinib in PFS at a 2-sided alpha level of 0.05. Phase 3 recruitment began in June, 2016 and currently has 98 active sites in 21 countries. The duration of recruitment will be approximately 28 months.

Clinical trial identification: NCT02767804.

Background: 3rd-generation EGFR-TKI, OSIME showed a remarkable efficacy for T790M+ NSCLC. Moreover, OSIME has proven superior progression-free survival (PFS) over 1st-generation EGFR-TKIs in front-line setting, and it will be widely used in front-line and later settings. Various resistant mechanisms were reported: C797S (cis/trans); EGFR uncommon mutations such as E709K and L844V; T790M- conversion; HER2-amp; MET-amp; PIK3CA/BRAF mutations; and histological transformation such as small cell and EMT. AFA is an irreversible EGFR-TKI with a potency as pan-HER inhibitor. Preclinical and clinical studies showed high sensitivity to EGFR uncommon mutations. Preclinical studies also showed a synergistic effect of AFA and BEV after acquired resistance (AR) to EGFR-TKIs. Our previously-conducted phase II study found a promising efficacy of AFA+BEV after AR: response rate (RR), 18.8%; disease control rate (DCR), 90.7%; and median PFS (mPFS), 6.3 months. Notably, preclinical data has suggested EGFR-TKI+BEV combination could overcome MET-associated resistance. Based on the above background, we hypothesize several resistant mechanisms (e.g., C797S (trans), uncommon EGFR mutations, and HER2) to OSIME are sensitive to AFA, and synergism of additional BEV maximizes AFA sensitivity.

Trial design: This ABCD-study is a phase II study conducted by HANSHIN Oncology Group. ECOG PS 0-1 patients with EGFR-mutant NSCLC are enrolled after failure of OSIME. Liquid/histological rebiopsies before enrollment after OSIME failure are essential to examine the resistant mechanisms. Liquid /histological samples are analyzed to confirm gene mutations/fusions and copy-number gain using next-generation sequencers. AFA is prescribed at 30-40 mg QD, and BEV is administered at 15 mg/kg tri-weekly until progression. The primary endpoint is PFS. Sample size of 26 is based on a null mPFS of 4.0 months, an alternative mPFS of 6.0 months, power of 80% and one-sided 15% of type I error. We plan an exploratory analysis regarding differential efficacies according to each resistant mechanism.

Clinical trial identification: UMIN000030545.

Background: Hypofractionated palliative radiotherapy for metastatic lung cancer patients is frequently used in order to ease pain, to increase bone stability, to treat local mass effects or to prolong progression-free survival at critical sites. Recently introduced, immunotherapy for patients with non-squamous non-small cell lung carcinoma (NSCLC) has significantly improved outcome in this cohort. Preclinical and early clinical data suggest that the combination of photon radiation with PD-1-targeting immunotherapies may promote a strong and durable immune response against tumor manifestations both within and beyond radiation targets.

Trial design: In this prospective, two-armed, non-randomized, open-label phase II trial, 130 patients with stage IV non-squamous non-small cell lung cancer in 2nd-line or 3rd-line treatment will be included. 65 patients with a clinical indication for palliative radiotherapy to non-cerebral non-pulmonary metastatic sites will receive nivolumab 240 mg followed by palliative radiotherapy with 5 x 4 Gy = 20 Gy photon radiation, which will be initiated within 72 hours after first nivolumab administration (Group A). 65 patients without an indication for radiotherapy will receive nivolumab (Group B). Nivolumab will be administered every two weeks in both groups and will be continued until progression or until limiting toxicities. The primary endpoint will be the objective response rate according to RECIST criteria 1.1. Secondary endpoints will be progression-free survival according to RECIST 1.1, overall survival, descriptive subgroup analyses according to PD-L1 expression, toxicity and quality of life. An extensive exploratory translational research program attached to this trial will focus on mechanisms of the immune-stimulating effect of radiotherapy and the identification of potential biomarkers predicting response to nivolumab. The FORCE trial will contribute prospective data to the observation that the combination of hypofractionated photon radiotherapy and medical immunotherapy is not only safe but will also promote antitumoral immune responses.

Background: Combining PD-1 and CTLA-4 inhibitors can augment antitumor immune responses. In the phase 1 CheckMate 012 study, first-line nivo (anti–PD-1 antibody) plus ipi (anti–CTLA-4 antibody) exhibited a higher objective response rate (ORR) and 2-year overall survival (OS) rate than nivo alone in pts with stage IIIB/IV NSCLC. Pts whose tumors expressed PD-L1 or had a high tumor mutational burden (TMB) showed better outcomes. High TMB was identified in the phase 2 CheckMate 568 (nivo + ipi) and phase 3 CheckMate 026 (nivo alone) studies and validated in phase 3 CheckMate 227 (nivo + ipi) as a potential predictive biomarker, independent of PD-L1 expression. High TMB may result in high expression of neoantigens, which could prime responses to checkpoint inhibitors. Beyond PD-L1 and TMB, there may be other important potential predictive biomarkers. CheckMate 592 (NCT03001882) is a two-part, exploratory, open-label phase 2 study exploring potential biomarkers, including PD-L1 and TMB, among others, and their association with clinical benefit with first-line nivo + ipi for stage IV or recurrent NSCLC.

Trial design: Pts aged ≥18 years with treatment-naïve stage IV or recurrent NSCLC and who had ECOG performance status 0–1 are being enrolled in the United States (parts 1 and 2) and Europe (part 2). Pts are ineligible if they have active autoimmune disease. In part 1, approximately 100 pts will be analyzed according to PD-L1 status (≥1% vs < 1%) before treatment. In part 2, approximately 150 pts will be treated regardless of PD-L1 status. The primary endpoint in part 1 is the association of ORR with baseline TMB, and candidate peripheral blood and tumor biomarkers at baseline and on treatment; secondary endpoints are ORR, disease control rate, response duration, time to response, progression-free survival (PFS), OS, and the association of

enteric biomarkers with efficacy. Primary endpoints in part 2 are the association of ORR with baseline tissue and blood TMB; secondary endpoints are ORR, PFS, OS, safety, and the association of enteric biomarkers with efficacy. The start date was March 2017. The estimated primary completion date is March 2019.

Clinical trial identification: NCT03001882.

Background: Nintedanib is an oral, triple angiokinase inhibitor approved by the EMA and other countries in combination with docetaxel for the treatment of adenocarcinoma NSCLC patients after first-line chemotherapy. Nintedanib plus docetaxel demonstrated significant and clinically meaningful OS benefits in adenocarcinoma patients, which were more pronounced in patients with aggressive or refractory tumors. During the past years the treatment landscape for advanced NSCLC has changed tremendously impacting individual treatment decisions and choice of adequate treatment sequences. Here we present the ongoing NIS VARGADO study design and set up to assess the efficacy and tolerability of nintedanib plus docetaxel in daily clinical routine in Germany.

Trial design: The NIS VARGADO (NCT02392455) is currently recruiting patients. Four hundred patients are planned to be enrolled at one hundred German centers. Adult NSCLC patients with advanced adenocarcinoma who are initiating treatment with nintedanib according to its label as part of routine clinical practice are eligible. The primary endpoint of the study is the one-year overall survival rate after start of therapy with nintedanib and docetaxel. Progression-free survival is one of the key secondary endpoints. Patients with aggressive or refractory tumors will be analyzed in detail with respect to efficacy in this real world setting. Documentation of patients treated with nintedanib plus docetaxel combination following first-line chemotherapy and/or immunotherapy will allow for analyses on treatment sequence. Analysis of tolerability will comprise the assessment of frequency and severity of adverse events. Furthermore, therapy management under routine conditions will be recorded and assessed.

Clinical trial identification: NCT02392455.

1505TiP A phase III, randomized, open-label, multicenter study of SHR-1210 (anti-PD-1 antibody) in combination with pemetrexed and carboplatin as first line therapy in subjects with advanced/metastatic non-squamous non-small cell lung cancer

F. Wu[1], G. Gao[1], C. Zhou1, X. Kang[2], Y. Zhou[2]

[1]Medical Oncology, Shanghai Pulmonary Hospital, Tongji University, Shanghai, China, [2]Department of Clinical R&D - Oncology, Shanghai Hengrui Phamaceutical Co.LTD, Shanghai, China

Background: SHR-1210 is a humanized anti–PD-1 antibody, with immunoglobulin gamma 4 (IgG4) as heavy chain and immunoglobulin kappa (IgK) as light chain expressed in the supernatant of a Chinese hamster ovary (CHO) stable cell line. Antitumor activity data for the ongoing clinical studies of SHR-1210 are currently being evaluated. SHR-1210 is currently being tested in 15 studies in advanced malignancies: 4 in advanced solid tumors, 3 in NSCLC, 2 in hepatocellular cancer (HCC; including 1 in HCC or gastric cancer [GC]), 2 in esophageal cancer (EC), 1 in melanoma, 1 in nasopharyngeal cancer (NPC), 1 in primary liver cancer (PLC), and 1 in classic Hodgkin lymphoma (cHL). Since 22 MAY 2017, 395 patients have been enrolled in this trial.

Trial design: In this trial, 412 patients will be randomly assigned in a 1:1 ratio, to receive either carboplatin-pemetrexed chemotherapy,OR receive SHR-1210 combined with carboplatin-pemetrexed chemotherapy. Randomization will be stratified according to gender and smoking history. All the patients will receive carboplatin(area under the curve 5) plus pemetrexed(500 mg/m^2), all administered as IV infusion on Day 1 of each 3-week cycle for 4 or 6 cycles of the investigator's choice, followed by pemetrexed(500 mg/m^2) every 3 weeks(Q3W) maintenance for the remainder of the study. Patients assigned to the SHR-1210 combined with chemotherapy arm, will additionally receive SHR-1210(200mg) administered as IV infusion on Day 1 of each 3-week cycle, for up to 35 cycles. Patients assigned to the chemotherapy arm will have the opportunity to crossover to receive SHR-1210(200mg) monotherapy every 3 weeks(Q3W) once they experience progression of disease (PD) defined by RECIST 1.1 and meet all crossover criteria.

1506TiP Phase I study of the AXL inhibitor DS-1205c in combination with osimertinib in subjects with metastatic or unresectable EGFR-mutant NSCLC

D. Planchard[1], P.A. Janne[2], H.A. Yu[3], D. Moro-Sibilot[4], T. Goldberg[5], X. Gu[6], J. Li[5], J. McGill[5], C. Yu[5], E. Slosberg[7]

[1]Medical Oncology, Institut Gustave Roussy, Villejuif, France, [2]Medical Oncology, Dana Farber Cancer Institute, Boston, MA, USA, [3]Medicine, Memorial Sloan Kettering Cancer Center, New York, NY, USA, [4]Thoracic Oncology Unit SHUPP, PTV, Centre Hospitalier Universitaire de Grenoble Alpes, Grenoble, France, [5]Clinical Development, Daiichi Sankyo Inc., Basking Ridge, NJ, USA, [6]Biostatistics, Daiichi Sankyo Inc., Basking Ridge, NJ, USA, [7]Translational Development, Daiichi Sankyo Inc., Basking Ridge, NJ, USA,

Background: In patients with metastatic EGFR-mutant (EGFRm) non-small cell lung cancer (NSCLC), resistance to EGFR tyrosine kinase inhibitors (TKIs) arises from the T790M EGFR mutation in over half of cases; up-regulation of "bypass track" activity in non-EGFR signaling pathways is observed in other cases. Up-regulation of expression of the AXL tyrosine kinase has been observed in EGFRm NSCLC patients experiencing disease progression on erlotinib, and xenograft studies have supported the role of AXL inhibition in combination with EGFR TKI treatment in overcoming such resistance. DS-1205c is a novel, orally administered, specific small molecule inhibitor of AXL.

Trial design: This is a multicenter, open-label, Phase 1, dose escalation and dose expansion study of DS-1205c in combination with osimertinib in metastatic or unresectable EGFR-mutant NSCLC subjects experiencing disease progression during treatment with erlotinib, gefitinib, or afatinib, and without T790M resistance mutation; or during treatment with osimertinib. Eligible subjects are at least 18 years of age, have ECOG PS 0 or 1, have radiological documentation of disease progression on erlotinib, gefitinib, afatinib, or osimertinib, and have at least one measurable lesion. This study includes two parts: Dose Escalation and Dose Expansion. In Dose Escalation, subjects receive DS-1205c during a run-in period, followed by combination treatment with DS-1205c and 80 mg daily of osimertinib. Escalation of DS-1205c dosing is guided by the modified Continuous Reassessment Method using a Bayesian logistic regression model following the escalation with overdose control principle. In Dose Expansion, subjects receive DS-1205c at the recommended dose for expansion (RDE) determined in Dose Escalation, in combination with 80 mg daily of osimertinib. Primary objectives are to determine safety, tolerability, and RDE of DS-1205c in combination with osimertinib. Secondary objectives are to assess pharmacokinetic parameters of DS-1205a (free form of DS-1205c), osimertinib, and osimertinib active metabolites, and to assess antitumor activity (RECIST v1.1). Retrospective analysis of AXL expression will be conducted using tumor tissue collected prior to study treatment. Enrollment opened in December 2017.

Background: Currently, there is no possibility to detect early tumor response in lung cancer patients within the first days after chemotherapy (CTx) or tyrosine kinase inhibitor (TKI) therapy induction. Using the current gold standard for therapy monitoring, i.e. the measurement of morphologic differences according to RECIST 1.1 by CT and MRI, changes are detected only after weeks or months. Thus, patients may undergo eventually ineffective treatment and suffer from unnecessary toxicity, with both causing relevant costs. This highlights the importance of early response detection to guide and optimize therapy. Monitoring treatment response with diffusion-weighted and dynamic contrast perfusion MR imaging has been proposed for some time as a new powerful tool that will allow determining tumor response much earlier than RECIST.

Trial design: This is an observational, prospective, multicenter, non-randomized, open clinical study. 150 patients with non-squamous NSCLC undergoing systemic treatment receive MRI before and after 1st-line therapy. The first follow-up (FU) MRI for patients undergoing chemotherapy is performed 24 hours post treatment. Patients treated with TKIs undergo MRI at days 7 and 14 after therapy induction. A thoracic MRI protocol is performed, including navigated diffusion-weighted imaging with the acquisition of 6 b-values, while the evaluation will focus on the non-perfusion sensitive b-values 400 and 800 (online calculated trace images) and the apparent diffusion coefficient (ADC). Software-based analysis of user-defined ROIs is used to assess the ADC value inside the tumor. ROIs are put in the solid part of the tumorous lesion. So far, 54 patients (28 TKI, 26 CTx) have been included. Findings will be correlated with routinely performed FU CT-imaging and the clinical outcome during FU visits. Further, an accompanying biomarker program aims to elucidate ultra-early blood-bound signs of apoptosis in correlation with MRI signals. This multicenter study will address the unmet clinical need of ultra-early detection of therapy response in NSCLC in order to translate this promising approach into broad clinical practice.

Background: Elderly patients represent a major population of non-small cell lung cancer (NSCLC) patients in routine clinical practice, yet are underrepresented in clinical trials. In particular, data regarding efficacy and safety in frail or elderly patients with respect to immunotherapy is lacking. Importantly, immunosenescence in elderly patients can result in altered activities of immune-modulating drugs such as PD-1/PD-L1 inhibitors. Thus, there is an urgent need to assess safety and efficiency of such inhibitors in this group.

Trial design: In this prospective, open label, treatment stratified, and randomized phase II study, 200 patients with stage IV NSCLC, >70 years old and/or "frail" (Charlson Comorbidity Index >1) or restricted performance score (ECOG >1), who are amenable for at least chemotherapy with gemcitabine or vinorelbine, will be included. Patients are stratified after a modified CARG Score (a predicting chemotherapy toxicity score): "Fit" patients are treated with doublet chemotherapy (carboplatin/nab-paclitaxel), while "unfit" patients receive monochemotherapy (gemcitabine or vinorelbine). Patients are then 1:1 randomized and receive either 4 cycles of chemotherapy + follow-up every 8 weeks (Arm A/D) or 2 cycles of chemotherapy followed by 2 cycles of durvalumab and subsequent maintenance durvalumab every 4 weeks (Arm B/C). The primary endpoint is the rate of treatment related grade III/IV adverse events (CTCAE V4.03). As secondary endpoints progression-free survival according to RECIST 1.1, overall survival, descriptive subgroup analyses according to PD-L1 expression, and quality of life will be addressed. Geriatric screening assessments and functional tests will be performed to complete the description of a potential "frail" and "elderly" patient cohort (G8-questionnaire, Timed up & go test, 6MWT). Further, a biomarker profiling program will analyse immune-related effects and potentially identify novel response predictors. The DURATION trial will prospectively investigate the safety and tolerability of PD-L1 treatment with durvalumab after chemotherapy in elderly and frail patients and thereby provide new insights into the effect of PD-L1 blockade and the impact of immunosenescence in this important cohort.

Background: Osimertinib has been shown to be superior to erlotinib or gefitinib in previously untreated patients with EGFR mutant (exon 19 deletion/L858R) NSCLC. Osimertinib is approved for the treatment of patients with metastatic T790M+ NSCLC who have disease progression after EGFR-TKI therapy. The majority of EGFR mutant NSCLC patients who are treated with a TKI ultimately acquire resistance, including those treated with osimertinib. We have recently completed a phase 2 randomized clinical trial demonstrating that patients with oligometastatic NSCLC treated with aggressive local consolidation therapy (surgery or radiation) have improved progression-free survival compared to those patients treated with systemic therapy alone (Gomez et al., Lancet Oncol, 2016). A retrospective review of EGFR-mutant subset of patients enrolled in the trial suggests that EGFR-mutant patients may derive greater benefit from this approach. Thus, two premises underlie the current randomized trial: 1) osimertinib is standard of care for treatment of primary and TKI resistant EGFR-mutant metastatic NSCLC, and 2) the majority of patients treated with osimertinib ultimately become resistant, and LCT has been found to improve outcomes compared to systemic therapy alone.

Trial design: A phase 2 randomized, multicenter, study to evaluate the efficacy of osimertinib with or without LCT for patients with EGFR-mutant metastatic NSCLC. Eligible patients include 1) Previously untreated patients with EGFR-mutant NSCLC (L858R or exon 19 deletion) or 2) NSCLC patients with acquired EGFR T790M that was acquired following progression on first or second generation TKI, this subset of patients must have not received prior third generation TKI. Patients who don't have disease progression after 6-12 weeks of induction osimertinib will be randomized 1:1 to osimertinib continuation or to osimertinib continuation with LCT Primary end point is progression free survival Exploratory biomarkers associated with resistance to osimertinib will be evaluated in tumor tissue and plasma collected at baseline and progression. 140 patients will be enrolled in 5 centers in North America.

Clinical trial identification: NCT03410043.

Background: TO (CetuGEX) is a second-generation anti-EGFR antibody that specifically binds to EGFR and acts as a competitive antagonist at the ligand binding site. GAT (PankoMab-GEX) is a novel humanized monoclonal antibody, which recognizes the tumor-specific epitope of mucin-1 (TA-MUC1) expressed on tumor cells. Both antibodies are glyco-engineered to potentiate antibody-dependent cellular cytotoxicity (ADCC). Compelling preclinical evidence suggests a complex interaction between EGFR and cell surface expressed TA-MUC1 in driving neoplastic processes and shows a synergistic antibody dependent cell cytotoxicity activity with the dual targeting of these molecules. Based on this evidence, this study aims to assess the tolerability, safety and preliminary activity of a combination with anti-EGFR and anti-TA-MUC1 glyco-engineered antibodies.

Trial design: The GATTO is an open label phase Ib dose evaluation study in patients with EGFR positive metastatic solid tumors, for whom no standard treatment is available. The proposed doses and schedule are 1200 mg Q2W for TO and 1400 mg Q2W for GAT. A staggered approach will be utilized in order to minimize the number of patients exposed and to evaluate the safety of the combination treatment. The first 6 patients will be enrolled into a safety run-in phase where the number of dose-limiting toxicities (DLTs) will be evaluated. Assuming that the safety criteria are met (ie. observation of 0 or 1 DLT), the dose will remain unchanged and further patients will be recruited at the highest dose level. If this is not the case, a step-wise dose reduction approach will be applied. The antitumor activity of the combined treatment will be evaluated as secondary endpoints including best overall response rate (ORR), duration of objective response (DOR), progression-free (PFS) and overall (OS) survival. Extensive pharmacokinetics (PK) and pharmacodynamics (PD) (cellular immune status, serum and tissue biomarkers) will be also analyzed. As of the beginning of May 2018 the study is ongoing and 6 patients are being treated.

1516P Effectiveness of a randomized control trial of an individualized, interactive advance care planning intervention in improving terminally ill cancer patients' psychological symptoms, quality of life and concordance between preferred and received life-sustaining treatments

S.T. Tang[1], J-S. Chen[2], W-C. Chou[2]

[1]School of Nursing, Chung Gung University, Taoyuan, Taiwan, [2]School of Medicine, Chung Gung University, Taoyuan, Taiwan

Background: To examine the effectiveness of an advance care planning (ACP) intervention in facilitating concordance between cancer patients' preferred and life-sustaining treatments (LSTs) received in the last month and in improving quality of life (QOL), anxiety symptoms, and depressive symptoms over the dying process.

Methods: Terminally ill cancer patients (N = 460) were randomly assigned 1:1 to the experimental and control arms. Data were obtained from 430 participants who died through December 2017. The experimental arm received an individualized, interactive ACP intervention tailored to participants' readiness to engage in ACP. The control arm received a sham intervention of education on symptom management. Group allocation was concealed, data collectors were blinded, and treatment fidelity was ensured. Outcome measures included concordance of preferences for and receipt of six LSTs, QOL (McGill Quality of Life Questionnaire scores), as well as anxiety and depressive symptoms (Hospital Anxiety and Depression Scale scores). Intervention effectiveness was evaluated by intention-to-treat analysis.

Results: Concordance between LST preferences and LSTs received were 58.2-77.5% and 59.0-75.7% for the experimental and control arms, respectively. Between-arm differences in concordance between the six preferred and received LSTs were not significantly (odds ratios [95% CI]: 0.966 [0.653, 1.428]-1.107 [0.690, 1.775]). Participants in the experimental arm had significantly lower anxiety (β [95% CI]=-0.583 [-0.977, -0.189], p = 0.004) and depressive (β [95% CI]=-0.533 [-1.036, -0.030], p = 0.038) symptoms than those in the control arm, but QOL did not differ.

Conclusions: Our individualized, and interactive ACP intervention facilitated participants' psychological adjustment to the end-of-life (EOL)-care decision-making process, but did not improve their QOL nor facilitate EOL care that honored their wishes before death. Our findings can ensure clinicians that ACP intervention is not detrimental to patients' psychological well-being, but improves it at EOL.

Clinical trial identification: NCT01912846, 2018/1/24.

1517P Current status of the integration of oncology and palliative care in Japan: A nationwide survey

U. Yu[1], K. Sato[2], T. Morita[3], M. Mori[4], C. Shimizu[5], Y. Horie[6], M. Hirakawa[6], T.E. Nakajima[6], S. Tsuneto[7], M. Muto[1]

[1]Department of Therapeutic Oncology, Graduate School of Medicine, Kyoto University, Kyoto City, Japan, [2]Department of Nursing, Nagoya University Graduate School of Medicine, Nagoya City, Japan, [3]Division of Supportive and Palliative Care, Seirei Mikatahara General Hospital, Hamamatsu City, Japan, [4]Palliative Care Team, Seirei Mikatahara General Hospital, Hamamatsu City, Japan, [5]Breast Center, Center Hospital of the National Center for Global Health and Medicine, Tokyo, Japan, [6]Department of Clinical Oncology, St Marianna University School of Medicine, Kawasaki City, Japan, [7]Department of Human Health Sciences, Graduate School of Medicine, Kyoto University, Kyoto City, Japan

Background: Based on recommendations from several agencies, including the European Society for Medical Oncology, palliative care (PC) services are increasingly recognised as an essential part of oncology care. However, the implementation of integration of oncology and palliative care (IOP) seems to be evolving slowly and detailed progress of IOP remain unclear. This was a cross-sectional nationwide survey to clarify the current status of IOP in Japan.

Methods: We performed comparison between designated cancer hospitals (DCHs) and non-designated cancer hospitals (non-DCHs), since considerable number of patients in Japan are receiving cancer treatment at non-DCHs. We distributed the questionnaire to executives or directors of oncology departments at cancer hospitals in November 2017 and sent a reminder mail later. Our questionnaire was developed based on indicators of IOP with international consensus. We conducted descriptive statistics, t-tests and Cochrane-Armitage trend tests where appropriate. To adjust the difference of inpatient beds scale, estimates at non-DCHs were weighted by the distribution of inpatient beds at DCHs.

Results: Among the 399 DCHs and 478 non-DCHs that were surveyed, 269 (67%) and 259 (54%) responded, respectively. DCHs had significantly more PC resources than non-DCHs did (e.g. both full-time physicians and nurses on a PC team, 53% vs. 14% ($p < 0.001$); the availability of outpatient PC service $\geq$ 3days per week, 48% vs. 21% ($p < 0.001$)). Clinical tools for PC services were well equipped (e.g. symptom management guidelines, 89% vs. 79% ($p = 0.238$); PC referral criteria, 72% vs. 59% ($p = 0.077$)). However, strategies to identify suitable patients for PC referral seemed to be undeveloped (e.g. clinical care pathways, 17% vs. 5% ($p < 0.001$); referral using time trigger, 9% vs 8% ($p = 0.358$); referral using needs trigger, 31% vs. 20% ($p = 0.820$)). Mutual rotation training for both oncology and PC fellows and research opportunities on IOP were limited.

Conclusions: Non-DCHs face a severe lack of PC resources, whereas DCHs might have relatively more resources to enhance IOP. Both education and research opportunities for IOP were limited. Further research is warranted to identify specific barriers to and facilitators for implementation of IOP.

1518P Access to palliative care before death in French cancer patients during the first two years after diagnosis: The national cancer cohort

M.K. Bendiane[1], A. Janah[1], D. Leufeuvre[2], P-J. Bousquet[2]

[1]Faculté de Médecine, Aix Marseille University, INSERM, IRD, Economics and Social Sciences Applied to Health & Analysis of Medical Information (SESSTIM), Marseille, France, [2]National Cancer Institute, INCa, Paris, France

Background: Palliative care (PC) is a part of a multidisciplinary approach that improves the quality of life of patients with potentially terminal illnesses including cancer. However, referrals to PC occur relatively late for the management of physical and psychological distress. In France, the proportion of patients who actually receive PC is not clear. This study aims to provide the prevalence and characteristics of dead cancer patients who have been referred at least one time to PC, and to identify the delay between PC access and death.

Methods: All people living in France (67 million population) with universal insurance coverage and diagnosed, treated or followed up for a cancer, such as survivors, are included and will be followed up for 25 years. Extracted from SNDS, the cancer cohort contains all healthcare consumption refunded data (i.e hospitalization, outpatient care, medication . . .) for subjects who have undergone cancer-related treatment since 2010. Every year, new cases are included in the cancer cohort. Data were extracted from the French "cancer cohort" databases for all people with cancer-related care between 2013 and 2015. Demographic characteristics, type of cancer, health care consumption, and delay between PC and death were determined.

Results: Of the 310 901 cancer patients included in the Cancer Cohort in 2013, 70 858 (22.8%) died between 2013 and 2015. Of these, the proportion of PC access was 52%. Access to PC of dead cancer patients was different according to age, gender, type of cancer and comorbidities. The median time between diagnosis and death, diagnosis and PC access, and PC access and death, were 225.0 days (Q1-Q3: 84.0 - 418.0), 158.0 days (Q1-Q3: 38.0 - 354.0) and 26.0 days (Q1-Q3: 11.0 - 56.0), respectively.

Conclusions: If more than half of cancer patients in our study had access to PC before death, differences in age and gender were observed confirming the results of previous studies. We also noted that the delay between PC access and death indicates a late referral to PC in the disease trajectory. General practitioners, PC specialists and the community at large need education so that cancer patients have access to quality PC as soon as possible and without necessarily being in near end-of-life situations.

1519P Anticancer therapy at the end of life of breast, prostate, and colorectal cancer patients

V. Heidt[1], K. Hermes-Moll[1], K. Blaschke[2], V. Lappe[2], P. Ihle[2], I. Schubert[2], W. Baumann[1]

[1]WINHO GmbH, Cologne, Germany, [2]PMV Forschungsgruppe, Universität Köln, Cologne, Germany

Background: The study addresses growing concerns regarding aggressive cancer treatment at the end of life. The extent of anticancer treatment at the end of life of breast, prostate, and colorectal cancer patients aged 60 years and older as well as its development in recent years is investigated.

Methods: Routine data of the statutory health insurance company AOK Hessen in Germany (approx. 1.4 million assured persons in 2014) for 2008-2013 are analyzed. Cancer patients are identified using ICD-10 codes: breast (C50), prostate (C61), and colorectal cancer (C18-21), and validated using inpatient and outpatient diagnoses. The last year before death is examined in 90-days periods and, in addition, the last 90 days in 30-days periods.

Results: Key results are that cancer patients aged 80 years and older less often receive anticancer therapy at the end of life (e.g. women with breast cancer in 2013: 20% in the last 90 days, 6% in the last 30 days before death) than patients aged 60-69 (56% and 29%) or 70-79 (46% and 18%). There is no clear development toward a reduction in anticancer treatment in women with breast cancer at the end of life between 2008 and 2013. The number of anticancer therapies at the end of life in men with prostate cancer aged 60-69 years reduced between 2008 and 2013, especially in the second (2008: 56%, 2013: 49%) and third 90-days period from last (2008: 57%, 2013: 45%) and reached the same level as patients aged 70-79. There are differences in the number of anticancer therapies between men and women with colorectal cancer at the end of life. Especially, women aged 80 and older with colorectal cancer rarely receive anticancer therapy in the year before death (in 2013: 5% in the last 90 days, 1% in the last 30 days before death) compared to men (12% and 5%).

Conclusions: These results support increased sensitivity regarding anticancer treatment at the end of life. To further investigate these results, studies should include cancer staging, general health status, and patient reported outcomes such as quality of life.

1520P Perspectives and attitudes towards the integration of oncology and palliative care in Japan: A nationwide survey

U. Yu[1], K. Sato[2], T. Morita[3], M. Mori[4], C. Shimizu[5], Y. Horie[6], M. Hirakawa[6], T.E. Nakajima[6], S. Tsuneto[7], M. Muto[1]

[1]Department of Therapeutic Oncology, Graduate School of Medicine, Kyoto University, Kyoto City, Japan, [2]Department of Nursing, Nagoya University Graduate School of Medicine, Nagoya City, Japan, [3]Division of Supportive and Palliative Care, Seirei Mikatahara General Hospital, Hamamatsu City, Japan, [4]Palliative Care Team, Seirei Mikatahara General Hospital, Hamamatsu City, Japan, [5]Breast Center, Center Hospital of the National Center for Global Health and Medicine, Tokyo, Japan, [6]Department of Clinical Oncology, St Marianna University School of Medicine, Kawasaki City, Japan, [7]Department of Human Health Sciences, Graduate School of Medicine, Kyoto University, Kyoto City, Japan

Background: Integration of oncology and palliative care (IOP) is recommended by several agencies, including the European Society for Medical Oncology. Given the slow evolution of IOP in practice, several barriers to its implementation may exist. Lack of institutional support is known to be one of the key barriers to IOP. However, institutional recognition towards IOP is less investigated. This was a cross-sectional nationwide survey to clarify the institutional perspectives and attitudes towards IOP in Japan.

Methods: We distributed a questionnaire to executives or directors of oncology departments at cancer hospitals on November 2017 and sent a reminder mail later. Since considerable number of patients are receiving cancer treatment at non-designated cancer hospitals (non-DCHs) in Japan, we performed comparison between designated cancer hospitals (DCHs) and non-DCHs. Questionnaire items were developed based on a comprehensive literature review. We conducted descriptive statistics, t-tests and Cochrane-Armitage trend tests where appropriate. To adjust the difference of inpatient beds scale, estimates of non-DCHs were weighted by the distribution of inpatient beds at DCHs.

Results: In total, 399 DCHs and 478 non-DCHs were surveyed, of which 269 (67%) and 259 (54%) responded, respectively. Most cancer hospitals considered their quality of palliative care (PC) services unsatisfying (75% vs. 76% ($p = 0.674$)), believed that IOP would be beneficial for their patients (85% vs. 89% ($p = 0.933$)) and did not regard it as costly (13% vs. 18% ($p = 0.217$)). DCHs had difficulty in recruiting PC physicians and non-DCHs in recruiting not only PC physicians but PC nurses and mental healthcare professionals. Although both were willing to facilitate an early referral to PC services (55% vs. 60% ($p = 0.001$)), less than 30% of hospitals was planning to increase full-time PC medical staff, inpatient PC beds and funding.

Conclusions: IOP was broadly recognised as beneficial for cancer patients and most institutions were willing to facilitate IOP. However, few institutions were planning to address their limited clinical resources. Strategies, such as the rearrangement of reimbursement systems or education for healthcare professionals, need to be investigated.

1521P Evolving concurrent integration of oncology and palliative care at an ESMO designated center over a decade

F. Strasser, T.C. Silzle, E.B. Schmidt

Clinic Medical Oncology & Hematology, Cantonal Hospital St. Gallen, St. Gallen, Switzerland

Background: Streamlining oncology (Onc) and specialist palliative care (SPC) into integrated patient (pt) care is increasingly a gold standard of optimized cancer care. The ways that integrated Onc/SPC manifests in clinical practice may change over time. Little is known about factors that drive evolution in integrated care practices.

Methods: From a pt's first appointment with outpatient SPC, all visits were chronologically color coded for Onc, SPC, and Neutral (e.g. emergency) or joint visits (Onc/SPC same day). Visual Graphic Analysis revealed 4 patterns of integration (Onc only; SPC only; CONCurrent: permanent exchange of Onc and SPC, $\geq$5 switches, joint visits; SEGmented: alternating periods of Onc or SPC, <4 switches), independent researchers approved reliability of patterns definitions. Data from 2006-2009 (presented 34-ESMO 2009) were compared with 2016-2017. Explanatory factors for patterns evolution were derived from multi-professional, consensual discussion reviewing descriptive statistics (e.g. impact of inpt admission on patterns, pattern stability over 3 months intervals, anticancer treatment administered by SPC, pt characteristics) and further explored in the data.

Results: 345 pts from 2006-09 and 64 from 2016 met eligibility criteria and were included. CONC occurred in 18% in 2006-09 and 45% in 2016 (X^2 (1, N = 409) = 22.66, $p < .001$)], and 14% vs 50% remained in the CONC pattern comparing 3 months intervals. Elimination of inpt visits left 3/4 of patterns unchanged. A double-boarded Onc/SPC physician saw 94% of pts in the 2016 sample and prescribed systemic anticancer treatment in > 1/3 of these visits, 77% of these pts were in the CONC Pattern. Joint Onc/SPC visits were increasing over time, also (bi-)weekly alternating visits by Onc and SPC (double-boarded). Pts of CONC had complex and high needs for palliative interventions, were in phase I studies, or refused standard anticancer treatment, but accepted later.

Conclusions: Concurrent Onc/SPC is an increasing and consistent pattern, not explained by mere bed availability. Prescribing anticancer therapy by a double-boarded physician may foster integration. Further research may determine how CONC affects pt outcomes and the influence of pt and physicians' characteristics.

1522P The impact of inclusion in home palliative program and distance to hospital on chemotherapy near end of life

J. Balsalobre[1], A. Checa-Soriano[1], P. Cerezuela-Fuentes[1], M. Martínez-Penella[1], M.J. Martínez-Ortíz[1], J.L. Alonso-Romero[2], M.I. Luengo-Alcázar[1], M.T. García-García[1]

[1]*Medical Oncology, Hospital Universitario Santa Lucia, Cartagena, Spain,* [2]*Medical Oncology, Hospital Universitario Virgen de la Arrixaca, Murcia, Spain*

Background: Chemotherapy (CT) near end of life is considered a marker of inadequate palliative care for cancer patients. The objectives of our work were to determine the influence of palliative care at home and the distance between the residence area and the cancer referral center on the interval between last chemotherapy cycle and death.

Methods: A retrospective observational study was conducted in a tertiary care hospital. All cancer patients deceased between January 2013 and June 2014 were included. Clinical, demographical and treatment variables were obtained from medical records.

Results: Our population of 951 patients had a mean age of 63 years; male: 601 (63%), females: 350 (37%). Tumor locations: lung, 261 (28%); colorectal, 125 (13%); breast, 99 (10.7%); pancreas, 79 (8.8%). The table shows an analysis of the CT used in all patients, indicating a high proportion of CT use near the end of life (68% in the last 3 months). Average time elapsed between the end of treatment and death was significantly longer in the group of patients included in home palliative care programs (n = 111; 24.5%) vs. those not included (n = 367; 75.5%): 42.3 vs. 24.7 days ($p < 0.05$). CT was stopped earlier in patients belonging to geographical areas farther from the referral center, with median times between last cycle of CT and death of 14.9 days for patients living near the referral hospital versus 51.9 days for > 70 km ($p = 0.041$) and 58 days for > 100 km ($p = 0.013$).

Table: 1522P Analysis of CT use in all patients

N = 901	n (%)
Treatment No CT CT	198 (22) 703 (78)
Nr of lines of CT 1 2 3 4 or more	441 (49) 198 (22) 135 (15) 127 (14)
Nr of drugs in last line of CT 1 2 3	378 (42) 414 (46) 109 (12)
CT in the last 3 months	604 (67)
CT in the last 4 weeks	405 (45)
CT in the last week	63 (7)

Conclusions: In our population, a high percentage of CT was observed in the final stages of life, including a high use of third and successive lines of treatment. Patients included in home palliative care programs and/or belonging to more distant geographical areas finished active treatment before, thereby suggesting that both factors impact on decision making for patients with advanced cancer. Understanding the factors that determine the use of CT near the end of life may contribute to limit its inadequate indication.

1523P Cancer patients' perceptions of palliative care

J. Yoong[1], B. Chosich[1], M. Burgess[1], A. Earnest[2], F. Runacres[1], L. William[1], M. Franco[1], P. Poon[1]

[1]*Supportive and Palliative Care Unit, Monash Health, Melbourne, Australia,* [2]*Epidemiology and Preventive Medicine, Monash University, Melbourne, Australia*

Background: Despite clear benefits and increased efforts towards earlier integration of palliative care (PC) with oncology, there are concerns that PC remains stigmatized and predominantly associated with end-of-life care (EOLC). This project aims to explore current perceptions and understanding of PC in cancer patients.

Methods: Prospective survey conducted in the oncology ward of a tertiary academic hospital in Melbourne, Australia. Over a 4-month period a 16-item questionnaire was distributed to all cancer patients upon admission to the ward (N = 103). Chi-Squared test was used to examine for significant factors related to patients' perceptions of PC.

Results: Ninety-six patients (93%) completed the questionnaire; of which 76% had metastatic cancer. Of the domains explored, salient findings were: 1) Familiarity and experience: 76% had heard of PC; while only 21% had received PC. Self-rating of PC knowledge was varied, and evenly distributed: 31% good/excellent, 36% average and 33% below average/poor. 2) Roles of PC and oncology: 86% believed they could receive concurrent oncology care and 81% believed they could receive anti-cancer treatment whilst receiving PC. Those who had heard of PC were significantly more likely to respond that they could receive concurrent anti-cancer treatment ($p = 0.005$), as well as those who had better self-rated PC knowledge ($p = 0.045$). 3) Perceptions: 45% believed PC was only associated with EOLC. Those more likely to disagree with this statement had received PC services ($p = 0.039$). The majority (77%) felt comforted with PC involvement; this was significantly associated with older age ($p = 0.047$) and

an understanding that oncology ($p < 0.005$) and anti-cancer treatment ($p = 0.013$) could continue. However, 40% felt frightened and 29% felt hopeless about a referral to PC. Notably, 50% felt more comfortable with "supportive care" services (versus PC), 25% were neutral and 25% were not.

Conclusions: This survey had an excellent response rate and results were reassuring that, in general, respondents had an accurate understanding of and positive perceptions of PC. Familiarity and comfort with PC were associated with significantly better understanding of PC. This may reflect overall progress in integration of PC and oncology care.

1524P Multicenter feasibility study of physician orders for life-sustaining treatment (POLST) for terminal cancer patients

H.J. An[1], H.J. Jeon[2], J. Cheon[3], S.H. Chun[4], H.A. Jung[5], H.K. Ahn[6], K.H. Lee[7], M-H. Kim[8], J.H. Kim[9], S. Kim[10], S-J. Koh[3]

[1]Department of Medical Oncology, St. Vincent's Hospital, College of Medicine, Catholic University of Korea, Suwon, Republic of Korea, [2]Department of Internal Medicine, Seoul Medical Center, Seoul, Republic of Korea, [3]Department of Oncology, Ulsan University Hospital, Ulsan, Republic of Korea, [4]Department of Internal Medicine, Bucheon St. Mary's Hospital, College of Medicine Catholic University of Korea, Bucheon, Republic of Korea, [5]Department of Internal Medicine, Hallym University Dongtan Sacred Heart Hospital, Hallym University College of Medicine, Dongtan, Republic of Korea, [6]Department of Internal Medicine, Gachon University Gil Hospital, Incheon, Republic of Korea, [7]Yeungnam University College of Medicine, Department of Internal Medicine, Daegu, Republic of Korea, [8]Ewha Institute of Convergence Medicine, Seoul, Republic of Korea, [9]Department of Hematology and Oncology, Ulsan University Hospital, Ulsan, Republic of Korea, [10]Department of Nursing, Changwon National University, Changwon, Republic of Korea

Background: Terminally ill patients can draw up Physician Orders for Life-Sustaining Treatment (POLST) with physicians to decide whether they want to suspend life-prolonging treatment near death. We conducted a multicenter, prospective study to assess the feasilibity of completing the POLST in real practice for cancer patients.

Methods: The inclusion criteria were patients with terminal cancer, age $\geq$19, and able to communicate. The purpose and concept of POLST was introduced first, and POLST was discussed with those whom wanted. Primary endpoint of this study was the completion rate of the POLST form in Korea.

Results: From June to December 2017, 336 patients were enrolled from seven hospitals. The median age was 66 (20-97) years, 177 (52.7%) were male, and 203 (60.4%) showed ECOG 3/4. Hepato-pancreato-biliary cancer (26.2%) was the most common, followed by lung (23.2%) and gastrointestinal (19.9%) origins. The mean expected survival duration was 10.6$\pm$7.3 months. At enrollment, 41.2% received hospice care, 29.6% stopped anti-cancer treatment, but 14.0% were in the middle of chemotherapy. The POLST were introduced in 203 patients (60.4%), and 105 patients (31.2%) completed the documentation of POLST. Barriers to introducing POLST were as follows; refusal from family members (29.8%); patients' denial or unawareness of prognosis (13.4%); lack of rapport with patients (13.3%); uncertainty of prognosis or timing (12.6%); guilty feelings (7.5%); and inadequate time/place (7.2%). Patients refused to sign the POLST due to lack of understanding (32.3%), emotional discomfort (32.3%), difficulty in making decision by themselves (29.8%), and denial of prognosis (5.7%).

Conclusions: Only one-third of patients completed the POLST, and various barriers were found among physicians, patients and families.

1525P Palliative care in advanced cancer: A clinical and ethical goal achieved?

J.C. Sanchez[1], R. Gomez-Bravo[1], A.M. Morito Aguilar[1], A. Royuela[1], B. Núñez García[1], T. Tojar[2], A. Ruano Ravina[3], C. Parejo[1], B. Cantos[1], M. Provencio Pulla[4]

[1]Servicio de Oncología Médica, Hospital Universitario Puerta de Hierro, Majadahonda, Spain, [2]Unidad de Cuidados Paliativos, Hospital Universitario Puerta de Hierro, Majadahonda, Spain, [3]Medicina Preventiva, Universidad de Santiago de Compostela, Santiago de Compostela, Spain, [4]Servicio de Oncología Médica, Hospital Universitario Puerta de Hierro, Majadahonda, Madrid, Spain

Background: There is a global consensus that at the end of life relief of symptoms and suffering must be guaranteed. It is considered by our national health system as a priority goal in advanced cancer to address all the needs both the patient and the family, and improve their quality of life. Palliative Care Units (PCU) are intended to achieve this objective. In the last months of life, despite these advances, active treatments continue to predominate over palliative care.

Methods: We conducted a retrospective observational study selecting all patients with a first consultation in the Medical Oncology Unit of the Puerta de Hierro University Hospital during 2014 and 2015, who died before December 31st, 2017. Treatments carried out, assessment by a PCU and home palliative care services (HPCS), during the last 6 months of life and place of death (hospital, home or PCU) were reviewed. We aim to assess quality of care evaluating the use of active therapies and PCU using a novel approach considering what was done during the last six months of life.

Results: 622 patients were selected (36% female/64% male), median age of 69 years (IQR 61-76). 89% were stage IV. Lung (32%) and gastrointestinal (31%) cancer were the most frequent. In the last 6 months of life, 59% of patients received chemotherapy (CT), 26% radiotherapy (RT) and 8% undergone surgery. Median time from the last CT and RT to death was 39 days (IQR 23-75) and 57 days (IQR 21-100) respectively. 28% of patients were not assessed by a PCU from whom 52% were first evaluated in the last 30 days before death and 28% had been followed for more than 60 days. Only 44% were followed by HPCS. In patients with HPCS, the number of deaths at home (41%) and at PCU (29%) was significantly higher, with only 30% dying at hospital. By contrast, among those never assessed by HPCS: these figures were 12%, 24% and 64% respectively ($p < 0{,}001$).

Conclusions: 1/3 of patients had never been assessed by a PCU and the selection of patients who benefit from active therapies in the last months of life must be clearly improved. The association between place of death and assessment by a HPCS suggests the efficiency of these units and the benefit of increasing their resources. The objective of a global approach for palliative care to all patients with advanced cancer is close but not achieved yet.

1526P The experience of onco-palliative care multidisciplinary meetings in Hotel Dieu de France University Hospital, an ESMO designated center of integrated oncology and palliative care

A. Houchan[1], T.S. Assi[2], Z. Bakouny[1], E. El Rassy[1], A. Tohme[3], M.C. Mouhawej[3], J.G. Kattan[1]

[1]Hematology-Oncology, Saint Joseph University, Faculty of Medicine, Beirut, Lebanon, [2]Medical Oncology, Institut de Cancérologie Gustave Roussy, Villejuif, France, [3]Palliative Care, Saint Joseph University, Faculty of Medicine, Beirut, Lebanon

Background: Current management strategies of cancer patients are adopting multidisciplinary meetings (MDM) and including the earliest palliative care intervention to improve the quality of life and survival. We have established, since 2015, a monthly onco-palliative care MDM for the management of our cancer patients. This study reports on the role of onco-palliative MDM in Hotel Dieu de France University Hospital, an ESMO Designated Center of Integrated Oncology and Palliative Care.

Methods: All cancer patients referred to the mobile palliative care unit and/or transferred to the palliative care unit, are presented and discussed during the onco-palliative care MDMs held between May 2015 and November 2017. Demographic, clinical and long-term characteristics were obtained from the electronic medical records and retrospectively nalysed. Demographic and survival data were compared between 2015 and 2017.

Results: 245 patients were presented during 20 MDMs. Median age was 68 years (range 59-77) and 58% of patients were male. The most common motive for palliative care consultation was social support (40%). Over the study period, no significant effect on the place of death was retained. However, patients had significant improvement in the symptomatic management of their disease between 2015 and 2017 (41.6% vs 7% in 2015) and better social support (60.7% vs 32.4% in 2015) ($p < 0.0001$). The median survival of patients after the onco-palliative care MDMS was 23 days (19.3- 26.7). No significant difference in survival was noted over the 3 year course ($p = 0.315$). Using the univariate cox regression model, in comparison to 2015, the hazard ratio is 0.780 (0.556 – 1.094, $p = 0.149$) for 2016, and 0.924 (0.3652 – 1.309, $p = 0.656$) for 2017.

Conclusions: The onco-palliative care MDMs is an innovative approach in Lebanon, a small conservative Middle Eastern society. These MDMs were shown to improve the quality of life of cancer patients with better symptomatic and social support. However, no significant impact on survival was demonstrated so far.

1527P End of life resource utilization among patients receiving immunotherapy for advanced cancer

J.T. Burkart[1], S. Patel[1], A.M. Noonan[1], P. Monk[1], C.J. Presley[1], T. Olencki[1], K.L. Kendra[2], G.A. Otterson[1], J. Gustin[3], L. Wei[1], D.H. Owen[1]

[1]Division of Medical Oncology, The Ohio State University James Cancer Hospital, Columbus, OH, USA, [2]Cutaneous Oncology Program, Ohio State University Comprehensive Cancer Center - James, Columbus, OH, USA, [3]Palliative Medicine, Ohio State University, Columbus, OH, USA

Background: Patients (pts) with advanced cancer have high rates of healthcare resource utilization at the end of life (EOL). Immunotherapy (IO) has changed the treatment landscape for many patients with cancer. The impact of IO on resource utilization at the EOL for pts with metastatic disease, including emergency department (ED) visits, hospitalizations, and referrals to hospice is unknown.

Methods: We conducted a single center, retrospective analysis of pts treated with PD-1/L1 or CTLA-4 antibodies alone or in combination from 2011 – 2017. We identified 1,113 pts from electronic health records and present here clinical information for 306 pts with metastatic disease and end of life outcome data for 188 decedents. Survival curves were compared using log-rank test for pts by disease, treatment type, ECOG performance status (PS) at treatment start, and age. Hospice referral rate was compared using Fisher's exact test.

Results: Of the 306 pts, 131 (43%) had melanoma, 42 (14%) had renal cell carcinoma, 33 (11%) had non-small cell lung cancer, 22 (7%) had head and neck carcinoma, and 78 (25%) had another advanced malignancy. Treatment consisted of nivolumab in 130 (42%) pts, ipilimumab in 73 (24%), pembrolizumab in 59 (19%), nivolumab/ipilimumab in 23 (8%), atezolizumab in 9 (3%), and other IO combinations in 12 (4%). Of the 188 (61%) pts who died, 93 (49%) had at least one ED visit in the last month of life, 110 (59%) had at least one hospitalization, and 21 (11%) died in the hospital. Of all pts who died, 156 (83%) had hospice referral with a median of 11 days (range 1-420) between hospice referral and death. Overall survival (OS) was not associated with disease type ($p = 0.11$) or treatment ($p = 0.832$), but was associated with ECOG PS ($p = 0.013$). Referral to hospice did not vary by disease type ($p = 0.945$), treatment type, ($p = 0.809$) or age ($p = 0.432$), but did vary by ECOG PS ($p = 0.006$). Death within 72 hours of hospice referral rate varied significantly by inpatient or outpatient referral ($p = 0.002$).

Conclusions: Hospitalizations and ED visits are frequent at the EOL among pts who received IO for advanced malignancies. There was a high referral rate to hospice, but the median time between hospice referral and death was short. Interventions to decrease aggressive EOL care are needed.

1528P Palliative chemotherapy for patient with advanced tumor and poor performance status: Are oncologists' hopes of benefit justified?

V.F. Vasconcellos, R.R.C.C. Bonadio, G. Avanco, M.V. Negrão, R. Riechelmann

Medical Oncology, ICESP - Instituto do Câncer do Estado de São Paulo, Sao Paulo, Brazil

Background: The recommendation to use palliative chemotherapy (PC) in patients (pts) with advanced cancer and poor performance status (ECOG-PS) is controversial and could be harmful. However, in routine practice some oncologists still recommend it. We sought to identify the outcomes and related prognostic factors of PC in these pts treated in a large academic cancer center.

Methods: We retrospectively reviewed all consecutive pts with poor ECOG-PS metastatic solid tumors who received PC during hospitalization for symptom control from January 2015 to September 2017. Eligible pts had ECOG-PS 3/4 and started first line PC or had ECOG-PS ≥ 2 and started second or further lines. Pts with known chemo-sensible tumors (germ cell, ovary, small cell lung cancer) and primary central nervous system were excluded. The primary end point was survival rate within 30 days from the date of first cycle. Logistic regression was used to identify prognostic factors associated with this mortality rate.

Results: We identified 228 consecutive pts. The median age was 56 years old, 133 pts (58%) were female, 150 pts (66%) were chemotherapy-naïve and almost half of pts had primary gastrointestinal tumors. 21.9%, 66.7% and 11.4% pts had ECOG-PS 2, 3 and 4, respectively. With a median follow-up of 49 days, 224 pts (98.2%) died. Nearly two thirds ($N = 142$) of pts died while hospitalized, with 31 (13.8%) dying while in ICU, 27 pts (12%) died in a hospice and 2 pts passed away at home. The median overall survival was 38.5 days and the survival rates within 30 and 60 days of chemotherapy were 55.7% and 38.5%, respectively. In the multivariate analysis, ECOG-PS 3/4 (OR 2.45; $p = 0.015$) and baseline values of anemia (OR 0.41; $p = 0.034$), hypercalcemia (OR 2.71; $p = 0.410$) and elevated total bilirubin level (5.14; $p < 0.001$) were significantly associated with 30-day mortality.

Conclusions: Most pts with advanced cancer and poor performance status clearly do not benefit from PC, especially those with ECOG-PS 3/4, hypercalcemia and elevated bilirubin. Transparent conversation with pts and their families about prognosis and the inefficiency of PC in this setting is crucial to avoid futile interventions.

1529P Integration of oncology and palliative care

S. Kaasa[1], J.H. Loge[1], T. Albreht[2], E. Bruera[3], A.T. Caraceni[4], A. Cervantes[5], I.J. Higginson[6], K. Jordan[7], P. Sjøgren[8], P. Stone[9], C. Zimmermann[10], T. Lundeby[1]

[1]Department of Oncology, Oslo University Hospital, Oslo, Norway, [2]Department of Health Care, National Institute of Public Health of Slovenia, Ljubljana, Slovenia, [3]Palliative, Rehabilitation & Integrative Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [4]Palliative Care, Pain Therapy and Rehabilitation, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [5]Department of Medical Oncology, University of Valencia, Valencia, Spain, [6]Cicely Saunders Institute of Palliative Care, Policy and Rehabilitation, King's College London, London, UK, [7]Innere Medizin V - Hämatologie, Onkologie, Rheumatologie, University of Heidelberg, Heidelberg, Germany, [8]Department of Oncology, University of Copenhagen, Copenhagen, Denmark, [9]Marie Curie Palliative Care Research Department, University College London, London, UK, [10]Department of Supportive Care, Princess Margaret Cancer Center, Toronto, ON, Canada

Background: Integration of oncology and palliative care (PC) combines two paradigms: the tumour-directed approach, which is the main focus of oncology, and the host-directed approach, which is the focus of PC. Contemporary PC aims to prevent, treat and reduce symptoms and suffering and to preserve and improve quality of life. A Lancet Oncology Commission was written on how PC and oncology can be integrated by combining these two approaches focusing content, models, organization of cancer care, public health, politics, education and research.

Methods: An international panel was established, consisting of experts in oncology, PC, public health and psycho-oncology. Literature searches were conducted, author meetings were held, and an interactive writing process was conducted.

Results: Integration is a complex process that involves various components of the health care system. The published RCTs on integration demonstrate health gains, but how and when to integrate is uncertain. Still, early delivery of specialist palliative care promotes patient-centeredness including shared-decision making, family involvement and regular use of patient-reported outcome measures. Barriers to integration include the perception of PC as end-of-life care, deficient planning at local, national and international levels, and insufficient infrastructure and funding. Furthermore, death and dying are stigmatized. The present competence in combined oncology and PC varies substantially and must be defined at all levels. The commission proposes to use standardized care pathways (SCPs) and multidisciplinary teams (MDTs) to promote integration. Integration raises new research questions: how much, when and how should PC be delivered and what is the minimum model for good care?

Conclusions: Integration involves the transition from a dualistic perspective - the tumor and the host- to a combined perspective. Integration must be recommended by health care authorities and decision-takers, followed by resource allocation and priority-setting. In all areas, the present volume of PC is too small to support integration on a broad scale. Implementation of integrated models is best secured by MDTs and SCPs. The combined perspective must be reflected in care models, education and research funding.

1530P Understandability of the standard arabic translation of the EORTC QLQ-C15-PAL questionnaire by Egyptian patients with incurable cancer

H.F. Masoud[1], S-E. Abdelmoneim[1], M.F. Ismael[1], S.A. Alsirafy[2]

[1]Clinical Oncology Department, Alexandria Faculty of Medicine, Alexandria, Egypt, [2]Palliative Medicine Unit, Kasr Al-Ainy Center of Clinical Oncology & Nuclear Medicine, Kasr Al-Ainy School of Medicine, Cairo, Egypt

Background: Many of the European Organisation for Research and Treatment of Cancer (EORTC) quality of life questionnaires is translated into standard Arabic. However, standard Arabic is not the language used for daily life communication in Arab countries where each country has its own local dialect. The aim of this study was to explore the understandability of the current standard Arabic version of the EORTC QLQ-C15-PAL by Egyptian advanced cancer patients with different educational levels.

Methods: The study included 100 adult patients with incurable cancer and different educational levels. Literate patients were asked to read the standard Arabic QLQ-C15-

PAL questionnaire and to state whether or not they understand each of its 15 questions. For illiterate patients, the questions (as they are written without explanation) were read for them.

Results: The median age of patients was 54 years (range: 27-78) and 56% were males. The education level was illiteracy in 49% of patients, less than high school in 18%, high school or equivalent in 18% and more than high school in 15%. The average number of questions understood by the whole group was 11 (range: 6 –15). Only 7 questions (1, 2, 5, 7, 10, 11 and 15) were understood by > 80% of patients. The average number of understood questions differed significantly according to the education level of patients ($p < 0.001$). The average number of understood questions was almost similar among illiterate patients and those with less than high school education with no significant difference between them (9.4 and 9.6, respectively; $p = 0.814$). Similarly, there was no significant difference in the average number of understood questions between high school and more than high school educated patients (13.8 and 14.5, respectively; $p = 0.102$).

Conclusions: The results suggest that the current standard Arabic translation of the EORTC QLQ-C15-PAL should only be used with patients with a high school level of education and above. There is a need to translate the EORTC QLQ-C15-PAL into "Egyptian" Arabic; otherwise, a vulnerable group of patients (illiterates and those with less than high school education) will not be included in studies using the EORTC QLQ-C15-PAL.

1531P How to practice oncology with a supportive and palliative care ambulatory unit: A French experience (HOASIS)

A. Gonzalez Moya[1], H. Bourgeois[2]

[1]Radiation Oncology, Centre Jean Bernard, Le Mans, France, [2]Medical Oncology, Clinique Victor Hugo Le Mans, Le Mans, France

Background: Early outpatients palliative care (EPC) in patients with metastatic cancer has been shown to impact quality of life and decrease healthcare utilization, but data describing these benefits are limited and referrals to palliative care services are often late. Our Ambulatory Unit named HOASIS offers an interdisciplinary approach to cancer management for patients.

Methods: HOASIS was created in March 2017 to receive EPC patients in order to foster autonomy and quality of life, both for patients and families. Multi-professional teams provide care in cooperation with physician.This retrospective study analyzed 152 EPC patients from march to december 2017.

Results: In total, 152 patients were evaluable. 97% had solid tumor (mainly breast and digestive cancer, respectively 24% and 37%) and 3% had hematologic malignancies. Median age was 66 years. ECOG PS 0-1 (18%), PS 2 (52%) and PS 3-4 (28%). Most common services used were nutrition (67%), psychological counseling (39%), physical therapy (53%) and social work intervention (30%). Patients were supported to understand their prognosis with clear information about their disease and treatment (45%) and make care decisions (11%). Medical prescriptions included pain control (46%), symptomatic treatment (38%), physiotherapy (27%), psychotropics (6%) and nutritional supplements (12%). Nurses delivered the information allowing 49% to chose their trusted person and 13% both completed advance directives and trusted person. After evaluation, 29% need a second appointment, 66% had oncology consultation, 26% had phone consultation and 21% were hospitalised. Home service was supplied to 63% of them. Out of the 152 patients, 13 (9%) were seen late in our unit, less than 1 month before death, and 83 (55%) were seen more than 1 month before death. Full data about chemotherapy around end of life will be delivered during the meeting.

Conclusions: Professionals should integrate EPC for patients with advanced cancer. Advantages to EPC include improvement in patient's quality of life, reduced aggressive care at the end of life, increased advanced directives. A web-based application for monitoring comfort in patients receiving EPC is currently being evaluated.

1532P Prognostic impact of end-of-life chemotherapy in the last weeks for patients with advanced cancer

S. Hiramoto[1], A. Kikuch[1], T. Hori[2], A. Yoshioka[1], T. Tamaki[3]

[1]Oncology and Palliative Medicine, Mitsubishi Kyoto Hospital, Kyoto, Japan, [2]Respiratory Surgery, Mitsubishi Kyoto Hospital, Kyoto, Japan, [3]Nursing, Mukogawa Woman's University, Nishinomiya, Japan

Background: Appropriately timed cessation of chemotherapy is important for patients with advanced cancer at the end-of-life stage. There are frequent discussions about over-treatment of end-of-life chemotherapy currently, but the definition of end-of-life chemotherapy remains unknown.

Methods: We analyzed patients' data between August 2011 and August 2016. The primary endpoints were prognostic factors (age, sex, primary site, clinical stage, comorbidity, Eastern Cooperative Oncology Group (ECOG) performance status (PS), and Glasgow Prognostic Score (GPS)) following the last administration of chemotherapy within 14 days of death. Patients with either C-reactive protein levels >1.0 mg/dL or albumin levels <3.5 g/dL were classified as GPS1; patients with both were classified as GPS2, and those with neither of the two were classified as GPS0. The secondary endpoints were prognostic factors following the last administration of chemotherapy within 30 days of death. The associations between end-of-life chemotherapy and the frequency of end-of-life symptoms (delirium, cancer pain, dyspnea, nausea and vomiting, and fatigue) and treatment (hydration, continuous sedation, and opioids) were evaluated.

Results: We obtained 300 patients' data including complete information about the last administration of chemotherapy. The number of patients within 14 and 30 days of death from the last administration of chemotherapy were 16 (5.3%) and 50 (16.7%), respectively. In multivariate analysis for end-of-life chemotherapy, ECOG-PS (odds ratio 0.26, $p = 0.046$) and GPS2 (odds ratio 0.19, $p = 0.043$) were significant prognostic factors within 14 days of death, while ECOG-PS (odds ratio 0.34, $p = 0.046$), GPS1 (odds ratio 0.28, $p = 0.010$), and GPS2 (odds ratio 0.22, $p < 0.001$) were significant prognostic factors within 30 days of death. The median survival time from the last administration of chemotherapy of patients with both GPS2 and EGOG-PS (≥2) was 41 days, and that of patients with both GPS0 and EGOG-PS (0-1) was 162.5 days. Prevalence rates at the end-of-life stage for nausea and vomiting (25.0%) within 14 days of death were significantly higher than those (7.4%) over 14 days of death. The mean amounts of hydration (0.50 L/day) at the end-of-life stage within 14 days of death were significantly higher than those (0.20 L/day) over 14 days of death.

Conclusions: GPS and ECOG-PS were significant prognostic factors for over-treatment of end-of-life chemotherapy. Information about these factors can aid clinical decision-making in individual patient risk stratification, especially in palliative care settings, and in the further development of prospective cohort studies about end-of-life chemotherapy.

1533P A novel electronic tool to implement palliative sedation (PS) in a department of oncologic medicine

A. Saviola[1], S. Cascinu[2], M. Salati[2], G. Longo[1], C. Fiorani[1], L. Ferrara[1], N. Malavasi[1], R. Postiglione[1], F. Cantile[1], L. Scarabelli[1], M. Rimini[3], F. Ferri[1]

[1]Dipartimento ad Attività Integrata n.4 "Oncologia ed Ematologia", Azienda Ospedaliero - Universitaria Policlinico di Modena, Modena, Italy, [2]Oncology, Azienda Ospedaliero - Universitaria Policlinico di Modena, Modena, Italy, [3]Medical Oncology, University Hospital of Modena, Modena, Italy

Background: Palliative sedation (PS) is a medical intervention aimed at relieving suffering in terminally ill cancer patients. Although specific guidelines exist, their application is challenging and varies greatly. We systematically collected relevant data concerning PS, including relatives' perception, in order to inform current practice patterns.

Methods: Electronic medical and nursing records of patients with advanced cancers undergoing PS at the Modena Cancer Centre between December 2016 and February 2018 were retrieved. Data regarding patient demographics, disease characteristics, PS details were collected and organized in items to create a personalized electronic PS record for each patient.

Results: A total of 259 deaths were recorded in our Department during the study period. Among them, 88 patients received PS. The median age was 67.6 years old; 71 (81%) patients had solid tumours, while 17 (19%) had hematologic cancers. At time of PS, 35 (39.8%) patients were receiving chemotherapy, 9 (10,2%) patients radiotherapy and 44 (50%) patients best supportive care alone. Four patients (4.5%) overtly expressed their informed consent to PS. Most frequently treated refractory symptoms were: delirium/agitation (70.5%), dyspnea (34%), intractable pain (16%), and global suffering (4.5%). Midazolam was used in 78 (88.6%) patients and diazepam in 6 (10.4%) patients. Morphine was added to PS in 65 (74%) patients. The Delirium Palliative Prognostic score reported a 30-day survival probability < 30% in 46 (52%) patients, between 30% and 70 % in 31 (35%) patients, >70% in 3 (3.5%) patients. The average duration of PS was 70 hours (range 3-281 hours). Patient's relatives reported peacefulness in 44 (71%) cases, agitation in 10 (16%) cases and concern for suffering in 8 (13%) cases.

Conclusions: The electronic tool permits to have data that provide an auditing of PS practice, facilitate the cooperation among professionals and obtain the standardization of PS. The involvement of patients' family could lead to a more effective communication. We propose this as a user-friendly electronic tool to improve the quality of PS as well as the planning and coordination of end-of-life care in an inpatient setting.

1534P Congruence between actual place of death and preferences of Egyptian patients with advanced cancer and their family caregivers

S. Alsirafy[1], O. Zaki[2], N.Y. Ibrahim[2], W. Elsherief[2], A. Hammad[1]
[1]Palliative Medicine Unit, Kasr Al-Ainy School of Medicine, Cairo University, Cairo, Egypt, [2]Clinical Oncology Department, Kasr Al-Ainy School of Medicine, Cairo University, Cairo, Egypt

Background: Identifying the preferred place of death (PPoD) of incurable cancer patients and their family caregivers is important for the delivery of end-of-life care that meets their needs. The PPoD was not studied before in our region where talking with patients about death is largely perceived as unacceptable. Our aim was to study the PPoD of Egyptian patients with incurable cancer and their family caregivers and the actual place of death (APoD) of these patients.

Methods: A prospective observational cohort study that included 92 patient/family caregiver dyads. Patients and family caregivers were asked about their PPoD (home, hospital or other) in the event of patient's death. Patients were followed up until death to know the APoD.

Results: Seventy-nine (86%) dyads answered the question about their PPoD. Home was the PPoD in 74 (93.7%) patients as well as their family caregivers. The congruence in the PPoD between patients and family caregivers was 94.9% (Kappa = 0.573). The APoD was home in 65 (82.3%) patients and hospital in 14 (17.7%). Overall, 78.5% of patients died in their PPoD; however, the kappa value was low (=0.013). Similarly, the congruence between caregivers' PPoD and APoD was poor (Kappa = 0.013). Patients who preferred death at home were more likely to die in their PPoD ($p = 0.001$).

Conclusions: The results suggest that, in the absence of the stand-alone hospice model, home is the PPoD for the vast majority of Egyptian patients with incurable cancer and their caregivers. Although the majority of patients die at home, other patients die in hospital contrary to their home death preference.

1535P Sarawak: Healthcare professionals' perception of palliative care at end of life

C.F. Cheah[1], L.H.Y. Winnie[1], A. Merriman[2], N.I. Mohd Naseri[1], S.W.Y. Chew[3]
[1]Palliative Care Ward, Sarawak General Hospital, Kuching, Malaysia, [2]Palliative Care Ward, Hospice Uganda, Kampala, Uganda, [3]Faculty of Health Science, University of Bristol, Bristol, UK

Background: Palliative care is fundamental to health and a basic human right. Healthcare professional are often the gatekeeper to palliative care for their patients, but there is great disparity in access to palliative care across Malaysia, and little knowledge about healthcare professionals' perception towards palliative care at the end of life in Sarawak.

Methods: We surveyed all healthcare professionals who attended a palliative care seminar and talk by Prof Dr Anne Merriman, founder and director of policy and International program, Hospice Africa when she visited Kuching, Sarawak on 5th and 6th April 2018. Participants were asked to answer a questionnaire designed by Prof Merriman which comprises of 25 questions in trochotomous scale.

Results: A total of 186 responses were obtained, of which 68% (127) were doctors and 25% (46) were nurses. 80% (149) responded that they would like to die at home, while only 5% (9) preferred to pass away in hospital. 96% (179) wished to have family with them and 84% (157) wanted spiritual guidance at the end of life. Only 41% (76) reported that they were afraid to die, yet majority responded that they were afraid of a painful death (86%;160), a prolonged dying process (89%; 164) and troubling others (90%; 167). Less than 50% of healthcare professional surveyed felt that they were able to help patients achieved adequate pain control (43%;80) or support patients emotionally (42%;78), and majority (58%) reported lack of knowledge being the barrier. 95% (176) reported that they would like to attend more palliative care seminars and 92% (171) would like to have palliative care in their unit. 26% (48) responded that they would like it to be lawful to practice euthanasia, but only 15% (28) were prepared to actively practice euthanasia if it is legal.

Conclusions: Home is the preferred place of death even amongst healthcare professional in Sarawak. Lack of knowledge and professional training remains a major barrier to access of palliative care. The survey highlighted the need for palliative care training for local healthcare professional as well the need to develop hospice home care services in our State to provide better palliative care and end of life care for patients and families. Advocacy for advanced directives should be initiated.

1536P Factors associated with length of stay in an acute palliative care unit: A retrospective analysis

D. Hausner[1], A. Pope[1], N. Kevork[1], L.W. Le[2], C. Zimmermann[1]
[1]Department of Supportive Care, Princess Margaret Cancer Centre, Toronto, ON, Canada, [2]Department of Biostatistics, Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: Acute palliative care units (APCUs) admit patients with cancer for symptom control, transition to community palliative care unit/hospice or end-of-life care. Prognostication is crucial for decision-making. We evaluated factors associated with patients' length of stay (LOS) on an APCU in a cancer centre.

Methods: We analyzed demographic, administrative and clinical data for patients admitted to the APCU in 2015. Clinical data included cancer diagnosis, palliative performance scale (PPS) on admission, delirium screening using the short Confusion Assessment Method (CAM), and Edmonton Symptom Assessment System (ESAS) symptoms. ESAS distress score (EDS; sum of all 9 symptoms) and FDSA sub-score (fatigue, drowsiness, shortness of breath, appetite) were calculated. We conducted univariable (UVA) and multivariable (MVA) regression analyses of factors associated with LOS of patients who died on the APCU and of those who were discharged.

Results: Among 280 patients, 156 (56%) died on the unit and 124 (44%) were discharged. Median LOS was 14 days for discharged patients and 8 days for those who died ($p < 0.001$). Discharged patients were older (median age 68 vs 64, $p = 0.003$) and had higher functional status (median PPS 50 vs 40, $p < 0.001$) than those who died. Patients who died had higher symptom burden (median EDS 44 vs 38, $p < 0.009$), were more likely to be admitted from an inpatient unit ($p < 0.001$) and for terminal care ($p < 0.001$), and were more likely to develop delirium ($p = 0.04$). On MVA of patients who died on the APCU, reason for admission ($p = 0.007$), delirium ($p = 0.02$) and FDSA score ($p = 0.002$) were associated with LOS. Shorter LOS was associated with admission for terminal care ($p = 0.05$) and missing FDSA (patients were too ill to complete) ($p < 0.001$); longer LOS was associated with delirium ($p = 0.02$). For patients who were discharged from the APCU, delirium was associated with longer LOS ($p = 0.02$).

Conclusions: In cancer patients admitted to an APCU, development of delirium was associated with longer LOS in patients who died on the unit as well as in patients who were discharged home or to PCU/hospice.

1537P Medical-aid-in-dying use in the US Pacific Northwest

C.D. Blanke[1], M. Leblanc[1], D. Hershman[1], F. Meyskens[1], L. Taylor[2], L.M. Ellis[1]
[1]SWOG, Portland, OR, USA, [2]Neuro-Oncology, University of Washington Medical Center, Seattle, WA, USA

Background: Eight venues in the US allow terminally ill residents to self-administer prescribed oral drugs to end life. The Pacific Northwest states Oregon (OR) and Washington (WA) report number of prescriptions written, pt demographics, and motives underlying the requests. To study reasons for medical-aid-in-dying (MAID) requests and to assess patterns of use, we evaluated a combined 28 years of information from the most extensive database in North America.

Methods: OR and WA Health Authorities monitor MAID compliance. Website data from 1998 –2017 (OR) and 2009-2016 (WA) were collated. Characteristics of those dying from ingested drugs were calculated independently by state and then combined. Time trends for deaths vs. prescriptions written were analyzed using logistic regression.

Results: 3368 prescriptions were writte; 2282 pts took drug and died. The percent ingesting medication per yr ranged from 48-87, with no significant time trend in OR but with an increase over time in WA (2-sided $p = 0.59$ and <0.01, respectively). 77% of pts had cancer; 10% neurologic illness; 5% lung disease (dz); 5% heart dz; 3% other. 4% were sent for psychiatric evaluation. M/F (%): 51/49. 31% were in the largest pt age group represented: 65-74 yrs (overall range 20-102). Race white/other/unknown (%): 95/4/0.8. Eighty-three percent died at home (93 OR, 71 WA); a prescriber was present in 10% of cases (16 OR: 5 WA). Time between drug intake and coma ranged from 1 to 660 min; to death: 1-6240 min. Fewer than 0.5% awoke in OR. Reasons for MAID (%): Poor QOL 87; loss of autonomy 88; loss of dignity 69; inadequate pain control 30 (OR 26; WA 36); financial concerns 6.

Conclusions: Unlike European countries allowing euthanasia, US MAID consists only of terminally ill pts self-administering lethal medication. Up to half the pts requesting prescriptions do not take the drugs. Pts must be legally competent but rarely are referred to psychiatrists for that assessment. Most MAID pts have cancer and most use MAID for conditions that are difficult to palliate (loss of autonomy/dignity/QOL). Of concern, some use it because of inadequate pain control or finances. MAID merits formal study, such as how to develop faster-acting medications, as well as comparing effectiveness and demographics (especially age) with assisted dying data from Canada and Europe.

1538TiP Brain metastases in Norway: A prospective cohort study

O.E. Yri[1], M.L. Smebye[1], M.J. Hjermstad[1], A.T. Karlson[1], N.K. Aass[1], J.H. Loge[1], S. Kaasa[2]
[1]*Department of Oncology, Oslo University Hospital, Oslo, Norway,* [2]*Department of Oncology, Oslo University Hospital and European Palliative Care Research Centre, Oslo, Norway*

Background: Brain metastases (BMs) cause significant morbidity and mortality, and the incidence is increasing. With continuous developments in neurosurgery, radiation techniques such as stereotactic radiotherapy, and novel systemic therapies, treatment decisions have become more challenging. Also, the role of whole brain radiotherapy is being debated due to its marginal survival benefits and potentially significant side-effects. International guidelines on treatment and follow-up exist, but the scientific evidence supporting these guidelines is limited. To improve patient-centered care and promote shared decision-making, systematic, population-based registrations of patient, disease, treatment, and outcome variables are necessary. We have launched a prospective cohort study in the South-East health-care region of Norway (appr. 3 million inhabitants). The study population will consist of consecutive patients newly diagnosed with BMs recruited over a two-year period. Follow-up will be for up to two years or until death. The primary aim is to establish a prospective, clinical registry with data on diagnostics, treatment, and follow-up, including Patient Reported Outcome Measures (PROMs). With this prospective information, evidence-based diagnostic and treatment algorithms and follow-up guidelines can be developed. Study outcomes include: • Detailed description of the study cohort (including patient-, disease-, and treatment characteristics) • Overall survival (from BM diagnosis) • Association between disease, treatment, and patient characteristics and survival • Patient reported symptoms and quality of life.

Trial design: This is a prospective cohort study conducted in the South-East health-care region of Norway. Inclusion criteria: •Radiologically confirmed BMs from solid cancers diagnosed during the study period, regardless of planned treatment for BM. •No previous treatment for BMs •Age $>$ 18 years Timeframe: Two-year consecutive inclusion, started November 2017. Estimated target population: 1,000 cases Data collection: Clinical data are registered every 3 months for up to 24 months. Patient-reported symptoms and quality of life are assessed with standardized questionnaires (EORTC QLQ-C15-PAL, BN-20, and EQ-5D) monthly for up to 12 months.

Clinical trial identification: NCT03346655.

[1]QoL, EORTC - European Organisation for Research and Treatment of Cancer, Brussels, Belgium, [2]School of Population and Public Health, University of British Columbia, Vancouver, BC, Canada, [3]Oncology, Institut Gustave Roussy, Villejuif, France, [4]Palliative Medicine, Bispebjerg Hospital, Copenhagen, Denmark, [5]Department of Neurology, VU University Medical Center & Brain Tumor Center, Amsterdam, Netherlands, [6]Department of Neurology, Leiden University Medical Center & Haaglanden Medical Center, Leiden, Netherlands

1541P Partners' perceptions of women's body image problems and satisfaction of breast reconstruction long-term after risk-reducing mastectomy

L. Bai[1], B. Arver[1], H. Johansson[1], M. Wickman[2], K. Sandelin[2], Y. Brandberg[1]

[1]Oncology-Pathology, Karolinska Institutet, Stockholm, Sweden, [2]Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden

Background: Knowledge is lacking about partners' perception of women's body image problems and satisfaction of breast reconstruction long-term after risk-reducing mastectomy (RRM) with immediate breast reconstruction (IBR) due to increased risk of hereditary breast cancer.

Methods: Partners' contact information was provided by women participating in a prospective long-term follow-up after going though RRM and IBR 6–18 years ago. They received an information letter about the study and questionnaires to be completed/returned in a prepaid return envelope. The Hospital Anxiety and Depression scale and the Swedish Short Term-36 Health Survey (SF-36) were answered from the partners' perspective, and the Breast Reconstruction Questionnaire (EORTC QLQ-BRR26), the Body Image Scale, and the Sexuality Activity Questionnaire from partners' perception of the women's experience. Partners' responses were compared to the women's responses, and with the SF-36 in the normative Swedish population.

Results: Sixty partners' names were provided by the 146 (73%) women participating in the long-term follow-up study. Thirty-six (60%) partners participated in total. The partners' perception of the women's satisfaction with the IBR was lower than the

women's own perceptions, p = 0.0362. Partners also perceived that the women had more problems with body image than the women themselves, p = 0.0419. Partners scored the sexuality items 'Pleasure', 'Discomfort', and 'Habit' similarly as the women. Both partners and women had in general a higher level of HRQoL compared to the age-standardised normative Swedish population.

Conclusions: This is one of the first studies designed to investigate partners' long-term perception of women's perception of their body image, sexuality, and satisfaction with IBR. The results are important when counselling couples in the decision-making process considering RRM, and to identify areas in need of support where the health care providers can assist the couples in the post-operative setting.

1542P The effect of music on the instant anxiety levels of oncologic patients receiving chemotherapy treatment

A. Alacacioglu[1], G. Dissiz[2], S. iriz[2], A. Usluoglu[2], N. Asik[2]

[1]Medical Oncology, Ataturk Training and Research Hospital, Izmir Katip Celebi University, Izmir, Turkey, [2]Medical Oncology, Izmir Katip Celebi University, Izmir, Turkey

Background: This paper aims to determine instant anxiety levels of cancerous patients during treatment, as well as the factors involved, and establish the altering role of music on patients with high levels of anxiety.

Methods: This study was conducted on patients who received treatment at the outpatient chemotherapy unit. The patients were divided into two groups as the study and control group, and those patients who were aged between 18-65, diagnosed with breast cancer, operated and started adjuvant chemotherapy were included in the first course of treatment. In the study group, patients were provided with mp3 players with which they could listen to any music of their taste throughout the first course of chemotherapy treatment, which allowed them to listen to music. The individuals in the control group did not listen to music. The anxiety levels of all patients were determined before and right after chemotherapy by using the state-trait anxiety inventory part of the evaluation scale.

Results: Both groups included 49 patients; the mean age of the study group was 48.8 ± 10.9, and the mean age of the control group was 54.6 ± 11.3. 81.6% of the patients in the study group were married, %18.4 were single, the majority (61.2%) of them were primary school graduates, and 85.7% were housewives. In the control group, 73.5% of the patients were married, 26.5% were single, most of them (65.3%) were primary school graduates, and 87.8% were housewives. Administered prior to treatment, the STAI-I state-trait anxiety inventory score was 52.4 ± 11.3 in the control group and 50.4 ± 11.9 in the study group (p = 0.372). After the treatment, the STAI-I state-trait anxiety inventory score was 45.9 ± 11.2 in the control group, whereas it was 32.7 ± 7.7 in the study group (p = 0.0001).

Conclusions: A comparison of the pre-treatment state-trait anxiety levels of the patients included in the study and control groups revealed no significant difference. However, the patients in the study group who listened to music after the treatment presented significantly decreased anxiety levels.

1543P Ostracism in adolescent cancer patients and predictors (OSTRACA Study): A study of the palliative care working committee of the Turkish Oncology Group (TOG)

A. Alkan[1], Z.G. Güç[2], T. Şakalar[3], G. Zengin[4], A. Yaşar[5], Y. Karakas[6], T. Yavuzsen[7], O.B. Oksuzoglu[8], F. Çay Şenler[9]

[1]Medical Oncology, Osmaniye Public Hospital, Osmaniye, Turkey, [2]Medical Oncology, Dokuz Eylül University School of Medicine, Izmir, Turkey, [3]Medical Oncology, Erciyer University School of Medicine, Kayseri, Turkey, [4]Medical Oncology, Ankara Abdurrahman Yurtaslan Oncology Hospital, Ankara, Turkey, [5]Medical Oncology, Ankara University School of Medicine, Ankara, Turkey, [6]Medical Oncology, Hakkari Public Hospital, Hakkari, Turkey, [7]Medical Oncology, Dokuz Eylul University School of Medicine, Institute of Oncology, Izmir, Turkey, [8]Medical Oncology, Dr. Abdurrahman Yurtaslan Ankara Onkoloji Training and Research Hospital, Ankara, Turkey, [9]Medical Oncology, Ankara University School of Medicine, Istanbul, Turkey

Background: Ostracism is defined as being ignored or excluded by others. Being excluded during adolescence can result in various problem behaviors and emotional disturbances. The purpose of the study is to evaluate ostracism in adolescent cancer patients and define the predictors of it.

Methods: The study was conducted as a multicenter survey study. Adolescent cancer patients, who were under remission, were evaluated with structured questionnaires to assess the Ostracism and clinical parameters associated with it. Turkish version of Ostracism Experience Scale for Adolescents (OES-A) and Kutcher adolescent depression scale (KADS) were used.

Results: Between December 2017 and April 2018, 52 patients were evaluated in 4 different cancer centers. Median age was 21 (14-24), 40.4% of them were female and most of them were university student (23, 44.2%). Median OES-A score was 23.5(11.0-41.0). While female sex (28.0 vs 19.0, p = 0.008) and low family income (28.0 vs 21.0, p = 0.02) were associated with more ostracization; patients working full/part time (19.0 vs 25.0, p = 0.01) and university students (19.0 vs 27.0, p = 0.01) were less ostracized. In multivariate analysis, being female was associated with high OES-A scores (OR: 7.8, CI(95%) 1.4-42.9, p = 0.018). Being university student (OR: 0.14, , CI(95%) 0.02- 0.71, p = 0.018) and working (OR: 0.07 , CI(95%) 0.007- 0.7, p = 0.02) were associated with low OES-A scores(Table). Higher OES-A scores were associated with high KADS scores (9.0 vs 7.5, p = 0.16).

Table: 1543P

	High OES-A Score		
Characteristics	OR	CI (95%)	p
Female	7.8	1.4- 42.9	0.018
Low income	3.2	0.6-16.3	0.14
University student	0.14	0.02-0.71	0.018
Working	0.07	0.007- 0.7	0.02

Conclusions: It is the first data about ostracism in adolescent cancer patients. OES-A score was higher than the scores of adolescents without cancer. While female adolescent patients were found to be under risk of ostracism, working and being university student were protective against ostracism. Ostracism in adolescent cancer patients should be studied in larger series.

Background: The loss of cognitive functions is a symptom that impairs the quality of life .The aim of this study is to analyze cognitive functioning in cancer patients who initiate chemotherapy and to study the relationship between coping strategies and psychological distress.

Methods: NEOcoping is a national, multicenter, cross-sectional, prospective study of the Continuous Care Group of the Spanish Society of Medical Oncology conducted between January 2016 and January 2018 in 14 Medical Oncology departments in Spain. The population consisted of patients with histologically confirmed, non-advanced cancer treated with surgery for which international clinical guidelines considered that adjuvant treatment could be an option.The information was collected and updated by medical oncologists through a web-based platform (www.neocoping.es). Questionnaires for doctors and patients were filled out before starting adjuvant chemotherapy and at the end of the treatment. The applied tests were: Mini-Mental Adjustment to Cancer (Mini-MAC), EORTC core quality of life questionnaire (EORTC QLQ-C30, cognitive function scale), and Brief Symptom Inventory (BSI-18).

Results: Seven hundred and ninety-five patients were recruited. The median age was 58 years and 60% were women. Most were married or partnered (77%) and had a primary level of education (56%). The most common employment status was retired (59%). The primary tumor localization was mainly colorectal (41%) and breast (34%) and the stage was I-II (56%) or III (44%).The results indicate that patients who perceived their

physical condition or chemotherapy interfered with their cognitive functions had more anxious coping strategies characterized by constant preoccupation with the type of health, fear of cancer recurrence and this led to a search for frequent reaffirmation ($p = 0.008$). The cognitive function problems were negatively related with somatization ($p < 0.001$), depression ($p < 0.001$) and anxiety ($p < 0.001$).

Conclusions: The perception of impaired cognitive abilities and uncertainty about the prognosis of cancer can make it difficult for patients to adapt to their situation, deteriorate quality of life and increase emotional distress.

1545P Cancer stigma related to beliefs of patients and care providers

G.S. Bhattacharyya[1], H. Malhotra[2], G. Babu[3], A. Vora[4], S. Bhattacharyya[5]

[1]Medical Oncology, Salt Lake City Medical Centre, Kolkata, India, [2]Division of Medical Oncology, Birla Cancer Center, Jaipur, India, [3]Medical Oncology, HCG Curie Centre of Oncology & Kidwai Memorial Institute of Oncology, Bangalore, India, [4]Medical Oncology, Pratiksha Hospital, Gurugram, Haryana, India, [5]Palliative Care, Salt Lake City Medical Centre, Kolkata, India

Background: Stigma refers to distinctive, discrediting characteristics, rendering its bearer tainted by others and recognises difference and devaluation. Evidence suggests that cancer is a stigmatized disease. Cancer-related stigma is not documented in India, little is known about how it impacts health-seeking behavior, treatment adherence, quality of life and psychosocial wellbeing in cancer patients. Limited study has explored perceptions and cultural representations of cancer. This context specific information is essential for relevant, effective intervention.

Methods: This qualitative study was conducted in two districts Kolkata and North 24 Parganas of West Bengal, India, and included participants from a range of cultural and racial groups. Cancer patients over 18 years ($n = 300$) were recruited through Salt Lake City Medical Centre to participate. Six focus groups and 40 in depth interviews were conducted with cancer patients. Data collection focused on understanding patient experiences of cancer stigma, cognitive, emotional and behavioural responses to this, and inputs on interventions to address this. Six focus groups were also conducted with friends and non-related service providers, ($n = 240$) in order to explore cultural perceptions of cancer and reasons for stigmatization. Data were recorded and were authenticatedly translated and transcribed; and analysed by thematic analysis.

Results: Results indicated very poor knowledge of cancer in patients and care givers. Findings highlight the perception of cancer as a 'death sentence' and a punishment from providence, influencing patients' interactions with others in numerous ways. The influence of cultural beliefs was relevant, exacerbating stigma in some cases. The location of the cancer also played a role in determining level of stigmatization. Certain body parts (associated with masculine and feminine roles) as well as more visible cancers/side-effects were more stigmatised.

Conclusions: Stigmatization is a factor for cancer patients and is related to education and social background, increasing social isolation and negatively impacting quality of life. The implications of the findings for intervention development will be discussed. Education is needed but requires a different focus for different cultural groups.

1546P Relationship between depressive symptoms at social cognitive processing in partners of long term breast cancer survivors

G.S. Bhattacharyya[1], H. Malhotra[2], G. Babu[3], A. Vora[4], T. Shahid[5], S. Misra Ghosh[6]

[1]Medical Oncology, Salt Lake City Medical Centre, Kolkata, India, [2]Division of Medical Oncology, Birla Cancer Center, Jaipur, India, [3]Kidwai Memorial Institute of Oncology, HCG Curie Centre of Oncology, Bangalore, India, [4]Medical Oncology, Pratiksha Hospital, Gurugram, India, [5]Oncology, Apollo Gleneagles Cancer Hospital, Kolkata, India, [6]Psychiatry, Fortis Hospital, Kolkata, India

Background: The number of breast cancer survivors are increasing, so does the number of partners effected by the illness. An estimated 20-40% of spouses suffer from mood disturbance, anxiety and other effective disorders related to the spouses' illness. The survivor usually has a trend of decreasing levels of depression, but about 25% have long term depression. Studies have found relationship between survivor and spousal outcomes. Previous studies have shown decreased quality of life, loss of sleep, fatigue, decline in general health and increase in cardiovasular disease in among partners of survivors. Little is known of the mechanisms of this and there is very little data from developing countries like India.

Methods: 208 partners of breast cancer survivors (post operative, post chemo, and/or radiotherapy) diagnosed between 3 yrs to 10 yrs prior to study, were sampled. Secondary data mediations were conducted to determine, if cognitive processing mediated the relationship between social constraints and depressive symptoms. Age related difference on all stage were tested. Depressive symptoms; secondary variables including social constraints; cognitive processing and potential confounding variables were the main research variables.

Results: Cognitive processing, mediated the relationship between social constraints and depressive syptoms for partners. Partners of younger breast cancer patients and with lower education status had worst outcomes. Younger survivors reported more depressive symptoms, higher scores on intrusive thoughts and more social constraints.

Conclusions: As predicted by the social cognitive processing theory cognitive processing mediated relationship between social constraints and depressive syptoms. In addition, partners of younger breast cancer survors faced worst on social constraints, intrusive thoughts and depressive symptoms more. Results provide support for using social cognitive processing theory in an intervention design with partners of long term breast cancer survivors to decrease depressive symptoms; open communication on social constraints and discsussion of these negative psychological impacts would help. Education of spouse would be important.

1547P Evaluation of the distinction and temporal relationship between prolonged grief disorder and depression in terminally ill cancer patients' caregivers' first two years of bereavement

W-I. Tsai[1,6], S-C. Kuo[2], F-H. Wen[3], J-S. Chen[4], S.T. Tang[5]

[1]Graduate Institute of Clinical Medical Sciences, Chung Gung University, Taoyuan, Taiwan, [2]Nursing Department, Yuanpei University of Medical Technology, Hsinchu, Taiwan, [3]Department of International Business, Soochow University, Taipei, Taiwan, [4]School of Medicine, Chung Gung University, Taoyuan, Taiwan, [5]School of Nursing, Chung Gung University, Taoyuan, Taiwan, [6]Department of Nursing, Meiho University of Medical Technology, Pingtung, Taiwan

Background: Prolonged grief disorder (PGD) and depression are common emotional disorders influencing bereaved caregivers' quality of life (QOL). However, the conceptual distinctiveness and temporal relationship of PGD and depression have been partially and not established, respectively. To fill these knowledge gaps, we conducted this longitudinal study.

Methods: Our convenience sample included 291 caregivers of terminally ill cancer patients. Caregivers' PGD, depression, and psychological QOL were measured 6, 13, 18, and 24 months postloss using the Prolonged Grief-13 scale (PG-13), Center for Epidemiologic Studies-Depression (CESD) scale, and Short Form-36 Health Survey mental health summary, respectively. We examined the associations of PGD and depression with psychological QOL by an incremental validity test, thereby clarifying their conceptual distinctiveness. The temporal relationship between PGD and depression was examined by longitudinal, lower-level mediation analysis with a lagged approach.

Results: After the variance in psychological QOL was significantly explained by CESD scores (pseudo R^2=44.19%, p<.001), PGD significantly, incrementally increased the explained variance in psychological QOL (pseudo R^2=.21%, p<.001), confirming the distinction between PGD and depression. Lower-level mediation analysis showed that CESD scores (depressive symptoms) mediated 90% of the relationship between time and PG-13 scores, whereas PG-13 scores only mediated 76% of the relationship between time and CESD scores. This result indicates that CESD scores assessed at a previous time mediated caregivers' current PGD during bereavement rather than vice versa.

Conclusions: PGD and depression are conceptually distinct disorders, and depression precedes development of PGD. Clinicians must distinguish between the two disorders and appropriately manage bereaved caregivers' depressive symptoms. Alleviating caregivers' depressive symptoms will prevent development of PGD, thus improving QOL.

1548P Patients' and partners' views of treatment and care provided for metastatic castrate resistant prostate cancer (mCRPC) in the UK

S.L. Catt[1], L. Matthews[1], H. Payne[2], M.D. Mason[3], V. Jenkins[4]

[1]Sussex Health Outcomes Research & Education in Cancer (SHORE-C), Brighton and Sussex Medical School, University of Sussex, Brighton, UK, [2]Oncology, University College London Hospital NHS Foundation Trust, London, UK, [3]Velindre Cancer Centre, Velindre Hospital, Cardiff, UK, [4]SHORE-C, BSMS, Brighton, UK

Background: Appraisals of information needs, expectations and experiences of treatment in prostate cancer have highlighted the lack of relevant data in advanced disease. We report interview data from the EXperiences of TREatment and Quality Of Life of men with mCRPC study (EXTREQOL). It aimed to examine factors driving treatment decision-making from the perspectives of patients and healthcare professionals and gather data on the impact of treatments on quality of life (QOL).

Methods: A prospective longitudinal mixed-methods observational design was employed. This included semi-structure interviews conducted with patients and their partners, in-person or by phone, at baseline =within 14 days of starting a systemic treatment (any line) for mCRPC and after 3 months of treatment. Topics explored included experiences of treatment decisions, information provision, what assisted decision-making and how perceived benefits and harms of treatment affected patients' and families' lives.

Results: Thirty three men (56-89yrs) and their female partners (54-79yrs) from 15 UK centres participated. They believed treatment aimed to delay progression (>75%), improve QOL (33%), alleviate pain (≈12%) and extend life (15% -patients, 36% -partners). ≈50% made a joint treatment decision with the doctor and 39% had as long as they needed to decide. The worst symptom most frequently identified was pain (46% -patients, 33% -partners). At baseline and 3 months (50% and 67% respectively) did not need to discuss pain control, those that did received "very/fairly" useful information. At baseline fatigue, nausea/vomiting and diarrhoea were the worst anticipated or experienced side-effects (SEs). The worst SE at 3 months was fatigue, 33% experienced unexpected SEs and 52% sought help for SEs. 75% had helpful SE discussions, 85% received written information and internet searching about SEs was common (33% -patients, 55% -partners). Only 50% had opportunity to talk with a specialist nurse and 50% accessed other supportive services.

Conclusions: More help to manage pain and other symptoms is required. Dedicated clinics maybe warranted, better specialist nurse access and earlier palliative care links would help to optimise symptom control.

1549P Exploring the effectiveness of crisis counselling and psycho-education in relation to improving mental wellbeing, quality of life and treatment compliance of breast cancer patients in Qatar

R. Alsulaiman[1], S. Bujassoum[1], A. Bener[2], L. Doodson[3], S. Ghuloum[4], A. Lemaux[1], H. Bugrein[1], R. Alasaam[1], A. Karim[5]

[1]Medical Oncology, National Center for Cancer Care and Research, Doha, Qatar, [2]Department of Biostatistics & Medical Informatics, Istanbul University, Istanbul, Turkey, [3]Psychology and Counseling Studies, Regent's College, London, UK, [4]Department of Psychiatry, Hamad General Hospital, Doha, Qatar, [5]Psychology, National Center for Cancer Care and Research, Doha, Qatar

Background: Insufficient number of studies have been carried out in the Middle East to evaluate the role of structured psychotherapeutic interventions in breast cancer patients. This study has been designed to explore the benefit of two structured interventions 'crisis counselling' and 'psycho-education' in enhancing breast cancer patient's psychological well-being, quality of life and treatment compliance in Qatar.

Methods: A total of 201 women with early stage breast cancer from Qatar were recruited and randomised into either the control group or one of the treatment groups (crisis counseling or psycho-education). Each of the two treatment interventions consisted of a total of six 60-90 minute sessions, which were provided over a period of 12 weeks. The short- and long-term benefits of the crisis counselling and psycho-education interventions were evaluated in terms of improving patients' psychological well-being, quality of life and treatment compliance through DASS21 and QLQ-C30 instruments and by monitoring their compliance to chemotherapy and radiotherapy treatment.

Results: This study revealed that both of the study interventions 'crisis counseling' and 'psycho-education' were effective in improving women's psychological well-being and quality of life over time in comparison to the control group but had no significant impact on patients' compliance with treatment. In addition, the study showed that psycho-education conferred a greater advantage than did the crisis counselling model, especially on improving women's psychological well-being over time.

Conclusions: This study is considered the first of its kind in Qatar to provide evidence on the benefit of crisis counseling and psycho-education interventions in improving the psychological wellbeing and quality of women with early-stage breast cancer. In addition, this study has provided an innovative research that can be used as evidence to propose changes to the psychotherapy services for breast cancer patients in Qatar and which will hopefully lead to a better healthcare system for other cancer patients in the country.

1550P Pilot study of anxiety, depression, and quality of life in patients with the diagnosis of metastatic uveal melanoma

R. Nshimiyimana[1], C.E. Guzzetta[2], M-M. Brown[3], Q. Zhou[4], J.M. Johnson[1], T. Sato[1], S. Keith[5]

[1]Medical Oncology, Kimmel Cancer Center-Thomas Jefferson University, Philadelphia, PA, USA, [2]School of Nursing, The George Washington University, Washington DC, USA, [3]Nursing, MedStar Health, Columbia, OH, USA, [4]School of Nursing, Virginia Science and Technology Campus, The George Washington University, Ashburn, VA, USA, [5]Biostatistics, Thomas Jefferson University & Jefferson Health, Philadelphia, PA, USA

Background: Awareness of a patient's anxiety, depression, and quality of life (QOL) in those with metastatic uveal melanoma (MUM) can influence care that meets patients' bio-psycho-social-spiritual needs. Objectives: To measure the level of anxiety, depression, and QOL in MUM patients and explore differences by gender, age range, time to metastatic disease, and duration of illness since metastasis.

Methods: We used a descriptive-comparative design. From 9/1/2017 - 12/1/ 2017, a convenience sample of 70 MUM patients aged $\geq$ 18 years, treated at a Mid-Atlantic hospital were invited to complete a combined survey of the Hospital Anxiety and Depression Scale and the World Health Organization Quality of Life-BREF.

Results: There were 65 respondents (93% response rate). 30.8% ($n = 20$) had at least borderline anxiety, 13.8% ($n = 9$) had at least borderline depression, and 32.3% ($n = 21$) had a decrease in global QOL. Patients aged 18 to $\leq$ 60 years had a significantly higher anxiety score (7.52 ± 3.65; $p = 0.003$) and lower QOL in environmental health (32.48 ± 5.23; $p = 0.006$). There was a significant difference in anxiety scores by the duration of illness since metastasis (< 1 year [7.79 ± 3.72], >1 year to < 5 years [5.75 ± 3.45], > 5 years [3.70 ± 2.79]; $p = 0.01$). No differences were found by gender or time to metastatic disease.

Conclusions: Up to 30% of participants had at least borderline anxiety and a decreased global QOL while up to 10% had at least borderline depression. These findings support the integration of bio-psycho-social-spiritual practices in the care of MUM patients.

1551P Making sense of self-conscious and emotion: Linking theory of mind and emotion in women with breast cancer

P.G. Chaudhuri[1], A. Datta[2]

[1]Institute of Psychiatry, Kolkata, India, [2]Psychooncology, Netaji Subhas Chandra Bose Cancer Research Institute, Kolkata, India

Background: During the period of breast cancer's treatment, they had to face many physical and facial changes that make them self-conscious. Self-conscious emotions are just like embarrassment and shame that are correlated with 2 factors of the theory of mind (ToM): 1. the ability to understand that behavior has social consequences in the eyes of others and (b) an understanding of social norms violations. The present study aimed to link ToM with the recognition of self-conscious emotion.

Methods: We compared the performance of patients with breast cancer ($N = 61$) those who were diagnosed and were willing to undergo the psychological assessment, with no history of past psychiatric illness and with age and sex match healthy controls ($N = 19$) who are psychologically and physically stable using the widely used ToM task, Reading the Mind in the Eyes test (RMT). Facial expression, supplemented by clinical examination by experienced researchers.

Results: ToM was assessed with the breast cancer group performed significantly worse than the control group ($p < 0.05$). The present study reports that breast cancer patients have greater impairment in identifying self-conscious emotions compared to healthy control. The degree of impairment is midway in self-conscious emotion between patients with breast cancer and that of normal controls after statistically controlled ToM.

Conclusions: Therefore it can be said that the breast cancer patients suffering from self-conscious emotion may have an additional burden of impaired social cognition, which needs to be addressed urgently for the better quality of life.

1552P Characteristics of the psychosomatic state of patients with lung cancer

G. Zhukova[1], A.I. Shikhlyarova[1], E. Shirnina[1], M. Zinkovich[2], N. Maschenko[1], E. Zlatnik[2], S. Pyltsin[1], P. Anistratov[2], M.I. Bragina[1], A. Zhadobina[1], L.Y. Vladimirova[3]

[1]Testing Laboratory Center, Rostov Research Oncology Institute, Rostov-on-Don, Russian Federation, [2]Medical Oncology, Rostov Research Oncology Institute, Rostov-on-Don, Russian Federation, [3]Medical Department, Rostov Research Institute of Oncology, Rostov-on-Don, Russian Federation

Background: The important issue of psychophysiological adaptation to malignant process is poorly studied. The aim of the research was to elucidate characteristics of the psychic, adaptive and hormonal status of patients with lung cancer (LC).

Methods: Studies were performed in 28 LC patients with receiving surgery and chemo-radiotherapy. The patients were divided into 3 groups: 1 - unresectable tumors, 2 - resectable tumors with metastases, 3 - resectable tumors without detected metastases. Personal (PA) and situational anxiety (SA) (Spielberger-Khanin test), depression (Zung test), the types of the mental response to disease (LOBI, Bechterew Institute Personality Inventory) were evaluated. With the help of blood count and the original computer program "Antistress", we calculated the quantitative indicator (QI) of the general nonspecific adaptation reactions of the body (AR) (Garkavi L. H. et al., 1975). Hormone levels of thyroid and pituitary-adrenal (PAS) systems in the blood were determined by electrochemiluminescent method (Cobase 411E).

Results: The studied groups did not differ in PA and SA. The signs of tension of the PAS, elevated thyroxine level and decline in the adaptive status were noted. At the same time, QI of AR in patients of the group 3 was 1.8-2.7 times higher than in patients of other groups ($p < 0.05$). Depression was observed in only one patient. The euphoric type of response to the disease dominated in the groups (39% of cases), the harmonic type was the second most frequent (18% of cases). The patients of group 3 with euphoric reaction (referred to non-rational types of response) were characterized by an uncomplicated postoperative period and the maximal QI of AR in the studied groups, which exceeded by 2 times the indices in the patients of group 3 with harmonic and other reactions ($p < 0.01$).

Conclusions: QI of AR of patients with LC reflected the prevalence of the malignant process. In these patients depression was not expressed, and the euphoric reaction dominated. That could be due to central effects of thyroxin. We assumed that the euphoric reaction in the patients with resectable LC without detected metastases was a favorable diagnostic characteristic. So the questions arise about the clarification of the concept of the euphoric reaction and the ways of its identification.

1553P Perception, magnitude and implications of cancer related fatigue in breast cancer survivors: Study from a developing country

A. Gupta[1], S.M. Hussain[1], R. Manaktala[2]

[1]Medical Oncology, Max Institute of Cancer Care, New Delhi, India, [2]Breast Cancer Support Group, Max Institute of Cancer Care, New Delhi, India

Background: Cancer Related Fatigue(CRF) is one of the most common, distressing & incompletely addressed symptom among breast cancer survivors. We have analyzed perceptions, magnitude & overall implications of CRF in breast cancer survivors.

Methods: Breast cancer survivors who attended breast cancer follow-up clinic at our institute between Jan-March 2018 were asked to fill a questionnaire. This questionnaire focused on assessing an individual's perception, severity, potential causes, implications on quality of life and measures taken to deal with CRF.

Results: 65 patients (median age 52 years) completed the CRF questionnaire. Of these 54(83%) had undergone surgery, 59(91%) chemotherapy, 43(66%) radiation therapy and 36(55%) hormonal/targeted therapy. 62(95%) patients experienced any grade CRF. 55(85%) patients experienced moderate to severe CRF affecting work (58%) and activities of daily living (27%). CRF was perceived as generalized weakness by 54(83%), diminished concentration/attention span by 24(37%), decreased motivation and interest in usual activities by 29(45%) and emotional labiality by 16(25%) patients. 56(86%) patients believed that fatigue was due to the effect of cancer treatment on the body, while only 8(12%) attributed it to underlying cancer. 21(32%) also attributed it to psycho-social factors and 5(8%) to genetic/environmental factors. CRF had negative impact on mood, daily activities, interpersonal relationships and professional work in 40(62%), 39(60%), 13(20%) and 10(15%) patients, respectively. Measures taken to overcome CRF were increased physical exercise, psychosocial interventions, mind-body interventions and pharmacological interventions in 32(49%), 8(12%), 28(43) and 17(26%) patients, respectively. 39(60%) patients reported persistence of CRF after completion of treatment while it took upto 6 months, 6-12 months and more than 12 months for resolution of CRF in 13, 10 and 3 patients, respectively.

Conclusions: Development and persistence of moderate to severe intensity CRF impacts multiple aspects of Quality of Life of breast cancer survivors. Current interventions are not able to substantially mitigate this problem and further research in this field is warranted.

1554P Impact of cancer on the quality of life of Tunisian pediatric patients

F. Letaief-Ksontini[1], T. Dorra[1], S. Masmoudi[2], K. Meddeb[2], A. Mokrani[3], Y. Yahyaoui[2], A. Gabsi[1], M. Ayadi[3], N. Chraiet[3], H. Raies[2], A. Mezlini[3]

[1]Medecine, Institut Salah Azaïz, Tunis, Tunisia, [2]Medical Oncology, Salah Azaiez Institute of Cancer, Tunis, Tunisia, [3]Medical Oncology, Institut Salah Azaïz, Tunis, Tunisia

Background: The PedsQL (Pediatric Quality of Life Inventory) is an instrument which measures health-related quality of life (HRQOL) in children and young adults. The PedsQL 4.0 Generic Core Scales (GCS) are child self-report and parent proxy-report scales developed to be integrated with the PedsQL disease specific modules. The PedsQL 3.0 Cancer Module (CM) was designed to measure pediatric cancer specific HRQOL. The aim of this study was to evaluate the impact of their disease and its treatments on their physical, mental and social health.

Methods: This prospective study included 26 patients newly diagnosed and relapsed, on-treatment, from the pediatric ward of Salah Azaiez Institute. Their ages were 5 to 25 years-old. The 23-item PedsQL 4.0 GCS encompass 4 scales: physical, emotional, social, and school functioning. The cancer module scales has 27 items which encompasses 8 scales: pain and hurt, nausea, procedural anxiety, treatment anxiety, worry, cognitive problems, perceived physical appearance and communication. The format instructions, response scale and scoring method are identical for GCS and CM. The scores are between [0-100]. We translated the English version of the GCS and the CM into arabic.

Results: All the children completed their self-report .The mean age was 15.5 years-old.53.8% were boys.27.07% of patients had brain tumors, 19.2% osteosarcoma,19.2% Ewing sarcoma and 11.5%Undifferentiated nasopharyngeal cancer (UCNT). Twenty patients were newly diagnosed. Eight cases had metastatic disease.The child total GCS mean was 60.86 physical score mean 64.06 and social score mean 67.5. For the child total CM score mean, it was 61.53 ; pain score mean 75, nausea score mean 50 which is the lowest and the worry score mean 62.49 . We found that the nausea score is higher for children with intensive chemotherapy (p value=0.026). The parent proxy total GCS mean was lower than the childs score 58.69 as well as the total CM parent score mean which was 60.17. We didn't find significant difference between the age of the patient, staging of his disease and the pedsQL scores.

Conclusions: The HRQL of children is adversely affected as a result of the uncontrolled symptoms from cancer treatment. In Tunisia, we should work more to improve the pediatric HRQL.

1569P The impact of primary care access on mortality in lung cancer patients from Bronx, New York

C. Su[1], H. Cheng[2]

[1]Department of Oncology, NYU Langone Medical Center, New York, NY, USA, [2]Microbiology and Immunology, Montefiore Medical Center Albert Einstein College of Medicine, Bronx, NY, USA

Background: Racial and ethnic disparities in cancer care are well described. Lack of access to primary care physicians (PCPs) may be an important contributor to disparities attributed to race and ethnicity. This study examined the effects of primary care access on mortality in lung cancer (LC) patients (pts) in an underserved community.

Methods: Medical records of all pts newly-diagnosed with primary lung cancer between 2012-2016 at a NCI-designated cancer center in the Bronx were reviewed. Demographic data and PCP status were collected. Addresses were correlated with the Health Resources and Services Administration (HRSA) database to identify residences located in primary care shortage areas (PCSAs). Survival data from time of first imaging to death or the end of follow-up on January 1, 2018 were recorded. Data analysis was performed via univariate methods. Survival analysis was performed using Kaplan-Meier and Cox hazards modeling.

Results: Among 1062 pts, 874 (82%) resided in a PCSA, 314 (30%) were Hispanic (H), and 445 (42%) were African-American (AA). Hs and AAs were more likely to reside in PCSAs ($p = 0.0002$ and $p = 0.0008$) and in ZIP codes with lower income (both $p < 0.0001$). Hs and AAs were more likely to depend on public insurance ($p = 0.01$ and $p = 0.02$). Pts who live in PCSAs presented at higher stages at the time of diagnosis ($p = 0.03$) and were diagnosed predominantly in inpatient settings with acute symptoms ($p < 0.0001$) rather than outpatient clinics ($p = 0.0002$). In the overall population, PCSA residence (mean: 24 vs. 30 months, $p = 0.03$, HR = 1.27) and no established PCP (mean: 22 vs. 28 months, $p < 0.0001$, HR = 1.50) were associated with increased all-cause mortality. In Cox modeling adjusting for stage at diagnosis and PCSA residence, lack of established PCP still predicts increased mortality ($p = 0.03$, HR = 1.20).

Conclusions: Among new pts with LC, lack of established PCP is associated with increased mortality. Hs and AAs are more likely to reside in PCSAs, suggesting the link between increased mortality and race/ethnicity may be mediated by lack of access to primary care. Our results demonstrate that effective health policy efforts to reduce lung cancer mortality must include approaches to improve access to primary care.

1570P Are socioeconomic position and region of residence barriers for referral to phase I trials?

K.T. Gad[1], S.O. Dalton[2], A.K. Duun-Henriksen[2], A. Krøyer[2], C. Johansen[1], M. Mau-Sorensen[1], U.N. Lassen[1]

[1]Department of Oncology, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark, [2]Unit of Survivorship, Danish Cancer Society Research Center, Copenhagen, Denmark

Background: Referral pattern to phase 1 oncology trials is a highly relevant topic as the rapid development of new anticancer agents requires increased recruitment to early clinical trials. In this study, we investigated possible recruitment bias. The objective was to compare the socioeconomic position (SEP) and region of residence of patients referred to the Phase 1 Unit at Copenhagen University Hospital to a matched control group. Moreover, we investigated the influence of SEP on the inclusion in trials.

Methods: Data from the Danish registries were compiled based on the civil registration number of patients referred to the Phase I Unit from 2005 to 2016. The association between SEP and referral was examined in a conditional logistic regression analysis based on referred patients and a matched control group. We adjusted for number of cancers, M-stage, comorbidity and psychological disturbances. The association between SEP and enrolment once referred was examined in a Cox regression analysis.

Results: 1255 patients were referred. 1143 of these patients were eligible for this study. Complete data for analyses were available for 1026 patients and 229,788 controls matched on age, gender, type of cancer, year of diagnosis and time from diagnosis to referral. As barriers for referral, we identified short education as compared to long (OR 0.57, 95% CI 0.47-0.69), being outside workforce as compared to being within (OR 0.67, 95% CI 0.56-0.80), living alone as compared to living with a partner (OR 0.85, 95% CI 0.74-0.99) and living far from the Phase 1 Unit 0.34 as compared to living close to (95% CI 0.29-0.40). 252 patients enrolled in trials. Once referred, the socioeconomic parameters did not affect enrolment.

Conclusions: In this single-center study, patients' SEP and region of residence affected referral pattern to phase 1 trials. This suggests inequality in the access to phase 1 trials.

1571P Breast cancer treatment waiting time, patient and provider contributions: An Egyptian breast cancer centre experience

A.H. Abdelaziz[1], A.M. Abdou[1], C.N. Habeeb[2]

[1]Clinical Oncology, Ain Shams University Hospital, Cairo, Egypt, [2]Medical Oncology, Baheya Foundation for Breast Cancer, Cairo, Egypt

Background: Breast cancer is the most common type of female cancer in Egypt and world wide. Most of the cases present as locally advanced or metastatic rather than early stages in Egypt. There is no data to assess waiting times in the Egyptian breast cancer patient journey from developing first symptom until initiating treatment.

Methods: This is a descriptive study in which the electronic records and paper notes of 200 patients presenting from April until September 2016 to a public non governmental breast cancer centre in Cairo were reviewed for different waiting times. The wait time from developing the first symptom until commencing treatment was divided into stages; Symptom to call (booking an appointment), call to review , review to diagnosis, diagnosis to multidisciplinary team meeting (MDT) and MDT to first therapy.

Results: The average time from developing symptom to booking an appointment (patient factor) was 131 days /4.4 months. The time lag from booking until medical review was 47 days /1.5 months. This is because of the booking system waiting list. The mean time taken from review until getting a final diagnosis was 11 days. All cases were discussed in the MDT and therapy ensued the MDT by 17 days in average. The mean in hospital waiting time (time from review until commencing treatment whether surgery, systemic therapy or radiotherapy) was 37 days while the mean time for the whole journey (symptom to treatment) was 214 days /7.1 months. Patients contributed to 61% of the wait time (131 days / 4.4 months) whereas the provider contributed by 39 % with average of less than 3 months.

Conclusions: Patients contributed to the biggest part of the delay. The second factor was the booking system waiting list. Once reviewed by the medical team the process was accelerated. This indicates a need to improve public awareness of breast cancer symptoms and facilitate patient access to services.

1572P Is age a barrier to chemotherapy? Rates of treatment in older patients with breast, colon or lung cancer in England in 2014: A national registry study

N.M.L. Battisti[1], M. Wallington[2], A. Ring[1], S. Payne[3], R. Birch[4], M. Bomb[5], J. Seligmann[6], T. Kalsi[7], L. Hounsome[2], D. Dodwell[8], S. Underhill[9], L. Mensah[10], E. Morris[4], P.J. Selby[6], J. Mansi[3]

[1]Breast Unit, The Royal Marsden NHS Foundation Trust, Sutton, UK, [2]National Cancer Registration and Analysis Service, Public Health England, London, UK, [3]Medical Oncology, Guy's and St Thomas' NHS Foundation Trust, London, UK, [4]Cancer Epidemiology Group, University of Leeds, Leeds, UK, [5]Data Projects, Public Health England, London, UK, [6]Oncology, St. James's University Hospital Leeds, Leeds, Yorkshire, UK, [7]Guy's and St Thomas' NHS Foundation Trust, London, UK, [8]Institute of Oncology, Leeds Teaching Hospitals NHS Trust, Leeds, UK, [9]Regional Programmes, Roche, London, UK, [10]Health Economics and Outcomes Research, Novartis Oncology, London, UK

Background: Survival from cancer in older patients is poorer in the UK than other countries with similar health systems and wealth possibly due to undertreatment and increased toxicities in this specific population. This population-based observational study describes factors affecting systemic anticancer treatment (SACT) use in older patients in England.

Methods: We identified patients aged ≥70 with stage II-III breast cancer, stage III colon cancer and stage IIIB-IV non-small cell lung cancer (NSCLC) diagnosed in 2014 from a dataset collected by the National Health Service in England. We used logistic regression to estimate factors affecting likelihood of receiving SACT and performed separate regression analyses for each disease, adjusting for age, gender, stage at diagnosis, pathological features, performance status, Charlson comorbidity index, ethnicity and socioeconomic group. We assessed 2-year overall survival (OS) using Kaplan-Meier method. Case mix adjusted treatment rates and workload volume were calculated at hospital level and presented using funnel plots, stratified by age groups (<70 and ≥70) to allow for assessment of variation between centres.

Results: 36892 patients were identified: 19879 with stage II-III breast cancer, 5292 with stage III colon cancer and 11721 with stage IIIB-IV NSCLC. Patients over 70 were less likely to receive SACT compared to those aged under 70: breast 11.7% vs 64.6%, $p < 0.001$; colon 37.4% vs 79%, $p < 0.001$; NSCLC 33.5% vs 60.2%, $p < 0.001$. 2-year OS for patients receiving SACT was similar for patients aged ≥70 and <70: breast 91.5% (95% CI: 89.3%-93.2%) vs 96.4% (95% CI: 95.9%-96.7%); colon 84.8% (95% CI: 82.6%-86.8%) vs 88.3% (95% CI: 86.7%-89.8%); NSCLC 16.7% (95% CI: 15.1%-18.4%) vs 19.8% (95%CI: 18.5%-21.1%). Patients receiving SACT had better OS than those untreated. SACT rates varied widely between hospitals after adjusting for case-mix across all ages.

Conclusions: Our study suggests that several factors affect the likelihood of receiving SACT but after adjusting for these, age remains determinant. Identifying hospitals with significantly lower SACT rates should prompt local review of multidisciplinary team practice.

1573P Awareness and attitude towards breast cancer among Egyptian nurses at university affiliated hospitals: Tanta University Hospitals experience

M.A. Alm El-Din, S.E. Amer, M.A. Elsayed, A.M. Elgohary, A. Ismael, A. Zakzouk, K.M. Emara, F. Elkady, S. Elnahrawy, F. Nada, A. Eissa

Clinical Oncology, Tanta University Hospital, Tanta Faculty of Medicine, Tanta, Egypt

Background: Breast cancer (BC) is the most common cancer among women. In Egypt, BC accounts for 38% of all types of cancer in females with the majority often present at advanced stages. This might be attributed to defective health education programs and poor awareness. The aim of this study is to evaluate the knowledge, attitude and practice of Egyptian nurses at Tanta university hospitals towards BC.

Methods: 421 female nurses from Tanta university hospitals completed a questionnaire that administred through face-to-face interviews by medical students and interns. The questionnaire included five sections: sociodemographic data, knowledge about BC symptoms, risk factors, screenings methods and treatment of BC.

Results: Mean knowledge score was 18.75 ± 5.76 with 57.2% of participants knew the right answers of more than 50% of the questions. The least level of knowledge was in questions related to BC symptoms and risk factors with 60.3% and 52.2% , respectively, of participants had scores of < 50% of the total score. The knowledge for nurses aged 30-39 years-old, those from urban areas and those who have years of work experience ranged between 16 and 25 years had statistically lower levels of knowledge compared to other groups (p value, 0.035, 0.048, 0.005, respectively).

Conclusions: The level of BC knowledge among Tanta university hospitals nursing staff is fair. The Knowledge about BC symptoms and risk factors needs more attention from health care authorities to specifically design educational programs focusing on these areas.

1574P Women oncologists participation at the Spanish Society of Medical Oncology (SEOM) annual meetings from 2009 to 2017 and their position in Spanish scientific societies

J. Hidalgo Coloma[1], A. Ruiz Hernández[2]

[1]Medical Oncology, Hospital Lluís Alcanyís, Xàtiva, Spain, [2]Internal Medicine, Hospital Clínico Universitario, Valencia, Spain

Background: Medical Oncology is a feminized profession in Spain. According to SEOM, 57,6% of the medical oncologists in this country are women. This situation will remain unchanged because women occupied 67% of the medical oncology training positions since 2008. However, women are underrepresented in leadership possitions, which may influence their career development.

Methods: We reviewed the participation, role and gender distribution of 2110 professionals at SEOM annual meetings between 2009-2017, the possition of the 237 members of SEOM executive boards (1976-2017) and the 355 members of the current executive boards of 13 of the most important Spanish cooperative groups.

Results: From 2009 to 2017 the 38,4% of the 2110 speakers at SEOM meetings were women. There wasńt a progressing increase over the years. The only year with >40% of female participation was 2017 (42,4%). At educational and clinical sessions, 26% of chairs and 35% of speakers were women. At original presentations sessions, 57% of presenters, 42% of discusors and 30% of chairs were women. At the plenary sessions, 50% of presenters, 17% of discusors and 5% of chairs were women. 31% of members of scientific committees were women; they chaired these panels in 22% of cases. Over the last decade, SEOM awarded 122 research grants, 42% of them to women. The SEOM executive board has been chaired 18 times by a man and 2 by a woman. The first female president was elected in 2011. There were no women at executive boards until 1987. Women occupied 17,3% of the possitions. Currently, 40% of the executive boards members and 2 of the 13 cooperative groups chairs are women.

Conclusions: Spanish women oncologists developed an active cientific activity in their everyday practice and communicated their research data at national meetings. However they were asked to chair or share their expertise in fewer occasions than men. In addition, women were underrepresented at executive boards of the main oncology scientific groups. According to our results, we consider further efforts are required to achieve gender equality. A good example are initiatives like the ESMO Women for Oncology (W4O) network, the Forum of Women in Oncology in Greece or W4O Italy.

1575P Working arrangements after cancer diagnosis: Who, what, when and how?

C. Alleaume, A-D. Bouhnik, M.K. Bendiane, P. Peretti-Watel

Faculté de Médecine, Aix Marseille Univ, INSERM, IRD, Economics and Social Sciences Applied to Health & Analysis of Medical Information (SESSTIM), Marseille, France

Background: Each year, 355,000 new individuals are diagnosed with cancer in France, nearly half of them being in working age and interrupting their professional occupation during treatments. As having working arrangements has been found to facilitate return to work after a long absence, it is provided by French law. This study aims to describe the use of working arrangements and to investigate how it is related to job retention.

Methods: This study combines analyses of quantitative and qualitative data: 1) VICAN5, a national representative survey on living conditions 5 years after cancer diagnosis conducted in 2015-2016 (n = 4,174), and 2) CAREMAJOB, a qualitative longitudinal study carried out in 2017 among patients on sick leave after a cancer diagnosis and interviewed about the impact of the disease on their working lives (n = 21). VICAN5 survey presents an overview about the use of working arrangements in France and the CAREMAJOB survey completes these results by giving the patients' point of view in a more comprehensive manner.

Results: Among the 1,854 cancer survivors aged between 23 and 59 at time of the VICAN survey, and who were employed at diagnosis, 62.7% used working arrangement(s) within the five years following diagnosis. Nearly half of them (45.5%) had a working time arrangement. The other kind of working changes were about working hours (38.8%), working conditions (35.8%), occupation (32.8%), workplace (20.4%), and security at work (19.2%). Moreover, working arrangements are associated with job retention (88.9% of workers with working arrangement were still employed five years after diagnosis versus 69.6% of others). Furthermore, in CAREMAJOB survey, when patient returned to work without any working arrangement, this led to bad experience because of workload. However, some of those who did have an arrangement reported a negative impact on their professional life: they felt discriminated or thought that it has affected their professional credibility.

Conclusions: In the French context, the use of working arrangement seems to be a good factor to enhance job retention. National surveys should however better take into account the context of the implementation of working arrangement to get better understanding of the potential selection bias.

1577P Financial burden and financial toxicity in patients with colorectal, gastro-oesophageal, and pancreatobiliary cancers: A UK study

N. Flaum[1], G. Papaxoinis[1], K. Hockenhull[1], J. Barriuso[2], W. Mansoor[1]

[1]Medical Oncology, The Christie NHS Foundation Trust, Manchester, UK, [2]Division of Cancer Sciences, University of Manchester / The Christie NHS Foundation Trust, Manchester, UK

Background: How cancer affects a patient (pt) in the UK financially and how this changes throughout treatment is unknown. We aimed to assess financial burden (FB) at baseline and financial toxicity (FT) throughout treatment of pts with upper GI (UGI), pancreatobiliary (PB) and colorectal (CR) cancers.

Methods: Pts with UGI, CR and PB cancer enrolled in 5 clinical trials (REAL-3, RAINFALL, ESPAC-4, QoL BIL and CAPITAL) at the Christie, Manchester, were identified. FB at baseline and FT throughout treatment were defined according to answers to the EORTC QLQ-C30 questionnaire (EQ) Q28 to which pts score financial difficulty relating to disease or treatment from 1 (not at all) to 4 (very much).

Results: 141 pts were included, 58 (41.1%) received adjuvant and 83 (58%) palliative treatment. 96 (68.1%) were men; median age was 62 yrs (range 39-84). 15 (10.6%) pts had CR, 85 (60.3%) PB and 41 (29.1%) UGI cancer. 87 (61.7%) had no FB (scored 1 on EQ), 35 (24.8%) scored 2, 12 (8.5%) scored 3 and 7 (5%) scored 4. 97 (68.8%) answered $\geq$2 EQs. Median EQ follow up was 6.3 months (range 0.5-63.1). 63.5% experienced no FT, 19.8% worse FT and 16.7% improving FT. The median index of multiple deprivation (IMD) (the measure of relative deprivation of English regions) was 16,083 (range 3-32,041). Multiple regression analysis showed that younger age, lower IMD and tumor type were independent predictors of FB. Significant covariates included IMD below vs. above median (OR 2.64, 95%CI 1.13-6.15, $p = 0.024$) and age below vs. above median (OR 7.83, 95%CI 3.23-18.94, $P < 0.001$). Of these, no factor predicted FT. Pts who experienced FT were significantly younger compared to those who did not (median age 55 vs. 69, $p < 0.001$) and had significantly lower IMD (median 9,483.5 vs. 19,277, $p = 0.002$). IMD in our series did not show significant interaction with age ($p = 0.270$). Palliative treatment and lower IMD were independent predictors of worse overall survival.

Conclusions: We report the first study of FB and FT in pts with UGI, PB and CR cancers living in UK, identifying independent baseline parameters predicting FB and the prognostic role of IMD. Younger pts and those of lower IMD are at significantly higher risk and should be offered additional support.

Background: Seasonal influenza vaccination is recommended for cancer patients despite concerns that disease- or treatment-associated immunosuppression may decrease vaccine effectiveness (VE). The objective of this study was to evaluate VE against laboratory-confirmed influenza among cancer patients.

Methods: We conducted an observational test-negative design study of previously diagnosed cancer patients aged $\geq$18 years who were tested for influenza during the 2010-11 to 2015-16 influenza seasons in Ontario, Canada. We linked individual-level cancer registry, respiratory virus testing, and health administrative data. Vaccination status was determined from physician and pharmacist billing claims. We used multivariable logistic regression to estimate VE, adjusting for age, sex, rurality, neighborhood income, cancer characteristics, chemotherapy exposure, comorbidities, previous healthcare use, influenza season, and calendar time of testing.

Results: We identified 24,668 cancer patients who underwent influenza testing, with 3991 (16%) testing positive and 10,929 (44%) vaccinated. Mean age was 70 years, 52% were male, mean time since cancer diagnosis was 6 years, 79% had a solid tumor malignancy, and 24% were receiving active chemotherapy. The overall adjusted VE (aVE) against laboratory-confirmed influenza was 21% (95%CI, 15%, 27%). The aVE among patients with a solid tumour malignancy was 25% (95%CI, 19%, 31%) as compared with –2% (95%CI, –20%, 14%) amongst patients with a hematologic malignancy (p-value for interaction <0.01). The aVE among patients receiving active chemotherapy was 9% (95%CI, –7%, 23%), compared with 23% (95%CI, 17%, 29%) among patients not on active chemotherapy (p-value for interaction=0.13).

Conclusions: Our results support recommendations for influenza vaccination among cancer patients and survivors. Influenza vaccination appears to be less effective among those undergoing active chemotherapy and we observed uncertain effectiveness among hematologic cancer patients. Strategies to improve VE and influenza vaccine uptake among cancer patients and their families are warranted.

1580P How advanced lung cancer patients are really treated at the population level? The Ontario, Canada experience

W.K. Evans[1], W. Flanagan[2], C. Gauvreau[3], P. Manivong[4], S. Memon[3], N. Fitzgerald[3], J. Goffin[5], R. Garner[2], E. Khoo[4], N. Mittmann[4]

[1]Oncology, McMaster University, Hamilton, ON, Canada, [2]Health Analysis, Statistics Canada, Ottawa, ON, Canada, [3]Health Economics, Candian Partnership Against Cancer, Toronto, ON, Canada, [4]Biostatistics, Cancer Care Ontario, Toronto, ON, Canada, [5]Medical Oncology, Juravinski Cancer Centre, Hamilton, ON, Canada

Background: Clinical trials define treatment recommendations but patients in the real world may be unable or unwilling to undergo treatments with demonstrated efficacy in fit patients. The Canadian Partnership Against Cancer has developed a model of lung cancer (LC) management (OncoSim-lung) in 2008 based on clinical trials data and expert advice. To credibly project the future clinical and economic impacts of cancer control measures using OncoSim, the model has been refined using real-world data.

Methods: Treatment data by histology and stage were extracted from the Ontario Cancer Registry for LC cohorts diagnosed in 2010 and 2013. All incident cases that satisfied the IARC rule of a new primary were included. Missing or unknown stage cases were excluded. Clinical pathways were validated by oncologists from different disciplines across Canada.

Results: The 2013 cohort included 8,086 staged LC: NSCLC ($n = 7,143$) Stage I 18.7%, II 8%, III/IIIa 11.4%, IIIb 4.9% IV 56.8%; SCLC ($n = 943$) limited 67.7%, extensive 32.3%. Of 813 stage III/IIIa patients, only 26% underwent surgery, 41% of whom received adjuvant chemotherapy or postoperative radical radiotherapy (16%); 13% received trimodality treatment. Of the 75% of Stage III not receiving surgery, 26% had NAT and 21% had palliative radiotherapy alone. Of those receiving active treatment, 20% received combined chemo +radiotherapy and 13% each had chemotherapy alone or radical radiotherapy alone. Of 356 stage IIIb patients, 17% had NAT, 28% received palliative radiotherapy and only 30% had chemo + radical radiotherapy. 18% had chemo alone. Of 4055 stage IV NSCLC, 47% had NAT, 24% received chemotherapy alone and 23% had palliative radiotherapy only. Of those who received first-line chemotherapy ($n = 1059$), 47% received second line chemotherapy and of those, 37% received third line therapy.

Conclusions: Compared to prior expert opinion, there was a much lower frequency of chemo-radiotherapy in Stage III disease and a higher frequency of NAT across all stages of disease. The updated OncoSim model will now have a credible real-world base from which the impacts of new treatment interventions on survival and budget impact can be better estimated.

1581P Anticoagulant treatment of patients (pts) with cancer associated thromboembolism (CAT) in Germany: Real world data from a 4 million people sample generated by insurance captured data

A. Kretzschmar[1], M. May[2], A. Heinken[3], H. Riess[4]

[1]Oncology, Klinikum St. Georg gGmbH, Leipzig, Germany, [2]Research, HGC Healthcare Consultants GmbH, Dusseldorf, Germany, [3]Research, Aspen Germany GmbH, Munich, Germany, [4]Oncology, Charite Berlin Mitte, Berlin, Germany

Background: CAT is a common complication of cancer with impact on overall prognosis. After 2003 low molecular weight heparin (LMWH) instead of vitamin K antagonists (VKA) became guideline recommended treatment. Direct oral anticoagulant drugs (DOAC) were investigated in CAT only recently. Little data is available concerning incidence and current treatment situation in Germany.

Methods: Data on drugs and coding of diagnosis for all continuously insured members of SHI were available. An anonymized health claims database (2011-2016) of German SHI was used for a retrospective analysis. With a wash out period of one year patients with preexisting conditions were eliminated. According to our definition pts with CAT had a new a cancer diagnosis and a new VTE diagnosis and a prescrition of any type of anticoagulant. Anticoagulant drug type and duration in CAT pts during the next year was analyzed and then classified according to their dominant (> 51 % of time) anticoagulant drug. Any coded bleeding diagnosis was captured as well. The study has descriptive character.

Results: Out of a sample of > 4 million MSHI which is 5,5 % of the German SHI population 322,600 tumor pts and 13,131 (4%) pts with initial VTE diagnosis were identified. 25% of them had no prescription of any anticoagulant. According to the definition 7,313 were CAT. Dominant anticoagulant was LMWH in 58% VKA in 24%, and DOAC in 18%, respectively. During prescription of anticoagulation approx. 20% of all pts with CAT suffered from bleedings with no significant differences between agents (LMWH, DOAC, VKA). The individual LMWH type (approved for secondary prophylaxis or not) and switch of therapy were analyzed as well.

Conclusions: Out of 7,313 pts with CAT more than half received secondary prophylaxis of VTE with LMWH in accordance with the German guideline. VKA (probably suboptimal choice) as well as DOAC (no data published before 2017) were used in a clinically relevant subset. Bleeding was comparable in different agents of anticoagulation. As compared to available small market research studies our data set offers more reliable information due to its comprehensive character. This has impact on future guidelines and education.

1582P Age distribution for different types of cancer in the United States (1996-2015)

M.A. Gouda

Department of Clinical Oncology, Faculty of Medicine - Menoufia University, Shebin El Kom, Menoufia Governorate, Egypt

Background: There has been an increasing concern about the changing incidence patterns of some types of cancers including age at diagnosis. While there is at least some evidence that some cancers currently occur at age earlier than that expected based on historical data, we still lack evidence about age trends in most types of cancers. This study aims to explore current age distributions for different types of malignancies in the United States based on data from SEER.

Methods: Data were obtained using SEER*Stat version 8.3.5, where (SEER 18 Regs Nov 2017 Submission) database was used as the data source. Only cases diagnosed between 1996-2015 with malignant behavior, known age, and microscopic confirmation were included. Data were exported using the case listing session and were analyzed using SPSS version 21.

Results: Median age at diagnosis was significantly higher in the period between 2006-2015 than in the period 1996-2005 for most types of cancers. GIT malignancies and CML, however, showed an exception with a significantly younger median age of diagnosis. The table shows age distribution as well as median age for some common types of cancers including comparison between cases in the 1996-2005 and 2006-2015 time periods.

Conclusions: Except for GIT malignancies and CML, cancer is still being diagnosed at higher median age. With few exceptions, patients who are over 55 years old are still constituting the vast majority of cases.

1583P Patient reported stressors in the practical domain of a cancer diagnosis: The impact of socioeconomic status and geographic location

C. Ho[1], B. Leung[1], H. Rennie[2], J. Laskin[1], J. Wu[3], A. Bates[2]

[1]Medical Oncology, BC Cancer, Vancouver, BC, Canada, [2]Psychosocial Oncology, BC Cancer, Vancouver, BC, Canada, [3]Radiation Oncology, BC Cancer, Vancouver, BC, Canada

Background: Socioeconomic status (SES) and geographic location may influence access to cancer care. In the Canadian health care system, cancer care is publically funded however, other factors including workplace absences and travel for treatment can be additional stressors. We aimed to assess patient reported distress in the practical aspects of accessing cancer treatment in relation to their SES and community size.

Methods: BC Cancer provides cancer care to a population of 4.6 million dispersed over 944, 735 km^2. All patients referred to BC Cancer from 2011 – 2016 who completed the Psychosocial Screen for Cancer (PSSCAN-R) within 6 months of cancer diagnosis were included in the study. Baseline characteristics were collected from the BC Cancer

Table: 1582P

	Median Age (in years)			Number and Percentage of Cases in Different Age Groups (1996-2015)							
				< 18 years		18-35 years		ears		> 55 years	
	1996-2015	1996-2005	2006-2015	N	%	N	%	N	%	N	%
CML	65	66 *	64	476	1.9%	2310	9.0%	6033	23.6%	16781	65.6%
NHL	67	66	67	4135	1.4%	13792	4.7%	61630	21.1%	212389	72.7%
HD	38	37	39 *	3501	8.6%	15123	37.3%	11242	27.8%	10638	26.3%
Lung Cancer	70	70	70	116	.0%	2571	.3%	100142	12.0%	731999	87.7%
Breast Cancer	61	61	62 *	11	.0%	23824	2.3%	340441	33.4%	655907	64.3%

Gonadal Cancer	63	63	63	97	.1%	2887	3.2%	26422	29.1%	61458	67.6%
Cervical and Uterine Cancer	60	59	60 *	22	.0%	13937	5.7%	77435	31.9%	151283	62.3%
Colorectal Cancer	69	71 *	67	338	.0%	10166	1.5%	133171	19.2%	550771	79.3%
Stomach Cancer	70	71 *	69	36	.0%	1952	1.8%	18304	17.3%	85274	80.8%
Liver Cancer	64	65 *	63	208	.2%	1100	1.0%	23862	22.0%	83175	76.8%
Pancreatic Cancer	70	71 *	69	58	.0%	998	.6%	22136	14.1%	134330	85.3%

*Significantly higher median age.

registry. The Canadian Postal Code Conversion File Plus (PCCF+) was used to link the patients' postal codes with standard 2011 census geographic areas and neighbourhood income quintiles. Chi squared test was used for comparisons.

Results: 48,954 patients completed the PSSCAN-R and 45 164 had PCCF+ data available. Baseline characteristics: median age 66, 55% female, 17% presented with metastatic disease. Tumor distribution: 22% breast, 19% GI, 13% GU, 13% lung and 33% other. Income quintiles were grouped into lowest/mid-lower, middle, mid-higher/highest. Community size: >1.5M 53%, 1.5M – 10K 17%, <10K 30%. Patients in lowest/mid-lower compared to mid-higher/highest income groups reported more distress around finances (19% vs 14.1%), getting to appointments (15.3% vs 9.7%) and accommodations during treatment (5.6% vs 3.8%). Concerns regarding school/work were similar (10.5% vs 10.9%). Patients in rural versus large communities (1.5M+) reported more distress around finances (19% vs 15.1%), getting to appointments (15% vs 11.9%), accommodations during treatment (9.7% vs 2.7%) and less distress around school/work (9.7% vs 11.8%).

Conclusions: Lower SES and rural geographic location are associated with higher levels of cancer patient distress in the practical domain, despite a publically funded medical system. Local navigational support services for workplace and income assistance should be developed to alleviate distress for patients in rural areas or with low income.

1584P Overview on the use of patient reported outcomes in colorectal cancer care

L. Neamtiu[1], S. Deandrea[2], Z. Saz Parkinson[1], L. Pylkkanen[3]

[1]Health in Society, JRC - ISPRA, Ispra, Varese, Italy, [2]Medical Department, ATS Milano, Milan, Italy, [3]Medical Department, Finnish Medicines Agency Fimea, Turku, Finland

Background: The burden of colorectal cancer is high in Europe and still increasing. The disease and treatment can have profound impacts on the patients quality of life (QoL), emphasizing the importance of measuring QoL. An important tool in this process is Patient Reported Outcome Measures (PROMs). The goal of this study is to give an overview on the use of PROMs throughout the colorectal cancer care pathway in Europe.

Methods: Studies were searched via Pubmed until end of April 2018 regarding the development, validation and use of PROMs in colorectal cancer , focusing on the whole care pathway, i.e., screening, diagnosis, treatment, rehabilitation, follow-up, and palliative care. Only studies conducted in Europe, with at least an abstract in English were included.

Results: In total, 49 studies and 7 systematic reviews were analysed. Thirty-six studies evaluated PROMs in clinical trial settings, while 20 focused on screening and patient management. Most of the studies were conducted in the Netherlands (n = 13) and United Kingdom (n = 19). Concerning care processes, most studies focused on treatment – systemic therapy, surgery and radiotherapy - in both trials and patient management. There is a great variation in the PROMs instruments used, as well as in the domains included in them (physical function, symptoms, psychological distress, general QoL, financial aspects, patient satisfaction/experience and decision sharing). The most used standardised instrument was EORTC QoL C30, sometimes in combination with other colorectal cancer specific questionnaires. In almost all studies included, PROMs were assessed at pre-defined key moments: at least before the treatment, during the intervention and at three time points after the intervention (up to 12 months).

Conclusions: In Europe, the use and content of PROMs in colorectal cancer varies, but is still limited. Implementation of a core standardised set of PROMs would allow comparability of patient-perceived quality of care across Europe. Despite some current initiatives (e.g. ICHOM) more work is still needed. Incorporation of a requirement for the use of PROMs in quality assurance measures (e.g. European Initiative on Colorecatal Cancer) may increase patient centredness of the care standards and improve patient experience.

1585P Completeness of staging investigation for colorectal cancer: Exploring the role of increasing age and comorbidity using mediation analysis

S. Benitez Majano[1], S. Vansteelandt[2], C. Di Girolamo[1], M. Morris[1], S. Walters[1], B. Rachet[1]

[1]Department of Non-communicable Disease Epidemiology, London School of Hygiene and Tropical Medicine, London, UK, [2]Department of Applied Mathematics, Computer Science and Statistics, Ghent University, Ghent, Belgium

Background: Older cancer patients often have fewer staging interventions and inferior treatment than younger patients. Suboptimal cancer management in older patients is frequently attributed to comorbidity, which may contraindicate procedures. We aim to examine how much of the age disparities in completeness of staging investigations for colorectal cancer (CRC) are explained by patients' health status and their diagnostic route.

Methods: Population-based cancer registries provided information on CRC patients diagnosed in England during 2010-2012. Staging investigations and comorbidities in the six years before the cancer diagnosis was derived from the National Bowel Cancer Audit and Hospital Episodes Statistics datasets. A mediation analysis quantified the proportion of the age effect on staging investigations mediated by health status, and by the diagnosis route. Sensitivity analyses for unmeasured confounding tested the robustness of the findings.

Results: Around half of patients had complete staging investigations. There was a U-shape association with more complete investigations among those aged 60-69. The age-investigation association was barely mediated by health status, but was partly mediated by being diagnosed through an emergency route. Overall, an important proportion of the age differential was not mediated by these factors, especially in older patients. These findings were robust to strong assumptions of unmeasured confounding of the relationship between the diagnosis route and having complete staging investigations.

Conclusions: CRC patients' health status and diagnostic route did not fully explain the age differential in the quality of staging investigations, contradicting prevailing beliefs. Findings suggest factors other than patients' health status may play an important role in the age differential. Although some patients may not benefit from aggressive treatment, having a complete investigation is essential to plan optimal management, regardless of age.

Background: Patient care quality is a discipline that has acquired enormous relevance in today's healthcare. Quality Oncology Practice Initiative (QOPI) is a referral worldwide in terms of quality for oncology practices. ECO Foundation is a platform of experts representing the major Spanish hospitals involved in the treatment of cancer patients. ECO reached an agreement with QOPI to involve Spanish hospitals in the QOPI program.

Methods: Five rounds of data collection have taken place (Fall 2015 to Fall 2017). Practices had to register online and submit data into the QOPI platform. ECO Foundation offers all centres the necessary support. 16 Spanish hospitals have participated in the five rounds. 7 of them have repeated participation. Core and Lung Cancer modules were completed.

Results: During the five rounds, 1745 charts were submitted by the Spanish practices. In the majority of the rounds, the highest scores were: Pathology report confirming malignancy, Number of chemotherapy cycles documented, Patient consent for chemotherapy and 5 measures of the Lung Cancer module. The lowest scores were: Chemotherapy treatment summary provided to patient within 3 months of chemotherapy end, Chemotherapy treatment summary provided or communicated to practitioner(s) within 3 months of chemotherapy end, Smoking/tobacco use cessation counselling recommended to smokers/tobacco users in past year and Tobacco cessation counselling administered or patient referred in past year. The percentage of participating practices that presented results higher than 70% was successively 64%, 50%, 75% and 100% in the last two rounds. For the 7 hospitals that repeated participation, 3 reported an improvement of their global scores. Regarding QOPI Certification, three Spanish hospitals received this accreditation in September 2017.

Conclusions: These preliminary results are a good starting point for the continued implementation of the QOPI program in Spain, thus providing a well-structured approach to analyse cancer care. ECO Foundation will continue pursuing excellence and quality with further activities like the QOPI Certification program and Quality Training Program, these being performed for the first time in Spain in 2017 and 2018 respectively.

1587P Can measuring quality lead to improvement? Evidence from international participants of ASCO's quality oncology practice initiative (QOPI®) during 2015-2017

M. Jahanzeb[1], T. Gilmore[2], A. Roach[2], S.S. Grubbs[2], D. Blayney[3], J. Hamm[4], A. Kamal[5], R.J. Kelly[6], E. Martin[7], J.A. Sanchez[8], R. Siegel[9], S.T.S. Crist[2], J. Rosenthal[2], C. Hendricks[10]

[1]Hem/Onc, University of Miami, Sylvester Comprehensive Cancer Center, Deerfield Beach, FL, USA, [2]Clinical Affairs, American Society of Clinical Oncology, Alexandria, VA, USA, [3]Medical Oncology, Stanford Comprehensive Cancer Institute, Stanford, CA, USA, [4]Oncology, Norton Health Care Medical Oncology & Hematology, Louisville, KY, USA, [5]Oncology, Duke University School of Medicine, Durham, NC, USA, [6]Medical Oncology/UAD Program, School of Medicine, Johns Hopkins University, Baltimore, MD, USA, [7]Oncology, Medical Oncology Hematology Consultants, Newark, DE, USA, [8]Oncology, Hospital Escuela, University of Honduras, Tegucigalpa, Honduras, [9]Oncology, St. Francis Hospital, Greenville, SC, USA, [10]Oncology, Associates in Oncology Hematology, Bethesda, MD, USA

Background: Management thinker Peter Drucker had famously said "If you can't measure it, you can't improve it." Similar sentiment among practicing oncologists led to the establishment of QOPI by ASCO in 2006. The availability of guidelines to construct measures should result in measurable and sustained improvement in cancer care. QOPI was launched internationally in 2015. Now several countries are participating and 3 (Brazil, Greece and Spain) have QOPI-Certified practices. For the current analysis, we initiated the proof of concept and hypothesized that measuring quality would not only confirm preconceived benchmarks, but lead to improvement.

Methods: Data for analysis was selected from countries' practices that repeat self-examination. We determined the 5 lowest performing measures excluding the two measures that were deemed not applicable in the Fall (F) and Spring (S) rounds of the years 2015-17. Measure 6 - Pain addressed appropriately (defect-free measures 3, 4a, and 5), Measure 9 - Documented plan for Chemotherapy, including doses, route, and time intervals, Measure 24 - Patient emotional well-being assessed by the second office visit, Measure 33 - Infertility risks discussed prior to chemotherapy with patients of reproductive age and Measure 81-Adjuvant cisplatin-based chemotherapy received within 60 days after curative resection by patients with AJCC Stage II or IIIA NSCLC.

Results:

Table: 1587P

Round	Measure 6	Measure 9	Measure 24	Measure 33	Measure 81
Aggregate Mean %					
F15	75.2	59.5	49.2	10.0	N/A
S16	58.2	67.1	27.3	16.6	66.6
F16	70.3	69.4	40.4	44.1	69.3
S17	74.3	80.3	43.4	27.9	50.0
F17	83.0	82.8	53.8	38.7	80.9

This analysis includes 331 physicians and 22 practices from 5 countries (Brazil, Greece, Romania, Saudi Arabia, and Spain) who participated in QOPI rounds between 2015 and 2017. While the scores fluctuated between rounds, first to last observation invariably showed improvement in mean scores.

Conclusions: Measuring quality led to improvement in the lowest performing quality measures in these participating practices. This bodes well for our patients.

1588P Treatment algorithm for multiple myeloma: Real-world insights across five European countries

A. Rocci[1], P. Bulger[1], A. Martinez de Pinillos[2], P. Nasuti[2], C. Anger[2], F. Manuguid[2]

[1]Haematology, Manchester University NHS Foundation Trust, Manchester Royal Infirmary, Manchester, UK, [2]Real World & Analytics Solutions, IQVIA, London, UK

Background: Therapy of multiple myeloma (MM) is based on proteasome inhibitors (PIs) and immunomodulatory agents (IMiDs) used alone or in combination. Bortezomib, Thalidomide and Lenalidomide are approved in Europe but national differences in terms of reimbursement policies may determine their diverse use in MM treatment algorithm.

Methods: Anonymized MM patient level data collected through a large cross-sectional survey between April to December 2017 in EU5 (France, Germany, Italy, Spain & UK) was used.

Results: 2472 patients (pts) were included in this study. In pts ≤65 years of age, PIs were largely used in first line across all countries (94% pts) followed by IMiDs (77% pts) with the exclusion of Germany (15% pts) where IMiDs were largely replaced by alkylating agents (78%). In second line, IMiDs were generally the drug of choice across most countries (90% pts) with the exclusion of the UK (36% pts). Opposite picture was observed for PIs: 73% of UK pts received these, whilst only 24% pts in Spain. In pts >65 years in first line, PIs were mostly used (70% pts) whilst IMiDs were only used in 35% pts. The use of alkylating agents varied from 32% (Germany) to 63% pts (France). In second line PIs ranged from 12% in France to 64% in the UK where IMiDs were less used (45%) compared to other countries. Irrespective of age, third line treatment was largely based on IMiDs. In Spain and Germany 1/3 of pts had access to monoclonal antibodies. Interestingly, bone protection treatment (99% bisphosphonate) was administered to 66% of pts in the UK, 52% in Germany and 42% in Spain, but only 24% in Italy and 22% in France.

Conclusions: IMiDs are the most used class of drug to treat MM as single agent or in combination irrespectively from line of treatment even if in Germany their use is less common as first line. PIs are used particularly in first line with the exception of the UK where they are common part of second line treatment. Further analyses to determine the impact on progression-free survival of the different treatment algorithms by country are needed.

1589P Are treatment recommendations provided by cognitive computing supported by real world data (Watson for Oncology with Cota RWE) concordant with expert opinions?

D.M. Atieh Graham[1], D.M. McNamara[1], S.E. Waintraub[1], S.L. Goldberg[2], A.D. Norden[2], J. Hervey[2], A.L. Pecora[2], C. Landstrom[2], J.L. Snowdon[3], P.M. Francis[3], N. Jungbluth[3], C.K. Wang[3], L. Latts[3]

[1]Breast Oncology, John Theurer Cancer Center, Hackensack, NJ, USA, [2]Cota, Inc, New York, NY, USA, [3]Watson Health, IBM, Cambridge, MA, USA

Background: Treatment selection requires review of patient (pt) and clinical features, medical literature, national guidelines, physician experience, and cost-value issues. The IBM Watson for Oncology with Cota RWE (WfO/Cota) point-of-care decision support tool ingests pt attributes from electronic health records and displays treatment recommendations (TRx) based on Memorial Sloan Kettering Cancer Center training and medical literature. The system has been recently supplemented with real world data curated by Cota listing historical treatments and survival outcomes drawn from the treating physician's institution and a national database. WfO/Cota is undergoing testing at John Theurer Cancer Center (JTCC, Hackensack, NJ, USA). Concordance of WfO/Cota with expert opinions is required to confirm that cognitive computing TRx match best practices.

Methods: 88 early stage post-menopausal breast cancer (BC) cases from the JTCC BC clinic were presented to 3 JTCC BC experts (without using WfO/Cota). The cases were compared against pts with similar demographic and disease characteristics from the Cota database (matched using Cota Nodal Address [CNA] algorithms).

Results: BC experts reviewed 223 cases (not all cases scored by each). WfO/Cota "recommended" option was concordant with selection by BC experts in 175 (78.5%) and "for consideration" option was selected in 21 (9.4%); experts agreed with WfO/Cota in 87.9%. 7 of 88 cases (8%) generated 59% of non-concordant responses with >=2 doctors disagreeing with WfO. The BC expert who worked at MSKCC deviated the least from MSKCC trained WfO. In the Cota database 69.3% of matched historical controls were treated with "recommended," 11.4% "for consideration", 19.3% "not recommended."

Conclusions: WfO/Cota recommendations are largely concordant with disease expert best oncology practices. The observation that nearly a fifth of pts with similar disease (CNA) characteristics received non-recommended options in a real world database highlights a need. WfO/Cota is an innovative decision support tool that derives new insights based on existing real world evidence to reduce variations in practice.

1590P Body shape trajectories and risk of breast cancer: Results from the SUN study project

R. Sanchez Bayona[1], C. Sayon[2], I. Gardeazabal[1], M.A. Martínez-González[2], M. Santisteban Eslava[1], E. Toledo-Atucha[2]

[1]Oncology, Clinica Universidad de Navarra, Pamplona, Spain, [2]Public Health and Preventive Medicine, Universidad de Navarra, Pamplona, Spain

Background: Obesity is a well-known risk factor for some types of cancer including post-menopausal breast cancer. Nevertheless, the influence of adiposity over life course on cancer risk remains poorly understood. The objective of this study was to assess body shape trajectories in early and middle life in relation to subsequent risk of breast cancer in a Mediterranean cohort.

Methods: We used a group-based modelling approach to assess body shape trajectories from age 5 to 40 years, among 10679 women from the SUN cohort study from 1999 to 2014. Four distinct body shape trajectories were identified (lean-heavy increase, medium-stable, medium-heavy increase and heavy-stable). Cox regression models were used to estimate the hazard ratio (HR) for breast cancer according to the assigned body shape trajectory.

Results: Among 106,537 women-years of follow-up a total of 133 probable incident cases of breast cancer were identified (70 of these cases were confirmed). When compared to those in the medium-stable category, women who were lean and had a marked increase (lean-heavy increase category) showed a subsequent higher risk of probable breast cancer (HR = 1.55, 95%CI 1.05-2.29). When stratifying according to menopausal status, there was a higher risk of probable postmenopausal breast cancer for women in the lean-heavy increase category (HR = 2.0, 95%CI 1.06- 3.80) compared to the medium-stable group. The statistical power was reduced and significance was lost when we considered only confirmed cases.

Hazard ratio (HR) and 95% confidence interval (95% CI) of breast cancer according to body shape trajectory in the SUN Project, 1999-2016. Adjusted for potential confounders and age as underlying time variable.

Conclusions: This is the first Mediterranean cohort to suggest that a marked increase in body shape from age 5 to 40 years is associated with a higher risk of breast cancer, especially for postmenopausal women, indicating a role for lifetime adiposity in breast carcinogenesis.

1591P Total polyphenol intake and breast cancer risk in the SUN project

I. Gardeazabal[1], A. Romanos-Nanclares[2], R. Sanchez Bayona[1], J.J. Graforio[3], M.A. Martínez-González[4], E. Toledo-Atucha[4]

[1]Medical Oncology, Clinica Universitaria de Navarra, Pamplona, Spain, [2]Preventive Medicine and Public Health, Universidad de Navarra, Pamplona, Spain, [3]Ciencias de la Salud, Universidad de Jaén, Jaén, Spain, [4]Public Health and Preventive Medicine, Universidad de Navarra, Pamplona, Spain

Background: Breast cancer (BC) is the most frequently diagnosed cancer in the world. Preventive strategies represent a public health priority. Dietary interventions for preventing BC have been evaluated, mainly using observational designs, with inconsistent results. In this context, polyphenols have shown in vitro and in vivo beneficial properties and anticancer mechanisms. Polyphenols are a wide family of phytochemicals present in diverse foods. Their role in chronic disease prevention including cardiovascular diseases and cancer has been repeatedly suggested. For this reason, we evaluated total polyphenol intake in association with the risk of BC in the SUN Project - a prospective cohort study in a Mediterranean population.

Methods: We included 10,709 middle-aged, Spanish female university graduates. Polyphenol intake was assessed using a validated semi-quantitative 136-item food frequency questionnaire and matching food consumption data with the Phenol-Explorer database. Diagnosis of BC was self-reported or by the next of kin or identified from death certificates. Self-reports of a medically-diagnosed BC were confirmed using medical records. Cox regression models were fitted to estimate multivariable-adjusted hazard ratios (HR) and 95% confidence intervals (CI) for the association between terciles of adherence to the total polyphenol intake and BC risk.

Results: After 10.3 years of median follow-up, 83 confirmed and 165 probable incident BC cases were identified. We observed a statistically significant inverse association between total polyphenol intake and BC risk for postmenopausal women when probable BC cases were used as outcome: HR for highest vs lowest tertile of total polyphenol intake 0.47 (95% CI 0.22-0.97; P for trend=0.041). No further significant associations were observed between total polyphenol intake and incident BC when total BC incidence or risk of premenopausal BC were considered.

Conclusions: Despite the small number of incident BC cases observed in this Mediterranean cohort, we observed that the higher total polyphenol intake, the lower risk of BC among postmenopausal women.

1592P No effect of length time bias on the genomic risk in ER+ HER2-stage I-IIA breast cancer (BC) patients according to diagnosis in a screening programme: An exploratory analysis

I. Gonzalez Barrallo[1], J.A. Perez Fidalgo[1], J. Ramirez[2], O. Burgues[3], J.V. Sorlí[4], O. Portoles[2], C. Hernando[1], D. Salas[5], A. Lluch[6]

[1]Medical Oncology, Hospital Clinico Universitario de Valencia, Valencia, Spain, [2]Department of Public Health, University of Valencia, Valencia, Spain, [3]Pathological Anatomy, Hospital Clínico Universitario de Valencia, Valencia, Spain, [4]Preventive Medicine and CIBER Fisiopatología de la Obesidad y Nutrición, Universitat de València, Valencia, Spain, [5]Area of Cancer and Public Health, Research Center in Public Health - Centro Superior de Investigación en Salud Publica (CSISP), Valencia, Spain, [6]Medical Oncology, Hospital Clinico Universitario de Valencia. INCLIVA.CIBERONC Spain, Valencia, Spain

Background: Length time bias is a form of selection bias that lead to the perception that screened patients have better outcome as more indolent tumors are diagnosed during screening. However, tumors diagnosed in the interval between mammographys or detected by symptom onset are likely more aggressive. The aim was to analyze using a genomic platform if unscreened tumors were more agresive than screened ones in a homogeneous cohort not affected by stage or subtype.

Methods: Since 2014 BC pts with T1-T2 N0-N1mic tumors and/or high ki67 are selected for genomic platform-based risk assessment in order to guide adjuvant treatment. We performed an exploratory retrospective cohort study in a single institution between 2014 and 2018 in operated stage I-IIA BC pts with ER and/or PR + who

Table: 1590P

Probable cases	Overall breast cancer		Premenopausal breast cancer		Postmenopausal breast cancer	
	Cases / woman-years	HR (95% CI)	Cases / woman-years	HR (95% CI)	Cases / woman-years	HR (95% CI)
Lean-heavy increase	43 / 18360	1.55 (1.05-2.29)	13/12456	1.34 (0.69-2.61)	21/5474	2.0 (1.06-3.80)
Medium-stable	65 / 57061	1 (ref.)	28/46602	1 (ref.)	19/9343	1 (ref.)
Medium-heavy increase	22 / 23738	0.81 (0.50-1.32)	12/20048	0.93 (0.46-1.87)	7/3281	1.03 (0.43-2.47)
Heavy -stable	3 / 7378	0.55 (0.17-1.76)				
Confirmed cases						
Lean-heavy increase	20/ 18453	1.22 (0.70-2.13)	8/12456	1.14 (0.49-2.67)	9/5474	1.32 (0.54-3.26)
Medium-stable	37/ 57210	1 (ref.)	18/46602	1 (ref.)	11/9343	1 (ref.)
Medium-heavy increase	13/ 23811	0.86 (0.45-1.62)	8/20048	0.88 (0.37- 2.10)	4/3281	0.24 (0.39-4.0)

underwent an Oncotype risk assessment before deciding adjuvant therapy. Results of the Recurrence score (RS) were compared according to the type of diagnosis of breast cancer as 1) Screened: Diagnosis during screening (when diagnosed occurred during a foreseen mammography visit) and 2) Unscreened: Diagnosis occurred outside screening (in an interval between mammographys or by symptom onset).

Results: 105 pts were included. Median age was 56.4 y (45.2-74.6 y). All patients were ER + (range 50-100%), HER2- and grade was I (12.4%) II (82,9%) or III (4.8%). Median tumor size was 13.7 mm (4-45). 89.5% were N0 and 10.5% N1mic. 68 pts (64.8%) were in the screened and 37 (35.3%) in the unscreened group. Foreseen adjuvant treatment was changed according to Oncotype results in 24.8% patients. Median RS was 18.2 (range 3-46). According to RS risk categories 81% were classified as low , 9.5% as intermediate and 9.5% as high risk. Median RS was 17.6 in the screened vs 19.2 in the unscreened group, these differences were not significant ($p = 0.34$). Differences by RS categories were also not significant (Chi square $p = 0.67$ for two categories low vs intermediate/high risk with a RR 0.92 (0.62-1.38) and $p = 0.2$ for three categories).

Conclusions: No risk differences according to RS was seen between screened vs unscreened patients. These suggest that length time bias in a cohort not affected by stage or subtype might have minimum impact on screening outcomes.

1593P Breast cancer screening: Impact on care pathways

D. Lefeuvre[1], N. Catajar[2], C. Le Bihan Benjamin[1], F. De Bels[2], J. Viguier[3], P-J. Bousquet[1]

[1]Survey, Monitoring and Assessment Department, INCa - Institut National du Cancer, Boulogne-Billancourt, France, [2]Screening Department, INCa - Institut National du Cancer, Boulogne-Billancourt, France, [3]Public Health and Healthcare Division, INCa - Institut National du Cancer, Boulogne-Billancourt, France

Background: Breast cancer screening represents a major public health challenge. In France, no evidence has been furnished that women with breast cancer diagnosed following a mammogram carried out within the framework of the screening programme (SP) underwent less aggressive treatment than women diagnosed by other means. The aggressiveness of treatment represents a supplementary indicator for studying the impact of SP.

Methods: To study this indicator, data from the "Cancer Cohort" were used. This consists of a unique cohort including all subjects suffering from cancer since 2010 in France, resulting in care at a hospital or medical practice. All women aged from 50 to 74 years at average risk and treated in 2014 for incident breast cancer were included. Women having undergone a mammogram within the framework of the SP (SP group) were compared to women having undergone a bilateral mammogram outside the SP, because of an opportunistic screening or a clinical symptom (NSP group).

Results: In 2014, 23,788 women aged from 50 to 74 years at average risk treated for incident breast cancer were identified: 13,530 (57%) in the SP group, and 10,258 (43%) in the NSP group. Women in the SP group had a higher rate of in situ or localised invasive breast cancer than in the NSP group. They had a higher rate of breast-conserving surgery (82% vs 70%), and a lower rate of chemotherapy (34% vs 53%). These findings were observed whatever the stage as defined in the study was. Women in the SP group had a higher rate of pathways involving breast-conserving surgery followed by radiotherapy. Finally, among women with metastatic cancer, those in the SP group had a lower proportion of liver, lung, brain and bone metastases, and a higher proportion of lymph node metastases (other than axillary), regardless of the time to onset of metastases.

Conclusions: The women whom cancer was diagnosed following a mammogram carried out within the framework of the SP had less advanced cancer and less aggressive treatments. This study on observational data contributes to illustrate the benefit of the SP in France using another approach than mortality or overall survival.

1595P 10-year results of the breast cancer screening program in Khanty-Mansiysk state region Ugra

N.A. Zakharova[1], A.R. Brentnall[2], J. Belaya[1], E. Bilan[3]

[1]Oncology, Radiology and Radiotherapy, Khanty-Mansiysk State Medical Academy, Khanty-Mansiysk, Russian Federation, [2]Centre for Cancer Prevention, Wolfson Institute of Preventive Medicine, Queen Mary University of London, London, UK, [3]Oncology Centre, Khanty-Mansiysk State Clinical Hospital, Khanty-Mansiysk, Russian Federation

Background: Breast cancer is the leading cancer in the female population and one of the most common causes of cancer deaths in women. Improved treatment and the implementation of mammography screening have contributed to substantial reductions in breast cancer mortality over recent decades. The main goal of this study was to evaluate 10-year results of the Breast Cancer Screening Program in Ugra since 2007.

Methods: Biannual mammography screening covers women 40 years old using single reading of two-view mammography. Screening data were obtained from the reports for the State Healthcare Department. Data on female population, breast cancer cases (invasive and in situ) and deaths were provided by the State Cancer Registry and State Information Centre. We studied expected absolute incidence and mortality from breast cancer were calculated over the years 2002-16. Expected absolute number of tumours T1N0M0 and with size over 20 mm detected among women 40+ were calculated over the period in question. Expected number assumed constant rate in pre/post screening epochs and its changes were only due to population size. Rate estimated using pre-screening epoch and were age-adjusted.

Results: During 2007-16 within the Program, 451139 women were screened. The screening coverage rate in the 2015-16 round was 41% (144777 women). 13464 (9.3%) of those screened were referred for further assessment. The screen detection rate was 3.5 per 1000 screened (1582 breast cancer cases). The test sensitivity for the first round was estimated as 80%. The observed T1N0M0 in 2016 was 126 compared with 73 expected (42% increase). The observed number of breast cancers more than 2cm was 231 compared with 292 expected (26% reduction). Breast cancer mortality in 2016 was 119 compared with 187 expected (57.5% reduction) using absolute mortality results.

Conclusions: Trends suggest that mammographic screening in Ugra has contributed to a significant improvement in the early disease diagnosis, and breast cancer mortality has fallen. Improved screening coverage s needed.

1596P Malignant lymphoma detected by screening program with esophagogastroduodenoscopy of one private screening center in Japan

T. Nakamura[1], M. Ikeda[1], S. Shibata[1], Y. Kon[1], K. Konuma[1], T. Sanada[1], H. Gonda[1], Y. Suto[1], K. Kobayashi[1], H. Tamura[1], M. Kobayashi[1], A. Hasegawa[1], Y. Amagasa[1], A. Suzuki[1], M. Fukuda[1], C. Aoyagi[1], N. Matsuura[1], Y. Kawashima[2], M. Shimura[2], N. Takita[2]

[1]Health Evaluation and Promotion, Ota Memorial Hospital, Ota, Japan, [2]Endoscopy, Ota Memorial Hospital, Ota, Japan

Background: Malignant lymphoma is rarely encountered in health screening program. It is often difficult to recognize it at early stage although the earlier detection would bring the better prognosis like other malignancies.

Methods: Data of screening program with esophagogastroduodenoscopy (EGD) at Ota Memorial Hospital (OMH) in Japan from June 2012 through December 2017 were reviewed and cases of malignant lymphoma detected were analyzed to reveal characteristics.

Results: 26886 individuals participated in EGD screening program of OMH in that term. 91 cases of malignant neoplasm were detected and six of them (6.6%) were diagnoses as malignant lymphoma (detection rate 0.02%). They consisted of three gastric and three duodenal lymphomas. None of them had B symptom. Histopathological exam diagnosed all gastric cases as MALT lymphoma locating at middle part of stomach. Their endoscopic findings were as follows; one was scar-like whitish mucosa without stricture, another was whitish mucosa mixed with erythema, and the other was scar-like lesion surrounded nodular and granular mucosae. Although all gastric lymphoma had no eradication history of Helicobacter pylori (Hp) and serum anti-Hp IgG antibody were less than 3 U/ml, one of them had advanced chronic atrophic gastritis. All gastric MALT lymphoma took irradiation therapy. All duodenal lymphomas were diagnosed as follicular lymphoma. One of them located around duodenal papilla was recurrent lesion that had originated in mesenteric lymph nodes and been treated with chemotherapy six years before. Its endoscopic findings were polypoid and granular lesions. Other two duodenal lymphoma were detected at inferior duodenal angle as nodular and granular appearance. The recurrent follicular lymphoma had the second line chemotherapy. Other two cases were treated by irradiation and molecular targeting therapy with rituximab respectively.

Conclusions: Nearly 7% of malignancy detected by EGD screening program of OMH was malignant lymphoma consisting of gastric MALT lymphoma and duodenal follicular lymphoma although it was rarely encountered. Since it shows non-specific endoscopic findings especially at its early stage, mandate biopsy to any suspicious lesion is strongly recommended.

1597P Worldwide trends in survival from childhood glioma 2000-2014 (CONCORD-3): Preliminary findings and plans for further research

F. Girardi, V. Di Carlo, A. Bonaventure, C. Allemani, M.P. Coleman, CONCORD Working Group

Non-Communicable Disease Epidemiology, London School of Hygiene and Tropical Medicine, London, UK

Background: The CONCORD programme was the first to establish global surveillance of cancer survival. The third cycle (CONCORD-3) collected data from 322 cancer registries in 71 countries. Survival from all brain tumours combined varied widely between countries, particularly in children. We propose to examine survival trends by relevant explanatory variables to help explain these disparities.

Methods: We present the numbers of children diagnosed with a glioma (ICD-O-3 morphology codes 938-948) and by each of the main glioma subtypes. Five-year net survival will be estimated by morphology, WHO grade, topography, sex, country and calendar period of diagnosis. Net survival is the probability that patients survive their cancer until a given time since diagnosis (e.g. 5 years), after controlling for competing risks of death (background mortality).

Results: Data were obtained for 56,507 children (aged 0-14 years) diagnosed with a glioma: 19,080 in Europe, 26,751 in North America, 6,111 in Asia, 3,103 in Central and South America, 1,379 in Oceania and 83 in Africa. In Europe, 5% of gliomas were ependymomas, 26% pilocytic astrocytomas, 8% astrocytomas, not otherwise specified (NOS), 5% glioblastomas NOS and 15% medulloblastomas NOS. The distribution was similar in North America. In Africa, Asia, and Central and South America, and in Oceania, pilocytic astrocytoma was less frequent (10%-13%) than in Europe or North America. In Africa, Asia, and Central and South America, astrocytoma NOS was more common (11-32%). The frequency of medulloblastoma was higher in Central and South America (28%) and Asia (23%). The distribution of the morphologic subtypes of childhood glioma varies widely around the world. Survival differs between morphologic groups. We will assess the extent to which the distribution of morphologic subtypes contributes to international variation in childhood glioma survival worldwide.

Conclusions: When comprehensive survival analyses are available for each type of glioma, this project will become the benchmark for future international comparisons of brain tumour survival in children, to inform cancer control plans.

1598P Referral patterns and predictors of survival for stage IV pancreatic ductal adenocarcinoma

A.E. Suo, P.A. Tang, D. Tilley, W.Y. Cheung, R. Lee-Ying

Medical Oncology, Tom Baker Cancer Centre, Calgary, AB, Canada

Background: We previously found that many patients with a diagnosis of advanced pancreatic ductal adenocarcinoma (PDAC) are not referred for palliative chemotherapy despite recent advances. We sought to investigate referral patterns, chemotherapy eligibility and predictors of overall survival (OS) in a large cohort of advanced PDAC in Alberta, Canada.

Methods: All patients with Stage IV PDAC from 2009 - 2015 in Alberta were identified using the Alberta Cancer Registry. Patients missing laboratory eligibility criteria for chemotherapy were excluded. Demographics, clinical characteristics, cancer centre referral, chemotherapy received, and OS were collected. Primary analysis explored referral patterns and treatment eligibility. Secondary outcomes identified predictors of survival using Kaplan-Meier with log-rank test and multivariable Cox regression analysis.

Results: 1412 patients were identified. ECOG (>1 = 83%; >2 = 72%), age (34%) and bilirubin (>ULN = 30%; >1.5xULN = 22%) were the most common reasons for chemotherapy ineligibility. A proportion of patients who were eligible by trial criteria for FOLFIRINOX (21%) and nab-paclitaxel/gemcitabine (20%) were not referred, yet some patients who were ineligible for any chemotherapy were still referred. Distance to travel to a cancer centre did not have a significant difference on referral patterns. Primary tumor location, any chemotherapy received, referral, ECOG, bilirubin, and ANC were significant predictors of survival in the Cox regression analysis.

Conclusions: More patients who are potentially eligible to receive palliative chemotherapy should be referred to a cancer centre. Patients with obstructive jaundice should have expedited biliary drainage procedures to facilitate systemic treatment eligibility.

Table: 1598P Cox regression analysis of predictors for overall survival

Characteristic		HR	95% CI	p
Tumor	Head/neck	1		.002
	Body	1.37	1.07 - 1.76	.012
	Tail	1.51	1.19 - 1.90	.001

1599P Gender difference in cancer survivors' perceived information 5-years after diagnosis: Data from the French national study - VICAN 5

G. Gravis[1], R. Touzani[2], A-D. Bouhnik[3], P. Marino[4], G. Pignot[5], M.K. Bendiane[6]

[1]Medical Oncology, Institut Paoli Calmettes, Centre de Recherche en Cancérologie de Marseille, Aix Marseille Université, Marseille, France, [2]Sciences Economiques & Sociales de la Santé & Traitement de l'Information Médicale, Aix Marseille University, Marseille, France, [3]Aix-Marseille University - Faculté de Médecine Timone, Marseille, France, [4]Institute Paoli-Calmettes, Marseille, France, [5]Chirurgie Oncologique 2, Institute Paoli Calmettes, Marseille, France, [6]Aix Marseille Univ, INSERM, IRD, Economics and Social Sciences Applied to Health & Analysis of Medical Information (SESSTIM), Marseille, France

Background: Information request for cancer patients is high with frequent reported unmet needs. Well informed patients are: more involved in shared decision making, report higher levels of satisfaction with care and better quality of life. The aim of this study is to compare perceived information on cancer evolution between women and men in cancer survivors five years after diagnosis.

Methods: The VICAN survey is a French representative sample of 4174, 5-years cancer survivors. Self-reported data were collected by telephone interviews and self-administrated questionnaires. Only non-gendered cancers were selected (excluded: breast, prostate cancer...). Univariate and multivariate analyzes have been performed using STATA 12.

Results: 2243 out of 4174 patients were selected, 54.2% were male, median age was 58 years and men were significantly older (63 vs 55, $p < 0.001$). Women had a higher level of education ($p = 0{,}011$), reported more attention difficulties ($p = 0.026$) and memory problems ($p < 0{,}001$) while men reported more hearing loss ($p < 0.001$). No difference was found for depression (assessed by HADS scale) and the level of literacy. Women reported being less informed of minor symptoms (28.6% vs. 20.5%, $p < 0.001$) and less informed of severe symptoms of their cancer (18.2% vs. 12.0%, $p = 0.001$) The gender difference was statistically significant for the overall population but not within each localization of cancer, except for kidney cancer: men were feeling not well informed about minor symptoms (21.1% vs 29.1%, $p = 0.020$). Women used more frequently internet to search information (27.6% vs 19.5%, $p < 0.001$). Only 2.7% of patients used internet to look for information about patients' associations and women used it more frequently (3.9% vs. 1.7%, $p = 0.009$).

Conclusions: Cancer survivors have been found to benefit from health care information. In this large prospective analysis in non-gendered cancers, women reported lower levels of information than men and searched online information more frequently. Gender difference and preference for information is an important issue in order to give appropriate information to cancer patients.

1600P Survival difference between microscopically confirmed and microscopically non-confirmed cancers

M.A. Gouda

Department of Clinical Oncology, Faculty of Medicine - Menoufia University, Shebin El Kom, Menoufia Governorate, Egypt

Background: Cancer is mainly diagnosed by histopathology, but some complex situations may provoke physicians' desire to avoid biopsy. This is particularly important when cancer diagnosis can be made based on other less accurate methods like radiological findings or elevated tumor markers e.g. suspicious ovarian mass with elevated CA125. However, data about these cases treated based on diagnosis "prediction" rather than accurate definition of histopathology are lacking. In this study, survival is compared between cases with microscopic confirmation of diagnosis and those diagnosed with other methods. This is presented for all types of cancer but with particular focus on four main tumors where other modalities for diagnosis may be appealing.

Methods: Data were obtained using SEER*Stat version 8.3.5 (SEER 18 Regs Nov 2017 Submission). Only cases diagnosed between 2001 and 2010 were included. Observed survival was calculated using SEER*Stat where other data analysis including Kaplan Meier analysis was made using SPSS.

Results: Microscopic confirmation (MC) was the mainstay for diagnosis in most of included cases (n = 3594344; 94.2%). In the remaining group (non-microscopically confirmed (NMC) diagnosis, n = 222907; 5.8%), radiography was used in 46% (n = 102401). Clinical diagnosis, positive laboratory test/marker, and direct visualization were used in 11.8%, 5.2%, and 2.7 respectively. There was a significant survival difference between MC and NMC that was consistent in prostate, ovarian, liver, and pancreatic cancer as well as in other types of malignancies ($p < 0.05$). The table shows the 5-years observed survival and 95% CI for different types of cancer in the two groups.

Table: 1600P

	5-years observed survival	
	MC	NMC
Prostate	85.3% (85.2-85.4)	26.6% (25.8-27.5)
Ovary	44.1% (43.6-44.6)	10.9% (9.8-12)
Liver	18.1% (17.7-18.5)	9.6% (9.2-10.1)
Pancreas	6.5% (6.3-6.7)	2.6% (2.3-2.9)
Others	67.4% (57.3-57.4)	14.7% (14.4-14.9)
All	60.5% (60.6-60.6)	13.7% (13.5-13.8)

Conclusions: Microscopic confirmation should be regarded as the only accurate method for diagnosis of cancer. Depending on other diagnosis methods may have a strong detrimental effect on survival. More studies needs to address possible explanations for these findings and potential implications on management.

1616P Quantitative multiplexed immune profiling of advanced gastrointestinal stromal tumors (GISTs): Impact of tyrosine kinase inhibitors on immune environment

C. Yoo[1], S-Y. Kim[2], J. Kim[3], Y-M. Ryu[2], M-H. Ryu[1], Y-K. Kang[1]

[1]Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [2]Department of Convergence Medicine, Asan Institute for Life Sciences, Seoul, Republic of Korea, [3]Department of Pathology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea

Background: Immune microenvironment of GISTs is largely unknown and there is no approved immunotherapeutic agent for the treatment of advanced GISTs. To investigate novel immunotherapeutic strategy in patients with GISTs, immune microenvironment was analyzed in this analysis.

Methods: In this study, 80 surgical specimens of GISTs from 65 patients in different clinical setting (TKI-naïve [n = 20], imatinib-progression [IM-PD, n = 30], and imatinib-progression and sunitinib-treated [IM-PD/SU-treated, n = 30]) were included. CD3, CD8, FoxP3, PD-L1, PD-1 and DOG-1 were simultaneously evaluated in one formalin-fixed paraffin-embedded tissue section using multiplexed immunohistochemistry (IHC) with computational image processing workflows for quantitative assessment.

Results: IM-PD/SU-treated group showed increased FoxP3+CD3+/CD3+, PD-1+CD3+/CD3+, and PD-1+CD8+/CD3+ T cell ratios compared to TKI-naïve ($p = 0.007$, $p = 0.004$, and $p = 0.007$, respectively) and IM-PD ($p = 0.008$, $p = 0.002$, and $p = 0.01$, respectively) groups. PD-1 expression (>1%) on tumor cells (PD-1+DOG-1+/DOG-1+) were also higher in IM/PD-SU-treated group (10%) compared to TKI-naïve (0%) and IM-PD (3%) groups. There were no significant differences in immune microenvironment profiles between TKI-naïve and IM-PD groups ($p > 0.05$).

Conclusions: Anti-angiogenic agents may have immunomodulatory activity in advanced GISTs. Immune exhaustion phenotype (increased Treg, PD-1+ T cells and PD-1+ tumor cells) in IM-PD/SU-treated patients might indicate that this group is a potential candidate for future immunotherapy trials.

1617P Multicentric retrospective analysis of patients with KIT exon 9 mutated GIST

A. Callejo Goena[1], S. Faouzi[2], O. Bouche[3], T. Chevalier[4], N. Isambert[5], F. Duffaud[4], O. Collard[6], O. Mir[2], P. Terrier[7], J-Y. Blay[8], A. Le Cesne[2]

[1]Medical Oncology, Hospital Universitario Cruces, Barakaldo, Bizkaia, Spain, [2]Medical Oncology, Gustave Roussy Institute, Villejuif, France, [3]Digestive Oncology, CHU de Reims - Hôpital Robert Debré, Reims, France, [4]Medical Oncology, CHU La Timone and Aix Marseille Université (AMU), Marseille, France, [5]Departement of Early Clinical Trials, Centre Georges-François Leclerc (Dijon), Dijon, France, [6]Medical Oncology, Institut de Cancérologie de la Loire - Lucien Neuwirth, La Loire, France, [7]Pathology Department, Gustave Roussy Institute, Villejuif, France, [8]Medical Oncology, Centre Léon Bérard, Lyon, France

Background: Patients (pts) with advanced GIST harbouring the KIT exon 9 mutation have a better progression-free survival (PFS) on a higher daily dose level, i.e. 800 mg of imatinib (IM), which is therefore held as standard treatment in this subgroup. This schedule in the adjuvant setting has been subsequently proposed despite the lack of any controlled trials.

Methods: We retrospectively evaluated characteristics of pts with KIT exon 9 mutated GIST in 6 different centers in France and Spain, treated with a daily dose of 400 mg of IM. Pts with localized and advanced GIST were separately analyzed: Kaplan-Meier and Cox proportional hazards model analyses were used to compare median relapse-free survival (mRFS) and OS (mOS) in the adjuvant setting, and overall response rate (ORR), median PFS to IM 400 mg (mPFS), median time to IM failure (mTIF) defined as time to 2nd progression (PD) or death, and mOS in the advanced setting.

Results: We identified 43 pts (44% of males) with a median age of 56 yrs (16-78). 67.4% of GIST was originated in the small bowel and 18.6% in the stomach. In adjuvant situation (31 pts), 42% of pts had a high risk (HR) of relapse (Miettinen classification) and 29% an intermediate risk (IR). 17 out of 31 pts received adjuvant 400 mg/d of IM for a median duration of 21 months (m). The mRFS of pts receiving adjuvant IM was 82 m vs 21 m for those who did not. In the advanced setting, 22 pts were treated with 400 mg of IM. The ORR was 37% (3 CR and 5 PR), with additional 7 stabilizations (benefit in 69% of pts). At PD, 77% of pts received the higher dose IM regimen (800 mg). The mPFS was 12.7 m (CI 95% 6.8-18.6) and the mTIF was 20.6 m (CI 95% 12.2-29). The mOS was 42.9 m. No prognostic variable (gender, age, PS, site of primary disease, diameter of largest lesion, prior surgery of primary) was significantly related with mOS or mTIF.

Conclusions: Despite the limitations of retrospective analysis and the small number of pts, benefit of adjuvant IM (400 mg/d) in pts with localized GIST harbouring KIT exon 9 mutations seems relevant. Pts with advanced GIST initially treated with 400 mg of IM have a similar outcome in terms of mTIF (20 m) than those receiving high-dose IM upfront (19 m in the initial MetaGIST trial, M.V. Glabbeke et al, JCO 2010).

1618P Prognostic factors for residual lesion surgery following disease control with standard dose imatinib (IM) treatment in patients (pts) with advanced gastrointestinal stromal tumor (GIST)

H. Cho[1], M-H. Ryu[2], H. Chae[2], S.M. Lee[3], Y. Park[3], K-H. Kim[4], C.W. Kim[4], B.S. Kim[4], M-W. Yoo[4], J. Ma[2], M.Y. Beck[2], M. Kim[2], Y-K. Kang[2]

[1]Department of Internal Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [2]Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [3]Department of Pathology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [4]Department of Surgery, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea

Background: Efficacy of residual lesion surgery in pts with advanced GIST responding to IM has been advocated in several retrospective studies. However, to date, no studies have identified the prognostic factors exclusively for these pts.

Methods: Between September 2002 and December 2015, a total of 107 pts with histologically documented initially metastatic or distant recurrent GIST received residual lesion surgery following disease control with IM 400 mg/day in Asan Medical Center, Seoul, Korea. Among these pts, 89 pts had complete data for potential prognostic factors and were included in the analysis.

Results: Median age was 57 years (range, 12-77) and 56 pts (62.9%) were male. Stomach (n = 41, 46.1%) and small bowel (n = 41, 46.1%) were the most common primary sites followed by peritoneum (n = 4, 4.5%). With a median follow up duration of 47.0 months (range, 16.7-174.7) from residual lesion surgery, the 5-year progression-free survival (PFS) and overall survival rates were 60.6% (95% CI, 47.3-73.9) and 85.7% (95% CI, 76.7-94.7), respectively. In multivariate analysis including potential prognostic factors, male gender ($HR = 3.4$, $p = 0.01$), presence of extra-liver metastasis ($HR = 4.3$, $p < 0.01$), and primary genotype other than KIT exon 11 mutation ($HR = 7.3$, $p < 0.01$) were independently associated with poor PFS. Compared to the good PFS (median 106.7 months) in patients with 0-2 poor prognostic factors, those with 3 factors had very poor PFS (median 8.5 months) ($p < 0.001$).

Conclusions: Our study confirms that long-term survival can be achieved in advanced GIST pts receiving residual lesion surgery following disease control with IM. However, further study is needed to define the role of residual lesion surgery in pts with 3 risk factors considering their poor survival outcomes.

1619P Systemic steroid treatment for severe skin rash induced by imatinib in patients with gastrointestinal stromal tumor (GIST): A phase II study

E. Kim[1], M-H. Ryu[2], S.R. Park[2], M.Y. Beck[3], W.J. Lee[4], M.W. Lee[4], Y-K. Kang[2]
[1]Internal Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [2]Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [3]Department of Oncology, Asan Medical Center, Seoul, Republic of Korea, [4]Department of Dermatology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea

Background: To achieve optimal clinical outcomes with imatinib in GIST patients, it is crucial to maintain standard imatinib dose. Skin rash is a common and sometimes severe adverse event of imatinib treatment and may affect compliance. Our previous retrospective study suggested that severe skin rash induced by imatinib can be managed by systemic steroid without interruption or dose reduction of imatinib. This phase II study was conducted to evaluate efficacy and safety of systemic steroid in GIST patients with imatinib-associated severe skin rash.

Methods: Between October 2014 and March 2016, 29 patients were enrolled and treated with oral prednisolone for imatinib-associated severe skin rash which was defined as grade 3 skin rash or grade 2 skin rash with pruritus. Prednisolone was started with 30mg daily for 3 weeks, and if skin rash is controlled, steroid was tapered over 12 weeks by determined schedule. The primary endpoint was treatment success rate (TSR). Treatment success was defined as maintaining imatinib without persistence or recurrence of skin rash requiring 1) additional systemic steroid treatment, and 2) interruption or dose reduction of imatinib.

Results: Of 29 patients enrolled, 16 patients (55.2%) received imatinib in adjuvant setting, and 13 (44.8%) in palliative setting. The median age was 61 years (range, 31-77). Eleven patients (37.9%) were male. Twenty-two patients (75.8%, TSR) were treated successfully, 2 (6.9%) were evaluated as treatment failures, and 5 (17.2%) were not evaluable. With a median follow-up of 22 months (range, 16.2-27.8), 71.5% of patients could maintain imatinib dose without recurrence of skin rash for 2 years. Patients aged <65 years showed higher TSR (odds ratio [OR]=4.38, p = 0.192). No one experienced disease progression during follow-up. All toxicities associated with systemic steroid were evaluated. One patient with myelodysplastic syndrome had Pneumocystis pneumonia. Otherwise, systemic steroid was well tolerated.

Conclusions: This study demonstrated that systemic steroid treatment can effectively control severe skin rash and minimize interruption or dose reduction of imatinib in GIST patients with imatinib-associated severe skin rash.

Clinical trial identification: NCT03440515.

1620P Phase II study of paclitaxel in patients with advanced gastrointestinal stromal tumor (GIST) after failure of at least both imatinib and sunitinib

H. Cho[1], M-H. Ryu[2], B.J. Kim[2], Y. Park[3], Y-S. Na[4], J. Ma[2], M.Y. Beck[5], Y-K. Kang[2]
[1]Department of Internal Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [2]Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [3]Department of Pathology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [4]Asan Institute for Life Science, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [5]Department of Oncology, Asan Medical Center, Seoul, Republic of Korea

Background: Most advanced GISTs are known to be resistant to conventional cytotoxic agents but sensitive to tyrosine kinase inhibitors (TKI) such as imatinib and sunitinib. However, majority of patients eventually develop resistance to TKIs and experience disease progression. Recent preclinical studies suggested that a few conventional cytotoxic agents such as paclitaxel might have antitumor effect on GIST. The current study was conducted to evaluate the efficacy and safety of paclitaxel in patients with advanced GIST after failure of at least imatinib and sunitinib.

Methods: Patients received paclitaxel 80 mg/m^2 intravenously on days 1, 8, and 15 of a 4-week cycle. The primary endpoint was 16-week disease control rate (complete response [CR] + partial response [PR] + stable disease [SD]). Secondary endpoints were progression-free survival (PFS) and overall survival (OS). Translational correlation of PFS with expression of P-glycoprotein (P-gp) was also evaluated. This trial is registered with ClinicalTrials.gov, no. NCT 02607332.

Results: A total of 25 patients were enrolled. Median age was 61 years (range, 38-71), and 16 patients (64.0%) were male. Small bowel was the most common primary site (n = 17, 68.0%), followed by stomach (n = 7, 28.0%). Median 2 cycles (range, 1-12) of paclitaxel were administered per patient. No CR was observed. PR and SD were observed in one patient (4.0%)and 10 patients (40.0%), respectively. The 16-week disease control rate was 20.1%. With a median follow up duration of 20.8 months (range, 17.9-24.0) in surviving patients, median PFS and OS were 1.7 months (95% CI, 0.23-3.13) and 10.9 months (95% CI, 0.0-23.68), respectively. The most frequent grade 3/4 adverse events were neutropenia (20.0%) and leukopenia (8.0%). P-gp expression was evaluable in 19 patients, and a trend toward poor PFS was documented in patients with high P-gp intensity score (3 vs. 1-2; HR 2.3, P = 0.12).

Conclusions: Paclitaxel was well tolerated with modest antitumor efficacy in heavily pretreated patients with advanced GIST. Additionally, P-gp maybe a potential biomarker for selecting patients for paclitaxel treatment.

Clinical trial identification: NCT 02607332.

1622P Heat shock protein 90 (HSP90) inhibitor as a candidate treatment option for gastrointestinal stromal tumor with acquired resistance for conventional receptor tyrosine kinase inhibitors

M. Yamamura[1], A. Yamauchi[2], N. Katase[3], Y. Katata[1], H. Tanioka[1], M. Okawaki[1], T. Nagasaka[1], Y. Yamaguchi[1]
[1]Medical Oncology, Kawasaki Medical School Hospital, Kurashiki, Japan, [2]Biochemistry, Kawasaki Medical School, Kurashiki, Japan, [3]Oral Pathology, Graduate School of Biomedical Sciences, Nagasaki University, Nagasaki, Japan

Background: Imatinib functions as a specific inhibitor of a number of tyrosine kinase enzymes, such as KIT and PDGFR, by occupying the TK active site, and thus improves the prognosis of gastrointestinal stromal tumor (GIST) patients. However, resistance to the drug appears with prolonged usage. Mechanisms of acquired resistance are still under elucidation.

Methods: To evaluate mechanisms of acquired resistance for imatinib, we established a imatinib-resistant GIST cell line, so-called T1R, by culturing the GIST cell line, GIST-T1, with increasing concentrations of imatinib. Next, we analyzed receptor tyrosine kinases (RTKs) and intracellular signals strongly expressed in T1R by western blotting and phosphorylated arrays. Finally, we examined the antitumor effect of an agent which was confirmed to inhibit upregulated RTKs in T1R.

Results: Interestingly, imatinib-resistant T1R showed cross resistance to sunitinib, which offers patients with imatinib-resistant GIST a new treatment option to stop further disease progression. By western blotting, T1R showed a suppression of phosphorylation in KIT in contrast to a promotion of phosphorylation in PDGFRA, which never observed before imatinib treatment. A phosphorylation multiplex array also revealed that T1R had additional promotion of phosphorylation in FGFR, Met, Eph, Axl, and Tie2. Therefore we considered activation of PDGFRA owing to one of the candidate machinery of acquired resistance for imatinib as well as sunitinib. HSP90 inhibitors is known to effective against both imatinib-sensitive and resistant GIST models. Therefore, we examined whether HSP90 inhibitors interact with PDGFRA TK kinase activity in T1R. HSP90 inhibitors inhibited the phosphorylation and protein expression of PDGFRA and other RTKs, resulted to inhibit cell proliferation and induce apoptosis in T1R.

Conclusions: Activation of multiple RTKs is an essential for acquired resistance for imatinib in GIST. Inhibition of PDGFRA and other RTKs by HSP90 inhibitors has a potential to the next treatment option for GIST which acquired drug resistance for conventional small-molecule, multi-targeted RTK inhibitors.

Background: Avapritinib (ava) is a potent and selective inhibitor of activated KIT and PDGFRA, which has shown broad activity against GIST in pts in the Phase 1 NAVIGATOR study (NCT02508532), particularly in those with PDGFRα D842 mutations. We investigated whether baseline ctDNA levels and changes in ctDNA during treatment were associated with response.

Methods: Plasma ctDNA was sequenced at baseline and 2 mos after the start of treatment. Pts (n = 20) in dose-escalation were profiled using the Sysmex OncoBEAM™ PDGFRA assay; Pts (n = 12) in dose-expansion were sequenced with a custom Personal Genome Diagnostics PlasmaSELECT™ 60 panel.

Results: As of 11 Jan 2018, response rate was 73% and stable disease rate was 23% per mRECIST v1.1 (modified for GIST). Median progression free survival (PFS) was not reached; estimated 12 mo PFS rate was 78%. Baseline ctDNA mutation allele fraction (MAF) correlated with target lesion size ($p < 0.002$). Lower than median baseline ctDNA MAF identified a group of pts with 100% PFS after a median follow up time of 16 mo (1.8 to 26.6 mo). Ava led to detectable ctDNA declines (median 5.2 fold) in all pts except those near the quantification limit (which changed minimally). Despite this, larger declines, or falling below the limit of quantification (BLQ), did not correlate with greater shrinkage or longer PFS. Instead, declines were barely quantifiable in pts with low baseline ctDNA approaching limit of detection, while larger declines were driven by high baseline MAF. Therefore, pts with the smallest declines in ctDNA had low baseline ctDNA and were least likely to progress.

Conclusions: Large ctDNA declines have been speculated to be a predictor of treatment response. We show in PDGFRα D842 mutant GIST low baseline ctDNA correlates with prolonged PFS yet ctDNA minimally declines due to detection limits. Surprisingly, large fold declines, even falling below the limit of detection, was not predictive of improved outcomes. Our data suggest that although highly effective targeted therapy achieves rapid declines in ctDNA, baseline ctDNA levels may be more prognostic and that declines in ctDNA levels, even to BLQ, may be falsely reassuring in this population.

Transpl.-Chirurgie, LMU Klinikum der Universität München, Munich, Germany, [5]Klinik für Strahlentherapie und Radioonkologie, LMU Klinikum der Universität München, Munich, Germany

Background: Anthracycline/ifosfamide-based neoadjuvant chemotherapy (NAC) is considered to improve survival in adult patients (pts) with high-risk soft tissue sarcoma (HR-STS) [Gronchi A et al., Lanacet Oncology 2017; 18(6):812-22]. Regional hyperthermia (RHT) combined with NAC has significantly improved radiological tumor response and survival in pts with HR-STS [Issels RD, Lindner LH et al., JAMA Oncology 2018 2018 Feb 15. doi: 10.1001/jamaoncol.2017.4996]. The purpose of this retrospective analysis was to assess whether the pathological tumor response after NAC with doxorubicin/ifosfamide (AI) combined with RHT can predict survival outcomes in adult pts with HR-STS.

Methods: In our database, we identified 138 pts who underwent NAC with AI in combination with RHT (01/09 – 10/16) followed by resection of the residual tumor. Pathological response after NAC + RHT was assessed in seventy-five pts and correlated with survival outcome. Pathological grade of regression of the resected tumor was evaluated according to Salzer-Kuntschik et al. and survival parameters using Kaplan Meier. In the patient group, we identified 28 pts with L-sarcoma (LS, lipo- and leiomyosarcoma) and 47 pts with non-LS.

Results: All 75 pts (22 – 78y, median age 60y) received perioperative (1 – 8 cycles, median 6 cycles) combined with RHT (2 – 16 RHT, median 8 RHT), 23 pts underwent neoadjuvant radiotherapy (NAR). Overall survival (OS) and disease progression free survival (DFS) was not significantly improved for a higher grade of regression, whereas pts with pathological regression grade ≥ 3 (n = 26) had a significant better local relapse free survival (LRFS) than pts with regression grade < 3 (n = 49) ($p = 0.017$).

Conclusions: Histopathological grade of regression after NAC + RHT seems to be predictive for LRFS in adult patients with HR-STS. Further investigations on molecular markers that can predict histopathological response are needed.

1625P Efficacy of metastasectomy on survival in patients with metachronous soft tissue sarcoma-metastasis: Results of a bi-centre study including 135 patients

A. Leithner[1], V. van Praag[2], F. Posch[3], M. Bergovec[1], L. Leitner[1], J. Friesenbichler[1], R. Heregger[3], F-M. Smolle-Jüttner[4], M. Fiocco[2], M. van de Sande[2], J. Riedl[3], M. Pichler[3], A. Gerger[3], J. Szkandera[3], H. Stöger[3], B. Liegl-Atzwanger[5], M.A. Smolle[1]

[1]Department of Orthopaedics and Trauma, Medical University of Graz, Graz, Austria, [2]Department of Orthopaedic Surgery, Leiden University Medical Centre, Leiden, Netherlands, [3]Division of Clinical Oncology, Medical University of Graz, Graz, Austria, [4]Division of Thoracic and Hyperbaric Surgery, Medical University of Graz, Graz, Austria, [5]Institute of Pathology, Medical University of Graz, Graz, Austria

Background: Metastasectomy is hypothesised to improve overall survival (OS) in patients with metachronous metastasis of STS. Evidence in favour of this approach comes from non-controlled single-arm studies subjected to selection bias. In the

present study, advanced comparative effectiveness methods were used to assess the efficacy of metastasectomy vs. "non-invasive" treatments (i.e. chemotherapy, radiotherapy, best supportive care) in patients with metachronous STS-metastasis.

Methods: 135 patients with metachronous STS metastasis, selected out of a population of over 1000 STS patients, who had primarily undergone surgery for localised STS between 1998 and 2015 at two tertiary tumour centres were retrospectively included. In order to evaluate the efficacy of metastasectomy on OS, a propensity score (PS) was estimated, including variables at time of treatment decision for metastatic disease ("baseline"). Based on the PS, an inverse-probability-of-treatment-weight (IPTW) model was calculated to allow analyses with adjustment for favourable prognostic factors prevailing in patients undergoing metastasectomy (for metastasectomy: IPTW=1/PS; for "non-invasive" treatment: IPTW=1/(1-PS)).

Results: OS was significantly better in those 68 patients (44.4%) who had undergone metastasectomy (10-year OS: 23% vs. 4%; log-rank test: $p < 0.0001$; hazard ratio (HR): 0.34, 95% confidence interval (CI): 0.22-0.53, $p < 0.0001$). This positive association prevailed after recalculation of time-to-event-analyses with IPTW-weighted data ((adjusted 10-year OS: 17% vs. 3%, log-rank-test: $p < 0.0001$; HR: 0.33, 95%CI: 0.20-0.52, $p < 0.0001$), compensating for positive prognostic factors prevailing in patients with metastasectomy (i.e. smaller number of metastases, better ECOG performance status, better haemoglobin- and albumin-levels).

Conclusions: In the present bi-centre study, metastasectomy was associated with a significant benefit on OS, persisting even after adjustment for favourable prognostic factors prevailing in patients undergoing metastasectomy. Our data indicate that metastasectomy should be considered as first choice in patients with metachronous metastasis of STS.

1626P Trabectedin and radiotherapy in advanced sarcoma: Experience of a reference center

I.C. Carrasco Garcia[1], N. Hindi[2], J. Peinado[3], I. Rincon[3], M. Cordeiro[4], F.J. Jimenez[5], A. Falcon Gonzalez[1], R. Lasso de la Vega[1], M. Noguer Mediavilla[1], P. Sancho Marquez[1], J. Martin-Broto[2]

[1]Medical Oncology Department, Hospital Universitario Virgen del Rocio, Seville, Spain, [2]Medical Oncology, Instituto de Biomedicina de Sevilla (IBIS) CSIC/US, Hospital Univ. Virgen de Rocio, Seville, Spain, [3]Radiation Oncology, Hospital Universitario Virgen del Rocio, Seville, Spain, [4]Medical Oncology, Hospital Universitario Son Espases, Palma de Mallorca, Spain, [5]Medical Oncology, Hospital Universitario Juan Ramon Jimenez, Huelva, Spain

Background: In patients with advanced soft tissue sarcomas (STS) there is low probability to obtain tumor shrinkage with second-line drugs. That means that patients requiring volumetric response to palliative relief have few therapeutic options since active second-line drugs in STS exhibit less than 10% of RECIST response. Trabectedin (T) has shown to be synergistic with radiation therapy (RT) in preclinical experiments. Additionally, a substantial activity of T+RT has recently been reported in a phase I trial with 71% of overall response rate (ORR) in the irradiated nodules.

Methods: Cases with advanced STS treated with T at standard dose of 1.5 mg/m^2 24-h infusion and RT 30-39 Gy (3 Gy per fraction) were collected for this retrospective series from one sarcoma reference center. RT was started 24 h later the trabectedin initiation. ORR according to RECIST 1.1, progression free survival (PFS) and overall survival (OS) were analized.

Results: Twenty patients with median age 51 (27-77) and male/female 9/11 were selected. STS subtypes were uterine and somatic leiomyosarcoma 5(25%) and 4 (20%) respectively, high grade myxoid liposarcoma 4 (20%) and non-L STS 7 (35%). All but one patient received previous systemic lines, 2 (0-6). Response assessment was, 5 (25%) PR, 9 (45%) SD and 6 (30%) PD. Considering only radiated lesions, response evaluation was as follows: PR 5 (25%), SD 13 (65%) and 2 (10%) PD. There were 8/12 minor responses. Patients with non-L sarcomas also had disease control (1 myxofibrosarcoma, 2 sarcoma NOS achieved minor responses, 1 fibrosarcoma, 1 malignant peripheral nerve sleath tumor, 1 synovial sarcoma with SD). There were not toxic deaths and only one G3 SAE (transaminitis). No dose-reductions or interruptions were registered. With a median follow-up of 11.2 mos (4.4-36), there were 11 progression and 6 death events. The median of PFS was 9.9 months (6.5-13.2 months) while the median OS has not been reached.

Conclusions: T + RT have shown relevant clinical activity in advanced STS, whatever the histotype and location. In 70% of cases there was some shrinkage in radiated lesions bringing up the opportunity of better disease control. Both ORR and PFS were clearly superior with T + RT than historical results obtained with T alone.

1627P Single arm prospective study evaluating the role of neoadjuvant chemotherapy in soft tissue sarcoma

A. Tiwari[1], S. Rastogi[2], S.V.S. Deo[3], D.N. Sharma[4], M.C. Sharma[5], S. Bakshi[6]

[1]Department of Medical Oncology, All India Institute of Medical Sciences, Delhi, India, [2]Medical Oncology, Sameer Rastogi, New Delhi, India, [3]Surgical Oncology, All India Institute of Medical Sciences, New Delhi, India, [4]Radiotherapy, AIIMS, New Delhi, India, [5]Pathology, AIIMS, New Delhi, India, [6]Medical Oncology, Sameer Bakshi, New Delhi, India

Background: Surgery is the primary standard of care for localized soft tissue sarcoma (STS). In certain cases, upfront surgery may not be possible, or it may be mutilating and disfiguring. We conducted this study to evaluate the role of neoadjuvant chemotherapy in this setting.

Methods: This single arm prospective study included patients of age $\geq$18 years with chemotherapy naïve STS of size $\geq$ 5 cm and which were grade II/III. These tumors were either upfront unresectable or possibly resectable with undesirable outcomes. Ewings sarcoma, osteosarcoma, rhabdomyosarcoma and other chemoresistant STS were excluded. The patients received three cycles of Ifosfamide (1.8 gm/m^2 d1-d5) and epirubicin (60 mg/m^2 d1-d2) followed by clinical and radiologic reassessment. The primary objective was overall response rate (ORR), and the secondary objective was to assess conversion to limb salvage surgery (LSS). Overall response was defined as complete response (CR) plus partial response (PR).

Results: We included 36 patients in this study with a mean age of 36.9$\pm$14.7 years. The ratio male: female was 1.1. The most common histology in our cohort was synovial sarcoma [16 (44.4%)] followed by MPNST [5 (13.8%)]. Extremity [23 (63.8%)] was the most common site followed by trunk [8 (22.2%)] and head and neck [5 (13.8%)]. PR was seen in 14 (38.8%) patients, 16 (44.4%) patients had stable disease, three patients had progression and none of the patients had CR. The response could not be assessed in three patients. The ORR was 44.4%. LSS could be done for 13 (56.5%) patients with extremity STS. Ten patients with extremity STS required amputation despite neoadjuvant chemotherapy of which 6 (60%) patients did not give consent for amputation. The chemotherapy regimen was well tolerated, febrile neutropenia was seen in 12.5%. There was no treatment-related mortality.

Conclusions: Neoadjuvant chemotherapy is an effective and safe option for unresectable STS or those who are resectable but require mutilating or disfiguring surgery. The acceptance of amputation as a mean of treatment of STS is low in our population.

Clinical trial identification: CTRI/2017/07/008997.

1628P Preoperative hypofractionated radiotherapy (RT) combined with chemotherapy in primary marginally resectable high grade soft tissue sarcomas (STS) of extremities or trunk wall: Interim analysis of prospective phase II clinical trial

M. Spalek[1], H.M. Kosela Paterczyk[2], A. Borkowska[1], M. Wagrodzki[3], A. Cieszanowski[4], P. Castaneda-Wysocka[4], T. Switaj[2], M.E. Dudzisz-Sledz[2], A.M. Czarnecka[2], E. Dabrowska-Szewczyk[4], P.L. Rutkowski[2]

[1]Radiotherapy, Maria Sklodowska-Curie Institute - Oncology Center, Warsaw, Poland, [2]Soft Tissue/Bone Sarcoma and Melanoma, Maria Sklodowska-Curie Institute - Oncology Center, Warsaw, Poland, [3]Pathology, Maria Sklodowska-Curie Institute - Oncology Center, Warsaw, Poland, [4]Radiology, Maria Sklodowska-Curie Institute - Oncology Center, Warsaw, Poland

Background: The management of marginally resectable STS is challenging. The study aim is to assess the efficacy and safety of preoperative hypofractionated RT combined with chemotherapy in primary locally advanced STS.

Methods: Single-arm clinical trial enrolls patients for one cycle of doxorubicin and ifosfamide (AI) chemotherapy followed by 5x5 Gy RT, and 2 cycles of AI in 7-8 weeks gap between RT end and surgery. Tumor response was assessed in DWI-MR imaging and pathologically by EORTC STBSG criteria. The primary endpoint is rate of limb-sparing surgeries and R0 resections.

Results: 24 patients(pts) met eligibility criteria: 21 finished the whole planned protocol treatment. 3 pts underwent extremity amputation, two after 1st AI cycle due to poor tolerance, one due to extensive tumor invasion without possibility of vessels reconstruction. One toxic death occurred outside our center related to severe bone marrow suppression with septic shock after 2nd AI cycle. Early tolerance of chemotherapy was acceptable. Grade 3+ CTCAE4.03 toxicity developed in 11pts. AI dose was reduced in 8pts who completed therapy (4pts in 2 cycles; 4pts in 1 cycle). Early RT tolerance was satisfactory. EORTC grade 1 radiation dermatitis developed in 13pts and grade 2 in 2pts. Postoperative wound complications occurred in 6pts, including 2 severe wound dehiscence with hospitalization. Very good pathological response (<1% of stainable tumor cells; grade A/B) was reported in 5pts, good pathological response (<50% tumor cells; grade C/D) - in 12pts.

Conclusions: Preoperative AI chemotherapy combined with hypofractionated RT is a feasible method of the management of marginally resectable STS providing a good pathological responses and acceptable treatment toxicity.

1629P Basket trial in advanced cancers: A clinical observation of apatinib in lung metastases and non-lung metastases

C. Tu, Y. Zhou, K. Yao, Y. Luo, W. Zhang, H. Duan, L. Min

Orthopedics, West China Hospital, Sichuan University, Chengdu, China

Background: Metastatic disease to the lung is one of the most common life-threatening complications of cancer and can be seen with most types of cancer. Apatinib, a tyrosine kinase inhibitor targeting VEGFR-2, has shown efficacy in lung cancer. And the preclinical data also showed plasma concentration of apatinib was high in the lung. This cancer registry study aims to make an exploratory assessment of the efficacy and safety of apabinib in lung metastases.

Methods: Between 2015/05 and 2018/03, this study recorded all patients with advanced cancers in our hospital, with apatinib 500 mg or 250 mg being given. Tumor response assessment and survival analysis were performed.

Results: For a total of 103 patients, 30 had no lung metastases, and 73 had lung metastases, among which most were bone sarcoma (56%) and soft-tissue sarcoma (37%) metastases to lung. Among 57 evaluable patients with lung metastases, 2 achieved CR, 29 achieved PR, and the ORR was 54%. In 11 evaluable patients with no lung metastases, no patient achieved CR, 3 patients achieved PR, and the ORR was 27%. For patients with lung metastases, the mPFS was 12.9 months (95%CI, 8.6-14.9 months), mOS was 21.9 months (95% CI, 15.9-31.3 months). For patients with no lung metastases, the mPFS was 6.0 months (95%CI, 4.6-NE months), the mOS was 10.7 months (95% CI, 5.2-NE months). In lung metastatic patients who received apatinib 500mg, the ORR and DCR were, respectively, 55.1% and 89.8%; when treated with apatinib 250mg, the ORR and DCR were 20% and 80%. When Apatinib was used as first line treatment, the ORR and DCR were respectively 64% and 88%; in second line treatment, the ORR and DCR were respectively 42% and 84%, and when apatinib was used in third line treatment, the ORR and DCR were 33% and 100%. For patients with lung metastases, 89.2% patients experienced adverse events (AEs); the most frequent AEs were hand-foot syndrome (21.6%), diarrhea (20%), hypertension (24.3%) and albuminuria (9.4%).

Conclusions: Based on this exploratory analysis, for bone sarcoma and soft-tissue sarcoma with lung metastases, apatinib 500mg showed promising trends in efficacy and safety profile. An expansion study will be needed.

[1]Medical Oncology, Affiliated Sixth People's Hospital, Shanghai Jiaotong University, Shanghai, China, [2]Oncology, Cancer Institute and Hospital, Chinese Academy of Medical Sciences (CAMS), Beijing, China, [3]Bone Oncology, Peking University Cancer Hospital, Beijing, China, [4]Oncology, Cancer Centre Sun Yat-sen University, Guangzhou, Guangdong, China, [5]Oncology, Hunan Cancer Hospital, Changsha, China, [6]Bone, Henan Cancer Hospital, Zhengzhou, China, [7]Bone, Liaoning Cancer Hospital and Institute, Shenyang, China, [8]Bone, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China, [9]Bone, Harbin Medical University Cancer Hospital, Harbin, China, [10]Bone, The First Affiliated Hospital of Bengbu Medical College, Bengbu, China, [11]Oncology, West China Hospital, Chengdu, Sichuan, China, [12]Bone, Gansu Provincial Cancer Hospital, Lanzhou, China, [13]Oncology, Wuhan Union Hospital (of Tongji Medical College of HUST), Wuhan, China, [14]Oncology, The First Affiliated Hospital of Fujian Medical University, Fuzhou, China, [15]Bone, Shanghai General Hospital, Shanghai, China, [16]Medical Oncology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China, [17]Oncology, The Affiliated Tumor Hospital of Guangxi Medical University, Nanning, China, [18]Oncology, Jiangxi Cancer Hospital, Nanchang, China, [19]Bone, The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background: ALTER0203 was a randomized phase IIB trial (NCT02449343) that demonstrated single-agent activity of anlotinib in advanced STS (aSTS). The primary endpoint progression-free survival (PFS) was met and presented as an oral presentation in 2018 ASCO. We evaluated the relationship between age, prior lines of therapy, and dose reductions on the efficacy of anlotinib in aSTS.

Methods: Median PFS (mPFS) was evaluated in subgroups of prior lines of therapy (0 or 1 prior line; 2+ prior lines), age (< 65 y; ≥65 y), and dose reductions (no dose reduction; ≥1 dose reduction). All analyses were descriptive and exploratory and required cautious interpretation.

Results: A total of 158 patients received anlotinib in the ALTER0203 study. Before enrollment, 20 patients of alveolar soft part sarcoma and clear cell sarcoma had no prior line of chemotherapy, 84 patients had received 1 prior line of chemotherapy and 54 patients had received 2+ prior lines of chemotherapy. Median PFS was similar in patients receiving anlotinib who had only 0 or 1 prior line of therapy vs 2+ prior lines of therapy (mPFS, 6.7 vs 6.33 months). In patients receiving anlotinib, mPFS was similar in ages < 65 than ≥65 y (6.33 and 5.9 months, respectively). In patients receiving anlotinib, mPFS was longer in patients requiring ≥ 1 dose reduction vs no reduction (10.43 and 5.73 months, respectively).

Table: 1630P

Subgroups	N	Anlotinib, mPFS, months (95% CI)
Lines of therapy		
0 or 1 prior line	104	6.7 (4.07-9.33)
2+ prior lines	54	6.33 (3.90-8.76)
Age		
< 65 y	152	6.33 (5.06-7.60)
≥65 y	6	5.9 (0.00-14.86)
Dose reduction		
No dose reduction	144	5.73 (3.76-7.7)
≥ 1 dose reduction	14	10.43 (-)

mPFS, median progression-free survival; CI, confidence interval.

Conclusions: In patients receiving anlotinib, longer mPFS was observed in patients requiring ≥ 1 dose reduction. Additionally, mPFS with anlotinib was maintained regardless of lines of therapy or patient age.

Clinical trial identification: NCT02449343.

1631P Efficacy and safety of apatinib in advanced sarcoma

J. Chen, T. Ye, Z. Zhang, Z. Wang, S. Yang, K. Yang, T. Li

Cancer Center, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

Background: Sarcoma constitutes a heterogeneous group of rare solid tumors and has no standard second-line treatment. Anti-angiogenesis tyrosine kinase inhibitors have shown promising efficacy for advanced sarcoma after failure of first-line chemotherapy. Apatinib is a highly selective vascular endothelial growth factor receptor 2 (VEGFR-2) antagonist from China. In the present study, we retrospectively assessed apatinib for safety and activity in advanced sarcoma patients from our cancer center.

Methods: Patients with advanced sarcomas treated with apatinib 250-500mg daily between August 2015 and February 2018 were retrospectively analyzed. Objective response was determined according to RECIST 1.1 criteria, progression-free survival (PFS) was estimated by the Kaplan-Meier curves and safety profile was analyzed.

Results: In total, 52 patients were treated with apatinib and 37 patients (23 males and 14 females) were included for analysis, including 7 alveolar soft part sarcoma (ASPS), 5 PNET/Ewing's sarcoma, 4 osteosarcoma, 4 chondrosarcoma, 3 synovial sarcoma, 4 undifferentiated pleomorphic sarcoma, 4 leiomyosarcoma, 2 angiosarcoma,1 rhabdomyosarcoma, 1 chordoma, 1dedifferentiated liposarcoma and 1 clear cell sarcoma. 5 (13.5%) patients received apatinib as first-line treatment, 17 (45.9%) and 15 (40.5%) were treated with apatinib as second line or later therapy respectively.18 (48.6%) achieved tumor regression, 1 patient with ASPS had complete response, 8 (21.6%) experienced partial response, and disease was stable in 21 (56.8%) patients. The disease control rate was 100% in 5 patients with ASPS. The median PFS for all patients was 12 months, and median PFS of patients except ASPS was 5.9 m. The most frequent treatment-related adverse events included hypothyroidism [11 (29.7%)], Proteinuria [8 (21.6%)], hypertension [11 (29.7%)), hand-foot syndrome [19 (51.4%)], diarrhea [9 (24.3%)], fatigue [5 (13.5%)], hemorrhage [4 (10.8%)], anorexia [5 (13.5%)], oral ulcer [3 (5.4%)], rash [2 (8.1%)], bleaching hair [2 (5.4%)] and aerothorax [2 (5.4%)].

Conclusions: Apatinib may be effective and tolerable in advanced sarcoma, especially in ASPS.

Background: ALTER0203 was a randomized phase IIB trial (NCT02449343) that demonstrated single-agent activity of anlotinib in advanced STS (aSTS). The primary endpoint progression-free survival (PFS) was met and presented as an oral presentation in 2018 ASCO. Similar to other vascular endothelial growth factor pathway-targeted therapies, hypertension and hand-foot syndrome (HFS) have been observed as major adverse events of anlotinib. The goal of our study was to assess if hypertension and hand-foot syndrome induced during treatment with anlotinib were associated with clinical outcome in aSTS patients treated with anlotinib.

Methods: We conducted a review of patients enrolled in ALTER0203. Median PFS was analysed in patients with hypertension and HFS vs patients with no hypertension and HFS. All analyses were exploratory and required cautious interpretation.

Results: A total of 158 patients received anlotinib in the ALTER0203 study. During the study, hypertension was observed in 99 patients (62.66%). HFS was observed in 76 patients (48.1%). Median PFS was longer in patients with hypertension vs patients with no hypertension (7.00 vs 4.37 months, $p = 0.36$). Patients with any grade hypertension while on anlotinib had an adjusted hazard ratio for progression of 0.81 compared to those without hypertension. Also, median PFS was longer in patients with HFS vs patients with no HFS (9.83 vs 4.3 months, $p < 0.01$). Patients with any grade HFS while on anlotinib had an adjusted hazard ratio for progression of 0.47 compared to those without hypertension.

Conclusions: Our data indicate that HFS may represent an interesting prognostic factor for clinical outcome in aSTS patients receiving anlotinib. There is a trend that mPFS of patients with hypertension is longer than those with no hypertension.

Clinical trial identification: NCT02449343.

Background: Osteosarcoma care is challenging especially in lower and middle income countries with limited resources & increasing patient volumes. We need to reduce inefficient practices &reallocate resources to strategies, which can make the greatest &sustainable improvements in patient care.

Methods: We compared the outcomes in non-metastatic osteosarcoma patients treated with 3 sequential non-HDMTX based combination chemotherapy protocols at a single tertiary care center in India over 2 decades. The 1st protocol "OGS-99", involved dose-intense, alternating doublets of, 4 drugs, doxorubicin(Dox),cisplatin(CDDP),ifosfamide(Ifo) & etoposide(Eto); the 2nd protocol, "OGS-99-enhanced", involved OGS-99 drugs with enhanced supportive care including growth factors. The 3 rd dose-dense , "OGS-12" protocol, involved administration of 8 sequential doublets of the 3 most active drugs,(Dox, Cis & Ifo), universal growth factor prophylaxis & targeted nutritional support including IV Iron if required . Event free survival (EFS), overall survivals (OS) and toxicity were estimated using retrospective chart review in OGS-99 & OGS-99-enhanced protocols & prospectively in OGS-12 protocol.

Results: A total of 41, 94 & 385 treatment naive, consecutive, non-metastatic,extremity patients were treated with OGS-99(year 2000-2005), OGS-99-enhanced (2010) & OGS-12 (2011-2016) respectively. At a median follow-up of 19(3-72), 85(2-99) and 36(6-78) months, the 5 year EFS rates are 36%, 50% and 69% in OGS-99, OGS enhanced & in OGS-12 respectively. The corresponding rates of 5 year OS are non-evaluable, 60% & 83% respectively. OGS-12 protocol fared better with respect to grade 3/4 toxicities; febrile neutropenia (40%), thrombocytopenia (36%), anaemia (51%) with 4(1%) chemo toxic deaths & compliance to therapy.

Conclusions: Sequential adaption of more rational chemotherapy regimens, including conception of novel "OGS-12" protocol with, better dose density and elimination of ineffective drugs, enhanced supportive care & thereby reducing the need for dose reductions, resulted in marked improvement in outcomes of non-metastatic osteosarcoma patients. This sustainable, economic efficient strategy is worthy of wide adaption.

1635P HBP-bound doxorubicin: Promising new therapy for bone cancer

E. David, S. Cagnol, J-Y. Goujon, M. Egorov, R. Le Bot

Atlanthera, Saint-Herblain, France

Background: Primary bone cancers and bone metastases derived from advanced cancers have low survival rates. To answer medical need to treat tumors localized in bone environment, we have developed bone-targeted drugs through covalent binding to hydroxybisphosphonates known for their high affinity to bone. Objectives were improvement of efficacy and reduction of systemic toxicity.

Methods: Preclinical proof of concept of lead compound 12b80, an HBP-bound doxorubicin, was carried out on rodents and dogs. 12b80 was administered by IV injection every 3 weeks. Antitumor effects were investigated on various rodent models of bone cancer (orthotopic xenograft models of osteosarcoma or Ewing's sarcoma, models of osteosarcoma-derived lung metastases and models of bone invasion by prostate or mammary adenocarcinoma) and on spontaneous osteosarcoma bearing dogs. Biodistribution was examined by radiolabeling and fluorescence analyses. Toxicity was evaluated by biological and clinical monitoring and histopathological analysis of organs.

Results: 12b80 displayed rapid and sustained targeting of bone tissue and tumor-associated heterotopic bone, and permitted a higher doxorubicin payload in tumor bone environment. Doxorubicin release from 12b80 was dependent on acidic pH associated with active bone tumor environment. 12b80 showed a much lower and reversible toxicity compared with doxorubicin: mild medullar toxicity was recovered within two weeks and no sign of cardiotoxicity or osteonecrosis were observed in rodents and dogs. 12b80 promoted strong antitumor effects on rodent primary bone sarcoma (orthotopic osteosarcoma and Ewing sarcoma), osteosarcoma-derived lung metastasis and on prostate or breast adenocarcinoma bone invasion. 12b80 displayed a dose-response therapeutic effect and was more potent than combination of doxorubicin and zoledronate. First cases of tumor response were also reported in dogs currently under veterinary trial.

Conclusions: HBP-bound doxorubicin 12b80 demonstrated a proof of concept of preclinical bone-targeted doxorubicin delivery. The next step is to complete regulatory phase before starting 12b80 clinical trial (phase I/IIa) as an orphan drug in osteosarcoma salvage therapy.

1636P Perceptions of clinical trial enrollment in patients with bone and soft tissue sarcoma

A. Rosenberg[1], S. Kircher[1], E. Hahn[2], A. Rademaker[3], K. Bilimoria[4], J.D. Wayne[4], M. Agulnik[1]

[1]Hematology/Oncology, Northwestern University, Chicago, IL, USA, [2]Medical Social Sciences, Northwestern University, Chicago, IL, USA, [3]Preventive Medicine, Northwestern University, Chicago, IL, USA, [4]Surgery, Northwestern University, Chicago, IL, USA

Background: Clinical trials represent a critical component in developing effective cancer therapies. Low rates of participation have negatively impacted progress in sarcoma trials. This survey study evaluated patients' attitudes, knowledge, self-efficacy for

decision-making, receptivity, general willingness to participate in trials, and perceptions related to molecular profiling (MP) of tumors.

Methods: IRB approval was obtained. Patients with sarcoma who were evaluated at an academic medical center between 2007 and 2017 were identified through the Enterprise Data Warehouse. A link to an online self-administered survey was emailed to patients. Data were analyzed using Spearman correlations and the Mann-Whitney test.

Results: Surveys were emailed to 750 patients of which 311 patients opened and 206 patients completed a portion of the survey (27.5% of total and 66.2% of opened surveys). Of the 206 patients, median age was 52 years, 57.8% were female, and 24.8% reported metastatic disease. Greater knowledge of trials correlated with increased positive attitudes toward trial participation ($p < 0.001$) and positive attitudes correlated with greater trial self-efficacy ($p < 0.001$). Patients with metastatic disease had more positive attitudes compared with nonmetastatic ($p = 0.033$). Trial enrollment was associated with greater knowledge ($p = 0.002$) and positive attitudes ($p < 0.001$). Among patients who reported knowledge of tumor MP ($n = 46$), 30.4% credit MP with a > 50% chance of isolating a targetable result, and 71.7% assume if an experimental treatment was found based on these results, there is a > 50% likelihood of it being effective. Better attitudes and higher self-efficacy were associated with expectations of lower likelihood of developing side effects from an experimental therapy ($p = 0.0096$; $p = 0.0184$). Of patients who had MP performed ($n = 18$), the most important consideration for this test was its ability to improve their survival and quality of life.

Conclusions: Improving knowledge of trials among sarcoma patients may lead to more positive attitudes and greater self-efficacy regarding trial enrollment. Sarcoma patients tend to overestimate the potential benefit of MP; thus, setting expectations with regards to potential benefit of MP is critically important.

1637P Pneumothorax is a novel sensitivity biomarker for targeting VEGFR2 in lung metastatic sarcoma

Q. Bao[1], Y. Shen[2], W. Zhang[2]

[1]Bone Sarcoma, Shanghai Ruijin Hospital, Shanghai Jiao Tong University, College of Medicine, Shanghai, China, [2]Oncological Orthopaedics, Ruijin Hospital, Shanghai, China

Background: The prognosis of metastatic bone and soft-tissue sarcoma remain distal. VEGFR2 inhibitor (VEGFR2i) has been recently found promising but is limited due to the heterogeneous durability of response.

Methods: From Jan 2016 to Jun 2018, 44 patients with lung metastatic sarcoma, including 32 osteosarcoma, 4 Ewing sarcoma, 3 leiomyosarcoma, 2 chondrosarcoma and 3 other sarcoma, given apatinib treatment were reviewed. Of these patients, extra-pulmonary lesions were noticed in 14 cases including local recurrence (9), bone (3), lymph node (2) and brain (1). A starting 250∼500 mg per day was chosen, with dose adjustment according to the individual tolerability. Progression-free survival (PFS) was accessed by RECIST 1.1 criteria and used to discover the potential predictor of durability of response.

Results: The mean 6 month PFS was 58.9 +/- 8.4%, with the duration of response varying from 1 months to no less than 17 months. 12 of the 44 (27.3%) patients required a long-term dose lowering while the remaining well tolerated or has a dose transient lowering less than 7 days. Adverse effects (AEs) greater than degree 2 was seen in 50.0%, including pneumothorax in 11 cases (25.0%). In 9 of 11 cases with pneumothorax, no or minimal drug discontinuance was conducted, with 5 spontaneous recoveries, 3 recoveries with tube drainage, and 1 thoracic empyema with video-assisted thoracoscopic debridement. Multivariate analysis showed that AEs ($HR = 0.29$ $p = 0.008$) and sarcoma type (osteosarcoma vs other, $HR = 0.17$, $p = 0.001$) were the independent predictors for PFS with VEGFR2i therapy. Surprisingly, pneumothorax was found to be the strongest predictor among all AEs based on the effect size ($HR = 0.29$, $p = 0.036$), indicating that the susceptibility of pneumothorax to VEGFR2i might be a new mechanism-based toxicity biomarker for lung metastatic osteosarcoma.

Conclusions: Our result suggested that pneumothorax is a favorable biomarker for targeting VEGFR2 in lung metastatic sarcoma and we encourage no or minimal drug discontinuation in this circumstance.

1638P Do Royal Marsden Hospital (RMH) and MD Anderson Cancer Center (MDACC) prognostic scoring systems predict survival in patients with bone sarcoma?

W. Alselwi[1], F. Azam[1], M.F. Latif[1], I.A.E-H. Osman[2], W.A.H. Taha[2], K. Bawazir[2], A. Farooq[3], N. Bukhari[2], F. Ibnshamsah[2]

[1]Medical Oncology, King Fahad Specialist Hospital, Dammam, Saudi Arabia, [2]Adult Medical Oncology, King Fahad Specialist Hospital, Dammam, Saudi Arabia, [3]Internal Medicine, East Lancashire Hospitals NHS Trust, Burnley, UK

Background: There is no specific prognostic scoring system for patients with bone sarcomas. Royal Marsden Hospital (RMH) and MD Anderson Cancer Center (MDACC) prognostic scoring systems are used for prognostic classification of different malignancies. The purpose of this study is to evaluate different clinical factors and their correlation with poor survival in bone sarcomas.

Methods: We retrospectively reviewed clinical files of patients (pts) diagnosed with bone sarcoma at the tertiary Oncology Centre between January 2006 and June 2017. Clinical factors including Serum albumin, serum lactate dehydrogenase (LDH), performance status (PS), number of metastases, (in RMH and MDACC scoring systems), platelet count, hemoglobin (HB), serum creatinine and gender were also evaluated. Data was analyzed using SPSS software.

Results: Total of 87 pts with bone sarcoma were identified of which 33 (38%) pts died. Twenty (61%) pts were males and 13 (39%) pts were females. Median age at the time of diagnosis was 23 (12-83) years. Median overall survival (OS) for the whole group was 12 (1-76) months (mo). Pts presented with metastatic disease had a median OS of 11 mo. Median survival of pts with locoregional disease was 19 mo. On univariate analysis, more than 2 sites of metastases was the only factor associated with poor survival ($p = 0.035$). On regression analysis the co-efficient between all the variables and survival time is high ($R = 0.823$) but this is not statistically significant ($p = 0.112$). There was no statistically significant association between poor survival and low serum albumin, high LDH, poor PS, high platelet count, low HB, high serum creatinine and male gender.

Conclusions: Our study concludes that there is a strong correlation between poor survival and more than 2 metastatic sites in patients with bone sarcomas. Other prognostic factors in RMH and MDACC scoring system were not found to be statistically significant in this study. Further studies are needed to validate these clinical factors.

1639P The study of molecular and genetic markers of apoptosis and proliferation, their role in the treatment and prevention of osteogenic sarcoma

M.N. Tillyashaykhov[1], D.S. Polatova[2], M-A. Gafur-Akhunov[2], K. Abdikarimov[2], U. Islamov[2], R. Davletov[2]

[1]Urology, National Research Center of Oncology and Radiology, Tashkent, Uzbekistan, [2]Bone and Soft Tissue Sarcomas, National Research Center of Oncology and Radiology, Tashkent, Uzbekistan

Background: The prognostic value of proliferative and apoptotic activity of tumors in patients with osteogenic sarcoma was investigated in order to determine which genes are involved in their pathogenesis and prognosis.

Methods: Immunohistochemical methods (IHC) were used to study the expression of p53, bcl-2, Ki-67 in patients with osteogenic sarcoma in comparison with the effectiveness of treatment. Patients with positive results of chemotherapy (group 1) underwent radiotherapy for a radical program in the total focal dose up to 60-70 Gy. When receiving a good effect from radiation therapy (group 2), patients received another 4-5 courses of chemotherapy. Surgical treatment was performed in 36 patients (41.9%) with a large pulpy component of the tumor and with ineffective chemotherapy or chemoradiotherapy (group 3).

Results: In group 1 patients, who received chemotherapy, the full effect was observed only in patients with negative and weakly positive IHC reactions to the p53 (18%), Ki-67 (16%) and bcl-2 (10%). For partial effect, the phenotype of tumor cells was as follows: negative and weakly positive IHC reaction to the mutant p53 gene was seen in 52% of patients, in Ki-67 - in 62%, and bcl-2 - in 48%. In 6% of patients in this group, the effect of therapy was negative. In the second group, only 10% of the patients had a full effect of the therapy, while in all patients, the tumor cells were mutant p53 negative, 5% had average Ki-67 and bcl2, and 5% were Ki-67 and bcl-2 negative. 25% of patients in this group had partial effects. In 20% of patients in this group, absence or weak expression of mutant p53 gene was detected in tumor cells, expression of Ki67 and bcl 2 genes in 15% was average, the remaining patients were with Ki-67 and bcl-2 negative. In group 3, 56% of patients had positive effect with therapy, among them, those with weak or no, expression of mutant gene p53 were 75% and only 12.5% showed moderate expression of this protein.

Conclusions: Our findings suggest that the study of the expression of the mutated p53 suppressor gene is a more informative prognostic factor in osteogenic sarcoma and contributes to an understanding of the mechanisms of cancer, development of new

diagnostic methods and pathogenetically valid approaches to the therapy of osteogenic sarcoma.

1640P Outcome of treatment in giant cell tumors of bones: A single institutional retrospective review

M.A. Elshenawy[1], A.A. Badran[2], M.A. Memon[3], A.M. Elshentenawy[4], T. Elhassan[3]

[1]Oncology, Faculty of Medicine - Menoufia University, Shebin El Kom, Egypt, [2]Oncology, Ain Shams University Hospital, Cairo, Egypt, [3]Oncology, King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia, [4]Oncology, Cairo University, Cairo, Egypt

Background: Giant cell tumor of bone (GCTB) is a locally aggressive tumor with 3% incidence of pulmonary metastasis. The standard treatment of GCTB had been surgery until denosumab was approved for these tumors.

Methods: Patients diagnosed to have GCTB in King Faisal Specialist Hospital and Research center, Riyadh, Saudi Arabia were eligible. The aim of this study was to evaluate the clinical outcome of GCTB in our institution in the era before and after denosumab.

Results: We identified 42 patients treated in the period between May 2008 and November 2017. Median follow-up time was 57 months. Median age was 31 years. Twenty-Six (62%) patients were females and 16 (38%) were males. Primary tumor was located in upper limb in 21 (50%) patients - mostly in humerus and radius, in lower limb in 17(43%) patients, and in pelvis/axial skeleton/ribs 3(7%) patients. Thirty patients (71%) had >10 cm. Thirteen patients received neoadjuvant denosumab (median number of cycles 9), all had clinical benefit from therapy.41(98%) had surgery, 27 (64%) patients had enbolic resection and 14 (33%) had intralesional curettage. Fourteen patients (33%) had post-surgical relapse [3(7%) received neoadjuvant denosumab],6(14%) patients with local recurrence and 8(19%) patients with lung metastasis. Denosumab was given to those with metastatic disease (median number of cycles 5). One patient had complete response,2 patients had partial response,3 patients had stable disease and1 patient had progressive disease. Treatment was well tolerated with no incidence of nephrotoxicity, hypocalcemia or osteonecrosis of the jaw.Median recurrence free survival was not reached.

Conclusions: Denosumab is efficient and tolerable in unresectable/metastatic disease as well as in a neoadjuvant setting in locally advanced tumors to facilitate complete surgical resection or avoid mutilating surgery. The risk of recurrences after curettage of GCTB following denosumab raises questions about the optimal management of such cases. Due to rarity of this tumor,larger multicenteric trials should be initiated to clarify the optimal treatment option .

1641P Adriamycin and ifosfamide-based regimen as induction chemotherapy in desmoplastic small round cell tumors: Results of a retrospective single-center study on 34 patients

T.S. Assi[1], A. Le Cesne[1], E. Nassif[1], A. Cavalcanti[2], M. Faron[2], T. Ibrahim[1], C. Le Pechoux[3], O. Mir[1], J. Adam[4], S. Dumont[1], P. Terrier[4], C. Honore[2]

[1]Medical Oncology, Gustave Roussy Institut de Cancérologie, Villejuif, France, [2]Surgery Department, Institut Gustave Roussy, Villejuif, France, [3]Radiation Oncology Department, Institut Gustave Roussy, Villejuif, France, [4]Pathology Department, Gustave Roussy, Villejuif, France

Background: Desmoplastic small round cell tumours (DSRCT) is a rare disease affecting predominantly children and young adults characterised by a specific translocation t(11:22)(p13;q12) which fuses the ESWR1 gene to the WT1 gene. DSRCT shares characteristics with other small-round blue cell cancers including Ewing's sarcoma. . The best induction chemotherapy (IC) is not yet defined. The aim of this study is to evaluate the role of Adriamycin and Ifosfamide (AI)-based regimen as IC in DSRCT.

Methods: All pts diagnosed in our tertiary care center with DSRCT treated with AI-based regimen as IC between 1991 and 2017 were included in this study. Demographic, clinical and long-term characteristics were obtained from the electronic medical records and retrospectively analyzed.

Results: 34 pts were identified. With a median age of 25 yrs (range 18-56), 25 pts were male (74%). All pts had PS 0-1. 28 pts had symptoms (82%) with pain being the most common (n = 25). 14 pts (41%) had extra-peritoneal metastases (EPM) at diagnosis (liver mets (n = 14) associated with lung mets in 4 pts). Out of 34 pts, 26 pts (77%) received AI as IC. The remaining 8 pts had AI in combination to platinum agents (n = 4) or Etoposide (n = 4). Median number of cycles was 6 ± 1 (range 3-9). Objective response and disease control rates were 71% and 91% respectively. Only 3 pts had progressive disease (PD) (9%). Dose reduction were noted in 2 pts with no treatment discontinuation. 41% had grade 3-4 toxicities. 7 pts (21%) developed febrile neutropenia. 17 pts (50%) underwent surgery (including 2 with EPM). Post-operative chemotherapy was given in 41 pts and radiotherapy in 21 pts. In pts who had surgery, local recurrence free survival was 10 months (95% CI: 7-12) while EPM-free survival was 13 months (95% CI: 7-19). Overall survival (OS) for pts without PD was 25.7 months (95% CI: 20.1-31.3). In pts who had surgery, OS was 28.3 months (95% CI: 13.6-43.1) while those who did not have surgery had an OS of 18.9 months (95% CI: 11.6-26.1).

Conclusions: AI-based regimen is a well-tolerated and active option with good response rate as an IC in DSRCT. Comparative data with currently used Ewing-type regimen are eagerly needed in the future.

1642P Determination of biological behavior of solitary fibrous tumors

L. Krsková[1], M. Kalinova[2], I. Odintsov[2], P. Galgonková[2], R. Kodet[1]

[1]Department of Pathology and Molecular Medicine, 2nd Faculty of Medicine, Motol University Hospital, Prague, Czech Republic, [2]Department of Pathology and Molecular Medicine, Motol University Hospital, Prague, Czech Republic

Background: Solitary fibrous tumor (SFT) is an uncommon neoplasm of pleural and extrapleural site of origin formed by cells with fibroblastic features. This tumor exhibits a spectrum of biological behavior and can occur at any age with the peak in the sixth and seventh decade of life. Most of these tumors grow slowly and their clinical behavior is mostly benign; however, up to 20 % of patients develop local recurrences and/or distant metastases.

Methods: We performed a retrospective study of 54 cases of SFTs. We investigated morphologic characteristics, proliferation activity evaluated using Ki-67 immunostain and existence of NAB2-STAT6 fusion gene together with Ki-67, TPX2, and hTERT mRNA expression levels. The aim was to define relationships between proliferation activity and biological potential and progression of the disease. Recently, several alterations within the TERT gene have been detected in human tumors. The most frequent alteration in the TERT gene, somatic promoter mutation, has been described. We measured Ki-67, TPX2, and hTERT mRNA levels using quantitative real-time reverse transcription PCR (RQ-RT-PCR). Determination of hot spot promoter mutation in TERT was analyzed.

Results: NAB2-STAT6 fusion transcript was found in 46/54 cases (85%) of amplifiable samples. The mRNA expression of Ki-67 correlated with local recurrences ($p = 0.025$) and biological behavior of the tumor ($p = 0.0027$), but did not correlate with the type of the NAB2/STAT6 fusion (0.24). The level of Ki-67 mRNA correlated with IHC established results ($p = 0.02$). The TPX2 mRNA expression did not correlate with local recurrences ($p = 0.26$) nor with biological behavior of the tumor ($p = 0.062$). The mRNA hTERT expression correlated well with biological behavior of the tumor ($p < 0.0001$). The majority of SFTs with benign behavior were without detectable expression of hTERT mRNA. A majority of the patients with hTERT expression had also somatic promoter mutation C228T or less frequently C250T. We observed a significant association between increased Ki-67 and hTERT mRNA levels and the SFTs with malignant potential.

Conclusions: Detection of hTERT mRNA expression and its promoter mutation at routine practice might lead to a better estimation of a biological potential of SFTs.

1643P Pazopanib in advanced or metastatic synovial sarcoma: The Gustave Roussy experience

M. Sroussi[1], S. De Percin[1], A.M. Grecea[1], M.A. Benderra[1], M. Velev[1], S. Akla[1], N. Lezghed[1], S. Dumont[1], C. Le Péchoux[2], C. Honore[3], L. Haddag[4], M. Faron[3], P. Terrier[5], O. Mir[1], A. Le Cesne[1]

[1]Medical Oncology Department, Institut Gustave Roussy, Villejuif, France, [2]Radiation Oncology Department, Institut Gustave Roussy, Villejuif, France, [3]Surgery Department, Institut Gustave Roussy, Villejuif, France, [4]Radiology Department, Institut Gustave Roussy, Villejuif, France, [5]Pathology Department, Institut Gustave Roussy, Villejuif, France

Background: Synovial sarcoma (SS) is a rare malignancy usually considered as sensitive to chemotherapy (CT) based on anthracyclins and ifosfamide. Therapeutic options are limited and prognosis of advanced or metastatic SS (a/mSS) remains dismal. Since approval of pazopanib in advanced soft tissue sarcomas (STS), very few data were reported on the activity of pazopanib in a/mSS.

Methods: We retrospectively reviewed all patients (pts) treated with pazopanib for a/mSS in our institution. The histological diagnosis was confirmed by a referral pathologist within the French Sarcoma Group. Data were obtained from medical records. Radiological response was assessed by CT-scan according to RECIST 1.1. Adverse events were graded according to the Common Terminology Criteria for Adverse Events

of the National Cancer Institute 4.03. The aim of this study was to evaluate the activity of pazopanib in a/mSS.

Results: From December 2006 to April 2018, 16 pts with a/mSS of extremities (10 pts), trunk (5 pts) or head and neck region (1 patient) were treated with pazopanib from 400 mg to 800 mg daily dose. Median age was 40 years old (range: 24-69). Pts received a median of 2 prior lines of doxorubicin-based CT in all but one case. Thirty-one per cent of pts received pazopanib in 2nd line therapy and 69% in subsequent lines. Before treatment, 15 pts (94%) had distant metastases (lung in 94%, bone in 25%, associated with local recurrence in 20%) and 1 patient (6%) had unresectable local recurrence. A clinical benefit was observed in 87.5% of pts: 7 (43%) experienced a partial response and 7 (43%) a stable disease. Two pts progressed rapidly during treatment. Two pts definitively interrupted pazopanib due to grade 3 sepsis or hemoptysia. The dose was reduced for 2 pts due to diarrhea and hematuria. On April 2018, 6 patients were still on treatment. The median progression free survival (mPFS) was 6.5 months (1-17+). After a median follow-up of 8.5 months, the median overall survival was not reached.

Conclusions: Pazopanib showed significant clinical activity in a/mSS along with manageable toxicity profile. We observed a prolonged mPFS compared with other subtypes of STS. These results need to be confirmed in prospective trials dedicated to this histological subtype of STS.

1644P Identification of effective drug combinations with regorafenib (REG) for the treatment of pediatric rhabdomyosarcomas (RMS)

D. Zopf[1], Y. Tsvetkova[1], J. Hoffmann[2]

[1]Drug Discovery, Oncology, Bayer AG, Berlin, Germany,[2]Experimental Pharmacology & Oncology, EPO Berlin-Buch GmbH, Berlin, Germany

Background: REG is a small-molecule multikinase inhibitor involved in normal cellular functions and pathologic processes such as oncogenesis, angiogenesis, and tumor immunity. REG is approved for the treatment of advanced colorectal cancer, gastrointestinal stromal tumors, and hepatocellular carcinoma. REG alone is currently being evaluated for its tolerability and safety in pediatric cancers in a clinical phase 1 study. Preclinically, we investigated a series of drugs, which are established or emerging for the treatment of pediatric patients with RMS, for their combination potential with REG to support its clinical development in pediatric indications.

Methods: Proliferation assays were performed in vitro. In vivo, subcutaneous xenografts derived from pediatric alveolar (RH30) and embryonal (RD) RMS tumor cell lines were treated with REG alone and in combination with 13 different compounds including a combination with irinotecan (IRI) and vincristine (VINC). A study design with one mouse per group and a stepwise dose escalation was applied. The body weight of the mice was closely monitored for tolerability and the tumor growth was determined by caliper measurements. Treatment was for four weeks and the time to tumor regression was followed thereafter.

Results: The pattern of response was heterogeneous, ranging from complete regression (CR) to insensitivity. REG alone at an oral dose of 10mg/kg/d delayed the growth of both RMS xenografts. CRs were observed for IRI (both models), paclitaxel (RH30 model), and VINC (RD model) alone near their maximum tolerated doses in mice. The strong monotherapy effects of IRI and VINC preclude a clear demonstration of a combination benefit with REG in this study. Beneficial combination effects were observed for some other drugs. IRI appeared as the most favorable combination partner of REG of the tested drugs. Surprisingly, the RH30 model was insensitive to VINC in this study. Treatment interruptions were required in some cases of treatment intolerability, but no drug-related deaths were observed.

Conclusions: These results warrant further exploration of a combination of REG with IRI and VINC in pediatric RMS.

1645P KS in the era of HAART: A single institutional retrospective review

K. Sankar[1], K. Foster[2], C. Achenbach[1], M. Agulnik[2]

[1]Medicine, Northwestern University, Chicago, IL, USA, [2]Hematology/Oncology, Northwestern University, Chicago, IL, USA

Background: Kaposi's Sarcoma (KS) is an angioproliferative tumor with 4 sub-types: classic (CKS), endemic, immunosuppression related, and epidemic (AIDS-KS). AIDS-KS prevalence has decreased since the introduction of highly active anti-retroviral therapy (HAART). KS lesions develop in patients (pts) with undetectable viral loads and high CD4 counts. KS is variable across subtypes, disease course, and clinical outcomes. Treatments are individualized.

Methods: IRB approval was obtained. A retrospective cohort was identified of KS pts evaluated and treated between 2005 and 2017 at the Lurie Cancer Center, Northwestern University. Pts were identified through the Enterprise Data Warehouse. Pt data was reviewed for demographics, clinical and pathological features and therapy. Descriptive statistics were used to assess disease severity and treatment.

Results: 130 pts with a diagnosis of KS were identified, of which 95 (73.1%) had AIDS-KS and 31 (23.8%) had CKS. There were 4 patients with immunosuppression therapy-related KS and no endemic cases. Males represented 91.5% of cases. The mean age at diagnosis was 66.8 years ± 14.4 among CKS pts and 42.1 years ± 9.6 in AIDS-KS pts. 18.9% of AIDS-KS pts had metastatic disease vs. 6.5% in the CKS group. At KS diagnosis, 50.5% of AIDS-KS pts had CD4 count >200 cells/mm3 and 33.7% had HIV viral load level < =20 copies/mL. Among the 53 pts who received chemotherapy, 45 were AIDS-KS pts (84.9%). 65% of pts with metastatic disease (lung or GI involvement) at diagnosis, of which 90% had AIDS-KS, received chemotherapy vs 36.3% of pts with skin/mucosa involvement. The most commonly used chemotherapy was liposomal doxorubicin (78.4%) with an average of 10 cycles. Other chemotherapy utilized includes paclitaxel and interferon. 16 pts (12.3%) died, of which only two died of disseminated AIDS-KS.

Conclusions: Our retrospective study confirms that 3/4 of pts diagnosed with KS have AIDS-KS. Despite introduction of HAART and the well-controlled nature HIV/AIDS, KS continues to develop. AIDS-KS pts are younger, more likely to have metastatic disease and more frequently require chemotherapy. Poorly controlled HIV still portends a worse outcome in AIDS-KS. Further investigations are required to better understand the etiology of AIDS-KS in pts with undetectable HIV viral loads.

1646P Carcinosarcoma: Clinical and epidemiological patterns in the United States

M.A. Gouda

Department of Clinical Oncology, Faculty of Medicine - Menoufia University, Shebin El Kom, Menoufia Governorate, Egypt

Background: Carcinosarcomas are rare tumors that comprise microscopic features of both epithelial tumors (carcinomas) and connective tissue tumors (sarcomas). Data about carcinosarcoma are relatively scarce. In this study, data about carcinosarcoma in the SEER's database were explored and further analyzed and summarized. SEER incorporates clinical and epidemiological data from 18 cancer registries all over the United States and presented data can be extrapolated to generate evidence on this rarely occurring tumor.

Methods: SEER*Stat Version 8.3.5 was used to obtain data from the SEER 18 Regs Nov 2017 Submission database. Cases diagnosed between 2000-2015 with carcinosarcoma (ICD-O-3 8980/3, 8981/3) were included. Both SEER*Stat and SPSS were used for further data analysis.

Results: A total of 8365 patients were diagnosed with carcinosarcoma between 2000 and 2015, with a median age of 68. The disease occurred predominantly in females (n = 7578; 90.6%) and was more common in white race (n = 6231; 74.5%). Incidence rate was 6.2 per million (CI: 6.1-6.3) with a significant increase of incidence over time (annual percent change = 6.1%) The most common sites for occurrence were the corpus uteri (n = 4656; 55.7%) and ovary (n = 1100; 13.2%) followed by other part of the female genital system (n = 886; 10.6%). The disease was the only primary tumor in 5969 (71.4%) of cases, and the first of 2 or more primaries in 493 patients (8.3%). It occurred as a second or later multiple primary in the remaining percentage of patients (n = 1903; 22.7%). Median survival was 20.5 months, with 5-years and 10-years observed survival being 30.6% (CI: 29.3-31.9%) and 22.4% (CI: 21-23.8%) respectively. Relative survival at 5 years and 10 years was 34.5% (CI: 33.1-36%) and 29.5% (CI: 27.7-31.3%) respectively.

Conclusions: Carcinosarcoma is a rare tumor that occurs with an incidence rate of 6.2 per million. It is predominantly a disease of females who represents 90.6% of cases with female genital system being the main site of occurrence. The disease occurred as a second (or later) primary in 22.7% of patients. It has a median survival of 20.5 months and a relative 5-years survival of 34.5%.

1647P First-line treatment of desmoid tumor: Systemic therapy versus upfront surgery

J.C.E.S.O.D. Souza, H.M. Lourenço, G. Mendes

Oncology Department, INCA - Instituto Nacional de Cancer, Rio de Janeiro, Brazil

Background: Desmoid tumor (DT) is a rare and locally invasive proliferative disease. The standard first-line treatment used to be radical surgical resection. However, during recent years it has been debated whether to offer an aggressive and morbidity treatment to a potentially indolent tumor. Desmoid tumor has uncertain behavior, some are aggressive cases, others indolent and there are some reports of spontaneous involution.

Nowadays, the guidelines suggest to watch and wait before offering an aggressive treatment, and avoiding the surgical treatment. But in our experience patients had less morbidity and disease progression with a surgical approach.

Methods: Patients with histological diagnosis of DT and treated at INCA between January 1998 and December 2015 were identified and their medical records were analyzed.

Results: Of 191 patients evaluated, there were 137 females (71.2%). The median age at diagnosis was 34 years (range:17.79-76.96y). Tumor locations were: thoracoabdominal wall (n = 100, 52.3%), extremities (n = 53,27.7%), abdominal cavity (n = 26; 13.6%), and head and neck (n = 12, 6.2%). Tumor sizes were documented in 152 cases (79.5%) and ranged from 1 cm to 37 cm (median, 10 cm). Twenty-seven pts (14.1%) received systemic therapy (ST) (n = 5 vinblastine and methotrexate; n = 22 tamoxifen) and 164 pts (85.8%) were submitted to surgery (4pts received adjuvant tamoxifen) as first-line treatment. There was no difference between gender (p = 0.86), tumor location (p = 0.30), or tumor size (p = 0.53) when choosing first-line treatment. The odds of severe morbidity were 2.13 higher with ST than with upfront surgery. Four pts were submitted to surgery after systemic first-line treatment. After a median follow-up of 71 months, there was significantly more disease progression in the ST group (17pts – 62.9%) than in the surgery group (55 pts – 33.5%) (p = 0.005), and they received more subsequent treatment (p = 0,01). There were 2 deaths in the ST group and 9 deaths in the surgery group, with 10-year survival of 93.2% and 92%, respectively.

Conclusions: DT is an indolent disease but has the propensity for locally invasive growth and recurrence. Although ST is a less aggressive treatment, it was associated with higher severe morbidity, more disease progression, and more subsequent treatment in this trial.

1648P Adult rhabdomyosarcoma in Tunisia: Clinical presentation, treatment and outcome

M. Saadi[1], D. Tajina[1], F. Letaief-Ksontini[1], K. Meddeb[1], A. Gabsi[2], Y. Yahyaoui[1], A. Mokrani[1], M. Ayadi[1], N. Chraiet[1], H. Rais[1], A. Mezlini[1]

[1]Medical Oncology, Salah Azaiez Institute, Tunis, Tunisia, [2]Medecine, Salah Azaiez Institute, Tunis, Tunisia

Background: We aimed to describe clinico-pathological features and outcomes of Rahbdomyosarcoma (RMS) in Tunisia.

Methods: We assembled a retrospective cohort of 47 patients aged 18 or older diagnosed with, and treated for RMS at our institute between 1994 and 2013. Patient's characteristics, tumor variables and treatment outcomes were evaluated. Tumors were classified according to the Intergroup RMS Study (IRS) staging.

Results: Median age was 39 and 66% were male. At presentation, 33 had localised disease and 14 metastatic. Metastasis site was lung in 17% of cases. Sixteen patients had node positive disease. Median tumor size was 9 cm. Patients presented with swelling or palpable mass in 63.8% of cases, pain in 17%, exophthalmia in 6.4% and bleeding in 4.3%. Less common clinical presentations were functional impairment, cranial nerve palsies, superior vena cava syndrome and nasal obstruction seen in one case each. Tumor site was extremities in 40.4% of cases, trunk in 23.4%, head and neck in 19.1% and genito-urinary tract in 17%. According to favorable/unfavorable prognostic location, tumor site was unfavorable in 65.9% of cases and favorable in 33.9%. RMS histologic subtype was pleomorphic in 36.2% of patients, embryonic in 25.5%, not mentioned in 23.4%, alveolar in 12.8% and combination of embryonic and alveolar in 2.1%. Among 38 patients who underwent surgery, 40.4% had complete resection (IRS stage I). Chemotherapy was adjuvant in 4 patients, neoadjuvant in 6 and 1st line in 13 with a median number of cycle of 3 in each schedule. Radiotherapy (RT) was adjuvant in 19.1% of cases and symptomatic/palliative in 21.1%. Median dose of adjuvant RT was 55 Gray. Median progression free survival after adjuvant treatment was 4.5 months, 47.1% relapsed locally, 35.3% developed distant metastasis and 17.6% presented local recurrence with distant metastases. Five year overall survival (OS) was 46% for localised RMS and 40% for metastatic disease. Among all studied factors, non operated patients and those under 30 years old had worse OS with p values of 0.005 and 0 respectively.

Conclusions: Adults with RMS have poor prognosis. All patients should therefore undergo multimodality treatment comprising of surgery, radiation, and chemotherapy to achieve better outcomes.

1649P A pan-cancer landscape analysis reveals a subset of endometrial stromal and pediatric tumors defined by internal tandem duplications of BCOR

L. Juckett[1], D.I. Lin[2], R. Madison[1], C. Patriquin[1], G.M. Frampton[3], V.A. Miller[3], J.S. Ross[3], J. Chung[3], A.B. Schrock[3], S.M. Ali[3], J.A. Elvin[3]

[1]Clinical Bioinformatics Operations, Foundation Medicine, Cambridge, MA, USA, [2]Pathology, Beth Israel Deaconess, Boston, MA, USA, [3]Genetics, Foundation Medicine, Inc., Cambridge, MA, USA

Background: Internal tandem duplications of BCOR (ITD) have been previously observed in pediatric cancers including clear cell sarcoma of the kidney, and rare adult tumors, most recently, in four cases of endometrial stromal sarcoma (ESS) identified by Sanger sequencing (Chiang, 2017; Mariño-Enriquez, 2018). We reviewed the genomic profiles of a large series of advanced cancer patients to identify all cases and diseases harboring BCOR-ITD.

Methods: Tissues from on 140,411 unique advanced cancers were sequenced by hybrid-capture-NGS based comprehensive genomic profiling of 186 to 315 genes plus introns from 14 to 28 genes commonly rearranged in cancer, as well as RNA for 265 genes for a portion of these cases.

Results: BCOR-ITDs were present in 0.024% of all cases (33/140,411), most frequently in sarcomas 63.6% (21/33) either of uterine origin 52.4% (11/21) or in children (non-uterine) 42.8% (9/21). Of the uterine cases, mean age was 42.2 years (range 14-59 years) and referring diagnoses: ESS (6/11), uterine sarcoma (NOS) (2/11), uterine leiomysarcoma (2/11), and undifferentiated uterine sarcoma (1/11). Expert gynecologic pathology central review identified all these cases as having a similar high-grade morphology consistent with ESS, and 90% of cases having a round cell component. The average age of the pediatric sarcoma patients was 3.33 years (range 1-11 years), and most commonly diagnosed as soft tissue sarcoma (NOS) (4/9) and fibrosarcoma (2/9). Cases carrying a BCOR-ITD had a mean Tumor Mutation Burden of 4.12 mut/MB (range 0.8-25.45). The identified BCOR-ITDs occurred most frequently in exon 15, 69.7% (23/33). These exon 15 events had a mean insertion length of 31.7 codons (range 30-38 codons). Of the uterine sarcoma cases harboring exon 15 BCOR-ITDs none simultaneously carried gene fusions typically associated with ESS.

Conclusions: BCOR-ITDs define a rare subset of pediatric and clinically aggressive endometrial stromal sarcoma cases, as defined by NGS for the first time. Our findings along with previous work delineate the pan-cancer landscape of this alteration and suggest the need for focused investigation to delineate the pro-oncogenic function of BCOR, along with any sensitivity to targeted therapies.

1650P The efficacy of eribulin for patients with taxane-resistant cutaneous angiosarcoma: Interim result of multi-center, prospective observational study

Y. Fujisawa[1], K. Yoshino[2], T. Fujimura[3], S. Matsushita[4], H. Uchi[5], Y. Yamamoto[6], H. Hata[7], A. Otsuka[8], T. Miyagi[9], M. Ishii[10], T. Funakoshi[10]

[1]Dermatology, University of Tsukuba, Tsukuba, Japan, [2]Dermatology, Tokyo Metropolitan Cancer Center, Tokyo, Japan, [3]Dermatology, Tohoku University, Graduate School of Medicine, Sendai, Japan, [4]Dermato-Oncology/Dermatology, Kagoshima University, Kagoshima, Japan, [5]Dermatology, University of Kyushu, Hakata, Japan, [6]Dermatology, Wakayama Medical University, Wakayama, Japan, [7]Dermatology, University of Hokkaido, Sapporo, Japan, [8]Dermatology, Kyoto University-Graduate School of Medicine, Kyoto, Japan, [9]Dermatology, University of Ryukyu, Naha, Japan, [10]Dermatology, Keio University School of Medicine, Shinjyuku, Japan

Background: Taxanes (TAX) are the current first-line treatment for advanced cutaneous angiosarcoma (CAS). On the other hand, eribulin (ERB) is a nontaxane microtubule inhibitor approved for treatment of advanced sarcoma in Japan. However, no study has evaluated ERB in CAS patients. We hypothesized that ERB would be well tolerated and active in patients with TAX-resistant CAS because TAX and ERB have different mechanisms of action to inhibit microtubule formation.

Methods: We designed a single-arm, prospective observational study of ERB administered at dose of 1.4 mg/m^2 on days 1 and 8 in every 21 days. TAX-resistant, advanced CAS patients for whom ERB use was planned were enrolled. The primary endpoint is overall survial (OS), and the secondary endpoint, response ratio (RR), progression-free survival (PFS), and toxicity assessment. The estimated median OS in a previous clinical study (ANGIOTAX), in which patients received TAX as the second-line treatment, was 6 months, so we set this number as the threshold and expected a 6-month OS of 70% with ERB treatment. Based on these numbers, the required number of patients to be enrolled was calculated as 31; thus, we set 35 patients as the target number.

Results: At the time of submissiion, 25 CAS patients, median age 74, were enrolled. All had prior TAX exposure. In all but 1 patient the primary tumor was in the head and neck, and 10 patients had a metastatic tumor. The performance status (PS) was generally good: 22 with PS0 or 1. The median follow-up period was 161 (47-464) days. The

respective Kaplan-Meier estimates for OS and PFS rates at 6 months were 70% and 31%. The respective median OS and PFS were not-reached and 94 days. The respective RR at weeks 7, 13, and 25 were 24%, 12% and 11%. No death related to treatment was observed. Although 9 patients experienced >grade 3 toxicity (7, neutropenia; 2, anemia; 1, retroperitoneal abscess), they all recovered.

Conclusions: ERB is a well-tolerated regimen with promising activity in TAX-resistant CAS. The common toxicity is neutropenia, which requires growth factor support. This study is underway and enrollment is expected to be completed in 2018. This study may provide a new treatment option for patients with PTX-resistant CAS.

1651P Multicenter, open-label phase II study of daily oral regorafenib for chemotherapy-refractory, metastatic and locally advanced angiosarcoma

M. Agulnik[1], B.A. van Tine[2], S. Attia[3], A. Rademaker[4], M. Milhem[5], S.H. Okuno[6]

[1]Hematology/Oncology, Northwestern University, Chicago, IL, USA, [2]Hematology Oncology, Siteman Cancer Center at Barnes-Jewish Hospital and Washington University, St. Louis, MO, USA, [3]Oncology, Mayo Clinic, Jacksonville, FL, USA, [4]Preventive Medicine, Northwestern University, Chicago, IL, USA, [5]Medicine, University of Iowa, Iowa City, IA, USA, [6]Hematology Oncology, Mayo Clinic, Rochester, NY, USA

Background: Angiosarcoma has a particularly poor prognosis with 5 year overall survival rates of approximately 30-40%. Treatment of locally advanced and metastatic angiosarcoma is inadequate. Data strongly suggest concurrent, potent inhibition of VEGFR and Tie2 represents an attractive therapeutic strategy in angiosarcoma. Regorafenib displays potent VEGFR and Tie2 receptor inhibition and also possesses activity against additional potential targets in angiosarcoma including PDGFRs, RAF, KIT and FGFR.

Methods: A multicenter phase II study of regorafenib in patients with locally advanced or metastatic angiosarcoma was conducted through the Midwest Sarcoma Trials Partnership. Adequate performance status, organ function, measurable disease (RECIST 1.1) and 1-4 prior therapies were required. Regorafenib 160 mg PO daily was given in 28 day cylces (21 days on, 7 days off) until disease progression (PD) or unacceptable toxicity. The primary endpoint was progression-free survival (PFS), assessed at 16 weeks. Secondary endpoints include overall response rate (ORR), clinical benefit rate (CBR), OS, and safety and tolerability. A Simon 2-stage design was used.

Results: A total of 18 pts were enrolled at 5 sites, 14 are evaluable for response. Median age was 55.6 (range 21-82); 61% were female; 72% metastatic disease. PFS at 4 months is 46% with a median PFS and OS of 2.7 and 15 months, median follow-up 7.9 months (0.4-23). 1 confirmed CR and PR, 5 SD and 7 PD were observed. ORR and CBR are 14 and 50%, respectively. Common grade 3-4 adverse events were as expected.

Conclusions: Regorafenib was well tolerated in this study of pretreated patients with angiosarcomas. Median PFS and PFS at 4 months are promising. Regorafenib will continue to be explored in this two-stage optimal Simon design, for a total of 31 patients.

Clinical trial identification: NCT02048722.

1652P Outcomes and prognostic factors for angiosarcoma: A 19-year single institution experience

M.E. Chirila[1], D.T. Eniu[2], N. Todor[3], V.M. Nagy[1], M.L. Galatir[4], D. Coza[5], V. Cernea[1], D.L. Martin[1], Z. Fekete[1]

[1]Radiotherapy, Ion Chiricuta Oncology Institute-IOCN, Cluj-Napoca, Romania, [2]Surgery, University of Medicine and Pharmacy Cluj-Napoca, Cluj-Napoca, Romania, [3]Biostatistics, The Oncology Institute "Prof.Dr.Ion Chiricuta" Cluj-Napoca, Cluj-Napoca, Romania, [4]Pathology, The Oncology Institute "Prof.Dr.Ion Chiricuta" Cluj-Napoca, Cluj-Napoca, Romania, [5]Epidemiology, The Oncology Institute "Prof.Dr.Ion Chiricuta" Cluj-Napoca, Cluj-Napoca, Romania

Background: Angiosarcoma is a rare malignancy, and the data about its clinicopathological features and prognostic factors are limited. The purpose of this study was to present a retrospective analysis of angiosarcoma patients treated at a single institution.

Methods: Clinical and pathological features of 41 patients treated in our institution between 1998 and 2016 were analyzed.

Results: Of the 41 patients included, 53.7% were women and 46,3% were men and median age was 60 (16-81). 34.1% cases were located in the soft tissues (ST) of the limbs or trunk, 24.4% in the viscera (V), 19.5% in the breast (B), 14.6% involved the head and neck (HN) and 7.3% in the bone (B). The overall survival (OS) at 5 years was 26% (IC: 15% - 42%), with a median survival of 14.9 months. For the 17.1% patients that were alive at the time of analysis, the median follow up was 60 months (16.1-222.1).The tumor sites for the 7 surivors involved B(4), ST(1), HN(1) and V(1). Radiation induced angiosarcoma was suspected in 17.1% patients. Chronic lymphedema was described/highly probable for 19.5% of the patients. Surgery(S) was performed in 82.9% cases, chemotherapy(CT) in 41.5% cases, and radiation therapy(RT) for 9.8% of cases. CT was more likely to be given to younger patients, but did not improve OS. The pathology report was uncertain for 39% cases at first examination. Superficial tumors (B, ST and HN) had a better OS than deep tumors (V,B) but not statistically significant (31%vs15%). Women had a significant better OS compared to men (36%vs16%, $p = 0.02$). OS at 5 years for patients under age 67 was 30%, and 17% for patients above 67 ($p = 0.07$). Tumor grade was assesed for 85.4% cases. Grade 1(G1) was found in 12.2%, G2 in 36.6% and G3 in 36.6% patients. Patients having G3 tumors had a lower OS, but not statistically significant. Relapse occured at 58.5% of the patients (from 1 to 4 episodes). Of all relapses, 68.3% occured locally, 7.3% regionally, and 48.8% were distant metastases. The most common metastatic sites were lung (7 cases), bone (4), skin (4) and liver (3).

Conclusions: Angiosarcoma is an agressive tumor that was often underrecognized, occuring in various sites. Women with history of radiotherapy or lymphedema are at higher risk, but have a better prognosis. Younger patients and lower grade seem to have a longer survival.

1653P Management of locoregional recurrence after radical resection of a primary non-metastatic retroperitoneal soft tissue sarcoma: Results of a retrospective series in a tertiary care center

C. Honoré[1], M. Faron[1], O. Mir[2], L. Haddag[3], S. Dumont[4], P. Terrier[5], J. Adam[5], C. Lepéchoux[6], A. Le Cesne[7]

[1]Surgery Department, Institut Gustave Roussy, Villejuif, France, [2]Cancer Medicine, Institut Gustave Roussy, Villejuif, France, [3]Radiology Department, Institut Gustave Roussy, Villejuif, France, [4]Department of Medicine, Institut Gustave Roussy, Villejuif, France, [5]Pathology Department, Institut Gustave Roussy, Villejuif, France, [6]Radiation Therapy, Gustave Roussy - Cancer Campus, Villejuif, France, [7]Department of Medicine, Gustave Roussy, University Paris-Saclay, Villejuif, France

Background: Retroperitoneal soft tissue sarcomas (RPS) are rare tumors. Despite surgery, 5% to 36% of patients experience locoregional recurrence (LR) the optimum treatment of which is still debated. The aim the study of to report our experience in treating LR.

Methods: All 297 consecutive patients operated for a non-metastatic primary RPS between 1994 and 2017 were retrospectively analyzed to identify patients who developed LR. Demographic data, treatment variables and long-term outcome were recorded to calculate disease free survival (DFS), overall survival (OS) and predictive factors of recurrence.

Results: After a median follow-up of 97 months, 55 patients (19%) developed LR. The first site of recurrence was locoregional in 100% with associated peritoneal metastases in 45% and distant metastases in 5%. The median disease free interval (DFI) was 24 months. After recurrence treatment, the 1-, 3- and 5-year OS rates were 71%, 46% and 33%, and 1-, 3- and 5-year DFS rates were 50%, 22%, and 15%. Low tumor grade, DFI above 24 months, exclusive LR and well-differentiated liposarcoma were predictive of better OS and DFS. Despite finding no statistical difference between treatment strategies, median OS was less than 1 month after best supportive care, 44 months after chemotherapy (including patients who underwent subsequent LR radiotherapy or surgery) and was not reached after upfront surgery or radiotherapy. Fourteen patients underwent initial surveillance for low-grade liposarcoma and eventually required treatment in 86% after a median delay of 20 months during which no patient developed distant metastases.

Conclusions: The management of LR in RPS is complex. An initial surveillance may not alter survival in asymptomatic low-grade and slow-growing LR. A LR decision scheme is proposed.

1654P Soft tissue sarcomas (STS) in elder patients: No impact of age on overall survival (OS) in an unselected cohort

J.A. Perez Fidalgo[1], A. Lopez[2], V. Gambardella[3], S. Navarro[4], A. Iranzo[5], N. Diaz Fernandez[2], P. Tolosa[5], A. Silvestre[6], E. Iriarte Moncho[2], M.C. Garcia Mora[7], A. De la Paz[2], J.J. Soler[8], A. Cervantes[9]

[1]Medical Oncology, Hospital Clinico Universitario de Valencia, INCLIVA, CIBERONC, Valencia, Spain, [2]Medical Oncology, Hospital San Juan, Alicante, Spain, [3]Medical Oncology, Hospital Clinico Universitario de Valencia, Valencia, Spain, [4]Pathology, Hospital Clinico Universitario de Valencia, Valencia, Spain, [5]Medical Oncology, Hospital Clinico Universitario de Valencia, INCLIVA, Valencia, Spain, [6]Orthopedic Surgery, Hospital Clinico Universitario de Valencia. INCLIVA, CIBERONC, Valencia, Spain, [7]Radiotherapy, Hospital Clinico Universitario de Valencia, Valencia, Spain, [8]Radiology, Hospital Clinico Universitario de Valencia, Valencia, Spain, [9]Medical Oncology, Hospital Clinico Universitario de Valencia, INCLIVA, CIBERONC Spain, Valencia, Spain

Background: A recent analysis of 12 trials in first line showed similar outcomes for elder vs younger patients. Nevertheless these results might be due to a selection bias. The aim of our study was to assess whether elder patients (pts) (>60 years) had the same outcomes than younger (<60 years) in an unselected population of STS stage I-IV.

Methods: A retrospective analysis of pts diagnosed with STS stages I-IV at two institutions between 2000 and 2015 was performed. GIST and other indolent STS such us low-grade stromal sarcoma tumors, cutaneous Kaposi Sarcoma, Desmoid tumors and dermatofibrosarcoma protuberans were excluded. Demographic, clinical and pathological variables were obtained from the medical charts. Overall survival (OS) was calculated according to the date of death by any cause or lost of follow-up.

Results: 115 pts, men/women 59/56 median age of 54.6 years (16.6-82.62) were included. 71 pts (61.7%) were <60 years (younger) and 44 (38.3%) were >60 years (older). Most frequent subtypes were liposarcoma (16.5%), leiomyosarcoma (14.8%) and undifferentiated sarcoma (9,6%). Most frequent sites were lower extremity (27.8%) , retroperitoneum (13.9%) and thorax (13.0%). TNM Stage (or FIGO in endometrial origin) were stage I-II (53%), III (38%) and IV (19%). 98 pts were operated of the primary tumor (Resection was R0 in 53, R1 in 30 and R2 in 4, in 11 data was missed). 37 pts (32.2%) received anthracyclines in any line (31 in younger and 6 in older pts). 68 pts (59.1%) had a local or systemic relapse. 53 pts died (46.1%). There were no differences by age group on stage, grade and radicality of surgery (chi squares $p = 0.52$, 0.48 and 0.47 respectively). Nevertheless elder patients were less likely to receive anthracycline-based therapy (RR 0.33 95%IC 0.16-0.72, $p = 0.001$). Grade and stage were significant prognostic factors for OS: median OS 104.4 m for Stage I-III vs 14.7 m Stage IV, $p < 0.0001$ and 146 m for low (grade 1-2) vs 49.1 m for high grade (grade 3) $p = 0.0025$, respectively. Age group had no effect on median OS (74.4 months for younger and 78.9 months for older log Rank $p = 0.13$).

Conclusions: Despite significant undertreatment with anthracycline regimens, elderly patients do not have worse survival outcomes in this exploratory analysis of an unselected population.

1656P Should we consider altering our patterns of care for elderly sarcoma patients?

S. Vari[1], C. Zoccali[2], V. Anelli[3], A. Annovazzi[4], M.G. Petrongari[5], G. Maggi[6], D. Giannarelli[7], N. Saldducca[2], L. Favale[2], M. Zeuli[1], R. Biagini[2], A. Latini[8], W. Faltyn[1], M.' Anza[1], R. Covello[9], J. Baldi[2], D. Pellegrini[1], E. Checcucci[7], F. Cognetti[1], V. Ferraresi[1]

[1]Oncology, IRCCS-Regina Elena National Cancer Institute, Rome, Italy, [2]Oncological Orthopedics, IRCCS-Regina Elena National Cancer Institute, Rome, Italy, [3]Radiology, IRCCS-Regina Elena National Cancer Institute, Rome, Italy, [4]Nuclear Medicine, IRCCS-Regina Elena National Cancer Institute, Rome, Italy, [5]Radiation Oncology, IRCCS-Regina Elena National Cancer Institute, Rome, Italy, [6]Psychology, IRCCS-Regina Elena National Cancer Institute, Rome, Italy, [7]Biostatistics, IRCCS-Regina Elena National Cancer Institute, Roma, Italy, [8]Dermatology, IRCCS San Gallicano Institute, Rome, Italy, [9]Oncology - Pathology, IRCCS-Regina Elena National Cancer Institute, Rome, Italy

Background: An increasing proportion of elderly patients (pts) are now being seen at cancer centres, with an increasing incidence of sarcoma. This has become a growing challenge for health care providers, because of the worse prognosis of these pts and our poor knowledge from trials, were they are underrepresented or excluded.

Methods: We performed a retrospective review of elderly pts with soft tissue and bone sarcomas treated between 2012 and 2017 at Regina Elena National Cancer Institute. Overall, 124 pts, median age of 77 (range 70-92), were evaluated for: surgery, radiotherapy (RT), medical treatment and related toxicities.

Results: The most common histological subtypes were: pleomorphic sarcoma (32%); liposarcoma (17%); leiomyosarcoma (13%); mixofibrosarcoma (9%); bone sarcoma (7%); and others (22%). A total of 107 pts had localized disease at diagnosis and 98 of them had surgical resection. 10 pts received adjuvant chemotherapy (CT) (8 Adriamicin (ADM), 1 Gemcitabine (Gem) and 1 Imatinib (IM)) and 35 pts adjuvant RT. 2 pts, unsuitable for surgery, were treated with RT, and 7 had best supportive care (BSC) (median age: 80, range: 73-85). Of the 17 metastatic pts, 13 were treated with palliative surgery. After surgery, 3 pts had RT and 3 had single agent CT (1 ADM, 1 Epirubicin (EPI) and 1 patient with GIST received IM followed by 2nd line Sunitinib). The remaining 3 pts had BSC due to age > 80 yr and PS 2. 10 non-metastatic pts had recurrent disease and were treated with 1st line CT (3 EPI, 1 Dacabarzine, 2 Gem, 1 Pazopanib, 1 ADM, 1 Docetaxel/Gem, 1 Bleomicine/Vinblastine). 6 received 2 lines of CT after progression (4 Trabectidin and 2 Gem). 13 of 21 pts treated with CT had no toxicities. The most common toxicities observed in 8 pts left were: haematological (37%); gastrointestinal (12%), and transaminitis (25%).

Conclusions: In our analysis, "fit" elderly pts were treated with the same medical treatments as non-elderly pts. Tolerability was fairly good, without discontinuation or hospitalization. Only 8% were treated with BSC, a relevant result considering the median age of our pts. Future studies designed for elderly pts and rare tumours, such as sarcomas, are needed to improve survival rates and quality of life of this poorly represented group of pts.

1657P Return to work and quality of life in disease-free adult sarcoma patients

A. Kollar[1], S. Müller[1], N. Fankhauser[2], I. Briner[1], F. Klenke[3], J. Bernhard[1]

[1]Medical Oncology, University Hospital Bern, Inselspital, Bern, Switzerland, [2]Clinical Trial Unit, University of Bern, Bern, Switzerland, [3]Department of Orthopedic Surgery, University Hospital Bern, Inselspital, Bern, Switzerland

Background: Treatment of extremital sarcoma patients may be associated with significant functional disabilities affecting quality of life (QoL) and therefore the return-to-work (RtW) process. Many studies report on RtW and QoL in childhood, adolescents and young adult cancer survivors of different malignancies. In contrast, studies looking at adult sarcoma patients in particular are limited.

Methods: Patients with the diagnosis of an extremital sarcoma of soft tissue and bone, surgically treated between 2000 and 2015, age at diagnosis of ≥ 18 or < 65 (age of retirement in Switzerland), alive and without evidence of sarcoma disease were invited for an interview. The primary objective was to investigate the employment rate. Secondary aims were to assess biomedical predictors of RtW and investigate the present QoL of adult sarcoma survivors. Health-related QoL measurements including physical, mental, and social domains were investigated with the following questionnaires: TESS (The Toronto Extremity Salvage Score), SF-36 (short-form health survey), CES-D (Center for Epidemiologic Studies-Depression Scale) and FoP-Q-SF (fear of progression).

Results: 5 out of 45 (11.1%) interviewed patients did not return to work. In the univariate analysis no statistically significant parameter predicting RtW could be detected. High educational level and full-time employment before sarcoma diagnosis showed a non-significant tendency towards predicting increased RtW probability. In the multivariate analysis full-time employment before sarcoma diagnosis is a significant predictor of RtW (OR 9.828 (1.318 – 73.303)) whereas high educational level does not show a significant influence. Neither the SF-36 physical and mental summary score nor the scores of the other interviews significantly correlated with RtW outcome. However, the mean difference in the FoP-Q-SF- score between the two groups (no RtW and RtW) was -10.981 (-18.242 to -3.720) in the multivariate model. Age at diagnosis, gender, type of sarcoma, tumor site/grade, amputation rate, Whoops procedure did not correlate with rate of RtW.

Conclusions: Our study reveals a high employment rate and good QoL of adult sarcoma survivors. Part-time employment and fear of progression might hamper the RtW process.

1658P No benefit of preoperative chemotherapy for primary retroperitoneal sarcomas: Results from a single center propensity-matched analysis

M. Faron[1], S. Dumont[2], J. Adam[3], O. Mir[2], L. Haddag[4], C. Le Pechoux[5], P. Terrier[6], A. Le Cesne[7]

[1]Surgery Department, Institut Gustave Roussy, Villejuif, France, [2]Department of Medicine, Institut Gustave Roussy, Villejuif, France, [3]Pathology, Institut Gustave Roussy, Villejuif, France, [4]Radiology Department, Institut Gustave Roussy, Villejuif, France, [5]Radiation Oncology Department, Institut Gustave Roussy, Villejuif, France, [6]Pathology Department, Institut Gustave Roussy, Villejuif, France, [7]Department of Medicine, Gustave Roussy, University Paris-Saclay, Villejuif, France

Background: Surgery for retroperitoneal sarcomas (RPS) is more and more standardized worldwide. Yet, the potential benefits of preoperative chemotherapy remain elusive.

Methods: All consecutive patients operated on for a primary RPS were retrospectively identified. Preoperative chemotherapy was mostly a doxorubicin-based chemotherapy

regimen for 2 to 6 cycles. Surgery was performed according to the "cluster resection" principles. A caliper restricted, propensity score matched analysis was used to balance the groups.

Results: 249 patients were identified, 49(19.7%) of whom had receive preoperative chemotherapy. After matching, 40 pairs of patients were available and well balanced for baseline characteristics. Seven patients had intermediate adipocytic tumors, 30 had malignant adipocytic tumor, 19 had smooth muscle tumors and 24 had other subtypes. The median tumor size at diagnosis was 20 cm (IQR: 12-26 cm). Sixteen tumors (%) were FNCLCC's grade 1, 28 (%) grade 2 and 36 (%) grade 3. Univariate analysis identified the size of the tumor ($p = 0.036$), the histological subtype ($p = 0.0015$), the FNCLCC's grade ($p = 0.0027$) and the postoperative chemotherapy ($p = 0.01$) as prognostic factors. In the multivariate analysis, only the sarcoma histotype ($p = 0.013$) and the FNCLCC's grade ($p = 0.022$) were retained as independent prognostic factor. Preoperative chemotherapy was neither associated with overall survival ($p = 0.41$) nor disease-free survival ($p = 0.11$).

Conclusions: Routine use of chemotherapy should be avoided in the preoperative setting of primary RPS. Targeted treatments and/or accurate selection criteria are needed.

1659P Combination of eribulin plus gemcitabine in L-sarcomas

D.S. Moura, M. Lopez-Alvarez, A. Salinas-Villegas, P. Sanchez-Bustos, N. Hindi, M. Taron Roca, J. Martin-Broto

Advanced Therapies and Biomarkers in Oncology Group, Instituto de Biomedicina de Sevilla, Seville, Spain

Background: Eribulin (Halaven®; Eisai Co., Tokyo, Japan) is a synthetic analogue of halichondrin B that was approved for advanced liposarcoma. Eribulin, besides its well stablished cytotoxic activity, induces vascular remodelling and increased tumor perfusion, as well as inhibits pericyte- and endothelial-driven angiogenesis, which could facilitate the distribution of other drugs within the tumor. Altogether, we hypothesize that eribulin and gemcitabine, acting in different cell cycle phases and modulating distintly tumour microenvironment, could be synergistic, without overlapping toxicity.

Methods: CP0024 human leiomyosarcoma primary cell line, SK-UT-1 human leiomyosarcoma cell line and, 93T449 and 94T778 human liposarcoma cell lines were treated with increased concentrations of eribulin ($1x10^{-7}$M to $1x10^{-11}$M) or gemcitabine ($1x10^{-9}$M to $1x10^{-13}$M) to determine IC50 values. Combination index values of eribulin plus gemcitabine were calculated, after treating L-sarcoma cell lines with both drugs using the following administration sequences: concomitant (E+G), eribulin followed by gemcitabine (E→G) and gemcitabine followed by eribulin (G→E). Cell viability, at 72 hours, was measured by MTS cell proliferation assay.

Results: The IC50 values determined for eribulin ranged between 0.28nM (SK-UT-1) and 1.98nM (94T778), while IC50 values of gemcitabine ranged between 2.10nM (SK-UT-1) and 7.02nM (94T778). The combination index values at ED50 (the effective doses at which 50% of cell killing occurred) ranged: between 0.27 (SK-UT-1) and 0.89 (94T778), when cell lines were treated with E+G; between <0.10 (SK-UT-1) and 0.33 (CP0024) when treated with G→E; and between <0.10 (SK-UT-1) and 0.20 (CP0024) when cells were treated with E→G. All the cell lines showed a higher synergism when treated using the E→G administration sequence.

Conclusions: Eribulin and gemcitabine combination is synergic in L-sarcoma cell lines. The administration of eribulin, followed by gemcitabine is the recommended administration sequence for further studies. The mechanisms underlying eribulin plus gemcitabine synergy, as well as predictive biomarkers of response to the combination, will be evaluated in in vitro and in vivo models of L-sarcoma.

1660P The role of chemotherapy in the landscape of liposarcoma

A. De Vita[1], F. Recine[1], L. Mercatali[1], G. Miserocchi[1], C. Liverani[1], C. Spadazzi[1], R. Casadei[2], D. Cavaliere[3], A. Bongiovanni[1], F. Pieri[4], L. Medri[4], N. Riva[1], V. Fausti[1], T. Ibrahim[1]

[1]Osteoncology and Rare Tumors Center, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola, Italy, [2]Department of Orthopedics, Istituto Ortopedico Rizzoli, Bologna, Italy, [3]Unit of Surgery and Advanced Oncologic Therapies, Morgagni-Pierantoni Hospital, Forlì, Italy, [4]Pathology Unit, Morgagni-Pierantoni Hospital, Forlì, Italy

Background: Liposarcoma (LPS) is one of the most common types of soft tissue sarcoma (STS), including four subtypes: well-differentiated/atypical lipomatous tumor (ALT/WDLPS), dedifferentiated liposarcoma (DDLPS), myxoid/round cell liposarcoma (MLPS/RCLPS) and pleomorphic liposarcoma (PLS). The morphological diversity of LPS reflects the heterogeneity in clinical and biological behavior and sensitivity to chemotherapy.

Methods: The study involved six patients affected by low/high grade LPS (1 ALT/WDLPS and DDLPS, 1 DDLPS, 2 MLPS, 1 RCLPS and 1 PLS). Patient-derived primary cultures were established after patient surgery. The cultures were exposed to drugs currently used (e.i. ifosfamide, epirubicin, trabectidin, eribulin) for the treatment of LPS. Drug concentrations were selected according to the human plasma peak in patients with solid tumors. Percentages of cellular survival were assessed by MMT and TUNEL assays.

Results: The results showed the sensitivity of the cultures to chemotherapy. The combination of ifosfamide and epirubicin was the most active regimen and statistically significant among cultures. Ifosfamide did not affect the survival of the cells, except in RCLPS suggesting its role in this LPS subtype. Epirubicin showed a comparable activity of the combination regimen in DDLPS (28%) and RCLPS (14%) while displayed a lesser cytotoxic effect in ALT/WDLPS and DDLPS (83%) and MLPS (65%). Trabectidin had no effect on the cellular survival in DDLPS and an equivalent activity in ALT/WDLPS and DDLPS and MPLS (61% and 65% respectively). In RCLPS exhibited an important activity (28%). Trabectidin showed a higher efficacy in ALT/WDLPS and DDLPS and a similar trend in MLPS compared to epirubicin. Eribulin displayed a comparable activity of trabectidin in ALT/WDLPS and DDLPS (70%), MLPS (68%) and RCLPS (26%) while was more active in DDLPS (83%). Finally, cellular survival of PLS was not affected by all the drugs.

Conclusions: This study provides a rationale for elucidate the role of chemotherapy for all liposarcoma subtypes using patient-derived LPS primary cultures. The improvement in the understanding of the molecular mechanisms in liposarcoma will help in selecting the appropriate treatment with a potential impact in the clinical setting.

1661TiP A randomized phase III study of denosumab before curettage for giant cell tumor of bone: Japan Clinical Oncology Group study JCOG1610

H. Urakawa[1], J. Mizusawa[2], K. Tanaka[3], J. Eba[2], H. Hiraga[4], M. Hosaka[5], A. Kawai[6], F. Nakatani[6], E. Kobayashi[6], Y. Nishida[1], T. Okamoto[7], T. Matsunobu[8], Y. Iwamoto[8], H. Fukuda[2], T. Ozaki[9]

[1]Orthopaedic Surgery, Nagoya University, Graduate School of Medicine, Nagoya, Japan, [2]JCOG Data Center/ Operations Office, National Cancer Center, Tokyo, Japan, [3]Endoprosthetic Surgery, Oita University Faculty of Medicine, Yufu, Japan, [4]Orthopaedic Surgery, National Hospital Organization Hokkaido Cancer Center, Sapporo, Japan, [5]Orthopaedic Surgery, Tohoku University Graduate School of Medicine, Sendai, Japan, [6]Orthopaedic Surgery, National Cancer Center Hospital, Tokyo, Japan, [7]Orthopaedic Surgery, Kyoto University Graduate School of Medicine, Kyoto, Japan, [8]Orthopaedic Surgery, Kyushu Rosai Hospital, Kitakyushu, Japan, [9]Orthopaedic Surgery, Okayama University Graduate School of Medicine, Okayama, Japan

Background: Giant Cell Tumor of Bone (GCTB) is a rare tumor known to be locally aggressive, but rarely metastasizing. Resectable GCTB without possible postoperative large bone defect has been treated by curettage with local adjuvant treatment, and its recurrence rate is as high as 20-30%. A recent phase II study demonstrated the effects of denosumab for patients with unresectable GCTB and resectable GCTB with possible postoperative large bone defect. However, the efficacy of preoperative denosumab for GCTB without possible postoperative large bone defect is still controversial. Therefore, we have commenced a phase III trial to confirm the superiority of preoperative denosumab for patients with GCTB who can be treated with curettage.

Trial design: Eligibility criteria include histologically proven GCTB, arising in the extremity, primary tumor (Campanacci grade II or III) and first or second local recurrent tumor, tumor which can be treated by curettage, no distant metastases, and aged 20 to 70. Patients are randomized to either arm A (curettage and adjuvant local therapy) or arm B (preoperative denosumab, curettage, and adjuvant local therapy). Preoperative denosumab is administered subcutaneously at a dose of 120 mg on day 1, 8, 15, 29, and 57. Only in a case of insufficient bone formation after 5 times of denosumab, it is allowed to add denosumab 3 times. The primary endpoint is relapse-free survival (RFS). Secondary endpoints include overall survival, joint-preserved survival, local relapse-free survival, metastasis-free survival, adverse events, serious adverse events, surgical and postoperative complications, and discontinuation of denosumab. We assume that the proportion of RFS at 3 years is 80% for arm A and expect a 10% increase in the proportion of RFS at 3 years for arm B. A sample size was calculated as 51 patients per arm to observe 25 total events with a one-sided alpha level of 10%, power of 70%, an accrual period of 5 years, and a follow-up period of 3 years. Thus, the total sample size was defined as 106 patients to account for loss to follow-up. This trial has started in October 2017 and current enrollment is 3 patients in April 2018.

Clinical trial identification: UMIN000029451 (release date: 6. Oct. 2017).

Legal entity responsible for the study: Japan Clinical Oncology Group (JCOG).

Funding: National Cancer Center, Japan.

1662TiP VOYAGER: An open-label, randomised, phase III study of avapritinib vs regorafenib in patients (pts) with locally advanced (adv) metastatic or unresectable gastrointestinal stromal tumour (GIST)

S. Bauer[1], S. George[2], Y-K. Kang[3], W.D. Tap[4], T. Zhou[5], N. Picazio[6], A.L. Boral[6], M. Heinrich[7]

[1]Medical Oncology, University Hospital Essen Westdeutsches Tumorzentrum, Essen, Germany, [2]Medical Oncology, Dana Faber Cancer Institute, Boston, MA, USA, [3]Medical Oncology, Asan Medical Center, Seoul, Republic of Korea, [4]Sarcoma Service, Department of Medicine, Memorial Sloan Kettering Cancer Centre, New York, NY, USA, [5]Biostatistics, Blueprint Medicines Corporation, Boston, MA, USA, [6]Clinical Development, Blueprint Medicines Corporation, Boston, MA, USA, [7]Knight Cancer Institute, Oregon Health and Science University, Portland, OR, USA

Background: Imatinib is an effective first-line treatment for pts with adv GIST; however, most pts inevitably relapse or progress. Approved second- and third-line agents, sunitinib and regorafenib, have shown limited activity/tolerability, defining an unmet need for pts with imatinib-resistant GIST. Avapritinib is a highly potent and selective oral kinase inhibitor that targets mutant forms of KIT and PDGFRA, including those that confer resistance to approved tyrosine kinase inhibitors. In the Phase 1 NAVIGATOR study (NCT02508532), avapritinib showed substantial clinical activity in pts with both KIT- and PDGFRA-mutant GIST that was resistant to all available therapies. Based on these findings, the VOYAGER study was initiated, comparing avapritinib with regorafenib in pts with adv GIST.

Trial design: VOYAGER (NCT03465722), an international, multicentre, open-label, randomised, Phase 3 study, will include pts (aged $\geq$18; ECOG PS 0–2) with locally adv metastatic or unresectable GIST. The study will evaluate avapritinib vs regorafenib in pts previously treated with imatinib and 1 or 2 other tyrosine kinase inhibitors, who have experienced disease progression, inadequate clinical benefit or intolerance to their prior therapy. Pts with GIST that is wild-type in both KIT and PDGFRA will be excluded. Approximately 460 pts will be enrolled across North America, Europe, Australia and Asia. Pts will be randomised 1:1 to receive avapritinib 300 mg orally, once daily (QD) or regorafenib 160 mg orally, QD (3 wks on/1 wk off), stratified by treatment regimen (third vs fourth), geographic region (Asia vs rest of the world) and mutation status (PDGFRα D842V present vs absent). Pts who experience disease progression on regorafenib, as confirmed by central radiology review, will be allowed to cross over to avapritinib. The primary objective is progression-free survival (PFS), based on central radiological assessment (mRECIST, v1.1). The study is designed to have 90% power to detect a hazard ratio of 0.67 (avapritinib vs regorafenib). Secondary objectives include evaluation of response rate, overall survival, health-related quality of life and safety.

Clinical trial identification: NCT03465722.

Background: Platinum and etoposide with concurrent thoracic radiation is the standard treatment for LS-SCLC. Elderly pts are common, and may experience higher rates of adverse events (AEs) and have a worse outcome from this treatment.

Methods: IPD were collected from 11 phase 2 or 3 trials for LS-SCLC conducted by the US National Cancer Institute-supported cooperative groups activated from 1990 to 2010. Overall survival (OS), progression-free survival (PFS) and AEs were compared between pts age $\geq$ 70 years (elderly) and for pts $<$ 70 years (younger). Unadjusted and adjusted hazard ratios (HRs) for survival time and CIs were estimated by univariate and multivariable frailty Cox models.

Results: IPD from 1049 younger and 254 elderly pts were analyzed. In the univariate and multivariable models, elderly pts compared with younger pts had worse OS (HR of 1.40; 95% CI, 1.20 to 1.65 and 1.36; 95% CI, 1.15 to 1.59). Median OS in elderly and younger pts was 17.8 months and 23.5 months, respectively. In the univariate and multivariable models, elderly pts had worse PFS (HR of 1.23; 95% CI, 1.06 to 1.43 and 1.19; 95% CI, 1.03 to 1.39). Median PFS in elderly and younger pts was 10.6 and 12.3 months, respectively. Elderly and younger pts had a similar rates of all grade $\geq$ 3 AEs, but elderly pts had a statistically significantly higher rate of all grade $\geq$ 4 AEs ($p < 0.01$), hematologic $\geq$ 4 AEs ($p < 0.01$), and grade 5 AEs (8% vs 3%, $p < 0.001$). When specific AEs were analyzed, elderly pts experienced a higher rate of grade $\geq$ 3 dyspnea ($p = 0.03$), but a lower rate of grade $\geq$ 3 vomiting ($p = 0.01$) and esophagitis ($p = 0.03$). Elderly pts compared with younger pts completed treatment at a lower rate ($p = 0.02$), stopped treatment at higher rates due to adverse events ($p = 0.02$), patient refusal ($p < 0.01$), and death during treatment ($p < 0.01$).

Conclusions: Elderly pts with LS-SCLC experienced a worse PFS and OS, and experienced a statistically higher rate of grade 4 and 5 adverse events. Future trials should investigate methods to identify vulnerable elderly pts and reduce the toxicity of treatment.

1669P Treatment beyond four cycles of first line platinum and etoposide chemotherapy in real-life patients with stage IV small cell lung cancer: A retrospective study of the Merseyside and Cheshire cancer network

M. Sallam[1], H. Wong[2], C. Escriu[3]

[1]School of Medicine, University of Liverpool, Liverpool, UK, [2]Department of Clinical Governance, Clatterbridge Cancer Centre, Merseyside, UK, [3]Medical Oncology, Clatterbridge Cancer Center, Merseyside, UK

Background: Dose intensity and dose density of first line Platinum and Etoposide (PE) chemotherapy does not influence Overall Survival (OS) of Small Cell Lung Cancer (SCLC) patients. The effect of treatment length, however, remains unclear. Current guidelines recommend treating beyond four cycles – and up to six - in patients that respond to and tolerate systemic treatment. This has led to variable practice both in real-life and clinical research. Here we aimed to quantify the possible clinical benefit of the extended regimen in our real-life patients treated with PE doublet.

Methods: Of all patients with SCLC treated in our network with non-concurrent first line PE chemotherapy between 2008 and 2015, we retrospectively identified patients that received four cycles (4c) or more (>4c), and compared clinical outcomes between both groups.

Results: We identified 671 patients overall; 578 (86%) received 4c and 93 (14%) received >4c. 74% of patients in the >4c group had stage IV disease. Of 310 patients with stage IV disease, 241 (78%) had 4c and 69 (22%) had >4c. Performance status, comorbidities and radiological responses were similarly distributed between the latter treatment groups. >4c patients were more likely to have sequential thoracic radiotherapy, which may indicate a lower metastatic burden in this group. Nevertheless, there were no statistically significant differences when comparing clinical outcomes. The median Duration of Response (time from last chemotherapy cycle to progression) was 5 months in both groups (HR 1.22; 95% CI 0.93-1.61). Median PFS (Progression-free Survival; time from diagnosis to progression) was 8 months (4c) versus 9 months (>4c) (HR 0.86; 0.66-1.13), and median OS (time from diagnosis to death) was 11 (4c) versus 12 (>4c) months (HR 0.86; 0.66-1.14).

Conclusions: Our results highlight a lack of clinical benefit by extending first line platinum combination treatment beyond four cycles in selected patients. This supports limiting the number of cycles to four until the superiority of a longer regimen is identified in a randomised study.

1670P Timing of treatment in small cell lung cancer

S. Bhandari[1], D. Pham[1], C. Pinkston[2], M. Oechsli[1], G. Kloecker[1]

[1]Hematology/Medical Oncology, Brown Cancer Center University of Louisville, Louisville, KY, USA, [2]Department of Bioinformatics and Biostatistics, School of Public Health, University of Louisville, Louisville, KY, USA

Background: Small cell lung cancer (SCLC) is an aggressive disease with 5-year survival rate of 31% in stage I and 2% in stage IV. Current general practice is to treat SCLC patients as soon as possible after diagnosis given its rapid doubling time and high growth fraction. There is no good evidence for appropriate timing of treatment from diagnosis (TTD) for SCLC. This study evaluates TTD in SCLC and its effect on survival.

Methods: SCLC patients were abstracted from 2012 to 2015 Kentucky Cancer Registry as a part of Lung Cancer Education Awareness Detection Survival (LEADS) Collaborative and included 2992 patients. Data collected included age at diagnosis, stage, gender, race, insurance and treatment. Factors associated with TTD were identified with logistic regression analyses adjusted for age, gender, race, stage, and insurance status. Derived odds ratios (OR) and 95% confidence intervals (CIs) are reported. Survival of patients by TTD ($\leq$4 weeks vs $>$ 4 weeks) was assessed with Cox proportional hazards models, adjusted for age, gender, race, stage, and insurance status. Hazard ratios (HR) and 95% CIs were reported.

Results: Among the 2992 SCLC patients, 67% were stage 4 and 27% were stage 3 diseases. 2371(79%) of SCLC patients were treated with one or more treatment modalities and 621(21%) received no treatment after diagnosis. Among treated patients 93% patient received chemotherapy $\pm$ radiation with mean time of treatment from diagnosis of 18 days. Most patients (80%) have TTD of $\leq$ 4 weeks with 33% treated within 1 week, 20% 1-2 weeks, and 27% 2-4 weeks from diagnosis. Delay in treatment (TTD >4 weeks) was less in stage III and IV disease (OR: 0.34 & 0.27 respectively, $p < 0.01$) but not significantly associated with age, race, gender and insurance. One and two-year survival of patients with TTD $\leq$4weeks was significantly worse when compared to $>$ 4 weeks (HR = 1.43, 95% CI 1.2-1.6, $p < 0.01$; HR = 1.45, 95% CI 1.3-1.6, $p < 0.01$ respectively). This is true even when stratified by stage.

Conclusions: These results show a trend towards poor survival with early treatment in SCLC which refutes current belief of better survival with early treatment. It is unclear why this trend exists, and further studies are needed to better clarify appropriate timing of treatment from diagnosis in SCLC and who will benefit from early vs late treatment.

1671P Trilaciclib (trila) preserves and enhances immune system function in extensive-stage small cell lung cancer (ES-SCLC) patients receiving first-line chemotherapy

J.A. Sorrentino[1], A. Lai[1], J.M. Weiss[2], K.H. Dragnev[3], T.K. Owonikoko[4], S. Adler[5], J.M. Antal[5], R.K. Malik[5], P.J. Roberts[1]

[1]Translational Medicine, G1 Therapeutics, Inc, Research Triangle Park, NC, USA, [2]Hematology/Oncology, University of North Carolina, Chapel Hill, NC, USA, [3]Hematology/Oncology, Norris Cotton Cancer Center Dartmouth-Hitchcock Medical Center, Lebanon, PA, USA, [4]Medical Oncology, Emory University Winship Cancer Institute, Atlanta, GA, USA, [5]Clinical Development, G1 Therapeutics, Inc, Research Triangle Park, NC, USA

Background: Chemotherapy (chemo) efficacy may be limited due to damage to hematopoietic stem and progenitor cells (HSPCs) leading to multi-lineage myelosuppression. Trila is an iv CDK4/6 inhibitor in development to preserve HSPC and immune system function during chemo (myelopreservation). Preclinically, transient trila-induced G1 arrest renders HSPCs resistant to chemo cytotoxicity, leading to faster hematopoietic recovery and enhanced anti-tumor immunity. In a randomized, placebo-controlled, double-blind Phase 2 trial (NCT02499770), the addition of trila to etoposide/carboplatin (EP) in ES-SCLC patients showed multi-lineage myelopreservation, fewer supportive care interventions and dose reductions, and encouraging duration of response and progression free survival. Peripheral blood immunophenotyping was performed to characterize the effects of trila on the immune system.

Methods: Whole blood from patients in the EP + trila or EP + placebo arms was collected at baseline, during, and after treatment for flow cytometry analyses of monocytes, T, B, NK, dendritic, and myeloid-derived suppressor cells. T cells were also stimulated ex vivo to evaluate their ability to produce cytokines upon activation.

Results: Preliminary analyses indicate that B cells were significantly depleted during treatment with EP + placebo, but not with EP + trila. In addition to an increase in total CD8+ cells during treatment, EP + trila resulted in a larger population of activated $CD8^+$ T cells, and fewer regulatory T cells which is consistent with a more robust immune response. Further analyses of trila's effect on other immune cell types is ongoing.

Conclusions: These clinical trial findings demonstrate that in addition to preserving neutrophil and red blood cell lineages, adding trila to EP treatment can preserve B cells and enhance T lymphocyte function. In preclinical models, trila similarly enhanced activity of intra-tumor T cells, leading to superior anti-tumor efficacy when combined with chemo + anti-PDL1. A Phase 2 study to assess safety and efficacy of trila or placebo with EP and atezolizumab in first-line ES-SCLC has completed enrollment (NCT03041311).

Clinical trial identification: NCT02499770.

Klinikum Koblenz-Montabaur, Koblenz, Germany, [13]Thoracic Oncology Centre Munich, LMU Klinikum der Universität München, Munich, Germany, [14]Medizinische Klinik IV, Klinik Kassel, Kassel, Germany

Background: The immune surveillance reactivator lefitolimod (MGN1703), a DNA-based TLR9 agonist, is currently in a comprehensive clinical development program including a phase 3 trial in mCRC. The phase 2 IMPULSE study was designed to evaluate efficacy and safety of lefitolimod in ES-SCLC, an indication with high unmet medical need and stagnant treatment improvement in the last decades.

Methods: IMPULSE is a randomized, international, multicenter, open-label trial to assess the effect of lefitolimod on overall survival (OS) in ES-SCLC. 103 patients with objective tumor response following 4 cycles of platinum-based first-line induction therapy were randomized 3:2 to receive either lefitolimod maintenance therapy or local standard of care until progression or unacceptable toxicity.

Results: From 103 patients, 62 were randomized to lefitolimod, 41 to the control arm. Patient demographics and response patterns to first-line therapy were balanced. Lefitolimod exhibited a favorable safety profile in this vulnerable population and pharmacodynamic assessment confirmed the mode-of-action showing clear activation of monocytes and production of interferon-gamma-induced protein 10. While in the ITT population no relevant effect of lefitolimod on OS could be observed, two pre-defined patient subgroups indicated promising results, favoring lefitolimod with respect to OS: Patients with a low frequency of activated $CD86^+$ B cells (HR 0.53, 95%CI 0.26-1.08; n = 38 of 88 analyzed) and patients with reported chronic obstructive pulmonary disease (COPD) (HR 0.48, 95%CI 0.20-1.17, n = 25 of 103). Notably, a post-hoc analysis revealed that a strong lefitolimod-induced immune activation translated into an OS benefit when analysed after 4 weeks of treatment. Two patients from the lefitolimod arm exhibited long-term disease control.

Conclusions: The IMPULSE study showed (1) the expected pharmacodynamic response, (2) positive efficacy signals in two pre-defined subgroups regarding OS and (3) a favorable safety profile. This data provides significant guidance for defining patient populations most likely to benefit from lefitolimod treatment.

Clinical trial identification: NCT02200081.

Background: Despite high sensitivity to first-line chemotherapy (CT), most small-cell lung cancer (SCLC) patients relapse. Efficacy of 2nd-line CT is modest and influenced by treatment-free-interval (TFI). Topotecan demonstrated modest activity and significant haematological toxicity. Paclitaxel-based regimens showed to be active in this setting. Nab-paclitaxel, compared to paclitaxel, has a reduced incidence of hypersensitivity reactions and of neutropenia. Safety and efficacy in relapsed SCLC have not been prospectively studied.

Methods: This open-label phase II study enrolled patients with extensive- (ED) or limited-disease (LD) SCLC progressed during or after etoposide/platinum-based 1st-line CT with the aim to assess the activity and safety of Nab-paclitaxel. Patients were classified as refractory (TFI $<$ 60 days) or sensitive (TFI $\geq$ 60 days). Eligible patients received Nab-paclitaxel 100 mg/mq on days 1,8,15 every 28 days for 6 cycles, progressive disease or intolerable toxicity. Computed tomography scan was performed every 2 cycles. Treatment could be continued beyond the 6^{th} cycle in presence of prolonged response, clinical benefit and good tolerance to drug. The primary endpoint was objective response, evaluated according to RECIST v1.1 criteria. The secondary endpoints were toxicity, measured according to NCI-CTCAE v4.03, progression-free and overall survival.

Results: From January 2017 to March 2018, 68 patients (25 refractory and 43 sensitive) were enrolled in the modified intentiontotreat population. Median age was 68.5 years (range 44-80). 44 patients were males and 57 had ED. Median follow-up was 5.8 months (IQR 3.37.1). Objective responses are currently being reviewed by an independent radiology panel. Most common toxicities (of all grades) were anemia (39%), leukopenia (27%), neutropenia (28%), nausea (19%), diarrhoea (21%), fatigue (52%), peripheral neuropathy (19%). The only severe toxicity (grade $\geq$3) was neutropenia (9%). In 13 patients treatment is still ongoing while 3/55 (5%) patients discontinued treatment for toxicity.

Conclusions: This is the first prospective study of Nab-paclitaxel for relapsed SCLC. Nab-paclitaxel demonstrated a manageable toxicity profile. Final activity data will be available for the meeting.

Clinical trial identification: EudraCT: 2016-000408-27; NCT03219762.

Legal entity responsible for the study: GOIRC (Gruppo Oncologico Italiano di Ricerca Clinica).

Background: For extensive-stage small cell lung cancer (ES-SCLC) patients with progressive or recurrent disease after platinum-based combination chemotherapy, topotecan is recommended as second-line treatment. However, although some patients may achieve at least an objective response with topotecan, response duration is often short. Belotecan, a camptothecin derivative, inhibits topoisomerase I. Previous studies have demonstrated that belotecan has active antitumor activity against advanced SCLC and ovarian cancers. We report safety data from a phase IIb randomized multicenter study of belotecan as second-line treatment for progressive/recurrent limited-disease (LD)- or ES-SCLC.

Methods: This study, conducted from March 2010 to March 2018, was designed to prove the non-inferiority of belotecan to topotecan. Patients with recurrent ES-SCLC were randomized (1:1 ratio) to belotecan 0.5 mg/m^2 or topotecan 1.5 mg/m^2 intravenously for 5 consecutive days every 3 weeks for 6 cycles or until disease progression. Adverse events (AEs) were reported according to NCI-CTCAE (ver. 4.0) and categorized by System Organ Class and Preferred Term.

Results: Overall, 161 patients (belotecan, n = 80; topotecan, n = 81) were evaluable in the safety analysis set. Clinical characteristics were well balanced between the treatment arms. Although belotecan recipients received significantly more treatment cycles than topotecan recipients (p = 0.0210), there were no between-group differences in the number of patients who required dose reductions or who omitted treatment in each cycle. There were no statistically significant between-group differences in safety results: any AEs (including grade 3 or 4 AEs), adverse drug reactions (ADRs), severe AEs (SAEs) or severe ADRs (SADRs). The most common AEs in the belotecan and topotecan groups, respectively, were decreased neutrophil count (61 patients [76.3%] vs. 67 patients [82.7%]), anemia (37 [46.3% vs. 44 [54.3%]), decreased platelet count (33 [41.3%] vs. 43 [53.1%]), nausea (35 [43.8%] vs. 30 [37.0%), and anorexia (32 [40.0% vs. 36 [44.4%]).

Conclusions: Our study indicates that belotecan is a safe second-line treatment option for patients with progressive/recurrent LD- or ES-SCLC.

Clinical trial identification: NCT01497873.

1675P Retrospective study of paclitaxel in advanced therapy lines in the treatment of SCLC

D. von Eiff[1], F. Bozorgmehr[1], P. Christopoulos[1], I. Chung[1], D. Bernhardt[2], S. Rieken[2], S. Liersch[3], T. Muley[4], S. Kobinger[4], M. Thomas[1], M. Steins[1]

[1]Thoracic Oncology, Thoraxklinik at Heidelberg University Hospital, Translational Lung Research Center Heidelberg (TLRC-H), German Center for Lung Research (DZL), Heidelberg, Germany, [2]Department of Radiation Oncology, Heidelberg University Hospital, Heidelberg Institute of Radiation Oncology (HIRO), Heidelberg, Germany, [3]Pharmacy Department, Thoraxklinik at Heidelberg University Hospital, Heidelberg, Germany, [4]Translational Research Unit, Thoraxklinik at Heidelberg University Hospital, Translational Lung Research Center Heidelberg (TLRC-H), German Center for Lung Research (DZL), Heidelberg, Germany

Background: Extensive-disease small cell lung cancer (ED-SCLC) is usually first treated with etoposide-/platinum-based chemotherapy. Despite high initial response rates, progression occurs frequently. While topotecan is approved as 2nd-line therapy, further treatment is not standardized. One of the drugs administered in progressed SCLC is paclitaxel. Here, we retrospectively analyzed prognostic factors and outcome of paclitaxel-treated SCLC patients.

Methods: SCLC patients treated with paclitaxel between 2005 and 2015 at Thoraxklinik at Heidelberg University Hospital were retrospectively reviewed. Significant prognostic factors were identified by univariate (Kaplan-Meier) and multivariate (Cox-Regression) analysis.

Results: 185 patients (119 men/66 women, median age 64 years, median ECOG performance status 1) were included. Paclitaxel was mainly given as 3rd- or 4th-line therapy (92%). The overall response rate was 17% and disease control rate (DCR) was 28%. Median progression-free survival (PFS) was 48 days (95%-CI: 42-54) and median overall survival (OS) 100 days (95%-CI: 84-116). Main toxicities were fatigue (25%) and peripheral neuropathy (17%), but no discontinuation of treatment was required. In 28%, the paclitaxel dose was reduced by 15-30%, mainly due to hematoxicities (in 57%). In univariate analysis, this was linked to a decrease in PFS ($p = 0,05$), while gender, age, performance status, number of metastatic sites, and presence of cerebral/hepatic metastases were not associated with changes in PFS. For OS, performance status, number of metastatic sites, cerebral/hepatic metastases, and dose reduction were significant ($p < 0,05$). In multivariate analysis, gender, age, and dose reduction retained as independent prognostic factors for PFS. In addition, performance status, cerebral/hepatic metastases, and pack years were identified as independent prognostic factors for OS.

Conclusions: With a DCR of 28% paclitaxel was still effective in heavily pretreated SCLC patients. However, patients should be selected carefully regarding age, performance status, and metastatic status. Especially, patients in good condition and without cerebral/hepatic metastases benefit from a paclitaxel therapy.

1676P Over-expression of shh is prognostic marker in patients with extensive stage small cell lung cancer

S. Lim[1], J. Kim[1], S.Y. Park[2]

[1]Hemato-Oncology, Wonju Severance Christianity Hospital, Gangwon-do, Republic of Korea, [2]Pathology, Konyang University Hospital, Daejeon, Republic of Korea

Background: Recent studies have reported that the sonic hedgehog (Shh) signaling pathway plays a crucial role during tumorigenesis, angiogenesis and cellular differentiation in various malignancies including lung cancer. The aim of this study is to investigate the value of Shh pathway as prognostic markers in extensive stage small cell lung cancer (ES-SCLC) patients.

Methods: We retrospectively analyzed the data of 36 patients with ES-SCLC between 2008 and 2012 in Yonsei Cancer Center. Using formalin fixed paraffin embedded tissues of primary tumors, immunohistochemistry was done for Gli1, Patched, Shh1, and Smo. We performed survival analysis to find out the prognostic impact of these markers.

Results: All the 36 patients were treated with platinum based doublet chemotherapy. Median progression free survival and median overall survival was 6.9 months (95% CI, 6.5-7.3) and 11.7 months (95% CI, 9.1-14.3), respectively. Overall response rate was 84%. Of the 36 specimens examined, the overexpression of Gli1, Patched, Shh, and Smo was found in 12 (33.3%), 5 (13.9%), 5 (13.9%), and 6 (16.7%), respectively. We found that high expression of Shh was associated with worse progression free survival (6.3 vs. 7.6 months, $p < 0.01$) and overall survival (9.2 vs. 12.0 months), whereas other markers were not related to the prognosis of patients.

Conclusions: To our knowledge, this is the first report of the relationship between components of the Shh signaling pathway and prognosis in SCLC. We found that a high proportion of tumors expressed proteins related to this pathway, and over-expression of Shh was correlated with worse survival in this analysis. Shh signaling in SCLC requires further investigation using a larger sample size.

1677P UCHL1 has prognostic relevance and is a therapeutic target in high-grade neuroendocrine lung cancers

Y. Shimada, T. Okano, T. Ohira, N. Ikeda

Department of Surgery, Tokyo Medical University Hospital, Tokyo, Japan

Background: We discovered that ubiquitin carboxy-terminal hydrolase L1 (UCHL1), which was usually found in nerve cells throughout the brain, was widely shown in mesenchymal non-small cell lung cancers (NSCLC) and their exosomes and was partly responsible for promoting NSCLC invasion and metastasis. However, little is known about the biologic function of UCHL1 and its therapeutic potential in high-grade neuroendocrine lung cancers (HGNEC) including small cell lung cancer (SCLC) and large cell neuroendocrine cancer (LCNEC). Despite a high overall mutation rate in HGNEC, there are currently no molecularly targeted agents with proven clinical benefit for this disease. Here we show preclinical efficacy evoked by targeting UCHL1 that was relevant to prognosis in HGNEC.

Methods: We assessed the protein expressions of UCHL1 in SCLC cell lines (H69, H82, H526) and NSCLC cell lines, additive chemotherapeutic effects by using the combination of cisplatin/etoposide (PE) or cisplatin/irinotecan (PI) with selective UCHL1 inhibitors (WP1130 and LDN57444), whether the immunohistochemical (IHC) expression level of UCHL1 was associated with prognosis and recurrence in HGNEC patients, and the detectability of UCHL1 mRNA by circulating extracellular vesicles (EVs) in lung cancer patients.

Results: UCHL1 was overexpressed in all the SCLC cell lines and mesenchymal NSCLCs but not an epithelial NSCLC cell line. In SCLC model in vitro, combined the target of UCHL1 by selective UCHL1 inhibitors significantly improved the response of PE and PI therapies. IHC analysis of 72 HGNEC patient's tumor samples (SCLC/LCNEC = 34/38) demonstrated that UCHL1 expression significantly correlated with unfavorable overall and recurrence-free survival and contributed to distinguishing SCLC from LCNEC. EVs isolated from lung cancer cell lines and the serum from SCLC and adenocarcinoma patient were verified by electron microscopy and nanoparticle tracking analysis. Increased EVs-derived UCHL1 level was shown in the serum from 2 out of 5 SCLC patients with immunohistochemically high UCHL1 expression while no expression was observed in that from 5 adenocarcinoma patients.

Conclusions: UCHL1 can be a potential prognostic marker and a promising druggable target in HGNEC.

1678P Robustness of DLL3 (SP347) immunohistochemistry assay for detection of DLL3 protein in small cell lung cancer

C. Powell[1], E. Elgabry[2], B. Holmes[2], D. Tyree[2], R. Marati[2], B. Admire[2], T. Birdi[2], A.E. Hanlon Newell[2], B. Damadzadeh[2], D. Dalvi[2], R.S.P. Huang[2]

[1]Development, Ventana Medical Systems, Inc., Tucson, AZ, USA, [2]Medical Affairs, Ventana Medical Systems, Inc., Tucson, AZ, USA

Background: Delta-like protein 3 (DLL3) is a transmembrane protein that is implicated in the tumorigenesis of small cell lung cancer (SCLC). The ability to quantify DLL3 protein may be useful to select patients that may be responsive to DLL3-targeted therapies; thus, the VENTANA DLL3 (SP347) Assay was developed for this purpose. Here, we present data on the robustness of the VENTANA DLL3 (SP347) Assay in SCLC.

Methods: Formalin-fixed, paraffin-embedded (FFPE) SCLC resection and biopsy specimens were used in a series of studies addressing robustness. These samples were stained with the VENTANA DLL3 (SP347) Assay and assessed by pathologists for percent tumor cell staining (%TC) at $\leq$ 4X magnification at any stain intensity. The %TC scores were stratified into bins (0-24, 25-49, 50-74 and 75-100 %TC) and assessed for precision across different antibody and detection kit lots, replicates, days, instruments, and platforms. For each case, the modal staining result based on %TC bin was determined and the result from each test sample was compared to its respective case-level modal staining result and deemed concordant or discordant. Results were aggregated across cases and the overall percent agreement (OPA) was calculated for each study.

Results: All studies (Table) showed >90% OPA for concordance to the %TC bins.

Table: 1678P Precision across lots, replicates, days, instruments, and platforms

Study	# of Cases	# DLL3 Observations	OPA
Intra-day	10	50	100.0%
Inter-day	10	100	94.0%
Inter-antibody lot, inter-detection kit lot, and intra-platform	24	648	95.8%
Intra-platform (GX)	14	84	98.8%
Intra-platform (XT)	14	84	97.6%
Intra-platform (ULTRA)	14	84	98.8%
Inter-platform (GX, XT, and ULTRA)	14	252	98.4%

Conclusions: The data shows that the VENTANA DLL3 (SP347) Assay can precisely evaluate DLL3 expression in SCLC.

1679P Residential radon and small cell lung cancer: A systematic review

Á. Rodríguez Martínez[1], A. Ruano Ravina[2], M. Torres Duran[3]

[1]Medical Oncology, Complejo Hospitalario de Pontevedra, Pontevedra, Spain, [2]Preventive Medicine, University of Santiago de Compostela, Santiago de Compostela, Spain, [3]Neumologia, Complejo Hospitalario de Vigo, Vigo, Spain

Background: Residential radon exposure is considered the second cause of lung cancer (LC) and the first in never smokers. Nevertheless, the association between the different histological types of LC and radon is not completely clear, and radon effect on small cell lung cancer (SCLC) is not completely understood. We aim to asses the effect of residential radon exposure on the risk of SCLC in general population and miners through a systematic review applying predefined inclusion and exclusion criteria.

Methods: We performed a literature research in PubMed and EMBASE following PRISMA methodology. We included: studies performed in humans; studies showing the specific effect of radon on SCLC histological type separately; studies with at least 10 SCLC cases and the overall sample size higher than 50 individuals; systematic reviews, pooling studies, cohort studies, case-control studies and mortality studies with comparison group; studies performed both in general population and on miners; studies with anatomopathological confirmation; studies in English, Spanish and French. To asses the quality of each of the included studies we designed a quality scale with 5 items which scored characteristics of the included papers: sample size, number of SCLC cases, results adjusted by covariates, study design, and method of assesment of radon concentration. We have given different weights to these characteristics creating a continuous scale from 0 to 10.

Results:

Conclusions: Exposure to radon increases the risk of SCLC. Nevertheless, more research should be addressed in order to know exactly the magnitude of this risk. It seems that SCLC is the LC histological type most associated to radon exposure, with this fact happening both in miners' and general population studies. To this end, more well-designed case-control studies are necessary. It is also necessary to increase radon awareness among citizens and administrations in order they can establish the necessary protective and mitigation measures against residential radon.

1680P Nomogram for predicting the benefit of surgery for stage IA-IIB small cell lung cancer

Y. Wang[1], Z. Wang[1], Q. Zheng[2]

[1]Department 1 of Thoracic Oncology Medicine, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Peking University Cancer Hospital & Institute, Beijing, China, [2]Department of Epidemiology and Biostatistics, Peking University, Beijing, China

Background: The role of surgical resection remains controversial in small cell lung cancer (SCLC) although there are some retrospective and population-based studies indicate that patients with very early stage SCLC has longer survival compared with those not given surgery. The specific aim of this study was to identify the survival benefit of surgery for patients with Stage IA-IIB SCLC and nomogram predictive model was created to select patients who are eligible to surgery.

Methods: Patients diagnosed with stage IA-IIB SCLC between 2004 and 2014 were selected from the SEER database. The primary endpoint was overall survival. Multivariate Cox proportional regression and coefficients of the predictors were calculated. A nomogram was constructed for predicting 1- and 3-year overall survival probability. All statistical analysis was performed with R software.

Results: 2246 patients with stage I-II were enrolled. 618 (27.5%) received surgery and 1628 (72.5) not. Unadjusted median overall survival (OS) was 23 months (95% CI: 21-24), which was 35 months (95% CI: 31-44) vs. 19 months (95% CI: 18-21) in surgery and non-surgery groups respectively ($p < 0.0001$). We used a propensity score to balance observed covariates. OS benefit was observed in all subgroups between the surgery and non-surgery group except in the non-White race, well or moderately grading, stage IIA or IIB and N1 lymph involvement. Multivariate Cox proportional hazards regression analysis showed a survival benefit in the surgery group compared with non-surgery group no matter balanced by propensity score weighting or not. The competing-risks nomogram was built for predicting 1-year and 3-year survival. The age, tumor size, extent of tumor, N0/1 and surgery with radiation and chemotherapy were introduced as variables. The calibration of internal validation for predicting survival at 1 and 3-year by this nomogram-predicted probability was identical to the actual probability.

Conclusions: Surgery was proved to benefit patients with stage IA-IIB SCLC by this relatively large number population-based study and a nomogram built from a parametric survival model from the SEER database can be used to predict which patients with stage IA-IIB SCLC may benefit from surgery.

Table: 1679P

Author (year)	Study design and location	Sample size	Lung cancer risk	Significance	Conclusion	Score
Biberman 1993	Case-control Israel	n = 70 20	Median radon level in SCLC group of 1.09 vs 0.9 pci/L. OR 1.5 (0.4-5.4).	Non significant	Exposure to radon was identified as an etiological agent of SCLC.	3
Darby 2004	Pooling study of 13 case-control studies Europe	n = 21,356 1,379	ERR per 100 Bq/m3 31,2%(12,8-60,6%) for SCLC vs 2,6% (0-10%) for other subtypes. p = 0.03	Statistically significant	Strong evidence of an association between residential radon concentration and SCLC. The dose-response relation was to be linear. The absolute risk to smokers was greater.	9
Wilcox 2007	Case-control New Jersey	n = 1,301 105	ERR 100-149 Bq/m3 3,05 (for men) and 2,46 (for women) For >150 Bq/m3 0,00 (for men) y 2,67 (for women)	Statistically significant	No significant increase of the risk of lung cancer with increasing radon levels; however, radon exposure showed stronger effect with SCLC on both males and females.	8

Continued

Table: 1679P *Continued*

Author (year)	Study design and location	Sample size	Lung cancer risk	Significance	Conclusion	Score
Wichmann 2005	Pooling study of 2 case-control studies Germany	n = 7,195 712	ERR per 100 Bq/m3 of 0,29 (0,04-0,78)	Non significant	The effect of radon is stronger for SCLC, whereas no association between radon and lung cancer was found.	8
Krewsky 2004	Pooling study of 7 case-control studies North América	n = 8,628 577	ERR per 100 Bq/m3 in 5-30 years of 0,23 (-0,08-0,88) for SCLC.	Non significant	Association between residential radon exposure and lung cancer, with strongest association for SCLC.	10
Field 1991	Case-control Iowa	n = 1,027 74	WLM 12,71-16,94 OR 1,36 (0,4-4,44) WLM > 16,95 OR 1,44 (0,47-4,35) p = 0.33	Non significant	Cumulative radon exposure in the residential environment is significantly associated with lung cancer risk, with strongest effect for SCLC.	5
Barros-Dios 2012	Case-control Galicia	n = 862 54	AOR p 101-147 Bq/m3 3,01 (1,01-8,97) AOR 147 Bq/m3 2,43 (0,79-7,45)	Statistically significant	Even with low exposures, radon is a risk factor of lung cancer, with greatest influence on SCLC. Additive interaction between radon exposure and tobacco consumption.	6
Sandler 2006	Case-control Connecticut and Utah	n = 3,285 51	ERR per 100 Bq/m3 increase in radon concentration for SCLC 0.165 (-0.35-0.69)	Non significant	No evidence of an increased risk for lung cancer (and SCLC) at the exposure level of radon observed.	7
Jonsson 2009	Cohort Sweden	n = 5,486 55	ERR p kBq year/m3 0,072 (-0,03-0,147)	Non significant	A significantly increased risk for SCLC was observed at low radon exposure levels. The proportion of SCLC among miners was high compared to the general population in Sweden.	5
Saccomanno 1988	Cohort Colorado	n = 383 121	For levels > 300WLM EOR of 57%.	Statistically significant	In levels > 300 WLM an increased risk of lung cancer was detected. The incidence in SCLC was significantly elevated (57%) over other types. An additive effect in smokers was observed.	5
Svensson 1989	Case-control Stockholm	n = 210 41	4500-6000 Bq/m3 RR 1,9 (1,2-5,8) +6000 Bq/m3 RR 4,7 (0,5-5,7) p = 0.01	Statistically significant	Association between cumulated radon exposure and lung cancer in women, particularly strong for SCLC.	2
Bochicchio 2005	Case-control Lazio	n = 788 43	EOR p 100 Bq/m3 0.22 (-0.21-0.89) for SCLC.	Non significant	A higher risk for SCLC at elevated radon levels was detected. Dietary antioxidants may act as an effect modifier.	4
Alavanja 1999	Case-control Mossouri	n = 1,058 117	OR of 3.33 for > 148Bq/m3 for SCLC. P = 0.3.	Non significant	A significant SCLC increased risk was found for radon concentrations at and above the action level for mitigation of houses in USA (148 Bq/m3).	5
Letourneau 1993	Case-control Canada	n = 1,476 117	OR 0.79 (0.44-1.41) cumulated exposure of radon 5-30 years. 3,750 Bq/m3-year	Non significant	No increase in the relative risk for any of the histologic types of lung cancer was observed in relation to cumulative exposure to radon.	7
Pershagen 1994	Case-control Sweden	n = 4207 166	ERR per unity of radon 0.15 (0.43) for SCLC, RR of 2.8 (1.3-5.9) for Ra > 400 Bq/m3.	Statistically significant	The risk of lung cancer increased in relation to both estimated cumulative and time-weighted exposure to radon. The strongest association was suggested for SCLC.	6
Blot 1990	Case-control North of China	n = 664 39	OR for SCLC increased with residential radon being SCLC de histological type with the highest risk.	There is no information on statistically significance	A moderate association of increased radon levels and SCLC is observed. A moderate association os increased radon levels and SCLC is observed.	6

1691P Updated meta-analysis of randomized controlled trials (RCTs) to determine the CDK 4/6 inhibitors associated venous thromboembolism (VTE) risk in hormone receptor-positive breast cancer (BC) patients

K.Z. Thein[1], S. Ball[2], M.H. Zaw[3], A.M. Tun[4], M. Quirch[2], F. Hardwicke[1], N. D'Cunha[1], L. Tijani[1], C. Jones[1], T.H. Oo[5]

[1]Hematology Oncology, Texas Tech University Health Sciences Center, Lubbock, TX, USA, [2]Internal Medicine, Texas Tech University Health Sciences Center, Lubbock, TX, USA, [3]Internal Medicine, The Brooklyn Hospital Center, Brooklyn, NY, USA, [4]Hematology Oncology, The Brooklyn Hospital Center, Brooklyn, NY, USA, [5]Benign Hematology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA

Background: Majority of BC express hormone receptors and cyclin dependent kinases especially CDK4/6 have been proven to mediate hormone therapy resistance. Many CDK 4/6 inhibitors have shown survival benefits. Yet, the VTE risk remains considerable. We undertook an updated meta-analysis of RCTs to determine the VTE risk among patients with hormone receptor-positive metastatic BC treated with CDK 4/6 inhibitors.

Methods: MEDLINE, EMBASE databases and meeting abstracts from inception through March 2018 were queried. RCTs that mention VTE as adverse effect were incorporated in the meta-analysis. The primary meta- analytic approach was a fixed effects model using the Mantel-Haenszel (MH) method. It was used to calculate the estimated pooled risk ratio (RR) and risk difference (RD) with 95% confidence interval (CI).

Results: Five phase III studies and one phase II study with a total of 3,159 patients were eligible. The study arms used palbociclib-letrozole, palbociclib-fulvestrant, ribociclib-letrozole, abemaciclib-fulvestrant, abemaciclib-letrozole/anastrozole while the control arms utilized placebo in combination with letrozole or anastrozole or fulvestrant. The I^2 statistic for heterogeneity was 16.452, and the heterogeneity X^2 (Cochran's Q) was 5 ($P = 0.308$), suggesting homogeneity among RCTs. The VTE incidence was 40 (2.03%) in CDK 4/6 inhibitors group vs 5 (0.42%) in control group. The pooled RR for VTE in CDK 4/6 inhibitors group was 3.561 (95% CI: 1. 574 to 8.057, $P = 0.002$) and the absolute RD was 0.014 (95% CI: 0.002 to 0.027, $P = 0.022$) according to the fixed effects model. By the random effects model, the pooled RR was 3.072 (95% CI: 1.138 to 8.294, $P = 0.027$) and RD was 0.015 (95% CI: 0.007 to 0.023, $P < 0.0001$).

Conclusions: Our meta-analysis showed that the addition of CDK 4/6 inhibitors to letrozole or fulvestrant, contribute to higher incidence of VTE. Patients on CDK 4/6 inhibitors group experienced a significant increase in the VTE risk with a RR of 3.56. VTE remains the second leading cause of death in cancer patients receiving antineoplastic therapy and close monitoring is required.

1692P Physicians' knowledge, attitudes and practice towards fertility and pregnancy-related issues in BRCA-mutated breast cancer (BC) patients (pts): Results from the BCY3/BCC 2017 survey

M. Lambertini[1], M. Di Maio[2], F. Poggio[3], O. Pagani[4], G. Curigliano[5], L. Del Mastro[6], S. Paluch-Shimon[7], S. Loibl[8], A.H. Partridge[9], H.A. Azim Jr[10], F.A. Peccatori[11], I. Demeestere[12]

[1]Medical Oncology, Institute Jules Bordet, Brussels, Belgium, [2]Department of Oncology, University of Turin, Turin, Italy, [3]Medical Oncology, IRCCS AOU San Martino - IST-Istituto Nazionale per la Ricerca sul Cancro, Genoa, Italy, [4]Breast Unit, Institute of Oncology of Southern Switzerland, Lugano, Switzerland, [5]Early Drug Development for Innovative Therapies Division, Istituto Europeo di Oncologia, Milan, Italy, [6]Internal Medicine, IRCCS AOU San Martino - IST-Istituto Nazionale per la Ricerca sul Cancro, Genoa, Italy, [7]Medical Oncology, Shaare Zedek M.C, Jerusalem, Israel, [8]Department of Medicine and Research, German Breast Group (GBG) Forschungs GmbH, Neu-Isenburg, Germany, [9]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, USA, [10]Internal Medicine, American University of Beirut, Beirut, Lebanon, [11]Fertility and Procreation Unit, Istituto Europeo di Oncologia, Milan, Italy, [12]Fertility Clinic, Hopital Erasme, Brussels, Belgium

Background: No data are available on physicians' knowledge, attitudes and practice towards fertility and pregnancy-related issues in BRCA-mutated BC pts.

Methods: A 26-item survey exploring fertility preservation and pregnancy after BC was emailed to physicians attending the 2016 3rd ESO-ESMO BCY3 and the 2017 15th St. Gallen BCC 2017 conferences. The present analysis investigated potential differences in physicians' knowledge, attitudes and practice towards these issues in BC pts with or without BRCA mutations. The McNemar test for paired proportions was used for statistical comparison.

Results: The survey was completed by 273 physicians (105 at BCY3 and 168 at BCC 2017) with a median age of 46 years (range 38-55); the majority were medical oncologists (56%) practicing in an academic setting (86%). A comparable proportion of respondents suggested the use of either embryo (43% vs. 39%; $p = 0.11$) or oocyte (62% vs. 63%; $p = 0.77$) cryopreservation as available options for BC pts with or without BRCA mutations, respectively. Conversely, ovarian tissue cryopreservation (33% vs. 40%; $p = 0.009$) and GnRHa during chemotherapy (74% vs. 81%; $p = 0.001$) were less commonly suggested in BRCA-mutated BC pts than in BC pts without BRCA mutations. 42% agreed or were neutral on the statement that controlled ovarian stimulation should not be considered safe in BRCA-mutated BC pts. 45% and 30% agreed or were neutral on the statement that pregnancy in BC survivors may increase the risk of recurrence in BRCA-mutated BC pts and in BC pts overall, respectively ($p < 0.001$). 15% and 3% disagreed that transplanting the cryopreserved ovarian tissue harvested at the time of BC diagnosis can be considered safe in pts with or without BRCA mutations, respectively ($p < 0.001$).

Conclusions: These results highlight the presence of several misconceptions on fertility preservation and pregnancy after BC that persist even among physicians directly involved in BC care. Focused research efforts to address fertility and pregnancy-related issues in BRCA-mutated BC pts and education to improve physicians knowledge and adherence to available guidelines are urgently needed.

1693P Analysis of parameters to predict the effectiveness of scalp cooling to prevent chemotherapy-induced alopecia in breast cancer patients

C.M. Kurbacher[1], S. Herz[1], A.T. Kurbacher[1], G. Kolberg[1], N. Kettelhoit[1], A. Schott[1], J.A. Kurbacher[2]

[1]Gynaecological Oncology, Gynaecological Center Bonn-Friedensplatz, Bonn, Germany, [2]General Gynaecology and Obstetrics, Gynaecological Center Bonn-Friedensplatz, Bonn, Germany

Background: Sensor-controlled scalp cooling (SCSC) has been found to be effective to prevent chemotherapy (Ctx)-induced alopecia (CIA). This retrospective study sought to obtain detailed information which clinical parameter is able to predict the success of SCSC in patients (pts) with primary (PBC) or recurrent/metastatic breast cancer (R/MBC) exposed to neoadjuvant (NACT), adjuvant (ACT), or palliative Ctx (PCT) using anthracyclines (A), taxanes (T), both given at different schedules (A+T/A→T, T→A) or none of them (non-A/non-T).

Methods: 109 pts who underwent SCSC were included: NACT, 47 (54.6%); ACT, 40 (45.4%); PCT 22; dose-dense (dd) Ctx, 38 (44.2%); non-dd Ctx 48 (55.8%); premenopausal, 48 (55.8%); postmenopausal, 38 (44.2%). Ctx regimens were: A+T/A→T, 41 (37.6%), T→A, 23 (26.7%), T, 34 (31.2%), non-A/non-T, 11 (10.1%). 3 wks after the last Ctx cycle, CIA was quantified according to the Dean score (DS). Data were analyzed in regard to the SCSC completion rate, and the quality of hair preservation (success: DS 0-2, failure: DS 3-4). The following parameters were investigated in regard to the success of SCSC: menopausal status, pretreatment, setting of Ctx, Ctx schedule, Ctx regimen.

Results: Success rate was 67.9% with 47 pts (43.1%) experiencing complete (DS 0), and 27 (24.8%) showing partial response (DS 1-2). 30 pts (27.5%) stopped SCSC prematurely with CIA being the reason in 21 pts (19.3%). Effectiveness of SCSC did not differ for most analyzed subgroups. The relative risk (RR) to experience CIA was 1.18 (CI: 0.91-1.53, p=NS) for post- vs premenopausal pts, 1.27 (CI: 0.99-1.64, p=NS) for Ctx-naïve vs pretreated pts, 1.18 (CI: 0.89-1.56, p=NS) for dd Ctx vs non-dd Ctx, 1.42 (CI: 1.03-1.80, $p = 0.05$) for NACT/ACT vs PCT, and 1.42 (1.11-1.85, 0.012) for A-based Ctx vs non A-based Ctx. Success rates for A+T/A→T, T→A, T, and non-A/non-T were 48.8%, 73.9%, 79.4%, and 90.9% ($p = 0.015$).

Conclusions: SCSC could effectively prevent CIA in a real-world population of pts with PBC or R/MBC with all subgroups of pts benefiting. NACT/ACT and A-based Ctx are associated with lower success rates of SCSC. However, the effectiveness of SCSC associated with A-based Ctx can be as high providing that Ctx does not start with an anthracycline.

1694P A phase I safety study of topical calcitriol (BPM31543) for the prevention of chemotherapy-induced alopecia (CIA): Final study results

M. Lacouture[1], H. Dion[2], S. Ravipaty[3], V.R. Akmaev[4], R. Sarangarajan[3], J.J. Jimenez[5], N.R. Narain[6], B. Berman[7], S. Goldfarb[8]

[1]Dermatology, Memorial Sloan Kettering Cancer Center, New York, NY, USA, [2]Clinical Operations, BERG, LLC, Framingham, MA, USA, [3]Biosystems, BERG, LLC, Framingham, MA, USA, [4]Analytics, BERG, LLC, Framingham, MA, USA, [5]Dermatology and Cutaneous Surgery, University of Miami Miller School of Medicine, Miami, FL, USA, [6]Biosystems, Analytics, & Precision Medicine, BERG, LLC, Framingham, MA, USA, [7]Dermatology, University of Miami Miller School of Medicine, Miami, FL, USA, [8]Oncology, Hematology and Oncology, Memorial Sloan Kettering Cancer Center, New York, NY, USA

Background: Chemotherapy-induced alopecia (CIA) negatively effects psychosocial health and quality of life. Currently there are no FDA approved pharmacologic agents available to prevent CIA. Topical calcitriol, a vitamin D3 analog, has been shown in

murine studies to reduce CIA, likely due to arrest of cell cycle in healthy hair follicles, and reduction in the sensitivity of follicular epithelium to chemotherapy.

Methods: A 3 + 3 dose-escalation Phase 1 study with 3-6 patients at 5, 10, 20, 40, 60, 80 μg/mL was examined in 23 patients (pts) with breast cancer, gynecologic cancer or sarcomas receiving a taxane-based chemotherapy regimen. Pts applied 1mL of topical calcitriol (BPM31543) to the scalp BID, ≥ 5 days prior to chemotherapy for 3 months or treatment completed. The maximum tolerated dose (MTD) was determined by dose escalation in stepwise increments of the prior dose, in the absence of dose-limiting toxicity (DLT) during the first 28 days of application. Adverse event (AE) monitoring, pharmacokinetics, blinded photographic assessments and patient self-assessment were assessed.

Results: 22 treated pts experienced 1 treatment emergent adverse event (TEAE). The most frequently experienced TEAEs were fatigue (47.8%), nausea (39.1%), peripheral sensory neuropathy (30.4%), maculopapular rash and elevated vitamin D (26.1%). Elevated vitamin D and rash were possibly or probably related to treatment, while fatigue, nausea, neuropathy were likely due to chemotherapy. The majority of AEs were mild to moderate in severity. 13 TEAEs were considered Grade 3, but were not considered treatment related by the investigators. Hair loss <50% from baseline was observed in 8 pts at Week 7. At Week 15, 2 pts had <50% hair loss maintained. There were no detectable effects of topical BPM31543 on serum levels of calcitriol.

Conclusions: BPM31543 applied topically twice daily to the scalp in patients receiving taxane-based chemotherapy is safe and well-tolerated with no apparent differences in safety between doses. Here, no DLT was observed at up to 80 μg/mL and MTD was not reached. Some efficacy was detected at each dose. These data are encouraging and support further investigation in Phase 2/3 trials.

Clinical trial identification: NCT01588522.

1695P Acupuncture for peripheral neuropathy in cancer patients: TCM diagnosis as a predictor of treatment response

W. Liu[1], A. Qdaisat[2], G. Lopez[1], S. Underwood[1], M. Spano[1], A.R. Akhila Reddy[1], Y. Guo[1], S-C. Yeung[2], E. Bruera[1], M.K. Garcia[1], L. Cohen[1]

[1]*Palliative, Rehabilitation & Integrative Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX, USA,* [2]*Emergency Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX, USA*

Background: Acupuncture has been recognized as an effective integrative modality for managing peripheral neuropathy. However, data regarding predictors for response to acupuncture in cancer patients experiencing neuropathy are limited. We explored associations between patient characteristics, including traditional Chinese medicine (TCM) diagnosis, and treatment response among cancer patients who received acupuncture for peripheral neuropathy.

Methods: We reviewed acupuncture records in cancer outpatients with a primary reason for referral listed as peripheral neuropathy from March 2016 to April 2018. Treatment response was assessed using numbness/tingling score with a modified Edmonton Symptom Assessment Scale (ESAS; 0-10 scale) administered before and after each acupuncture treatment. Associations between TCM diagnosis, individual patient characteristics, and treatment response rate were analyzed by Wilcoxon's test.

Results: A total of 1745 acupuncture records (333 patients) were identified. The majority were female (71%), and 96 (29%) had breast cancer. The median (IQR) reduction in numbness/tingling score was 20% (0-50; $P < 0.001$). The most frequent TCM diagnosis was qi stagnation (86%) followed by blood stagnation (79%). Presence of blood stagnation and damp accumulation were predictors of poorer response as indicated by less reduction in numbness/tingling score (20% vs. 25%, $P < 0.001$ and 17% vs. 20%, $P = 0.036$; respectively). Factors associated with greater reduction in numbness/tingling score included age ≥ 60 (20% vs.17%, $P = 0.006$), female sex (22% vs. 17% in males, $P = 0.039$), and BMI ≥ 30 (25% vs. 20% in BMI < 30, $P = 0.016$).

Conclusions: Certain features of TCM diagnoses were associated with a poorer response, while being older, female, and obese were associated with a better response to treatment with acupuncture for peripheral neuropathy in cancer patients. This data may help design future clinical trials to better understand these factors and evaluate overall response to acupuncture in patients with peripheral neuropathy.

Köhler/Fuchs, Langen, Germany,* [7]*Hämatologie, Onkologie und Stammzelltransplantation, University of Freiburg Medical Centre, Freiburg, Germany,* [8]*Klinik für Innere Medizin I, Hämatologie, Onkologie und Stammzelltransplantation, Westpfalz-Klinikum GmbH, Kaiserslautern, Germany,* [9]*Praxis für Interdisziplinäre Onkologie & Hämatologie, Freiburg, Germany,* [10]*Clinical Development, Merckle GmbH, Ulm, Germany*

Background: Lipegfilgrastim (LONQUEX®) has proven to be non-inferior to pegfilgrastim (NEULASTA®) in the reduction of the duration of severe neutropenia (DSN) in breast cancer patients. The efficacy and safety of lipegfilgrastim versus pegfilgrastim in elderly patients with B-NHL at high risk for R-CHOP-21-induced neutropenia was investigated. The primary efficacy endpoint was the DSN in cycle 1.

Methods: One hundred and one patients with NHL, median age of 74 years, were randomized to receive either 6 mg of lipegfilgrastim or pegfilgrastim per cycle during 6 cycles of R-CHOP-21.

Results: Lipegfilgrastim was non-inferior to pegfilgrastim in the DSN in cycle 1: the mean DSN (days) in cycle 1 was 0.8±.96 and 0.9±1.08 in the per-protocol population, respectively with an adjusted mean difference (95% confidence interval) between groups of -0.3 (-0.70, 0.19). The upper boundary was below the predefined non-inferiority margin of 1. Non-inferiority was also demonstrated in the intent-to-treat population. The incidence of febrile neutropenia (FN) in cycle 1 was 2% (1/41) in the lipegfilgrastim and 0% (0/44) in the pegfilgrastim group. The incidence of severe neutropenia in cycle 1 was similar in the lipegfilgrastim (21/41; 51%) and pegfilgrastim (23/44; 52%) groups. The mean time to absolute neutrophil count recovery to a threshold of $\geq 2.0 \times 10^9$/L was similar in lipegfilgrastim (8.3 days) and pegfilgrastim (8.7 days) groups. Adverse events (AEs) occurred in 98% of patients; in 45/46 of lipegfilgrastim and 49/50 of the pegfilgrastim group. Serious AEs occurred in 46% of patients; 21/46 in the lipegfilgrastim and 23/50 in pegfilgrastim group; none were assessed as treatment-related by the investigator. Fatal AEs occurred in 4% (2/46) of lipegfilgrastim and 10% (5/50) of the pegfilgrastim group. Study withdrawal due to AEs occurred in 2% (1/46) of the lipegfilgrastim and 18% (9/50) of the pegfilgrastim group.

Conclusions: Lipegfilgrastim was non-inferior to pegfilgrastim in the reduction of the DSN in elderly patients with B-NHL. The safety of lipegfilgrastim was comparable to pegfilgrastim.

Background: Lipegfilgrastim (Lonquex®) is a long-acting glycopegylated G-CSF, which was proven to be non-inferior to pegfilgrastim in breast cancer patients. The objectives of this study were to evaluate effectiveness and safety of lipegfilgrastim in everyday clinical practice in adult patients with different tumor types, who are treated with cytotoxic chemotherapy.

Methods: Patients with different tumor types treated with cytotoxic chemotherapy, who received lipegfilgrastim in primary (PP) or secondary prophylaxis (SP) were included in this prospective non-interventional study. Evaluation of chemotherapy (CT) and biological therapy (BT) dose modifications as well as neutropenic events following the first lipegfilgrastim supported treatment cycle is presented here.

Results: A total of 1,313 patients were included in the safety set. Mean age of included patients was 58.4±13.3 and 70.2% were female. The majority of patients had breast cancer (46.7%) and lymphoma (26.4%). A total of 895 (68.2%) patients received lipegfilgrastim in PP starting from CT cycle 1 and 192 (14.6%) patients received it in SP for

the first time. They were included in the effectiveness analysis. In the first cycle febrile neutropenia (FN) was reported in 1.8% of patients receiving lipegfilgrastim in PP and in 1.0% of patients receiving lipegfilgrastim in SP. Grade 3/4 neutropenia was reported in 7.5% (PP) and 6.7% (SP) of patients. CT and/or BT was delayed, reduced or omitted in 20.1% of patients receiving lipegfilgrastim in PP and in 28.1% of patients receiving it in SP. This was associated with FN and grade 3/4 neutropenia in only 1.0% and 2.2% of these patients in case of PP and 2.1% and 5.5% in case of SP. A total of 284 (21.6%) patients reported at least one adverse drug reaction (ADR) throughout the study. The most common ADRs were bone pain (5.86%), myalgia (3.43%) and back pain (1.83%). Serious ADRs were reported by 42 (3.2 %) of patients.

Conclusions: Lipegfilgrastim is effective and well tolerated in the real world setting administered either in PP or SP. Both effectiveness and safety data obtained in this study are in line with published data for lipegfilgrastim.

1698P Safety analysis of proposed biosimilar pegfilgrastim in phase I and phase III studies

N. Harbeck[1], J. Wang[2], G. Otto[3], A. Krendyukov[4]

[1]Breast Cancer Dept. Ob & Gynae and CCCLMU, University of Munich, Munich, Germany, [2]Biostatistics, Sandoz Inc., Princeton, NJ, USA, [3]Clinical Research, Hexal AG, Holzkirchen, Germany, [4]Medical Oncology/Hematology, Hexal AG, Holzkirchen, Germany

Background: Granulocyte colony-stimulating factors (G-CSFs), including filgrastim and its long-acting form pegfilgrastim, are widely used to prevent chemotherapy-induced neutropenia in patients undergoing cytotoxic chemotherapy. Bone pain is the most frequently reported adverse event (AE) associated with G-CSF. In cancer patients receiving pegfilgrastim, bone pain incidence ranges from 25–38%, compared with 52–84% in healthy volunteers (HVs).[1] This study compares safety data for Sandoz proposed biosimilar pegfilgrastim in Phase I and III studies.

Methods: Three studies were included: 103, a single-dose, randomized, double-blind, crossover phase I study in HVs receiving proposed biosimilar (n = 92) or reference pegfilgrastim (n = 92)[2] and 2 randomized, double-blind Phase III confirmatory studies (PROTECT1[3] and 2[4]) in breast cancer (BC) patients undergoing cytotoxic chemotherapy (≤6 cycles) receiving proposed biosimilar (PROTECT1: n = 159; PROTECT2: n = 155) or reference pegfilgrastim (PROTECT1: n = 157; PROTECT2: n = 153). Results were compared for a single dose of pegfilgrastim in 103, and for 1st treatment cycle in PROTECT1 and 2.

Results: Differences in baseline characteristics between 103 and PROTECT included younger age, lower BMI and inclusion of men in 103 (Table). Treatment related bone pain was reported by 58% (biosimilar) and 53% (reference) in 103; in 4.4% (biosimilar) and 5.1% (reference) in PROTECT1, and 4.5% (biosimilar) and 8.5% (reference) in PROTECT2. AEs were generally mild in 103 and mild/moderate in PROTECT.

Table: 1698P

	Study 103[2]	PROTECT1[2]	PROTECT2[3]
Baseline characteristics			
Age, mean (SD)			
Proposed biosimilar	26.7 (7.35)	49.9 (9.53)	48.8 (10.50)
Reference		50.5 (10.87)	49.1 (10.07)
Female gender, n (%)			
Proposed biosimilar	67 (36)	159 (100)	155 (100)
Reference		157 (100)	153 (100)
BMI, mean (SD)			
Proposed biosimilar	23.9 (2.17)	27.5 (5.67)	26.6 (5.77)
Reference		27.4 (5.60)	26.5 (5.13)
Safety			
Bone pain, n (%)			
Proposed biosimilar	102 (58)	7 (4.4)	7 (4.5)
Reference	94 (53)	6 (3.8)	13 (8.5)
RR (CI)	1.10 (0.93 - 1.30)	1.15 (0.40 - 3.35)	0.53 (0.22 -1.30)
Headache, n (%)			
Proposed biosimilar	100 (57)	2 (1.3)	3 (1.9)
Reference	99 (56)	3 (1.9)	3 (2.0)
RR (CI)	1.02 (0.87 - 1.20)	0.66 (0.11 - 3.89)	0.99 (0.20 - 4.81)

BMI, body mass index; CI, confidence interval; RR, relative risk; SD, standard deviation.

Conclusions: Bone pain was similar with proposed biosimilar and reference pegfilgrastim, in studies of BC patients and HVs. Pivotal Phase I and Phase III studies support the matching safety and efficacy of Sandoz proposed biosimilar and reference pegfilgrastim. References: 1. 1699P New approach to evaluate survival benefit of granulocyte colony-stimulating factor in cancer patients receiving myelosuppressive chemotherapy

A. Krendyukov[1], L. Yau[2]

[1]Medical Oncology/Hematology, Hexal AG, Holzkirchen, Germany, [2]Biostatistics, Hexal AG, Holzkirchen, Germany

Background: In cancer patients undergoing myelosuppressive chemotherapy, granulocyte colony-stimulating factor (G-CSF) reduces the risk of neutropenic complications and decreases need for dose reductions,[1] allowing potential improvement of survival. A recent meta-analysis found that those receiving G-CSF have significantly improved overall survival (OS) versus those who do not.[2] Deemed a "gold standard" approach for estimating probabilities of survival for time-to-event data,[3] Kaplan-Meier (KM) estimates are a non-parametric method with no underlying distributional assumptions, allowing comparison between studies. Meta-analysis methods based on KM curves have been proposed.[4,5] We present a new approach of pooling KM curves, improving their accuracy in assessing survival probabilities.

Methods: Our new approach pinpoints specific coordinates on KM curves using web-based digital graphics data extraction tools. When the amount of at risk patients during a specific time period is known, the number of patients experiencing events can be calculated, or if unknown, imputed by "borrowing" event percentages from a study with a similar KM survival profile. Using minimum squared distances between pairs, the similarity between two KM curves can be determined. Reconstructed event times can be used for meta-analyses, using fixed or random effect modeling with weights for each study.

Results: This approach was applied to 70 reports of OS in cancer patients receiving chemotherapy with or without G-CSF prophylaxis, including recent meta-analysis data.[2] Preliminary results are in line with published data. Supporting reports of better survival in patients receiving G-CSF, the new approach provides synthesized KM curves, allowing comparisons of survival probabilities between treatments at any given time points.

Conclusions: Our preliminary results support findings of significantly improved OS in cancer patients receiving G-CSF. References: 1. Aapro et al. Support Care Cancer 2010;18:529–41. 2. Lyman et al. 1700P Safe switch of treatment from the reference product to RGB-02, a proposed biosimilar pegfilgrastim: Analysis of the results of three clinical trials

A. Illes[1], L. Perjesi[1], K. Horvat-Karajz[1], N. Jeszenoi[1], I. Aradi[1], N.K. Singh[2], S.J. Mair[2], Z. Kahan[3]

[1]Clinical Development of Biologics, Gedeon Richter Plc., Budapest, Hungary, [2]Medical Department, Quotient Sciences, Ruddington, UK, [3]Department of Oncotherapy, University of Szeged, Szeged, Hungary

Background: Treatment with recombinant human granulocyte-colony stimulating factor (G-CSF) is an accepted standard for prevention of chemotherapy-induced neutropenia. RGB-02, a pegylated G-CSF (pegfilgrastim) developed by Gedeon Richter is a proposed biosimilar to the reference product Neulasta®. Therapy switch from a reference product to its biosimilar is expected to occur in the daily practice. Here we are presenting the outcome of treatment switch in two randomized cross-over design comparative PK/PD studies (EudraCT nr: 2011-001737-17 and 2016-005051-25) and a randomized, comparative, multicenter efficacy and safety study of RGB-02 (EudraCT nr: 2013-003166-14).

Methods: Efficacy, safety and PD data of two PK/PD studies (enrolling 110 and 150 healthy volunteers, respectively) and a comparative efficacy and safety study (enrolling 239 breast cancer patients) were analyzed in order to assess whether treatment switch from Neulasta® to RGB-02 has any impact on the PD response, efficacy or safety. The PK/PD studies had a cross-over design. Patients in the reference arm of the comparative

efficacy and safety study were switched to RGB-02 treatment following the first two chemotherapy cycles. Endpoints assessed were related to the change in ANC count in healthy volunteers, duration of severe neutropenia (DSN; ANC $< 0.5 \times 10^9$/L) in the comparative efficacy and safety study, as well as safety data including immunogenicity collected in each clinical study.

Results: None of the PD endpoints showed any difference following the cross-over in the comparative PK/PD studies. The mean DSN values after the therapy switch were similar to the values prior to the switch and the switched arm (mean DSN: 0.6) did not show decreased efficacy compared to the arm received RGB-02 from the first cycle (mean DSN: 0.9). Safety results, including immunogenicity of the 3 studies did not reveal any negative impact of the treatment switch.

Conclusions: Treatment switch from Neulasta® to RGB-02 can be considered safe while maintaining the therapeutic effect of pegfilgrastim therapy.

Clinical trial identification: EudraCT: 2011-001737-17; EudraCT: 2016-005051-25; EudraCT: 2013-003166-14.

1701P Use of primary and secondary pegfilgrastim prophylaxis for reducing incidence of neutropenia: Findings from a large study in German clinical practice (PROTECT)

C.M. Kurbacher[1], M. Schmidt[2], M. Geberth[3], B. Otremba[4], H. Eschenburg[5], P. Ramdohr[6]

[1]*Gynecologic Center, Medizinisches Zentrum Bonn Friedensplatz, Bonn, Germany,* [2]*Johannes Gutenberg-Universität Mainz, Mainz, Germany,* [3]*Praxisklinik am Rosengarten, Mannheim, Germany,* [4]*Onkologische Praxis, Oldenburg, Germany,* [5]*Internistische Gemeinschaftspraxis Duda/Eschenburg/Wilhelm, Güstrow, Germany,* [6]*Medical Development, Amgen GmbH, Munich, Germany*

Background: The EORTC guidelines recommend primary prophylaxis with G-CSF when the overall risk of febrile neutropenia (FN) is $\geq$ 20% (high risk [HR]) or if the chemotherapy FN risk is 10–20% (medium risk [MR]) with additional patient (pt)-related risk factors. This study assessed the acceptance of these guidelines in German routine practice.

Methods: Non-interventional study of pegfilgrastim use in pts receiving Ctx for solid tumors or lymphomas (2007–2014 in 123 German centers). Pts were >18 yrs, had breast, ovarian, gastric, prostate or lung cancer, or aggressive lymphoma, EORTC-defined FN risk $\geq$10%, and prophylactic pegfilgrastim use. Primary endpoint: proportion of pts receiving pegfilgrastim as primary (prior to neutropenia) or secondary (following neutropenia occurrence) prophylaxis.

Results: Data were available from 1914/2069 pts (average age 58 yrs, 79% female, 60% had breast cancer, 69% had prior tumor-related therapy and 20% prior Ctx). Of those receiving prior Ctx, 39% needed neutropenia treatment. Of the 1914 pts, pegfilgrastim was used as primary and secondary prophylaxis in 78% and 22%, respectively (primary endpoint). Primary prophylaxis was more frequent than secondary in the HR (87 vs 13% of 936 pts) and MR (73 vs 27% of 835 pts) groups. At a pt level, overall FN rate was 8% and varied across tumors: gastric 12%, breast 9%, lung 7%, lymphoma 8% and ovarian 3%. Across these tumors, the number of cycles with FN were 1.9%, 3.2%, 1.9%, 1.9%, 2.1% and 0.6%, respectively. Overall, 2% had a dose reduction or therapy switch due to FN. In breast cancer, dose reductions or therapy switches occurred in 1% of pts receiving primary prophylaxis and 3% receiving secondary prophylaxis.

Conclusions: In this study of pts receiving pegfilgrastim prophylaxis in routine German practice, the majority of HR pts with overall FN risk of > 20% were treated with primary pegfilgrastim prophylaxis in concordance with the EORTC guidelines. Primary prophylaxis with pegfilgrastim was associated with a low FN incidence and a low rate of dose reductions and treatment delays.

1702P Associations between hematologic toxicity and health-related quality of life during first-line chemotherapy in advanced non-small-cell lung cancer: A pooled analysis of two randomized trials

A. Kristensen[1], T.S. Solheim[1], Ø Fløtten[2], B.H. Grønberg[1]

[1]*The Cancer Clinic & European Palliative Care Research Centre (PRC), Department of Clinical and Molecular Medicine, St. Olav's Hospital & NTNU, Norwegian University of Science and Technology, Trondheim, Norway,* [2]*Department of Thoracic Medicine, Haukeland University Hospital, Bergen, Norway*

Background: Many patients experience toxicity from chemotherapy that can negatively impact their health-related quality of life (HRQoL), but side effects often go undetected by health care personnel. Hematologic toxicity (HT) is the main dose-limiting toxicity of chemotherapy. Our aim was to investigate whether patients who experienced severe HT had more negative changes in HRQoL than those who did not. If so, blood counts could represent a simple and objective method for identifying patients at risk of severely impaired HRQoL who may benefit from more supportive care during the treatment period.

Methods: Data from two phase III trials of first-line chemotherapy in advanced non-small-cell lung cancer (NSCLC) were analyzed (n = 873). Blood counts were measured weekly. We categorized patients as having severe (CTCAE grade 3-4) or non-severe (grade 0-2) HT during the first chemotherapy cycle. HRQoL was reported on the EORTC QLQ-C30 and LC13 before and at the end of the cycle. The primary endpoints were changes in global quality of life, fatigue, nausea/vomiting and dyspnea (LC13). Mean differences of 5-10 points was considered to represent a small clinical difference.

Results: Of the 766 patients with complete data set, 177 (23%) developed severe HT during the first chemotherapy cycle. Severe neutropenia and thrombocytopenia was observed in 149 (19%) and 67 (9%) patients, respectively, while only three (0.4%) patients had severe anemia. Changes in fatigue and nausea/ vomiting were significantly worse for patients experiencing severe compared to patients with non-severe HT (difference in mean change of 4.9 points; $p = 0.01$, and 6.4 points; $p = 0.01$, respectively), but this association was limited to neutropenia, not thrombocytopenia or anemia. There were no significant associations between HT and global quality of life or dyspnea (difference in mean change of 2.1 points; $p = 0.28$, and 3.3 points; $p = 0.053$, respectively).

Conclusions: Patients developing severe HT had worse changes in two out of four HRQoL endpoints, but the association was not strong enough to use blood counts to identify patients who experience deterioration of HRQoL during chemotherapy.

Background: DN has shown superiority in delaying skeletal related events when given q4w over zoledronic (ZA) acid given q4w. Newer data have shown that ZA given q12w is non-inferior to ZA q4w. The primary endpoint of REDUSE is to show non-inferiority

for DN q12w versus q4w (SSE). Here we present the data for the secondary endpoint hypocalcemia (HC).

Methods: Patients with metastatic breast cancer (BC) or metastatic castration resistant prostate cancer (PC) (planned N = 1380) were randomized 1:1 to receive DN q4w (Arm A) versus q12w (Arm B) after a 3-month induction phase with application q4w. All patients received vitamin D 400 U (ViD) and calcium (Ca) 500 mg daily. Measurement of serum-calcium was mandatory before each DN injection. This safety interim analysis was performed after 3.5 years of accrual. (N = 634; BC N = 351, PC N = 283).

Results: Patients who received at least 1 dose of DN were considered evaluable. HC was the most common side effect with 23.7% overall (BC 18.6%, PC 30.2%). While HC occurred in 31.6% in Arm A, the rate was 15.8% in Arm B. Grade 3/4 HC was rare (overall: 1.3%, all with PC). After 1 year of treatment, the incidence of HC was lower in both arms (A: 27.2%, B: 14.3%). Since HC improved in more patients in Arm B than Arm A whereas it got worse in Arm A compared to Arm B, a remarkable difference for HC was noticed between the two arms (Table).

Table: 1703P

Change in HC grade after week 16 in patients with HC during induction treatment (196/634) (week 1 – 12: DN q4w Arm A+B, thereafter q4w Arm A, q12w Arm B)	Arm A (N = 106) n (%)	Arm B (N = 90) n (%)
Worsening	48 (45.3%)	23 (25.6%)
Stable	29 (27.4%)	15 (16.7%)
Improving	29 (27.4%)	52 (57.8%)

Arm A: Denosumab q4w, Arm B: Denosumab q12w.

Conclusions: In our trial up to 30% of all patients treated with DN experienced HC in the q4w induction phase despite mandatory supplementation and measurement of ViD and Ca. This rate was considerably higher than reported in the registration trials of DN (PC 13.0%, BC 5.5%). After randomization the appearance of HC is remarkably lower in the q12w arm compared to q4w. This suggests that DN given q12w has a more favorable long time toxicity profile (HC) compared to DN q4w.

Clinical trial identification: NCT02051218.

1704P A prospective randomized controlled trial of metoclopramide combined with triple antiemetic therapy to prevent anthracycline-based chemotherapy-induced nausea and vomiting in patients with breast cancer

U. Oflazoglu[1], U. Varol[1], A. Alacacioglu[1], T. Salman[1], Y. Kucukzeybek[1], H. Taskaynatan[1], Y. Yildiz[1], G. Dissiz[1], S. Iriz[1], M.O. Tarhan[2]

[1]Medical Oncology, Izmir Katip Celebi University, Izmir, Turkey, [2]Medical Oncology, Dokuz Eylul University Institute of Oncology, Izmir, Turkey

Background: Triple antiemetic therapy, such as a 5-HT3 receptor antagonist (5H3-RA), aprepitant and dexamethasone, is recommended for the prophylaxis of highly emetogenic chemotherapy induced nausea and vomiting in patients with breast cancer. In the present study, we aimed to verify whether adding metoclopramide to the triplet antiemetic therapy is superior to the triplet antiemetic therapy in preventing CINV in patients with breast cancer.

Methods: A single-blind, randomized trial was performed on ninety-seven patients who received HEC among chemotherapy-naive patients with breast cancer. The visual analogue scale (VAS) utilized to detect nausea, and FLIE was used in order to determine its impact on the patients' quality of life. The patients were randomized to arm A(n:48, dexamethasone and 5HT3RA on day 1, aprepitant on day 1-3, and metoclopramide on days 1-5) and arm B (n:49, dexamethasone and 5HT3RA on day 1and aprepitant on day 1-3). The primary endpoint was complete response (CR) (no nausea, no vomiting, and no rescue medication) during the overall phase (days 1–5).

Results: The demographic and clinical features such as age, educational background, height and weight measurements were similar in both groups. The CR was found in twenty patients (45.8%) of the forty-eight patients in the arm A, while it was found in thirteen patients (26.5%) of the forty-nine patients in the arm B (p:0.038).The mean total FLIE score was 31.31 (SD: 20.5) in arm A, which was42.29 (SD: 26.4) in arm B (p:0.045).

Conclusions: A triple or quadruple antiemetic combination is proposed to alleviate CINV for female patients with breast cancer treated with HEC. In patients receiving anthracycline-based chemotherapy, quadruple antiemetic therapy with dexamethasone, aprepitant, palonosetron and metoclorpropamide is associated with a significant CR and clinically relevant improvement in FLIE score, compared to dexamethasone, aprepitant and palonosetron. Therefore, a quadruple antiemetic combination including metpamid might be a treatment option for patients receiving highly emetogenic chemotherapy.

Background: The combination of palonosetron (PAL), aprepitant (APR) and dexamethasone (DEX) is the standard regimen in controlling highly emetogenic chemotherapy-induced nausea and vomiting (HEC CINV) in cancer patients. We previously demonstrated that ramosetron (RAM), 5-HT3 receptor antagonist, is superior to ondansetron. This prospective, multicenter, single blind, randomized and phase IV study compares RAM, APR and DEX (RAD) with PAL, APR and DEX (PAD) to prove the non-inferiority of RAD in controlling HEC CINV.

Methods: Patients were randomly assigned at 1:1 ratio to receive either RAD or PAD regimen: RAM(0.3mg IV) or PAL(0.25mg IV), D1 in combination with APR(125mg PO, D1 and 80mg PO, D2-3) and DEX(12 mg PO or IV, D1 and 8 mg PO, D2-4). They were stratified by gender, chemotherapy (cisplatin vs non-cisplatin) and administration schedule (single vs multi-day). The primary endpoint, overall complete response (CR) was defined as no emesis and no rescue regimen within 5 days of HEC. The secondary endpoints were overall complete protection (CP: CR + nausea score<25mm) and total control (TC: CR + nausea score<5mm). Quality of life (QOL) was assessed by Functional Living Index–Emesis (FLIE) questionnaire on D0 and D6.

Results: A total of 279 patients receiving RAD (n = 137) or PAD (n = 142) were evaluated for the efficacy and safety. The overall CR rates of RAD vs PAD were 72.3% vs 74.6% (relative difference [RD] -2.4%, 95% CI: -12.8 to 8.0), respectively. The overall CP and TC rates in RAD vs PAD were 52.6% vs 57.0%(RD -4.5%, 95% CI: -16.2 to 7.2) and 45.3% vs 43.0%(RD 2.3%, 95% CI: -9.4 to 14.0%), respectively. FLIE score≥108 (no impact of daily life) was comparable between RAD (n = 134) and PAD (n = 139) (73.9% vs 73.4%, p = 1.00 respectively). Each nausea and vomiting domain (FLIE score≥ 54) was 67.2% vs 64.0 %(p = 0.61) and 91.8% vs 90.6 %(p = 0.83), respectively. The adverse events were similar between the two groups.

Conclusions: In all aspects of the efficacy, safety and QOL, our data suggested RAD was comparable to PAD for the control of CINV in cancer patients receiving HEC.

1706P Prognostic factors associated with prevalence of nausea, and time to development of nausea in patients receiving guideline-based anti-emetic prophylaxis: A prospective, observational, real world study

T. Smit, B.L. Rapoport

Pharmacy, The Medical Oncology Centre of Rosebank, Sandton, South Africa

Background: The development of effective anti-emetic treatments has contributed to the resolution of emesis in chemotherapy patients (pts). There is a growing concern that the emesis focus is primarily on vomiting. Nausea seems to be underestimated and its incidence and impact remains a major unmet medical need. The study focused primarily on nausea in patients undergoing highly-, moderately- or low emetogenic chemotherapy (HEC, MEC, LEC). The primary endpoint was no nausea during the 120-hours overall phase after cycle 1. The analysis focused on the prevalence of nausea and time to nausea development following the first cycle of chemotherapy.

Methods: This prospective, observational single centre study enrolled 95 patients undergoing LEC (25 pts), MEC (24 pts) or HEC (46 pts) for malignancy. Prophylactic antiemetics were administered according to MASCC/ESMO 2016 guidelines. Patient diaries were used to collect data from day-1 to day-5, day-7 and day-10 beginning with cycle-1 for up to 3 cycles.

Results: The incidence of nausea of the entire population was 59% compared to only 24% pts experiencing vomiting. ($Chi^2 = 23.5956$; $p > .000001$). Significant variables predicted for nausea included gender, age and history of motion sickness. The level of emetogenicity did not correlate with the incidence of nausea (LEC = 25%, MEC = 60%, HEC = 67%), ($Chi^2 = 5.1893$; $p > .07$). On univariate analysis, factors associated with shorter time to the first nausea episode included; age < 60 years (log-rank test $p < 0.0213$, Chi sq = 2), then motion sickness ($p < 0.0229$), gender ($p < 0.0321$) and emetogenicity ($p < 0.29$). In a Cox-proportional multivariate proportional hazard model age < 60 years, ($p < 0.0213$), gender ($p < 0.0321$) and motion sickness ($p < 0.0229$) retained its significance – while emetogenicity lost its significance.

Conclusions: Chemotherapy induced nausea is underreported and remains a major unmet medical need. Gender, age and motion sickness are significant risk factors associated with nausea independent of the level of emetogenicity of the chemotherapy utilized in patients receiving guideline-based antiemetic prophylaxic treatment.

1707P Usefulness of bone modifying agents for non-weight bearing bone metastasis in breast cancer

K. Kawaguchi[1], M.A.H.M. Latif[2], K. Hayashi[2], S. Ogita[3]

[1]Orthopedic Surgery, Lizuka Hospital, Lizuka, Japan, [2]Statistics, St. Luke's International University, Tokyo, Japan, [3]Medical Oncology, St. Luke's International Hospital, Tokyo, Japan

Background: Bone metastasis is common in breast cancer. No previous study evaluated the usefulness of bone modifying agents (BMA) in breast cancer patients whose metastases are limited to non-weight bearing bones.

Methods: We retrospectively collected data at St. Luke's International Hospital between 2006 and 2016. Weight bearing bones were defined as vertebral body, lower limbs, and pelvis, and all the other bones were defined as non-weight bearing bones. Breast cancer patients, age ≥20 years old, who were newly diagnosed to have bone metastasis only in non-weight bearing bones were included in this study. Bone metastases were detected by either bone scintigraphy or PET-CT. The selected patients were divided into 2 groups: patients of Group A started BMA within 3 months from the diagnosis, and those of Group B did not start BMA within the 3 months. We are interested in comparing the Groups A and B in terms of time to skeletal related events (SRE) and overall survival (OS), where SRE were defined as orthopedic surgery, percutaneous vertebroplasty, and/or palliative radiation to bone metastasis.

Results: Out of 418 breast cancer patients with bone metastasis, only 101 patients were found to have bone metastasis only in non-weight bearing bones. The median follow-up time was 32 months. The number of patients in Group A and B were 54 and 47, respectively. Eight patients in Group A and 5 patients in Group B developed SRE ($p = 0.568$). Median SRE free survival (i.e. timeto SRE) was 118.5 months, and 117.3 months in Group A and Group B, respectively ($p = 0.490$, Hazard ratio: 1.48). Median overall survival (OS) was 39.7 months in group A and 78.3 months in group B ($p = 0.203$, Hazard ratio: 1.45).

Conclusions: Early initiation of BMA did not improve SRE free survival or OS in breast cancer patients who have only non-weight bearing bone metastasis. Further prospective studies are needed to confirm this finding.

1708P Analysis of bone events in patients with aromatase inhibitors (AI)

S.F. Arrojo[1], E. Garcia-Carús[2], C. Gómez[2], P. Rodriguez[3], D. Rivas[3], L. Faez[1], C. Iglesias Gomez[1], M.E. Izquierdo Manuel[1], Y. Fernandez Perez[1]

[1]Medical Oncology, Hospital Universitario Central de Asturias, Oviedo, Spain, [2]Internal Medicine, Hospital Universitario Central de Asturias, Oviedo, Spain, [3]University of Oviedo, Hospital Universitario Central de Asturias, Oviedo, Spain

Background: Nowadays breast cancer (BC) may have high cure rate, so is important how to prevent or resolve adjuvant treatments adverse effects. AI are an essential treatment in patients with early diagnosed estrogen-dependent BC. Our aim is to analyse bone mass loss in BC, focussing on fractures incidence and their risk as well as preventive methods. The latest consensus establishes as intervention criteria a BMD value> -2T Score and 2 or more risk factors.

Methods: 114 BC patients and 272 without BC sent to our centre in 2010 to perform densitometry (DXA) were included in our review. Beyond DXA and anthropometry we carried out an extensive clinical questionnaire on co-morbidity, risk factors for osteoporosis, medication, personal and relatives history of fractures. Hospital and primary care records were reviewed in BC patients until May 2017 to determine fractures incidence.

Results: There were significant differences in age (BC 59 ± 11 vs 62 ± 11 years, $p = 0.01$). No differences in weight, height, menarche/menopause or toxic habits. 25% had personal history of fracture (31% control $p = 0.05$) and 17% relatives history (27% control $p = 0.03$). 4.3% of corticosteroid intake (16% control $p = 0.01$). There were no differences in T Lumbar Score (0.97 ± 1.3 vs -0.94 ± -1.2) or in femur neck (-.0.93 ± 1.2 vs-1.1 ± 1) but yes in the fracture risk assessment tool (FRAX) for major fractures with BMDM (BC 7 ± 5% vs 11 ± 6% p0.02) and hip fractures (1.2 ± 2 vs 2.4 ± 4 p 0.02). Patients with AI lost bone mass at two years (BMD 0.96 ± 1.87 to 0.921 ± 0.18 g / cm2 p0.03), without changes in control group. At 7 years follow-up, 8 fractures appeared in patients with AI (3 Colles, 3 vertebral and 2 humerus), 4 patients with Exemestane (E), 2 with Letrozole (L) and 2 with Anastrozole (A) (40% took E, 26% A and 20% L). Only 3 of the 8 had baseline T Lumbar Score <-2. 7% BC patients received antiresorptives and 9% vitamin D.

Conclusions: There were more fractures and bone mass loss in BC pacients treated with AI in our sample. Despite the small sample size, it is striking that, patients with BC would not meet the indication of preventive treatment according to the latest recommendations, since only 30% of the patients would be covered. It could be considered to associate other diagnostic measures to treat patients with greater risk of fracture (FRAX).

1709P Assessment and treatment of breakthrough cancer pain in Spain: A self-audit study

R. Lopez Lopez[1], J.J. Reina Zoilo[2], D. Monge[3], F. Caballero[3], V. Guillem Porta[4], E. Aranda Aguilar[5], A. Carrato Mena[6], E. Diaz Rubio[7], J. Garcia Foncillas[8], M. Feyjoo[9], C. Camps[10]

[1]Medical Oncology, Complejo Hospitalario Universitario de Santiago de Compostela SERGAS, Santiago De Compostela, Spain, [2]Medical Oncology, Hospital Universitario Virgen Macarena, Seville, Spain, [3]Department of Health Sciences, Francisco de Vitoria University, Madrid, Spain, [4]Medical Oncology, Fundación Instituto Valenciano de Oncología, Valencia, Spain, [5]Medical Oncology, University Hospital Reina Sofia, Cordoba, Spain, [6]Medical Oncology, Hospital Universitario Ramon y Cajal, Madrid, Spain, [7]Vicepresidente, Real Academia de Medicina, IdISCC, CIBERONC, Madrid, Spain, [8]Medical Oncology, University Hospital "Fundacion Jimenez Diaz", Madrid, Spain, [9]Medical Oncology, Hospital Universitario La Moraleja, Sanitas, Madrid, Spain, [10]Medical Oncology, Consorcio Hospital General Universitario de Valencia, Valencia, Spain

Background: In Spain 77% of the episodes of Breakthrough cancer pain (BTcP), a common condition for cancer patients, are not properly diagnosed or treated. The ECO Foundation (Excellence and Quality in Oncology) has promoted this study with the collaboration of Francisco de Vitoria University, to compare the real-life clinical practice with the previous perception of the oncologists of the management of BTcP and to determine if clinical inertia exists in the approach of the BTcP episodes.

Methods: Observational and descriptive study consisting in two phases: a) opinion poll (self-completed online) answered by Spanish oncologists, and b) BTcP episodes screening and assesment (performed by the oncologist surveyed) in patients with a prior or current history of cancer pain (5 patients per oncologist). A recent expert consensus (1) and Davies algorithm were used to evaluate the correct diagnosis and optimal management of BTcP. A total of 108 oncologists participated in the study and 540 patients were evaluated.

Results: Although most oncologists (>80%) refer questioning their patients about the possibility of BTcP, only 34% of them do it systematically in their clinical practice. Most specialists believed that BTcP episodes were unlikely to go unnoticed in their consultations (62%). After evaluating real-life clinical practice, the overall prevalence of BTcP obtained was 91% (493/540). The doctors had previously detected the BTcP condition in 59% of patients (291/493), demonstrating that the under-diagnosis of BTcP exceeds 40%. In addition, 42% of patients with known BTcP were not able to control their episodes of pain and, despite the persistence, in 13% of them, no changes or adjustments had been made in the dose intensity or schedule.

Conclusions: The study confirms that there is a significant prevalence of BTcP and a notable inertia in the management of BTcP episodes, which seems to be poorly detected and treated in patients with cancer. Expanding the use of tools to diagnose BTcP, such as Davies algorithm, might be useful to improve the QoL of patients suffering pain.

Background: Opioid-induced constipation (OIC) is a common distressing symptom associated with cancer pain opioid treatment. Beyond the recommendations for the treatment of OIC, there are no specific guidelines for the management of the patient with OIC and little is known about the decision tree health care professional (HCP) use to manage OIC. The ECO Foundation (Excellence and Quality in Oncology) has promoted this study to learn about the diagnostic and treatment criteria of OIC in clinical practice.

Methods: An on-line survey was completed by 135 investigators: 122 medical oncologists (90.4%) and 13 palliative care specialists (9.6%). The questionnaire included 50 items about the management of OIC.

Results: According to HCP, most of the cancer patients with pain (71.2%), received opioid treatment for more than 6 months and 54.4% developed OIC. Although 97% of HCP considered OIC as a major health problem only 14.8% of HCP used algorithms for the diagnosis of OIC and 14.1% for OIC treatment. Laxatives were considered second-line treatment for 60% of HCP, after healthy life-style recommendations. Laxatives were prescribed by 99.3% of HCP, but only 38.3% recommended them throughout the opioid treatment period. HCP considered laxatives did not achieve a therapeutic response on 33% of the cases. Peripherally Active μ-Opioid Receptor Antagonist (PAMORA) were considered by 80% of HCP a good alternative for the specific treatment of OIC in cancer patients. Indeed, PAMORA were considered the most effective measure with a score of 8 out of a 10 points scale.

Conclusions: OIC is considered a frequent and relevant opioid side effect among cancer patients in Spain. Although most HCP are aware of the potential for OIC with opioid treatment, there is limited consensus on the OIC diagnostic and treatment criteria. The insufficient efficacy of traditional therapies and the emerging of more specific and effective pharmacological approaches, suggest new clinical guidelines are needed for the management of OIC in cancer patients.

1711P Opioid-induced constipation in patients with cancer pain in Japan: Prospective observational study using Rome IV OIC diagnostic criteria (OIC-J Study)

H. Imai[1], S. Fumita[2], T. Harada[3], T. Noriyuki[4], M. Gamoh[5], Y. Akashi[2], H. Sato[6], Y. Kizawa[7], A. Tokoro[8]

[1]Division of Respiratory Medicine, Gunma Prefectural Cancer Center, Ota, Japan, [2]Department of Medical Oncology, Kindai University Nara Hospital, Ikoma, Japan, [3]Center for Respiratory Diseases, JCHO Hokkaido Hospital, Sapporo, Japan, [4]Department of Surgery, Onomichi General Hospital, Onomichi, Japan, [5]Department of Medical Oncology, Osaki Citizen Hospital, Osaki, Japan, [6]Medical Affairs, Shionogi & CO., Ltd., Osaka, Japan, [7]Department of Palliative Medicine, Kobe University Graduate School of Medicine, Kobe, Japan, [8]Department of Psychosomatic Internal Medicine and Supportive and Palliative Care Team, National Hospital Organization Kinki-Chuo Chest Medical Center, Sakai, Japan

Background: Opioid-Induced Constipation (OIC) is a common side effect of opioid analgesic therapy. However, there were no prospective studies to assess the incidence of OIC of cancer patients. The aim of this study was to evaluate the incidence of OIC from the start of opioid therapy.

Methods: This study was a multicenter, prospective, observational study of cancer patients who started opioid therapy in Japan (UMIN000025864). The incidence of OIC was determined by ROME IV OIC diagnostic criteria based on the record of patient diary for 14 days. The proportion of patients with OIC was calculated for each 1-week period (Week 1 and Week 2) and overall 2-week period. Medication for constipation was allowed during the study period. Patients with <3 bowel movements in the previous week before starting opioid therapy were not allowed to be enrolled. Bowel Function Index (BFI; score >28.8), spontaneous bowel movement (SBM; <3 SBM/week), and physicians' assessment were also utilized to assess OIC and compare the results.

Results: In total, 212 cancer patients (145 males; mean age 69.1 years)—inpatients and outpatients—with ECOG Performance Status score of 0-2 were included in the study. Mean morphine equivalent dose was 21.9 mg/day. Overall incidence rate of OIC during 2 weeks by weekly diagnosis of Rome IV criteria (total proportion diagnosed as OIC in either Week 1 or Week 2) was 56.1%. The proportion of patients with OIC in Week 1 was 47.6% and in Week 2 was 36.8%. Use of prophylactic laxative reduced the overall incidence rate of OIC from 65.0% to 47.7%. Other diagnostic criteria instead of Rome IV criteria varied the rate; BFI (59.1%), physicians' assessment (61.4%), SBM frequency (44.8%). When overall 2-week period data were applied to Rome IV OIC criteria, the incidence rate was reduced to 44.2%. Sex and age were not considered as risk factors as opposed to the previous report in some cross-sectional studies. The frequency of SBM/week before starting opioids was identified as the most influencing factor for OIC.

Conclusions: OIC can occur quickly after the initiation of opioid therapy in cancer patients, even if laxatives were utilized prophylactically. The current tools for diagnosing OIC result in varied rates of diagnosis.

Clinical trial identification: UMIN000025864.

1712P Efficacy and tolerability of naldemedine in patient with cancer and opioid-induced constipation: A pooled subgroup analysis of 2 randomized placebo-controlled studies

E. Satomi[1], H. Ishiki[1], T. Yokota[2], Y. Tada[3], H. Sato[4], M. Okamoto[5], I. Osaka[6]

[1]Palliative Medicine, National Cancer Center Hospital, Tokyo, Japan, [2]Project Management, Shionogi & Co., Ltd., Osaka, Japan, [3]Biostatistics Center, Shionogi & Co., Ltd., Osaka, Japan, [4]Medical Affairs, Shionogi & Co. Ltd., Osaka, Japan, [5]Medical Affairs, Shionogi & Co., Ltd., LTD, Osaka, Japan, [6]Palliative Medicine, Shizuoka Cancer Center Hospital, Tokyo, Japan

Background: Opioid-Induced Constipation (OIC) is a common side effect of opioid analgesic therapy. Naldemedine (NAL), an orally available peripherally-acting μ-opioid receptor antagonist (PAMORA), has been shown to improve OIC without affecting analgesic effect of opioids across several clinical studies. However, the predictive factors determining the response to OIC treatment have not been elucidated. We conducted a subgroup analysis with the pooled data to explore the predictive factors in patient population for the efficacy and safety of NAL.

Methods: Data were pooled from 2 randomized, double-blinded, placebo (PBO)-controlled studies of NAL 0.2mg QD (Ph2b and Ph3) for cancer patients (JapicCTI-132340, JapicCTI-111510). Subgroup analysis (age, BMI, gender, opioid type or dosage, concomitant laxatives, with or without anti-cancer therapy, with or without possible disruption of blood brain barrier (BBB)) of spontaneous bowel movement (SBM) responder rate (percentage of patients with $\geq$ 3 SBMs/week and an increase from baseline of $\geq$ 1 SBM/week) was conducted. Overall safety and the incidence of diarrhea were evaluated. The pain intensity numerical rating scale (NRS) and clinical opiate withdrawal scale (COWS) were also analyzed in the population with or without possible BBB disruption.

Results: SBM responder rate was 73.5% (114 of 155 patients) for the NAL group and 35.5% (54 of 152 patients) for the PBO group for all subjects. The difference between the groups was 38.0% and was statistically significant ($P < 0.0001$). In the subgroup analysis, the difference of proportion between NAL vs PBO for each efficacy and safety endpoint was consistent across all subgroups (The all point estimates were greater than zero). Although the difference of the incidence of diarrhea between the groups was relatively larger in the possible disruption of BBB group, there was no difference between with or without possible BBB disruption for NRS and COWS.

Conclusions: Overall, this analysis of subgroups supported that the benefits of NAL were observed regardless of background factor, and its safety profile in various subgroups was consistent with that observed in the overall population.

Clinical trial identification: JapicCTI-132340, JapicCTI-111510.

1713P Left ventricular ejection fraction (LVEF) change for the first 6 months predicts development of trastuzumab-related cardiotoxicity in patients with breast cancer: An implication for the more efficient cardiac surveillance

J.H. Yeo[1], H. Ahn[2], I. Park[2], Y.S. Kim[2], S.J. Sym[2], E.K. Cho[1], D.B. Shin[2]

[1]Internal Medicine, Gachon Univeristy Gil Medical Center, Incheon, Republic of Korea, [2]Medical Oncology, Gachon University Gil Medical Center, Incheon, Republic of Korea

Background: Current guidelines recommend cardiac function monitoring every 3 months in patients receiving trastuzumab, however evidences for optimal cardiac surveillance strategy are lacking. The aim of this study is to identify risk factors and to characterize clinical patterns of trastuzumab related cardiac dysfunction(TRCD) within 1 year of treatment in patients with breast cancer.

Methods: We identified and reviewed consecutive patients with breast cancer received trastuzumab and adequate cardiac monitoring (baseline and subsequent cardiac echocardiogram at least every 4 months) between Jan 2010 - Apr 2017 at a single center. TRCD were defined as an absolte decrease of ejection fraction(EF) $\geq$15% or $\geq$ 10% to below the lower limit of normal.

Results: Among 364 patients(median age 51 years), TRCD was developed in 33 patients (9.3%). Median time from trastuzumab to TRCD was 6.3 months(range 2.6-12.3). Incidence of TRCD was significantly higher in patients with prior anthracycline (12.1% vs. 5.1%, $p = 0.026$). In 20 out of 33 patients (60.6%), TRCD was diagnosed within the first 6 months of trastuzumab. Earlier TRCD was significantly associated with prior anthracycline (72% vs. 25%, $p = 0.035$). Among the patients with later TRCD development after 9 months of trastuzumab ($n = 13$), absolute EF decrease >5% in the first 6 months preceded in 10 patients (76.9%). Incidence of later TRCD was significantly lower in patients whose absolute EF decrease < =5% in the first 6 months (2.1%) than in whom with more than 5% of absolute EF decrease (11.8%).

Conclusions: TRCD development occurs earlier within the first 6 months of trastuzumab in patients with prior anthracycline use. The degree of absolute EF decrease in the first 6 months can predict later development of TRCD. Therefore, cardiac monitoring for the first 6 months of trastuzumab treatment should not be missed, especially in whom with prior exposure to anthracyclie. Adaptive less frequent cardiac surveillance strategy after 6 months may be considered in patients without significant EF change.

1714P Predicting the occurrence and prevention of early anthracycline cardiotoxicity of chemotherapy in patients with breast cancer

A. Askolskyi[1], L. Syvak[1], O. Zharinov[2], N. Khranovska[3]

[1]Chemotherapy of Solid Tumors, National Cancer Institute, Kiev, Ukraine, [2]Department of Functional Diagnostics, Shupyk National Medical Academy of Postgraduate Education, Ministry of Healthcare of Ukraine, Kiev, Ukraine, [3]Laboratory of Experimental Oncology and Laboratory of Molecular-Genetics Diagnostics, National Cancer Institute, Kiev, Ukraine

Background: Methylenetetrahydrofolate Reductase (MTHFR) is the key enzyme of xenobiotic detoxification, involved in the metabolism of anticancer drugs. Genotyping of the polymorphism MTHFR allows to make prognosis of chemotherapy side effects in different patients, personalize pharmacotherapy.

Methods: QTc interval and myocardial systolic and diastolic function of 100 patients with breast cancer stages T1-3N0-3M0 treated with neo/adjuvant anthracycline chemotherapy were investigated. In the main study group 50 patients received cardioprotective medications (enalapril 2.5 mg orally twice daily and carvedilol 6.25 mg orally twice daily). The polymorphisms of MTHFR gene in control group were evaluated using Real-Time PCR. Statistica10.0 software was used to perform analysis of variance.

Results: It was established that the specific manifestations of early cardiotoxicity of doxorubicin at a cumulative dose 300 mg/m^2 were QTc prolongation over 460 msec in the main group in 5 (10%) patients, in the control group – 13 (26%) patients, as well as diastolic dysfunction (DD) of the left ventricle type 1 in the main group in 5 (10%) patients, in the control group – 15 (30%) patients.The absence of cardioprotective therapy in our study was a risk factor for these complications: QTc interval prolongation (OR = 3.15, 2.05 – 4.21, $p = 0.03$) and DD (OR = 3.85, 2.75 – 4.96, $p = 0.01$).A molecular genetic analysis had shown that QT prolongation and DD were detected in 36.4% of patients with T/T genotype, in 36.6% – with C/T genotype and only 9.1% patients with genotype C/C. The risk of cardiotoxicity of chemotherapy in patients with breast cancer, which is the carrier of one or two mutant alleles of the gene MTHFR (genotype C/T and T/T) is 2.68 times higher (OR = 2.68; 95% CI = 1.24 – 5.78; $p < 0.01$) in comparison with carriers of genotype C/C.

Conclusions: It is reasonable to determine the MTHFR gene polymorphism in patients with early breast cancer prior to treatment which allow to identifying a high-risk cardiotoxicity group for timely and adequate cardioprotective therapy administration.

1715P Baseline prevalence of cardiovascular disease (CVD) risk factors in women with breast cancer

N. Bhoo-Pathy[1], S. Subramaniam[2], H. Zaharah[3], Y.C. Kong[4], N.A. Taib[5], A. Deniel[6], K-H. Chee[7], R.S. Bustamam[6], M-H. See[5], A. Fong[8], C.H. Yip[9]

[1]Centre for Clinical Epidemiology and Evidence Based Medicine, Faculty of Medicine, University of Malaya, Kuala Lumpur, Malaysia, [2]Clinical Epidemiology Unit, National Clinical Research Centre, Ministry of Health Malaysia, Kuala Lumpur, Malaysia, [3]Radiotherapy and Oncology, National Cancer Institute, Putrajaya, Malaysia, [4]Clinical Epidemiology Unit, National Clinical Research Centre, Kuala Lumpur, Malaysia, [5]Department of Surgery, University Malaya Medical Center, Kuala Lumpur, Malaysia, [6]Radiotherapy and Oncology, Kuala Lumpur Hospital, Kuala Lumpur, Malaysia, [7]Cardiology Unit, University Malaya Medical Center, Kuala Lumpur, Malaysia, [8]Heart Centre, Sarawak General Hospital, Kuching, Malaysia, [9]Breast Clinic, Subang Jaya Medical Centre, Subang Jaya, Malaysia

Background: Pre-existing CVD risk factors in women with breast cancer increases their risk of developing adjuvant therapy induced cardiotoxicity. We measured the prevalence of major CVD risk factors in women newly diagnosed with breast cancer in a multiethnic setting.

Methods: From 2015 to 2017, 2159 women with newly diagnosed invasive breast cancer were consecutively recruited from four tertiary hospitals in Malaysia. Demographic, medical and drug history were collected through interviews and verified with medical records. Pre-treatment height, weight, blood pressure, serum glucose, and cholesterol levels were measured. Risk of cardiotoxicity was estimated using the Cardiotoxicity Risk Score proposed by Herrmann, et al.

Results: Median age at diagnosis was 54 years. Median tumor size at presentation was 2.7 cm and 54% had node-negative disease. A majority (70%) of patients had estrogen receptor positive tumors. Prevalence of hypertension was 43%, while hypercholesterolemia was found in 48%. Seventeen percent of patients had diabetes mellitus and 19% were obese. Only 2% were current smokers. Four percent of patients had pre-existing coronary heart disease, arrhythmias or valvular disease. Overall, 40% of patients presented with two or more major CVD risk factors (clustering). The clustering of CVD risk factors was substantial across all age groups; age < 40 years: 16%, 40-49 years: 24%, 50-64 years: 46%, > =65 years: 62%. The Malay and Indian patients were twice more likely to have CVD risk clustering than the Chinese. Of 1880 patients with non-metastatic breast cancer, 45% were planned for anthracycline-based chemotherapy, and 54% for adjuvant radiotherapy. Taking the adjuvant treatment plan into account, it appeared that approximately one in two women with breast cancer in our settings were at high risk of developing cardiotoxicity.

Conclusions: Our findings highlight the need to accelerate the establishment of coordinated partnerships between the oncology and cardiology specialties to improve cardiac outcomes following breast cancer. In the era of precision medicine, these findings also lend support to the notion that the next generation adjuvant therapy decision-making tools in breast cancer should incorporate data on major CVD risk factors.

1716P Cardiovascular and other competing causes of death among cancer patients, 2006-2015: An Australian population-based study

Y. Ye[1], P. Otahal[1], T. Marwick[2], K. Wills[1], A. Neil[1], A. Venn[1]

[1]Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia, [2]Baker Heart and Diabetes Institute, Baker Heart and Diabetes Institute, Melbourne, Australia

Background: Cardiovascular disease (CVD) is the leading cause of death worldwide. With improved cancer treatment and survivorship, CVD and other non-cancer events compete with cancer as the underlying cause of death. However, their mortality risk in competing risk settings is not well characterised.

Methods: We identified 21,637 individuals with a first cancer registered between January 2006 and December 2013 in the population-based Tasmanian Cancer Registry, Australia. Cumulative incidence functions were applied to assess the cumulative incidence of deaths due to specific competing events with follow-up to December 2015. Standardised mortality ratios (SMRs) and absolute excess risks (AERs) for non-cancer deaths were calculated to allow comparison with the general population.

Results: Overall, 8,844 deaths were observed with 1,946 (22.0%) from competing events (332 from subsequent cancer, 741 from CVD and 873 from other non-cancer events). The cumulative incidence of deaths due to CVD increased significantly with age at first cancer diagnosis (5-year cumulative mortality by age group: 15-64y – 0.7%; 65-74y – 2.1%; 75-84y – 6.0%; 85+y – 13.1%) and exceeded other competing events for those with a first cancer diagnosis at age 65 years or older. For the whole follow-up period, CVD deaths were as expected for the general population (SMR, 0.97; 95%CI 0.90-1.04), however within the first follow-up year, CVD deaths were more common than expected (SMR, 1.44; 95%CI 1.26-1.64; AER, 36.8/10,000 person-years). The SMR and AER for CVD deaths varied by first cancer sites showing an increased risk after a first diagnosis of lung cancer, haematological malignancies and urinary tract cancers. For other non-cancer events, the SMRs significantly increased for infectious disease and respiratory disease for the whole follow-up and within the first year of diagnosis.

Conclusions: CVD was the leading cause of competing mortality among Tasmanian cancer patients diagnosed from 2006-2013. The higher than expected risk of death due to CVD and other non-cancer events was greatest during the first year after cancer diagnosis highlighting the importance of early preventive interventions.

1717P Cancer associated thrombosis with primary prophylaxis in a tertiary hospital in the Philippines from 2010-2015

A.T.B. Gerona

Medical Oncology, St. Luke's Medical Center, Quezon City, Philippines

Background: Venous thromboembolism, consisting of pulmonary embolism or peripheral venous thrombosis is the second most common leading cause of death in cancer. Prophylactic measures are now being done to prevent its occurrence. In an financially-challenged patient does primary prophylaxis really protect our patients?

Methods: Data from the hospital's database for year 2010-2015 with either Venous Dupplex Scan or Computed Tomographic Pulmonary Angiography (CTPA). Each result were reviewed for presence of acute pulmonary embolism or acute venous thrombosis. Only the first event after the diagnosis of cancer was considered therefore, all subsequent events were ignored. Among those with positive venous thromboembolism results, review of chart and computerized data system on histologic diagnosis of carcinoma.

Results: A total of 10,380 CTPA/Venous duplex scan were performed for year 2010-2015, where 916 (8.8%) had positive venous thromboembolism (VTE). Of patients with VTE, 712(6.8%) were not associated with malignancy, 204(2%) had malignancy. Average age of patient 61.3(range 19-90), mostly female (61.7%) and had normal body mass index (62.2%). Most common symptom was swelling of the extremity(54%) followed by pain(32%) and dyspnea (12.6%). Lower extremity (77.4%) thrombosis was more common than upper extremity thrombosis (9.8%). Breast cancer (n = 37, 18.9%) had the most number of VTE, followed by lung (n = 31, 15%). Gynecologic malignancies had up to 21.5%, followed by gastrointestinal malignancies 21.5% (n = 44). Most patients had prior hospitalization (n = 146, 71.5%) within the past three months prior to the diagnosis of VTE. Up to 81.8% (n = 167) had no VTE prophylaxis while 9.8% (n = 20) had primary prophylaxis prior to the occurrence of VTE. However, among those who had prophylaxis with heparin, two had no prior hospitalization for three months prior to the VTE diagnosis, and mostly had gynecologic malignancy, breast cancer, and hepatocellular cancer. Seventy percent of them had normal BMI and were mostly <65 years of age.

Conclusions: Cancer patients still develop VTE even with primary prophylaxis and no hospitalization for the past three months which were the leading risk factors for developing VTE in prior studies. There is no difference in patient profile for those who received primary prophylaxis in our center compared to the general profile.

1718P The incidence of recurrent venous thromboembolism (VTE) and bleeding depending on practical treatment pattern of anticoagulation in the cancer patients with VTE

S-M. Bang[1], J-H. Kang[2], M.H. Hong[3], J.S. Ahn[4], S.Y. Oh[5], J.H. Baek[6], Y.J. Choi[7], S.H. Shin[8], Y-J. Kim[9], J-H. Cha[9], J. Lee[10]

[1]Hematology and Medical Oncology, Seoul National University Bundang Hospital, Seongnam, Republic of Korea, [2]Internal Medicine and Medical Oncology, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Republic of Korea, [3]Internal Medicine, Yonsei Cancer Center, Severance Hospital, Yonsei University College of Medicine, Seoul, Republic of Korea, [4]Hematology and Medical Oncology, Samsung Medical Center, Seoul, Republic of Korea, [5]Hematology and Medical Oncology, Pusan National University Yangsan Hospital, Yangsan, Republic of Korea, [6]Hematology and Medical Oncology, Ulsan University Hospital, Ulsan, Republic of Korea, [7]Hematology and Medical Oncology, Korea University Anam Hospital, Seoul, Republic of Korea, [8]Hematology and Medical Oncology, Kosin University Gospel Hospital, Busan, Republic of Korea, [9]Outcomes Research/Real World Data Team, Corporate Affairs and Health & Value Division, Pfizer Pharmaceuticals Korea Ltd., Seoul, Republic of Korea, [10]Biostatistics, Korea University College of Medicine, Seoul, Republic of Korea

Background: Even low molecular weight heparin (LMWH) for 3 to 6 months (Ms) is recommended for cancer-associated VTE, little has been known about practical treatment (Tx) pattern of anticoagulants and clinical outcome in Asia.

Methods: This retrospective cohort study was conducted from Oct 2016 to Jul 2017 at 8 university hospitals in Korea. Data was extracted from the medical chart of each individual hospital. Active cancer patients (pts), ≥19 years, with cancer-associated deep vein thrombosis or pulmonary embolism diagnosed from 2013 to 2015, and on anticoagulants, were enrolled and followed for 1 year. Demographic data will be published in abstract book of ISPOR 2018. Pts were classified by the form of anticoagulants; the group with LMWH Tx over 3 consecutive Ms allowing at most 14 days of temporary discontinuation and the non-LMWH group with other anticoagulants. The cumulative incidence of 1st recurrent VTE and bleeding for 1st 6 Ms of Tx was compared between LMWH and non-LMWH groups. LMWH group was further divided into ≤ 6 and > 6 Ms of Tx period. 3-group comparison was completed for the cumulative incidence of 1st recurrent VTE and bleeding from 6 to 12 Ms of Tx.

Results: Of total 748 pts (age: 63.8±11.5, male: 50.3%), the major cancer type was lung cancer (24.6%). 15.2% received LMWH over 3 Ms whereas 84.8% had various non-LMWH anticoagulants. The incidence of recurrent VTE was 17.5% in LMWH and 19.4% in non-LMWH. Bleeding events of LMWH and non-LMWH were 12.3% and 21.6%. Of the pts with bleeding, 28.6% in LMWH had major bleeding while 33.6% in non-LMWH. Up to 6 Ms after the 1st Tx, the cumulative incidence of first recurrent VTE in LMWH (8.4, CI: 3.09, 13.67) was lower than that of non-LMWH (9.7, CI: 7.33, 12.11) (p = 0.0048). Likewise, the cumulative incidence of 1st bleeding until 6 Ms was significantly lower in LMWH (8.9, CI: 3.28, 14.48) than non-LMWH (9.7, CI: 7.32, 12.02) (p = 0.0006). For following 6 Ms after 1st 6 Ms of Tx, the group with LMWH > 6 Ms (6.7, CI: 0.00, 19.29) had the lowest cumulative incidence of VTE recurrence among 3 groups (p = 0.0024).

Conclusions: Our data suggest that LMWH be used for 3 to 6 Ms and be maintained even afterwards to minimize the incidence of recurrence and bleeding in the cancer patients with VTE.

1719P Prevention and prophylaxis of thrombosis in cancer patients

N.G. Tsoukalas, P. Papakotoulas, A.N. Christopoulou, A. Ardavanis, G. Koumakis, C. Papandreou, G. Papatsimpas, P. Papakostas, C. Andreadis, G. Aravantinos, N. Ziras, H. Kalofonos, E. Samantas, M. Sougleri, P. Makrantonakis, G. Pentheroudakis, A. Athanasiadis, E. Bournakis, I.I. Varthalitis, I. Boukovinas

HeSMO - Hellenic Society of Medical Oncology, Athens, Greece

Background: Cancer Associated Thrombosis (CAT) is a significant problem in oncology that is underestimated sometimes. Venus ThomboEmbolism (VTE) is the 2nd cause of death in cancer patients. Currently, the standard of care not only for the treatment but also for the prophylaxis of CAT is the Low Molecular Weight Heparines (LMWHs). Thromboprophylaxis is an important medical decision for cancer patients in daily clinical practice.

Methods: This is an observational study conducted by HeSMO in Greek Oncology units, for 1 year, aiming to record CAT management. Patients with active cancer received antithrombotic agents for thromboprophylaxis were enrolled, after signing informed consent.

Results: All participating centers reported that approximately 4.300 cancer patients are managed on monthly basis, where the majority (80%) as outpatients. 426 cancer patients enrolled from 18 oncology units with mean age 65.2 years old and mean Body Mass Index (BMI) 26.10. Primary cancers were: lung 25%, pancreas 14%, stomach 8.6%, breast 8.6%, ovarian 7.7%, colorectal 7.5%, bladder 5.6% and other 22.8%. 50% of patients received LMWH at prophylactic doses while the rest received therapeutic doses [mean duration 4.42 months (SD +/- 2.68)]. 126 (30%) patients had Khorana score ≥3. 300 (70%) had Khorana score ≤2 and of these patients 68% were metastatic and 58% were receiving High Thrombotic Chemotherapy Agents (HTCA, e.g. platinum). 16 (3.8%) patients experienced VTE while 9 (56%) of them were incidental. Lower VTE risk [OR: 0.32 (95% CI 0.10, 1.0) p = 0.04] was observed in patients on therapeutic doses LMWH while higher VTE risk [OR: 3.14 (1.01, 9.9)] was observed in patients on prophylactic doses LMWH. High BMI>35 was related to significant higher risk for VTE [OR 5.37 (1.6, 18). Only six (1.4%) grade 1 bleedings were recorded in all patients who receive thromboprophylaxis.

Conclusions: CAT is an important problem in oncology. Therapeutic doses of LMWH for thromboprophylaxis are effective and safe. Apart from Khorana score, some other factors such as disease stage and administration of HTCA might be taken into consideration for better CAT risk assessment in oncology patients.

1720P Is it appropriate to use a fixed prophylactic dose of enoxaparin for hospitalized cancer patients? Results from a prospective tertiary referral single center study

C. Maurice-Dror[1], M. Litvak[1], A. Keren[2], S. Akerman[2], B. Brenner[2], N. Haim[1], Y. Nadir[2]

[1]Oncology, Rambam Health Care Center, Haifa, Israel, [2]Hematology, Rambam Health Care Center, Haifa, Israel

Background: Thromboprophylaxis with low molecular weight heparin (LMWH) is recommended in hospitalized cancer patients with reduced mobility and/or other risk factors for venous thromboembolism. An unresolved issue is whether the commonly used LMWH, enoxaparin should be given in a fixed dose for thromboprophylaxis or adjusted to weight. The aim of this study was to examine whether hospitalized cancer patients, treated with a fixed dose of enoxaparin (40 mg/day) reach appropriate target level of anti-Xa, and whether anti-Xa level in these patients is correlated to body size, gender, and blood creatinine level.

Methods: Between Oct 2015 to June 2017 hospitalized cancer patients with indication for thromboprophylaxis and without contraindication for SC enoxaparin (40 mg/day) were entered into the study. Prior to the initiation of enoxaparin, patients were weighed and measured and blood samples were collected for PT/PTT, CBC and Creatinine. Blood samples for peak anti Xa level were collected at 48-120 hrs post initiation of enoxaparin (3 hrs after injection). Target anti-Xa was defined as 0.2-0.5 U/ml.

Results: Eighty patients were enrolled (male/female: 46/34; age: 25-84, median 66yrs). 72 patients met inclusion criteria and had full data for analysis. The most common indication for prophylactic enoxaparin treatment was ECOG performance status 3-4 (82%). Median anti Xa level was 0.255 U/ml (range 0.01-0.77). Anti Xa levels were within target range in 40 patients (55.6%), below target in 26 patients (36.1%) and above target in 6 patients (8.3%). Anti Xa was higher in females (median 0.3 vs. 0.19 U/ml; $p < 0.001$) and correlated positively with serum creatinine ($p = 0.003$), and negatively with body weight ($p < 0.001$). Optimal threshold weight for predicting sub-therapeutic levels of anti Xa was identified at 78kg (sensitivity 43%, specificity 85%).

Conclusions: Using a policy of fixed dose enoxaparin resulted in under-treatment in more than one-third of a non-selective population of cancer patients, mainly in those whose weight was above 78kg. We suggest that prophylactic dosage of enoxaparin higher than 40 mg should be considered for patients with body weight above 80 kg.

1721P Long-term prognosis of acute pulmonary embolism: A focus on idiopathic and neoplastic etiologies

I.M.C. Guerreiro[1], H. Magalhães[1], S. Coelho[1], A.M. Ribeiro[2], S. Ferreira[2], E. Araújo[2], M. Fontes-Sousa[1], P. Bettencourt[3], P. Lourenço[2]

[1]Department of Medical Oncology, Portuguese Oncology Institute of Porto (IPO-Porto), Porto, Portugal, [2]Department of Internal Medicine, Hospital Centre of São João, Porto, Portugal, [3]Department of Internal Medicine, CUF Hospital Centre Porto, Porto, Portugal

Background: Acute pulmonary embolism (PE) is a fatal condition when untreated. Long term prognosis of acute PE in the 21st century has not been fully reported. We aimed to determine the long-term prognosis of acute PE and assess if there were survival differences between patients with idiopathic and secondary PE.

Methods: We retrospectively analysed a cohort of patients hospitalized with acute PE between 2006 and 2013. Excluded: 1) <18 years old, 2) embolism of non-pulmonary veins and 3) chronic pulmonary embolism. The vital status was ascertained by consulting the National Registry of Portuguese Patients platform. Patients were grouped according to acute PE aetiology: idiopathic, secondary to a neoplastic condition and secondary to conditions other than a neoplasia. A Cox-regression analysis was used to study the prognostic implications of PE aetiology. Multivariate models were built.

Results: A total of 872 patients with acute PE were admitted, median age: 70 years old, 496 (56.9%) were female. In 36.8% the PE was of central arteries and in 56.9% bilateral. PE was considered idiopathic in 376 (43.1%), secondary to a neoplastic condition in 284 (32.6%) and secondary to a condition other than neoplasia in 212 (24.3%). Patients were followed for a median period of 25 months and 508 (58.3%) patients died. Patients with acute PE attributed to a neoplastic condition had the worst survival and those with PE secondary to a non-neoplastic condition the best survival. Patients with idiopathic PE had a multivariate adjusted HR of mortality of 1.46 (1.08-1.99) during the over 2-year follow-up period when compared to those with acute PE secondary to a non-neoplastic condition.

Conclusions: Acute PE attributed to a neoplasia portended the worst prognosis. Patients with idiopathic PE had 46% higher risk of death than those with PE secondary to a non-neoplastic condition. Idiopathic PE should probably be looked at more carefully by physicians treating acute PE patients.

1722P Systematic literature review and network meta-analysis of oral anticoagulants for the treatment of venous thromboembolism in patients with cancer

H. Park, J-C. Kim, J. Cho, J.H. Lim, M.H. Lee

Hemato-Oncology, Inha University Hospital, Incheon, Republic of Korea

Background: Based on the current guideline, treatment options for cancer-associated thrombosis include low molecular weight heparin (LMWH), unfractionated heparin (UFH), warfarin, and fondaparinux. However, in patients who do not have cancer, direct oral anticoagulants are preferred for the treatment of VTE. In some cases, the use of LMWH is limited due to administration by the subcutaneous route. In this study, we compared the efficacy and safety of oral anticoagulants including vitamin K antagonists (VKA) and direct-acting oral anticoagulants (DOAC) for the treatment of cancer-associated VTE.

Methods: We conducted a systematic literature review to identify all eligible randomized controlled trials (RCT) by searching PubMed, Web of Science, ASH, ASCO, EHA, and ESMO databases. The relative risks (RR) of recurrent VTE (efficacy) and major bleeding (safety) were analyzed using Bayesian network meta-analysis with a fixed-effect model.

Results: Four DOACs (apixaban, dabigatran, edoxaban, rivaroxaban) were identified in five RCTs. When comparing the efficacy between VKA and DOACs, the recurrence rate of VTE was lower in the treatment with DOACs than with VKA, but not statistically significant. (apixaban: odds ratio [OR] 0.55, 95% credible intervals [CrI] 0.10-2.4; dabigatran: OR 0.76, 95% CrI 0.32-1.8; edoxaban: OR 0.49, 95% CrI 0.12-1.7; rivaroxaban OR 0.57, 95% CrI 0.19-1.7). In safety, the risk of major bleeding was relatively low in the use of DOACs compared to VKA, except for edoxaban (apixaban: OR 0.42, 95% CrI 0.058-2.2; dabigatran: OR 0.82, 95% CrI 0.25-2.7; edoxaban: OR 1.6, 95% CrI 0.38-8.4; rivaroxaban OR 0.47, 95% CrI 0.14-1.5).

Conclusions: For the treatment of VTE in cancer patients, DOAC has a favorable tendency for the efficacy and safety compared to VKA. DOACs could be one of the standard treatment options for management of VTE in cancer patients. Among DOACs, epixaban has a relatively good outcome.

1723P Comparison of venous thromboembolism risk assessment models in patients receiving chemotherapy

K. Talasiewicz, P. Ozdowska, B. Milanowska, K. Gepner, B. Jagielska

Department of Oncology Diagnostics, Cardioncology and Palliative Medicine, Maria Sklodowska Curie Memorial Cancer Centre and Institute of Oncology (MCMCC), Warsaw, Poland

Background: Venous thromboembolic events (VTEs) remain one of the most common causes of morbidity and mortality in cancer patients. Various risk scores were developed to help oncologists in the decision-makingprocess relating to VTE in this challenging group of patients.

Methods: We retrospectively analyzed a group of 124 cancer patients diagnosed with VTE between September 2012 and June 2017 in M.Sklodowska-Curie Memorial Cancer Center and Institute, Warsaw, Poland and selected patients receiving chemotherapy ($n = 72$). We compared the patients KHORANA, PROTECHT and CONKO scores in order to determine which of them would be more precise in terms of VTE prediction during chemotherapy. Statistical analysis was made using descriptive statistics, differences between scales were tested using chi-squared test applying Bonferroni correction.

Results: VTE's were observed mainly during chemotherapy treatment (n = 72, 58.1%). VTE's occurred significantly more frequently in patients who received Cisplatin- or Gemcitabine- basedchemotherapy ($p < 0,05$). In 27 (21.8%) cases VTE was the first manifestation of the disease and/or appeared during the diagnostic process. Most of the patients (69,64% - 88,89% depending of the scale) were classified as having low/intermediate risk, without the potential need for thromboprohylaxis use. The PROTECHT score was the best indicator to discriminate between patients with high or low/intermediate risk, followed by the CONKO score and finally by the KHORANA score. The PROTECHT score more often assigned patients to the "high-risk group" and this difference was statistically significant comparing with the KHORANA score, p = 0,016 (Table).

Table: 1723P

Risk	KHORANA		PROTECHT		CONKO	
	N	%	N	%	N	%
Low	21	29,17%	17	23,61%	26	36,11%
Intermediate	43	59,72%	33	45,83%	34	47,22%
High	8	11,11%	22	30,56%	12	16,67%
chi^2	10,99					
df	4					
p	0,0267					
	KHORANA vs. PROTECHT		KHORANA vs. CONKO		PROTECHT vs. CONKO	
chi^2	8,27		2,38		4,84	
df	2		2		2	
p	0,0160		0,3036		0,0889	
Bonferroni	0,0480		0,9108		0,2667	

Conclusions: The PROTECHT score discriminated better between low- and high-risk patients and appeared to have the highest sensitivity. The implementation of VTE prophylaxis in patients assessed as high-risk patients, according to the PROTECHT score, could potentially prevent the largest amount of VTEs.

1724P Personalised nutritional care during chemotherapy using survey on taste changes during chemotherapy: First experience from tertiary chemotherapy day care center in Northern India

A. Vora[1], S. Chatterjee[1], A. Upadhyay[1], N. Hazarika[1], G.S. Bhattacharya[2]

[1]Medical Oncology, H.O.P.E. Oncology Clinic, New Delhi, India, [2]Medical Oncology, Fortis Hospital, Kolkata, India

Background: Personalised care is the current practice of treating cancer patients. Taste changes during chemotherapy also should be personalised depending on changes observed during chemotherapy. We attempted the same using a survey in each patient of chemotherapy at our center. This is first of its kind from india to the best of our knowledge.

Methods: Every patient coming for chemotherapy at our center was given one page survey along with consent form. Survey included: specifying taste changes for sweet, salt, bitter, sour and humami. Taste of water was included. Based on survey findings, nutrition advice was given to patient. Feedback from patient also was taken about food items they like, religious belief and any other preferences. Weight loss and albumin level was checked during each chemotherapy.

Results: Total 71 patients participated in the study. 24 makes and 47 females. Age range: 13 to 77. Diagnosis: breast: 17; ovary:14; GI:19;hematological:6; head neck:5; lung:4; CNS:3; sarcoma:3. All patients completed at least 2 cycles of chemotherapy (range: 2 -16). Survey of taste changes: except 1, all other 70 patients preserved sweet taste during chemotherapy. Highest change was in salt: 59% (42/71) followed by bitter 22%. Surprisingly, 24% reported water to be tasteless. Intervention: with the help of endocrinologist; all patients were advices to take fresh fruits and sweets. Salt and bittertaste was overcome by use of sour (lemon pickle etc). In fact, majority of patients loved addition of sour food items. Coconut water, lemon flavoured water were easily consumed in patients with water taste problems. Except 5 patients, all patients preserved weight n albumin.

Conclusions: This is first experience of personalised nutrition care in cancer patients with chemotherapy. Patients really enjoyed eating to their taste and thus were happy and were able to retain their weight n albumin. We are continuing this study with help of taste bud strips and professional nutritionists.

1725P Role of megestrol acetate versus dexamethasone for improvement in appetite in patients with cancer associated anorexia cachexia: A randomized controlled pilot trial

S.P. Ostwal[1], N.S. Salins[2], J.K. Deodhar[2], M. Maryann[2]

[1]Palliative Medicine, Gujarat Cancer and Research Institute, Ahmadabad, India, [2]Palliative Medicine, Tata Memorial Hospital, Mumbai, India

Background: Loss of appetite, also known as anorexia, is a frequent and distressing symptom in patients with advanced cancer and other life-limiting illnesses. Prolonged periods of anorexia, can lead to both serious physical and psychological distress to patients and their families, which ultimately can contribute to a poorer quality of life. This study compare the clinical benefits between Dexamethasone and Megestrol acetate in an Indian setting, its positive impact on appetite, QOL, and lean body mass.

Methods: A prospective, randomized controlled pilot study conducted in outpatient clinic of Palliative Medicine from September to December 2015. Registered adult advanced cancer patients meeting the inclusion criteria and exclusion criteria were assessed for anorexia, measured by ESAS scale, lean body weight (by Hume's Formula) and QOL (EORTC-QOL PAL15). Patients received either Dexamethasone (4mg) or MA (160mg in divided doses) for 21 days. No associated appetite stimulants or multivitamins were prescribed to study patients. All patients were encouraged to eat normal diet and provided standard medical care. Follow up done at days 7, 21 and 35.

Results: Total 40 patients were enrolled in the study. Patients in both groups showed statistically significant improvement in appetite, lean body weight and quality of life at weeks 3 and 5, compared to baseline. However, study failed to show any significant difference for primary (appetite improvement) and secondary (lean body weight and quality of life) objectives between two groups, at weeks 3 and 5. Dexamethasone was found to be associated with more side effects.

Conclusions: Comparison between Megestrol acetate and dexamethasone failed to show any statistical significant difference in improvement of anorexia, lean body weight and quality of life. Both drugs individually improved the same, as compared to baseline. Improvement in fatigue and other symptom scores were seen to be statistically significant in megestrol acetate arm. There is no significant difference in side effect profiles of both dexamethasone and megestrol acetate arms except for difficulty in standing from sitting position and nausea and vomiting.

Clinical trial identification: CTRI: REF/2015/10/009871.

1726P Population pharmacokinetics (PPK) of anamorelin (ANAM), an oral selective ghrelin receptor agonist

A. Bernareggi[1], S. Kaasa[2], M. Fallon[3], R.J.E. Skipworth[4], D. Currow[5]

[1]Helsinn Healthcare SA, Lugano, Switzerland, [2]Department of Oncology, Oslo University Hospital and University of Oslo, Oslo, Norway, [3]Institute of Genetics and Molecular Medicine, University of Edinburgh, Edinburgh, UK, [4]Clinical Surgery, University of Edinburgh, Edinburgh, UK, [5]ImPACCT – Improving Palliative, Aged and Chronic Care through Clinical Research and Translation, Faculty of Health, University of Technology Sydney, Sydney, Australia

Background: ANAM, in advanced clinical development, showed benefits in cachectic patients with advanced non-small cell lung cancer (NSCLC). Typical values (TV) of ANAM PPK parameters, effects of demographic and physiopathologic covariates on PK parameters and their variability, and individual ANAM steady-state PK profiles in patients were assessed by PPK modeling.

Methods: Cachectic (body mass index $<20\ kg/m^2$ or $\geq 5\%$ weight loss in prior 6 months) NSCLC patients (ROMANA 1 [NCT01387269; N = 477]) were randomized 2:1 to 100 mg once daily oral ANAM/placebo up to 12 weeks. Sparse blood samples were collected (day 43, 0.5–6 h post-treatment) in 70 patients consenting to the PK analysis. For modeling purposes, patients' PK dataset was enriched with PK profiles from phase 1 (healthy subjects) and phase 2 studies. The PPK analysis included 243 PK profiles, 70 of which were from ROMANA 1. Non-linear mixed effect modeling with first-order conditional estimation with interaction was used for the PPK analysis. Correlations between ANAM PK parameters and continuous or categorical covariates were assessed by Spearman's correlation coefficient or analysis of variance models, respectively. Individual steady-state ANAM PK profiles in the 70 patients were simulated by post-hoc empirical Bayes estimates of ANAM PK parameters, and used to assess ANAM exposure and elimination.

Results: The final model selected was a two-compartment model with first-order absorption and lag time, and no covariates as fixed effects. Patient vs healthy subject status was considered to cause no significant difference. TV of PPK parameters for absorption rate constant ($5.39\ h^{-1}$), lag time (0.24 h), volume of central (135 L) and peripheral (67.8 L) compartments, systemic clearance (CL/F, 49.5 L/h), and

inter-compartmental clearance (8.8 L/h) were characterized by low relative standard errors (1.6%–15.9%). In patients, predicted ANAM peak plasma concentration, exposure ($AUC_{0–24}$), and CL/F averaged 675 ng/mL, 2775 ng·h/mL, and 46.1 L/h, respectively.

Conclusions: The final PPK model described ANAM's PK profile in healthy subjects and patients, and is suitable for predicting ANAM exposure in various clinical settings.

Clinical trial identification: NCT01387269.

1727P Health care providers' experiences of positive and negative effects of parenteral nutrition therapy in cancer patients

K. Sand[1], L. Thoresen[2], T.S. Solheim[1], R.G. Helgås[1], E.T. Løhre[1], T.R. Balstad[1]

[1]Department of Clinical and Molecular Medicine and Cancer Clinic, Norwegian University of Science and Technology and St. Olavs Hospital, Trondheim University Hospital, Trondheim, Norway, [2]Cancer Clinic, St. Olavs Hospital, Trondheim University Hospital, Trondheim, Norway

Background: As of today, health care providerś (HCP) have little evidence in research to guide decisions for parenteral nutrition (PN) therapy in cancer patients. Uncertainties prevail concerning both the initiation and the duration of the treatment, as well as the benefits of the intervention. The aim of this study was to explore community HCP's experiences of benefits and challenges with PN in cancer patients.

Methods: An 18-item online survey was emailed to 309 community care HCP. In two of the questions, respondents were asked to describe in free text their positive and negative experiences with PN therapy in cancer patients, and these answers were analysed by use of content analysis.

Results: Out of total 135 responses, 102 (75.6%) reported experience with cancer patients receiving PN and completed the entire survey. The majority of the respondents were female (93%); nurses/cancer nurses (86.4%); and worked in home care (48.5%) or nursing homes (37.9%). The most common positive effect of PN reported was an impression that it increased patients' quality of life through increased vitality, increased hope and the ability to spend time at home (reported by 40.2%). Other reported positive effects were the experience that PN improved tolerance to, and enhanced recovery after, cancer treatment; reduced the family's eating-related distress; and was regarded a good treatment alternative for patients with symptoms such as swallowing problems, nausea or obstruction. The most common negative effect reported was the difficulties of knowing when to terminate PN, primarily because this removes patients' and family's hope (reported by 26.4%). Poor information to patients and their family at initiation of PN, made termination even more difficult. PN therapy was also reported to cause side effects such as fluid retention and oedema and prolong suffering at end of life.

Conclusions: Despite a limited evidence-base in support of benefits of PN treatment in cancer patients, HCP in this study reported several positive effects based on their clinical experience. Some of the positive effects were related to earlier phases of the disease, while the negative effects mainly regarded communication and decision challenges when ending PN therapy at the end of life.

1728P Assessment of anorexia and weight loss in newly diagnosed upper gastrointestinal cancer patients with localised and metastatic disease, using the functional assessment of anorexia cachexia therapy anorexia/cachexia subscale (FAACT A/CS)

M. Abraham[1], Z. Kordatou[2], W. Mansoor[3]

[1]Nutrition & Dietetics, The Christie NHS Foundation Trust, Manchester, UK, [2]Medical Oncology, Bank of Cyprus Oncology Center, Nicosia, Cyprus, [3]Medical Oncology, The Christie NHS Foundation Trust, Manchester, UK

Background: Anorexia often predisposes to weight loss, leading to poor outcomes in cancer patients. Therefore early recognition is clinically important. Although no gold standard exists to diagnose anorexia, the FAACT A/CS has been suggested to identify cancer patients with anorexia. A previous study has validated the cut-off score of ≤ 37 to diagnose anorexia. In our study we assessed the incidence of anorexia and weight loss in patients with gastric and gastro-oesophageal junction (GOJ) cancer based on the FAACT A/CS.

Methods: Newly diagnosed gastric and GOJ adenocarcinoma patients of all stages, attending outpatient clinics at The Christie Hospital NHS Foundation Trust, from September 2016 to December 2017 completed the FAACT A/CS at initial consultation. BMI and weight change over the last 3-6 months were recorded as standard of care. SPSS was used for statistical analysis.

Results: Based on the FAACT A/CS questionnaire, 127 (69%) out of the 182 patients included in this analysis had anorexia. The mean anorexia score of all the patients was 29.5 (4-48). The incidence of anorexia was greater in metastatic compared to non-metastatic patients (82% vs 52%: $p < 0.01$). Overall, the metastatic group achieved lower mean anorexia scores than the non-metastatic group (25.9 vs. 34.7, $p < 0.01$). Patients in the metastatic group had lower mean body weight compared to those in the non-metastatic group (74 vs 79 kg, $p = 0.069$). Their mean BMI was also lower (25 vs 27, $p = 0.05$). 76% of the metastatic group and 33% of the non-metastatic group had $\geq$5% of weight loss that may classify them as high risk for cancer cachexia, despite their normal or high BMI ($p < 0.01$).

Conclusions: 69% of the patients with gastric/GOJ cancer who attended clinic were anorexic on initial consultation. The incidence of anorexia was higher in patients with metastatic disease (82%). Assessment of anorexia using the FAACT A/CS along with classification of weight loss prior to treatment should be integrated into nutritional assessment. BMI used independently may be unsuitable for identifying patients at nutritional risk.

1729P Body composition factor is independent prognosticator in advanced pancreatic cancer patients

S. Kang[1], H.S. Park[2], H-C. Jeung[1]

[1]Internal Medicine, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Republic of Korea, [2]Internal Medicine, St. Vincent Hospital, Suwon, Republic of Korea

Background: The purpose of this study is to evaluate the body composition including skeletal muscle and fat component as a prognostic factor in advanced pancreatic cancer patients.

Methods: Body composition factor comprised skeletal muscle index (SMI), muscle Hounsfield Unit (HU), subcutaneous fat index (SFI), and visceral fat index (VFI), which were measured at L3 level in abdomino-pelvic computed tomography (CT). region was quantified using the pre-established HU thresholds for skeletal muscle tissue (HU: -30∼150). Visceral fat and subcutaneous fat areas (HU:-150∼-30) were also measured. Continuous variables were dichotomized according to the normal range or the best cut-off values by Contal and O'Quigley method. Kaplan-Meier analysis was applied for relevance between each body composition factor and overall survival (OS).

Results: A total of 414 patients was enrolled. Median age was 66 years old with male predominance (49.8%). Median baseline values were 38.7 cm^2/m^2 for SMI, 33.4 HU, 32.2 cm^2/m^2 for SFI, and 30.1 cm^2/m^2 for VFI. Patients with lower value of the body composition factor has poorer survival (median OS; SMI, 6.9 vs. 10.0 months, $P < 0.001$; HU, 7.6 vs. 9.3 months, $P = 0.0004$; SFI, 6.6 vs. 9.8 months, $P = 0.0008$; VFI, 6.6 vs. 9.8 months, $P = 0.0008$). A body composition risk score was devised by summing the number of lower value of body composition factors, and patients were divided into two groups (low risk = score 0∼1, high risk = score$\geq$2). Patients with high risk score had shorter OS (6.4 vs. 11.5 months). In multivariate analysis, age, ECOG performance status, WBC, neutrophil-lymphocyte ratio (NLR), carcinoembryonic antigen (CEA) at initial presentation was significant. In addition, body composition risk score was independent prognostic factors (hazard ratio, HR 1.56, 95% confidence interval 1.24-1.95, $P < 0.001$).

Conclusions: The body composition risk score significantly predicted prognosis in patients of pancreatic cancer. CT data are readily obtainable during routine clinical practice, which makes this approach useful for identifying prognostic biomarkers.

1730P Current use of clinical nutrition in oncology patients: Real world evidence from big data in Italy

F. Di Costanzo[1], R. Caccialanza[2], A. Santoro[3], C. Gavazzi[4], P. Pedrazzoli[5]

[1]SOD Medical Oncology, AOU Careggi, Florence, Italy, [2]Clinical Nutrition and Dietetics Unit, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy, [3]Department of Medical Oncology and Hematology, Istituto Clinico Humanitas, Rozzano, Italy, [4]Clinical Nutrition Unit, IRCCS Istituto Nationale die Tumori, Milan, Italy, [5]Division of Medical Oncology, Department of Hemato-Oncology Fondazione IRCCS, Policlinico San Matteo, Pavia, Italy

Background: In cancer patients, research indicates that approximately half of selected patients may suffer from malnutrition. Insufficient nutritional intake, muscle protein depletion and systemic inflammation are key clinical problems. Little is known about the current use of clinical nutrition (CN) in the real world. We set out to investigate the use of CN in patients with metastasized cancer in Italy.

Methods: This observational, retrospective study used an integrated administrative database from 10 Italian Local Health Units covering 5.9 million people. Between 2009 and 2015, CN use, based on Anatomical Therapeutic Chemical Classification codes and ICD-9-CM procedural codes for Enteral/Parenteral Infusion of Concentrated Nutritional Substances and at home nutritional product prescription was examined in patients with metastatic head and neck, gastrointestinal, respiratory, genitourinary or hematologic malignancies (ICD-9-CM diagnosis).

Results: Out of 58,468 metastatic cancer patients with the diagnoses of interest, only 8.2% received clinical nutrition (89% had parenteral nutrition (PN)). Only 4.9% of patients who received CN had concomitant chemotherapy. Among those who received CN, only 11% of patients were diagnosed with malnutrition. The mean time between the diagnosis of metastasis and first use of CN and between the first use of CN and death were 6.6 and 3.5 months, respectively. About half of the patients commenced CN therapy in their last 20 days. Receiving PN was associated with a statistically significant improvement in survival of over 3 months in patients with gastrointestinal and genito-urinary cancer who were diagnosed with malnutrition.

Conclusions: CN is under-utilized among cancer patients with metastasis and there is a discrepancy between malnutrition diagnosis rates and uptake of clinical nutrition, which appears to have been used mainly as an end of life measure. Overall, our big data highlights an important unmet need and potential for improved procedures for malnutrition diagnosis and earlier nutritional care, which may improve outcomes of cancer patients.

1731P Nutritional cancer care: Slowly evolving clinical practice reveals regional and professional HCP variability

F. Strasser[1], J. Arends[2], A. Laviano[3], A. O'Callaghan[4], R.A. Audisio[5], M.B. Sawyer[6], S. Kaasa[7]

[1]Clinic for Oncology/Hematology, Kantonsspital St. Gallen, St. Gallen, Switzerland, [2]Department of Medicine, Universitätsklinikum Freiburg Klinik für Innere Medizin Hämatologie, Onkologie und Stammzelltransplantation, Freiburg, Germany, [3]Clinical Medicine, Sapienza University, Rome, Italy, [4]Global Medical Affairs, Nutricia Advanced Medical Nutrition, Schiphol Airport, Netherlands, [5]Department of Surgery, Institute of Clinical Sciences, Sahlgrenska University Hospital, Göteborg, Sweden, [6]Medical Oncology, University of Alberta Cross Cancer Institute, Edmonton, AB, Canada, [7]Department of Oncology, Oslo University Hospital, Oslo, Norway

Background: Cancer-related weight loss correlates with poor anticancer treatment (Tx) outcomes and reduced quality of life (QoL). A survey at ESMO 2016 suggested that integration of nutritional care in clinical practice is inadequate. Outcomes of a follow-up survey conducted at ESMO 2017 are reported.

Methods: ESMO 2017 delegates visiting the Nutricia booth took part in the survey. The 2017 survey questions were identical to 2016, except 1 new question: "What source helps to determine patient need for nutritional support?"

Results: The 1,894 participants (75% medical oncologists; 64% European) demonstrated consistent overall practice patterns (malnutrition screening and assessment methods, eligibility criteria for nutritional support, goals of nutritional treatment, multimodal management) between 2016–2017. Unfortunately, >40% of HCPs still underestimate the impact of malnutrition on anticancer Tx continuity or toxicity, and QoL or function. Timely and individual tailored dietary advice to minimize/avoid weight loss increased significantly (36% to 49%; P <.001), surpassing medications, but only in Western countries (53%). Further geographic differences were seen. For example, in Africa (n = 183) compared with Europe (n = 1,215), nutritional aspects were more often considered in tumor boards (70%, 54%), but physical exercise programs were less often combined with nutrition (29%, 42%); perceived impact of malnutrition was more about anticancer treatment discontinuation (67%, 28%) than toxicities (44%, 62%); and meetings (42%, 33%) surpass guidelines (44%, 73%) for nutritional decision-making. Concerning HCP specialty, nutritionists (n = 20) estimated the impact of malnutrition 50% less than medical oncologists, and consulted guidelines less (26%, 60%). Surgeons (n = 64) and radiation oncologists (n = 65) judged eligibility for nutritional support and its goals differently than medical oncologists, with less emphasis on weight loss and QoL.

Conclusions: HCP recognition of the impacts of malnutrition and its assessment remains insufficient, while dietary advice is increasing. Our survey data may suggest tailoring nutritional care recommendations at regional and HCP levels.

1732P Unidentified cachexia patients in the oncologic setting: Cachexia UFO's do exist

E. De Waele[1], J. Demol[1], R. Caccialanza[2], P. Cotogni[3], H. Spapen[1], M. Malbrain[1], J. De Grève[4], J.J. Pen[5]

[1]Intensive Care, UZ Brussel, Brussels, Belgium, [2]Clinical Nutrition and Dietetics Unit, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy, [3]Pain Management and Palliative Care, Department of Anesthesia and Intensive Care, S. Giovanni Battista Hospital, University of Turin, Turin, Italy, [4]Medical Oncology, UZ Brussel, Brussels, Belgium, [5]Diabetes Clinic, UZ Brussel, Brussels, Belgium

Background: Cachexia is an important outcome-modulating parameter in cancer patients. In the context of a randomized controlled trial on cachexia and nutritional therapy, the TiCaCONCO trial (NCT03058107 on Clinicaltrials.gov), the contacts between cancer patients and health care practitioners/oncologists were screened. The aim of this retrospective study is to identify in the charts the input of data on body weight (necessary to identify cachexia stage), relevant nutritional data and nutritional interventions triggered or implemented by oncologists and dieticians.

Methods: In a tertiary, university oncology setting, over a time span of 8 months (34 weeks), the charts of patients admitted to an oncology, gastroenterology or abdominal surgery unit were screened for the presence of information contributing to a cancer cachexia diagnosis. Data (patient characteristics, tumor type and location) was gathered.

Results: We analyzed 9694 files. In > 90% of patients, data on body weight was present. 118 new diagnoses of cancer were present in 9694 screenings (1.22% of patient contacts). Information on weight evolution or nutritional status was absent in 46% of cases. In contacts between oncologists and cancer patients, at the time of diagnosis, the prevalence of cachexia was 42%. In 14% of these patients, no nutritional information was present in the notes. In those 50 patients with cachexia, a nutritional intervention was initiated by the physician in 8 patients (16%). Nutritional interventions were documented in the medical note in 9% of the overall study population. Dieticians made notes regarding nutrition and weight in 42% of patients.

Conclusions: Newly diagnosed cancer patients are not systematically identified as being cachectic and if they are interventions in the field of nutrition therapy are largely lacking. Important barriers exist between Oncologists and Nutritionists, the former being mandatory to the success of a nutrition trial in cancer.

Clinical trial identification: NCT03058107.

1733P The effect of sarcopenia on acute chemotherapy toxicity in gastrointestinal cancer patients undergoing systemic therapy

N. Ozdemir[1], O. Yazici[2], K. Silay[3], G. Ucar[4], T. Eren[4], D. sener dede[1], M.A.N. Sendur[1], M.B. Akinci[1], A. Baykal[4], B. Yalcin[1], N. Zengin[1]

[1]Department of Medical Oncology, Ankara Yildirim Beyazıt University Faculty of Medicine, Ankara, Turkey, [2]Medical Oncology, Gazi University, Ankara, Turkey, [3]Department of Geriatrics, Ankara Yildirim Beyazıt University Faculty of Medicine, Ankara, Turkey, [4]Medical Oncology, Ankara Numune Education and Research Hospital, Ankara, Turkey

Background: We aimed to evaluate the effect of sarcopenia on tolerability of chemotherapy during systemic treatment of pts with gastrointestinal system cancer (GISC).

Methods: Patients with GISC who had not previously received chemotherapy or radiotherapy were included. All of the pts muscle mass was evaluated by bioimpedance prior to the first cycle of chemotherapy, and pts who had normal muscle mass according to first bioimpedance evaluation were re-evaluated after 2-3 cycles of chemotherapy. The acute toxicities were compared in sarcopenic and non-sarcopenic pts. To define the sarcopenia results of a Turkish validation study was used (sarcopenia for male $<9.2\ kg/m^2$, female: $7.4\ kg/m^2$).

Results: A total 116 pts who had nosarcopenia in the first evaluation were included in the study population. Median age was 57 (min:26-max:76) and 2/3 of them were male (67.6%). Primary tumor locations were colorectal (51.8%), gastric (44.1%), esophagus (4.1%). Chemotherapy was given as adjuvant (46.9%), neoadjuvant (22.1%) and palliative (31%). In the second bioimpedance evaluation sarcopenia was detected in 36 (31%) pts. Basal body-mass index (BMI) evaluation of pts showed that rate of obese and overweight pts was significantly lower in sarcopenic pts compared to non-sarcopenic pts (44.4% vs 68.8%, $p < 0.05$). At the time of thesecond bioimpedance measurement, there was no significant difference between BMI of sarcopenic and non-sarcopenic pts. The rate of chemotherapy toxicities of the sarcopenic and non-sarcopenic group is shown in the table:

Table: 1733P

Toxicity	Sarcopenic (n = 36) %	Non-sarcopenic (n = 80) %	p
Thrombocytopenia Yes, No	33.3, 66.7	58.8, 41.3	0.011
Neutropenia Yes, No	55.6, 44.4	72.5, 27.5	0.073
Anemia Yes, No	63.9, 36.1	67.2, 32.9	0.73
Delay of chemotherapy Yes, No	27.8, 72.2	43.0, 57.0	0.11
Dose reduction Yes, No	28.4, 71.4	37.5, 62.5	0.35

Conclusions: In GISC pts non-sarcopenic at time of diagnosis, BMI remains unchanged after 2-3 cycles of chemotherapy. However, muscle loss had developed in 1/3 of them. Pts who developed sarcopenia had lower rates of chemotherapy-associated toxicity. The reasons for this difference should be further investigated. However, the different lipophilic and hydrophilic properties of chemotherapy agents might be one of possible explanation.

1734P Early detection of skeletal muscle atrophy using a multiple plasma-free amino acid index in the advanced aged patients with advanced pancreatic cancer

S. Mitsunaga[1], M. Takada[2], S. Nishikawa[2], A. Imaizumi[2], M. Ishii[2], M. Ikeda[3]

[1]Hepatobiliary and Pancreatic Oncology, National Cancer Center Hospital East, Kashiwa, Japan, [2]Institute for Innovation, Ajinomoto Co., Inc., Kawasaki, Japan, [3]Hepatobiliary and Pancreatic Oncology, National Cancer Center Hospital East, Kashiwa, Chiba, Japan

Background: Loss of skeletal muscle mass (SMM) is related to aging, pancreatic cancer (PCa) and the deterioration of symptoms and quality of life (QOL). This study aimed to identify the factors associated with SMM atrophy in PCa patients during first-line chemotherapy. At the end of our study, the biomarker of early detection of SMM atrophy was established using a multivariate index composed of plasma free amino acid (PFAA) levels.

Methods: Patients with treatment-naïve advanced PCa were enrolled. The whole body skeletal muscle index (wSMI) and symptoms were measured at baseline and one month later using bioelectrical impedance analysis and the MD Anderson Symptom Inventory, respectively. Each patient was assigned to an atrophy or a non-atrophy group based on the change in wSMI after one month. The concentrations of 19 PFAAs were measured using liquid chromatography–mass spectrometry. An index consisting of the PFAAs at baseline was evaluated for its ability to discriminate atrophy one month later.

Results: The advanced aged group (≥ 70 years, $N = 52$) showed a decrease of wSMI ($-0.35\ kg/m^2$ in mean) to be compared to younger group (< 60 years, $N = 34$, $0.35\ kg/m^2$, $P = 0.09$). The change of wSMI in the middle aged group (≥ 60 and < 70 years, $N = 75$) was $0.03\ kg/m^2$ in mean. Atrophy was observed in 60% of the advanced aged group. The worsened activity, fatigue and appetite loss became more severe after one month in the advanced aged group with atrophy. The areas under the curves (AUCs) based on a receiver operating characteristic (ROC) curve analysis of the PFAA index for discriminating atrophy from non-atrophy were calculated using single or multiple PFAAs. The best AUC for the multiple PFAA indices was 0.83 in the advanced aged group.

Conclusions: SMM atrophy was related to aging, the deteriorated activity, fatigue and appetite loss in patients with advanced PCa during first-line chemotherapy. A multiple PFAA index is a promising biomarker for the early detection of atrophy.

1735P Trajectory of skeletal muscle index (SMI) loss during palliative systemic treatment (Tx) predicts time to progression (TTP) in metastatic colorectal cancer (mCRC) patients

S.A. Kurk[1], R.K. Stellato[2], P.H.M. Peeters[2], M. Oskam[2], B.D. Dorresteijn[3], M. Jourdan[3], C.J.A. Punt[4], M. Koopman[5], A.M. May[6]

[1]Medical Oncology, UMC - University Medical Center Utrecht, Utrecht, Netherlands, [2]Epidemiology, Julius Center for Health Sciences and Primary Care, Utrecht University, Utrecht, Netherlands, [3]Nutricia Advanced Medical Nutrition, Danone Nutricia Research, Utrecht, Netherlands, [4]Medical Oncology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [5]Medical Oncology, University Hospital Utrecht, Utrecht, Netherlands, [6]Julius Center, University Hospital Utrecht, Utrecht, Netherlands

Background: In mCRC patients, SMI loss is suggested to be related with poor survival. Little is known on the trajectory of SMI and its relation with TTP. The CAIRO3 study (Simkens, Lancet 2015) randomized 557 mCRC patients after 6 cycles CAPOX-B to maintenance CAP-B vs. observation (obs). Upon 1st disease progression (PD1), CAPOX-B or other Tx was reintroduced until 2nd progression (PD2). Here we study if SMI trajectory predicts TTP in CAIRO3.

Methods: 104 randomly selected CAIRO3 patients (mean age 65.4 ± 8.3 years) were analyzed for SMI (skeletal muscle area at the L3 level in cm^2/m^2) using 9-weekly repeated CT scans (854 in total). Joint longitudinal-survival modeling, using mixed effects models for longitudinal SMI measures and Cox regression models for TTP analysis, was used to estimate hazard ratios (HR) for absolute SMI and SMI trajectory (per unit SMI loss per month) during two time periods: p1) from randomization to PD1 and p2) from PD1 to PD2. SMI trajectories were modeled throughout each time period and change was investigated at 9 and 4 weeks pre-PD.

Results: During p1 (less intensive CAP-B / obs), patients gained SMI (mean $+1.1 \pm 3.2\ cm^2/m^2$). Absolute SMI was not related with PD1 (HR SMI 9 weeks pre-PD1 0.99 [0.96-1.02], 4 weeks pre-PD1 0.99 [0.96-1.02]). A decrease in SMI preceding PD1 showed a higher, but non-significant, risk of early PD1 (HR SMI change 9 weeks pre-PD1 1.04 [0.83-2.56], 4 weeks pre-PD1 1.53 [0.91-2.55]. During p2, (more intensive CAPOX-B / other Tx), patients lost SMI (mean $-2.7 \pm 3.4\ cm^2/m^2$). Both SMI and SMI trajectory were significantly related to PD2 (HR SMI 9 weeks pre-PD2 1.03 [1.01-1.08], 4 weeks pre-PD2 1.04 [1.01-1.08], SMI change 9 weeks pre-PD2 1.37 [1.07-1.75], 4 weeks pre-PD2 1.23 [0.83-1.82]).

Conclusions: In mCRC patients, a decrease in SMI tended to predict shorter TTP during less intensive CAP-B or obs. SMI and SMI trajectory predicted shorter TTP during more intensive CAPOX-B or other reintroduction Tx. This large longitudinal analysis is the first to show that the trajectory of SMI loss predicts early TTP. These data suggest that SMI preservation may be a therapeutic goal.

1736P Clinical impact of whey protein and nutritional counseling in gastrointestinal cancer patients

M. Roberto[1], E. Sarfati[1], M. Di Girolamo[2], F.M. Schipilliti[1], E. Crimini[3], A. Botticelli[1], L. Marchetti[4], M. Muscaritoli[5], P. Marchetti[1], F. Mazzuca[1]

[1]Clinical and Molecular Medicine, Az. Ospedaliero-Universitaria St. Andrea, Rome, Italy, [2]Radiology Department, Az. Ospedaliero-Universitaria St. Andrea, Rome, Italy, [3]Oncology Unit, Sapienza University of Rome, Rome, Italy, [4]Oncology Unit, San Pietro FBF Hospital, Rome, Italy, [5]Clinical Medicine Department, Sapienza University of Rome, Rome, Italy

Background: Malnutrition frequently affects gastrointestinal (GI) cancer patients. It is known how protein supplementation could prevent loss of lean body mass and sarcopenia. Therefore, we present a placebo-controlled study, to explore the effect and safety of whey proteins in GI cancer patients.

Methods: Patients with GI cancer referred for 5-fluorouracil based chemotherapy, without metabolic alteration, were considered eligible. After informed consent was obtained, they were blind-randomized 1:1 to whey protein (PROLYOTIN®) (arm A) vs placebo (arm B). Patients were assessed, before chemotherapy, after 3 and 6 months, on a physical-nutritional examination, Body Impedance Assessment, MNA® and MUST questionnaire. At the same time frames, tumor characteristics, dietary practices and laboratory values were collected by a specialist team of medical oncologists and dieticians.

Results: Forty subjects with a median age of 65.53 years old were included in this preliminary analysis. Baseline patients characteristics were well balanced between the two arms (A and B) for age, sex, localization and stage of disease, clinical status, nutritional condition and laboratory values (Vitamin D proved to be insufficient in both groups:17,3 ng/ml in A and 15,4 ng/ml in B). After three months of chemotherapy, 32 patients were reevaluated. Overall, no patient was found underweight or malnourished, nor were any differences in blood analysis. Meanwhile, clinical and anthropometric parameters (PS ECOG= 0: 89% A vs 59% B; lean body mass 69,7 % to 71,8% A vs 67,6% to 63,6% B, p value=0,013), nutritional status (MNA>27=34% to 100% A vs 42% to 65% B, p value=0,001) and toxicity (hematological: no adverse effects 86% A vs 29% B, p value 0,005; gastrointestinal: 94% A vs 29% B, p value 0,001) resulted to be significantly different between the two groups.

Conclusions: The nutritional counselling and whey proteins intake during chemotherapy showed a significant benefit in nutrition, performance status and treatment tolerability in GI cancer patients. However, further studies are needed to improve the knowledge of whey protein protective role against chemotherapy toxicity and to select more accurately those patients who may benefit from a preventive whey protein supplements.

1737P Impact of taste alterations during systemic anti-tumour therapy on the liking of oral nutritional supplements with adapted flavours

J.J. De Haan[1], Y. Moshage[1], D. Kluifhooft[1], R. Renken[2], C. Corbier[3], H. Blanchard[3], A.K.L. Reyners[1]

[1]Medical Oncology, University Hospital Groningen (UMCG), Groningen, Netherlands, [2]Neuro Imaging Center, University Hospital Groningen (UMCG), Groningen, Netherlands, [3]Danone Nutricia Research, Nutricia Advanced Medical Nutrition, Utrecht, Netherlands

Background: Taste alterations are often reported by cancer patients, especially during systemic anti-tumour therapy, with a negative impact on food intake and quality of life. Little is known about the relation between taste alterations and taste preferences. This study aimed to explore the occurrence of taste alterations (i.e. changes in taste perception or intensity) in patients receiving systemic anti-tumour therapy, and to investigate overall likings of oral nutritional supplements (ONS) with flavours designed to better address the needs of patients with taste alterations.

Methods: Fifty adult patients with cancer undergoing systemic anti-tumour therapy were recruited. Exclusion criteria were allergies/intolerances to ONS ingredients or coexisting morbidities affecting taste or smell. Participants filled out a questionnaire on taste alterations, and evaluated overall liking of 5 Nutridrink® Compact Protein on a 10-point scale via a sip test (hot tropical ginger, hot mango, cool red fruits, cool lemon and neutral). Permutation analysis was performed to investigate differences between patients with and without taste alterations.

Results: Various types of cancer and treatments (n = 34 chemotherapy, n = 5 chemoradiation, n = 4 immunotherapy, n = 2 targeted therapy, n = 5 other form of systemic therapy) were observed. Thirty patients (60%) reported taste alterations. Overall liking scores were: cool red fruits 6.8 ± 1.7 (mean ± SD); neutral 6.5 ± 1.9; hot tropical ginger 6.0 ± 2.0; cool lemon 5.5 ± 2.3 and hot mango 5.5 ± 2.0. Larger variation in overall liking per product was observed in patients with taste alterations (range 4.9 - 7.0) versus without taste alterations (range 5.9 – 6.5). Posthoc analysis showed that taste alteration was associated with a difference in overall liking for neutral ($\Delta = 1.0$; $p < 0.05$) and hot mango flavours ($\Delta = -1.1$; $p < 0.05$).

Conclusions: More than half of patients undergoing anti-tumour therapy experienced taste alterations. Patients without taste alterations were less discriminant in liking score compared to patients with taste alterations. These findings indicate that the presence of taste alterations should be taken into account when selecting or developing ONS for cancer patients.

1738P Overweight, obesity and weight gain after breast cancer (BC): A prospective clinical study

A. Di Meglio[1], M. El-Mouhebb[1], S. Michiels[2], L. Jones[3], M. Annonay[4], A. Zingarello[5], M. Matias[1], S. Everhard[6], A.L. Martin[7], P. Arveux[8], O. Tredan[9], P. Soulie[10], P.H. Cottu[11], A.H. Partridge[12], L. Del Mastro[13], J.A. Ligibel[12], F. André[1], I. Vaz-Luis[1]

[1]Medical Oncology, Institut Gustave Roussy, Villejuif, France, [2]Team Oncostat, CESP, Gustave Roussy, Villejuif, France, [3]Exercise Oncology Research Program, Memorial Sloan Kettering Cancer Center, New York, NY, USA, [4]Institute Bergonié, Bordeaux, France, [5]INSERM UMR 981, Gustave Roussy, Université Paris-Saclay, Villejuif, France, [6]UCBG, UNICANCER, Paris, France, [7]Research & Develpment, UNICANCER, Paris, France, [8]Medical Oncology, Centre Georges-François Leclerc, Dijon, France, [9]Medical Oncology, Centre Léon Bérard, Lyon, France, [10]Medical Oncology, Centre Paul Papin, Angers, France, [11]Medical Oncology, Institut Curie, Paris, France, [12]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, USA, [13]Medical Oncology, Ospedale Policlinico San Martino, Genoa, Italy

Background: Overweight and obesity are a growing health problem worldwide and are linked to poor quality of life and BC outcomes. Fewer data are available that describe patterns of weight change or evaluate robust associations with weight gain following BC in a European population.

Methods: We used data collected from 4875 women with Stage I-III BC included in an ongoing prospective French multicenter clinical study from 2012-14 (CANTO, NCT01993498). Body Mass Index (BMI) and physical activity (PA) were assessed at diagnosis (dx), 3-6 (T1) and 12 (T2) months after primary treatment. Weight changes ≥ 5% of weight at dx were considered significant. Group based trajectory models (GBTM) described risk of overweight or obesity over time. Multivariate logistic regression assessed factors associated with significant weight gain at T1 and T2.

Results: At dx, mean age was 56 y (range 22-88), median BMI was 24.6 (range 14.7-59.0), 29% pts were overweight and 19% obese. 54% pts received chemo (CT) and 82%

Table: 1738P Multivariate logistic regression of factors associated with weight gain after BC in the overall population (N = 4875)

	T1 (3-6 months after treatment)		T2 (12 months after treatment)	
	% pts who gained weight	aOR* (95% CI)	% pts who gained weight	aOR* (95% CI)
Total	17	-	24	-
Age (years) <50 50-65 >65	25 17 8	2.8 (1.8-4.2) 2.2 (1.6-3.0) ref	35 24 11	2.1 (1.3-3.2) 2.0 (1.5-2.7) ref
BMI at diagnosis (kg/m^2) Underweight (<18.5)	25 18 16 14	1.7 (0.9-3.0) 1.3 (1.1-1.7)	33 26 24 18	1.9 (1.1-3.4) 1.7 (1.2-2.3)
Normal (18.5-24.9) Overweight (25.0-29.9)		1.4 (1.1-1.9) ref		1.7 (1.3-2.4) ref
Obese (≥30)				
Level of Physical Activity^	16 17	1.0 (0.8-1.2) ref	26 22	1.3 (1.1-1.6) ref
Failing to reach 10 Reach/maintain ≥10				
Receipt of chemotherapy Yes No	21 12	1.3 (1.1-1.7) ref	29 18	1.6 (1.3-2.1) ref
Receipt of endocrine therapy Yes No	16 19	1.1 (0.7-1.5) ref	24 25	1.7 (1.1-2.7) ref
Weight gain at T1 Continuous, for 1 Kg gained	-	-	-	1.6 (1.5-1.6)

[a]OR= adjusted odds ratio; CI= confidence interval.

*Adjusted for all variables in the table + menopausal status, education, smoking status, alcohol, tumor stage, subtype, breast and axillary surgery.

^In Metabolic Equivalent of Task (MET)-hours/week, based on World Health Organization recommendations on physical activity and expressed as change in physical activity behavior from diagnosis to T1 and to T2, respectively.

endocrine therapy (ET). GBTM found that the majority of overweight and obese pts remained so over time. By T2, weight increased in 24% pts (median gain + 5 Kg [range 2-33]), was stable in 63% pts and decreased in 13% pts in the overall population. Factors associated with higher risk of significant weight gain by T2 included age <50 vs > 65 (adjusted odds ratio 2.1 [95% Confidence Interval 1.3-3.2]), receipt of CT vs no (1.6 [1.3-2.1]), receipt of ET vs no (1.7 [1.1-2.7]), PA < 10 MET-hours/week vs ≥ (1.3 [1.1-1.6]) and having already gained weight by T1 (for each Kg gained, 1.6 [1.5-1.6]) (Table).

Conclusions: In this large contemporary epidemiology study of French BC survivors, a significant proportion of pts were overweight or obese at dx, and one in four of all pts gained substantial weight after treatment. Weight gain is particularly common in pts who are younger, treated with CT or ET and less physically active. Our data will inform weight loss survivorship programs targeting pts at higher risk of overweight, obesity and weight gain after BC.

Background: Obesity and unfavorable energy balance affect physical and psychological outcomes among BC survivors. There is little data describing the impact of weight loss on PROs in obese pts.

Methods: We used a prospective French nationwide longitudinal cohort (CANTO, NCT01993498) to select obese (Body Mass Index ≥ 30 kg/m^2) stage I-III BC pts diagnosed from 2012-14. Nurses assessed weight change from BC diagnosis (dx) to 3-6 months post treatment (surgery, chemo [CT] or radiotherapy [RT]), defined as weight gain (≥ 5%), stability (± 5%) or loss (≤ 5%). PROs were assessed by EORTC QLQ C30/BR23. Functional scores <60 and symptom scores ≥40 defined severe dysfunctions and symptoms, respectively (Giesinger, 2016). Multivariate logistic regression explored associations of weight change with severe PROs.

Results: We included 892 obese pts, 19% of CANTO population. Mean age was 59 y (range 27-87). 92% received RT, 54% CT and 84% endocrine therapy. Mean BMI at dx was 34.5 (range 30.0-59.0). 14% pts gained weight, 67% were stable and 19% lost weight post treatment. There was a significant differential reduction in physical activity in 39% pts who gained weight, 37% pts with stable weight, and 28% pts who lost weight (mean change [Standard Deviation] was -5 [77], -4 [66] and +4 [69] MET-hours/week, respectively [p=.036]). Prevalence of any severe dysfunction or symptom was 83% at dx and further increased over time, being highest in pts who gained weight. Weight loss was associated with lower odds of severe dysfunctions or symptoms vs weight gain, consistently across all PROs (Table).

Conclusions: The majority of obese pts report severe physical or psychological distress at BC dx and post treatment. A comprehensive approach to the care of obese BC pts should address the burden of morbidity caused by obesity and further post treatment weight gain. Weight loss may prevent physical and psychological deterioration, thus lifestyle interventions of purposeful weight loss should be encouraged.

1740P Patient reported outcomes: Web-monitoring versus nurse assessment to improve anticancer therapies

M. Korostelev[1], K. Sejean[1], C. Lepage[1], J. Stevens[2], B. Bonan[1], P. Beuzeboc[3], F. Scotté[3]

[1]Pharmacy, Hopital Foch, Suresnes, France, [2]Direction, Direct Medica, Boulogne, France, [3]Supportive Care in Cancer Unit, Oncology, Hopital Foch, Suresnes, France

Background: Patients treated in a chemotherapy day unit can benefit from "STAR", an innovative monitoring program to improve cancer management and reduce waiting-time as well as drug wastage. Two days before anticancer treatment, according to patient preference, a nurse (call) or the patient himself (web) completes a clinical data questionnaire. The aim of the study was to compare the reliability of those two methods of data collection.

Table: 1739P Prevalence of severe dysfunctions and symptoms at BC diagnosis and post treatment by weight change category among obese pts in CANTO (N = 892)

	Diagnosis	Post treatment			
	Overall	Overall	By weight change category (% pts)		
PRO Domain	-	-	Gain (14.0)	Stable (67.0)	Loss (19.0)

aOR= adjusted odds ratio; CI= Confidence Interval; [a]EORTC QLQ-C30 subscale; [b]EORTC QLQ-B23 subscale; *pts surveyed before start of treatment; All models adjusted for age, menopausal status, education, smoke, alcohol, physical activity, tumor stage, subtype, BC and axillary surgery, receipt of CT, RT, endocrine therapy, and level of the outcome at BC diagnosis.

Methods: Clinical information prospectively collected on STAR questionnaires during 11 months were compared using Mantel-Haenszel khi^2 (p-values) in the 2 groups (nurse call versus web self-questionnaire). Numbers of symptoms were classified into 3 categories: 0, 1 and at least 2 symptoms for each grade of severity (NCI-CTC AE, version 4.0).

Results: From May 2017 to April 2018, 622 (67.1%) of 928 patients admitted to daily hospital for a chemotherapy cycle were included in the STAR program. Monitoring was ensured by nurse phone calls for 477 patients (76.7%) versus 145 (23.3%) by web questionnaires. Patient's average age (66±11 years) and sex repartition (61% of men) were not different in the 2 groups. The overall rate of response was significantly better with nurse calls (84.8%) than with web questionnaires (78.2%) ($p < 0.0001$). Global incidence of grade 3 and grade 4 toxicities was similar in the two groups ($p = 0.1$ and 0.06 respectively) whereas web questionnaires mentioned significantly more grade 2 and grade 1 toxicities ($p < 0.0001$). When chemotherapy cycle was cancelled for a clinical reason, this information was similarly mentioned in the 2 groups ($p = 0.35$). Overall, global rate of delayed chemotherapy did not differ between the two groups.

Conclusions: Web questionnaires appear to be an interesting and reliable method for patient clinical monitoring. To take full advantage of STAR program, the importance of clinical evaluation should be reminded to patients to increase the rate of response. Web monitoring improvement in grade 1-2 toxicities screening should be explained by a better patient understanding and will be investigated in further studies.

1741P Polymedication in elderly cancer patients treated with chemotherapy

A-L. Couderc[1], F. Correard[2], C. Tabele[2], E. Nouguerede[1], L. Greillier[3], F. Duffaud[4], P. Auquier[5], A. Daumas[1], P. Bertault-Peres[2], P. Villani[1], S. Honore[2]

[1]Department of Geriatric and Internal Medicine, Assistance Publique Hopitaux de Marseille, Marseille, France, [2]Pharmacy, Assistance Publique Hopitaux de Marseille, Marseille, France, [3]Department of Multidisciplinary Oncology and Therapeutic Innovations, Assistance Publique Hopitaux de Marseille, Marseille, France, [4]Department of Oncology, CHU La Timone Adultes, Marseille, France, [5]Public Health Research Unit EA 3279, Aix Marseille Université, Marseille, France

Background: Medication reconciliation (MedRec) including complementary and alternative medicine is considered as an important way to increase the safety of medication use. However, there are few studies in literature showing the impact of an oncogeriatric approach integrating MedRec program in elderly cancer patients (ECP). The objective is to measure the impact of a pharmacogeriatric approach (PGA) on ECP before treatment by chemotherapy.

Methods: A monocentric prospective study was implemented to evaluate the overall survival (OS), rate of readmission hospital (RRH) at 1stand 3rdmonth and Early Discontinuation of active treatment (ED). These variables were analyzed according to number of reviewed drugs in MedRec and geriatric tools of Comprehensive Geriatric Assessment (CGA).

Results: 144 patients were received in oncogeriatric consultations between 01/2017 and 10/2017 (mean age was 80.9 ± 5.5 years, 52.1 % were men, 48.6 % had metastatic tumors). Main cancers were lung (31.9 %), gastrointestinal (18.1 %), breast and gynecological (16.7 %). At 1st and 3rdmonth, death rates were 3 % and 12 %; RRH were 11.1 % and 16.3 %. Received treatment was analyzed and 62.5% received systemic treatment after oncogeriatric consultations. Concerning ED at 3rd month, 48 % had prematurely stopped it (because of cancer progression in 14.2 % and infections in 7 %) and 23.6 % reduced dose (because of chemotoxicity in 33 % and geriatric conclusions in 20 %). OS prognostic factors were malnutrition ($p = 0.03$) and metastatic status ($p = 0.05$), prognosis factors of early death at 1 month were lymphopenia ($p = 0.005$) and RRH ($p = 0.04$), and at 3 months: malnutrition ($p = 0.01$), ADL dependence ($p = 0.03$), and RRH ($p = 0.01$).

Conclusions: To our knowledge, this is the first study evaluating and describing the outcomes of PGA with MedRec and CGA in same time for the ECP. First month death rates and RRH are lower compared to literature in our study. RRH, ADL and nutritional disorder are OS prognostic factors. Full analyzes will be presented during the congress to show the real impact of PGA.

1742P Geriatric oncology (GO): Long term follow-up of a prospective series of the GO unit at A.C. Camargo Cancer Center

A.L.A. Dettino[1], M.D.S. Donadio[1], A. Cabral[1], V.H.F.D. Jesus[1], M.F. Fanelli[2], S.M. Sanches[1]

[1]Oncologia Clinica, A.C. Camargo Cancer Center, Sao Paulo, Brazil, [2]Oncologia Clinica, Rede d'Or S Luiz, Sao Paulo, Brazil

Background: Ageing is a global phenomenon and has huge impact in healthcare. Still emerging in developing nations, there has been no major national innitiative focusing on oncologic geriatric patients (pts). The study describes a program to > 70y cancer pts in A C Camargo Cancer Center. We hypothesized that incorporating CGA into daily practice can improve individualized care.

Methods: Previous aims were to evaluate if: 1) CGA could be feasible in daily practice; 2) it could be useful as a tool in treatment/tx decision making; 3) analyse the impact of CGA in the selection of tx, with its ability to predict complications (such as dosis reduction, hospitalization, or tx discontinuation) in an Oncogeriatric Unit. The present study is to present the long term survival of those pts, candidates to receive systemic tx, who underwent CGA assessments, which included scales of: ADL (Katz, Lawton), mini-nutritional assessment, depression (GDS), comorbidities and polypharmacy. Patients were classified as fit, borderline or frail. Fit pts received mainly full treatment; frail/borderline pts, mainly modified tx or specific supportive care.

Results: From Oct 25/10-Dec/12/12, 638 pts were included to be prospectively evaluated - female 55%; cancers (%): breast 26, prostate 12, colorectal 12, hematologic 8. Katz A = 68%, Lawton 27=45%; polipharmacy (> =5): 48%; depression 29%, undernutrition: 21%. We have previously presented (ASCO 2014) that there was an association between the choice of oncologic treatment (original vs modified or with additional dose reduction) with Katz, Lawton, depression and nutrition scales ($p < =0.035$); as well as the ability to complete the individualized proposed treatment, which was correlated with Lawton ($p = 0.04$) scale. Hospitalization during chemotherapy was associated with comorbidities, altered Katz, Lawton and depression scales ($p < =0.038$). With 610 pts evaluable, median survival was 51.7 months.

Conclusions: We could find a high long term survival of 70+ cancer pts, showing CGA to be feasible and allowing long term survival follow-up. However, many pts have been lost to follow-up. How to better perform in pts' adherence and to reduce bias must be a concern in real world geriatric oncology.

1743P Developing a predictive model for chemotherapy related toxicities in older Asian adults

S.L.A. Pang[1], F. Ho[2], Y.S. Ng[1], C. Cai[3], M. Wang[3], W.C. Yong[4], B.C. Tai[5]

[1]Haematology Oncology, National University Cancer Institute, Singapore, [2]Radiation Oncology, National University Cancer Institute, Singapore, [3]Yong Loo Lin School of Medicine, National University of Singapore, Singapore, [4]Palliative Medicine, National University Cancer Institute, Singapore, [5]Saw Swee Hock School of Public Health, National University of Singapore, Singapore

Background: Elderly patients (pts) are at increased risk of developing chemotherapy (CTx) related toxicities. There are several prediction tools including the Cancer and Aging Research Group (CARG) chemotoxicity calculator (CTC) but this has not been validated in the Asian population. The objective of our study is to identify predictors of G3-5 CTx toxicities and evaluate the utility of the CTC in older Asian adults.

Methods: We enrolled cancer pts aged ≥ 70 years, requiring outpatient treatment with chemotherapy at the National University Cancer Institute, Singapore. A comprehensive geriatric assessment was performed and baseline cancer characteristics, including the 11 variables in the CTC were collected prior to the initiation of CTx. Primary treating oncologists were asked to give an estimated likelihood of CTx related toxicities. Pts were then followed up to 3 months after completion of treatment and CTx toxicities were recorded.

Results: Amongst the 131 pts (mean age: 75 years; range: 70 – 89), their CA diagnoses include colorectal (CRC) (36; 27.5%), lung (27 ; 20.6%), non-CRC gastrointestinal (17; 13%) , breast (14 ; 10.7%), genitourinary (10 ;7.6%), head and neck (10 ; 7.6%), gynaecological (8; 6.1%) and other (9; 6.9%) cancers. 54 pts (41%) received CTx with curative intent, and 77 (59%) with palliative intent. The incidence of G3-5 toxicities was 58% (76). The most common toxicities were neutropenia (38 ; 29%) and anaemia (26; 20%) and there was 1 mortality from CTx related pneumonitis. In the multivariable analysis, the factors associated with the incidence of CTx related toxicities were i) Age >72 years, ii) GI/GU cancer, iii) Haemoglobin < 10g/dL (Female) ; <11g/dL (Male), iv) Limited ability to walk 1 block, iv) Limited social support and v) Disease interference with social activity. Based on this new model comprising the above 5 variables, the area under the receiver operating characteristic curve (ROC) is 0.776, whereas that for the CTC and oncologists' prediction of CTx related toxicities were 0.765 and 0.594 respectively.

Conclusions: Our new model for predicting CTx related toxicities appears to be comparable to the CTC. In our follow up study, we hope to further validate this model's utility in predicting CTx related toxicities in our elderly cancer population.

1744P Palliative local therapy of advanced breast cancer

T. Letodiani[1], M. Shavdia[2], N. Shavdia[3], K. Chaava[2], N. Gegeshidze[2],

[1]Palliative Care, National Cancer Center of Georgia (NCCG), Tbilisi, Georgia, [2]Paliative Care, Tbilisi State Medical University, Tbilisi, Georgia, [3]Palliative Care, JSC 'Neo Medi' Tbilisi, Georgia

Background: Objective: Initial nidus tumor infiltration is often revealed in patients with advanced breast cancer. In such cases, all treatment is focused on improvement of the quality of life.

Methods: Special mixture of Linimentam Synthomycin 10% (25 gr) + Tegafur (Ftorafur) 800 mg was prepared for anti inflammatory and tumor therapy. The mixture was used in bandaging of breast tumor infiltration in 99 patients for 10 days (interval - 20 days). Tumor infiltration in 84 patients -15 cm, in 15 patients > 30 cm. In 3 cases double-sided process was observed. All the patients had low hematological indicator and KPS (40,0 %).

Results: After II course of treatment: significant improvement of dynamics of tumor infiltration in 49 (49,5%) patients (reduction of hyperemia, pain syndrome, itching, temperature, etc). After the III-IV courses: wound cleansing from purulent, formation of granulation areas and improvement of the quality of life in 10 patients (Tumor reduction and full epithelization in 10 (10,1%) patients enabling sanitation of mastectomy). Worsening of condition - in 18 (18.2%), stabilization in 71 (71.7%) patients. After the IV course of local therapy tumor infiltration was reduced by 9 cm in average (Maximum effect was seen in patients with infiltration of 15 cm) KPS average indicator improved from 40,0% to 53,4% ($p < 0,05$).

Conclusions: 1. Administration of Synthomycin 10% (25 gr) + Tegafur (Ftorafur) 800 mg for local chemotherapy and anti – inflammatory therapy of breast cancer tumor infiltration contributes to reduction of hyperemia, temperature reaction, itching, suppuration, size of nidus, pain syndrome and accordingly improvement of the quality of life (KPS has improved from 40,0% to 53,4%; 2. Practically there are no side effects upon a local chemotherapy of breast.

1745P General and dedicated cancer emergency room: Clinical and financial implications

N. Malavasi[1], C. Fiorani[1], L. Ferrara[1], R. Postiglione[1], L. Scarabelli[1], F. Cantile[1], A. Saviola[1], G. Longo[1], A. Luciani[2], S. Cascinu[1]

[1]Oncology and Hematology, Azienda Ospedaliero-Universitaria Policlinico di Modena, Modena, Italy, [2]General Emergency Room, Azienda Ospedaliero-Universitaria Policlinico di Modena, Modena, Italy

Background: Emergency department (ED) visits among cancer patients (pts) exceed those of the general population; acute oncology teams can influence strategy determining a reduction in ED accesses and hospitalizations. Local services may reflect number and type of admissions often referred to ED. Onco-Hemato Emergency Room (OHER) in Modena Hospital is a service completely dedicated to cancer pts needs integrated with Oncology Department since 2001.Medical team is composed by oncologists and hematologists, from Monday to Friday (08, 00-18, 00), Saturday (08, 00-12, 00). Otherwise pts must refer to ED. We tried to describe pts admitted to OHER between January, 1, 2007 and December, 31, 2017 by cancer types, reasons for visits and percentage of hospitalizations from OHER and ED with financial implications.

Methods: OHER data were obtained through the query of a relational database used to collect medical records, concerning all disease history including hospitalizations and planned evaluations. Pts were received regardless disease stage from suspected tumor to palliative care setting. ED term searches were conducted using a dedicated database.

Results: 28.680 admissions to OHER, of 11.239 pts, 5326 (47%) had a single access, the most recurrent one had 51 visits, 165 (0.6%) died there. According to the site of primary malignancy: digestive tract 24%, lung 16.5%, lymphoma 9%, acute and chronic leukemia 10%, breast 7.2%, colon-rectal 8.4%, urological 8%, myeloma 5%, head neck 4%, melanoma 1.4%, sarcoma 1.7%, hematologic 2.3%, thrombotic purpura 0.2%,other 2.3%. Most common reasons determining visits were worsening of disease (14.6%), pain (12%), therapy toxicities (8.6%), suspected tumor (5.6%), deferrable (7%). January was the most crowded month (2900, 10%), December the less one (1952, 6.8%), Monday (6926) the most haunted day of the week. Hospitalizations in Oncology Department were 6.781 (23%), 1.710 (5.8%) in others. 10.246 cancer pts acceded to ED in the same period (1.4% of all pts); 5961(58%) were hospitalized. Average long of stay was 10 days.

Conclusions: Acute oncology can play a key role in management of emergencies; despite true level of saving is difficult to quantify accurately, OHER lead to save 81430 bed days with hypothetic financial saving.

1746P Comparing cancer patients' and support persons' preferences for the type of consultation and the format of information provided when making a treatment decision

A. Herrmann[1], R. Sanson-Fisher[1], A. Hall[1], L. Wall[2], N. Zdenkowski[3], A. Waller[1]

[1]School of Medicine and Public Health, University of Newcastle, Callaghan, Australia, [2]School of Psychology, University of Newcastle, Callaghan, Australia, [3]Department of Medical Oncology, Calvary Mater Newcastle, Waratah, Australia

Background: Cancer patients and their support persons often feel overwhelmed when being confronted with their diagnosis and treatment options. Such information is commonly provided during one consultation with their clinician. We compared cancer patients' and their support persons' preferences for: i) attending one 40-minute consultation or two 20-minute consultations when making a treatment decision; and ii) receiving additional information in written form only or in both written and online forms.

Methods: An Australian cross-sectional survey, using a discrete choice experiment (DCE), of 159 adult medical oncology patients, and 64 of their support persons. Participants were presented with four hypothetical scenarios and asked to indicate their most and least preferred option. They were told that both treatments would have the same impact on participants' life expectancy, and that there would be no difference between the scenarios in terms of when treatment would start.

Results: 147 patients and 59 support persons completed the DCE. The proportions of patients and support persons choosing each scenario did not differ statistically significantly from each other ($p > 0.05$). Of the four scenarios, most patients and support persons preferred to receive two consultations along with written and online information ($n = 65$, 44% and $n = 30$, 51% respectively). Significantly more participants preferred to receive two shorter consultations rather than one longer consultation when this was combined with written and online information ($p < 0.05$).

Conclusions: When making a cancer treatment decision, both patients and support persons seem to prefer to receive two shorter consultations combined with written and online information. Clinicians should consider offering this consultation style.

1747P EXTEND: Safety and efficacy of exercise training in men receiving enzalutamide (ENZ) in combination with conventional androgen deprivation therapy (ADT) for hormone naïve prostate cancer (HSPC)

M.R. Harrison[1], P.G. Davis[2], M.G. Khouri[3], R.T. Gupta[4], A.J. Armstrong[1], M.A. McNamara[1], T. Zhang[1], M. Anand[5], K. Onyenwoke[5], H. Hood[5], S. Edwardson[6], D. Craig[6], Y. Wu[7], P. Healy[7], B. Coyne[8], L. Jones[9], D.J. George[1]

[1]Division of Medical Oncology, Duke Cancer Center, Durham, NC, USA, [2]Department of Kinesiology, UNCG, Greensboro, NC, USA, [3]Division of Cardiology, Duke Cancer Center, Durham, NC, USA, [4]Department of Radiology, Duke Cancer Center, Durham, NC, USA, [5]GU Oncology, Duke Cancer Center, Durham, NC, USA, [6]Health and Fitness Center, Duke University, Durham, NC, USA, [7]Biostatistics, Duke Cancer Center, Durham, NC, USA, [8]Cardiac Diagnostic Unit, Duke University Health System, Durham, NC, USA, [9]Exercise Oncology Research Program, Memorial Sloan Kettering Cancer Center, New York, NY, USA

Background: ADT is associated with physical side effects and a decline in cardiorespiratory fitness that can be mitigated with exercise (EX). Addition of a more potent androgen receptor inhibitor such as ENZ might worsen these effects. In this pilot study, we

investigated whether an EX program could mitigate adverse changes from ADT + ENZ treatment.

Methods: Men starting ADT for M0 HSPC were treated with ADT + ENZ for 8 months and randomized to usual care (UC) or EX for 16 weeks. EX began 4 weeks prior to starting ADT + ENZ and consisted of 48 supervised exercise sessions delivered 3x/week between 55-80% of exercise capacity (VO_2peak) for aerobic training and 60-85% of one repetition maximum (1-RM) for resistance training. The primary endpoint was change in VO_2peak from baseline to 16 weeks. Secondary endpoints included 6 minute walk distance (6MWD), upper and lower body strength (1-RM), body composition (DXA), and patient reported outcomes (FACT-P, FACIT-Fatigue). The study was originally designed to recruit 56 subjects (N = 28/arm) but was halted early due to funding issues.

Results: 26 men (UC, N = 13; EX, N = 13) completed the protocol. Baseline age and BMI (mean ± standard deviation [SD]) were 65.0 ± 8.1 yr and 28.5 ± 4.6 kg/m2. Intention to treat analyses for mean 16-week change from baseline with a 95% confidence interval (CI) for each assessment by arm are presented in the table.

Table: 1747P

Endpoint	UC + ADT + ENZ (mean change [95% CI])	EX + ADT + ENZ (mean change [95% CI])
VO_2peak (ml kg^{-1} min^{-1})	-3.2 (-6.3, -0.2)	-0.9 (-2.4, 0.5)
6MWD (ft)	-32.0 (-71.2, 7.3)	+42.0 (5.6, 78.4)
1-RM Leg Press (lbs)	+6.7 (-46.7, 60.0)	+107.1 (43.2, 171.0)
1-RM Chest Press (lbs)	+4.9 (-11.0, 20.9)	+24.3 (9.2, 39.4)
1-RM Row (lbs)	+3.0 (-10.5, 16.5)	+14.9 (0.7, 29.0)
Fat Mass (g)	+2949 (565, 5333)	-122 (-1593, 1350)
Lean Mass (g)	-3088 (-5384, -792)	-2094 (-3549, -640)
FACT-P TOI	-11.6 (-20.3, -2.9)	-5.4 (-10.8, 0.1)
FACIT-F Score	-9.2 (-16.0, -2.4)	-5.0 (-8.0, -2.1)

Conclusions: Supervised aerobic and resistance EX resulted in less decline in VO_2peak, as well as improved function and strength in men treated with ADT + ENZ for M0 HSPC. EX was associated with less fat gain and muscle mass loss, less decline in QOL, and less increase in fatigue. Larger trials of EX in this setting are warranted.

Clinical trial identification: NCT02256111.

1748P Cancer care-related social media (SM) and internet usage differences between adolescents and young adults (AYA), adults and elderly patients with cancer

L. Eng[1], J. Bender[2], K. Hueniken[3], S. Kassirian[3], D. Yang[3], L. Mitchell[4], C.B. Paulo[5], A. Magony[3], E.C. Smith[3], M. Liang[3], M.C. Brown[3], W. Xu[3], S.M.H. Alibhai[6], G. Liu[3], A. Gupta[7]

[1]Medical Oncology and Hematology, Princess Margaret Cancer Center, Toronto, ON, Canada, [2]Department of Epidemiology, Dalla Lana School of Public Health, Toronto, ON, Canada, [3]Department of Medical Oncology and Hematology, Princess Margaret Cancer Center, Toronto, ON, Canada, [4]Adolescent and Young Adult Program, Hospital for Sick Chidlren, Toronto, ON, Canada, [5]Medical Oncology, Princess Margaret Cancer Center, Toronto, ON, Canada, [6]Geriatrics and General Internal Medicine, Toronto General Hospital, Toronto, ON, Canada, [7]Department of Hematology and Oncology, Hospital for Sick Chidlren, Toronto, ON, Canada

Background: Internet and SM provide important information and support to cancer patients. Evaluating age-related differences on how patients use these resources is important as it can impact decision-making. Here, we evaluated associations between patients' age, confidence in computer-use, and use of Internet/SM for cancer care.

Methods: Cancer patients completed a cross-sectional survey of cancer-related SM/Internet use and self-confidence using these resources. Multivariable logistic regression evaluated factors associated with Internet/SM use.

Results: Among 320 patients, 127 were AYA (age 18-39), 127 were adult (40-64) and 66 were elderly (65+). Most (>95%) had a smartphone/tablet/computer and used the Internet daily. Compared to AYA, non-AYA were less likely ($P < 0.001$) to own a data plan (77% vs 92%), have a SM account (72% vs 95%) or feel confident using computers (76% vs 98%). 75% used Internet and 43% used SM for cancer care information and support; 37% felt confident using online information for decision-making. AYA were more likely than non-AYA to use the Internet (aOR = 1.60, 95%CI [0.93-2.81], P = 0.09) and SM (aOR = 1.75 [1.04-2.95], P = 0.04) for cancer care. Adults were more likely than elderly patients to use the internet for cancer care (aOR = 3.10 [1.56-6.25], P = 0.001), while no difference was seen in their SM use for cancer care (P = 0.79). Confident computer users were more likely to use Internet (aOR = 5.36 [2.67-11.00], $P < 0.001$) and SM (aOR = 4.61 [1.98-12.14], $P < 0.001$) for cancer care and were more confident using this information in decision-making (aOR = 5.12 [1.92-17.81], $P < 0.001$). Age was not associated with self-confidence using online information for decision-making ($P > 0.10$).

Conclusions: Despite higher use of internet/SM for cancer care, AYA did not feel more self-confident evaluating online cancer information. Confidence in computer use was associated internet/SM usage and confidence evaluating online information. Patient education programs should focus on improving patients' confidence in using online resources so they can better evaluate online information for cancer care.

1749P Ultrasound-guided femoro-popliteal block in lower limb sarcoma and cutaneous malignancy patients: Is it the time to abandon spinal anaesthesia for foot and ankle surgeries?

N. Moda

Department of Anesthesia, Critical Care and Pain Medicine, IMS & SUM Hospital SOA University, Bhubaneswar, India

Background: Ultrasound-guided regional anaesthesia has recently become very popular. The aim of this study was to compare the efficiency of Ultrasound-guided femoro-popliteal block (US-FPB) against spinal anaesthesia (SA) for foot and ankle surgeries in lower limb cancer (sarcoma and skin cancer) patients and to further define its role in intra-operative anaesthesia and post-operative analgesia.

Methods: This randomized controlled trial included 52 adult lower limb cancer patients. They were randomized into two groups. Patients from group A (experimental) received Ultrasound-guided femoro-popliteal block, while a spinal anesthesia (SA) was given in group B patients. In both the groups, Bupivacaine (0.5%) was used as local anaesthetic drug. The statistical analysis was done using student's t-test and p value <0.05 was considered significant.

Results: 25 patients from the first and 24 patients from the second group completed the study. Using modified Bromage score, levels of anaesthesia were found to be sufficient in both the groups without any statistically significant differences (p value=0.67). Average duration of postoperative analgesia was 12.3 hours and 2.7 hours in group A and B, respectively (p value<0.001).

Conclusions: Both US-FPB and SA provided sufficient and comparable anaesthesia for ankle and foot fractures. However, post-operative analgesia was significantly longer in US-FPB group with subsequent much less requirement of post-operative analgesics. Better and longer post-operative analgesia in US-FPB group also resulted in shorter rehabilitation periods and decreased time-gaps for beginning of joint movements.

1750P Assessment of socio-economic, physical and mental health status of long-term cancer survivors

A. Gallego Martínez, B. Martínez, I. Ghanem, E. Espinosa, B. Castelo, M.P. Zamora Aunon, A. Pinto Marin, L. Ruiz-Giménez, A. Redondo, J. Feliu Batlle

Medical Oncology, Hospital Universitario La Paz, Madrid, Spain

Background: Long-term survival rates for many types of cancer have substantially improved in past decades. In order to improve follow-up and comprehensive care of this population a specific medical office was started up three years ago at our institution. This is the health and socio-economic analysis of the long-term cancer survivors in our area.

Methods: A 54-item questionnaire was developed based on QLACS (Quality of Life in Adult Cancer Survivors) and SF-36 Health Survey. 347 patients completed the questionnaire from January 2015 to December 2016. A medical questionnarie (63-item) was also completed for each patient by oncologists responsible for the medical office. The information was collected in a database and processed with SPSS 18.

Results: Median age at the time of diagnosis was 56.8 years and median time from cancer diagnosis to questionnarie completion was 7.1 years. 53.9% were women and 46.1% men. At the time of diagnosis 72% were married/committed relationship, 27.9% had university studies and 32.8% were retired. 35.4% had hipercolesterolemia and 3.2% anxiety/depression syndrome. Colon and breast carcinomas accounted for 49.9% of all cases and 67.1% were diagnosed in stages I and II. 91.8% underwent surgery, 59.6% received chemotherapy and 32.3% radiotherapy. After the diagnosis and treatment of cancer relationship status of patients scarcely changed, 19.9% more of the patients retired, 17.9% of those who kept their

employment status decreased their income, though only 9 patients reduced their working hours. Despite 24.3% made healthy dietary modifications, 25.4% gained al least 5 kg over their recommended weight and the anual incidence rate of hipercolesterolemia was 5.8%. 34.9% patients more had anxiety/depression syndrome and 68.9% reduced their sexual activity with significant differences between colon and breast cancer (OR:3.3; p = 0.007). 78.7% were satisfied with the information received by their oncologist about their cancer.

Conclusions: Long-term cancer survivors are patiens with major health and socio-economic issues who need a multidisciplinaty follow-up. Despite their median age, more than half had cardiovascular risk factors, sexual difficulties or were retired and more than one-third had anxiety/depression syndrome.

1751P Usability testing of EirV3-a computer-based tool for patient reported outcome measures in cancer

H. Krogstad[1], S.M. Sundt-Hansen[2], M.J. Hjermstad[3], L.Å. Hågensen[4], S. Kaasa[3], J.H. Loge[5], S.X. Raj[1], A. Steinsbekk[6], K. Sand[1]

[1]European Palliative Care Research Centre (PRC) and Department of Clinical and Molecular Medicine, Faculty of Medicine and Health Sciences, Cancer Clinic, Norwegian University of Science and Technology and St.Olavs Hospital, Trondheim University Hospital, Trondheim, Norway, [2]Department of Medicine, St.Olavs hospital, Trondheim University Hospital, Trondheim, Norway, [3]European Palliative Care Research Centre, Institute of Clinical Medicine and Department of Oncology, University of Oslo and Oslo University Hospital, Oslo, Norway, [4]Coordination Unit Orkdal Region, Orkdal Region, Orkanger, Norway, [5]Institute of Basic Medical Sciences, Faculty of Medicine and Department of Oncology, University of Oslo and Oslo University Hospital, Oslo, Norway, [6]Department of Public Health and Nursing, Faculty of Medicine and Health Sciences, Norwegian University of Science and Technology, Trondheim, Norway

Background: Eir Version 3 (V3) is an electronic tool for registration administration of patient reported outcome measures (Eir-Patient) that immediately presents patient scores on the physiciań s computer (Eir-Doctor). Perceived usability is an important determinant for successful implementation.The objective was to assess the number, type, and severity of usability issues of the Eir-Patient and Eir-Doctor modules respectively, when used by cancer patients and physicians in three different settings: 1) outpatient clinics, 2) at home, and 3) at the general practitioner's office.

Methods: A usability evaluation using observations, think-aloud sessions, individual and focus group interviews in patients and their physicians was conducted. Identified usability issues were graded on a severity scale from 1 (irritant) to 4 (unusable).

Results: Overall, 73 Eir registrations were performed by 37 patients, and used by 17 physicians in clinical consultations. All patients were able to complete the Eir-Patient symptom registration, which was perceived easy. Seventy-two usability issues were identified. None of them were graded as unusable. 62% of the identified usability issues in Eir-Patient were graded as irritant (grade 1), 18% and 20% as moderate or severe (grade 2-3), none as unusable. For the Eir-Doctor module, 46% of the identified usability issues were graded as irritant, 36% as moderate and 18% as severe. Observations of physician consultations showed that Eir-Doctor was intuitive and easy to use.

Conclusions: Patients and physicians found EirV3 easy to use. Results indicate that EirV3 is usable for a heterogeneous population of cancer patients, in different settings. In the subsequent Eir-version, issues in the severe and moderate categories have been changed, to optimize the usability and feasibility of using real time PROMs in clinical practice.

1752P Monitoring quality of life in Dutch women with breast cancer: The Care Notebook study

R.T. Lugtenberg[1], M.J. Fischer[2], F. de Jongh[2], K. Inoue[3], A. Matsuda[4], S.R.S. Ramai[5], J.W. Nortier[1], H. Putter[6], K. Yamaoka[7], K. Kubota[8], K. Kobayashi[9], A.A. Kaptein[2], J.R. Kroep[1]

[1]Medical Oncology, Leiden University Medical Center (LUMC), Leiden, Netherlands, [2]Medical Psychology, Leiden University Medical Center (LUMC), Leiden, Netherlands, [3]Division of Breast Oncology, Saitama Cancer Center, Ina, Japan, [4]Hygiene and Public Health, Teikyo University School of Medicine, Tokyo, Japan, [5]Pulmonology, Leiden University Medical Center (LUMC), Leiden, Netherlands, [6]Medical Statistics, Leiden University Medical Center (LUMC), Leiden, Netherlands, [7]Graduate School of Public Health, Teikyo University, Tokyo, Japan, [8]Division of Pulmonary Medicine and Oncology, Nippon Medical School, Tokyo, Japan, [9]Respiratory Medicine, Saitama Medical University International Medical Centre, Saitama, Japan

Background: For many patients the diagnosis and treatment of cancer are associated with negative consequences for their physical, psychological and social well-being. However, patients' needs for care cannot be addressed unless they are recognized by healthcare providers (HCP). The use of quality of life (QoL) assessments with feedback to clinicians might facilitate the discussion of QoL-items, resulting in improved QoL.

Methods: Women with stage I-IIIB breast cancer treated with chemotherapy were included in this randomised study. All respondents completed questionnaires regarding QoL, illness perceptions, self-efficacy, satisfaction with communication, and distress at three moments. Women in the experimental arm completed 'the Care Notebook' (CNB) questionnaire, assessing QoL, distress and care needs before every hospital visit. Results were automatically stored and presented in patients' medical files. From the 2nd visit onwards, patients and HCPs received a copy of the latest QoL overview before the consultation. Women in the control arm received care as usual. Audio-recordings were used to investigate effects on communication and patient management.

Results: presented here are drawn from a collaborative study between Japan and the Netherlands. From July 2012 to May 2016, 60 out of 113 Dutch patients were randomized to the experimental arm. In the experimental condition, more QoL-items 'were discussed (0.7 items each visit, p=.04), compared with the control condition, especially regarding disease-specific and psychosocial issues (p<.01). There were no differences in patient management, QoL, illness perceptions or distress. Patients in the experimental arm had higher scores on satisfaction with communication (p<.05). All patients perceived high self-efficacy in interacting with HCP. Patients in the intervention condition perceived the tool as user-friendly and a valuable addition to regular care.

Conclusions: Use of the QoL-monitor 'The Care Notebook' resulted in more frequent discussion of psychosocial and disease-specific issues, associated with high levels of patients' satisfaction. However, patient management and patients' QoL were unaffected by the intervention.

1754P Prognostic factors for critically ill patients with solid cancer tumours admitted to a medical intensive care unit

C. Baylot[1], A. Francopoulo[2], A. Quivy[1], O. Guisset[3], G. Hilbert[4], E. Frison[2], A. Ravaud[1], A. Daste[5]

[1]Department of Medical Oncology, CHU Bordeaux Hopital St. André, Bordeaux, France, [2]Medical Information Department, CHU Bordeaux, Bordeaux, France, [3]Department of Medical Intensive Care Unit, CHU Bordeaux Hopital St. André, Bordeaux, France, [4]Department of Medical Intensive Care Unit, CHU Bordeaux, Hôpital Pellegrin, Bordeaux, France, [5]Gironde, CHU Bordeaux Hopital St. André, Bordeaux, France

Background: The decision to transfer patients (pts) with solid cancer tumours to an intensive care unit (ICU) is still controversial and difficult. Few studies have assessed the outcome for these patients. The aim of this study was to identify 30-day prognostic factors/mortality for pts with solid cancer tumours admitted to an ICU.

Methods: We conducted a retrospective cohort study of all consecutive pts with solid cancer tumours admitted to ICUs at Bordeaux University Hospital, between January 2010 and December 2015. The study end point was 30-day mortality. Secondary end points were to describe the characteristics and outcomes for pts, and ethical practices.

Results: We included 235 patients with solid tumours. Most of them were in a metastatic setting (60%).The most common causes for ICU admission were sepsis (56%) and/or respiratory failure (52%). ICU, 30-day, 90-day mortality rates were 24%, 36% and 50% respectively. After ICU stay, 44% of pts had restarted an anti-tumoral treatment. In multivariate analysis and after excluding SAPS 2 score, two or more organ failures (p = .005) and being under non-curative care (p = 0.028) were independent prognostic factors of 30-day mortality. A support person was designated in 81% of cases, advance directives expressed in 2% and collective decision reported in 21%. Limitation of life-sustaining therapy was decided for 23% and 43% of pts before admission and during the ICU stay, respectively.

Conclusions: The number of organ failures is a rapidly assessable variable that can help oncologists and intensive care specialists in their decision. A support person is often designated but advance directives are still unusual.

1755P A pilot study of exercise intervention in patients with metastatic cancer: Feasibility, safety, and patient reported outcome

J-H. Park[1], E.Y. Kim[2], K.D. Park[3], S.M. Kang[4], H. Ahn[1], Y.S. Kim[1], I. Park[1], S.J. Sym[1], D.B. Shin[1]

[1]Medical Oncology, Gachon University Gil Medical Center, Incheon, Republic of Korea, [2]Radiology, Gachon University Gil Medical Center, Incheon, Republic of Korea, [3]Rehabilitation Medicine, Gachon University Gil Medical Center, Incheon, Republic of Korea, [4]Pulmonology and Allergy, Gachon University Gil Medical Center, Incheon, Republic of Korea

Background: Skeletal muscle loss is a central component of cancer cachexia syndrome and is a poor prognostic factor in patients with cancer. We investigated prevalence of sarcopenia and the feasibility of exercise intervention in patients with newly diagnosed advanced solid cancer.

Methods: Between July 2017 and February 2018, consecutive patients with newly diagnosed advanced solid cancer were enrolled to our prospective cohort. Sarcopenia was defined as the third lumbar vertebra(L3) muscle index of less than 55 cm^2/m^2 for men and of less than 39 cm^2/m^2 for women. Patients were recruited to participate in a 12-week, combined resistance and aerobic exercise program consisted of supervised, hospital-based (2x/week) and home-based training (3x/week), during the first-line palliative chemotherapy. The primary endpoint were feasibility and safety of the exercise intervention. Pre- and post- exercise intervention skeletal muscle mass by bioelectrical impedance analysis(BIA) and patients' quality of life questionnaires were measured and compared.

Results: Among 76 patients enrolled in the prospective cohort, sarcopenia was present in 58 (76.3%) patients (94.3% in men, 34.8% in women). Nineteen patients was enrolled in the exercise program, however 5 patients withdrew consent before commencement. Reasons for withdrawal were health concern (n = 2), distance to the hospital (n = 1) and unspecified (n = 2). The completion rate of the 12-week exercise program was 78.6% (11/14). Disease progression (n = 2) was the main reason for early discontinuation. The adherence rate of the supervised exercise session was 78.1% (207/265) and there was no adverse event associated with the exercise training. Among participants in the exercise program, there was no significant change in skeletal muscle index from baseline to post-intervention (mean, $9.4\pm1.3kg/m^2$ vs $9.4\pm1.2kg/m^2$, p = 0.982). FACIT-fatigue scale was non-significantly improved after the exercise intervention (mean, 35.2 ± 10.4 vs 38.2 ± 9.8, p = 0.635).

Conclusions: Exercise interventions appear to be feasible and safe in patients with advanced solid cancer and might have a role of preventing skeletal muscle loss without fatigue exacerbation during palliative chemotherapy.

1756P A prospective analysis of 30-day mortality following palliative chemotherapy at an Australian tertiary cancer centre

J.A. McCracken[1], A. Dabscheck[1], M. Coperchini[1], I. Hornung[2], A. Jalali[2], G. Akers[2], A. Karahalios[3], L. Lipton[2]

[1]Palliative Care, Western Health, St Albans, Australia, [2]Medical Oncology, Western Health, St Albans, Australia, [3]Melbourne School of Population and Global Health, The University of Melbourne, Parkville, Australia

Background: 30 day mortality for patients receiving palliative intent chemotherapy has been suggsted by the 2008 NCEPOD as a measure of quality of cancer care. This has to a number of global audits, with rates ranging from 8-43%. This world first prospective study aimed to benchmark an Australian tertiary cancer centre, and identify factors associated with 30 day mortality.

Methods: A Prospective cohort study of all patients with a diagnosis of malignancy referred for palliative intent intravenous chemotherapy to the Western Health Chemotherapy Day Unit from the 8th December 2014 to 8th December 2015. The primary outcome was death within 30 days of receiving palliative intent chemotherapy.

Results: A total of 314 patients were enrolled in the study. The average age was 63 years, 45% were female, and 60% were born overseas. 98 patients died during the audit period. Of these, 21 (6.6%) died within 30 days of commencing palliative intent chemotherapy, and 60 (18.8%) died more than 30 days after receiving chemotherapy. Of the 34 patients that were referred, but did not start chemotherapy, 17 (52%) died. Multivariable logistic regression found that patients who had been referred to palliative care and received chemotherapy were more likely to die within 30 days, although this did not reach statistical significance. There was no difference in mortality rate by gender, age, tumour type, number of lines of previous chemothearpy, or patient performance status. Patient's who commenced chemotherapy were more likely to die in hospital (n = 44, 74%), as those who were referred but did not commence chemotherapy were more likely to die at home (n = 9, 50%). 199 patients ceased chemtoehrapy during the study period, with the most common reason being progression of disease (n = 78, 39.2%), and toxicity (n = 60, 30.2%).

Conclusions: This prospective cohort study demonstrated taht 6.6% of patients died within 30 days of administration of palliative intent chemotherapy. Multivariate analysis did not identify any pre-specified variables that were significantly associated with 30 day mortality. in our study, the strongest predictor of 30 day mortality was referral to outpatient palliative care.

1757P Characterisation of oncologic patient visits at the ED at an Austrian tertiary care center

B. Pauzenberger[1], T. Fuereder[2], A. Laggner[3], C.C. Zielinski[2], C. Minichsdorfer[2]

[1]Clinical Division of Oncology, Department of Medicine I, Medizinische Universitaet Wien, Vienna, Austria, [2]Clinical Division of Oncology, Department of Medicine I & Comprehensive Cancer Center, Medizinische Universitaet Wien, Vienna, Austria, [3]Department of Emergency Medicine, Medizinische Universitaet Wien, Vienna, Austria

Background: Oncologic patients with tumor or therapy associated complications often seek out the ED as first contact point. Next to the rare classic oncologic emergencies, other causes are supposed to be more frequent. However, little is known about other reasons of patients with cancer to consult the ED.

Methods: The study is a retrospective data analysis of emergency visits of patients with active cancer or adjuvant therapy, who were taken by ambulance to the ED. From 1.1.2017–31.7.2017 data from all patient contacts were collected. The medical history of adult patients were searched for diagnosis of active malignant disease or adjuvant therapy, to be eligible for this study.

Results: From a total of 1029 patient contacts 743 met the inclusion criteria. 425 male contacts (57%) and 318 female contacts (43%) were recorded. The median age was 67 years. The vast majority of patients (648, 87%) were in a palliative setting. 339 patients (46%) were under active treatment and 111 patient contacts (15%) were treatment associated. 384 patient contacts (52%) were tumor related. The most common malignancies were lung cancer (141, 19%), pancreatobilliary cancer (73, 10%), colorectal cancer (67, 9%) and breast cancer (54, 7%). The most frequently reasons for ED consultations were detorriation of general condition (140, 19%), pain (130, 18%), dyspnea (106, 14%) and fever (97, 13%). The most common diagnosis were infections (142, 19%) with pneumonia as the leading cause (61, 8%). Followed by pain (130, 18%), with cancer pain beeing the most common complication (52, 7%) and tumor progression (103, 14%). Data regarding OS until the date of censorship (28.2.18), 3 month mortality (3MM) and factors possibly influencing 3MM are yet immature, but will be added at time of presentation.

Conclusions: The majority of cancer patients seeking help at the ED are in a palliative setting. Cancer associated complications pose the most frequent cause for ED consultation. Lung cancer, pancreatobiliary and colorectal cancer present the most common malignancies related to ED visits. The results of the study may help to optimize the supportive treatment of cancer patients and may help to inform both oncological patients and primary care units about frequent complications associated with the diagnosis of cancer.

1758P High proportion of prostate cancer survivors continue to experience a negative impact on quality of life long after diagnosis: Patient reported outcomes for an Australian population-based sample

Q. Tran[1], A.C. Ward[2], K. Lisy[3], J.F. Bishop[4], M. Jefford[5]

[1]Cancer Care Centre, St Stephen's Hospital, Urraween, Australia, [2]Biostatistics, The Social Research Centre, Melbourne, Australia, [3]Department of Cancer Experiences Research, Peter MacCallum Cancer Centre, Melbourne, Australia, [4]Department of Medical Oncology, Victorian Comprehensive Cancer Centre, Melbourne, Australia, [5]Department of Medical Oncology, Peter MacCallum Cancer Center, Melbourne, Australia

Background: Prostate cancer is a leading cause of cancer-related burden of disease in Australia. Despite careful patient selection and advances in therapy, men may experience complications beyond completion of treatment. There is a lack of robust population-based data regarding the quality of life (QoL) of prostate cancer survivors. We aimed to determine the feasibility of collecting health and quality of life (QoL) data

from an Australian population-based sample of prostate cancer survivors, using standard measures.

Methods: A cross-sectional survey was mailed to a representative group of patients approximately 1, 3 or 5 years post cancer diagnosis. Eligible participants were 18 years or older, had prostate cancer, and registered with the Victorian Cancer Registry. QoL was assessed using the EQ-5D-5L, Functional Assessment of Cancer Therapy-Prostate (FACT-P) and the Social Difficulties Inventory (SDI-21). The results were compared to an English dataset that used similar methods.

Results: 494 of 1078 eligible participations returned the survey (RR 45.8%). The majority reported their prostate cancer had responded fully to treatment (69.9%). QoL was similar between the Australian and English data, and at 1, 3 and 5 years post diagnosis. Symptoms were commonly reported; from FACT-P: erectile dysfunction 84%; problems with satisfaction with present comfort level 74%; poor appetite 61%; aches and pains that bother me 61%; and from the EQ-5D-5L: anxiety 32%. Improved QoL and improved social wellbeing was associated with full response to treatment (EQ-5D-5L, $p \leq 0.001$; SDI-21, $p \leq 0.01$). Reduced QoL was associated with not having a care plan (EQ-5D-5L, $p \leq 0.01$) and having another medical condition (EQ-5D-5L, $p \leq 0.001$; SDI-21, $p \leq 0.01$).

Conclusions: The method of assessment is feasible in the Australian setting. A high proportion of men experience difficulties that continue to impact their QoL long after diagnosis. This highlights an unmet need and that a process to identify and respond to these issues is needed. Care plans may assist.

1759P A systematic approach to smoking cessation in regional cancer centres in Ontario, Canada

W.K. Evans[1], E. Cameron[2], M. Haque[2], N. Schwartz[2], S. Khan[2], R. Truscott[2]

[1]Oncology, McMaster University, Hamilton, ON, Canada, [2]Population Health and Prevention, Cancer Care Ontario, Toronto, ON, Canada

Background: Cancer patients who continue to smoke gain less benefit from treatments, experience greater toxicities, are at increased risk of cancer recurrence and second primaries, experience poorer quality of life and decreased survival. Despite awareness of the negative health benefits of continued smoking after a diagnosis of cancer, a systematic approach to help newly diagnosed cancer patients in cancer centres to quit smoking is uncommon.

Methods: In 2012, Cancer Care Ontario established a framework to implement smoking cessation (SC) in all 14 regional cancer centres (RCCs) in the province of Ontario, Canada. The Framework included: use of the 5A's (ask, advise, assess, assist, arrange), recruitment of regional champions to promote the program, and data collection to document that new ambulatory cancer patients were screened for smoking status, advised on the health benefits of cessation and recommended a referral for cessation support. Screening rates became a performance metric to drive implementation and were reviewed quarterly with provincial and regional leaders. During fiscal 2014/15, just over 50% of patients were screened for smoking status. Recent efforts to improve performance include the transition to the 3A's (ask, advise, act) model, using proportion of smokers accepting a referral for SC services as a performance metric, and use of an "opt-out" approach to referrals where tobacco users are automatically referred to cessation services. An environmental scan and site visits resulted in RCC site-specific improvement plans.

Results: The majority of RCCs are exceeding the screening target of 70% (5 centres with proportions $> 80\%$) but the proportion of smokers accepting a referral remains low. The opt-out referral approach is anticipated to increase referral rates and preliminary data are encouraging for centres that have transitioned to the opt-out approach.

Conclusions: To improve program efficiency and impact, Cancer Care Ontario's provincial smoking cessation initiative has transitioned from a 5 to 3 A's model and introduced an opt-out referral process. Front-line staff are adopting the simplified approach and early results show a promising increase in the number of smokers accepting referrals for SC services.

1760P A longitudinal study of a new point-of-care nerve conduction device for quantitative assessment of chemotherapy-induced peripheral neurotoxicity

A. Matsuoka[1], O. Maeda[1], A. Mitsuma[1], K. Uehara[2], G. Nakayama[3], M. Nagino[2], Y. Kodera[3], Y. Ando[1]

[1]Clinical Oncology and Chemotherapy, Nagoya University Hospital, Nagoya, Japan, [2]Surgical Oncology, Nagoya University Hospital, Nagoya, Japan, [3]Gastroenterological Surgery, Nagoya University, Graduate School of Medicine, Nagoya, Japan

Background: Chemotherapy-induced peripheral neurotoxicity (CIPN) exacerbates cumulatively and dose-dependently. Assessment of CIPN usually depends on subjective grading scales, such as the Common Terminology Criteria for Adverse Events (CTCAE). We previously validated a newly developed point-of-care nerve conduction device (POCD) for the quantitative assessment of CIPN (Cancer Sci 2016). The aim of the present study was to prospectively assess CIPN using this POCD.

Methods: Patients scheduled to receive 8 cycles of adjuvant CapeOX therapy (capecitabine and oxaliplatin) for colorectal cancer were enrolled. Sural nerve amplitude potentials (SNAP, μV), a quantitative measure of the axonal degeneration, and sural nerve conduction velocity (SNCV, m/s), that of the degree of demyelination, were recorded using a portable and automated POCD (DPN-Check®, Neurometrix Inc., Waltham, MA, USA) at baseline, each cycle of chemotherapy, and within 1 month after the end of chemotherapy. The severity of CIPN was evaluated according to the CTCAE. The total sum of SNAP/SNCV was calculated for each patient, and compared according to each CTCAE grade.

Results: A total of 39 patients (M/F: 22/17; median age 61 years, range 36-76; worst CTCAE G1/G2/G3: 25/10/4) were enrolled. Mean SNAP/SNCV at baseline, each cycle of chemotherapy, and within 1 month after the end of chemotherapy are shown in the table. SNAP decreased significantly during each cycle of chemotherapy (repeated ANOVA, $P < 0.001$), whereas SNCV remained relatively unchanged. The mean total sum of SNAP was 112.6±36.8 G1, 69.8±19.2 G2, and 44.8±12.8 G3. The mean total sum of SNCV was 451.1±34.9 G1, 454.2±24.7 G2, and 429.8±30.1 G3. The total SNAP differed significantly among each CTCAE grade (ANOVA, $P < 0.001$), whereas the total SNCV did not.

Conclusions: This POCD demonstrates SNAP-dominant neuropathy in patients who receive oxaliplatin, indicating axonal degeneration as a mechanism of CIPN.

Clinical trial identification: UMIN000017868.

1761P Risk of health-related quality of life events and pulmonary toxicities in recurrent ovarian cancer patients treated with poly adenosine diphosphate ribose polymerase (PARP) inhibitors maintenance

K.Z. Thein[1], A. Sultan[1], M.H. Zaw[2], M.M. Han[3], N.H. Yu[4], H.P. Igid[1], C. Jones[1], N. D'Cunha[1], S. Awasthi[1], F. Hardwicke[1]

[1]Hematology Oncology, Texas Tech University Health Sciences Center, Lubbock, TX, USA, [2]Internal Medicine, The Brooklyn Hospital Center, Brooklyn, NY, USA, [3]Oncologic Emergency, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [4]Internal Medicine, Kingsbrook Jewish Medical Center, Brooklyn, NY, USA

Background: Pain and fatigue are the major determinants of health-related quality of life (HRQOL) in cancer patients undergoing chemotherapy. Ovarian cancer is the seventh most common cause of cancer in women worldwide. PARP inhibitors maintenance has shown to improve survival in recurrent ovarian cancer patients with notable toxicities. We undertook a systematic review and meta-analysis of randomized controlled trials (RCT) to determine the risk of HRQOL events and pulmonary toxicities.

Methods: We conducted a comprehensive literature search using MEDLINE, EMBASE databases and meeting abstracts from inception through March 2018. Phase III RCTs that mention HRQOL events and pulmonary toxicities as adverse effects were incorporated in the analysis. Mantel-Haenszel (MH) method was used to calculate the estimated pooled risk ratio (RR) with 95% confidence interval (CI). Fixed effects model was applied.

Table: 1760P

	baseline	2nd	3rd	4th	5th	6th	7th	8th	afterwards
SNAP (μV)	15.2±8.9	12.7±5.3	12.8±6.7	11.9±5.1	9.8±4.1	9.2±2.9	8.4±3.9	7.7±3.7	7.4±4.1
SNCV (m/s)	52.7±5.6	52.7±4.4	53.7±5.1	52.5±5.9	50.4±5.2	48.0±5.8	47.3±4.1	46.3±4.4	46.1±4.7

Results: Three phase III RCTs with a total of 1401 patients with recurrent ovarian cancer were eligible. The study arms used olaparib or niraparib or rucaparib while the control arms utilized placebo. The randomization ratio was 2:1 in all studies. The RR of all-grade side effects were as follows: fatigue, 1.54 (95% CI: 1.37 – 1.73, P < 0.001); back pain, 0.93 (95% CI: 0.70 – 1.24, P = 0.64); arthralgia, 1.05 (95% CI: 0.79 – 1.40, P = 0.69); headache, 1.75 (95% CI: 1.34 – 2.29, P < 0.001); decreased appetite, 1.76 (95% CI: 1.36 – 2.28, P < 0.001); cough, 1.87 (95% CI: 1.33 – 2.63, P < 0.001); dyspnea, 2.39 (95% CI: 1.64 – 3.48, P < 0.001); and upper respiratory infections (URI), 1.71 (95% CI: 1.16 – 2.53, P = 0.007). The RR of high-grade side effects were as follows: fatigue, 3.94 (95% CI: 1.90 – 8.17, P < 0.001); back pain, 0.49 (95% CI: 0.10 – 2.48, P = 0.39); arthralgia, 2.00 (95% CI: 0.22 – 17.82, P = 0.53); headache, 1.00 (95% CI: 0.18 – 5.47, P = 0.99); decreased appetite, 1.16 (95% CI: 0.17 – 7.82, P = 0.87); and dyspnea, 1.28 (95% CI: 0.30 – 5.48, P = 0.73).

Conclusions: Our study showed that the risk of developing any-grade headache, decreased appetite, cough, dyspnea and URI as well as all grades of fatigue with PARP inhibitors was high. Prompt intervention with good supportive care is required.

1762P Chemotherapy-induced peripheral neurotoxicity (CIPN): What are patients telling us?

G. Cavaletti

School of Medicine and Surgery, Università degli Studi di Milano Bicocca, Monza, Italy

Background: This is a secondary analysis of the original CI-PeriNomS study dataset to formally test in CIPN patients: a) which is the correlation between patients' perception of activity limitation and actual neurological impairment, and b) how the responses to simple questions regarding daily activities potentially related to sensory and/or motor impairment are interpreted by the treating oncologist.

Methods: For the purposes of the current study we have analyzed data on the presence (frequency) of CIPN-associated peripheral nerve damage, without taking into account its severity. Comparison was performed between the oncologists' responses and the scores obtained in strength and vibration detection threshold using the Total Neuropathy Score (clinical, TNSc) criteria compared to patients answers to 8 tasks scored as "impossible" to be performed by at least 5% of the patients.

Results: The distribution of the scores attributed by oncologists to each daily life maximum limitation ("impossible") allowed categorizing the responses into 3 groups: Group 1 included the limitations that the oncologists attributed mainly to motor impairment (item median motor score = 7, item median sensory score 2-3), Group 2 consisted of limitations mainly attributed to sensory impairment (item median sensory score = 8, item median motor score = 1-2) and Group 3 included limitations with uncertain motor and sensory impairment (item median sensory score = 4-6, item median motor score = 5). We demonstrate that the interpretation of patients' report provided by the panel of oncologist is poorly consistent with the actual neurological impairment, and that activity limitations capture more than simple impairments and reflect a broader impact than impairment measures.

Conclusions: These observations form a critical basis for further research on the core set of outcome measures needed for future trials in CIPN and at the same time suggest a careful use of available PROs alone as main endpoints in CIPN trials. Presented on behalf of the CI-PeriNoms study group.

Legal entity responsible for the study: CI-PeriNoms study group.

1763P Malnutrition in cancer patients: Is late diagnosis a missed opportunity to improve care?

C. Tlemsani[1], G. Zalcman[2], R. Bernard[3], A. Zerouali[3], F. Goldwasser[4]

[1]APHP, Hôpital Cochin, Paris, France, [2]Oncology, Hôpital Bichat, Paris, France, [3]Baxter Healthcare, Guyancourt, France, [4]Oncology, Hôpital Cochin, Paris, France

Background: Malnutrition (MN) related metabolic defects, through the tumor or its treatment, can negatively impact on cancer patients' outcomes. Yet, MN is often undiagnosed and untreated. This study investigated diagnoses of MN and hospital resource use in patients with gastro-intestinal (GI) system cancers.

Methods: The study used the French Hospital database PMSI MCO. We identified 644,720 GI cancer patients (colon-rectal-anal, liver/biliary tract, pancreas, stomach, esophagus) with a first related hospital stay (no stay 2 years pre-index) between 2013 and 2016. Patients were grouped into: no MN diagnosis, MN diagnosis at first hospitalization and MN diagnosis after first hospitalization. Resource use (number and duration of hospitalizations) was analyzed by patient group, GI cancer category and by presence/absence of metastases. Propensity score matching for key characteristics, such as age, gender and comorbidities was used to adjust for differences between groups.

Results: MN diagnoses at first hospitalization occurred in 10% of patients, 13% were diagnosed after first hospitalization and 77% had no diagnosis of MN during the study period. Patients without MN had on average 5.2 hospitalizations of 13 days. Compared to MN diagnosed at first hospitalization, hospital stays were twice as frequent and longer when MN was diagnosed after 1st cancer hospitalization (6.8 vs. 13.9 stays and 38 vs. 53 days, respectively). After propensity score matching, a significantly higher frequency of hospitalizations in those with a late compared to early diagnosis of MN remained. Differences in frequency and duration of hospitalizations increased linearly with a later MN diagnosis (1, 3, 6 months after first hospitalization), with the strongest association in patients without metastases.

Conclusions: The data suggests that an earlier diagnosis of MN should help to reduce frequency and length of hospitalizations, particularly in patients without metastases, potentially improving patients' clinical outcomes and reducing health economic costs. Further research is warranted to understand the potential of early nutritional therapy in improving cancer patients' outcomes and in reducing resource use.

1764P A survey on acceptable nomenclature in addressing patient needs among the delegates of a national conference on supportive medicine

R.D. Arora

Palliative Medicine, All India Institute of Medical Sciences, New Delhi, India

Background: The scope and ambit of services offered in an integrated inpatient palliative medicine unit located in tertiary cancer centre is explored through various questions pertaining to multiple domains encompassing clinical management of advanced cancer patients. The survey tests the attitudes of the respondents while laying the foundation of building and sustaining a novel model where Supportive cancer care services, Pain management and Palliative medicine interventions (including End of life care) are offered as part of a continuum.

Methods: The survey was carried out among the registered delegates of the annual national conference of the Indian Association of Palliative Care.

Results: 48 percent (84/175) felt that Palliative medicine and Supportive oncology are mutually exclusive domains in patient management. 40 percent (71/175) agreed that the terms Palliative medicine and Palliative care are different entities in patient management. 47 percent (96/203) agreed that the term Palliative medicine should be substituted by Supportive medicine while only 22 percent (38/172) agreed that using the term Supportive oncology would be justified in place of Palliative medicine. 34 percent (59/169) felt that substitution of the term Palliative medicine by Supportive oncology might remove the stigma associated with the referral of the patient to avail these services.

Conclusions: These results reflect the multiplicity of views which underlie existing divergent schools of thought in this nascent subspeciality. An indigenous academic model based on the premise of closeknit integration of supportive care and medical oncology which dispels the myth of pure palliation as a segregated entity is the need of the hour. The services offered should reflect the understanding that recognition and management of supportive care needs of cancer patients is of utmost important in making the model economically viable and socially sustainable.

Legal entity responsible for the study: Rahul D. Arora.

Funding: Has not received any funding.

Disclosure: The author has declared no conflicts of interest.

1765P A survey on purview of palliative medicine services among the delegates of a national conference on supportive medicine

R.D. Arora

Palliative Medicine, All India Institute of Medical Sciences, New Delhi, India

Background: The provision of personalized, symptom oriented, patient centered care at an early stage in the patient's trajectory of illness is the philosophy that underlies supportive care.

Methods: A questionnaire based on clinical scenarios encountered in the integrated inpatient palliative medicine unit was carried out among the registered delegates of the annual Indian association of Palliative care conference.

Results: Interventional pain procedures (65.49 percent) and counseling regarding goals of care and provision of palliative sedation (57.75 percent) were considered the main indications for an inpatient palliative medicine unit admission. A majority (66.89 percent) agreed that the duration of inpatient stay should be defined by the stage of the illness. 48.9 percent agreed that pulse oximetry should be available for all inpatients. Acute kidney injury and dyselectrolytemia were considered valid indications for an ICU admission. 36.9 percent felt that use of non-invasive ventilation strategies, antibiotic stewardship, management of sepsis and dyselectrolytemia should be duties of a palliative medicine professional in the ICU. 48.3 percent, 65.31 percent and 50.34 percent of individuals reported that the timing of intervention, healthcare professional involved and subset of patients involved were the differences between supportive oncology and palliative medicine.

Table: 1765P Purview of early palliative medicine

1.	Management of complex psychiatric symptoms	34.87 %
2.	Management of chemotherapy related complications	40.79 %
3.	Counselling regarding goals of care	80.92 %
4.	Assessment of quality of life	73.68 %
5.	Interventional pain management techniques	50.66 %

Conclusions: There is an overlap in nature of supportive medicine services provided by a medical oncology and palliative/supportive medicine team. A practical, cost effective and resource intensive solution lies in building a workforce of health care professionals from palliative/supportive medicine who are well trained in supportive oncology. Inpatient admission is integral to sustain a cost effective model of delivery of supportive medicine services, however a consensus on the guidelines which govern the establishment and functioning of such a unit need to be developed.

1766P Sexual functioning and depression among Egyptian breast cancer patients following surgery and neoadjuvant/adjuvant chemotherapy

S.A. Al Hassanin[1], S. Alsirafy[2]

[1]Clinical Oncology Department, Faculty of Medicine, Menoufia University, Shebin El Kom, Egypt, [2]Palliative Medicine Unit, Kasr Al-Ainy Center of Clinical Oncology and Nuclear Medicine, Kasr Al-Ainy School of Medicine, Cairo University, Cairo, Egypt

Background: Breast cancer and its treatment may have a negative impact of the sexual wellbeing of patients and psychological morbidity may further add to this impact. Little is known about the sexuality of Egyptian patients with breast cancer. This may be due to barriers related to health care professionals, patients and their families and the culture. Aim: To evaluate sexual functioning among Egyptian breast cancer patients following treatment and to determine the relation between their sexual wellbeing and anxiety and depression and other possible factors.

Methods: This prospective cross-sectional observational study included married breast cancer patient from 20 to 50 years of age who underwent surgery and received neoadjuvant/adjuvant chemotherapy. The Female Sexual Function Index (FSFI) was used to assess their sexual wellbeing. FSFI total score cutoff value of 26.55 was used to determine sexual dysfunction. The Hospital Anxiety and Depression Scale (HADS) was used to assess anxiety and depression. In addition, demographic and clinical data were collected.

Results: Thirty-six out of 38 patients (94.7%) invited to participate in the study signed an informed consent and completed the FSFI questionnaire. The mean FSFI total score was 23.1 ± 7.4 and 61% of patients had sexual dysfunction. The HADS depression scale was >7 (borderline-abnormal/abnormal) in 12 (33%) patients and the HADS anxiety scale was >7 in 25 (69%). Patients with borderline-abnormal/abnormal HADS depression score had a significantly lower FSFI total score compared to those with normal HADS depression score (20 vs. 25, respectively; $p = 0.029$). The HADS anxiety score did not correlate significantly with the FSFI scores.

Conclusions: Unlike the common belief, the majority of Egyptian female breast cancer patients included in this study was willing to discuss their sexual wellbeing. The results suggest that a significant proportion of Egyptian patients who completed treatment for breast cancer experience sexual dysfunction and psychological morbidity and that sexual dysfunction correlate significantly with depression among them.

1767P Supportive care: Patient expectations, availability and uptake

H. Simon[1], J. Viguier[1], G.M. Ganem[1], C. Touboul[1], C. Lhomel[1], H. Naman[1], J.F. Morère[1], F. Eisinger[1],

[1]Medical Oncology, CHRU Brest Hôpital Morvan, Brest, France, [2]Medical Oncology, CHRU Bretonneau, Tours, France, [3]Medical Oncology, Clinique Victor Hugo, Le Mans, France, [4]Statistics, Kantar Health, Paris, France, [5]Medical, Roche, Boulogne-Billancourt, France, [6]Oncology, Centre Azuréen Cancérologie, Mougins, France, [7]Oncology, Hôpital Paul Brousse, Villejuif, France, [8]Département d'Anticipation et de Suivi du Cancer DASC, Institute Paoli Calmettes, Marseille, France

Background: Integrative oncology uses complementary approaches alongside conventional medical therapy to improve quality of life, improve outcomes and reduce the risk of recurrence. The Calista2 survey sought to identify, understand, and rank cancer patients' expectations and utilization of supportive care and activities. Accessibility of such supportive care was also assessed.

Methods: The 82 physicians who accepted to take part in the survey recruited 666 patients. Inclusion criteria were: patients already on specific therapy for breast cancer (BC), colorectal cancer (CC) or lung cancer (LC). Patient questionnaires were self-reported. Questions covered drug management of pain, fatigue, adverse effects of treatments (AE), and sleep disorders, social and psychological support, physical activities, and complementary and alternative medicines. Questionnaires were collected between September 2016 and October 2017. This analysis focuses on the patients' expectations, the supportive care or activity made available to patients, and how they were used.

Results: After exclusion of non-valid patient questionnaires, 467 were analyzed. All cancer localizations combined, patients rated the medical management of adverse events (AE) and pain as highly important (>7/10). Of the 18 items considered, physical activity and management of fatigue were rated as moderately important (5-7/10). The different types of supportive care or activity provided included predominantly the management of adverse events (AE, 81%) and pain (72%), psychological support (56%), and diet/nutrition (49%). Patients primarily used drug management of AE (72%) and pain (61%), diet/nutrition (34%), and self-image improvement techniques (31%). There is a lack of availability of complementary medicine, fatigue management, and relaxation techniques according to 28%, 27% and 24% of patients, respectively.

Conclusions: In our sample, the complementary approaches currently available practically satisfied patient requirements with regards to management of AE and pain. However, these findings also highlight the need for greater access to fatigue management, complementary medicine, and relaxation techniques.

1768P Novel approach for counselling of young cancer patients

U., Seifart[1], T. Langer[2], I-K. Na[3], J. Schulze[4], M.R.F. Freund[4]

[1]Rehabilitation, Clinic Sonnenblick, Marburg, Germany, [2]Department for Pediatric Oncology and Hematology, University Hospital Schleswig-Holstein, Campus Lübeck, Lübeck, Germany, [3]Medical Department, Division of Hematology, Oncology and Tumor Immunology, Charité – University Hospital Berlin, Berlin, Germany, [4]Project Young Cancer Portal, German Foundation for Young Adults with Cancer, Berlin, Germany

Background: About 80% of cancer patients between the age of 18 to 39 survive their disease. They have to cope with different problems than children or older adults. They suffer from short- and long-term social burden as well as from physical disorders associated with the disease or cancer treatment. The objective of this project is to consult patients on options for social support to avert financial problems and to provide medical help to reduce disease- or therapy-associated disorders. The consultation takes place in collaboration with the attending physicians.

Methods: The Young Cancer Portal of the German Foundation for Young Adults with Cancer is a nation-wide, open-access service for young patients. The advisory process rests on an independent softwaredatabase. Patients are initially asked to register with their personal information and to raise their first questions. A questionnaire captures their current situation regarding the disease status and daily life. Expert advice is given in writing, by phone, or in person by a regionally assigned oncologist with extra training. In addition, a special access offers the exchange of expertise of for medical professionals. The protected database allows an anonymous collection and systematic analysis of the data by the foundation.

Results: The module for social law questions started on Nov 24, 2015, the module for endocrinological ques-tions on Sep 22, 2016, and the module on immune defects in Aug 2017. Thus far, 495 people have registered and 345 patients have been advised. Female patients represent 72% of the pool, male patients 28%. The average median age is 30.5 years (ranges from 18 to 52).

Conclusions: The Young Cancer Portal is unique throughout Germany and offers a new way for expert-patient-communication with high acceptance by long-term survivors. The portals basic structure is appropriate for a enables the modular addition of topics. Modules for long-term effects and integrative oncology will be established.

1769P Health-related quality of life priorities in adolescents and young adults (AYA) with cancer: Discrepancies with health care professionals' perceptions

S.E.J. Kaal[1], J.B. Prins[2], R. Jansen[1], E. Manten-Horst[3], P. Servaes[2], W.T.A. van der Graaf[4], O. Husson[4]

[1]Medical Oncology, Radboud University Medical Centre Nijmegen, Nijmegen, Netherlands, [2]Medical Psychology, Radboud University Medical Centre Nijmegen, Nijmegen, Netherlands, [3]Dutch AYA Young & Cancer Platform, IKNL, Utrecht, Netherlands, [4]Division of Clinical Studies, Royal Marsden Hospital Institute of Cancer Research, Sutton, UK

Background: Health-related quality of life (HRQoL) measurement among adolescents and young adults (AYA) with cancer is instrumental to identify areas of need and to organize age-specific psychosocial care. Health care professionals (HCP) are not always aware of what matters most to patients. The aims of the current study were to determine top 10 HRQoL priorities relevant to AYA cancer patients and HCP and to determine discrepancies between items prioritized by AYA and HCP.

Methods: Patients aged 18 to 35 years at time of cancer diagnosis and who had been seen by one of the members of the multidisciplinary AYA team of Radboud university medical center in the Netherlands, and Dutch HCP involved in AYA oncology were invited to complete the Quality of Life for Cancer Survivors questionnaire.

Results: 83 AYA cancer patients and 34 HCP completed the questionnaire. Patients scored significantly lower on negatively formulated HRQoL issues (e.g. fatigue, coping difficulties, feeling isolated) and significantly higher on positive formulated issues (e.g. support from others, overall physical health, happiness). Most important HRQoL items scored by AYA patients were: perceived support from others, distress about initial cancer diagnosis, distress for family, overall quality of life and happiness. HCP perceived distress about initial cancer diagnosis, distress for family, cancer treatment distress, interference of illness with employment/study and fatigue as most important HRQoL items. Patients and HCP had a congruence on 5 out of 10 HRQoL items where distress about initial cancer diagnosis, distress for family and cancer treatment distress were the main overlapping issues. There was a incongruence on fatigue, sexuality and concerns about fertility as these items only appeared in the top 10 HRQoL items rated by HCP and not in the top 10 for AYA patients.

Conclusions: AYA cancer patients perceived most HRQoL items as less problematic in comparison to HCP, in particular regarding physical symptoms, psychological and social HRQoL issues. The discrepancy between patients and HCP illustrates the importance of patient participation, i.e. involving patients in organizing and prioritizing their own (psychosocial) care.

1770P What information and features do young and older adults with cancer want in their hospital-based social media cancer resource?

C.B. Paulo[1], L. Eng[1], L. Mitchell[2], I. Geist[1], S. Kassirian[1], A. Magony[1], E.C. Smith[1], C. Brown[1], M. Liang[1], K. Hueniken[1], D. Yang[1], W. Xu[1], G. Liu[1], A. Gupta[3], J. Bender[4]

[1]Department of Medical Oncology and Hematology, Princess Margaret Cancer Center, Toronto, ON, Canada, [2]Adolescent and Young Adult Program, Hospital for Sick Children, Toronto, ON, Canada, [3]Department of Hematology and Oncology, Hospital for Sick Children, Toronto, ON, Canada, [4]Department of Epidemiology, Dalla Lana School of Public Health, Toronto, ON, Canada

Background: Social media is increasingly used by patients for cancer information and psychosocial support. Certain information/features may be more desired in a new hospital-based social media cancer resource; these may vary between adolescent-young adult (AYA; age <40) and non-AYA (age 40+).

Methods: Using age specific sampling, cancer patients across all disease sites completed a cross-sectional survey of demographics, health status, and social media/online resource use for cancer education. Clinical information was abstracted.

Results: Of 127 AYA cancer patients and 193 non-AYA (older adult) patients, 100% (AYA) and 92% (non-AYA) stated they use the internet ($p < 0.001$); 95% AYA and 72% non-AYA used social media ($p < 0.001$). When asked about attitudes towards social media, 64% AYA and 50% non-AYA believed they could judge social media information quality; 18% AYA and 18% non-AYA recommended use of current social media resources. When asked what types of features they would want in an online resource for their cancer care, both AYA and non-AYA most frequently reported wanting to view their own personal health records (82% AYA/63% non-AYA), followed by an online library of cancer resources (73% AYA/56% non-AYA), ability to communicate with healthcare professionals (73% AYA/55% non-AYA), and appointment reminders (72% AYA/58% non-AYA). The most frequently desired information for both groups were treatment options (61% AYA/56% non-AYA), causes/risk factors/symptoms (65% AYA/56% non-AYA), and prognosis/outcomes (52% AYA/46% non-AYA). The largest difference in information preference between the two age groups were in wellness programs (62% AYA/39% non-AYA) and work return (42% AYA/20% non-AYA) ($p < 0.001$).

Conclusions: There is significant agreement between AYA and non-AYA patients in the most desired information and features they want in a social media resource, though AYA patients wanted a greater number of features. Patients' desired information suggested a patient preference for more autonomy and insight into their disease, regardless of age. There is a lack of satisfaction with current social media resources. A single set of informational tools can therefore be developed for all adults.

1771P Hypothyroidism in cancer patients received multikinase inhibitors: Risk factors and outcomes

S. Hansuranant[1], H. Nimitphong[2], O. Pattanaprateep[3], R. Phraewphiphat[4], D. Muntham[5], T. Reungwetwattana[1]

[1]Medical Oncology, Ramathibodi Hospital, Bangkok, Thailand, [2]Endocrinology, Ramathibodi Hospital, Bangkok, Thailand, [3]Section for Clinical Epidemiology and Biostatistics, Ramathibodi Hospital, Bangkok, Thailand, [4]Section for Data Health for Informatics Section, Ramathibodi Hospital, Bangkok, Thailand, [5]Department of Mathematic, Rajamangala University of Technology Suvarnabhumi, Nonthaburi, Thailand

Background: Hypothyroidism was a known and common side effect from multikinase inhibitors notably in sunitinib, pazopanib and sorafenib. The goal of this study was to explore risk factors in developing hypothyroid and whether the occurrence of this endocrine adverse event (AE) leading to better survival outcomes.

Methods: Seventy-one renal cell carcinoma (RCC) patients and 136 hepatocellular carcinoma (HCC) patients were retrospectively analyzed. Data relating to the treatment course and development of hypothyroid were collected, extracted and presented in separate cohort.

Results: The incidence of hypothyroidism was 47.8% in RCC patients treated with either sunitinib or pazopanib. For HCC patients whom received sorafenib, the incidence of hypothyroidism was 31.8%. We found no factor significantly associated with hypothyroidism in RCC patients. HCC patients whom had duration of treatment of less than 3 months tend to develop hypothyroidism. There was no significant association between the development of hypothyroid and PFS or OS in RCC patients. In HCC group, euthyroid patients had statistically significant longer mPFS [7.6 vs. 2.2 months; HR = 6.38; 95%CI 1.87-21.8; $p = 0.003$] and mOS (16.9 vs. 5.2 months; HR = 22.96; 95%CI 4.45-118; $p = 0.<001$) than the hypothyroid group.

Conclusions: Hypothyroid is the most common endocrine AE of multikinase inhibitors. There are no significant clinical factors associated with the development of hypothyroid. This AE might serve as a good predictive marker for multikinase inhibitors treatment in HCC patients and their survival outcomes. The larger cohort is needed to confirm this evidence.

1772P Immune related adverse events across cancer types: Incidence, risk factors and survival

D.H. Owen[1], J. Burkart[1], S. Patel[1], L. Wei[2], G. Tinoco[1], D. Liebner[1], K. He[1], P.G. Shields[1], E.M. Bertino[1], C.J. Presley[1], A. Johns[1], E. Folefac[1], T. Olencki[1], D.P. Carbone[1], C. Verschraegen[1], G.A. Otterson[1], K.L. Kendra[1]

[1]Division of Medical Oncology, Department of Internal Medicine, The Ohio State University James Cancer Hospital, Columbus, OH, USA, [2]Center for Biostatistics, The Ohio State University James Cancer Hospital, Columbus, OH, USA

Background: Immune checkpoint inhibitors (ICI) have transformed oncology practice, however serious immune-related adverse events (irAE) occur and are poorly understood. A correlation between irAE and clinical benefit has been suggested in melanoma, non-small cell lung cancer (NSCLC), and renal cell carcinoma (RCC). The incidence of irAEs has been described in clinical trials but risks factors remain undefined. This study reports the incidence and risks factors of irAE in patients (pts) with multiple cancers treated with any ICI, as well as overall survival.

Methods: A retrospective study of pts with any malignancy treated with ICI (alone or in combination) between January 2010 and June 2017 was carried out at The Ohio State University. Grade >= 2 irAEs were abstracted based on the treating physician diagnosis. Overall survival (OS) was calculated from the date of initiation of ICI to death from any cause or date of last follow-up. The associations between irAE incidence

and categorical outcomes were studied using chi-square or Fisher's exact test. The Wilcoxon test was used for continuous outcomes. Survival outcomes were studied using log-rank test or cox regression model.

Results: Of 1,113 pts identified, 417 pts had complete irAE data: 156 pts with melanoma, 117 pts with NSCLC, 33 pts with RCC, and 111 pts with other cancers. irAEs occurred in 120/417 pts (28.78%). Gender, age at treatment, and smoking history were not associated with irAE. Incidence of pneumonitis and colitis were 3.84% and 6%, respectively. Pneumonitis was more common in NSCLC ($p = 0.004$), and colitis was more common in melanoma ($p = 0.016$). Rates of thyroid, hepatic, and neurologic irAE were 5.29%, 4.08%, and 0.84%. irAEs were associated with length of therapy ($p = 0.021$), and were more common in 29 pts treated with combination ICI ($p < 0.001$). For 366 pts with metastatic disease, irAEs were associated with longer survival: median OS 21.1 months vs 9.2 months (HR = 0.48, 95% CI: 0.35 - 0.66, $p < 0.001$). Thyroid toxicity (HR = 0.25, 95% CI: 0.10 – 0.29, $p = 0.002$) and hepatitis (HR = 0.32, 95% CI: 0.12 – 0.85, $p = 0.023$) were associated with longer OS.

Conclusions: Increased awareness of irAE patterns across different cancer and treatment types will allow for rapid identification and treatment of irAE.

1773P Effect of yoga on chemo-radiotherapy induced diabetes and hypertension (CRID-H) among cervical cancer patients at a regional cancer institute in south India

N.K. Nelson[1], I.A. Khaleel[1], M. ROY[2], H.B. Govardhan[2], N. Jasti[2], S. Suresh[2], R. Kashyap[2], L. Lokanath[2]

[1]Radiation Oncology, Kidwai Cancer Institute, Bangalore, India, [2]Radiation Oncology, Kidwai Memorial Institute of Oncology, Bangalore, India

Background: Prior studies suggest the benefits of yoga in maintaining Diabetes and Hypertension. In this study we aim to evaluate the effect of yoga on Chemo-Radiotherapy induced Diabetes and Hypertension (CRID-H) in cervical cancer patients.

Methods: 60 cervical cancer subjects (stage II - IV) undergoing chemo-radiation therapy were randomized into yoga ($n = 30$) and control group ($n = 30$). Yoga group was given loosening, breathing, chanting and meditation for 5 days/ week for 6 weeks. Weekly assessment of Random Blood Sugar and blood pressure was recorded from baseline to discharge. Appropriate statistical analysis was conducted.

Results: 6 yoga and 6 non-yoga patients were found to be known case of hypertension and on medications. During the course of chemo-radiation 4 yoga and 6 non-yoga patients developed hypertension. The systolic pressure among the yoga group remained constant with a mean difference of just 11.3mm of Hg while non-yoga group recorded 37.2mm of Hg Comparative analysis between the two groups show Systolic BP attained significance of $p = 0.3$ and Diastolic BP, $p = 0.11$. Diastolic BP in non-hypertensive patients of yoga group ($p = 0.01$) achieved good significance while hypertensive patients ($p = 0.14$) and all patients ($p = 0.11$) the results incline towards significance. Thus, yoga is effective to maintain BP among non-hypertensive patients and attain moderate control in hypertensive ones. RBS data reveals 5 yoga and 6 non-yoga subjects had pre-existing diabetes. 4 yoga and 6 non-yoga subjects developed diabetes with chemo-radiation by the 3rd week of treatment. Good significance was achieved between the two groups as a whole ($p = 0.02$). The difference was highly significant at $p = 0.009$ among pre-existing diabetic patients.

Conclusions: Adjuvant yoga therapy helps to control CRID-H in cervical cancer efficiently. The control achieved in RBS is highly significant. Considerable effect in hypertension was also observed. The above direction can be employed in future studies with larger sample size. Acknowledgement- Ministry of AYUSH, Government of India.

1774P Fatigue prevalence and adherence to treatment: A real-world data survey and mathematical model application

D.A. Vorobiof, E. Malki, I. Deutsch, M. Bivasbenita

Medical Oncology, Sandton Oncology Centre, Sandton, South Africa

Background: Fatigue is a common symptom reported by cancer patients (pts) and has been previously documented to affect patient's quality of life.

Methods: A real-world data survey was designed to evaluate, from the pts perspective, the fatigue effect and treatment adherenceA survey was created in a digital format. This was sent randomly and replied anonymously by users of the Belong app a dedicated social network for cancer pts and their caregivers. Belong leveraged both push notifications as well as DPROs (Digital patients reported outcome feature) which appeared on user's apps dashboards for their increased engagement.

Results: 505 replies were received from pts (85%) and caregivers (15%). The data was then extracted from the digital platform and analysed. A statistical mathematical predictive model was utilized. A machine learning analytical model was programmed to obtain the results. The most common diagnoses were Breast Cancer (all stages, 34.5%), lung (10.1%) and colorectal cancer (7.7%). 67.1% of the pts were on active treatment at the time of the survey and 11.5% finished the treatment less than 6 months before. 66% of the pts experienced daily fatigue (described as mild, moderate and severe) and 17.2% experienced it weekly. As a direct result of fatigue, 10.1% of all pts reported that their ongoing treatments were delayed, stopped or changed (poor adherence). 137 (27%) of the total number of replies (mainly advanced breast and lung cancers pts) reported severe fatigue and 19% of them confirmed poor treatment adherence. However, better adherence was seen in the subgroup of pts which experienced mild to moderate fatigue.

Conclusions: This survey describes the prevalence and adverse impact of severe fatigue present in certain cancer pts subgroups (advanced breast and lung cancers) which can alter significantly their adherence to planned treatments. Uniquely, while poor treatment adherence was observed in some cancer diagnosis, most of patients who experienced mild to moderate fatigue maintained their treatment schedule. Effective strategies and efforts should aim to solve this common side effect and its deleterious consequences.

1775P A survey on attitude towards euthanasia among delegates of a national conference on supportive medicine

R.D. Arora

Palliative Medicine, All India Institute of Medical Sciences, New Delhi, India

Background: There is a widespread belief that Euthanasia and good palliative medicine are mutually exclusive. It is important to explore whether the philosophy of palliative medicine which lays an emphasis on a good death also recognizes the individual's right to seek death as a means to end suffering.

Methods: A survey exploring the attitude and opinion of respondents on the extent of involvement of Palliative/Supportive medicine professionals in the provision of Euthanasia was conducted among the registered delegates of Indian association of Palliative Care conference 2018.

Results: 55.66 percent (85/153) of the respondents agreed that the debate on Euthanasia was within the purview of Palliative Medicine, while 52.71 percent (78/148) agreed that the provision of Euthanasia was within End of Life care. 61.27 percent (87/152) of the respondents believe that a set of multidisciplinary experts should be introduced to initiate the discussion on Euthanasia in a terminally ill patient when the same is expressly demanded by the patient or family members. A majority (37.68 percent - 52/138) disagreed with the use of the terms Passive and Active euthanasia. A majority of the respondents (51.74 percent - 74/143) also strongly disagreed with the use of the term physician assisted suicide. 42.46 percent (62/146) of the individuals agreed that the right to a good death and Euthanasia were mutually exclusive. 40.13 percent (61/152) agreed that they do not recognize the right to Euthanasia.

Conclusions: The right to seek Euthanasia as a means of a respectable death is a debatable subject which should be approached carefully keeping in mind the distinct socio-politicocultural thread which runs through the moral fiber of each society. The involvement of experts from multiple subspecialities (as suggested by the highest court of law in India) while ignoring the pivotal role of the palliative medicine professional in establishing a framework of guidelines surrounding Euthanasia does not seem to be justified. The importance of having the tenets of law firmly on their side should not be underestimated by Palliative/supportive medicine professionals who are bound by duty to take the lead in the discourse surrounding End of life care.

1776P Acute toxicity of concurrent radiochemotherapy for locally advanced head and neck cancer: A prospective study

E. Dewaele[1], P.J. van Dam[2], B. De Laere[2], C. Verschueren[3], P.M.C. Specenier[3]

[1]Oncology, Sint Trudo Ziekenhuis, Sint-Truiden, Belgium, [2]Oncology, University of Antwerp, CORE, Antwerp, Belgium, [3]Oncology, Antwerp University Hospital, Edegem, Belgium

Background: Concurrent chemoradiation (CCRT) is the standard treatment for patients with inoperable locoregionally advanced squamous cell carcinoma of the head and neck (HNSCC). CCRT can be associated with severe acute toxicity. Usually only the maximum grade of a limited selection of adverse events (AEs) is reported, without mentioning the evolution of toxicity over time. By the lack of the time factor, the global burden of toxicity experienced by the patient is not adequately reflected.

Methods: Adverse events (AEs) were prospectively scored according to the Common Terminology Criteria for Adverse Events (CTCAE) version 4.0 scoring system by 2 dedicated medical oncologists. AEs were evaluated at predefined time point from the start of CCRT up to 21 weeks after the start of CCRT. The cumulative toxicity load was measured by calculating the area under the curve (AUC) from AE score versus time functions. The AUC for each AE was obtained by multiplying the time and grade of each AE during that time. Mean AUC's per patient category (i.e. HPV status, tobacco use, localisation of primary tumour and the use of ICT) were compared by Kruskal-Wallis testing.

Results: Forty patients (31 men), mean age 62.15 years, were included. The primary tumour site was located in 42.5% at the oropharynx and 45% were p16-positive. The AEs, with exception of xerostomia, typically developed in the second and third week of CCRT, with the intensity and frequency increasing during the treatment. Two weeks after ending CCRT (week 9), the side effects decreased. AEs were recorded in 85% (radiation dermatitis), 97% (orofacial pain), 89.7% (stomatitis), and 97.5% (anorexia) of patients. Significant different mean AUCs were seen for hoarseness (non-oropharynx group, $p = 0.027$), alopecia (the use of ICT, $p = 0.00014$), sensory PNP (the use of ICT, $p = 0.00016$), diarrhea (the use of ICT, $p = 0.021$), nausea (p16 positive, $p = 0.047$), and hoarseness (p16 negative, $p = 0.015$). For tobacco use no significant differences were seen.

Conclusions: This prospective trial recorded the maximum intensity and frequency of the different AEs, but also the evolution over time and the global AE load. More prospective trials with a larger number of patients are required to confirm the results.

1778P Chemotherapy effect on daytime sleepiness and contributing factors in older adults with cancer

S. Sadighi[1], B. Saberzadeh-Ardestani[2], B. Khosravi[2], J. Zebardast[2]

[1]Medical Oncology, Cancer Research Centre of Cancer Institute of Iran, Teheran, Iran, [2]Medicine, Tehran University of Medical Sciences, Tehran, Iran

Background: Excessive daytime sleepiness has been related with several functional and psychological disabilities. The objective of this study was to determine the prevalence of excessive daytime sleepiness (EDS) among older Iranian patients with cancer and to analyze the effect of chemotherapy treatment on patients' sleep problems. The relationship between sleep disturbances and physical activity, psychological factors, and demographic data were also explored.

Methods: This cross-sectional study, carried out in Cancer Institute of Iran, consisted of interviews with patients older than 60 years with a solid tumor; once prior to receiving chemotherapy and the second time after two cycles of chemotherapy. Questionnaires consisted of Epworth Sleepiness Scale (ESS), Hospital Anxiety and Depression Scales (HADS), Activities of Daily Living (ADL), Instrumental Activities of Daily Living (IADL), and Eastern Cooperative Oncology Group performance status. Medical data were also gathered from hospital records. Logistic regression was used to identify predictors of excessive daytime sleepiness after chemotherapy.

Results: From the cases, 56.8% were female ($n = 42$). Mean participants' age was 68.26 ($SD = 6.77$) and 78.4% had advanced tumors. Bivariate analysis did not show any significant association between education, tumor stage, and the number of comorbidities and daytime sleepiness after receiving chemotherapy. The results showed a significant association between EDS and receiving chemotherapy. Initially EDS rate was reported as 8.1% which increased to 21.6% after chemotherapy ($P < 0.001$). Anxiety before chemotherapy and number of regions of recurrence, were identified as independent predictors of daytime sleepiness.

Conclusions: Given that, EDS prevalence increases with chemotherapy treatment, and this can affect patients' quality of life and treatment outcomes, caregivers should bear in mind that older patients with cancer, especially those with anxiety and cancer recurrence, need special attention before decision making over starting chemotherapy in order to prevent and manage EDS in the course of chemotherapy.

1779P Group pre-chemotherapy education: Improving patient experience through education and empowerment

K. McIntyre, R. Blackwood, V. Riley, L. Carballo, H. Plant, T. Marler-Hausen

Chemotherapy Daycare, University College Hospital London, London, UK

Background: Patients are not always adequately prepared to start chemotherapy. Information given may not be consistent and little education is given on how patients can be empowered to support themselves to manage side effects of treatment. A pre-chemotherapy education session delivered in a group setting was developed to improve and standardise the information given to patients prior to starting treatment and to reduce the amount of time delivering one to one pre-chemotherapy sessions.

Methods: The project was led by senior cancer nurses who identified four themes that became the focus of the education session; safety, patient experience, process and patient empowerment. The education session was piloted for gynaecology patients before expanding to all new referrals. We collected both qualitative and quantitative data pre and post the sessions using a 0-10 rating scale to evaluate how informed, how worried and how confident patients felt about their prospective treatment.

Results: Since April 2017 we have had a total of 211 attendees, inc relatives which is approx 25% of new patient referrals to Chemotherapy Daycare. When asked about how informed patients felt about their treatment plan they had an average score of 6.7[SD2.5] before the session, increasing by 28% to 8.6[SD1.6] afterwards. When asked about how worried patients felt about their treatment they had an average score of 6.3[SD2.7], decreasing by 19% to 5.1[SD2.8] afterwards. When asked how confident patients felt, they had an average score of 6[SD2.4], increasing by 16% to 7[SD2.3] afterwards. Analysis of the qualitative data showed positive feedback but also highlighted problems with patients understanding the process to treatment.

Conclusions: The education session is a useful way of providing information to patients and improves their confidence. Patients on average become less worried after attending the session although some patients felt more worried, likely to be because they were confronted with the reality of their situation. The main challenges were to engage the clinical teams as this was a change in practice. In response to concerns around travelling distance and numerous appointments we are developing a patient education video for patients to watch at their convenience.

1780P Clinical and psychometric validation of the BreSAS questionnaire for symptom assessment among breast cancer survivors

R. Giusti[1], E. Scarpi[2], K. Cannita[3], R.R. Silva[4], M. Filetti[1], M. Mazzotta[1], R. Rossi[5], V. Cocciolone[3], T. Sidoni[3], M. Tudini[4], C. Ficorella[3], A. Botticelli[1], P. Marchetti[1], G. Porzio[3], L. Verna[3]

[1]Medical Oncology Unit, Azienda Ospedaliero Universitaria Sant' Andrea, Rome, Italy, [2]Biostatistics and Clinical Trials Unit, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola, Italy, [3]Medical Oncology Unit, S. Salvatore Hospital, University of L'Aquila, L'Aquila, Italy, [4]Medical Oncology Unit, Ospedale E. Profili U.O. Oncologia Medica, Fabriano, Italy, [5]Palliative Care Unit, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola, Italy

Background: Today a large number of breast cancer (BC) patients survive many years post diagnosis. The large number of women surviving many years post BC diagnosis has heightened interest in studying long-term effects of cancer on quality of life. A number of cancer-specific health-related quality of life (QoL) measures have been developed but these measures may not be appropriate for use with long-term survivors. With this study we want to evaluate the reliability, clinical and psychometric validity of the BreSAS Questionnaire (BQ) among BC survivors.

Methods: The BQ is a quick, simple 10 items module for the assessment of long-term physical, psychological, sexual and cognitive effects that may influence quality of life (pain, anxiety, depression, fatigue, irritability, quality of sleep, impaired concentration, hot flashes, vaginal itching, other). The total BreSAS score ranks from 0-100, with a low score indicating a better QoL. Patients were not stratified into predetermined clinically distinct groups. QoL data were collected alongside standard outcomes in patients undergoing treatment for BC. Patients complete the BQ, the FACT-ES questionnaire, case report forms for clinical and socio-demographic data at different time points during follow up visits. Reliability, and clinical and psychometric validity of the questionnaires are assessed by correlation analyses, exploration of known group comparisons, and responsiveness to clinical changes.

Results: From September 2015 to February 2016, 149 patients from three Italian oncology units were enrolled. Baseline questionnaires were returned from all and the majority of patients ($n = 134$ - 89%) completed the BQ and FACT-ES in less than 15 min. For reliability, Cronbach's alpha coefficients for each scale were greater than 0.70 in all analyzed symptoms. Convergent validity of BQ showed by Pearson's r demonstrated a high correlation between intensity of symptoms and QoL, especially for pain and depression. No data were provided about reproducibility with test-retest study.

Conclusions: The BQ demonstrates sufficient validity and reliability to support its use to assess patient-reported outcomes and symptom assessment during planned follow-up clinical visits among BC survivors.

[1]Medical Oncology, Hospital de Clinicas Universitario, La Paz, Bolivia, [2]Medical Oncology, Instituto Nacional de Cancerologia, Mexico City, Mexico, [3]Nutrition, Instituto Nacional de Ciencias Medicas y Nutrición Salvador Zubiran, Mexico City, Mexico

Background: Chemotherapy is the cornerstone of the treatment of patients with non-metastatic breast cancer; however, its toxicity may be limiting. It has been reported that some degree of toxicity is present in 98% of patients. To date, no predictors of this toxicity have been identified. Bioimpedance and Phase Angle (PA) are non-invasive procedures to evaluate nutritional status. The aim of this study was to associate the PA with chemotherapy toxicity during (neo)adjuvant (neoCT) treatment of breast cancer.

Methods: 172 patients were prospectively evaluated, 31 were excluded because they had metastatic disease or had received endocrine therapy. Only chemotherapy candidates were enrolled, patient selection criteria were PS 0-1, adequate liver, hematologic and renal function tests. The chemotherapy regimen consisted in AC-T at standard doses and schedules +/- cisplatin in triple-negative tumors. Toxicity was evaluated per NCI CTC v4.0. In all patients bioimpedance by SECA mBCA 514 and Inbody 720 were registered. Statistical analysis was done with SPSS v20.0.

Results: 141 were analyzed, median age was 50 years old, 53.2% of them received neoCT and 46.8% adjuvant CT. Regarding comorbid status, 10.6% had diabetes, 14.0% had hypertension, most of the patients were obese or over weight, median BMI was 27.7kg/m^2 (13.79-39.84 kg/m^2), median waist circumference was 97.30cm (72-135 kg/m^2), overall metabolic syndrome per ATPIII criteria was found in 34.1% of all patients. 54.3% were diagnosed in early stage (I-IIb), 24.2% were HER2-positive, 46.8% were HR-positive and 29.1% were triple negative. Any grade of toxicity was present in 98.6%, 9.9% required hospitalization and in 2.1% toxicity led to death, most common side effects were gastrointestinal 85.8%, fatigue 70.9%, peripheral neuropathy 50.4% and hematologic 48.9%. PA average was 4.8° (2.8-6.26°). We found a correlation between PA and any grade of toxicity ($p = 0.022$). Patients with low PA had more G3-5 toxicity ($p = 0.045$). and more peripheral neuropathy ($p = 0.045$).

Conclusions: PA helps us to assess nutritional status and it seems to be useful as a toxicity predictor. However, external validation is necessary to confirm this benefit.

1782P Hepatitis screening for patients to undergo chemotherapy in Cyprus

P. Kountourakis, A. Agathocleous, E. Kakouri, Y. Marcou, G. Orphanos, F. Kyriacou, D. Papamichael, H.C. Charalambous

Medical Oncology, Bank of Cyprus Oncology Centre, Nicosia, Cyprus

Background: Cancer patients undergoing chemotherapy who have Hepatitis B (HBV) infection may be at elevated risk of liver failure from HBV reactivation, resulting in treatment interruptions/delays, hospitalization, even liver transplantation and death. There is conflicting guidance regarding screening for HBV infection, given that the US Center for Disease Control recommends universal screening for all patients receiving cytotoxic or immunosuppressive therapies, whilst ASCO suggests a selective approach.

Methods: A screening initiative was set up from November 2010, with the aim of identifying patients with chronic infection and referring them for chemoprophylaxis to prevent re-activation. Patients prior to receiving chemotherapy, were offered HBV and HCV testing after being given information leaflets explaining the rationale and implications. Testing included HBsAg surface antigen, HBcAb core antibody, and for those –ve HBsAg and +ve HBcAb, viral load for HBV was recommended. HCV Abs were also tested. Patients HBsAg +ve, or HBcAb +ve and detectable viral load were referred for consideration of antiviral therapy, as were patients with +ve HCV Abs. Patients with Hepatocellular cancer and known Hepatitis infections were excluded from this analysis.

Results: 1353 patients were screened between November 2010 and May 2015. With about 2.2% being positive for HBsAg, 14.8% for HBcAb and 1.2% for HepCAb, however with significant differences for gender and ethnicity. HepBcAb+ve: males 17.19% (99/576), females 12.78% (86/673). HepCAb +ve: Greek Cypriot 0.83% (9/1085), Turkish Cypriot 0% (0/49), Greeks 13.33% (2/15). Further data will be provided on the poster. In a sub-study for HepBcAb +ve but HepBsAg -ve, viral load was negative in 55 and positive in 3 patients. Of interest is that during this period two patients were diagnosed with Hepatitis re-activation, that were not part of this study; both patients had to stop chemotherapy and start anti-viral therapy.

Conclusions: This study confirms the low percentage of Hepatitis B and C infection in the Cyprus population, and that hepatitis re-activation although rare, is a real complication of chemotherapy. Patients born outside Cyprus have a higher incidence of HBV and HCV infections. The results are going to be used to set up local guidelines.

1783P Hepatitis B virus (HBV), hepatitis C virus (HCV) and human immunodeficiency virus (HIV) screening prior to chemotherapy initiation among patients with solid tumors

S.H. Giordano[1], Z. Duan[2], H. Zhao[2], J. Hwang[3], M. Chavez MacGregor[1]

[1]Breast Medical Oncology, Health Services Research, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [2]Health Services Research, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [3]Internal Medicine Department, The University of Texas MD Anderson Cancer Center, Houston, TX, USA

Background: Cancer patients with HVB, HCV and HIV receiving systemic therapy are at risk of reactivation. It is relevant to determine the serologic status of patients at high risk. The CDC has broad screening recommendations for HBV, HCV and HIV. ASCO recommends HBV screening in patients with risk factors, before starting anti-CD20 therapy or stem-cell transplantation. In this population-based study we determine the rates of screening in a large cohort of elderly patients with solid tumors.

Methods: Patients with solid tumors (>66 yo) diagnosed between 2007-2013 and treated with systemic anticancer therapy were identified in the SEER-Medicare database. HBV, HCV and HIV testing was identified using HCPCS codes, the screening period was defined as testing within the first year of cancer diagnosis and no later than 30 days after the first dose of systemic anticancer therapy. Descriptive statistics and logistic regression were used.

Results: A total of 70,488 patients were included. The rates of HBV, HCV and HIV screening were 4.13%, 2.05% and 0.73%, respectively. The median time from cancer diagnosis to screening were 26, 24 and 22 days for HBV, HCV and HIV respectively. Screening rates varied according to cancer type. The highest HBV screening rates were in pancreas (18.9%), melanoma (4.7%) and prostate cancer (5.7%). For HCV, melanoma (7.6%), prostate (3.6%) and anal/penile/vagina/vulvar cancers (2.9%). For HIV, the highest rates were in patients with anal/penile/vagina/vulvar cancers (6.7%), melanoma (2.7%), cervix/endometrial cancers (1.5%). Screening rates increased over time, in addition, males, younger patients and those living in urban areas had higher screening rates (all $p < 0.001$). Asians had the highest screening rates of HBV and HCV while African Americans had the highest HIV screening rate.

Conclusions: HBV, HCV and HIV screening rates were very low among elderly cancer patients receiving systemic anticancer therapy. There was significant variability in the screening rates according to cancer site and patient characteristics. Guidance is needed to select patients that can benefit from screening in order to avoid potential complications.

1784P Rapid identification of bloodstream infection pathogens

N.I. Panova[1], O.I. Kit[1], O.Y. Kutsevalova[1], I.B. Lysenko[1], V.V. Dmitrieva[1], D.A. Rozenko[1], Y.A. Gevorkyan[1], E.E. Pak[1], O.V. Kozyuk[1], E.A. Kapuza[1], O.N. Shatokhina[1], N.V. Nikolaeva[1], E.A. Kalabanova[1], I.S. Mitashok[1], L.Y. Vladimirova[1],

[1]Laboratory of Microbiology, Rostov Research Institute of Oncology, Rostov-on-Don, Russian Federation, [2]Department of Surgical Oncology, Rostov Research Institute of Oncology, Rostov-on-Don, Russian Federation, [3]Department of Hematology, Rostov Research Institute of Oncology, Rostov-on-Don, Russian Federation, [4]Department of Anesthesiology and Reanimation, Rostov Research Institute of Oncology, Rostov-on-Don, Russian Federation, Medical Department, Rostov Research Institute of Oncology, Rostov-on-Don, Russian Federation

Background: Sepsis remains the leading cause of death in cancer patients. Biomarkers allow an objective and reliable possibility of rapid prediction of the septic process. The purpose of the study was to assess the prognostic significance of a rapid and accessible verification of the sepsis pathogens with biomarkers – procalcitonin and Platelia Candida Ag Plus

Methods: The study included 440 patients with clinical manifestations of the inflammatory response in intensive care units, oncological and oncohematological departments. Levels of procalcitonin and Platelia Candida Ag Plus were determined by ELISA together with the blood sterility testing using the BacT/ALERT 3D analyzer.

Results: The most common pathogens (78%) were bacteria (K. pneumoniae. E. coli, less often other members of the Enterobacteriaceae family, P. aeruginosa, A. baumannii, E. faecalis, E. Faecium, etc.); yeasts of Candida spp. – 22%; mixed pathogens – 7.5%, comprising 37.5% bacteria and 62.5% bacterial-fungal pathogens. Positive blood cultures were found in 106 (24.1%) patients. The results of a blood culture took on average 3 days. The use of two biomarkers allowed predicting a pathogen in the first hours after the blood collection. An increase in the levels of one biomarker in 137 (31.1%) patients with negative blood cultures indicated the presence of bacterial, fungal or bacterial-fungal infections. The blood culture examination together with determination of biomarkers improved verification of sepsis pathogens in 243 (55.2%) patients with clinical manifestations of sepsis and hastened preliminary results and empirical therapy.

Conclusions: The study of the blood culture and determination of levels of the biomarkers allowed the prediction of pathogens in 243 (55.2%) patients with clinical manifestations of sepsis. 197 (44.8%) patients with negative blood cultures and normal levels of biomarkers required additional tests.

1785P Pathogens and characteristics of candidemia in hospitals of Rostov-on-Don: Multicenter study in Russia

O.Y. Kutsevalova[1], O.I. Kit[2], N.I. Panova[1], I.B. Lysenko[3], V.V. Dmitrieva[1], D.A. Rozenko[4], E.A. Kalabanova[5], I.S. Mitashok[5], G. Klyasova[6], Y.V. Shatokhin[7], I.V. Snezhko[7], D.V. Martynov[7], V.N. Malygin[7], O.V. Korosteleva[8], A.A. Matsuga[8], K.S. Aslanyan[9], L.Y. Vladimirova[5]

[1]Laboratory of Microbiology, Rostov Research Institute of Oncology, Rostov-on-Don, Russian Federation, [2]Department of Surgical Oncology, Rostov Research Institute of Oncology, Rostov-on-Don, Russian Federation, [3]Department of Hematology, Rostov Research Institute of Oncology, Rostov-on-Don, Russian Federation, [4]Department of Anesthesiology and Reanimation, Rostov Research Institute of Oncology, Rostov-on-Don, Russian Federation, [5]Medical Department, Rostov Research Institute of Oncology, Rostov-on-Don, Russian Federation, [6]Hematology, National Research Center for Hematology, Moscow, Russian Federation, [7]Rostov State Medical University, Rostov-on-Don, Russian Federation, [8]Hospital, Rostov-on-Don, Russian Federation, [9]Rostov Regional Children's Hospital, Rostov-on-Don, Russian Federation

Background: Invasive candidiasis is a serious nosocomial infection developing generally in patients at risk; it is characterized by a severe clinical course and high (10-49%) additive mortality. It develops predominantly in immunocompromised, especially cancer, patients and patients in intensive care units. The purpose of the study was to analyze the etiology of invasive candidiasis and in vitro activity of caspofungin and azoles for isolates of Candida fungi.

Methods: Isolates were obtained in hospital departments in Rostov-on-Don and Rostov region in 2013-2016. Candida fungi were identified using MALDI-TOF MS; interpretation was performed according to CLSI 2012, M27-S4 criteria. Sensitivity testing was performed using the Sensititre system (Trek Diagnostic Systems, England).

Results: 92 Candida isolates were obtained from blood culture: C. albicans - 31.5% (29) and non-albicans - 68.5% (63), including C. tropicalis 30.2% (19), C. parapsilosis 28.6% (18), C. glabrata 19.0% (12), C. krusei 15.9% (10) and C. guilliermondii 6.3% (4). Fungal-bacterial associations were found in 5 cases; such combinations worsened the patient's condition and complicated the treatment. The table demonstrates comparative activities of caspofungin, fluconasole and voriconasole (susceptible – S, intermediate – I, resistant – R) in % to Candida spp.

Table: 1785P

Species	n	Caspofungin S/ I/ R (%)	Fluconazole S/ I/ R (%)	Voriconazole S/ I/ R (%)
C. albicans	29	100/ 0/ 0	82/ 3/ 15	90/ 6/ 4
C. parapsilosis	18	98/ 0/ 2	82/ 4/ 14	88/ 11/ 1
C. tropicalis	19	100/ 0/ 0	90/ 5/ 5	100/ 0/ 0
C. glabrata	12	95/ 5/ 0	86/ 9/ 5	N/A
C. krusei	10	83/ 4/ 13	N/A	100/ 0/ 0

Conclusions: Candida non albicans prevailed among invasive candidiasis pathogens (68.5%), which could be associated with the use of azole antifungal agents for the prophylaxis and empirical therapy. Dominating isolates showed decreased activity to caspofungin and azoles. Acquired resistance to azoles was noted for C. parapsilosis and C. albicans. Special attention should be paid to C. glabrata characterized by high lethality and high resistance rates. The results demonstrate the advisability of microbiological monitoring of invasive candidiasis pathogens.

1786P Antiviral prophylaxis cannot reduce the risk of hepatitis B reactivation during chemotherapy for non-HCC solid tumor patients with lower HBV DNA titer: A retrospective cohort study

Q. Gin[1], A. Zhou[2], L. Yang[2], D. Zhong[3]

[1]Medical Oncology, Tianjin Medical University General Hospital, Tianjin, China, [2]Department of Medical Oncology, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China, [3]Medical Respiratory, Tianjin Medical University General Hospital, Tianjin, China

Background: The high-risk factors related to HBV reactivation during chemotherapy include lymphoma, hematopoietic stem cell transplantation (HSCT), treatment regimen containing rituximab, a high HBV viral load before chemotherapy and baseline prechemotherapy HBeAg positivity. However, the role of antiviral prophylaxis in preventing HBV reactivation in patients with non- hepatocellular carcinoma (HCC) solid tumor and lower HBV DNA titer is unclear.

Methods: Between January 2011 and March 2018, all HBsAg seropositive patients with solid tumor receiving cytotoxic chemotherapy were retrospectively evaluated. The titer of HBV DNA and liver function were routinely examined before chemotherapy. The patients whose titer of HBV DNA was under 100 IU/ml were eligible. HBV reactivation, hepatotoxicity and disruption of chemotherapy attributed to HBV reactivation were compared according to antiviral prophylaxis.

Results: Of 170 consecutive patients eligible for, 102 were treated without antiviral prophylaxis and 68 received antiviral prophylaxis. 55 patients were treated with entecavir, 7 for lamivudine and 6 for adefovir. The two groups were comparable in most clinical baseline characteristic including gender distribution, age, tumor types, tumor stage, the use of prednisone and/or anthracyclines. There was no significant difference between the two groups ($P = 0.587$). Patients without antiviral prophylaxis had a similar prevalence of HBV reactivation (6.8% vs 4.4%, $P = 0.741$) and severe hepatitis attributable to reactivation (4.9% vs 4.4%, $P = 0.882$). No patients died ultimately from fulminant hepatitis. Furthermore, no significant difference in disruption of chemotherapy was noted between patients with or without antiviral prophylaxis (3.9% vs 4.4%, $P = 0.875$).

Conclusions: For patients with non-HCC solid tumors and the titer of HBV DNA less than 100IU/ml before chemotherapy, antiviral prophylaxis failed to further reduce the reactivation of HBV. For such patients, regular monitoring of HBV viral load maybe more reasonable and cost-effective optimal choice.

1787P Prospective observational study to evaluate the persistence of treatment with denosumab (dmab) in patients (pts) with bone metastases (BM) from solid tumors (ST) in routine clinical practice: Final analysis

F. Haslbauer[1], A.L. Petzer[2], M. Safanda[3], A. Tomova[4], M. Porubska[5], Z. Bajory[6], D. Niepel[7], C. Jäger[8], D. Kalinin[9], R. Greil[10]

[1]Oncology, Krankenhaus Voecklabruck, Voecklabruck, Austria, [2]Department of Internal Medicine I - Oncology, Hematology and Gastroenterology, Ordensklinikum Linz Barmherzige Schwestern/Elisabethinen, Linz, Austria, [3]Department of Clinical Oncology, Nemocnice Na Homolce, Prague, Czech Republic, [4]1st Internal Dept, Complex Cancer Center, Plovdiv, Bulgaria, [5]Department of Internal Medicine, St. Elisabeth Cancer Institute, Bratislava, Slovak Republic, [6]Department of Urology, University of Szeged, Szeged, Hungary, [7]Global Medical Affairs, Amgen (Europe) GmbH, Zug, Switzerland, [8]Medical Affairs, Amgen, Vienna, Austria, [9]Biostatistics, Quartesian, Kharkov, Ukraine, [10]Department of Internal Medicine III, Salzburger Landeskliniken - Universitätsklinikum Salzburg, Paracelsus Medizinische Privatuniversität, Salzburg Cancer Research Institute, Salzburg, Austria

Background: Persistence with dmab therapy may impact clinical efficacy in preventing skeletal-related events (SREs), but is undetermined in real-world.

Methods: Single-arm, prospective, observational, non-interventional study in pts with BM from ST (breast, prostate, lung, other) treated with dmab in real-world in Austria, Czech Republic, Hungary, Slovakia, and Bulgaria between 10/2012 and 05/2017. Primary objective: persistence at 24 weeks (wks) (=6 dmab subcutaneous injections; permissible intervals: 4±1 wks). Secondary objectives: persistence at 48 wks, time to non-persistence, calcium (Ca) / vitamin D supplementation, (serious) adverse drug reactions ([S]ADRs) incl. non-adjudicated osteonecrosis of the jaw (ONJ) rate.

Results: 598 patients were included, 451 completed 24 wks, 387 completed 48 wks of study, 211 discontinued before 48 wks due to death (n = 80), loss to follow-up (n = 35), informed consent withdrawal (n = 7), dmab discontinuation (n = 56, [S]ADRs [n = 5]), other reasons (n = 28). 10.9% (n = 65) had previous SREs. Persistence with dmab and safety are shown in the table. Persistence at 24/48 wks was 62.6/40.1% overall, 69.5/45.5% for breast, 69.3/46.6% for prostate, 26.1/10.9% for

lung, and 40.7/21.1% for other cancers. Median (IQR) duration of dmab exposure was 309 days (168.0, 319.0) and 11 doses (6.0, 12.0). The most frequent reason for non-persistence was the violation of one time window. Overall, analgesics use trended towards weaker analgesics over time, with ~60% of pts not requiring any analgesics. Serum Ca remained within the normal range of 2.2 to 2.7 mmol/L throughout the study. ~70% of pts received Ca and vitamin D supplements at baseline, increasing to ~80% at dose 2 and steadily decreasing thereafter.

Table: 1787P

	N = 598
Persistence, % (95% CI)	
At 24 wks	62.6 (58.4, 66.7)
At 48 wks	40.1 (35.9, 44.4)
KM-median (95% CI) time to non-persistence, days	274.0 (232.0, 316.0)
ADRs, n (%)	61 (10.2)
SADRs, n (%)	8 (1.3)
ONJ	3 (0.7)
Incidence of ONJ per pt-year (95% CI)	0.012 (0.004, 0.029)

Conclusions: Persistence (Diel, ESMO 2015) and ONJ rate (Stopeck, JCO 2010, Fizazi, Lancet 2011, Henry, JCO 2011) were comparable with previous reports.

1788P A multicenter retrospective investigation on the efficacy of perioperative oral management in cancer patients

S-I. Yamada[1], S. Soutome[2], T. Hasegawa[3], I. Toujou[4], H. Nakahara[5], M. Kawakami[6], M. Hirose[7], S. Fujita[4], T. Komori[3], T. Kirita[6], Y. Shibuya[7], M. Umeda[2], H. Kurita[1]

[1]Department of Dentistry and Oral Surgery, Shinshu University, School of Medicine, Matsumoto, Japan, [2]Department of Clinical Oral Oncology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [3]Department of Oral and Maxillofacial Surgery, Kobe University Graduate School of Medicine, Kobe, Japan, [4]Department of Oral and Maxillofacial Surgery, Wakayama Medical University, Wakayama, Japan, [5]Department of Dentistry and Oral Surgery, Osaka City University Graduate School of Medicine, Osaka, Japan, [6]Department of Oral and Maxillofacial Surgery, Nara Medical University, Kashihara, Japan, [7]Department of Oral and Maxillofacial Surgery, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan

Background: Patients suffer from various oral complications in cancer treatments. Oral bacteria associate with the onset of dental focal infections and the progression of oral mucositis. Moreover, dental focal infections frequently associate with the onset of bacteremia, sepsis, and pneumonia systemically. The oral function degeneracy with these complications may become obstacle in cancer treatments. In Japan, the comprehensive oral management, including oral care and removal of dental focal infections, are performed in cancer patients. The aim of present study was to investigate the incidence of dental/oral complications in the cancer patients who underwent perioperative oral managements (POMs) based on large number of case series with a multicenter retrospective analysis.

Methods: In cancer patients who underwent POMs, medical records were reviewed and the incidence of oral complications and the efficacy of oral management were investigated retrospectively. This study protocol was approved by the Committee on Medical Research of Shinshu University (♯3639).

Results: Two thousand seven hundred and forty-four cancer patients underwent POMs (1,684 males and 1080 females, mean age 65.9±13.0 years) were investigated in this study. Among 2,744 patients, 2,097 patients (76.4%) started POMs before the initiation of cancer treatment, in which 2,130 patients (77.6%) underwent only oral care, and 391 patients (14.2%) invasive treatment such as tooth extraction. The incidence of dental focal infections during the period of cancer treatment was 8.2%. Acute periodontitis including alveolar abscess was most frequently seen (112 patients, 4.1%). The incidence of grade 2 and 3 oral mucositis was 2.8%. And the fever of unknown origin was seen in 113 patients (4.1%). Among them, dental focal infections were proved to be associated in 7 cases (6.2%). These incidences were thought to be lower than those of previously reports.

Conclusions: The efficacy of oral management in cancer patients might be suggested based on the analysis of large number of patients in this study. However, the further investigation is needed to establish the adequate oral management guideline in cancer patients.

1790P Correlation between fatigue evaluated with a visual analog scale (VAS) and quality of life (QoL) in cancer patients treated with biosimilar epoetin alfa for chemotherapy-induced anemia (CIA): The CIROCO study

J. Desrame[1], J. Loup Mouysset[2], T. Altwegg[3], L. Zelek[4], N. Baize[5]

[1]Institut Privé de Cancérologie, Hôpital Privé Jean Mermoz, Lyon, France, [2]Department of Medical Oncology, Clinique Rambot Provençale, Aix-en-Provence, France, [3]Oncology, Institut de Cancérologie de Bourgogne, Dijon, France, [4]Oncology Department, Hôpital Avicenne, Bobigny, France, [5]Oncology, Centre Hospitalier Universitaire d'Angers, Angers, France

Background: Anemia often occurs in cancer patients receiving chemotherapy. QoL can be affected by symptoms of anemia, fatigue being the most common. Evaluation of QoL with validated tools (eg EORTC QLQ C30) is time-consuming. Correlation between fatigue assessed with a VAS and QoL is unclear. Aim: To determine the correlation between fatigue assessed by a VAS and QoL in cancer patients treated with biosimilar epoetin alfa (Sandoz) for CIA.

Methods: CIROCO is a non-interventional, prospective, multicenter study of adult patients (Full Analysis Set [FAS] population, n = 538) with ≥2 cycles of chemotherapy planned after study inclusion, with CIA and receiving biosimilar epoetin alfa. Data were collected on day of inclusion (T0), and after 2–3 (follow-up; T1) and 4–6 chemotherapy cycles (end of follow-up; T2). Patients and physicians separately assessed fatigue using a VAS (range 0–10); patients assessed QoL with the EORTC QLQ C30 questionnaire.

Results: Data are reported for a subgroup of patients with solid tumors (FAS population, n = 434). Mean (SD) hemoglobin (Hb) at baseline was 9.7 (±0.8) g/dL. Mean (SD) increase in Hb was 1.2 (±1.4) g/dL between T0 and T1 and 0.4 (±1.5) g/dL between T1 and T2. In the safety population (n = 464), 151 (32.5%) had adverse events (AEs; n = 320), 64 patients (13.8%) had serious AEs (n = 144) and 14 patients (3%) experienced AEs considered related to study treatment (n = 25). In the FAS population, between T0 and T2, mean (SD) change in fatigue VAS score (patient-reported) was +5.2 (±92.6) % and mean (SD) change in QoL was 29.9 (±98.0) %. The Pearson correlation coefficient for fatigue VAS score and QoL was –0.4993 ($p < 0.0001$) at T0, –0.5726 ($p < 0.0001$) at T1, and –0.5681 ($p < 0.0001$) at T2. Using fatigue VAS, physician assessment of fatigue was consistent with patient perceptions at T0 (5.0±2.1 vs 5.3±2.2), T1 (4.3±2.2 vs 4.8±2.3) and T2 (4.2±2.3 vs 4.7±2.3).

Conclusions: Biosimilar epoetin alfa was effective in this study, with improvements observed in Hb and QoL. A correlation was observed between reduced fatigue assessed with a VAS and improved QoL.

1791P Quality of life, late effects, and related clinical factors among Korean colorectal cancer survivors

J.S. Park[1], T.I. Kim[2]

[1]Cancer Prevention Center, Yonsei Cancer Center, Yonsei University, Seoul, Republic of Korea, [2]Division of Gastroenterology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea

Background: Colorectal cancer (CRC) is one of the most common cancers worldwide, and the third most common cancer in Korea. Although the number of Korean CRC survivors is estimated over 220,000, we have insufficient survivorship care program to improve survival and quality of life (QoL) of CRC survivors.

Methods: We started to build a prospective cohort on October, 2016, and collected clinicopathological and social factors from 265 Korean CRC survivors in Cancer Prevention Center, Yonsei Cancer Center, Seoul, Republic of Korea. Health-related QoL (HRQOL) was assessed using EORTC-QLQ C30, CR29, ELD14, CIPN20, and EQ-VAS in 189 CRC survivors.

Results: Median duration of cancer survivorship was 70.7 months (range, 0.7-209.8), and 80 patients (42.3%) was long term CRC survivor (who live with cancer more than 5 years). In terms of HRQOL, median scale was 63.4 (standard deviation [SD], ±21.2) for global health, 81.7 (±15.3) for function, and 19.1 (±14.7) for symptom in all CRC survivors. Symptom scale was higher in the long-term survivors (21.8 vs. 17.1; P = 0.040), and in female patients (21.4 vs. 15.3; P = 0.006). Higher stage of disease (III or IV) was related to higher symptom scale (21.6 vs. 17.2; P = 0.042), and lower

functional scale (78.2 vs. 84.3; P = 0.005). Frequently reported late effects were fatigue, insomnia, flatulence, bloated feeling, defecation problem, urinary frequency, sexual dysfunction in male, and sensory neuropathy. Insomnia (P = 0.018), sexual dysfunction in male (P = 0.003), and sensory neuropathy (P = 0.043) were significantly correlated with lower HRQOL scales. In the patients who were treated with oxaliplatin (n = 41), chemotherapy-induced neuropathy is related to worse global health (hazard ratio [HR], -3.29; 95% confidence interval [CI], -8.34- -2.0; P = 0.002).

Conclusions: Various late effects are found in CRC survivors, and late effects may worsen the HRQOL of Korean CRC survivors. We are developing personalized and integrative management programs for CRC survivors.

1792P Comparison of palonosetron and granisetron in triplet antiemetic therapy in nonmetastatic breast cancer patients receiving high emetogenic chemotherapy. A multicenter, prospective, and observational study

M. Araz[1], M. Karaağaç[2], L. Korkmaz[2], L. Koral[3], F. İnci[4], I. Beypinar[1], M. Uysal[1], M. Artac[2]

[1]Medical Oncology, Afyon Kocatepe University School of Medicine, Afyonkarahisar, Turkey, [2]Medical Oncology, Necmettin Erbakan University, Konya, Turkey, [3]Medical Oncology, Çanakkale Onsekiz Mart University, Çanakkale, Turkey, [4]Medical Oncology, Karabük State Hospital, Karabük, Turkey

Background: In the literature, there have been only two head to head trials investigating first and second generation 5HT3 receptor antagonists in triplet antiemetic regimens in cancer patients receiving high emetogenic chemotherapy (HEC). In these two Japanese studies, granisetron(G) was compared with 0.75 mg palonosetron(P). However, P is approved as 0.25 mg in Turkey and most other countries. Therefore, we aimed to investigate the efficacy of 0.25 mg of P and G in triplet antiemetic regimen for HEC.

Methods: This study was carried out between April 2017 and December 2017 at four different cancer center in Turkey. Patients with nonmetastatic breast cancer who received HEC (doxorubicin or epirubicin plus cyclophosphamide (AC/EC)) were enrolled in this study. The prophylactic triplet antiemetic regimens were used during the first cycle of HEC as intravenous dexamethasone and P (0.25 mg) or G (3mg) as well as oral aprepitant(125 mg on day 1 and 80 mg/day on days 2–3). The choice of P or G was left to the doctor's preference. The primary endpoint was complete response rate (CCR) in acute and delayed chemotherapy-induced nausea and vomiting (CINV). MASCC Antiemesis Tool was used to assess the CINV.

Results: A total of 118 female patients were included in the study. None of them had alcohol consumption story. The mean age of the patients was 51 years. Patients received AC (83%), EC (3%), and dose-dense AC (14%) as adjuvant (88%) or neoadjuvant (12%). The majority of patients received P (59%) containing antiemetic treatment. The dexamethasone dose used in the majority was 8 mg (%80). The CCRs on vomiting were high in two arms and not statistically different with P and G (acute 87% vs. 96%, p = 0.089; delayed 90% vs. 92%, p = 0.508), respectively. Nevertheless, the CCRs of either acute or delayed nausea were lower than compared with vomiting (acute 50% vs. 53%, p = 0.475; delayed 41% vs 31%, p = 0.186), respectively.

Conclusions: To best our knowledge, this is the first study that compared 0.25 mg P and G in triplet antiemetic regimens in cancer patients receiving HEC. There were no differences between P and G, in terms of CCRs of acute and delayed CINV.

1793P Painkiller-related dizziness in malignant tumors: A systematic review

R. Spiegel[1], S.I. Rothschild[2], R. Sutter[3], R. Kalla[4]

[1]BG Unfallklinik, Anästhesie, Intensivmedizin und Schmerztherapie, Berufsgenossenschaftliche Unfallklinik Tübingen, Tübingen, Germany, [2]Onkologie, Universitätsspital Basel, Basel, Switzerland, [3]Medizinische Intensivstationen und Neurologische Klinik, Universitätsspital Basel, Basel, Switzerland, [4]Neurologische Klinik, Inselspital (University Hospital Bern), Bern, Switzerland

Background: To our knowledge, there is no systematic review on painkiller-related dizziness, which often occurs.

Methods: Papers from core clinical journals on PubMed-database resulted in 340 articles on dizziness in malignant tumors until 31st Dec 2017. Eight studies with level of evidence (LoE) 1 focused on dizziness as a side effect of painkillers.

Results: In a meta-analysis on codeine, dizziness was reported in 18.06 % of patients (LoE 1a) [1]. In randomized controlled trials (LoE 1b), oxycodone-associated dizziness was only seen in controlled release (8.3 %) and not in immediate release oxycodone [2]. In a systematic review (LoE 1a) [3], controlled release oxycodone was associated with 11.9 % of dizziness reports. A meta-analysis on immediate release morphine and transmucosal fentanyl (7 % dizziness) favoured transmucosal fentanyl for breakthrough cancer pain, but did not differentiate between the painkillers for dizziness [4]. Effective analgesia with rare (1.8 to 7.5 %) events of dizziness was reported for intranasal fentanyl spray (LoE 1b) [5]. For long-acting analgesia, a systematic review favoured transdermal fentanyl over sustained release oral morphine (LoE 1a) [6]. A randomized controlled trial in bone metastases favoured the combination of two nonsteroidal anti-inflammatory drugs (NSAIDs) plus morphine (10.3 % dizziness reports) over one NSAID plus morphine (> 25 %), presumably due to lower morphine need in two NSAIDs (LoE 1b) [7]. Finally, both hydromorphone and morphine had at least 15 % of dizziness reports in a systematic review (LoE 1a) [8].

Conclusions: There is level of evidence 1a to 1b that immediate release oxycodone, transmucosal or intranasal fentanyl are associated with the lowest incidence of dizziness. For long-acting analgesia, transdermal fentanyl is a promising option. References: 1. Straube C, et al. Cochrane Database Syst Rev. 2014;9:CD006601. 2. Salzman RT, et al. 1794P Prevalence, risk factors and management of opioid-induced constipation in cancer pain: A nationwide, cross-sectional study in Korea

S.Y. Lee[1], Y.S. Hong[2], K.T. Lee[3], S.H. Shin[4], M.Y. Choi[5], S.J. Sym[6], H-S. Oh[7], S.N. Lee[8], E-K. Song[9]

[1]Medical Department, Mundipharma Korea Ltd, Seoul, Republic of Korea, [2]Medical Oncology, The Catholic University of Korea, Seoul St. Mary's Hospital, Seoul, Republic of Korea, [3]Medical Oncology, Soon Chun Hyang University Hospital Cheonan, Cheonan, Republic of Korea, [4]Hematology-Oncology, Kosin University Gospel Hospital, Busan, Republic of Korea, [5]Medical Oncology, Inje University Busan Paik Hospital, Busan, Republic of Korea, [6]Medical Oncology, Gachon University Gil Medical Center, Incheon, Republic of Korea, [7]Medical Oncology, GangNeung Asan Hospital, Republic of Korea, [8]Medical Oncology, Ewha Womans University School of Medicine, Seoul, Republic of Korea, [9]Medical Oncology, Chonbuk National University Medical School, Jeonju, Republic of Korea

Background: As opioid therapy is the mainstay treatment for moderate-to-severe cancer pain, a thorough investigation of opioid-induced constipation (OIC) is important due to high prevalence in cancer pain patients undergoing opioid therapy. This study aimed to investigate the prevalence, risk factors and management of opioid-induced constipation among cancer pain patients in Korea.

Methods: A cross-sectional analysis of cancer patients with pain from 30 teaching hospitals was performed, with data extracted from patient charts and questionnaires. Clinical characteristics, prevalence and management for AEs were assessed.

Results: Among 2,395 patients, the most common opioid-related AE was constipation (29.69%). The impact of overall AEs on patients' daily activities was the highest for constipation (69.80%, ≥3). Route of opioid administration was not associated with increased opioid-induced constipation. However, OIC occurrence was dependent to opioid dose. Although approximately half of patients used laxatives prophylactically, 18.50% of those patients experienced constipation. In particular, opioid-use duration, use of laxatives, dose and GI surgery history were significantly associated with constipation.

Conclusions: This study evaluated opioid-induced constipation in cancer pain patients in Korea. As evidenced by the negative impact on patients' daily activities, proper management of OIC is critical as OIC persists although with the use of laxatives. Use of prophylactic laxatives was an important effector as the occurrence of constipation was lower in patients using laxatives prophylactically compared with those using laxatives for constipation treatment. Patients may also benefit from more specific and innovative therapy such as agonist/antagonist combination as stated in EFIC guideline.

1795P Bald is beautiful: No more. The stigma of alopecia during chemotherapy: Brindisi oncology department experience

D. Loparco, L. Orlando, M. Caloro, P. Fedele, P. Schiavone, A. Quaranta, C. Caliolo, M. Cinefra, P. Ferrara, L.L. Falcone, V. Capone, C. Destro, A. Morleo, A. Ricco, V. Bonuso, G. Lotti, M. D'amico, P. Rizzo, A. Marino, S. Cinieri

UOC Oncologia Medica, Ospedale A. Perrino, Brindisi, Italy

Background: The cancer treatments (T) bring with it body image challenges, causing low self-esteem and contributing to worsen the quality of life. Chemotherapy (CT)-induced hair loss (HL) is one of the most emotionally distressing side effects of several breast cancer (BC) T. The DigniCap system (DCS), using the scalp cooling system, has been shown to reduce CT-induced alopecia (A) in a multicenter prospective trial. The purpose of this prospective observational study was to describe our experience.

Methods: Two DCS device are available at the Brindisi Oncology Dpt. From February 2016 and May 2018, 86 consecutive early stage BC pts who received anthracycline and/or taxane-based T were enrolled. A nurse and a psychologist were dedicated for these pts. Success of scalp cooling was defined according to the Dean's scale: G0= no HL; G1 < 25% HL; G2=25–50% HL; G3=50–75% HL; G4 >75% HL.

Results: A total of 86 women were included in the following T cohorts: n = 37 (43%) received 4 courses of EC (IV) on day 1, with 21 days between cycles) followed by 12 courses of weekly Paclitaxel (P); n = 39 (45%) received only 4 courses of EC and n = 10 pts (12%) P and concurrent weeklyTrastuzumab for 12 consecutive doses. Median age was 48 years (range 31-74). Overall success (G0-G2) was observed in 61 pts (71%). Full preservation of the hair (G0) was observed in 16 pts (19%), G1 in 31 pts (36%) and G2 in 14 pts (16%) (tab 1). Most frequent scalp cooling-related symptoms were: coldness (n = 70, 81%) and headache (n = 60, 70%). Overall, 11% (n = 9) of pts discontinued DCS because of unsatisfactory hair preservation (n = 5, 6%) and cold discomfort (n = 2; 2.5%). Furthermore, we observed a hair growth when DCS was continued for pts with A G3 – G4.

Table: 1795P

ALOPECIA H/L	G0	G1	G2	G3	G4
N (%)	16 (19%)	31(36%)	14(16%)	20 (23%)	5 (6%)

Tab 1: A/HL

Conclusions: Our results reinforced previous evidences, showing that DCS is a good chance to prevent A during CT with anthracycline and/or taxane-based regimen and supported the wider use to all women with early stage BC.

1796P A large multi-center, randomized, double-blind, crossover study in healthy volunteers to compare pharmacokinetics and pharmacodynamics of a proposed biosimilar pegfilgrastim with EU and US reference pegfilgrastim: Methodological approach

R. Nakov[1], S. Schussler[2], S. Schier-Mumzhiu[3], A. Skerjanec[4], A. Bellon[4], J. Wang[5], A. Krendyukov[6], G. Otto[3]

[1]Hematology, Hexal AG, Holzkirchen, Germany, [2]Clinical Research, Sandoz Inc., Princeton, NJ, USA, [3]Clinical Research, Hexal AG, Holzkirchen, Germany, [4]Clinical Pharmacology, Hexal AG, Holzkirchen, Germany, [5]Biostatistics, Sandoz Inc., Princeton, NJ, USA, [6]Medical Oncology/Hematology, Hexal AG, Holzkirchen, Germany

Background: Biosimilar development applies a totality of evidence approach, in which Phase I (pharmacokinetic [PK]/pharmacodynamics [PD]) studies have a pivotal role. Phase I studies are particularly important in biosimilar pegfilgrastim development due to high inter-subject variability (ISV) mainly linked to target-mediated clearance.[1] A pivotal Phase I study confirmed that Sandoz proposed biosimilar pegfilgrastim (LA-EP2006) and EU-reference biologic have matching PK/PD profiles.[2] For FDA approval of LA-EP2006, a bridging study is necessary to confirm that PK/PD properties of LA-EP2006 match EU and US reference pegfilgrastim. This Phase I bridging study is ongoing and here we present the methodology.

Methods: To meet FDA requirements of LA-EP2006, EU and US reference pegfilgrastim PK/PD similarity, and to address ISV, a three-way crossover design was chosen following FDA advice. The study was sufficiently powered (90%) to achieve confidence intervals within margins 0.8–1.25 in co-primary endpoints pairwise comparisons.

Results: Due to historically known high intra- and inter-subject variabilities with reference biologic (CV: 45% and ~80%, respectively)[3] in $AUC_{0\text{-}inf}$, a randomized, double-blind, single-dose, 3-treatment, 6-sequence crossover, Phase I study in healthy volunteers is suitable to demonstrate similarity of PK/PD, safety and immunogenicity between LA-EP2006, EU and US reference pegfilgrastim. Multiple centers, regions, contract research organizations and medicine batches are required, which further amplifies operational complexity of study conduct and scientific standards. The study is ongoing in 5 US and 1 Dutch study sites.

Conclusions: Phase I methodology applying a 3-way crossover design addresses known high ISV with pegfilgrastim and establishes the scientific bridge between proposed biosimilar and reference US and EU biologics. 1797P Quality of life in breast cancer Tunisian women: A monocentric survey

S. Labidi, C. Bousrih, M. Saadi, H. El Benna, M. Nesrine, N. Daoud, H. Boussen

Department of Medical Oncology, Abderrahman Mami Hospital, Ariana, Tunisia

Background: Quality of life (QoL) has become an integral part of breast cancer (BC) management and been considered an important endpoint of clinical trials. Our objective was to report the results of the first Tunisian study assessing the QoL in BC and to identify the specific demographic characteristics.

Methods: One hundred and ten patients with BC from the department of Medical oncology of the Abderrahman Mami hospital were enrolled in the study in April, 2018. EORTC QLQ-BR23 (European Organization for Research and Treatment of Cancer) Questionnaire was used to assess specifically functional and symptoms scales/items of BC patients. Functional scales consisted of body image (BRBI), sexual functioning (BRSEF), enjoyment (BRSEE) and future perspective (BRFU). Symptom scales / items included systemic therapy side effects (BRST), breast (BRBS), arm (BRAS) symptoms and upset by hair loss (BRHL). A high score for a functional scale represents a healthy level of functioning and a high score for a symptom scale / item represents a high level of symptomatology.

Results: Median age was 52 years (range, 27-75 years) and 70.9% were above the age of 40. Fifty six of patients were menopausal and 19.1% had metastatic disease. Most of women were married (68.2 %), housekeepers (46.4%) and living in urban area (61.8%). Radical surgery was performed in 45.5% of cases and 59.1% of patients were receiving chemotherapy. We identified low scores of BRSEE (47.91, ± 31.44) and BRFU (51.81, ± 37.12) and high scores of BRBS (30.50, ±25.6) and BRAS (26.74 ±24.08) indicating a poorer QoL. Whereas, BRBI (74.33±26.07), BRSEF (77.42±27.79), BRST (40.6 ±20.16) and BRHL (38.46, ± 42.66) were not associated with poorer QoL. Marital status had significant positive effect on body image (Married women: 70.83 vs 70, p = 0.03), sexual functioning (98.14 vs 70.88, p = 0.011) and future perspective (60.80 vs 22.22, p = 0.00). Systemic therapy side effects were significantly higher among patients having chemotherapy (41.53 vs 32.53, p = 0.031). Arm symptoms were as well significantly more reported in patients aged above 40 (35.41 vs 26.78, p = 0.022) and menopausal (33.33 vs 24.80, p = 0.039).

Conclusions: Our study demonstrates the impact of demographic factors in QoL, which need to be systematically assessed by clinicians in breast cancer care.

1798P Anticancer therapy within the last 30 days of life in a regional cancer centre

M. Nguyen

Medical Oncology, Goulburn Valley Health, Shepparton, Australia

Background: Anticancer therapy within the last 30 days of life is an important indicator of quality end of life care. The decision to cease treatment is complex with several patient, family and clinician driven factors. Similarly, the development of novel anticancer therapies create opportunities for more treatment options. This is reflected in trends toward more aggressive treatment near the end of life. Other institutions in Australia have reported treatment rates within the last 30 days of life of between 10 - 26%.

Methods: Deaths between 1 January 2015 and 30 June 2018 of patients who attended the oncology department were analysed through a retrospective review of medical records.

Results: 122 of 444 deaths (27%) occurred in patients who had received anticancer therapy within the last 30 days of life. The majority (96%) were treated with palliative intent. Palliative care service referral status was low (50%) and tended to be later in those who received treatment within the last 30 days of life. Treatment within the last 30 days of life was associated with other indicators of aggressiveness of care including more emergency presentations, hospitalisations and ICU admissions.

Conclusions: A significant number of patients received anticancer therapy within the last 30 days of life. This emphasises difficulties in disease prognostication, the conflict between treatment cessation and trialling other tempting treatment options and the need for referral to palliative care services.

1799P Febrile neutropenia management and concordance of institutional protocol with clinical practice

A.F. Oliveira, L. Bretes, I. Furtado, B.E. Gosalbez Pequeno, J.G. Magalhaes
Medical Oncology, Centro Hospitalar Universitário Algarve, Faro, Portugal

Background: Febrile Neutropenia (NF) is an oncologic emergency defined as fever (oral temperature greater than 38.3 °C) and neutrophil count <500. It is one of the most common complications due to chemotherapy. NF is responsible for a considerable morbidity since 20% to 30% of the patients present complications that require hospitalization, with global hospital mortality around 10%. The objective of this study is to evaluate the initial approach to patients with NF in Oncology Day Unit (ODU), Service of Unplanned Care (SUC) and Emergency (ER) and compare the procedures performed in these patients with the protocol at our institution, which is based on guidelines (ESMO/NCCN).

Methods: Retrospective, unicentric study, with the consultation of the clinical records of the patients who presented at ODU, SUC, ER and hospitalized in the Oncology ward with FN and cancer, during a period of 3 months in 2017. Patients were diagnosed by the attending physician with fever and N < 500 or with fever and N < 1000 and> 500, with a drop expected in the next 7 days.

Results: There were 21 episodes, all with solid tumors. The most frequent sites were lung (23%), breast (19%) and colon (17%). 61% of the patients had stage IV cancer. About half developed FN after 1st cycle of chemotherapy. 52% were male, with a mean age of 66.2 years (36-86). In terms of infectious site, the most frequent were fever without a focus (42%) followed by respiratory, skin and urinary tract infections. The MASCC was described in 20% of the cases. The first antibiotic therapy was performed in the SUC in 30% of the cases, in the ER in 65% and in the ODU in 10%. The hospitalization was performed in 11 patients with a median of 13 days of hospitalization. 8 patients underwent outpatient therapy, 3 of whom were subsequently hospitalized for FN. 60% of the patients were treated with G-CSF (N < 500). There were no deaths. The total agreement between clinical practice and the institutional protocol was 17/21 (81%).

Conclusions: Not all patients initiated antibiotic therapy at SUC. The description of the MASCC in the clinical record would be ideal for arguing the therapeutic decision. We have found the overuse of G-CSF. This analysis served to investigate and improve our approach in FN. Protocols can improve the consistency and quality of care.

1800P Salient features of an indigenous integrated inpatient model of delivery of supportive medicine services: A narrative review

R.D. Arora
Palliative Medicine, All India Institute of Medical Sciences, New Delhi, India

Background: The multiplicity of existing models has the potential to act as a deterrant to the development of an economically feasible and self-sustaining model of delivery of supportive medicine services. A uniformity in guidelines governing the delivery of these services is urgently needed.

Methods: The department recently submitted an application for recognition as an ESMO Designated Centre for Integrated Oncology and Palliative Medicine. This paper tries to highlight the features unique to this model and builds upon the argument that the western model cannot be transplanted to the Indian setting.

Results: The following salient features were identified. The department encourages cancer directed therapy where feasible and prides itself as being ahead of the times in proposing a model which incorporates various aspects of disease-directed therapy, supportive care and palliative care (including quality end of life care provision) as a continuum. A larger role for the palliative medicine professional with direct involvement in critical areas of supportive oncology, procedures such as therapeutic paracentesis, pigtail insertion and interventional pain management techniques is envisaged. We have been able to cut down significantly on the time spent for the patient in obtaining an expert liaison with specialists from other super-specialities. A weekly clinico-radiological conference is held where important cases are discussed with radiologists. The fact that advanced cancer patients (who are not recieving any cancer directed therapy) are being treated alongside those receiving active anticancer treatment has also been instrumental in creating an environment where there is no discrimination and stigma attached to the term palliation.

Conclusions: This model of delivery of supportive medicine services can act as a benchmark on which other regional centres can be modelled. The close involvement of professionals from disciplines such as anaesthesiology and radiology could be one of the important reasons in ensuring that this model has been successful in pushing the boundaries and managing patient issues which were traditionally considered outside the scope and ambit of palliative medicine.

1801P Novel online drug-drug interaction resource reveals clinically relevant interactions in > 20% of the searches

N.A.G. Lankheet[1], K.R.M. Ferrier[1], S.E. Gibbons[2], D.M. Burger[1], K. McAllister[2], J.L.M. Martin[2], S.H. Khoo[2], N. van Erp[1], F.G. Jansman[3]
[1]Pharmacy, Radboud University Medical Centre Nijmegen, Nijmegen, Netherlands, [2]Molecular and Clinical Pharmacology, University of Liverpool, Liverpool, UK, [3]Clinical Pharmacy, Deventer Ziekenhuis, Deventer, Netherlands

Background: Patients with cancer are at risk to endure a drug-drug interaction (DDI) with their oncolytic drugs. To facilitate the safe prescription and use of oncolytics, the freely available website www.cancer-druginteractions.org was introduced. Hereby we present the results of the use of this online DDI resource since the launch in June 1st, 2017.

Methods: For the most frequently used co-medications (>400) in cancer patients DDI potential was reviewed based on registration documents and scientific literature. A simple "traffic light" system was used to warn for the interaction potential. Background information and level of evidence is provided in the summary for each interaction. Since the launch of the website the demographic use, the number of unique visitors and the number and severity of the interactions consulted are monitored every 3 months.

Results: 34 targeted oncolytics used for ten different malignancies have been added to the website. These represent 24 targeted oral oncolytics and 10 monoclonal antibodies (MoABs). Between June 1st, 2017 and March 31st, 2018 a total of 11,295 searches has been performed by 3,428 unique visitors from 35 countries. 78% of the searches were performed for oral oncolytics and 22% for MoABs. 20.8% of the searches showed a potential interaction which requires action of the prescriber. The table gives an overview of the searches performed. Frequently checked co-medications were for example coumarins, PPIs, dexamethasone, metamizole and aspirin. Currently, a user-friendly app is under development which will be launched in October 2018.

Table: 1801P Overview of DDI queries

Interaction classification 'traffic light' (%)	
Green No clinically significant interaction	63.3
Yellow Interaction of weak/moderate intensity; no a priori dosage adjustment required	15.9
Amber Potential interaction which may require dosage adjustment or close monitoring	14.3
Red Do not co-administer	6.5
Countries consulted the website (%)	
United Kingdom	68
The Netherlands	16
Other European countries (top 3: Spain, France, Switzerland)	7
USA and Canada	3
Asia-Pacific (top 3: Australia, India, Hong Kong)	2
Other	4

Conclusions: Thus far, the DDI checker is being used all over the world. More than 20% of the performed searches showed a clinically relevant interaction. The freely available website, and the soon to be launched app, will facilitate health care professionals' awareness of potential DDIs between oncolytics and frequently used co-medications and this supports safe prescription.

1802P The concordance with antiemetic guideline for pediatric, adolescent and young adult patients with cancer using a large-scale administrative database

S. Bun[1], S. Kunisawa[1], N. Sasaki[1], K. Fushimi[2], K. Matsumoto[3], A. Yamatani[4], Y. Imanaka[1]

[1]Healthcare Economics and Quality Management, Kyoto University, Kyoto, Japan, [2]Health Policy and Informatics Section, Tokyo Medical and Dental University Graduate School, Tokyo, Japan, [3]Children's Cancer Center, National Center for Child Health and Development, Tokyo, Japan, [4]Pharmacy, National Center for Child Health and Development, Tokyo, Japan

Background: In the field of adult patients, the risk factors for discordance with antiemetic guideline (GL) are reported to be hematological malignancy, older age, and the use of low emetic risk chemotherapy. However, there are scarce reports in the field of pediatric or adolescent and young adult (AYA) patients. Therefore, we assessed the concordance with antiemetic GL in the field of pediatric and AYA patients who received chemotherapy.

Methods: Using the Diagnosis Procedure Combination system in Japan, we identified patients with cancer aged 30 years or younger from July 2010 to March 2016. Patients' data included age, gender, diagnosis, anticancer drugs, and antiemetic drugs. We assessed the concordance with antiemetic GL of ASCO in patients of each emetic risk category. Furthermore, we assessed the risk factors for discordance with antiemetic GL, using logistic regression.

Results: A total of 21,106 patients who underwent chemotherapy were included. We classified patients into the following 6 age categories: 0-2 yo (n = 2,480), 3-5 yo (n = 1,983), 6-11 yo (n = 2,782), 12-17yo (n = 3,495), 18-23 yo (n = 3,941) and 24-29 yo (n = 6,425). The median age was 16 (0-29) years old. The rate of concordance with GL in each emetic risk category was 18.2% in high risk (18 yo >, n = 2,531), 51.1% in high risk (18 yo ≤, n = 4130), 32.1% in moderate risk (n = 7,188), 52.0% in low risk (n = 5,806), and 51.6% in minimum risk (n = 1,451). In multivariate analysis, risk factors for discordance with antiemetic GL were high emetic risk chemotherapy, lower age (0-2 yo), hematological malignancies, and brain tumor.

Table: 1802P Risk factors for discordance with antiemetic guideline

		Odd ratio	95% CI	P Value
Age category	0-2 yo	1.71	1.55-1.89	<0.05
	3-5 yo	1.16	1.04-1.29	<0.05
	6-11 yo	1.12	1.02-1.24	<0.05
	12-17yo	1.49	1.37-1.63	<0.05
	18-23 yo	1.13	1.04-1.23	<0.05
Emetic risk category	High	2.27	2.0-2.55	<0.05
	Moderate	1.43	1.27-1.60	<0.05
	Low	0.98	0.87-1.11	0.79
Disease	non-malignancy	0.75	0.52-1.11	0.15
	Brain tumor	1.46	1.31-1.62	<0.05
	Hematorogical malignancy	1.28	1.20-1.37	<0.05
	Breast cancer	0.53	0.42-0.67	<0.05
	Ovarian/Cervical cancer	0.39	0.34-0.44	<0.05

Conclusions: Our study identified substantial room for improvement in antiemetic practice and risk factors for discordance with antiemetic GL in pediatric and AYA patients. These identified risks are different from those in adult patients. Further investigation of the causes of this discordance is warranted, especially considering the unique background of this field.

Background: No effective prophylactic managements are established for chemotherapy-induced peripheral neuropathy (CIPN). We developed a new, feasible method to prevent CIPN, using compression therapy with surgical gloves (SGs), called SG compression therapy, and recently reported that this method significantly reduced the overall occurrence of grade 2 or higher nanoparticle albumin-bound-paclitaxel (nab-PTX)-induced peripheral neuropathy (PN) from 76.1% to 21.4%, as SGs decreased the microvascular flow to each fingertip (Breast Cancer Res Treat. 2016; 160:61-67). To avoid the major disadvantages of PN for the non-SG-wearing patients by a randomized controlled trial, we investigated the efficacy and safety of SG compression therapy for nab-PTX induced PN in a multicenter single-armed confirmatory study, comparing to the incidence of 44.1% grade 2 or higher PN found in known literature, which we considered as a control group.

Methods: Primary breast cancer patients who received 260 mg/m^2 of nab-PTX were eligible for this study. Patients wore two SGs of the same size, i.e., one size smaller than the size that fit their both hands, for 90 minutes. PN was evaluated at each treatment cycle using Common Terminology Criteria for Adverse Events (CTCAE) version 4.0 and the Patient Neurotoxicity Questionnaire (PNQ). The temperature of each fingertip was measured by using thermography.

Results: Between October 2016 to June 2017, 61 patients were enrolled, and 58 were evaluated. The incidence of sensory PN of CTCAE grade 2 or higher was as low as 13.8% following SG compression therapy. The occurrence rate of grade 4 or higher PNQ responses, which indicate interference with activities of daily living, was also as low as 10.3%. A goodness-of-fit test using a chi-square test proved that the overall incidence of 13.8% grade 2 or higher PN obtained in this study is equal to 13% of the hypothesis-predicted value. All patients completed this study because they tolerated the compression from the SGs. SG compression therapy significantly reduced the temperature of each fingertip by 1.3–2.3 °C compared to that before chemotherapy.

Conclusions: This study demonstrated that SG compression therapy is effective and safe for reducing CIPN.

Background: Progressive decrease of serum magnesium levels occurs in virtually all patients treated with anti-EGFR antibodies. This is supposedly linked to an inhibition of renal TRPM6 activity. This Mg loss may ultimately require stopping the anti-cancer treatment. In patients with congenital TRPM6 deficiency, high dose oral Mg supplementation allows to maintain acceptable serum Mg levels but may induce significant diarrhea. We hypothesized that oral Mg gluconate substitution may prevent and/or treat Mg wasting due to anti-EGFR treatment in colorectal cancer (CRC).

Methods: We performed a prospective randomized multi-centre trial in patients treated with anti-EGFR antibodies for CRC evaluating the efficacy and tolerability of oral Mg gluconate for prevention and/or treatment of Mg wasting. Upon initiation of anti-EGFR treatment, patients were randomized to no intervention (arm A) or Mg gluconate 3 g bid (arm B). After occurrence of hypomagnesaemia grade 1, Mg gluconate 3 g bid was initiated in arm A, whereas the dosage was increased to 3g 6 times daily in arm B. The co-primary outcome variables were the slope of the serum Mg levels since baseline and the mean number of bowel movements per day. An a priori statistical analysis plan estimated the need to screen 180 patients ($\beta = 0.90$) to demonstrate an effect on serum Mg slopes.

Results: After excluding 7 patients during screening, 89 were randomized to arm A (no intervention) and 84 to arm B (Mg supplementation). In an ITT approach, the mean serum Mg slope was significantly ($p = 0.015$) steeper in arm A: -0.0045 (95%CI: -0.0062 to -0.0034) vs. -0.0021 (95%CI: -0.0037 to -0.0009) mg/dl/day in arm B. Hypomagnesaemia occurred in 12 and 4 patients respectively ($p = 0.05$). This lead to insufficient number of patients to draw conclusions for the second part of the trial. The mean number of bowel movements was not different across arms. Oral Mg supplementation was not associated to significant adverse events.

Conclusions: This prospective randomized trial demonstrated that oral Mg gluconate 3 g bid. significantly decreased Mg wasting during anti-EGFR treatment in colorectal cancer, thereby delaying the occurrence of hypomagnesemia. This treatment was well tolerated.

Background: Up to half of patients receiving chemotherapy of moderate or high emetic risk experience CINV despite optimal anti-emetic prophylaxis. Limited evidence suggests cannabinoid medicine in the form of tetrahydrocannabinol (THC) may reduce CINV, and addition of cannabidiol (CBD) may improve efficacy and tolerance. The aim of this multi-centre, randomised, placebo-controlled, phase II/III trial is to determine efficacy and cost-effectiveness of addition of an oral cannabinoid-rich THC/CBD cannabis extract for control of CINV.

Trial design: The target population is adult patients experiencing CINV during moderate and highly emetogenic chemotherapy regimens despite appropriate anti-emetic therapy, who are scheduled to receive at least 2 more consecutive cycles (A, B and, where applicable, C). Treatment consists of oral THC 2.5mg/CBD 2.5mg (Tilray TN-TC11M) capsules or placebo TDS days -1 to 5, in addition to guideline-consistent anti-emetics, including rescue medications. Patients will start with 1 tablet PO TDS and can dose-titrate to a maximum of 4 tables PO TDS based on nausea control and side-effects. In the pilot trial ($N = 80$), subjects are randomised for cycle A, cross-over for cycle B, and nominate preferred treatment for cycle C. The planned definitive trial ($N = 250$) will randomise subjects to investigational product or placebo for cycles A, B and C in a parallel design. The primary end-point is the proportion of patients gaining a complete response (no emesis and no use of rescue medications) (0 – 120h), with additional end-points of (i) complete response, (ii) no emesis, (iii) no significant nausea and (iv) no use of rescue medication during the a) acute, b) delayed, and c) overall phases of cycle A, B and C, (iv) adverse events, (v) quality of life, and (vi) cost-effectiveness. As of 09/05/2018, 52 of 80 patients have been recruited to the pilot study, with expected recruitment completion in 3rd quarter 2018. Funding: NSW Department of Health. Maria della Misericordia, Perugia, Italy, [11]Department of Lung & Thoracic Tumours, The Maria Sklodowska-Curie Memorial Institute and Oncology Centre, Warsaw, Poland, [12]Oncology, Humanitas Gavazzeni, Bergamo, Italy

Background: Tumor Treating Fields (TTFields) are an anti-mitotic, regional treatment modality, using low intensity alternating electric fields delivered non-invasively to the tumor using a portable, medical device. In vitro, human mesothelioma cells were highly susceptible to TTFields. TTFields have been shown to extend survival of patients with glioblastoma when added to chemotherapy.

Methods: The trial accrued 80 patients with unresectable, untreated mesothelioma. Patients were treated with continuous 150 kHz TTFields in combination with pemetrexed and platinum. Inclusion criteria included ECOG 0-1 and at least one measurable lesion according to modified RECIST. Patients were followed q3w (CT scan q6w) until disease progression. The primary endpoint was overall survival (OS). This single arm study assumed historical control with a median survival of 12.1 months (Vogelzang et al. 2003). The sample size provided 80% power with a two-sided alpha of 0.05 to detect an increase in median OS of 5.5 months.

Results: All patients had a minimum follow up of 12 months. Median age was 67 (range 27-78), 84% were male and 56% smokers. 16% (13 patients) had metastatic disease and 44% (35 patients) had an ECOG PS of 1. 66% (53 patients) had epithelioid histology. Compliance with TTFields was 68% (16.3 hours/day) during the first 3 months of therapy. Median OS was 18.2 months (95% CI 12.1-25.8) compared to 12.1 months in historical controls. Median PFS was 7.6 months (95% CI 6.7-8.6) compared to 5.7 months in historical controls. Partial responses were seen in 40.3% of patients and clinical benefit (PR+SD) was seen in 97.2% of patients. No device-related serious adverse events (AEs) were reported. Expected TTFields-related dermatitis was reported in 46% (37 patients). Only 4 patients (5%) had grade 3 dermatitis.

Conclusions: The study met its primary endpoint of significant extension of survival for previously untreated mesothelioma patients. Secondary efficacy endpoints were also improved compared to historical control. The study demonstrated no safety concerns for the combination of TTFields to the thorax with chemotherapy. These results support the addition of TTFields to chemotherapy in the first-line treatment of malignant pleural mesothelioma.

1808P Role of evaluating tumor infiltrating lymphocytes, programmed death-ligand 1 and mismatch-repair proteins expression in malignant mesothelioma

L. Losi[1], F. Bertolini[2], L. Scurani[1], G. Guaitoli[2], C. Baldessari[2], A. Ambrosini Spaltro[3], L. Botticelli[3], A. Maiorana[3], F. Barbieri[2], S. Cascinu[2]

[1]Department of Life Sciences, Unit of Pathology, University of Modena and Reggio Emilia, Modena, Italy, [2]Department of Oncology and Haematology, Azienda Ospedaliero - Universitaria Policlinico di Modena, Modena, Italy, [3]Department of Diagnostic Medicine, Clinic and Public Health, Unit of Pathology, University of Modena and Reggio Emilia, Modena, Italy

Background: Malignant mesothelioma (MM) is an aggressive and fatal tumor, mainly related to prolonged exposure to asbestos. MM can induce infiltration of immune cells and immunity-mediated death. Tumor microenvironment plays a major role in neoplastic progression, favoring tumor cell evasion from adaptive immunity and T-cell checkpoint pathways. Expression of programmed death-ligand 1 (PD-L1) on tumor cells and tumor-infiltrating lymphocytes (TILs) has been described in literature. Cancer cells expressing PD-L1 increase apoptosis of antigen-specific human T-cell clones and inhibit CD4+ and CD8+ T-cell activation, thus decreasing the immune action on the tumor cells. Some mismatch repair–deficient tumors make them sensitive to immune checkpoint blockade, because of the increased number of neoantigens encoded by cancers, which enhances anti-tumor response.

Methods: The aim of this study is to analyze the expression of PD-L1 on both tumor cells and TILs and to characterize TILs. Furthermore, MisMatchRepair (MMR) protein expression was evaluated. Immunohistochemistry was applied using the automated system BenchMark XT (VENTANA) for PD-L1 (DAKO, clone 22C3), CD4, CD8 and MLH1, MSH2, MSH6, PMS2.

Results: 55 malignant mesotheliomas, 10 from women and 45 from men, were studied. The range of age was 43-88 years old. Tumors consisted of 44 epithelioid, 3 sarcomatoid, 7 biphasic and 1 desmoplastic. 51 were localized to pleura and 4 to peritoneum. 18 tumors were in stage I, 13 in stage II, 15 in stage III and 5 in stage IV. For 4 cases the stage was not evaluable. Our results showed expression of PD-L1 $\geq$50% in tumor cells in 9 cases (5 epithelioid, 2 sarcomatoid, 1 biphasic and 1 desmoplastic). In two of these the positivity was observed both in tumor cells and in TILs. 15 tumors were negative and 31 showed a positive staining $\geq$1. A presence of TILs was observed in 53 cases. A prevalence of CD4+ expression was highlighted in 45 cases. 6 of them showed elevated expression of PD-L1 ($\geq$50%). Alteration in MMR staining was not found.

Conclusions: Our data underline the role of tumor immune microenvironment and its characterization in MM and open the possibility to use combined therapies according to different PD-L1 expression.

1809P Development and validation of a deep learning model using biomarkers in pleural effusion for prediction of malignant pleural mesothelioma

S. Ikegaki[1], Y. Kataoka[1], T. Otoshi[2], T. Takemura[1], M. Shimada[1]

[1]Department of Respiratory Medicine, Hyogo Prefectural Amagasaki General Medical Center, Amagasaki, Japan, [2]Division of Respiratory Medicine, Department of Internal Medicine, Kobe University Graduate School of Medicine, Kobe, Japan

Background: Malignant pleural mesothelioma (MPM) is an aggressive asbestos-related disease that is challenging to diagnose. The value of tumour biomarkers in pleural effusion fluid is limited in patients with the disease. We have developed and validated a deep learning model that can predict a diagnosis of MPM using pleural tumour biomarkers and patient characteristics.

Methods: This retrospective cohort study included patients who underwent thoracentesis for undiagnosed pleural effusion at a single tertiary medical centre between September 2014 and August 2016. The diagnosis was established by two independent physicians who were blinded to the pleural effusion data. A deep learning model was constructed to differentiate MPM from other diseases and evaluated using biomarkers in pleural effusion (carcinoembryonic antigen, cytokeratin 19 fragment, soluble mesothelin-related peptides, lactate dehydrogenase), total protein in pleural effusion, and patient age and sex as input parameters. Missing data were handled by single imputation. The model consisted of three hidden layers and was trained for 4000 steps. The data were divided into a training set and a test data set and processed using TensorFlow 1.7.0 and Python 3.6 software. The performance of the model was evaluated by accuracy and the area under the receiver-operating characteristic curve (AUROC).

Results: Twenty-eight of the 188 patients who underwent thoracentesis were diagnosed to have MPM and divided into a training data set (containing first 150 records with 20 MPM patients) and a test data set (38 records with 8 MPM patients). The accuracy values for the training and test data sets were 0.99 and 0.97, respectively, and the respective AUROC were 1.00 and 0.92.

Conclusions: Our deep neural network model had good diagnostic accuracy for MPM and may help in making a definitive diagnosis when there is an indication for invasive pleural biopsy.

1810P Elective nodal irradiation as adjuvant radiotherapy for advanced thymomas and thymic carcinomas

Y.J. Kim[1], S.S. Kim[2], S.Y. Song[2], E.K. Choi[2]

[1]Radiation Oncology, Kangwon National University Hospital, Chuncheon, Republic of Korea, [2]Radiation Oncology, Asan Medical Center, Seoul, Republic of Korea

Background: Elective nodal irradiation (ENI) targeting the entire mediastinal and supraclavicular regions is not routinely recommended as adjuvant treatment for thymomas due to the low rate of lymphogenous metastasis. Also, it is not widely used for thymic carcinomas since the majority of nodal disease metastasized to anterior mediastinal lymph nodes. However, there are little clinical data directly comparing the local radiation therapy (LRT) targeting the tumor bed and anterior mediastinal areas only and ENI for thymic tumors. We evaluated the clinical outcome of patients with stage III–IV thymomas (Ts) or stage II–IV thymic carcinomas (TCs) treated with complete thymectomy and LRT or ENI.

Methods: Data from 47 patients diagnosed with Ts or TCs and treated with surgery and adjuvant RT from May 2002 to May 2015 were analyzed. The standard RT dose was 50.4 Gy in 25 fractions; patients with a positive resection margin received a further 4–10 Gy. Survival outcomes determined at 5 years included local recurrence-free survival (LRFS), regional recurrence-free survival (RRFS), distant metastasis-free survival (DMFS), and overall survival (OS).

Results: Five year LRFS was similar in both groups (LRT, 94.7% vs ENI, 96.2%; $p = 0.849$). Significant differences were seen in 5 year RRFS (LRT, 55.1% vs ENI, 83.7%; $p = 0.006$); however, tumor size was seen to be a significant factor (<7 cm, 95.2% vs ≥ 7 cm, 48.9%; $p = 0.000$) and the LRT group contained a greater proportion of patients with ≥ 7 cm tumors (70% vs 33%). Multivariate analysis demonstrated that tumor size was the only significant prognostic factor ($p = 0.000$). No differences in 5 year OS were seen (LRT, 91.7% vs ENI, 100%; $p = 0.106$).

Conclusions: ENI showed no additional benefit in reducing recurrence or improving survival. LRT can, therefore, be considered sufficient to achieve excellent patient outcomes.

1811P Clinicopathological features of thymoma with the expression of programmed death-ligand 1

S. Hakiri[1], T. Fukui[1], S. Mori[1], K. Kawaguchi[1], S. Nakamura[1], N. Ozeki[1], T. Kato[1], M. Goto[1], Y. Yatabe[2], K. Yokoi[1]

[1]Thoracic Surgery, Nagoya University, Graduate School of Medicine, Nagoya, Japan, [2]Pathology and Molecular Diagnostics, Aichi Cancer Center Hospital, Nagoya, Aichi, Japan

Background: Programmed death-ligand 1 (PD-L1) is reportedly expressed in various malignancies and is considered a prognostic factor. We attempted to characterize the association between the PD-L1 expression and the clinicopathological features of patients with thymoma.

Methods: Eighty-one patients with thymoma who underwent surgical resection between 2004 and 2015 were retrospectively reviewed. The PD-L1 expression was evaluated by immunohistochemistry and stratified by the proportion of positive tumor cells. Strong membranous reactivity of the PD-L1 antibody in $\geq 1\%$ of tumor cells was considered 'positive'. The association between the PD-L1 expression and the clinicopathological features was investigated.

Results: The PD-L1 expression was positive in 22 patients (27%) and negative in 59 patients (73%). PD-L1 positivity was significantly associated with type B2 and B3 thymoma ($p < 0.001$) and stage III and IV disease ($p = 0.048$). In addition, PD-L1-positive tumors showed a significantly higher maximum standardized uptake value (SUVmax) than PD-L1-negative tumors ($p = 0.026$). The 5-year disease-free survival (DFS) rate was 83% in PD-L1-positive patients and 88% in PD-L1-negative patients, showing no significant difference ($p = 0.576$). Furthermore, PD-L1 positivity was not an independent prognostic factor for the DFS on a Cox proportional hazard analysis ($p = 0.590$).

Conclusions: A strong expression of PD-L1 in thymoma was significantly associated with type B2 and B3 and higher pathological stages. In addition, PD-L1 positivity was associated with an increased SUVmax of the tumor. However, patients with PD-L1-positive thymomas did not show a significantly worse prognosis than those with PD-L1-negative tumors.

1812P The impact of PD-L1, TGF-β expression and tumor-infiltrating CD8+ T cells on clinical outcome of patients with advanced thymic epithelial tumors

J. Duan[1], X. Liu[2], H. Chen[3], H. Bai[4], T. Xu[5], S. Cai[6], J. Wang[7]

[1]Department of Medical Oncology, Cancer Hospital of Chinese Academy of Medical Sciences, Beijing, China, [2]Oncology Department, Dong Ying People's Hospital, Dongying, China, [3]Peking University Cancer Hospital, Peking University Health Science Center, Beijing, China, [4]Department of Medical Oncology, Cancer Hospital of Chinese Academy of Medical Sciences, Beijing, China, [5]Medical Department, 3D medicines Inc., Shanghai, China, [6]The Medical Department, 3D medicines Inc., Shanghai, China, [7]Department of Medical Oncology, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China

Background: Thymoma and thymic carcinoma are indolent and poorly responsive to chemotherapy. PD-1/PD-L1 inhibitors have shown remarkable clinical benefit in several cancers. However, many immunomodulatory molecules have been identified to affect the efficacy of immunotherapy. This study aimed to examine the expression of PD-L1, transforming growth factor-β (TGF-β), and $CD8^+$ tumor-infiltrating lymphocytes ($CD8^+$ TILs) in patients with advanced thymic epithelial tumors (TETs) and evaluated their prognostic roles.

Methods: Retrospective analysis was performed on 20 patients with stage IV thymic carcinoma and 13 patients with stage III/IV invasive thymoma. Tissue biopsies were obtained before the first-line chemotherapy. The expression level of PD-L1, TGF-β and CD8 were assessed using IHC. The high or low expression was seprated by the median value of the IHC score. The outcomes including objective response rate (ORR), overall survival (OS) and progression-free survival (PFS) were then analized.

Results: The proportion of PD-L1 high was relatively higher in patients with advanced thymic carcinoma compared to patients with advanced invasive thymoma (65.0% vs 46.2%, $p = 0.472$). The proportion of TGF-β high in patients with thymic carcinoma was significantly higher than that in patients with invasive thymoma (65.0% vs 15.4%, $p = 0.011$). 5 of 7 patients in advanced thymic carcinoma with low PD-L1/TGF-β expression exhibited high level of CD8 staining. Among all patients, the median OS was 29.5 ms (95%CI: 20.0-39.0) with PD-L1 high versus 42.6 ms (95%CI: 0-98.3) ($p = 0.186$) with PD-L1 low. The median OS was 29.5 ms (95%CI: 18.6-40.4) with TGF-β high versus 62.9 ms (95%CI: 15.6-110.1) ($p = 0.052$) with TGF-β low. Among patients in advanced thymic carcinoma, the ORR was 30.0% with CD8 high versus 14.3% with CD8 low ($p = 0.603$), the median PFS was 13.3 ms with PD-L1 high versus 23.5 months ($p = 0.043$) with PD-L1 low. Furthermore, the ORR was 40.0% with TGF-β low vursus 16.7% with TGF-β high ($p = 0.538$).

Conclusions: Our results showed the prognostic role of PD-L1, TGF-β and $CD8^+$ TILs in patients with advanced TETs, and their potential for development of anti-PD-1/PD-L1 therapies.

1813P Prevalence and prognostic value of PD-L1 expression in molecular subtypes of metastatic large cell neuroendocrine carcinoma (LCNEC)

B.C.M. Hermans[1], J.L. Derks[1], E. Thunissen[2], R.J. van Suylen[3], M.A. den Bakker[4], H.J.M. Groen[5], E.F. Smit[6], R.A. Damhuis[7], E.C. van den Broek[8], P. PALGA-group[8], C.M. Stallinga[9], G.M. Roemen[9], E.J. Speel[9], A-M.C. Dingemans[1]

[1]Pulmonary Diseases, Maastricht University Medical Center (MUMC), Maastricht, Netherlands, [2]Pathology, VU Medical Centre, Amsterdam, Netherlands, [3]Pathology-DNA, Jeroen Bosch Ziekenhuis, Den Bosch, Netherlands, [4]Pathology, Erasmus University Medical Center, Rotterdam, Netherlands, [5]Pulmonary Disease, University Hospital Groningen (UMCG), Groningen, Netherlands, [6]Thoracic Oncology, Netherlands Cancer Institute, Amsterdam, Netherlands, [7]Research, Comprehensive Cancer Association, Utrecht, Netherlands, [8]PALGA foundation, Houten, Netherlands, [9]Pathology, Maastricht University Medical Center, Maastricht (MUMC), Netherlands

Background: Pulmonary LCNEC is a rare tumor. Two mutually exclusive subtypes of LCNEC are recognized, the co-mutated TP53 and RB1 and the STK11/KEAP1 (predominantly RB1 wildtype) group. We investigated PD-L1 expression in a well characterized stage IV LCNEC cohort and compared expression in the two subtypes.

Methods: Panel-consensus pathology revision was performed along with targeted next generation sequencing (TNGS) for genes TP53, RB1, STK11 and KEAP1 and immunohistochemical (IHC) analysis of RB1, on pretreatment tumor samples of stage IV LCNEC treated with chemotherapy (Derks et al. CCR 2018). IHC staining for PD-L1 (DAKO 28-8) was performed according to standard protocols on the DAKO autostainer and evaluated by an experienced screener. Tumors were scored positive if > 1% of tumor cells showed any membranous staining. Overall survival (OS) was evaluated by Kaplan Meier analysis and differences estimated with Log-Rank test. Cox-regression analysis included PD-L1, age and gender.

Results: PD-L1 IHC expression data could be generated in 98/147 confirmed LCNEC samples along with RB1 IHC (n = 97) of which 77 passed quality control for TNGS. PD-L1 expression was positive in 16/98 cases (16%); n = 5 (5%) with >50%, n = 11 (11%) having >1-50% and n = 82 (82%) with ≤1% membranous staining, respectively. No significant correlation of PD-L1 expression with molecular subtyping of LCNEC was identified (Table). PD-L1 expression was correlated with a superior OS, hazard ratio (HR) 0.54 ((95% Confidence interval (CI), 0.31-0.96) P = 0.034.

Table: 1813P Expression of PD-L1 in LCNEC, correlated to molecular data

	PD-L1 +	PD-L1 -	P-value
LCNEC (n = 98)	16%	84%	-
1-5%	7 %	-	-
5-20	4%	-	-
>50	5%	-	-
Rb1 IHC (n = 97)			
RB1 (+) (n = 29)	10%	90%	NS
RB1 (-) (n = 68)	19%	81%	
Mutation status (n = 76)			
RB1/TP53 mutated (n = 33)	15%	85%	NS
RB1 wildtype (n = 43)	16%	84%	
OS in months (95% CI)	8.9 (4.2-13.6)	6.6 (5.7-7.6)	HR 0.54 (0.31-0.96) P = 0.034

Conclusions: PD-L1 expression was positive in 16% of stage IV LCNEC tumors. PD-L1 expression is an independent process from LCNEC molecular subgroups. In LCNEC patients with PD-L1 expression superior OS is observed compared to those with negative PD-L1 tumors.

1814P Computed tomography features of resected lung adenocarcinomas with spread through air spaces

Y. Yamada[1], G. Toyokawa[2], T. Tagawa[3], T. Kamitani[4], Y. Yamasaki[4], F. Shoji[2], K. Yamazaki[2], S. Takeo[2], Y. Oda[1]

[1]Department of Anatomic Pathology, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan, [2]Department of Thoracic Surgery, National Hospital Organization, Kyushu Medical Center, Fukuoka, Japan, [3]Department of Surgery and Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan, [4]Department of Clinical Radiology, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan

Background: Spread through air spaces (STAS) is a recently-recognized invasive pattern of lung cancer defined as 'micropapillary clusters, solid nests or single cells beyond the edge of the tumor into air spaces.' Since STAS has been shown to be a significant prognosticator for the postoperative survival, predicting STAS preoperatively by computed tomography (CT) might help determine the optimum surgical procedures.

Methods: Information on STAS and preoperative CT were availablen 327 patients with resected lung adenocarcinomas. STAS was defined as tumor cells within air spaces in the lung parenchyma beyond the edge of the main tumor. The association of STAS with CT characteristics, such as vascular convergence, ground glass opacity (GGO), air bronchogram, notch, pleural indentation, spiculation, and cavitation, was analyzed.

Results: Among the 327 patients with resected adenocarcinoma, 191 (58.4%) were positive for STAS. A univariable analysis demonstrated that STAS-positive adenocarcinomas were significantly associated with a larger radiological tumor diameter (P = 0.02), the presence of vascular convergence (P < 0.01), notch (P < 0.01), pleural indentation (P = 0.03), spiculation (P < 0.01), and the absence of GGO (P < 0.01) compared with STAS-negative ones. In a multivariable analysis, the presence of notch (P = 0.01) and the absence of GGO (P < 0.01) were shown to be significantly associated with the STAS phenomenon. The odds ratio for STAS of notch-positive and GGO-negative adenocarcinomas against notch-negative and GGO-positive ones was 5.01 (P < 0.01).

Conclusions: The presence of notch and the absence of GGO were independently associated with the STAS phenomenon. These results will prove helpful in identifying STAS-positive adenocarcinoma by CT prior to surgical resection.

1815P Comparative proteomic analysis of acetylation profiles in esophageal squamous carcinoma cells

Y. Dai[1], J. Li[2]

[1]Radiation Oncology, Fujian Medical University Cancer Hospital, Fujian Medical University, Fuzhou, China, [2]Radiation Oncology, Fujian Cancer Hospital, Fuzhou, China

Background: To explore the different expression of proteins and the acetylations between esophageal squamous carcinoma cells (ESCCs) and cancer stem-like cells (CSCs) by proteomic analysis.

Methods: The Eca109 cells were divided into CSCs group and ESCCs group by using serum-free culture and serum culture. We measured the CD44 expression levels, CCK8 cell proliferations and plate cloning formation to identify the characteristics of cancer stem cells. Furthermore, Tandem Mass Tags (TMT)-based quantitative proteomics and bioinformatic analysis were used to detect proteomics and bioinformatic analysis.

Results: The positive rate of CD44 and CCK8 cell proliferation experience in the CSCs group were higher than ESCCs group (P < 0.05). The plate cloning formation showed that the values of D0, Dq, N and SF2 were significantly higher in the CSCs group, and the radiation sensitization ratio was 1.556. Furthermore, 5,262 proteins were identified in the two groups in total. The up-regulation of 187 proteins and down-regulation of 83 proteins were detected in CSCs group (>1.5 times). Bioinformatic analysis further revealed that those quantifiable proteins were mainly involved in multiple biological functions and metabolic processes, including steroid biosynthesis, protein processing in endoplasmic reticulum, metabolic pathways and oxidative phosphorylation pathways. In addition, 53 acetylated sites were increased and 67 acetylated sites were decreased in CSCs group (>1.5 times). Those acetylated sites were involved in the regulation of DNA metabolic process, the function of cell adhesion, glycolysis and gluconeogenic pathway.

Conclusions: We provides a global survey of proteins and acetylations in ESCCs and CSCs. These proteins and acetylations may be related to the radiosensitivity, recurrence and metastatic of esophageal squamous carcinoma and could be a potential new target for esophageal squamous carcinoma.

1816P Survival outcomes for patients with lobectomy and wedge resection in lung cancer

S. Alshafie, S. Ahmed

Faculty of Medicine, Suez Canal University, Ismailia, Egypt

Background: Lobectomy is the most performed surgical procedure for lung cancer, however, patients who are eligible to lobectomy undergo wedge resection. The purpose of this study is to compare the survival of patients who underwent wedge resection versus lobectomy.

Methods: Using SEER18 Registries Research Database, we collected the data of 638 patients diagnosed with lung cancer from 2010 to 2012. Out of these patients, 423 underwent wedge resection, while 156 had lobectomy. We assessed the prognostic value of age, sex, stage, laterality and primary site. Kaplan-Meier method was used for survival analysis.

Results: Patients with lung cancer who underwent lobectomy had significantly better 3-year relative survival rates 47.2% than those who underwent wedge resection (47.2% versus 26.7%, respectively, p-value = 0.044). Subgroup analysis revealed better survival rates among female patients and stage III lung cancer. However, no advantage was associated with specific age, laterality, or primary site.

Conclusions: Patients who underwent lobectomy were associated with better 3-year relative survival rate compared to wedge resection.

1817TiP SAKK 17/16 - Lurbinectedin monotherapy in patients with progressive malignant pleural mesothelioma: A multicenter, single-arm phase II trial

Y. Metaxas[1], A. Xyrafas[2], M.T. Mark[1], M. Pless[3], M. Frueh[4], P.R. Froesch[5], M. Schneider[6], C. Biaggi Rudolf[6], F. Grosso[7], R. von Moos[1]

[1]Oncology/Hematology, Kantonsspital Graubünden, Chur, Switzerland, [2]Statistics, SAKK - Swiss Group for Clinical Cancer Research, Bern, Switzerland, [3]Oncology/Hematology, Kantonsspital Winterthur, Winterthur, Switzerland, [4]Oncology/Hematology, Kantonsspital St. Gallen, St. Gallen, Switzerland, [5]Medical Oncology, IOSI Istituto Oncologico Svizzera Italiana, Locarno, Switzerland, [6]Clinical Trial Management, SAKK - Swiss Group for Clinical Cancer Research, Bern, Switzerland, [7]Oncology/Hematology, Ospedale di Alessandria, Alessandria, Italy

Background: Unresectable malignant pleural mesothelioma (MPM) is treated with first-line platinum-based chemotherapy. Unfortunately, there is no standard second-line treatment for progressive patients. As widely available options like gemcitabine and vinorelbine provide only modest efficacy, progressive MPM poses an unmet medical need for further treatment strategies. Lurbinectedin (PM01183) is a novel compound, which covalently binds to the DNA minor groove, inducing double-strand breaks, as well as selectively reducing the tumor-associated macrophages. It has already been tested as monotherapy or in combination with chemotherapy in several Phase I-III trials in different tumor entities (including small cell lung cancer and ovarian cancer) with encouraging results. Based on MPM cases treated with lurbinectedin within the respective Phase I trials, where promising activity had been shown, we are currently conducting this proof-of-concept trial of safety and efficacy of lurbinectedin monotherapy in progressive MPM.

Trial design: This is a prospective 2-stage single-arm multicenter phase II trial. MPM patients progressing after platinum-based chemotherapy with good performance status are eligible for the trial. Prior surgery and/or radiotherapy and pretreatment with immunotherapy are allowed. Treatment will be given with 3.2 mg/m^2 lurbinectedin intravenously every 3 weeks (one cycle) until progression, unacceptable toxicity or patient withdrawal. Re-staging using contrast-enhanced computer tomography will be performed every 6 weeks. The primary endpoint of the trial is progression-free survival (PFS) at 12 weeks. Secondary endpoints are PFS, objective response rate, disease control rate at 12 weeks, overall survival, time-to-treatment failure and adverse events. A total of 6 Swiss and 3 Italian sites will participate for a total of 43 patients, as required by Simon's two-stage design. Accrual has already begun in Switzerland, is expected for February 2018 in Italy, and is estimated to be completed by beginning of 2019. Up to now 11 patients have been treated within the trial.

Clinical trial identification: NCT03213301.

Legal entity responsible for the study: Swiss Group for Clinical Cancer Research (SAKK).

Funding: SAKK, PharmaMar.

1818TiP Multicentre, double-blind, randomised phase II study evaluating gemcitabine with or without ramucirumab as II line treatment for MPM

M. Pagano[1], F. Zanelli[1], R. Gnoni[1], C. Bonelli[1], M. Tiseo[2], L. Boni[3], G.L. Ceresoli[4], P.A. Zucali[5], F. Grosso[6], G. Pasello[7], F. Cappuzzo[8], C. Pinto[1]

[1]Oncology Unit, AUSL-IRCCS Reggio Emilia, Reggio Emilia, Italy, [2]Medical Oncology, AOU di Parma, Parma, Italy, [3]Istituto Toscano Tumori, Clinical Trial Coordinating Center, AOU Careggi, Florence, Italy, [4]Oncology Unit, Humanitas Gavazzeni, Bergamo, Italy, [5]UO Oncologia Medica e Ematologia, Humanitas Cancer Center Istituto Clinico Humanitas - IRCCS, Rozzano, Italy, [6]Oncology Unit, Ospedale di Alessandria, Alessandria, Italy, [7]Oncology Unit, Istituto Oncologico Veneto IRCCS, Padua, Italy, [8]Oncology Unit, Ospedale Civile di Ravenna - S.ta Maria delle Croci, Ravenna, Italy

Background: Malignant Pleural Mesothelioma (MPM) is still a fatal cancer and median overall survival is still approximately 1 year after diagnosis and new therapies are being awaited. After first line therapy patients inevitably progress and usually they are in good conditions and inquire about a second-line treatment. Even if a second line therapy is frequently considered in common clinical practice, the optimal treatment has not been defined yet. Gemcitabine was largely used in association with platinum compounds before the registration of platinum-pemetrexed doublet in first line setting. Pre-clinical data suggest the importance of angiogenesis in tumour biology of MPM. Considering the documented high VEGFR-2 expression in MPM and the high affinity of ramucirumab for the same receptor, and given the failure of previous anti-angiogenetic drugs as single agent, we hypothesised a significant activity of ramucirumab in MPM in association with gemcitabine.

Trial design: RAMES is a multicentre, double-blind, randomised Phase 2 study,to evaluate the efficacy and the safety of the addition of ramucirumab to gemcitabine as the second-line treatment of patients with MPM.Randomisation will be done via a centralized system and will stratified by performance status (0-1 vs 2) age ($\leq$70 vs $>$ 70) histology (epithlioid vs others) and time to progression after first line therapy ($<$ 6 months vs $\geq$ 6 months).The primary objective is overall survival. Secondary objectives are progression free survival and safety. Patients will be randomly assigned (1:1) to receive intravenous gemcitabine (1000 mg/mq) on days 1 and 8 every 21 days with placebo or combined with intravenous ramucirumab 10 mg/kg (ramucirumab group) on day 1 of a 21-day cycle until progression disease or unacceptable toxicity. The interim analysis was performed 6 weeks after enrolment of the 80th patient. Blood samples were collected for pharmacokinetic and immunogenic analyses. The study duration will be 24 months for the accrual. The great amount of interest and the scarce availability of ongoing trials have made recruitment rapid. This will allow information on the possible benefit of ramucirumab in MPM to be given much earlier than expected.

Clinical trial identification: EudraCT: 2016-001132-36.

1823P Synergistic anti-cancer effect of histone deacetylase inhibition and blockade of the glycolytic pathway

S.Y. Kim, Y.S. Lee, H. Chang, H-S. Chang, C.S. Park

Thyroid Cancer Center, Department of Surgery, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Republic of Korea

Background: Advanced cancer has been shown to have a higher percentage of epigenetic changes are more often events than genetic mutations. Preclinical models have showed that combination of the HNHA (N-hydroxy-7-(2-naphthylthio) heptanomide) and 2DG (2-Deoxy-D-glucose) is a play crucial role in ATC (cancer stem-like cell, anaplastic thyroid cancer). The aim of this research is to study that caspase cleavage dependent apoptosis by combination therapy of HNHA and 2DG in ATC.

Methods: ATC cell lines were exposed to HNHA and 2DG alone or combined, and cell viability was determined by MTT assay. Synergistic anti-cancer effects of the combination therapy on cell cycle and intracellular signaling pathways were estimated by flow cytometry and immuno blot analysis. The ATC cell lines xenograft model was used to examine the anti-tumor activity in vivo.

Results: Consequently, our results are suggest that combination therapy of HNHA and 2DG is synergistically decreased cell viability in ATC cell, and also significantly induced apoptotic cell death in this cells, as showed by the cleavage of caspase-3. HNHA and 2DG combination was reduced anti-apoptotic factor in these cells. Thus, combination therapy with HNHA and 2DG most significantly reduced tumor volume in ATC cell xenografts.

Conclusions: The current study suggests that HNHA and 2DG combination treatment was more effective than treatment with the HNHA or 2DG alone. These findings may offer a new therapeutic approach to ATC include the cancer stem-like cells.

1824P Lenvatinib and pembrolizumab as save and effective combination treatment in 8 patients with metastasized anaplastic (ATC) or poorly differentiated thyroid carcinoma (PDTC)

C. Dierks[1], C. Miething[1], O. Thomusch[2], N. von Bubnoff[1], J. Duyster[1]

[1]Haematology Oncology, University Medical Center Freiburg, Freiburg, Germany, [2]Surgery, University Medical Center Freiburg, Freiburg, Germany

Background: Introduction: Anaplastic thyroid carcinomas (ATC) and metastasized PDTC have a dismal prognosis of only few months despite extensive multimodal therapy. The tumors are high-proliferative and aquire numerous somatic mutations (often over several hundred mutations). These specifics implicate a special sensitivity of the tumors towards anti-angiogenic therapies and immune checkpoint inhibitors.

Methods: In the presented cases, we have combined anti-angiogenic therapy with lenvatinib and the immune checkpoint inhibitor pembrolizumab in 8 patients with metastasized ATC (n = 6) or metastasized PDTC (n = 2). All patient tumors had more than 100 somatic mutations as identified by whole exome sequencing (WES) and PD-L1 > 1%. Lenvatinib was started at 24 mg/kg BW and reduced to minimally 14 mg/kg BW upon appearance of intolerable side effects (uncontrollably high blood pressure, weight loss, loss of appetite). Pembrolizumab was started 3 - 8 weeks later and was given at a fixed dose of 200 mg every 3 weeks. Maximum treatment duration with this combination was 27 months (27, 24, 19, 11, 7, 6, 3, 1 month) and 6 patients are still on therapy.

Results: No continuous °III/IV toxicities were seen with the combination treatment. Weight loss (3 pts) and uncontrollably high blood pressure (3 pts) were normalized after reducing lenvatinib doses. One patient died 5 days after the first dose of pembrolizumab due to disease progression of the cervical tumor. All other patients have reached at least a SD (n = 2), most patients had reached a PR (n = 4) and one patient has reached a complete remission (CR). The majority of patients is still on therapy (27,24,19,7,6 and 3 months), implicating this treatment combination as a safe and effective treatment regimen for this extremely bad prognostic patient cohort.

Conclusions: Our results implicate that a combination of lenvatinib and pembrolizumab is safe and effective in patients with ATC or PDTC. The combination treatment shall now be systematically examined in a phase II clinical trial (ATLEP) in ATC/PDTC patients.

1825P Both HIF-1α and GAB1 can regulate pim-1 in the papillary thyroid carcinoma

X. Zhu[1], Q. Wen[2], M. Ge[2]

[1]Zhejiang Cancer Institution, Hangzhou, China, [2]Head and Neck Surgery, Zhejiang Cancer Hospital, Hangzhou, China

Background: As a oncogene, Pim-1 has been proved to play key role in proliferation, apoptosis and angiogenesis. Thyroid cancer represents the most common malignancy in the endocrine system, and a marked increase in the incidence has occurred in recent years. Among them, papillary thyroid carcinoma (PTC) is the most common form. So it is worthwhile to discuss the function of Pim-1 in the development and progression of PTC.

Methods: 34 PTC patients were selected to investigate the levels of Pim-1, HIF-1α and GAB1 protein by IHC. After hypoxia treatment for 24h, Westernblot was carried out to detect the Pim-1, HIF-1α and GAB1 in the PTC cell BCPAP and TPC-1. BCPAB was trasfected with GAB1 shRNA and Full-length vector to achieve GAB1 knockdown and overexpression. CCK-8 assay was used to measure the ell proliferation. The migration and invasion capacity were tested by wound-healing and transwell methods respectively.

Results: Both Pim-1 and HIF-1α were overexpressed in the PTC tissues and Pim-1 levels were significant correlated with HIF-1α. Meanwhile, Pim-1 had a significant relationship with the tumor number - patients with multiple tumor have a higher Pim-1 level than that have solitary tumor and HIF-1α showed a significant correlation with patients' age. After bioinformatics screen, we found that there were 4 hypoxia response elements (HRE) in the Pim-1 promoter area, which suggested HIF-1α could transcriptional regulate Pim-1 directly. Moreover, hypoxia could signifcantly drive HIF-1α and Pim-1 elevation in both BCPAP and TPC-1. GAB1 was found to express higher in PTC tissues than that in the adjacent normal tissues and GAB1 level was significant associated with the tumor size. Morover, Pim-1 expression was significantly decrease and increase after GBA1 knockdown and overexpression in BCPAP. Meanwhile, GAB1 did not affect the cell viability but exerted a strong effect on the migration and invasion capacity of BCPAP. However, there was no change in GAB1 expression after hypoxia treatment in both BCPAP and TPC-1.

Conclusions: Taken together, our current data showed the important role of Pim-1 in the PTC. It also can be deduced that both HIF-1α and GAB1 are involved in the upstream regulation of Pim-1, but the detailed mechanism are different, which depended on the different tumor microenvironment.

1826P Increase in thyroid cancer (TC) incidence in Cyprus: Overdiagnosis or true increase of clinically relevant TC?

H.C. Charalambous[1], A. Demetriou[2], S. Frangos[3], P. Pavlou[2]

[1]Oncology, Bank of Cyprus Oncology Centre, Nicosia, Cyprus, [2]Cyprus Cancer Registry, Ministry of Health, Nicosia, Cyprus, [3]Nuclear Medicine, Bank of Cyprus Oncology Centre, Nicosia, Cyprus

Background: An increase in Thyroid Cancer (TC) incidence has been seen in most countries worldwide. The same has also been reported for Cyprus[1]. The most fundamental issue is whether this increase is due to increased investigations (opportunistic screening) and overdiagnosis of small incidental TC or due to a true increase in clinically relevant TC.

Methods: Data collection in the Cyprus Cancer Registry (CyCR) is guided by the MECC Manual of Coding and Staging for Cancer Registration. In this study, we considered only invasive cancer (ICD-O-3 behavior code=3). From 1998 until 2015 there were 2490 thyroid cancer diagnoses recorded in the CyCR, from which 2309 (92.7%) had histology and staging information recorded. We undertook analysis of the staging of recorded cases in the CyCR and calculated APC (Annual Percent Change) to ascertain whether the increase seen is due to small localized cancers (suggesting opportunistic screening) or also true for locally advanced / Lymph node positive tumours.

Results: The APC for all patients is 11.1% yearly increase. When analyzing by stage, the APC for regional (i.e. locally advanced) TC was 16.3% higher than for localized disease at 11.9%. There was also a statistically significant increase in metastatic cases, but this needs to be interpreted with caution due to the small number of patients with metastatic disease (data not presented).

Table: 1826P

Subgroup	Joinpoints	APC	Lower CI of APC	Upper CI of APC	Significance probability at $\alpha = 0.05$
Total	0	11.1	9.4	12.8	0.000
Local	1	11.9	10.1	13.7	0.000
Regional	0	16.3	12.5	20.2	0.000

Conclusions: Analysis of the Cyprus Cancer Registry data provide evidence of a large increase in TC in Cyprus, being due to an increase of both localized and also locally advanced tumours. It is therefore likely that the increase in TC is not only due to opportunistic screening, but also due to a true increase of larger, clinically relevant tumours.

1827P Surgery for lymph node metastases of sporadic medullary thyroid carcinoma

W. Fan, H. Jiang

Medical Oncology, The First Affiliated Hospital, Zhejiang University, Hangzhou, China

Background: Medullary thyroid carcinoma (MTC) arises from malignant proliferation and differentiation of C cells, approximately 2% of all thyroid malignancies. Calcitonin (CT) and carcinoembryonic antigen (CEA) secreted by C cells are the main secretory product and serves as a marker for the diagnosis of this disease. It is also used in the follow-up of MTC patients after thyroidectomy for the identification of relapse or progression of disease. Compared with other thyroid cancers, MTC has unique biological characteristics and is insensitive to radiotherapy, chemotherapy and iodine therapy. Surgical intervention is currently the only effective, curative treatment for medullary thyroid cancer. The 2015 American Thyroid Association recommended total thyroidectomy and different range of lymph node dissection, but controversy remains surrounding the indication for prophylactic lateral lymph node dissection. This study was performed to analyze the risk factors for cervical lymph node metastases and predict the indication for prophylactic lateral neck dissection in patients with sporadic medullary thyroid carcinoma (SMTC).

Methods: The aims of this study were to analyze the risk factors of cervical lymph node metastases, and also to predict the indication of prophylactic lateral neck dissection in SMTC patients.

Results: Metastases rates in central and lateral compartment were 46.2% (30/65) and 40.0% (26/65), respectively. Univariate analyses showed the incidence of cervical lymph node metastases was significantly higher in patients with tumor size >1cm, tumor multifocality and thyroid capsule invasion. Multivariate analyses revealed that only thyroid capsule invasion was an independent predictive factor for central compartment metastases ($p < 0.001$, OR = 11.080) and lateral neck metastases ($p < 0.001$, OR = 9.067). Moreover, the possibility of central compartment metastases was higher when preoperative value of serum carcinoembryonic antigen (CEA) was above 30 ng/mL (60% vs 34.3%, χ^2=4.298, P = 0.038).

Conclusions: The medullary thyroid carcinoma has a high incidence of cervical lymph node metastases. Prophylactic lateral node dissection is necessary in patients with thyroid capsule invasion or with high value of serum carcinoembryonic antigen (CEA).

1828P Role of SPECT-CT somatostatin-receptor scintigraphy in the management of medullary thyroid cancer (MTC)

S. Sergieva[1], M. Atanasova[2], A. Fakirova[3], S. Velchova[4]

[1]Nuclear Medicine, Specialized Hospital for Active Treatment in Oncological Diseases-Sofia City, Sofia, Bulgaria, [2]Medical Oncology, UH "City Clinic", Sofia, Bulgaria, [3]Pathology, Military Medical Academy, Sofia, Bulgaria, [4]Medical Oncology, Sofia Cancer Center, Sofia, Bulgaria

Background: The MTC arises from the parafollicular, calcitonin-secreting malignant transformed thyroid C-cells who express on the surface somatostatin SSTR receptors. The most of aggressive locally advanced/metastatic MTC tumors, found to be positive for RET proto-oncogene mutation, are treated with Vandetanib. SPECT-CT somatostatin-receptor scintigraphy with 99mTc-Tektrotyd should be considered for MTC imaging before and after therapy for exact staging and follow-up of the disease due to its highly sensitivity and specificity for detection of neuroendocrine tumors, expressed SSTR. The aim of this study was to evaluate clinical role of SPECT-CT scintigraphy with ^{99m}Tc-Tektrotyd in the management of patients with MTC.

Methods: 25pts (7M;18F) with MTC were studied; whole body somatostatin scintigraphy followed by target SPECT-CT studies were performed 2-4 hrs post i.v.inj. of 740 MBq ^{99m}Tc-Tektrotyd (Polatom). SPECT-CT camera Symbia T2, Siemens was used. Three of them were studied for initial pre-operative N/M-staging, 17 were follow-up after surgery. In 5 patients with metastatic disease SPECT-CT with ^{99m}Tc-Tektrotyd were performed before and after target therapy with Caprelsa (Vandetanib), 300mg/d orally.

Results: Initial pre-operative staging showed 3 positive results for the primary tumor and metastatic lymph nodes and 2 false negative imaging of small 1-4 mm lung metastases. True negative results were obtained in 5 cases after thyroidectomy. True positive results were obtained in 17 cases with local recurrence in the thyroid bed, lymphadenopathy, osteolytic bone metastases, lung and subcutaneous lesions. False positive result was in 1 case with benign ovary cyst. Plasma levels of calcitonin vary from 94 to 5496 pg/ml in all 17 patients with local recurrence and/or metastatic lesions. In 5/17 cases SPECT-CT studies were used to evaluate effect of target therapy, respectively: partial response – in 2 cases, stable disease – in 2 cases and progressive disease – in 1 cases.

Conclusions: SPECT-CT somatostatin-receptor scintigraphy with ^{99m}Tc-Tektrotyd is very useful functional imaging modality in patients with MTC in order to determinate personalized therapeutic disease approach.

1829TiP A noninferiority trial of cabozantinib (C) comparing 60 mg vs 140 mg orally per day to evaluate the efficacy and safety in patients (pts) with progressive, metastatic medullary thyroid cancer (MTC)

J. Krajewska[1], B.G. Robinson[2], B. Keam[3], J. Capdevila[4], A. Klochikhin[5], H. Gan[6], E. Kapiteijn[7], R. Elisei[8], J. Partyka[9], A.E. Borgman[9], M. Schlumberger[10]

[1]Oncology Center, M. Sklodowska-Curie Institute, Gliwice, Poland, [2]Sydney Medical School, The University of Sydney, Sydney, Australia, [3]Internal Medicine, Seoul National University Hospital, Seoul, Republic of Korea, [4]Gastrointestinal and Endocrine Tumor Unit, Vall d'Hebron University Hospital, Barcelona, Spain, [5]Oncology, Yaroslavl Regional Clinical Oncology Hospital, Yaroslavl, Russian Federation, [6]Clinical Trials Austin Health, Olivia Newton-John Cancer Wellness & Research Centre, Heidelberg, Australia, [7]Medical Oncology, Leiden University Medical Center (LUMC), Leiden, Netherlands, [8]Endocrine Unit, University Hospital of Pisa, Pisa, Italy, [9]Clinical Research & Development, Exelixis, Inc, San Francisco, CA, USA, [10]Department of Nuclear Medicine and Endocrine Oncology, Gustave Roussy, Villejuif, France

Background: C inhibits receptor tyrosine kinases including MET, VEGF receptors, AXL, and RET. C has been approved in the US for the treatment of progressive, metastatic MTC and in the EU for progressive, unresectable locally advanced or metastatic MTC. In the phase 3 registrational study EXAM, pts were randomized 2:1 to receive 140 mg C or placebo (P) once daily (qd). The primary analysis for EXAM demonstrated a statistically significant improvement in progression-free survival (PFS) with a median PFS of 11.2 mo for C vs 4.0 mo for P (hazard ratio [HR] 0.28, 95% CI, 0.19–0.40; $p < 0.001$) (Elisei, JCO 2013). Dose reductions occurred commonly in the C arm with 82% of pts experiencing at least one dose reduction. While overall survival (OS) was

not significantly improved in the overall population (median OS of 26.6 mo for C vs 21.1 mo for P; HR 0.85, 95% CI 0.64–1.12; p = 0.24), median OS was 44.3 mo for C vs 18.9 mo for P (HR 0.60, 95% CI 0.38–0.94) in the RET M918T-positive subgroup (Schlumberger, Ann Oncol 2017).

Trial design: EXAMINER (NCT01896479) is a global, randomized, double-blind study comparing the safety and efficacy of C at 60 vs 140 mg qd in pts with progressive, metastatic MTC using a noninferiority study design. Approximately 188 pts will be randomized 1:1 to receive C at 140 mg qd as capsules or 60 mg qd as tablets in Europe, Asia, Canada, and other regions. Eligible pts must have measurable disease and documented progressive disease within 14 mo prior to enrollment. A recent tumor tissue sample to test for RET and RAS mutations or documentation of a RET or RAS mutation is required. Pts will be stratified based on RET M918T status. After randomization, pts will be treated until disease progression per RECIST 1.1 or intolerable toxicity. Tumor assessments will be performed every 12 weeks. PFS and objective response rate evaluated by independent review are the primary and secondary efficacy endpoints, respectively; safety and correlation of tumor mutation status with clinical response are additional endpoints. The EXAMINER study continues to enroll pts.

Clinical trial identification: NCT0189647.

(cancer-cohort, n = 50) or that did not present NSCLC or any other tumors at an advanced age (cancer-free cohort, n = 50). We sequenced their germline DNA using the Agilent Human Exome Capture v5, which includes 21,522 genes (357,999 exons). We selected genetic variants located in the exonic regions and splice sites of the genes evaluated; that codified for non-synonymous codons; and that showed allelic differences >15% between both cohorts.

Results: The mean age for the cancer and cancer-free cohorts was 50 (range 34-55) and 78 years (72-90). Mean tobacco consumption was 44 (range 6-72) and 55 pack-years (20-124). Median exome sequencing coverage was 96% at > 10X and median depth was 97X. We identified 229 differential variants between both cohorts, located in 189 genes. The most significant variants ($p < 10^{-4}$) are shown in the table. Twenty genes or family genes included >3 differential genetic variants (range 3-25): ADAMTS, ALPK2/3, ankyrins, APOL4, CCDC, CRIPAK, FYCO1, HLA-A, keratins, mucins, olfactory receptors, PDPR, PRAME family, RFPL2, RP1L1, SAMD9, SLC transporters, anoctamins, TTN, and ZNF family.

Conclusions: We identified genetic variants associated with individuals presenting extreme phenotypes of high and low risk to develop tobacco-induced NSCLC. These variants warrant further study to characterize their impact in the development of these extreme phenotypes.

1838P CANscript™ as a patient-derived predictive platform for individualizing treatment in lung cancer

G. Babu[1], K. Deepak[2], B. Balakrishnan[3], M. Biswas[4], A. Prasath[3], P. Radhakrishnan[5], A. Chatterjee[3], S. Thiyagarajan[3], P. Chaudhuri[3], P.K. Majumder[5]

[1]Kidwai Memorial Institute of Oncology, HCG Curie Centre of Oncology, Bangalore, India, [2]Medical Oncology, Kidwai Memorial Institute of Oncology, Bangalore, India, [3]Cancer Biology, Mitra Biotech, Bangalore, India, [4]Molecular Pathology, Mitra Biotech, Bangalore, India, [5]Cancer Biology, Mitra Biotech, Woburn, MA, USA

Background: Lung cancer causes nearly 1.69 million deaths globally and 5-year survival rate is less than 20%. Several biomarkers have improved treatment selection and overall prognosis in lung cancer to some extent (JNCCN; 2017;15:504). However, clinical relevance of these biomarkers is limited to only a small percentage of patients. Hence, there is a need for an individulized tool that can accurately predict an individual's response to a therapy, especially in scenarios where there is a choice of equivalent treatment regimens and no specific biomarkers.

Methods: CANscript™ effectively recreates a patient's tumor microenvironment ex vivo by preserving the native contexture. The platform provides phenotypic assessment of response to the drug(s) tested for a given tumor and generates clinically relevant predictions for real-time treatment selection (Nat. Commun. 2014, 6:6169). We used this platform to assese phenotypic response of lung tumors.

Results: Twenty-one lung cancer patient tumors were treated with one or more FDA approved regimens including targeted therapy and chemotherapy in CANscript platform. We did not observe any advantage of targeted therapy (EGFR, PD1 inhibitors) over chemotherapy. Six tumors, which were non-responders to gefitinib, were predicted responders to carboplatin/pemetrexed and/or carboplatin/docetaxel. Further, out of 4 gefitinib responders, 3 were predicted to respond to chemotherapies carboplatin/pemetrexed or carboplatin/docetaxel. Highest efficacy was observed in carboplatin/pemetrexed and carboplatin/docetaxel (47% and 46% respectively). 25% tumors treated with anti-PD1 responded to the therapy, matching the reported clinical response rate of anti-PD-1 therapy.

Conclusions: CANscript™ is used as an ex-vivo, personalized platform that can predict an individual's response to various classes of anticancer drugs. The platform has been validated over a large number of clinical samples and the current study indicates that CANscript is a preferred platform for selecting individualized drug responses for treatment of lung cancer.udy indicates that CANscript is a preferred platform for selecting individualized drug responses for treatment of lung cancer.

Background: Whole-exome sequencing of plasma cell-free DNA (WES-cfDNA) is an emerging liquid biopsy approach for identification of somatic mutations and yields high-concordance when compared to WES of the tumours of patients with advanced disease. Here we show that sequential WES-cfDNA provides insight regarding the evolution of metastatic breast cancer and that global mutation profiles relate to clinical response and progression to different lines of treatment.

Methods: A patient with inherited BRCA2 breast cancer was recruited at disease relapse and blood samples were then taken over a 2 year period on treatment until death. Whole-exome sequencing was performed on 12 DNA samples: primary tumor, 2 biopsies at relapse and 8 sequential cfDNA samples. Results were validated by targeted amplicon sequencing and ddPCR. Somatic Single Nucleotide Variants (SNVs) were called with Mutect2. Mutational signatures (MS) and their contributions to each sample were detected using the R package deconstructSigs.

Results: WES profiling showed that MS-3 (associated with germline BRCA2 status) was the predominant signature in the primary tumour, whereas the signature of the two relapse biopsies were MS-3, MS-4 and MS-5, and MS-3, MS-4 and MS-6. The first blood sample taken at relapse with bone disease also had a mixed MS profile. The MS-3 signature was detected in cfDNA with progression to lung and initially resolved in response to carboplatin treatment. MS-3 also predominated in cfDNA on subsequent disease progression and was the dominant MS at the time of death. SNV analysis identified a Tier-1 PIK3CA mutation in the primary and relapse tissue, whereas three other Tier-2 mutations in DNM2, DCC and ATP1A1 were specific to relapse, indicative of cancer evolution. All four variants were detected at high levels by WES-cfDNA. Lastly, an ESR1 emergent mutation was identified by targeted sequencing in cfDNA and predicted failure of letrazole therapy.

Conclusions: Our study demonstrates the capacity of sequential WES-cfDNA to capture the genomic profiles of advanced cancer. The MS in cfDNA can be used track tumour evolution, and give insight into the characteristic of the dominant and lethal clone.

Background: Inducible T cell Co-Stimulator (ICOS) is a co-stimulatory receptor, induced on activated T cells (TC) upon TC receptor engagement. Emerging clinical and preclinical data for checkpoint inhibitors demonstrate increased ICOS expression on effector TC, which has been linked to improved clinical outcomes. We have therefore developed an ICOS antibody optimized for agonist activity.

Methods: Syngeneic mouse tumor models and human ex-vivo PBMC and tumor infiltrating lymphocyte culture assays were utilized to evaluate the activity of a murine (7E.17G9) or human (H2L5) specific ICOS agonist antibody alone and in combination with PD-1 blockade. A selection of flow cytometry, IHC, multiplex IF, nanostring, and in silico analysis was performed to characterize and develop H2L5 for subsequent clinical evaluation.

Results: ICOS induction either with 7E.17G9 or H2L5 agonist antibody induced significant activation and clonal expansion of both CD4+ and CD8+ effector TC. These TC had increased effector function (higher IFN-γ and Granzyme B) and increased homing to tumors resulting in antitumor responses when administered alone and in combination with PD-1 blockade. The level of expression of ICOS on effector and regulatory TC was found to overlap, suggesting that Fc-mediated depletion associated with IgG1 may result in depletion of effector TC. Preclinical data using different Fc isotypes supported the selection of the stabilized IgG4PE isotype for optimal agonism in the absence of NK-mediated depletion of effector TC. Drug concentrations associated with ICOS receptor occupancy, increases in TC activation and tumor reduction, support selected

doses and biomarker strategy in the clinic. Select solid tumors types were identified for clinical studies based on expression of ICOS, ICOS-L, PD-L1 and PD-1.

Conclusions: IgG4PE provides the optimal isotype for delivering ICOS agonism whilst reducing the risk of depletion of ICOS positive effector TC. The comprehensive preclinical data package generated, supports clinical testing of the H2L5 IgG4PE ICOS agonist antibody (GSK3359609), currently being investigated alone and in combination with pembrolizumab, in a first in human clinical study (INDUCE-1).

1841P Refining criteria of hyperprogression (HPD) with immune checkpoint inhibitors (ICIs) to improve clinical applicability

I. Matos Garcia[1], A. García Ruiz[2], J. Martin-Liberal[1], C. Hierro[1], M. Ochoa De Olza Amat[3], C. Viaplana[4], G. Mur[1], M. Vieito Villar[1], I. Brana[3], A. Azaro[3], C. Perez[1], V. Rodriguez Freixinos[3], G. Argiles[5], M. Oliveira[3], E. Felip Font[6], E. Muñoz-Couselo[3], J. Tabernero[3], R. Dienstmann[4], E. Garralda[7]

[1]Medical Oncology, Vall dHebron Institute of Oncology (VHIO)-Cellex Center, Barcelona, Spain, [2]Radiomics Group, Vall d'Hebron Institute of Oncology (VHIO)-Cellex Center, Barcelona, Spain, [3]Department of Medical Oncology, Vall d'Hebron Institute of Oncology, Barcelona, Spain, [4]Oncology Data Science (ODysSey) Group, Vall d'Hebron University Hospital, Barcelona, Spain, [5]Gastrointestinal and Endocrine Tumors Group, Vall d'Hebron Institute of Oncology, VHIO, Barcelona, Spain,[6]Medical Oncology Service (Lung Cancer Unit), Vall d'Hebron University Hospital, Barcelona, Spain, [7]Early Drug Development Unit, Vall d'Hebron Institute of Oncology (VHIO)-Cellex Center, Barcelona, Spain

Background: Rapid progression while on ICIs has been clinically described as HPD, however there is still not a consensus definition for this phenomenon. Institute Gustave Roussy (IGR) firstly described HPD as $\geq$ two-fold increase in tumor growth rate (TGR) during experimental period (EXP) vs. Reference period (REF). We recently described VHIO HPD using EXP only, as the following: PD at first restaging with $\geq$40% increase in sum of target lesions or $\geq$ 20% with appearance of multiple new lesions, with minimum absolute increase in measurable lesions of 10 mm (Matos I. et al. ASCO 2018).

Methods: Patients (pts) treated with ICIs in Ph1 trials at VHIO were analysed (n = 214). Our aim was to assess overall survival (OS) in pts who achieved PD as best response, evaluate HPD according to IGR or VHIO criteria and investigate discordances between both definitions.

Results: From Jan'12 to Oct'17, 214 pts were treated with ICIs (53% in combinations). Best response was PD in 47% pts (n = 101). Only 50 pts were evaluable for the primary endpoint (20 had PD before the first evaluation and 31 had no REF CT-scan). Using IGR criteria, median OS was 4.5 m (95% CI: 3.6-5.3) in HPD group (n = 15) versus 6.3 m (95% CI 1.7-10.9) in non-HPD group (HR = 1.85; 0.86-3.9; p = 0.11). Using VHIO criteria, median OS was 3.6 m (0.8-6.3) in HPD group (n = 21) versus 8.7 m (4.2-13.2) in non-HPD group (HR = 2.33; 1.10-4.95; p = 0.02). Overall concordance rate between the two criteria was 56% (p = 0.45). Most discordances were HPD by VHIO and non-HPD by IGR (28%). Baseline target lesion summatory in EXP was not different in pts with HPD by IGR or VHIO (p > 0.1). Importantly, pts with HPD by IGR had significantly lower TGR-REF (p < 0.001). Using VHIO criteria, we found no difference in TGR-REF between HPD vs non-HPD (p = 0.15). However, higher TGR-EXP was found in pts with HPD using VHIO criteria (p < 0.001).

Conclusions: We were able to validate IGR HPD criteria in our cohort, despite substantial loss in evaluable pts due to missing REF CT scans. No concordance was observed between IGR and VHIO HPD definitions. VHIO HPD criteria is strongly prognostic, easy-to-use in the clinic (EXP only) and biologically sound (not affected by small TGR during previous therapy and linked to high TGR during ICI exposure).

1842P Foretinib circumvents the NTRK1 G667C mutation-associated entrectinib-resistance in the brain and liver metastases produced by NTRK1 fusion-positive tumor cells

S. Yano, A. Nishiyama, K. Kita, S. Takeuchi

Division of Medical Oncology, Kanazawa University, Kanazawa, Japan

Background: Rearrangement of the neurotrophic tropomyosin receptor kinase 1 (NTRK1) gene, which encodes tyrosine receptor kinase A (TRK-A), occurs in various cancers, including colon cancer. Although entrectinib is effective in the treatment of central nervous system (CNS) metastases that express NTRK1 fusion proteins, acquired resistance inevitably results in recurrence. CNS is a sanctuary for targeted drugs; however, the mechanism by which CNS metastases become entrectinib-resistant remains elusive and must be clarified to develop better therapeutics.

Methods: The entrectinib-resistant cell line KM12SM-ER was developed by continuous treatment with entrectinib in the brain metastasis-mimicking model inoculated with the entrectinib-sensitive human colon cancer cell line KM12SM, which harbors the TPM3-NTRK1 gene fusion. The mechanism of entrectinib resistance in KM12SM-ER cells was examined by next-generation sequencing. Compounds that overcame entrectinib resistance were screened from a library of 122 kinase inhibitors.

Results: KM12SM-ER cells, which showed moderate resistance to entrectinib in vitro, had acquired the G667C mutation in NTRK1. The kinase inhibitor foretinib inhibited TRK-A phosphorylation and the viability of KM12SM-ER cells bearing the NTRK1-G667C mutation in vitro. Docking-simulated models based on the crystal structures of the foretinib/EphA2 and entrectinib/Alk complexes support the inhibitory effects of foretinib and entrectinib on the wild-type and G667C mutant of TRK-A. Moreover, foretinib markedly inhibited the progression of entrectinib-refractory KM12SM-ER-derived liver metastases and brain tumors in animal models, predominantly through inhibition of TRK-A phosphorylation.

Conclusions: These results suggest that foretinib may be effective in overcoming entrectinib resistance associated with the NTRK1-G667C mutation in NTRK1 fusion-positive tumors in various organs, including the brain, and provide a rationale for clinical trials of foretinib in cancer patients with entrectinib-resistant tumors harboring the NTRK1-G667C mutation, including patients with brain metastases.

1843P Molecular alterations and matched treatment in older patients: Results from the MOSCATO 01 trial

P. Vuagnat[1], C. Baldini[1], L. Verlingue[1], P. Martin Romano[1], A. Varga[1], A. Hollebecque[1], S. Postel-Vinay[1], A. Gazzah[1], R. Bahleda[1], A. Marabelle[1], V. Ribrag[1], S. Champiat[1], J-M. Michot[1], J-C. Soria[2], C. Massard[1]

[1]Drug Development Department (DITEP), Gustave Roussy, Villejuif, France, [2]Drug Development Department (DITEP), Medimmune, Gaithersburg, MD, USA

Background: Previous works in molecular portraits of cancer have shown differences by ages with the accumulation of somatic mutations, suggesting that older patients may have aged specific genomic profiles. However, there is a lack of data concerning genomic alterations in metastatic older patients. We aimed at analyzing the clinical and pathological characteristics and outcomes by genomic alterations of older patients enrolled in MOSCATO-01 trial.

Methods: We retrospectively collected data from MOSCATO-01 trial from all patients over > 70 years old enrolled from November 2011 to March 2016 and performed a descriptive analysis of this sub group of patients with advanced solid tumor.

Results: Among the 1035 patients enrolled in the MOSCATO trial, 85 patients (8,2%) over 70 years old were included, with a median age of 74 (range 71-86). Urologic cancers were the most frequent cancer. All tumor biopsies were performed and a molecular portrait was obtained in 66 patients (77.6%). Almost 40 different molecular alterations were identified. An actionable molecular alteration was identified in 46 patients (54%). Among them, 13 patients had $\geq$ 2 (range 1-5) actionable targets. The most frequent alteration pathways were: Pi3K (21%), NOTCH (11,3%), FGF and FGFR mutation (both 9.7%), PTEN (6,5%), FBXW7, MDM2 and EGFR (4,8% each). A total of 23 (27%) patients were treated with a targeted therapy matched to a genomic alteration, and 15 of them were enrolled in phase 1 or 2. The PFS2/PFS1 ratio was >1.3 in 31.8 % of the patients (7/22, one missing data). Among the 46 patients with actionable molecular alteration, median overall survival was better in the group of patient with matched therapy (18.4 vs 5.4 months, p = 0,07 NS).

Conclusions: The genomic profile > 70 years old is feasible in advanced geriatric malignancies and can lead to a better understanding in the biology of cancer among the elderly and could improve outcomes with molecular target agents.

Clinical trial identification: MOSCATO 01 (NCT01566019).

1844P Prognostic implications of mismatch repair deficiency in patients with early-stage colorectal and endometrial cancer

E. Fountzila, V. Kotoula, G. Pentherdoudakis, K. Manousou, E. Vrettou, C. Poulios, C. Papadimitriou, G. Raptou, E. Pectasides, G. Polychronidou, G. Karayannopoulou, S. Chrisafi, P. Papakostas, T. Makatsoris, A. Psyrri, E. Samantas, M. Bobos, C. Christodoulou, D.G. Pectasides, G. Fountzilas

Data Office, Hellenic Cooperative Oncology Group (HeCOG), Athens, Greece

Background: The clinical relevance of mismatch repair deficiency (MMRd) in patients with early-stage cancer remains unclear. Our goal was to investigate the prognostic role of MMRd in patients with colorectal and endometrial cancer.

Methods: From 05/1990 to 03/2013, formalin-fixed paraffin-embedded primary tumors were prospectively collected from patients with early-stage colorectal (991) and endometrial (167) cancer, referred to the Departments of Medical Oncology affiliated with the Hellenic Cooperative Oncology Group. Protein expression of MMR proteins was evaluated by immunohistochemistry. The primary outcome measure was overall survival (OS).

Results: Overall, 1158 patients were included (median age, 64 years). Stage III disease was diagnosed in 58% and 19% of patients with colorectal and endometrial cancer, respectively. All patients with colorectal cancer but only 13% of those with endometrial cancer received adjuvant treatment. MMRd was observed in 114 (11.5%) of colorectal and 80 (48%) of endometrial tumors. MMRd was associated with younger age at diagnosis (62 vs. 60y, Mann-Whitney, $p = 0.003$), higher tumor grade (26.3% vs 16.5%, chi-square, $p < 0.001$) and lower tumor stage (72% vs. 42.6%, $p < 0.001$). Colorectal MMRd tumors were more likely right-sided (64.6% vs. 27.2%, $p < 0.001$), and with a mucinous component (63.7% vs. 41.4%, $p < 0.001$). Endometrial MMRd tumors were more often endometrioid (74/144, 51.4%) than serous/clear cell (3/15, 20%) carcinomas ($p = 0.020$). Compared to MMR proficiency, MMRd was associated with improved OS in the entire cohort (HR = 0.66, 95% CI 0.47-0.92, Wald's $p = 0.013$) and in patients with endometrial cancer, (HR = 0.39, 95% CI 0.20-0.77, $p = 0.006$) but not in patients with colorectal cancer (HR = 0.73, 95% CI 0.49-1.09, $p = 0.120$). In multivariate analysis adjusting for tumor type, stage and grade, MMRd maintained its favorable prognostic significance in the entire cohort (Wald's $p = 0.014$) and in patients with endometrial cancer ($p = 0.017$).

Conclusions: MMRd is associated with improved outcomes in patients with early-stage endometrial cancer, but not in patients with early-stage colorectal cancer.

Background: Agents that generate breaks in DNA are frequently used in the treatment of cancer. These agents induce different forms of DNA damage including double-strand breaks (DSBs), which are the most lethal if left unrepaired. M3814 targets tumor cell growth and survival by inhibiting DNA-PK, which is part of a critical DSB DNA damage repair mechanism. M3814 has been explored as a single agent (A; NCT02316197) and in combination with radiotherapy (RT) (B; NCT02516813).

Methods: In both trials patients (pts) were treated with ascending doses of M3814 to establish the safety and maximum tolerated dose (MTD) or recommended phase 2 dose (RP2D) (primary endpoint) and efficacy (secondary endpoint). Dose-limiting toxicity (DLT) was evaluated after 3 (A) or 5 weeks (B). Rich pharmaco-kinetic and -dynamic (PK and Pd) sampling was performed (exploratory endpoint). In A, M3814 was continued until progression, unacceptable toxicity, pt wish, or physician decision. In B, M3814 was given during RT to tumor or metastasis in the head and neck or thoracic region, 10 x 3 Gy.

Results: Up to Apr 1, 2018, 31 pts in A and 16 pts in B have been enrolled. In A one DLT was seen (prolonged low-grade AEs), the RP2D selected was 400 mg BID. In B, dose escalation is ongoing with DLTs of grade 3 mucositis ($n = 3$) and grade 3 odynophagia tox ($n = 1$). Most frequent adverse events (AE) were in A, nausea, vomiting, decreased appetite, constipation, diarrhea, pyrexia, fatigue, and rash, in B, dysphagia, prolonged mucosal inflammation/ stomatitis and radiation skin injury. One case of radiation pneumonitis has been reported. No pts discontinued due to AE. PK analysis demonstrated high variability of exposure. Pd in surrogate tissue showed robust inhibition of the induction of phosphoDNA-PKi (pDNA-PKi) for up to 6 hours. No objective responses were reported in A, while in B durable in field responses were seen ($n = 7$).

Conclusions: M3814 was found to be well tolerated as monotherapy and dose escalation combination with palliative RT is ongoing. PK of the current formulation showed a high inter-pt variability, Pd suppression of pDNA-PKi was observed as predicted by modelling and simulation.

Clinical trial identification: NCT02316197 and NCT02516813.

1846P Role of TP53 mutations in relation to response to anti-ALK agents in EML4-ALK-translocated NSCLC patients

M. Canale[1], A. Delmonte[2], C. Dazzi[3], A. Gamboni[4], C. Casanova[3], M. Papi[5], M. Mariotti[2], N. De Luigi[2], M.A. Burgio[2], G. Minuti[6], D. Calistri[1], M. Bonafè[1], L. Crinò[2], P. Ulivi[1]

[1]Biosciences Laboratory, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola, Italy, [2]Medical Oncology, Istituto Scientifico Romagnolo per Lo Studio e La Cura Dei Tumori (IRST)- IRCCS, Meldola, Italy, [3]Medical Oncology, Umberto I Hospital, Lugo, Italy, [4]Medical Oncology, Degli Infermi Hospital, Faenza, Italy, [5]Medical Oncology, Ospedale Infermi, Rimini, Italy, [6]Medical Oncology, Santa Maria delle Croci, Ravenna, Italy

Background: EML4-ALK translocation is a predictive mutation for responsiveness to anti-ALK drugs, and it is present in 3-7% cases of NSCLC patients. Though patients are usually responsive to targeted therapy against EML4-ALK translocation, about 30-40% show drug resistance. We analyzed the impact of TP53 mutations on response to anti-ALK treatment in EML4-ALK-translocated NSCLC patients.

Methods: 83 EML4-ALK-translocated NSCLC patients were enrolled, and TP53 status was evaluated in 61 patients, on the basis of DNA availability. Of these patients, 28 patients received an anti-ALK agent in second-or-more line treatment and follow up data were available. TP53 status was considered in relation to disease control rate (DCR: complete response [CR], partial response [PR] or stable disease [SD]).

Results: In the overall case series, TP53 mutations were observed in 14 (23%) patients, 6 (43%), 1 (7%), 3 (21%) and 4 (28%) in exon 5, 6, 7 and 8, respectively. We found 1 insertion (7%), 1 deletion (7%) and 12 point mutations (86%). In the subgroup of 25 patients treated with an anti-ALK agent and evaluable clinical response, TP53 mutations were observed in 5 (20%) patients, 2 (40%), 1 (20%) and 2 (40%) in exon 5, 6 and 8, respectively. The DCR was 60% in TP53-mutated patients with respect to 92% in TP53 wild type (wt) patients. Three patients had a non evaluable clinical response, as they early stopped anti-ALK agent treatment due to rapid PD/deterioration of general conditions and they succumbed to their disease in a few weeks. Two of these where found with a stop mutation in exon 5.

Conclusions: TP53 mutations are associated with a worse DCR in EML4-ALK-translocated NSCLC patients treated with an anti-ALK agent. These results highlight the importance of tumor-suppressor genes in determining response to TKIs. Data analysis for PFS and OS of patients are ongoing.

1847P Meta-enrichment analysis to identify a higher response patient population to S-1/cisplatin for advanced gastric cancer

M. Takeuchi[1], M. Takeuchi[2], H.W.M. van Laarhoven[3], X. Fang[1], P. Pfeiffer[4], J.A. Ajani[5]
[1]Clinical Medicine (Biostatistics), Kitasato University, Tokyo, Japan, [2]Faculty of Environment and Information Studies, Keio University, Fujisawa, Japan, [3]Medical Oncology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [4]Experimental Research in Medical Cancer Therapy, Odense University Hospital, Odense, Denmark, [5]GI Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA

Background: Previous publications of the FLAGS and the DIGEST trials have shown that S-1/Cisplatin (CS) had a similar overall survival (OS) compared to 5-fluorouracil/cisplatin (CF) in patients with advanced gastric cancer (AGC) (Ajani JA et al, Eur J Cancer 2013. Ajani JA et al, Ann Oncol 2017). Although a co-enrichable population (Eastern Cooperative Oncology Group performance status (ECOG PS) 1) that respond favorably to CS compared to CF was identified with predictive enrichment strategy analysis by the FLAGS and the DIGEST trials respectively (Takeuchi et al, ESMO 2017), a more enrichable population may exist. Here we report the result of a meta-enrichment analysis assessing whether such a population exists.

Methods: To overcome differences in baseline characteristics of the FLAGS and the DIGEST a meta-enrichment analysis was performed after combining the data from the two trials. Since the treatment effect is consistent in the FLAGS and the DIGEST trial, meta-enrichment analysis allows for the combination of the two datasets and identify a robust subgroup of high response patients. Eleven clinicopathological factors were selected and a high response enrichable population was determined. It must be noted that although peritoneal metastases was included in the previous analysis as a clinicopathological factor, it was removed from this analysis due to inconsistent date readings between the individual and the central review committee.

Results: The efficacy of the combined data set of 1365 patients (n = 1019 from FLAGS and n = 346 from DIGEST) were analyzed. A total of 683 patients (n = 374 from CS, n = 309 from CF) were identified as the high response enrichable population. High response patients were classified as patients with ECOG PS1, more than two metastatic sites and low Neutrophil-Lymphocyte ratio (log(NL ratio)) In the high response enrichable population, the median OS in the CS group was 241 days compared to 210 days in the CF group (Hazard ratio 0.776 ; 95% Confidence interval 0.658 to 0.915 ; P value 0.004).

Conclusions: Through meta-enrichment analysis, a higher response enrichable population to CS was identified. This statistically robust analysis indicated that for selected patients with AGC, CS is more beneficial compared to CF.

1848P Predictive significance of tumour angiogenic and anti-angiogenic VEGF-A splice variants in patients with metastatic colorectal cancer

G. Pentheroudakis, V. Kotoula, G-A. Koliou, K. Papadopoulou, E. Samantas, T. Makatsoris, V. Karavasilis, D. Mauri, I. Efstratiou, D. Bafaloukos, P. Papakostas, A. Psyrri, G. Papatsibas, G. Zarkavelis, A. Goussia, I. Bompolaki, G. Oikonomopoulos, A.N. Christopoulou, D.G. Pectasides, G. Fountzilas
Data Office, Hellenic Cooperative Oncology Group (HeCOG), Athens, Greece

Background: Alternate (distal) splicing of VEGF-A isoforms results in production of VEGF-Axxxb anti-angiogenic proteins that fail to activate the angiogenic cascade. Bevacizumab, widely used in patients with metastatic colorectal cancer (mCRC), binds both VEGFA and VEGFAxxxb isoforms.

Methods: Formalin-fixed paraffin-embedded primary tumours from mCRC patients treated in 1st line with FOLFIRI+Bevacizumab (Nbev=285) or FOLFIRI only (Nchem=75) were collected, mRNA was extracted, amplified and quantified with qRT-PCR (Taqman-MGB-assays) for the relative expression of VEGF-A 121a, 121b, 145a, 145b, 165a, 165b mRNA transcripts.

Results: At a median follow-up of 101.5 months, patients with left-sided (L-CRC) compared to those with right-sided primaries (R-CRC) had longer overall survival (OS) [median OS: 29.2 vs. 18.2 months, p = 0.015]. High VEGFA 145b mRNA expression was an unfavourable factor for PFS (HR = 1.66,95% CI 1.13-2.44, p = 0.009) in Nbev patients, with no prognostic significance in Nchem patients (HR = 0.70, 95% CI 0.34-1.44, p = 0.33). The adverse PFS prognostic effect of 145b was more pronounced in R-CRC patients (HR = 2.62, 95% CI 1.35-5.12, p = 0.005), especially when bevacizumab-treated (HR = 2.85, 95% CI 1.31-6.21, p = 0.008). High VEGFA 121b was adversely prognostic for PFS (HR = 2.48, 95% CI 1.23-5.04, p = 0.012) , OS (HR = 2.00, 95% CI 1.08-3.72, p = 0.028) in right, but not left colon, while high 165b was a favourable prognosticator in left sided disease (PFS HR = 0.76, 95% CI 0.59-0.99, p = 0.044, OS HR 0.68, 95% CI 0.52-0.90, p = 0.006). At multivariate analysis, right-sided primary was associated with inferior PFS (HR = 1.28, 95% CI 1.00-1.64, p = 0.051) and OS (HR = 1.33, 95% CI 1.02-1.73, p = 0.037), while high 145b mRNA expression consistently retained predictive significance for lack of PFS benefit from bevacizumab therapy (HR = 1.71, 95% CI 1.16-2.53, p = 0.007).

Conclusions: In a cohort of mCRC patients treated with bevacizumab, RQ of VEGF-A 145b mRNA, an anti-angiogenic isoform, may predict for resistance to bevacizumab, without prognostic utility in patients not exposed to the antibody. Differences in biological relevance of various VEGF-A isoforms were shown for right versus left-sided primaries.

1849P ATR inhibition with radiation creates an inflammatory tumour microenvironment

M.T. Dillon[1], K. Bergerhoff[1], M. Pedersen[1], H. Whittock[1], E. Patin[1], H. Smith[1], J. Paget[1], R. Patel[1], G. Bozhanova[1], S. Foo[1], J. Campbell[1], C. Ragulan[2], E. Fontana[3], A. Wilkins[1], A. Sadanandam[3], A. Melcher[4], M. McLaughlin[1], K.J. Harrington[1]
[1]Targeted Therapy Team, The Institute of Cancer Research, London, UK, [2]Systems and Precision Cancer Medicine, The Institute of Cancer Research, London, UK, [3]Division of Molecular Pathology, The Institute of Cancer Research, London, UK, [4]Translational Immunotherapy, Institute of Cancer Research, London, UK

Background: ATR inhibitors (ATRi) are in early phase clinical trials and have been shown to sensitise to chemotherapy and radiotherapy (RT) in preclinical data. No data have been published about the effect of these drugs on the tumour microenvironment. We demonstrate significant modulation of the immune microenvironment by ATRi + RT.

Methods: We used an immunocompetent mouse model of HPV-driven malignancies (TC1) to investigate the effect of the ATRi, AZD6738, in combination with RT 8 Gy in 4 fractions. Gene expression analysis, flow cytometry and cytokine quantification were used.

Results: There was sensitisation to RT by ATRi in this model. ATRi + RT caused a marked increase in a number of adaptive immune cells infiltrating the tumour at 5 days after treatment. There were significantly more dendritic cells, macrophages, and myeloid-derived suppressor cells after ATRi + RT. We also identified increased numbers of CD3+ and NK cells after the combination treatment. Transcriptional analysis found evidence of increased T-cell activation with the combination therapy. We found evidence of an interferon (IFN) response, with transcriptional upregulation of IFN-stimulated genes including those playing a role in nucleic acid sensing: Ddx58/RIG-I, and Ifih1/MDA5, Zbp1/DAI and Ddx60. We identified significant modulation of cytokine gene expression (CCL2, CCL5, CXCL10), and found that cultured tumour cells secreted CCL3, CCL5 and CXCL10 after ATRi + RT. We hypothesise that DNA damage and micronucleus formation caused by ATR + RT (as previously reported by us, Dillon et al. MCT 2016;16:25-34) leads to an IFN response through activation of nucleic acid sensing pathways, leading to influx of innate immune cells.

Conclusions: To our knowledge this is the first comprehensive analysis of the immune tumour microenvironment after radiation with a radiosensitising targeted drug. Further understanding of the effect of this combination on immune response may allow modulation to maximise tumour control through activation of anti-tumour immunity. 1850P RNA-based analysis of anaplastic lymphoma kinase (ALK) fusions in non-small cell lung cancer (NSCLC) cases showing immunohistochemistry/fluorescence in-situ hybridisation (IHC/FISH) discordance

C. Vollbrecht[1], D. Lenze[1], M. Hummel[1], A. Lehmann[1], M. Moebs[1], N. Frost[2], P. Jurmeister[3], L. Schweizer[1], U. Kellner[4], M. Dietel[1], M. von Laffert[1]

[1]Institute of Pathology, Charité – Universitätsmedizin Berlin Corporate Member of Freie Universität Berlin, Humboldt-Universität zu Berlin, Berlin Institute of Health (BIH), Berlin, Germany, [2]Department of Infectious Diseases and Pneumonology, Charité – Universitätsmedizin Berlin Corporate Member of Freie Universität Berlin, Humboldt-Universität zu Berlin, Berlin Institute of Health, Medical Department, Berlin, Germany, [3]Charité Comprehensive Cancer Center, Charité – Universitätsmedizin Berlin Corporate Member of Freie Universität Berlin, Humboldt-Universität zu Berlin, Berlin Institute of Health, Berlin, Germany, [4]Institute for Pathology, Johannes Wesling Klinikum Minden, Minden, Germany

Background: Rearrangements of ALK are established targets in the current therapy of advanced NSCLC and are predominantly detected by IHC and/or FISH. However, both methods occasionally produce discordant results. This may occur especially in so-called borderline (BL) cases, showing ALK FISH-positive signals in 10–20% of tumour nuclei around the cutoff (15%) for ALK FISH-positivity. This leads to a diagnostic, and thus therapeutic, dilemma.

Methods: We selected 18 unequivocal samples (12 ALK IHC- and FISH-negative; 6 ALK IHC- and FISH-positive) and 15 equivocal samples with discordance between FISH (Vysis LSI ALK Dual Color) and IHC (D5F3), including cases with FISH-BL results, for further RNA based-analysis. To detect ALK rearrangement at the transcriptional level, RNA was analysed using a targeted multiplex-PCR panel followed by S5 sequencing and direct transcript counting using a digital probe-based assay (Nanostring). Sensitivity of both methods was defined using RNA obtained from an ALK-positive NSCLC cell-line dilution series.

Results: Cases with unequivocal IHC/FISH results showed concordant data with both RNA-based methods. Three IHC-negative/FISH-positive samples were negative with both RNA-based methods. The four IHC-negative/FISH-BL-negative cases, as well as the five IHC-negative/FISH-BL-positive samples, showed negative results by sequencing and digital probe-based assay. The two IHC-positive/FISH-BL-positive cases were both positive on the RNA level; whereas a tumour with questionable IHC and FISH-BL-positive status displayed no ALK fusion transcript.

Conclusions: The comparison of methods for the confirmation of ALK rearrangements revealed that the detection of ALK protein by IHC and ALK fusion transcripts on transcriptional level by sequencing and probe-based assay leads to concordant results. Only a small proportion of clearly ALK FISH-positive cases are unable to express the ALK protein and ALK fusion transcript, which might explain non-response to ALK inhibitors. Therefore, our findings led us to conclude that ALK testing should be based on IHC- or RNA-based methods, especially for ALK FISH BL cases.

1851P The combination of MEK inhibitor and anti PD-L1: Effects on organoid models from NSCLC biopsies

C.M. Della Corte[1], G. Barra[2], V. Ciaramella[3], R. Di Liello[3], M. Fasano[3], F. Ciardiello[3], F. Morgillo[3]

[1]Thoracic Head and Neck, MD Anderson Cancer Center, Houston, TX, USA, [2]Immunologia, AOU Seconda Università degli Studi di Napoli (AOU-SUN), Naples, Italy, [3]Precision Medicine, Università degli Studi della Campania Luigi Vanvitelli, Naples, Italy

Background: The combination of immune-checkpoint (IC) inhibitors with targeted therapies represent a new goal of immunotherapy, aimed at personalizing and potentiating the self-response against cancer. Organoids as novel 3D cancer models, allow the study in vitro of the tumor microenvironment (TME), including tumor-infiltrating lymphocytes (TILs) and their interaction with tumor cells. In this study we analyzed whether the combination of anti-PD-L1 drugs with MEK inhibitor (MEKi) affect the growth of organoids and TILs obtained from tumor biopsy of NSCLC patients.

Methods: Lung biopsies from 3 NSCLC patients were enzymatically digested. Cells were cultured in matrigel for 6 days and treated with atezolizumab or avelumab, alone or in combination with MEKi. Immunofluorescence (IF) staining for CD3, CD8 and CD45 was conducted; cells were also stained for FACS analysis with anti- CD45, CD3, CD4, CD8, CD14, CD56, CD19, CD11c, PD-1; a staining for EPCAM and PD-L1 allowed a better characterization of tumor cells. After 6 days of treatment, MTT assay verified cell viability; the expression levels of IFNg, IL-10, PD-1, PD-L1, TIM-3, LAG-3 and IDO-1 were analysed through real-time PCR.

Results: IF staining revealed that in organoids the interactions between tumor cells and TILs are preserved. FACS analysis confirmed that TILs were mainly TCD8+ and tumor cells analysed were EPCAM+ for almost 40%. The combination of anti PD-L1 and MEKi is associated with a reduction in organoid's dimensions and viability, especially in PD-L1+ tumors and with a higher percentage of TCD8+/PD-1+ lymphocytes. The combination of MEKi with anti PD-L1 is also associated to a higher expression of the pro-inflammatory cytokine IFNg and a reduction of the anti-inflammatory IL10. The expression of IC molecules was also modified by this combination; in particular LAG-3 and IDO-1 expression were dramatically reduced.

Conclusions: Organoid models allow to study tumors more realistically, because they show some typical features of the organ they derive. This model become particularly useful for the analysis of TME of each patient and for the testing of combination drugs and the development of precision and personalized immunotherapies.

1852P Intraoperative fluorescent image-guided detection of esophageal cancer in rabbit and patient specimens

J. Rho[1], Y.H. Quan[2], B.H. Choi[2], B-M. Kim[3], K.N. Han[4], Y.H. Choi[4], H.K. Kim[4]

[1]Biomedical Science, Korea University College of Medicine, Seoul, Republic of Korea, [2]Department of Biomedical Sciences, Korea University College of Medicine, Seoul, Republic of Korea, [3]Department of Bio-Convergence, Korea University, Seoul, Republic of Korea, [4]Department of Thoracic and Cardiovascular Surgery, Korea University Guro Hospital, College of Medicine, Seoul, Republic of Korea

Background: This is the first study, to our knowledge, aimed at assessing the feasibility of intraoperative detection of esophageal cancer (EC) after intravenous indocyanine green (ICG) injections in rabbit and patient specimens using near-infrared (NIR) fluorescence imaging.

Methods: VX2 tumors were surgically implanted in the esophageal muscular layer of 45 rabbits 2 weeks before esophagectomy. They received 1, 2, or 5 mg/kg of intravenous ICG injections 3, 6, 12, 24, or 48 hours before surgery. Twenty-five consecutive patients (21 men; age, 63.9±8.59 years) who were scheduled to undergo esophagectomy for squamous cell EC were enrolled. Five patients received neoadjuvant concurrent chemoradiotherapy (CCRT) before surgery. All patients received 1 or 2 mg/kg of ICG intravenously 6, 12, or 24 hours before surgery. The fluorescence intensity was measured in all resected rabbit and patient specimens using an NIR fluorescence imaging system on a back table after surgery.

Results: EC was successfully detected in all rabbits; the mean tumor size was 0.86±0.21 (range, 0.5–1.3) cm. Fluorescence signals were detected in all animals. The tumor-to-normal fluorescence signal ratio (TNR) in rabbits was higher between 6 (6.89±0.35) and 12 (7.53±0.26) hours at 1 mg/kg ($p < 0.01$), between 12 (10.59±0.41) and 24 (12.06±0.57) hours at 2 mg/kg ($p < 0.01$), and between 24 (14.88±0.63) and 48 (13.73±0.19) hours at 5 mg/kg ($p < 0.01$) of ICG than at other times. Fluorescence signals were detected in all except 4 patients without residual tumors after preoperative CCRT. One false-positive case involved no residual tumor with inflammation (TNR, 13.64). The mean tumor size in 20 patients was 3.9±2.1 (1.1–10) cm. The TNR in the patients was higher between 6 (15.22±0.59) and 12 (17.01±0.18) hours at 1 mg/kg ($p < 0.01$) and between 12 (18.92±0.01) and 24 (19.81±0.73) hours at 2 mg/kg ($p < 0.01$) of ICG than at other times.

Conclusions: NIR fluorescence imaging revealed EC 6 to 24 hours after systemic ICG injections per their doses. However, passive ICG accumulation could not help discriminate tumors with inflammation; thus, tumor-targeted fluorescence should be developed to solve this problem in the future.

Clinical trial identification: This study was approved by the Institutional Review Board, Korea University Guro Hospital (2017GR0075).

1853P Interaction between cancer associated fibroblasts and cancer cells influence immune infiltrate and is modulated by therapeutic agents

A.J. Rullan Iriarte[1], E. Arwert[1], E. Milford[1], P. Chakravarty[1], A. Melcher[2], K. Harrington[3], E. Sahai[1]

[1]Tumour Cell Biology Laboratory, The Francis Crick Institute, London, UK, [2]Translational Immunotherapy, Institute of Cancer Research, London, UK, [3]Head and Neck/Skin Units, The Institute of Cancer Research, London, UK

Background: Cancer associated fibroblasts (CAFs) can help tumours evade immune-surveillance by affecting the immune cell infiltrate, mainly via secretion of cytokines and chemokines. CAFs phenotype and spatial relationship to cancer cells alter the kind of cytokines and chemokines they secrete. In Squamous cell carcinoma (SCC), cancer-associated fibroblasts can trigger a Type I Interferon when in direct cell-cell contact with cancer cells.

Methods: Bioinformatics: we used publicly available RNAseq data from The Cancer Genome Atlas (TCGA) for Head and Neck Squamous Cell Carcinoma (HNSCC 518 tumours. [http://firebrowse.org/]) . Using the RSEM normalized gene expression, we divided tumours according to the expression of CAF markers not expressed in cancer cells (FAP, Thy-1, s100a4and PDGFRb). We used CIBERSORT to estimate the abundance of immune cells in the tumours. In vitro assays: we used A431 (human SCC cell line) and CAFs extracted from a human tumour in our lab. We cultured them in either direct cell-to-cell contact or using a transwell. We treated the A431 with AZD6738 (ATR inhibitor), 5-aza-2′-deoxycytidine and cisplatin. We analysed mRNA expression of different interferon response genes by qRT-PCR.

Results: To explore the relevance of CAF influence in the immune infiltrate we analysed RNA seq data from HNSCC in TCGA. Tumours with higher expression of FAP and PDGFRb showed a higher proportion of infiltrating M0 and M2 macrophages. Tumours with lower expression of FAP and PDGFRb had higher proportions of activated dendritic cells and CD8 positive lymphocytes. In an "in vitro" human SCC model, heterotypic cancer cell-CAF contact leads to transfer of double stranded DNA from the cancer cell to the fibroblasts. This interaction triggers cGAS-STING mediated production of Interferon b (IFNb) in the CAFs. We treated cancer cells with drugs that generate genomic damage i.e. AZD6738, 5-aza and cisplatin. Treatment with these drugs increased the signal initiated by IFNb.

Conclusions: CAF subtypes abundance correlates with an immunosuppressive tumour microenvironment in HNSCC. Drugs currently used for routine treatment or in clinical trials for HNSCC modulate cytokine and chemokine production by CAFs in an "in vitro" model.

1854P Dynamic change of immune-related gene expression status during chemoradiotherapy in locally advanced esophageal cancer

T. Mizukami[1], Y. Sunakawa[1], H. Arai[1], M. Chosokabe[2], A. Doi[1], Y. Horie[1], M. Hirakawa[1], O. Saji[3], S. Naruki[2], N. Izawa[1], T. Ogura[1], T. Tsuda[1], T. Enomoto[3], S. Mikami[3], T. Fujino[2], T. Otsubo[3], T.E. Nakajima[1]

[1]Clinical Oncology, St. Marianna University School of Medicine, Kanagawa, Japan, [2]Pathology, St.Marianna University School of Medicine, Kanagawa, Japan, [3]Gastroenterological and General Surgery, St. Marianna University School of Medicine, Kanagawa, Japan

Background: Either chemotherapy or radiotherapy is standard of care for esophageal cancer (EC), and they are known to offer enhancement of both tumor and host immune system [B Park, et al. Int J Mol Sci 2014; Emens LA, et al. Cancer Immunol Res 2015]. However, there are few reports regarding the impact of chemoradiotherapy (CRT) on the tumor immunity.

Methods: We retrospectively examined patients (pts) with available tumor samples at 2 points (pre- and post-treatment) among EC pts who received chemotherapy with platinum and/or radiation in our institute between 2010 and 2015. Immunohistochemistry (IHC) staining for the samples was performed and the positivity of PD-L1 was determined as score >1 of the Allred methods. In addition, expression levels of immune-related genes were analyzed using HTG EdgeSeq Immuno-Oncology Assay (HTG Molecular Diagnostics, Inc., Tucson, United States).

Results: Eighty-four pts were evaluable (median age of 68yrs, 88% male, 7%/9%/34%/48%/1% for primary tumor of Ce/Ut/Mt/Lt/Ae, 12%/19%/52%/17% for Stage I/II/III/IV, 95% squamous cell carcinoma, 48%/52% pts treated with chemotherapy/CRT). Frequency of PD-L1 IHC expression was higher in the samples after chemotherapy compared in those before chemotherapy (14% to 36%), while it was lower in the samples after CRT compared in those after CRT (13% to 7%). There was a significant difference in the positive rate at post-treatment between chemotherapy and CRT ($P = 0.01$). Comprehensive analysis to compare gene expression levels of immune-related genes between pre- and post-treatment found 17 up-regulated and 34 down-regulated genes in pts treated with CRT. Specially, IL18, GZMA, and SPINK5 genes were identified for elevated genes, while PDGFRB, TNFRSF12A, and ITGB1 genes for degraded genes.

Conclusions: Positivity of PD-L1 was different after the treatment between in EC pts receiving chemotherapy and in those receiving CRT. Genes related to inflammatory response and angiogenesis may contribute to the change of tumor immune status by CRT in EC.

Background: Non-Small Cell Lung Cancer (NSCLC) represents almost 80% of lung cancer cases. Despite the advances achieved in the last years, there is still a lack of knowledge concerning tumour microenvironment. This research is focused on two immunoregulatory genes, CD5 and CD6 as potential prognostic biomarkers in resectable NSCLC.

Methods: CD5 and CD6 gene expression was analysed by RTqPCR in 201 paired fresh-frozen tumour and normal tissue samples of resected NSCLC (training cohort). The Cancer Genome Atlas (TCGA) database was used to obtain an independent validation cohort with available gene expression data for normal and tumour tissue. Relative gene expression was calculated by Pfaffl formula. Prognostic value was assessed by Cox regression and Kaplan-Meier curves (log rank-test), considering significant $p < 0.05$.

Results: Training cohort consisted mainly of men, current or former smokers, with good performance status ($PS = 0$). Survival analyses showed that patients with higher CD5 expression had significantly increased overall survival (OS, 53.3 vs. NR months, $p = 0.011$). A multivariate analysis reported that CD5 expression could be established as an independent prognostic biomarker for OS in early-stage NSCLC [HR = 0.539; 95% CI, 0.329-0.883; $p = 0.014$]. Survival analyses performed on 97 patients from TCGA database confirmed that higher expression levels of both CD5 and CD6 had a significant prognostic value for relapse-free survival (34.98 vs. 75.57 months, $p = 0.033$; 25.31 vs. 75.57 months, $p = 0.020$, respectively) and OS (40.49 vs. 77.97 months, $p = 0.038$; 39.02 vs. 77.97 months, $p = 0.034$, respectively). Therefore, these analyses support that NSCLC patients with higher expression levels of CD5 are associated with better outcomes. Besides, CD6 could potentially be a prognostic biomarker.

Conclusions: Our results support a role of the inmmunodulatory receptor CD5 as an independent prognostic biomarker in resectable NSCLC. Supported from Fundació La Marató TV3 (201319-30), ISCIII (PI12-02838 and PI15-00753), and MECD (SAF2016-80535-R) -co-financed by European Development Regional Fund. FA and IS are recipients of fellowships from ISCIII (Sara Borrell Program; CD15/00016) and Portuguese FCT (SFRH/BD/75738/2011), respectively.

1856P Identification of the rational combination of two epigenetic inhibitors therapy in refractory AML using patient tumor derived ex vivo platform

P.K. Majumder[1], G. Babu[2], C. Rajagowda[2], S. Thiyagarajan[3], M. Biswas[4], P. Radhakrishnan[1], P. Chaudhuri[3], A. Chatterjee[3]

[1]Cancer Biology, Mitra Biotech, Woburn, MA, USA, [2]Kidwai Memorial Institute of Oncology, HCG Curie Centre of Oncology, Bangalore, India, [3]Cancer Biology, Mitra Biotech, Bangalore, India, [4]Molecular Pathology, Mitra Biotech, Bangalore, India

Background: Acute myeloid leukemia (AML) is a highly heterogenous hematological malignancy. Though there has been substantial progress in understanding of AML biology and identification of new therapeutic targets, treatment of AML has largely remained unchanged over the last couple of decades, with ∼40% patients not achieving remission with standard chemotherapies.

Methods: In this study, we employed an ex-vivo tumor explant model (CANscript™) to select a treatment course for AML patients. CANscript™ offers a comprehensive system that mimics patient tumor microenvironment. 31 AML patients tumors were analyzed to predict response to cytarabine. We next evaluated azacitidine and panobinostat alone and in combination, as alternate treatment regimens for cytarabine refractory tumors.

Results: More than 50% of the treated samples showed response to the combination therapy. In AML, frequent upregulation of DNA-methyltransferase enzymes (DNMTs) have been reported with poor survival. We assessed the level of DNMTs using RNAseq and methylation data (n = 100) from the TCGA database. Data indicated increased expression of DNMT and hyperacetylation of HDACs indicating mechanism of high responsiveness to treatment by epigenetic modulators in these tumors. We further noted hypomethylation of IFNGR1 and IFNGR2 genes in TCGA data suggesting activation of JAK/STAT pathway. Hypomethylation of several gene components of JAK-STAT pathway was correlated with an increased expression of these genes in RNAseq data. 8 out of 12 cytarabine refractory tumors were showed response of which 5 were non-responders to epigenetic modulators.

Conclusions: Taken together our data indicates that CANscript™ is capable in guiding optimal treatment selection for various classes of agents including novel targeted therapies.

1857P Tyrosine kinase inhibitors and acid-inhibitory drugs: Strong concomitant dispensing and drug-drug interaction risk

F. Grude[1], C. Vigneau-Victorri[2], D. Deniel Lagadec[3], E. Michaud[4], H. Bourgeois[5], B. Forestier[4], F. Marhuenda[1]

[1]Cancer Observatory, ICO Paul Papin, Angers, France, [2]Service de Pharmacologie Clinique, Faculté de Médicine, Nantes, France, [3]Cancer Observatory, CHRU Brest, Brest, France, [4]Medical Department, Regional Health Insurance, Nantes, France, [5]Oncology Department, Clinique Victor Hugo Le Mans, Le Mans, France

Background: Tyrosine Kinase Inhibitors (TKIs) have rapidly become an established therapy in oncology and have been shown to be effective in a wide variety of solid and hematologic malignancies. Acid-inhibitory drugs (AID) (such as antacids, anti-ulcerous drugs and proton pump inhibitors - PPIs) increase the intragastric pH, which may subsequently decrease TKI solubility, bioavailability, and treatment efficacy. The Observatory of Drugs Bretagne/ Pays de la Loire (B-PL) and the Medical Department of the French Regional Health Insurance (FRHI PL) has made an observational study about TKIs and AIDs concomitant dispensing.

Methods: FRHI has made an extract in its database for patients treated with TKIs and AIDs in 2016. Concomitant dispensing is defined as the dispensing of a TKI and AIDs during the same calendar month. To complete the study, a survey about PPIs prescription has been proposed to cancer specialists from B and PL areas during 15 days last December.

Results: 2309 patients, mean age of 62.9 y (2-93) have been treated with TKIs in 2016 in the PL area. 6.6 dispensings have been done per patient. 795 pts (34%) had no AID dispensing. 274 pts (12%) had no concomitant dispensing of AID and TKI. 1240 pts (54%) had at least one concomitant dispensing. 67% of these patients had a concomitant dispensing of PPIs and 25% a concomitant prescription throughout the TKI treatment. Among these concomitant takes, 34% showed no interaction, 23% showed interactions (34% unknown cases, 9% diverging data). Data from the Bretagne area will be shown at the meeting. 43 clinicians have answered the survey about PPI prescription: 98% have prescribed them. The major reasons were: treatment of gastroesophageal reflux disease (88%), prevention/treatment of NSAID-associated ulcers (67%) or of esophageal duodenal and stomach ulcers (55%), for unknown reasons (31%), and for Zollinger-Ellison syndrome (31%). Duration of treatment was between 7 days and 2 months.

Conclusions: Drug-Drug Interaction (DDI) analyses would be performed to underline for which TKIs, TKIs-PPIs interaction was the most harmful. Clear practice tools should be created to help clinicians to evaluate this DDI and what to do for their patients. Guidelines will be presented at the meeting.

Background: Identification of tumor margin during surgery is necessary for limited resection of non-small cell lung cancer (NSCLC). In this study, we developed a novel technique of lung cancer margin visualization by intraoperative inhalation of indocyanine green (ICG) and verified its clinical applicability using mouse and rabbit lung cancer model.

Methods: By observing the distribution of the inhaled ICG in each organ (lung, liver, brain, spleen, and kidneys) of mice at five different time intervals, we demonstrated that the inhaled ICG was delivered rapidly and was mainly distributed in the lung tissue. In the mouse model of lung cancer, we confirmed that the inhaled ICG entered the normal lung through phagocytosis by alveolar macrophages of normal lung tissue and rarely spread in lung cancer tissue because of mechanical airway obstruction by the tumor.

Results: Therefore, the fluorescent signal of inhaled ICG was mainly visualized in normal lung tissue but not in lung cancer tissue, which could assist in identifying the tumor margin. For clinical applicability, the inhaled dose of ICG was optimized in a rabbit lung cancer model. Compared to intravenous administration, this method accurately defined the tumor margin with 5.3-fold higher detection efficiency when 20 times lower dose of ICG was used. The ICG inhalation technique provided more clear visualization of tumor margin with lower dose and in shorter time during surgery compared to the conventional intravenous injection method.

Conclusions: The ICG inhalation technique provided more clear visualization of tumor margin with lower dose and in shorter time during surgery compared to the conventional intravenous injection method. Lung-specific delivery of the clinically approved ICG could be used effectively and safely in real clinical practice in the near future.

1859P Proteomic-based machine learning computational analysis discovered biomarkers of aberrant vesicle-exosomal trafficking to determine chemotherapeutic responses in breast cancer

H. Ryu[1], D.H. Han[2], K-M. Lee[3], K. Kim[3]

[1]Pathology and Proteomics Core Facility, Seoul National University Hospital (SNUH)-Yongon Campus, Seoul, Republic of Korea, [2]Proteomics Core Facility, Seoul National University Hospital, Seoul, Republic of Korea, [3]Biomedical Research Institute, Seoul National University Hospital, Seoul, Republic of Korea

Background: The chemotherapeutic response is still low, and the need for a biomarker to overcome chemo-resistance is necessary.

Methods: We performed quantitative proteomics mass spectrometry in paired 20 FFPE biopsy breast cancer samples consist of non-responsive and responsive groups to chemotherapy. For verification of enriched biomarkers and biological pathways, ten human breast cancer cell lines enrolled and verified biological functions through molecular biology-driven assays, including RNAi, celltiter-glo luminescent assay, mitochondrial membrane potential assay (MMPA), IF, exosome uptake assay, time-lapse live cell imaging system, and the 3D tumor spheroid-based function assays. Machine learning analysis using r-caret recursive feature elimination to select and apply them to an independent cohort with 50 FFPE biopsy samples to discover the most optimal combination of immunohistochemical biomarkers to predict chemo-responsiveness.

Results: A total of 6,424 proteins were identified and 254 were confirmed to be significantly altered proteins related to chemotherapeutic response. From the patient group with chemo-resistance, we featured 56 upregulated proteins considerably in six closely related subcellular organelles concerning transcellular transportation system based on domain knowledge for text-mining and public network databases for network analysis.

14 intracellular exosomal transportation markers were identified to control chemosensitivity through siRNA array panel assay. Live cell images showed changed exosomal trafficking in cell lines manipulated by candidate markers. Through the verification step by machine learning analysis, we selected five markers and applied them to an independent cohort with FFPE biopsy samples to discover the most optimal combination of immunohistochemical biomarkers to predict chemo-responsiveness.

Conclusions: The present study provides the first evidence to identify a predictive biomarker for chemotherapeutic response based on in-depth proteomics. The newly discovered biomarkers and biological evidence can provide the novel insight to overcome chemoresistance in breast cancer.

Background: Diagnosis and treatment of Cancer of Unknown Origin (CUP) continues to be a challenge. In the era of personalized medicine, genomic profile by Next-Generation-Sequencing (NGS) in addition to immunohistochemistry (IHC) tests may complement clinical features improving diagnosis and detecting targetable mutations. In the present study we have analysed the clinical utility of theOncoDEEP® CUP platformfor tissue of origin assessment and genotyping in a cohort of CUP patients.

Methods: We conducted this multicentric prospective exploratory study across 22 institutions (September 2017- March 2018). The cohort included 60 patients with histologically diagnosed metastatic CUP and available FFPE tumor samples. The molecular analysis was performed using the OncoDEEP® CUP platform, which includes a deep genomic tumor characterization as well as a panel of IHC tests.

Results: Patient's median age was 60 years [24-80], 61.7% were females. At time of diagnosis,48% presented a single metastatic site whereas 52% has multimetastaticlocations. Predominant histology was adenocarcinoma (36.7%) followed by carcinoma NOS (25%), squamous cell carcinoma (13.3%) and others (25%). In 10% of the cases, the analysis could not be completed due to insufficient tumor samples. In the remaining 54 samples, a probable primary origin was assessed in 43 patients (80%). Potentially actionable mutations were found in 36 cases (61%). As expected, the most frequently mutated gene was TP53 (12/36), followed by KRAS, TPMT, ARID1A,BRAF, CDKN2A, PI3KCA, PTEN and STK11. During follow up 11 deaths have been recorded, whereas the rest of the patients remain in the study.

Conclusions: OncoDEEP® CUP may provide an opportunity for CUP patients to benefit from site-specific treatments and personalized therapies if druggable mutations are identified. 1861P Pre-treatment circulating cytokines predict toxicity with combination anti-PD1 and anti-CTLA4 immunotherapy

J.H. Lee[1], S.Y. Lim[2], A.M. Menzies[3], M.S. Carlino[4], A. Guminski[3], K. Nahar[5], D. Palmieri[6], E. Breen[2], R. Kefford[7], R. Scolyer[8], G.V. Long[3], H. Rizos[1]

[1]Biomedical Science, Macquarie University, Melanoma Institute Australia, Sydney, Australia, [2]Biomedical Science, Macquarie University, Sydney, Australia, [3]Department of Medical Oncology, Melanoma Institute Australia, The University of Sydney, Royal North Shore and Mater Hospitals, North Sydney, Australia, [4]Medical Oncology, The Crown Princess Mary Cancer Centre, Melanoma Institute Australia, Sydney University, Westmead, Australia, [5]Medical Oncology, Melanoma Institute Australia, University of Sydney, North Sydney, Australia, [6]Medical Oncology, The Crown Princess Mary Cancer Centre, Westmead, Australia, [7]Clinical Medicine, Macquarie University, Melanoma Institute Australia, Westmead Hospital, The University of Sydney, Sydney, Australia, [8]Pathology, Royal Prince Alfred Hospital, Melanoma Institute Australia, Sydney University, Camperdown, Australia

Background: Immune checkpoint inhibitors improve survival of patients with advanced melanoma. Combination anti-PD1 and anti-CTLA4 therapy improves the response rate compared to single agent anti-PD1, at the expense of far greater toxicity. While efforts have been made to identify biomarkers to predict treatment response, there are no biomarkers to predict for immunotherapy toxicity.

Methods: 198 plasma samples from 99 patients (discovery cohort – 50 patients, validation cohort – 49 patients) receiving combination anti-PD1 (nivolumab or pembrolizumab) and anti-CTLA4 (ipilimumab) were studied. The expression of 65 cytokines, measured at baseline (PRE) and early during treatment (EDT: week 1-3), was correlated with immune-related toxicity, defined as toxicity that warranted discontinuation of treatment and administration of high dose steroids ($\geq$ 50mg PO prednisolone equivalent), within 6 months of starting treatment (hypophysitis requiring steroid replacement was excluded).

Results: Toxicity rates were comparable between the discovery and validation cohorts, 21/50 (42%) and 22/49 (45%) respectively. The median expression of all 65 cytokines was significantly higher in patients with immune-related toxicity, compared to patients without toxicity in both the discovery cohort (PRE; $p = 0.01$, EDT; $p < 0.01$) and validation cohort (PRE; $p = 0.03$, EDT; $p = 0.02$). In addition, the median expression of six pro-inflammatory cytokines associated with autoimmune disease (IFN, IL-2, IL-17A, IL-1α, IL-1β, IL12) was significantly higher at baseline and EDT in patients with toxicity; discovery (PRE and EDT, $p < 0.01$) and validation (PRE, $p < 0.01$; EDT, $p = 0.01$). Expression of FGF-2, IL-12P70, IL13, IL-1 β, IL-2, MIL-1β and VEGF-A was also significantly higher in patients with toxicity at PRE and EDT, in both the discovery and validation cohorts, compared to patients without toxicity.

Conclusions: Elevated levels of circulating cytokines at baseline and EDT predict development of immune-related toxicity. Pre-treatment measurement of circulating inflammatory cytokines may have an important role in treatment selection for metastatic melanoma patients.

1862P A phase I trial of vorolanib (X-82t vascular endothelial growth factor receptor (VEGFR) inhibitor, in patients (pts) with advanced solid tumors

J. Bendell[1], K.N. Moore[2], M.R. Patel[3], C. Chua[4], H-T. Arkenau[5], G. Dukart[6], K. Harrow[7], C. Liang[8]

[1]GI Oncology Research, Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN, USA, [2]Medical Oncology, Stephenson Cancer Center/University of Oklahoma, Oklahoma City, OK, USA, [3]Oncology, U Minnesota Medical School, Minneapolis, MN, USA, [4]Medical Oncology, Oncology Hematology Care, Inc., Blue Ash, OH, USA, [5]SCRI, Sarah Cannon Research Institute SCRI UK, London, UK, [6]Xcovery Holdings, Inc., Palm Beach Gardens, FL, USA, [7]Clinical Operations, Xcovery Holding Company, LLC, Palm Beach Gardens, FL, USA, [8]Xcovery Holdings, Inc., Palm Beach Gardens, FL, USA

Background: Vorolanib is an orally available, potent, small molecule VEGFR inhibitor. It was designed based on the sunitinib scaffold with the goals of a shorter half-life to meet the pharmacokinetic (PK)/ pharmacodynamic (PD) requirement of intermittent inhibition and no accumulation in tissues. This first-in-human study (NCT01296581) was designed to determine the maximum tolerated dose (MTD) or the recommended dose, dose-limiting toxicity (DLT), safety, PK, and preliminary antitumor activity of vorolanib.

Methods: Patients aged ≥ 18 years with advanced solid tumors were enrolled at the starting dose of 20 mg and escalating doses in an accelerated design. Safety was evaluated in every 4-week cycles, and tumor assessment was performed every 8 weeks using RECIST 1.1. Plasma PK samples and time-matched ECG data were collected.

Results: 52 patients received vorolanib in 17 cohorts, with doses ranging from 20mg QD to 800 QD and 140-200 mg BID. During the study, the formulation was changed from capsule to tablet. The most common tumor type was ovarian (19%). No DLT occurred and the MTD was not officially reached. Due to apparent saturation of absorption in the 400 – 800 mg QD range, dose escalation was stopped at 800 mg, and 400 mg QD was chosen as the dose for the expansion cohort. The most common treatment-related adverse events (TRAE) were fatigue, nausea, diarrhea, hair color change, vomiting, rash, peripheral edema and asthenia, mostly grade 1-2. Five patients had a grade 3TRAE, with proteinuria (4%) being the most common. The plasma half-life of vorolanib was approximately 6.5 hours, and no accumulation was observed after 21-days of daily dosing. 1 pt with pancreatic adenocarcinoma receiving vorolanib had a complete response, 1 pt with Hurthle cell carcinoma had a partial response, and 11 pts (20%) had stable disease for ≥ 6 cycles.

Conclusions: Vorolanib was generally well tolerated up to 800 mg QD in patients with advanced solid tumors. Based on the safety profile, PK/PD model and patient responses, 400 mg QD was selected as the single agent dose for advanced cancer patients.

Clinical trial identification: NCT01296581.

1863P Longitudinal analysis of circulating biomarkers to monitor advanced EGFR mutated (EGFR+) non-small cell lung cancer (NSCLC)

P.N. Ding[1], T. Becker[1], V.J. Bray[2], W. Chua[2], Y.F. Ma[1], A. Luk[1], J. Po[1], D. Lynch[1], N. Caixeiro[1], P. de Souza[1], T.L. Roberts[1]

[1]Translational Medical Oncology Group, Ingham Institute for Applied Medical Research, Liverpool, Australia, [2]Medical Oncology Department, Liverpool Hospital, Liverpool, Australia

Background: Circulating tumour DNA (ctDNA) and circulating tumour cells (CTC) can be used as a 'liquid biopsy' to detect gene mutations. Serial blood collection for ctDNA and CTC analyses allows monitoring for treatment response and to understand the mechanisms of acquired resistance. We hypothesised that longitudinal ctDNA and CTC analyses may be used for disease monitoring and could have prognostic significance in patients with advanced EGFR+ NSCLC.

Methods: In this prospective study, patients with advanced EGFR+ NSCLC were recruited, with blood and plasma samples collected prior to starting treatment, 4 weeks into treatment and at disease progression. CTCs were enumerated and ddPCR for EGFR activating mutations and the T790M resistance mutation performed on ctDNA. We evaluated the relationship between baseline and decrease in CTC and ctDNA at 4 weeks with clinical outcomes.

Results: A total of 56 plasma specimens from 28 patients were studied. ctDNA was detectable at baseline in 19/28 (68%) patients starting first line EGFR inhibitors. Detectable baseline ctDNA was associated with higher disease burden ($p < 0.01$). Early disappearance of ctDNA at 4 weeks was associated with radiological response 12 weeks into treatment ($p = 0.04$) and improved PFS (Median PFS 136 vs 511 days, HR 4.49, $p < 0.01$) and OS (Median OS 311 days vs NR, HR 5.32, $p = 0.01$), which remained significant after adjustment for burden of disease. Drop in CTC count at 4 weeks was associated with improved PFS (HR 3.11 $p = 0.02$) but not OS. Drop in CTC counts at 4 weeks was associated with radiological response, just reaching significance ($p = 0.05$).

Conclusions: Longitudinal assessment of ctDNA and CTC is an accurate predictor of tumour response and survival outcomes for patients with advanced EGFR+ NSCLC. This offers a potentially cheaper, highly informative and minimally invasive way of monitoring malignancies.

1864P Genotyping of circulating tumor DNA in biliary tract cancer reveals diagnostic and prognostic information

T.J. Ettrich[1], D. Schwerdel[1], A. Dolnik[2], F. Beuter[1], T. Blätte[2], S.A. Schmidt[3], N. Stanescu-Siegmund[3], J. Steinacker[3], R. Marienfeld[4], A. Kleger[1], L. Bullinger[2], T. Seufferlein[1], A.W. Berger[1]

[1]Internal Medicine I, Ulm Medical University, Ulm, Germany, [2]Internal Medicine III, Ulm Medical University, Ulm, Germany, [3]Diagnostic and Interventional Radiology, Ulm Medical University, Ulm, Germany, [4]Pathology, Ulm Medical University, Ulm, Germany,

Background: Biliary tract cancer (BTC) shows increasing incidence and is associated with a high mortality. Diagnosis is difficult due to the frequently occurring inaccessibility of the tumor for biopsy. Noninvasive approaches for assessing and monitoring the tumor-specific molecular setup are desirable to improve diagnosis and tailor treatment.

Methods: Blood and tumor tissue samples from patients with locally advanced or metastatic BTC were collected prior to and during palliative treatment. Tumor tissue and corresponding ctDNA samples were subjected to targeted resequencing of 15 genes frequently mutated in BTC (TP53, KRAS, ARID1A, BAP1, PBRM1, PIK3CA, SMAD4, FBXW7, IDH1, BCL2, BRAF, CDKN2A, ERBB2, IDH2, NRAS). Findings were correlated with clinical and imaging data.

Results: 24 therapy naive patients with histologically confirmed BTC were included into the analyses. The mutational concordance (blood/tissue) was 74% overall and 92% for intrahepatic tumors only. Mean variant allele frequency (VAF) detected in tumor tissue was significantly higher compared to ctDNA ($p = 0.0291$). In turn, the sequencing depth for ctDNA was about double of that for tissue samples (1010x vs. 465x), enabling the detection of variants in ctDNA. ctDNA VAF at baseline significantly correlated with tumor load (Spearman, $r = 0.4073$, $p = 0.0433$). Interestingly, for intrahepatic BTC baseline ctDNA VAF also significantly correlated with progression-free survival (Spearman, $r = -0.5878$, $p = 0.0288$). 36% of therapy naive patients had a change in their mutational profile during chemotherapy.

Conclusions: The molecular landscape of BTC is represented in ctDNA and most tumor specific variants are detectable in ctDNA, especially in intrahepatic BTC. In this subgroup the baseline VAF in ctDNA was also of prognostic significance. Additionally, we detected hints for tumor evolution in a relevant portion of the analyzed BTC patients during chemotherapy, which have to be further investigated. Altogether, ctDNA analysis in BTC may support diagnosis, prognosis and the adaption of therapeutic strategies according to the specific molecular setup of the tumor detected at any time point during chemotherapy.

Background: Lung cancer stem cells (CSCs) are a small subpopulation of cells with self-renewal, tumorigenic properties and the ability to grow to form tumorspheres in non-adherent conditions. Recently, the study on soluble molecules has been a new focus to understand the interaction between CSCs and tumor microenvironment. The aim of this work is to compare the release of cytokines between monolayer cells and tumorspheres of NSCLC cultures.

Methods: The study was performed on medium supernatant of cells from 8 NSCLC tumour patients samples and 10 cell lines (A549, H1650, H460, H23, H358, H2228, HCC827, PC9, H1993, SW900) grown in monolayer and tumorspheres at 2 different densities (10^4 and 10^5 cells/ml); supernatant was recollected at 12h and 24h. We analyzed 8 soluble factors with immunosuppressive (IL-4, IL-10, IL-13), and immunoregulatory (IL-6, IL-8, IL-17A, TNFa, IFN) capacity through sensitivity bead-based multiplex assay using the Millipore kit from the Luminex 100/200.

Results: IL-4, IL-6, IL-8, TNFa levels were detected in all samples while IFNγ, IL-10, IL-13, IL-17A were beyond the detectable range in adherents for most of cultures (Detection range [pg/ml] of IL-4: 1.83-7497.38, IL-6: 0.18-813.66, IL-8: 0.31-1042.75, TNFa: 0.43-1758.47, IFNγ: 0.61-2468.39, IL-10: 1.46-6056.85, IL-13: 0.24-1002.76,

IL-17A: 0.73-3074.88). We observed significant differences in levels of IL-6, IL-13, IL-17A, TNFa, IFNγ between adherent cells and tumorspheres. Moreover, IL-4, IL-10, IL-13, IL-17A, IFNγ levels in tumorspheres were higher than monolayer. Otherwise, IL-6 and TNFa were secreted more in monolayer. IL-8 is the most secreted molecule in both adherents and tumorspheres by all cultures.

Conclusions: Our preliminary results suggest that high levels of IL-6 and IL-8 were detected in all samples. IL-8, IL-13, IL-17A and IFNγ secreted by lung CSCs could be involved in the modulation of the immune microenvironment. Additionally, adherent cells show increased levels of IL-6 and TNFa compared to tumorspheres, and IL-8, IL-4, IFNγ, IL-10, IL-13, IL-17A show the opposite. The next is to extend the cohort to validate our results and to study others immunoregulatory factors.

1866P Association of the rs1883832 variant of CD40 with NSCLC risk and overall survival

F-I.D. Dimitrakopoulos[1], A. Antonacopoulou[2], A. Kottorou[2], S. Marousi[2], I. Koukourikou[1], C. Scopa[3], D. Dougenis[4], V. Tzelepi[3], H. Kalofonos[5]

[1]Medical Oncology, University Hospital of Patras, Patras, Greece, [2]Molecular and Clinical Laboratory, University of Patras, Patras, Greece, [3]Pathology, University Hospital of Patras, Patras, Greece, [4]Thoracic Surgery, University Hospital of Patras, Patras, Greece, [5]Medical Oncology, University of Patras, Patras, Greece

Background: During the last few years a growing number of studies has attempted to shed light on the role of CD40 (Tumor Necrosis Factor Receptor Superfamily Member 5) in non-small-cell lung cancer (NSCLC), which remains the leading cause of cancer-related deaths worldwide. The aim of the current study was to investigate the clinical relevance of CD40 functional single nucleotide polymorphism (SNP) rs1883832 (-1C/T) with susceptibility to NSCLC, the clinicopathological parameters, relapse and survival rates of NSCLC patients, as well as with the protein expression of CD40.

Methods: CD40 SNP rs1883832 was genotyped in 268 randomly selected NSCLC patients and 279 age- and gender-matched healthy donors. Patients were under observation during a five-year period. Immunohistochemical analysis for CD40 was performed on 106 NSCLC tumor tissue samples. All the participants were Greeks with Caucasian origin.

Results: Genotype frequencies of rs1883832 (CC, CT, and TT) were significantly different between healthy controls and patients. CC homozygotes had higher risk for NSCLC compared to T allele carriers in univariate ($P < 0.001$), as well as in multivariate analysis ($P = 0.006$). In addition, rs1883832 was related to overall survival. More specifically, CT heterozygotes had worse clinical outcome after two-, three- and five-year observation compared to TT and CC homozygotes ($P = 0.015$, $P = 0.005$ and $P = 0.017$, respectively). Stratifying according to histological subtype, this association was observed only in patients with adenocarcinomas ($P = 0.028$) and not in patients with squamous- and large-cell carcinomas. Furthermore, taking into consideration disease stage, worse survival for CT heterozygotes was observed in stage II patients and not in patients of other stages ($P = 0.016$). Moreover, the variant had also strong association with brain metastases, with T allele carriers developing more often metastatic disease in CNS ($P = 0.018$). Interestingly, rs1883832 was related to CD40 protein expression in malignant cells ($P < 0.001$) as well as in stromal cells ($P = 0.004$).

Conclusions: The present findings suggest that investigated SNP rs1883832 may be a useful and independent biomarker in NSCLC. However, more studies are needed in order to further demonstrate their role in NSCLC.

1867P Circulating tumour DNA (ctDNA) as a tool to assess response and guide therapy adaptation in rectal cancer

S. Khakoo[1], P. Carter[2], N. Valeri[3], R. Shaikh[2], T. Jones[2], R. Begum[1], I. Rana[1], S. Picchia[4], M. Bali[4], G. Brown[4], A. Wotherspoon[5], M. Terlizzo[5], K. von Loga[6], I. Ahmed[5], D. Watkins[1], I. Chau[1], N. Starling[1], D. Tait[1], M. Hubank[2], D. Cunningham[1]

[1]Medicine, Royal Marsden Hospital NHS Foundation Trust, Sutton, UK, [2]Clinical Genomics, Royal Marsden Hospital NHS Foundation Trust, Sutton, UK, [3]Molecular Pathology, The Institute of Cancer Research/Royal Marsden NHS Foundation Trust, Sutton, UK, [4]Radiology, Royal Marsden Hospital NHS Foundation Trust, Sutton, UK, [5]Histopathology, Royal Marsden Hospital NHS Foundation Trust, London, UK, [6]Histopathology, Royal Marsden Hospital NHS Foundation Trust, Sutton, UK

Background: Neo-adjuvant chemoradiation (CRT) is associated with varied response in patients (pts) with localised rectal cancer. Early identification of poor responders and pts at risk of developing systemic disease using ctDNA would allow tailoring of treatment.

Methods: Tissue and serial plasma was collected from 47 pts with localised rectal cancer scheduled to undergo long course CRT. Cell-free DNA (cfDNA) was purified from a mean of 3.6 ml plasma per time-point. Somatic variants were identified in tissue by sequencing using a targeted capture panel. Up to 3 variants per patient in genes of interest were tracked in plasma using custom TaqMan assays on a droplet digital PCR platform. Tumour response assessments were conducted according to RECIST. Statistical analysis included Fisher's exact test and Spearman's correlation.

Results: 62% of pts were male, median age 59, range 30-83. On baseline MRI, circumferential resection margin was involved or threatened in 75% and EMVI positive in 81%. Plasma was collected at a median of: 6 days (d) prior to CRT (baseline), 21 d from the start of CRT (mid) and 37 d after completion of CRT (end). The frequency (%) of mutation detection in tissue was: TP53 (85), APC (74), KRAS (36), PIK3CA (15), NRAS (4) and BRAF (2). ctDNA was detectable in 74% of pts at baseline and in 21% at mid and end of CRT. ctDNA detection increased with stage at baseline: stage 1 ($n = 0/1$), stage 2 ($n = 3/5$, 60%) and stage 3 ($n = 32/41$, 78%). Stage had no impact on detection at mid or end of CRT. At baseline, ctDNA was detectable in all 15 CEA secretors ($\geq$5 ug/l) compared to 63% in 30 non-secretors ($P = 0.008$). Baseline ctDNA levels were not associated with ki67 tumour assessment. MRI response assessment of the primary tumour was not associated with ctDNA detection at any timepoint. 11 patients developed metastases of which 3 occurred after surgery. End of CRT ctDNA detection was higher in pts that developed metastases (64%) compared to those that did not (8.3% $P = 0.0005$). Detection of ctDNA at baseline that persisted at mid CRT was also higher in pts that developed metastases (36% vs 11%, $p = 0.07$).

Conclusions: ctDNA detection can help identify rectal cancer pts with localised disease at risk of developing metastases. These pts could benefit from earlier intervention with systemic therapy.

1868P A genetic analysis of gemcitabine-induced high-grade neutropenia in pancreatic cancer patients

F. Innocenti[1], C. Jiang[2], A.B. Sibley[3], S. Denning[1], A.S. Etheridge[1], D. Watson[3], D. Niedzwiecki[4], A.J. Hatch[3], H. Hurwitz[5], A. Nixon[3], Y. Furukawa[6], M. Kubo[7], D.J. Crona[1], H. Kindler[8], H.L. McLeod[9], M.J. Ratain[8], K. Owzar[2]

[1]Division of Pharmacotherapy and Experimental Therapeutics, UNC-Institute for Pharmacogenomics and Individualized Therapy, Chapel Hill, NC, USA, [2]Alliance Statistics and Data Center, Duke Cancer Institute, Durham, NC, USA, [3]Duke Cancer Institute, Duke University Medical Center, Durham, NC, USA, [4]Department of Biostatistics and Bioinformatics, Duke University Medical Center, Durham, NC, USA, [5]Medical Oncology, Duke University Medical Center, Durham, NC, USA, [6]Center for Genomic Medicine, RIKEN, Yokohama, Japan, [7]Center for Integrative Medicine, Riken, Kanagawa, Japan, [8]Oncology, The University of Chicago Medical Centre, Chicago, IL, USA, [9]Department of Cancer Epidemiology, Moffit Cancer Center, Tampa, FL, USA

Background: One of the standard of care regimens for advanced pancreatic cancer is gemcitabine-based chemotherapy. The efficacy of gemcitabine is reduced by dose-limiting hematologic toxicities, especially neutropenia. Uncovering the variability of these toxicities attributed to germline DNA variation is of great importance.

Methods: CALGB 80303 was a randomized study in advanced pancreatic cancer patients treated with gemcitabine with or without bevacizumab. The study protocol included genotyping of genes of gemcitabine disposition (CDA, DCTD, SLC29A1, SLC28A1, SLC29A2), as well as a genome-wide analysis. The clinical phenotype was time to high-grade early neutropenia event accounting for progression or death, with other treatment-terminating adverse events as competing informative events. The inference was conducted on the basis of the association between genotype and cause-specific hazard of a neutropenic event.

Results: The primary analyses were conducted on the basis of 294 genetically estimated Europeans. For CDA rs2072671 (A>C), AC and CC patients had a lower risk of neutropenia than AA patients (unadjusted P-value 0.01, HR 0.61, 95% CI 0.41-0.89). For SLC28A1 rs3825876 (G>A), AA patients have a higher risk of neutropenia than GA and GG patients (unadjusted P-value 0.02, HR 1.51, 95% CI 1.06-2.16). The C allele of CDA rs2072671 was associated with increased mRNA expression in whole blood in three studies (unadjusted P-values 2.7e-14, 6.61e-62, 9.70e-65). In the genome-wide analysis, variants in TGFB2 were among the top hits (unadjusted lowest P-value 1.62e-06) but had no effect in luciferase assays.

Conclusions: The first genetic analysis of gemcitabine-induced neutropenia using a competing risk model in a prospective randomized clinical study has proposed a potentially novel mechanism of the protective effect of the CDA rs2072671 variant. We hypothesize that the rs2072671 (A>C) variant acts through a local effect in either the bone marrow or in circulating neutrophils (or both), by protecting neutrophils from the anti-proliferative effects of gemcitabine. Further confirmation is needed.

1869P Effect of a combined treatment with iPS cells derived dendritic cells and proton beam irradiation in a murine subcutaneous melanoma model

Y. Wang[1], L. Sun[1], X. Li[2], K. Tsuboi[1]

[1]Proton Medical Research Center, University of Tsukuba, Tsukuba, Ibaraki, Japan, [2]Division of the Transplantation Immunology, National Research Institute for Child Health and Development, Tokyo, Japan

Background: In situ dying and just died tumor cells after irradiation give danger signals and release tumor-specific antigens which are sequentially incorporated into dendritic cells (DCs). Our previous studies on a murine subcutaneous tumor model showed that injection of bone marrow derived DCs (BM-DCs) after X-ray therapy significantly delayed tumor growth. As compared to X-rays, the unique biological and physical benefits of proton beam therapy may prove superior in the systemic immune effect. In addition, usage of DCs induced from iPS cells (iPS-DCs) may overcome practical problems of BM-DCs such as a limited number of applicable cells and an induction period of 7 days. The purpose of this study is to investigate: 1) whether proton beam therapy are superior in induction of anti-tumor immune response compared to X-ray therapy. 2) whether the function of induced iPS-DCs is superior to that of BM-DCs.

Methods: DCs were induced by using GM-CSF and IL-4 from autologous bone marrow cells or iPS cells of C57BL/6 mice. Syngeneic B16 melanoma cells subcutaneously implanted at the thighs of C57BL/6 mice were treated with X-ray or proton beam 5 days after inoculation. After 1, 3, 5, 7 days from irradiation, induced BM-DCs or iPS-DCs were injected directly into the tumor site. Tumor growth was monitored, and survival analyses were performed.

Results: Proton beam therapy induced superior immunogenicity of cancer cell comparing to X-ray therapy. Also, iPS-DCs showed an excellent ability to incorporate antigens in vitro comparing to BM-DCs. The combination treatment of proton beam and iPS-DCs significantly delayed tumor growth in vivo.

Conclusions: iPS-DCs should overcome the practical problems of BM-DCs in cancer treatment. The combination therapy of proton beam and iPS-DCs administration can offer a promising novel cancer therapy.

1870P Developing the liquid biopsy in gastroesophageal adenocarcinoma: Disease monitoring and detection of minimal residual disease

M.R. Openshaw, B. Ottolini, C.J. Richards, D. Guttery, J.A. Shaw, A. Thomas

Leicester Cancer Research Centre, University Hospitals of Leicester NHS Trust Leicester Royal Infirmary, Leicester, UK

Background: Gastroesophageal adenocarcinoma (GOA) is a molecularly defined group of cancers with shared genetic alterations, poor overall survival and no routine blood based biomarker. The liquid biopsy, including circulating tumour DNA (ctDNA) is a promising technology that may improve our ability to monitor disease and enhance survival. This study aimed to determine the utility of ctDNA in GOA.

Methods: A pilot study of 37 patients with GOA were recruited. These comprised 24 patients treated with curative intent and 13 palliative patients. Tumour DNA was sequenced using a custom ampliseq six gene targeted next generation sequencing (NGS) panel. Tumours from patients treated with curative intent with no detectable somatic mutation were also analysed for gene amplification via Nanostring™ nCounter. Plasma from blood samples taken at multiple time points were analysed by NGS and digital droplet PCR to detect ctDNA.

Results: Somatic mutations at $>5\%$ allele frequency were identified in 30 of 37 (81%) tumours, most commonly in TP53. Gene amplification was detected in a further three. In 11 of 13 (85%) palliative patients that had a detectable somatic mutation ctDNA was detected in 9 (82%). These ctDNA levels were dynamic, falling with treatment response and rising with disease progression, often prior to clinical relapse. 22 of 24 (92%) patients treated with curative intent had a detectable somatic mutation or gene amplification. 9 of these 22 (41%) relapsed during follow-up. CtDNA was detected prior to relapse in 7 of 22 (31%) patients and predicted poor survival (median PFS 298 vs $>$ 1000 days, HR = 11.8, $p < 0.001$). In 4 patients, ctDNA was detected in the postsurgical blood test, of these 3 have relapsed and one remains disease free at 5 months (median PFS 203 vs $>$ 1000 days, HR = 9.6, $p = 0.004$). This patient will be followed up for evidence of relapse as these ctDNA positive post surgical bloods suggest detection of minimal residual disease.

Conclusions: Tracking of ctDNA in patients with GOA provides valuable clinical information regarding disease progression and response, and presence of ctDNA is generally a poor prognostic sign. In addition, ctDNA may define patients with minimal residual disease who are at high risk of relapse after surgery.

1871P Survival from breast cancer in patients with BRCA1/2, CHEK2, NOD2 mutations and TP53 (c.[215G>C]) polymorphisms

J. Huszno[1], Z. Kolosza[2]

[1]Outpatient Clinic, Maria Sklodowska Curie MSC Memorial Cancer Institute in Gliwice, Gliwice, Poland, [2]Biostatistics Unit, Maria Sklodowska Curie MSC Memorial Cancer Institute in Gliwice, Gliwice, Poland

Background: The purpose of this study is to estimate 5-year survival rates for patients with early onset breast cancer, with and without a BRCA1/2, CHEK2, NOD2 mutation or TP53 polymorphisms and to identify prognostic factors among mutation carriers in breast cancer patients.

Methods: In a study conducted in the years 2007-2016 in the Maria Skłodowska Curie Memorial Cancer Centre and Institute of Oncology, Gliwice Branch (COI) were analyzed prognostic factors and survival in 622 breast cancer including 60 BRCA mutation carriers, 46 CHEK2 mutation carriers, 29 NOD2 mutation carriers and 87 patients with TP53 polymorphisms. Control group was selected from breast cancer patients without mutation and polymorphisms ($n = 400$).

Results: The five–year rate of OS was 75.9% for pts with BRCA mutation, 94.4% for CHEK2 mutation carriers, 96.6% for NOD2 mutation carriers and 100% for patients with TP53 polymorphisms. BRCA mutation carriers had insignificantly worse survival as compared to control group ($p = 0.180$). Patients with CHEK2 mutation had significantly better OS than control group ($p = 0.032$). Similarly NOD2 mutation carriers had also significantly better OS than control group ($p = 0.043$). Patients with TP53 polymorphisms carriers had higher OS in comparison to control group ($p = 0.002$). In subgroup of pts with N0 (Without lymph node metastases) BRCA mutation carriers was characterized by the worst OS (81.1%) among carriers of other mutations: CHEK2 (94.7%, $P = 0.021$), NOD2 (95.3%, $p = 0.092$) and TP53 polymorphisms (100%, $p = 0.007$) or control group (94.4%, $p = 0.022$). Similar tendency was observed according to N+ subgroup and subgroup with tumor size T1-T2. Higher tumor size (HR = 2.85), lymph node metastases (HR = 2.93) and HER2 overexpression (HR = 1.49) were significant factors for worse OS. Positive ER status was associated with a better OS (HR = 0.52, $p = 0.001$). Age <40 years (HR = 0.71, $p = 0.255$) was insignificantly favorable factor.

Conclusions: CHEK2, NOD2 mutation carriers and patients with TP53 polymorphisms had better 5-year survival in comparison to patients with BRCA mutation and control group. Higher tumor size (T) and lymph node metastases (N+) were negative prognostic factors independently from the presence of mutations and polymorphisms.

1872P Phase I pharmacological study of continuous chronomodulated capecitabine treatment

J. Roosendaal[1], B.A.W. Jacobs[2], D. Pluim[2], H. Rosing[1], B. Nuijen[1], J.H. Beijnen[1], A.D.R. Huitema[1], J.H.M. Schellens[2], S. Marchetti[2]

[1]Department of Pharmacy & Pharmacology, The Netherlands Cancer Institute and MC Slotervaart, Amsterdam, Netherlands, [2]Division of Clinical Pharmacology, Department of Medical Oncology, The Netherlands Cancer Institute, Amsterdam, Netherlands

Background: Capecitabine is an oral prodrug of the anti-cancer drug 5-fluorouracil (5-FU). The 5-FU degrading enzyme, dihydropyrimidine dehydrogenase, and the target enzyme thymidylate synthase, are subject to circadian rhythmicity. The primary aims of this study were to determine the maximum tolerated dose (MTD), dose-limiting toxicity (DLT), recommended dose (RD) and safety of capecitabine therapy adapted to this circadian rhythm (chronomodulated therapy).

Methods: Patients aged $\geq$ 18 years, with WHO performance status of ≤ 2, and advanced solid tumors potentially benefitting from capecitabine therapy were enrolled. DPYD*2A or 2846A>T mutation carriers were excluded. A classical dose escalation 3 + 3 design was applied. Capecitabine was administered twice daily without interruptions. The daily dose was divided in morning and evening doses that were administered at 09:00h and 24:00h, respectively. The ratio of the morning to the evening dose was 3:5 (morning:evening). Toxicity was assessed according to the Common Terminology Criteria for Adverse Events version 4.03. DLT was evaluated during the first three weeks of treatment.

Results: A total of 21 patients was enrolled. The daily capecitabine dose was escalated from 1000 mg/m^2 up to 2550 mg/m^2 over five dose-levels. Three DLTs were observed in two patients at the highest dose-level (grade III hand-foot syndrome (2x) and grade III diarrhea (1x)). The MTD was established at 2000 mg/m^2 per day (750 mg/m^2 at 9:00 h and 1250 mg/m^2 at 24:00 h). Continuous chronomodulated capecitabine therapy was

generally well tolerated at the MTD level with main adverse events being grade 1-2 hand-foot syndrome and fatigue.

Conclusions: The cumulative dose of capecitabine at the MTD/RD (i.e., 750 mg/m^2 at 9:00h and 1250 mg/m^2 at 24:00h, continuous chronomodulated regimen) is 20% higher than the cumulative dose of the approved regimen (1250 mg/m^2 bi-daily on day 1-14 of every 21-day cycle). Chronomodulation therefore represents a promising strategy as it could lead to improved tolerability and efficacy of capecitabine. Further investigation is warranted.

Clinical trial identification: EudraCT: 2014-000889-22.

1873P Head and neck (HN) primary sarcomatoid carcinoma (PSC) profile by high-throughput somatic mutation profiling

V. Fallet[1], R. Taouachi[2], R. Saffroy[3], A. Ben Lakhdar[4], N. Rabbe[5], F. André[6], S. Temam[7], A. Lemoine[3], M. Wislez[1]

[1]Thoracic Oncology, APHP, CancerEst, Tenon University Hospital/GRC-04 Theranoscan, Sorbonne Universités, UPMC Université Paris 06, Paris, France, [2]Department of Surgery, Institut Curie, PSL Research University, Saint Cloud, France, [3]Department of Biochiemistry and Oncogenetics, AP-HP, GH Paris-Sud, Hôpital Paul Brousse/Platform Oncomolpath/INCA, Villejuif, France, [4]Pathology, Gustave Roussy Institute, Villejuif, France, [5]GRC n°04, Theranoscan, APHP, CancerEst, Tenon University Hospital, Paris, France, [6]Breast Cancer Unit, Department of Medical Oncology, Gustave Roussy - Cancer Campus, Villejuif, France, [7]Department of Head and Neck Surgery, Institut Gustave Roussy, Villejuif, France

Background: The Head & Neck Primary Sarcomatoid Carcinoma (HN PSC) is a rare sub-type of squamous cell carcinoma with poor prognosis. This study sought to describe the mutational profile of HN PSC using high-throughput genotyping technology Massarray, (Agena, Hamburg).

Methods: We included 45 patients with HN PSC. We used PCR mass spectrometry detection to establish the DNA mutation profiles of 72 samples from these patients (45 primary tumors, 5 metastatic cervical nodes and 22 non tumoral tissues) studying 214 mutations affecting 26 oncogenes and tumor suppressor genes.

Results: In total, 33/45 (77.3%) patients were male and 31/45 (69%) were smokers. Median age was 60 years (range 13 – 93 years) and 28/45 (62.2%) were metastatic. The main tumor sites were oral cavities (31.1%) and larynx (28.1%). The predominant histological subtype was the pleomorphic form (66,7%). In the 72 tumors, 18 distinct somatic alterations were identified, 15 tumors (33%) harboring at least one mutation. The most frequent mutations were TP53 (11.1%), PIK3CA (8.9%), EPHA5 (4.4%), MET (4.4%), NOTCH1 (4.9%), NTRK2 (2.2%), BRAF (2.2%), JAK2 (2,2%), KRAS (2,2%) and NRF2 (2,2%). The presence of a mutation was not correlated with any clinical characteristic (age, sex, primary located site, cancer stage, tobacco and alcohol status). Only 1/45 (2.2%) tumor presented a targetable mutation with tyrosine kinase inhibitor (mutation BRAF). The mutational profile was identical between the local tumor site and the cervical node in 4/5 patients.

Conclusions: Our results demonstrated that HN PSC had a similar mutational profile of other HN carcinoma such as TP53, PIK3CA and NOTCH1 mutations. It reinforced the hypothesis of a single cell clone, which is acquired with different histological phenotypes by different, still unknown mechanisms involving epithelial to mesenchymal transition.

Medizinische Klinik und Poliklinik, München, Klinikum rechts der Isar, Technische Universität München, Munich, Germany, [4]Gastroenterology and Gastrointestinal Oncology, Universitätsmedizin Göttingen, Göttingen, Germany, [5]Gastroenterology and Endocrinology, University of Marburg, Marburg, Germany, [6]Hämatology, Oncology, University Hospital Ruhr-University-Bochum, Minden, Germany, [7]Gastroenterology, Infectious Diseases and Rheumatologyh, Charité University Medicine Berlin, Berlin, Germany, [8]Internal Medicine, Oncology/Hematology, Klinikum Esslingen, Esslingen, Germany, [9]Pathology, Ruhr-Universität Bochum, Bochum, Germany, [10]Surgical Clinic, Katholisches Klinikum Bochum - St. Josef-Hospital, Bochum, Germany, [11]Department of Internal Medicine I, Ulm Medical University, Ulm, Germany

Background: Due to the dismal prognosis of the pancreatic ductal adenocarcinoma (PDAC) biomarkers are needed to facilitate the early and preferably noninvasive diagnosis. The use of circulating tumor DNA (ctDNA) was already examined in the metastatic situation but not at all in a resectable stage with lower tumor load. Currently, CA19-9 is the only validated biomarker for PDAC but inherits poor performance. Recently, it has been reported that elevated levels of thrombospondin-2 (THBS2) protein are detectable in PDAC. Here we aimed at improving sensitivity and specificity of THBS2 based detection of early PDAC by combining THBS2 analysis with further markers.

Methods: 39 patients with proven PDAC, enrolled to the NEONAX trial (identifier: NCT02047513), were selected for this study-independent retrospective translational analysis. 15 patients with benign pancreatic disease (IPMN) served as controls. cfDNA concentration was measured fluorometrically. KRAS genotyping of ctDNA was done by digital droplet PCR targeting the 7 most frequently occurring KRAS mutations in PDAC. CA 19-9 (Roche, cut-off 55 U/ml) and THSB2 levels (Quantikine, R&D Systems, cut-off 42 ng/ml) were determined by ELISA.

Results: PDAC patients had significantly more cfDNA (12.6 ng/ml) than IPMN patients (5.5 ng/ml, $p = 0.0006$). Only 5 % of PDAC patients and 7 % of IPMN patients had detectable KRAS mutations in ctDNA. CA19-9 was elevated in 56 % and THBS2 in 44 % of PDAC patients. Both markers were not elevated in any of the IPMN patients. Therefore, the assessment of THBS2 and CA19-9 levels was most suitable to discriminate the PDAC cohort from the IPMN cohort, with a sensitivity of 77 % and a specificity of 100 %.

Conclusions: THBS2 and CA19-9 panel assessed in human blood using a conventional ELISA assay may improve the diagnosis of pancreatic lesions as PDAC at an early stage. While total cfDNA amount differs between patients with benign and malignant pancreatic lesions, ctDNA genotyping for KRAS mutations failed to improve non-invasive diagnostic strategies in resectable PDAC most likely due to a low tumor load.

Clinical trial identification: NCT02047513.

1875P Acquired chemoresistance of colorectal cancer (CRC) cells is accompanied by pro-invasive VEGF-signaling that can be attenuated by aflibercept

A.K. Larsen[1], P. van Dreden[2], B. Chibaudel[3], A. de Gramont[4], G. Gerotziafas[5], S. Thouroude[6]

[1]Cancer Biology and Therapeutics, Centre de Recherche Saint-Antoine, Hôpital Saint-Antoine, INSERM U938 & Sorbonne University, Paris, France, [2]Laboratoire RD, Diagnostica Stago (SAS), Gennevilliers, France, [3]Medical Oncology, Institut Hospitalier Franco-Britannique/Franco-British Institute, Levallois-Perret, France, [4]Medical Oncology, Institut Hospitalier Franco-Britannique, Levallois-Perret, France, [5]Cancer Biology & Therapeutics, APHP, CancerEst, Tenon University Hospital, Paris, France, [6]Cancer Biology and Therapeutics, Centre de Recherche Saint-Antoine, INSERM U938 and Université Pierre et Marie Curie (UPMC), Sorbonne Universités Paris, France

Background: Cancer mortality is principally associated with the presence of drug-resistant, invasive subpopulations of tumor cells. However, the functional and mechanistic interactions between the two phenotypes are incompletely understood. Colorectal cancer (CRC) cells produce the vast majority of VEGF in the cancer environment and display endogenous VEGFR1/VEGF signaling which is believed to promoted survival under stress.

Methods: Migration and invasion was determined by the transwell assay (Boyden Chamber). For the tube formation assay, CRC cells were seeded onto 3D matrigels and incubated at 37° for 24 hr monitored by videomicroscopy. Determination of VEGF ligands was carried out by ELISA.

Results: We here characterize a panel of 4 isogenic CRC cell lines comprised of the parental HCT-116 cells and three independently derived sublines resistant to 5-fluorouracil, oxaliplatin and SN-38. Resistant cells secreted 3-7 fold more VEGF, while the

HCT-116/5-FU cells also secreted 2 times more PlGF, compared to the parental cells. VEGF signaling is known to promote CRC cell migration and invasion. In agreement, resistant cells showed 6-11 fold increased migration, whereas the invasive capacity had increased 6-15 fold. Aflibercept inhibits all three VEGFR1 ligands (VEGF-A, VEGF-B and PlGF) on CRC cells. Accordingly, addition of aflibercept resulted in a significant decrease in both migration and invasion. Two of the three resistant cell lines were able to do vascular/vasculogenic mimicry by forming capillary-like cellular networks which could be significantly attenuated by aflibercept.

Conclusions: Taken together, our results indicate that acquired resistance to genotoxic agents may be accompanied by an increased invasive potential mediated, in part, by VEGF signaling that can be attenuated by aflibercept.

1876P Actionable mutations and overall survival in 3,211 patients with cancer: The Hellenic cooperative oncology group precision medicine initiative

E. Fountzila[1], V. Kotoula[2], G-A. Koliou[2], E. Giannoulatou[3], H. Gogas[2], C. Papadimitriou[2], I.S. Tikas[2], K. Papadopoulou[2], F. Zagouri[2], C. Christodoulou[2], A. Koutras[2], E. Razis[2], P. Papakostas[2], E. Samantas[2], G. Aravantinos[2], A. Psyrri[2], D.G. Pectasides[2], A. Futreal[4], A-M. Tsimberidou[1], G. Fountzilas[2]

[1]Department of Investigational Cancer Therapeutics, MD Anderson Cancer Center, The Univesity of Texas, Houston, TX, USA, [2]Data Office, Hellenic Cooperative Oncology Group (HeCOG), Athens, Greece, [3]Department of Bioinformatics, Victor Chang Cardiac Research Institute, Darlinghurst, Australia, [4]Genomic Medicine, MD Anderson Cancer Center, Houston, TX, USA

Background: We evaluated the impact of tumor type and molecular profiling on overall survival of patients (pts) with cancer referred to Medical Oncology Departments affiliated with the Hellenic Cooperative Oncology Group (HeCOG).

Methods: Pts referred from 1989 to 2017 had molecular testing (for research) of archival tumor tissue collected at the time of diagnosis (stage I-III, 82%; stage IV, 18%). Tumor-specific (e.g. breast, colon) gene panels (45-101 genes) were used to identify pathogenic mutations in clinically relevant genes. Deep sequencing was performed at the Laboratory of Molecular Oncology, Aristotle University of Thessaloniki and HeCOG. Mutation annotation was performed at MD Anderson Cancer Center. All pts received standard-of-care anticancer therapy.

Results: We analyzed 3,211 pts (median age, 58 years; men, 29%) with informative sequencing data. Results by tumor type and molecular pathway are shown in the table. Overall, 1,193 (37%) pts had $\geq$1 actionable alterations [115 (3.6%) $\geq$4]. The most common affected pathways were PI3K, RAF/MEK, homologous recombination repair (HRR), and tyrosine kinase; 294 (9.2%) pts had alterations in $>$ 1 pathways. The median follow-up of alive patients is 7.48 years (yrs) (95%CI, 7.36-7.59). Of 3,211 pts, 1,060 (33.01%) have died. The median overall survival is 16.08 yrs (95%CI, 13.25-16.75). Of pts with breast cancer and actionable mutations, the 5-yr survival rates were: stage I-III (n = 501) 88.8%; stage IV (n = 14), 51.1% (p<.0001). Of pts with colorectal cancer and actionable alterations, the 5-yr survival rates were: stage I-III (n = 299), 76.5%; stage IV (n = 50), 15.2% (p<.0001).

Conclusions: Tumor sequencing revealed clinically relevant genomic mutations in several molecular pathways. Prospective clinical trials validating the clinical utility of tumor profiling are warranted.

1877P DNA repair genetic profiling in epithelial ovarian cancer: An opportunity for clinical improvement?

J. Assis[1], S. Coelho[2], A. Nogueira[1], R. Pinto[1], M. Brandao[3], J. Dias[2], S.G.C.M. Alves[2], D. Pereira[2], R. Medeiros[1]

[1]Grupo de Oncologia Molecular e Patologia Viral - Centro de Investigação, Instituto Portugues de Oncologia Centro do Porto (IPO-Porto), Porto, Portugal, [2]Medical Oncology, Instituto Portugues de Oncologia Centro do Porto (IPO-Porto), Porto, Portugal, [3]CTSU, Institute Jules Bordet, Brussels, Belgium

Background: In a recently published systematic review and meta-analysis, we provided an updated assessment of the association between genetic polymorphisms and epithelial ovarian cancer (EOC) first-line treatment outcome. Results highlighted the role of DNA Repair mediators, namely for variants in ERCC1 and ERCC2. Therefore, this study aims to evaluate the role of ERCC1 (rs11615 and rs3212986) and ERCC2 (rs13181 and rs1799793) variants in the outcome of EOC patients.

Methods: We conducted a hospital-based study in a cohort of EOC patients submitted to platinum-based first-line treatment (n = 340). DNA was extracted from peripheral blood samples, and genotypes were determined by Real-Time PCR using validated assays. Overall survival (OS) was the primary endpoint of this analysis. Survival analyses using Kaplan-Meier method and Cox proportional-hazards model were applied and the statistical significance was set at $p < 0.05$.

Results: The definition of a genetic profile reveals that patients harboring the combination of ERCC1 rs11615 A allele/ERCC1 rs3212986 AA genotype/ERCC2 rs13181 T allele/ERCC2 rs1799793 C allele have a significantly lower survival when compared to other genotype patients (136 vs. 161 months; log-rank test, P = 0.034). Specifically, this genetic profile is associated with a poorer prognosis (26 months vs. 69 months, respectively; log-rank test, P = 0.036) and a higher risk of death (HR, 2.7; $P_{bootstrap}$=0.019) among FIGO stage IV patients.

Conclusions: In an era where DNA repair ability is stated as a major cornerstone in EOC management, the characterization and definition of a DNA repair profile might be a useful tool for EOC clinical outcome prediction. According to the results of a meta-analysis, we validate the influence of ERCC1 and ERCC2 genetic polymorphisms in the survival of EOC patients submitted to platinum-based first-line chemotherapy. Particularly, this profile seems to have a preponderant role for the subgroup of advanced disease patients. Further considerations should be applied for the functional evaluation of these mediators in this clinical setting, as they might reveal an opportunity to improve survival in a subgroup with unfavorable prognosis.

1878P Strategy to improve the antitumor efficacy of dendritic cell-based nanovaccine under magnetic field control

O. Gorbach[1], N. Khranovska[1], O. Skachkova[1], M. Inomistova[1], I. Shumeiko[1], V. Orel[2]

[1]Experimental Oncology, National Cancer Institute of the MPH Ukraine, Kiev, Ukraine, [2]Research Laboratory of Medical Physics and Bioengineering, National Cancer Institute of the MPH Ukraine, Kiev, Ukraine

Background: One of the approaches for increasing DC vaccine efficacy is the direct delivery of generated DC to the regional lymph nodes and tumor site. The aim was to investigate the antitumor efficacy of DC loaded with tumor antigens and iron oxide nanoparticles (INP) under the influence of an external magnetic field.

Methods: In experimental study, 60 CBA mice were involved. Sarcoma 37 (S37) was used as experimental tumor model, and cells in lethal dose ($9*10^5$ cells per animal) were injected into the hip. DCs were obtained from syngeneic mice splenocytes and loaded by mechanically modified lyophilized Sa 37 cells (0.05 mg/ml) with Fe_2O_3 nanoparticles ($8x10^{-12}$ g/cell, Sigma-Aldrich). DC vaccine was injected intradermally 3 times with three-day interval starting on the 7^{th} day after tumor transplantation. After DC administration, animals were exposed under magnetic field for 1 hour. Tumor volume was evaluated with three days interval starting after 10 days of tumor transplantation. Tumor mass, leukocyte formula of the peripheral blood and absolute number of cells in the lymphoid organs of animals were assessed at the 25^{th} day of the experiment. The expression levels of GAPDH, FOXP3, VEGF-a, IL-10, TGF-b, IFNγ and IL-4 genes were analyzed in tumor, spleen and regional lymph nodes using a quantitative PCR method.

Results: The application of generated DCs with INP promoted a reduction of primary tumor volume compared to the control group ($p = 0{,}022$) and DC monotherapy ($p = 0.005$). DCs with INP didn't significantly effect on the hematological parameters in mice with S37. The combined effect of DCs with INP reduced mRNA expression levels of FoxP3 by 1.9 times ($p = 0.04$), VEGF-α by 2.9 times ($p = 0.02$), IL-10 by 2.9 times ($p = 0.005$) and TGF-β by 10 times ($p = 0.002$) in tumor cells compared to the control. The administration of DC vaccine with INP led to reduce tumor immunosuppression in the regional lymph nodes, namely FoxP3 mRNA level decreased in 2,4 times and Il-10 mRNA level – in 1.9 times compared to the control group, $p = 0.012$.

Conclusions: Application of DC vaccine with INP under magnetic field resulted in a pronounced antitumor effect in tumor-bearing mice.

1879P Potential role of RICTOR copy number gain (CNG) as a key biomarker of mTOR activity: A comprehensive preclinical analysis in squamous cell lung cancer (SQLC) models

A. Gkountakos[1], S. Pilotto[2], M. Simbolo[1], C. Vicentini[1], A. Mafficini[1], A. del Curatolo[1], A. Scarpa[3], G. Tortora[2], V. Corbo[1], E. Bria[4]

[1]Department of Diagnostics and Public Health, Section of Anatomical Pathology, University and Hospital Trust of Verona, Verona, Italy, [2]Medical Oncology, University of Verona, AOUI Verona, Verona, Italy, [3]ARC-Net Research Centre and Department of Diagnostics and Public Health - Section, AOU Integrata Verona "Borgo Roma", Verona, Italy, [4]UOC Oncologia Medica, Università Cattolica del Sacro Cuore - Fondazione Policlinico Universitario Agostino Gemelli, Rome, Italy

Background: We previously performed a multi-step genomic study in almost 100 resected SQLC patients dichotomized according to the prognosis. Among the pathways with a biological impact on SQLC oncogenesis, PI3K/mTOR-Rictor emerged as a crucial axis [Pilotto WCLC 2016]. In order to explore the potentiality of mTOR inhibition, we present a set of in vitro experiments in RICTOR-aberrant SQLC preclinical models.

Methods: Next-generation sequencing (NGS), fluorescence in situ hybridization (FISH) and Western Blot were performed in 3 SQLC cell lines (H-1703, SK-Mes-1, Calu-1) for detecting CNG/protein profile of the PI3K/mTOR-Rictor components. The activity of PI3K/mTOR pathway targeted inhibitors in the SQLC cell lines was examined in short- (72 hours) and long-term (1 week) cell viability assays.

Results: NGS analysis revealed a different amount of RICTOR CNG among SQLC cell lines. FISH confirmed that H-1703 harbors the highest number of RICTOR copies (6) followed by SK-Mes-1 (4) and Calu-1 (3.5), suggesting polysomy of the short arm of chromosome 5 as the main mechanism of RICTOR gain. Although Rictor protein levels were similar among the cell lines, p-mTOR S2448 (active form of mTOR complexes) was higher in H-1703 than SK-Mes-1 and Calu-1. PI3K/mTOR inhibition proved more effective in H-1703, with lower IC50 values in short term treatment (Table). Similar findings were confirmed in long-term assays.

Table: 1879P

Drugs	H-1703	Calu-1	SK-Mes-1
		IC50 (nM)	
PF-05212384 (PI3K/mTOR inhibitor)	18	26	335
AZD-2014 (Dual mTORC1/C2 inhibitor)	145	217	215
Everolimus (mTORC1 inhibitor)	Unable determine IC50	Unable determine IC50	Unable determine IC50
MK-2206 (pan-Akt inhibitor)	Unable determine IC50	Unable determine IC50	Unable determine IC50

Conclusions: Overall, the results of our study suggest the potential implication of PI3K/mTOR-Rictor pathway in SQLC oncogenesis, thus rendering it a promising target for a targeted approach. Among the mTOR components, RICTOR CNG seems to predict a higher sensitivity to PI3K/mTOR inhibition and might represent a potential biomarker to be explored as a stratification tool in clinical trials. Confirmatory RICTOR silencing experiments are currently ongoing.

1880P Final results of the phase I study in healthy volunteers of AB928, a dual antagonist of the A2aR and A2bR adenosine receptors being studied as an activator of anti-tumor immune response

L.C. Seitz[1], D. Ashok[1], M. Leleti[2], J. Powers[2], B. Rosen[2], D. Miles[2], E. Sharif[2], L. Jin[3], A. Park[1], S. Young[1], A. Rieger[4], U. Schindler[5], J. Karakunnel[4], M. Walters[5]

[1]Quantitative Biology, Arcus Biosciences, Inc., Hayward, CA, USA, [2]Chemistry, Arcus Biosciences, Inc., Hayward, CA, USA, [3]Pharmacokinetics and Drug Metabolism, Arcus Biosciences, Inc., Hayward, CA, USA, [4]Clinical Development, Arcus Biosciences, Inc., Hayward, CA, USA, [5]Biology, Arcus Biosciences, Inc., Hayward, CA, USA

Background: Adenosine suppresses anti-tumor immune responses via $A_{2a}R$ and $A_{2b}R$ receptors on intra-tumoral immune cells. This effect is mediated by increased cAMP levels and phosphorylation of the transcription factor CREB. A placebo-controlled study in healthy volunteers was conducted to assess the safety, tolerability and PK/PD (pCREB levels in blood T cells) profile of AB928, in order to select AB928 doses for the ongoing studies in cancer patients.

Methods: This placebo-controlled double-blind study had single ascending dose (SAD) and multiple ascending dose (MAD) arms. AB928 doses between 10 and 200 mg qd and 100 mg bid were evaluated. Whole blood from AB928 and placebo-treated subjects was stimulated ex vivo with the adenosine agonist NECA. Flow cytometry was used to assess levels of pCREB. AB928 plasma concentrations were determined using LC-MS-MS.

Results: The study enrolled 85 participants (randomized 3:1, active:placebo), 40 each in the SAD and MAD arms, plus 5 in a food-effect assessment cohort. The effects of 1, 5 and 10 mM NECA were assessed in whole-blood samples obtained at various time points post-dose. The PD response at each timepoint was correlated with the associated AB928 plasma levels. In all dose groups, significant inhibition at peak plasma concentrations was observed. Significant inhibition was also observed 24 hours post-dose in the higher dose groups. Final unblinded safety and PK/PD results from this study will be presented.

Conclusions: AB928 was well tolerated in this study. No stopping rules were met and dose escalation continued until maximal PD effects were observed. There was no evidence of the physiological effects associated with other adenosine receptor antagonists tested in humans. The MTD was not reached in this study. Significant inhibition of $A_{2a}R$-mediated CREB phosphorylation in blood T cells was observed in all dose groups at peak plasma concentrations, as well as at trough in the higher dose groups. The resulting PK/PD correlations were used to guide dose selection in several ongoing oncology studies, the outlines of which will be described in this presentation.

Background: Treatment resistance in cancer has been linked to a population of tumor cells with self-renewal properties called cancer stem cells (CSCs). The aim of this study was to isolate and characterize CSCs from lung cancer cell lines and tumor tissue from resected non-small cell lung cancer (NSCLC) patients.

Methods: The study was performed on tumor cells from 8 resected NSCLC patients and 12 NSCLC cell lines. Suspension cultures were established for CSC isolation (3D tumorspheres), whereas differentiated tumor cells were cultured under adherent conditions (2D). In vitro differentiation, proliferation and chemotherapy resistance and in vivo tumor initiation capacity were tested. 60 CSC-related genes were evaluated by RTqPCR. Gene expression results were validated at protein level by immunoblot and IF.

Results: 8 out of 20 primary NSCLC cultures were successfully established, forming 3D tight spheroids or loose aggregates. Tumorspheres showed proper differentiation capacity, unlimited exponential growth, high resistance to cisplatin, paclitaxel, vinorelbine and pemetrexed, and great tumor initiation potential. Gene expression analysis revealed high variability between cell lines and patient cultures and that 2D cultures were more homogenous than 3D. Tight tumorspheres expressed more ECAD than loose ones. Lung tumorspheres had significantly higher expression of CSC-related genes (ALDH1A1, KLF4, NANOG, CD44, CD90, CDKN1A, JUNB, MDM2), invasion promoters (MMP9, SNAI1, ITGA6), ligands and receptors of Notch (NOTCH1, NOTCH3, DLL4, JAG1) and Wnt components (CTNNB1 and GSK3B) than their corresponding 2D cultures cells. Based on their significant and consistent overexpression in all tumorspheres: CD44, NANOG, CDKN1A, SNAI1, ITGA6 and NOTCH3 were selected to constitute a gene signature. Protein expression analyses showed overexpression of proteins encoded by the gene signature on tumorspheres from ADC patients.

Conclusions: Lung tumorspheres are a useful platform for CSCs characterization. The expression signature proposed could provide the basis for developing novel therapies for the treatment of lung ADC. Supported by grants RD12/0036/0025 from RTICC-FEDER, PI12-02838 and PI15-00753 from ISCIII.

1882P Development of primary human NSCLC patient derived xenograft and organoids models as a precision approach to tumor treatment

O.J. Juan Vidal[1], C. Gandia[2], J.M. Pardo-Sánchez[2], M. Benet[3], S. Aparisi[4], S. Palanca[5], E. Ansotegui[6], C. Jordá[7], J.A. Cerón[7], N. Mancheño[1], M. Sánchez-Céspedes[8], A. Lahoz[3], J. Carretero[4], R. Farràs[2]

[1]Medical Oncology, Hospital Universitari i Politècnic La Fe, Valencia, Spain, [2]Oncogenic Signalling Lab., Centro de Investigación Príncipe Felipe, Valencia, Spain, [3]Biomarkers and Precision Medicine Unit, Hospital Universitari i Politècnic La Fe, Valencia, Spain, [4]Department of Physiology, Faculty of Pharmacy, University of Valencia, Valencia, Spain, [5]Department of Clinical Analysis, Molecular Biology Unit, Hospital Universitari i Politècnic La Fe, Valencia, Spain, [6]Servicio de Neumología, Hospital Universitari i Politècnic La Fe, Valencia, Spain, [7]Servicio de Cirugía Torácica, Hospital Universitari i Politècnic La Fe, Valencia, Spain, [8]Cancer Epigenetics and Biology Program (PEBC), Genes and Cancer Group, Bellvitge Biomedical Research Institute (IDIBELL), Hospitalet de Llobregat, Spain

Background: The prognosis of advanced non-small cell lung cancer (NSCLC) patients is poor. The lack of in vitro models that would faithfully recapitulate the heterogeneity of lung tumors and response to treatment is one of the reasons hampering progress in the development of new therapies. Patient-derived tumor models are becoming the standard for pre-clinical drug testing and biomarker discovery. However, the emerging technology of lung cancer organoids has not yet been broadly implemented in research and have yet to be better established. In this study, our objective was to generate and characterize a collection of NSCLC patient-derived xenograft (PDX) and tumor organoids to demonstrate their applicability to the study of lung cancer.

Methods: Surgically resected tumors were obtained from patients with stage I/II NSCLC during curative-intent surgery. Portions of the tumors were subcutaneous xenografted in NSG mice and expanded 5 passages. In addition, matched portions of tumor and adjacent non-tumor tissues were employed to develop and characterize patient-derived organoids (PDOs). Tumors grew in mice and PDOs were analyzed by histologic and molecular techniques.

Results: We describe the derivation and characterization of 8 PDX models and 20 pairs of PDOs from NSCLC tumors and adjacent non-tumor tissue. PDX could established with a succesful rate of 22,8% (8 out of 35 samples). PDX retain histologic and molecular characteristics of their donors and recapitulate the heterogeneity of human lung tumors. PDOs could be established with a success rate of 100%. We reached a successful long-term expansion of primary NSCLC cells in vitro (> 120 days). Tumor organoids displayed tumor-like cellular morphology and tissue architecture. Tumor-dependent lymphocyte infiltration were observed in these models. We assesed CD45, EpCAM, CD133, CD44 protein expression, as well as Nanog and Oct4 stem cell markers.

Conclusions: We have generated a collection of PDX and PDOs models from NSCLC tumors. These models promise to facilitate the study of cancer stem cell biology and tumor heterogeneity, and may be valuable for drug screening. These models enables the potential long term studies such as the establishment of drug resistant models.

1883P PBRM1 is a novel candidate low-penetrance familial cancer predisposition gene

I. Volodin[1], V.M. Kozlova[2], K.I. Anoshkin[1], A.S. Tanas[1], D.V. Zaletaev[3], V.V. Strelnikov[4]

[1]Epigenetics Lab, Research Centre for Medical Genetics, Moscow, Russian Federation, [2]N.N. Blokhin Russian Research Center for Oncology, Moscow, Russian Federation, [3]Laboratory of Medical Genetics, Sechenov First Moscow State Medical University, Moscow, Russian Federation, [4]Epigenetics, Institute of Molecular Medicine, Moscow, Russian Federation

Background: Chromatin remodeling gene PBRM1 is frequently altered somatically in epithelioid sarcomas and clear cell renal cell carcinomas, but its germline mutation had been reported only once, in a pedigree with familial clear cell renal cell carcinoma (Benusiglio et al., 2015). We present another evidence of a cancer caused by PBRM1 germline mutation in a family with two young sibs, one of whom deceased of round cell soft tissue sarcoma 13 years old.

Methods: For search of mutations we used next generation sequencing (NGS) on Ion S5 platform. For verification of mutations identified by NGS, for mutation segregation analysis and for evaluation of allelic expression expression we used DNA and cDNA Sanger sequencing.

Results: Exome sequencing of cancer related genes identified a heterozygous germline genetic variant p.F1026L (c.3078C>G) in PBRM1 in the leucocyte DNA of the living sibling. This variant is absent from databases and bioinformatic predictors provide ambiguous estimates as to its pathogenicity. Search for this genetic variant in other family members showed that it is also being carried by the father and the older brother of the proband. Sanger sequencing of this variant in the archived tumor material of the deceased revealed its presence in the heterozygous state indicating no signs of allelic imbalance as an inactivation event that would have been consistent with Knudson's two-hit model. Yet, further examination of allelic expression in tumor revealed loss of expression of the normal allele suggesting functional loss of heterozygosity in favor of the mutant one.

Conclusions: Our finding of functional two-hit inactivation of PBRM1 in the tumour supports its role as a tumour suppressor gene. Moreover, we present a second description of PBRM1 pathogenic germline mutation, and the first to be presumably causative for a soft tissue sarcoma. Absence of any tumours in other PBRM1 mutation carriers in the family described here provides the evidence of low penetrance of this mutation.

1884P Liprin-alpha4 contributes to increased proliferation and decreased chemosensitivity under hypoxia for small cell lung cancer as a downstream mediator of HIF-1alphaα

H. Onishi, A. Yamasaki, M. Kawamoto

Department of Cancer Therapy and Research, Kyushu University, Fukuoka, Japan

Background: Cancer microenvironment is extremely hypoxic condition and the analysis of cell biology under hypoxia is significantly important. Previously we have shown that leukocyte common antigen related interacting protein (liprin)-α4 could be a new

therapeutic target for pancreatic cancer. In the present study, the biological significance of liprin-α4 in small cell lung cancer (SCLC) which was one of the refractory cancers and less therapeutical options was investigated.

Methods: SCLC cell lines (SBC-3 and SBC-5) were used as target cells. Cells were cultured under normoxia (20%O_2) and under hypoxia (1%O_2). Gene inhibition was performed using small interfering RNA. Proliferation was performed by MTT assay. Invasion was estimated by matrigel invasion assay. Chemosensitivity was analyzed using CDDP and 5-FU. Mice xenograft experiments were performed using BALB/c nude mice. Twenty human SCLC specimens were used for immunofluorescent staining.

Results: 1) Expression of liprin-α4 increased under hypoxia compared to normoxia. 2) Liprin-α4 inhibition decreased proliferation in vitro under hypoxia. 3) Liprin-α4 suppression did not affect migration and invasion under hypoxia. 4) Tumor volume in mice injected with liprin-α4-inhibited SCLC cells was significantly lower than that in control mice. 5) Signaling from liprin-α4 was through MAPK signaling pathway. 6) Chemosensitivities of CDDP and 5-FU under hypoxia were significantly lower than those under normoxia. Liprin-α4 inhibition significantly enhanced chemosensitivity of CDDP under hypoxia. 7) HIF-1α regulated liprin-α4 expression in SCLC cells. 8) HIF-1α inhibition led to decreased proliferation under hypoxia. 9) HIF-1α inhibition significantly improved chemosensitivity of CDDP under hypoxia. 10) Liprin-α4 and HIF-1α expressions were observed in all patients examined in SCLC specimen.

Conclusions: These results suggest that liprin-α4 which is expressed more under hypoxia, plays a pivotal role for increased proliferation and decreased chemosensitivity under hypoxia for SCLC as a downstream mediator of HIF-1α. Inhibition of HIF-1α and Liprin-α4 could be a new therapeutic strategy for SCLC.

Background: MOSCATO 01 trial (NCT01566019) is a prospective molecular screening program using high-throughput molecular analysis to guide targeted therapy for patients (pts) with advanced cancers. This approach resulted in enrichment of early phase clinical trials with rare genomic alterations and rare tumors, that may lack an approved standard of care.

Methods: A retrospective clinical and molecular analysis of pts with rare tumors, enrolled in the MOSCATO 01 trial. An on-purpose tumor biopsy was performed, followed by high-throughput molecular analysis using targeted Next Generation Sequencing (NGS), comparative genomic hybridization array (CGHa) and Whole Exome Sequencing (WES) after histological control. Matched therapy was decided accordingly for pts who had targeted molecular alterations.

Results: Between December 2011 and March 2016, 122 pts with 58 different tumors types were enrolled in the MOSCATO 01 trial. Median age was 59 years (range, 19-89), median number of previous systemic therapies was 4 (range, 0–13), 51% (63/122) were women, 90% had ECOG performance 1and 2. Most prevalent histologies were adenocarcinoma of unknown primary (12%), lung NE tumor (8%) and SCC of unknown primary (5%). Most frequent actionable alterations were PIK3CA mutation (14%), ERBB2 amplification (10%), and EGFR amplification (4%). Of 122 pts, 62 (51%) harbored ≥ 1 actionable genomic alterations. Thirty pts (25%) received matched therapy. Of these, 6 had a partial response, 9 had stable disease as the best response. Overall response rate (ORR) was 20%. Median PFS2 for matched therapy was 2.8 [95% C.I (1.2 – 4.3)] versus median PFS1 for last standard line 4.6 months, $p = 0.8$. Pts harboring EGFR amplifications had the best median duration of response 9.8 months on matched therapy. Median overall survival was not significantly improved in pts who received matched therapy when compared to pts with unmatched therapy, 14.8 and 8.4 months, respectively($p = 0.1$).

Conclusions: Precision medicine using high-throughput molecular analysis of rare cancers is feasible in clinical practice and can affect their clinical outcomes. Rare tumors harboring EGFR amplification showed prolonged response to targeted treatment. Larger studies and more effective targeted molecules are still needed.

1886P Streamlining multi-omic and artificial intelligence analysis through interrogative biology and baicis for translational precision medicine applications in clinical oncology

L. Rodrigues[1], M.A. Kiebish[2], G. Miller[1], L. Zhang[1], V. Vemulapalli[1], V.K. Vishnudas[3], R. Sarangarajan[3], N.R. Narain[4], V.R. Akmaev[1]

[1]Analytics, BERG, LLC, Framingham, MA, USA, [2]Precision Medicine, BERG, LLC, Framingham, MA, USA, [3]Biosystems, BERG, LLC, Framingham, MA, USA, [4]Biosystems, Analytics, & Precision Medicine, BERG, LLC, Framingham, MA, USA

Background: Despite advances in high throughput molecular technologies, increased availability of clinical information, and access to complex population level datasets, translating this information into causal and actionable clinical guidance in oncology remains a challenge.

Methods: The BERG Interrogative Biology platform deconstructs the established paradigm by using patient biology to guide the entire drug development process from R&D to clinic, leading to improved clinical outcome. In order to properly characterize the molecular phenotype of patients or disease states, this platform allows for systematic interrogation of each biological sample by high-throughput multi-omic technologies such as proteomics, lipidomics and metabolomics. This is then combined with further analytical methods that allows for assessment of sample quality through statistical, environmental/demographic influence, sample handling, and pharmacological impact markers to elucidate causal molecular signal from inherent noise.

Results: BERG ETL System uses a proprietary data-driven algorithm to automatically extract, normalize, correct eventual systematic errors, align and unify all data sources and types, outputting a harmonized molecular and/or clinical profile, which can be used for summary reports such as patient dashboards, standard analysis such as statistics and machine learning, and to be analyzed by BERG's Artificial Intelligence (AI) Technology, bAIcis. When applied to clinical trial information, bAIcis uses a multi-layer method to identify clinical and molecular markers that can stratify patients based on trial outcomes such as "Response to Treatment", "Quality of Life" or "Adverse Events" as well as identification of disease drivers.

Conclusions: Using this approach a comprehensive understanding of causal drivers, predictive biomarkers aligned with therapeutic benefit, and identification of adverse event populations in cancer indications can be elucidated. This is streamlined through an AI driven platform based on quality metric to support precision medicine in oncology drug development.

1887P Prediction of response to vemurafenib in BRAF V600E mutant cancers based on a network approach

R. Falcone[1], P. Paci[2], A. Verrienti[1], G. Fiscon[2], M. Sponziello[1], F. Conte[2], V. Pecce[1], F. Rosignolo[1], G. Grani[1], L. Lamartina[1], V. Ramundo[1], C. Durante[1], L. Farina[3], S. Filetti[1]

[1]Dipartimento di Medicina Interna e Specialità Mediche, Policlinico Umberto I, Sapienza University of Rome, Rome, Italy, [2]Institute for Systems Analysis and Computer Science "Antonio Ruberti", National Research Council, Rome, Italy, [3]Department of Statistical Sciences, Sapienza University of Rome, Rome, Italy

Background: Selective small-molecule BRAF inhibitors are approved, alone or in combination with trametinib, for the treatment of patients with BRAF V600 metastatic melanoma and non-small cell lung cancer (NSCLC). So far, several studies showed that different histotypes of BRAF V600 mutant tumors do not respond uniformly to BRAF inhibitor vemurafenib: high response rates in hair cell leukemia and melanoma, intermediate responses in thyroid and NSCLC, low responses in colorectal cancer. Using a bioinformatics tool, we sought to elucidate, through a network unbiased approach, why different tumors harboring BRAF V600E mutation show heterogeneity in response to vemurafenib.

Methods: We exploited SWItchMiner (SWIM) software to analyze gene expression profiles available on The Cancer Genome Atlas. SWIM is able to identify a small pool of regulatory genes (switch genes), which are likely to be critically associated with drastic changes in cell phenotypes. We selected among those genes, the ones who encode for kinases. Then, we employed Geneious R11 desktop platform to identify those kinases with the maximum identity score to kinases reported as known targets of vemurafenib.

Results: Lung adenocarcinoma is the tumor with the highest number of switch genes (298) compared to its normal tissue, followed by thyroid (227) and colorectal (183) cancers. Switch genes codifying for kinases were 14, 7 and 3 respectively. We looked for

three homology sequences identified across vemurafenib targets and we found that thyroid cancer and lung adenocarcinoma have a similar number of putative targetable switch genes kinase (5-6); on the contrary, colorectal cancer has just one, with minor homology sequence.

Conclusions: Our network analysis may provide additional approaches to explore the molecular mechanisms underlying the different response to vemurafenib in BRAF V600E mutant tumors, elucidating how precision medicine cannot leave out of consideration the tumor histology. It is likely that, while different cancers share the major driver event, the response to therapy may vary based on the number of kinases with homology sequences to the druggable kinase targets. In vitro data are needed to validate this prediction.

1888P Improving value for cancer patients: A European study of outcomes in practice

R. Hazarika[1], T. Albreht[2], B. Berger[3], D. Duplay[4], L. Makaroff[5], Z. Maravic[6], R. Mortuza[7], V. Muthu[8], K. Oliver[5], R. Price[5], M.V.M. van Meerveld[5], K. Steinmann[5], A. Krukowsk[5], R. Catena[5], S. Wait[9], V. Zilli[5]

[1]Implementation & Benchmarking, International Consortium for Health Outcomes Measurement, London, UK, [2]Department of Health Care, National Institute of Public Health of Slovenia, Ljubljana, Slovenia, [3]ECCO, London, UK, [4]Healtheo360, London, UK, [5]Policy & Research, The Health Policy Partnership, London, UK, [6]EuropaColon UK, Salisbury, UK, [7]Implementation, International Consortium for Health Outcomes Measurement, London, UK, [8]Management, Marivek Ltd, Epsom, UK, [9]Research, The Health Policy Partnership, London, UK

Background: ICHOM (International Consortium for Health Outcomes measurement) and All.Can– an international multi-stakeholder initiative – are in partnership to identify and support a community of European hospitals to assess how they can optimize the efficiency of cancer care in breast and lung cancer patients.

Methods: A community of 10 hospital sites for lung cancer and 10 for breast cancer will be supported to implement and measure the ICHOM standard sets of outcomes. This community will measure clinical and patient reported outcomes and will use Time Driven Activity Based Costing to measure the cost to deliver cancer care. Guidance will also be provided to the community to support the utility of outcomes and cost data. The All.Can Patient Survey will also be deployed at the sites to obtain patient insights on sources of potential inefficiency in their care. Additional aspects of care, including intervention type and delivery of care, will also be measured based on results of an international literature review on determinants of value in the two indications. Outcome domains for collection for lung cancer patients include survival, complications, other outcomes such as treatment delays and quality of measures at the end of life. For breast cancer, the outcomes domains include survival and cancer control, disutility of care such as the impact of acute complications and degree of health. All data will be collected over a six-month period. Outcomes data will be collected on all patients with a first diagnosis of lung or breast cancer, followed up over a 6-month period, with three data collection points: (1) immediately after diagnosis, prior to treatment initiation; 3 months and 6 months after treatment initiation.

Results: Risk adjusted outcomes and costing data for the lung and breast pathways will be compared to one another to identify variation and its potential drivers. Qualitative interviews and insights from the All.Can Patient Survey will be used to identify barriers and enablers to value measurement and innovative value improvement strategies.

Conclusions: Findings will guide All.Can policy recommendations to improve the efficiency of cancer care.

Background: Non-small cell lung cancer (NSCLC), the most common subtype of lung cancer, is characterized by low response rates and a poor prognosis. The majority of patients are diagnosed in advanced stages, where chemotherapy remains the gold standard of treatment. However, the resistance has been associated to cancer stem cells (CSCs), a highly tumorigenic subpopulation of cells with the ability to grow as spheres in non-adherent conditions. The aim of this study was to discover novel therapeutic strategies through screening platforms in order to target CSCs population.

Methods: High-throughput screening with commercial chemical libraries (Prestwick and Myria) was performed, comparing cytotoxic effect in monolayer cells vs. lung-tumorspheres derived from 8 resected NSCLC patients and 11 NSCLC cell lines. Compounds were added per triplicates at different concentrations (0.01 to 50 μM). Cell viability was measured after 48h using MTS Assay. Consecutively, 8 tumors were induced by inoculating resected NSCLC patient and H1650 lung-tumor-spheroids in NOD/SCID mice. Selected drugs were administered intraperitoneally (3 times a week, 100 mg/kg). Characterization of the inhibition pathway involved in the mechanism of action of these drugs was performed by RT-qPCR.

Results: Three drugs of the commercial chemical libraries (DSF, Compound 1 and Compound 2) were identified with greater cytotoxic potential against lung tumorspheres, compared to a poor or null effect on monolayer cells. These results were validated in vivo, which demonstrated the capacity of these drugs to inhibit tumor growth in mice treated respect to the control (Table). We are currently characterizing the signaling pathways involved in the mechanism of action of these drugs.

Conclusions: Our findings reveal that these drugs can inhibit CSCs like properties, as evidenced in the lung tumorspheres in vitro and in vivo assays. Therefore, these compounds could be a promising targeted therapy as potential inhibitors of lung CSCs.

Table: 1889P Percentage of tumor reduction in the mice treated respect to the control

Mice (Line/Patient)	Tumor Volume (mm^3)	Tumor Reduction (%)
H1650_CNT	1593,11	
H1650_DSF	541,44	66.02
H1650_Compound 1	483,72	69.64

Univ. Puerta De Hierro, Majadahonda, Spain, [4]Quirón Dexeus University Hospital, Pangaea Biotech S.L., Barcelona, Spain, [5]Medical Oncology , Hospital General Universitario Valencia, Valencia, Spain, [6]Cancer Biology & Precision Medicine Program, Germans Trias i Pujol Science Inst., Catalan Institute of Oncology (ICO Badalona), Hospital Germans Trias i Pujol, Barcelona, Spain, [7]Medical Oncology, Consorcio Hospital General Universitario de Valencia, Valencia, Spain, [8]Servicio de Oncología Médica, Hospital Universitario Puerta de Hierro, Madrid, SpainKeyword: NSCLC, T790M, EGFR, TKI, resistance, blood

Background: EGFR- mut NSCLC patients benefit from EGFR-TKIs therapy. However, most patients relapse within 1 to 2 years. In 40-60% of the cases, the mechanism of resistance is the emergence of the EGFR p.T790M mutation, and third generation TKIs have shown efficacy in this setting. The availability of new biopsies at relapse to TKIs is limited and guidelines recommend testing for the p.T790M in blood at relapse to TKIs, and rebiopsy only in case of a negative result. Several blood based methodologies for EGFR-mut detection have been developed, including some NGS approaches, but comparison studies are limited. We aim to evaluate the agreement, specificity and sensitivity of methodologies available for T790M testing in liquid biopsies and to determine the best pre-analytical conditions for T790M mutation identification.

Trial design: The RING is a non-PAS, non-interventional, cross-sectional, diagnostic study that will enroll 75 patients from different Spanish institutions. Blood samples will be collected at the time of progression to first and second generation TKIs, and sent to the laboratories participating in the study. Three DNA extraction procedures will be tested; Maxwell® RSC cfDNA (Promega), the QIAamp® Circulating Nucleic Acid Kit (Qiagen) and automatic extraction using Qiasymphony® (Qiagen). The presence of the p.T790M in the purified DNA will be tested by 7 methodologies, namely cobas® EGFR Mutation Test v2 (Roche Diagnostics), Therascreen EGFR Plasma RGQ PCR Kit (Qiagen), QuantStudio® 3D Digital PCR System (Applied Biosystems), a 5′-nuclease real-time PCR (Taqman®) assay in presence of PNA, BEAMing digital PCR (Sysmex Inostics), NGS with the Oncomine® panel for Ion Torrent (Thermofisher) and NGS with the Lung Cancer Panel for GeneReader® (Qiagen). The kappa coefficient values and its corresponding 95% confidence intervals (95% CI) will be used to assess the agreement between methodologies and the Intraclass Correlation Coefficients (ICC) and Bland & Altman plots to evaluate the concordance between quantitative methodologies. Finally, we calculate that 40 patients will have a re-biopsy mutation T790M analysis, which will be considered the gold standard to estimate the sensitivity and specificity of each method.

Background: Triple negative breast cancer (TNBC) is a BC subtype featured by lack of estrogen and progesterone receptor and HER2. It is an aggressive type linked with poor prognosis and chemotherapy-resistance. Cancer malignancy can be caused by epithelial-mesenchymal transition (EMT). It allows cells' phenotype change and is driven by proteins such as Twist, ZEB, SNAIL and SLUG. SWI/SNF chromatin remodeling complexes (CRCs) modify chromatin structure, hence changing expression patterns. Disruption of their stoichiometry can lead to development of many types of cancer including BC. This work is focused on the role of BRM – the catalytic subunit of SWI/SNF CRCs in the TNBC development.

Methods: 102 paraffin embedded tissue samples were analysed by immunohistochemistry (IHC). In vitro analysis was performed on MDA-MB-231 and MCF7 cancer cell lines using Western Blot, coimmunoprecipitation (Co-IP) and bimolecular fluorescence complementation (BiFC).

Results: Upon IHC analysis of data available for TNBC patients we identified subgroups based on BRM level in cancer samples (high >90% and low <30% expression). In patients with low BRM level the higher number of lymph node metastasis was observed. Moreover, these patients exhibited significantly higher number of brain and liver metastasis but no metastasis to lung. On the contrary patients with high BRM level had metastasis located mostly in lung. Additionally, the group of patients with low BRM level had higher amount of vimentin in cancer cells, providing a likely explanation for the higher number of lymph node metastasis. Moreover, using Co-IP and BiFC the direct interaction between SNAIL and SLUG proteins (EMT drivers) with SWI/SNF CRC subunits was found. The in vitro overexpression of SNAIL in MDA-MB-231 cell line caused BRM protein level downregulation. The inhibition of proteasome in this cell line resulted in the upregulation of BRM protein, suggesting the link between SNAIL, SLUG, BRM and proteasome in EMT.

Conclusions: Malignancy of TNBC might be dependent on BRM - SWI/SNF CRCs and its direct connection with EMT. SNAIL and SLUG, overexpressed during EMT, might influence the stoichiometry of SWI/SNF CRC in BC cells leading to development of aggressive TNBC. BRM protein level may have a predictive value for place of metastasis.

1899P Fluoropyrimidine and inflammatory genes promoter methylation in Egyptian CRC patients

M.A. Fouad, S.E. Salem, M.M. Hussein, A.N. Zekri, D.M. Badr, H.F. Hafez, E. Eldesouky, S.A. Shouman

Cancer Biology, National Cancer Institute-Cairo University, Cairo, Egypt

Background: Methylation of CpG islands in the promoter region of a gene is commonly associated with gene silencing and frequently observed in colorectal cancer (CRC) disease. Fluoropyrimidine (FP) based therapy received as single agent or in combination is still the backbone in CRC treatment according to the stage of the disease at diagnosis.

Methods: This prospective study was conducted on 43 Egyptian CRC patients and 32 healthy individuals. Baseline whole blood samples were collected from the patients and after 3 and 6 months of FP based therapy. Methylation specific PCR (MS- PCR) was performed for FP metabolizing genes: thymidylate synthase (TS), thymidine phosphorylase (TP), dihydropyrimidine dehydrogenase (DPD), and for the inflammatory gene: cyclooxygenase-2 (COX-2). Genes expression were calculated as fold change relative to healthy control by real time PCR.

Results: TS gene was unmethylated in 90.7 % of CRC patients who had upregulation of TS gene (median= 23.43 folds). TP gene was fully methylated in all CRC patients and upregulated by a median of 22 folds. Significant DPD down-expression ($\leq$ 0.3 folds) was found in 58.8 % CRC patients with full DPD gene promoter methylation ($P < 0.001$) while significant COX-2 down-expression ($\leq$ 5.86 folds) was encountered in 25.5 % CRC patients with partial promoter gene methylation ($P = 0.006$), and significantly down-expressed in 35.3 % of CRC patients with full methylation ($P = 0.002$).TS, DPD and COX-2 genes expression were significantly increased with FP therapy while TP expression was significantly decreased but FP therapy did not change the form of promoter genes methylation.

Conclusions: Both DPD and COX-2 genes expression were dependent on the methylation status of their promoter regions. FP therapy affects FP metabolizing and inflammatory genes expression but not the methylation status of genes promoter.

1900P Real-world prospective data of small biopsy samples for tumor PD-L1 expression in non-small cell lung cancer

K. Morikawa, A. Tsunoda, T. Inoue, M. Mineshita

Division of Respiratory Diseases, St. Marianna University School of Medicine, Kawasaki, Japan

Background: PD-1 antibody has been effective in patients with PD-L1-positive advanced NSCLC. However, surgically resected specimens or core-needle biopsy samples were used to estimate drug potency in past clinical trials.

Methods: The aim is to prospectively investigate small sample reliability for NSCLC to determine the PD-L1 expression status. We prospectively enrolled patients who underwent diagnostic biopsy by any procedures (bronchoscopy, CT/US-guided core-needle) from 2017.3 to 2018.3. Pathologically confirmed NSCLC PD-L1 expression was evaluated in our institution using companion diagnostic PD-L1 IHC. We evaluated: 1) the total number of tumor cells and sample size; 2) compared PD-L1 expression for each procedure using tumor proportion score: TPS (50%≦, 1～49%, <1%), 3) the concordance rate of PD-L1 expression status by biopsy and surgical materials.

Results: 137 cases of PD-L1 expression were evaluated. 112 cases were sampled by bronchoscopy (98 TBBs using BF-1T260/P260F in 23/75 cases, 20 TBNAs), and 25 cases

of CT or US-guided core-needle biopsy. The TPS (50%≦ / 1∼49% / <1% / undiagnosed) for total cases was 31/29/37/3% respectively which was similar to the past report. In histological subtype, TPS for adenocarcinoma (n = 82) were 28/27/43/2% and squamous cell carcinoma (n = 49) were 35/35/27/4% respectively. TPS for TBBs using BF-P260F (thin bronchoscopy) were 20/33/43/4% and TBBs using BF-1T260 (normal bronchoscopy) were 48/22/30/0%. TPS for TBNAs were 50/25/25/0% and CT or US-guided sample showed 37/21/37/5%. Four cases were not able to be diagnosed for TPS because we couldn't obtain enough tumor cells (less than 100 tumor cells) for diagnosis of TPS. The concordance rate of PD-L1 expression status by biopsy and surgical materials was 83.3% for comparison of 24 cases.

Conclusions: Utilizing smaller samples to evaluate PD-L1 expression, the frequencies of TPS were comparable to past clinical trials which used larger samples for evaluating TPS. In this study, the larger samples showed higher PD-L1 expression than smaller samples due to their containing more squamous cell carcinoma cases or advanced stage. The concordance rate of PD-L1 expression for surgically resected tissue and biopsy sample was relatively good in our institution.

1901P ATM as a DNA damage response protein in uveal melanoma: Association with clinicopathological factors and prognostic outcome

J. Jha[1], M.K. Singh[2], N. Pushker[1], S. Sen[2], S. Kashyap[2]

[1]Ophthalmology, All India Institute of Medical Sciences, New Delhi, India, [2]Ocular Pathology, All India Institute of Medical Sciences, New Delhi, India,

Background: Uveal melanoma (UM) is an intraocular malignancy commonly arising from choroid which can cause visual loss or metastasis. Till date, there is no current study available on UM with respect to ATM (Ataxia Telangiectasia Mutated) protein that induces DNA damage response. Several studies revealed that loss of nuclear ATM (nATM) in various cancers like pancreatic, colorectal, gastric cancer leads to poor prognosis. This signifies ATM protein as a prognostic biomarker for cancer progression. Therefore, the aim of the study is to detect the expression/localization of ATM protein in uveal melanoma patients.

Methods: Expression of nATM was investigated on 69 formalin fixed paraffin embedded choroidal melanoma samples by immunohistochemistry and validated by western blotting. Results were then correlated with clinical and histopathological parameters. To determine the prognostic significance, Kaplan–Meier analysis and multivariate analysis by Cox's Proportional Hazards Model was performed.

Results: There was a male preponderance in our study. Histopathological high-risk factors were identified in 30/69 (43.5%) cases. Loss of nATM was found in 65.2% of the cases. Loss of nATM was statistically significant with epithelioid cell type, high pigmentation, LTD >10mm, HRFs>1, tumour height and advanced tumour staging ($p < 0.05$). On multivariate analysis, advanced tumour staging found out to be an independent prognostic factor.

Conclusions: Our data suggest that loss of nATM protein might serve as a potential prognostic marker in the pathogenesis of uveal melanoma and leads to increased risk of metastasis. These findings demonstrate an important role of ATM protein and may have a therapeutic potential in uveal melanoma. However, further studies are required in a larger cohort of patients with longer follow up and translational validation needs to be performed.

1902P BRCA mutation and castration-resistant prostate cancer

L.V. Spirina

Laboratory of Tumor Biochemistry, Tomsk Cancer Research Institute RAMS, Tomsk, Russian Federation

Background: Mutations of BRCA genes are an independent poor prognostic factor in the development of prostate cancer. It is known that the mutations BRCA1 / 2 are most often associated with the AKT / m-TOR signaling cascade hyperactivation. The purpose was to study the AKT/m-TOR pathway components in castration-resistant prostate cancer patient, depending on the presence of the BRCA mutations.

Methods: 40 patients with prostate cancer, 15 patients with castration-resistant prostate cancer and 20 patients with benign hyperplasia are enrolled in the investigation. The expression of AKT, c-Raf, GSK-3, PDK1, and m-TOR, 70-S64, E-BP1 was determined by real-time PCR. The BRCA 1/2 mutation was determined in allele-specific PCR in real time.

Results: Activation of the AKT / m-TOR signaling cascade was detected in prostate cancers. The high levels of AKT and m-TOR expression were revealed. The increase in the level of phosphatase PTEN was found in benign hyperplasia and cancer tissues. The level of mRNA 4E-BP1 was decreased in castration-resistant prostate cancer patients. At the next stage of the study, the incidence of inherited BRCA1 / 2 mutations were studied in patients with castration-resistant cancer. The BRCA1-5382insC mutation was detected in 3 patients (20%), BRCA1-4153delA – in 5 patients (33%), BRCA1-185delAG – in 2 patients (13%), BRCA1-T300G – in 2 patients (13%) and BRCA2-6174del – in 4 patients (27%). BRCA1-deficiency activates the AKT oncogenic pathway, one of the most common alterations associated with human malignancy. Mutation of BRCA1 gene increases the phosphorylation and the kinase activity of AKT. The decreased AKT expression in cancers was found in patients with BRCA1-5382insC mutation. Mutation of BRCA1-4153delA increased expression of 70S, m-TOR, in the presence of BRCA1-T300G - increased PTEN. The inherited BRCA2-6174del mutation was correlated with the increased expression of AKT.

Conclusions: Therefore, the development of PCa is accompanied by activation of this signaling cascade, even more pronounced in the presence of mutations BRCA2-6174del, BRCA1-4153delA, BRCA1-T300G. It should be noted that the frequency of occurrence of these mutations varies from 13 to 33%. At the same time, a greater accumulation of hereditary mutations BRCA1-4153delA and BRCA2-6174del was noted.

1903P Prevalence of KRAS mutation subtypes and MSI status in pancreatic cancer

P. Gultawatvichai[1], I. Puthawala[2], K. Tomaszewicz[3], V.G. Bathini[1], L. Hutchinson[3]

[1]Hematology-Oncology, University of Massachusetts Medical Center UMass Memorial Medical Center, Worcester, MA, USA, [2]Internal Medicine, University of Massachusetts Medical Center UMass Memorial Medical Center, Worcester, MA, USA, [3]Pathology, University of Massachusetts Medical Center UMass Memorial Medical Center, Worcester, MA, USA

Background: KRAS is the most prevalent driver mutation in pancreatic ductal adenocarcinoma (PDAC) which impacts cell differentiation, proliferation, migration and apoptosis. KRAS subtypes may have prognostic significance but this finding remains uncertain. Microsatellite Instability / mismatch repair deficiency (MMR) has also been reported in PDAC but at a low frequency (0.8%) and these patients are eligible for immunotherapy. This study investigates the effect of KRAS subtype on survival rate and the prevalence of mismatch repair deficiency in our patient cohort.

Methods: 91 patients enrolled from 2005 to 2012 with biopsy proven PDAC of all stages. All clinical data were collected from the medical records of each patient. Next generation sequencing was performed on all 91 samples. We also evaluated MMR expression in all resection specimens who underwent adjuvant treatment. Statistical analysis: Data were summarized as descriptive analysis statistics and analyzed using unpaired t-test. Overall survival (OS) was measured from the date of diagnosis to last known follow up or date of dead from disease.

Results: The most common type of mutation in all stages is KRAS (95%). KRAS mutation subtypes in the order of frequency were: G12D, G12V, G12R, Q61H, Q61L and G12C. Among codon 12 mutations, G12V showed the best OS at 20.12 months. Mutations in codon 61 carry better OS compared to codon 12 by 24 months ($P = 0.0002$, 95% CI 11.85 to 37.03). The staining for MMR status was performed on 30 of 91 specimens and all were mismatch repair protein proficient (analogous to MSI-stable [MSS]).

Conclusions: The prevalence and distribution of KRAS mutations from our study is similar to previous reports. Patients with a KRAS codon 61 mutation had better OS than with a codon 12 mutation. Interestingly, Q61 variants are far less common than the G12 variants which may explain why most of the pancreatic patients have an aggressive disease course. Our results support the conclusion that MMR defects are uncommon in PDAC. Germline mutation analysis could be considered to find other targetable mutations found in hereditary cancer syndromes such as BRCA1/2 or PALB2.

1904P Molecular signature in malignant pleural mesothelioma (MPM): Preliminary data of Italian RAMES study

F. Zanelli[1], M. Pagano[1], C. Bonelli[1], R. Gnoni[1], L. Boni[2], G.L. Ceresoli[3], M. Larocca[1], M. Tiseo[4], P. Zucali[5], F. Grosso[6], F. Cappuzzo[7], A. Ciarrocchi[8], F. Torricelli[9], C. Pinto[1]

[1]Oncology Unit, AUSL di Reggio Emilia-IRCCS, Reggio Emilia, Italy, [2]Istituto Toscano Tumori, Clinical Trial Coordinating Center, AOU Careggi, Florence, Italy, [3]Oncology, Humanitas Gavazzeni, Bergamo, Italy, [4]Medical Oncology, AOU di Parma, Parma, Italy, [5]Oncology, Humanitas Clinical and Research Hospital, Rozzano, Italy, [6]Oncology/ Hematology, Ospedale di Alessandria, Alessandria, Italy, [7]Dipartimento di Oncologia Medica, Azienda Unità Sanitaria Locale della Romagna, Ravenna, Italy, [8]Laboratory Research, AUSL-IRCCS Reggio Emilia, Reggio Emilia, Italy

Background: MPM is a highly aggressive pleural tumor associated with asbestos exposure. The ability to analyze entire genomes opens the door to identification of new treatments.

Methods: RAMES is a ongoing phase II study to evaluate the efficacy and the safety of the addition of ramucirumab to gemcitabine as the second-line treatment in 160 pts with MPM. We designed a custom panel covering 1040 amplicons spanning 33 genes frequently altered in MPM. To establish the genetic asset of MPMs we used an amplicon-based next generation sequencing approach.

Results: To date, 40 FFPE mesothelioma cancer tissues were successfully sequenced A total of 2930 variants passing quality filters were detected. Focusing on potentially functional alterations, polymorphisms and non-coding variants were excluded, leaving 143 alterations in 23 of the analyzed genes. Of these, 59.4% (85/143) were missense mutations, 22.4% (32/143) lead to frameshift alteration of the gene sequence, 13.3% (19/143) were splice variants, while the remaining 4.9% (7/143) were start loss, stop gain alterations and deletion. 97.5% of patients (39/40) displayed at least one mutation, while the average number of mutations per sample was 3.6 (range 0-8), confirming the high mutational load of these tumors. The most frequently altered genes identified were PIK3CA (62.5%), RDX (40%), MXRA5 (20%), BAP1 (15%), NF2 (15%). Molecular analyses have been correlated with Histology and Stage (thoracic vs extrathoracic MPM). We found the following NF2, PIK3CA, RDX altered genes in 9 biphasic tumor and MXRA5, NF2, PIK3CA, RDX, CUL1, BAP1, NF2, TAOK1 altered genes in 31 ephitelioid tumor. We observed a significant correlation between mutations in RDX gene (23.1%) and extrathoracic MPM. CUL1 and RDX genes were found in pts with progression free survival $\geq$6 months from prior treatment.

Conclusions: This preliminary data supports the generation of a genetic signature based on tumor mutational status useful to discriminate MPM with different clinicopathological features and possible correlation with treatment choice.

1905P N-Myc and STAT interactor (NMI) as a key determinant of chemosensitivity in breast cancer: Proteomic-based computing network mapping and in vivo verification with a mouse model

H. Lee[1], K-M. Lee[2], D. Han[3], H. Ryu[4]

[1]Radiation Oncology, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [2]Biomedical Research Institute, Seoul National University Hospital (SNUH)-Yongon Campus, Seoul, Republic of Korea, [3]Proteomic Core Facility, Seoul National University Hospital (SNUH)-Yongon Campus, Seoul, Republic of Korea, [4]Pathology and Proteomic Core Facility, Seoul National University Hospital (SNUH)-Yongon Campus, Seoul, Republic of Korea

Background: We targeted NMI based on our previous proteomics analysis using FFPE breast cancer samples with neoadjuvant settings and text-mining analytics to verify NMI as a target agent to overcome chemoresistance through in vitro and in vivo studies.

Methods: Quantitative proteomics was analyzed for three different breast cancer cell lines with NMI gene silencing. We performed computation pathway enrichment based on domain knowledge for text-mining and bioinformatics tools to identify critical pathways related to chemotherapeutic sensitivity. A total of 8 breast cancer cell lines with or without endogenous chemoresistance were enrolled to define the important pathways and molecules in determining chemosensitivity through cell-titer glo assay, FACS, 3D spheroid and invasion assay, ROS assay by DCFDA and Mitotracker. Interaction network analyses were investigated to define the signaling pathway landscapes with public network databases and bioinformatic network evaluations. To verify the chemosensitive roles of NMI in vivo setting, we are conducting animal tests and immunostaining in human breast cancer samples where the patients received neoadjuvant chemotherapy.

Results: A total of 972 were confirmed to be significantly altered proteins after NMI gene silencing. A vast number of cell cycle-related proteins, which were downregulated considerably in NMI suppressed group led us to verify NMI's biological function on chemosensitivity through molecular biology-driven assays. Cell-titer glo assay and FACS revealed significantly induced cytotoxicity and apoptosis in both hormone receptor positive and negative groups without NMI gene after treatment with three different chemotherapeutic agents. The 3D-spheroid assay demonstrated a reduced spheroid formation in the case group. DCFDA and Mitotracker assay revealed increased intracellular and intramitochondrial ROS levels. We built biological network models based on in-silico and biology-driven assays. Currently, we are conducting in vivo validation using an animal test model and human samples.

Conclusions: Our biological evidence for NMI can provide novel insights to overcome chemo-resistance in breast cancer.

1906P Lung cancer predisposition in women with previous breast cancer identified by whole exome sequencing

F. Grossi[1], C. Genova[1], D. Cittaro[2], S. Bonfiglio[2], S. Boccardo[1], I. Vanni[1], M. Mora[3], M.G. Dal Bello[1], F. Biello[1], E. Rijavec[1], C. Sini[1], G. Rossi[1], M. Tagliamento[1], A. Alama[1], G. Burrafato[1], G. Barletta[1], A. Ballestrero[4], S. Coco[1]

[1]Lung Cancer Unit, Ospedale Policlinico San Martino, Genoa, Italy, [2]Centre for Translational Genomics and Bioinformatics, IRCCS San Raffaele Scientific Institute, Milan, Italy, [3]Pathology Unit, Ospedale Policlinico San Martino, Genoa, Italy, [4]Department of Internal Medicine, University of Genoa, Genoa, Italy

Background: Women treated for breast cancer (BC) are at risk to develop a subsequent lung cancer (LC; relative risk ranging from 1.38 to 5.05), especially in case of smoking history and if adjuvant radiation (aRT) was administered for BC. We hypothesized that genetic variants might predispose patients (Pts) to develop LC after BC. Our aim was to perform whole exome sequencing (WES) to identify genes associated with such predisposition.

Methods: 28 women with diagnosis of LC after BC (Study Population, SP) were enrolled, as well as 32 women treated for BC and with no secondary cancer after a follow-up $\geq$10 years (control population; CP). DNA was extracted from tumors and normal tissue samples from both SP and CP. Libraries were prepared with Agilent SureSelect All Exon kit and sequenced on Illumina HiSeq2500. Variant calling was performed with FreeBayes software.

Results: The median age of SP at BC diagnosis was 63.5 years (range: 47-76); the median interval between diagnosis of BC and occurrence of LC was 4.5 years (range: 0-11). 13 Pts (46%) were never-smokers and, among the 21 Pts who had received aRT, 13 (62%) developed ipsilateral LC. At somatic analysis, no common mutation among known driver genes was shared between each BC and LC pair in SP Pts. WES performed on BC and LC samples identified two mutational signatures (S1 and S2). S1 (C>T substitutions) was observed in all BC samples and 16/28 (57%) LC samples and was more frequent in never-smokers (11 vs. 5 Pts) and among Pts who developed ipsilateral LC after aRT (10 vs. 6 Pts). S2 (C>A transversions) was observed in 12/28 LC samples (43%) and was strongly associated with smoking habit (10 vs. 2 Pts). When compared with COSMIC libraries, S2 results were similar to COSMIC 4, common in LC samples collected from smokers. Since S1 was largely shared between paired BC and LC samples, we explored the eventuality of a genetic predisposition to S1-related malignancies with a gene-based burden test over rare germline variants in normal tissue of S1-LC Pts compared with CP Pts; 249 candidate genes were identified (FDR<0.05).

Conclusions: Our data identified two mutational signatures underlying the LC development. Germline analysis suggests that genetic variants may contribute to increase the risk of LC after BC.

1907P Discordance of the PAM50 intrinsic subtypes compared with IHC-based surrogate in breast cancer patients: Potential implication of genomic alterations of discordance

Y.H. Park, H.K. Kim, J.H. Cho

Internal Medicine, Samsung Medical Center Sungkyunkwan University School of Medicine, Seoul, Republic of Korea

Background: In recent decades, 5 intrinsic molecular subtypes have been characterized according to variation in gene expression patterns of breast cancer. However, in real-world practice, immunohistochemistry (IHC)-based classification such as estrogen receptor (ER), progesterone receptor (PR) and human epidermal growth factor (HER2) are routinely used. We aimed to analyze the discordance between IHC-based surrogate subtyping and PAM50 intrinsic subtypes and to assess overall survival (OS) according to discordance.

Methods: A total of 607 patients were analyzed. Hormone receptor (HR) was evaluated by IHC and HER2 by IHC and/or FISH. PAM50 intrinsic subtypes were determined according to 50 cancer genes using NanoString nCounter Analysis System. In addition, we used Ion Ampliseq Cancer Panel v2 to identify the genomic alteration related with discordance between IHC subtype and PAM50 intrinsic subtype. The Kaplan-Meier method was used for estimation of OS.

Results: The majority of patients were HR + (343/607, 56.5%) by IHC and luminal A/B (283/607, 46.6%) by PAM50. We matched concordant tumor as luminal A and HR+/HER2-, luminal B and HR+/HER2+, HR-/HER2+ and HER2-enriched, TNBC and Normal- or Basal-like. 233 patients (38.4%) were discordant between IHC-based subtypes and PAM50 intrinsic subtypes. The discordant patients were mostly HR + (176 of 234, 75.2%) and 12.4% (29 of 234) were HER2+. Using targeted sequencing with Ampliseq, we detected somatic mutation related discordant breast cancer including VHL gene in HR+/HER2- group (31% in concordant group, 0% in discordant group, P = 0.03) and IDH and RET genes (7% vs. 12%, P = 0.02, 0% vs. 25%, P = 0.02, respectively) in TNBC group. In survival analysis, among the patients with HR+, basal-like group by PAM50 showed significantly inferior OS compared with other intrinsic subtypes (p = 0.010).

Conclusions: A substantial portion of patients showed discrepancies between IHC-based subtypes and PAM50 intrinsic subtypes in our study. The survival analysis demonstrated that current IHC-based classification could misdirect treatment and result in poorer outcomes. Current guidelines of IHC for ER, PR, and HER2 would better be updated accordingly.

1908P Impact of invasive lobular carcinoma in Latin American breast cancer patients' disease-free survival: The new paradox

D. Flores-Díaz[1], C. Arce Salinas[1], L. Flores[2], F. Lara[1], J.A. Matus Santos[3], J.E. Bargallo Rocha[3], V. Perez[3], N. Reynoso-Noveron[4], P.A. Cabrera[3], A. Mohar[4]

[1]Breast Medical Oncology, Instituto Nacional de Cancerología, Mexico City, Mexico, [2]Epidemiology Department, Instituto Nacional de Salud Publica, Mexico City, Mexico, [3]Breast Cancer Department, Instituto Nacional de Cancerología, Mexico City, Mexico, [4]Epidemiology Breast Cancer Unit, Instituto Nacional de Cancerología, Mexico City, Mexico

Background: Traditionally invasive lobular breast carcinoma (LBC) has been considered a good prognosis histology. However, it has a unique molecular pathogenesis and different genomic profile. Our objective was to establish whether there is a difference in disease-free survival (DFS) between LBC and ductal carcinoma.

Methods: We evaluated a cohort of 5185 breast cancer patients with lobular and ductal carcinoma (DC) treated the at National Cancer Institute Mexico between 2006 and 2016. We compared presentation variables using the chi squared test. A Cox proportional hazards regression model was constructed to evaluate disease-free survival.

Results: With a median of 60 months follow-up, patients with LBC were older ($p < 0.001$), more frequently patients with Ki67 <18% (40.2% vs 28.6% $p < 0.001$), had lower nuclear grade ($p < 0.001$), and predominantly hormone receptor positive disease (77.9% vs 56.9% $p < 0.001$). Nevertheless, LBC patients had a higher recurrence rate (25.2% vs 21.1% p = 0.011). For both LBC and DC patients, factors that negatively influence 5-years DFS in the univariate analysis were stage III (71.9% vs 78.9% $p < 0.001$), Ki67>18% (83.3% vs 93.1% p = 0.016), low nuclear grade (82.1% vs 95.9% $p < 0.001$), triple negative (46.7% vs 71.8% p = 0.002), and Her2 positive (72.4% vs 84.5% p = 0.023). In the multivariate analysis patients with stage III, (OR 10.8, 95%CI 5.9–19.9), high nuclear grade (OR 1.5, 95%CI 1.0-2.4), Ki67 >18 (OR 1.5, 95%CI 1.1–1.9), triple negative phenotype (OR 2.7, 95% CI 1.1-6.6) and lobular carcinoma (OR 1.8, 95%CI 1.1-2.7) are independent negative factors for DFS.

Conclusions: The presence of lobular invasive carcinoma is an independent negative factor for DFS. Despite the high rate of good prognosis elements in pathological reports, lobular carcinoma seems to be another disease and we need to evaluate deeply new and old treatment strategies to provide better disease control. Particulary in clinical stage III, Latin America has a challenge to be aware of it.

1909P Clinical validation of an NGS-based assay for the detection of BRCA1 and BRCA2 variants in Chinese patients with breast cancer or ovarian cancer

G. Zhu[1], H. Ge[2], X. Li[2], L. Ruan[1]

[1]Medical Oncology, Amoy Diagnostics Co., Ltd., Xiamen, China, [2]NGS, Amoy Diagnostics Co., Ltd., Xiamen, China

Background: Variation in BRCA1 and BRCA2 genes are associated with the development of hereditary breast cancer and ovarian cancer (HBOC) and sensitivity to poly ADP-ribose polymerase inhibitors (PARPi). A genetic testing assay based on next-generation sequencing (NGS) method, named AmoyDx BRCA1 and BRCA2 Mutation Detection Kit (ADx-BRCA NGS kit), has been developed for the detection of BRCA1/2 variants. The present study evaluated the clinical performance of the ADx-BRCA NGS kit in detecting BRCA variants in peripheral blood-derived DNA.

Methods: A cohort of 1,341 peripheral blood samples from Chinese patients were analyzed for BRCA1/2 variation using ADx-BRCA NGS kit, including 1,035 patients with breast cancer and 306 with ovarian cancer. BRCA MASTR Dx assay (Multiplicom) was used as a reference method to test the same cohort. ADx-BRCA NGS kit allows identification of variants in complete coding regions of BRCA1/2 genes which are also covered by the reference method, and 22 additional UTR regions beyond the coverage of the reference assay. The concordance of BRCA variation detected with ADx-BRCA NGS kit was calculated compared to the reference assay.

Results: In this study, all the 1,341 samples were successfully detected and the classification for BRCA1/2 variants identified by ADx-BRCA NGS kit in breast and ovarian cancer is listed in the table. Using BRCA MASTR Dx assay as relference, the overall concordance of BRCA variation status determined by ADx-BRCA NGS kit was 99.92% (1,286/1,287). In addition, 54 samples were excluded from the analysis due to the variation detected in the UTR regions that were not covered by reference method.

Table: 1909P Classification for BRCA1/2 variants detected by ADx-BRCA NGS kit

Class	Definition	Variant amount in breast cancer	Variant amount in ovarian cancer	Total
5	Definitely pathogenic	63 (6.09%)	73 (23.86%)	136 (10.14%)
4	Likely pathogenic	33 (3.19%)	6 (1.96%)	39 (2.91%)
3	Uncertain	101 (9.76%)	40 (13.07%)	141 (10.51%)
2	Likely benign	213 (20.58%)	53 (17.32%)	266 (19.84%)
1	Benign	625 (60.38%)	134 (43.79%)	759 (56.6%)
Total		1,035	306	1,341

Conclusions: ADx-BRCA NGS assay has shown a high concordance rate of 99.92% compared to the BRCA MASTR Dx assay, demonstrating that it is a highly accurate method for the detection of BRCA1/2 variants and can be used to screen patients with germline BRCA mutations.

1910P Correlation beetween the expression of androgens receptor (RA) and histopathological characteristics and survival parameters of breast cancer

I.D. Sillero[1], A. López González[1], L.F. Sanchez Cousido[1], M. López-Flores[1], E. Honrado Franco[2], L. Lopez Gonzalez[3], O. Sanz[4], C. Castañón López[1], A. García Palomo[1]

[1]Oncología Médica, Complejo Asistencial Universitario de León, León, Spain, [2]Pathology, Complejo Asistencial Universitario de León, León, Spain, [3]Radiology, Complejo Asistencial Universitario de León, León, Spain, [4]General Surgery, Complejo Asistencial Universitario de León, León, Spain

Background: Clinical trials have attempted to demonstrate a correlation between the expression of androgen receptor (RA) and the prognosis of breast cancer. We have analyzed a sample of women with diagnosis of triple negative breast cancer (TN) in order to establish their prognostic value.

Methods: We retrospectively analyzed a cohort of women diagnosed of early stage TN breast cancer in the Universitary Hospital of León from 2008 to 2013. Our first end point was to establish a correlation between RA expression, clinical parameters, immunohistochemical characteristics and PFS and OS.

Results: A total of 58 women with TN breast cáncer were included. From the total number of biopsies, 20% expressed RA, and the 80% of this subgroup had an apocrine histology. The RA expression was associated to a favourable grade (G) :(RA + G3: 45.5% vs. RA - G3 79%, p = 0.05); smaller size (11.1% T1, 77% T2 .11.1% T3-T4), and lower percentage of Ki-67: (mean in RA + 23.6% ± 5 vs 41.4% ± 3, p = 0.005). There was also a trend towards association with premenopausal status (60% vs 40% postmenopausal p = 0.02) and axillary involvement at the time of diagnosis (65% N1-2 vs. 35% N0 p = 0.045). Regarding OS and PFS, we did not find statistical significant differences between RA positive and negative tumors (p = 0.89 and p = 0.34 respectively).

Conclusions: The RA expression in TN breast cancer is associated with more favourable histopathological characteristics except the axillary involvement. Although most of our cases were N+, we did not find a worse prognosis in these patients. It is possible that with the antiandrogenic therapy a better survival could be obtained, which would justify the design of clinical trials.

1911P Metabolic syndrome in breast cancer patients: An observational study

S. Khare

General Surgery, PGIMER, Chandigarh, India

Background: With significant increase in the prevalence of overweight population in India, there might be a similar increase in the prevalence of metabolic syndrome. Positive association between metabolic syndrome in Indian subjects, if any, may translate into significant changes in the risk factors for breast cancer and may have a significant impact on the incidence and mortality related to breast cancer in India. Hence, we undertook this study to find any correlation between metabolic syndrome and breast cancer.

Methods: We did a prospective study from August, 2016 to July, 2017. Measurements of height, weight, BMI and waist circumference and fasting blood sugar, fasting triglycerides, fasting HDL and HBA1c were done. Metabolic syndrome was defined according to International Diabetes Federation consensus statement 2006. TNM staging, type and grade of tumour, hormone receptor status, Her2 neu status and Ki67 index along with other known risk factors of breast cancer like age at menarche, age at first child birth (FCB), breastfeeding, presence or absence of family history of breast cancer and mammographic density were recorded. K-S test was used to check the normality of the data. Student's t test and Mann Whitney U test, Chi Square test or Fisher exact test (whichever was applicable) was used for comparison.

Results: Total of 305 patients were recruited into the study with 191 (62.6%) patients having metabolic syndrome. The mean age was of 50.7±12.4 years. There was no correlation of metabolic syndrome to any of the known risk factors (Age, age at menarche, age at FCB, early menarche, parity, no breast feeding, breast density on mammography or family history of breast cancer). Patients with metabolic syndrome were found to be less likely to have hormone receptor positive tumours ($p = 0.025$), more likely to have Her2 positive tumours ($p = 0.011$). They were also more likely to have Her2 enriched and basal like subtype and less likely to have Luminal A and B subtypes ($p = 0.027$). There was no correlation between metabolic syndrome and T, N, M or overall staging. It also had no relation to type of tumour (IDC vs No IDC), grade or Ki67.

Conclusions: Metabolic Syndrome may emerge as a significant prognostic factor in breast cancer in the future.

1912P The prognostic value of different molecular subtypes of breast cancer in relation to enhancer-of-zeste homologue 2 expression

Z. Sanaat, R. Dolatkhah

Hematology and Oncology Research Center, Tabriz University of Medical Science, Tabriz, Iran

Background: Studies have shown that Enhancer-of-zeste homologue 2 (EZH2) plays an important role in carcinogenesis in the breast cancer, and invasion and progression of the disease. We aimed to assess the prognostic value of different molecular subtypes of breast cancer in relation to EZH2 expression.

Methods: We performed a cross-sectional analytical research study on 100 breast cancer women. Survival analysis was then performed using the Kaplan–Meier method, with log-rank tests to assess statistical significance between groups. To assess the effects of variables on OS and DFS, a Cox proportional-hazard model was then used to give adjusted hazard ratios (HRs) with 95% confidence intervals (CIs).

Results: Samples were collected for 100 women with breast cancers, with follow-up data collected over a 5-year period. The mean age was 51.5 ± 9.54 years (range, 34–75 years), By molecular subgroup, 43% had luminal A tumors, 41% had luminal B tumors, 9% had HER2 tumors, and 7% had TNBC tumors. Overall, 74% had high EZH2 expression, which was most common for the luminal A subtype (43.2%) and least common for the TNBC subtype (8.1%). There was no significant correlation between subgroups by EZH2 expression ($P = 0.33$).

Conclusions: In conclusion, although our results provide some interesting insights, there remains controversy about the prognostic value of different molecular subtypes of breast cancer in relation to EZH2 expression. Given that there are very few studies on this topic, we advocate further research with larger sample sizes and the inclusion of molecular techniques.

1913P A guided and personalised treatment in metastatic breast cancer: Optimisation of gene and protein expression in tumor tissue

E. Seront[1], S. Lejeune[1], B. Petit[1], V. Samartzy[2], S. Sauvage[3], J-F. Laes[3]

[1]Medical Oncology, Centre Hospitalier Jolimont-Lobbes, Haine Saint Paul, Belgium, [2]Gynecology, Centre Hospitalier Jolimont-Lobbes, Haine Saint Paul, Belgium, [3]Scientific, OncoDNA, Gosselies, Belgium

Background: The better understanding of the signaling pathways involved in cancer has led to the use of targeted therapies, such as everolimus (E), a mammalian target of rapamycin (mTOR) inhibitor and palbociclib, a cyclin-dependent kinase (CDK) 4/6 inhibitor, in the treatment of metastatic breast cancer (mBC). However, treatment response is variable, and resistance occurs systematically. We hypothesised that the combination of gene sequencing and protein expression analysis could help, in a patient, to identify resistance mechanisms occurring on a specified treatment as well as to determine potential further treatments.

Methods: We studied paired-biopsies performed in a 69-year-old woman patient with mBC who achieved a durable (16 months) partial response to E-exemestane association. Biopsy 1 was performed before E initiation and biopsy 2 at the progression on E. Analyses were realised with OncoSTRAT&GO™, from OncoDNA company, which combines sequencing of oncogenic genes panel and expression analysis of proteins that could be targeted by current antitumoral agents.

Results: Biopsy 1 revealed PIK3CA(E542K) gene mutation and a high expression of phospho 4EBP1, an effector of mTOR, reflecting an excessive activation of the mTOR pathway that explains the E sensitivity. Biopsies 1 and 2 showed a high expression of phospho-retinoblastoma (pRb), reflecting a continuous cell cycle activation by CDK4/6. Palbociclib was thus initiated in association with letrozole at the progression on E and resulted in a rapid and long-duration (17 months) partial response. In the paired biopsies, the tyrosine kinase receptor cMET was not detected on biopsy 1, but was highly expressed in biopsy 2, suggesting that cMET could play a role in the development of resistance to E. In this context, we are currently treating our patient with cabozantinib (cMET inhibitor). Response profile will be further specified.

Conclusions: These gene and protein expressions reflect correctly the efficacy of targeted therapies this patient received. PIK3CA mutation was associated with E sensitivity and pRb with impressive response to palbociclib. cMET could play a role in the development of resistance to E and its inhibition should be evaluated in mBC.

1914P HER2 staining intensity has prognostic impact on patients with HER2 type invasive breast cancer

H. Yi-Hsuan[1], L. Yen-Shu[2], H. Chih-Yi[3], T. Ling-Ming[2]

[1]Department of Surgery, Cardinal Tien Hospital, New Taipei, Taiwan, [2]Department of Surgery, Taipei Veterans Hospital, Taipei, Taiwan, [3]Department of Pathology, Taipei Veterans Hospital, Taipei, Taiwan

Background: Human epidermal growth factor receptor 2 (HER2) is a key marker for breast cancer and HER2-targeted therapy has improved the prognosis for patients with HER2 overexpressed breast cancer. HER2 positivity is defined as HER2 protein overexpression measured by immunohistochemistry (IHC) or HER2 gene amplification evaluated by in situ hybridization (ISH). As the protein expression of HER2 IHC 3+ is higher than that of HER2 IHC 2+, we suppose patients with HER2 IHC 3+ tumor would have better response to anti-HER2 therapy, and their prognosis would better than that of HER2 IHC 2+ tumor. This study aimed to evaluate whether the degree of HER2 IHC positivity affected the outcome of early breast cancer.

Methods: Clinicopathological information of 785 consecutive cases of HER2+ early breast cancer who underwent surgery at Taipei Veterans General Hospital, Taiwan, ROC from 2007 October to 2015 December were retrieved from the medical records. Survival curves were plotted by Kaplan-Meier method, and their differences were calculated by log-rank test. Cox regression model was used to evaluate the hazard of recurrence and death, and the influences of the age of patients, stage, hormonal receptor status, anti-HER2 treatment were adjusted.

Results: Recurrence-free survival of cases with HER2 IHC 3+ tumor was significantly better than that of cases with HER2 IHC 2+ tumor ($p = 0.018$). Multivariate Cox regression revealed the hazard ratios of cases with HER2 IHC 3+ was significant smaller than those with HER2 IHC 2+ in both RFS ($p = 0.001$) and OS ($p = 0.007$).

Conclusions: We confirmed that the intensity of HER2 IHC provided prognostic information for HER2 positive breast cancer. The prognosis of HER2 IHC 3+ cases was significantly better than that of HER2 IHC 2+ and ISH amplified cases. Accurate HER2 testing is important to maximize the benefit of anti-HER2 therapy.

1915P Does the minimal axillary approach lead to loss of prognostic factors in breast cancer?

R.A. de Araujo[1], C.P. Nascimento[2], C.L.P. Da Cunha[2], E.D.C. Marinho[2], E.R.T. Mosca[2], F.A.C. Da Luz[2], P.F.R. Delfino[2], R.M. Antonioli[2], T.R. Mendes[2], M.J.B. Silva[3]

[1]Oncologia Clínica, COT - Centro Oncológico do Triângulo, Uberlandia, Brazil, [2]Hospital do Câncer em Uberlândia, Universidade Federal de Uberlândia, Uberlândia, Brazil, [3]Instituto de Ciências Biomédicas, Universidade Federal de Uberlândia, Uberlândia, Brazil

Background: There are several factors for metastasis in breast cancer, such as tumor size (T) and lymph node involvement (N). In this study was investigated the association of T and N with metastasis in breast cancer patients treated in the Oncology Sector of a public Hospital of Minas Gerais.

Methods: Observational and retrospective study. A total of 1671 medical records of women with breast cancer treated in the period of 1981-2013 were analyzed, of which 797 were excluded for lack of pathologic data or by being diagnosed in advanced stage. Fisher's exact test or χ^2 were performed.

Results: As expected, the positivity of lymph node metastasis increased with tumor size: of the Tis patients, 5.55% were N + (3.7% N1, 1.85 N2); of T1, 25.29% were N + (21.01% N1, 4.28% N2); of T2, 51.45% were N + (37.21% N1; 9.88% N2; 4.36% N3); of T3, 77.05% were N + (55.74% N1; 18.03% N2; 3.28% N3); and of T4, 80% were N + (48.57% N1; 17.14% N2; 14.29% N3). When analyzed by T, decreased odds of metastasis in Tis (OR = 0.3435; p = 0.0197) and T1 (OR = 0.3805; p < 0.0001) were observed, while increased odds in T2 (OR = 1.469; p = 0.0364), T3 (OR = 2.114; p = 0.0081) and T4 (OR = 4.222; p < 0.0001). When analyzed by N, decreased odds of metastasis in N0 (OR = 0.1587; p < 0.0001) was observed and increased odds in N1 (OR = 2.56; p < 0.0001), N2 (OR = 3.703; p < 0.0001) and N3 (OR = 4.328; p = 0.0002). Overall, N+ had an increased odd of metastasis when compared with N- (OR = 6.321; p < 0.0001) patients. Increased odds only in T1N + (OR = 9.49; p < 0.0001) and T2N + (OR = 3.557; p < 0.0001) was observed when compared with their N- counterparts. Moreover, a borderline increase in the odds (OR = 3.667; p = 0.0533) was observed in T1N2 compared with in T1N1, but not in T2 (p = 0.9190) nor T3 (p = 0.4639) patients.

Conclusions: Lymph node involvement (N) is a greater risk factor for metastasis than tumor size (T). Adjuvant therapy is based on T, N and molecular subtype. In the minimal axillary approach by sentinel lymph node (SL) the pathologic analysis of this unique sample, and maybe including two other lymph nodes, have a great prognostic weight, mainly in early stage. These data corroborate the lack of necessity in dividing, as formerly, between the 12 or more dissected lymph nodes in a clinically negative axilla.

1916P The influence of the surgical approach in women diagnosed with breast neoplasia

R.A. de Araujo[1], C.P. Nascimento[2], C.L.P. Da Cunha[2], E.D.C. Marinho[2], E.R.T. Mosca[2], F.A.C. Da Luz[2], P.F.R. Delfino[2], R.M. Antonioli[2], T.R. Mendes[2], M.J.B. Silva[3]

[1]Oncologia Clínica, COT - Centro Oncológico do Triângulo, Uberlandia, Brazil, [2]Hospital do Câncer em Uberlândia, Universidade Federal de Uberlândia, Uberlândia, Brazil, [3]Instituto de Ciências Biomédicas, Universidade Federal de Uberlândia, Uberlândia, Brazil

Background: Although recent years have seen improvement in systemic therapies and radiotherapy, the surgical approach is still a keystone in oncologic treatment. In this study we investigated the association between surgical margin status and surgical approach with disease progression and death of breast cancer patients treated in the Oncology Sector of a Public Hospital of Minas Gerais.

Methods: Observational and retrospective study: A total of 1979 medical records of women with breast cancer treated in the period of 1981 to 2013 were analyzed. The surgical approach and surgical margin were obtained from anatomopathological reports. Of the total, 987 were excluded for lack of pathologic data, being diagnosed at stage IV or pathogical 0 stage.

Results: Of the subtotal, 992 medical records reported the surgery approach (radical or breast-conserving), and 905 reported surgical margins, of which 110 had positive margin and 795 negative margin. The median age was of 55 y.o. (27-91). It was observed that 49.69% (n = 493) of surgeries were breast-conserving. No association between surgical approach and local relapse (p = 0.2672) was observed. However, increased odds of surgical margin impairment (OR = 1.531; p = 0.0395) and decreased odds of distant relapse (OR = 0.4068; p < 0.0001) and death (OR = 0.1455; p < 0.0001) was observed for breast-conserving surgeries compared with radical surgeries. No association between surgical margin and local relapse was observed (p = 0.1063). However, patients with positive surgical margin had greater odds of distant relapse (OR = 1.940; p = 0.0052) and death (OR = 2.002; p = 0.0494). When analyzed by pathological stage (I-III), it was observed that positive surgical margin increased the odds of distant relapse in stage II (OR = 2.280; p = 0.00499) and III (OR = 2.820; p = 0.0132) patients.

Conclusions: Although an association between radical surgery and death was observed, factors such as tumor complexity and locally advanced tumor could be involved. However, it is noteworthy that positive surgical margin increased the odds of distant relapse, mainly in stage III patients, and death. These data corroborate the fact that the surgical approach is still a keystone in breast cancer treatment and it has a strong impact in patients with locally advanced tumors.

1917P Use of comparative proteomics to identify potential cisplatin-resistance mechanisms in neuroblastoma

M.A. Merlos Rodrigo, H. Buchtelova, V. Strmiska, Z. Heger, V. Adam

Chemistry and Biochemistry, Mendel University in Brno, Brno, Czech Republic

Background: Neuroblastoma (Nbl) is an embryonal tumour, originating from progenitor cells of the sympathetic nervous system, and is the most common extra-cranial solid tumour of childhood. Cisplatin is one of the most commonly used drugs in the treatment of Nbl. Unfortunately, the development of resistance against this cytotoxic agent limits its clinical use. We aimed to gain further understanding of the mechanisms underlying development of cisplatin resistance using an in vitro cell line model.

Methods: Cytotoxicity of cisplatin, carboplatin and oxaliplatin in neuroblastoma UKF-NB-4 and UKF-NB-4^{CDDP} cells cultured in the exponential growth was determined. Peptide separations were carried out on an Easy-nLC 1000 nano system. MS analysis was performed using a Q-Exactive MS. MS data were analyzed with Proteome Discoverer (version1.4.1.14) using standardized workflows. The mass spectrum *.raw file was searched against the human SwissProt 57.15 database (20266 sequences protein entries) using MASCOT search engine (version 2.3, Matrix Science).

Results: The two cell lines that were used were the following: cisplatin-resistant UKF-NB4CDDP and UKF-NB4 cell lines. We proved decreased sensitivity of line UKF-NB-4^{CDDP} to cisplatin and crossresitance to carboplatin and oxaliplatin. Out of a total 1802 identified proteins, 1448 were common expressed in two datasets. A total of 281 significant protein expressions were exclusively registered in the UKF-NB4CDDP cell line and 73 proteins were exclusively identified in UKF-NB4 cell line. UKF-NB-4^{CDDP} and UKF-NB-4 cell lines showed overexpression of trafficking of transport in two datasets: comparison between of UKF-NB-4^{CDDP} and UKF-NB-4 cell lines and proteins exclusive identified in UKF-NB-4^{CDDP}. Exosome vesicles assay showed increase of vesicles in UKF-NB-4^{CDDP} cell lines.

Conclusions: The Orbitap MS results could shed some light on the proteins involved in inducing resistance to cisplatin in cancer cells. These data strongly suggest that exosomes potently induce properties of Nbl cells and their chemoresistance to cisplatin and reinforces the potential benefit of trafficking of biological material across membranes in cancer.

1918P Acquired resistance mechanism of osimertinib targeting EGFR in human lung cancer

V. Ciaramella, C.M. Della Corte, G. Barra, R. Di Liello, G. Viscardi, M. Orditura, E. Martinelli, F. Ciardiello, F. Morgillo

Precision Medicine, Università degli Studi della Campania Luigi Vanvitelli, Naples, Italy

Background: Significant progress has been achieved by the development of epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKIs) targeting EGFR mutations in non-small cell lung cancer (NSCLC), however the acquisition of resistance to these agents are always the main cause of disease progression. Osimertinib (AZD9291), an oral potent drug, has developed as 3rd generation EGRF-TKIs with activities against sensitising mutations and the EGFR Thr790Met resistance mutation, which account for about 50% of the mechanisms of acquired resistance to 1st or 2nd generation EGFR-TKIs.

Methods: We developed in vitro model of acquired resistance to EGFR-inhibitors by treating human NSCLC cell lines with Osimertinib. PC9 and H1975 cell lines, which were initially sensitive to Osimertinib treatment (IC50: 0.1 and 0.5 μM, PC9 and H1975, respectively), became resistant after 8 months of continuous treatment reaching an IC50 ≈ 20 μM. This phenomenon was accompanied by visible morphological changes of the cells that acquire the typical characteristics of mesenchymal cells.

Results: We verified if this morphological change is translated into a functional change through the activation of specific pathways; protein lysates from harvested resistant cells showed higher levels of phosphorilation of EGFR, AKT and MAPK proteins than parental cell lines. We next examined whether resistant cell lines exhibit molecular changes known to occur during Epiteliali-to-Mesenchymal Transition (EMT) and we

found a significant expression of mesenchymal protein like Vimentin, Snail and Slug in Osimertinib-resistant cells as compared to with Osimertinib-sensitive cells.

Conclusions: This data, indicates the importance of EMT as a crucial event in the acquisition of resistance to third-generation EGFR-TKIs inhibitors and suggests new opportunities to design new treatment strategies in lung cancer.

1919P Interaction of oncostatin M and its receptor OSMR promotes gastric cancer progression via STAT3/FAK/Src signaling

L. Su, X. Wu, J. Li, Z. Yu, B. Liu

Surgery, Shanghai Ruijin Hospital, Shanghai Jiao Tong University, School of Medicine, Shanghai, China

Background: Gastric cancer (GC) is one of the deadliest cancers in the world. With its lacking of early diagnostic methods, metastasis and recurrence lead to a low 5-yeard survival rate. Discovering mechanisms of gastric cancer and thus developing new strategies for gastric cancer diagnosis and therapy is urgent for clinicians and scientists. OSM receptor (OSMR) is a member of the interleukin 6 (IL-6) receptor family and transduces signaling events induced by its major ligand OSM. Interaction between OSMR and OSM plays key roles in inflammation, hematopoiesis, and development, and is increasingly being recognized as an important contributor to cancer progression. However, the role of OSM-OSMR interaction on GC is still not known.

Methods: Expression of OSM receptor (OSMR) was performed by RT-PCR, immunohistochemistry and Western Blot in gastric cancer tissues and cell lines. The malignant effects of OSM-OSMR interaction on gastric cancer cells in vitro and in vivo were examined.

Results: OSMR is highly expressed in GC tissues and cell lines, and OSMR levels are positively associated with age, T stage, tumor size, lymph node metastasis, TNM stage, Lauren Classification and poor prognosis. In GC cells that overexpress OSMR, recombinant human OSM (rhOSM) treatment promotes cell proliferation, migration, invasion, EMT in virto, as well as tumorigenesis and peritoneal metastasis in vivo. These multiple pro-malignant effects induced by OSM-OSMR interaction are mediated by activation of STAT3/FAK/Src signaling pathway. Specific inhibition of OSM-OSMR interaction by silencing OSMR expression significantly inhibits STAT3/FAK/Src activation, leading to reduced cell proliferation, migration, invasion and EMT.

Conclusions: OSM-OSMR interaction contributes to the progression of GC through the activation of t STAT3/FAK/Src signaling pathway and OSMR could be a potential target for gastric cancer treatment.

1920P Role of pioglitazone on gene/protein expression profile, bioenergetics and TGFβ/SMAD signaling pathway in NSCLC

R. Di Liello, G. Viscardi, V. Ciaramella, G. Barra, G. Esposito, M. Fasano, F. Ciardiello, F. Morgillo

Precision Medicine, Università degli Studi della Campania Luigi Vanvitelli, Naples, Italy

Background: Pioglitazone is an antidiabetic drug of the Thiazolidinediones (TZDs) class that acts as ligand for PPAR-γ, a member of peroxisome proliferator activated receptors (PPARs), that regulates lipid and glucose cell metabolism. Prior studies in in vitro and in vivo models of non-small cell lung cancer (NSCLC) showed that PPAR-γ modulation affects cancer cells proliferation and differentiation but few reported studies have investigated molecular pathways involved in the potential role of PPAR-γ agonists as anti-cancer agents.

Methods: NSCLC cell lines H460 and H1299, were treated with different doses of Pioglitazone. Anti-proliferative effect was determined by MTT, colony-forming assay and flow-cytometry. Protein expression was detected by Western Blot analysis while functional mitochondrial measurements were performed with SeaHorse© stress test. Finally, cell lines samples were analyzed with a cDNA microarray assay.

Results: Pioglitazone significantly reduces cell proliferation and invasion with an IC_{50} of 1-5 μM. Analysis of apoptosis confirmed the data. Western blot analysis demonstrated a dose-related reduction of Survivin and phosphorylated proteins of MAP kinase pathway and cDNA microarray expression profiling showed a down-regulation of MAPK, Myc and RAS genes. Oxygen Consumption Rate (OCR) and proportional Glut-1 protein expression reduction of treated cells demonstrated cell bioenergetics modulation. Interestingly cDNA microarray analysis showed that also TGFβ pathway is regulated by Pioglitazione through pTGFβR1 and pSMAD3 down-regulation and consecutive up-regulation of total TGFβR1.

Conclusions: Pioglitazone regulates NSCLC cell lines proliferation and bioenergetics. Moreover, affecting TGFβ/SMAD signaling pathway, it could have a role in epitelial-to-mesenchymal transition (EMT) and cancer invasive phenotype development. These results encourage the study of PPAR-γ agonists as anti-cancer agents and promote research to explore the mechanisms beyond their activity in NSCLC models.

1921P Somatostatin receptor 2 expression and clinical significance in pulmonary lymphoepithelioma-like carcinoma

S. Han[1], J. Yeong[2], C.X. Lim[3], M-K. Ang[1], W.T.D. Lim[1], C.K. Toh[1], Q.S. Ng[1], D.S. Tan[1], T.K.H. Lim[2], J.H. Loh[2], A. Tanako[2], R. Kanesvaran[1], W.L. Tan[1], T. Rajasekaran[1], W. Nei[4], A. Jain[1]

[1]Division of Medical Oncology, National Cancer Centre Singapore, [2]Department of Pathology, Singapore General Hospital, Singapore, [3]Medical Oncology, National Cancer Centre Singapore, [4]Division of Radiation Oncology, National Cancer Centre, Singapore

Background: Pulmonary lymphoepithelioma-like carcinoma (PLELC) is a rare Epstein-Barr virus (EBV) associated cancer, histologically indistinguishable from nasopharyngeal carcinoma (NPC). Somatostatin receptor type 2 (SSTR2) is a bonafide theranostic target in neuroendocrine tumour. It is also demonstrably expressed in NPC, with autoradiography and positron emission tomography (PET). SSTR2 expression has not been reported in PLELC. In this study, we aimed to investigate SSTR2 expression and its co-localization with EBV positive PLELC cells using immunohistochemistry (IHC); and to investigate the clinical significance of SSTR2 in PLELC.

Methods: Clinical demographics including age, gender, TNM staging, EBV titre, smoking status, survival and treatment regime were collected. Archival formalin fixed, paraffin embedded (FFPE) tissue from patients diagnosed with PLELC between 2003 and 2016 at National Cancer Centre Singapore were retrieved and studied retrospectively. IHC staining for SSTR2 and Epstein-Barr encoding region in-situ hybridisation (EBER-ISH) were performed using a dual-staining technique.

Results: We report clinical data and dual staining from 20 PLELC patients. The median age at diagnosis was 56.5; 80% (16/20) of the patients were female; all non-smokers (except 3 with unknown status); 55% (11/20) of the patients had stage IV disease and the rest stage I-IIIB. High serum EBV titres were also noted in PLELC patients. Sixteen out of 20 patients (80%) stained positive for SSTR2 on IHC. SSTR2 expression co-localised with EBER positive cells. Nine out of 11 (82%) patients with stage IV PLELC stained positive for SSTR2 while 7 out of 9 (78%) stage I-III disease stained positive. Two year OS by SSTR2 status is 100% in SSTR2 negative and 65.2% (CI 35.1, 84.0) in SSTR2 positive patients, $p = 0.467$ by Log Rank Test. Two year OS by stage is 85.7% (CI 33.4, 85.7) for stage I-III and 63.6% (CI 29.7, 84.5) for stage IV disease, $p = 0.014$.

Conclusions: In PLELC, high levels of SSTR2 IHC expression is reported with co-localisation with EBV infected cells. A high proportion of stage IV patients have SSTR2 positive tumours. These patients have limited treatment options. This study opens up the possibility of using SSTR2 theranostics for these patients.

1922P The role of neurotrophic factors in nerve-cancer crosstalk

A. Planken[1], L. Truu[2], K. Oselin[1], V. Valvere[1]

[1]Department of Oncology and Hematology, North Estonia Medical Centre Foundation, Tallinn, Estonia, [2]Department of Bioenergetics, National Institute of Chemical Physics and Biophysics, Tallinn, Estonia

Background: "Nerve-cancer crosstalk" has been suggested as an important mechanism of tumor growth and dissemination. Cells in the cancer microenvironment secrete biomolecules which induce neoneurogenesis, while tumor cells utilize nerves for dissemination to other organs, thru a process of perineural invasion. The molecular basis for this crosstalk has remained unclear and no targeted approaches against these mechanisms exist. The current study evaluates the neuronal effects of cancer from the viewpoint of neurotrophic growth factors (NTFs). We screened various tumors for changes in gene expression of NTFs, in order to characterize the role of these factors in human cancers.

Methods: TNTF gene expression data was assesed from the Cancer Genome Atlas (TCGA) and GTEx transcriptomic databases for 33 cancers, totaling to 9736 tumor and 8587 normal samples. Data was analyzed by Gene Expression Profiling Interactive Analysis software (http://gepia.cancer-pku.cn/index.html), as transcripts per million using the log2 FC cutoff of 1 and by ANOVA. qRT-PCR for NTFs MANF and CDNF from patients with colorectal (CRC) and breast cancer (BC) was performed. Trizol and Qiagen RNeasy Mini Kit was used for RNA extraction, cDNA was synthesized using

High Capacity cDNA RT-kit and TaqMan® qRT-PCR analysis was done with Roche LightCycler 480 system. Data was analyzed by the 2-ΔCT method and the unpaired Student t-test.

Results: The expression levels for the 3 NTFs: mesencephalic astrocyte-derived neurotrophic factor (MANF), cerebral dopamine neurotrophic factor (CDNF) and growth differentiation factor (GDF15) were profiled from the TCGA and GTEx databases. MANF RNA was upregulated in 9 different cancers, CDNF was up- in 1 and downregulated in 5 cancers and GDF15 was up- in 14 and downregulated in 3 cancers. qRT-PCR for MANF and CDNF from 52 patients with CRC showed that MANF is significantly upregulated 2-fold ($p < 0.001$) in CRC as compared to controls from the same patients, and upregulation was already seen in tumor-nearby samples. The analysis of RNA samples from 38 BC patients showed significant down-regulation for CDNF ($p < 0.05$).

Conclusions: These results support the hypothesis that NTFs indeed play a role in tumors and provide the basis for the need of further study for these factors within the cancer paradigm.

1924P Glutathione S-transferase M subfamily in TMZ-resistant glioblastoma cells

S.Y. Cheng[1], W-F. Chen[2], Z-H. Wen[3]

[1]Doctoral Degree Program in Marine Biotechnology, National Sun Yat-sen University, Kaohsiung, Taiwan, [2]Department of Neurosurgery, Chang Gung Memorial Hospital, Kaohsiung, Taiwan, [3]Department of Marine Biotechnology and Resources, National Sun Yat-sen University, Kaohsiung, Taiwan

Background: Glioblastoma multiforme (GBM), the most aggressive central nervous system cancer, is highly angiogenetic and infiltrative with high potential of resistance to chemotherapy and radio therapy. The median survival of primary GBM patients is approximately 14.6 months, despite patients receiving aggressive treatment with surgery, radiotherapy, and alkylating chemotherapy drugs such as temozolomide (TMZ). Some research results point out more than 90% of patients show no response after the second cycle of current GBM chemotherapy. Glutathione S-transferase (GST) is an important detoxification protein family that highly correlates with drug inactivation and multidrug resistance.

Methods: In our study, we generated TMZ-resistant glioblastoma GBM8401 cells (GBM8401-TMZ-R) over a 130-day period. We compared TMZ resistance level in TMZ-sensitive cell lines U87MG, A172 and GBM8401 with TMZ-resistant cell lines GBM8401-TMZ-R, T98G and U138 through cell toxicity assays and O-6-Methylguanine-DNA Methyltransferase (MGMT) expression. Moreover, we investigated the mRNA profiles of GBM8401, GBM8401-TMZ-R, and T98G cells by using next generation sequencing (NGS) for analyzing.

Results: We found GBM8401-TMZ-R cells with significantly higher MGMT expression and increased TMZ tolerance. GSTM subfamily proteins, which are located in human chromosome 1, showed different basal expressions in the GBM cell lines we tested. Surprisingly, GBM8401-TMZ-R cells showed higher GST activity and increased GSTM1 and GSTM5 protein levels than GBM8401. GBM8401-TMZ-R cells also displayed higher glycolytic capacity in a Seahorse extracellular flux (XF) analyzer. We also analyzed the expression of GST subfamilies and drug resistance-related genes by NGS.

Conclusions: From these results, we theorized that certain GST proteins may play a key role in TMZ-resistant glioblastoma cells. We hope this study will provide potential therapeutic targets for TMZ-resistant GBM patients.

1925P Combining 2D angiogenesis and 3D osteosarcoma microtissues to improve vascularization

H.M. Chaddad

Regenerative Nanomedecine, Faculté de Médecine de Strasbourg, Strasbourg, France

Background: The number of patients suffering from cancers worldwide is increasing, and one of the most challenging issues in oncology continues to be the problem of developing active drugs economically and in a timely manner. Considering the high cost and time-consuming nature of the clinical development of oncology drugs, better pre-clinical platforms for drug screening are urgently required. So, there is a need for high-throughput drug screening platforms to mimic the in vivo microenvironment. Angiogenesis is now well known for being involved in tumor progression, aggressiveness, emergence of metastases, and also resistance to cancer therapies.

Methods: In this study, to better mimic tumor angiogenesis encountered in vivo, we used 3D culture of osteosarcoma cells (MG-63) that we deposited on 2D endothelial cells (HUVEC) grown in monolayer. Combination 2D HUVEC/3D MG-63 was characterised by Indirect immunofluorescence, scanning electron microscopy, optical microscopy and mRNA expression (qPCR).

Results: We report that endothelial cells combined with tumor cells were able to form a well-organized network, and those tubule-like structures correspond to new vessels infiltrating tumor spheroids. These vessels presented a lumen and expressed specific markers, such as CD31 and collagen IV. The combination of 2D endothelial cells and 3D microtissues of tumor cells also increased expression of angiogenic factors as VEGF, CXCR4 and ICAM1.

Conclusions: The cell environment is the key point to develop tumor vascularization in vitro and to be closer to the tumor encountered in vivo.

1926P Survival analysis of sorafenib in hepatocellular carcinoma patients with microvascular invasion after hepatectomy

Z. Zhang, Y. Huang, Y. Zhou, J. Yang, K. Hu, Z. Wang

Department of Hepatobiliary Surgery, Xiangya Hospital of Central South University, Changsha, China

Background: Hepatocellular carcinoma (HCC) is the most common primary liver cancer. The recurrence rate after hepatectomy remains high, which seriously affects the prognosis. Microvascular invasion (MVI) has been proved to be an independent risk factor for the recurrence of liver cancer. If patients with MVI can receive timely and effective treatment, it will help reduce the recurrence rate, and prolong the survival time. The aim of the study was to analyze the effect of sorafenib on the clinical outcomes in HCC patients with MVI after hepatectomy.

Methods: Patients with HCC who underwent hepatectomy and were pathologically diagnosed as MVI at the research center between January 2009 and December 2016 were retrospectively analyzed. Patients were divided into sorafenib group and control group according to whether or not sorafenib (Nexavar®) was taken after surgery. Sorafenib was administered orally, 0.4 g each time, twice daily. Follow-up was performed after hepatectomy. The recurrence-free survival (RFS) and overall survival (OS) were observed. Associated factors were analyzed using univariate and multivariate COX regression.

Results: This study included 16 patients in the sorafenib group and 33 patients in the control group. There was no significant difference in age, gender, hepatitis B surface antigen level, preoperative prethrombin time (PT), BCLC stage, preoperative a-fetoprotein level, maximum tumor diameter, and tumor number (all $P < 0.05$). The RFS and OS were both longer in the sorafenib group (both $P < 0.05$). The three-year RFS rates of the sorafenib group and the control group were 9 (56.3%) and 8 (24.2%), respectively, with significant difference ($P = 0.027$). The three-year OS rates of the sorafenib and control group were 13 (81.3%) and 13 (39.4%), respectively, with significant differences ($P = 0.006$). The results of multivariate COX regression indicated that preoperative PT and sorafenib treatment were the independent associated factors for RFS and OS.

Conclusions: The use of sorafenib after hepatectomy in HCC patients with MVI can prolong survival time.

1927P FAM115c that upregulates proliferation and invasion under hypoxia could be a predictive biomarker for pancreatic cancer

K. Saeki[1], H. Onishi[2], Y. Oda[3], M. Nakamura[4]

[1]Department of Surgery and Oncology, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan, [2]Department of Surgery and Oncology, Kyushu University Hospital, Fukuoka, Japan, [3]Department of Anatomic Pathology, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan, [4]Department of Surgery and Oncology, Kyushu University Hospital, Fukuoka, Japan

Background: In pancreatic cancer whose microenvironment is extremely hypoxic, the analysis of signal transduction under hypoxia is thought to be important. Recently, we have found that the expression of TRP channel-associated factor family, FAM115c, increased under hypoxia in pancreatic cancer. In the present study, the biological significance of FAM115c was investigated in pancreatic cancer, and whether FAM115c could be a new therapeutic target for pancreatic cancer was evaluated.

Methods: Three pancreatic ductal adenocarcinoma cell (PDAC) lines (ASPC-1, SUIT-2, and PANC-1) were cultured under normoxia (20%O_2) and under hypoxia (1%O_2) and were used as target cells. Inhibition or overexpression of FAM115c was performed using FAM115c siRNA and plasmid, respectively. Expression of FAM115c was analyzed by qRT-PCR, western blot and immunohistochemical staining (IHC). Proliferation

was performed by MTT assay. Migration was estimated using time-lapse imaging analysis. Mice xenograft experiments were performed using BALB/c nude mice. Forty surgically resected human pancreatic cancer specimens were used for qPCR experiment and IHC.

Results: 1) Expression of FAM115c increased in PDAC under hypoxia compared to normoxia. 2) FAM115c suppression significantly increased migration and invasion in PDAC under hypoxia. 3) FAM115c inhibition significantly increased proliferation in vitro in PDAC under hypoxia. 4) FAM115c overexpression led to decreased proliferation, migration and invasion in PDAC under hypoxia. 5) Tumor volume in mice injected with FAM115c-inhibited PDAC was significantly higher than that in control mice. 6) Signaling from FAM115c was through PI3K and MAPK signaling pathways. 7) FAM115c expression was observed in all 40 patients examined by IHC. 8) In qPCR experiment FAM115c expression correlated with better prognosis in patients with pancreatic cancer.

Conclusions: These results suggest that FAM115c upregulates proliferation and invasion in pancreatic cancer under hypoxia and that FAM115c may be a predictive biomarker for better prognosis of patients with pancreatic cancer. FAM115c gene transfer may be a new therapeutic strategy for pancreatic cancer.

1928P Pathologic assessment following neoadjuvant immunotherapy or chemotherapy demonstrates similar patterns in non-small cell lung cancer (NSCLC)

A. Weissferdt[1], B. Sepesi[2], A. Pataer[2], N. Kalhor[1], C.A. Moran[1], W.N. William[3], X. Le[3], B. Glisson[3], F. Skoulidis[3], G. Blumenschein[3], J. Zhang[3], M. Altan[3], D. Rice[2], R. Mehran[2], J.J. Lee[4], A. Vaporciyan[2], D.L. Gibbons[3], S.G. Swisher[2], J.V. Heymach[3], T. Cascone[3]

[1]Pathology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [2]Thoracic and Cardiovascular Surgery, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [3]Thoracic/Head and Neck Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA, [4]Biostatistics, MD Anderson Cancer Center, Houston, TX, USA

Background: Neoadjuvant chemotherapy (CT) and immunotherapy (IT) are associated with features of pathologic treatment response (PTR) in NSCLC. Comparison of such features in NSCLC following neoadjuvant CT, IT or upfront surgical resection is lacking. Nivolumab (N) and/or N plus ipilumumab (NI) are being investigated in resectable NSCLC (NCT03158129). We analyzed the histopathologic patterns of CT- and IT-treated NSCLC vs untreated surgically resected tumors.

Methods: Histopathologic assessment of untreated, CT- and IT-treated NSCLC was performed (n = 30, 10/group). Hematoxylin and eosin-stained tumor sections were scored for parameters of PTR: percentage of viable tumor, fibrosis, and necrosis; inflammation, tertiary lymphoid structures (TLS), macrophages, lymphovascular invasion (LVI), cholesterol clefts (CC), giant cells (GC) and neovascularization (NV) were reported as a score (0-3). Values for each variable were expressed as a mean (± SD). Statistical comparison between two groups was calculated with unpaired two-sided t-test. Significance was defined as p-value <0.05.

Results: CT and IT were associated with significantly less viable tumor cells (p = 0.04 and p = 0.02, respectively), IT with more fibrosis (p = 0.04) and CT with more CC (p = 0.03) than untreated tumors. Trends towards higher amounts of inflammation, macrophages and CC were seen in IT-treated compared to untreated tumors. CT had a trend towards more fibrosis and GC compared with untreated NSCLC (Table).

Table: 1928P Summary of PTR parameters

	Untreated	CT-treated	IT-treated
Viable tumor	67.7%	42.4%*	37.5%*
Fibrosis	26.6%	46.6%	52.3%*
Necrosis	5.6%	11.0%	10.1%
Inflammation	1.46	1.54	1.87
TLS	0.80	1.00	1.00
LVI	0.23	0.16	0.33
Macrophages	0.12	0.94	1.17
CC	0.13	0.92*	1.04
GC	0.40	0.80	0.70
NV	0	0	0

*p-value <0.05

Conclusions: Neoadjuvant CT and IT are associated with similar histopathological changes compared to untreated tumors but with lower proportions of viable tumor and higher degrees of fibrosis. Neoadjuvant treatment is also associated with a trend towards higher amounts of inflammation, macrophages, CC and GC. Analysis of a larger cohort, including comparison of N- vs NI-treated tumors (estimated n = 80) is ongoing and will be presented in due course.

1929P Tumor-infiltrating CD3+ lymphocytes and ICOS+ T-cells predict a favorable survival in resected esophageal squamous cell carcinoma

M.H. Hong[1], S-J. Shin[2], Y-L. Choi[3], B.C. Cho[1], H.R. Kim[1]

[1]Department of Internal Medicine, Yonsei Cancer Center Yonsei University, Seoul, Republic of Korea, [2]Department of Pathology, College of Medicine, Hanyang University, Seoul, Republic of Korea, [3]Department of Pathology, Samsung Medical Center, Seoul, Republic of Korea

Background: The prognosis of advanced esophageal squamous cell carcinoma (ESCC) is extremely poor. With an increasing potential of immune checkpoints modulators in oncology, the aim of the current study was to assess the extent of tumor-infiltrating lymphocyte (TIL) and expression and significance of various immune checkpoints in the resected ESCC.

Methods: Total 396 patients who underwent radical surgery for ESCC between 2005 and 2013 were included. Using immunohistochemistry (IHC) with tissue microarray, type of T-cells including CD3, CD8, and Foxp3 T-cell and the expression of checkpoints including programmed cell death-ligand 1 (PD-L1), programmed cell death-1 (PD-1), inducible co-stimulator (ICOS), lymphocyte activation gene-3 (LAG-3), and T-cell immunoglobulin and mucin-dominant containing-3 (TIM-3) was manually scored. Outcome measures included recurrence-free survival (RFS) and overall survival (OS). The expression was defined as high density when the expression level was above the median value/4HPFs (high-power fields).

Results: With median follow-up period of 24.8 months, 32.6% of recurrence and 45.7% of death occurred. Patients with a high frequency of CD3+ TILs (n = 198) demonstrated a significant longer RFS (hazard ratio [HR] = 0.61, P = 0.0005) and OS (HR = 0.59, P = 0.0005). High ICOS expression group (n = 184) displayed longer RFS (HR = 0.72, P = 0.021) and OS (HR = 0.67, P = 0.007) than low ICOS expression group. Regarding PD-1 expression, the RFS (HR = 0.67, P = 0.004) and OS (HR = 0.66, P = 0.006) were significantly better in high expression group (n = 179). In multivariate Cox analyses, high CD3+ TIL and ICOS were also indicated as an independent prognostic factor for better PFS (HR = 0.59, P < 0.001 and HR = 0.64, P = 0.002, respectively) and OS (HR = 0.48, P < 0.001 and HR = 0.60, respectively) and high TIM-3 expression in immune cells was related to the shorter RFS (HR = 1.46, P = 0.020) and OS (HR = 1.54, P = 0.013). Even though various cut-off applied, the expression of PD-L1 in tumor or immune cells failed to report any association with prognosis.

Conclusions: Our analysis involving TMA and IHC of multiple immune checkpoints in resected ESCC suggests that CD3+ TILs and ICOS+ T-cells might be a favorable prognostic factor.

1930P Chemokine receptor CXCR7 expression, function and clinical implications in head and neck squamous cell carcinoma

M-W. Lee[1], N. Kim[2], S. Kim[2], M. Joo[2], H. Ryu[1], H.J. Lee[2]

[1]Internal Medicine, Chungnam National University Hospital, Daejeon, Republic of Korea, [2]Departments of Internal Medicine and Medical Science, College of Medicine, Chungnam National University, Daejeon, Republic of Korea

Background: The atypical chemokine receptor, CXCR7, has been shown to play an important role in the progression of several types of cancer. However, there have been few reports on the biological role of CXCR7 in head and neck squamous cell carcinoma

(HNSCC). In this study, we investigated the functional role of CXCR7 and the underlying molecular mechanism of disease progression in HNSCC.

Methods: We examined the association between CXCR7 expression and clinicopathological characteristics in 103 cases of HNSCC using tissue microarrays by immunohistochemical staining. The biological roles of CXCR7 and CXCR7-mediated signaling pathways were investigated in HNSCC cell through CXCR7 overexpression and treatment of SDF-1α, a major ligand of CXCR7, as well as knockdown of CXCR7 in vitro and in vivo.

Results: CXCR7 was differentially expressed in human HNSCC tissues. High expression of CXCR7 was significantly related to depth of tumor invasion ($P = 0.007$), lymph node metastasis ($P = 0.004$), and tumor stage ($P = 0.02$). Overexpression of CXCR7 dramatically enhanced cell migration and invasion in HNSCC cells in vitro, and promoted lymph node metastasis in vivo. CXCR7 knockdown using siRNA in HNSCC cells recovered the cell migratory and invasive behavior of HNSCC cells. CXCR7 overexpression also induced the epithelial-mesenchymal transition. Vimentin, Slug, and Twist were increased but E-cadherin and Ep-CAM were decreased by CXCR7 expression. Akt phosphorylation and Smad2 signaling activation were induced in HNSCC cells with CXCR7 overexpression. Treatment with a PI3K inhibitor reduced Slug and Twist levels while suppression of Smad2 signaling by siRNA reduced Akt phosphorylation, as well as Slug and Twist. Furthermore, inhibition of Smad2 decreased tumor cell migration and invasion in HNSCC.

Conclusions: CXCR7 expression was associated with an aggressive tumor behavior in HNSCC. CXCR7 contributed to cell migration and invasion of HNSCC cell through the Smad2/Akt signaling axis in vitro, and was involved in lymph node metastasis in vivo, suggesting that CXCR7 might be a therapeutic target for the treatment of HNSCC.

1931P Assessment of PD-1/PD-L1 colocalization in hepatocellular carcinoma (HCC) using bright-field double labeling and quantitative digital image analysis

T. Mrowiec[1], F. Wilm[1], E. Frick-Krieger[1], M. Silva[1], L. Terracciano[2], I. Dussault[3], C. Ihling[1]

[1]Clinical Biomarkers & CDx Department, Merck KGaA, Darmstadt, Germany, [2]Department of Pathology, University of Basel, Basel, Switzerland, [3]Clinical Biomarkers, Immuno-Oncology, EMD Serono, Billerica, MA, USA

Background: Tumors may suppress host defenses by activating immune checkpoints (eg, the programed cell death [PD-1/PD-L1] pathway). Colocalization (CL) is a requirement for PD-1/PD-L1 interaction. PD-1/PD-L1 CL in tissue sections, as determined by immunohistochemistry (IHC), may be an indicator of PD-L1/PD-1 pathway activity.

Methods: We assessed CL of PD-L1 and PD-1 in situ by applying a novel duplex bright-field IHC technique on 49 formalin-fixed, paraffin-embedded HCC samples using digital image analysis (DIA; Definiens Tissue Studio®) to determine the percentage of single PD-1^+ and PD-$L1^+$ cells, PD-L1/PD-1 double-labeled cells, and PD-1^+ cells adjacent to ≥ 1 PD-$L1^+$ cells.

Results: All cases showed typical HCC morphology (low- to high-grade trabecular [4/49], pseudoglandular [1/49], solid [40/49], clear cell [2/49], or desmoplastic [2/49]). PD-L1 was largely observed in immune cell infiltrates. On average, 2.6% ± 3.6% (median, 1.5%) of the cells (immune + tumor) within the tumor area were PD-1^+, and 4.3% ± 5.5% (median, 1.9%) were PD-$L1^+$. There was considerable variation among samples in the number of PD-1^+ (range, 0.05%-21.2%) and PD-$L1^+$ (range, 0.2%-30.3%) cells. In 18/49 cases (37%), the number of PD-1^+ cells exceeded the number of PD-$L1^+$ cells; in 31/49 cases (63%), the number of PD-L1+ cells exceeded the number of PD-1^+ cells. PD-1/PD-L1 double-stained cells were present in 31/49 cases (63%), and 1.6% ± 4.1% (median, 0.13%) of the cells were double labeled, with considerable intersample variation (range, 0.5%-22.9%). Finally, 10.5% ± 8.03% (median, 9.4%) of PD-1^+ cells were in the immediate vicinity of a PD-$L1^+$ cell (range, 1.1%-43.3%).

Conclusions: By combining a novel duplex bright-field IHC technique with DIA, we quantitated the number/distribution of PD-1^+ and PD-$L1^+$ cells in HCC. Variation in the numbers of PD-1^+ and PD-$L1^+$ cells, and PD-1^+ cells with $\geq$1 PD-$L1^+$ adjacent cells, in HCC was seen. Future studies can use these techniques to explore the predictive potential of PD-L1/PD-1 expression in patients who are being considered for immunotherapy. Our proof of concept results suggest that the methods may also be applied for other tumors.

1932P Pulmonary tumor thrombotic microangiopathy (PTTM): 24 case series and its criteria for pathological diagnosis

N. Sato[1], T. Tasaki[1], H. Noguchi[1], K. Irie[2], T. Nakayama[1]

[1]Department of Pathology, University of Occupational and Environmental Health, Kitakyushu, Japan, [2]Department of Diagnostic Pathology, Kitakyushu General Hospital, Kitakyushu, Japan

Background: PTTM is a fatal complication of malignancy causing progressive pulmonary hypertension (PH) or right heart failure. It is considered as a rare disease, but a growing number of cases have been reported. The pathogenesis is hypothesized that widespread cancer emboli in microscopic pulmonary arteries activate fibrocellular intimal proliferation and thrombosis. Adenocarcinomas, especially gastric ones, are the major cause. Pathological diagnosis of PTTM is apparently easy. However, microscopic pulmonary tumor emboli are a sporadic finding of cancer patients, which can resemble PTTM when followed by intimal changes and other pulmonary diseases. The increase of misdiagnosis is a concern as PTTM becomes better known. The purpose of this study is to build diagnostic criteria of PTTM.

Methods: 24 cases diagnosed as PTTM in multiple institutions were collected and classified into two groups; (1) a definite group ($n = 13$), those who had been clinically diagnosed as PH, and (2) a suspicious group ($n = 11$), those who revealed respiratory symptoms but lacked clinical assessment of PH. As a control group, autopsy cases with PTTM-like lesions but who were lacking progressive respiratory symptoms were selected ($n = 7$). PTTM-like lesions in these groups was observed and counted.

Results: The numbers of PTTM-like lesions (fibrocellular intimal proliferation and thrombi with tumor cells) in the definite and non-PTTM group were 26.5-68.8 and 0.5-5.9/cm^2 area of lung specimen. In definite cases, peripheral arterioles smaller than 150 μm in diameter were predominantly involved. In the suspicious group, 7 of 11 cases had as many lesions (25.4-68.9/cm^2) in small arterioles as in the definite cases, while the remaining 4 had as few lesions (1.3-9.6/cm^2) as the non-PTTM group. Lymphangitis carcinomatosa was seen in these 4 cases.

Conclusions: We suggest that the pathological criteria of PTTM is as follows: 1) fibrocellular intimal proliferation and thrombi with tumor cells 2) involvement of microscopic pulmonary arteries and arterioles, predominantly small ones in alveolar septa (<150 μm in diameter), and 3) the innumerable spreading of more than approximately 100 lesions/5 cm^2 area of lung specimen.

1933P Autofluorescence: A new marker for identifying cancer stem cells (CSCs) in primary tumors

M. López Gómez[1], E. Casado[1], M. Muñoz[2], S. Alcalá[3], J. Moreno-Rubio[4], S. Salinas[2], F. Zambrana[1], A.M. Jiménez-Gordo[1], B. Sainz Jr[3]

[1]Medical Oncology/Precision Oncology Laborary, Infanta Sofia University Hospital, San Sebastian De Los Reyes, Spain, [2]Pathology, Hospital Universitario Infanta Sofía, San Sebastian De Los Reyes, Spain, [3]Biochemistry, Universidad Autónoma de Madrid, Madrid, Spain, [4]Precision Oncology Department, Infanta Sofia University Hospital, San Sebastian De Los Reyes, Spain

Background: CSCs, specifically their involvement in tumor progression and chemoresistance, represents one of the cornerstones of current cancer research. CSCs autofluorescence analysis has proven to be an accurate method to detect these cells in tumor tissues, offering an ideal setting to study the prognostic and predictive implications of this marker. More importantly, it also offers a new scenario for the development of personalized screening platforms, which could be widely universalized in the hospital setting. However, a straightforward and reproducible model for the identification and isolation of autofluorescent CSCs is still lacking.

Methods: Fresh tissues from 97 resected tumors were analyzed over 24 months. The percentage of CSCs in primary tumors was analyzed using autofluorescence, the result of Riboflavin accumulation in discrete cytoplasmic vesicles over expressing the ATP-dependent transporter ABCG2. These results were correlated with the established CSCs markers CD133 and CD90. Fumitremorgine C (FTC), a specific inhibitor of ABCG2, was used to verify the specificity of the autofluorescence observed.

Results: Autofluorescent cells (AC) in the epithelial cell compartment (EpCAM+) of the tumors analyzed were identified in 60% of the samples, primarily in gastrointestinal tumors (e.g. colon, gastric, rectal). AC also co-expressed other established CSC markers, such as CD90. Autofluorescence disappeared when tumoral cells were incubated with FTC confirming that the autofluorescence observed was ABCG2-dependent.

Conclusions: CSCs can be efficiently identified and isolated from gastrointestinal tumors using autofluorescence. The simplicity of this method would allow for its applicability to the broader scientific community in order to investigate the behaviour of CSCs in tumor progression and drug resistance. Moreover, upon their isolation, AC could be used in screening platforms to assess the chemoresistance of CSCs, thus allowing for the development of new molecular targeted therapies.

1934P NACC1 as a target of microRNA-331-3p regulates cell proliferation in urothelial carcinoma cells

K. Morita[1], T. Fujii[2], K. Shimada[3], H. Itami[1], K. Hatakeyama[1], M. Miyake[4], K. Fujimoto[4], C. Ohbayashi[1]

[1]Diagnostic Pathology, Nara Medical University, Nara, Japan, [2]Clinical Pathology, Nara Medical University, Nara, Japan, [3]Diagnostic Pathology, Nara City Hospital, Nara, Japan, [4]Urology, Nara Medical University, Nara, Japan

Background: microRNA (miRNA) constitutes a class of small non-coding RNAs, which are involved in cell proliferation, differentiation, and progression of tumors. miRNAs and their target molecules are utilized for molecular diagnosis of urothelial carcinoma. Nucleus accumbens-associated protein 1 (NACC1), one of several transcription factors, is constitutively expressed in the urothelium, wherein it regulates cell growth, senescence, autophagy, epithelial-mesenchymal transition. We previously reported that NACC1 is the target molecule of miR-331-3p and is associated with cell proliferation in prostate and cervical cancer.

Methods: Functional experiments involving miR-331-3p and its target molecule, NACC1, was analyzed using urothelial carcinoma (UC) cell lines, T24, UMUC6, and KU7. Quantitative reverse transcription polymerase chain reaction, and immunostaining were performed to evaluate the expression of miR-331-3p and NACC1 in UC derived from transurethral resection of bladder tumor (TUB-Bt) specimens.

Results: The MTS assay revealed that cell proliferation was significantly reduced after transient transfection of miR-331-3p precursor and/or NACC1 siRNA in UC cells. Cell senescence via cell cycle arrest at the G1 phase was induced by NACC1 inhibition. Immunohistochemistry with TUR-Bt specimens revealed that greater than 90% of both UC and normal urothelial cells were positive for NACC1 in contrast to no or limited expression in squamous cell carcinoma of the esophagus, cervix, and oral cavity. The NACC1 expression profile is not significantly associated with the pathological parameters including the pT stage.

Conclusions: The present results suggest that NACC1 regulated by miR-331-3p contributes to cell proliferation and is a new potential target molecule for the diagnosis and treatment of UC.

1935P Somatic-stem transition of tumor cells is a key link in the metastasis

N.V. Litviakov[1], M.K. Ibragimova[1], E.M. Slonimskaya[2], E.G. Skurikhin[3], M.M. Tsyganov[1], O.V. Pershina[3], I.V. Deriusheva[1], P.V. Kazantseva[2]

[1]Laboratory of Oncovirology, Cancer Research Institute, Tomsk National Research Medical Center, Russian Academy of Sciences, Tomsk, Russian Federation, [2]General Oncology, Cancer Research Institute, Tomsk National Research Medical Center, Russian Academy of Sciences, Tomsk, Russian Federation, [3]Laboratory of Regenerative Pharmacology, Goldberg Research Institute of Pharmacology and Regenerative Medicine, Tomsk National Research Medical Center, Russian Academy of Sciences, Tomsk, Russian Federation

Background: Hypothesis: Non-stem (differentiated and progenitor) cancer cells can form metastases by performing a reverse transition to cancer stem cells (CSC) in organs under the influence of cytokines (SST - Somatic-Stem Transition). The ability to SST is acquired in the course of evolution and is ensured by ectopic expression of several stemness genes (such as SOX2, OCT3/4, MYC, KLF4, NOTCH1, NANOG ...), due to amplifications in chromosomal regions of their localization (3q, 5p, 6p, 7q, 8q, 13q, 9p, 9q, 10p, 10q21.1, 16p, 18chr, 19p). If there are no amplifications in the tumor, it is not capable of SST and will not metastasize.

Methods: Breast cancer cells of two patients were used to induce a SST. One patient had amplifications of 3q, 6q, 8q, 9q, 10q22.1 in the tumor, in which the SOX2, MYC, KLF4, NOTCH1, NODAL genes were localized. The other patient had no amplifications of stemness genes in the tumor. Magnetic separation was used to extract populations of $EpCAM^+CD44^-$ tumor cells of both patients. SST was IL6-induced. Following this, the content of $EpCAM^+CD44^+CD24^-$ CSC was evaluated via flow cytometry, the increase in the number of cells after 3 passages, and the induction of mammospheres were measured.

Results: Under the influence of IL6, CSC emerged in the population of $EpCAM^+CD44^-$ tumor cells with amplifications, the number of cells after 3 passages increased by a factor of 33, and mammospheres of 7-15 cells were induced. While SST was not induced in the population of $EpCAM^+CD44^-$ tumor cells taken from the patient with no amplifications, the number of cells after 3 passages was increased only by a factor of 5 and no mammospheres were formed. Prospective trials: in 11 breast cancer patients with stemness genes amplifications in the tumor, neoadjuvant chemotherapy (NAC) eliminated the clones with amplifications. All patients have a metastatic-free survival. 11 patients had no amplifications and they did not undergo NAC. All patients had100% survival. 9 patients had no amplifications of their stemness genes before the treatment, and NAC induced their occurrence, 90% of the patients developed metastases.

Conclusions: We showed an SST in $EpCam^+CD44^-$ tumor cells, the importance of amplifications of stemness genes loci for its induction, and the importance of amplifications of stemness genes for metastasis.

1936P Survival effect of lncRNA-X expression in EGFR-mutant adenocarcinoma

Y. Nakano[1], K. Isobe[1], A. Kakimoto[1], H. Kobayashi[1], K. Kaburaki[1], G. Sano[1], S. Sakamoto[1], Y. Takai[1], N. Tochigi[2], T. Mikami[3], A. Iyoda[4], S. Homma[1]

[1]Respiratory Medicine, Toho University Medical Center Oomori Hospital, Tokyo, Japan, [2]Surgical Pathology, Toho University Medical Center Oomori Hospital, Tokyo, Japan, [3]Pathology, Toho University School of Medicine, Tokyo, Japan, [4]Chest Surgery, Toho University Medical Center Oomori Hospital, Tokyo, Japan

Background: Long non-coding RNAs (lncRNAs) are RNAs longer than 200 nucleotides that do not code for protein. Recently, the lncRNA-X was implicated in physiological and pathological processes such as proliferation, invasion, and metastasis. However, the roles of lncRNA-X in epidermal growth factor receptor (EGFR)-mutant lung adenocarcinoma are poorly understood.

Methods: qRT-PCR was used to measure lncRNA-X expression in 5 lung cancer cell lines (A549, H1299, PC9, H4006, H1975). Non–small cell lung cancer (NSCLC) cells with knockout of lncRNA-X were generated with a CRISPR-Cas9 system and used to investigate the effect of lncRNA-X on gefitinib-induced cell death in an MTT assay. We studied 21 patients with recurrent postoperative EGFR-mutant lung adenocarcinoma (exon 19 deletion in 11, L858R in 8, G719C in 2) treated with gefitinib during the period from January 2008 to January 2018. Relative quantification of lncRNA-X expression on real-time PCR analysis of formalin-fixed paraffin-embedded slides of surgical specimens was used to determine lncRNA-X expressions in tumors and adjacent normal tissues.

Results: lncRNA-X expression was greater in the cell lines harboring EGFR exon 19 deletions and L858R (PC-9, H4006, H1975) than in those without EGFR mutation (A549, H1299) ($p < 0.001$). H1299 cells with lncRNA-X knockout were more sensitive to gefitinib. lncRNA-X expressions were significantly greater in NSCLC tumors than in adjacent normal tissues ($p < 0.01$). Patients with high lncRNA-X expression in tumors had significantly shorter progression-free survival (PFS) after gefitinib therapy and overall survival than did those with low expression (median PFS: 304 vs 1125 days, $p = 0.046$; MST: 1271 vs 1876 days, $p = 0.014$).

Conclusions: lncRNA-X expression in EGFR-mutant adenocarcinoma is associated with shorter overall survival and shorter PFS after gefitinib therapy.

CN5 Patients: Power sources for cancer nurses

C. Beisel

Paediatric Oncology, Haematology and Immunology, Heidelberg University Hospital, Heidelberg, Germany

Background: It's obvious that cancer nurses have to deal with a lot of different burdens during their everday work. These burdens are obvious and very well known. If one has an overall view at cancer nursing staff at a ward one will recognise two huge groups: Beginners, which passed their exam recently and colleagues, that are working with cancer patients for more than 15 years and often until retirement. The question which arises is therefore why can these "senior nurses" resist these strains and stay healthy?

Methods: Study of literature focussing on • spiritual, physical and psychological needs • groups (especially cancer nurses) that are known for be on stress • published European Standards regarding physical burden at workplace Own empiric cases from working life, which had a lasting influence Informal interviews with colleagues.

Results: The intensity of work has increased in most clinics: pressure on time, more severe ill patients, complexicity of treatment. The working conditions deteriorated considering payment, job confidence, team work and support. Nevertheless, cancers nurses do stay in their workplace for a very long time because of • spiritual background, rituals and general upbringing • resilience • inspiring contacts and interaction with their patients.

Conclusions: With all the burden of and to the care of the patients and their relatives: it is more than coping with their needs. They also give back enormous energy, provided one give space to the moving moments and allow it to draw strength from this particular source.

CN6 BRAF/MEK-inhibition for patients with metastatic melanoma: Towards patient-centered care

J.J. Koldenhof[1], S.C. Vervoort[1], C.A. Nierop[2], K.P. Suijkerbuijk[1]

[1]Medical Oncology, University Medical Center Utrecht, Utrecht, Netherlands, [2]Master Advanced Nursing Practice, HU University of Applied Sciences, Utrecht, Netherlands

Background: The incidence of melanoma – the deadliest form of skin cancer - is steadily increasing. Over the last few years, treatment options for inoperable or metastatic melanoma have increased. Treatment with BRAF/MEK-inhibitors (BMi) induces fast responses in the large majority of patients with BRAF-mutant melanoma. As a result, BMi are often used as a palliative treatment for patients with aggressive metastatic melanoma. A successful palliative treatment - a treatment in which life is prolonged and the patient experiences an acceptable quality of life - requires intensive support. Nursing interventions are aimed at empowering people and helping them to achieve, maintain or (re)acquire their independence. This Dutch study was set up to collect building blocks in order to develop an evidence-based nursing intervention that supports patients during palliative treatment with BMi.

Methods: Using the van Meijel model, a problem analysis, a literature review, a patient needs analysis and a current practice analysis, were performed. A literature search was performed to collect available, appropriate interventions. Nationwide questionnaires – in patients as well as in nurses - were used to gain insight into patient needs and the current practice.

Results: The problem analysis and results of the literature review showed that patient education, disease and/or treatment related symptoms and support with self-management are key components during treatment with BMi in adult patients with metastatic melanoma. When considering nursing care, the available literature focusses on promoting adherence in particular.

Conclusions: Treatment with BMi is a life-prolonging treatment. As a result, medication adherence seems more important in relation to symptom burden and quality of life than to the effectiveness of the treatment alone. In conclusion, future nursing interventions should not only focus on treatment adherence, but also on quality of life and quality of dying, with respect to the patient's needs and wishes.

CN7 Perceptions of rural nurses extending their role to administer chemotherapy

Q. Alnasser[1], K. Cameron[2], J. Prouse[3]

[1]Oncology/Nursing Development and Saudization, King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia, [2]Nursing Development, Adelaide University, Adelaide, Australia, [3]Oncology Department, Royal Adelaide Hospital, Adelaide, Australia

Background: Nurses in rural regions of South Australia are currently administering chemotherapy in centres where this was not previously the case. To prepare these nurses; a state-wide chemotherapy education and assessment programme was implemented in 2013. This research project explored the perceptions of nurses working in level-one rural centres administering low-risk chemotherapy protocols. The study explored how registered nurses who administer chemotherapy in low-risk chemotherapy services in rural SA perceive their expanded roles and whether they felt equipped with the knowledge and skills required to undertake them.

Methods: This is a qualitative study. Individual interviews were conducted with eight registered nurses working in low-risk chemotherapy centres in rural settings. The data analysis methods were based on critical social theory.

Results: Four main categories of findings are identified: 1) role extension, preparedness and self-confidence; 2) chemotherapy services in rural areas; 3) power relationships, referrals and knowledge sustainability; and 4) communication with other cancer settings and professionals. Overall, participants highly valued the service as valuable support for rural patients with cancer, but they identified areas of concern, including the rural nurses' roles in cancer care, the need to maintain knowledge and skills and to establish their role in referral and follow-up processes.

Conclusions: Participants expressed their perceptions of their role. Then, through critical theory, their voices were revealed, expressing their needs and suggestions for changing and improving their role and the service.

CN8 AYA cancer nursing, an emerging sub-speciality: The first book about AYA cancer nursing, edited and authored by nurses

S. Smith

Nursing and Clinical Services, Teenage Cancer Trust, London, UK

Background: During the last twenty years, adolescents and young adults with cancer have gained increased attention in healthcare. The body of knowledge is growing accordingly. Nurses who have led the way amongst the now widening circle of professionals engaged in providing specialist care for young people with cancer are now ready to describe their contributions within education, clinical nursing, rehabilitation, research and leadership.

Methods: To provide healthcare professionals with knowledge about the distinct developments made within AYA cancer nursing internationally a book entitled Nursing Adolescents and Young Adults with Cancer. Developing knowledge, competence and best practice is under production.

The book is based on international collaboration between the publisher Springer, the two editors and an authorship of nurses with thorough knowledge and expertise in AYA cancer care from the Netherlands, Belgium, Australia, Ireland, Norway, Denmark and England.

Results: The book will be published by Springer in 2018. It contains chapters describing 1) The history of the speciality and AYA nursing competence development, 2) Approaches, Interventions and Innovations in AYA cancer nursing and 3) Aspects and challenges for future AYA cancer nursing.

Conclusions: The authors offer insights into the development of AYA cancer care; why it matters; how it should be delivered; and how it might be done better – and with recognition of the unique needs and wants of each young person at the centre of it all.

CN9 Nurse led follow-up for CML patients on oral cancer treatment

S. De Wilde, J. De Munter, M. Quaghebeur, D. Mazure, A. De Pauw, B. Casteels
Hematology, University Hospital Ghent, Ghent, Belgium

Background: Chronic myeloid leukemia (CML) is a bone marrow disorder accounting for 15% of newly diagnosed leukemia in adult patients (Rychter A et al. 2017 & Trivedi D et al. 2014). The introduction of tyrosine kinase inhibitors (TKIs) has changed the CML treatment significantly. Patients' concerns have shifted from reduced life expectancy to management of long-term toxicities and improvement of quality of life (QoL) (Isfort S & Brümmendorf TH 2018). In 2016 Moulin et al. showed that closely monitoring patients affects adherence. Poor adherence is associated with greater overall health care utilization and medical costs in CML (Jabbour EJ et al. 2012). An increase in the patient health is expected from improvements in adherence.

Methods: After receiving information from the doctor, patients remember approximately half of the information provided (Hillen MA et al. 2015). The hematology department in UZ Ghent has an interdisciplinary approache to CML patients. In a nurse led consultation patients who start with TKIs receive additional written information. The purpose is to reduce the information gap and manage patients concerns. Over time the nurse led consultation transforms to monthly telephone follow-up. This includes the assessment of the patient's condition, adverse events (AEs) and the influences on their QoL. Individual nurse led consultation supports a solid health care provider-patient relationship, offers patient tailored care and is ideally placed to detect psychological and social problems. Referral to other health care providers must always be based on shared decision making.

Results: The aim is to educate the patients and offer psychosocial support. By creating a strong health care provider-patient relationship the goal is to make sure the patient feels free to talk about any issues. This also empowers the patient, improves adherence and helps to detect and control AEs prematurely.

Conclusions: An interdisciplinary approach and establishing a care pathway is a necessity to streamline the patient treatment process. A more structured questionnaire is needed to improve the telephone nurse led follow-up and the handover to the doctor. After implementing such a structured tool the effectiveness of the project must be reviewed by using questionnaires that assess the adherence and QoL.

CN10 Introducing a new role in cancer care, coordinating contact nurses: Patient-reported evaluation

B. Westman[1], H. Ullgren[2], L. Sharp[3]
[1]Stockholms Läns Landsting, Regional Cancer Center Stockholm Gotland, Stockholm, Sweden, [2]Theme Cancer/ Regional Cancer Center, Karolinska University Hospital-Solna, Stockholm, Sweden, [3]Cancer Care Improvments, Regional Cancer Center Stockholm Gotland, Stockholm, Sweden

Background: According to the Swedish National Cancer Plan, every cancer patient is entitled to supportive care strategies such as a contact nurse (CN) and a written care plan (IWCP). The National Cancer Plan also highlights the importance of patient's right to actively participate in care planning and decision-making regarding their care. A new cancer nursing role, coordinating contact nurses (CCN)s, was initiated in the Stockholm-Gotland region, Sweden 2015. The CCNs, with an overarching leading role in the cancer process, work on a regional level with co-operation between different care-givers aiming to reduce inadequate continuity and fragmentation in cancer care and improve person-centered care. The CCNs are also supposed to support CNs with implementation of IWCPs and routines for safe handover procedures where the patient actively is involved in the process. We have evaluated the impact of CCNs from a patient perspective with baseline and follow-up data. The aim was to evaluate the usefulness of the new role from the patients' perspective.

Methods: Data was collected through a project-specific questionnaire (including questions on information exchange, continuity, patient involvement, collaboration and communication) from patients diagnosed in 2014 ($n = 869$), before the implementation of the CNN role, and follow-up data from patients diagnosed in 2016 ($n = 1003$).

Results: Patients report significantly higher access to CN (2014 53%, 2016 66%, $p = <0.0001$) and IWCP (2014 40%, 2016 54%, $p = 0.0001$) after the introduction of the CCN role. Patients also report higher satisfaction with their involvement on decisions in care (2014 29%, 2016 34%, $p = 0.042$).

Conclusions: Experiences so far are that the CCNs have a unique opportunity to impact and improve cancer care which has been difficult previously for the clinical staff.

CN11 The role of the nurse in the detection of geriatric frailty and the risk of chemotherapy toxicity in elderly patients with cancer: Preliminary study

E. Mahía[1], G. Simó[1], E. Heras[2], M. Pascual[2], F. Cobo[1], J. Pujadas[1], S. Albiol[1]
[1]Oncology-Hematology Unit, Servei Andorra Atenció Sanitaria, Escaldes-Engordany, Andorra, [2]Internal Medicine Service, Servei Andorra Atencio Sanitaria, Escaldes-Engordany, Andorra

Background: The increase in life expectancy along with the higher incidence of cancer with age motivates the need for a model of care to optimize the management of elderly patients with cancer and avoid complications associated with treatment. We used two questionnaires: the G8 Oncodage that screens frail elderly patients and the Hurria that predicts the risk of chemotherapy toxicity; both are vulnerability screening tools that help establish the most appropriate treatment in oncogeriatric patients. We present our initial experience with this approach in a single institution in Andorra.

Methods: From November, 2017 to April, 2018, the oncology nurse evaluated twenty-six patients with cancer $\geq$70 years of age. The tools used are short questionnaires (8 items in the G8 and 16 items in the Hurria), clear, simple and quick to perform. They are always used before starting the treatment. Patients with scores G8 $>$ 14 and Hurria $<$ 6 are considered fit for standard oncologic management. Patients with scores G8 $\leq$ 14 or Hurria $\geq$ 6 are considered at risk of vulnerability and then an integral geriatric assessment (CGA) is performed. The care plan is established by a multidisciplinary care team.

Results: Twenty-six patients were evaluated, with a majority of males (81%) and the average was 75.9 years (range 70-86 years). A score G8 $\leq$ 14 or Hurria $\geq$ 6 occurred in 24 (92.31%) and 22 (84.62%) patients, respectively, 5 were women and 19 men. Two patients with low risk of chemotherapy toxicity (1 woman and 1 man), 15 patients with moderate risk (3 women and 12 men) and 7 at high risk (1 woman and 6 men) were detected. 24 patients were referred to the gerontologist for CGA. Half of patients received a modified treatment.

Conclusions: According to preliminary results, the use of the two questionnaires would allow to select those patients who could benefit from CGA and a personalized treatment. The study proposes a model of nurse-led oncogeriatric screening that could offer objective and useful information in the decision making of the therapeutic plan in elderly patients with cancer. Due to the limited number of patients included, it is necessary to continue the longitudinal and prospective study to draw definitive conclusion.

CN12 Systemic anticancer therapy administration safety

S. Toland[1], A. Simons[2]
[1]Oncology, Birmingham City University, Birmingham, UK, [2]Birmingham City University, Birmingham, UK

Background: SACT safety in administration and waste disposal Our original article explored the immediate adverse effects experienced by nurses during the administration of systemic anti-cancer therapy (SACT), specifically cytotoxic chemotherapy, and whether closed systems are being used tominimise exposure risk. Many SACT agents are known to be carcinogenic, teratogenic and mutagenic and this has led to concerns relating to the increased number of healthcare workers potentially exposed to these agents.

An anonymous online survey was designed, made up of four questions, to elicit whether adverse effects were experienced by nurses during preparation, administration or following administration of chemotherapy. A total of 46% of respondents stated that they experienced some form of adverse effect either during preparation, administration or following administration of SACT. More formal research is required in this area to explore the relationship between exposure to SACT and perceived adverse effects in healthcare workers administering SACT. As a follow up to this survey, we are going to develop a further survey to elicit healthcare professionals awareness of SACT exposure risk, education / training provision and current practices in relation to SACT administration and waste disposal.

Methods: In our original study, a short anonymous online survey was designed made up of four questions to elicit whether adverse effects were experienced by nurses during preparation or administration or following administration of chemotherapy. This was distributed via social media and networking contacts. For our follow-up survey, we will replicate this method, including questions about awareness, education / training and current practice in relation to SACT administration and waste disposal

Results: of the original study were obtained through the questionnaire responses which were analysed and presented using a quantitative approach. The follow up survey will require a mixed methods approach to analysis to elicit greater depth of information from participants.

Conclusions: Following quantitative analysis of our original survey, we concluded that further research was required in this area, hence the need for additional data collection via a further online survey.

CN13 Increasing incidence and prevalence of immune-related adrenal insufficiency in patients with cancer: The role of the nurse practitioner for early recognition and management

C. Roth, M. Labots, A.J. Eertwegh

Medical Oncology, Vrije University Medical Centre (VUMC), Amsterdam, Netherlands

Background: Immune checkpoint inhibitors have improved the outcome of patients with advanced cancer significantly over the last decade. Disadvantageous effects of these novel treatments include auto-immune toxicities, named immune-related adverse events (irAEs), that most commonly affect the skin, gastrointestinal tract, liver and endocrine glands. Immune-related endocrine toxicities that involve the pituitary gland or adrenal glands may cause adrenal insufficiency (irAI), which can be life-threatening if not early recognized and managed.

Due to the expanding number of novel immunotherapies and indications, the number of patients with irAI will increase. We report a clinically applicable algorithm, with a key role for the nurse practitioner (NP), to manage irAI and to improve safety using a system-focused approach.

Methods: A collaboration between NP, oncologists and endocrinologists, taking input and perspectives from patients into account, was used to develop consensus regarding irAI management. Based on literature, institutional experience and group consensus, a clinically applicable algorithm was created.

Results: Team members were educated on algorithm application and to improve safety. The NP was the first point of call and coordinated collaboration between patient, medical specialists and family physician. The NP was appointed a key role for patient education and information. Patients were educated to recognize symptoms of adrenal insufficiency and react promptly by increasing the dose of the corticosteroid substitution therapy. Patients were encouraged to contact the NP in case of problems or questions about the prophylactic dose of corticosteroids for stressful events.

Conclusions: Due to the increased use and the long-term efficacy of immune checkpoint inhibitors in patients with cancer, the incidence and prevalence of immune-related adrenal insufficiency (irAI) will increase. The here reported algorithm provides a streamlined approach for the management of irAI that is expected to improve safety and quality of life of patients.

CN14 Experiences from a new advanced cancer nursing role in Sweden: An analysis based on EONS Cancer nursing education framework using the Delphi method

H. Ullgren

Theme Cancer/Regional Cancer Center, Karolinska University Hospital, Stockholm, Sweden

Background: A new advanced nursing role - Coordinating contact nurse (CCN) were implemented as a pilot in 2015, aiming to improve care transitions, collaboration and communication between different teams, as well as strengthening the nurses and clinicians in the whole team. The CCNs has a regional role over one patient trajectory within the Stockholm-Gotland region. When interviewing patients at start of the project, many patients wished for more support regarding coordination and felt they had to be responsible themselves for important clinical information exchange. Collaboration and communication between the teams within the acute hospitals different disciplines, as well as acute and palliative care (PC) were sub-optimal, and it affected for example emergency admissions from PC to acute care. A baseline survey was performed before implementation of the CCN project. It showed that some of the supportive care resources were accessible for only half of the patients.

Methods: Experiences from this new role are currently analyzed, based on the 8 modules included in EONS Cancer Nursing Education Framework. Data is analyzed using the Delphi process including different groups of staff and patient representatives.

Results: Preliminary results show that the CCN role cover all 8 modules in the framework and indicate that the CCN role fulfill the criteria described for advanced cancer nursing roles. The practice competencies have been useful both in recognizing what cancer nurses do, and highlights areas in need of development.

Conclusions: Patient-reported evaluation of the CCN role is needed and ongoing. Preliminary data shows significant improvement in areas such as perceived information about self-care and access to supportive care. This new advanced cancer nursing role could contribute to improved experiences and outcome for cancer patients. If formally established, the CCN role could be an important clinical career opportunity for Swedish cancer nurses.

CN15 Opinions and experiences of patients receiving oral chemotherapy: A qualitative study

S. Kutlutürkan[1], Ö. Yurtal[2], K. Kirca[3]

[1]Nursing, Gazi University, Ankara, Turkey, [2]Nursing, Gazi Üniversitesi Sağlik Uygulama ve Araştirma Merkezi Gazi Hastanesi, Ankara, Turkey, [3]Nursing, Kirikkale University, Kirikkale, Turkey

Background: The importance of oral chemotherapy in cancer patients is increasing day by day. Oral chemotherapy drugs provide many advantages in terms of social and economic. The desired impact in oral chemotherapy treatment can be achieved with patient adherence. The aim of this study was to investigate the opininons and experiences of who are receiving oral chemotherapy.

Methods: This research was designed as a qualitative study. The study is conducted on eighteen patients who were admitted to the oncology clinic of a university hospital in January 2018. The patients who agreed to participate in the study were included in the study. There is no limitation in the type of cancer disease in the practice of the study. In this study a semi structured interview form was used, this form created as a result of review of the literature. Data were collected through face-to-face individual interviews. All interviews were recorded with voice recorder with permission from the patients. The data obtained from the interviews were transcripted after each interview and evaluated with the thematic content analysis method.

Results: As a result of the content analysis identified five main themes. These themes were prescribing oral chemotherapy, administering oral chemotherapy, side effects and control of oral chemotherapy, approach of health professionals, support of family and relatives. In the interviews, the majority of patients were using capecitabine as oral chemotherapy. Patients stated that health professionals for drug use may differ in their recommendations. patients stated that they had problems such as constipation, nausea / vomiting, change of taste, fatigue and mouth instability, and that information on side effect control was made by the physician at the beginning of the treatment.

Conclusions: Interdisciplinary approaches are needed to increase compliance of patients with treatment, to monitor treatment side effects and to ensure safe use of medications. It is necessary for nurses to take an active role in patient education and counseling in order to determine the weaknesses and opportunities for recovery of patients during oral chemotherapy.

CN16 Introducing cancer nurse led consultations to improve sexuality & fertility outcomes for adolescents and young adults (AYAs) with an hematological disease

J. De Munter[1], S. De Wilde[2], M. Quaghebeur[2]

[1]Cancer Centre, Ghent University Hospital, Ghent, Belgium, [2]Hematology, Ghent University Hospital, Ghent, Belgium

Background: With improving survival rates among AYAs with cancer, sexuality and fertility are important quality of life (QoL) concerns before, during and after treatment. Healthcare providers aren't always knowledgeable about infertility risks associated with prescribed therapies. Cancer nurses are often the first professionals to identify and address sexuality concerns. Different barriers are the reason of not addressing sexuality concerns and fertility preservation options prior treatment. It is crucial that AYAs are well informed prior treatment to support them in their decision-making about fertility preservation options.

Methods: An Interdisciplinary team developed an evidence-based care pathway for Hodgkin's disease. Healthcare providers from different staffs shared knowledge, expertise and skills to have positive impact on young patients survivorship outcomes. Standard infertility counselling was included prior to treatment for AYAs and a nurse led consultation prior therapy gives the opportunity to discuss important topics such as sexuality.

Results: Implementation a care pathway increased the awareness about discussing sexuality and fertility preservation options among all healthcare providers within the haematology department. Collaboration between fertility specialists, physicians and cancer nurses will improve reproductive outcomes in AYA cancer care. Systematic feedback after fertility preservation procedures is helping to reduce reproductive concerns. Discussing sexuality during a nurse led consultation results in a better understanding of the effects of the disease and treatment and will improve QoL.

Conclusions: Cancer nurses have a key role in discussing sexual concerns. A cancer nurse led consultation through the whole treatment process allows patients the opportunity to discuss sexual issues and concerns. Knowing that they can have their questions answered, makes them feel more confident and comfortable during treatment. Multidisciplinary care pathways are needed to establish systems to ensure that fertility is adequately addressed and comprehensive fertility counselling is offered to all AYAs prior to therapy and during survivorship.

CN17 Standardising the psychosocial assessment of oncological patients at Donostia university hospital

E. Uranga, A. Valverde, M.A. Landa, M.J. Esnaola, L. Basterretxea, G. Agirre, O. Aizpurua, A. Barrio, M. Centeno, I. Delgado, G. Jauregui, L. Moreno, M. Murguiondo, J. San Francisco, H. Telleria

Oncology, Hospital Donostia, San Sebastian, Spain

Background: A cancer diagnosis often causes an emotional impact with signs of anxiety, uncertainty and subjective discomfort. It is necessary to identify and assess emotional discomfort to offer quality treatment articulated around the patient and his / her demand. The design of a questionnaire that is easy to use and understand, allows the detection of patients susceptible to referral to the Psycho-oncology Unit (POU) The POU consists of a Psychiatrist and a Nurse with specific training in Psycho-oncology.

Methods: Prepare a PAQ that includes: Evaluation of emotional distress assisted by visual analogue scales (VAS); Modified Gijón scale (sociofamilar assessment scale); previous use of psychoactive drugs - Include PAQ in the first nursing visit - Quick referral to POU - Interview with psycho-oncology nurse - Valuation, diagnosis and treatment planning by POU - Data recording.

Results: Patients with a positive PAQ are referred to the POU where the liaison nurse performs an interview with the patient and / or family. The nurse collects data on psychobiography, oncological disease, psychic sphere, frequent affections, previous contacts with psychologists / psychiatrists and treatments with psychoactive drugs. The POU will offer the patient the most appropriate resource for their needs (Psychotherapy, Psychopharmaceuticals, Social Work Service).

Conclusions: The inclusion of the PAQ in the first visit of nursing allows the detection and early treatment of disorders in the psychosocial area. We achieve an optimal use of resources, a greater adherence to the proposed oncological treatment, alleviate problems that are found throughout the oncological treatment and improve the quality of life of our patients by reducing emotional discomfort.

CN18 Are there differences between nurses' and patients' perceptions of cancer patients' quality of life in Greece?

M. Lavdaniti, E. Gogou, G-C. Karagiannidou, M. Delibaltidou, E. Zioga, K. Marmara, E.C. Fradelos

Nursing, Alexander Technological Educational Institute, Thessaloniki, Greece

Background: Cancer and its treatment affect negatively patients' quality of life. Nurses and their perceptions about patient quality of life should be vital in order to provide high-quality care and increase patients' QoL. The aim of this study is investigate nurses' and patients' perceptions about cancer patients' quality of life.

Methods: This was a non-experimental and descriptive study. It was conducted in two large hospitals in a major Northern Greek city. The subjects were 50 pairs of cancer patients and their nurses. Patients and nurses had completed the Greek Version of the World Health Organization quality of life (WHOQoLBREF) questionnaire, separately

Results: The majority of patients was female (50%) with mean age 59.8 years (S.D. 15.1). Regarding nurses' demographic characteristics 88% was female with mean age 45.8 years (S.D. 8.8). According to the patients' perceptions the mean of physical health domain was 14.8 (S.D. 3.2), psychological domain was 15.1 (S.D. 2.6), social relationships domain was 14.2 (S.D. 3.7) and environment domain was 15.7 (S.D. 2.3). The corresponding scores of nurses were 12.6 (S.D. 1.9), 12.9 (S.D. 2.6), 13.1 (S.D. 3.4), 14.1 (S.D. 2.9) respectively. Wilcoxon test was shown statistically significant differences between patients' perceptions and nurses' perceptions in 3 domains (physical health ($p = 0.001$), psychological domain ($p = 0.001$), environment domain ($p = 0{,}003$) except from social relationships. Specifically, the quality of life was scored lower by nurses than the corresponding drawings of patients. Additionally, correlation was found between the time which nurse spends with patients and psychological domain ($r = 0.313$) and environment domain ($r = 0.372$) respectively.

Conclusions: There were differences between Greek cancer patients and their nurses about cancer patients QoL. The results of the present study stress the need for further research in order to increase nursing understanding about patients' life and enhance holistic nursing approach.

CN19 How an empowerment program can touch cancer survivor's life by improving post-traumatic growth?

Y.S. Uzar Ozcetin

Psychiatry Nursing, Hacettepe University Faculty of Nursing, Ankara, Turkey

Background: Cancer experience can cause traumatic symptoms with higher levels of stress. Although cancer has been traditionally seen as a destructive illness, in recent years, this perspective has been abandoned, and it is being argued that coping with cancer and developing growth is possible. Research in this area has supported this new perspective, and the results have shown that cancer does not always contain traumatic effects and people can also have positive attainments during this process. Re-meaning of life during cancer process enables posttraumatic growth (PTG), which improves interpersonal relations, inner resurgence, and deeper spirituality.

Methods: Researcher has studied on an empowerment program in her PhD thesis and keeps working on this area. Hence, the aim in this study is to point out the effects of an empowerment program to improve PTG of cancer survivors. Literature review and sharing experience in such works.

Results: Having resilience in cancer experience help people to understand the value of life, find new meanings, determine the priorities in life, and reach spiritual well-being. Re-meaning of life during cancer process enables posttraumatic growth, which improves interpersonal relations, inner resurgence, and deeper spirituality. In this regards, using an empowerment program can be an effective way in helping the participants recognize the nature of the problem in their life, and created a safe and therapeutic environment to improve their social skills. Also, such programs refer to the use of not only intrinsic sources, such as self-efficacy and self-esteem, but also extrinsic ones, such as social support and social coherence. On the other hand, providing supportive activities/programs are valuable to help them learn from others who had similar experiences; in this way, they can feel understood, accept the process with its positive and negative consequences, and have better coping strategies.

Conclusions: Empowerment program could improve both PTG in cancer survivors and nurses caring for cancer survivors can use such programs to improve PTG and resilience, in addition to the usual medical care in cancer. By this way, cancer survivor can have enough psychological support which usually forgotten among routine medical care.

CN20 Organising a general oncology nursing outpatient clinic

C. Lundgren[1], A. Lagerquist[1], M. Högman[2], U. Östlund[3]

[1]Oncology, Sjukhus Gävle, Gävle, Sweden, [2]Medical Sciencies, Uppsala University, Uppsala, Sweden, [3]Centre for Research and Development, Region Gävleborg, Gävle, Sweden

Background: The complexity of living with, being treated for or dying from cancer present numerous issues and needs for patients and their families. Many those are appropriately dealt with based on oncology nursing. Despite this most general oncology outpatient clinics in Sweden are physician-led. The development of general nurse-led cancer care services has been suggested to improve the care of cancer patients. Consequently a general oncology nursing outpatient clinic has been implemented. The aim of this study was to describe the feasibility of organizing an oncology nursing outpatient clinic, its implementation and outcomes.

Methods: This study had a descriptive multi methods design. Qualitative data to describe nurses, physicians and managers perspectives was collected and analysed with qualitative content analysis. Quantitative data was collected for referral, for patients' problems being within nurses' competences and for patient views of the quality of the care they received.

Results: The oncology nursing clinic became a valid complement to the existing organisation. The use of the nursing competence in a more structured way resulted in greater possibilities for patients to get relevant care for their problems. The continuity of and access to care improved. Experiences from patients can be summarised as better quality care. The implementation of the clinic was described as a way of "putting the right competence in the right place". The clinic was both part of the oncology team and had an autonomic function. For most of the patients problems presented the nurses could independently solve them, for some they had to contact the oncologist. Before the implementation of the clinic most expectations were high and at the follow-up mostly described as fulfilled. The implementation can be seen as a process with some difficulties that had to be solved but the use of the clinic has constantly increased over time.

Conclusions: The implementation of a general oncology nursing outpatient clinic is a feasible way to improve patient care. Due to the positive results the clinic is now a permanent part of the organisation. The implementation process could have been improved as it took nearly a year to get the oncology nurse outpatient clinic to run efficiently.

CN21 Job content of advanced practice nurses in Flanders

E. Decoene[1], A. Van Hecke[2]

[1]Cancer Center, Ghent University Hospital, Ghent, Belgium, [2]Public Health - UCVV Nursing Science, University Ghent, Ghent, Belgium

Background: Current evolutions in medicine, the emphasis on cost-effectiveness in healthcare and the increase of complex healthcare needs addressed the need for highly educated and specialised nurses, such as advanced practice nurses (APN). By means of scientifically specialised knowledge, skills and competences, APN should enhance expansion, advancement and innovation in nursing care.

Methods: A cross sectional design was used to explore the job content performed by APN. 58 APN in Flemish hospitals participated. A validated self-reported questionnaire was used, combined with non-participant observational data (40 days).

Results: APN in Flanders are mainly experts in the domain of oncology, pain and wound care. Based on the self-reported data, the job content of APN is diverse and is linked with the APN roles as described by Hamric. 94.8% are involved in professional development and teaching of nurses in the hospital. 65.5% develops a nursing consultation and 63.8% performed these consultations autonomously. Medical delegated tasks are performed to a lesser extent. 87.9% of APN reads and evaluates scientific literature to enhance evidence based nursing in practice. Initiating and executing domain-specific nursing research is performed by 70.7%. 91.4% participates in quality improvement projects in their specific domain. APN actively participate in international and national professional organizations. There is a limited participation in working groups within governmental agencies, national and international advisory boards. Based on observational data, APN spent the following working percentages to: clinical expert (33,2%), educator (11,7%), innovator and implementation (7,3%), research (7,2%), leader and policy advisor (5,1%) and facilitator in ethical decision making (0,1%).

Conclusions: APN are 'young' professionals, in age and in working experience in the specialist domain. They are less involved in policy-making and work related to extramural activities. The focus is mainly on clinical expert care. Although APN can significantly contribute to high-quality, evidence-based patient care by providing training and coaching to nurses, initiating and guiding quality projects, conducting research and translating research findings into practice, there is room for further growth.

CN22 Developing and testing a theory-based e-learning intervention to enhance healthcare professional's self-efficacy when supporting parents newly diagnosed with cancer who have dependent children

C.J. Semple[1], E. McCaughan[2]

[1]Institute of Nursing and Health Research/Cancer Services, Ulster University/South Eastern Health and Social Care Trust, Belfast, UK, [2]Institute of Nursing and Health Research, Ulster University, Coleraine, UK

Background: Families impacted by parental cancer need advice from healthcare professionals on how to communicate this devastating news to their children and support them while having treatment. Despite the evident need, this support is often inadequate, due to lack of confidence and training for healthcare professionals. To address this gap, a theory-based e-learning intervention has been development using a 'person-based approach', aimed at enhancing healthcare professionals' self-efficacy when supporting parents newly diagnosed with cancer who have dependent children.

Methods: Using the person-based approach two qualitative focus groups (n = 23) were conducted at the planning phase, with frontline oncology professionals. During the development phase, an iterative approach was adopted incorporating 'think aloud' interviews (n = 14) for usability testing, hence moving between data collection, analysis and modifications of the e-learning intervention. The data was analysed using thematic analysis.

Results: Drawing upon existing evidence and data generated from the two focus groups at the planning phase, an e-learning prototype was developed. Three cycles of refinement followed with user retesting, using 14 think-aloud interviews. Key themes identified during think-aloud interviews which led to modifications included: 'navigational difficulties' and 'enhancement of content and visibility'. Four positive themes were also reported to include: 'appropriate use of children's drawings', 'superior look and feel', 'value of the 'Talking, Telling and Sharing framework'' and 'pedagogical methods to improve impact'.

Conclusions: This study provides a detailed description of how the person-based approach was used to plan, develop and test an e-learning intervention, aimed at improving its acceptability, feasibility and effectiveness during implementation. Providing a detailed description of the foundations that underpinned the development of this e-learning intervention, promotes transparency in the planning and design process, therefore aids methodological rigour.

CN23 Supporting melanoma patients and their carers: A qualitative exploration of social interaction between patients, carers and healthcare professionals

J. Bird[1], M. Nolan[2], S.J. Danson[1]

[1]Academic Unit of Clinical Oncology, University of Sheffield, Sheffield, UK, [2]School of Nursing & Midwifery, University of Sheffield, Sheffield, UK

Background: Melanoma incidence continues to rise in Europe, the USA and Australia with mortality rates remaining relatively stable, meaning more patients undergoing surveillance. Treatments may include multiple surgeries, BRAF/MEK inhibitors and immune therapies. Clinical Nurse Specialists (CNS) provide support for melanoma patients and their carers in the UK. The aim of the overall study was to explore the changing experiences and support needs of melanoma patients and their carers throughout the disease pathway. Here we report the specific interactions between healthcare professionals and patients.

Methods: The study employed a qualitative methodology using a constructivist grounded theory approach. Theoretical sampling was used to recruit 17 melanoma patients from outpatient clinics within a UK teaching hospital. 11 carers and 11 Healthcare professionals (HCPs) participated with patient agreement. Patients and carers were interviewed in-depth, up to 6 times over 2 years and HCPs were interviewed on 2 occasions. Initial topics were modified as interviews took on an emergent design. Focus groups were conducted at the end of data collection: one with patients and one with CNSs.

Results: Owing to differing job titles used by nurses in the UK, not all patients recognised that there was a nurse available to support them. Patients and carers needed to build a trusting relationship with nurses in order to use them for support with nurse-led clinics providing continuity. Patients, carers and CNSs agreed on important points in the pathway resulting in four key phases: diagnosis and initial treatment, surveillance, metastatic disease and bereavement. Patients and carers did not appear to use the service more for knowing it was there, but it provided reassurance. Stage IV disease had the greatest input, with access to community services.

Conclusions: Developing a trusting relationship with a nurse enabled patients to feel supported. This was facilitated by the continuity provided in nurse-led clinics but differing job titles could create a barrier to patients understanding that there was someone they could contact with concerns or worries. CNSs recognised the key time points where support was most needed.

CN24 Assessing the effect of telephone support on patients with myeloma multiple (MM) in the Catalan oncology institut in Girona

C.L. Puigmarti, M. Sole, G. Osca, Y. Gonzalez, N. Kelleher

Haematology, Catalan Institute of Oncology (ICO)-Hospital Universitari Josep Trueta, Girona, Spain

Background: MM is an incurable plasma cell malignancy characterized by excess paraprotein secretion with secondary organ effects including bone destruction and anaemia, renal damage and immune system impairment. MM presents as a relapsing-remitting illness throughout the patient's life, resulting not only in individualized management but also in complicated treatment with continuous revision and management of the cumulative secondary effects. MM is diagnosed at a median age of 69 years and due to the increase of the population age, it is expected that its incidence be doubled in coming years. Our Myeloma Functional Unit (MFU) has been working since 2017. The MFU is a multidisciplinary team set up in order to provide better care to these patients. In this unit, the MM specialist nurse is in charge of supporting all aspects of patient care as well as contacting with them to ensure adherence to treatment and to control secondary effects. Telephone contact also serves as a clinical support for patients. This study aimed to assess the effect of telephone support on patients with MM and whether the results can be used to identify weak points in education and patient care.

Methods: We prospectively collected phone calls made between January and April 2018 for evaluation. Calls were evaluated using a questionnaire which took into account patient's sex; maker of the call; the enquire motive; date of the call and overall results.

Results: The data is gathered from a sample of 169 calls registered. 62% of patients were male and 38 % female. Call makers were: 49% from MM specialist nurse, 31% patients, 17% caregivers and 3% others. Some of the calls were to clarify more than one issue. The enquiry motives of calls were: 49 % related to secondary effects, 39% related to appointments, 29, 5 % related to treatment information, 17% general issues. Finally regarding out comes: 80% were resolved by MM specialist nurse and 20 % of the calls required a physician help.

Conclusions: Most of the calls were resolved by MM specialist nurse. A greater nurse – led communication between the MM specialist nurse and patient and the option of resolving doubts or problems by telephone can reduce the medical visits of patient with MM between treatments and improve their quality of life.

CN28 Transmural collaborative care in oncology: Experiences of general practitioners

M. Daem[1], E. van Roekeghem[2], M. Grypdonck[2], P. Pype[3]

[1]Cancer Center, Ghent University Hospital, Ghent, Belgium, [2]University Centre for Nursing and Midwifery, Ghent University, Ghent, Belgium, [3]Department of Family Medicine and Primary Health Care, Ghent University, Ghent, Belgium

Background: Cancer care is mostly situated in hospitals. Advanced practice nurses (APN) play an increasing role in this care. The role of Belgian general practitioners (GPs) in oncology is unclear. Clarification of the roles taken up by GPs is necessary to understand how communication between those involved in the patients' care can be improved. The aim of this study is to explore what Flemish GPs see as their role in oncology and what relations and information is needed to provide care for oncology patients.

Methods: A qualitative study based on individual interviews with a convenience sample of 14 Flemish GPs. Techniques of Grounded Theory are used to analyze the data.

Results: The participating GPs describe their role in the first and last phases of the illness trajectory as mostly clear. During the treatment and follow-up phase, their role is more variable because it depends on their perception of responsibility towards the

patient. Their perception of medical responsibility, whether they work proactively and expectations of the specialist define care. As follow-up is less systematic, proactively working GPs feel like they are left out of care. They would like to receive more and timely information (on psychosocial aspects). There is no true transmural teamwork and GPs are rarely well informed about the role of APNs.

Conclusions: Because of the variety of roles GPs describe, differentiation in communication is recommended, where an APN could be involved. To improve this collaboration, across the borders of primary and secondary/tertiary care, further efforts are needed.

CN29 The use of patient reported outcome (PRO) instruments in immune checkpoint inhibitor (ICI) therapy for cancer: A systematic review

S. Colomer-Lahiguera[1], D. Bryant-Lukosius[2], S. Rietkoetter[2], L. Martelli[2], K. Ribi[3], A. Orcurto[4], R. Juergens[5], M. Eicher[1]

[1]Department of Oncology - Institute of Higher Education and Research in Healthcare (IUFRS), Centre Hospitalier Universitaire Vaudois (CHUV), Lausanne, Switzerland, [2]School of Nursing/Department of Oncology, McMaster University, Hamilton, ON, Canada, [3]Institute of Higher Education and Research in Healthcare (IUFRS), University of Lausanne, Lausanne, Switzerland, [4]Department of Oncology, Centre Hospitalier Universitaire Vaudois (CHUV), Lausanne, Switzerland, [5]Division of Medical Oncology, Juravinski Cancer Centre, Hamilton Health Sciences, Hamilton, ON, Canada

Background: ICI have shown significant clinical benefit for patients diagnosed with varied types of cancer. With an increasing use of these therapies, it is of urgent interest to achieve a comprehensive understanding of the overall patient experience – thus PROs should be systematically included in clinical ICI trials. We conducted a systematic review of published literature to identify and categorize PRO instruments and examine related utility and measurement issues in studies reporting on ICI.

Methods: Literature was searched using PubMed, Embase, PsycINFO, Medline and CINAHL databases (June 2017). Search terms included controlled vocabulary and specific keywords related to: (1) Food and Drug Administration (FDA) approved ICI, (2) PRO, and (3) Oncology. Eight reviewers independently screened titles/abstracts followed by a full text selection based on predefined criteria. We included clinical trials, intervention studies, systematic reviews, study protocols, observational studies, and case reports. Information regarding the clinical trial protocol and PRO tools was collected. (PROSPERO CRD42018090912).

Results: Of the 24 articles included in the review, 13 reported PRO data from primary clinical studies, nine were quality-adjusted life year analyses, and two were study protocols. These articles referred to a total of 14 clinical trials reporting PRO results. Of these, 12 used cancer-specific (11 EORTC-QLQ-C30 and 1 FACT-G) and 11 a generic quality of life (QoL) questionnaire (10 EQ-5D and 1 SF-36). Whereas in seven cases, only cancer-specific and generic questionnaires were used, five studies combined them with disease-specific modules, and two included a symptom-specific questionnaire. Furthermore, six studies used PROs to conduct analyses of health economics and work productivity.

Conclusions: Cancer-specific or generic QoL questionnaires are the most widely used PRO measures in clinical ICI trials. As ICI therapies exhibit unique characteristics different from conventional cancer therapies, such broad instruments may not capture the specific ICI-related symptoms, toxicities, and impact on the patient's QoL. Hence, the adaptation or development of ICI specific PRO tools should be further investigated.

CN30 Laryngectomized patients caregivers' life experience: A phenomenological study

V. Bressan[1], E. Dri[1], S. Stevanin[2], L. Cadorin[3], A. Rizzuto[4], G. Bulfone[1], L. Ghirotto[5]

[1]Department of Medical Sciences, University of Udine, Udine, Italy, [2]Agency for Health and Social Care, Veneto Region, Venice, Italy, [3]Continuing Education Center, National Cancer Institute CRO Aviano, Aviano, Italy, [4]Department of Otolaryngology/Head & Neck Surgery, Udine University Hospital, Udine, Italy, [5]Research, Azienda Santa Maria Nuova-IRCCS, Reggio Emilia, Italy

Background: Laryngectomized patients often depend on their caregivers who have a central and difficult role in supporting them dealing with financial, social, and relational issues. In fact, they feel very responsible and committed, especially considering the time devoted to take care of their beloved. Besides, providing care induces caregivers high stress levels, emotional distress, anxiety and the fear of cancer recurrence or progress. Few studies investigated laryngectomized patients caregivers' life experience during both the whole course of illness and at the end of the treatment. Therefore, the purpose of our study was to explore, through a phenomenological approach, the lived-experience of primary family caregivers of laryngectomized patients undergoing radical surgery.

Methods: Qualitative semi-structured and audiotaped interviews were held with 12 laryngectomized patients' primary family caregivers. Data were analysed using the descriptive phenomenological approach outlined by Colaizzi.

Results: Three key themes emerged: the caregivers lived experience of illness; the change of caregivers' daily life and how they support their sick beloved. The experience of caregivers' lived relations changes from being a family member to a supportive carer, and the illness of their beloved negatively affects their psychological lived experience. Their perception of time and Quality of Life change as their perception of the future becomes uncertain. Finally, they feel guilty mainly because of the limited amount of time they can devote to their beloved.

Conclusions: The study findings allowed to understand in depth how the presence of a laryngectomized person in the family may affect the life of the caregiver, even after the treatment phase. This suggests the need for healthcare professionals to support caregivers throughout the whole care journey and especially in dealing with the perception of time during the diagnosis and care phases. Further research should be conducted on factors contributing to time perception alteration and possible interventions to support caregivers to cope with it.

CN31 Comparing nurses' and patients' research priorities in cancer care: A mixed methods systematic review

L. Cadorin[1], I. Truccolo[2], V. Bressan[3], N. Suter[1]

[1]Continuing Education Centre, CRO Aviano National Cancer Institute, Pordenone, Italy, [2]Scientific and Patient Library, CRO Aviano National Cancer Institute, Aviano, Italy, [3]ENT Department, University of Udine, Udine, Italy

Background: Cancer nurses struggle to meet the challenges in providing quality nursing care in changing environments characterized by advances in drugs and technologies, aging populations, increasing rates of cancer and survival, rising costs, long-term survival patients and increasing economic constraints. Research priorities need to be established within this context because they can encourage the new generation of nurses to respond competently to patients' advanced care needs.

Methods: A systematic review was performed to compare and discuss nurses' and cancer patients' main cancer research priorities according to the PRISMA guidelines (PROSPERO registration: CRD42017059721). Studies retrieved were evaluated with a Mixed Methods Appraisal (MMAT). All medical databases were searched from January 2000 to July 2017. Study inclusion, data extraction, and assessment were performed by two researchers independently (inter-rater agreement, kappa =0.70; SE = 0.87; $p < 0.01$).

Results: Among 16 studies identified, 13 included nurses' research priorities, 2 patients', and 1 both. They included descriptive cross-sectional (50%), Delphi (44%), and exploratory qualitative studies (6%). Qualitative studies varied from 75% to 100% of the total MMAT score. Nurses' priorities were as follows: cancer behavioral psychological/social issues and professional dimensions. Patients' priorities were patient life dimensions and health promotion. Cancer care dimensions and continuum of care emerged as research priorities of both.

Conclusions: The results underline nurses' and patients' research priorities to investigate the patients' advanced care needs and provide a useful template to guide cancer-nursing research. Identifying priorities helps focus on particular issues rather than promoting isolated and unrelated studies of patients' needs. Most of the nurses who participated were affiliated with professional associations and do not reflect the entire nursing population. Moreover, very similar survey questionnaires have been used (the items did not cover all areas) with the possible priorities not considered by participants. More studies are needed for the creation of a cancer research priority agenda.

CN32 Most prevalent unmet supportive care needs in Greek ambulatory advanced breast cancer female patients receiving chemotherapy

A. Psychogyiou, S. Katsaragakis, C. Lemonidou, D. Protogiros, E. Patiraki

Nursing, National and Kapodistrian University of Athens, Athens, Greece

Background: This cross-sectional study, supported by the National and Kapodistrian University of Athens, aimed to describe the unmet supportive care needs of ambulatory advanced breast cancer female patients receiving chemotherapy and the association between patients' characteristics and their unmet needs.

Methods: A convenient sample of 117 ambulatory (response rate 96%) advanced breast cancer (stage III or IV) female patients receiving chemotherapy, from two outpatient units of cancer hospitals in Attica consented to participate between July 2017 to February 2018. Patients were assessed by the translated in Hellenic language Short-Form Supportive Care Needs Survey Questionnaire: a 34 items 5-point (1-5) Likert type scale that covers five domains of need: health system and information (HIS),

psychological (PS), physical (PH), care and support (CS), and sexuality needs (S). Their unmet needs were determined overall and by domain (rated 3 to 5 points). A form consisting of demographic and clinical characteristics were also collected. The level of statistical significance was set at 0.05.

Results: The mean age was 62.2 (±11.3) years. Most patients were married/ partnered (47.9%) with children (84.6%), retired (56.4%), with a low income (56.4%) who had undergone antineoplasmatic treatment previously (96.6%). The mean number of unmet needs of each patient was 16.7 (±7.5) (0-34) and the median number was 18. The mean/ median number of unmet needs in each domain was PS 7.0 (±3.4) (0-10)/ 9, HIS 5.1(±3.3) (0-11)/5, PH 3.5(±1.6) (0-11)/ 4, CS 0.9 (±1.4) (0-5)/0 and S 0.4 (±0.9) (0-3)/ 0. The prevalence of the ten most frequent unmet needs was over 70% and belonged to PS (6 items) PH (3 items), and HIS (1 item) domain. None of the sample's demographic and clinical characteristics was statistically significant associated with the total need score of SCNS-SF34 or PS, PH, HIS domains ($p>.050$). Higher income was associated with less PS ($x(3)^2=9.1$, $p=.028$) and HIS needs ($F(3)=3.1$, $p=.029$). Having children was associated with less HIS needs ($t(115)=2.1$, $p=.042$).

Conclusions: The most prevalent unmet supportive care needs in our Greek sample were psychological informational and physical, but further research is needed to clarify them.

CN33 A new beginning of collaboration: The Danish Cancer Nursing Research Network

K.B. Dieperink[1], M. Kjerholt[2], P.R. Riis Olsen[3]

[1]Department of Oncology, Odense University Hospital, Odense, Denmark, [2]Haematology, Sjællands Universitets Hospital, Roskilde, Denmark, [3]Oncology, Aarhus University Hospital, Aarhus, Denmark

Background: Research in cancer nursing is pivotal for patients, their families and for the nursing profession. Cancer nurses have to deliver good quality care during the whole trajectory from pre-diagnosis to treatment, rehabilitation and palliation. However, the numbers of Danish nursing researchers within the cancer discipline are small and they work somewhat isolated all over Denmark. The researchers would benefit from forming a stronger network and to collaborate across the country.

Methods: The network was established during a snowball effect and from mouth to mouth. Members invited are nurses with a PhD from all over Denmark, researching within different areas of the cancer discipline. The network is organized with a steering committee consisting of three members representing three of the five Danish regions.

Results: In October 2016 the Danish Cancer Nursing Research Network was born. At the moment 31 Danish nursing researchers are affiliated to the network, and is growing. The aim of the network is to: ○ Draw national and international attention to nursing research to the benefit of cancer patients and their families ○ To facilitate collaboration in cancer research among members ○ To exert influence on a political level to promote developments in healthcare and to raise attention to the importance of nursing research The network has during 1.5 years arranged four successful meetings and a master class for PhD student, and is beginning to include PhD students. The network also aims to connect and collaborate with international nurse researchers. We have flashed our existence and call for collaboration through EONS' newsletter February 2018.

Conclusions: The Danish Cancer Nursing Research Network is a new but already strong and expanding organization which will influence Danish cancer nursing on different levels.

CN34 Individual network meetings in cancer care: From young people with cancer to adults with brain tumours

P.R. Riis Olsen

Oncology, Aarhus University Hospital, Aarhus, Denmark

Background: A malignant brain tumour often includes cognitive impairment. This affects both patients and families. Compared to other cancer patients, studies show that they are significantly in more need of social support and help for everyday activities. A network focused approach offering individual network meetings with and for young people with cancer has shown to facilitate the involvement of a supportive social network around the patient and the family, which can assist them in keeping their world together.

Methods: A participatory action research design was employed to develop and implement a researched based service that would promote and encourage a supportive social network for patients with primary brain tumours and their families. Patients and close relatives preferences and attitudes towards an offer of a network meeting were explored. The study involved parallel processes of individual interviews with patients and usually their spouses, focus group interview and group sessions of co-operative inquiry, education and interaction between the researcher and a group of ten clinical nurses.

Results: Based on the findings the individual network meeting for patients with brain tumours has been shaped to fit their needs and wishes and are now fully implemented in the clinic. A group of nurses has been trained in planning and leading network meetings and acts as implementation agents. Early presentation of individualised network meetings is welcomed as an opportunity and accepted by about 40% of the patients and relatives. Data from the study are currently being analysed for publication.

Conclusions: Network meetings are highly valued by patients and their social network who have experienced a meeting. The interactive approach in action research has supported the implementation of the complex service - a service which has potential in other nursing areas. The presentation will focus on preparing and conducting network meetings and findings will be highlighted.

CN35 Does being cancer patient or family caregiver of cancer patient effect bone marrow donation awareness?

G. Bagcivan[1], N. Ozen[2], D. Bayrak[3], F.I. Cınar[4]

[1]Education Department, Gulhane Training and Reseach Hospital, Ankara, Turkey, [2]Faculty of Health Sciences, Istinye University, Istanbul, Turkey, [3]Health Science Faculty, Cankiri Karatekin University, Cankiri, Turkey, [4]Gulhane Nursing Faculty, University of Health Sciences, Ankara, Turkey

Background: Extensive literature from Turkey and around the world have described factors associated with donating bone marrow and knowledge about bone marrow donation. However to the best of our knowledge, this is the first study that focused on awareness of cancer and non-cancer patients and their family caregivers as well bone marrow donation and transplantation. The aim of this study was to determine if there are any differences between cancer and non-cancer patients and their family caregivers' awareness of bone marrow donation and transplantation.

Methods: This is a descriptive study conducted in Turkey. We recruited the patients and family members who were admitted to Medical Oncology, Hematology and General Medicine. This study was approved by the hospital Institutional Review Board. Data was collected by researchers after written inform consent was obtained from each patient and family member via face to face interviews using the data collection form developed by researchers based on literature.The SPSS 21.00 was used to analyze the data. The Chi-square test was performed to evaluate differences among groups.

Results: Although most of the patients and family caregivers were aware of what bone marrow transplantation and bone marrow donation are they did not know how to donate bone marrow. Most of the patient and family caregivers who know what the bone marrow transplantation and donation are stated that they learned about bone marrow transplantation and donation through television, internet, and health professionals. Compared to the non-cancer patients, believing in bone marrow transplantation is lifesaving, knowing exactly what the bone marrow transplantation is, and how to donate bone marrow were more in the cancer patients. Likewise cancer patients' family caregivers were more aware of what exactly bone marrow transplantation is, and how to donate bone marrow.

Conclusions: Several studies showed that those who have been informed about BMT, and National marrow donation program were significantly more willing to donate bone marrow. This is important since in many cases lack of encouragement and insufficient information discourage a person from bone marrow donation.

CN36 A review of the challenges faced by carers of patients diagnosed with head and neck cancer before, during and after treatment

C.E. Johnston[1], M.A. Tanay[2]

[1]Haematology/Oncology, Guy's and St. Thomas' Hospital NHS Trust, London, UK, [2]Faculty of Nursing, Midwifery and Palliative Care, King's College London, London, UK

Background: Caring for individuals with cancer has been identified as a rewarding task for carers to undertake. However, it has also been identified as a stressful burden, often negatively impacting the carers physical and psychosocial health and wellbeing. Head and neck cancer (HNC) patients experience a range of complex care needs such as the inability to swallow safely, communication difficulties and poor psychological health following treatment. These side effects consequently impact those looking after the patient at home.

Methods: In January 2017 four electronic databases, CINAHL, Medline, PsycINFO and ASSIA, were systematically searched to identify relevant literature addressing the proposed research question. A manual hand search was then conducted so that further

relevant papers could be retrieved. A total of eight qualitative research papers and one mixed methods paper were selected that met the eligibility criteria. These papers were then critically appraised using CASP's critical appraisal tool and analysed using thematic analysis.

Results: Nine studies involving 105 carers were included in this review. All studies utilised semi-structured interviews to gather data. The studies were conducted in the United Kingdom (n = 3), Canada (n = 1), Sweden (n = 1), Australia (n = 2), Ireland (n = 1) and America (n = 1). From the thematic analysis four themes emerged from the data set identifying the specific challenges HNC carers faced; challenges due to new roles and responsibilities, information challenges, support challenges and relationship challenges.

Conclusions: This review identified the specific challenges experienced by carers of individuals diagnosed with HNC. The multiple caregiving responsibilities they undertake, impacted both their physical and emotional wellbeing. Furthermore, these challenges were found to be exacerbated by the inadequate provision of information and support facilitated by healthcare professionals. Awareness of these extensive challenges will help to identify ways of supporting carers in adapting to their new roles and responsibilities. Results may also guide development of future interventions and strategies aimed at providing information and psychosocial support for carers.

CN37 Evaluation of support and information needs for patients with cancer in a phase I trials unit

S. Stapleton[1], L. O'Leary[1], M. van Zyl[1], J. Hanwell[1], T. Wiseman[2]

[1]Drug Development Unit, Royal Marsden Hospital NHS Foundation Trust, London, UK, [2]Applied Health Services Research, The Royal Marsden NHS Foundation Trust, London, UK

Background: Advances in the understanding of the biological basis of cancer have resulted in a paradigm shift in drug development. Phase I trials with translational elements are conducted in clinical trials units for patients with cancer. The objective of this study was to evaluate any unmet needs of support and information for patients on Phase I trials. The aim was to utilise patient exerience to assess the need to change or develop delivery of information and support.

Methods: A qualitative approach was used. Patients and relatives of patients with cancer on Phase I trials formed two focus group. Group 1 consisted of 8 participants and group 2 10 participants, both lasted one hour. A semi structured schedule was used to prompt discussion, the focus groups were audio-recorded and transcribed verbatim. The data were organised using the Nvivo software package and analysed using Braun and Clarke's thematic analysis framework.

Results: Four themes emerged from the data 1) face to face support; there was a general consensus that the best way to recieve information about treatment and disease was face to face. The relationships with the clinical staff were strong and important to maintain. At times when the trials unit was not accessible patients felt vulnerable 2) remote support; email was felt to be a good way to communicate information regarding appointments, the telephone clinic was useful for contact regarding sympton issues. Digital methods of information and support were potentially useful but needed to be thought through properly 3) getting the right information, at the right time , in the right way; patients felt that they needed extra information particularly in terms of feedback regarding the trials and signposting to support services 4) Relationships with other patients; this theme was about the benefit and value patients had in supporting each other within the treatment areas, however this was conflicted and may require extra support at times as there was a negative impact when fellow patients became unwell or died.

Conclusions: Based on the results from the analysis written patient information was redesigned. A quarterly forum is in development where patients can meet recieve well being advice and also feedback regarding the trials they are participating in.

CN38 Dignity of Greek patients with advanced cancer: A cross-sectional study

S. Katsaragakis[1], F. Deskou[2], S. Sgourou[1], M. Christou[1], M. Dimoula[1], K. Maniati[2], D. Protogiros[1], E. Patiraki[1]

[1]Nursing, National and Kapodistrian University of Athens, Athens, Greece, [2]Palliative Care Unit Galilee, Palliative Care Unit Galilee, Spata, Greece

Background: A core concept in caring patients with advanced cancer is to treat them and preserve dignity independently the service of care. This cross-sectional study's purpose was to explore the dignity of patients with advanced cancer.

Methods: A convenience sample of 99 (response rate 85%) patients with advanced cancer was recruited between April to December 2017 by a palliative care unit (PCU) (day (PDC) and home care (PHC)) and oncology units (chemotherapy outpatient (OU) and inpatient (IU)) of Athens. Patients with advanced cancer (stage III or IV) who consented, completed the Patient Dignity Inventory (PDI), a 25 items scale, 5 point Likert scale (1 (no problem) -5 (overwhelming problem) divided into: Symptom (SD) and Existential distress (ED), Peace of Mind (PM), Dependency (D), and Social Support (SS). Also Hospital Anxiety and Depression Scale (HADS), Edmonton Symptom Assessment Scale - short version and a demographic/ clinical form were collected.

Results: Most patients were female (54.5%), the mean age was 64.9 years. Breast (22.2%), colorectal (16.2%) and lung cancer (15.2%) were the most frequent diagnoses. Almost half patients (56.6%) were hospitalized (36.4% OU, 20.2% IU) and the others were cared for at the PCU (28.2% PHC, 15.2% PDC). The PDI mean scores were: Total Dignity (TD) 50.2 (25-125), SD 15.3 (6-30), ED 12.7 (6-30), PM 4.7 (3-15), D 5.8 (3-15), SS 4.5 (3-15). Most of the demographic and clinical characteristics were not associated with total or subscales scores of PDI. On the other hand, women ($p=.035$) and breast cancer patients reported less SS ($p=.022$). The OU patients reported better TD ($p=.029$), SD ($p=.001$), ED ($p=.002$) and D ($p=.003$) than OU and PHC but not PDC. Higher scores of TD were significantly correlated with experience of pain, tiredness, lack of appetite, shorten of breath, anxiety and depression ($p<.006$). Reports of anxiety and depression measured by HADS were correlated with higher total and subscales dignity scores ($.001 < p < .006$).

Conclusions: The findings of this study support a quite good level of perceived dignity in Greek patients with advanced cancer. More research is needed to clarify the differences of dignity among various care settings. We thank Special Account for Research Grants and National and Kapodistrian University of Athens.

CN39 Development and implementation of national guidelines on lifestyle issues and cancer: Report from an ongoing quality improvement project

K. Vuollet Karlsson[1], C. Landegren[2], B. Westman[3]

[1]Regional Cancer Centre North, Norrlands Universitetssjukhus, Umea, Sweden, [2]Regional Cancer Center Syd, Region Skåne, Lund, Sweden, [3]Stockholms Läns Landsting, Regional Cancer Center Stockholm Gotland, Stockholm, Sweden

Background: Lifestyle habits such as tobacco use, alcohol consumption, insufficient physical activity, sun exposure and unhealthy eating habits are risk factors for cancer but also increase the risk of side-effects and poor outcome from cancer treatments. The Swedish Cancer Nursing Society initiated and developed a multi-professional project where they adapted the current national guidelines for lifestyle habits of preventing disease (by National Board of Health and Welfare), to the cancer context.

Methods: The project includes developing written guidelines for staff and an evidence-based educational program for cancer contact nurses (CNs). The CNs has a unique position to inform and support patients and their families on lifestyles changes. The education program (one full day training and one half day follow-up) started in May 2018 and includes lectures and case discussions that cover all cancer related lifestyle issues. It also includes systematic assessment and models for change. All Swedish CNs (approx. 1000) will be invited to participate.

Results: A first evaluation of the program will be presented during EONS11 at ESMO 2018. Data will be collected via surveys and interviews with CNs and also from cancer care provider data sources (on what lifestyle interventions that have been delivered to patients).

Conclusions: The project will be on the way to implement evidence-based knowledge about lifestyle habits to CN.

Legal entity responsible for the study: Swedish Nurses Oncological Associations.

CN40 Developing a patient reported experience measure (PREM) in secondary breast cancer (SBC)

C. Farrell, S. Foy, A. May, R. Lee, C. Gaskell, J. Yorke

School of Oncology, The Christie NHS Foundation Trust, Manchester, UK

Background: Metastatic breast cancer (SBC) is now seen as a chronic disease, however the number of patients currently living with SBC is unknown. Despite widespread recognition of the importance of understanding and evaluating patients' experiences, little research has been undertaken within SBC. Generally, there has been significant expansion in the development and application of patient reported questionnaires that measure care experiences (PREM), which is a major indicator of healthcare quality, however there is no specific PREM for people with SBC.

Methods: This study aims to develop and pilot test a unidimensional PREM in SBC for clinical application using a mixed methods sequential exploratory design. Semi-structured interviews were conducted with 25 people with SBC to explore their experiences,

priorities and needs diagnosis of metastatic disease and during palliative treatment. Potential items for PREM-SBC were extracted from interview data focusing on patients' experiences and priorities for care. Cognitive interviews were undertaken with patients to ensure all items listed were clear and easily understood.

Results: Following cognitive interviews a draft PREM questionnaire was created for patients with SBC. The structured questionnaire contains 48 items (statements) based on patients' experiences, treatment / care, priorities and needs. A five point scale is used to rate each item from strongly agree to strongly disagree. Patients report the PREM is easy to complete, taking less than 5 minutes. Further pilot testing is currently being undertaken (n = 130) to assess the validity, reliability and repeatability of PREM-SBC, drawing comparisons with other quality of life measures.

Conclusions: There is currently a lack of research focusing on patients with SBC. A draft PREM-SBC questionnaire was developed and pilot tested for clinical use. This will increase understanding of patients' experiences, needs and priorities to enhance patient care.

CANCER NURSING: LEADERSHIP

CN41 Cancer situation in Sub-Saharan countries: Development of educational, diagnosis and treatment plans

J.C. de la Torre-Montero[1], N. Gil-Gómez[2], J.L. Ribes bernal[3], N. Domenech Climent[4], A. Ojer Perea[5], P. Beorlegui Murillo[5], J.M. Gavala Arjona[6], R. Cumplido Corbacho[7], I. Magallon Pedrera[8], M.A. Peñuelas Saiz[8]

[1]Spanish Society of Oncology Nursing, Comillas Pontifical University, Madrid, Spain, [2]Spanish Society of Oncology Nursing, Hospital Quirón Madrid, Madrid, Spain, [3]Spanish Society of Oncology Nursing, Hospital Clinic, Barcelona, Spain, [4]Spanish Society of Oncology Nursing, Hospital Virgen de los Lirios, Alcoy, Spain, [5]Spanish Society of Oncology Nursing, Clinica Universitaria de Navarra, Pamplona, Spain, [6]Spanish Society of Oncology Nursing, Hospital son Espases, Palma de Mallorca, Spain, [7]Spanish Society of Oncology Nursing, Hospital Universitario Virgen del Rocio, Seville, Spain, [8]Spanish Society of Oncology Nursing, Hospital Universitari Vall d'Hebron, Barcelona, Spain

Background: The situation of patients with cancer around the world means, in terms of access to diagnostic tools, adequate surgical interventions, medical treatments and optimal radiotherapy, as well as the educational tools for professionals, presents a great disparity in terms of access throughout the globe, but especially in sub-Saharan countries. Once again, putting into evidence this situation is necessary in order to raise awareness among the participants involved in this situation: patient, professionals, Scientific Societies, but especially governments and international organizations. Health services, sanitary equipment and medical access in developing countries are unequable: from rural areas to cities, the ratios of population, patients and professionals are far from the recommendations of the WHO. The aim of this project is to determinate the dimension of educational and non-educational needs, such as: diagnostic methods and treatments, based on the difficulties presented while having access to the different resources.

Methods: A qualitative approach was performed as first step. Objectives are to determinate needs about diagnosis equipment, treatments, and level of expertise within the personnel: including physicians, nurses, physiotherapist, technicians, and community health workers (this is a common figure in these countries). Quantitative analyses will start taking place during summer campaigns by African and European health professionals.

Results: Access to medicines is expensive, even for the most basic treatments; when a patient begins a chemotherapy treatment, usually completes the first or second cycles of treatment. Only people who have access (economically) to a regular health system can afford a complete line of chemotherapy. About cancer diagnosis, in many countries there are basic X-ray services, including CT scan, but no PET or RMI.

Conclusions: If we think in oncology services, there is a big gap from developed societies in terms of education resources. If we think in patients with cancer in some countries in Africa, we can sadly affirm that most of them are patients in palliative care, and instead of receiving the most qualified and supportive care, their options about pain control or other treatments are very few.

CN42 The Gastrointestinal and Lymphoma Unit lead nurse research role in Royal Marsden Hospital

J. Duncan[1], V. Michalarea[1], T. Coyne[2], J. Thomas[1], D. Cunningham[2]

[1]GI and Lymphoma, Royal Marsden Hospital NHS Foundation Trust, London, UK, [2]GI Research, Royal Marsden Hospital NHS Foundation Trust, London, UK

Background: Clinical research has expanded in many fields with oncology growing vastly in the last 5 years. Specialised nursing and healthcare support is imperative for the smooth operation of the research aspect of a unit, aiming to deliver better care to patients (pts) participating in clinical trials.

Methods: Retrospective review of the structure of the Research Clinics between November 2016 and April 2018 in Royal Marsden Hospital in the Gastrointestinal and Lymphoma Unit.

Results: The Lead Research Nurse (LRN) structured the team by identifying the complexities involved in running a dedicated Research clinic, developing new roles and assigning the appropriate research team members to support the Clinical Research Fellows. The LRN introduced the role of Assistant Practitioners (APs)who support the running of the clinic by taking vital signs, performing ECG's and other trial related procedures, such as entering source data into the Electronic Case Report Forms for the sponsor of each clinical study. This has enabled the Clinical Research Nurses (CRN) to spend more time with pts, assessing them for new or existing adverse events, recording concomitant medications, checking blood results, and completing Holistic Needs Assessments at required points throughout treatment. The LRN expanded the role of the Biological Specimen Coordinator (BSC) enabling them to perform phlebotomy on Research pts and take consent for a Translational Research protocol, making their role more hands on and improving retention in this job group.

Conclusions: The LRN has a crucial role leading, supervising and developing a split site team consisting of ten CRNs: 5 senior CRNs, 5 junior CRNs, a Translational Research Manager, 5 BSCs and 2 APs. We have achieved a holistic approach for the trial pts whose needs might differ from the usual treatment setting due to the experimental nature of these trials. Our well-structured process has helped pts build better rapport with the team, understanding the importance of all members and various aspects in clinical research. Further training is warranted with Research nurses undertaking advanced practice education, with the view for this model to be adopted in other specialties and institutions.

CANCER NURSING: PATIENT SAFETY

CN43 Patients' learning and participation in their breast cancer care

L.E. Boman[1], K. Sandelin[2], Y. Wengström[3], C. Silén[1]

[1]Department of Learning, Informatics, Management and Ethics, Karolinska Institute, Stockholm, Sweden, [2]Molecular Medicine and Surgery, Department of Oncology-Pathology, Karolinska Institutet, Stockholm, Sweden, [3]Department of Neurobiology, Care Sciences and Society, Division of Nursing, Karolinska Institutet, Huddinge, Sweden

Background: Patients' participation in treatment and care is considered to increase their safety and well-being. There is a lack of knowledge about what participation means for the patients and how it can be supported in breast cancer care. A prerequisite for patients' participation is their knowledge. Changing perspective, from patients' information needs to their learning, can increase our understanding about how participation can be facilitated. The purpose of this study was to explore patients' experiences of learning, understanding and participation in their breast cancer care.

Methods: Sixteen patients with breast cancer were interviewed. The interviews were analyzed according to abductive content analysis taking the perspective from learning theories.

Results: The first part of the study explored patients' learning. The patients are forced to interact with a vast amount of information. Bodily sensations and experiences from being part of events are important sources. The information is interpreted to an understanding which is concealed or expressed which affect patient participation. The struggle to understand and manage the new life situation is an ongoing process for a long time. The preunderstanding and driving forces of the patients, time for contemplation and dialogue with staff, were essential features in this struggle(1). The second part explores patient participation. The concept of patient participation was defined differently by different patients and there was uncertainty about its meaning. The patients' understanding of their disease, treatment and care affected their participation. A prerequisite for participation was the respectful treatment from health care staff contributing to a feeling of being "seen" as a human being. The patients' wishes varied as did their needs to participate in treatment decisions. Participation also meant a continuous struggle to manage self-care during a long period of time and access to health care is needed to support patients. (1)Engqvist Boman et al. Patients' learning and understanding during their breast cancer trajectory. Patient Education and Counseling 100 (2017) 795–804.

Conclusions: New kinds of training programs for staff and patients are suggested, focusing on patients' learning and the new roles of partnership.

CN44 Incidence and risk factors of phlebitis in patients with peripheral parenteral nutrition administration

S.Y. Oh[1], J.M. Lee[1], J.W. Kim[1], S.H. Kim[1], J.M. Park[1], G.Y. Yeo[1], J.E. Hyun[1], J-H. Park[2]

[1]Nursing, Asan Medical Center, Seoul, Republic of Korea, [2]College of Nursing, Ajou University, Suwon, Republic of Korea

Background: Peripheral parenteral nutrition is one of the easiest ways to provide nutrition for patients who have difficulty with enteral nutrition. But, on the other hand it is attended with danger such as, phlebitis. The purpose of this study was to investigate incidence of phlebitis and its risk factors in patients with peripheral parenteral nutrition administration.

Methods: Prospective observational study was performed with 289 hospitalized adult patients with gastrointestinal diseases. The researchers evaluated peripheral venous catheter that administered peripheral parenteral nutrition until their removal and investigated the incidence of phlebitis using phlebitis scale of Infusion Nurses Society (2016). Logistic regression model was used to identify risk factors involved with occurrence of phlebitis. The statistical significance limits were set at $p < 0.05$.

Results: The incidence of phlebitis was 37.0% (107 cases). Among them, Grade I was 24.6% (71 cases), Grade II was 12.4% (36 cases) and Grade III and IV did not occur. Platelet count (OR 2.13, CI 1.07-4.26, p=.032), nutrition infusion rate (OR 0.36, CI 0.16-0.79, p=.012) and infusion period (OR 1.02, CI 1.00-1.03, p=.033) had statistically significance with phlebitis occurrence.

Conclusions: Using peripheral parenteral nutrition must be carefully reconsidered for patients with risk factors of phlebitis. In using peripheral parenteral nutrition, adjusting infusion rate deserves to be considered with care. Moreover, in case of extension of peripheral parenteral nutrition therapy, medical team must regards using another way such as middle line or central line for nutrition therapy in a serious light.

CN45 Specialized nursing interventions in optimizing patient communication undergoing total laryngectomy

A.A. Frade, S.S.A. Miguel

Service of Head and Neck Surgery, Otorhinolaryngology and Endocrinology, Instituto Português de Oncologia de Lisboa Francisco Gentil, E.P.E., Lisbon, Portugal

Background: Permanent and immediate laryngeal voice loss, resulting from total laryngectomy can be psychologically devastating to the patient and family, generating feelings of stress, fear, and frustration (Brunner et al, 2016). In the immediate postoperative period, writing and lip read are the most commonly methods of communication used by patients. However, this surgery is often accompanied by neck dissection, resulting in neck swelling, which difficult the movement of the lips and limits limb mobility required for readable writing (Matos et al, 2009). In conclusion, these approaches may not be effective, leaving patients frustrated and unable to express their care needs (Brunner et al, 2017). Thus, communication between patients and health professionals becomes difficult, generates anxiety and anguish in the person and family and has implication in the process care. Specialized care is therefore required for this type of patients, especially those provided by nursing, highlighting the use of augmentative and/or alternative communication strategies (AAC).

Methods: A critical reflection based on the results of a previous review, were performed to identify which AAC strategies promoting effective communication in the laryngectomized patient.

Results: Strategies identified as promoting effective communication include the use of low-technology and high-technology devices.

Conclusions: The use of AAC strategies improves the quality of care provided and allows a better understanding of the needs of the laryngectomized patient, which consequently will give them greater autonomy, control over their life and facilitating their adaptation. Beyond these implications for nursing, effective communication is a right of the individual and an essential component of the quality of care and patient safety.

CN46 Safe navigation of CARs in a changing landscape

M. Davies[1], E. Dolan[2], S. Neeson[2], E. Blowers[3], K. Linton[4], F. Thistlethwaite[5]

[1]The National Institute for Health Research (NIHR) Manchester Clinical Research Facility, The Christie NHS Foundation Trust, Manchester, UK, [2]Clinical Research Facility, The Christie NHS Foundation Trust, Manchester, UK, [3]Patient Recruitment, The Christie NHS Foundation Trust, Manchester, UK, [4]Medical Oncology, Manchester Cancer Research Centre, Manchester, UK, [5]Medical Oncology, The Christie NHS Foundation Trust, Manchester, UK

Background: Advanced Therapy Medicinal Products (ATMPs) such as CD 19 chimeric antigen receptor (CAR) therapies offer unprecedented promise for long term remission and even cure in pre-treated and refractory B cell malignancies. Extensive interest in new T cell engineered treatments for other malignancies has developed as a result. These complex treatments are associated with acute and potentially fatal toxicities, making patient safety paramount. CARs are often delivered on haematopoietic stem cell transplant (HSCT) units with JACIE accreditation, an internationally recognised quality system. To enhance capacity for growing numbers of ATMP trials The Christie has utilised the NIHR clinical research facility (CRF).

Methods: Process mapping of the patient pathway alongside a gap analysis using JACIE standards has provided a framework to underpin the development of the CRF including: Advanced therapies team Increase in establishment Practice educator Education programme & HSCT placements JACIE quality manager to align SOPs and policies Changes to medical cover.

Results: Engagement across the organisation is a priority, with a focus on safety and mitigating risk. Recruitment to key posts is underway, along with specialised staff training. Relationships are being forged and strengthened with essential specialties such as critical care and neurology. The first clinical trials are open but recruitment and use of

the CRF will be carefully managed to ensure the infrastructure and processes are fit for purpose. The Christie is the lead organisation in a new consortium, iMATCH (Innovate Manchester Advanced Therapy Centre Hub) which has been awarded substantial funding from Innovate UK to scale up delivery of ATMPs and form a national network of Advanced Therapy Centres.

Conclusions: CD19 specific CAR therapy is poised to become a new standard care for selected B cell malignancies. Trials of ATMPs for a range of malignancies are growing exponentially, therefore safe delivery outside of an experienced area such as HSCT is important but challenging. Creative approaches to patient care, wide collaboration and executive level support are key. While iMATCH sets the challenge to increase the number of ATMPs available it has also facilitated city wide links and a national network to find solutions to complex problems.

CN47 Patients' interpretations and experiences of participation in cancer care

J. Jackson, J. Rundgren

Coordinating Contact Nurse, Regional Cancer Center Stockholm Gotland, Stockholm, Sweden

Background: The definition of patient participation is multifaceted but often reduced to solely implicate the involvement in treatment decisions. In many countries, including Sweden, there is a current shift from patient-centered care to person-centered care. This emphasizes the importance to view the patient as an equal partner and always include his or her description of their unique situation. To facilitate the participation of patients and to put their needs first, we need a wider understanding of how participation is interpreted and experienced by the patients themselves. Hence our aim was to examine this among patients with gynecological, hematological, head-neck or upper gastrointestinal cancer.

Methods: A qualitative cross-sectional study was carried out. This included all patients in the Stockholm-Gotland region, diagnosed in 2016 with one of the above-mentioned cancer types. A free-text question was formulated which asked the participants to describe their experiences of participation. The question was included in a larger questionnaire study from the Regional Cancer Center and sent out to 1658 patients. Framework Analysis was used as the method to analyse and interpret the data.

Results: A total of 434 participants chose to answer the study specific free-text question and 222 of those answers were deemed to meet the aim of the study. The analytical process resulted in three themes; communication, staff attitudes and relation. Above all, the participants described how individualized information and a perceptive attitude among staff were key prerequisites for participation. Furthermore, they pointed out that absence of continuity became an obstacle for creating meaningful relations with their care provider and thus hindering their participation.

Conclusions: To meet the current and future demands of individualized cancer care we need to redefine our understanding of patient participation. The emphasis, according to patients, should be on facilitating conditions to aid participation. Our understanding is that these conditions resonate the key aspects of person-centered care. The challenge lies in implementing person-centered care in the whole team and across each patient's cancer trajectory.

CN48 Peripherally inserted central venous catheters did not increase the risk of deep venous thrombosis in advanced colorectal cancer and lung cancer patients with bevacizumab

M. Qiu, Y. Chen, B-L. Zhang, X-Y. Wang

Cancer Center, West China Hospital, Sichuan University, Chengdu, China

Background: Deep Venous thrombosis (DVT) is one of the serious adverse events associated of bevacizumab, which is also one of the most notable complications associated with peripherally inserted central catheters (PICCs). However, there was no report about their correlation directly. The purpose of this study was to explore whether the use of PICCs increases the risk of DVT in advanced colorectal cancer and lung cancer patients with bevacizumab.

Methods: From June 2011 to April 2017, patients with documented advanced colorectal cancer and lung cancer who received bevacizumab were selected from West China hospital log-out registries. The patients inserted with central venous catheters (CVCs) or ever had thrombosis were excluded. According to whether use PICCs or not, patients were divided into two groups. The incidence of DVT during the use of bevacizumab between two groups was compared. Many risk factors were also analyzed.

Results: A total of 217 patients received bevacizumab were included in this analysis. 186 patients were colorectal cancer, 31 were lung cancer. Among them, 137 patients were inserted with PICCs and 80 patients were not. 5.1% (11/217) patients had DVT during the use of bevacizumab. 4 cases had upper extremity vein thrombosis, 1 had subclavian vein hrombosis and others were lower extremity vein thrombosis. Single factor analysis revealed that patients inserted with PICCs were more likely to have DVT than others (6.6% vs. 2.5%, $P = 0.318$), but it had no statistical difference. The incidence of DVT was higher in patients with diabetes mellitus (DM) than non-(DM) (21.1% vs. 3.5%, $P < 0.05$). Logistic analysis revealed that the use of PICCs had no statistical significance for the occurrence of the DVT. However, diabetes was a risk factor for DVT in advanced colorectal cancer and lung cancer patients with bevacizumab.

Conclusions: Peripherally inserted central venous catheters did not increase the risk of DVT in advanced colorectal cancer and lung cancer patients with bevacizumab. The patients with diabetes mellitus may be prone to develop DVT, whom we should manage more carefully during the use of bevacizumab.

CN49 Cancer nurse perspective on the emerging field of biosimilars in cancer care

J. De Munter[1], P. Crombez[2]

[1]*Cancer Centre, Ghent University Hospital, Ghent, Belgium,* [2]*Hematology, Jules Bordet, Brussel, Belgium*

Background: Biological medicines has transformed cancer care drastically. As Biologics are incorporated into cancer treatment, cancer nurses play a key role in education, administration, pharmacovigilance and managing side effects of biological medicines. Expiring patents of innovator biologics creating opportunities to develop biosimilars and the number in oncology will continue to increase. The use of biosimilars will bring new challenges for cancer nurses related to education, treatment and follow-up of cancer patients.

Methods: A search of PubMed, Sciencedirect and regulatory agency websites was conducted for references related to the use of biosimilars and cancer nursing.

Results: To ensure optimal and safe use of biosimilars, all stakeholders incl. physicians, cancer nurses, pharmacists and patients need to understand the complexities of biosimilars and take decisions that will improve patients treatment, safety and Quality of life outcomes. As biosimilars are introduced into clinical practice, education of cancer nurses is paramount to ensure the best outcomes for patients safety. Training of nurses on new products, incl. biosimilars is often ad hoc and incomplete. As a result, cancer nurses may be unaware of the complexities and consequences of using biologics, incl. biosimilars. The knowledge gap in biosimilar medicines and switching or substitution of these medications could result in incorrect patient information, non-optimal use and adverse events which can lead to a delay in access and a decreased therapeutic gain for the patient.

Conclusions: Cancer nurses have an important role in the multidisciplinary approach and treatment of patients on biologics, incl. biosimilars. They have a lead role in education and counselling during introducing and follow-up of the transition between innovator and biosimilar medicines and vice versa, to improve patient outcomes and drug safety. Additional studies on biosimilars are needed to identify current knowledge gaps and educational needs of cancer nurses across Europe. Education about biosimilars is critical for successful incorporation in to oncology practice. A deeper understanding is needed across all cancer related professions with a strong emphasis on collaboration with all stakeholders including patients.

CN50 Overview of an acute oncology service in a UK cancer centre

M.R. Foulkes

Berkshire Cancer Centre, Royal Berkshire Hospital - NHS Foundation Trust, Reading, UK

Background: In the UK there has been increasing emphasis on the ability to review oncology patients who are admitted as an emergency. Two reports, NCEPOD report into systemic Anti-Cancer Therapy: For better, for worse? (2008) and the NPSA Report 'Patient safety risks of incorrect dosing of oral anti-cancer medicines' (2008) identified shortcomings in the manner in which patients presenting to emergency departments following systemic anti-cancer treatmentrs (SACT) were cared for. This had led to increased mortality, morbidity and extended lengths of stay. In addition to the above patients presenting as an emergency with Metastatic Spinal cord compression were found to have delays in urgent treatment and patients who had a cancer diagnosis following an emergency admission had poortrer outcomes than those identified in a more controlled fashion. At the Royal Berkshire NHS Foundation trust we responded to NHS England guidance by establishing an oncologist-led acute oncology service with nursing support. We have been succesful in reducing length of stay for oncology

patients, forming sucesaful partnerships with acute physicians, succeasfully auditing and treating neutropaenic sepsis and bringing in a 7 day Acute Oncology service. This poster p[resentation will provide an overview of this service as part of the Oncology Nursing Track.

Methods: The presentation will cover a narrative overview of our experience of establishing, auditing and developing an Acute Oncology Service at a busy District General Hospital with a Cancer Centre. We will present audit information to support this narrative review.

Results: We will present data covering Acute Oncology activity, effectiveness, presentation and referral by tumour group, referral type and source. This will be presented in graphical format in order to support the narrative review.

Conclusions: The overall conclusions will outline our generally positive exprience of establishing and developing Acute Oncology services. We hope that this will be relevant to others wishing to do the same across Europe.

CN51 The development and evaluation of an online oncology portal

J. De Munter[1], E. Decoene[1], A. Van Hecke[2]

[1]Cancer Center, Ghent University Hospital, Ghent, Belgium, [2]Public Health, UCVV Nursing Science, University Ghent, Ghent, Belgium

Background: Care for patients with cancer is complex and the number of cancer survivors is increasing. This involves frequent monitoring and adequate medical and psychosocial support. The need for health related information among cancer patients is large. In Flanders, patients with a chronic disorder show a high degree of interest in online consultation of their medical records.

Methods: An online oncology portal was developed on the basis of literature, best practices and in co-design with patients, health care providers and IT developers. Co-design guarantees that the portal is tailored to the needs of the cancer patients. In this innovative project, a qualitative and quantitative evaluation of the portal was performed with patients (n = 45) and care providers (n = 10).

Results: On the platform the cancer patient can consult his individual treatment plan. In each phase of the care pathway online information, questionnaires and symptom diaries are attached. The platform provides a secure chat with the care providers (sending messages, video call), an overview of appointments and finally the patient can access his test results. Patients were positive about the possibility of consulting test results and reporting their side effects. Patients felt safely 'monitored' at home and experienced a strict follow-up from the oncology team. Generally, they found the platform user-friendly and complete.

Conclusions: This eHealth project is dynamic and is continuously optimized. This includes the implementation of the portal in patients with other types of cancer and in other hospitals. Finally, a mobile app is developed, signals for care providers are implemented in the system when patients report alarm symptoms and patients are empowered actively offering self-management advice. Up to today, more than 70 healthcare institutions are connected to the eHealth hub and all hospitals have the possibility to use all the functionalities of the oncology platform.

CN52 Pilot study: Nurses' role in management of cutaneous toxicity in patients with targeted therapies anti EGFR-Is' treatment

O. Diamanti[1], T.M. Zacheo[2], C. Lando[1], C. Magro[1], G. Pauletti[1], E. Zemella[1], C. Fano[1], F. Bonadies[1], E. Sarno[1], A. Venturi[1], P. De Vecchi[1], S. Menuzzo[1], S. Gallimberti[1], D. Grosso[1]

[1]Centro Coordinamento "Infermieri di Ricerca", Istituto Oncologico Veneto IRCCS, Padua, Italy, [2]Direzione Professioni Sanitarie, Istituto Oncologico Veneto IRCCS, Padua, Italy

Background: EGFR-Is (Epidermal Growth Factor Inhibitors) such as cetuximab, panitimumab and RTK (Receptor Tyrosine Kinase) such as erlotinib, regorafenib are "Targeted Therapies" with a selective capacity. However their use causes new side effects, such as the skin toxicity, the most prevalent of which is the maculo-papular rash. Several studies emphasize that education and prevention can reduce this toxicity which, if not treated promptly, may compromise the ongoing chemotherapy treatment and have a negative impact on the patient's QoL.

Methods: This is a randomized mono center, two-treatment arms and interventional study. 178 patients, enrolled in approximately 2 years, will be randomized 1:1 to receive intravenous treatment (Cetuximab or Panitumumab) or oral treatment (Erlotinib or Regorafenib). All patients, in Arm A (experimental group) and in Arm B (control group), will complete a HOC Questionnaire Created composed by 14 items and Dermatology Life Quality Index (DLQI). Furthermore, it will be created a HOC brochure by nurses containing advice and information about the skin toxicities and their management. Questionnaires, brochure and interviews will be administered as shown in the table. Note: a and b only Arm A

Table: CN52

Study period	Screening phase (-14 to -1)	Every 4 weeks (until at first tumor assessment)
Informed Consent Form	X	
Inclusion/Exclusion Criteria	X	
HOC Questionnaire Created	X	
DLQI Questionnaire	X	X
Brochure[a]	X	
Interview with nurse[b]	X	X

Results: The sample size will be hypothetical that the incidence of cutaneous toxicity in the Arm A group, will be lower than that of the Arm B group as per CTCAE 5.0. It will be considered clinically relevant to observe a better QoL and a 20% reduction in the incidence of cutaneous toxicity in the Arm A and a redistribution of toxicity levels such as to produce an effect size of 0.068.

Conclusions: Allowing patients to be more involved in their treatment and toxicity management of toxicities related, oncology nurses can help them to maintain their QoL and to promote adherence to treatment. The project hopes to confirm the hypothesis of cutaneous toxicity reduction 20% in Arm A and a better QoL compared to Arm B (control group).

CN57 Does individual genetic background predict acute radiation skin reactions in women undergoing adjuvant breast cancer radiotherapy?

D. Oliva[1], F. Lewin[1], N. Lewin[2], M.P. Nilsson[3], M. Strandéus[1], B-Å. Andersson[2], L. Sharp[4]

[1]Oncology, County Hospital Ryhov, Jönköping, Sweden, [2]Department of Laboratory Medicine, Region Jönköping, Laboratory Medicine, Jönköping, Sweden, [3]Futurum - The Academy for Healthcare and Department of Medical and Health Sciences, Linköping University, Linköping, Futurum -, Jönköping, Sweden, [4]Cancer Care Improvments, Regional Cancer Center Stockholm Gotland, Stockholm, Sweden

Background: Skin reactions during radiotherapy (RT) are common in women with breast cancer (BC). Different methods have been tested to reduce or prevent this toxicity. The aim of this study was to explore if genetic variation can be linked to acute radiation skin reactions (ARSR).

Methods: One hundred and nineteen women undergoing RT for BC during the period of 2011 to 2013 were included. Symptoms such as itching, burning and irritation were self-reported twice (during the first and last week of RT) using the VAS-scale. Assessments of the irradiated skin were measured using the Radiation Therapy Oncology Group scoring system for acute RT (RTOG-scale). Blood-based SNP analysis were performed using peripheral blood sample (obtained before start of RT). In total, 29 SNPs of well-defined functional genes were investigated.

Results: All women were assessed with ARSR in various degree according to the RTOG-scale. During the last week of RT, the women self-reported itching (n = 97, 82 %), burning (n = 64, 54 %) and irritation (n = 96, 81 %.). Three SNPs in the following genes were found to be associated with ARSR: XRCC2, IFNg and CCL5/Rantes.

Conclusions: We found an association between three SNPs and ARSR. The possibility of using these SNPs as prognostic biomarkers for radiation-induced toxicity needs further investigation.

Legal entity responsible for the study: County Hospital Ryhov, Jönköping Sweden.

CN58 Effect of aromatherapy massage on chemotherapy-induced peripheral neuropathic pain and fatigue in patients receiving oxaliplatin

N. Izgu[1], L. Ozdemir[1], F. Bugdayci Basal[2]

[1]Nursing Faculty, Hacettepe University, Ankara, Turkey, [2]Medical Oncology, Ataturk Chest Diseases and Surgery Training and Research Hospital, Ankara, Turkey

Background: Patients receiving oxaliplatin may experience peripheral neuropathic pain and fatigue. Aromatherapy massage, a nonpharmacological method, may help to control these symptoms.

Methods: The aim of this open-label, parallel-group, quasi-randomized controlled pilot study was to investigate the effect of aromatherapy massage on chemotherapy-induced peripheral neuropathic pain and fatigue in patients receiving oxaliplatin. Stratified randomization was used to allocate 46 patients to 2 groups: intervention (n = 22) and control (n = 24). Between week 1 and week 6, participants in the intervention group (IG) received aromatherapy massage 3 times a week. There was no intervention in weeks 7 and 8. The control group (CG) received routine care. Neuropathic pain was identified using the Douleur Neuropathique 4 Questions; severity of painful paresthesia was assessed with the numerical rating scale; fatigue severity was identified with the Piper Fatigue Scale.

Results: At week 6, the rate of neuropathic pain was significantly lower in the IG, when compared with the CG. The severity of painful paresthesia based on numerical rating scale in the IG was significantly lower than that in the CG at weeks 2, 4, and 6. At week 8, fatigue severity in the IG was significantly lower when compared with CG ($P < .05$).

Conclusions: Aromatherapy massage may be useful in the management of chemotherapy-induced peripheral neuropathic pain and fatigue. This pilot study suggests that aromatherapy massage may be useful to relieve neuropathic pain and fatigue. However, there is a need for further clinical trials to validate the results of this study.

CN59 Cancer pain knowledge and attitudes of nursing and medical professionals in a Greek general hospital

C. Palassari, S. Katsaragakis, J. Kaklamanos, D. Protogiros, E. Patiraki

Nursing, National and Kapodistrian University of Athens, Athens, Greece

Background: Health care professional's knowledge and attitudes are strongly related with sufficient cancer pain management. The study explored nursing and medical professionals' cancer pain management knowledge and attitudes.

Methods: A cross-sectional survey was conducted. The convenience sample consisted of nursing and medical professionals (internal medicine sector) of a public general hospital, Athens. Sample's inclusion criteria: informed consent and > 5 months' work experience. Between September - December 2016, 98 physicians (P), 70 registered nurses (RN) and 36 nurse assistants (NA) with response rates 81.8%, 77.8%, 90% respectively, completed the Greek version of the Nurses' Knowledge and Attitudes Survey Regarding Pain: a 39 items tool divided into 22 true/ false, 13 multiply choices and 4 pain case studies items, as well as a demographic form.

Results: Most of the participants were women (76.5%), reporting caring for more than 100 patients in cancer pain per year (40.7%). The sample's mean age was 39.5 years and work experience 12.8 years. The prevalence of the five most frequent wrong responses (over 88.2%) was related with assessment and pain management interventions, addiction, patient pain self-report, and route of medication's administration. Opioids titration, patients' religious and cultural related pain behaviors, older patients and pain tolerance were the five most frequent correct answers (over 80.4%). P responded more correct answers (mean 20.8) than RN (17.5) and NA (15.8) ($p < 0.0001$). Age, education and clinical experience in cancer care explained 28% variance of correct answers. Younger participants, working at oncology wards, holders of a doctoral and attending continouing cancer pain education (strongest indepented factor (R^2Change=.007)), were related with more correct answers.

Conclusions: Greek participants knowledge deficits in pain management support the universal concern of inadequate knowledge and attitudes of health care professionals, however, encouraging theoretical and clinical training may enhance their ability to improve practice. We thank Special Account for Research Grants and National and Kapodistrian University of Athens for funding to attend the meeting.

CN60 The experience of dysgeusia in allogenic hematopoietic cell transplantation survivors: A qualitative study

D. Bomben[1], A. Bin[2], M. Venturini[1], T. Bulfone[1], L. Ghirotto[3], V. Bressan[1]

[1]Department of Medical Sciences, University of Udine, Udine, Italy, [2]Oncology Department, Udine University Hospital, Udine, Italy, [3]Research, Azienda Santa Maria Nuova-IRCCS, Reggio Emilia, Italy

Background: Taste disorders are one of the most common side effects of treatment in oncology patients and often occur after allogeneic hematopoietic cell transplantation (allo-HCT). Dysgeusia is rarely a life-threatening complication, therefore, in many cases it does not receive close medical attention. Furthermore, information about this disorder is largely based on the clinician's own experience. However, taste disorders, can impact on the quality of life in survivors of allo-HCT, and compromise their enjoyment of eating, food intake, weight and nutritional status. The number of performed annual transplantations continues to grow annually and the number of older long-term survivors increases. There is little literature that is focused on studies of survivors of allo-HCT with taste disorders. We conducted a qualitative descriptive study to explore experiences of dysgeusia in patients that have undergone of allo-HCT and examined what strategies they used to mitigate it.

Methods: Using purposive sampling, survivors of allo-HCT were recruited. Audiotape interviews were conducted until data saturation was achieved. Each interview was transcribed verbatim, and content analyses were performed to extract significant themes and subthemes.

Results: Three major themes embracing various aspects of allo-HCT survivors' experiences were identified: 1) the shape of taste; 2) everything is irritating and it is arduous to eat; 3) finding new strategies to overcome the problems. Together, they highlight the experiences of survivors showing how taste disorders can affect the physical, psychological and social dimensions of a person for the rest of their life.

Conclusions: A cumulative burden is the result of dysgeusia and its clinical course reinforced also by related symptoms. Healthcare professionals must focus their attention on the management of these symptoms and offer interventions to safeguard the patient's social, physical and psychological well-being. Finally, further research is needed to explore the experiences of allo-HTC patients who have taste disorders throughout their cancer journey that introduces a more holistic approach which involves health professionals, caregivers and family members.

CN61 "It may not affect you": Lived experiences and support needs of women who developed peripheral neuropathy following chemotherapy treatment for cancer

M.A. Tanay[1], J. Armes[2]

[1]Faculty of Nursing, Midwifery and Palliative Care, King's College London, London, UK, [2]Faculty of Health and Medical Sciences, University of Surrey, Surrey, UK

Background: Some cancer drugs cause chemotherapy-induced peripheral neuropathy (CIPN) or damage to the nerves. CIPN affects the hands and feet, with patients reporting symptoms such as numbness, tingling, pain and muscle weakness. The nature of symptoms depends on the chemotherapy agents and drug dose that patients receive. Options to minimise the severity of symptoms may involve dose reduction, delay or discontinuation of chemotherapy. This study explored lived experiences of women who developed peripheral neuropathy following cancer chemotherapy treatment.

Methods: The study was conducted in the United Kingdom and was advertised through cancer charity websites and social media accounts. Using set eligibility criteria, purposeful convenience sampling was carried out. Women diagnosed with breast or ovarian cancer who experienced or are still experiencing neuropathy following chemotherapy treatment were recruited. Semi-structured recorded telephone interviews were conducted (n = 15). Interpretative phenomenological analysis (IPA) was used to analyse data.

Results: The analysis resulted to four main themes: struggle to process CIPN information, information and trust when making treatment decisions, experience of symptom reporting and challenges of mitigating CIPN symptoms. Similar to previous studies, participants used analogies to describe CIPN symptoms such as 'like walking on pebbles, sand, needles or gravel'.

Conclusions: Findings suggest that interventions to improve understanding of CIPN symptoms by patients and clinicians are needed in practice. A broader insight of patients' experiences of CIPN helps progress development of interventions to enhance communication, assessment and management of CIPN symptoms.

CN62 App about chemotherapy: Helping the patient with cancer

B.T. Espersen

Department of Oncology, Aarhus University Hospital, Aarhus, Denmark

Background: Patients with cancer are bombarded with information – both in connection with examinations, diagnosis and treatment. Patients cannot always cope with the huge quantity of oral and written information from the hospital. Even highly educated patients voice their inability to take in the amount of given information. Reading skills and the ability to understand are often not taken into account. Furthermore 15-20 % of the normal population is known to be weak readers. The use of mobile technology in health care has shown a fortified self care and improved quality of life. Therefore, we aimed at developing an app which could serve several purposes: Opportunity to use different sources of information, information at the right time and the right place, information "on the go", the text read out loud (or earphones) and information to relatives and friends – no matter where they live.

Methods: The text from our written information was adjusted to the electronic media. The new text has been commented by patients, relatives and health care personnel. Finally, the text can be read out loud with a tap on the loudspeaker icon. There are 2 apps, which can be downloaded for free (Google play and App Store) App 1 is a general guide with focus on the most asked questions in relation to cancer, chemotherapy and targeted treatment - e.g: Does the treatment influence other people? How can my disease affect my relatives? What will I tell my children? Can I go on holiday? What about work? Can I drink alcohol? Can I be physically active? What about alternative treatment? App 2 describes 16 possible side effects separately and guides the patients and relatives in relation to preventing and minimizing the discomfort.

Results: See conclusion.

Conclusions: Some patients prefer the apps to the traditional written information. They download to both mobile phone and tablet. They find it very manageable and easy to navigate, and the text short and straight forward. The apps are an extra source of information for some patients, and they recommend the apps to family, friends and other patients. If patients find the oral and written information satisfying, they do not use the apps. The technology can be a barrier especially with older patients.

CN63 Usability test for a CINV diary application for smartphones at oncology nursing

P. Fernández- Ortega[1], Y. Escobar[2], E. Trigoso[3], R. Blat[4], M. Cantero[2], A. Alvarez[5]

[1]Nursing Resarch, Institut Català d'Oncologia Hospital Duran i Reynals, Barcelona, Spain, [2]Department of Medical Oncology, Hospital General Universitario Gregorio Marañón, Madrid, Spain, [3]Nursing OncoPediatric, Hospital La Fé, Valencia, Spain, [4]Nursing, Hospital Mar Parc Salut, Barcelona, Spain, [5]Nursing, Hospital de Leon, Leon, Spain

Background: Chemotherapy-induced nausea and vomiting (CINV) continue to be a clinical problem, particularly in the delayed phase. Great variability between perception of healthcare professionals and patients, regarding incidence & severity of CINV[1-9]. CINV lack of control worsens the quality of life of patients and it is associated with complications[12-13] increasing costs for healthcare services[14].CINV app is a free service addressed to patients treated with emetogenic chemotherapy (CT), empowering patients to report CINV impact in life and relevant information. This study aims to evaluate the usability and acceptability of a smartphone app to improve CINV management in patients receiving CT, by cancer nursing.

Methods: We used 4-dimensions test (content, graphic design, navigation and clinical utility) to evaluate APP's usability and acceptability. Clinical and technical researchers worked together to develop the app's test. 8 National Hospitals with specialized oncology nursing services were included. 45 cancer nurses invited to participate (from 9 to 23 April 2018) and 33 filled in the test, after making a clinical case simulation through the app.

Results: Described Table

Table: CN63

Variables	N = 33	Nurses level agreement
Contents		84%
Navigation		84%
Graphic design		94%
Utility		89%

App was easy to use and had relevant content, although improvement is possible. 91% nurses agree that more than 50% of their patients will be able to use the APP and 88% believe that report generated will be useful in practice.

Conclusions: The CINV app addresses main concerns for patients receiving chemotherapy, clinical situation and individual emetic risk of patient or complexity of the prescribed antiemetic regimen and impact of CINV in their daily life. Soliciting feedback from oncology nurses, we ensured that the app was acceptable and beneficial for patients and clinicians. Some points to improve the app in future. Reporting of symptoms after CT enhances CINV management, self-care, and participation without being a burden to patients, indicating that app can be used in clinical practice by patients.

CN64 Perceived symptoms of Greek cancer patients during chemotherapy using the memorial symptom assessment scale

D. Palitzika[1], E.C. Fradelos[1], V. Alikari[1], P. Charitopoulos[1], E. Zioga[1], S. Zyga[2], M. Lavdaniti[1]

[1]Nursing, Alexander Technological Educational Institute, Thessaloniki, Greece, [2]Nursing, University of Peloponnesus, Thessaloniki, Greece

Background: Cancer patients experience a variety of concurrent symptoms during their chemotherapy. These symptoms can be physical or psychological and may vary in terms of occurrence, severity and distress. The aim of the present study was to assess the existence of symptoms during chemotherapy.

Methods: This was a non-experimental and descriptive study. It was conducted in a large hospital in a major Northern Greek city. The subjects were 200 cancer patients undergoing chemotherapy in cycle 2 and cycle 3. Data was collected using the Memorial Symptom Assessment Scale (MSAS) and questionnaire with demographic and clinical characteristics.

Results: The majority of patients was male (61%) with mean age 58.9 (S.D. 9). 79.5% was married 47.5% had completed compulsory education. Moreover, 48% suffered from lung cancer, 42% colorectal cancer, 7.5% pancreatic cancer and 2.5% stomach cancer. In the 2nd cycle of chemotherapy the mean of Global Distress Index (GDI) was 2.20, Physical Symptom Subscale (MSAS PHYS) was 2.38, Psychological Symptom Subscale (MSAS-PSYCH) was 2.26 and Total MSAS score (TMSAS) was 2.26. Also, in the 3rd cycle of chemotherapy the mean of GDI was 2.20, MSAS PHYS was 2.43, MSAS-PSYCH was 2.17 and TMSAS was 2.27. The following symptoms presented increase between 2nd and 3rd cycle of chemotherapy: feeling nervous, nausea, feeling drowsy, and problems with urination, vomiting, diarrhea, problems with sexual interest or activity, mouth sores, weight loss. The symptoms with the highest mean in 2nd and 3rd cycle of chemotherapy were numbness/tingling in hands/feet and feeling drowsy.

Conclusions: The results of this study demonstrate that cancer patients undergoing chemotherapy experience various symptoms. Therefore, nurses should take into account these findings and plan appropriate, suitable care plans and interventions in order to alleviate them and improve patients' quality of life.

CN65 How to monitor outpatients undergoing active anticancer treatment? A feasibility study of the web-based tool "Onco'nect®"

M. Belhadj, E. Kempf, A. Lebel, A. Guillemin, H. Boussion, C. Joly, I. Baumgaertner, E. Assaf, C. Saldana, B.J-C. Rousseau, C. Tournigand

Oncologie Médicale, Hôpital Henri Mondor, AP-HP, Créteil, France

Background: Monitoring adverse effects (AEs) induced by antitumor therapies remain a clinical challenge for outpatients with cancer. Their delayed management might impair patient quality of life and lead to dose-lowering or discontinuation of treatment. The use of e-health may improve the communication between caregivers and patients, as well as the continuity of care. We assessed if Onco'nect®, a new digital follow-up tool, could be used easily by cancer outpatients undergoing active antitumor treatment in a routine clinical practice setting.

Methods: Outpatients diagnosed with any type of cancer and undergoing intravenous or oral anticancer in the department of Medical Oncology of Creteil Teaching Hospital were eligible. No informatics knowledge was required for patients to be included in the study. At different times of each chemotherapy cycle, patients were sent a standardized 12-question survey assessing AEs. A chat was available for patients and caregivers to improve their communication. Grade $\geq$2 AEs, and deliberate requests of patients raised an alert system. Caregivers were notified of such events by emails and "red alerts" on the web-based interface.

Results: Our study enrolled 51 patients, with distinct types of anticancer treatment (chemotherapy, oral therapy, immunotherapy and clinical trial therapy): 5 (9.8%) patients were over 75-year-old. Four patients could not use a computer or a smartphone but had a relative able to help. We called 21 (41.2%) patients at least once because they reported $\geq$ grade 2 AEs. We modified symptomatic treatments, or diet and lifestyle in 11 (21.6%) cases. Four patients deliberately raised the alert system, resulting in one hospitalization. The chat was used to: manage daily AEs, answer patients' questions, send prescriptions, receive medical imaging and blood test results. After a 2-month use, all the patients asked reported that Onco'nect® was easy to use and clinically-efficient.

Conclusions: Onco'nect® is a user-friendly web-based tool to monitor outpatients undergoing anticancer treatment. It can be integrated in a current practice in oncology, even with elderly patients. Onco'nect® might help to anticipate chemotherapy prescriptions and reduce the admission in emergency rooms.

CN66 Medical makeup in cancer patients and its impact in their quality of life

R. Lechou, M. Lavdaniti

Nursing, Alexander Technological Educational Institute, Thessaloniki, Greece

Background: Cancer treatment cause many toxicities included skin toxicities. Although skin toxicity often resolve upon therapy discontinuation these side effect can negatively affect self esteem, treatment compliance and quality of life.

Methods: A literature review was conducted using the electronic databases PubMed and Google scholar, with respect to the period from 2008 to 2018. The following key words were entered: "medical makeup", "cancer", "anticancer treatment" and a combination thereof. The exclusion criteria for the articles were languages other than English.

Results: Medical makeup was tested under dermatological control on damaged skin. It was water- and sweat-resistant, perfume-free, preservative-free, superior coverage (40-50% pigments) and has natural results. In a multicenter study (9 centers) were studied 90 patients presenting with visible cutaneous side effects from chemotherapy: altered complexion, total or partial eyebrow alopecia, irregularity of lip contour, dry lips. The corrective medical makeup improved the quality of life in 81.2% of patients and helped 76.8% of patients to brave the stares of others. Also, health professionals should inform women cancer patients about medical make-up, its benefits and give some instructions for applying make-up.

Conclusions: Medical makeup has many benefits in enhancing patients' self-esteem. Health professionals must find ways to implement it in cancer patients who have skin toxicity. Also, in Greece there is a great need for further research for this issue, on a large population with precise characteristics in order to arrive at safe results about medical makeup.
