Background: Precise clinical staging by diagnostic imaging is essential for determination of initial treatment for gastric cancer. Indeed, cT3 and T4 diseases with lymph node metastasis (T3-4/N+) were candidate of neoadjuvant chemotherapy (NAC) followed by gastrectomy, defined as cStageIII in 8th edition of AJCC/UICC TNM classification. However, pathological T3-4/N+ diseases could contain some cases that were underestimated as cStage I/II and excluded from target of NAC. This study aims to examine the accuracy of preoperative diagnosis and the prognosis from each cStage in pathological T3-4/N+ gastric cancers.

Methods: The study analyzed gastric cancer patients who received gastrectomy and diagnosed as pathological T3-4/N+ deseases between Jun 2000 and Jun 2012 at Kanagawa Cancer Center. The clinical and pathological data were analyzed retrospectively. Patients who received preoperative chemotherapy were excluded. The proportion of each cStage was investigated based on the 8th edition of AJCC/UICC, and 5-year overall survival rate (5yOS) for each cStage was calculated using the Kaplan-Meier method.

Results: In total, 337 patients were diagnosed as pathological T3-4/N+ diseases and included in this study. In clinical staging, 48 patients (14.2%) were diagnosed as cStageI, 10 patients (3.0%) as cStageIIA, 109 patients (32.3%) as cStageIIB, 159 patients (47.2%) as cStageIII, 6 patients (1.8%) as cStageIVA, and 5 patients (1.5%) as cStageIVB. 5yOS stratified by cStage was 77.0% in cStageI, 90.0% in cStageIIA, 52.2% in cStageIIB, 49.0% in cStageIII, and 0% in cStageIVA/IVB. Furthermore, survival curve of cStageIIB and cStageIII were approximately overlapped.

Conclusions: Among pathological T3-4/N+ diseases, the underestimation as cStageI and cStageIIA was acceptable, because of relative low frequency and good prognosis without NAC. Meanwhile, the underestimation as cStageIIB could not be ignored, because patients diagnosed as cStageIIB occupied one third of pathological T3-4/N+ disease and had poor prognosis comparable to cStageIII. We need to consider underestimation of preoperative diagnosis, when we determine target of NAC for advanced gastric cancer.

658P Patient reported outcomes (PRO) results from phase II MONO and FAST zolbetuximab (IMAB362) trials in patients with advanced CLDN18.2+ gastric and gastroesophageal junction adenocarcinoma (GA/GEJA)

R. Morlock[1], M.R. Krukas-Hampel[2], Ö. Türeci[3]

[1]HEOR, Astellas Pharma Global Development, Inc., Northbrook, IL, USA, [2]Advisory Analytics, IQVIA Global Consulting Services, New York, NY, USA, [3]CI3- Cluster of Individualized Immune Intervention, Formerly Ganymed Pharmaceuticals GmbH, Mainz, Germany

Background: The single-arm MONO trial (NCT01197885) assessed IMAB362 (600 mg/m^2) monotherapy as salvage therapy in GA/GEJA patients and showed a 30% disease control rate. The FAST trial (NCT01630083) assessed IMAB362 (loading dose 800 mg/m^2 then 600 mg/m^2) combination therapy as 1st line therapy (IMAB362+EOX followed by single agent IMAB362 maintenance until disease progression [DP]) vs EOX alone in GA/GEJA patients. IMAB362+EOX significantly prolonged progression-free and overall survival. We describe the MONO and FAST PRO results.

Methods: EORTC QLQ-C30 and STO22 were collected at baseline, end of IMAB362 treatment (EOT), and every 8 wks post-EOT in MONO; and at baseline, Cycle 5, EOX EOT, and post-EOT every 12 wks until DP in FAST. Both studies used mixed model repeated measures (MMRM) assuming missing at random to assess HRQoL changes from baseline. The proportion of MONO patients per minimally clinically important difference (MCID) category (deterioration, no change, improvement) was evaluated at EOT; in FAST, time to HRQoL deterioration (TTD) based on MCID thresholds was assessed using Kaplan-Meier estimates and Cox models.

Results: Patients in MONO (n = 40) had stable scores in all STO22 domains but deteriorated in C30 functional (role, cognitive and physical) and symptom scales (fatigue, insomnia, pain, nausea/vomiting and appetite loss). MONO treatment responders (n = 9) showed less deterioration in C30 scales. Most patients stayed stable or had clinically meaningful improvement in HRQoL. In FAST (EOX n = 74, IMAB362+EOX n = 68), a significant difference in change from baseline was only seen for the nausea/vomiting symptom scale (P=.01) favoring EOX. IMAB362+EOX delayed TTD for global health status, trouble belching, eating restrictions, feeling tense, pain interference, acid indigestion/burning, shortness of breath and HRQoL vs EOX (all P<.05). Patients remaining on IMAB362 alone post EOX EOT generally showed better HRQoL and physical functioning than EOX alone.

Conclusions: For patients with advanced CLDN18.2 expressing GA/GEJA, IMAB362 maintained HRQoL and delayed TTD in both monotherapy and combination chemotherapy settings.

Clinical trial identification: NCT01197885 and NCT01630083.

Background: Avelumab, a human anti–PD-L1 IgG1 monoclonal antibody that can induce innate effector function against tumor cells in preclinical models, is an approved treatment for metastatic Merkel cell carcinoma in various countries and platinum-treated advanced urothelial carcinoma in the US and Canada. We report updated results from the dose-expansion part of a phase 1b trial of avelumab in Japanese patients (pts) with advanced GC/GEJC (NCT01943461).

Methods: Pts had stage IV GC/GEJC adenocarcinoma and progression after 1 or 2 prior lines of chemotherapy including a platinum and fluoropyrimidine agent (initially enrolled pts) or progression after platinum/fluoropyrimidine followed by a taxane or irinotecan (later pts). Pts received avelumab 10 mg/kg Q2W by IV infusion until confirmed progression, unacceptable toxicity or withdrawal. PD-L1 expression was assessed using the Dako PD-L1 IHC 73-10 assay (≥1% tumor cell cutoff).

Results: At data cutoff on Aug 10, 2016, 40 pts had received avelumab (median treatment duration 2.7 mo; range 0.5–21.4). 21 pts (52.5%) had received ≥3 prior lines of therapy for advanced disease. The objective response rate (ORR) was 10.0% (95% CI 2.8–23.7), including complete response in 1 pt and partial response in 3 pts. 17 pts had stable disease as best response and the disease control rate was 52.5%. Median progression-free survival was 2.5 mo (95% CI 1.4–2.8). Median overall survival (OS) was 9.1 mo (95% CI 7.2–11.2) and the 12-mo OS rate was 31.0% (95% CI 15.6–47.8). In evaluable pts with PD-L1 + (n = 11) or PD-L1 − (n = 27) tumors, ORR was 27.3% and 3.7%, respectively. Treatment-related adverse events (TRAEs) of any grade occurred in 32 pts (80.0%), including infusion-related reaction (27.5%; all grade 1/2), pruritus (15.0%), pyrexia (12.5%) and rash (10.0%) in ≥ 10% of pts. Grade 3 TRAEs occurred in 3 pts (7.5%; ALT increase, anemia and hyponatremia); no pt had a grade ≥4 TRAE. 5 pts had an immune-related AE (all grade 1/2); the most common were pruritus (n = 3) and maculopapular rash (n = 2).

Conclusions: Avelumab showed acceptable safety and clinical activity in Japanese pts with advanced GC/GEJC progressed after chemotherapy.

Clinical trial identification: EMR 100070-002 (NCT01943461).

660P Safety and efficacy of a DKK1 inhibitor (DKN-01) in combination with pembrolizumab (P) in patients (Pts) with advanced gastroesophageal (GE) malignancies

S.J. Klempner[1], J. Bendell[2], V. Meucci Villaflor[3], L. Tenner[4], S. Stein[5], C.A. Sirard[6], W. Newman[7], M. Kagey[7], K. Schlienger[8], J. Strickler[9]

[1]Medical Oncology, The Angeles Clinic and Research Institute, Los Angeles, CA, USA, [2]GI Oncology Research, Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN, USA, [3]Medical Oncology, Northwestern University Feinberg School of Medicine, Chicago, IL, USA, [4]Medical Oncology, University of Texas Health Science Center, San Antonio, TX, USA, [5]Medical Oncology, Yale School of Medicine, New Haven, CT, USA, [6]Medical Oncology, Leap Therapeutics, Inc., Cambridge, MA, USA, [7]Research, Leap Therapeutics, Inc., Cambridge, MA, USA, [8]Oncology, Merck & Co, Kenilworth, NJ, USA, [9]Medical Oncology, Duke University Medical Center, Durham, NC, USA

Background: Dickkopf-1 (DKK1) is a modulator of the Wnt and PI3K/AKT signaling pathways and contributes to an immunosuppressive tumor microenvironment by activating MDSCs and Tregs. DKN-01 (D), an mAb against DKK1, acts on innate immune cells, and in preclinical studies demonstrates upregulation of both PD-L1 and IFNγ-related chemokines, suggesting a role for immune checkpoint combination. Anti-PD-1 plus DKN-01 shows additive antitumor effects in the B16 syngeneic mouse model; clinical studies are underway. GE cancers commonly overexpress DKK1 and harbor Wnt pathway alterations.

Methods: Phase 1b study to evaluate dose, safety and efficacy of D (150 mg or 300 mg on Days 1 & 15) plus P (200 mg on Day 1) of each 21-day cycle in pts with advanced GE cancer. Safety, efficacy, and correlative analyses (cytokines, PBMC immunophenotyping, tumor genomics and intra-tumoral DKK1/PD-L1) are ongoing.

Results: Pts enrolled in 2 cohorts: D (150 mg [n = 2] or 300 mg [n = 11]) + P. All 13 pts had adenocarcinomas (4 pts: EC, 6 pts: GEJ, 3 pts: GC). Three pts (23%) were refractory to prior checkpoint inhibitor, and only 1 pt was known to be PD-L1+ at study entry. No DLTs or treatment related SAEs were observed. Most TEAE were Grade 1/2 and commonly gastrointestinal disorders. ≥Grade 3 TEAE included hyponatremia & anorexia (each 2 pts), lymphopenia, transfusion reaction, GI bleed, abdominal pain, dehydration, weight loss, thrombotic event & weakness (each 1 pt); only lymphopenia felt related to D. Among 9 evaluable patients there was one confirmed PR, SD in 5 pts (including one IO-refractory pt with minor response) and PD in 3 pts. The 6-week disease control rate was 75%; 6 pts remain on therapy. Most PR/SD pts have had downward trend of peripheral MDSC; more evident in pt with PR. Complete cohort details and correlative work will be presented.

Conclusions: Preliminary results demonstrate that D + P is well tolerated with no new safety signals and shows encouraging early efficacy signals in advanced GE cancer. A subset of pts with features typically associated with lower response to single agent anti-PD-1 therapy (KRAS amp, PD-L1 neg, and MSS) exhibited prolonged clinical benefit and warrant further study. Expansion to confirm efficacy is ongoing.

Clinical trial identification: NCT02013154.

661P Updated results from a phase I trial of M7824 (MSB0011359C), a bifunctional fusion protein targeting PD-L1 and TGF-β, in patients with pretreated recurrent or refractory gastric cancer

Y-J. Bang[1], T. Doi[2], S. Kondo[3], H.C. Chung[4], K. Muro[5], I. Dussault[6], C. Helwig[7], M. Osada[8], Y-K. Kang[9]

[1]Internal Medicine (Medical Oncology), Seoul National University Hospital, Seoul, Republic of Korea, [2]Medical Oncology, National Cancer Center Hospital East, Chiba, Japan, [3]Hepatobiliary and Pancreatic Oncology Division, National Cancer Center Hospital, Tokyo, Japan, [4]Oncology, Yonsei University College of Medicine, Seoul, Republic of Korea, [5]Department of Clinical Oncology, Aichi Cancer Center Hospital, Nagoya, Aichi, Japan, [6]Clinical Biomarkers, Immuno-Oncology, EMD Serono, Billerica, MA, USA, [7]Biostatistics, Merck KGaA, Darmstadt, Germany, [8]Medical Oncology, Merck Serono, Tokyo, Japan, [9]Medical Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea

Background: Objective response rates (ORRs) in patients (pts) with gastric cancer (GC) treated with anti–PD-(L)1 antibodies range from 11.2% (PD-L1 unselected) to 15.5% (PD-L1+) for second line therapy. Inhibiting the transforming growth factor β (TGF-β) pathway, which plays a key role in tumor immunosuppression, may enhance the response to anti–PD-L1 treatment. We report results for M7824, an innovative first-in-class bifunctional fusion protein composed of a monoclonal antibody against PD-L1 fused with the extracellular domain of TGF-β receptor II (a TGF-β "trap") in pts with GC.

Methods: Pts in Asia with recurrent GC or gastroesophageal junction adenocarcinoma for whom standard therapy does not exist or has failed were enrolled in this expansion cohort of the ongoing, phase 1, open-label trial NCT02699515 and received M7824 1200 mg q2w until disease progression, unacceptable toxicity, or trial withdrawal. The primary objective is to assess safety/tolerability; secondary objectives include assessment of best overall response (BOR) per RECIST v1.1.

Results: As of February 15, 2018, 31 heavily pretreated pts with advanced GC (74.2% received ≥3 prior therapies) received M7824 for a median duration of 10.1 (range, 2-52) wks; 4 pts remained on treatment. 6 pts (19.4%) had grade 3 treatment-related adverse events (TRAEs): anemia (2), diarrhea (1), abnormal hepatic function (1) and rash (2). No grade 4 TRAEs occurred. 1 Grade 5 AE of death occurred after 5 doses with suspected rupture of pre-existing thoracic aortic aneurysm as per investigator's assessment. 7 pts had a confirmed objective response based on investigator-assessed BOR (ORR, 22.6%; DCR, 38.7%). There were 5 partial responses (2.4, 3.6+, 4.1+, 8.3+, and 9.7+ mo) and 2 complete responses (0.3+ and 9.0 mo). The initial assessment of PD-L1 tumor expression (22C3 assay) does not hint towards predictivity for ORR.

Conclusions: M7824 monotherapy had a manageable safety profile in heavily pretreated Asian pts (74% ≥3 prior therapies) with GC. Early signs of clinical efficacy, with an ORR of 22.6% and long lasting responses, are encouraging. Updated data will be presented.

Clinical trial identification: NCT02699515.

Background: Trastuzumab (T) + chemo is standard 1st line therapy (tx) for HER2+ GEA patients (pts). Pts typically progress in 6-8 months, with loss of HER2 positivity in 40% of treated pts. No anti-HER2 agents are approved in the post-T setting. We report the results of M, an anti-HER2 monoclonal antibody Fc-optimized for antibody-dependent cellular cytotoxicity, + P in HER2+ GEA pts and describe potential strategies for biomarker-guided response enrichment based on ERBB2 amplification and/or PD-L1 expression.

Methods: HER2+, PD-L1-unselected, 2nd line GEA pts post T progression received M (15 mg/kg Q3) + P (200 mg Q3). Safety, objective response rate (ORR), median overall and progression-free survival (mOS, mPFS), disease control rate (DCR), circulating-tumor DNA (ctDNA), and tumor PD-L1 expression were assessed.

Results: At data cutoff, 60 GEA pts were dosed in cohort expansion; 16.7% had treatment-related adverse events $\geq$ Grade 3. Overall, 21.6% had objective response (OR), 10 confirmed and 3 unconfirmed. DCR was 55% and mOS was 15.6 mos (95% CI: 7.26, NR). In GC pts, OR occurred in 10 of 34 (29.4%), mPFS was 4.24 mos (95% CI: 1.68, 5.62), and mOS not reached. Notably, only 31 of 51 (61%) of pts with baseline ctDNA testing showed ERBB2-amplification; 21 of 30 (70%) of pts with fresh tumor biopsy were HER2 3+ by IHC (80% concordance). Tumors were PD-L1+ positive in 13 of 28 (46%) pts tested, with higher rates in pts with GC. The presence of ERBB2 amplification by ctDNA and tumor PD-L1 expression by IHC were both associated with increased probability of OR: 33.3% v. 10.5% ($p = 0.0948$) and 43.8% v. 16.7% ($p = 0.0769$), respectively. ORR was 5 of 8 (62.5%) in ERBB2 amplified/PD-L1+ pts. In pts with activating HER2 mutations DCR was 11/15 (73%), indicating ADCC.

Conclusions: Consistent with prior tissue-based reports, many GEA pts progressing on T have lost ERBB2 amp. ERBB2 status by ctDNA NGS post-T could help identify patients more likely to respond to M+P, particularly in PD-L1+ pts. Our results suggest that M+P is well tolerated and has encouraging preliminary activity in 2nd line HER2+ GEA. Biomarker selection may further enrich for responding pts, advancing a potential chemo-free regimen in this population.

663P HER2 alterations is associated with higher tumor mutation burden in gastric cancer

B. Wei[1], Z. Li[2], Q. Han[3], X. Xing[4], Y. Hao[5], J. Zhou[6], Y. Zhang[7], S. Cai[7], Y. Gu[8]

[1]Department of Gastrointestinal Surgery, The Third Affiliated Hospital, Sun Yat-Sen University, Guangzhou, China, [2]Department of Gastrointestinal Surgery, Beijing Cancer Hospital, Beijing, China, [3]Department of Oncology, The General Hospital of People's Liberation Army (301 Hospital), Beijing, China, [4]Department of Hematology and Breast Cancer, Cancer Hospital of China Medical University, Liaoning Cancer Hospital and Institute, Shengyang, China, [5]Department of General Surgery, Southwest Hospital, Chongqing, China, [6]Gastrointestinal Surgery, Peking University People's Hospital, Beijing, China, [7]The Medical Department, 3D Medicines Co., Ltd, Shanghai, China, [8]Department of Oncology, Jiangsu Province Hospital, Nanjing, China

Background: Immunotherapy has been proven to be effective in gastric cancer (GC) patients. But the efficacy of immunotherapy for HER2 positive GC has not been defined. Tumor mutation burden (TMB) has been considered as predictive biomarkers of immunotherapy. However, the association between HER2 alterations and TMB in GC is still unclear. We therefore analyzed the associated between HER2 alterations and TMB in Chinese patients with GC.

Methods: Genomic profiling of DNA from fresh or FFPE tumor tissue of 163 Chinese GC was performed using next-generation sequencing on 381 cancer associated genes in 3D Medicines laboratory. Whole-exome sequencing and Genomic Identification of Significant Targets in Cancer (GISTIC) data of 435 GC from The Cancer Genome Altas (TCGA) were also analyzed to evaluate the association between HER2 alterations with TMB. TMB was defined as number of somatic non-synonymous mutations in coding region. HER2 amplification in TCGA was defined as "2" derived from the copy-number analysis algorithms GISTIC.

Results: HER2 alterations including amplification, missense and fusion were present in 11.0% (18/163) of Chinese cohort and 17.0% (74/435) of TCGA cohort. 5.5% (9/163) of Chinese cohort and 14.3% (62/435) of TCGA cohort harbored HER2 amplification. Higher TMB level was observed in patients carrying any HER2 alterations ($P = 0.004$) in Chinese cohort, but the association was not found in TCGA cohort ($P = 0.379$). Prognosis analysis was also performed on patients in TCGA cohort. HER2 status was not an independent risk factors affecting disease free survival (HR, 1.007; 95%CI 0.60-1.69; $P = 0.979$) or overall survival (HR, 0.828; 95%CI 0.56-1.24; $P = 0.357$). Higher TMB level was associated with significantly better disease free survival (median, 43.04 vs. 25.53 months; HR, 0.685; 95%CI 0.47-1.00; $P = 0.048$) and a borderline improvement in overall survival (median, 42.51 vs. 25.69 months; HR, 0.75; 95%CI 0.56-1.02; $P = 0.070$).

Conclusions: HER2 alterations are associated with higher TMB in Chinese GC patients, but not in patients from TCGA. Chinese GC patients may exhibit distinct characteristics. Further studies are warranted to evaluate the efficacy of immunotherapy in GC patients with HER2 alterations.

664P Phase I/II study of single agent MCLA-128, a full length IgG1 bispecific antibody targeting the HER3 pathway: Overall safety at the recommended phase II dose (R2PD) and preliminary activity in HER2+ metastatic gastric/gastroesophageal junction cancer (GC/GEJ)

M. Alsina[1], A. Varga[2], A. Amatu[3], J.H.M. Schellens[4], P.O. Witteveen[5], V. Boni[6], V. Moreno[7], K. Bol[8], A. Lourbakos[8], M. Magin Ferrer[9], E. Wasserman[10]

[1]Medical Oncology, Vall d'Hebron University Hospital, Barcelona, Spain, [2]DITEP, Gustave Roussy, Villejuif, France, [3]ASST Grande Ospedale Metropolitano Niguarda, Milan, Italy, [4]Clinical Pharmacology & Medical Oncology, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, [5]Hoofd Medische Oncologie, UMC - University Medical Center Utrecht, Utrecht, Netherlands, [6]Medical Oncology, START Madrid-CIOCC HM Hospital Sanchinarro, Madrid, Spain, [7]Medical Oncology-Start Madrid-FJD, University Hospital "Fundacion Jimenez Diaz", Madrid, Spain, [8]Clinical Pharmacology, Merus NV, Utrecht, Netherlands, [9]Clinical Research, Merus NV, Utrecht, Netherlands, [10]Medical Oncology, Merus NV, Utrecht, Netherlands

Background: MCLA-128 is a novel bispecific antibody targeting HER2 and HER3 receptors with enhanced antibody-dependent cell-mediated cytotoxicity. No DLT was seen during dose escalation and the R2PD was 750 mg q3w. We report safety across solid tumor expansion indications, and efficacy in metastatic GC/GEJ patients (pts).

Methods: Safety, PK, immunogenicity and biomarkers were evaluated in heavily pretreated advanced metastatic cancer pts treated with MCLA-128, 750 mg q3w, 2-hr IV. Response (RECIST 1.1) and clinical benefit rate (CBR; CR + PR + SD $\geq$ 12 wks) were assessed in HER2-positive GC/GEJ pts who had progressed on trastuzumab.

Results: As of 15 Feb 2018, 100 pts were enrolled in the expansion cohorts, 97 of whom were treated. Mean age was 58 ± 11 years, M/F: 26/74, ECOG PS 0/1: 36/63 (1 missing). Pts received a median of 2 MCLA-128 cycles (range 1 - 27). Common related AEs were infusion-related reactions (19%), diarrhea (17%), asthenia/fatigue (15%), nausea (6%), and decreased appetite (5%). Four (4%) pts had suspected related grade 3-4 AEs. No clinically significant LVEF decline (>10% from baseline and LVEF <50%) was seen. Mean T1/2 was ~100 hr (n = 89). Steady state serum concentrations of MCLA-128 were achieved after 2 cycles. As of 25 Mar 2018, 25 GC/GEJ pts were evaluable for response, with a median 3 metastatic sites (range 1-6), and progression on 1-2 prior anti-HER2 agents. They received a median of 2 MCLA-128 cycles (range 1-17). 1 pt had a confirmed CR (8+ cy), 9 pts had SD (sustained: 4, 5, 6, 12, 17 cy). CBR was 24% (6/25 pts). Based on central analysis variable HER2 levels were observed by HER2 IHC, and HER2 amplification was confirmed by FISH in all CBR patients. 4 of the 6 CBR pts had HER2 IHC 3+.

Conclusions: MCLA-128 is very well tolerated with mainly grade 1/2 AEs. Promising single agent antitumor activity was seen in heavily pretreated GC/GEJ pts progressing on anti-HER2 therapy. Further clinical exploration of MCLA-128 in GC/GEJ pts is warranted.

Clinical trial identification: EudraCT: 2014-003277-42.

665P NRF2 activation via PI3K/AKT/mTOR/RPS6 causes resistance to anti-HER2 agents among HER2 amplified gastric cancer

V. Gambardella[1], F. Gimeno-Valiente[1], N. Tarazona[2], T. Fleitas Kanonnikoff[1], P. Tolosa[1], M. Belda Moscardò[3], B. Garcia-Mico[1], M. Huerta[1], S. Roselló[2], D. Roda[1], A. Cervantes[2], J. Castillo[2]

Background: Personalized treatment for gastric cancer (GC) represents a big challenge. HER2 is an important driver in 7-34% of cases, playing a relevant role in cell growth and survival. Trastuzumab (T), when combined with chemotherapy, improves survival. No further anti HER2 drugs demonstrated clinical benefit. Resistance to treatment is a serious problem.

Methods: OE 19 and NCI N87, HER2+ GC cell lines, were treated with increasing doses of Lapatinib (L) and T to obtain resistant clones. These were isolated and characterized by performing mutational analysis by Sequenom MassArray and Western blot (WB) to evaluate protein expression. Genome-wide expression profile was conducted. Inhibition of the altered pathways was performed with specific drugs and siRNA to verify if those alterations were responsible for resistance. In vivoexperiment was performed to corroborate the obtained results. A retrospective cohort of HER2 amplified patients treated with T was also analysed. Clinical characteristics and outcomes were collected. An immunohistochemistry (IHC) analysis to evaluate the altered pathway detected in preclinical models was conducted.

Results: L and T resistant clones were obtained. Protein expression underlined the activation of PI3K pathway and of its downstream effector RPS6 protein. Data obtained by microarray were analysed, identifying a large number of genes regulated by NFR2, a transcriptional regulator involved in oxidative stress, detoxification, and drug resistance. NRF2 expression was detected by WB and immunofluorescence. Cells were treated with GSK048 (G), a dual PI3K/TORCH1/2 inhibitor, showing a decrease in cell growth. siRNA of both RPS6 and NRF2 confirmed the decrease of proliferation and when treatment with antiHER2 was administered, sensitivity was restored. Interestingly after inhibiting PI3K pathway NRF2 expression decreases. In xenografts L and G were tested. G reduced both the expression of pRPS6 and NRF2. Patients with high IHC expression of pRPS6 treated with T, experienced worse outcome, suggesting that hyperactivation of the PI3K pathway may make antiHER2 treatment less effective.

Conclusions: Activation of NRF2 via PI3K seems to be consistently related to anti HER2 resistance in HER2 amplified GC.

666P Discordance between HER2 expression status in primary tumor and matched malignant ascites in gastric adenocarcinoma

Y. Yang[1], H. Kim[1], S-M. Son[2], H.S. Han[3]

[1]Department of Internal Medicine, Chungbuk National University Hospital, Cheongju-si, Republic of Korea, [2]Department of Pathology, Chungbuk National University Hospital, Cheongju-si, Republic of Korea, [3]Department of Internal Medicine, Chungbuk National University, College of Medicine, Cheongju-si, Republic of Korea

Background: Test for the human epidermal growth factor receptor 2 (HER2) expression is an essential step to select gastric cancer patients for HER2 molecular targeted therapy. Peritoneal carcinomatosis with ascites is the most common manifestation of gastric cancer metastases, prevalence upto 40% in previous reports. The aim of this study is to compare the HER2 expression status in primary gastric adenocarcinoma and paired cell block of malignant ascites.

Methods: Forty-five patients with evaluable tissue samples of both primary gastric lesion and ascites cell block were enrolled. HER2 expression status was evaluated by immunohistochemistry (IHC) in primary tumor and in paired cell blocks of ascites which was confirmed by the qualified pathologist.

Results: HER2 expression was detected in 16 patients (35.6%) from primary gastric adenocarcinoma tissue and in 10 (22.2%) from ascites cell block. HER2 overexpression defined by IHC 3+ was observed in 2 (4.4%) and 3(6.7%) of primary lesion and ascites samples, respectively. However the HER2 status of primary tumor and ascites cell block showed discordance in all of those patients with HER2 overexpression. Patients with HER2 overexpression in primary gastric tissue showed HER2 negativity in ascites cell block, and vise versa. Of the 14 patients whom with two or more serial ascites samples, the HER2 IHC score differences between the samples were observed in five patients (35.7%).

Conclusions: Incidence of HER2 overexpression was slightly lower than previous reports in primary gastric tumor and metastatic ascites samples in this study. Discordances of HER2 expression status between the primary gastric adenocarcinoma and ascites cell block or between serially sampled ascites were observed in a significant proportion of the patients (20%). HER2 testing from both primary tumor and ascites cell block and from serial ascites sample could increase the sensitivity of HER2 overexpression detection, and assist to select adequate patients for HER2 molecular targeted therapy.

Background: Trastuzumab with cisplatin and fluoropyrimidines(FUs) improved the overall survival of patients with human epidermal growth factor receptor type 2 (HER2)-positive advanced gastric cancer (AGC). S-1 plus oxaliplatin (SOX) is a one of the standard regimen for HER2-negative AGC especially in Japan. However, to date, few studies have evaluated the efficacy and safety of trastuzumab combined with SOX in patients with HER2-positive AGC.

Methods: This is the multi-central, phase II study that is conducted in 10 Japanese institutions. Patients with HER2-positive AGC received S-1 (80mg/m^2) twice a day orally on days 1–14, oxaliplatin (130mg/m^2) intravenously on day 1, and trastuzumab (course 1, 8mg /kg; course 2-, 6mg/kg) intravenously on day 1 of a 21-day cycle. The primary end point was confirmed response rate (cRR); secondary end points included overall survival (OS), progression-free survival(PFS), and adverse events.The sample size was determined to be 75cases based on a hypothesis of threshold RR of 50% and an expected RR of 65%, 90% power, with an alpha value of 0.1 (one-sided) using the binomial test.

Results: From June 2015 to January 2018, a total of 78 patients were screened, of whom 75 were enrolled and eligible. The median age was 64 years. ECOG PS(0/1);57/18, unresectable/recurrence; 66/9, Gastric/EGJ; 64/11, pathology(tub1/tub2/por/sig); 13/33/24/5, metastatic sites(LNs/liver/peritoneum/lung/bone/others); 40/35/20/9/3/8. The proportion of IHC 3+ was 73.3%. In the full analysis set of 75 patients as of March 2018, cRR was 65.2% (95% confidence interval (CI).52.4–76.5); n = 66: excluding unconfirmed 9 cases; and the disease control rate was 89.4% (95% CI.79.4-95.6). Median OS,

PFS, were estimated as 20.6 (95% CI.14.8–30.6) and 9.4(95% CI.7.4-14.7) months, respectively. Major grade 3 or 4 adverse events included sensory neuropathy (14.7%), neutropenia (9.3%), diarrhea (6.7%), and anemia (6.7%). There were no treatment-related deaths.

Conclusions: Trastuzumab in combination with SOX showed promising activity with well-tolerated toxicities in patients with HER2-positive AGC as well as other platinum and FUs. Final analysis based on confirmed response will be reported at the conference.

Background: Trastuzumab (T-mab) combined with cisplatin and fluoropyrimidines is the standard first line treatment for the patients with HER2-positive advanced gastric cancer (AGC). We conducted first phase II trial to assess the efficacy and safety of T-mab combined with S-1 and oxaliplatin (HER-SOX130) for HER2-positive AGC or recurrent gastric cancer.

Methods: Patients with IHC 3+ or IHC 2+/FISH positive received 80 mg/m^2 (80-120 mg/body) S-1 per day orally on days 1–14, 130 mg/m^2 oxaliplatin intravenously on day 1, and T-mab (8-mg/kg loading dose and 6 mg/kg thereafter) intravenously on day 1 of a 21-day cycle until one of the criteria for withdrawal of the study treatment occurred. The primary end-point was the response rate (RR). The secondary end-points were adverse events, progression-free survival (PFS), overall survival (OS), time-to-treatment failure (TTF), duration of treatment, time to failure of strategy (TFS) and dose intensity. Adverse events were recorded based on the CTCAE Ver.4.0.

Results: 42 patients were enrolled from June 2015 to May 2016. Efficacy and safety analyses were conducted in the full analysis set of 39 patients. The data cut off specific to the survival status was February 19, 2018. The proportion of patients with IHC 3+ was 87%. The incidence of grade 3 or 4 adverse events (>10%) were platelet count decreased (17.9%), anorexia (17.9%), neutrophil count decreased (12.8%), anemia (10.3%), and hyponatremia (10.3%). The confirmed RR assessed by the independent review committee was 82.1%(32/39) (95%C.I.: 67.3–91.0), and the disease control rate was 87.2%(34/39) (95%C.I.: 73.3–94.4). 9 cases underwent curative surgery after HER-SOX130. Median PFS, TTF and OS was 7.0 (95%C.I.: 5.5–14.1), 5.7 (95%C.I.: 4.6–7.0) and 27.7 (95%C.I.: 15.6–) months, respectively.

Conclusions: HER-SOX130 demonstrates promising response and survival with avourable safety profile. HER-SOX130 should be considered for the patients with HER2-positive AGC.

669P Differences in outcome according to chemotherapy backbone and maintenance treatment in HER2 positive metastatic gastric cancer (GC) or gastroesophageal junction (GEJ)

N. Martinez Lago[1], S. Candamio Folgar[2], C. Grande Ventura[3], M. Salgado Fernandez[4], J. De la Camara Gomez[5], J.C. Méndez Méndez[6], D. Arias Ron[4], F. Vazquez[7], M. Reboredo Lopez[1], Y. Vidal Ínsua[2], B. Graña Suarez[1], M. Jorge Fernandez[3], M.E. Brozos Vazquez[8], M.L. Pellon Augusto[5], J. Prato Varela[1], P. Gonzalez Villarroel[3], A. Fernandez Montes[9]

[1]Medical Oncology, Hospital Universitario a Coruna, A Coruna, Spain, [2]Medical Oncology Department, University Clinical Hospital of Santiago de Compostela, Santiago de Compostela, Spain, [3]Medical Oncology, Hospital Universitario Alvaro Cunqueiro, Vigo, Spain, [4]Medical Oncology Department, Complejo Hospitalario de Ourense, Ourense, Spain, [5]Medical Oncology Department, Complexo Hospitalario Universitario de Ferrol, Ferrol, Spain, [6]Medical Oncology Department, Centro Oncológico de Galicia, A Coruña, Spain, [7]Medical Oncology Department, Complejo Hospitalario Universitario de Santiago de Compostela SERGAS, Santiago de Compostela, Spain, [8]Medical Oncology, Complexo Hospitalario Universitario de Santiago, Santiago de Compostela, Spain, [9]Medical Oncology, Complexo Hospitalario Universitario de Ourense, Ourense, Spain

Background: Although the TOGA study used cisplatin plus capecitabine (XP) or fluorouracil (FP), oxaliplatin schedules (CAPOX or FOLFOX) are commonly used. There is also a discrepancy in the no. of cycles and the maintenance treatment with trastuzumab (T).

Methods: We conducted an observational, retrospective, multicentric study of patients with metastatic HER2 GC or GEJ treated at 6 spanish hospitals belonging to Galician Research Group on Digestive Tumors (GITuD). Demographic, clinic and pathological data were retrospectively collected and correlated with overall survival (OS) and progression free survival (PFS).

Results: 91 pts treated between May 2010 to January 2018 were recorded. Median age was 68 years (range 38-84 years), 74.7% were male, 39.6% GEJ location, 82.9% intestinal Lauren subtype, 64.5% well-moderate differentiated, 82.4% synchronous disease and 24.2% primary tumor resection. Median of metastatic locations was 2 (range 1-4). Chemotherapy backbone: FP 4.7%, XP 21.2%, CAPOX 37.6%, FOLFOX 36.5%. With a median follow up of 45.6 months, 85 pts were evaluable for efficacy. Median OS was 14.2 months (CI 95% 10.3-18.0 months) and median first line PFS was 8.9 months (CI 95% 7.7-10.1 months). Overall response rate 57.6% and disease control rate 78.8%. Median cycles of induction treatment were 6 (range 1-18). No PFS differences were found according to the platinum ($p = 0.579$) or fluropirimidine used ($p = 0.955$). Of 47 non-progressive patients after 6 months the majority received maintenance treatment for a median of 6.5 cycles (range2-77) with T +/- fluoropirimidine (21 and 16 pts) while 10 discontinued treatment. Post-induction PFS favors those who continued treatment with a PFS of 7.6 vs 5.0 months ($p = 0.033$), without differences between schemas ($p = 0.890$)). Primary tumor surgery (HR 0.380; $p = 0.010$), neutrophil to lymphocyte ratio < 5 (HR 0.461; $p = 0.008$), platelet to lymphocyte ratio <200 (HR 0.557; $p = 0.030$) were associated with prolonged OS.

Conclusions: Maintenance treatment with T has a benefit in terms of PFS even in patients who received T during induction. The practice of continuing the fluoropirimidine during maintenance doesńt appear to add any PFS benefit in our series.

Background: Neoadjuvant chemotherapy is an accepted treatment method to improve the survival for advanced gastric cancer in worldwide. This phase II study, KSCC1601, aimed to investigate efficacy and safety of S-1 and Oxaliplatin for locally advanced gastric (LAGC) and esophago-gastric cancer (EGC).

Methods: Patients received oral S-1 40-60 mg twice daily on days 1 to 14 every 3 weeks plus intravenous oxaliplatin 130 mg/m^2 on day 1 every 3 weeks for 3 courses, followed by gastrectomy with D2 lymphadenectomy. The primary endpoint was pathological response rate (pRR) according to the proportion of necrosis in the tumor: grade 0, no necrosis; grade 1a, < 1/3 necrosis; grade 1b, > 1/3 or < 2/3 necrosis; grade 2, > 2/3 or < all necrosis; and grade 3, all parts of the tumors affected by necrosis. A sample size of 46 was set according to one-sided significance level of 0.05 and power of 80% based on an exact binomial distribution, and assuming the null hypothesis of a 30% pRR and an alternative hypothesis of a 50% pRR. The incidence of anastomosis leakage in EGC was the main secondary endpoint. Other secondary endpoints were R0 resection rate, overall survival, relapse free survival and safety.

Results: Between 2016 April and 2017 July, 47 patients (24 EGC, 23 LAGC) were enrolled in this study. All patients were eligible for analysis. 42 patients (89.4%:95%CI 76.9-96.5) underwent surgery, and curative resection was performed in 41 patients. The rate of protocol treatment completeness was 42 patients (89.4%:95%CI 76.9-96.5%). pRR, the primary endpoint (grade 1b to 3), was 25 cases (59.5%:90%CI 45.7-72.3%) of primary lesions. The main toxicities of neoadjuvant chemotherapy were grade 3/4 thrombocytopenia (10.6%), neutropenia (6.4%), anemia (4.3%), grade 3/4 anorexia (12.8%). The number of anastomosis leakage so as to 20 EGC according to the Clavien–Dindo classification was 2 for grade IIIa, 2 for grade IIIb, and 1 for grade IV (25.0%:90%CI 10.4-45.6%). Survival data will be updated in further investigation.

Conclusions: The S-1 and oxaliplatin was well tolerated and is promising as a preoperative chemotherapy regimen for patients with LAGC and EGC.

Background: D2 gastrectomy followed by postoperative S-1 is the standard therapy for the patients (pts) with stage III gastric cancer (GC) in East Asia, but 40% of the pts develop a recurrence. We hypothesize that the perioperative capecitabine and oxaliplatin (CapeOx) might improve survival for clinical stage III GC.

Methods: In this phase II trial, the eligibility criteria included pathologically confirmed clinical SS/SE N1-3 M0 GC according to Japanese Classification of GC (JCGC) 3rd English Edition. Perioperative CapeOx consisted of three cycles of CapeOx (capecitabine; 2,000 mg/m^2 for 14 days, oxaliplatin; 130 mg/m^2 day 1) every 3 weeks as neoadjuvant chemotherapy (CT), followed by five cycles of adjuvant CapeOx after the D2 gastrectomy. The primary endpoint was the pathological response rate (pRR) according to JCGC (≥ Grade 1b). The planned sample size was 34 pts calculated on the hypothesis that the expected pRR was 65% and the threshold was 40%, with one-sided alpha of 0.05 and power of 90%.

Results: Thirty-seven pts were enrolled from Apr. 2016 to May. 2017, and fully evaluated for efficacy and toxicity. R0 and R1 resection were achieved in 29 and three pts, respectively. One pt underwent R2 resection, and four pts could not undergo surgical resection. Sixteen pts underwent total gastrectomy, and 17 pts underwent distal gastrectomy. The pRR was 54.1% (one-sided p = 0.058, 95% CI: 36.9-70.5). The relative dose intensity (RDI) of Capecitabine and Oxaliplatin were 90.7% and 92.0%, respectively. Twenty-seven pts received adjuvant therapy, and the RDI of capecitabine and Oxaliplatin were 80.9% and 63.4%, respectively. Grade 3/4 toxicities of neoadjuvant CT included neutropenia (8%), thrombocytopenia (8%), and anorexia (8%). Grade 3/4 toxicities of adjuvant CT included neutropenia (27%), diarrhea (8%), and anorexia (3%). Grade IIIa surgical complications included intraabdominal abscess (3%), bowel obstruction (3%), and anastomotic leakage (3%).

Conclusions: This phase II trial of perioperative CapeOx showed favorable antitumor activity with an acceptable safety profile for stage III GC, although pRR as primary endpoint did not meet the prespecified threshold.

672P Comparison of preoperative neoadjuvant chemotherapy (SOX) with different courses of treatment on the patients with advanced gastric cancer

X. Wang

General Surgery, Chinese PLA General Hospital, Beijing, China

Background: Objective: To analyze the safety and efficacy of different periods of preoperative adjuvant chemotherapy (SOX) regimen in the treatment of advanced gastric cancer.

Methods: From June 1 2010 to June 1 2017, 120 patients aged from 25 to 80 with clinical stage IIA-IIIC gastric cancer received neoadjuvant chemotherapy with S-1 and oxaliplatin and gastrectomy in Chinese PLA General Hospital. Patients were randomly assigned to two groups with different length of treatment in preoperative neoadjuvant chemotherapy. There were 60 patients in the group with 3 periods preoperative neoadjuvant chemotherapy of treatment, and 60 patients in the group with 5 periods preoperative neoadjuvant chemotherapy of treatment. An ambispective cohort study was conducted. We compared short-term surgical outcomes between the two groups.

Results: There was no significant difference in clinical pathological features between the two groups. However, the five-cycle group had less operative time (229 minutes vs 240 minutes, P = 0.031) and less intraoperative blood loss (158 ml vs. 201 ml, P = 0.006). The short-term prognosis was similar in both groups. The R0 resection rate was higher in the 5-cycle group, especially in stage III subgroup.

Conclusions: The longer preoperative chemotherapy in neoadjuvant chemotherapy, the better the effect of the neoadjuvant chemotherapy in patients with advanced gastric cancer, so we can try to use more preoperative neoadjuvant chemotherapy.

673P Phase II trial of neoadjuvant therapy using apatinib plus SOX regimen in locally advanced gastric cancer: Updated results

Y. Zheng, X. Yang, H. Shi, Z. Yang, C. Yan, Z. Ni, M. Li, B.K. Sah, W. Liu, W. Xu, X. Yao, Z. Zhu, M. Yan, Z. Zhu, C. Li

Department of Gastrointestinal Surgery, Ruijin Hospital affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai Institute of Digestive Surgery, Shanghai Key Laboratory of Gastric Neoplasms, Shanghai, China

Background: Locally advanced gastric cancer (LAGC) has a poor prognosis. Neoadjuvant chemotherapy can reduce tumor loading, degrade staging and increase possibility of complete resection, thus prolonging the survival of LAGC patients (pts). We conducted a phase II trial to assess the feasibility of SOX regimen in combination with apatinib (an anti-angiogenic agent) as neoadjuvant therapy in LAGC.

Methods: This study recruited untreated LAGC pts with pathologically and/or cytologically confirmed adenocarcinoma. Treatment included three 21-day cycles of apatinib (oral, 500 mg qd; discontinued in the last cycle), S-1 (oral, 40-60 mg, bid, day 1-day 14) and oxaliplatin (iv, 130 mg/m^2, day 1), followed by radical surgery after 4 weeks. The primary outcome was neoadjuvant therapy related toxicity, and the secondary outcomes included tumor response, R0 resection rate, postoperative pathological evaluation and surgical morbidity. The target sample size was 30 pts.

Results: From Dec 2016 to Apr 2018, 30 eligible pts were enrolled. 70% was males. The median age was 60 years (range 43–73 years). At the cut-off date for data analysis (24th Apr, 2018), 24 pts completed the three cycles of neoadjuvant therapy. One complete response, 17 partial response, 5 stable disease and 1 progressive disease (PD) were achieved, yielding an objective response rate of 75.0% and disease control rate of 95.8%. 23 pts received radical surgery except the one who had PD, and all achieved R0 resection. Of the 23 pts receiving surgery, the first 18 pts had completed the postoperative pathological analysis, and the median tumor regression was 85%. Among the pts who had received at least one dose of the preoperative treatment, the incidence of adverse events (AEs) and grade 3/4 AEs were 96.4% and 32.1%, respectively. The main grade 3/4 AEs included hypertension, leukopenia, diarrhea and oral mucositis (all 7.1%). In regard to surgical morbidity, 6 (26.1%) experienced fever, 1 (4.3%) had a duodenal stump fistula, and 1 (4.3%) had incision fat necrosis. No surgical mortality occurred.

Conclusions: Three-weekly neoadjuvant therapy with apatinib plus SOX followed by radical surgery for LAGC showed acceptable toxicity and promising efficacy.

674P The efficacy and safety of (neo)adjuvant therapy for gastric cancer: A network meta-analysis

T. van den Ende[1], E. Ter Veer[1], M. Machiels[2], R.M.A. Mali[1], F.A. Abe Nijenhuis[1], L.D. Waal[1], M. Laarman[1], S.S. Gisbertz[3], M.C.C.M. Hulshof[2], M.G.H. van Oijen[1], H.W.M. van Laarhoven[1]

[1]Medical Oncology, Academic Medical Center (AMC), Amsterdam, Netherlands, [2]Radiotherapy, Academic Medical Center (AMC), Amsterdam, Netherlands, [3]Surgery, Academic Medical Center (AMC), Amsterdam, Netherlands

Background: Alternatives in treatment-strategies exist for resectable gastric cancer treated with curative intent including: perioperative chemotherapy, adjuvant chemoradiotherapy and adjuvant chemotherapy. Our aims were (1) to assess the benefit of perioperative, neoadjuvant and adjuvant treatment-strategies and (2) to determine the optimal adjuvant regimen for gastric cancer treated with curative intent.

Methods: PubMed, EMBASE, CENTRAL, and ASCO/ESMO conferences were searched up to August 2017 for randomized controlled trials on curative treatment for resectable gastric cancer. We performed two network-meta-analyses (NMA). NMA-1 compared perioperative, neoadjuvant and adjuvant strategies only if there was a direct comparison. NMA-2 compared different adjuvant regimens with chemotherapy or chemoradiotherapy, after curative resection. Overall-survival (OS) and disease-free-survival (DFS) were analyzed using random-effects NMA on the hazard ratio (HR)-scale and calculated as combined HRs and 95% credible intervals (95%CrIs).

Results: NMA-1 consisted of 9 direct comparisons between strategies for OS (14 studies, n = 4,187 patients). NMA-2 consisted of 16 direct comparisons between adjuvant chemotherapy/chemoradiotherapy regimens for OS (37 studies, n = 10,761) and 14 for DFS (30 studies, n = 9,714 patients). Compared to taxane-containing-perioperative-chemotherapy, surgery-alone (HR = 0.58, 95%CrI = 0.38-0.91) and perioperative-chemotherapy (HR = 0.79, 95%CrI = 0.58-1.15) were inferior in OS. Compared to surgery-alone neoadjuvant chemotherapy was non-significant (HR = 1.00, 95%CrI = 0.67-1.47). After curative-resection, the doublet oxaliplatin-fluoropyrimidine (for one-year) was the most efficacious adjuvant regimen in OS (HR = 0.47, 95%CrI = 0.28-0.80). The addition of radiotherapy to chemotherapy did not improve OS and DFS.

Conclusions: For resectable gastric cancer treated with curative intent, (1) taxane-containing perioperative-chemotherapy is the preferred treatment strategy; and (2) adjuvant oxaliplatin-fluoropyrimidine is the optimal regimen after curative resection.

675P Irinotecan, oxaliplatin, 5-fluorouracil/leucovorin (FOLFIRINOX) as first-line therapy in advanced HER2-negative gastric or gastroesophageal adenocarcinoma (G/GEA)

E. Obarevich, N. Besova, E. Trusilova, V. Gorbunova

Chemotherapy Department, N. N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation

Background: G/GEA is relatively chemosensitive, but triplet chemotherapy (CT) regimens with docetaxel have the most efficacy with overall response rate (ORR) 37-58%, median progression free survival (MPFS) 5.2-9.7 mo, median overall survival 9.2-18.8 mo. Irinotecan is active drug for the 1st line CT of G/GEA patients (pts). FOLFIRINOX regimen have shown promising activity in other GI cancers (pancreatic, colorectal). The aim of our study was to evaluate efficacy and tolerability of mFOLFIRINOX in G/GEA.

Methods: G/GEA patients (pts) received 9 cycles of irinotecan 180mg/m^2+oxaliplatin 85mg/m^2+leucovorin 200mg/m^2+5-fluorouracil 250mg/m^2 bolus followed by 2200mg/m^{2}x48h (mFOLFIRINOX) on d1 every 2 weeks without subsequent maintenance therapy. Primary G-CSF prophylaxis was not provided.

Results: 108 CT-naïve pts with G/GEA were included from Jan 2012 to Oct 2015 (48 female, 60 male). ECOG 0/1/2/3/4 were 41/51/7/1% pts. ORR was 52,8%, SD–39,8%, PD–5,6%. MPFS and MOS were 7,83 mo and 16,8 mo, respectively. The main toxicities Grade(gr) ≥3 in pts included neutropenia–47,2%, febrile neutropenia–5,6%, diarrhea–5,6%; we noted else thrombocytopenia gr 1-2 - 29,6%, asthenia gr 1-3 - 87%, hepatotoxicity - 25%/gr 3–0,9%, neurotoxicity–15,7%/gr–1,9%. 31(28,7%) pts received G-CSF on 8,5% cycles. There were no deaths and treatment discontinuation due to toxicity. After the complete regression of distant metastases 11 pts were operated (D2 gastrectomy). For these pts MPFS was18,47 mo, MOS–29,33 mo.

Conclusions: mFOLFIRINOX showed remarkable ORR, PFS and OS in patients with advanced gastroesophageal or gastric adenocarcinoma in the fist-line setting. This regimen may be one more reasonable therapeutic option for these pts. We recommend mFOLFIRINOX for Phase III clinical trial compared with FLOT regimen.

676P Efficacy and safety for apatinib combined with oxaliplatin and S1 in initially treated metastatic gastric cancer: A single-center observational study

J. Peng, L. Peng, H. Wu, K. Wu, W. Chen, C. Xie, J. Xu, X. Zhang, D. Chen, S. Cai, Y. He

Gastrointestinal Surgery Center, The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background: Currently, S-1 combined with oxaliplatin (SOX) is widely used in the first-line treatment of advanced gastric cancer in China. Apatinib has demonstrated encouraging anti-cancer activity in gastric cancer within both in vitro and in vivo models. We evaluated the efficacy and safety of apatinib combined with SOX in initially treated patients with metastatic gastric cancer.

Methods: In this single arm study, patients with unresectable metastatic gastric adenocarcinoma was enrolled to received chemotherapy with apatinib (500mg, once daily) and SOX regimen. Oxaliplatin was administered at a dose of 130 mg/m^2 on day 1, and S-1 (40–60 mg depending on patient's body surface area) was given orally twice daily for 2 consecutive weeks followed by a 1-week rest. The primary end point was response rates, Secondary endpoints were safety, median progression-free survival and median overall survival.

Results: Thirty-one eligible patients were enrolled between January 2016 and September 2017. Two patients achieved a complete response and 19 patients had partial response. The objective response rates was 67.7%. Seven patients had stable disease and the disease control rates was 90.3%. Disease progression was seen in 3 cases (9.7%). Progression-free survival was 5.9 months (95% confidence interval: 3.2–12.6) and median overall survival was 13.6 months (95% confidence interval: 7.3–22.1). The most common grade 3 to 4 hematologic adverse events (AE) were leucopenia (12.9%), neutropenia (38.7%), thrombocytopenia (6.5%) and anaemia (25.8%), nonhematologic AE were nausea (12.9%), anorexia (32.3%), hand-foot syndrome (6.5%), hypertension (9.7%) and proteinuria (3.2%). No treatment-related death was documented during the drug administration.

Conclusions: Apatinib plus SOX is effective for initially treated metastatic gastric cancer with more favorable safety.

677P Afatinib in combination with cisplatin and 5-fluorouracil (5-FU) as first line treatment in inoperable gastric and gastro-esophageal junction (GEJ) cancer: A phase II study by the Hellenic Cooperative Oncology Group

T. Makatsoris, E. Samantas, K. Manousou, V. Karavasilis, G. Aravantinos, D. Tryfonopoulos, A. Psyrri, D.G. Pectasides, E. Pazarli, C. Petraki, A. Tsipoura, I.G. Kaklamanos, G. Fountzilas, G. Pentheroudakis

Data Office, Hellenic Cooperative Oncology Group (HeCOG), Athens, Greece

Background: Inoperable gastric and GEJ cancer is usually treated with platinum- and fluoropyrimidine-based combination chemotherapy. Targeting of the epidermal growth factor family of receptors has been unsuccessful except in the case of HER2 targeting with trastuzumab. Afatinib, has shown activity in preclinical models of gastric cancer and has been combined with cisplatin and 5-FU in phase I studies.

Methods: Patients (pts) were treated with the combination of cisplatin (75 mg/m^2 ; day 1), 5-FU (750 mg/m^2; continuous infusion days 1-4) and afatinib (40 mg/day; week1: days 3-5, weeks 2, 3: days 1-5), in an effort to optimize therapy efficacy and tolerability. Primary endpoint was the objective response rate (ORR) in the intention to treat (ITT) and the per-protocol (PP) population. Secondary endpoints were progression-free survival (PFS), overall survival (OS), and safety profile.

Results: Among the 55 pts (median age 64; range 20-77) enrolled (ITT), the ORR was 34.5% (44.2% in PP pts; N = 43). After a median follow-up of 33.3 months, median PFS and OS were 5 (95% CI 4-6; 49 relapses) and 9.3 (95% CI 6.7-11.5; 43 deaths) months, respectively. Median relative dose intensities administered were 0.97 for 5-FU, 0.96 for cisplatin and 0.94 for afatinib. Grade 3/4 adverse events (AEs) occurred in 34 pts (61.8%) and 9 pts (16.4%), respectively. Most common grade 3/4 AEs were

neutropenia (27.3%), anemia (12.7%), hypokalemia (10.9%), diarrhea (5.4%), infections (5.4%). Acneiform rash grade 1/2 was noted in 20% of pts, while there were 4 (7.3%) thromboembolic events (grade 1-3). There were no treatment related deaths. Pts with GEJ cancers had worse OS than pts with gastric cancer ($p = 0.03$).

Conclusions: The combination of afatinib with cisplatin / 5-FU in pts with inoperable gastric / GEJ cancer has modest activity, however afatinib weekend breaks optimized the compliance and tolerability of the combination. Identification of predictive biomarkers could potentially help in further evaluation of the role of afatinib in gastric / GEJ cancer.

Clinical trial identification: NCT01743365 (December 6, 2012).

Background: The purpose of this study was to evaluate chemotherapy patterns and changes in quality of life (QOL) during first-line palliative chemotherapy for Korean patients with unresectable or metastatic/recurrent gastric cancer (GC).

Methods: This was a non-interventional, multi-center, prospective, observational study of 527 patients in Korea. QOL assessments were conducted using the European Organization for Research and Treatment of Cancer (EORTC) Quality of Life Questionnaires (QLQ)-C30 and QLQ-STO22 every 3 months over a 12-month period during first-line palliative chemotherapy. The specific chemotherapy regimens were selected by individual clinicians.

Results: Most patients (93.2%) received combination chemotherapy (mainly fluoropyrimidine plus platinum) as their first-line palliative chemotherapy. The median progression-free survival and overall survival were 8.2 and 14.8 months, respectively. Overall, 'a little' changes (differences of 5-10 points from baseline) were observed in some of the functioning or symptom scales; none of the QOL scales showed either 'moderate' or 'very much' change (i.e., $\geq$11 point difference from baseline). When examining the best change in each QOL domain from baseline, scales related to some aspects of functioning, global health status/QOL, and most symptoms revealed significant improvements ($p < 0.05$). Throughout the course of first-line palliative chemotherapy, most patients' QOL was maintained to a similar degree, regardless of their actual response to chemotherapy.

Conclusions: This observational study provides important information on the chemotherapy patterns and QOL changes in Korean patients with advanced GC. Overall, first-line palliative chemotherapy was found to maintain QOL, and most parameters showed an improvement compared with the baseline at some point during the course.

679P Meta-analysis of biweekly irinotecan plus cisplatin versus irinotecan alone as second-line treatment for advanced gastric cancer

K. Nishikawa[1], W. Koizumi[2], A. Tsuburaya[3], T. Yamanaka[4], S. Morita[5], K. Fujitani[6], Y. Akamaru[7], K. Shimada[8], H. Hosaka[9], N. Nakayama[10], Y. Miyashita[11], T. Tsujinaka[12], J. Sakamoto[13]

[1]Surgery, National Hospital Organization Osaka National Hospital, Osaka, Japan, [2]Gastroenterology, Kitasato University School of Medicine, Kanagawa, Japan, [3]Surgery, Tsuboi Cancer Center Hospital, Koriyama, Japan, [4]Biostatistics, Yokohama City University Hospital, Yokohama, Japan, [5]Biomedical Statistics and Bioinformatics, Kyoto University Graduate School of Medicine, Kyoto, Japan, [6]Surgery, Osaka General Medical Center, Osaka, Japan, [7]Surgery, Ikeda Municippal Hospital, Ikeda, Japan, [8]Internal Medicine, Showa University Kouto-Toyosu Hospital, Tokyo, Japan, [9]Gastroenterology, Gunma Prefectural Cancer Center, Ohta, Japan, [10]Gastroenterology, Kanagawa Cancer Center, Yokohama, Japan, [11]Data Center, Epidemiological & Clinical Research Information Network, Okazaki, Japan, [12]Surgery, Kaizuka City Hospital, Kaizuka, Japan, [13]Surgery, Tokai Central Hospital, Kakamigahara, Japan

Background: Biweekly CPT-11 plus CDDP (BIRIP) and CPT-11 alone are both expectable options for treating advanced gastric cancer (AGC) in second-line setting. Recently, two randomized phase III trials (TCOG GI-0801 and ECRIN TRICS) employing the same regimens have been reported. Both trials did not demonstrate the survival benefit of BIRIP due to underpowered. Therefore, we conducted a meta-analysis to compare the efficacy and safety of these two regimens in patients who have been enrolled in these two randomized trials.

Methods: Individual patient–level data from these two trials were collected for this study. In these two trials, patients with metastatic or recurrent gastric cancer refractory to S-1-based chemotherapy were randomly allocated to BIRIP (CPT-11, 60 mg/m^2; CDDP, 30 mg/m^2, q2w) or CPT-11 (150 mg/m^2, q2w). Overall survivals (OS) and progression-free survival (PFS) were described using Kaplan-Meier methods. Tumor responses were evaluated using RECIST ver. 1.0. Adverse events were evaluated using CTCAE ver. 3.0.

Results: Cumulative data from eligible 290 patients from these two trials were evaluated. OS were 12.3 (95% confidence interval [CI]: 10.5–14.1) in BIRIP group and 11.3 (95% CI: 10.0–13.2) months in CPT-11 group (hazard ratio 0.87; 95% CI: 0.68–1.12, $P = 0.272$). PFS was significantly longer in BIRIP group (4.3months [95% CI: 3.5–5.1]) than in CPT-11 group (3.3months [2.9–4.1]; HR 0.77; 95% CI: 0.61–0.98, $P = 0.035$). The response rate was 20.5% [95% CI: 13.3–27.7] in BIRIP group and 16.0% [95% CI: 9.6–22.4] in CPT-11 group ($P = 0.361$). The disease control rate was significantly better in BIRIP group (72.1% [95% CI: 64.2–80.1]) than in CPT-11 group (59.2% [95% CI: 50.6–67.8]) ($P = 0.032$). The incidences of grade 3 or worse adverse events did not differ between the two groups, for example neutropenia (35.9% vs. 32.4%) and elevation of serum creatinine (0.7% vs. 0.7%). The incidences of anemia (16.6% vs. 10.3%) was higher for BIRIP than for CPT-11. But diarrhea (1.4% versus 4.1%) was more common in CPT-11 group.

Conclusions: BIRIP significantly prolonged PFS as compared with CPT-11 alone and was tolerated as second-line treatment for AGC, but did not demonstrate the survival benefit.

Background: Although emerging treatments have been introduced to patients with metastatic or recurrent gastric cancer (MRGC) as second-line therapy, paclitaxel or irinotecan are still viable options. This phase III study compared the efficacy and safety of

paclitaxel versus irinotecan in patients with MRGC who failed to first-line chemotherapy.

Methods: Patients were randomized to receive either paclitaxel (70 mg/m^2; days 1, 8, 15, every 4 weeks) or irinotecan (150 mg/m^2 biweekly). The primary endpoint was progression-free survival (PFS).

Results: This study was stopped early due to low accrual rate. A total of 112 patients were enrolled, of which 54 were allocated to paclitaxel, and 58 to irinotecan. Median PFS of paclitaxel or irinotecan group were 3.5 and 2.1 months, respectively [hazard ratio (HR) 1.27; 95% confidence interval (CI), 0.86-1.88; p = 0.234]. Non-inferiority of irinotecan to paclitaxel was not proven according to the predefined upper margin of non-inferiority (1.32). Median overall survival (OS) was 8.6 months in the paclitaxel group, and 7.0 months in the irinotecan group (HR, 1.39; 95% CI, 0.91-2.11; p = 0.126). There was no difference in response rate (p = 0.783) between paclitaxel (15.8%) and irinotecan (13.6%). Among toxicities of ≥ grade 3, neutropenia (11.5%) was the most common toxicity, followed by peripheral neuropathy (7.7%) in the paclitaxel group, and neutropenia (34.5%) followed by nausea, vomiting and anemia (8.6%, respectively) in the irinotecan group.

Conclusions: Although paclitaxel showed numerically longer PFS and OS compared with irinotecan, this was statistically insignificant. Both irinotecan and paclitaxel are valid second-line treatment options in MRGC.

Editorial acknowledgement: This study was partly funded by Boryung Pharmaceutical and CJ HealthCare Corp. The research was supported in part by the Korean Cancer Study Group (KCSG) and KCSG data center (Study Number: KCSG ST10-01).

681P Impact of adding ramucirumab to paclitaxel in patients with advanced gastric cancer according to the level of ascites: A multicenter retrospective study

T. Masuishi[1], S. Kadowaki[1], H. Hirano[2], S. Kawai[3], T. Yamada[4], T. Moriwaki[4], N. Machida[3], N. Boku[2], K. Muro[5]

[1]Department of Clinical Oncology, Aichi Cancer Center Hospital, Nagoya, Japan, [2]Gastrointestinal Medical Oncology Division, National Cancer Center Hospital, Tokyo, Japan, [3]Division of Gastrointestinal Oncology, Shizuoka Cancer Center, Shizuoka, Japan, [4]Division of Gastroenterology, Faculty of Medicine, University of Tsukuba, Tsukuba, Japan, [5]Department of Clinical Oncology, Aichi Cancer Center Hospital, Nagoya, Aichi, Japan

Background: Adding ramucirumab (Ram) to paclitaxel (PTX) improved the overall survival (OS) in patients with advanced gastric cancer (AGC) in the RAINBOW trial, which excluded patients with high levels of ascites.

Methods: This retrospective study included patients with AGC who received PTX alone or PTX+Ram as a 2nd-line treatment from Nov. 2013 to Nov. 2016. Selection criteria were ECOG PS of 0–2, refractory or intolerant to fluoropyrimidines, and no prior use of taxane or Ram. The level of ascites was classified as low (no or limited to either the pelvic cavity or upper abdomen) or high (extended from the pelvic cavity to the upper abdomen). An adjusted HR (aHR) for progression-free survival (PFS) and OS was calculated by a multivariate Cox model that contained variables with p < 0.05 in the univariate analysis to reduce imbalance between both treatments.

Results: Among 305 patients, 201 (PTX/PTX+Ram, 115/86) and 104 patients (PTX/PTX+Ram, 63/41) were classified into the low and high ascites groups, respectively. There were no significant differences in the baseline characteristics between PTX and PTX+Ram in either group, excepting the proportion of patients with PS of 2 (PTX/PTX+Ram, 18/9% and 24/10% in the low and high groups, respectively) and high ALP levels (PTX/PTX+Ram, 36/23% in the low group). The median PFS in PTX/PTX+Ram was 3.0/5.2 months (m) (HR 0.56, 95%CI 0.42–0.75, p < 0.0001; aHR 0.59, 95%CI 0.44–0.79, p = 0.0004) in the low group and 2.2/3.5 m (HR 0.61, 95%CI 0.40–0.92, p = 0.02; aHR 0.57, 95%CI 0.42–0.77, p = 0.0003) in the high group, and the median OS was 6.9/10.6 m (HR 0.67, 95%CI 0.48–0.93, p = 0.02; aHR 0.69, 95%CI 0.49–0.97, p = 0.03) in the low group and 4.8/6.2 m (HR 0.57, 95%CI 0.37–0.88, p = 0.01; aHR 0.64, 95%CI 0.40–0.99, p = 0.046) in the high group. The incidence of febrile neutropenia was not different between PTX (3%) and PTX+Ram (3%) in the low group but was higher in PTX+Ram (12%) than in PTX (3%) in the high group.

Conclusions: Our study suggests that adding Ram to PTX may prolong survival in patients with AGC, regardless of the level of ascites. However, there is a risk of febrile neutropenia when administering PTX+Ram to patients with a high level of ascites.

Background: A prospective, multicenter, non-intervention registered study of apatinib is being conducted in advanced gastric cancer patients (pts). The result of interim analysis on efficacy and safety was released in ESMO 2017 Congress (695P). Herein, we mainly aimed to identify pts who benefit from apatinib treatment.

Methods: Pts with advanced or metastatic adenocarcinoma of stomach or gastro-esophageal junction who received apatinib administration were included in this real world study. The subgroup analyses were stratified by numbers of metastatic sites, ECOG PS, dosage of apatinib, and occurrence of adverse events (AEs).

Results: As of January 2018, data on 321 pts were available for final analysis. The median progression free survival (mPFS) and median overall survival (mOS) were 4.0 mos and 8.2 mos, respectively. 239 pts (74.5%) reported AEs. Main AEs were proteinuria (17.1%), hypertension (15.9%), and hand-foot syndrome (8.7%). As in table, the mPFS and mOS of pts with ≤2 metastatic sites were longer than those of pts with >2 metastatic sites (mPFS: p = 0.0087, mOS: p = 0.0006). For pts with ECOG PS 0, 1, and ≥2, the differences among groups were significant (mPFS, p < 0.001; mOS, p = 0.0316). Among different dose groups, dose ≥500 mg got longer mPFS (p < 0.001) and mOS (p = 0.0059). What's more, pts who reported proteinuria, hypertension, hand-foot syndrome, or leukopenia had longer mPFS (ps < 0.05) and mOS (ps < 0.05) compared with those who didn't.

Table: 682P Prognostic factors associated with apatinib treatment

		n	mPFS, mos	p	mOS, mos	p
Metastatic site	≤2	199	5.0	0.0087	9.1	0.0006
	>2	67	4.0		6.6	
ECOG PS	0	80	5.7	<0.001	8.7	0.0316
	1	168	4.3		8.2	
	≥2	73	3.0		6.6	
Dosage, mg	250	111	3.4	<0.001	7.7	0.0059
	500	187	4.5		9.5	
	>500	23	5.0		11.8	
Proteinuria	No	266	3.6	0.0003	8.0	0.0035
	Yes	55	5.6		9.2	
Hypertension	No	270	3.6	<0.001	8.0	0.0212
	Yes	51	6.0		8.8	
Hand-foot syndrome	No	293	3.8	0.0015	8.0	<0.001
	Yes	28	6.2		11.3	
Leukopenia	No	261	3.5	<0.001	7.7	<0.001
	Yes	60	7.3		9.6	

Conclusions: The real world study confirms that apatinib is safe and effective for advanced gastric cancer pts. Factors associated with better prognosis were ≤2 metastatic sites, ECOG PS 0/1, dose ≥500 mg, and occurrence of proteinuria, hypertension, hand-foot syndrome, or leukopenia.

Background: Apatinib, a small molecule VEGFR TKI, has been approved in the treatment of advanced or metastatic gastric cancer (GC) in China. We performed a real world study to observe the current status, efficacy and safety of apatinib treatment in clinical practice, and preliminarily define patients (pts) who could benefit from apatinib.

Methods: From September 2017, pts (age ≥18 yrs) with pathologically or histologically diagnosed GC who were given apatinib treatment met the inclusion criteria. The target sample size is 1000.

Results: As of April 2018, 651 pts from 37 centers were eligible. There are 491 (75.4%) males and 160 (24.6%) females. The median age was 62.5 yrs. The majority pts were at stage IV (399, 61.3%), had prior surgery (370, 56.8%) and chemotherapy (341, 52.4%). Pts with ECOG PS 0–2 were 520 (79.9%), and ECOG PS 1 was most common (403, 61.9%). Metastases were detected in 370 (56.8%) pts, which mainly were hepatic and pulmonary metastases. Pts received apatinib monotherapy or in combination with chemotherapy. The dose of apatinib in most pts (70.0%) was 500 mg qd. Apatinib was used in perioperative treatment for 269 (41.3%) pts. 382 (58.7%) pts with unresectable locally advanced, recurrent, or metastatic disease received apatinib as different lines of systemic therapy; among whom, 284 pts were evaluable for response, and 113 pts obtained complete clinical efficacy and safety assessment. 12 achieved partial response, 79 had stable disease and 22 got progressive disease. Thus, the objective response rate (ORR) and disease control rate (DCR) were 10.6% and 80.5%. 78.8% pts reported adverse events (AEs). The incidence of grade 3-4 AEs was 22.1%. Main apatinib-related AEs were hypertension (20.3%), and hand-foot syndrome (26.5%). There were tendencies showed that prognostic factors related with higher ORR were lines of apatinib (≤2, 11.3%; >2, 9.5%) and duration of medication (< 90 days, 7.1%; 90-120 days, 6.7%; >120 days, 11.9%).

Conclusions: In the real world, GC pts receiving apatinib therapy are mainly elderly men, stage IV, and ECOG PS 1. Apatinib is confirmed to be effective and safe for GC pts. Further analysis is needed to identify pts who obtain benefits from apatinib treatment.

Clinical trial identification: NCT03333967.

Legal entity responsible for the study: The First Affiliated Hospital of Anhui Medical University.

Background: Oral fluoropyrimidine plus platinum is a standard treatment for advanced gastric cancer but cannot be applied to peritoneal disseminated patients with inadequate oral intake. mFOLFOX6 has been reported to be tolerable and active for this population. In addition, we have reported the safety and efficacy of intraperitoneal (IP) paclitaxel (PTX) combined with S-1 based regimens in clinical trials. Therefore, we conducted a multicenter, exploratory study of IP PTX combined with mFOLFOX6 for peritoneal disseminated patients with inadequate oral intake.

Methods: Eligibility criteria included: pathologically proven gastric adenocarcinoma; peritoneal metastasis; no or short term (<1 month) previous chemotherapy without progression; inadequate oral intake; and age between 20–80 years. mFOLFOX6 was administered at the standard doses on days 1 and 15, and IP PTX was administered at 20 mg/m^2 on days 1, 8 and 15 every 4 weeks. The primary endpoint was 1-year overall survival (OS) rate. Secondary endpoints were progression-free survival (PFS), time to treatment failure (TTF), response rate, negative conversion rate on peritoneal cytology and safety.

Results: Among 36 patients enrolled from January 2016 to April 2017, 34 receiving at least one dose of protocol treatment were evaluated in terms of efficacy and safety. Sixteen patients had malignant ascites. The median number of courses was 6 (range 1–17). The 1-year OS rate was 55.9% (95% confidence interval [CI], 37.9%–72.8%). The median PFS was 7.5 months (95% CI, 5.1–12.5 months). The median TTF was 5.6 months (95% CI, 4.4–7.7 months). The best overall response was stable disease in all three patients with target lesions. The negative conversion rate on peritoneal cytology was 73.1% (95% CI, 52.2%–88.4%). Major grade 3 or 4 adverse events included neutropenia, elevation of alanine aminotransferase and aspartate aminotransferase, febrile neutropenia, sensory neuropathy, and diarrhea. There were no treatment-related deaths.

Conclusions: mFOLFOX6 plus IP PTX is well tolerated and active in gastric cancer patients with peritoneal metastasis and inadequate oral intake.

685P Relation of overall survival, progression free survival, post progression survival and response rate in four randomized Japanese phase III trials comparing various combinations of S-1 therapy for first-line treatment of advanced gastric cancer

M. Takeuchi[1], W. Ichikawa[2], K. Shitara[3], Y. Sunakawa[4], K. Oba[5], W. Koizumi[6], Y. Sakata[7], H. Furukawa[8], M. Takeuchi[9], M. Fujii[10]

[1]Faculty of Environment and Information Studies, Keio University, Fujisawa, Japan, [2]Medical Oncology, Showa University Fujigaoka Hospital, Yokohama, Japan, [3]Gastroenterology and Gastrointestinal Oncology, National Cancer Center Hospital East, Kashiwa, Japan, [4]Clinical Oncology, St.Marianna University School of Medicine, Kanagawa, Japan, [5]Biostatistics, The University of Tokyo School of Public Health, Tokyo, Japan, [6]Gastroenterology, Kitasato University School of Medicine, Sagamihara, Minami-li, Sagamihara, Japan, [7]Misawa City Hospital, Misawa, Aomori, Japan, [8]Department of Surgery, Kindai University Faculty, Osaka-Sayama, Japan, [9]Clinical Medicine (Biostatistics), Kitasato University, Tokyo, Japan, [10]Digestive Surgery, Nihon University School of Medicine, Tokyo, Japan

Background: S-1 is a commonly used agent in first line therapy of advanced gastric cancer in Japan. Several randomised studies compared S-1 monotherapy and various S-1 combination for gastric cancer. However, there has been no analysis of the relation of overall survival (OS), progression free survival (PFS), post progression survival (PPS) and response rate (RR) in gastric cancer trials.

Methods: Data from four randomized Japanese Phase III trials (START, SPIRITS, GC0301/TOP-002, G-SOX) were combined to evaluate the relation of OS, PFS, PPS and RR. The correlation between OS and PFS and OS and PPS was evaluated. OS, PFS and PPS was also evaluated for each of the RECIST categories and responders were defined as patients with complete response (CR) or partial response (PR).

Results: A total of 1911 patient data was available for analysis. 424 patients had either missing or not available RECIST data and were excluded leaving 1487 patients for analysis of which 678 patients were defined as responders (22 CR and 656 PR). 1276 patient data was used for the analysis of PPS. The correlation of OS and PFS was moderate with a Spearman's correlation coefficient of 0.611. The correlation of OS and PPS was strong with a Spearman's correlation coefficient of 0.8705. As the RECIST categories worsened, OS, PFS, PPS shortened. The median OS for the responders and non-responders (530.5 days, 272 days p-value<0.005) the median PFS for responders and non-responders (207 days, 82.5 days p-value<0.005) and the median PPS for responders was significantly longer than non-responders (316 days, 179 days p-value<0.005).

Conclusions: Although there are limitations, the analysis shows positive linear correlation between OS and PFS as well as OS and PPS. Patients in better RECIST categories have longer time to OS, PFS and PPS. From the correlation observed, response rate may be a surrogate endpoint to OS, PFS and PPS. Formal validation of the surrogacy of response rate to OS, PFS, and PPS in gastric cancer patients will be analyzed and presented using joint modeling of the survival data.

686P Immune gene expression profiling (GEP) of resected gastric adenocarcinomas (GAs) to identify biomarkers associated with immune checkpoint inhibitor (ICPI) response in early stage disease

J. Chao[1], H. Yin[2], J. Lee[3], S.J. Klempner[4], R. Pillai[2]

[1]Department of Medical Oncology and Therapeutics, City of Hope, Duarte, CA, USA, [2]Department of Pathology, City of Hope, Duarte, CA, USA, [3]Medicine, Samsung Medical Center, Seoul, Republic of Korea, [4]Medical Oncology, The Angeles Clinic and Research Institute, Los Angeles, CA, USA

Background: Clinical trials of ICPIs in early stage GA are ongoing. Nanostring (NS) GEP allows for simultaneous interrogation of a wide range of genes involved in immune signaling. We conducted a retrospective analysis of resected GAs to gain insight on the immune landscape in this setting.

Methods: We profiled 45 archival GAs treated with upfront surgery (pT2N0 to pT4N3 AJCC7) using a 770-gene immune profiling panel on the NS platform. Clinicopathologic data were abstracted and overall survival (OS) was analyzed using Kaplan-Meier methods.

Results: The majority of patients (44/45) had ≥ stage II disease. NS GEP demonstrated 4 distinct molecular signatures, A-D. Group D exhibited the greatest downregulation of pro-inflammatory genes relative to the other 3. Grouping was not correlated to tumor location, Lauren histology, or stage. When applying an analogous 18 gene T-cell inflamed signature from the KEYNOTE-059 trial, 10/45 GAs matched this signature, indicative of higher likelihood of response to single agent ICPI. OS did not differ between T-cell inflamed vs. non-T-cell inflamed (Table). Comparing signatures associated with greatest (B+C) vs. least (A+D) CD8+ T-cell gene expression as a surrogate for T-cell infiltration, OS favored groups B+C. We also observed a 4 gene (MS4A1, CD19, BLK, TNFRSF17) B-cell signature significantly favored high vs. low expressors for OS.

Table: 686P

NS GEP (n)	Median OS (mo)	Log-rank Test
T-cell inflammed (10)	Not reached (NR)	p = .52
Non-T-cell inflamed (35)	59.9	
Group B+C (24)	NR	p = .07
Group A+D (21)	33.0	
High B score (23)	NR	p = .02
Low B score (22)	33.0	

Conclusions: This data supports ongoing trials of ICPIs in early stage GA. ICPIs alone are unlikely to be sufficient for the majority of patients, necessitating biomarkers to guide addition of ICPIs to current multimodality approaches. Subsets of GAs were quantifiable by NS GEP to exhibit pre-existing CD8+ T-cell infiltration or B-cell signaling and more favorable prognosis. This suggests ICPIs alone or chemotherapy de-escalation strategies should be explored. Tumor-immune cell immunohistochemistry and MSI data will be presented.

687P Significant prognostic markers related to lymphocytes in gastric cancer

T. Hashimoto, Y. Kurokawa, T. Takahashi, Y. Miyazaki, K. Tanaka, T. Makino, M. Yamasaki, K. Nakajima, M. Mori, Y. Doki

Department of Gastroenterological Surgery, Osaka University Graduate School of Medicine, Osaka, Japan

Background: There is growing consensus that host immunity, of which lymphocytes are well-known as an indicator, plays important roles against the development of malignancy. Based on this concept, many studies reported the prognostic value of preoperative markers related to lymphocytes. This study aimed to investigate the prognostic value of pre- and postoperative lymphocyte counts and representative markers related to lymphocytes in predicting overall survival (OS) in patients with gastric cancer.

Methods: A total of 177 consecutive patients who underwent curative gastrectomy for pStage II or III gastric cancer from 2010 to 2014 were enrolled. We evaluated pre- and postoperative lymphocytes and representative markers including neutrophil to lymphocyte ratio (NLR), lymphocyte to monocyte ratio (LMR), platelet to lymphocyte ratio (PLR), and prognostic nutrition index (PNI). The optimal cutoff values of them were determined using the receiver operating characteristic (ROC) curve analysis. Prognostic value of them were analyzed using both Kaplan-Meier and multivariate Cox regression methods.

Results: Elevated pre- and postoperative lymphocytes, especially postoperative lymphocytes tended to be associated with better OS when classified into three groups [5-year OS: 46.2% in low-group (<1000), 62.5% in middle-group (1000-2000), and 80.9% in high-group (≥2000)]. ROC analysis revealed a higher predictive power for recurrence with the postoperative markers compared with preoperative ones. Postoperative lymphocyte (>1400), NLR (<2.3), LMR (>2.8), PLR (<150), and PNI (>47.0) were significantly associated with better OS ($P < 0.001$, $P < 0.001$, $P = 0.007$, $P = 0.001$, and $P < 0.001$, respectively). Of these markers, postoperative PNI (>47.0) was most associated with better OS on each pStage ($P = 0.003$ on pStage II, and $P = 0.070$ on pStage III). Multivariate analysis revealed that postoperative PNI (>47.0) and pN(-) were independent prognostic factors for OS.

Conclusions: Postoperative markers related to lymphocytes could have higher predictive power compared with preoperative ones, and postoperative PNI may be a better predictor of OS in patients with gastric cancer.

688P Correlation between clinic-pathological features, MSI, PD-L1 and survival in resectable gastric cancer: Looking for prognostic biomarkers

M. Ratti[1], N. Valeri[2], J.C. Hahne[2], A. Lampis[2], M. Ghidini[1], G. Tomasello[1], G. Tanzi[1], L. Toppo[1], C. Pizzo[1], B. Donida[1], C. Senti[1], M. Salati[3], M. Trombatore[1], M. Fassan[4], R. Passalacqua[1]

[1]Oncology, Istituti Ospitalieri di Cremona, Cremona, Italy, [2]Medicine, The Royal Marsden NHS Foundation Trust in Chelsea, London, UK, [3]Oncology, Azienda Ospedaliero - Universitaria Policlinico di Modena, Modena, Italy, [4]Medicine, University of Padova, Padua, Italy

Background: The identification of prognostic biomarkers (PB) for gastric cancer (GC) patient selection is compelling to improve survival outcomes. Microsatellite instability (MSI) is related with a positive prognostic effect in resected GC, whereas perioperative chemotherapy (CT) is detrimental. In metastatic MSI GC, immunotherapy (IT) with anti-PD1/PDL-1 drugs has shown promising results. Nevertheless, in early stages (ES), data on the relation between MSI, clinic-pathological (CP) features, PDL-1 expression and overall survival (OS) remain sparse, especially in Western population. In this study, the prognostic role of MSI status, CP features and PDL-1 status in a large cohort of Italian GC patients (pts) was examined.

Methods: CP data of 148 consecutive stage I-III GC pts resected in Cremona Institute between 2010 and 2014 (mostly chemo and/or radio-naive) were collected. MSI analysis was performed on tissue samples for all cases by polymerase chain reaction. PDL-1 expression, evaluated by immunohistochemistry, was assessed in MSI group. Differences between subgroups were evaluated with Chi-square test; Kaplan-Meier method and Long Rank test were used to calculate OS.

Results: Female sex ($p = 0.012$), earlier TNM stages ($p = 0.011$) and lower nodal involvement ($p = 0.029$) significantly correlated with MSI status. MSI is significantly associated with prolonged survival ($p < 0.001$), with an advantage of 28.6 months in OS compared to the microsatellite stable (MSS) group. Most MSI pts (71%) expressed PDL-1. Although not statistically significant, MSI pts without PD-L1 expression showed a better trend in OS compared with MSI GC pts expressing PDL-1 and with MSS group.

Table: 688P Main CP differences between MSS and MSI groups and survival outcomes

	MSS 110 (79.7%)	MSI 38 (25.7%)	p
SEX M F	77 (70) 33 (30)	18 (47.4) 20 (52.6)	0.012
STAGE (TNM)	19 (17.3) 26 (23.6)	13 (34.2) 13 (34.2)	0.011
I II III	65 (31.6)	12 (31.6)	
NODAL METASTASES NO YES	26 (23.6) 84 (76.4)	16 (42.1) 22 (57.6)	0.029
OS (months)	16.1	44.7	<0.001

Conclusions: MSI is an independent PB in GC and identifies a subset of pts with better OS and specific CP characteristics, including high expression of PDL-1. MSI could be a promising biomarker to select pts for CT vs IT in ES of GC.

689P Neutrophil-lymphocyte ratio (NLR) as an important prognostic factor for paclitaxel as a second line chemotherapy in advanced gastric cancer (AGC): Results from phase III DREAM study

M-H. Ryu[1], J.H. Kim[2], S.C. Oh[3], S. Park[4], J.G. Kim[5], J.W. Kim[6], S-H. Cho[7], K-E. Yoon[8], Y-K. Kang[9]

[1]Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [2]Internal Medicine, Asan Medical Center, Seoul, Republic of Korea, [3]Division of Hematology/Oncology, Internal Medicine Department, Korea University Guro Hospital, College of Medicine, Korea University, Seoul, Republic of Korea, [4]Hematology-Oncology, Samsung Medical Center Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [5]Department of Oncology, Kyungpook National University Medical Center, Daegeu, Republic of Korea, [6]Department of Internal Medicine, Seoul National University Bundang Hospital, Seoul, Republic of Korea, [7]Oncology, Chonnam National University Hwasun Hospital, Hwasun, Republic of Korea, [8]Clinical Trial Team, Daehwa Pharmaceutical, Co., Ltd., Seoul, Republic of Korea, [9]Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Songpa-gu, Republic of Korea

Background: Paclitaxel is the most commonly used second-line chemotherapy in AGC. Recently, the DREAM phase 3 study (NCT01839773) have demonstrated that the efficacy and safety of DHP107, an oral paclitaxel, is comparable to those of intravenous (i.v.) paclitaxel. This post-hoc analysis was conducted to evaluate whether NLR is related with the treatment outcomes for both oral and i.v. paclitaxel.

Methods: In the DREAM study, pts were randomized 1:1 to DHP107 (200 mg/m^2 orally twice daily on days 1, 8, 15, every 4 weeks) or i.v. paclitaxel (175 mg/m^2 on day 1, every 3 weeks). High vs low NLR was defined by the baseline median. With comparable efficacy between two arms in the original DREAM study, all the patients ($n = 236$) enrolled in the DREAM study were included in this post-hoc analysis for NLR.

Results: Median age was 59 years (range, 27–83) and 185 pts (78.4%) were male. The median for NLR was 2.08. Thirty-four (28.8%) out of the 118 pts with low NLR (<2.08) achieved a complete or partial response, while 17 (14.4%) out of the 118 pts with high NLR (>2.08) showed responses ($p = 0.007$). With a median follow up duration of 10.8 months (range, 0.4-27.8) in surviving pts, median progression-free survival (PFS) was 4.1 months (95% confidence interval [CI], 2.8-4.3) with low NLR and 1.6 months (95% CI, 1.4-2.5) with high NLR ($p = 0.0012$); and median overall survival (OS) was 12.0 months (95% confidence interval [CI], 9.7-14.5) with low NLR and 7.1 months (95% CI, 5.4-9.1) with high NLR ($p = 0.0004$). With a multivariate analysis including important clinical factors, low NLR remained an independent factor for better PFS (HR 0.66, 95% CI 0.49-0.89, $p = 0.0065$) and OS (HR 0.57, 95% CI 0.42-0.78, $p = 0.0005$).

Conclusions: The current study demonstrates that low NLR is correlated with better treatment outcomes for both oral and intravenous paclitaxel as a second-line chemotherapy in AGC.

Clinical trial identification: NCT01839773.

690P Combination versus single-agent as palliative chemotherapy for gastric cancer: Significance of age and platelet-to-lymphocyte ratio

M.S. Ahn, Y.W. Choi, H. Lee, S.Y. Kang, J-H. Choi

Hematology-Oncology, Ajou University School of Medicine, Suwon, Republic of Korea

Background: Although combination chemotherapy (CC) is generally recommended in recurrent or metastatic gastric cancer, the results of randomized trials are conflicting.

Methods: A retrospective review was conducted on 687 patients who received palliative chemotherapy for recurrent ($n = 304$) or primary metastatic ($n = 383$) gastric cancer. We compared the overall survival (OS) between CC and single-agent chemotherapy (SC) among these patients, while analyzing clinicopathological characteristics affecting outcome including neutrophil-to-lymphocyte ratio (NLR) and platelet-to-lymphocyte ratio (PLR).

Results: While 521 (75.8%) patients underwent CC, SC was more frequently performed in old age (≥70) (57.6%) and ECOG performance status (PS) 2/ 3 (65.8%) patients ($p < 0.0001$, both). The median OS of patients who received CC was significantly longer than that of patients who received SC (11 vs. 8 months, $p < 0.0001$). Although patients with CC showed better OS in the majority of subgroups, no difference in OS between CC and SC was observed in patients with old age ($p = 0.599$), ECOG PS 2/3 ($p = 0.821$), signet ring cell histology ($p = 0.40$), palliative surgical resection ($p = 0.407$), and high PLR ($P = 0.137$), with a significant interaction between age and type of the regimen (CC vs. SC) ($p = 0.011$). Multivariate analysis revealed that palliative resection and ≥2nd line chemotherapy were independently associated with favorable OS ($p < 0.0001$, both), whereas ECOG PS 2/3 ($p = 0.004$), poorly differentiated and signet ring cell histology ($p = 0.02$, $p < 0.0001$), peritoneal metastasis ($p = 0.045$), high NLR ($P = 0.001$), and high PLR ($P = 0.028$) were independent prognostic factors of poor OS. In patients who underwent palliative resection before chemotherapy, there was a significant interaction between PLR and type of the regimen ($p = 0.017$), without significant difference in OS between CC and SC in patients with high PLR ($p = 0.306$).

Conclusions: Although CC is the standard of care in recurrent or metastatic gastric cancer, SC can be considered as a reasonable option in certain subgroups, such as elderly patients or those with high PLR after palliative resection.

691P Venous thromboembolism during preoperative chemotherapy in the CRITICS gastric cancer trial

A.E. Slagter[1], K. Sikorska[2], C. Grootscholten[3], H.W.M. van Laarhoven[4], H. Boot[5], E. Meershoek-Klein Kranenbarg[6], C.J.H. van de Velde[6], N.C. van Grieken[7], E.P.M. Jansen[1], M. Verheij[1], A. Cats[5]

[1]Radiation Oncology, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, [2]Biometrics, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, [3]Medical Oncology, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, [4]Medical Oncology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [5]Gastrointestinal Oncology, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, [6]Surgical Oncology, Leiden University Medical Center, Leiden, Netherlands, [7]Pathology, Vrije University Medical Center (VUMC), Amsterdam, Netherlands

Background: Venous thromboembolism (VTE) is a common complication in patients with cancer. Gastric cancer (GC) has been associated with one of the highest risks of VTE. Risk factors for VTE in GC have mainly been investigated in Asian populations and/or in metastasised setting and include: gender, age, body mass index (BMI), stage, primary tumour localisation and chemotherapy, in particular cisplatin. Limited data is available on risk factors for VTE in resectable GC in Western patients. The aim of this study was to identify risk factors for VTE during preoperative chemotherapy in resectable GC patients. In addition, we addressed the question whether VTE was a risk factor for not proceeding to surgery.

Methods: Patients with resectable GC selected from the CRITICS trial (stages Ib-IVa; American Joint Cancer Committee, sixth edition; no distant metastasis) should preoperatively be treated with 3 cycles of 3-weekly epirubicin, cisplatin/oxaliplatin and capecitabine (ECC or EOC). Inclusion criterion for this analysis was start of at least 1 chemotherapy cycle. VTE was defined as any thrombus in the venous system, excluding superficial and/or device related VTE. Risk factors of interest were fitted in a multivariable logistic regression model: age, gender, BMI, ECC/EOC and tumour localisation.

Results: A total of 781 patients were included in this analysis of whom 78 (10%) developed a VTE during the preoperative period. Results of the multivariable analysis are shown in the table. Seventy four patients with VTE proceeded to surgery (95%), compared to 666 patients (95%) without VTE (p = 0.99).

Table: 691P Multivariable analysis

Variable		No VTE (n = 703)		VTE (n = 78)		OR (95%CI)	p value
		n	%	n	%		
Age in years	<60	287	91	28	9	*	
	60-69	261	88	34	12	1.31 (0.76-2.23)	0.329
	70+	155	91	16	9	1.01 (0.53-1.94)	0.970
Gender	Male	474	91	49	9	*	
	Female	229	89	29	11	1.20 (0.72-1.98)	0.483
BMI¤	<25	368	92	33	8	*	
	25-30	246	90	28	10	1.30 (0.76-2.21)	0.342
	≥30	88	84	17	16	2.16 (1.14-4.09)	0.018
ECC/EOC	ECC	564	89	68	11	*	
	EOC	139	93	10	7	0.61 (0.30-1.22)	0.162
Tumour localisation	Distal	223	88	29	12	*	
	Middle	209	89	26	11	0.96 (0.54-1.68)	0.877
	Proximal	150	94	10	6	0.52 (0.24-1.12)	0.094
	GOJ	121	90	13	10	0.87 (0.43-1.76)	0.693

* reference; ¤ BMI unknown (n = 1); OR= Odds Ratio; CI= Confidence Interval

Conclusions: High BMI (≥30) was the only independent risk factor for developing VTE in resectable GC, preoperatively treated with ECC/EOC. Cisplatin was not identified as a significant risk factor for VTE in this cohort. A diagnosis of VTE did not influence the clinical decision to proceed to surgery.

Clinical trial identification: NCT00407186.

692P The difference of risk factor for gastric cancer surgery between elderly and non-elderly patients

T. Hayashi[1], T. Oshima[1], K. Hara[1], Y. Shimoda[1], M. Nakazono[1], S. Nagasawa[1], Y. Kumazu[1], T. Yamada[1], Y. Rino[2], M. Masuda[2], T. Ogata[1], T. Yoshikawa[1]

[1]Gastrointestinal Surgery, Kanagawa Cancer Center, Yokohama, Japan, [2]Surgery, Yokohama City University, Yokohama, Japan

Background: The risk factor for gastric cancer surgery is expected to be characteristic feature of elderly in comparison to non-elderly due to decline in organ function and co-morbidities related to aging. However, the differences in the risk factors for gastric cancer surgery between elderly and non-elderly have not been evaluated. The aim of this study was to identify characteristics of risk factors of gastric cancer surgery for elderly.

Methods: This retrospective study examined 2500 patients who underwent gastrectomy with D1, D1+, D2, or D3 lymphadenectomy during 2000 to 2016 at Kanagawa Cancer Center hospital with curative intent. Patients were divided into two groups according to age, more than 75 years old (n = 406), E group; and less than 75 years old (n = 2094), Y group. Multivariate logistic regression analysis was performed to assess the independent contribution of variables to postoperative complication in each group.

Results: Mean age was 61.3 y.o. in Y group and 78.3 y.o. in E groups. Charlson Index (0/1/2) was 1523/557/14 in Y group, and 228/173/5 in E group ($p < 0.001$). ECOG-PS was (0/1/2/3) was 1918/173/2/1 in Y group, and 345/59/1/1 in E group ($p < 0.001$). Extent of the stomach resection (total/proximal/distal) was 768/37/1289 in Y group, and 149/4/253 in E group. Stage (I/II/III/IV) was 1227/323/331/213 in Y group, 225/58/86/37 in E group. Postoperative complications were observed in 267 patients (13%) in Y group and 84 patients (21%) in E group. The most frequent complication was pancreatic fistula (n = 41), followed by anastomotic leakage (n = 36) in Y group, and pneumonia (n = 20), followed by anastomotic leakage (n = 19) in E group. Multivariate analysis identified male sex (odds ratio: 1.87), and total gastrectomy (odds ratio: 1.58) as independent predictors of postoperative complications in Y group, and male sex (odds ratio: 3.01), stage IV (odds ratio: 2.54), and Charlson score > 1 (odds ratio: 1.76) in E group.

Conclusions: In elderly patients, co-morbidity more strongly affects postoperative complications compared with non-elderly patients. Co-morbidities especially in major organ function should be taken into consideration for future trials evaluating gastric cancer surgery for elderly patients.

693P Gastric cancer in young patients

M.M. Seker, A. Bahceci, T. Kacan

Medical Oncology Department, Cumhuriyet University Faculty of Medicine, Sivas, Turkey

Background: The majority of gastric cancer-related studies include elderly patients. Studies have shown that gastric cancer carries more poor prognostic factors in younger patients.

Methods: In this study we retrospectively reviewed the results of gastric cancer patients under age 30 who had diagnosed and treated at our hospital. Statistical analysis of the study was done by the Kaplan-Meier test, Long Rank test and Cox regression analysis in the SPSS17 statistical program.

Results: 824 patients had diagnosed with gastric cancer at our clinic. Of these, 30 (3.6%) patients were under 30 years of age. 17 of them were women (56.6%) and 13 of them were men (43.4%). Of these, the results of 22 patients, 9 males and 13 females, whose data were available, had evaluated. At the time of diagnosis, 5 patients (23%) were stage 2, 6 patients (27%) were stage 3, and 11 patients (50%) had metastatic disease. R0 resection was performed in 10 patients (90.9%) and R2 resection was performed in 1 patient (9.1%). Palliative surgery had performed in 4 (36.3%) of 11 metastatic patients. The tumor was grade 1 in 5,5% of patients, grade 2 in 16,6%, grade 3 in 77,8%. The tumor was diffuse type in 83.3% of patients and intestinal type in 16.6% of patients. The median follow-up was 11 months (2-101 months). Median progression free survival (PFS) was 3 months in metastatic patients, but median PFS was not achieved in non-metastatic patients. The 1 year PFS was 58% (p = 0.001) in non-metastatic patients (Figure 1A). Median overall survival (OS) was 6 months in metastatic patients, and median OS was not achieved in non-metastatic patients (p = 0.001). The estimated OS was 67 months in non-metastatic patients (Figure 1B). Tumor grade, histopathological subtype, presence of lymphovascular and perineural invasion and chemotherapy regimens were not correlated with PFS and OS. There was no correlation between OS and serum CEA, AFP, Ca19-9 and Ca125 levels at the time of diagnosis.

Conclusions: The ratio of gastric cancer under age 30 varies between 1-2% in the literature. In our study, the ratio of patients under 30 years old was 3.6%. Although young patients have more poor prognostic criteria such as diffuse type, proximal location, high grade, and lymphovascular invasion, the survival rates were similar to the elderly patients, according to the other studies in the literature.

694P Differences in presentation and outcomes among young and old patients with gastric cancer

M. Al Otaibi[1], J. Al Barak[2], J. Al Abbad[1], A. Akbar[3]
[1]Medical Oncology Department, Kuwait Cancer Control Centre Al Sabah Hospital, Shuwaikh, Kuwait, [2]Medical Oncology, Kuwait Cancer Control Center, Kuwait, [3]Histopathology Department, Kuwait Cancer Control Centre Al Sabah Hospital, Shuwaikh, Kuwait

Background: The worldwide incidence of gastric cancer (GC) has been increasing in young patients (YP) over the past few decades. It is unclear whether there are differences in disease characteristics and prognosis between YP and older patients (OP). This review examines the differences in presentation and outcomes between YP and OP.

Methods: A retrospective review of all cases of sporadic GC referred to the Kuwait Cancer Control Center (KCCC) between 2008 and 2016 was conducted. We collected data on patients' demographics, risk factors, disease clinicopathologic characteristics, stage at diagnosis and survival. Patients at the age of 50 years or younger at the time of diagnosis were designated as YP. Continuous variables were summarized with mean and standard deviation, or median and interquartile range (IQR) as appropriate and compared with Mann-Whitney U test. Categorical variables were described as frequencies (percent) and compared with Fisher's exact test. A level of 0.05 was defined as statistically significant.

Results: Evaluable data were available for 167 patients. 52 (31.1%) where YP. The mean age was 43.2 ($\pm$5.7) years for YP compared with 64.3 ($\pm$8.4) years for OP. In YP 63.5% were males compared to 72.2% in EG, $p = 0.28$. YP tends to present more with epigastric pain as opposed to OP who presented with GI bleed (hematemesis, melena or symptomatic anemia). There were less smokers in YP (23.1%) relative to OP (42.5%), $p = 0.009$. We found no difference with regards to family history, H. Pylori status, histological subtype, grade or stage at diagnosis. The overall survival was 78.8% for YP versus 63.5% for OP, $p = 0.051$.

Conclusions: Compared to their older counter parts, YP with GC tend to present with more epigastric pain and less likely to be smokers. No significant differences were found in disease characteristics or outcomes between YP and OP. More research is needed to further understand the raise of GC among YP.

Background: POCOP is a novel prospective scientific database including oesophagogastric cancer patients, initiated by the Dutch Upper GI Cancer Group (DUCG) to stimulate multidisciplinary research. Within POCOP treatment and diagnostic strategies as well as prognostic and predictive factors for outcome can be evaluated on a population-based level. We present the design and current proceedings.

Methods: All patients with oesophagogastric cancer in the Netherlands are eligible. Patients need to provide consent for: 1) the reuse of clinical data collected by the Netherlands Cancer Registry (NCR), 2) longitudinal collection of patient reported outcomes (PROs), receiving future information on new interventional studies (including cohort multiple randomized controlled trials (cmRCT)), and/or 3) linkage with Dutch databases e.g. the Dutch Upper GI Cancer Audit, the biobank of The Parelsnoer Institute and general practitioner databases. Funding: Dutch Cancer Society (UVA 2014-7000).

Results: Thus far, clinical data is being collected from almost all Dutch patients with oesophagogastric cancer diagnosed from 2015 onwards. Clinical data mainly consist of patient, tumour and multidisciplinary sequential treatment characteristics. The collection of longitudinal PROs started in 2016. Of all patients who gave consent ($N = 1000$), 92% also participated in the PRO-registry. PRO compliance was 87%, 67% and 46% (not accounted for death or drop-out) at diagnosis, 3 and 6 months follow-up, respectively. 81% of patients consented to receive future information on new interventional studies, including cmRCTs. Collaborations with phase II/III trials and other cohort studies were established to reduce patient burden regarding completion of PROs and trial registration burden. Obtained data is governed by the DUCG scientific committee which includes members of participating hospitals, the study team and the NCR.

Conclusions: POCOP provides real world population-based data to stimulate (inter-)national multidisciplinary research and provides the opportunity to perform novel trials within the established infrastructure. Researchers can acquire data by submitting a research proposal to the scientific committee of the DUCG (www.ducg.nl).

Background: Codrituzumab (Cod) is a recombinant humanized monoclonal antibody against Glypican-3 (GPC3). GPC3 is over-expressed in hepatocellular carcinoma (HCC). Cod elicits antibody-dependent cellular cytotoxicity against human HCC cell lines and shows more potent anti-tumor activity when combined with anti-PD-L1 antibody in syngeneic mouse model. This is a phase I dose-escalation study to evaluate safety/tolerability and pharmacokinetics in combination with the anti-PD-L1 antibody, atezolizumab (Atezo) in advanced HCC patients.

Methods: This study is composed of a 3 + 3 dose-escalation part and an expansion part. Patients with advanced or metastatic HCC who had failed prior systemic therapy, GPC3 high expression, ECOG PS 0-1, Child-Pugh A-B7 were eligible. Cod given intravenously 800 or 1600 mg on Day 1, 4, then weekly from Day 8 combined with 1200 mg every 3 weeks dosing of Atezo until disease progression/toxicity. The objectives were to determine MTD of Cod and Atezo combination primarily, to assess safety, antitumor effect (RECIST 1.1) and pharmacokinetics secondarily, and to assess biomarkers exploratory.

Results: Ten patients each were enrolled in dose-escalation and expansion parts, respectively. There were 16 men/4 women, median age 58, all Asian, HBV/HCV/neither 11/4/5, ECOG 0/1 15/5. No dose limiting toxicities were observed in dose-escalation part. The most frequently observed adverse events (AEs) were pyrexia (80%), fatigue (50%), decreased appetite (30%), aspartate aminotransferase increased, lymphocyte count decreased (25%), constipation, cough, nasopharyngitis (20%). Grade 3 or higher AEs ($\geq$ 2 patients) were aspartate aminotransferase increased, lymphocyte count decreased (20%), anemia (15%), and ascites (10%). There was 1 confirmed PR, 10 SD (including 1 unconfirmed PR) among 18 evaluable patients and 6 of them had SD for more than 6 months before progression.

Conclusions: Cod + Atezo combination was well-tolerated and showed antitumor activity in this advanced, previously treated and GPC3 highly expressed HCC patients.

Gemelli, Rome, Italy, [3]Medical Oncology, CHU Saint Eloi, Montpellier, France, [4]University Cancer Center, University Hospital Carl-Gustav-Carus, Dresden, Germany, [5]Oncology, IRCCS San Raffaele, Milan, Italy, [6]Service d'Hépato-Gastro-Entérologie, Centre Hospitalier de la Croix Rousse, Lyon, France, [7]Hepatology and Medical Oncology, CHU Bordeaux Haut-Lévêque, Bordeaux, France, [8]Hepatology, Jean Verdier Hospital, Bondy, France, [9]Biostatistic, Merck KGaA, Darmstadt, Germany, [10]Clinical Biomarker & Companion Diagnositics, Merck KGaA, Darmstadt, Germany, [11]Clinical Research, EMD Serono Inc, Billerica, MA, USA, [12]Medical Oncology, Hopital Beaujon, Clichy, France

Background: MET is a potential therapeutic target in advanced HCC; tepotinib is a highly selective MET inhibitor. Here we report final analysis results from a single-arm multicenter phase 2 study investigating the efficacy and safety of tepotinib in pts with sorafenib-treated advanced MET+ HCC (NCT02115373).

Methods: Adults with advanced MET+ HCC, Child-Pugh Class A, Eastern Cooperative Oncology Group performance status 0–1, and ≥4 weeks of prior sorafenib therapy were eligible for treatment. MET status was assessed by immunohistochemistry (2+ or 3+) and in-situ hybridization. Pts received tepotinib at the recommended phase 2 dose (RP2D) of 500 mg once-daily. The primary endpoint was progression-free survival status at 12 weeks; secondary endpoints included safety and other efficacy parameters.

Results: 49 pts had received treatment; median (range) duration of therapy was 3.02 (0.03–16.49) months. Median (range) age was 66 (19–82) years and most patients were male (83.7%). The null hypothesis that the rate of progression-free subjects at 12 weeks is ≤ 15% has been rejected as 31/49 pts (63.3%; 90% confidence interval [CI]: 50.5, 74.7) were progression-free at 12 weeks; median PFS was 3.4 months (90% CI: 2.8, 4.2). Overall, there were 4/49 responders (8.2%; 90% CI: 2.8, 17.7; 1 complete and 3 partial responses). Median overall survival was 5.6 months (90% CI: 5.1, 8.2 months). The most common treatment-related adverse events (AEs) were peripheral edema (n = 32; 38.8%), fatigue (n = 10; 18.4%) and diarrhea (n = 16; 16.3%). 17 pts (34.7%) discontinued treatment due to AEs and 1 pt (2%) died from a treatment-related AE (hypoglycemic coma).

Conclusions: These data indicate that tepotinib has anti-tumor activity in pretreated MET+ advanced HCC and was well tolerated at the RP2D, with no new safety signals detected.

Clinical trial identification: NCT02115373.

699P Real-world data on nivolumab treatment in Asian patients with advanced hepatocellular carcinoma

S.E. Yoon[1], J.Y. Hur[1], K.K. Lee[1], S.J. Lee[1], J. Lee[1], S.W. Paik[2], H.Y. Lim[1]

[1]Hematology-Oncology, Samsung Medical Center Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [2]Gastroenterology, Samsung Medical Center, Seoul, Republic of Korea

Background: Nivolumab, an anti-PD-1 antibody showed durable responses and long-term survival in patients with hepatocellular carcinoma (HCC) and was approved by FDA as 2nd line treatment after sorafenib treatment in 2017. We present real-world experience with nivolumab in HCC.

Methods: We retrospectively reviewed the medical records of HCC patients who had nivolumab treatment at Samsung Medical Center. Nivolumab treatment was given every two weeks until progression or intolerable toxicity. Response evaluation was done based on RECIST v1.1.

Results: A total of 76 patients were treated with nivolumab between March 2017 and May 2018. The median age was 60 years (range; 30-83 years) and 86% were male patients. The cohorts included 56 patients with hepatitis B viral infection, 7 with hepatitis C viral infection and 19 without viral infection. Most of patients (96.0%) were ECOG performance statue 0 or 1 and patients with Child-Pugh A were 59 (77.6%). 70 patients (92.1%) had previous sorafenib therapy and 8 patients received nivolumab as 3rd or more line (10.5%). There were three patients with previous history of liver transplantation. With median follow-up duration of 15 weeks (range, 5-39), the median treatment cycle was 4 (range,1-26). 17 patients (22.4%) received standard dose of 3mg/kg, whereas 59 patients (77.6%) received less than 3mg/kg of nivolumab. Partial response was observed in 6 patients (ORR 7.9%) and they all are on nivolumab therapy for 4-13 months. Disease control rate was 39.5%. The most common adverse events (AEs) were anorexia(15.6%) and puritus(15.8%)., nausea (13.1%), liver dysfunction (21%) and fatigue(7.9%). However, these were almost grade 1 or 2 except for two cases of grade 3 liver dysfunction and grade 3 diabetes. There was no HBV reactivation observed.

Conclusions: Compared to phase I/II study of nivolumab (CheckMate 040), our real-world data showed lesser ORR and DCR. Move advanced disease status, liver dysfunction and short follow-up duration might explain it. However, nivolumab showed a manageable safety profile even in transplanted patients.

700P Stemness in hepatocellular carcinoma reduced by inhibition of WEE1 expression

K.U. Park[1], M.J. Ko[2], H.M. Ryoo[3], Y-H. Lee[4]

[1]Oncology, Dongsan Medical Center Kemyung University Hospital, Daegu, Republic of Korea, [2]Department of Hematology/Oncology, Keimyung University School of Medicine, Daegu, Republic of Korea, [3]Hematology/Oncology, Daegu Catholic University, Daegu, Republic of Korea, [4]Department of Molecular Biology, Keimyung University School of Medicine, Daegu, Republic of Korea

Background: Chemotherapy targets proliferating cells, not cancer stem cells (CSCs). Targeting agents, e.g. sorafenib for hepatocellular carcinoma (HCC), do not seem to target CSCs as evidenced by frequent tumor relapse and resistance after therapy. Identification and characterization of signaling pathways and biomarkers associated with CSC biology are priorities for developing new paradigms of molecular cancer therapeutics. Increase of WEE1 kinase activity through an epigenetic regulation plays an important role in the development of HCC. However, the functional role of WEE1 in HCC progression remains to be clarified.

Methods: Human HCC cell lines were transfected with WEE1 siRNA and tested for growth inhibition, apoptotic induction, molecular changes in both RNA and protein levels, and changes in CSC phenotype using various methods such as MTS, FACS, microscopic analysis, Real-time PCR, Western blotting, sphere forming assay. To find the molecular changes in response to WEE1 knockdown, global changes in gene expression were examined using RNA sequencing.

Results: We demonstrated that WEE1 siRNA silencing caused inhibition of HCC cell growth through blockade of cell cycle progression and induction of apoptosis. The anti-proliferative effects were driven by a subset of molecular alterations including the upregulation of cdk inhibitor p21 and the downregulation of AKT1, CDK2, cyclin B1, PARP1 and GPAM which are functionally involved in control of cell cycle, apoptosis and lipid metabolism. WEE1 silencing resulted in a strong inhibition of lipogenesis and caused a marked decrease in fat accumulation. Knockdown of WEE1 dramatically reduced the portion of liver CSC population through co-downregulation of cancer stemness genes, weakened the capacity of sphere formation and cancer cell migration. Systemic delivery of a modified WEE1 siRNA encapsulated in lipid nanoparticles nhibited human HCC growth in murine xenograft models, and increased survival.

Conclusions: Our findings suggest that the epigenetic modifier WEE1 functionally involve to HCC lipid metabolism and CSC-like phenotype maintenance and that molecular targeting of WEE1 may be an effective systemic therapy for prevention of tumor recurrence via elimination of CSCs in liver tumor microenvironment.

701P Analysis of single-nucleotide polymorphisms (SNPs) in the phase III RESORCE trial of regorafenib versus placebo in patients with hepatocellular carcinoma (HCC)

K. Köchert[1], G. Meinhardt[2], J. Bruix[3], M. Teufel[4]

[1]*Clinical Statistics EU – SBU Oncology, Bayer AG, Berlin, Germany,* [2]*Clinical Development Oncology, Bayer HealthCare Pharmaceuticals, Whippany, NJ, USA,* [3]*BCLC Group, Liver Unit, Hospital Clinic, University of Barcelona, IDIBAPS, CIBEREHD, Barcelona, Spain,* [4]*Translational Medicine Oncology, Bayer HealthCare Pharmaceuticals, Whippany, NJ, USA*

Background: Regorafenib is a multikinase inhibitor that improved overall survival (OS) and time to progression (TTP) in patients with HCC who progressed during sorafenib treatment in the phase 3 RESORCE trial. This exploratory analysis evaluated the impact of SNPs on regorafenib treatment benefit (OS and TTP) and the occurrence of hand–foot skin reaction (HFSR) in the RESORCE trial.

Methods: Genotyping of 187 SNPs was performed on whole blood DNA from 330/573 (58%) patients from RESORCE using a custom NimbleGen™ kit and sequencing libraries that were made using NimbleGen™ KAPA Hyper construction kits. The prognostic and predictive effects of the SNPs, as well as the impact on the occurrence of grade $\geq$1 HFSR, were assessed using Cox proportional hazards regression with Breslow tie handling or logistic regression, respectively. Models were adjusted for clinical covariates as determined by Akaike information criterion (AIC)-based selection and adjusted for population stratification. P values were corrected for multiple testing using Bonferroni correction and deemed significant at an adjusted $\alpha \leq 0.05$.

Results: The overall RESORCE and biomarker cohorts were generally similar for demographic variables (except the latter had a smaller proportion of Asian patients) and outcomes. None of the assessed SNPs were prognostic or predictive of OS. In contrast, 6 SNPs (positioned in the UGT1A1, VEGFC, and TIE2 genes) were prognostic for TTP; SNP rs4148323 in the UGT1A1 gene was predictive for TTP (HR 0.24, 95% CI 0.12–0.49; adjusted p = 0.012). The rs1547651 SNP in the VEGFA gene showed a significant prognostic effect on the occurrence of grade $\geq$1 HFSR (odds ratio [OR] 0.04, 95% CI 0.01–0.19; adjusted p = 0.037), while the rs114681547 SNP, also in the VEGFA gene, showed a predictive effect (OR 26.23, 95% CI 5.39–197.96; adjusted p = 0.038).

Conclusions: These exploratory results suggest that the detected SNP biomarkers may be candidates for future research to gain deeper understanding of the biological mechanisms determining clinical benefit of regorafenib treatment in HCC.

Clinical trial identification: NCT01774344.

702P Outcomes by baseline alpha-fetoprotein (AFP) levels in the phase III CELESTIAL trial of cabozantinib (C) versus placebo (P) in previously treated advanced hepatocellular carcinoma (HCC)

R.K. Kelley[1], A.B. El-Khoueiry[2], T. Meyer[3], L. Rimassa[4], P. Merle[5], S.L. Chan[6], A. Tran[7], F. Parnis[8], V.C. Tam[9], S. Cattan[10], D.W. Markby[11], D.O. Clary[11], A-L. Cheng[12], G.K. Abou-Alfa[13]

[1]*Oncology, UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA, USA,* [2]*Medical Oncology, USC/Norris Comprehensive Cancer Center, Los Angeles, CA, USA,* [3]*Medical Oncology, Royal Free Hospital, London, UK,* [4]*Oncology, Humanitas Cancer Center, Milan, Italy,* [5]*Hepatology, Groupement Hospitalier Lyon Nord, Lyon, France,* [6]*Clinical Oncology, The Chinese University of Hong Kong, Shatin, Hong Kong, China,* [7]*Hepatology, Groupe Hospitalier L'Archet, Nice, France,* [8]*Oncology, Adelaide Cancer Centre, Adelaide University, Kurralta Park, Australia,* [9]*Medical Oncology, University of Calgary, Calgary, AB, Canada,* [10]*Diseases of the Digestive System - Hepatology, CHRU Lille, Lille, France,* [11]*Medical Affairs, Exelixis Inc., San Francisco, CA, USA,* [12]*National Taiwan University Hospital, Taipei, Taiwan,* [13]*Oncology, Memorial Sloan Kettering Cancer Center, New York, NY, USA*

Background: High baseline AFP levels are associated with poor prognosis in patients (pts) with HCC and are associated with a distinct molecular profile. C, an inhibitor of MET, VEGFR, and AXL, improved overall survival (OS) and progression-free survival (PFS) in the phase 3 CELESTIAL trial (NCT01908426). Median OS was 10.2 mo with C vs 8.0 mo with P (HR 0.76, 95% CI 0.63–0.92; p = 0.0049), and median PFS was 5.2 mo with C vs 1.9 mo with P (HR 0.44, 95% CI 0.36–0.52; p < 0.0001).

Methods: 707 pts were randomized 2:1 to receive C (60 mg qd) or P. Eligible pts had pathologic diagnosis of HCC, Child-Pugh score A, and ECOG PS $\leq$ 1. Patients must have received prior sorafenib and 1–2 prior lines of systemic therapy for HCC and must have progressed following at least one. Stratification was by disease etiology, geographic region, and extent of disease. Outcomes were analyzed by baseline AFP levels using cut-offs of 20, 200, and 400 ng/mL.

Results: Overall, 69% of pts had baseline AFP $\geq$20 ng/mL, 49% had AFP $\geq$200 ng/mL, and 41% had AFP $\geq$400 ng/mL. For pts with baseline AFP <400 ng/mL, median OS was 13.9 mo with C vs 10.3 mo with P (HR 0.81), and median PFS was 5.5 mo with C vs 1.9 mo with P (HR 0.47). For pts with baseline AFP $\geq$400 ng/mL, median OS was 8.5 mo with C vs 5.2 mo with P (HR 0.71), and median PFS was 3.9 mo with C vs 1.9 mo with P (HR 0.42). C also improved OS vs P in pts with AFP $\geq$200 ng/mL or $\geq$ 20 ng/mL, and C improved PFS irrespective of AFP levels (Table). Pts with high baseline AFP experienced high-grade transaminitis more frequently in both treatment groups; grade 3/4 elevated aspartate aminotransferase with C vs P was 8% vs 4% for AFP <400 ng/mL and 17% vs 11% for AFP $\geq$400 ng/mL.

Table: 702P

Baseline AFP, ng/mL	Patients, N		HR C vs P (95% CI)	
	C	P	OS	PFS
<20	139	77	0.97 (0.67–1.40)	0.57 (0.41–0.78)
$\geq$20	331	160	0.67 (0.54–0.84)	0.41 (0.33–0.51)
<200	242	118	0.83 (0.63–1.10)	0.52 (0.40–0.67)
$\geq$200	228	119	0.70 (0.54–0.91)	0.39 (0.30–0.50)
<400	278	136	0.81 (0.62–1.04)	0.47 (0.37–0.60)
$\geq$400	192	101	0.71 (0.54–0.94)	0.42 (0.32–0.55)

Conclusions: C improved OS and PFS vs P in patients with previously treated advanced HCC across a range of baseline AFP levels. High AFP levels were associated with a larger treatment benefit with C for both OS and PFS.

Background: Extrahepatic spread (EHS) and macrovascular invasion (MVI) are poor prognostic factors in HCC. In the CELESTIAL trial (NCT01908426), C improved overall survival (OS) and progression-free survival (PFS) vs P in patients (pts) with previously treated advanced HCC. Median OS was 10.2 mo with C vs 8.0 mo with P (HR, 0.76; 95% CI, 0.63–0.92; P = 0.0049). Median PFS was 5.2 mo with C versus 1.9 mo with P (HR, 0.44; 95% CI, 0.36–0.52; P < 0.0001). Here, we analyze OS and PFS based on (i) EHS, (ii) MVI, and (iii) the sum of target lesion diameters (SOD) at baseline.

Methods: A total of 707 pts, stratified by disease etiology, geographic region, and the presence of EHS and/or MVI, were randomized 2:1 to receive C, 60 mg once daily (N = 470) or P (N = 237). Eligible patients had a pathologic diagnosis of HCC, Child-Pugh score A, and ECOG performance status ≤1. Pts received prior sorafenib and ≤2 lines of prior systemic therapy. Tumors were assessed every 8 weeks by investigator.

Results: In the overall population, 78% pts had EHS, 30% had MVI and 85% had EHS and/or MVI. Among pts with EHS, 50% had metastasis to the lung, 40% to lymph nodes and 17% to bones. C improved OS (HR ≤ 0.8) vs P in pts with or without MVI (Table). C also improved OS vs P in pts with EHS or high SOD. PFS was improved with C irrespective of the extent of the disease.

Table: 703P

	No. pts		Median OS, mo		OS HR (95% CI)	Median PFS, mo		PFS HR (95% CI)
	C	P	C	P		C	P	
EHS								
Yes	369	182	9.6	6.9	0.72 (0.58-0.89)	5.0	1.9	0.46 (0.37-0.56)
No	101	55	12.0	12.3	0.96 (0.63-1.46)	5.4	1.9	0.45 (0.31-0.66)
MVI								
Yes	129	81	7.6	5.3	0.75 (0.54-1.03)	3.7	1.8	0.42 (0.31-0.58)
No	339	156	12.4	9.7	0.80 (0.64-1.01)	5.5	1.9	0.48 (0.38-0.59)
SOD								
< median	231	120	12.5	10.5	0.94 (0.71-1.24)	5.5	1.9	0.48 (0.37-0.61)
≥ median	234	117	8.2	5.3	0.58 (0.45-0.76)	4.2	1.9	0.44 (0.34-0.57)

Conclusions: C generally improved OS in pt subgroups defined by extent of disease burden. The presence of MVI, EHS, or high SOD at baseline was associated with shorter OS in both treatment groups.

Clinical trial identification: NCT01908426.

Background: Pts with HCC and localized disease commonly receive treatment with TACE but often progress and require systemic therapy. In the CELESTIAL trial (NCT01908426), C, an inhibitor of MET, VEGFR, and AXL, improved overall survival (OS) and progression-free survival (PFS) vs P in previously treated pts with advanced HCC. Median OS was 10.2 mo for C vs 8.0 mo for P (HR 0.76, 95% CI 0.63–0.92; p = 0.0049), and median PFS was 5.2 mo for C vs 1.9 mo for P (HR 0.44, 95% CI 0.36–0.52; p < 0.0001) (Abou-Alfa, JCO 2018). Here, outcomes were analyzed for pts who received prior TACE.

Methods: 707 pts were randomized 2:1 to receive C (60 mg qd) or P stratified by disease etiology, geographic region, and extent of disease. Eligible pts had pathologic diagnosis of HCC, Child-Pugh score A, and ECOG PS ≤ 1. Pts must have received prior sorafenib and could have received up to two lines of prior systemic therapy for HCC. Outcomes were analyzed by number of prior TACE treatments (0, ≥1, 1-2, ≥3).

Results: Overall, 203 (43%) pts in the C arm and 111 (47%) pts in the P arm had received prior TACE with a median of 2 and 3 treatments, respectively. For pts who received TACE, 54% received 1-2 treatments and 46% received ≥3. 61% of pts enrolled in Asia, 39% in Europe, and 37% in North America received prior TACE. For pts who received prior TACE vs no TACE, 67% vs 76% received 1 prior systemic regimen and 32% vs 23% received 2. C was associated with improved OS and PFS vs P irrespective of prior TACE treatment (Table). Median OS was 11.4 mo for C vs 8.6 mo for P in pts with prior TACE and 9.5 mo for C vs 7.2 mo for P in pts with no prior TACE. Grade 3/4 adverse events were similar for pts with and without prior TACE in both arms.

Conclusions: C improved OS and PFS compared with P in pts with previously treated advanced HCC irrespective of whether they had received prior TACE.

Table: 704P

	No Prior TACE		Prior TACE					
			≥1		1-2		≥3	
	C (N = 267)	P (N = 126)	C (N = 203)	P (N = 111)	C (N = 118)	P (N = 52)	C (N = 85)	P (N = 59)
OS HR (95% CI)	0.69 (0.54–0.90)		0.82 (0.62–1.09)		0.89 (0.59–1.37)		0.80 (0.54–1.17)	
PFS HR (95% CI)	0.43 (0.33–0.54)		0.50 (0.38–0.64)		0.58 (0.41–0.84)		0.38 (0.26–0.57)

705P Clinicopathological evaluation of skin lesions (SL) in patients with hepatocellular carcinoma (HCC) treated with sorafenib

L.G.D. Fonseca[1], A. Díaz[2], V. Sapena[1], Á. Díaz-González[1], L. Boix[1], M. Sanduzzi-Zamparelli[1], C. Fuster[2], N. Llarch[1], G. Iserte[1], F. Torres[3], J. Bruix[4], M. Reig[1]

[1]BCLC Group. Liver Unit, Hospital Clínic of Barcelona. IDIBAPS. CIBERehd, Barcelona, Spain, [2]Department of Pathology, Hospital Clínic of Barcelona. IDIBAPS. CIBERehd, Barcelona, Spain, [3]Medical Statistics Core Facility, Hospital Clínic of Barcelona. IDIBAPS. CIBERehd, Barcelona, Spain, [4]BCLC Group, Liver Unit, Hospital Clinic, University of Barcelona, IDIBAPS, CIBEREHD, Barcelona, Spain

Background: Dermatologic adverse events (DAE) are frequently experienced in patients under sorafenib. Although the majority appear as rash or hand-foot reaction, some patients may present SL requiring biopsy or local procedures that may impact in the treatment. While there are series of patients with melanoma and BRAF inhibitors presenting SL, there is no information on HCC patients with sorafenib.

Methods: We analyzed a prospective database of patients with HCC treated with sorafenib. Patients who developed biopsed SL were included and the pathology samples were reviewed.

Results: Between oct-2007 and jan-2018, 313 patients were treated with sorafenib (54.6% BCLC-C, 88.7% ECOG-PS0 and 83.6% CPA), 88 (28.1%) presented DAE in the first 60 days (eDAE) and 24 (7.7%) developed SL submitted to excisional biopsy. From the 24 patients, 33 SL were biopsied and 5 patients presented more than 1 SL. Most of the patients with SL were male (79.2%), CPA (87.5%), HCV etiology (87.5%) and 2 had liver transplantation. The median time from sorafenib initiation until SL biopsy was 8.5 months (IQR 4.4 to 18.1). SL are described in the table. Lymphocyte proliferation at the interface between the SL and dermis was noted in 61.1%. The median treatment duration (MTD) and OS in the whole cohort were 6.5 months [IQR 3.3-13.9] and 13.6 months [CI95% 12.2- 15.6], respectively. For the subgroup with SL, the MTD and OS was 12.5 [9.5 - 22.0] and 26.5 months [CI95% 17.0 - 43.9], respectively. For those with both eDEA and SL, the MTD and OS was 17.9 months [7.7-28.9] and 26.5 [22.0-51.6] respectively. There was no permanent discontinuation related to the SL.

Table: 705P SL subtypes

	n = 33 lesions (100%)
Tumor SL	22 (66.7%)
Keratoacanthomas	7 (21.2%)
Squamous cell carcinomas	5 (15.2%)
Basal cell carcinomas	3 (9.1%)
Seborrheic queratosis	3 (9.1%)
Hypertrophic keratoma	1 (3%)
Sebaceous hyperplasia	1 (3%)
Pilomatrixioma	1 (3%)
Trichilemmal cyst	1 (3%)
Non-Tumor SL	7 (21.2)
Suppurative folliculitis	2 (6.1%)
Interphase dermatitis	2 (6.1%)
Subacute spongiform dermatitis	1 (3%)
Septal panniculitis/ Erythema nodosum	1 (3%)
Lichen planus	1 (3%)
Livedo reticularis	2 (6.1%)
Thrombotic vasculopathy	1 (3%)
Epi/Hypodermic necrosis	1 (3%)

Continued

Conclusions: This is the largest series on patients with HCC and sorafenib that presented biopsed SL. Similar to other tumors treated with BRAF inhibitors, patients with HCC and sorafenib are in risk of developing SL. Interestingly, the majority presented lymphocyte proliferation. This reinforces the need to understand the immune modulation by sorafenib.

706P Relationship between ethnicity and overall survival (OS) in patients with advanced hepatocellular carcinoma (HCC) treated with sorafenib (S): Results from a Canadian multi-centre HCC database

D.E. Meyers[1], R. Lee-Ying[1], M. Alghamdi[1], H-W. Sim[2], V.O. Zaborska[3], Y-J. Ko[4], T. Raycraft[3], E. Batuyong[1], W.Y. Cheung[1], H. Samawi[1], J.M. Davies[3], V.C. Tam[1]

[1]Medical Oncology, Tom Baker Cancer Centre, Calgary, AB, Canada, [2]Oncology, Princess Margaret Cancer Center, Toronto, ON, Canada, [3]Faculty of Medicine, University of British Columbia, Vancouver, BC, Canada, [4]Sunnybrook Health Sciences Centre, Odette Cancer Centre, Toronto, ON, Canada

Background: The SHARP and Asia-Pacific (AP) trials showed that S improves OS compared to placebo in advanced HCC. However, OS was worse in the AP trial, which included predominantly East Asian (EA) patients. The purpose of this study was to determine whether ethnicity affects OS in patients with advanced HCC being treated with S.

Methods: Patients who received S for the treatment of HCC between 01/01/08 and 30/06/16 in the provinces of British Columbia and Alberta, as well as Princess Margaret Cancer Centre and Sunnybrook Odette Cancer Centre in Toronto, Ontario were included. Patient demographics and clinical variables were retrospectively collected. Patients were dichotomized by ethnicity as either EA or not according to a validated list of surnames. Survival outcomes were assessed with Kaplan-Meier curves and compared with the log-rank test. A Cox-proportional hazard model was constructed with ethnicity and relevant clinical characteristics to assess their impact on survival.

Results: A total of 757 patients were included. Mean age was 64 years. 81% men, 36% East Asian, and 86% Child-Pugh (CP) A at initiation of S. Underlying cause of liver disease was 31% hepatitis B Virus (HBV) and 30% hepatitis C virus (HCV). Majority of patients had a performance status of 0 (30%) or 1 (58%). EA compared to non-EA were more likely to have HBV (68 vs 11%) and less likely to have HCV (13 vs 39%), $p < 0.01$. Median OS was 8.6 months for EAs and 9.6 months in non-EAs ($p = 0.89$). On multivariate analysis, ethnicity (HR 1.01, 95% CI 0.82 – 1.27, $p = 0.89$) was not a significant prognostic factor for OS. However, no previous localized treatment (HR 1.66 95%CI 1.39 - 1.99, $p < 0.01$), higher ECOG (HR 1.63 95% CI 1.34-1.97. $p < 0.01$), CP B at initiation of S (HR 1.72 95% CI 1.34 - 2.20, $p < 0.01$) and HBV compared to HCV (HR 1.39 95% CI 1.08-1.80, $p = 0.01$) were associated with worse survival.

Conclusions: Ethnicity does not affect OS in HCC patients treated with S. However, patients treated with S who have a history of HCV appear to have a better OS than those with HBV. Higher baseline ECOG, no previous localized treatments and CP B liver function appear to negatively affect OS.

707P Efficacy and safety of sorafenib (SFN) in elderly patients with hepatocellular carcinoma (HCC)

L. Gomes Da Fonseca, G. Nader Marta, M.I. Braghiroli, P. M. Hoff, J. Sabbaga

Medical Oncology, ICESP - Instituto do Câncer do Estado de São Paulo, São Paulo, Brazil

Background: HCC is the second leading cause of cancer-related deaths worldwide. Sorafenib (SFN) has been the backbone of advanced HCC treatment over the past decade. Since the mean age of HCC presentation is between 50 and 60 years, data on SFN use in the elderly patients (pts) remain scarce due to underrepresentation of this population in pivotal clinical trials. Thus, the treatment of elderly HCC pts represents a

clinical challenge given the concomitance of advanced age with chronic hepatopathy, raising concerns about clinical benefit and increased toxicity in this subgroup. We analyzed a cohort of HCC pts with the aim of evaluating the efficacy and safety of SFN in this specific population.

Methods: A cohort of pts with advanced HCC treated with SFN was retrospectively evaluated. Pts were divided into 2 groups: (A) those younger than 70 years-old (y-o) and (B) those who were 70 y-o or older at the time of SFN initiation. Survival (OS) was calculated from the first day of SFN to death or last data record. Time to treatment failure (TTF) due to disease progression or toxicity was calculated from the first to the last day on SFN. TTF and OS were estimated using Kaplan-Meier and curves were compared by log-rank test.

Results: We analyzed 226 HCC pts treated with SFN from Oct-2007 to Jan-2017. Group B was comprised of 37 (16.4%) pts, median age 73.5 years (70-85), 75.7% male, 29.7% had HCV, 86.5% Child-Pugh A, 37.8% had extrahepatic spread. Reduced starting dose SFN (< 800 mg/d) was more common in Group B than in Group A (27% vs 11.8%, p = 0.026). No statistically significant differences in OS (7.9 vs 9.8 months, p = 0.534) or TTF (3.5 vs 4.3 months, p = 0.962) were detected between Groups A and B. The incidence of dermatologic adverse events (38.6% vs 34.1%, p = 0.596) and hypertension (7% vs 5%, p = 0.641) did not differ significantly between Groups A and B, respectively. Intolerance leading to SFN discontinuation occurred in 11% and 9.5% of pts in Groups A and B, respectively (p = 0.780).

Conclusions: Our findings suggest that the efficacy and the incidence of adverse events were similar in elderly HCC pts treated with SFN when compared to younger pts. Thus, age alone should not be used to determine the therapy of pts with advanced HCC being considered for SFN.

708P Relationship between change in α-fetoprotein (AFP) and patient (pt) survival in hepatocellular carcinoma (HCC): A real-world electronic medical records (EMR) database study

L.M. Hess[1], Z.L. Cui[2], T. Sugihara[3], Y. Fang[3], A. Girvan[1], P.B. Abada[4]

[1]*Global Patient Outcomes and Real World Evidence, Eli Lilly and Company, Indianapolis, IN, USA,* [2]*Global Statistics, Eli Lilly and Company, Indianapolis, IN, USA,* [3]*Clinical Solutions, Syneos Health, Indianapolis, IN, USA,* [4]*Medical, Eli Lilly and Company, Indianapolis, IN, USA*

Background: Serum AFP levels are used as a diagnostic and prognostic marker for pts with HCC. Assessment of the clinical relevance of changes in AFP over time outside of clinical trials is lacking. This study was designed to explore the relationship between changes in AFP levels and overall survival (OS) in a real-world setting.

Methods: This retrospective analysis used the IMS Oncology EMR database (US patients, 12/01/2007-12/31/2014). Eligible pts were diagnosed with HCC, 18+ years old, had at ≥ 1 AFP test recorded 60 days prior to 180 days after diagnosis, and received anticancer therapy ≤180 days after diagnosis. Survival analyses were by Kaplan-Meier method. The gamma-frailty model was used to correlate AFP change utilizing previously-reported definitions of AFP change (above/below 400 ng/mL, ≥20 ng/mL, ≥7 ng/mL/month, ±20%, ±50%) and OS.

Results: A total of 907 pts met eligibility criteria (77.3% male, median 65 years of age). Of 697 pts with AFP prior to start of first-line therapy, the 453 (65%) with a baseline AFP <400 ng/mL had an OS of 4.2 months and the 244 (35%) with ≥400 ng/mL an OS of 2.9 months. An increase in AFP was associated with a decrease in OS in the 278 patients with baseline and first-line therapy (1L) AFP (Table). Of the 101 pts with an AFP test before start of second line therapy, 32.7% had AFP ≥400 ng/mL. Relationship between change in AFP and OS.

Table: 708P

Observed AFP change during 1L	N	Median OS (95% CI), months	Cross ratio	Kendalls Tau
Decrease (↓) to < 400 from ≥ 400 ng/mL	20	14.3 (4.8-30.9)	1	0
↓ ≥ 20 ng/mL	85	7.4 (5.7-11.9)	1	0
↓ ≥ 7 ng/mL/month	68	6.8 (5.0-12.7)	1	0
↓ ≥ 20%	98	11.1 (7.3-13.2)	1	0
↓ ≥ 50%	51	12.2 (7.3-18.2)	1	0
Increase (↑) to ≥ 400 from < 400 ng/mL	18	5.9 (3.6-7.4)	1.506	0.202
↑ ≥ 20 ng/mL	140	4.8 (3.7-5.5)	1.902	0.311
↑ ≥ 7 ng/mL/month	124	4.5 (3.1-5.2)	2.006	0.335
↑ ≥ 20%	141	5.2 (4.1-6.5)	1.841	0.296
↑ ≥ 50%	109	5.4 (4.5-6.9)	1.755	0.274

Conclusions: Increases and decreases in AFP during 1L, regardless of AFP change definition, were generally associated with shorter and longer OS, respectively. Conclusions are limited by the risk of immortal time and selection bias, as not all patients had multiple AFP measures recorded.

Legal entity responsible for the study: Eli Lilly and Company.

709P Antiviral therapy improves outcomes after radiofrequency ablation for HBV-related hepatocellular carcinoma: A propensity score matching analysis

K. Wang, F. Shen, J. Liu, Z. Yan, J. Li, Y. Xia, L. Shi, G. Qian, Z. Lu, Y. Chen, X. Wan, M. Wu, Y. Zhang

Hepatobiliary Surgery, Eastern Hepatobiliary Surgical Hospital (EHSH), 2nd Military Medical University, Shanghai, China

Background: We intended to explore hepatitis B virus (HBV) reactivation after percutaneous radiofrequency ablation (PRFA) for HBV-related hepatocellular carcinoma (HCC) and the impact of antiviral therapy (AVT) on post-PRFA outcomes.

Methods: Data on 538 consecutive patients who underwent PRFA for HBV-related early HCC at the Eastern Hepatobiliary Surgery Hospital between 2007 and 2011 were studied. Propensity score matching (PSM) analysis was used to compare the outcomes between the study groups. Recurrence free survival (RFS) and tumor recurrence were endpoints. Post-PRFA viral reactivation, hepatitis, and patterns of tumor recurrence were also observed. Logistic regression, Kaplan-Meier method and Cox proportional regression were used during the analysis.

Results: Viral reactivation developed in 10.8% of patients who underwent PRFA. Patients with HBV reactivation had higher 1-, 3-, and 5-year tumor recurrence rates than patients without viral reactivation after PRFA (46.9%, 81.6% and 81.6% vs 36.0%, 63.5% and 65.4%, P = 0.004). AVT reduced viral reactivation rate (P < 0.001) and decreased 1-,3-,5-year tumor recurrence rate when compared with the no-AVT (30.2%, 58.6% and 61.4% vs 44.1%, 72.6% and 73.0%, P = 0.001). The local recurrence of tumor after PRFA was only associated with tumor diameter (P = 0.010), however, viral reactivation (P = 0.015) and AVT (P < 0.001) were independent risk factors of intrahepatic distant recurrence.

Conclusions: HBV could be reactivated after PRFA. Viral reactivation and AVT had opposite impact on intrahepatic distant recurrence but not local tumor progression of HCC patients after PRFA.

[1]Digestive Oncology, Institut de Cancérologie de l'Ouest, Nantes, France, [2]Clinique Universitaire d'Hépato-gastroentérologie, CHU Grenoble Alpes, Grenoble, France, [3]Calgary Liver Unit, Division of Gastroenterology and Hepatology, Department of Medicine, Cumming School of Medicine, University of Calgary, Calgary, AB, Canada, [4]2nd Department of Internal Medicine, Medical School of Athens, Hippokration Hospital, Athens, Greece, [5]Department of Hepatology and Gastroenterology, Aarhus University Hospital, Aarhus, Denmark, [6]Department of Hepato-Gastroenterology, Centre Hospitalier Universitaire Reims, Reims, France, [7]Bayer AG, SBU Oncology, Pharmaceuticals, Wuppertal, Germany, [8]National Taiwan University Hospital, Taipei, Taiwan, [9]Kindai University Faculty of Medicine, Osaka, Japan, [10]Asan Medical Center, Seoul, Republic of Korea, [11]Bayer HealthCare Pharmaceuticals, Whippany, NJ, USA, [12]Medical University of Vienna, Vienna, Austria, [13]Klinikum Klagenfurt am Wörthersee, Klagenfurt, Austria

Background: TACE is commonly used in patients (pts) with unresectable HCC (uHCC). However, there is no global consensus on appropriate TACE use. Evaluating the risks associated with TACE is critical to ensure pt eligibility for subsequent effective therapies.

Methods: OPTIMIS is an international, prospective, non-interventional study of uHCC pts for whom the decision to treat with TACE was made prior to enrollment. Here we report practice patterns, subsequent treatments, and liver deterioration data from Europe and Canada (Eur/Can) and the global population. TACE ineligibility was defined using international and regional guidelines.

Results: Overall, 1650 enrolled pts received TACE including 497 from Eur/Can (n = 447 Eur, n = 50 Can). Of those, 40% of pts in Eur/Can and 39% globally were TACE ineligible according to guidelines (Table). After exclusion of pts with prior sorafenib use, 35% of pts in Eur/Can and 31% globally became TACE ineligible during the study (to be assessed for primary endpoint). Of those, 8% in Eur/Can and 9% globally received sorafenib immediately after TACE ineligibility. At inclusion, most pts were BCLC stage B, and the presence of extrahepatic spread and portal vein thrombosis was lower in Eur/Can vs globally (Table). In pts with available laboratory values, chronic liver function deterioration (worsening in CTCAE grade 30–90 days post TACE) after first TACE was noted in Eur/Can and the global population: ALT 19% and 19%, albumin 30% and 29%, AST 25% and 24%, bilirubin 9% and 11%, and INR 15% and 14%, respectively.

Table: 710P Disease characteristics and TACE ineligibility at inclusion

n (%)	Europe/Canada (n = 497)	Global total (Europe/Canada, Central/South America, Asia) (N = 1650)
Disease status Extrahepatic spread Portal vein thrombosis	19 (4) 15 (3)	118 (7) 123 (7)
BCLC stage B C D Missing	298 (60) 149 (30) 2 (<1) 48 (10)	1034 (63) 529 (32) 19 (1) 68 (4)
Ineligible for TACE	201 (40)	636 (39)

Conclusions: Adherence to TACE eligibility guidelines appear to be similar in Eur/Can and the global population. In the Eur/Can subgroup, chronic deterioration of liver function was observed. These results also suggest that systemic therapies are not commonly used after TACE ineligibility in Eur/Can clinical practice.

Clinical trial identification: NCT01933945.

711P Hepatocellular carcinoma and liver metastasis treated by hafnium oxide nanoparticles activated by stereotactic body radiation therapy

M. Pracht[1], E. Chajon[1], T. de Baere[2], F. Nguyen[2], J-P. Bronowicki[3], V. Vendrely[4], A-S. Baumann[5], V. Croisé-Laurent[3], E. Rio[6], Y. Rolland[1], S. Le Sourd[1], P. Gustin[2], C. Perret[6], F. Mornex[7], D. Peiffert[5], P. Merle[7], E. Deutsch[2]

[1]Radiation Oncology, Centre Eugene - Marquis, Rennes, France, [2]Radiation Oncology, Institut Gustave Roussy, Villejuif, France, [3]Hepatology and Gastroenterology, Hôpital de Brabois, Vandoeuvre les Nancy, France, [4]Radiotherapy, Groupe Hospitalier Sud - Hôpital Haut-Lévêque, Pessac, France, [5]Radiotherapy, Institut de Cancérologie de Lorraine, Nancy, France, [6]Radiotherapy, Institut de Cancérologie de l'Ouest, Nantes, France, [7]Hepatology and Gastroenterology, Centre Hospitalier de la Croix Rousse, Lyon, France

Background: For patients (pts) with hepatocellular carcinoma (HCC) or liver metastasis (liver mets), stereotactic body radiation therapy (SBRT) is a well-tolerated option. Yet, the risk of injury to normal tissues limits the ability to efficiently sterilize tumor cells. Thus, hafnium oxide nanoparticles, NBXTR3, were developed, which increase the interaction of radiotherapy energy dose deposition within tumor cells when activated by an ionizing energy source like SBRT. NBTXR3 innovative approach does not engage liver function, is characterized by a single injection and fits with radiotherapy standards with no change in patient treatment protocol or equipment occupancy. NBTXR3 is currently being evaluated in this population in a phase I/II clinical trial.

Methods: A 3 + 3 dose-escalation design was implemented for pts with HCC with/without portal vein tumor thrombosis or liver mets, including pts who received previous liver resection or other treatments. Pts were treated with a single intralesional injection of NBTXR3 followed by SBRT (45Gy / 3 fractions / 5 to 7 days). The escalating dose levels of NBTXR3 were 10%, 15%, 22%, 33% and 45% (intraarterial injection) of the baseline tumor volume. The primary endpoints were to identify the recommended dose and observe dose-limiting toxicities (DLTs). Secondary endpoints included NBTXR3 residency/leakage and investigator assessment on target lesions by mRECIST via MRI.

Results: So far, 13 pts are enrolled. Dose levels are completed at 10% (6 pts) and 15% (4 pts) and currently enrolling at 22% (3 pts). To date, no early DLTs and no adverse events related to NBTXR3 were observed. In 9 evaluable pts, the investigator mRECIST assessment on target lesions resulted with the following best observed responses: 3 complete responses, 3 partial responses, 1 stable disease and 2 progressive disease. In the same pts, NBTXR3 did not present leakage and did not affect liver function.

Conclusions: NBTXR3 activated by SBRT currently reveals an encouraging safety profile with a favorable efficacy in a vulnerable population with two different liver affections. These outcomes were the result of a complex multidisciplinary cooperation of different medical expertise from different centers.

712P Molecular profiling of PDAC and response to chemotherapy: An update from the COMPASS trial

G.M. O'Kane[1], S. Fischer[2], R.E. Denroche[3], G.H. Jang[3], A. Zhang[3], A. Dodd[1], H. Albaba[1], S. Moura[1], S. Holter[4], K. Aung[1], R.C. Grant[1], P. Krzyzanowski[5], E. Elimova[1], N. Dhani[1], D. Hedley[1], F. Notta[3], J.M. Wilson[3], S. Gallinger[1], J.J. Knox[1]

[1]Department of Medical Oncology and Hematology, Princess Margaret Cancer Center, Toronto, ON, Canada, [2]Department of Pathology, Toronto General Hospital, University Health Network, Toronto, ON, Canada, [3]PanCuRx Translational Research Initiative, Ontario institute for Cancer Research, Toronto, ON, Canada, [4]Zane Cohen Centre for Digestive Diseases, Mount Sinai Hospital, Toronto, ON, Canada, [5]Genomics Program, Ontario institute for Cancer Research, Toronto, ON, Canada

Background: Predictive mutational and transcriptional features in advanced PDAC are urgently needed for improved patient stratification and treatment selection.

Methods: As part of the COMPASS trial patients (pts) with advanced PDAC are prospectively recruited prior to first-line combination chemotherapy for whole genome sequencing (WGS) and RNA sequencing (RNASeq). Fresh tumor tissue is acquired by percutaneous core needle biopsy. Laser capture microdissection ensures high-resolution genomic analyses with results available within 8 wks. Tumor responses and clinical outcomes in this update were correlated with molecular characteristics.

Results: 121 pts underwent a biopsy between December 2015 and April 2018; WGS and RNASeq were successful in 120 (99%) and 119 (98%) respectively, meeting all QC endpoints. 113 genomes have been reported in pts planned to receive chemotherapy; the median time from biopsy to report was 35.5 days. The median age was 63 years (29-81), 53% were male, and 17 (15%) had locally advanced disease. 20 pts (18%) were non evaluable for response. 64 (57%) received modified FFX as first line treatment. 24 (21%) tumors displayed the Moffitt basal-like RNA expression signature which associated with chemotherapy resistance, with tumor shrinkage mainly observed in the classical RNA subtype ($p = 0.002$). GATA6 expression (log10 scale) clearly separated Moffitt subgroups with classical tumors exhibiting high expression ($p < 0.0001$). EGFR overexpression was associated with the basal subtype ($p = 0.002$). The tumor of 1 pt at progression, switched from a basal to a classical phenotype. Of 89 pts with ≥ 6 months follow-up, median overall survival in the classical group was 10 mths vs. 5.1 months in the basal group (HR 0.32 95% CI 0.16–0.68, $p = 0.0025$). Signatures of homologous recombination deficiency were found in 4 pts (4%) including 2 with germline BRCA2 mutations, 1 of which was newly detected. 2 of 3 pts with a novel duplicator phenotype responded to folfirinox. 30% of pts had potentially actionable genetic alterations.

Conclusions: Prospective comprehensive profiling of advanced PDAC indicates that chemotherapy response differs according to genomic/transcriptomic subtypes, providing strong rationale for improved first line trial design.

Clinical trial identification: NCT02750657.

713P Analysis of BRCAness with MLPA in pancreatic ductal adenocarcinoma patients using FFPE sample obtained via EUS-FNAB

K. Okuwaki[1], H. Imaizumi[2], H. Masutani[1], T. Yoshida[3], M. Kida[1], T. Iwai[1], H. Yamauchi[1], T. Kaneko[1], R. Hasegawa[1], E. Miyata[1], K. Adachi[1], M. Tadehara[1], W. Koizumi[1]

[1]Gastroenterology, Kitasato University School of Medicine, Sagamihara, Japan, [2]Gastroenterology, Japan Community Health care Organization, Sagamino Hospital, Sagamihara, Japan, [3]Pathology, Kitasato University School of Medicine, Sagamihara, Japan

Background: A breakthrough in chemotherapy for pancreatic ductal adenocarcinoma (PDAC) may be achieved using precision medicine, which involves identifying cases that are highly likely to respond to a certain treatment and then performing that treatment. BRCAness is a condition resulting from an abnormality in the BRCA pathway, in addition to breast cancer susceptibility gene 1 (BRCA1)/BRCA2 mutation, and is currently a focus of interest as a predictive factor for sensitivity to new anticancer drugs for PDAC. Platinum agents and poly (ADP-ribose) polymerase inhibitors are expected to be effective against BRCAness PDAC. Presently, searching for abnormalities in driver genes such as BRCA 1/2 would require considerable time and expense. Therefore, use of the Multiplex Ligation-dependent Prove Amplification (MLPA) method to diagnose BRCAness is advantageous in being a low-cost method that allows for analysis within a short time frame, and may help to make precision medicine a reality for patients with pancreatic cancer.

Methods: This study included 20 patients with the largest number of in-specimen pancreatic cancer cells among 40 patients with PDAC continuing from endoscopic ultrasound-guided fine-needle aspiration biopsy (EUS-FNAB) conducted at Kitasato University Hospital. Evaluation of the number of cancer cells was conducted by a pathologist. An unstained preparation was created from formalin-fixed paraffin-embedded (FFPE) PDAC tissue obtained via EUS-FNAB, and DNA was extracted. BRCAness was analyzed using the MLPA method.

Results: A BRCAness diagnosis was possible in 15 of 20 (75%) patients using the MLPA method and FFPE tissue obtained via EUS-FNAB in PDAC. Difficulties in BRCAness analysis occurred in 1 patient due to an insufficient amount of DNA and in 4 patients due to poor DNA quality. BRCAness was diagnosed in 1 of 20 (5%) patients.

Conclusions: BRCAness analysis in PDAC patients was possible with the MLPA method using small FFPE obtained via EUS-FNAB, which we believe is the first study to attempt this. Obtaining low-cost analysis results in a short time frame is a key benefit, suggesting this method may be feasible and important in practicing precision medicine to choose a effective drugs in treting PDCA.

714P Repeated mutKRAS ctDNA measurements in patients with advanced pancreatic cancer patients: Kinetics, response prediction and therapy monitoring in comparison to protein-based tumor markers

S. Kruger[1], V. Heinemann[1], C. Ross[2], F. Diehl[2], S. Ormanns[3], S. Liebmann[3], C.B. Westphalen[1], M. Haas[1], A. Jung[3], T. Kirchner[3], M. von Bergwelt-Baildon[1], S. Holdenrieder[4], S. Boeck[1]

[1]Department of Internal Medicine III and Comprehensive Cancer Center, Ludwig Maximilians University, Munich, Germany, [2]Research and Development, Sysmex Inostics GmbH, Hamburg, Germany, [3]Institute of Pathology, Ludwig Maximilians University, Munich, Germany, [4]Institute of Laboratory Medicine, German Heart Center, Technical University of Munich, Munich, Germany

Background: The presence of mutated KRAS circulating tumor DNA (^{mut}KRAS ctDNA) in plasma samples has been consistently shown to be a negative prognostic indicator in pancreatic cancer (PC). Only small pilot studies have evaluated the value of serial ^{mut}KRAS ctDNA-measurements in PC.

Methods: We used BEAMing technology to determine levels of ^{mut}KRAS ctDNA, CA 19-9, CEA and CYFRA 21-1 in 284 plasma samples of 54 patients with advanced PC receiving gemcitabine-based first-line chemotherapy. Absolute levels and kinetics of ^{mut}KRAS ctDNA, CA 19-9, CEA and CYFRA 21-1 were correlated to radiological response, progression free- and overall survival.

Results: ^{mut}KRAS ctDNA was present in a majority of advanced PC patients (n = 36/54, 67%) and indicated tissue KRAS mutation status with a high sensitivity (74%) and specificity (100%). Presence of ^{mut}KRAS ctDNA, as well as higher levels of CA 19-9, CEA and CYFRA 21-1 at treatment initiation were significantly correlated to an adverse overall survival. During therapy, changes in ^{mut}KRAS ctDNA levels were more rapid and pronounced than changes in protein-based tumor markers. Kinetics of ^{mut}KRAS ctDNA were an early indicator of response to therapy, while there was no significant correlation between kinetics of CA 19-9, CEA or CYFRA 21-1 and response to chemotherapy during the first four weeks of treatment. Repeated ^{mut}KRAS ctDNA measurements during follow-up indicated progressive disease with high sensitivity (84%) and specificity (100%).

Conclusions: ^{mut}KRAS ctDNA kinetics appear to be a powerful and highly specific tool in early response prediction and therapy monitoring of advanced PC patients receiving chemotherapy.

[1]Department of Oncology, Herlev and Gentofte Hospital, Herlev, Denmark, [2]Department of Clinical Oncology, Aarhus University Hospital, Aarhus, Denmark, [3]Statistics and Pharmacoepidemiology, Danish Cancer Society Research Center, Copenhagen, Denmark, [4]Experimental Clinical Oncology, Aarhus University Hospital, Aarhus, Denmark, [5]Experimental Research in Medical Cancer Therapy, Odense University Hospital, Odense, Denmark, [6]Department of Clinical Biochemistry, Herlev and Gentofte Hospital, Herlev, Denmark, [7]Department of Oncology, North Zealand University Hospital, Hillerød, Denmark, [8]Department of Oncology, Zealand University Hospital in Næstved, Næstved, Denmark, [9]Department of Oncology, Aalborg University Hospital, Aalborg, Denmark, [10]Department of Pathology, Zealand University Hospital in Roskilde, Roskilde, Denmark

Background: Reliable biomarkers in patients (pts) with pancreatic cancer (PC) are highly warranted. The aim of this prospective-retrospective biomarker study was to investigate the clinical value of cell-free DNA (cfDNA) in pts with PC.

Methods: A total of 377 consecutive pts with histologically confirmed PC and 94 healthy controls were included. Total cfDNA levels were determined by a direct fluorescent assay in EDTA plasma samples obtained before operation (stage I and II) or start of palliative chemotherapy (stage III and IV). Serum CA19-9 (IMMULITE 2000, Siemens), hyaluronic acid (HA) (ELISA, R&D), interleukin-6 (IL-6) (ELISA, R&D) and YKL-40 (ELISA, Quidel) were measured. The main outcome was association of cfDNA with overall survival (OS) for pts with PC. Hazard ratios (HRs) and 95% confidence intervals (CIs) were estimated by Cox proportional hazards regression.

Results: Pts with PC had significantly higher level of plasma cfDNA (median (range): 1.15 [0.45, 4.94] ng/uL) compared with healthy subjects (0.52 [0.48, 0.57] ng/uL, ROC analysis AUC 0.89). The level of plasma cfDNA was significantly increased with advanced stage, presence of liver metastases and worse Performance Status (PS). When analyzed as a continuous parameter, cfDNA higher than median of 1.15 ng/uL alone was associated with reduced OS (HR = 1.40, 95% CI 1.13-1.72, P = 0.002) in univariate analyses along with age >50, worse PS, higher stage, presence of liver metastases, and log2-transformed serum levels of CA19-9, HA, IL-6 and YKL-40. In multivariate analysis, plasma cfDNA (median and 75% quartile as cutoff) was not statistically

significantly associated with OS, but CA19-9 and IL-6 along with higher age, PS, stage and presence of liver metastases were associated with shorter OS.

Conclusions: Plasma cfDNA concentrations measured with a simple assay was higher in PC patients than in healthy individuals. High plasma cfDNA levels were associated with a short OS. Adjusted for a number of known prognostic parameters cfDNA was not statistically significantly associated with OS.

716P Cell free tumor-DNA can predict treatment outcome in advanced PDAC

S. Payr[1], J. Beck[2], U. König[1], M. Brunner[1], J. Gaedcke[3], A. Azizian[3], M. Ghadimi[3], V. Ellenrieder[1], E. Schütz[2], A-O. König[1]

[1]Gastroenterology and Gastroenterological Oncology, Universitätsmedizin Göttingen, Göttingen, Germany, [2]Liquid Biopsy center, Chronix Biomedical GmbH, Göttingen, Germany, [3]Department of General-, Visceral-, and Pediatric Surgery, Universitätsmedizin Göttingen, Göttingen, Germany

Background: Determination of chemotherapy response in pancreatic cancer (PDAC) relies on imaging such as CT or MRI scan, where reliable results can be obtained not earlier than 12 weeks after treatment start. Herein we report, that determination of cell-free DNA (cfDNA) can improve treatment monitoring and may allow prediction of treatment response after administration of the first cycle of chemotherapy.

Methods: 26 patients with advanced PDAC were treated with the FOLFIRINOX regime. Cell-free DNA (cfDNA) was determined from blood samples before treatment start and before each cycle (d1 and d15) for 3 months. In a subset, cfDNA was also determined during first FOLFIRINOX administration after infusion of oxaliplatin and irinotecan (8hrs). Tumor status was evaluated before treatment start and after 3 month by CT scan. cfDNA was extracted from at least 2 mL of plasma and $\geq$10ng total cfDNA was used for sequencing library preparation. Sequencing reads, obtained with a NextSeq500 (Illumina) were mapped to the reference genome (HG19) and read counted in 701 bins of autosomes, with an average size of 5.5Mb. After normalization and transformation into log2 ratios, Z-values were calculated versus a healthy reference group (133 cfDNA samples). Z-Scores of bins significantly different from the reference were summed to generate the CNI-score.

Results: The risk of patients (n = 11) with an elevated pre-therapeutic CNI-Score of > 200 for not responding to chemo was 82%. Patients with CNI-Score above the 95thpercentile of the reference population (CNI >24) after cycle 3, had a significantly higher risk to progress (80%), with a 73% accuracy of prediction (p = 0.03). The prediction of therapy failure was even better after 4 cycles with a 90% predictive value and an overall 83% accuracy (p = 0.02). In 13 patients CNI-score was determined after 8hrs of initiation therapy to assess a possible cytolytic tumor burst. Only patients showing a significant increase of CNI-scores, compared to pre-therapeutic values were responders (n = 2), one of three stable patients had a borderline burst, whereas all progressive patients (n = 8) did not show any sign of tumor burst.

Conclusions: Determination of cell free DNA represents a powerful tool to predict outcome very early during medical treatment of advanced PDAC.

717P Germline and somatic DNA damage repair gene mutations and overall survival in metastatic pancreatic ductal adenocarcinoma patients treated with FOLFIRINOX

A. Sehdev[1], O. Gbolahan[1], B.A. Hancock[2], M. Stanley[1], S. Shahda[3], J. Wan[4], H.H. Wu[5], M. Radovich[2], B. O'Neil[6]

[1]Medicine, Indiana University, Indianapolis, IN, USA, [2]Surgery, Indiana University, Indianapolis, IN, USA, [3]Department of Clinical Medicine, Indiana University Melvin Bren Simon Cancer Center, Indianapolis, IN, USA, [4]Medical and Molecular Genetics, Indiana University, Indianapolis, IN, USA, [5]Pathology, Indiana University, Indianapolis, IN, USA, [6]Medicine, Indiana University School of Medicine, Indianapolis, IN, USA

Background: Pancreatic ductal adenocarcinoma (PDAC) is a lethal cancer with lack of predictive biomarkers. We conducted a study to assess DNA damage repair gene mutations (DDRGM) as a predictive biomarker in PDAC patients treated with FOLFIRINOX.

Methods: Indiana University Simon Cancer Center pancreatic cancer database was used to identify patients with recurrent metastatic PDAC, treated with FOLFIRINOX and had tissue available for DNA sequencing. Baseline demographic, clinical and pathologic information was gathered. DNA isolation and targeted sequencing was performed using the Ion AmpliSeq protocol. Chi-square or t-test was used for univariate analyses. Overall survival (OS) analyses was conducted by Kaplan-Meier method, logistic regression (OS categorized as above and below 3rd quartile) and Cox proportional hazard model. Multivariate models were adjusted for age, gender, margin status, CA 19-9, adjuvant chemotherapy, tumor and nodal stage.

Results: Overall, 36 patients were sequenced. DDRGM were found in 12 patients. Mutations were seen in BRCA1 (N = 7), BRCA2 (N = 5), BRCA1/2 (N = 3), PALB2 (N = 3), MSH2 (N = 1) and FANCF (N = 1) of all the DDR genes sequenced (BRCA1, BRCA2, PALB2, CHEK1, CHEK2, RAD51, MLH1, MSH2, ERCC1, ERCC4, PARP1, FANCF, ATR and MDC1). Median age was 65.5 years, 58% were male, 97.2% were Caucasian and 51.4% had any family history of cancer. There were no significant differences between those with DDRGM present and absent except age (64.6 vs. 66.0 years, p = 0.002). The median OS was near significantly superior in those with DDRGM present vs. absent (14 vs. 5 months; HR 0.58 [0.29-1.14], log-rank p = 0.08). Multivariate logistic (OR 1.47 [1.04-2.06], p = 0.04) and Cox regression (HR 0.37 [0.15-0.94], p = 0.04) showed presence of DDRGM was associated with improved OS. Similar analyses limited to only germline BRCA1/2 mutations also showed significantly improved OS with the presence of BRCA1/2 mutations.

Conclusions: In a single institution, retrospective study, we found that the presence of germline and somatic DDRGM as well as germline BRCA1/2 mutations are associated with improved OS in PDAC patients treated with FOLFIRINOX.

718P A three-gene signature to predict lymph node metastasis of pancreatic cancer

C. Liang, X. Yu

Department of Pancreas Surgery, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Pancreatic cancer, specifically pancreatic ductal adenocarcinoma (PDAC), represents one of the most aggressive malignancies. Lymph node (LN) status is considered as one of the most significant risk factors for survival of PDAC patients, and it is of great importance for making reasonable therapeutic strategies to individual patients. Imaging techniques are widely used in the evaluation of LN status in PDAC patients, however, their application are limited because of the inconsistent sensitivities and specificities findings.

Methods: Gene Set Enrichment Analysis (GSEA) and leading edge analysis were used to analyze the data from The Cancer Genome Atlas (TCGA) on 177 PDAC patients to identify genes associated with LN metastasis. The identified genes with LN metastasis were indexed by Spearman's rank-correlation test to construct the risk score model. Risk scores were used to predict LN metastasis and overall survival (OS). For validation, we used 80 specimens from patients with PDAC diagnosed at Fudan University Shanghai Cancer Center.

Results: A risk model consisting of three genes (MAPK9, ITGA5, AKT2) was developed. This model could correctly predict the LN metastasis evaluated by receiver operating characteristic (ROC) curves [area under curve (AUC) = 0.668, P = 0.001], and risk score positively associated with the number of metastatic lymph node (NLN; Spearman r = 0.3309, P < 0.0001), especially in the PDAC with greatest dimension $\leq$ 4 cm and total lymph nodes dissected (TLN) > 12 [AUC = 0.80, P = 0.003; Spearman r for MLN = 0.4237, P = 0.0004; Spearman r for lymph node rate (LNR) = 0.3171, P = 0.0089]. In the set of PDAC patients with TLN > 12, patients with high risk had a worse OS than that with low risk with hazard ratio (HR) of 2.657 (P = 0.0044) for all stage and HR of 2.548 (P = 0.045) for stage I and II. Patients from stage I and stage IIA with high risk scores had a similar OS with stage IIB (median survival = 21.13 months vs. 20.23 months, P = 0.8227). In the validation set, high risk scores could also effectively predict the LN metastasis and poor prognosis in resectable PDAC.

Conclusions: Our findings highlight three-gene signature with effective capacity for identification of PDAC patients with poor prognosis that are likely to suffer from LN metastasis.

Background: Pancreatic cancer (PC) remains a disease difficult to treat. Afatinib, a novel, oral irreversible ErbB family blocker has shown efficacy in non-small-cell lung cancer bearing driver mutations of the epidermal growth factor receptor. This open-label, multicenter, randomised phase II trial evaluated the efficacy and safety for gemcitabine/afatinib vs. gemcitabine in metastatic PC.

Methods: Patients with histologically proven metastatic PC were randomised in a 2:1 ratio to receive either gemcitabine (1000mg/m^2 i.v. weekly for three weeks followed by one week of rest, repeated every four weeks) and afatinib (40mg orally once daily) vs. gemcitabine alone as first-line treatment for metastatic disease. Overall survival (OS) was the primary endpoint.

Results: Between April 2013 and January 2017, 119 patients from 25 German centers were randomised (79 patients for gemcitabine/afatinib and 40 for gemcitabine), of which 115 received at least one dose of study medication and 108 were eligible for the primary analysis. Median OS was 7.3 months for gemcitabine/afatinib vs. 7.4 months for gemcitabine, HR 1.06 (95% CI 0.68-1.65), p = 0.80. Median progression free survival (PFS) was 3.9 months for gemcitabine/afatinib vs. 3.8 months for gemcitabine, HR 0.87 (95% CI 0.56-1.34), p = 0.52. The objective overall response rate (ORR) was 9.9% for gemcitabine/afatinib vs. 10.8% for gemcitabine, respectively (p > 0.99). The rate of serious adverse events (SAEs) per patient was slightly higher for gemcitabine/afatinib vs. gemcitabine (1.66 vs. 1.53). The rate of adverse events was higher for gemcitabine/afatinib vs. gemcitabine, e.g. for main adverse events known for afatinib like diarrhoea (71% vs. 13%), epistaxis (33% vs. 0%) and skin rash (70% vs. 5%). However, the share of grade ≥3 in these events was low (16% for diarrhoea, 0% for epistaxis, 5% for skin rash; no grades 4 or 5).

Conclusions: The addition of afatinib to gemcitabine did not improve treatment efficacy. The combination had an acceptable safety profile with the main side effects for afatinib ranging within the known scope.

Background: The anti-retroviral agent, nelfinavir, demonstrates radiosensitising effects in pre-clinical models of pancreatic cancer. The primary objective of Stage 1 was to establish the maximum tolerated dose (MTD) of nelfinavir combined with capecitabine-chemoradiation (CRT) after gemcitabine+nab-paclitaxel (GEMABX) induction chemotherapy.

Methods: Patients with inoperable, histologically/cytologically proven LAPC and WHO performance status 0-1 were eligible for this rolling-six dose-escalation stage. After 3 cycles of induction GEMABX (28-day cycle of nab-paclitaxel 125mg/m^2 and gemcitabine 1000mg/m^2 on days 1, 8, and 15), patients with non-progressive disease had 1 further cycle followed by CRT (50.4Gy/28 fractions, capecitabine 830mg/m^2 bd on radiotherapy days) and 1000mg or 1250mg nelfinavir bd continuously during CRT. Other outcomes included overall survival and progression-free survival.

Results: 27 patients were recruited from 8 UK centres (March 2016-June 2017). Median age was 62 years, 30% were male, 78% had head tumours, and 30% had biliary stents. Baseline median tumour diameter was 36mm. 67% commenced CRT. 11 patients received 1000mg and there was one dose-limiting toxicity (DLT) in this group: grade 3 acute coronary syndrome. The nelfinavir dose was escalated as per the rolling-six design. 7 patients received 1250mg nelfinavir and no DLTs were observed. During GEMABX, common grade ≥3 toxicities among participants were neutropenia (30%), fatigue (22%), and diarrhoea (15%). During CRT, grade ≥3 toxicities included fatigue (6%) and anorexia (6%). No grade 5 adverse events were reported in Stage 1. Survival analysis will be presented.

Conclusions: 1250mg nelfinavir was recommended for combining with capecitabine-CRT in the ongoing randomised component of the trial (Stage 2).

Clinical trial identification: ISRCTN50083238.

721P A phase I study of IRISOX (irinotecan/S-1/oxaliplatin) in the second-line treatment for gemcitabine-refractory pancreatic cancer

E. Miyata[1], K. Okuwaki[1], H. Imaizumi[2], M. Kida[1], T. Iwai[1], H. Yamauchi[1], T. Kaneko[1], R. Hasegawa[1], K. Adachi[1], M. Tadehara[1], W. Koizumi[1]

[1]Gastroenterology, Kitasato University School of Medicine, Sagamihara, Japan, [2]Gastroenterology, Japan Community Health Care Organization, Sagamino Hospital, Sagamihara, Japan

Background: In Japan, gemcitabine based chemotherapy has been a standard regimen as one of the first-line treatment for unresectable pancreatic cancer. FOLFIRINOX was introduced in the second-line treatment for the gemcitabine-refractory pancreatic cancer of patients with an ECOG performance status score of 0 or 1. However, FOLFIRINOX requires close monitoring and must be limited to patients with good performance status because of significant toxicity. Further FOLFIRINOX requires a central veins port, and a trouble such as the port infection may occur. Therefore, it is difficult to administer FOLFIRINOX as second-line treatment. The first time in the world, we introduced IRISOX which substituted S-1 for fluorouracil and leucovorin in the second-line treatment. We aimed to evaluate the tolerance, safety, and clinical efficacy of IRISOX in the second-line treatment for the gemcitabine-refractory pancreatic cancer in a phase 1 study.

Methods: The primary objective was to determine the maximum tolerated dose (MTD) and recommended dose (RD) of IRISOX. The study was designed in accordance with a standard 3 + 3 method. Patients received 2-week cycles of treatment. Irinotecan was administered as an intravenous infusion at 100, 120, or 150 mg/m^2 on day 1, S-1 was administered orally at 80 mg/m^2 twice daily for 7 days, and oxaliplatin was administered as an intravenous infusion at 85 mg/m^2 on day 1.

Results: Among the 12 patients enrolled, dose-limiting toxicity was observed in a patient at level 1 (irinotecan 100 mg/ m^2 on day 1, S-1 80 mg/m^2 twice daily, and

oxaliplatin 85 mg/m^2 on day 1) , and in two patients at level 2 (irinotecan 120 mg/ m^2 on day 1, S-1 80 mg/m^2 twice daily, and oxaliplatin 85 mg/m^2 on day 1). The MTD was established as level 2. The RD was established as level 1. The most common grade 3-4 toxicity was neutropenia (33.3 %). The overall response rate was 9.0 %. The overall disease control rate was 45.4 %.

Conclusions: Based on the present results, the RD was determined as level 1 (irinotecan 100 mg/ m^2 on day 1, S-1 80 mg/m^2 twice daily, and oxaliplatin 85 mg/m^2 on day 1). IRISOX was well tolerated and showed antitumor efficacy in the second-line treatment for the gemcitabine-refractory pancreatic cancer in a phase 1 study.

Background: Chemotherapy is effective in metastatic pancreatic ductal adenocarcinoma (mPDAC) but new approaches are still needed to improve patients (pts) survival and quality of life. We have here made exploratory analyses of 400 pts enrolled in 2 previously reported randomized phase II trials.

Methods: Chemotherapy-naive pts with proven mPDAC, bilirubin levels < 1.5 ULN and performance status (PS) 0-2 were randomized to receive either Gemcitabine + nab-paclitaxel (A: MPACT regimen), FOLFIRINOX (B: PRODIGE 4 regimen), FOLFIRINOX in a stop and go strategy with maintenance LV5FU2 at 4 months (C: PANOPTIMOX regimen), sequential gemcitabine for 2 mo, followed by FOLFIRI.3 (D: FIRGEM regimen) or sequential gemcitabine+nab-paclitaxel for 2 mo, followed by FOLFIRI.3 (E: FIRGEMAX regimen). mITT pts were defined as patients receiving at least one dose of treatment, preplanned per-protocol (PP) pts were defined as patients reaching 2 mo of treatment and analyzed considering the real treatment received.

Results: Between Jan 2015 and Nov 2016, 400 pts were enrolled in the 2 trials. Mean age was 63 (38-76), 56% were men, pts PS was 0/1/2 in 40/56/4%. Groups were comparable regarding baseline characteristics. Grade 3-4 toxicities (at least one event per pt) in arms A/B/C/D/E were 90/85/85/91/89% ($p > 0.05$), mainly gastrointestinal, hematological and neurological disorders. Efficacy results are summarized in the table.

Table: 722P

	Gem+ nab (n = 63)	FOLFIRINOX (n = 91)	PANOPTIMOX (n = 92)	FIRGEM (n = 90)	FIRGEMAX (n = 64)
mITT - ORR (%) ($p^{\#}$=0.11)	25	36	34	23	40
Median ITT - PFS (mo) (p*=0.12)	4.2	6.3	5.7	4.5	5.7
Median PP - PFS (mo) (p*=0.05)	6.0	7.7	7.5	6.3	7.6
Median ITT - OS (mo) (p*=0.09)	11.3	10.1	11.2	7.3	11.6
Median PP - OS (mo) (p*=0.08)	12.4	12.2	13.0	9.8	15.8

*Overall Log-rank test # Chi2 test.

Conclusions: FOLFIRINOX seems confirmed as a reference treatment for mPDAC. These exploratory analyses show no major differences between the different treatment options offered in these 2 studies except for the FIRGEM sequential strategy that seems both in ITT and preplanned PP analyses less efficient than the other options. The addition of nab-paclitaxel to this sequential approach seems to dramatically improve patients' oncological outcomes.

723P First-line (1L) full dose (f) and modified (m) FOLFIRINOX and gemcitabine+nab-paclitaxel (GN) treatment (tx) for metastatic pancreatic adenocarcinoma (mPAC) patients (pts) in routine clinical practice across Europe

J. Taieb[1], A. Carrato[2], B. Westphalen[3], D. Melisi[4], G. Prager[5], T. Macarulla Mercade[6], Å.B.C. Mellbring[7], N. d'Esquermes[8], A. Ferreras[8], F. de Jong[9]

[1]Gastroenterology and Digestive Oncology Department, Georges Pompidou European Hospital, Sorbonne Paris Cité, Paris Descartes University, Paris, France, [2]Medical Oncology, Ramón y Cajal University Hospital, Madrid, Spain, [3]Comprehensive Cancer Center München, Klinikum der Universität München, Munich, Germany, [4]Medical Oncology, University of Verona, Verona, Italy, [5]Comprehensive Cancer Center Vienna, Medical University of Vienna, Vienna, Austria, [6]Medical Oncology, Vall dHebron Institute of Oncology (VHIO)-Cellex Center, Barcelona, Spain, [7]Oncology, Shire Sweden AB, Stockholm, Sweden, [8]Advanced Analytics, Genactis, Mougins, France, [9]Global Medical Affairs Oncology, Shire International GmbH, Zug, Switzerland

Background: FOLFIRINOX and GN have shown superior OS but with increased toxicity in fitter and younger pts vs gemcitabine. In routine practice, FOLFIRINOX is often modified at start (eg no 5FU bolus). No randomized phase III data are available and real world data are scarce.

Table: 723P

First-line treatment	N	% pts with dose adjustment	% pts >65 year	% female pts	% pts 0-1 ECOG Performance Score	% pts received 2L	Median OS/PFS (months)
gemcitabine+nab-paclitaxel (GN)	660	20.5%	44.8%	43.2%	76.5%	67.4%	12/7
FOLFIRINOX	912		23.9%	36.3%	87.2%	78.1%	15/10
mFOLFIRINOX	164	6.7%	18.3%	41.5%	89.0%	78.0%	16/10
fFOLFIRINOX	748	26.1%	25.1%	35.2%	86.8%	78.1%	15/10
fFOLFIRINOX modified in cycle 2/3	27		25.9%	48.1%	92.6%	66.7%	
fFOLFIRINOX modified in cycle 3+	168		27.4%	41.1%	88.1%	77.4%	
fFOLFIRINOX never modified	553		24.4%	32.7%	86.1%	78.9%	

Methods: In this observational electronic chart review data were retrospectively recorded of pts ≥18 y who completed 1L mPAC tx JUL14-JAN16. Physicians (HCPs) were recruited across different regions and settings and encouraged to enter pts in/beyond 2L. Baseline characteristics and outcomes of 1L FOLFIRINOX and GN are reported. Data are descriptive.

Results: 2,565 records were completed by 225 HCPs; 500–504 from FR/GER/IT/SP/UK. Of 912 1L FOLFIRINOX pts, 18% started mFOLFIRINOX. Of 748 fFOLFIRINOX pts, 26% were later dose modified. Of 660 1L GN pts, 20% were dose modified. Compared with GN, more FOLFIRINOX pts were <65 y, male and fitter (Table). Compared with fFOLFIRINOX, more mFOLFIRINOX pts were <65 y and female. Female fFOLFIRINOX pts were a little more often dose adjusted. Of FOLFIRINOX/GN pts, 12/23% stopped further tx after 1L, 10/9% were awaiting 2L and 78/67% were in ≥ 2L. mOS/mPFS in this selected population was 15/10 mo for FOLFIRINOX and 12/7 mo for GN. mFOLFIRINOX (16/10 mo) had similar outcomes vs fFOLFIRINOX (15/10 mo). On average, 1.5 reasons were reported to stop tx. Most common for FOLFIRINOX/GN were: radiological PD (39/54%), clinical PD (24/32%), tx completed as planned (36/18%) and toxicity (13/9%). No overall benefit of continued tx by pt (8%/9%) or HCP decision (7%/7%) were noted, no differences between f/mFOLFIRINOX were seen.

Conclusions: In this large retrospective chart review, pt characteristics and outcomes for 1L mPAC f/mFOLFIRINOX tx were similar. GN had somewhat lower mOS/mPFS; however, more GN pts were >65 y, female, less fit, and less received 2L tx.

724P Real-world comparative effectiveness of nab-paclitaxel plus gemcitabine (nab-P/G) vs FOLFIRINOX (FFX) in patients (pts) with advanced pancreatic cancer (aPC)

E.G. Chiorean[1], W.Y. Cheung[2], G. Giordano[3], G. Kim[4], S-E. Al-Batran[5]

[1]Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, USA, [2]Oncology, Alberta Health Services, Calgary, AB, Canada, [3]Oncology, IRRCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy, [4]Oncology, 21st Century Oncology, Jacksonville, FL, USA, [5]Oncology, Nordwest-Krankenhaus, Frankfurt am Main, Germany

Background: Current guidelines recommend chemotherapy with nab-P/G or FFX as the preferred first-line (1L) treatment for metastatic (m)PC pts with good performance status. However, no clinical trial has directly compared 1L nab-P/G vs FFX in mPC or aPC. We conducted a systematic review of the real-world comparative effectiveness of nab-P/G vs FFX in this setting.

Methods: Embase, Medline, and ASCO GI 2018 were searched through January 2018 for real world, retrospective studies directly comparing 1L nab-P/G vs FFX in mPC/aPC. Radiotherapy studies were excluded.

Results: 550/580 records did not meet eligibility criteria, mainly as they were not comparative (264) nor 1L (188). After removing 5 duplicates, the remaining 25 studies (16 mPC; 9 aPC) assessed > 5464 pts who received nab-P/G or FFX. Generally, a lower proportion of pts in the nab-P/G group (range, 59% - 100%) had an ECOG PS score of 0 or 1 vs FFX (82% - 100%) (12 studies). Median overall survival (OS; 19 studies) ranged from 5.5 mo to "not reached" for nab-P/G, and 8.6 to 15.9 mo for FFX (Table); median progression-free survival (12 studies) ranged from 4 to 8.5 mo and 3.7 to 11.7 mo, respectively. In 2 studies that reported OS based on ECOG PS, the median OS for pts with ECOG PS 0/1 was 12.1 and 14.1 mo for nab-P/G vs 11.4 and 13.7 mo for FFX. Overall response rates ranged from 10% to 41% for nab-P/G and 6% to 34% for FFX (4 studies), and disease control rates ranged from 50% to 92% and 56% to 89%, respectively (5 studies). Safety outcomes were heterogeneously reported in 1667 pts (10 studies) receiving nab-P/G or FFX (Table).

Conclusions: Several real-world studies have compared the effectiveness of nab-P/G vs FFX, highlighting the clinical significance. A systematic review of these studies shows that nab-P/G and FFX have comparable effectiveness in mPC/aPC. Differences were observed in the toxicity profiles for the 2 regimens, which may drive treatment decisions. Table. Studies reporting OS, PFS, and safety.

725P Efficacy and safety of nab-paclitaxel plus gemcitabine (AG) vs. FOLFIRINOX (FFX) as first line chemotherapy for metastatic pancreatic cancer (mPC): Retrospective analysis

K. Lee, I. Hwang, J. Kang, C. Yoo, K-P. Kim, J.H. Jeong, H-M. Chang, B-Y. Ryoo

Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea

Background: Nab-Paclitaxel plus Gemcitabine (AG) and FOLFIRINOX (FFX) have been established as standard first-line treatment in metastatic pancreatic cancer (mPC) based on the superior efficacy compared to gemcitabine monotherapy. Although FFX is recommended for patients with relatively young age and good performance status (PS), there is lack of data for optimal choice between these two regimens. We performed retrospective analysis comparing the efficacies and safety of AG and FFX in mPC patients as first line therapy.

Methods: A total of 308 patients with mPC who were treated with AG (n = 149) or FFX (n = 159) as first-line treatment between January 2013 and December 2016 at Asan Medical Center, Seoul, Korea were included. Treatment outcomes including survivals, response rates and toxicities of each regimen were evaluated.

Results: Patients treated with AG were older (62 vs. 60 years, p = 0.02) and they had higher Charlson Comorbidity Index (CCI) score (≥9, 46.3% vs. 32.7%, p = 0.02). There were no significant differences between the two groups in terms of other baseline characteristics. The response rates (34% vs 34%, p = 0.88) and median progression-free survival (PFS) (6.8 vs 5.1 months, p = 0.19) were comparable, but median overall survival (OS) was significantly better with AG (11.4 vs 9.6 months; p = 0.002). In subgroup analyses, PFS with AG was longer in patients with age ≥ 65 years, peritoneal metastasis, and higher CCI than that with FFX. While grade 3-4 peripheral neuropathy was more common in the AG group (10% vs 3%), grade 3 nausea was more frequent in the FFX group (2% vs 17%); granulocyte colony-stimulating factor was required only in the FFX group (n = 27, 18%).

Conclusions: AG was well tolerated and showed comparable efficacy outcomes with FFX. Of note, AG might be preferentially considered as the first-line treatment in mPC patients with peritoneal metastasis, comorbid medical conditions or old age. As both regimens are feasible as first-line treatment for mPC, further investigations are needed for the personalized uses of these regimens.

Background: There are concerns about more severe toxicities of FOLFIRINOX use in case with recurrent disease after pancreatic resection, because a certain number of these patients suffer from malnutrition, weight loss, and diabetes mellitus induced by pancreatic exocrine or endocrine insufficiency. Today, FOFIRINOX is widely adopted also in recurrent disease after resection beside metastatic disease studied in the ACCORD trial, yet can be associated with significant severe toxicity. We aimed to clarify toxicity and tolerance of FOLFIRNOX use in patients with recurrent disease after resection.

Methods: This study was carried out as an incidental research of JASPAC 06 study which examined multi-institutional experience with FOLFIRINOX use in pancreatic cancer by registration study. We focused on toxicity and tolerance of FOLFIRINOX use in case with recurrent disease after resection, and correlated them with those of locally advanced or metastatic disease group.

Results: From Nov. 2014 to May. 2015, 399 patients were registered in JASPAC 06, 80 patients (20%) had recurrent disease, 78 (20%) had locally advanced disease, and 241 (60%) had metastatic disease. There were no difference in background such as age, sex, ECOG PS, pathology and CA19-9 level between recurrent disease group and locally advanced or metastatic disease group. FOLFIRINOX was initiated as modified manner in 69% of recurrent group and 67% of locally advanced or metastatic group. The major grade 3-4 toxicities observed in recurrent group and locally advanced or metastatic disease group were neutropenia (68% vs 63%), febrile neutropenia (4% vs 15%, $p = 0.007$), thrombocytopenia (4% vs 3%), anemia (8% vs 10%), fatigue (4% vs 3%), anorexia (14% vs 14%). The median treatment duration and median treatment cycle in recurrence group and locally advanced or metastatic group was 2.9 months vs 4.1 months, and 4cycle vs 6cycle. There was no difference in relative dose intensity between two groups.

Conclusions: Toxicity and tolerance of FOLFIRINOX use in recurrent disease after pancreatic resection were similar to those of use in locally advanced or metastatic disease.

727P A phase II study of nab-paclitaxel and gemcitabine in Korean patients with metastatic pancreatic cancer

S.J. Lee[1], D-Y. Oh[2], J-H. Kang[3], H.J. Choi[4], M.A. Lee[5], S.Y. Oh[6], S-T. Kim[7], Y.S. Park[8], B-Y. Ryu[9], J.O. Park[1]

[1]Medicine, Samsung Medical Center Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [2]Internal Medicine, Seoul National University Hospital, Seoul, Republic of Korea, [3]Internal Medicine, Gyeongsang National University School of Medicine, Jinju, Jinju, Republic of Korea, [4]Internal Medicine, Yonsei University College of Medicine Department of Internal Medicine, Seoul, Republic of Korea, [5]Internal Medicine, Seoul St. Mary's Hospital, of the Catholic University, Seoul, Republic of Korea, [6]Internal Medicine, Dong-A University College of Medicine, Busan, Republic of Korea, [7]Medicine, Samsung Medical Center, Seoul, Republic of Korea, [8]Hematology-Oncology, Samsung Medical Center Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [9]Internal Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea

Background: Nab-paclitaxel (nab-P) in combination with gemcitabine (G) significantly improved overall survival in patients with pancreatic cancer and is considered as standard first line therapy. However, the efficacy and safety data in Korean patients are lacking as the phase III study was done only in Western countries.

Methods: This open-label, multicenter, phase II, single-arm study was conducted at seven hospitals in South Korea (NCT02426281). Patients with pathologically confirmed metastatic pancreatic cancer were enrolled. Patients received nab-P (125mg/m^2) followed by G (1000mg/m^2) on days 1, 8, and 15 every 4 weeks until disease progression or unacceptable toxicity. The primary endpoint was progression-free survival (PFS). Through a randomized phase III trial, Von Hoff et al. observed a median PFS of 3.7 months from the G alone arm and 5.5 months from the nab-P + G arm. This study is to confirm this outcome from the Korean population. We will not be interested in the combination therapy of nab-P + G if its median PFS is 3.7 months or shorter and will be highly interested in it if its median PFS is 5.5 months or longer. (90% of power and by the one-sample log-rank test with a one-sided alpha=5%).

Results: A total of 65 patients were enrolled between May 2015 and November 2016. The median age of patients was 60 years (range 43-83), 75% of patients were male, and all had an ECOG performance status of 0 or 1. The median PFS was 7.0 months (95% CI; 5.6-8.3), which met primary endpoints. Median overall survival was 12.9 months (95% CI; 10.1-15.6) and the objective response rate was 41.5 % (95% CI; 29.5-53.5) according to RECIST v1.1. The median relative dose intensity was 84% for nab-paclitaxel and 88% for gemcitabine. Grade 3-4 adverse events included neutropenia (62%), anemia (14%), neuropathy (12%) and febrile neutropenia (9%). There was one treatment-related deaths of septic shock.

Conclusions: In Korean patients with metastatic pancreatic cancer, nab-paclitaxel plus gemcitabine regimen showed comparable efficacy and safety profile to previous phase III study of Western countries. Based on this result, we are conducting a phase II trial with the nab-P + G in an expansion cohort of locally advanced pancreatic cancer.

Clinical trial identification: NCT02426281.

728P Nab-paclitaxel plus gemcitabine for unresectable pancreatic cancer: A pooled meta-analysis

Y. Zhang, S. Shi, X. Yu

Department of Pancreatic Surgery, Fudan University Shanghai Cancer Center, Shanghai, China

Background: About 80%-85% of patients with pancreatic cancer are unresectable at first diagnosis. Several studies have examined nab-paclitaxel plus gemcitabine (NG) in patients with locally advanced pancreatic cancer (LAPC) and metastatic pancreatic cancer (MPC). The objective of this analysis was to evaluate the effectiveness of NG as first-line treatment in this specific patient population.

Methods: We searched Pubmed for eligible studies from the day of inception to April 15th, 2018 for studies of chemo(radiation)therapy-naïve patients who accepted NG as first-line treatment of unresectable pancreatic cancer (UPC). Overall objective response rate (ORR), 1-year overall survival (OS) and 6-month progression free survival (PFS) rates were estimated by randomized-effect model. Subgroup analyses were conducted in LAPC and MPC.

Results: Of 890 patients included from 16 studies, 53 patients were LAPC and 837 patients were MPC. Median OS from the start of NG of all patients ranged from 8.7 months to 20.0 months with a 1-year survival rate of 50.9% (95%CI 40.1% to 61.8%). Median PFS ranged from 2.2 months to 8.4 months with a 6-month PFS rate of 52.8% (95%CI 33.2% to 72.3%). In single arm analysis, the overall ORR in unresectable pancreatic cancer was 34.4% (95%CI 25.3% to 43.5%). In patients with LAPC, 90.6% (48/53) underwent surgery and the R0 resection rate was 81.2% (ranging from 70% to 100%), achieving a 1-year survival rate of 97.5%. In patients with MPC, the ORR was 30.8% and the 1-year survival rate was 44.6%. Five hundred and fifty six grade 3/4 adverse events and no death caused by toxicity were reported in 15 studies consisting of 871 patients.

Conclusions: This is the first meta-analysis to evaluate the effectiveness of NG for UPC. More than 50% of patients with UPC treated with NG survived longer than 12 months. NG showed favorable tumor reducing effect with acceptable toxicity profile. Randomized controlled trials are needed to confirm the efficacy of NG in patients with LAPC.

729P Prognostic implication of inflammation-based scores in patients with metastatic pancreatic cancer (mPC) treated with first-line nab-paclitaxel plus gemcitabine (AG)

I. Hwang[1], J. Kang[2], C. Yoo[1], J.H. Jeong[1], K-P. Kim[1], H-M. Chang[1], B-Y. Ryoo[1]

[1]Medical Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [2]Oncology, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea

Background: AG is standard first-line chemotherapy for patients with mPC. However, prognostic factors for patients with mPC treated with AG are largely unknown. This retrospective analysis was performed to identify the prognostic factors including

inflammation-based prognostic scores in mPC patients treated with AG as first-line treatment.

Methods: A total of 203 patients with histologically confirmed recurrent (n = 55) or metastatic (n = 148) pancreatic cancer who were treated with first-line AG in Asan Medical Center, Seoul, Korea, between January 2013 and January 2018, were included in this analysis. As inflammation-based scores, baseline Neutrophil-lymphocyte ratio (NLR), Platelet-lymphocyte ratio (PLR) and modified Glasgow prognostic score (mGPS) were tested. Cox-proportional hazards model were used to identify prognostic factors in univariate and multivariate analyses.

Results: Median age was 62 years (range, 32-82) and 116 patients (57%) were male. With median follow-up duration of 21.5 months (range, 0.5-34.3), median overall survival (OS) and progression-free survival (PFS) in overall patients were 15.1 (95% CI 12.6-17.6) and 7.1 (95% CI, 6.2-8.0) months, respectively. In multivariate analysis, elevated CA19-9 level (HR 1.75, p = 0.008), liver metastasis (HR 1.8, p = 0.001), distant lymph node metastasis (HR 1.4, p = 0.04), and high mGPS (≥1 vs.0: HR 1.6, p = 0.005) were significantly associated with poorer OS. For PFS, poor performance status (PS) (ECOG PS ≥ 2 vs 0/1: HR 2.1, p = 0.048), liver metastasis (HR 1.4, p = 0.03), distant lymph node metastasis (HR 1.5, p = 0.02), and elevated CA 19-9 level (HR 1.1, p = 0.02) were significantly related with poorer outcomes. Neither NLR nor PLR was significantly associated with PFS or OS.

Conclusions: CA 19-9 level, liver and distant lymph node metastasis were independent prognostic factors in mPC patients treated with first-line AG. Among the inflammation based prognostic scores, mGPS may be the reliable indicator for the prediction of OS.

730P A pilot study of gemcitabine, nab-paclitaxel, PEGPH20 (PAG) and rivaroxaban for advanced pancreatic adenocarcinoma: Interim safety and efficacy analysis

K. Yu[1], S. Mantha[1], C. Tjan[1], E. Kaufmann[1], R.B. Brenner[1], M. Lowery[1], G. Ku[1], N. Raj[2], M. Shcherba[1], Z. Goldberg[1], J. Li[1], A. Zervoudakis[1], A. Hamilton[1], E. Won[1], R.K.G. Do[1], E.M. O'Reilly[1]

[1]Medicine, Memorial Sloan Kettering Cancer Center, New York, NY, USA, [2]Medical Oncology, Memorial Sloan Kettering Cancer Center, New York, NY, USA

Background: PEGPH20 (P) degrades hyaluronan (HA), a key component of pancreatic adenocarcinoma (PDAC) tumor microenvironment, leading to reduction of tumor interstitial pressure, decompression of tumor blood vessels and improvement in delivery of chemotherapeutics. A prior study of P with chemotherapy in PDAC (HALO-202) found an increased risk of thromboembolic (TE) events, 43%, effectively reduced with enoxaparin prophylaxis. Rivaroxaban (R) is a safe and effective oral anticoagulant for treating cancer-related TE.

Methods: Patients considering frontline therapy for advanced PDAC and with KPS ≥ 70 were studied. 28 patients without prior TE (cohort 1) and 14/28 planned patients with prior TE (cohort 2) were enrolled. Patients received treatment with PAG (P; 3 μg/kg IV 2x/wk x 3 wks in C1, then 1x/wk x 3 wks in C2+, plus standard dose and schedule nab-paclitaxel and gemcitabine (AG)) every 28 days, with R (15 mg twice daily for 21 days, followed by 20 mg once daily). Primary endpoint is TE event rate. Secondary endpoints include PFS, OS, major bleeding rate and RR.

Results: All 42 patients are evaluable for efficacy and safety. Key patient characteristics: median age = 61, M/F 22/20, stage III/IV 5/37. Median follow-up is 10.9 mo. One (2.4%) grade 4 TE event occurred. Two grade 3 GI hemorrhages occurred, both resolved with supportive measures. Best responses: complete response 2 (4.8%), partial response 19 (45.2%), stable disease 15 (35.7%), progressive disease 2 (4.8%), and overall disease control rate of 85.7%. Median PFS is 7.0 mo, mOS has not been reached. Safety and efficacy are similar across both cohorts (see Table).

Table: 730P

Variable	Cohort 1	Cohort 2	Overall
Safety	n = 28	n = 14	n = 42
TE Events	1 (3.6%)	0 (0%)	1 (2.4%)
Major Bleeding	2 (7.1%)	0 (0%)	2 (4.8%)
Efficacy			
Complete Response	1 (3.6%)	1 (7.1%)	2 (4.8%)
Partial Response	14 (50.0%)	5 (35.7%)	19 (45.2%)
Stable Disease	8 (28.6%)	7 (50.0%)	15 (35.7%)
Progressive Disease	2 (7.1%)	0 (0%)	2 (4.8%)
Not Evaluable	3 (10.7%)	1 (7.1%)	4 (9.5%)
PFS	6.0 mo	8.0 mo	7.0 mo
OS	Not Reached	Not Reached	Not Reached

Conclusions: Interim analysis shows R is safe and effectively prevents TE events in patients receiving PAG. Responses and disease control rate are encouraging in this tumor HA-level unselected patient population. Updated safety and efficacy data will be reported.

Clinical trial identification: NCT02921022.

Background: Presence/absence of family/personal history of breast/ovarian/pancreatic cancer has been reported to be a useful predictive marker in patients with pancreatic adenocarcinoma (PA) receiving platinum-based chemotherapy (Fogelman D, 2015). We planned a prospective phase II study to evaluate the efficacy and safety of platinum-based chemotherapy in this population.

Methods: Eligible patients were those with chemotherapy-naïve metastatic PA with one or more of the following: 1) family history of pancreatic (P)/breast (B)/ovarian (O)/prostate (PR) cancer in a first-degree relative, 2) at least two family members with P/B/O/PR cancer within third-degree relatives, and 3) personal history of B/O/PR cancer. Patients received gemcitabine 1,000 mg/m^2 and oxaliplatin 100 mg/m^2 every two weeks (GEMOX). The primary endpoint was the one-year survival rate, and the outcome in 19 of 43 patients (pts) (44%) were desired. The target sample size was determined as 43, with a one-sided alpha of 5% and a power of 80%.

Results: A total of 45 pts were enrolled. The first consecutive 43 pts were included in the efficacy analysis. The one-year survival rate (90% confidence interval) was 27.9% (17.0-41.3) and did not meet the expected threshold. The response rate was 27.9%. A tendency towards prolonged survival was observed in patients with two or more family histories of P/B/O/PR cancer (HR 0.65, 95% CI [0.34-1.23]). Presence of a family/personal history of B/O/PR cancer tended to be associated with a better response and longer survival. In this study population, patients with a family history of pancreatic cancer seemed to show a poorer response. The most common adverse events of grade 3 or higher severity were neutropenia (36%), leukopenia (27%) and thrombocytopenia (23%).

Conclusions: GEMOX did not show expected efficacy in patients with metastatic PA with a family/personal history of P/B/O/PR cancer. Selection of GEMOX based on family/personal history alone is not recommended, especially in patients with a family history of P cancer.

Clinical trial identification: UMIN000017894 (registeration date: 17-Jun-2015).

Background: A more accurate identification of tumors by image-guided radiation therapy (IGRT) and improved radiation delivery by advanced technology have led to a wider use of hypofractionated radiation schedules for the treatment of locally advanced pancreatic cancer (LAPC). The aim of this prospective phase II study was to evaluate the effect of neoadjuvant GEMOX plus accelerated hypofractionated radiotherapy on the resectability of LAPC.

Methods: From April 2011 to August 2016, a total of 42 patients with non resectable LAPC were enrolled onto the study, of whom 40 were evaluable. Median age was 67 years (range 41-78). Patients were treated as the following: gemcitabine (GEM) 1000 mg/m2 on day 1, and oxaliplatin (OX) 100 mg/m2 on day 2, every two weeks (GEMOX regimen) for 4 cycles, 15 days off, hypofractionated radiotherapy, 15 days off, a further 4 cycles of GEMOX, restaging. Radiotherapy was delivered by helical tomotherapy at a dose of 35 Gy (with an inhomogeneous dose distribution inside the target volume of up to 30% of the prescription dose) in 7 fractions (one fraction per day) over 9 days on the gross tumor volume; 28 Gy-35 Gy was administered on the clinical target volume (CTV) 1-2 on the basis of nodal status.

Results: Overall 5 patients (12.5%) obtained a partial tumor response and 20 (50%) a stable disease. Of these, 9 underwent surgical laparotomy (5 radical pancreatic resection 1 termoablation and 3 explorative laparotomy), 1 patient became operable but refused surgery. The overall resectability rate was 25%, while the R0 resection rate was 12.5%. Toxicity to GEMOX was similar to that reported elsewhere. Radiotherapy was well tolerated and the most frequently encountered adverse events were mild to moderate nausea and vomiting, abdominal pain and fatigue. At a median follow-up of 50 months, the median progression free survival and overall survival were 9.3 (95% CI 6.2-14.9) and 15.8 (95% CI 8.2-23.4) months, respectively.

Conclusions: Our results show the feasibility of using accelerated hypofractionated radiotherapy on tumor volume and locoregional lymph nodes in LAPC. Treatment was well tolerated and survival rates are promising.

Clinical trial identification: EudraCT / RSO2010-020379-22.

733P NAPOLI-1 phase III trial outcomes by prior surgery, and disease stage, in patients with metastatic pancreatic ductal adenocarcinoma (mPDAC)

T. Macarulla Mercade[1], G. Bodoky[2], J. Siveke[3], K-H. Lee[4], J. Chen[5], B. Mirakhur[6], A. Dean[7], L-T. Chen[8], F. de Jong[9]

[1]*Medical Oncology, Vall d'Hebron Institute of Oncology (VHIO)-Cellex Center, Barcelona, Spain,* [2]*Oncology, St. László Hospital, Budapest, Hungary,* [3]*Medical Oncology, University Hospital Essen West German Cancer Center, Essen, Germany,* [4]*Medical Oncology, Seoul National University Hospital, Seoul, Republic of Korea,* [5]*Biostatistics, Shire plc, Cambridge, MA, USA,* [6]*Medical Affairs, Ipsen Biopharmaceuticals, Inc., Basking Ridge, NJ, USA,* [7]*Medical Oncology, Saint John of God Hospital Subiaco, Subiaco, Australia,* [8]*National Institute of Cancer Research, National Health Research Institutes, Tainan, Taiwan,* [9]*Global Medical Affairs Oncology, Shire International GmbH, Zug, Switzerland*

Background: The NAPOLI-1 phase 3 trial (NCT01494506) reported significantly increased median OS with nal-IRI+5-FU/LV vs 5-FU/LV (6.1 mo vs 4.2 mo; HR = 0.67; p = 0.012) in mPDAC patients who progressed after gemcitabine-based therapy. We report subgroup analysis outcomes in NAPOLI-1 patients who had undergone prior surgery and by disease stage at diagnosis.

Methods: This post-hoc analysis investigated outcomes with or without prior surgery, and by disease stage at diagnosis (stage IIA, IIB, or III, vs IV). P values are descriptive.

Results: In the NAPOLI-1 trial, OS and PFS were increased in ITT patients who had undergone prior surgery compared to those who did not (Table). In patients with prior surgery receiving nal-IRI+5-FU/LV (n = 40), OS and PFS were increased vs 5-FU/LV (n = 43) (HR = 0.84 and 0.72). Patients without prior surgery had significantly increased OS and PFS with nal-IRI+5-FU/LV (n = 77) vs 5-FU/LV (n = 76) (HR = 0.56, p = 0.003 and HR = 0.47, p < 0.001). OS was significantly increased in ITT patients with disease stages IIA (n = 36, HR = 0.59, p = 0.013), IIB (n = 77, 0.54, <0.001), and III (n = 75, 0.57, <0.001) vs stage IV (n = 213). A consistent OS increase was also seen in patients treated with nal-IRI+5-FU/LV: stage IIA (HR = 0.63, ns) stage IIB (HR = 0.50, p = 0.024) and stage III (HR = 0.43, p = 0.021) vs stage IV.

Conclusions: OS and PFS were increased in ITT patients who had undergone surgery prior to trial inclusion. Patients treated with nal-IRI+5-FU/LV showed a consistent increase in OS and PFS vs 5-FU/LV. ITT patients with stages IIA, IIB, and III had significantly improved OS vs those with stage IV disease. Treatment with nal-IRI+5-FU/LV showed a survival benefit across disease stages IIA, IIB, and III, vs stage IV. Limited patient numbers should be taken into consideration when interpreting these findings.

Clinical trial identification: NCT01494506.

734P Impact of dose reduction or dose delay on the efficacy of liposomal irinotecan (nal-IRI)+5-fluorouracil/leucovorin (5-FU/LV): Survival analysis from NAPOLI-1

L-T. Chen[1], T.M. Macarulla[2], J. Blanc[3], B. Mirakhur[4], F.A. de Jong[5], B. Belanger[6], T. Bekaii-Saab[7], J. Siveke[8]

[1]Internal Medicine, National Health Research Institutes – National Institute of Cancer Research, Tainan, Taiwan, [2]Vall d'Hebron Institute of Oncology (VHIO), Vall d'Hebron University Hospital (HUVH), Barcelona, Spain, [3]CHU Bordeaux, Groupe Hospitalier Hau-Lévêque, Pessac, France, [4]Medical Affairs, Ipsen Biopharmaceuticals,Inc., Basking Ridge, NJ, USA, [5]Medical Affairs, Shire GmbH, Zug, Switzerland, [6]Biometry R&D, Ipsen Biopharmaceuticals,Inc., Basking Ridge, NJ, USA, [7]Internal Medicine, Division of Hematology/Medical Oncology, Mayo Clinic, Phoenix, AZ, USA, [8]Division of Solid Tumor Translational Oncology, West German Cancer Center, University Hospital Essen, Essen, Germany

Background: Chemotherapy dose modifications to manage adverse events (AEs) is common in clinical practice. In NAPOLI-1 (NCT01494506), a randomized phase 3 study in patients with metastatic pancreatic cancer previously treated with gemcitabine-based therapy, nal-IRI+5-FU/LV improved overall survival (OS; primary endpoint) vs 5-FU/LV (6.1 mos vs 4.2 mos; HR = 0·67, 95% CI 0.49–0.92; P = 0.012). The study protocol permitted dose modifications (reduction or delay) to address toxicity. In this exploratory post-hoc analysis, we evaluated the impact of nalIRI dose modifications on overall survival (OS) and progression-free survival (PFS).

Methods: All pts enrolled under protocol v2 who received nal-IRI+5-FU/LV during the first 6 wks were included in the analysis. Pts were grouped according to those with dose modification or those without dose modification. Dose reduction was defined as any decrease from initial dose, delay as any dosing delay >3 days from target date. Pts without dose modification received the first 3 scheduled doses of nal-IRI+5-FU/LV without qualifying delay/reduction. OS and PFS (KaplanMeier estimates) were compared within the nal-IRI+5-FU/LV arm. Unstratified hazard ratios (HRs) were calculated using Cox regression.

Results: Among pts in the nal-IRI+5-FU/LV arm (n = 93), 40 pts had no dose modification and 53 had a dose modification (delay, n = 49; reduction, n = 34). Within the nal-IRI+5-FU/LV arm, there was no significant difference in median OS or PFS between pts with vs without dose modification (Table).

Conclusions: Dose modification of nal-IRI+5-FU/LV in the first 6 wks does not significantly impact OS or PFS compared to patients without dose modifications. This suggests that tolerability-guided dose modification of nal-IRI does not adversely affect efficacy outcomes.

Table: 734P

	Median OS			Median PFS		
	Pts (n)	Months	HR (95% CI)	Pts (n)	Months	HR (95% CI)
nal-IRI+5-FU/LV Delay	49	8.4	1.10 (0.71, 1.70)	49	4.2	1.03 (0.66, 1.61)
nal-IRI+5-FU/LV No delay	43	8.3		43	4.0	
nal-IRI+5-FU/LV Reduction	34	9.4	0.87 (0.54, 1.39)	34	4.2	0.91 (0.56, 1.48)
nal-IRI+5-FU/LV No reduction	48	8.4		48	4.1	

Clinical trial identification: NCT01494506.

735P Real-world dosing patterns of patients (pts) with metastatic pancreatic cancer (mPC) treated with liposomal irinotecan (nal-IRI) in US oncology clinics

D. Ahn[1], A. Barzi[2], R.A. Miksad[3], A. Surinach[4], F.A. Corvino[4], A. Valderrama[5], K. Mamlouk[5], S. Pulgar[5], T. Bekaii-Saab[1]

[1]Division of Medical Oncology, Department of Internal Medicine, Mayo Clinic, Phoenix, AZ, USA, [2]Norris Comprehensive Cancer Center, University of Southern California, Los Angeles, CA, USA, [3]Research Oncology, Flatiron Health, New York, NY, USA, [4]Real World Data Analytics, Genesis Research, Hoboken, NJ, USA, [5]Health Economics and Outcomes Research, Ipsen Biopharmaceutical, Basking Ridge, NJ, USA

Background: nal-IRI + 5FU/LV therapy demonstrated significant survival improvement in mPC pts previously treated with gemcitabine-based therapy (NAPOLI-1). The generally recommended nal-IRI initiation dose is 70 mg/m^2 (free base, equivalent to 80 mg/m^2 salt based dosing). This retrospective observational analysis describes the real-world dosing patterns of nal-IRI.

Methods: Using the Flatiron Health® longitudinal database, data was extracted and analyzed for adult pts with mPC treated with nal-IRI between Nov 2015 to Aug 2017. Dose intensity (DI) over the first 6 weeks of treatment, dose modifications anytime (mods), and overall duration of exposure (DOE) to nal-IRI were assessed. All dosing is expressed in terms of the free base.

Results: 257 mPC pts (median age: 67y; IQR 61–74) treated with nal-IRI were identified; DI was calculated for 231 pts with available dose, height, and weight data. Mean DI was 177.8 mg/m^2 (SD: 74.9 mg/m^2). Median DOE was 7.3 (IQR: 3.4 – 17.1) weeks (wks). Median dose at initiation was 69.4 (IQR 56.7–70.2) mg/m^2. Stratified into groups based on median DI (190 mg/m^2), more pts below median DI initiated at a lower dose (LD) (30 - 65 mg/m^2) compared to the pts at/above the median DI (44.4% vs 13.8%). Pts below median DI were also older: median age 70y (IQR 63 - 76) vs 65y (IQR 61 - 72). Mean DI was similar for pts who initiated nal-IRI in 1st/2nd line (176.4 mg/m2; n = 131) vs later lines (179.6 mg/m2; n = 100). In 1st/2nd line pts, median DOE was 8.9 (IQR: 3.1 – 19) wks vs 6.3 (IQR :3.4 – 12.1) wks in 3rd+ line. Median DOE in pts initiated at the recommended dose of 65-75 mg/m^2 (n = 152) was 8.1 wks. DOE in LD (n = 67) and higher dose (75–90 mg/m^2; n = 11) pts was 7.1 and 6.1 wks, respectively. 27.2% of pts experienced a dose mod (18.3% in 1st/2nd line; 8.9% in 3rd+ line). Pts with dose mods had a median DOE of 13.1 vs 6.1 wks in pts without mods.

Conclusions: This real-world analysis showed similar DI results to the NAPOLI-1 trial, while dose mods were slightly lower. Pts with higher DI had longer DOE. Pts who experienced a dose mod, initiated nal-IRI in 1st/2nd line, were at/above median DI had, on average, longer DOE. Larger pt cohort analyses will elucidate dosing patterns and outcomes in nal-IRI treated pts.

736P Multicenter, phase II trial of biweekly S-1, leucovorin (LV), oxaliplatin and gemcitabine (SLOG) in metastatic pancreatic adenocarcinoma (mPDAC): Final report of TCOG T1211 study

N-J. Chiang[1], K.K. Tsai[1], J-S. Chen[2], S-H. Yang[3], H-H. Hsiao[4], Y-S. Shan[5], L-T. Chen[6]

[1]National Institute of Cancer Research, National Health Research Institutes, Tainan, Taiwan, [2]School of Medicine, Chung Gung University, Tao Yuan, Taiwan, [3]Department of Oncology, National Taiwan University Hospital, Taipei, Taiwan, [4]Department of Internal Medicine, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan, [5]Medical Oncology, National Cheng Kung University, Tainan, Taiwan, [6]Internal Medicine, National Health Research Institutes, Tainan, Taiwan

Background: Our previous studies showed a triplet GOFL regimen consisting of gemcitabine plus modified FOLFOX4 was well-tolerated and moderate active in advanced PDAC, and the feasibility of replacing infusion 5-FU/LV with oral S-1/LV, the SLOG regimen, in a dose-escalating, phase I study. Herein, we report the phase II results of the SLOG in mPDAC patients.

Methods: Patients with chemo-naïve mPDAC, ECOG PS 0-1, and 20-75 y/o of age were eligible. Intravenous fixed-rate infusion of 800 mg/m^2 gemcitabine followed by 2-hr infusion of 85mg/m^2 oxaliplatin on D1 plus oral S-1/LV 35/20 mg/m^2, twice daily, D1-D7 were given Q 14 days as a cycle. The primary endpoint was objective response rate (ORR). Simon's optimal two-stage design was used with estimated p_0=25% and p_1=40%.

Results: Between Jun. 2013 and Oct. 2015, a total of 54 patients were included, with median age of 59 y/o, ECOG PS = 1 in 82%, and the presence of liver metastases in 66.7%. At the cut-off Feb.01, 2017, nine patients remained alive and their median follow-up time was 21.3 months. The ORR was partial response in 22 patients (ORR=40.7%, 95% CI, 28-55%) and stable diseases in 19 patients (35.2%). Long-term disease control rate (stable disease >16 weeks) was 64.8% (95% CI, 51-77%). The median progression-free survival and overall survival was 7.6 (95% CI, 4.4-10.7) and 11.4 (95% CI, 8.1-16.3) months, respectively. One-year and two-year survival rates were 46% and 17%, respectively. The most common treatment-related grade 3-4 adverse events included neutropenia (40.7%), anorexia (14.8%), nausea (11.1%), thrombocytopenia (9.3%), and diarrhea (7.4%).

Conclusions: Current study demonstrated SLOG is a highly active regimen with manageable and favorable safety profiles for mPDAC patients. A randomized phase II trial comparing SLOG vs. modified FOLFIRINOX in advanced PDAC patients is ongoing.

Clinical trial identification: NCT01415713.

737P A phase II trial of gemcitabine, S-1 and LV combination therapy in patients with advanced pancreatic cancer

K.O. Saito[1], Y. Nakai[1], H. Isayama[2], K. Ishigaki[1], T. Saito[1], N. Takahara[1], S. Mizuno[1], H. Kogure[1], K. Koike[1]

[1]Department of Gastroenterology, The University of Tokyo, Tokyo, Japan, [2]Department of Gastroenterology, Juntendo University, Tokyo, Japan

Background: The aim of this single center, open label, single arm phase II trial was to assess the efficacy and toxicity of gemcitabine, S-1 and leucovorin (LV) combination therapy for advanced pancreatic cancer (UMIN-CTR 000010678).

Methods: Chemotherapy-naïve patients with histologically or cytologically proven advanced pancreatic cancer were enrolled. Gemcitabine was administered at a dose of 1,000 mg/m^2 by 30min infusion on days 1, S-1 40mg/m^2 orally twice daily and LV 25mg orally twice daily on days 1 to 7 every 2 weeks. Primary end point was progression free survival (PFS), and secondary endpoints were overall survival (OS), response rate, disease control rate and adverse events.

Results: A total of 49 patients with advanced pancreatic cancer (19 locally advanced and 30 metastatic) were enrolled between May 2013 and March 2017. Median age was 68 (range, 44-84) and PS was 0 in 26 and 1 in 23. Overall response rate and disease control rate were 32.7% and 87.8%. The median PFS and OS were 10.8 (95% confidence interval [CI], 7.4-13.5) and 20.7 (95% CI 13.0-NA) months with 1-year survival rate of 73.4%. The median PFS of locally advanced and metastatic diseases was 12.7 and 7.4 months, and the median OS of locally advanced and metastatic diseases was 26.1 and 18.8 months, respectively. Conversion surgery was performed in 2 patients among 19 locally advanced diseases. The reasons for treatment failure was disease progression in 31, unacceptable toxicities in 4, deteriorated general conditions in 6, consent withdrawn in 3, others in 3. A second line chemotherapy was introduced in 29 patients. Major Grade 3-4 toxicities were neutropenia (22.4%) and mucositis (14.3%). No toxicity related death was observed.

Conclusions: In this phase II trial, gemcitabine, S-1 and LV combination therapy was tolerable and can potentially be a treatment option for advanced pancreatic cancer.

Legal entity responsible for the study: The University of Tokyo.

738P Antibiotics may enhance the efficacy of gemcitabine treatment for advanced pancreatic cancer

Y. Sunakawa, H. Arai, N. Izawa, T. Mizukami, Y. Horie, A. Doi, M. Hirakawa, T. Ogura, T. Tsuda, T.E. Nakajima

Clinical Oncology, St. Marianna University School of Medicine, Kawasaki, Japan

Background: It has been reported that bacteria can metabolize gemcitabine (gem) into its inactive and contribute to the drug resistance. It was also reported that the resistance was abrogated by cotreatment with antibiotics [Geller LT, et al. Science 2017], in which, many of human pancreatic ductal adenocarcinoma samples contained causal bacteria which potentially mediates tumor resistance to gem. We therefore hypothesized the use of antibiotics may affect clinical outcomes of gem therapy in patients (pts) with pancreatic cancer (PC).

Methods: We retrospectively investigated pts with advanced PC who were treated with gem alone as first-line treatment in our single institute between 2009 and 2017. The association of use of antibiotics before gem treatment with progression-free survival (PFS) and overall survival (OS) was analyzed using Cox proportional hazards model and log-rank test.

Results: One hundred twenty-four pts were treated with gem alone as first-line therapy and had the following characteristics: median age of 72yrs, 59% male, 39%/54%/4%/3% for PS0/1/2/3, 53%/26%/19% for primary tumor of head/body/tail, median PFS of 3.4 months, and median OS of 7.7 months. In 124 pts, 59% used antibiotics before treatment with gem. One hundred pts discontinued due to disease progression, while 24 pts due to toxicity or pts' wish. Pts who received antibiotics had significantly longer PFS than pts who did not receive antibiotics (4.2 vs. 2.1 months, HR 0.64, 95%CI 0.43-0.96, P = 0.029). The association was not statistically significant after multivariate analysis adjusted for PS, tumor location, and number of metastatic sites (HR 0.73, 95%CI 0.45-1.17, P = 0.19). Median OS was numerically longer in pts with use of antibiotics than in pts without antibiotics (8.0 vs. 5.5 months).

Conclusions: Our study indicated that antibiotic use before gem therapy was associated with favorable outcome in pts with advanced PC treated with gem. These findings warrant further exploratory studies and suggest scientific approach to identify antibiotics as an enhancer for gem.

Background: Nab-paclitaxel/gemcitabine (NPG) is standard first-line therapy for metastatic pancreatic cancer (mPC), but the pivotal study did not include QoL analyses.

Methods: QoliXane/PARAGON is a platform for Outcome, Quality of Life, and Translational Research on Pancreatic Cancer. In this prospective QoL-study, patients (pts) were recruited from 95 German centers. QoL was prospectively measured (prior to and every month thereafter): therapy and efficacy were prospectively collected. QoL and efficacy endpoints were analyzed in the intention-to-treat population (ITT), defined as all pts who were enrolled. The primary endpoint was the rate of pts without deterioration of QoL/Global Health Score (QoL/GHS) at 3 mos.

Results: 601 pts were included. Median progression-free survival was 6 mos (95% CI: 5.26, 6.25). Median overall survival (OS) was 10 mos (8.22, 11.74). 1-year OS was 41%. Median survival by ECOG PS of 0, 1, 2, and 3 was 11.1 mos, 8.9 mos, 4.8 mos, and 2.1 mos (p<.0001). The KM-analysis showed that 61% and 41% of pts had maintained QoL/GHS after 3 and 6 mos, respectively. Median time to deterioration of QoL/GHS was 4.7 mos [4.04, 5.59]. Mean QoL/GHS improved from 46.1 at baseline to 52.8 after 6 mos. In the QoL response analysis, 35%, 37% and 28% of evaluable pts had improved, stable and worse QoL/GHS after 3 mos, respectively. In the Cox regression analysis, a 10-point increase in baseline QoL/GHS correlated to 13% decreased risk of death (HR = 0.87; 0.83-0.91; p<.0001).

Conclusions: The QoliXane/PARAGON is among the largest studies on QoL of pancreatic cancer ever conducted. It shows that a relevant group of patients have improved or maintained QoL after 3 and 6 months and that QoL is a predictor of patient's outcome.

Clinical trial identification: NCT02691052.

Background: QOL parameters may be predictive of treatment efficacy in PDAC.

Methods: Eligible consenting patients (pts) received n-P/Gem or Gem in standard regimens. CO was possible at progression. Monthly EORTC QLQ-C30 v3.0 QOL questionnaires were used. Deterioration-free rate of global health status (GHS) at 3 months (mths) was the primary endpoint. Safety, efficacy and molecular studies on blood were secondary endpoints.

Results: One hundred forty-six pts (125 metastatic), median age 65, were included in 17 hospitals of the Belgian Group of Digestive Oncology network between May 2014 and Nov 2015 and randomized to n-P/Gem (72) or Gem (74); 37 crossed-over. Median duration on treatment was 5 mths (0-28). Ninety-nine pts (68%) experienced at least one serious adverse event; 6 events had fatal outcome, one was possibly related to Gem (sepsis). Gastrointestinal toxicity and infections were frequent. Hemolytic uremic syndrome occurred in 5 pts. Overall, 1465 QOL questionnaires were completed; 85% of pts responded to a series of at least three. Deterioration-free rate of GHS at 3 mths was 83% (60/72) with n-P/Gem, 60% (28/47) with Gem alone and 96% (26/27) after CO. Median times to definitive deterioration were 12.8, 8.9 and 12.3 mths respectively. Baseline GHS scores correlated at 0.05 significance level with survival time in the n-P/Gem group. Other QOL indicators showed equivalent patterns. Tumour response was locally assessed in 43% of pts (95%CI 31-55) with n-P/Gem, 19% (95%CI 6-32) with Gem and 24% (95%CI 10-39) in the CO group (p = 0.006) with 2 pts in complete response. Median PFS was 6.8 mths (95%CI 5.5-8.1) in all pts, with 7.4 in n-P/Gem, 7.2 in Gem and 5.4 mths in CO (1st progression). Median PFS for 2nd progression in CO was 10.8 mths. Overall survival was 11.9 mths (95%CI 10-14) with 10.7, 8.8 and 13 mths in the three groups.

Conclusions: Survival was long and response rates significantly higher in pts receiving the combination. Pts receiving n-P/Gem reported better quality of life scores for longer duration compared to pts on Gem alone. QOL analyses and translational studies will be presented at the congress. Academic study with support from Celgene.

Clinical trial identification: EudraCT: 2013-004101-75, NCT02106884.

Legal entity responsible for the study: Academic study governed by the Belgian Group of Digestive Oncology network. Sponsored and coordinated by University Hospitals Leuven.

741P Health-related quality of life (HRQoL) in patients with early-stage pancreatic cancer (ESPC) receiving adjuvant or neoadjuvant chemotherapy (A/NAC): A systematic literature review (SLR)

T. Macarulla Mercade[1], A. Hendifar[2], C-P. Li[3], M. Reni[4], H. Riess[5], M.A. Tempero[6], A. Dueck[7], M.F. Botteman[8], C. Deshpande[8], E. Lucas[8], D-Y. Oh[9]

[1]Medical Oncology, Vall d'Hebron Institute of Oncology (VHIO)-Cellex Center, Barcelona, Spain, [2]IM/Hematology/Oncology, Cedars-Sinai Medical Center, Los Angeles, CA, USA, [3]Medical Oncology, Taipei Veterans General Hospital, Taipei City, Taiwan, [4]Medical Oncology, Ospedale San Raffaele Srl, Milan, Italy, [5]Medical Oncology, Charité - Universitätsmedizin Berlin, Berlin, Germany, [6]Medical Oncology, University of California, San Francisco, Helen Diller Comprehensive Cancer Center, San Francisco, CA, USA, [7]Health Sciences Research, Mayo Clinic, Phoenix, AZ, USA, [8]Medical, Pharmerit International, LP, Bethesda, MD, USA, [9]Medical Oncology, Seoul National University Hospital, Cancer Research Institute, Seoul National University College of Medicine, Seoul, Republic of Korea

Background: Few studies have evaluated HRQoL in patients with ESPC (resectable or borderline resectable) who received A/NAC. This SLR aimed to summarize the available evidence on HRQoL in this population.

Methods: Key electronic databases (all years), conference abstracts (2013-2017), and clinical trial registries were searched according to PRISMA guidance to identify relevant studies reporting HRQoL as assessed by patient-reported outcomes measures (PROMs) in A/NAC for ESPC. HRQoL scores were compared with reference values (ie, norms) and assessed longitudinally when possible. Minimally important difference (MID) estimates for the most frequently used PROMs were also assessed.

Results: Of 645 identified records, 37 PROMs and HRQoL outcomes studies were retained. The EORTC QLQ-C30 and/or QLQ-PAN26 were used in 31 studies; other PROMs were used in 11 studies, including the Functional Assessment of Cancer Therapy (n = 4), 36-Item Short Form Survey (n = 2), and the Center for Epidemiologic Studies Depression Scale (n = 2). At baseline (before and/or immediately after surgery), EORTC QLQ-C30 global health status/QoL scores for patients with ESPC were similar to reference values for PC but lower than those for all cancers. Among studies that reported QoL over time, longitudinal QoL trends varied: 4 studies reported improvement from baseline, whereas 4 studies reported initial declines, upon which QoL increased to or above baseline (n = 3) or below baseline (n = 1) within 3 to 6 months. An MID of 10 was identified for EORTC QLQ-C30. An MID for QLQ-PAN26 does not seem to have been comprehensively assessed to date.

Conclusions: The EORTC QLQ-C30 and QLQ-PAN26 are the most commonly used HRQoL PROMs for studies of A/NAC in ESPC. Poor HRQoL was reported by EORTC QLQ-C30 global health status/QoL scores, indicating a high unmet need. Some studies indicated improved HRQoL over time; however, this may reflect survivor selection bias. The MID for QLQ-C30 may be useful in understanding the clinically relevant impact of ESPC treatment on HRQoL. Future research should validate the QLQ-PAN26 and establish its MID in A/NAC for ESPC.

742P Outcome following centralisation of pancreatic cancer care in Ireland

R. Abdul Rahman[1], M. Moriarty[2], G. McVey[2], P. Ridgway[3], D. Maguire[3], E. Hoti[3], J. Geoghegan[3], K. Conlon[3], R. McDermott[1]

[1]Medical Oncology, St. Vincent's University Hospital, Dublin, Ireland, [2]Radiation Oncology, St. Luke's Hospital, Rathgar, Ireland, [3]Hepatobiliary Surgery, St Vincents University Hospital, Dublin, Ireland

Background: Centralisation of pancreatic cancer surgery led to increased resection rates and significantly better survival rates in high volume centres (Gooiker et al, Br J Surg 2014). Pancreas cancer care was centralised to two high volume cancer centres in Ireland since 2010. The National Cancer Registry (NCRI) is a publicly appointed body, established in 1991, to collect and classify information on all cancer cases which occur in Ireland. We analysed these data with the objective to examine the outcomes of pancreatic cancer care since the centralisation of pancreatic cancer surgery in Ireland.

Methods: Pancreatic cancer data have been collected by NCRI since 1994. Only those with stage 1 – 3 adenocarcinoma of the pancreas (PDAC) were included in the final analyses. Descriptive statistics, Pearson chi-square test and survival analysis using Kaplan Meier curve with log-rank test and cox regression was performed.

Results: Between Jan 1994 and Dec 2013, of the 8230 patients with pancreatic cancer identified from the NCRI database, 4298 pts had histologically proven adenocarcinoma. Among these, 1177/27% of patients (pts) had stage 1 – 3 disease. 52% of these were male and 74% of pts were over 60 years of age. Stage 1, 2 and 3 disease comprised 25%, 32% and 42% of pts respectively. Overall 48 % of pts had surgery. Pre- and post-2010 resection rates increased from 44% to 49% ($p = 0.14$). 44% of pts had chemotherapy with significantly increased chemo utilisation post-2010, 39% vs 54% ($p < 0.0005$). 21% of pts had radiotherapy. Pre- and post- radiation rates were 19% versus 23% ($p = 0.12$) respectively. Overall survival (OS) for all pts were 9.0 mos (95% CI 8.1 – 9.9). This significantly improved post-centralisation of care, 8 mos to 14 mos, HR 0.67 (95% CI 0.58-0.78, $p < 0.0005$). In those who underwent resection, OS was 17 mos vs 25 mos pre- and post-2010, HR 0.66 (95% CI 0.51-0.84, $p = 0.01$). Among resected pts, 52% and 20% had chemo- and radio-therapy within the first year respectively. Also noted was that there were significantly fewer pts who received no treatment at all, 24% vs 35%, $p < 0.0005$.

Conclusions: Centralisation of PDAC surgery in Ireland has resulted in an improvement in utilisation rates of surgery, chemotherapy and radiotherapy leading to significantly improved overall survival for patients.

743P Initial treatment and survival in a national unselected Danish cohort of 4161 patients with pancreatic cancer

L.S. Rasmussen[1], B. Vittrup[2], M. Ladekarl[3], P. Pfeiffer[4], M.K. Yilmaz[1], L.Ø. Poulsen[1], K. Østerlind[5], H. Skuladottir[6], C.P. Hansen[7], M.B. Mortensen[8], F.V. Mortensen[9], M. Sall[10], U.G. Falkmer[1], C. Fristrup[11]

[1]Department of Oncology, Clinical Cancer Research Center, Aalborg University Hospital; Department of Clinical Medicine, Faculty of Medicine, Aalborg University, Aalborg, Denmark, [2]Department of Oncology, Herlev and Gentofte Hospital, University of Copenhagen, Copenhagen, Denmark, [3]Department of Oncology, Aarhus University Hospital, Aarhus, Denmark, [4]Department of Oncology, Odense University Hospital, Odense, Denmark, [5]Department of Oncology, North Sealand Hospital, Hillerød, Denmark, [6]Department of Oncology, Herning Hospital, Herning, Denmark, [7]Department of Surgical Gastroenterology, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark, [8]Department of Surgery, Odense Pancreas Center (OPAC), Odense University Hospital, Odense, Denmark, [9]Department of Surgical Gastroenterology, Aarhus University Hospital, Aarhus, Denmark, [10]Department of Surgical Gastroenterology, Aalborg University Hospital, Aalborg, Denmark, [11]Department of Surgery, Odense University Hospital; Danish Pancreatic Cancer Database, Odense, Denmark

Background: Nationwide data on the effect of primary treatment on median overall survival (mOS) in an entire unselected population of patients (pts) with pancreatic cancer (PC) have not been reported before. The aim of the present study was to investigate the effect of initial treatment on mOS in all incident pts with PC in Denmark in a recent five-year period (2011 to 2016).

Methods: From 1 May 2011 to 30 April 2016, 4260 pts diagnosed with PC were identified in the national Danish Pancreatic Cancer Database. Last follow up was 10 September 2017. Excluded were 99 pts (2%), 56 due to combined preoperative chemotherapy followed by resection, 22 due to other malignancies, 13 due to incorrect registration of treatment, 6 pts treated with unknown chemotherapy and 2 were lost to follow up, leaving 4161 pts included. The mOS was analysed from the date of the initial treatment, either resection or chemotherapy or from the date of diagnosis in case of best supportive care (BSC).

Results: Initial treatment and mOS for all 4161 pts.

Table: 743P

Treatment	Pts, No.	mOS, months	95% CI
Resection*			
N +	466	17.5	15.4-20.1
N-	215	36.9	28.6-44.7
Chemotherapy			
Gem	958	5.1	4.8- 5.6
FOLFIRINOX	414	10.0	8.9-11.0
GemCap	125	8.4	6.8-9.8
GemS1	111	9.0	7.2-10.3
GemPac	85	7.1	5.5-9.7
Others	53	9.3	8.2-14.0
BSC	1696	1.6	1.5-1.8

Abbreviations: CI: confidence interval, N: lymph node status, without – or with +, Gem: gemcitabine, FOLFIRINOX: 5-flourouracil, leukovorin, irinotecan and oxaliplatin, Cap: capecitabine, S1: tegafur/gimeracil/oteracil, Pac: nab-paclitaxel, others: other regimens. *There were 38 pts without histopathological reports on lymph node status.

Conclusions: The initial resected lymph node negative pts had the longest survival; double that of lymph node positive pts. Pts initially treated with chemotherapy had slightly shorter mOS than found in randomized trials, reflecting patient characteristics in an unselected population. The outcome of gemcitabine monotherapy was poor, possibly reflecting less treatment effect and selection of less fit pts. The BSC group was larger than expected and further investigations, particularly in early diagnosis of PC are of utmost importance.

744P Trends of care of non-metastatic pancreas cancer patients in Ireland

R. Abdul Rahman[1], G. McVey[2], M. Moriarty[2], D. Maguire[3], E. Hoti[3], P. Ridgway[3], K. Conlon[3], J. Geoghegan[3], R. McDermott[1]

[1]Medical Oncology, St. Vincent's University Hospital, Dublin, Ireland, [2]Radiaiton Oncology, St. Luke's Hospital, Rathgar, Ireland, [3]Hepatobiliary Surgery, St Vincents University Hospital, Dublin, Ireland

Background: Surgery offers the only chance of cure in non-metastatic pancreatic cancer. However, chemo- and radio-therapy also play important roles in pancreatic cancer care. How each of these different modalities of treatment impact on pancreatic cancer outcome is unclear. The National Cancer Registry (NCRI) is a publicly appointed body, established to collect and classify information on all cancer cases which occur in Ireland. We analysed these data with the objective to examine the trend of care of stage 1 to 3 pancreas cancer in Ireland.

Methods: Pancreatic cancer data have been collected by NCRI since 1994. Only those with stage 1 – 3 adenocarcinoma of the pancreas (PDAC) were included in the final analyses. Descriptive statistics, Pearson chi-square test and survival analysis using Kaplan Meier curve with log-rank test and cox regression was performed.

Results: Between Jan 1994 and Dec 2013, of the 8230 patients with pancreatic cancer identified from the NCRI database, 4298 pts had histologically proven adenocarcinoma. Among these, 1177/27% of patients (pts) had stage 1 – 3 disease. 52% were male and 74% of pts were over 60 years of age. Stage 1, 2 and 3 disease comprised 25%, 32% and 42% of pts respectively. Overall 48 % of pts had surgery, 44% had chemotherapy and 21% had radiotherapy. 364, 31% pts did not have any therapy at all. Compared to those who did not have any treatment, there was an incremental benefit in overall survival (OS) with the more number of different modalities of treatment involved (Table). OS was 3 mos with no treatment, 8 mos with either chemo or radiation (HR 0.57), 11 mos with chemo and radiation (HR 0.46), 18 mos with surgery only (HR 0.27) and 20 mos with surgery with chemo and/or radiation therapy (HR 0.24).

Table: 744P

	N	OS	HR
No treatment	364, 31%	3 months	
Multimodality therapies including surgery	287, 25%	20 months	0.24 (95% CI: 0.20 – 0.28)
Surgery only	245, 21%	18 months	0.27 (95% CI: 0.22 – 0.32)
Multimodality therapy (no surgery)	95, 8%	11 months	0.46 (95% CI: 0.36 – 0.58)
Single modality therapy (no surgery)	179, 16%	8 months	0.57 (95% CI: 0.48 – 0.69)

Conclusions: Multimodality therapy with surgery improves OS in non-metastatic pancreatic cancer with incremental benefit seen from even single modality therapy.

745P Anti-hypertensive medication, sRAGE, and risk of pancreatic cancer: Results from the women's health initiative study

Z. Wang[1], D.L. White[2], L. Chen[3], E.A. Whitsel[4], P.A. Richardson[3], J. Garcia[5], H.B. El-Serag[3], L. Jiao[3]

[1]Dan L Duncan Cancer Center, Baylor College of Medicine, Houston, TX, USA, [2]Center for Translational Research on Inflammatory Diseases, Michael E. DeBakey VA Medical Center, Houston, TX, USA, [3]Center for Innovations in Quality, Effectiveness and Safety (IQuESt), Michael E. DeBakey VA Medical Center, Houston, TX, USA, [4]Gillings School of Public Health, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA, [5]Section of Endocrinology, Department of Medicine, University of Washington, Seattle, WA, USA

Background: Pancreatic cancer is the 4th leading cause of cancer death in the United States. With its anti-inflammatory property, soluble receptor for advanced glycation end-product (sRAGE) has been associated with lower risk of pancreatic cancer. Anti-hypertensive (anti-HT) medications were shown to modulate sRAGE levels and AGE/RAGE signaling pathway. However, few large-scale population based study have evaluated the associations between antihypertensive medications and risk of pancreatic cancer.

Methods: A total of 145,551 postmenopausal women aged 50 to 79 years with no prevalent cancer from Women Health Initiative (WHI) were included with a mean follow-up of 13.8 year. Medication data including product and generic name, duration of use, and dosage form were collected at baseline recruitment (1993-98). We examined four anti-HT drugs including β-blockers, diuretics, angiotensin converting enzyme inhibitors (ACEi) and calcium channel blockers (CCBs). Serum levels of sRAGE were measured in a subset of 1,466 study participants using immunoassay. Cox proportional hazard regression model was performed to obtain hazard ratio (HR) and its 95% confidence interval (CI) for each anti-HT medication use and its duration of use in association with risk of pancreatic cancer.

Results: By August 29, 2014, a total of 841 incident pancreatic cancer cases were ascertained through annual self-administered questionnaires and confirmed by central adjudication. Increased risk of incident pancreatic cancer was found among ever users of short-acting CCB (HR = 1.66, 95% CI: 1.20-2.29) and long-term (> 3 years) users of short-acting CCB (HR = 2.07, 95% CI: 1.42-3.02) compared to ever users of other anti-HT medications. Average sRAGE levels were lower in short-acting CCB ever users than those who took other anti-HT medication (1,158 pg/ml versus 1,446 pg/ml, P = 0.032).

Conclusions: We found a positive association between short-acting CCB use and risk of incident pancreatic cancer in postmenopausal women. Future studies are warranted to confirm these findings and elucidate potential mechanisms by which short-acting CCBs may influence development of pancreatic cancer, such as modulating RAGE signaling pathway.

746P Usefulness of the first screening using apolipoprotein A2 isoforms as the enrichment strategy for pancreatic cancer and its risk diseases

Y. Sato[1], T. Kobayashi[1], S. Nishiumi[1], S. Okaya[2], M. Yoshida[1], Y. Kodama[1], K. Nagashima[3], K. Honda[2]

[1]Gastroenterology, Kobe University Graduate School of Medicine, Kobe, Japan, [2]Department of Biomarkers for Early Detection of Cancer, National Cancer Center Hospital, Tokyo, Japan, [3]Research Center for Medical and Health Data Science, The Institute of Statistical Mathematics, Tokyo, Japan

Background: We recently reported the usefulness of apolipoprotein A2 isoforms (apoA2-i) as a plasma/serum biomarker for the early detection of pancreatic cancer (PC) and its risk diseases, and the level of ApoA2-ATQ/AT, which is one of apoA2-i, was significantly decreased in early stage PC and risk diseases. To evaluate the possibility of usefulness as the screening biomarker, we prospectively tested the performance of ApoA2-ATQ/AT as a first screening method for PC and its risk diseases in general population.

Methods: Study participants were prospectively enrolled from the subjects of medical checkup at 6 institutions between Oct 2015 and Jan 2017. We measured the plasma level of ApoA2-ATQ/AT by using ELISA, and all participants with the positive results from the level of ApoA2-ATQ/AT (ApoA2-ATQ/AT < 35 μg/mL) were recommended for 2nd examination with contrast enhanced-CT (CECT), MRI, or EUS.

Results: Among a total of 5,120 participants registered in this study, 83 were positive (Positive rate: 1.6%). In the 83 subjects with the positive results, 55 (66.3%) underwent 2nd examination. Finally, pancreatic diseases were detected in 23 (41.8%) of 55. They included 1 PC, 12 pancreatic cystic lesions (PCL), and 3 chronic pancreatitis (CP). Furthermore, 14.5% of ApoA2-ATQ/AT positive subjects had abnormal ultrasonographic findings in the pancreas, while the subjects with ultrasonographic abnormalities of the pancreas under a medical checkup were 3.2% of the participants who underwent transabdominal ultrasonography. Taken together, ApoA2-ATQ/AT could significantly accumulate the subjects with abnormal ultrasonographic findings by 4.53 times in comparison with a normal medical checkup for general population.

Conclusions: Plasma ApoA2-ATQ/AT as a first screening method in general population could improve an efficiency of detection of PC and its high-risk diseases.

747P Survival-associated factors and a prognostic nomogram in resected pancreatic cancer: A large international population-based cohort study

L. Huang[1], Y. Balavarca[2], L. van der Geest[3], V. Lemmens[3], L. van Eycken[4], H. De Schutter[5], T.B. Johannesen[6], V. Zadnik[7], M. Primic-Žakelj[7], M. Mägi[8], R. Grützmann[9], M.G. Besselink[10], P. Schrotz-King[2], H. Brenner[1], L. Jansen[1]

[1]Division of Clinical Epidemiology and Aging Research, German Cancer Research Center, Heidelberg, Germany, [2]Division of Preventive Oncology, German Cancer Research Center (DKFZ) and National Center for Tumor Diseases (NCT), Heidelberg, Germany, [3]Netherlands Cancer Registry (NCR), Netherlands Comprehensive Cancer Organization (IKNL), Utrecht, Netherlands, [4]Belgian Cancer Registry (BCR), Brussels, Belgium, [5]Research Department, Belgian Cancer Registry, Brussels, Belgium, [6]Registry Department, The Cancer Registry of Norway (CRN), Oslo, Norway, [7]Epidemiology and Cancer Registry, Institute of Oncology Ljubljana, Ljubljana, Slovenia, [8]Estonian Cancer Registry, National Institute for Health Development, Tallinn, Estonia, [9]Department of Surgery, Friedrich-Alexander-University Erlangen-Nürnberg, Erlangen, Germany, [10]Dutch Pancreatic Cancer Group (DPCG), Department of Surgery, Cancer Center Amsterdam, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands

Background: Pancreatic cancer (PaC) remains extremely lethal worldwide even after resection. This large international population-based study aimed at exploring factors associated with survival in resected PaC, and at developing and globally validating a survival-predicting nomogram.

Methods: Data of PaC patients resected in 2003-2014 were obtained from multiple European national cancer registries and the US SEER-18 Program. Multivariable Cox proportional hazards models were constructed to investigate the associations of patient and tumor characteristics with overall survival. Prognostic factors remaining after backward selection in SEER-18 were used to build a nomogram, which was subjected to bootstrap internal validation and external validation using the European databases. Predictive accuracy was assessed using the concordance-index.

Results: Totally 24,863 resected PaC patients were included, with median survival of 12-19 months and 3-year survival rates of 14%-28%. In main analysis, patient age, tumor T, N, and M stages, histology, and differentiation were significantly associated with survival, with country-specific association patterns and strengths. Additionally, hospital type, tumor size, harvested lymph node number, performance status, and certain comorbidities were associated with survival in countries with available information. A nomogram incorporating the backward-selected variables in the main analysis was established. Calibration curves showed good agreement between nomogram-prediction and actual observation. The concordance-index of the nomogram was significantly higher than that of the TNM staging for predicting survival.

Conclusions: In these international population-based cohorts, resected PaC patients have distinct characteristics independently associated with survival. A personalized postoperative survival-predicting nomogram is established and internationally validated, which would be practical and helpful clinically and aid to patient stratification in international studies.

748P Predicting survival of pancreatic cancer using supervised machine learning

M.H. Osman

Faculty of Medicine, Zagazig University, Zagazig, Egypt

Background: Pancreatic cancer is one of the major deadliest cancers, ranking fourth among causes of cancer-related deaths. Pancreatic cancer patients suffer from a poor prognosis with a 5-year survival rate of only 6%. Predicting pancreatic cancer survival is challenging due to different tumor characteristics, treatments and patient populations. Reliable predictions can help in achieving more personalized care and better management. In this study we test the ability of machine learning to predict pancreatic cancer survival.

Methods: Pancreatic cancer patients were identified through the Surveillance, Epidemiology and End Results database (2010-2014). Clinical data for patients were extracted including: age, sex, race, tumor site, tumor histology, grade, cancer sequence number, TNM stage, surgery, tumor size, tumor extension, and survival months. Patients' records were randomly divided into a training set (80%) and a validation set (20%) to predict survival at 6, 12 and 24 months. Different supervised machine learning models were tested to identify models with best predictions.

Results: We identified 14631 patients with median survival of 13 months. Random Forest algorithm achieved better results compared to other tested models. For evaluating model performance, the Area Under the Receiver Operating Characteristic Curve (AUC) of survival prediction was calculated. The trained model yielded AUCs of 85.3% at 6 months, 84.6% at 12 months and 83.2% at 24 months. The most important characteristics which influenced model prediction were: age at diagnosis (19.9%), tumor size (18.5%), surgery (14.6%), and tumor extension (8.4%).

Table: 748P Performance metrics of the trained machined learning model

	Area Under Curve (AUC)	Precision (positive predictive value)	Accuracy	Recall (sensitivity)	F1 Score
6-months Survival	85.3%	81%	81.6%	82%	81%
12-months Survival	84.6%	78%	77.8%	78%	78%
24-months Survival	83.2%	80%	80.1%	81%	80%

Conclusions: Predicting survival of patients with pancreatic cancer can be achieved using machine learning with good performance of prediction. Improved survival prediction can help in making better treatment decisions and planning social and care needs.

749P The prognostic value of the modified glasgow prognostic score (mGPS) in predicting overall survival (OS) in patients with metastatic pancreatic ductal adenocarcinoma (mPDAC) receiving liposomal irinotecan (nal-IRI)+5-fluorouracil and leucovorin (5-FU/LV)

L-T. Chen[1], T.M. Macarulla[2], B. Belanger[3], B. Mirakhur[4], F.A. de Jong[5], J. Siveke[6]

[1]Internal Medicine, National Health Research Institutes – National Institute of Cancer Research, Tainan, Taiwan, [2]Vall d'Hebron Institute of Oncology (VHIO), Vall d'Hebron University Hospital (HUVH), Barcelona, Spain, [3]Biometry R&D, Ipsen Biopharmaceuticals,Inc., Cambridge, MA, USA, [4]Medical Affairs, Ipsen Biopharmaceuticals,Inc., Basking Ridge, NJ, USA, [5]Medical Affairs, Shire GmbH, Zug, Switzerland, [6]Division of Solid Tumor Translational Oncology, West German Cancer Center, University Hospital Essen, Essen, Germany

Background: mGPS has been identified as a prognostic factor of OS in patients with pancreatic cancer. Here we report the association between mGPS and OS in a post-hoc analysis of the NAPOLI-1 study (NCT01494506), which demonstrated improved

survival for nal-IRI+5-FU/LV vs 5-FU/LV in the treatment of patients with mPDAC previously treated with gemcitabine-based therapy.

Methods: All patients treated in the NAPOLI-1 study with available baseline plasma Creactive protein (CRP) and albumin data (data cutoff: Nov 16, 2015) were included in this post-hoc analysis. Eligible patients were stratified by mGPS (mGPS-0: CRP ≤10 mg/L regardless of albumin level; mGPS-1: CRP >10 mg/L, albumin ≥35 g/L; and mGPS-2: CRP >10 mg/L, albumin <35 g/L). OS was assessed in individual and pooled treatment arms. A stepwise Cox regression model of OS was used to evaluate the prognostic significance of mGPS.

Results: Baseline plasma C-reactive protein and albumin data was available for N = 184 patients: mGPS-0, n = 79; mGPS-1, n = 88; mGPS-2, n = 17. For patients in pooled treatment arms, median OS was worse for the mGPS-1 group than for the mGPS-0 group (4.0 vs 8.0 months, respectively), but was comparable between the mGPS-2 and mGPS-1 groups (3.2 vs 4.0 months, respectively). Multivariate analysis revealed both mGPS-1 and mGPS-2 were independent predictive factors of death (mGPS-1: HR, 3.34; 95% CI, 2.25–4.95, P < 0.0001; mGPS-2: HR, 5.89; 95% CI, 3.21–10.80, P < 0.001). Similarly, analysis by treatment arm showed OS of patients treated with nal-IRI+5-FU/LV was significantly worse in the mGPS-1 (N = 26) and mGPS-2 (N = 5) groups than in the mGPS-0 (N = 27) group (4.6, 3.3 vs 9.3 months, respectively)

Conclusions: Data from this post-hoc analyses of mGPS in patients with mPDAC previously treated with gemcitabine-based are consistent with the reports of the prognostic value of the mGPS in estimating OS. Median OS was significantly improved in pts with a mGPS-0 vs mGPS-1 or mGPS-2, including the treatment group of patients receiving nal-IRI+5-FU/LV.

Clinical trial identification: NCT01494506.

750P Prognostic value of the neutrophil-lymphocyte ratio and CA 19-9 in predicting survival inpatients with metastatic pancreatic cancer

I. Dede[1], M. Cetin[2], S. Cetin[3]

[1]Oncology, Mustafa Kemal University Faculty of Medicine, Hatay, Turkey, [2]Medical Microbiology, Mustafa Kemal University, Antakya- Hatay, Turkey, [3]Biostatistics, Ondokuzmayis University, Samsun, Turkey

Background: The predictive value of different prognostic biomarkers has been studied in various cancer types. The aim of our study is to determine the degree of risk and prognostic significance of the pre-treatment neutrophil-to-lymphocyte ratio (NLR) and CA19-9 level in patients with metastatic pancreatic cancer and establish its relation with survival.

Methods: In our study, clinical and laboratory data of 118 patients with metastatic pancreatic cancer at the time of diagnosis were retrospectively analyzed. Overall survival (OS) rates were calculated using the Kaplan–Meier method. The Cox regression analysis was used to determine the prognostic factors affecting pancreatic cancer.

Results: The mean age of the patients was 67 ± 9.57 years. The patients were analyzed during the follow-up, and theirmedian OSwas 12 months (95% CI: 9.73–14.26). According toROC [Editor1] curve analysis, the cut-off value was 3.54 (AUC:0.653,95%CI:0.56–0.73, p = 0.006)for NLR and 437 (AUC:0.670,95%CI:0.57–0.75, p = 0.002) for the CA19-9 level. Astatistically significant differencewas observed between the CA19-9 level (p < 000.1) and NLR (p < 000.1) and OS. As a result of the multivariate Cox regression analysis, NLR (≥3.54 vs < 3.54, HR = 2.17, 95% CI: 1.17–4.03, p = 0.013) andthe CA19-9 level (≥437 vs < 437, HR = 1.81, 95% CI: 1.08–3.03, p = 0.022) were found to be significant prognostic factors in OS analysis.

Conclusions: In our study, the pre-treatment NLR and CA19-9 level were found to be reliable predictive markers for poor prognosis in patients with metastatic PC. According to the results of our study, the NLR and CA19-9 level can be used in predicting the survival of patients with pancreatic cancer. We believe that our findings will shed light on the management of treatment protocols for patients diagnosed with metastatic pancreatic cancer.

751P Effects of random glucose (Glc) levels on outcomes of patients (pts) with pancreatic ductal adenocarcinoma (PDAC)

R. Pihlak[1], R. Almond[2], P. Srivastava[3], H. Raja[3], R. Broadbent[4], L. Hopewell[5], C. Higham[5], A. Lamarca[4], R. Hubner[4], J.W. Valle[1], M.G. McNamara[1]

[1]Medical Oncology/Division of Cancer Sciences, The Christie NHS Foundation Trust/University of Manchester, Manchester, UK, [2]Analytics and Development, Clinical Outcome Unit, The Christie NHS Foundation Trust, Manchester, UK, [3]Faculty of Biology, Medicine and Health, University Manchester, Manchester, UK, [4]Medical Oncology, The Christie NHS Foundation Trust, Manchester, UK, [5]Endocrinology Department, The Christie NHS Foundation Trust, Manchester, UK

Background: Pancreatic ductal adenocarcinoma is a dismal disease with poor outcomes; ∼85% of pts with PDAC have impaired Glc tolerance or diabetes. This study explored how random Glc levels influence pt outcomes.

Methods: Consecutive pts with PDAC (all stages) (Jan 12-Jul 17) were included; 3 blood Glc level thresholds were referenced: >8 mmol/L (requiring monitoring), ≥14 mmol/L (requiring antidiabetic treatment), >11mmol/L on 2 occasions (fulfilling WHO diabetes criteria). Survival outcomes/prognostic factors were analysed by log-rank, Kaplan Meier and multivariable Cox regression.

Results: Of 640 pts: 53 % were male, median (med) age 68y, 64% ECOG PS 0/1, 22% PS 2, 14% PS 3/4; 26% stage 1/2 disease, 74% stage 3/4; 81% treated with palliative intent (chemotherapy in 325) and 15% adjuvant; 29% pts had a previous diabetes diagnosis. Med baseline Glc: 7.3mmol/L (range 3.8-37.1); 377 (59%) and 145 (23%) pts had Glc >8mmol/L and ≥14 mmol/L respectively, either at baseline or during treatment, 124 (19%) had Glc >11mmol/L on 2 occasions (of whom 81 were known diabetic). Med PFS and OS for all stages were 6.7 (95%CI 6.0-7.1) and 8.1 (95%CI 7.4-8.8) months (mo) respectively. Med OS for stage 1/2: 11.3 mo (95%CI 9.4-13.8), stage 3/4 disease 5.3 mo (95%CI 4.8-6). Previous diabetes diagnosis and antidiabetic treatment did not significantly impact OS (P = 0.26, P = 0.5 respectively). Baseline Glc levels (>8mmol/L and ≥14 mmol/L; Table), but not hyperglycaemia during treatment, significantly affected OS in all pts. Multivariable analysis (once adjusted for age and primary site) found increasing stage (P < 0.001), high minimum Glc (ever)(P < 0.001), high CA19-9 (P < 0.001), worse ECOG PS (P < 0.01) , and low albumin (P = 0.02) were prognostic for worse OS.

Conclusions: This study demonstrated for the first time that baseline Glc above thresholds and the absolute minimum random Glc confers worse outcomes, irrespective of previous diabetes diagnosis. Whether this risk is modifiable is subject to further research.

752P Clinical utility of serum type III collagen in patients with pancreatic carcinoma

I. Chen[1], N. Willumsen[2], C. Dehlendorff[3], A. Johansen[1], B.V. Vittrup[1], M. Krüger[1], P. Pfeiffer[4], J.K. Bjerregaard[4], S.E. Bojesen[5], S.E. Nielsen[6], N.H. Holländer[7], M.K. Yilmaz[8], L.S. Rasmussen[9], M. Karsdal[2], J.S. Johansen[1]

[1]Department of Oncology, Herlev and Gentofte Hospital, Herlev, Denmark, [2]Biomarkers and Research, Nordic Bioscience A/S, Herlev, Denmark, [3]Statistics and Pharmacoepidemiology, Danish Cancer Society Research Center, Copenhagen, Denmark, [4]Experimental Research in Medical Cancer Therapy, Odense University Hospital, Odense, Denmark, [5]Department of Clinical Biochemistry, Herlev and Gentofte Hospital, Herlev, Denmark, [6]Department of Oncology, North Zealand University Hospital, Hillerød, Denmark, [7]Department of Oncology, Zealand University Hospital in Næstved, Næstved, Denmark, [8]Department of Oncology, Aalborg University Hospital, Aalborg, Denmark, [9]Oncology, Aalborg University Hospital, Aalborg, Denmark

Background: Collagen is highly expressed in pancreatic cancer (PC) stroma. Collagen accumulation compromises penetration of macromolecules into tumor tissues and is associated with poorer outcome and increased tumor invasion. The aim of this biomarker study was to investigate the clinical utility of serum pro-peptide of type III collagen (PRO-C3) in patients (pts) with PC.

Methods: A cohort from the Danish BIOPAC study (ClinicalTrials.gov ID: NCT03311776) including 851 consecutive subjects with histologically confirmed PC, ampullary carcinoma (n = 45), distal biliary tract cancer (n = 32) and benign lesions (n = 88) were enrolled. Serum PRO-C3 was determined by ELISA (Nordic Bioscience, PRO-C3 protocol). The main outcome was survival among pts with PC (male/female: 458/393; age <50 vs. 50-69 vs. ≥70: 41/477/333; ECOG Performance Status (PS) of 0/1/2+: 315/340/110; stage 1 + 2/3/4: 234/142/456; diabetes yes/no: 207/629; smoking yes/no: 508/265; alcohol yes/no: 183/588; body mass index: low/normal/overweight: 62/426/254; Charlson Age-Comorbidity index (CACI) 0/1-2/3+: 34/296/504) in relation to PRO-C3 levels. Serum CA19-9, hyaluronic acid (HA), C-reactive protein (CRP), interleukin-6 (IL-6) and YKL-40 were measured. Hazard ratios (HRs) and 95% confidence intervals (CIs) were estimated by Cox proportional hazards regression.

Results: HA, CRP, IL-6, YKL-40, higher PS and stage were all risk factors for poor outcome in univariate analyses, as was log2-transformed PRO-C3 (HR = 1.15, 95% CI 1.09-1.22, P < 0.001). No statistically significant difference for serum PRO-C3 was observed in multivariate model, while CA19-9, CRP, YKL-40 along with higher PS and stage remained independently significant. PRO-C3 was positively correlated with higher stage (P = 0.012) and was significantly higher in pts with PC compared to subjects with benign lesions (P < 0.001).

Conclusions: Compared with subjects with benign lesions serum PRO-C3 was higher in pts with PC, and increased with greater stage. Higher levels were associated with shorter OS. Serum PRO C3 did not provide independent prognostic value compared to other markers. Further investigations are warranted based on these initial results.

753P Venous thromboembolism in Asian patients with pancreatic cancer who underwent palliative chemotherapy: Low prevalence, but a poor prognostic factor for early onset

W-C. Chou[1], J-S. Chen[2], Y-Y. Chen[3], C-H. Lu[4], P-H. Chang[5]

[1]Hematology and Oncology, Chang Gung Memorial Hospital-Linkou, Taoyuan, Taiwan, [2]Hematology/ 0ncology, Chang Gung Memorial Hospital-Taipei, Taipei City, Taiwan, [3]Hematology and Oncology, Chang Gung Memorial Hospital-Kaohsiung, Kaohsiung, Taiwan, [4]Hematology and Oncology, Chiayi Chang Gung Memorial Hospital, Puzi City, Taiwan, [5]Hematology and Oncology, Keelung Chang Gung Memorial Hospital, Keelung, Taiwan

Background: Venous thromboembolism (VTE) is a common complication in patients with pancreatic cancer. VTE in Asian patients with cancer is known to be less prevalent than in Western patients; however, few studies have reported the epidemiology and clinical outcomes of VTE in Asian patients with pancreatic cancer. This study investigated the incidence, risk factors, and clinical outcome of VTE in patients with pancreatic cancer who underwent palliative chemotherapy.

Methods: Medical records of VTE incidence in patients after initiation of chemotherapy for newly diagnosed locally advanced or metastatic pancreatic cancer from 2010 to 2016 at four institutes in Taiwan were retrospectively reviewed. The clinical characteristics of 838 patients were analyzed to identify independent predictors of VTE and survival outcome.

Results: With a median follow-up period of 7.7 months (0.6–55.6), VTE occurred in 67 (8.0%) of the 838 patients. The 6-, 12-, 24-, and 36-month cumulative incidences of VTE were 5.0%, 8.9%, 19.4%, and 24.5%, respectively. Of the 67 patients who developed VTE, 26.9%, 53.8%, and 70.2% of VTE occurred within 2, 4, and 6 months of chemotherapy initiation, respectively. Predictors of VTE were white blood cell count >11,000/μL of peripheral blood and presence of liver metastases. Khorana risk score was not a significant predictor of VTE. Patients with VTE were not significantly associated with a poorer survival outcome than were those without VTE. However, occurrence of VTE within 2 months after the initiation of chemotherapy was an independent poor prognostic factor for overall survival.

Conclusions: This was the largest study to evaluate the incidence, predictors, and effects of VTE in Asian patients with pancreatic cancer that underwent palliative chemotherapy. The incidence of VTE in Asian patients was found to be half that in Western patients. Only patients with early onset VTE had a poorer prognosis than those without VTE. Awareness of the clinical characteristics and survival outcome of patients with VTE may assist clinicians and patients in choosing the appropriate prophylaxis and management of VTE for Asian patients with pancreatic cancer.

754P Targeted therapy based on the genetic alterations prolongs the progression-free survival of patients with advanced biliary tract cancer

F. Feng[1], Q. Cheng[1], D. Zhang[2], B. Li[1], H. Qin[2], C. Xu[1], M. Han[2], Y. Yu[1], Z. Li[1], J-Y. Li[2], Z. Qiu[1], L. Xiong[2], C. Liu[1], F. Li[2], B. Yi[1], X. Jiang[1]

[1]Department of Biliary I, Eastern Hepatobiliary Surgical Hospital (EHSH), 2nd Military Medical University, Shanghai, China, [2]Research and Development Institute of Precision Medicine, 3D Medicine Inc., Shanghai, China., Shanghai, China

Background: Targeted therapy based on a certain genetic alteration has been proven to be an effective treatment in some kinds of cancers. We aimed to evaluate the clinical efficacy of personalized targeted therapy for advanced biliary tract cancer (BTC) patients based on individual actionable mutations.

Methods: In this single-center study, the targeted next generation sequencing (NGS) was employed for consecutive 49 patients with BTC and the recommendation of biologic agent was offered according to most potentially targetable genetic alteration of each person. Among 32 patients with stage IV and R2 resection, 21 patients underwent conventional chemotherapy (mGEMOX), while the rest 11 patients received a personalized targeted agent alternative to chemotherapy. The progression-free survival (PFS), overall survival (OS) and disease control rate (DCR) were assessed.

Results: The genomic landscape of 49 patients demonstrated that TP53 (n = 31, 63.3%) variation was most prevalent and was followed by KRAS (n = 12, 24.5%), ARID1A (n = 6, 12.2%), PIK3CA (n = 6, 12.2%), SMAD4 (n = 6, 12.2%), CDKN2A (n = 5, 10.2%) and ERBB4 (n = 5, 10.2%). Further analysis of copy number alterations (CNAs) showed low recurrent amplified genes, such as PIK3CA, SMAD4, FGFR3, SRC, PIK3R2, CDK4, ERBB2, and CDK6. After a median follow-up of 12 months, the targeted group had a significant prolonged PFS (4.5 months vs. 1.5 months, P = 0.014) and a trend of prolonged OS (12.9 months vs. 4.1 months, P = 0.104) in comparison with the chemotherapy group. The DCR in targeted group was a little higher but without significance (63.6% vs. 33.3%, P = 0.142). In addition, the ratio of patients with more than Grade 2 treatment-related toxicities in the targeted therapy group was a little higher compared to that of chemotherapy group but without significance (36.4% vs. 19.0%, P = 0.397).

Conclusions: This mono-center small cohort study suggested that personalized targeted therapy for advanced BTC patients based on individual most potentially actionable mutation detected by NGS, which offered such patients a longer PFS and trends of better OS and DCR, could be an option alternative to conventional chemotherapy.

755P Evaluation of genetic alterations in biliary tract cancer using targeted exome sequencing

H. Chae[1], C. Yoo[1], D. Kim[2], J.H. Jung[1], H-M. Chang[3], B-Y. Ryoo[1], K-P. Kim[1]

[1]Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [2]Pathology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [3]Medical Oncology, Asan Medical Center, Seoul, Democratic People's Republic of Korea

Background: Biliary tract cancer (BTC) is a heterogeneous group of cancers anatomically divided into gallbladder cancer (GBC), intrahepatic cholangiocarcinoma (ICC) and extrahepatic cholangiocarcinoma (ECC). None of molecular target agents has been proven to improve the prognosis of BTC yet. To gain a deeper understanding of BTC's pathophysiology and find its new potential therapeutic targets, this study aims to investigate genetic profiles of BTC and their clinical implication.

Methods: A total of 124 patients with adenocarcinoma of biliary tract from Jan 2014 to Feb 2018 were enrolled. With DNA specimen extracted from previously-collected tumor tissue, somatic mutation and copy number analyses were performed using targeted exome sequencing. Data regarding baseline patient characteristics and treatment outcomes were retrospectively obtained from medical records.

Results: Twenty-five patients with GBC (20.2%), 55 with ICC (44.4%) and 44 with ECC (35.5%) were included in the analysis. Genetic mutation were observed in 104 patients (83.8%) and the rest 20 (16.1%) did not have any genetic alterations. The most commonly mutated gene was TP53 (n = 55, 44.4%), followed by KRAS (n = 36, 29.0%), ARID1A (n = 15, 12.1%) and IDH1 (n = 12, 9.7%). IDH1/2 mutation appeared more frequently in ICC (n = 12, 21.8%, P = 0.012) compared to GBC (n = 1, 4.0%) or ECC (n = 1, 2.3%) while ERBB2 and ERBB3 mutation were found only in GBC and ECC. ERBB2 amplification was observed in 7 patients (4 with GBC and 3 with ICC). Among those, one patient showed 3+ for HER2 test by immunohistochemistry (IHC) while four patients were 2+. Survival outcomes were analyzed among 122 patients who had eventually received palliative chemotherapy for their advanced disease. Patients harboring TP53 mutation had shorter PFS (5.7 vs. 7.1 months, P = 0.08) and OS (15.2 vs. 37.8 months, P = 0.03) compared to those without TP53 mutation, while IDH1 mutation was likely to be related to favorable PFS (10.6 vs. 6.1 months, P = 0.069). On the other hand, there were no significant differences in PFS or OS depending on KRAS or ARID1A mutation.

Conclusions: Genetic profile of BTC is heterogeneous according to its anatomic location. Our results indicate that subgroup of BTC may benefit from targeted therapy such as anti-IDH and anti-HER2 inhibitor.

Background: Dysregulation of FGFR signaling by FGFR translocations is involved in the pathogenesis of CCA. FGFR2 translocations occur almost exclusively in pts with intrahepatic CCA (iCCA) with an incidence of 13%–15%.[1] INCB054828, a selective, potent oral inhibitor of FGFR1, 2, and 3, is being evaluated in a phase 2 study (NCT02924376) of pts with previously treated CCA.

Methods: Pts are enrolled into cohort A (FGFR2 translocations), cohort B (other FGF/FGFR genetic alterations [GA]), or cohort C (no FGF/FGFR GAs) and receive oral INCB054828 13.5 mg once daily on a 21-day cycle (2 weeks on, 1 week off) until disease progression or unacceptable toxicity. The primary endpoint is objective response rate (ORR) per RECIST v1.1 in cohort A based on independent review. Secondary endpoints include ORR in cohorts B and C, progression-free survival (PFS), overall survival, and safety. We report interim efficacy and safety data.

Results: At data cutoff (27 Nov 2017) 47, 22, and 18 pts were enrolled in cohorts A, B, and C, respectively. In cohort A, 94% (44/47) had iCCA, 98% (46/47) had ECOG PS $\leq$ 1, and 60% (28/47) received $\geq$ 2 prior therapies. Of 45 evaluable pts in cohort A, 8 (18%) had a confirmed partial response (PR; 1/8 with unconfirmed complete response) and 26 (58%) had stable disease (3/26 had unconfirmed PRs); the best ORR was 24% (95% CI, 12%–37%). Median PFS was 6.8 months (95% CI, 3.6–9.2 months). No responses were observed in cohorts B or C; median PFS was 1.4 and 1.5 months, respectively. The most common treatment-emergent adverse events (TEAEs) in all pts (N = 87) were hyperphosphatemia (56%), alopecia (36%), and diarrhea (32%). Hyperphosphatemia was managed with diet, phosphate binders, or dose modification. Most frequent grade 3/4 TEAEs were hyponatremia (8%) and hypophosphatemia (7%).

Conclusions: INCB054828 was generally well tolerated and showed preliminary efficacy in pts with previously treated advanced iCCA with FGFR2 translocations. Long-term follow-up data will be presented. 1. Graham RP, et al. Hum Pathol. 2014;45:1630-1638.

Background: Biliary tract cancers (BTCs) are a group of aggressive cancers with limited treatment options. Overall response rates (ORRs) with 2L chemotherapy in BTC are <10%, and no standard of care exists. M7824 is an innovative first-in-class bifunctional fusion protein composed of a human anti–PD-L1 IgG1 monoclonal antibody fused with 2 extracellular domains of the transforming growth factor β (TGF-β) receptor II (a TGF-β "trap"). We report on the safety and efficacy of M7824 in patients (pts) with pretreated BTC.

Methods: In this expansion cohort of the ongoing phase 1, open-label trial NCT02699515, Asian pts who progressed after platinum-based 1L treatment received M7824 1200 mg q2w until confirmed progressive disease, unacceptable toxicity or trial withdrawal. The primary objective is safety/tolerability; secondary objectives include assessment of best overall response per RECIST v1.1. Tumor cell PD-L1 expression was evaluated (antibody clone 73-10).

Results: As of March 20, 2018, 30 pts with pretreated BTC received M7824 for a median duration of 8.9 (range, 2-57.6) wk; 5 pts remained on treatment. The most common treatment-related adverse events (TRAEs) were pyrexia, maculopapular rash (both 13.3%) rash and lipase increase (both 10%); 10 pts (33.3%) experienced grade $\geq$3 TRAEs. 3 deaths due to AEs were reported; 1 death was due to septic shock (bacteremia, etiology unknown) after 14 doses, and 2 deaths due to interstitial lung disease (ILD), 1 on treatment after 3 doses and 1 with grade 3 ILD after 3 doses that recovered, initiated chemotherapy due to PD, and worsened with death 6 months after initial ILD diagnosis and last M7824 dose. 7 pts had an objective response (ORR, 23.3%, including one late PR pending confirmation), with 4 of 6 PRs ongoing (0.7+, 2.8, 3.9+, 5.5+, 5.6, and 6.9+ mo) and 1 CR ongoing for 5.6+ mo. 1 additional pt had ongoing PR for 7.6+ mo after initial pseudoprogression. Confirmed ORR by PD-L1 expression was 25% and 15.4% in pts with PD-L1 + ($\geq$1%) and PD-L1− tumors, respectively.

Conclusions: M7824 monotherapy has promising efficacy in Asian pts with pretreated BTC, including long-lasting responses in 8 of 30 pts (27%).

758P A new ProTide, NUC-1031, combined with cisplatin for the first-line treatment of advanced biliary tract cancer (ABC-08)

M.G. McNamara[1], J. Bridgewater[2], D. Palmer[3], H. Wasan[4], W.D. Ryder[5], C. Gnanaranjan[6], E. Ghazaly[7], T.R.J. Evans[8], J.W. Valle[1]

[1]Medical Oncology, The Christie NHS Foundation Trust, Manchester, UK, [2]Oncology, University College London Hospitals, London, UK, [3]Medical Oncology, Clatterbridge Cancer Centre, Liverpool, UK, [4]Medical Oncology, Imperial College London - Hammersmith Hospital, London, UK, [5]MAHSC-CTU, The Christie NHS Foundation Trust, Manchester, UK, [6]Cancer Institute, Barts Cancer Institute-Queen Mary University of London, London, UK, [7]Centre for Haemato-Oncology, Barts Cancer Centre, London, UK, [8]Institute of Cancer Sciences, Beatson Institute for Cancer Research, Glasgow, UK

Background: Cisplatin + gemcitabine (cis/gem) is the global standard of care for 1st-line treatment of patients (pts) with locally advanced/metastatic biliary tract cancer (BTC). No agents have regulatory approval for this disease. Cis/gem achieves an objective response rate (ORR) of 26% and median overall survival (OS) of 11.7 months (ABC-02). Inherent/acquired resistance mechanisms limit gemcitabine efficacy. NUC-1031, a phosphoramidate transformation of gemcitabine, is designed to overcome resistance mechanisms associated with poor gemcitabine response.

Methods: Pts with locally advanced/metastatic BTC, ECOG PS of 0-1 and no prior systemic therapy received NUC-1031 (625 or 725 mg/m^2) combined with cisplatin (25 mg/m^2) on days 1 + 8 every 21 days. Primary endpoints: safety and determination of RP2D. Secondary endpoints: ORR, pharmacokinetics, progression-free and OS.

Results: 14 pts (median age 61 yrs, 8 male; 5 hilar, 4 distal bile duct, 2 intrahepatic, 2 ampullary and 1 gallbladder) were enrolled across cohorts 1 (625 mg/m^2, n = 8) and 2 (725 mg/m^2, n = 6). 11 pts completed >1 cycle and were efficacy evaluable, receiving a median of 6.5 cycles (range 3.5-12). ORR was 64% (1 CR, 6 PRs) and DCR: 73%. PFS/OS data collection is ongoing. High, durable intracellular levels of the active anti-cancer metabolite dFdCTP were generated in PBMCs ($t_{1/2}$=22 h). Treatment was well tolerated with no unexpected AEs/DLTs. Grade 3 TEAEs included neutropenia (14%), fatigue (14%), pyrexia (14%), ALT (7%), AST (7%), GGT (7%) and nausea (7%). Based on high response rate and favourable safety profile, 625 mg/m^2 was deemed RP2D. An expansion cohort is ongoing (n = 6).

Table: 758P

	ITT			Efficacy evaluable		
	625 mg/m^2 (n = 8) n (%)	725 mg/m^2 (n = 6) n (%)	Total (n = 14) n (%)	625 mg/m^2 (n = 6) n (%)	725 mg/m^2 (n = 5) n (%)	Total (n = 11) n (%)
CR	1 (13)	0 (0)	1 (7)	1 (17)	0 (0)	1 (9)
PR	3 (38)	3 (50)	6 (43)	3 (50)	3 (60)	6 (55)
ORR	4 (50)	3 (50)	7 (50)	4 (67)	3 (60)	7 (64)
SD	0 (0)	1 (17)	1 (7)	0 (0)	1 (20)	1 (9)
DCR	4 (50)	4 (67)	8 (57)	4 (67)	4 (80)	8 (73)

Conclusions: NUC-1031 + cisplatin demonstrated a very high ORR, with a favourable safety profile, and may provide an improved treatment option over cis/gem for advanced BTC. Further development of NUC-1031 in BTC is planned.

Clinical trial identification: NCT02351765.

759P Phase II study of evofosfamide (TH-302) monotherapy as a second-line treatment in advanced biliary tract cancer

J.S. Yoon[1], K-H. Lee[2], G.J. Cheon[3], Y-J. Bang[2], D-Y. Oh[2]

[1]Department of Internal Medicine, Seoul National University Hospital, Seoul, Republic of Korea, [2]Medical Oncology, Seoul National University Hospital, Seoul, Republic of Korea, [3]Department of Nuclear Medicine, Seoul National University Hospital, Seoul, Republic of Korea

Background: Evofosfamide (TH-302), a nitroimidazole-linked prodrug of a brominated version of isophosphoramide mustard, is converted to an activated form and acts as a DNA crosslinking agent when exposed to a hypoxic environment. Biliary tract cancer (BTC) is well known to contain large hypoxic area, and there is no standard 2nd line chemotherapy in advanced BTC. This study is a prospective, open-label, single-arm phase II trial to evaluate the efficacy and safety of evofosfamide as 2nd line treatment in advanced BTC.

Methods: Patients (pts) with unresectable or recurred BTC whose disease progressed after 1st line chemotherapy were enrolled. Pts received evofosfamide at a dose of 340 mg/m^2 via intravenous (IV) infusion over 30 minutes on Day 1, 8, and 15 of every 28-day cycle. The primary end point was progression-free survival (PFS) rate at 4-months. Secondary end points included overall survival (OS), PFS, objective response rate (ORR), disease control rate (DCR), metabolic response by 18 F-FDG PET, and safety profile. Response evaluation was done every 8 weeks using RECIST v.1. Metabolic response was evaluated by PERCIST v.1, and toxicity was assessed by CTCAE v4.03.

Results: A total of 20 pts were treated with IP and 16 were response-evaluable. The median age was 58.7 years (range 54.90 - 62.29). The primary origin of tumor was intrahepatic cholangiocarcinoma in 9 pts, extrahepatic BTC 3, gallbladder cancer 6, and ampulla of vater 2. 16 pts had ECOG PS 0, and 4 had ECOG 1. There was no objective response, stable disease was observed in 9 pts, results in DCR 56.3%. The PFS rate at 4-months was 31.25%. The median PFS was 3.80 months (95% CI 1.03 - 6.57), and the median OS was 6.37 months (95% CI 3.94 - 8.79). Liver metastasis was associated with poor PFS. Reduction of tumor metabolic activity was observed in 8 pts out of 14 (57.1%). Majority of adverse events (AEs) were grade 1/2 ; neutropenia(30%), anemia (50%), thrombocytopenia (40%), nausea (15%), arthralgia (5%). Grade 3 anemia was observed in 15%, anorexia 5% and arthralgia 5%. There was no treatment-related death.

Conclusions: Evofosfamide monotherapy showed promising efficacy in terms of disease stabilization and PFS and OS, and acceptable AE profiles used as 2nd line treatment in advanced BTC.

Clinical trial identification: NCT02433639.

Legal entity responsible for the study: Do-Youn Oh, Seoul National University Hospital.

760P PhotoChemical internalization of gemcitabine followed by gemcitabine/cisplatin in perihilar cholangiocarcinoma: Results from a phase I dose escalation trial

J. Trojan[1], R. Sturgess[2], D. Harrison Palmer[3], B. Neu[4], S. Kasper[5], A. Dechene[6], C. Jürgensen[7], J. Schirra[8], R. Jakobs[9], A. Högset[10], L. Finnesand[11], H. Olivecrona[11]

[1]Gastrointestinale Onkologie, Goethe University Medical Center, Frankfurt am Main, Germany, [2]The Aintree Digestive Diseases Unit, University Hospital Aintree, Liverpool, UK, [3]Institute of Translational Medicine, University of Liverpool Cancer Research UK Centre, London, UK, [4]Medizinische Klinik II - Gastroenterologie, Hepatologie und Onkologie, Krankenhaus Landshut-Achdorf, Landshut, Germany, [5]Medical Oncology, University Hospital Essen Westdeutsches Tumorzentrum, Essen, Germany, [6]Gastroenterology and Hepatology, University Hospital Essen Westdeutsches Tumorzentrum, Essen, Germany, [7]Medizinische Klinik II - Gastroenterologiekologie, Charité, Berlin, Germany, [8]Medizinische Klinik und Poliklinik II, Klinikum der Ludwig-Maximilians-Universität, Munich, Germany, [9]Medical Department C, Klinikum Ludwigshafen, Ludwigshafen, Germany, [10]CSO, PCI Biotech AS, Oslo, Norway, [11]Clinical Development, PCI Biotech AS, Oslo, Norway

Background: Cholangiocarcinoma is a rare cancer with a poor survival and an approximate response rate of 26% and a median PFS/OS of 8.0 and 11.7months respectively with current standard treatment (gemcitabine/cisplatin). Photochemical Internalisation (PCI) is a novel technology that utilizes wave-length specific light (652nm) and a photosensitizer ($TPCS_{2a}$; Amphinex®) to enhance the local therapeutic effect of a variety of molecules, including gemcitabine.

Methods: This was a Phase I, dose escalation, multicenter trial of a single PCI induction of gemcitabine (1000 mg/m^2) in 16 patients with inoperable perihilar cholangiocarcinoma (CCA). Following the procedure, patients received standard therapy with gem/cis for up to 8 cycles. Patients were on-study for 6 months, and are currently followed for survival. Adverse events, including biliary complications, and tumor effects were characterized.

Results: A total of 16 patients were treated in four different dose cohorts. 11 patients completed the 8 cycles of combination therapy; 5 patients were early withdrawals. PCI of gemcitabine was well tolerated with no Dose Limiting Toxicities, and with a general safety profile characteristic of the patient population included. At 6 months, in the two highest dose cohorts independent reading showed that 7 out of 8 patients had radiologically evaluable tumours. Of these, 2 were complete and 2 partial responses, with one stable disease. In 17/19 target lesions before treatment, a > 20% reduction in tumour size was seen, with 12 lesions undetectable at 6 months. Median OS ended at 14.4 months. As of March 2018, 4 of the 16 patients are alive 24.3 to 38.8 months after treatment (overall study average 17.4 months).

Conclusions: In this dose escalation trial of PCI of gemcitabine in perihilar CCA patients, a safe and tolerable dose of light and Amphinex® was established. The overall safety profile and promising results, including a proportion of patients with highly durable objective tumor response, are encouraging. A larger, controlled and randomized study is underway.

Clinical trial identification: NCT01900158.

Legal entity responsible for the study: PCI Biotech AS.

Funding: PCI Biotech AS.

Disclosure: A. Högset, L. Finnesand, H. Olivecrona: Employee: PCI Biotech AS. All other authors have declared no conflicts of interest.

761P FOLFIRINOX as a first-line chemotherapy for patients (pts) with advanced biliary tract cancer (BTC)

A. Ulusakarya[1], W. Karray[1], J. Abdou[1], A. Karaboué[2], M. Haydar[1], S. Krimi[1], Y. Gumus[1], W. Almohamad[1], E. Goldschmidt[1], P. Biondani[1], J.F. Morère[1]

[1]Medical Oncology Department, AP-HP, Hôpital Paul Brousse, Villejuif, France, [2]Medical Oncology Department, GHI Le Raincy-Montfermeil, Montfermeil, France

Background: FOLFIRINOX is a first-line regimen in the treatment of pancreatic cancer. Historically, BTC and pancreatic cancers were treated similarly with gemcitabine alone or combined with a platinum compound. A growing body of evidence supports the role of fluoropyrimidines in the treatment of BTC.

Methods: We retrospectively analyzed data of all our pts with locally advanced (LA) or metastatic (M) BTC who received FOLFIRINOX as a first-line therapy from 12/2013 to 11/2017 at Paul Brousse university hospital. The main endpoints were OS, TTP, ORR, DC, secondary resection and toxicity.

Results: There were 42 pts: 17 male (40%) and 25 female (60%) pts aged 36 to 84 years (median: 67). Pts had PS of 0 (55%) and 1 (45%). They had intrahepatic cholangiocarcinoma (iCCA) (21 pts, 50%), gallbladder carcinoma (8 pts, 19%), perihilar CCA (7 pts, 17%), distal CCA (4 pts, 10%) and ampulloma (2 pts, 5%). No biopsy could be obtained in 2 pts. BTC was LA or M in 9 (21%) and 33 pts (79%) respectively. Biliary stent was placed in 14 pts (33%). A median (m) of 10 courses was given with m treatment duration of 6 months (mo). At the cutoff on 01/01/2018, regimen was ongoing in 7 pts (18%). Dose intensity (m) was 74, 34 and 1150 mg/m^2/w for irinotecan, oxaliplatin and 5FU respectively. The most common nonhematological toxicity was sensory neuropathy: grade 1/2 in 15 pts (36%), no grade 3/4. We observed 15 PR (36%), 16 SD (38%), and 10 PD (24%); 1 pt has not been evaluated for efficacy. Fifteen pts (36%) were alive, 24 pts (57%) died, 3 pts (7%) were lost to follow-up. Four out of 5 pts who underwent resection were alive without disease. At a median follow-up time of 12 mo (1 to 26), mTTP was 9 mo [95%CL, 5 – 12] and mOS was 15 mo [14 – 16]. mTTP was better for LA (not reached) than M-BTC (8 mo), $p = 0.05$; OS was statistically similar. mTTP was worse in pts with iCCA than other primaries (7 mo [4 – 10] vs 14 mo [9 – 19], $p = 0.005$); OS was not significantly different. ORR and DC were associated with both better TTP and OS. ORR: mTTP (16 vs 5 mo, $p < 0.001$), mOS (19 vs 11 mo, $p = 0.01$); DC: mTTP (10 vs 2 mo, $p < 0.001$), mOS (18 vs 7 mo, $p = 0.002$).

Conclusions: First-line FOLFIRINOX offers promising results in patients with LA and M-BTC. It deserves prospective evaluation to further improve outcomes for advanced BTC.

Background: No adjuvant chemotherapy regimens after major hepatectomy for biliary tract cancer (BTC) have been standardized due to the frequency of adverse events. Survival benefits of adjuvant gemcitabine (GEM) or S-1 (S1) chemotherapy were investigated with the recommended dose determined in our previous clinical trial (KHBO1003), with 10% dose-limited toxicity.

Methods: We performed a phase II multicenter randomized trial. The primary endpoint was 1-year recurrence-free survival (RFS), and the secondary end-points were other RFS, overall survival (OS), and others. The following 6-month adjuvant chemotherapy regimens were performed within 12 weeks after R0 or R1 major hepatectomy (hemihepatectomy or trisectionectomy) for BTC: GEM (1000 mg/m2) every 2 weeks or S1 (80 mg/m2/day) for 28 days every 6 weeks. Thirty-five patients were assigned to each arm (alpha error, 10%; beta error, 20%). P values of < 0.10 were considered to indicate a statistically significant difference.

Results: No patients were excluded for the per-protocol analysis. There were no statistically significant differences in the patient characteristics of the two arms. The 1-year RFS and the 1-year OS rates of the GEM arm were 51.4% and 80.0%, respectively, while those of the S1 arm were 62.9% and 97.1%, respectively. The 2-year RFS rate, the 1- and 2-year OS rates, and the OS curve of the S1 arm were superior to those of the GEM arm ($p = 0.0894$, $p = 0.0242$, $p = 0.0679$, and $p = 0.0606$, respectively), although the 1-year RFS rate was not significantly different ($p = 0.334$). With regard to the OS curve, the hazard ratio of the S1 group was 0.477 (90% confidence interval, 0.245-0.927).

Conclusions: The adjuvant chemotherapy with S1 may provide better survival benefits compared with that with GEM after major hepatectomy for BTC.

763P Neoadjuvant vs. adjuvant chemotherapy for cholangiocarcinoma: A propensity score matched analysis

S. Yadav[1], H. Xie[1], I.B. Riaz[1], P. Sharma[2], A. Mahipal[1], R. McWilliams[1]

[1]Department of Oncology, Mayo Clinic, Rochester, MN, USA, [2]Department of Internal Medicine, Bridgeport Hospital, Yale New Haven Health System, Bridgeport, CT, USA

Background: The role of neoadjuvant-chemotherapy (NADJ) in cholangiocarcinoma is unknown. The purpose of this study is to evaluate whether NADJ improves overall survival (OS) in cholangiocarcinoma compared to adjuvant-chemotherapy (ADJ).

Methods: Using the National Cancer Database, we identified patients who underwent surgery and chemotherapy for stage I-III cholangiocarcinoma between 2006 and 2014. Patients with metastatic disease at diagnosis or unknown chemotherapy sequence with surgery were excluded. Propensity score for NADJ was calculated by multivariate logistic regression method. Matching with patients who received ADJ was then performed at the ratio of 1:3 using nearest neighbor method with a caliper width of 0.2. Covariates included in matching were: age at diagnosis, sex, race, insurance status, Charlson score, year of diagnosis, location of tumor, tumor grade, clinical stage, and use of radiation.

Results: 1450 patients met our inclusion criteria, 299 (20.6%) received NADJ while 1151 (79.3%) received ADJ. The median age at diagnosis was 63 years. Factors associated with higher ($p < 0.05$) use of NADJ compared to ADJ were: ages <54 (35% vs. 23%), white race (91% vs. 86%), year of diagnosis 2012-2014 (48% vs. 40%),

intrahepatic tumor location (74% vs. 54%), clinical stage I (46% vs. 38%), and unknown grade of tumor (36% vs. 14%). 279 patients in NADJ group were matched to 698 patients in ADJ group, with resulting standardized mean difference of < 0.1 for all covariates. In the matched cohort, patients who received NADJ had a significantly better OS compared to those who received ADJ (HR: 0.79; 95% CI: 0.65 – 0.96, p = 0.01). The 1- and 5-year OS was 85.9% and 42.1% respectively for NADJ, while it was 85.0% and 32.7% respectively for ADJ.

Conclusions: In this large national database study, NADJ compared to ADJ improved OS in a select group of patients with cholangiocarcinoma.

[1]Medical Oncology 1, Department of Clinical and Experimental Oncology, Istituto Oncologico Veneto IRCCS, Padua, Italy, [2]Oncology Radiodiagnostics Department, Istituto Oncologico Veneto IRCCS, Padua, Italy, [3]U.O. Oncologia 2 Universitaria, Azienda Ospedaliero-Universitaria Pisana, Pisa, Italy, [4]Medical Oncology 1, Istituto Nazionale Tumori Regina Elena, Rome, Italy, [5]Oncology, Policlinico S. Orsola-Malpighi, Bologna, Italy, [6]Medical Oncology, San Raffaele Scientific Institute, Milan, Italy, [7]Oncology, Udine University and General Hospital, Udine, Italy, [8]Medical Oncology, IRCCS Istituto di Candiolo, Candiolo, Italy, [9]Oncology, Campus Bio-Medico di Roma, Rome, Italy, [10]Department of Surgery, Hepatobiliary Surgery and Liver Transplantation, Padua University Hospital, Padua, Italy

Background: Most of iCCA patients die because of hepatic progression, even in metastatic stage. Chemotherapy leads to modest increase in life expectancy; arterial-directed therapies (ADT), such as chemoembolization (TACE) or radioembolization (TARE), have been proposed to obtain local disease control, eventually leading to a survival benefit.

Methods: We conducted a multicenter retrospective study involving 8 Italian Cancer Centers to evaluate efficacy outcomes and safety of ADT in advanced iCCA. Primary endpoint was overall survival (OS) from the first ADT.

Results: 99 patients received at least one ADT from 2007 to 2017. TACE was performed in 74 patients, TARE in 25 patients. Median time from diagnosis of advanced disease to first ADT was 7.0 months. Median OS from first ADT was 11.9 months (95% CI 9.9-16.1); progression-free survival was 3.4 months (95% CI 3.2-4.0) with a disease control rate of 64% and an objective response rate of 20%. Adverse events (AE) after procedure were reported in 37 patients, more commonly low grade (G1-G2) abdominal pain (19%) and fever (18%); G3-G4 AE were reported in 11% of patients, while one fatal (G5) AE occurred due to brain hemorrhage one week after the procedure. No survival differences were observed in patients receiving more than one ADT (n.47) compared to those receiving only one procedure (n.52). OS according to procedure (TARE or TACE) was 19.1 and 10.5 months respectively (HR 0.53; 95% CI 0.32-0.88; p.031). Extrahepatic disease and Ca19.9 levels >100 kU/L were significantly associated with worse OS at univariate analysis (HR 1.77 and 2.73, respectively).

Conclusions: Patients receiving ADT had good survival outcomes when compared with historical data of systemic chemotherapy, although authors acknowledge these data could also be driven by a selection bias. Procedures were feasible and tolerable, with limited serious AEs. Notably, patients receiving more than one procedure did not gain an OS benefit compared to those receiving only one ADT. According to these retrospective data, performing ADT in presence of extrahepatic disease may be questionable. Specific prospective studies should be designed in order to confirm ADT role in iCCA.

Background: Benefit of CT beyond standard 1st-line (L1) gemcitabine plus cisplatin (GEMCIS) or oxaliplatin (GEMOX) in aBTC is unclear. Our aim was to identify and validate prognostic factors for L2OS in aBTC to guide patient selection for 2nd line (L2) CT.

Methods: All consecutive patients with aBTC receiving L2 CT after GEMCIS/GEMOX L1 between 2003-2016 in 28 French centers were included. The association of clinico-biological data with L2OS was investigated in univariate and multivariate Cox analyses. A simple score was derived from the multivariate model. The model and score were validated in 3 external cohorts with similar inclusion criteria (Italy, France, UK).

Results: The development cohort included 405 patients treated with L1 GEMOX (91%) or GEMCIS. 55% were men; median age was 64 years. 27% had prior surgical resection; 95% had metastatic disease. Performance status (PS) was 0/1/2 in 18%/52%/30%. Of the 251 patients with available CA19.9 at the beginning of L2, 35% had a CA19.9 ≥ 400 IU/L. Among 22 clinical parameters, 8 were associated with L2OS in univariate analysis. In multivariate analysis, 4 were independent prognostic factors: PS, reason for L1 stopping, prior surgery, peritoneal carcinomatosis (PC) (Table). Type of L2 CT regimen was not associated with L2OS. The clinical model had a C-index of 0.659, a good calibration and was validated in the 3 external cohorts (Table). Analysis of patients with complete data for the 4 clinical factors and CA19.9 (multiple imputations for missing data) showed that CA19.9 was independently associated with L2OS. A score was derived from this model.

Table: 765P Multivariate Cox Model for L2OS (HR, P-value)

	AGEO (N = 405)		ITALY (N = 288)		France (N = 70)		UK (N = 24)	
Prior surgery								
Yes No	1 1.3	0.031	1 1.4	0.013	1 1.8	0.16	1 4.8	0.045
Reason for L1 stopping								
Toxicity/ Other Progression	1 1.5	<0.001	1 1.8	<0.001	1 3.0	0.0063	1 31.9	<0.001
PS								
0 1 2	1 1.5 3.0	<0.001	1 1.2 2.1	0.001	1 2.0 6.7	<0.001	1 7.4 20.4	0.011
PC								
No Yes	1 1.3	0.018	1 1.4	0.019	1 1.0	1.0	1 15.3	0.001

Conclusions: We validated L2OS prognostic factors previously reported and identified PC as a new pejorative one in 800+ patients. Our model and score will be useful for guiding therapeutic decisions and stratifying randomization in future clinical trials.

766P Prognostic factors in patients with advanced biliary tract cancer (BTC) who showed durable disease control with first-line gemcitabine plus cisplatin (GemCis)

J. Hyung, C. Yoo, K-P. Kim, B.J. Kim, J.H. Jeong, H-M. Chang, B-Y. Ryoo

Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea

Background: GemCis is the standard first-line chemotherapy for patients with advanced BTC. In ABC-02 study, the BTC patients received up to 6-8 cycles of three-weekly GemCis. Currently, treatment strategy and prognostic factors of patients without progression to first-line GemCis is not well defined.

Methods: Advanced BTC patients treated with GemCis between April 2010 and February 2016 at Asan Medical Center, Seoul, Korea, were retrospectively analyzed. The patients without progression after 6-8 cycles were included in the study. Univariate and multivariate analyses were performed to identify prognostic factors for overall survival (OS).

Results: Among the 740 BTC patients in the initial screen, 231 cases (31.2%) were eligible for analysis. Median follow-up period was 23.8 months [IQR 5.1-86.3 months], the median OS from the initiation of treatment was 22.3 months [95% CI 19.0-25.7], and the median PFS was 12.5 months [95% CI 11.1-13.9]. Median age was 60 year-old (29-77) and 211 patients (91.3%) had ECOG performance status of 0 or 1 at the time of diagnosis. Objective response was achieved in 49 patients (21.2%). OS was significantly associated with number of metastatic site (>2 vs < 2: Hazard ratio [HR]=1.5, 95% CI 1.0-2.3, $p = 0.04$), best response to GemCis (stable disease vs partial response: HR = 1.9, 95% CI 1.3-2.7, $p = 0.006$). Maintenance therapy after durable disease control after at least 6 cycles of GemCis was not associated with OS ($p = 0.47$).

Conclusions: In patients who showed durable disease control to first-line GemCis, number of metastatic sites and objective response were significant poor prognostic factors. These results might help to design future clinical trials for this patient population.

767P Predictive factors of outcome in patients with advanced biliary tract cancer receiving gemcitabine plus cisplatin as first-line chemotherapy

Y. Suzuki[1], M. Kan[1], G. Kimura[1], K. Umemoto[1], K. Watanabe[1], M. Sasaki[1], H. Takahashi[1], Y. Hashimoto[1], H. Imaoka[1], I. Ohno[1], S. Mitsunaga[1], M. Ikeda[1]

[1]*Department of Hepatobiliary and Pancreatic Oncology, National Cancer Center Hospital East, Kashiwa, Chiba, Japan*

Background: Gemcitabine plus cisplatin (GC) is acknowledged as standard chemotherapy for advanced biliary tract cancer (BTC). Few studies have been conducted to identify the prognostic factors in patients receiving this therapy. The purpose of this study was to identify and validate predictive factors of outcome in patients with advanced BTC receiving GC therapy.

Methods: The data of 307 patients with advanced BTC who received GC as the first-line chemotherapy at our institution from January 2007 to June 2017 were reviewed retrospectively. All patients were randomly assigned to the investigation and validation datasets at the ratio of 2:1. Multivariate analysis was conducted to identify the prognostic factors in the investigation dataset ($n = 205$) and the patients were classified, according to the prognostic factors, into three risk groups, that is, groups with a good, intermediate and poor prognosis. This classification was then applied to the validation dataset ($n = 102$).

Results: The median overall survival (OS) and 1-year survival rate in the investigation dataset were 13.0 months (95% confidence interval, 11.0-13.9) and 54.7% respectively. Multivariate analysis identified the performance status, pretreatment serum lactate dehydrogenase level and pretreatment neutrophil-to-lymphocyte ratio as independent predictive factors of the OS. The patients were classified into three groups according to the identified prognostic factors, and the outcomes were found to differ significantly among the three groups ($p < 0.01$). When this classification was applied to the validation dataset, the OS was found to differ significantly among the three risk groups ($p < 0.05$).

Conclusions: This study identified three predictive factors of outcome, which allowed patients of advanced BTC receiving GC therapy to be classified into three risk groups.

768P Nomograms predicting survival of patients with advanced or recurrent biliary tract cancer receiving a first-line chemotherapy

N. Takahara, Y. Nakai, K.O. Saito, M. Sato, H. Ooyama, S. Kanai, T. Suzuki, T. Sato, R. Hakuta, K. Ishigaki, T. Takeda, S. Mizuno, H. Kogure, M. Tada, K. Koike

Department of Gastroenterology, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan

Background: Some clinical factors are known to be associated with the survival of patients with advanced biliary tract cancer (BTC). A comprehensive model based on these variables is necessary for prediction of an individual's survival and appropriate patient counseling.

Methods: A nomogram for predicting 1-year survival in patients with advanced BTC in the palliative chemotherapy setting was developed using clinical data from 222 patients with advanced or recurrent BTC who had received first-line systemic chemotherapy from 2006 to 2017 at The University of Tokyo Hospital (Baseline Nomogram). For 214 patients whose initial response to chemotherapy is known, another nomogram (ChemoResponse-based Nomogram) was constructed using the response to chemotherapy as additional variable. Nomogram performance in terms of discrimination and calibration ability was evaluated using the C statistic.

Results: Two different nomograms were developed and subjected to internal validation. The baseline nomogram incorporated 8 baseline clinical variables (age, sex, performance status, tumor location, disease status, CEA, CA19-9, and modified Glasgow prognostic score), whereas the chemoresponse-based nomogram was composed of 9 variables including initial response to chemotherapy evaluated by RECIST ver1.1. Internal validation revealed good performance of the two nomograms in discrimination: C statistics of 0.685 for the baseline and 0.734 for the chemoresponse-based nomogram, which showed better discrimination performance than the baseline nomogram.

Conclusions: This study suggests that individual 1-year survival probability of patients receiving first-line systemic chemotherapy for advanced or recurrent BTC can be reliably predicted by a nomogram-based method incorporating clinical variables and initial response to chemotherapy.

769P Stromal progesterone receptor expression and long-term survival in patients with resected periampullary adenocarcinoma

G. Andersson, S. Olsson-Hau, S. Lundgren, M. Heby, B. Nodin, K. Jirstrom

Department of Clinical Sciences Lund, Division of Oncology and Pathology, Lund, Sweden

Background: Early trials have reported a beneficial effect from tamoxifen treatment in patients with unresectable pancreatic cancer, in particular in women. However, the presence and prognostic significance of female hormone receptors in pancreatic or other periampullary cancers has not yet been described.

Methods: Immunohistochemical screening of normal and malignant pancreatic tissue revealed that the predominantly expressed female hormone receptor was the progesterone receptor (PgR), in particular in the cancer-associated stroma. The impact of PgR expression on overall survival (OS) was further examined on tissue microarrays with primary tumours from a consecutive retrospective cohort of 175 patients with resected periampullary adenocarcinoma.

Results: Median follow-up time was 29.7 (range 1.9–185.1) months. Stromal PgR positivity (PgR+), allover denoted in 31% of the cases, was significantly higher in pancreatobiliary-type than in intestinal-type tumours (38.7% vs 19.0%, $p = 0.008$), with an equal distribution between sexes. Stromal PgR+ was significantly associated with a prolonged OS in KRAS-mutated tumours, whereas the opposite was seen in KRAS wild-type tumours (p for interaction =0.015). This association was particularly evident in women, with a median OS of 60.5 months for PgR+/KRAS mutated tumours and 9.9 months for PgR+/KRAS wild-type tumours (p for interaction <0.001). PgR expression was not prognostic in male patients.

Conclusions: The finding of stromal PgR expression, and its link to clinical outcome in a considerable proportion of pancreatic and other periampullary cancers is novel. The concept of tamoxifen treatment for patients with unresectable disease, in particular elderly women, should be pursued, and PgR and KRAS may be relevant biomarkers for improved patient stratification.

770P A novel immune-inflammatory score to predict survival in patients (pts) with advanced biliary tract cancer (ABTC) receiving first-line chemotherapy (1-line cht)

M. Salati, F. Caputo, A. Spallanzani, M. Rimini, F. Gelsomino, K. Andrikou, S. Cascinu
Medical Oncology, University Hospital of Modena, Modena, Italy

Background: Cht is the mainstay of treatment for ABTC with median overall survival (mOS) < 12 months. Given the palliative intent of treatment, its limited survival gain and not negligible toxicities it is of paramount importance to properly select pts. Determinants of immune-inflammation are regarded as promising prognostic factors in ABTC.

Methods: Clinical and laboratory data before starting 1-line cht were evaluated in 123 pts with unresectable locally advanced and metastatic ABTC (intrahepatic, perihilar and distal cholangiocarcinoma and gallbladder cancer) treated from 1st January 2010 to 31st July 2017 at Modena Cancer Centre. Potential prognostic factors were assessed by univariate (Cox proportional hazard univariate model) and multivariate analyses (multiple Cox proportional hazard regression with the likelihood ratio test).

Results: At univariate analysis ECOG PS > 0, metastatic disease, gallbladder cancer, no previous surgery, monocht, LDH > upper limit of normal, albumine < 3.5 gr/dl, absolute neutrophil count (ANC) > 8000/μl, lymphocyte/monocyte ratio (LMR) < 2.1, neutrophil/lymphocyte ratio (NLR) > 3, platelet/lymphocyte ratio > 160, AST > 40 IU/L, gamma-glutamyl-transpeptidase > 40 IU/L, CEA > 9.5 ng/ml, CA19-9 >700 U/L were significantly associate with shorter OS. At multivariate analysis, LMR < 2.1, NLR > 3, ANC > 8000/μl, albumine < 3.5 gr/dl retained statistical significance as poor prognostic factors. By combining these four variables, three different risk groups were identified: low-risk group (0 factors), intermediate-risk group (1-2 factors) and high-risk group (3-4 factors), with mOS of 22, 12, and 5 months respectively ($P < 0.001$). The prognostic value of the score was indipendent from treatment procedures (doublet vs monocht) and primary tumour site ($P < 0.001$).

Conclusions: We developed a cost-effective and easily-available scoring system that discriminates ABTC treated with 1-line cht into three, different, statistically significant prognostic groups. It could become a useful tool to add to established factors for improving pts' selection in daily practice.

771P "The German- Registry" of incidental gallbladder cancer and the GAIN - phase III trial: Transformation from a registry to treatment platform due to a trial in trial concept

T.O. Götze[1], V. Paolucci[2], S-E. Al-Batran[1]
[1]Institute of Clinical Cancer Research, Nordwest-Krankenhaus, Frankfurt am Main, Germany, [2]Surgical Deptartment, Ketteler- Krankenhaus, Offenbach, Germany

Background: The biggest biliary platform in Europe - the German- Registry (GR) shows significant survival benefit for radical resection (RR) in gallbladder carcinoma. But nevertheless results for T2-3 are still disappointing even after RR.

Methods: For data analysis the GR was used. Currently more than 1100 cases of incidental gallbladder carcinoma (IGBC) are registered. Based on the GR a new multicenter a neoadjuvant trail (GAIN) with the support of the DFG (grant) /AIO/CALGP/ACO has been started in 20 centers in Germany and in addition a trial in trial concept, including GAIN and the GR is planned. GAIN is a randomized multicenter phase III study for T2-3 IGBCs + resectable and borderline resectable biliary tract cancers (BTC), evaluating the role of neoadjuvant CTX with Gem/Cis in a multimodal setting in front of and after surgery vs. upfront surgery alone. If screened pts. is not eligible for curative treatment, pts. will be directly included in another 1st. line trial (trial- in- trial concept) under the direction of the GR. All IGBCs in addition will be directly registered in the GR.

Results: In the GR (n > 1100pts) in T1b- T3 cases there is a significant survival benefit for patients with IRR. Wedge resection of the liver showed good data in T1b and T2. For T3 more radical techniques showed better results. Less than 50% of T2–3 tumors in the GR have had RR.

Conclusions: There is a significant benefit after RR in T1b- T3 IGBC but the results in T2-3 are disappointing like in the whole entity of BTC. Data of current (PRODIGE 12, BILCAP) adjuvant trials are inconsistent. Therefore the multimodal concept based on a biliary network is needed. The GAIN trial is supported by the DFG and is also supported by the German AIO and the German CALGP/ACO. Due to the trial in trial concepts patients screened for GAIN but are candidates for 1st line will be directly included in another 1st line trial without time delay so the project directly closes a healthcare gap. The data of the GR were already able to change the current treatment standards for GBCA in Germany, reflected by the current S3- Guidelines. So GR will now transform to treatment platform and potentially create a new way how to treat biliary pts.

Claude Huriez, Lille, France, [8]Gastroenterology, Hôpital Cochin, Paris, France, [9]Gastroenterology and Digestive Oncology, Hopital European George Pompidou, Paris, France, [10]Hepato-Gastroenterolgy and Digestive Oncology, C.H.R. Orleans - La Source, Orleans, France, [11]Gastroenterology, CHU Haut Lévèque, Pessac, France, [12]Surgery, CHU Lariboisière, Paris, France, [13]Gastroenterology and Digestive Oncology, Hôpital St. Louis, Paris, France, [14]Oncology, CHU Saint Antoine, Paris, France

Background: Small bowel adenocarcinoma (SBA) is a rare tumour. Data are coming from register study or monocentric retrospective studies. The purpose of the NADEGE cohort is to describe characteristics and prognosis of SBA in unselected patients (pts) at a nationwide level.

Methods: All the pts with a SBA diagnosed from January 2009 to December 2012 were enrolled in the NADEGE cohort. The study involved 74 centres that enrolled 347 eligible pts.

Results: Pts were predominantly male (59%), median age: 63 years [23-90]. Primary locations were duodenum (60.6%), jejunum (20.7%) and ileum (18.7%). The tumour was poorly differentiated (20.9%), moderately (38.6%), well differentiated (40.5%) and not determined (7.5%). A predisposing disease was reported in 68 (19.7%) cases: Crohn disease 30 (8.6%), Lynch syndrome 24 (6.9%), familial adenomatous polyposis (FAP) 6 (1.8%), celiac disease 6 (1.8%) and Peutz-Jeghers syndrome 2 (0.6%). The tumour was metastatic at diagnostic in 122 (35.2%) pts, localized and resected in 202 (58.2%) and locally advanced in 19 (5.5%). Crohn disease was significantly associated with younger age, poor differentiation and ileum primary and Lynch syndrome with younger age, poor differentiation, early stage and duodenal primary. Adjuvant chemotherapy was performed in 61.5% pts with locally resected tumour mainly with oxaliplatin based regimen (89.9%). Palliative chemotherapy was performed in 85.1% of pts with metastases mainly with oxaliplatin based regimen (69.8%). With a median follow-up of 54 months, the 5 years overall survival (OS) rate was 87%, 78% and 55% for stage I, II, III respectively and the median survival was 12.7 months for stage IV. In pts with resected tumour multivariate analysis revealed a higher risk of death associated to poor differentiation (HR = 1.85, 95%CI 1.01-3.39, p = 0.047) and T4 (HR = 2.51, 95%CI 1.45-4.36, p = 0.001). Stage IV pts treated by chemotherapy had a better survival than pts not treated (14.3 vs 2.2 months, p = 0.0002).

Conclusions: NADEGE cohort provide data on SBA treated in a recent period. Tumours characteristics differ according to predisposing disease. FOLFOX chemotherapy is the main regimen used in adjuvant and metastatic setting. Tumour grade and T stage are prognostic factors for OS in resected tumour.

773P Impact of the number of nodes examined on survival in node negative small bowel adenocarcinoma: A SEER database analysis

M. Thiessen, P.A. Tang, R. Lee-Ying, J.G. Monzon
Medical Oncology, Tom Baker Cancer Centre, Calgary, AB, Canada

Background: Adjuvant chemotherapy (AC) may have benefit in both node negative (N-) and node positive (N+) non-metastatic small bowel adenocarcinoma (SBA). In N- cases, increased number of nodes examined (NNE) has been associated with increased survival. The objective of this analysis was to determine whether N- status is associated with lower NE at time of curative surgery compared to N+ cases, and how many NNE represents adequate sampling.

Methods: SAS 9.4 software and cases of non-metastatic SBA with complete AJCC staging (2004+) from the SEER database were used for this analysis. Age, gender, race, grade, NNE and T stage were compared between N+ and N- cases. Survival analysis

using N- cases was performed to determine which nodal cut-offs and variables best predicted survival.

Results: 613 cases of non-metastatic SBA (183 N- and 430 N+) diagnosed from 2004 to 2014 were analyzed. T stage and nodal sampling were the only two variables that differed statistically between N- and N+ cases (Table). Using the Log-rank test, a statistical separation in survival curves was identified at a minimum of > =13 NNE ($p = 0.0136$), a maximum of > =21 NNE ($p = 0.0142$), and with the greatest statistical separation at > =17 NNE ($p = 0.0003$). Out of age, gender, race, grade, > =13 NNE, > =17 NNE, > = 21 NNE, and T stage, only age, node cut-off of > =17 (HR 0.47, p=.0032) and T stage remained after stepwise selection of variables for Cox regression modelling. ROC's for Cox Regression models at 60 months, which included Age, T stage and either > = 13 NNE, > = 17 NNE, or > = 21 NNE were associated with AUC's of 0.700, 0.717 and 0.667, respectively.

Table: 773P

	Node -	Node +	p
Median Nodes Sampled	9	12	0.0008
Proportion of Cases by T Stage			
T1	10.9%	0.7%	<.0001
T2	11.5%	1.6%	<.0001
T3	60.7%	45.4%	0.0006
T4	16.9%	52.3%	<.0001

Conclusions: N- SBAs are associated with decreased nodal sampling compared to N+ SBAs. Low sampling is associated with decreased survival, possibly related to the presence of occult nodal disease. While further work is needed to determine what is considered adequate nodal sampling in N- SBA's, this analysis suggests that N- cases where less than 17 nodes have been examined have a poorer outcome.

Background: Small bowel adenocarcinoma (SBA) is a rare malignancy that accounts for 1-2% of gastrointestinal tumours. We evaluated the clinico-pathological characteristics, outcomes and prognostic factors of patients who underwent surgery for SBA.

Methods: We retrospectively analysed the features and outcome parameters of 54 SBA patients from 6 italian institutions between 2005 and 2017.

Results: The primary tumour was in the duodenum, jejunum and ileum in 30 (55.6%), 18 (33.3%) and 6 (11.1%) patients, respectively. Among the 54 patients studied, adjuvant chemotherapy were performed in 35.2 % of patients with stage II and in 27.8 % of patients with stage III. Relapse rates were higher for chemonaive patients compared to treated patients (50% vs 23.5%). Median overall (OS) and progression-free survival (PFS) were 26.98 and 19.78 months, respectively. Duodenal adenocarcinoma ($p = 0.022$), lymph node metastases ($p = 0.00269$), long-term treatment with metformin ($p = 0.0095$), no adjuvant treatment ($p = 0.0006$) and PLR >0,1766 ($p = 0,0137$) were associated with poor overall survival outcomes. The factors associated with PFS were patients with older age (>75 years) ($p = 0.04$) and T4 according to TNM system ($p = 0.02$).

Conclusions: The lack of well-defined guidelines for treatment of SBA justifies the heterogeneity of therapeutic choices resulting in negative impact on patient outcomes. Thus, there is an urgent need for prognostic and predictive biomarkers to guide therapy decisions for these patients. Our results suggest that the site, lymph node metastases, metformin and PLR >0,1766 could be novel prognostic markers for SBA patients who undergo curative surgery. However, prospective studies are necessary to confirm the role of these factors and identify new potential biomarkers of treatment efficacy, that could improve the selection of the right treatment for the right patient.

775TiP A phase III, randomized, open-label study to compare the efficacy of tislelizumab versus chemotherapy as second-line therapy for advanced unresectable/metastatic esophageal squamous cell carcinoma (ESCC)

L. Shen[1], J.A. Ajani[2], S-B. Kim[3], E. Van Cutsem[4], B. Guo[5], J. Song[6], V. Paton[7], K. Kato[8]

[1]GI Oncology, Peking University Cancer Hospital & Institute, Beijing, China, [2]MD Anderson Cancer Center, The University of Texas, Houston, TX, USA, [3]Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [4]Leuven Cancer Institute, University Hospitals Leuven, Leuven, Belgium, [5]Medical Oncology, BeiGene (Beijing) Co., Ltd., Beijing, China, [6]Biometry, BeiGene USA, Inc., Fort Lee, NJ, USA, [7]Clinical Development, BeiGene USA, Inc., Emeryville, CA, USA, [8]Gastrointestinal Medical Oncology Division, National Cancer Center Hospital, Tokyo, Japan

Background: Approximately 40% of patients (pts) with esophageal cancer are diagnosed with advanced unresectable or metastatic disease; the 5-year survival rate for advanced disease is < 5%. Inhibition of PD-1 has demonstrated antitumor activity and was generally well tolerated in pts with advanced unresectable or metastatic ESCC. Tislelizumab, a humanized IgG4 monoclonal antibody, has high affinity and specificity for PD-1. Tislelizumab was specifically engineered to minimize $F_c\Upsilon R$ binding on macrophages that, based on preclinical evidence, is believed to minimize potentially negative interactions with other immune cells. A first-in-human study (NCT02407990) demonstrated that single-agent tislelizumab was generally well tolerated and had preliminary antitumor effects in pts with solid tumors, including ESCC. A recommended phase 3 dose of 200 mg administered IV every 3 weeks (Q3W) has been established for tislelizumab.

Trial design: This phase 3, randomized study (NCT03430843) was designed to evaluate the efficacy, safety, and tolerability of tislelizumab compared with chemotherapy for second-line treatment of advanced unresectable/metastatic ESCC. Adult pts, aged ≥18 years, with histologically or cytologically confirmed ESCC that has progressed with first-line therapy, have ≥1 measurable/evaluable lesion, and have an Eastern Cooperative Oncology score ≤1 will be enrolled. Approximately 450 pts will be randomized (1:1) to receive either tislelizumab 200 mg IV Q3W or investigator-chosen chemotherapy (paclitaxel 135–175 mg/m^2 IV Q3W or 100 mg/m^2 IV weekly for 6 weeks with 1 week of rest [Japan only], docetaxel 75 mg/m^2 or 70 mg/m^2 IV Q3W, or irinotecan 125 mg/m^2 IV Q3W). Overall survival is the primary endpoint; secondary endpoints include objective response rate, progression free survival, duration of response, and health-related quality-of-life outcomes. Safety/tolerability will be assessed by monitoring adverse events (AEs), including immune-related AEs, as well as physical examinations, vital signs, and electrocardiograms. As of 11 April 2018, 6 patients have been enrolled.

Clinical trial identification: NCT03430843.

Background: Unresectable HCC accounts for 70% of diagnosed HCC. Tislelizumab is a humanized IgG4 monoclonal antibody with high affinity and specificity for programmed cell death receptor-1 (PD-1). Tislelizumab was specifically engineered to

minimize $F_c\gamma R$ binding on macrophages that, based on preclinical evidence, is believed to minimize potentially negative interactions with other immune cells. A phase 1A/1B study (NCT02407990) demonstrated that single-agent tislelizumab was generally well tolerated and showed preliminary evidence of antitumor activity in patients with advanced solid tumors, including HCC. A recommended phase 3 dose of 200 mg administered intravenously (IV) every 3 weeks (Q3W) has been established for tislelizumab.

Trial design: This global, phase 3, randomized, multicenter study (NCT03412773) was designed to evaluate the efficacy and safety of tislelizumab compared with sorafenib as a potential first-line treatment of unresectable HCC. Adult patients, aged ≥18 years, with unresectable, histologically confirmed HCC, an ECOG score ≤1, Child-Pugh A classification, BCLC Stage C disease or BCLC Stage B disease that has relapsed after loco-regional therapy, and who have not received prior systemic therapy, are being enrolled. Approximately 640 patients from 100 international centers are planned to be randomized (1:1) to receive tislelizumab 200 mg IV Q3W or sorafenib 400 mg orally BID. The primary outcome of this study is overall survival (OS) of patients treated with tislelizumab compared with OS of patients treated with sorafenib; secondary outcomes include objective response rate, progression-free survival, duration of response, time to progression, and quality-of-life outcomes. Safety/tolerability assessments include monitoring adverse events (AEs), including immune-related AEs, as well as physical examinations, vital signs, and electrocardiograms. Exploratory endpoints include assessment of potential biomarkers, characterization of the tislelizumab pharmacokinetic profile in patients with HCC, and assessment of host immunogenicity to tislelizumab. As of 11 April 2018, 11 patients have been enrolled.

Clinical trial identification: NCT03412773.

777TiP A phase III, double-blind, randomized study of pamiparib versus placebo as maintenance therapy in patients with inoperable, locally advanced, or metastatic gastric cancer that responded to platinum-based first-line chemotherapy

F. Ciardiello[1], Y-J. Bang[2], J. Bendell[3], A. Cervantes[4], R. Brachmann[5], K. Zhang[6], M. Raponi[7], H. Farin[8], L. Shen[9]

[1]Medical Oncology, University of Campania "Luigi Vanvitelli", Naples, Italy, [2]Medical Oncology, Seoul National University Hospital, Seoul, Republic of Korea, [3]GI Oncology Research, Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN, USA, [4]Medical Oncology, Instituto de Investigación Sanitaria INCLIVA, Valencia, Spain, [5]Clinical Development, BeiGene USA, Inc., Emeryville, CA, USA, [6]Biostatistics, BeiGene USA, Inc., Emeryville, CA, USA, [7]Translational Research and Biomarkers, BeiGene USA, Inc., Emeryville, CA, USA, [8]Clinical Development, BeiGene USA, Inc., Cambridge, MA, USA, [9]Medical Oncology, Beijing Cancer Hospital, Beijing, China

Background: Gastric cancer is the fifth most common cancer, and is the third leading cause of cancer deaths worldwide. In patients with locally advanced or metastatic gastric cancer, fluoropyrimidine- and platinum-based combination chemotherapy is first-line standard of care. Despite refinement in chemotherapy regimens, outcomes are poor and median survival after first-line treatment remains low. A subset of gastric cancers exhibit platinum sensitivity and genomic instability that is characteristic of homologous recombination deficiency (HRD). Poly(ADP-ribose) polymerase proteins 1 and 2 (PARP1/2) are involved in DNA damage repair, and their inhibition is cytotoxic for cells with HRD. Pamiparib (previously known as BGB-290) is a selective PARP1/2 inhibitor that crosses the blood-brain barrier, has shown potent DNA–PARP trapping, and has demonstrated antitumor activity in preclinical models. In early phase clinical studies (NCT02361723; NCT03333915), pamiparib was generally well tolerated and showed preliminary antitumor activity. These studies also established 60 mg orally twice daily as the recommended pivotal dose.

Trial design: This double-blind, placebo-controlled, randomized, multicenter phase 3 study (NCT03427814) conducted in Asia, Australia, Europe, and North America is designed to compare the efficacy, safety, and tolerability of pamiparib with placebo as maintenance therapy in ~540 patients with advanced gastric cancer who have responded to first-line, platinum-based chemotherapy. Patients who are ≤8 weeks after their last platinum dose of first-line chemotherapy will be randomized 1:1 to receive either pamiparib 60 mg twice daily or placebo. Patient randomization will be stratified by genomic loss of heterozygosity status (ie, high versus low), region, and ECOG status. Radiologic assessments will be centrally evaluated per RECIST every 8 weeks after first dose. The primary endpoint is progression-free survival; key secondary endpoints include safety/tolerability, overall survival, objective response rates, and duration of response.

Clinical trial identification: NCT03427814.

[1]Hematology-Oncology Practice Eppendorf (HOPE), University Cancer Center Hamburg (UCCH), Hamburg, Germany, [2]University Cancer Center Hamburg (UCCH), University Medical Center HH-Eppendorf, Hamburg, Germany, [3]III. Medizinischen Klinik, Rechts der Isar Hospital,TUM, Munich, Germany, [4]Medizinische Klinik m.S. Hämatologie, Onkologie und Tumorimmunologie, Universitätsklinik Charité, Campus Virchow Klinikum, Berlin, Germany, [5]Institute of Clinical Cancer Research, Nordwest-Krankenhaus, Frankfurt am Main, Germany, [6]Cancer Clinical Research Consulting, CCRC, Berlin, Germany, [7]HOPE, Hämatologisch-Onkologische Praxis Eppendorf, Hamburg, Germany

Background: Inhibition of PD-1 has demonstrated improved survival as single agent in refractory EGA compared to placebo. In 1st line HER2 negative EGA combination regimens of PD-1 inhibitors (i) with chemotherapy or CTLA4i are currently investigated. Since a survival benefit could not be shown for the addition of pertuzumab, the TOGA regimen with platinum, fluoropyrimidine and trastuzumab remains the standard of care in 1st line HER2+ EGA. Combination regimens with PD-1i +/- CTLA4i have not yet been evaluated in HER2+ EGA. Thus, the INTEGA trial will evaluate two trastuzumab and PD-1i based combinations to determine the best regimen to challenge the TOGA regimen in a phase 3 trial.

Trial design: INTEGA is a randomized exploratory phase II investigator initiated trial by the AIO esophagogastric working group with two experimental arms. Patients (pts) with previously untreated (for metastatic disease) HER2 + (IHC3+ or 2+/ISH+) EGA will be randomized to receive trastuzumab and nivolumab in combination with either mFOLFOX6 or ipilimumab (3mg/kg every 3 weeks). Treatment with nivolumab is limited to a maximum of 12 months, ipilimumab to 4 applications. Primary endpoint is 12month overall survival rate, which should be increased from 55% (TOGA regimen) to 70% in each arm. Based on a type I error of 5% and 80% power 41 pts per arm are required and with a 15% drop out rate overall 97 pts will be randomized. An early stopping rule will be applied in case of an increase in toxicity after the first 15 pts received at least two months of treatment. The trial is flanked by a large translational program including immunoprofiling to determine and correlate the respective immune response signatures with clonal dynamics. Recruitment has started in March 2018. Overall 40 German sites are planned. Conclusion: The INTEGA trial will determine the feasibility and efficacy of trastuzumab and nivolumab in combination with either mFOLFOX6 or ipilimumab in 1st line HER2+ EGA. The translational research program will shed light on the potential mode of action of these novel combinations.

Clinical trial identification: NCT03409848.

Background: Although standard treatment for locally advanced unresectable esophageal SCC (LAUEC) has been dCRT consisted of CDDP plus FU, treatment outcome is limited. In the phase II trial of induction chemotherapy (Cx) with DCF followed by conversion surgery (CS) or dCRT plus CS for patients (pts) with LAUEC, 39.6% of pts received R0 resection via CS and achieved better 3-year overall survival (OS) of 71.4% with manageable toxicity.

Trial design: Eligibility criteria include as follows; histologically proven SCC, cT4b or cT3 but highly suspicious of cT4b and/or unresectable lymph nodes metastasis (LNM) invading to adjacent organs, no distant metastasis except for supraclavicular LNM, age 20 to 75, and performance status 0-1. Pts are randomized into following two arms stratified by institution, invasion to adjacent organs (definitive versus suspicious) and supraclavicular LNM (yes versus no). Pts in arm A receive dCRT consisted of CDDP (70 mg/m^2/day, days 1 and 29) and FU (700 mg/m^2/day, days 1-4 and 29-32, civ) with concurrent radiotherapy (60 Gy/30 fr) followed by additional Cx (CDDP [80 mg/m^2/day, day 1 and 29] and FU [800 mg/m^2/day, days 1-5 and 29-33, civ]). Pts in arm B receive 3 courses of DCF (DOC [70 mg/m^2, day 1], CDDP [70 mg/m^2, day 1] and FU [750 mg/m^2, days 1–5] every 3 weeks) followed by CS if converted to be resectable, or dCRT same as Arm A if not converted to be resectable based on the radiological evaluation. Salvage surgery or endoscopic resection are acceptable in arm A (if residual, progressive, or recurring after dCRT) and in arm B (if converted to be resectable during or after dCRT). Primary endpoint is OS to confirm the superiority of arm B. We assumed 3-year OS with arm A to be 30% and expected a 12% increase for arm B. The planned sample size was calculated as a total of 230 pts (115 pts per arm) with a one-sided alpha of 5%, power of 70%, an accrual period of 4.5 years, and a follow-up period of 3 years. This trial was registered with UMIN-CTR, number UMIN000031165 and started in February 2018.

Clinical trial identification: UMIN000031165.

780TiP Phase II trial of perioperative PD-L1 inhibition with avelumab and mDCF chemotherapy for resectable locally advanced gastric and esophago-gastric adenocarcinoma

T. Alcindor[1], A. Awan[1], T. Opu[1], J. Asselah[2], M. Vanhuyse[3], C. Mueller[4], L. Ferri[4]

[1]Medicine & Oncology, McGill University Health Centre - Glen Site, Montreal, QC, Canada, [2]Oncology, The McGill University Health Centre - Glen Site, Montreal, QC, Canada, [3]Oncology, Cedars Cancer Center, Montreal, QC, Canada, [4]Surgery, The McGill University Health Centre - Glen Site, Montreal, QC, Canada

Background: Perioperative chemotherapy improves survival in locally advanced gastric and esophago-gastric adenocarcinoma (EGA), in comparison with surgery alone. The pathologic complete response rate (pCR) is as a possible surrogate for survival and is influenced by the chemotherapy regimen given. We and others have previously described the efficacy of docetaxel/cisplatin/fluorouracil (DCF) in the perioperative management of this cancer. Research by other groups has shown equivalent efficacy and lesser toxicity of a modified DCF regimen. Given the promising activity of immune checkpoint inhibitors in these malignancies, we hypothesize that the addition of immunotherapy with avelumab, an anti-PD-L1 agent, to mDCF chemotherapy (immunochemotherapy), will result in improved outcomes. Our trial is approved by Health Canada and our hospital Research Ethics Board. It is registered as NCT03288350 (www.clinicaltrials.gov).

Trial design: Eligible patients will receive neoadjuvant therapy consisting of 4 cycles of avelumab + mDCF, followed by surgery and assessment of pathologic response. Then they will receive 4 cycles of adjuvant therapy of mDCF + avelumab. Primary endpoint is pCR. Secondary endpoints are 2-year disease-free survival rate and incidence of non-hematological grade 3-4. Exploratory translational studies are planned. We hypothesize that immunochemotherapy will yield a pCR rate of 20% in comparison with 7% for chemotherapy only (historical data). Main inclusion criteria are : diagnosis of gastric or EGA adenocarcinoma, locally advanced disease, adequate organ function, performance status 0-1, stages Ib-III. Main exclusion criteria are: other histologies, metastatic disease, use of immunosuppressants, serious autoimmune disease, daily prednisone intake $>$ 10 mg or equivalent. To validate the hypothesis with power of 0.80 and α error of 0.05, 50 participants will be needed. Enrolment has started and is following a 2-stage Simon rule : accrual will stop if no more than 1 pCR is seen in the first 16 patients ; if more than 6/50 patients show pCR, the trial will be considered successful in that the alternate hypothesis cannot be rejected.

Clinical trial identification: NCT03288350, posted September 20, 2017.

Background: PC is an aggressive malignancy and the 4th cause of all cancer deaths worldwide. More than 30% of patients with PC are unresectable because of the local extension with a median overall survival (OS) of less than one year. The standard of care remains gemcitabine (gem) alone. 5FU, irinotecan, oxaliplatin (Folfirinox) is superior to gemcitabine in the treatment of metastatic PC, in terms of OS and progression-free survival (PFS).

Trial design: This phase 3, multicenter randomised study (NCT02539537) was designed to evaluate the efficacy of FOLFIRINOX versus gem in the treatment of locally advanced PC (LAPC). This study enrols patients $>$ 18 year of age, with cytologically or pathologically proven adenocarcinoma of the pancreas, who had a LAPC proven to be unresectable after multidisciplinary discussion, a performance status ECOG $<$ 2, normal hematologic, hepatic, and renal functions, adequate other vital functions; the tumour has to be measurable (RECIST criteria) and the patient has to give his informed

consent. The primary endpoint of this study is PFS; secondary endpoints include a composite index for induction treatment severe toxicity: biliary tract infection Grade3-4 + any grade 5 toxicities + induction chemotherapy interruption for toxicity, OS, time to treatment failure, quality of life, percentage of surgery with curative intent. Treatment regimens is: Arm A: gem 1000 mg/m^2 30-minute infusion, weekly for 7 weeks followed by one week rest and then weekly for 3 weeks followed by one week. Arm B: leucovorin 400 mg/m^2 D1, irinotecan 180 mg / m^2 D1, Oxaliplatin 85 mg / m^2 D1, 5 Fluorouracil 2400 mg/m^2 IV continuous infusion over 46 h (no bolus of 5FU), treatment repeated every two weeks for 4 months (12 cycles). Duration of treatment: 6 months in both arms. After this 6-month period, each center has to choose for its patients between 3 strategies: stop of treatment, maintenance chemotherapy with gem or capecitabine and radio-chemotherapy. At this time 74 among the 170 planned patients have been enrolled. The first IDMC meeting has recommended continuing the study without any change.

782TiP Atezolizumab + bevacizumab vs sorafenib in locally advanced or metastatic hepatocellular carcinoma: The randomised phase III study IMbrave150

M.P. Ducreux[1], A-L. Cheng[2], S. Qin[3], A.X. Zhu[4], M. Ikeda[5], T-Y. Kim[6], D-Z. Xu[7], W. Verret[8], J. Liu[7], R.S. Finn[9], P.R. Galle[10]

[1]Medical Oncology, Gustave Roussy, Villejuif, France, [2]Medical Oncology, National Taiwan University Hospital, Taipei, Taiwan, [3]Medical Oncology, People's Liberation Army Cancer Center, Nanjing, China, [4]Harvard Medical School, Massachusetts General Hospital, Boston, MA, USA, [5]Medical Oncology, National Cancer Center Hospital East, Kashiwa, Japan, [6]Medical Oncology, Seoul National University College of Medicine, Seoul, Republic of Korea, [7]Roche Product Development, F. Hoffman-La Roche Ltd., Shanghai, China, [8]Product Development Oncology, Genentech, Inc., South San Francisco, CA, USA, [9]Geffen School of Medicine, University of California, Los Angeles, CA, USA, [10]I. Medical Department, University Medical Center Mainz, Mainz, Germany

Background: Advanced hepatocellular carcinoma (HCC) is a disease of high unmet medical need. Despite considerable toxicities, sorafenib (sor) is the 1L standard of care. Single-agent inhibition of PD-L1/PD-1 or VEGF signalling has only modest activity in HCC, but in a Phase Ib study of atezolizumab (atezo; anti–PD-L1) + bevacizumab (bev; anti-VEGF) combination, a response rate of 61% with a manageable safety profile (Pishvaian ESMO 2018, submitted) is observed. Clinical benefit with atezo + bev was also seen in 1L renal cell carcinoma and 1L non-small cell lung cancer (Motzer ASCO GU 2018, Reck ESMO IO 2017). The potential synergy between atezo and bev may stem from bev's additional immunomodulatory effects in the tumour microenvironment (increased DC maturation, enhanced T-cell infiltration, reduced MDSCs and Tregs in tumours) that may potentiate the efficacy of atezo in re-invigorating the anti-tumour T-cell response.

Trial design: IMbrave150 is a global, multicentre, randomised, open-label, Phase III trial enrolling 1L patients (pts) with locally advanced or metastatic and/or unresectable HCC. Key inclusion/exclusion criteria are shown in the table. Pts will be randomised 2:1 to receive atezo (1200 mg) plus bev (15 mg/kg) IV Q3W or sor (400 mg) PO BID until loss of clinical benefit or unacceptable toxicity. Crossover is not allowed. Stratification factors are ECOG PS (0 vs 1), baseline alpha fetoprotein level (< 400 vs ≥ 400 ng/mL), macrovascular invasion and/or extrahepatic spread (presence vs absence) and region (Asia excluding Japan vs rest of world). Co-primary endpoints are investigator (INV)–assessed ORR (RECIST v1.1) and OS, which will be tested in parallel. Secondary endpoints are INV-assessed PFS, DOR and time to progression (TTP; RECIST v1.1), along with independent review facility (IRF)–assessed ORR, PFS, DOR and TTP (RECIST v1.1 and HCC mRECIST). Approximately 480 pts will be enrolled globally.

Table: 782TiP Eligibility criteria

Inclusion Criteria	Exclusion Criteria
- $\geq$ 1 measurable untreated lesion (per RECIST v1.1) - Naive to prior systemic therapy for HCC - Child-Pugh class A liver function - ECOG PS 0/1 - Adequate haematologic and end-organ function	- Co-infection of HBV and HCV - Pts with untreated varices with bleeding or high risk for bleeding - History of autoimmune disease or immune deficiency - Inadequately controlled arterial hypertension

Clinical trial identification: NCT03434379.

Background: Despite significant improvements in the treatment of early HCC, curative therapies remain associated with high recurrence rates (≈70% at 5 y) (EASL. J Hepatol 2018), and therefore, adjuvant therapies are needed. Nivolumab (NIVO) has demonstrated durable tumor responses and a manageable safety profile in patients (pts) with advanced HCC, regardless of HCC etiology (CheckMate-040 study) (El-Khoueiry, et al. Lancet 2017). Additionally, NIVO has shown clinical benefit as adjuvant therapy in melanoma (CheckMate-238 study) (Weber, et al. NEJM 2017). This phase 3, randomized, double-blind, placebo-controlled study will evaluate the safety and efficacy of adjuvant NIVO in pts with HCC who are at high risk of recurrence after curative hepatic resection or ablation, a population for whom no effective therapies are currently available.

Trial design: The trial will include 530 pts aged $\geq$18 y with a first diagnosis of HCC (any etiology) who are at high risk for HCC recurrence after curative resection or ablation, and who have well-preserved liver function (Child-Pugh score 5 or 6), randomized (1:1) to receive NIVO (480 mg intravenous Q4W) or placebo (PBO). Additional eligibility criteria include Eastern Cooperative Oncology Group performance status of 0 or 1, no evidence of tumor metastasis, no prior therapy for HCC (including loco-regional therapies), and no liver transplant. Pts will be treated until recurrence per blinded independent central review (BICR) assessment, unacceptable toxicity, or withdrawal, or for up to 1 y total duration. Survival follow-up will continue for up to 5 y. The primary endpoint is to compare recurrence-free survival, per BICR assessment. Secondary endpoints include overall survival and time to recurrence (defined as time from randomization to first documented disease recurrence). The trial will be open for enrollment in 20 countries worldwide and is currently recruiting.

Clinical trial identification: NCT03383458.

Background: Pembro is FDA-approved for the treatment of pts with recurrent locally advanced or metastatic G/GEJ adenocarcinoma whose disease has progressed on or after $\geq$2 prior therapies and whose tumors express PD-L1 (combined positive score $\geq$1). Combining chemo with pembro in the neoadjuvant/adjuvant setting may benefit pts with locally advanced, resectable G/GEJ cancer. KEYNOTE-585 (NCT03221426) is a phase 3, randomized, double-blind study of chemo + pembro vs chemo + placebo as neoadjuvant/adjuvant treatment for locally advanced resectable G/GEJ cancer.

Trial design: Eligibility criteria are age $\geq$18 years; previously untreated, resectable G/GEJ adenocarcinoma (pts with Siewert type 1 tumors are eligible if initial treatment is planned perioperative chemo and resection), with no evidence of metastatic disease; planned surgery after preoperative chemo; adequate organ function; ECOG performance status 0/1; and no active autoimmune disease. Pts will be randomly assigned 1:1 to receive chemo + pembro (arm 1) or chemo + placebo (arm 2). Pts will receive neoadjuvant (preoperative) chemo + pembro every 3 weeks (Q3W) for 3 cycles or chemo + placebo Q3W for 3 cycles followed by surgery, then adjuvant chemo + pembro Q3W for 3 cycles or chemo + placebo Q3W for 3 cycles, then monotherapy with pembro or placebo Q3W for 11 cycles; overall treatment is up to 17 cycles. Chemo is cisplatin 80 mg/m^2 IV on day 1 + either capecitabine 1000 mg/m^2 orally twice daily $\times$ 14 days or 5-fluorouracil (5-FU) 800 mg/m^2 IV daily $\times$ 5 days (investigator's choice). Pembro 200 mg IV is given on day 1. Adjuvant monotherapy is pembro (arm 1) or placebo (arm 2). In a separate safety cohort, 5-FU 2600 mg/m^2 IV + docetaxel 50 mg/m^2 IV + oxaliplatin 85 mg/m^2 IV + leucovorin 200 mg/m^2 IV (FLOT) is being studied as a potential chemo option. Primary end points are overall survival, event-free survival per central review, and rate of pathologic complete response (no invasive disease and histologically negative nodes). Adverse events are graded and monitored for up to 90 days after treatment. Pts will be followed up for survival status. Planned enrollment is 860 pts.

Clinical trial identification: NCT03221426. Study start date was October 9, 2017.

Editorial acknowledgement: Medical writing and/or editorial assistance was provided by Sarita Shaevitz, PhD, of the ApotheCom pembrolizumab team (Yardley, PA, USA).

Background: In the phase 1b KEYNOTE-028 study, pembrolizumab monotherapy demonstrated manageable safety and durable antitumor activity in heavily pretreated pts with PD-L1–positive advanced esophageal carcinoma. KEYNOTE-590 (ClinicalTrials.gov, NCT03189719) is a phase 3, randomized, double-blind, multicenter study of cisplatin and 5-fluorouracil plus pembrolizumab vs cisplatin and 5-fluorouracil plus placebo in pts with previously untreated advanced E/EGJ carcinoma.

Trial design: Eligibility criteria are age $\geq$18 years; locally advanced unresectable or metastatic adenocarcinoma or squamous cell carcinoma of the esophagus or metastatic Siewert type 1 adenocarcinoma of the EGJ; no prior therapy for advanced disease; measurable disease per RECIST v1.1; ECOG performance status 0/1; adequate organ function; no autoimmune disease; no active infection; and provision of tissue sample for evaluation of PD-L1 expression and gene expression profiling. Pts will be randomly assigned 1:1 to receive cisplatin 80 mg/m^2 IV every 3 weeks (Q3W) (capped at 6 doses) plus 5-fluorouracil 800 mg/m^2 continuous IV on days 1-5 Q3W plus pembrolizumab 200 mg IV Q3W or cisplatin 80 mg/m^2 IV Q3W (capped at 6 doses) plus 5-fluorouracil 800 mg/m^2 continuous IV on days 1-5 Q3W plus placebo Q3W IV. Pts will continue treatment for up to 2 years. Crossover from one treatment arm to another is not permitted. Coprimary end points are overall survival and progression-free survival per RECIST v1.1 by blinded independent central review in all pts and in pts with PD-L1–positive tumor expression (combined positive score $\geq$10%). Secondary end points include objective response rate per RECIST v1.1, duration of response, safety, and health-related quality of life. Response will be assessed using computed tomography (preferred) or magnetic resonance imaging every 9 weeks by central imaging review per RECIST v1.1. Adverse events (AEs) will be graded per NCI CTCAE v4.0 and monitored for at least 30 days (90 days for serious AEs) after the last dose of study treatment. Pts will be followed up for survival status. Planned enrollment is approximately 700 pts.

Clinical trial identification: NCT03189719. The study start date was July 25, 2017.

786TiP Prospective multicenter feasibility study of laparoscopic sentinel basin dissection after endoscopic submucosal dissection for early gastric cancer

K.W. Ryu[1], B.W. Eom[1], H.M. Yoon[1], Y-W. Kim[2], J.S. Min[3], G.S. Cho[4], I. Cho[4], Y.J. Lee[5], J-H. Park[5], H. Hur[6], Y.K. Park[7], O. Jeong[7], M.R. Jung[7], J.H. Lee[8], J.Y. An[8]

[1]Center for Gastric Cancer, National Cancer Center, Gyeonggi-do, Republic of Korea, [2]Graduate School of Cancer Science and Policy, National Cancer Center, Gyeonggi-do, Republic of Korea, [3]Department of Surgery, Dongnam Institute of Radiological and Medical Sciences, Cancer Center, Busan, Republic of Korea, [4]Department of Surgery, Soonchunhyang University College of Medicine, Bucheon, Republic of Korea, [5]Department of Surgery, Gyeongsang National University, Jinju, Republic of Korea, [6]Department of Surgery, Ajou University School of Medicine, Suwon, Republic of Korea, [7]Department of Surgery, Chonnam National University Hwasun Hospital, Hwasun, Republic of Korea, [8]Department of Surgery, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea

Background: Although standard radical gastrectomy is recommended after non-curative resection of endoscopic submucosal dissection for early gastric cancer, in most cases, no residual tumor and no lymph node metastasis was revealed after surgery. Lymph node metastasis can be evaluated using sentinel basin dissection, however, there was no evidence that sentinel lymph node concept can be applied after endoscopic resection.

Trial design: This trial is an investigator-initiated, multicenter prospective phase II trial. Patients who underwent endoscopic submucosal dissection for clinical stage T1N0M0 gastric cancer and the resections were proven as non-curative were eligible. Qualified investigators who completed the prior phase III trial (Senorita I) are exclusively allowed to participate in this study. Intraoperative endoscopic submucosal injection of a standardized dual tracer was administered to normal mucosa nearby the scar, and sentinel basins were detected using gamma-probe and dissected. Then, standard laparoscopic gastrectomy with lymphadenectomy was performed. Sample size was calculated based on inferior confidence interval of detection rate of 95%, and estimated accrual was 237. The primary and secondary end-points were detection rate and sensitivity of sentinel basin, respectively. This study is expected to evaluate the feasibility of laparoscopic sentinel basin dissection after endoscopic submucosal dissection. If the feasibility is identified, multicenter phase III trial will be started comparing laparoscopic sentinel node navigation surgery versus laparoscopic standard gastrectomy in early gastric cancer after endoscopic resection.

Clinical trial identification: NCT03123042; registered April 21st, 2017.

Legal entity responsible for the study: Sentinel Node Oriented Tailored Approach (SENORITA) Study Group.

Funding: Has not received any funding.

Disclosure: All authors have declared no conflicts of interest.

787TiP A phase III study of adjuvant docetaxel, capecitabine and oxaliplatin triplet vs capecitabine and oxaliplatin doublet in patients with curatively resected stage IIIB or IV(M0) (AJCC 6th ed) gastric adenocarcinoma (TRIUMPH, KCSG ST14-05)

M-H. Ryu[1], D.Y. Zang[2], K-W. Lee[3], B.Y. Shim[4], M.H. Lee[5], S.Y. Rha[6], Y-K. Kang[1]

[1]Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [2]Division of Hematology and Oncology, Hallym University Sacred Heart Hospital, Hallym University College of Medicine, Anyang, Republic of Korea, [3]Department of Internal Medicine, Seoul National University Bundang Hospital, Seoul, Republic of Korea, [4]Medical Oncology, St. Vincent's Hospital, Suwon, Republic of Korea, [5]Internal medicine, Inha University Hospital, Incheon, Republic of Korea, [6]Internal Medicine, Yonsei Cancer Center, Seoul, Republic of Korea

Background: In stage IIIB or IV(M0) (by AJCC 6th edition) gastric cancer (GC), recurrence rate is higher than 50% even with curative D2 surgery and current standard adjuvant chemotherapy with capecitabine and oxaliplatin (XO) or S-1. Accordingly, more effective treatment is needed to reduce recurrence rate in these far advanced GCs. Our previous phase II study of adjuvant chemotherapy in stage IIIB or IV(M0) GC (Yoon S, et al. Gastric Cancer. 2017;20:182) suggested that docetaxel-containing triplet was safe and might be better in terms of recurrence-free survival (RFS) when compared with historic data of fluoropyrimidine plus platinum or fluoropyrimidine alone. Based on this background, a phase III randomized study to evaluate adjuvant docetaxel, capecitabine and oxaliplatin (DXO) triplet vs current standard XO in patients (pts) with curatively resected stage IIIB or IV(M0) GC has been initiated (NCT01935778).

Trial design: Since October 2013, pts with curatively resected stage IIIB or IV(M0) gastric or gastroesophageal junction adenocarcinoma have been recruited from 6 sites in Korean Cancer Study Group (KCSG). Other key eligibility criteria include ECOG performance status 0-1, age of 20-75 years, D2 surgery, and adequate organ functions. Three to 8 weeks after surgery, pts are randomized 1:1 in open label to adjuvant DXO arm vs XO arm. Stratification factors for randomization include pathologic stage (IIIB vs IV(M0)) and extent of gastrectomy (total vs subtotal). In DXO arm, pts receive docetaxel 60 mg/m^2 i.v. on day 1, capecitabine 800 mg/m^2 p.o. twice daily on days 1-14, and oxaliplatin 100 mg/m^2 i.v. on day 1, every 3 weeks for 6 cycles; in XO arm, pts receive capecitabine 1000 mg/m^2 p.o. twice daily on days 1-14, and oxaliplatin 130 mg/m^2 i.v. on day 1, every 3 weeks for 8 cycles. Primary endpoint is 3-year RFS rate. Secondary endpoints include overall survival and safety. With power of 80% and two-sided α level of 5%, 183 events are required to detect 15% difference in 3-year RFS rate, i.e., 50% in DXO arm vs 35% in XO arm (HR = 0.66). With 10% of drop-out rate, target enrollment is 286 subjects.

Clinical trial identification: NCT01935778.

788TiP ACELARATE: A randomised phase III, open label, clinical study comparing NUC-1031 with gemcitabine in patients with metastatic pancreatic carcinoma

D. Harrison Palmer[1], P.J. Ross[2], P. Silcocks[1], W. Greenhalf[3], O. Faluyi[4], Y.T. Ma[5], J. Wadsley[6], C. Rawcliffe[1], J. Neoptolemos[7], J.W. Valle[8], H. Wasan[9], N. Starling[10], K. Patel[11], J. Bridgewater[12]

Background: Pancreatic ductal adenocarcinoma (PDAC) is predicted to be the second leading cause of cancer-related death by 2030 (Rahib et al, 2014). The overall 5-year survival rate is currently less than 7%. Gemcitabine is used for patients who are not suitable for combination therapy, but the response is poor at less than 10% (Conroy et al, 2011). Gemcitabine efficacy is limited due to intrinsic or acquired resistance mechanisms associated with transport, activation and breakdown. NUC-1031, a phosphoramidate transformation of gemcitabine, is designed to overcome the three key resistance mechanisms responsible for a poor survival prognosis to gemcitabine. In a Phase I study, NUC-1031 was well tolerated and demonstrated anti-tumour activity across a wide range of advanced cancers, including PDAC (Blagden et al, ASCO 2015). This ongoing Phase III study is designed to compare NUC-1031 with gemcitabine as first-line treatment in patients with PDAC who are unsuitable for combination chemotherapy.

Trial design: First-line patients with metastatic PDAC are being randomised to either NUC-1031 (825 mg/m^2) or gemcitabine (1000 mg/m^2) on days 1, 8 and 15 of a 28-day cycle until disease progression. Patients unsuitable for combination chemotherapy with a PS of 0-2 are eligible. Over 125 patients have been randomised across more than 20 centres. To detect a hazard ratio of 0.705 between the two arms, 270 events must be obtained from 328 patients, assuming a median survival of 6 months in the control (gemcitabine) arm. The primary outcome measure is overall survival. Secondary outcome measures include progression free survival, objective response rate, disease control rate, quality of life and safety. Translational research will explore the use of biomarkers for predictive benefit of NUC-1031 over gemcitabine.

Clinical trial identification: ISRCTN16765355.

Background: Poor outcome in PDA is associated with high stromal HA content (HA-high). In vitro, PEGPH20 degrades tumor HA and may increase access and efficacy of tumor therapies. In a Phase 2 study, PEGPH20 + standarddose nabpaclitaxel/gemcitabine (PAG) improved PFS over chemotherapy alone (AG) in tumors retrospectively identified as HA-high. In this Phase 3 study, we investigate the efficacy and safety of PAG vs AG in patients with HA-high, previously untreated, Stage IV PDA. There are 2 primary endpoints: PFS and OS. Secondary endpoints are objective response rate, duration of response, and safety.

Trial design: Patients $\geq$18 years with untreated HA-high, Stage IV PDA and ECOG PS 0–1 are eligible. Exclusion criteria include a history of thromboembolic events (TEs) or cerebrovascular accident. Patients ($N \leq 570$) are randomized 2:1 to PAG (PEGPH20=3.0 μg/kg + A = 125 mg/m^2 + G = 1000 mg/m^2) or AG (A = 125 mg/m^2 + G = 1000 mg/m^2) and stratified by region (North America/Europe/Other). HA-high status is prospectively determined by the RxDx Assay and scoring methodology codeveloped by Ventana Medical Systems, Inc., and Halozyme Therapeutics, Inc. The assay identifies HA in the extracellular matrix, with PDA defined as HA-high when the HA score is $\geq$ 50% based on HA staining. Treatment is provided in 4-week cycles (3 weeks on treatment, 1 week off) until disease progression, unacceptable toxicity, death, or consent withdrawal. PEGPH20 or placebo are dosed twice-weekly (Cycle 1) then weekly ($\geq$Cycle 2); AG is dosed weekly (all cycles). Dexamethasone is used before and after PEGPH20 to reduce PEGPH20-related musculoskeletal symptoms, and enoxaparin prophylaxis is administered subcutaneously once daily at 1 mg/kg to minimize TEs. Tumor response is independently assessed per RECIST v1.1. Adverse events are graded per NCI CTCAE v4.03. An independent data monitoring committee is overseeing the safety data. The trial was initiated in 2016, is open at $>$ 200 study sites across $>$20 countries, and is expected to complete by 2020.

790TiP A phase II clinical investigation of BPM31510-IV (ubidecarenone) in patients with advanced pancreatic cancer

A.A. Niewiarowska[1], D.M. Lucius[2], R. Sarangarajan[3], N.R. Narain[4], R. Ramanathan[5], P. Ritch[6], J. Strauss[7], M. Kundranda[8], D. Propper[9]

[1]Hematology, Vita Medical Associates, Bethlehem, PA, USA, [2]Clinical Operations, BERG, LLC, Framingham, MA, USA, [3]Biosystems, BERG, LLC, Framingham, MA, USA, [4]Biosystems, Analytics, & Precision Medicine, BERG, LLC, Framingham, MA, USA, [5]Oncology, Mayo Clinic Cancer Center, Scottsdale, AZ, USA, [6]Hematology and Oncology, Medical College of Wisconsin, Milwaukee, WI, USA, [7]Oncology, Mary Crowley Medical Research Center, Dallas, TX, USA, [8]Gastrointestinal Medical Oncology, Medical Oncology, Banner MD Anderson Cancer Center, Gilbert, AZ, USA, [9]Oncology, St. Bartholomew's Hospital, London, UK

Background: BPM31510-IV is an ubidecarenone containing intravenous nanodispersion targeting the metabolic machinery in cancer, shifting bioenergetics from lactate dependency towards mitochondrial OxPhos and reversing the Warburg effect. BPM31510-IV enables delivery of ubidecarenone preferentially into cancer cell mitochondria, generating reactive oxygen species and activation of apoptosis. In a phase I study, BPM31510-IV was well-tolerated as a monotherapy, and in combination with gemcitabine, with an established maximum tolerated dose (MTD) of 110mg/kg and thus, formed the basis for the Phase 2 investigation.

Trial design: In this study eligible patients (aged $\geq$ 18 y) relapsed/refractory to standard treatment for advanced metastatic pancreatic cancer and meeting inclusion/exclusion criteria receives either two 72 hr infusions of 110mg/kg BPM31510-IV or in combination with gemcitabine (1000 mg/m^3 over 30 min, weekly x 3 weeks every 28 days). Tumor response is evaluated at wk 10, and then every 8 wks. This study occurs in two parts: Part 1 is designed to enroll 10 patients in the BPM31510-IV (monotherapy arm) and 10 patients in the BPM31510-IV plus gemcitabine (combination therapy arm) with intent to enroll an additional 15 patients (Part 2) into the applicable treatment arm(s). Endpoints will include overall response rate in both groups along with overall survival, progression-free survival, and time to progression. Additionally, patient reported Quality of Life using the validated FACT-HEP as well as tumor response measured by CA 19-9 levels will be combined with multi-omic molecular profiling to assess adaptive molecular responses. An exploratory objective of this study is to comprehensively perform multi-omic profiling for identification of biomarker panels for patient stratification for later stages of clinical development.

Clinical trial identification: NCT02650804.

800P **The prognostic value of the proportion and subtype patterns of intraductal carcinoma of the prostate in patients with *de novo* metastatic prostate cancer: A propensity score matching study**

J. Zhao, J. Liu, G. Sun, P. Shen, J. Chen, X. Zhang, H. Zhang, Z. Liu, Y. Bao, Y. Yang, P. Zhao, K. Shu, H. Zeng

Department of Urology, Institute of Urology, West China Hospital, SiChuan Univer, West China Hospital, Sichuan University, Chengdu, China

Background: Intraductal carcinoma of the prostate (IDC-P) is an adverse prognosticator of prostate cancer (PCa). However, the role of IDC-P proportion and architectural patterns in patient outcome remain unclear.

Methods: Data of 644 *de novo* metastatic PCa (mPCa) patients between 2010-2017 were retrospectively analyzed. IDC-P was identified from 12-core prostate biopsy. IDC-P proportion were calculated. IDC-P were classified into two architectural patterns according to the 2016 WHO classification: pattern-1 (loose cribriform or micropapillary) and pattern-2 (solid or dense cribriform). Propensity-score matching (PSM) was conducted to balance the baseline characteristics between patients with and without IDC-P. Kaplan-Meier curves and COX regression were utilized in survival analysis. The endpoints were castration-resistant PCa free survival (CFS) and overall survival (OS).

Table: 800P The CFS for patients of different IDC-P groups and patients without IDC-P after propensity-score matching

A. The survival outcomes for *de novo* mPCa patients of different IDC-P groups

IDC-P group	CASE	Median CFS (95%CI)	Log-rank test				
			Group 0	Group 1	Group 2	Group 3	Group 4
Group 0	180 (50.0%)	17.8 (15.3-20.3)	-	0.663	0.019	0.104	0.000
IDC-P-Group 1	41 (11.4%)	18.0 (12.7-23.2)	0.663	-	0.194	0.264	0.001
IDC-P-Group 2	58 (16.1%)	14.2 (10.1-18.3)	0.019	0.194	-	0.785	0.014
IDC-P-Group 3	22 (6.1%)	11.9 (6.0-17.8)	0.104	0.264	0.785	-	0.080
IDC-P-Group 4	59 (16.4%)	8.4 (6.7-10.1)	0.000	0.001	0.014	0.080	-
IDC-P group	**CASE**	**Median OS (95%CI)**	**Log-rank test**				
			Group 0	**Group 1**	**Group 2**	**Group 3**	**Group 4**
Group 0	180 (50.0%)	68.8 (58.9-78.7)	-	0.655	0.098	0.028	0.000
IDC-P-Group 1	41 (11.4%)	Not reached	0.655	-	0.569	0.201	0.049
IDC-P-Group 2	58 (16.1%)	45.9 (29.7-62.1)	0.098	0.569	-	0.530	0.061
IDC-P-Group 3	22 (6.1%)	39.7 (25.1-54.3)	0.028	0.201	0.530	-	0.441
IDC-P-Group 4	59 (16.4%)	29.9 (20.7-39.2)	0.000	0.049	0.061	0.441	-

B. The survival outcomes for *de novo* mPCa patients of different risk group

Risk group	CASE	Median CFS (95%CI)	Log-rank test		
			Group 1 or 0	Group 2 or 3	Group 4
Favorable-risk: Group 1 or 0	221 (61.4%)	17.8 (15.5-20.1)	-	0.009	0.000
Intermediate-risk: Group 2 or 3	80 (22.2%)	14.1 (10.3-17.9)	0.009	-	0.007
Poor-risk: Group 4	59 (16.4%)	8.4 (6.7-10.1)	0.000	0.007	-
Risk group	**CASE**	**Median OS (95%CI)**	**Log-rank test**		
			Group 1 or 0	**Group 2 or 3**	**Group 4**
Favorable-risk: Group 1 or 0	221 (61.4%)	72.6 (63.8-72.6)	-	0.027	0.000
Intermediate-risk: Group 2 or 3	80 (22.2%)	43.2 (35.2-51.1)	0.027	-	0.080
Poor-risk: Group 4	59 (16.4%)	29.9 (20.7-39.2)	0.000	0.080	-

CFS: CRPC-free survival; OS: Overall survival; IDC-P: Intraductal carcinoma of the prostate; CI: Confidence interval; mPCa: metastatic prostate cancer

Results: Totally, 180/644 (28.0%) patients harboured IDC-P. IDC-P ≥10% (CFS: HR: 2.27, p < 0.001; OS: HR: 2.63, p < 0.001) and IDC-P pattern-2 (CFS: HR: 1.98, p < 0.001; OS: HR: 2.11, $p = 0.003$) were independently associated with worse prognosis in the post-PSM cohort. Based on these two risk factors, all men could be classified into five groups with significant differences in survival (Table 1). Patients in Group 0 (Without IDC-P) and IDC-P-Group 1 (IDC-P < 10% AND IDC-P pattern-1) had favorable mCFS (18.0- vs. 17.8-Mo, $p = 0.663$) and mOS (68.8-Mo vs. Not reached, $p = 0.655$), while men of IDC-P-Group 4 (IDC-P ≥ 10% AND IDC-P pattern-2) harboured the worst outcomes (mCFS: 8.4-Mo; mOS: 29.9-Mo). IDC-P-Group 2 (IDC-P < 10% AND IDC-P pattern-2; mCFS: 14.2-Mo; mOS: 45.9-Mo) and IDC-P-Group 3 (IDC-P ≥ 10% AND IDC-P pattern-1; mCFS: 11.9-Mo; mOS: 39.7-Mo) had intermediate prognosis.

Conclusions: IDC-P proportion ≥10% and pattern-2 were two unfavorable prognosticators for mPCa. Pathological reporting criterion based on IDC-P could further improve the prediction of patient outcome and optimize treatment decision.

Lurie Comprehensive Cancer Center, Northwestern University Feinberg School of Medicine, Chicago, IL, USA, [6]Medicine, University of Minnesota, Minneapolis, MN, USA, [7]Medical Oncology, Moffitt Comprehensive Cancer Center, Tampa, FL, USA, [8]Medical Oncology, City of Hope, Duarte, CA, USA, [9]Translation and Clinical Science Program / Oncology, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA, USA, [10]Oncology, US Oncology Research c/o Comprehensive Cancer Crts of NV, Las Vegas, NV, USA, [11]Urology, Christus Health, San Antonio, TX, USA, [12]Oncology/ Internal Medicine, Huntsman Cancer Institute, Salt Lake City, UT, USA

Background: BMB are independently prognostic for survival in men with metastatic castration resistant PC. It is unclear whether prognostic or predictive value of BMB applies to an earlier HSPC state. We prospectively assessed BMB in men enrolled in S1216, a phase III trial of ADT +/- orteronel with an ultimate goal to identify HSPC patient (pt) subsets defined by BMB that have differential survival outcomes. Here we report initial results of baseline BMB from S1216 & their relationship to clinical variables.

Methods: Bone resorption [C-telopeptide(CTx) & Pyridinoline (PYD)] & formation markers [C-terminal collagen propeptide (CICP) & bone alkaline phosphatase (BAP)] were measured. Elevated BMB was defined as above median or in upper quartile for each BMB. Men were grouped as having all four, 1-3, or no BMB elevated. Frequency tables of BMB distribution across pt subsets were generated. To

account for multiple comparisons, a p-value of < 0.001 was considered potentially significant.

Results: Of 1,313 men, 799 had baseline BMB. Pt characteristics [median (range) or n (%)]: age 67y (19-92); PSA 29 ng/dL (2-6710); Gleason >7: n = 479 (64%); bone mets: 604 (76%); bisphos/denosumab: 44 (5.5%); Zubrod PS 0: 547 (68%); & minimal disease extent: 389 (49%). Median BMB: CTx 0.46 ng/mL (0.03-12.2); PYD 1.68 nmol/L (0.35-17.5); CICP 116 ng/mL (0.25-3360); BAP 1.66 u/L (0-1001). At least one BMB was > median in 87% & in top quartile in 57%. In 604 w/ bone mets, 540 had at least 1 BMB > median while distribution of BMB elevation >median differed significantly w/ in groups defined by PSA ($p < 0.0001$), Gleason score ($p = 0.0001$), PS ($p < 0.0001$) & disease extent ($p < 0.0001$). For example, in 292 with PSA>29, 30% had all 4 BMB elevated; in those with PSA < 29, only 6% had all 4 elevated. BMB distribution in all men did not differ within race/ethnicity, age, & bisphos/denosumab groupings. Trends were similar when BMB upper quartile was used.

Conclusions: In men with HSPC initiating ADT, at least one BMB was elevated in 87%. Differences in BMB distribution were seen within pre-defined subsets, with BMB elevation tracking with higher tumor grade, disease burden & lower PS. Assessment of BMB association with patient outcomes is planned.

802P Comparative efficacy and cost-effectiveness of maximum androgen blockade (MAB), docetaxel with androgen deprivation therapy (ADT), and ADT alone for the treatment of metastatic hormone-sensitive prostate cancer (mHSPC) in China

W. Jiang[1], S. Qu[2], Y. Liu[2], X. Yao[3], M. Liu[4]

[1]Department of Urology, Fujian Medical University Union Hospital, Fuzhou, China, [2]Real-World Insights, IQVIA, Shanghai, China, [3]Health Economics & Outcome Research, Sanofi, Shanghai, China, [4]Department of Pharmacy, Fujian Medical University Union Hospital, Fuzhou, China

Background: The study aims to compare the efficacy and cost-effectiveness of maximum androgen blockade (MAB), docetaxel with androgen deprivation therapy (Doce-ADT), and ADT alone for the treatment of patients with metastatic hormone-sensitive prostate cancer (mHSPC) from healthcare system perspective in China.

Methods: English and Chinese databases were systematically searched for head-to-head randomized controlled trials among the 3 therapies up to January 30th 2018. The network meta-analysis was conducted for overall survival (OS) and progression-free survival (PFS). A Markov model with a lifetime survival projection was adopted for economic evaluation. The quality-adjusted life years (QALYs), direct medical costs and incremental cost-effectiveness ratios (ICERs) were reported. One-way and probabilistic sensitivity analyses (PSA) were used to test the robustness of the results.

Results: Nine RCTs involving 5861 patients were included: 1181 (20%) patients with Doce-ADT, 1463 (25%) patients with MAB, and 3217 (55%) patients with ADT alone. The hazard ratios for PFS and OS were 0.625 (95% CI: 0.565-0.690) and 0.782 (95% CI: 0.700-0.876) respectively for Doce-ADT versus ADT-alone; 0.823 (95% CI: 0.701-0.961) and 0.867 (95% CI: 0.790-0.949) for MAB versus ADT alone; and 0.764 (95% CI: 0.630-0.916) and 0.904 (95% CI: 0.778-1.046) for Doce-ADT vs. MAB. The cost-effectiveness analysis showed that Doce-ADT, MAB and ADT alone were associated with 5.03, 4.56 and 4.02 QALYs, at an average cost of RMB 423,109, 397,440 and 326,771 per patient, respectively. [GM/1] Therefore, Doce-ADT was cost-effective with an ICER of RMB 95,247 and RMB 54,095 per QALY gained compared with MAB and ADT alone, respectively. MAB was cost-effective with an ICER of RMB 131,617 per QALY gained compared with ADT alone. Sensitivity analyses confirmed the results.

Conclusions: As the first study comparing the three therapies treating mHSPC patients in China, the study suggests that Doce-ADT is likely to be the best option from both clinical outcomes and economic evaluation perspectives, followed by MAB.

Legal entity responsible for the study: IQVIA.

Funding: This study was funded by Sanofi China.

803P Randomized trial of androgen deprivation therapy (ADT) + enzalutamide (Arm A) versus ADT + bicalutamide (Arm B) in metastatic hormone sensitive prostate cancer (mHSPC)

U.N. Vaishampayan[1], L. Heilbrun[2], P. Monk[3], G. Sonpavde[4], S. Tejwani[5], E.I. Heath[6], J. Fontana[2], S. Chinni[2]

[1]Oncology, Karmanos Cancer Institute, Detroit, MI, USA, [2]Oncology, Karmanos Cancer Center, Detroit, MI, USA, [3]Oncology, Ohio State University, Columbus, OH, USA, [4]Medical Oncology, Dana Farber Cancer Institute, Boston, MA, USA, [5]Oncology, Henry Ford Hospital, Detroit, MI, USA, [6]Oncology, Karmanos Cancer Center, Detroit, MI, USA

Background: The addition of abiraterone or docetaxel has shown overall survival (OS) benefit in mHSPC. There is adequate rationale for clinical efficacy of enzalutamide and ADT combination in mHSPC. We compared the combination of enzalutamide (Arm A) or bicalutamide (Arm B), each with ADT in mHSPC.

Methods: The primary endpoint was the seven month PSA remission (SMPR), with PSA nadir of < 4 ng/ml, as this is an accepted surrogate for overall survival (OS) outcomes. Secondary endpoints were toxicities, biochemical and radiologic progression free survival (PFS), and OS. Stratification was by presence of bone pain (yes/no) and race; (AA or other). PSA was monitored monthly for first 7 months and then every 3 months. Metastatic site biopsies were mandatory pretherapy and optional post therapy.

Results: 71 men; 29 African American (AA),41 Caucasian and 1 Asian were enrolled. The median age was 67 years (range 46-87 years) and median baseline PSA was 56.3 ng/ml in Arm A (4.2- 10,431 ng/ml) and 60 (4.9-12,030 ng/ml) in Arm B. 26 pts (39%) had bone pain and 37(52%) had extensive disease. Predominant grade 3+ adverse events on Arm A were: Hypertension (13%), infection (7%), and syncope (7%) and on Arm B were: Hypertension (21%), Fatigue (7%), and Hematuria (7%). No seizures were noted. PSA nadir < 4ng/ml at month 7 was achieved in 29/31 (94%) pts in arm A and 16/24 (67%) pts in arm B. 53% on arm A and 43% on Arm B continue to maintain PSA< 4 ng/ml. 4 (11%) deaths have occurred on enzalutamide arm as compared to 13 (37.1%) deaths on Arm B. Among AA patients, SMPR was 100% on Arm A and 46% on Arm B. 53 (75%) biopsy samples had tumor tissue available. TMPRSS-ERG fusion gene and CXCR4 expression and androgen biosynthetic enzyme levels were determined in metastatic biopsies. Patients with low copy number of ERG had an increased likelihood of SMPR (19/20 or 95%) as compared to high copy number (14/20 or 70%).

Conclusions: Early enzalutamide use in mHSPC improved PSA remission rates and has the potential to subsequently improve OS outcomes High ERG copy number was associated with decreased SMPR. This is the first randomized trial to report efficacy results of the combination of ADT and enzalutamide compared with ADT and bicalutamide in mHSPC.

Background: Compared with PBO, APA prolongs the median metastasis-free survival (MFS) by > 2 y (HR = 0.30; 95% CI, 0.24-0.36), and provids a 55% reduction in the risk of symptomatic progression (Sx PD) (HR = 0.45; 95% CI, 0.32-0.63) in patients (pts) with nmCRPC (SPARTAN study, Smith MR, et al. NEJM 2018), with no decline in HRQoL in either treatment group up to the time of developing distant metastases (Mets). Here, we report pt HRQoL following PD.

Methods: 1207 pts (median age, both arms: 74 y) with nmCRPC were randomized 2:1 to APA (240 mg QD) or PBO. ADT was continued in all pts. HRQoL was assessed using

Table: 804P PRO group mean scores

	APA			PBO		
	Baseline	**Before Mets**	**After Mets[a]**	**Baseline**	**Before Mets**	**After Mets[a]**
All pts, n	797	772	157	396	384	184
Group mean (SE)						
FACT-P FACT-G	117.2 (0.7) 84.1 (0.4)	117.4 (0.7) 83.9 (0.5)	112.5 (1.9) 80.7 (1.3)	116.6 (1.0) 83.4 (0.7)	116.6 (1.0) 83.2 (0.7)	114.5 (1.6) 81.8 (1.1)
	Baseline	**Before Sx PD**	**After Sx PD[a]**	**Baseline**	**Before Sx PD**	**After Sx PD[a]**
Sx PD subgroup, n	64	64	30	63	63	30
Group mean (SE)						
FACT-P FACT-G	115.2 (2.5) 84.4 (1.9)	117.0 (2.4) 84.2 (1.7)	108.6 (3.7) 78.6 (2.9)	117.8 (2.0) 85.2 (1.5)	114.5 (2.2) 82.6 (1.7)	105.6 (4.3) 75.3 (3.4)

[a]Includes pts with and without subsequent approved treatment for metastatic CRPC. SE, standard error.

the pt-reported outcome (PRO) questionnaire Functional Assessment of Cancer Therapy-Prostate (FACT-P). Following development of Mets, pts in the 2 arms received similar treatments, and PROs were collected at 4, 8, and 12 mo. Sx PD was defined as 1) development of a skeletal-related event; 2) initiation of new systemic anticancer treatment due to pain progression or worsening of disease-related symptoms; or 3) development of clinically significant symptoms due to loco-regional tumor progression requiring surgery or radiation. Descriptive statistics were performed for all FACT-P subscales.

Results: Group mean PRO scores after PD were available from 341 pts and from 60 pts after Sx PD (Table). These PRO scores were similar for APA vs PBO up to 12 mo after PD. While APA delayed time to Sx PD, once Sx PD was reached there were similar numeric decreases from baseline across FACT-P subdomains up to 12 mo after Sx PD.

Conclusions: Relative to PBO, pts treated with APA had a longer MFS, with no decline in HRQoL through the time of Mets, and similar HRQoL after Mets. Sx PD was delayed with APA vs PBO and was associated with a decline in HRQoL in both groups. Thus, HRQoL decline for pts treated with APA was delayed because of a longer time to Sx PD.

Clinical trial identification: NCT01946204.

Background: Men with M0 CRPC are at high risk of developing metastatic (M1) CRPC. The goal of M0 CRPC treatment is to delay M1 disease progression, delay additional antineoplastic therapies, and ultimately prolong survival and maintain quality of life. In the primary analysis of PROSPER, ENZA improved metastasis-free survival (MFS) in men with M0 CRPC. Here we report results in subgroups of patients (pts) by age and region.

Methods: Eligible men with M0 CRPC, prostate-specific antigen (PSA) doubling time $\leq$ 10 mo and PSA $\geq$ 2 ng/mL at screening continued androgen deprivation therapy and were randomized 2:1 to ENZA 160 mg or PBO. The primary endpoint was MFS. Secondary endpoints included time to PSA progression, time to first use of new antineoplastic therapy, overall survival, and safety.

Results: 1401 men were enrolled with a median age of 74 y (standard deviation, 7.8 y). Baseline characteristics were generally similar across regions and age groups (Table). Baseline use of bone-targeting agents was higher in North America compared with the other 2 regions. A greater proportion of pts aged $\geq$ 75 y had and ECOG PS of 1 than pts aged $<$ 75 y. In all men, ENZA reduced the risk of metastasis or death by 71% (HR,

Table: 805P

	Overall (N = 1401)	Age $<$ 75 y (n = 756)	Age $\geq$ 75 y (n = 645)	Europe (n = 690)	Rest of world (n = 507)	North America (n = 204)

Efficacy						
MFS HR (95% CI) P value	0.29 (0.24-0.35) $<$ 0.0001	0.25 (0.20-0.33) $<$ 0.0001	0.35 (0.26-0.47) $<$ 0.0001	0.24 (0.18-0.32) $<$ 0.0001	0.32 (0.23-0.43) $<$ 0.0001	0.41 (0.25-0.66) $<$ 0.0001

Abbreviation: ECOG PS, Eastern Cooperative Oncology Group Performance Status.

0.29; 95% CI, 0.24-0.35; P < 0.0001). The risk reduction with ENZA use was similar across all subgroups (Table). Safety results were generally similar among all subgroups, except that more pts in the group aged ≥ 75 y reported adverse event as the primary reason for discontinuation (13% with ENZA vs 10% with PBO) than in the overall pt population (9% with ENZA vs 6% with PBO), and more pts in North America reported falls (15%) than in Europe (7%) or rest of world (10%).

Conclusions: In men with M0 CRPC and rapidly rising PSA, ENZA treatment resulted in a clinically meaningful and statistically significant reduction of developing metastases or death. Results were consistent across subgroups of pts by age and geographic region.

Clinical trial identification: NCT02003924.

806P Relationship between apalutamide (APA) exposure and metastasis-free survival (MFS) in patients (pts) with nonmetastatic castration-resistant prostate cancer (nmCRPC) from SPARTAN

M.R. Smith[1], C. Perez-Ruixo[2], O. Ackaert[2], D. Ouellet[3], C. Chien[3], H. Uemura[4], D. Olmos[5], P.N. Mainwaring[6], J.Y. Lee[7], M.K. Yu[8], J-J. Perez-Ruixo[2], E.J. Small[9]

[1]Hematology/Oncology, Massachusetts General Hospital Cancer Center and Harvard Medical School, Boston, MA, USA, [2]R&D, Janssen Research & Development, Antwerp, Belgium, [3]R&D, Janssen Research & Development, Spring House, PA, USA, [4]Urology & Renal Transplantation, Yokohama City University Medical Center, Yokohama, Japan, [5]Prostate Cancer Clinical Research Unit, CNIO - Spanish National Cancer Center, Madrid, Spain, [6]Medical Oncology, Centre for Personalised Nanomedicine, University of Queensland, Brisbane, Australia, [7]Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Republic of Korea, [8]Clinical Oncology, Janssen Research & Development, Los Angeles, CA, USA, [9]Helen Diller Family Comprehensive Cancer Center, University of California San Francisco, San Francisco, CA, USA

Background: The phase 3 SPARTAN study evaluated the efficacy and safety of APA vs placebo (PBO) in men with high-risk nmCRPC. Because dose reductions/interruptions for the management of AEs that occur during treatment can affect drug efficacy, this analysis sought to understand the relationship of APA pharmacokinetic exposure and the primary end point of SPARTAN, MFS.

Methods: 1207 pts were randomized in a 2:1 ratio to APA 240 mg/d or PBO. APA levels, and that of its active metabolite N-desmethyl APA (NAPA), were measured by a validated LC/MS/MS assay. APA and NAPA exposures were quantified as the area under the concentration–time curve at steady state (AUC_{24}) at the average daily dose received, up to the MFS event. Exposure levels were evaluated as quartiles or continuous variables. Univariate and multivariate Cox regression models evaluated the relationship between APA/NAPA exposure and MFS and were adjusted by pre-specified stratification factors (prostate-specific antigen doubling time, bone-sparing agent use, locoregional disease status) and other potential prognostic factors (age, ECOG PS).

Results: 1206 pts were included in the analysis. AEs led to dose reduction/interruption in 33% vs 19% of APA and PBO pts, respectively, with average daily dose of 225 mg (APA) vs 229 mg (PBO) in pts with dose reduction/interruption. Mean (coefficient of variation [CV]%) PK exposure levels measured as AUC_{24} for APA and NAPA, respectively, were 117 (24 CV%) μg·h/mL and 155 (17 CV%) μg·h/mL for APA-treated pts without dose reductions/interruptions, and 112 (24 CV%) μg·h/mL and 148 (18 CV%) μg·h/mL for those with dose reductions/interruptions. MFS benefit was similar across the range of APA/NAPA exposures. In univariate and multivariate Cox regression models, no significant differences in the exposure-MFS relationship were observed for APA and NAPA.

Conclusions: 240 mg/d APA provided efficacious drug exposure for the majority of pts, including those who required dose reductions/interruptions due to AEs. The MFS benefit was similar across the range of APA exposure. Dose reductions/interruptions due to AEs did not reduce the efficacy of APA.

807P Prolonged urinary and bowel symptom control in men with non-metastatic castration-resistant prostate cancer (nmCRPC) treated with enzalutamide: Results from the PROSPER study

B. Tombal[1], M. Hussain[2], D. Penson[3], G. Attard[4], C.N. Sternberg[5], D. Phung[6], R. Morlock[7], K. Modelska[8], K. Ramaswamy[9], C. Ivanescu[10], F. Saad[11]

[1]Department of Urology, Cliniques Universitaires Saint-Luc, Brussels, Belgium, [2]Robert H. Lurie Comprehensive Cancer Center, Northwestern University, Chicago, IL, USA, [3]Department of Urologic Surgery, Vanderbilt University Medical Center, Nashville, TN, USA, [4]Medical Oncology, The Institute of Cancer Research and The Royal Marsden, Surrey, UK, [5]Medical Oncology, San Camillo Forlanini Hospital, Rome, Italy, [6]Data Science, Astellas Pharma Inc, Leiden, Netherlands, [7]Health Economics and Outcomes Research, Astellas Pharma Inc, Northbrook, IL, USA, [8]Medical Oncology, Pfizer Inc., San Francisco, CA, USA, [9]Oncology, Pfizer Inc., New York, NY, USA, [10]Advisory Analytics, IQVIA, Hoofddorp, Netherlands, [11]Urology, Centre Hospitalier de l'Université de Montréal/CRCHUM, Montreal, QC, Canada

Background: The PROSPER trial (NCT02003924) showed a clinically and statistically significant improvement in metastasis-free survival (HR 0.292 [95% CI 0.241, 0.352], p < 0.0001) with enzalutamide (ENZ; n = 933) versus placebo (PBO; n = 468) in asymptomatic men with nmCRPC and prostate-specific antigen doubling time ≤10 months. All men without prior orchiectomy continued androgen deprivation therapy. We assessed the impact of ENZ on prostate cancer symptoms (PCS) and health-related quality of life (HRQoL).

Methods: PCS and HRQoL were assessed at baseline (BL) and subsequently every 16 weeks, using the EORTC Quality of Life Questionnaire-Prostate 25 (QLQ-PR25) and the EuroQol 5-domain 5-level (EQ-5D-5L). Clinically meaningful symptom worsening in PCS scores was defined using thresholds derived as 1/2 standard deviation at BL. Clinically meaningful deterioration in EQ-5D-5L visual analogue scale was defined using the pre-established threshold of 7. Time to first confirmed (at two consecutive visits) and unconfirmed (one visit) deterioration in QLQ-PR25 and EQ-5D-5L scores were assessed using Kaplan-Meier estimates and Cox models.

Results: Completion rates were high for patients (pts) remaining on study (>85% for all visits). BL scores were similar between arms and showed low symptom burden (including urinary and bowel symptoms) and high HRQoL. The proportion of pts reporting either no change or improvement in HRQoL and PCS scores at week 49 was higher with ENZ (67 − 87%) than PBO (62 − 81%). Over the course of treatment, ENZ significantly delayed worsening of symptoms including urinary and bowel symptoms/function (Table). In contrast, ENZ significantly increased the risk of worsening of hormonal treatment related symptoms compared to PBO (Table).

Conclusions: In addition to delayed disease progression in the PROSPER trial, ENZ prolonged urinary and bowel symptom control and delayed decline in HRQoL scores versus PBO.

Clinical trial identification: NCT02003924.

808P Non-metastatic castration-resistant prostate cancer (nmCRPC): Meta-analysis of efficacy and safety with novel hormonal agents apalutamide and enzalutamide

D.V.P. Almeida[1], C.Z. de Oliveira[2], R.C. Mariano[1], F.R. Kater[1], M.C.L.A. Souza[1], V.C. Ruiz-Schutz[3], R. Yamamura[1], R. Saraiva De Carvalho[1], F.C. Maluf[1], A.K. Morgans[4], S. Srinivas[5], S. Gupta[6], T. Dorff[7], E.Y. Yu[8], F.A. Schutz[1]

[1]Medical Oncology, BP - A Beneficência Portuguesa de São Paulo, São Paulo, Brazil, [2]Biostatistcs, BP - A Beneficência Portuguesa de São Paulo, São Paulo, Brazil, [3]Internal Medicine, Universidade de São Paulo, São Paulo, Brazil, [4]Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL, USA, [5]Department: Medicine - Med/Oncology, Stanford University, Stanford, CA, USA, [6]Division of Hematology, Oncology and Transplantation, University of Minnesota, Minneapolis, MN, USA, [7]Medical Oncology, City of Hope, Duarte, CA, USA, [8]Medical Oncology, Fred Hutchinson Cancer Research Center, Seattle, WA, USA

Background: Androgen deprivation therapy (ADT) is the cornerstone treatment of prostate cancer. However, androgen independent status inevitably develops over time, leading to the castration resistant prostate cancer (CRPC) phenotype. Several treatments, including chemotherapy agents and novel hormonal agents, have been shown to improve outcome of patients with metastatic CRPC (mCRPC). Recently, two randomized controlled trials (RCT) demonstrated increased metastasis free survival (MFS) with apalutamide (SPARTAN Trial) and enzalutamide (PROSPER Trial) in nmCRPC patients, but failed to demonstrate a statistically significant increase in overall survival (OS).

Methods: A meta-analysis at trial level was performed including published data from SPARTAN and PROSPER trials. Efficacy data was investigated and retrieved to calculate hazard-ratio (HR) for OS and MFS, with 95% CI. The safety profile was investigated for fatal adverse events (FAEs) and the relative risk (RR) calculated, with 95% CI. Random-effects or fixed-effects models were performed on the basis of the heterogeneity of included studies. A p-value <0.05 was considered statistically significant.

Results: A total of 2,602 patients were included for efficacy (intention-to-treat [ITT] population) and 2,596 for safety analysis (per-protocol population). 1736 patients received novel hormonal agents (806 apalutamide and 930 enzalutamide) and 866 placebo. Efficacy analysis confirmed improved MFS (HR 0.29; 95% CI, 0.25-0.33; $p < 0.0001$) and also demonstrated a significant increase in OS (HR 0.76; 95% CI, 0.59-0.76; $p = 0.03$). Safety analysis showed an increased risk of FAEs (HR 5.24; 95% CI, 1.89-14.55) with apalutamide and enzalutamide, however this should be interpreted with caution due to the much longer exposure time to the experimental arm compared to placebo.

Conclusions: This meta-analysis reinforces the benefit of MFS and demonstrated a significant increase in OS with novel hormonal agents apalutamide and enzalutamide in patients with nmCRPC. Further analysis will be necessary to determine the breakdown of treatment-related versus –unrelated deaths.

809P Statin use and outcome in metastatic castration-resistant prostate cancer (mCRPC) patients (pts) treated in the TROPIC trial

D. Lorente[1], G.A. De Velasco Oria[2], J. Carles[3], S. Gillessen[4], K. Fizazi[5], A. Joshua[6], M. Eisenberger[7], O. Sartor[8], J.S. de Bono[9]

[1]Medical Oncology, Hospital Universitario La Fe, Valencia, Spain, [2]Medical Oncology, University Hospital 12 de Octubre, Madrid, MA, Spain, [3]Medical Oncology, Vall Hebron Institute of Oncology, Barcelona, Spain, [4]Division of Cancer Sciences, University of Manchester and the Christie, Manchester, UK and Division of Medical Oncology and Haematology, Kantonsspital St. Gallen, St. Gallen, University of Bern, Switzerland, [5]Cancer Medicine, Institut Gustave Roussy, Villejuif, France, [6]Medical Oncology, The Kinghorn Cancer Centre, Darlinghurst, Australia, [7]Medical Oncology, Johns Hopkins Sidney Kimmel Cancer Center, Baltimore, MD, USA, [8]Tulane Cancer Center, Tulane Medical School, New Orleans, LA, USA, [9]Prostate Targeted Therapy Group & Drug Development Unit, The Institute of Cancer Research (ICR), London, UK

Background: Statins have been shown to block DHEAS uptake by prostate cancer cells by competitively binding to SLCO2B1, an organic anionic intracellular transporter. Use of statins by prostate cancer pts has been associated with longer time to progression (TTP) during ADT in the hormone-sensitive setting (Harshman, JAMA Oncol 2015).

Methods: We evaluated the impact of statin use in PFS and OS in mCRPC patients treated with cabazitaxel or mitoxantrone in the TROPIC phase III trial. Kaplan-Meier, univariable (UV) and multivariable (MV) cox-regression models were constructed to evaluate the association between use of statins and overall survival (OS), PSA progression-free survival (PSA-PFS) and radiographic PFS (rPFS). Covariates included in the multivariable model are listed in the table.

Results: 755 pts were included in the analysis. 138 (18.6%) pts received statins: atorvastatin (53 pts, 38.4%), simvastatin (56 pts, 40.6%), rosuvastatin (14 pts, 10.1%), pravastatin (9 pts, 6.5%), lovastatin (4 pts, 2.9%) and fluvastatin (2 pts; 1.4%). 72 pts (52.2%) were allocated to the mitoxantrone arm and 66 pts (47.8%) to the cabazitaxel arm of the trial. Statin use was associated with longer median OS (15.8 vs 13.4m; HR: 0.74; $p = 0.01$) but no difference in PSA-PFS (4.8 vs 4.6m; HR: 0.98; $p = 0.824$) or rPFS (8.3 vs 7.2m; HR: 0.94; $p = 0.661$) was observed. Statin use was associated with a longer time on prior hormone-therapy (5.3 vs 3.7 yrs; $p < 0.001$). In MV cox-regression models, the impact of statin use in survival was independent of treatment arm (cabazitaxel vs mitoxantrone) and other prognostic factors (Table).

Table: 809P Multivariable Cox-Regression OS Analysis

Variable	HR (95%CI)	p-value
Statin Use	0.79 (0.62-0.99)	0.048
Treatment Arm	0.66 (0.55-0.79)	< 0.001
Baseline PSA	1 (1-1)	0.394
Baseline Hb	0.89 (0.85-0.93)	< 0.001
Baseline ALP	1 (1-1)	0.009
Visceral Metastases	1.36 (1.11-1.68)	0.003
ECOG PS	1.67 (1.43-1.96)	< 0.001

Conclusions: Use of statins by pts treated in the TROPIC trial was associated with a longer OS, independent of treatment arm and other prognostic variables. Further analyses will elucidate the role of statins in mCRPC.

Clinical trial identification: EudraCT: 2006-003087-59; NCT00417079.

810P Abiraterone acetate plus prednisone and LHRH therapy versus abiraterone acetate plus prednisone while sparing LHRH therapy in patients with progressive, metastatic and chemotherapy-naïve, castration-resistant prostate cancer: Results from the SPARE-trial (NCT02077634)

C. Ohlmann[1], Z. Roger[2], C. Rüssel[3], E. Hellmis[4], H. Suttmann[5], M. Janssen[6], A. Hübner[7], J. Dahm[8], J. Gleißner[9], M. Scheffler[10], S. Feyerabend[11], J. Telle[12], J. Klier[13]

[1]Urology, Malteser Krankenhaus Bonn, Bonn, Germany, [2]Urology, Praxis für Urologie Pankow, Berlin, Germany, [3]Urology, Praxisgemeinschaft für Urologie, Borken, Germany, [4]Urology, Urologikum Duisburg, Duisburg, Germany, [5]Urology, Urologikum Hamburg, Hamburg, Germany, [6]Urology, Saarland University Medical Center, Hamburg, Germany, [7]Urology, WK Nord GmbH & Co. KG, Rostock, Germany, [8]Urology, PandaMED - ÜBAG, Wuppertal, Germany, [9]Urology, DGU Wuppertal, Wuppertal, Germany, [10]Urology, Gemeinschaftspraxis für Urologie, Zwickau, Germany, [11]Urologic Oncology, Studienpraxis Urologie, Nürtingen, Germany, [12]Urology, Urologische Praxis Würzburg, Würzburg, Germany, [13]Urology, Praxis, Cologne, Germany

Background: The value of continuation of luteinizing hormone-releasing hormone (LHRH) therapy in castration-resistant prostate cancer (CRPC) remains controversial and clear evidence is lacking. Especially upon treatment with the life-prolonging cytochrome P450 17-alpha-hydroxylase/$C_{17,20}$ lyase (Cyp17)-inhibitor, abiraterone, which in combination with prednisone, has the ability to further suppress testosterone serum levels over LHRH therapy alone, continuation of LHRH therapy seems to be negligible. The aim of the SPARE trial therefore was to explore the role of continuation of LHRH therapy when starting treatment with abiraterone acetate plus prednisone (AA+P) in patients with asymptomatic or mildly symptomatic, chemotherapy-naïve CPRC.

Methods: Patients were randomized to receive continuing LHRH therapy versus LHRH withdrawal at the time of starting abiraterone AA+P therapy (NCT02077634). The primary endpoint was rate of rPFS at month 12. Secondary endpoints included PSA response rate, objective response, time to PSA progression and safety.

Results: Altogether, 68 patients were randomized. Median age was 75 (60-86) years with a median PSA at baseline of 23.9 (0.17-1680) ng/ml. Results of the secondary endpoints were evaluated.

Table: 810P

	LHRH+AA+P	AA+P	HR (p-value)
Patients (n)	34	33	
Median age (range)	74 (60-86) years	76 (60-86) years	
Median baseline PSA (range)	31.9 (0.17-313.2) ng/ml	20.59 (1.97-1680) ng/ml	
PSA-decline ≥50%	23/34 (67.6%)	24/33 (72.7%)	
Median treatment duration (d)	266	420	1.667 (0.197)*
Time to PSA progression (d)	288	336	1.733 (0.188)*

*study was not powered for these endpoints.

Conclusions: The results of the exploratory study show that AA + P without continuation of LHRH therapy leads to considerable PSA response rates and longer time to PSA progression. The currently assessed efficacy is comparable to the results of the COU-AA-302 trial, hypothesising that continuation of LHRH therapy may not be necessary upon treatment with AA + P. Results on the primary endpoint and the safety profile are pending and are currently being evaluated.

811P Association of grade ≥3 neutropenia (NP) with outcomes in patients with metastatic castration-resistant prostate cancer (mCRPC) receiving cabazitaxel

A. Meisel[1], R. de Wit[2], S. Oudard[3], O. Sartor[4], F. Stenner-Liewen[5], Z. Shun[6], A. Ozatilgan[7], M. Eisenberger[8], J.S. de Bono[9]

[1]Internal Medicine - Hematology and Oncology, Stadtspital Ward; Department of Nuclear Zurich, University Hospital of Zurich; Institute of Pharmaceutical Sciences, Federal Institute of Technology, Zurich, Switzerland, [2]Medical Oncology, Erasmus University Medical Center, Rotterdam, Netherlands, [3]Service d'Oncologie Médicale, Georges Pompidou European Hospital, Rene Descartes University, Paris, France, [4]Medicine and Urology, Tulane Cancer Center, New Orleans, LA, USA, [5]Department of Oncology, University Hospital of Basel, Basel, Switzerland, [6]Biostatistics, Sanofi, Bridgewater, NJ, USA, [7]Global Medical Oncology, Sanofi, Cambridge, MA, USA, [8]The Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins Hospital, Baltimore, MD, USA, [9]Division of Clinical Studies, Drug Development Unit, Royal Marsden NHS Foundation Trust/The Institute of Cancer Research, Sutton, UK

Background: Subset analysis of trials investigating taxanes in patients with mCRPC suggest an association between Grade ≥3 NP and disease outcomes. In the Phase 3 PROSELICA trial (NCT01308580), NP was more common in patients receiving cabazitaxel 25 mg/m^2 (C25) vs cabazitaxel 20 mg/m^2 (C20) - 73% vs 42%, respectively. Post hoc analyses of PROSELICA examined the relationship between incidence of NP, survival and response.

Methods: PROSELICA assessed the non-inferiority of C20 (n = 598) vs C25 (n = 602) in terms of overall survival (OS) in men with mCRPC. Prophylactic granulocyte colony-stimulating factor was given to patients with Grade ≥3 NP. OS and progression-free survival (PFS) were analyzed using Kaplan-Meier (KM) estimates and Cox proportional hazard models. Nominal p values were determined by log-rank tests. Prostate-specific antigen response rate (PSArr; defined as proportion of patients with a > 50 % PSA decline from baseline) was analyzed in the eligible population using KM estimates with Chi^2 tests and odds ratios. OS, PFS and PSArr were correlated with Grade ≥3 NP occurrence and baseline neutrophilia (neutrophils ≥7000 G/l) by univariate analysis.

Results: In the intent-to-treat (ITT) population, development of Grade ≥3 NP was associated with better PSArr, PFS and OS ($p < 0.001$; Table). The positive association was observed in both treatment arms and in poor-risk patients with baseline neutrophilia.

Table: 811P

Population	Outcome	Grade ≥3 NP	No Grade ≥3 NP	Hazard ratio/Odds ratio	p value
ITT population (n = 1200)	OS, months (mo)	15.1	12.4	0.78	0.0002
	PFS, mo	3.7	2.8	0.79	0.0001
	PSArr, % n = 1079	44.1	25.5	2.3	<0.0001
C25 (n = 602)	OS, mo	15.3	12.2	0.77	0.009
	PFS, mo	3.5	3.5	0.84	0.07
	PSArr, % n = 538	46.2	34.5	1.6	0.015
C20 (n = 598)	OS, mo	14.6	12.6	0.78	0.006
	PFS, mo	4.2	2.3	0.75	0.0008
	PSArr, % n = 541	40.7	21.3	2.5	<0.0001
Neutrophilia (n = 174)	OS, mo	12.8	7.5	0.63	0.004
	PFS, mo	4.1	2.1	0.66	0.008
	PSArr, % n = 156	43.8	16.9	3.8	0.0002

Conclusions: Post hoc assessment of Grade ≥3 NP in PROSELICA was associated with improved survival and response to cabazitaxel independent of dose. These results are consistent with data obtained in the Phase 3 TAX327 (docetaxel) and TROPIC (cabazitaxel) trials. Funded by Sanofi.

812P Post hoc responder analysis of health-related quality of life (HRQL) in patients with metastatic castration-resistant prostate cancer (mCRPC) receiving cabazitaxel in the phase III PROSELICA and FIRSTANA trials

A. Thiery Vuillemin[1], K. Fizazi[2], O. Sartor[3], S. Oudard[4], D. Bury[5], S. Guillonneau[6], A. Ozatilgan[7], M. Eisenberger[8], J.S. de Bono[9]

[1]Medical Oncology, Centre Hospitalier Régional Universitaire, Besancon, France, [2]Cancer Medicine, Institut Gustave Roussy, Villejuif, France, [3]Medicine and Urology, Tulane Cancer Centre, New Orleans, LA, USA, [4]George Pompidou European Hospital, René Descartes University, Paris, France, [5]Real World Evidence/Global Clinical Outcomes, Sanofi US, Cambridge, MA, USA, [6]Biostatistics, Sanofi, Chilly-Mazarin, France, [7]Global Medical Oncology, Sanofi US, Cambridge, MA, USA, [8]The Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins Hospital, Baltimore, MD, USA, [9]Division of Clinical Studies Drug Development Unit, Royal Marsden NHS Foundation Trust/The Institute of Cancer Research, Sutton, UK

Background: PROSELICA (NCT01308580) assessed the non-inferiority of cabazitaxel 20 mg/m^2 (C20) vs 25 mg/m^2 (C25) in patients (pts) with mCRPC post docetaxel, while FIRSTANA (NCT01308567) investigated whether C20 and C25 were superior to docetaxel 75 mg/m^2 (D75) in chemotherapy-naive mCRPC. This analysis evaluated the impact of cabazitaxel on HRQL in both trials.

Methods: Alongside pain and analgesic score, HRQL was assessed using the Functional Assessment of Cancer Therapy Prostate (FACT-P) questionnaire. The analysis focused on FACT-P (clinically meaningful improvement or deterioration of total score [TS]) among responders.

Results: Pt baseline characteristics are shown in the table. In PROSELICA, 57.2% and 59.4% of pts receiving C20 and C25 had FACT-P TS improvements; in FIRSTANA, 63.5%, 62.3% and 57.7% of pts receiving C20, C25 and D75 had FACT-P TS improvements. In FACT-P responders, FACT-P TS improvements occurred as early as Cycle (C) 1 (mean change from baseline: PROSELICA C20 10.4, n = 264; C25 10.6, n = 266; FIRSTANA C20 11.7, n = 206; C25 11.7, n = 202; D75 9.0, n = 195); these were largely maintained. For pts with a pain response in PROSELICA, FACT-P TS improvements occurred as early as C1 (C20 6.8, n = 71; C25 11.1, n = 81) and were maintained until C8 (C20 10.6, n = 43; C25 9.6, n = 44). In FIRSTANA, FACT-P TS improvements in pts with a pain response were seen as early as C1 or C2 (C1: C20 15.5, n = 41; C25 12.5, n = 41; D75, 7.9, n = 32) and maintained until C9 (C20 9.0, n = 27; C25 10.5, n = 26; D75 16.4, n = 20). In pts with a tumor or PSA response, HRQL was maintained for all treatment arms in both studies. Additional results for clinical responder subgroups and FACT-P subscales will be presented.

Conclusions: More than half of the pts experienced HRQL improvements, which were maintained. Pts with a pain response experienced HRQL improvements. Funding: Sanofi.

813P Treatment of metastatic castration-resistant prostate cancer (mCRPC); Survival by type of progression at initiation of treatment

D.G. Robbrecht[1], R.J. van Soest[2], I.F. Tannock[3], S. Oudard[4], B. Tombal[5], M. Eisenberger[6], F. Mercier[7], R. de Wit[1]

[1]Medical Oncology, Erasmus MC Daniel den Hoed Cancer Center, Rotterdam, Netherlands, [2]Urology, Erasmus MC Daniel den Hoed Cancer Center, Rotterdam, Netherlands, [3]Medical Oncology, Princess Margaret Hospital, Toronto, ON, Canada, [4]Immunothérapie et Traitement Antiangiogénique en Pathologie Cancérologique, Hopital European George Pompidou, Paris, France, [5]Urology, Cliniques Universitaires St. Luc, Brussels, Belgium, [6]Medical Oncology, Johns Hopkins Sidney Kimmel Cancer Center, Baltimore, MD, USA, [7]Stat Process, Sanofi, Charlotte, Nc, France

Background: The usual sequence of progression events in mCRPC patients treated with new hormonal agents is known: PSA progression, followed by radiological progression and finally pain progression (Ryan, NEJM 2013; Beer, NEJM 2014). Although pain was associated with poor overall survival (OS) in the TAX 327 (Berthold, Clin Cancer Res 2008) and CALGB trials (Halabi, JCO 2008), the influence of type of progression on outcomes is not well documented in phase III trials with chemotherapy. Here, we investigated the impact of type of progression on OS in mCRPC patients receiving docetaxel-based chemotherapy.

Methods: Data from the phase III study VENICE evaluating docetaxel 75mg/m^2 q3w ± aflibercept (Tannock, Lancet Oncol 2013) was used as a training dataset. At randomization, group 1 (G1) had PSA progression only (n = 231), G2 had radiological progression (± PSA) but no pain (n = 348), and G3 had pain (± PSA, ± radiological) (n = 447). The TAX327 definition for pain was used: Mean present pain intensity $\geq$ 2 and/or mean analgesic score $\geq$ 10 within 7 days prior to randomization (Tannock, NEJM 2004). The impact of type of progression on OS was evaluated in a multivariate Cox regression analysis with backward elimination (5% level), stratified for ECOG performance status (0-1 vs 2) and treatment arm.

Results: In the VENICE trial median OS was 28.6 months for G1, 26.3 months for G2 and 16.9 months for G3. Hazard ratios [95% CI] for death were 1.14 [0.92-1.41] in G2

Table: 812P

Baseline characteristics	FIRSTANA			PROSELICA	
	D75 (n = 391)	C20 (n = 389)	C25 (n = 388)	C20 (n = 598)	C25 (n = 602)
Median age, years (range)	69.0 (41–87)	68.0 (44–90)	68.5 (42–85)	68.0 (45–89)	69.0 (45–88)
ECOG PS, n (%)					
0–1	374 (95.7)	370 (95.1)	376 (96.9)	539 (90.1)	540 (89.7)
2	17 (4.3)	19 (4.9)	12 (3.1)	59 (9.9)	62 (10.3)
Mean PSA, ng/mL (SD)	252.8 (625.2)	213.2 (434.2)	257.9 (578.8)	451.5 (881.0)	444.0 (834.0)
Median present pain intensity, score (range)	1.0 (0.0–4.0)	1.0 (0.0–4.0)	1.0 (0.0–4.0)	1.0 (0.0–5.0)	2.0 (0.0–5.0)
Median FACT-P TS (range)	107.4 (41.1–152.0)	107.1 (47.2–151.0)	105.7 (40.1–148.8)	102.8 (37.0–152.8)	101.6 (33.9–150.9)

C20, cabazitaxel 20 mg/m^2; C25, cabazitaxel 25 mg/m^2; D75, docetaxel 75 mg/m^2; ECOG PS, Eastern Cooperative Oncology Group Performance Status; FACT-P TS, Functional Assessment of Cancer Therapy Prostate Total Score; PSA, prostate-specific antigen; SD, standard deviation.

and 2.13 [1.75 - 2.59] in G3 compared to G1. In multivariate analysis, pain at randomization was the strongest predictor of poor OS: HR 1.71, 95% CI 1.39-2.11, vs PSA progression only. Other significant prognostic factors included older age, high alkaline phosphatase, short duration of first androgen deprivation therapy, low hemoglobin level and high neutrophil-lymphocyte ratio. Docetaxel led to ≥ 50% decline in PSA in 67.5%, 80.5% and 77% in G1, G2 and G3 respectively.

Conclusions: The type of progression at initiation of first-line chemotherapy in mCRPC is prognostic. Patients with pain at initiation of chemotherapy had a median OS of ~1 year shorter than those having PSA progression only. Validation of these results by an independent dataset (TAX 327) is ongoing. Results will be presented at ESMO.

Background: Platinum compounds have been tested in a larger number of mostly small to medium sized clinical trials in molecularly unselected prostate cancer patients (pts). Advances in castration-resistant prostate cancer (CRPC) molecular profiling have shown that a significant proportion of pts harbor DNA repair defects, which may serve as predictive markers for sensitivity to platinum agents. Our aim was to evaluate the antitumour activity of platinum agents in a contemporaneous mCRPC cohort with or without DNA repair defects.

Methods: International, multicenter retrospective database project in 14 centers worldwide. Pts with mCRPC treated with a platinum agent were included. Pts with primary pure small cell carcinoma and/or insufficient outcome data were excluded. For antitumour activity PSA levels at baseline, after 4-, 8- and 12-weeks of therapy (tx) were analyzed as well as soft tissue response and duration of platinum-based chemotherapy. Overall survival (OS) was analyzed by Kaplan Meier method.

Results: A total of 167 pts have been included in this analysis, 33 (20%) received platinum monotherapy, 134 (80%) a platinum combination therapy. Carboplatin was used in 140 (84%), cisplatin in 26 (16%) of pts. Combination tx with etoposise was used in 45 (27%), paclitaxel in 35 (21%) and docetaxel in 28 (17%) of pts. At start of platinum tx median age was 68 years, median PSA 78 ug/l, median ALP 185 U/l, median hemoglobin 103 g/l. The metastatic sites at start of platinum therapy were: bone 84%, lymph node 59% and visceral 60%. Outcome data by DNA repair defect status are summarized in the table.

Table: 814P

Outcome of platinum based tx	DNA repair defects: assessed, present N = 40	DNA repair defects: assessed, not present N = 42	DNA repair defects not assessed N = 85
	N (%)	N (%)	N (%)
PSA decline ≥50%	13/32 (41)	8/23 (35)	24/73 (33)
Soft tissue response (PR/CR)	9/32 (28)	7/29 (24)	16/48 (33)
median time on platinum tx: months (m), interquartile range (IQR)	2.5m (IQR 1.8-5.9)	2.8m (IQR 1.4 – 4.6)	3.5m (IQR 1.4 – 4.6)
OS from start of platinum therapy (m, IQR)	9.1m (IQR 4.8 – NR)	11m (IQR 6.7-22)	12m (IQR 7-29)

Conclusions: In this retrospective analysis of a contemporary cohort of men with mCRPC and poor prognostic characteristics platinum-based treatment seems to have significant anti-tumor activity irrespective of DNA repair status. Comparison of subgroups is limited by small sample size. Updated analyses will be presented.

Background: Bone metastases are common in CRPC patients and these patients (pts) are at risk for symptomatic skeletal related events (SSE). Bone directed therapy and early initation of a life-prolonging drug (LPD) therapy can prevent or prolong time to SSEs. The objective is to evaluate whether delay in LPD has adverse outcome in CRPC pts and a shorter SSE-free interval.

Methods: CAPRI is an investigator-initiated, observational study in 20 hospitals in the Netherlands. All treated CRPC pts are retrospectively included in subgroups based on type of first line treatment: LPD (docetaxel, abiraterone, enzalutamide or radium-223) or non-LPD (other drugs as anti-androgens, prednisone). SSEs are defined as the occurrence of either radiotherapy (RT) to the bone, surgery to the bone, pathological fracture or spinal cord compression (SCC).

Results: 1,618 pts were included in this analysis. Median follow-up was 26 months (IQR 15-39). 466 (29%) were treated with LPD (mostly docetaxel 15%) and 1,152

(71%) with non-LPD (mostly bicalutamide 62%) in first line. In the non-LPD subgroup, LPD was postponed in 712 patients. The LPD subgroup had frequent bone metastases, worse ECOG and, higher LDH, ALP and PSA at the start of first line therapy. 36% of all patients experienced a SSE during follow-up (32% RT to the bone, 4% surgery to the bone, 4% pathological fracture and 6% SCC). There was a small difference in total SSEs between subgroups (39% for LPD vs 35% for non-LPD, $p = 0.064$). Median SSE-free survival was 13.0 vs 21.2 months for LPD and non-LPD respectively (HR 1.626, $p = 0.007$). Correction for prognostic factors showed that type of first line therapy (LPD/non-LPD) was not associated with SSE-free survival (HR 1.021, $p = 0.817$). Worse ECOG and presence of bone metastases were significant predictors for worse SSE-free survival.

Conclusions: Approximately 40% of CRPC-patients developed a SSE during follow-up. Worse patient and disease characteristics probably influenced timing of LPD. These factors were also related with worse SSE-free survival. Delay in the initiation of a LPD at castration-resistant state does not appear to influence outcome related to time-to-SSE.

Clinical trial identification: The CAPRI study is registered in the Dutch Trial Registry as NTR3591.

Legal entity responsible for the study: Institute for Medical Technology Assessment, Erasmus University Rotterdam.

Funding: The CAPRI registry was funded by Sanofi-Aventis Netherlands B.V., Janssen-Cilag B.V., Astellas Pharma B.V., and Bayer B.V. 816P Androgen decline and outcome in castration resistant prostate cancer (mCRPC) patients treated with docetaxel (Doc), prednisone +/- bevacizumab (B)

C.J. Ryan[1], S. Dutta[2], W. Kelly[3], M.J. Morris[4], M-E. Taplin[5], S. Halabi[6]

[1]Division of Hematology, Oncology and Transplantation, Masonic Cancer Center, Minneapolis, MN, USA, [2]Department of Biostatistics and Bioinformatics, Duke University, Durham, NC, USA, [3]Medicine, Thomas Jefferson University, Philadelphia, PA, USA, [4]Medicine, Memorial Sloan-Kettering Cancer Center, New York, NY, USA, [5]Lank Center for Genitourinary Oncology, Dana-Farber Cancer Institute, Boston, MA, USA, [6]Biostatistics and Bioinformatics, Duke University, Durham, NC, USA

Background: Androgen levels are associated with overall survival (OS) in mCRPC. Doc impairs microtubules and has AR inhibitory effects. This analysis evaluates change in androgen levels (Testosterone (T), Androstenedione (A) and DHEA (D) and outcome in Doc-treated mCRPC patients.

Methods: Data from 1,050 men treated on CALGB 90401 with Doc, prednisone and either B or placebo were used. Pre-treatment, 6 week and progression serum assays for T, A and D were performed via tandem Liquid Chromatography-Mass Spectrometry (LC-MS/MS). Ratio of change in androgen (6 week value /baseline value) was calculated. Decline was further evaluated as high or low ($>$ or $<$ median decline for all patients). The logistic regression and proportional hazards models were used to assess the prognostic significance of changes in T, A, and D in predicting PSA response, PFS and OS adjusting for known prognostic factors.

Results: Median values for baseline T, A, and, D were 1.0, 13.5 and 8.1, ng/dL respectively, while androgen levels at 6 weeks were 0.64, 7.0 and 6.8, ng/dL respectively. At 6 weeks a decline in all three androgens was observed. The ratio of 6weeks/baseline in T, A and D were 0.93, 0.56 and 0.86, respectively. There was interaction between levels of T decline and treatment arm (p-value=0.047). Among 291 patients with high levels of T decline, those who also received B were more likely to experience a $\geq 50\%$ decline in PSA (87%) compared to those who did not receive B (67%,). Associations between androgen decline and PFS were NS. In multivariable analysis adjusting for prognostic factors, the hazard ratio (HR) for OS demonstrated that decline in T at 6-weeks/baseline was associated with longer OS, HR 1.02 (95% CI 1.01 ,1.03 $p = 0.001$). Median OS for low T change (ratio $>=0.93$) is 20.9 mos vs 26.3 mos for high T change (<0.93).

Conclusions: Patients treated with Doc who experience a greater drop in T on therapy experience a significantly longer OS and higher rate of PSA decline but no effect on PFS. B and androgen decline may confer interacting beneficial effects. Data are consistent with the favorable prognostic significance of higher serum androgens in the CRPC setting and reflecting the potential effect of Doc on AR signalling.

817P Cabazitaxel treatment in metastatic castration-resistant prostate cancer (mCRPC) clinical trials compared to usual care in CAPRI: An observational study in the Netherlands

H.M. Westgeest[1], M. Kuppen[2], A.J.M. van den Eertwegh[3], J. Van Moorselaar[4], N. Mehra[5], I. van Oort[6], A.C.M. van den Bergh[7], J.L. Coenen[8], K.K.H. Aben[9], R. Somford[10], R. de Wit[11], A. Bergman[12], J. Lavalaye[13], C.A. Uyl-de Groot[14], W.R. Gerritsen[5]

[1]Medical Oncology, Amphia Ziekenhuis, Breda, Netherlands, [2]Institute for Medical Technology Assessment, Erasmus School of Health Policy and Management, Rotterdam, Netherlands, [3]Medical Oncology, VU Medical Center, Amsterdam, Netherlands, [4]Urology, Vrije University Medical Centre (VUMC), Amsterdam, Netherlands, [5]Medical Oncology, Radboud University Medical Centre Nijmegen, Nijmegen, Netherlands, [6]Urology, Radboud University Medical Centre Nijmegen, Nijmegen, Netherlands, [7]Radiation Oncology, UMCG, Groningen, Netherlands, [8]Medical Oncology, Isala Klinieken, Zwolle, Netherlands, [9]IKNL, Netherlands Comprehensive Cancer Organisation, Utrecht, Netherlands, [10]Urology, Canisius Wilhelmina Ziekenhuis, Nijmegen, Netherlands, [11]Medical Oncology, Erasmus MC Daniel den Hoed Cancer Center, Rotterdam, Netherlands, [12]Division of Internal Medicine (MOD) and Oncogenomics, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, [13]Nuclear Medicine, Antonius Ziekenhuis, Nieuwengein, Netherlands, [14]Institute for Medical Technology Assessment, Erasmus University Rotterdam, Rotterdam, Netherlands

Background: Cabazitaxel (CAB) has been shown in the TROPIC trial to improve overall survival (OS) in mCRPC patients after docetaxel (DOC). However clinical trial populations may not reflect the real world population. The objective is to compare patient characteristics and outcome of CAB within clinical trials and in standard of care (SOC) from data extracted from the CAPRI registry.

Methods: CRPC pts treated with CAB directly after DOC, before 1-1-2017, either within a clinical trial or as SOC were retrospectively identified and followed to 1-1-2018. For multivariable analyses, missing values were imputed by multiple imputation using the Monte Carlo Markov Chain method.

Results:

Table: 817P Baseline characteristics at start cabazitaxel (baseline period defined as 42 days before to 7 days after start of cabazitaxel).
Total percentages may not equal 100 because of rounding.

	Cabazitaxel 1st line post-docetaxel (n = 173)		
	Usual care (n = 109)	Trial (n = 64)	p-value
Age (years) Median (IQR) ≥75 years (%)	68 (64-72) 17	67 (64-72) 13	0.502
Period on ADT (months) Median (IQR)	25 (18-37)	30 (19-45)	0.091
ALP (U/L) Median (IQR) Missing (%)	222 (100-360) 18	192 (97-366) 11	0.799
PSA (ug/L) Median (IQR) Missing (%)	200 (65-567) 12	209 (79-500) 8	0.711
Hemoglobin (mmol/L) Median (IQR) Missing (%)	7.1 (6.3-7.8) 17	7.7 (6.7-8.1) 11	0.029
LDH (U/L) Median (IQR) Missing (%)	328 (252-504) 26	268 (209-397 14)	0.010
ECOG performance (%) 0 1 >1 Missing	16 49 9 27	23 56 3 17	0.186
Visceral disease (%) No Yes Missing	29 19 52	45 11 44	0.038
Opioid use (%) No Yes Missing	23 28 50	41 27 33	0.140
Symptoms (%) No Yes Missing	6 78 16	17 72 11	0.033
Docetaxel cycles Median (IQR) Missing (%)	7 (5-10) 1	10 (7-10) 3	0.002
Time since last docetaxel dose (months) Median (IQR) <6 months (valid %) Missing (%)	2.2 (0.9-4.7) 86 5	3.9 (2.0-6.0) 74 5	0.001

From a total of 3,616 pts in the CAPRI database, we identified 356 pts treated with CAB, of which 173 pts were treated directly post-DOC. Trial pts had less symptoms and visceral disease, lower LDH, higher hemoglobin, received more DOC cycles and had a longer treatment-free interval since last DOC (see Table). The median number of CAB cycles was higher in trials compared to SOC (5 vs 4, p = 0.031). Median OS was 13.6 vs 9.6 months for trial pts and SOC, respectively (HR 0.73, p = 0.07). PSA response (≥ 50% decline) was 27 vs 11%, respectively (p = 0.210). However, after correction for prognostic factors, trial participation did not retain statistical significance (HR 0.94, p = 0.73), but longer period on ADT, lower LDH and absence of visceral metastases were significant for better OS. In addition, lower PSA and absence of symptoms had a trend for better OS.

Conclusions: The OS in the trial subgroup is in agreement with the OS of the TROPIC trial in a contemporary real world setting. However, the SOC pts had a trend for worse OS which may be explained by worse prognostic factors at CAB initiation. Accordingly, pts whose disease has progressed post-DOC should be carefully selected for treatment to ensure optimal outcomes.

818P Post hoc analysis of the effect of baseline characteristics on treatment duration in patients with metastatic castration-resistant prostate cancer (mCRPC) receiving cabazitaxel in the compassionate use (CUP)/ expanded access programs (EAP) and CAPRISTANA registry

Z. Malik[1], A. Pichler[2], G. Di Lorenzo[3], U. De Giorgi[4], S. Hitier[5], E. Ecstein-Fraisse[6], A. Ozatilgan[7], J. Carles[8]

[1]The Clatterbridge Cancer Centre, NHS Foundation Trust, Wirral, UK, [2]Department of Hematology and Oncology, Regional Hospital Hochsteiermark, Leoben, Austria, [3]Genitourinary Cancers Section, AOU Feder, University of Naples Federico II, Naples, Italy, [4]Medical Oncology, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola, Italy, [5]Biostatistics & Programming, Sanofi, Chilly-Mazarin, France, [6]Medical Evidence Generation, Sanofi, Paris, France, [7]Global Medical Oncology, Sanofi, Cambridge, MA, USA, [8]Vall d'Hebron University Hospital, Vall d'Hebron Institute of Oncology, Barcelona, Spain

Background: Cabazitaxel is approved for patients with mCRPC, post docetaxel. The CUP (CABAZ_C_05005) and EAP (NCT01254279) provided access to cabazitaxel before commercial availability and assessed real-world safety. CAPRISTANA (CABAZC 06092), a prospective, observational study, evaluated the routine clinical use of cabazitaxel. In this analysis we examined factors associated with cabazitaxel treatment duration in a real-life setting.

Methods: Patients ≥18 years of age with mCRPC previously treated with docetaxel, received cabazitaxel 25 mg/m^2 intravenously every 3 weeks until disease progression, death, unacceptable toxicity or physician/patient decision. Of note, treatment was capped at 10 cycles in some countries.

Results: The CUP/EAP/CAPRISTANA studies combined included 1,621 patients (CUP/EAP, N = 1,432; CAPRISTANA, N = 189). The median number of cabazitaxel cycles received was 6. Overall, 708 patients (43.7%) received >6 cycles (Table); 211 (13.0%) received >10 cycles. For patients receiving >10 cycles, the median number of cabazitaxel cycles received was 14. Patients receiving more cabazitaxel cycles tended to have better ECOG performance status of 0–1 (Table; P = 0.0017 for ≤6 vs > 6 cycles). In total, 348 patients (21.5%) were ≥75 years of age, of which 40% (n = 139) received >6 cabazitaxel cycles. Further analysis into the patient subgroups and reasons for treatment discontinuation are ongoing.

Conclusions: Cabazitaxel was well tolerated by patients across these global studies, including elderly patients. Many patients derived benefit from cabazitaxel and went on to receive a greater number of cycles. Further analyses may identify prognostic factors that could indicate which patients are likely to receive >6 cabazitaxel cycles and derive greater benefit. Funding: Sanofi.

Background: The availability of multiple treatments for metastatic castration-resistant prostate cancer (mCRPC) mandates the need to identify prognostic factors applicable to clinical practice. Variations in (PSA) levels are widely used in the monitoring of response to treatment with abiraterone acetate (AA) or enzalutamide, but are not validated as an early biomarker for overall survival (OS). Objective: To evaluate the association between early PSA changes and OS following enzalutamide or AA treatments in mCRPC.

Methods: We retrospectively evaluated mCRPC patients treated with AA or enzalutamide, before or after docetaxel, in 11 reference hospitals between 2011 and 2017. A descriptive and multivariate analysis of the data was carried out in order to establish the association of PSA variations at 4 and 12 weeks (expressed as 30% and 50% percentage modifications, respectively, relative to baseline value at the start of AA or enzalutamide) with OS. Association with OS was analyzed using multivariate Cox regression and log-rank analyses. Spearman's rho correlation coefficient (r) was calculated to evaluate the association between PSA changes at 4 and 12 weeks.

Results: We analyzed 450 mCRPC patients with a median follow-up of 16 months (1-65). A 30% PSA decline at 4 weeks was associated with longer OS (30 vs 20 months; hazard ratio [HR] 0.55 (0.42-0.73), $p < 0.001$), as well as a 50% PSA decrease at 12 weeks (39 vs 19 months; HR 0.42 (0.31-0.56), $p < 0.001$). We found a detriment in survival in patients with a 30% PSA rise at 4 weeks, with shorter OS (22 vs 26 months; HR 1.5 (1.07-2.21), $p = 0.025$) and a 50% PSA increase at 12 weeks after starting treatment (14 vs 29 months; 2.66 (1.93-3.67) $p < 0.001$), in both univariate and multivariable models. The percentage PSA decline at 4 weeks was significantly correlated with the percentage PSA change at 12 weeks ($r = 0.635$; $p < 0.001$). Limitations include the retrospective design of this analysis.

Conclusions: PSA changes as early as 4 weeks after enzalutamide or AA initiation are highly associated with OS in mCPRC. Prospective multicentre validation studies are needed to confirm these findings.

820P Cabazitaxel under routine conditions for the treatment of patients with metastatic castration-resistant prostate cancer (mCRPC): Interim results of the non-interventional SCOPE study

J. Gschwend[1], C. Lange[2], C. Bokemeyer[3]

[1]Department of Urology, Klinikum rechts der Isar, Technical University of Munich, Germany, Munich, Germany, [2]Urology, Medical Office Bernburg, Bernburg, Germany, [3]Department of Oncology, Hematology and Bone Marrow Transplant, Hematology and Bone Marrow Transplant, University Medical Center Hamburg-Eppendorf, Germany, Hamburg, Germany

Background: Several treatment options are currently available for patients with mCRPC who were treated with a docetaxel-containing regimen. As one therapeutic option, cabazitaxel (CABA) in combination with prednis(ol)one can be administered. SCOPE is the first multinational, non-interventional study to address this question prospectively.

Methods: Within the ongoing SCOPE study, data on medical history, therapeutic management and outcome of mCRPC patients starting treatment with CABA under routine conditions are assessed with a target recruitment of 900 patients. For the current interim analysis (cut-off: MAR 16, 2018) descriptive statistics were used to analyze preliminary data on treatment outcomes.

Results: Of 551 enrolled patients, 137 patients (median age: 73 (47 to 88) years, ECOG of ≤ 1: 81.8%, median duration of CRPC at study inclusion: 20.4 (0.8 to 109.1) months) have completed CABA therapy. For 27 patients, first line therapy with an androgen-receptor targeted agent (ARTA) was documented (ARTA 1st line), of which 10 patients received an ARTA in 2nd line (ARTA post ARTA). None (0.0%) of the 10 ARTA post-ARTA patients had reductions in PSA levels $\geq 50\%$ (PSA_{50} response) compared to baseline. Median progression-free survival (PFS) after the start of the respective therapy was longer for 1st line ARTA than for ARTA post-ARTA therapy (10.8 vs. 3.5 months, $p = 0.0106$). Fifty patients received docetaxel as 1st line therapy directly followed by CABA (CABA 2nd line) and for 24 patients ARTA therapy was documented after docetaxel and prior to CABA (CABA 3rd line). PSA_{50} response to CABA was 38.0% (CABA 2nd line) and 37.5% (CABA 3rd line), respectively. Median PFS after start of CABA therapy showed no significant differences between the CABA 2nd line and CABA 3rd line group (4.2 vs. 5.1 months, $p = 0.5663$).

Conclusions: The current results indicate that the outcome of ARTA post-ARTA is unfavourable compared to 1st line ARTA therapy and that CABA is effective in both ARTA and docetaxel refractory patients. However, interpretation of results is challenging due to the highly diverse treatment sequences administered in patients with mCRPC under routine conditions.

821P Kinetics of prostate-specific antigen (PSA) as a marker of abiraterone acetate (AA) efficacy in patients (p) with metastatic castrate-resistant prostate cancer (mCRPC)

S. España Fernandez[1], J.M. Piulats[2], N. Sala[3], J.M. Velarde[1], U. Ferrandiz[1], O. Etxaniz Ulazia[1], L. Heras Lopez[4], M.P. Barretina Ginesta[5], X. Garcia del Muro[6], A. Font[1]

[1]Medical Oncology, Catalan Institute of Oncology (ICO Badalona), Hospital Germans Trias i Pujol, Badalona, Spain, [2]Medical Oncology, Catalan Institute of Oncology, Barcelona, Spain, [3]Medical Oncology, ICO Girona, Hospital Josep Trueta, Girona, Spain, [4]Medical Oncologist, ICO, Barcelona, Spain, [5]Medical Oncology, Catalan Institute of Oncology (ICO)-Hospital Universitari Josep Trueta, Girona, Spain, [6]Medical Oncology, Institut Català d'Oncologia L'Hospitalet, Barcelona, Spain

Background: Studies have suggested an association between PSA kinetics and outcome to AA. In order to identify p with resistance to AA, we assessed potential factors associated with overall survival (OS) in p with mCRPC treated with AA after progression to docetaxel.

Methods: We included 104 p with mCRPC treated with AA plus prednisone after progression to docetaxel at three centers of the Catalan Institute of Oncology from August 2011 to October 2014. All p were assessed monthly to check PSA levels and hematological parameters. We used a multivariable Cox proportional hazards model to explore the association of baseline characteristics and PSA parameters with OS.

Results: Median OS was 16.4 months (m) and the median of duration of treatment was 7.54 m. In the univariate analysis, 14 factors were significantly associated with OS: ECOG PS, metastatic site, hemoglobin, alkaline phosphatase, lactate dehydrogenase (LDH), baseline PSA levels (classified by terciles), neutrophil-lymphocyte ratio (NLR), interval between end of docetaxel and start of AA, early PSA response (decrease >30% at week 4), PSA nadir, time to PSA nadir, PSA decrease >50%, end-of-treatment (EOT) PSA levels, and EOT PSA doubling time (PSADT). The multivariate analysis identified lymph node metastases ($P = 0.016$), NLR <4 ($P = 0.038$), baseline PSA levels <43 ng/ml ($P = 0.026$), normal LDH ($P = 0.035$), early PSA response ($P = 0.001$), and EOT PSADT >1.5 m ($P < 0.001$) as independent markers of longer OS.

Conclusions: Our results suggest an association between PSA kinetics, primarily early PSA response, with outcome to AA after progression to docetaxel. Taken together with other factors, lack of an early PSA response could identify patients that will probably not obtain a benefit from AA and who might be considered for alternative therapies.

Background: Abiraterone acetate (AA) improves OS and rPFS in asymptomatic/minimally symptomatic mCRPC patients (pts) who are chemotherapy (CT) naïve. Upon progression to this strategy, Docetaxel (D) is currently one of standard treatments. However, the value of maintaining AA along with D despite progression to the former has not been tested yet. ABIDO is a randomized-phase II trial that evaluates efficacy and safety of D + AA vs. D after disease progression to first line AA in mCRPC.

Methods: mCRPC CT naïve pts with no visceral metastases, ECOG PS 0-1, testosterone < 50 ng/dL and adequate, hematologic, hepatic, and renal function were included. The study has two stages. In stage I pts receive AA at the approved regime (AA 1000mg/day-prednisone (P) 5 mgbid) until progressive disease determined by PSCWG2 criteria. Upon progression, in stage II, pts are randomized to receive either three-weekly D + daily AA+P (Arm A) or three-weekly D alone (Arm B).

Results: So far 148 pts have been included and 88 were randomized already. Of those 77 have completed D and have been analyzed (39 in arm A and 38 in Arm B). Median age was 72 y/o, 43% had ECOG 0 and 88% had bone metastases and 16% visceral metastases. Patients received 255 and 274 cycles of D in Arm A and B respectively with a median number of cycles of 7 and 8. Docetaxel median dose intensity was 90% and 92% for each arm and 94% for AA. Nine pts discontinued treatment due to toxicity, 5 in arm A and 4 in arm B. Most frequent G3-4 toxicities per arm (A/B) were: neutropenia (56%; 29%), febrile neutropenia (21%; 8%), diarrhea (10%; 8%), and asthenia (13%; 11%). Most common toxicities all grades per arm were: asthenia (74%; 66%), neutropenia (59%; 34%), alopecia (44%; 45%), nail toxicity (49%; 34%), diarrhea (46%; 42%), neurotoxicity (39%; 42%), nauseas (28%; 26%), mucositis (26%; 29%) and anemia (23%;11%).

Conclusions: In the AA maintenance cohort, more frequent and severe hematological treatment related adverse events (neutropenia, febrile neutropenia and anemia) were observed. No other differences were relevant. Prophylactic G-CSF use is encouraged in all patients. These preliminary data require confirmation once the study is completed.

Clinical trial identification: NCT02036060; EudraCT: 2013-003811-23.

Background: Addition of D to ADT increased overall survival in high volume disease mHSPC. Nevertheless, there is a lack of information about the management after disease progression and predictive factors of efficacy for subsequent therapies are unknown.

Methods: Retrospective analysis of 163 mHSPC patients (pt) treated with D in 23 Spanish Centers from July 2014 to April 2018. Objectives of the study are: describe baseline and progression characteristics, treatment choices and efficacy outcomes of subsequent therapies based on pretreatment features.

Results: After a median follow up of 18.04 months (m), 93 pt (57.1%) developed CRPC. Median time to CRPC was 15.97 m (CI 95%: 10.97 m – 28.16 m). 80 pt received subsequent treatment after progression: 23 (28.8%) received chemotherapy (CT) (3 D, 17 cabazitaxel, 3 carboplatin-etoposide), 52 (65%) androgen receptor axis-targeted agents (31 enzalutamide, 21 abiraterone) and 5 radium-223. Baseline characteristics of pt at CRPC disease were: median age: 67.1 year; median PSA doubling time (PSADT): 2 m, and median PSA, Hemoglobin (Hb), LDH and alkaline phosphatase (alk-P) was 20.3 ng/mL, 12.95 g/dL, 326 UI/mL and 144 UI/mL, respectively. 26.4% of pt had visceral progression. Median progression free survival (PFS) of pt in first-line treatment for mCRPC was 6.93 m (CI95%: 3.58-10.02). In univariate analysis, hormonal therapy showed a significant longer PFS compared to CT (7.49 m vs 6.27 m; HR 0.55; p 0.048), but no association was found after adjustment by other prognostic characteristics (HR 0.77; p 0.79). Although no significant association was observed in multivariate analysis, pt with more aggressive clinical characteristics achieved a longer PFS with CT (Table).

Table: 823P PFS at first-line treatment of mCRPC

	HT (m)	CT (m)	p
PSADT < 3 m PSADT > = 3 m	4.46 9.39	6.27 3.59	0.6 0.07
Visceral PD Non Visceral PD	4.33 5.95	5.59 3.54	0.59 0.12
LDH H LDH L	4.34 12.0	5.59 8.21	0.29 0.3
Hb H Hb L	NR 4.0	5.58 6.27	0.03 0.63
alk-P H alk-P L	3.81 11.99	6.93 5.52	0.94 0.03
PSA H PSA L	3.81 8.54	5.52 5.58	0.35 0.14

Conclusions: Baseline characteristics at CRPC disease could help us to identify the best therapy option for pt pretreated with D + ADT in mHSPC. Our analyses suggest that CT could benefit pt with more aggressive clinical features.

824P Radium-223 (Ra-223) therapy after abiraterone (Abi): Analysis of symptomatic skeletal events (SSEs) in an international early access program (iEAP) in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC)

K. Miller[1], D. Heinrich[2], J.M. O'Sullivan[3], J. Carles[4], M. Wirth[5], S. Nilsson[6], L. Huang[7], J. Kalinovsky[8], A. Heidenreich[9], F. Saad[10]

[1]Urology, Charité Berlin, Berlin, Germany, [2]Oncology, Akershus University Hospital, Oslo, Norway, [3]Centre for Cancer Research & Cell Biology, Queen's University Belfast, Belfast, UK, [4]Medical Oncology, Vall d'Hebron University Hospital, Barcelona, Spain, [5]Urology, University Hospital Carl Gustav Carus, Dresden, Germany, [6]Oncology-Pathology, Karolinska University Hospital, Stockholm, Sweden, [7]Statistics, Bayer HealthCare Pharmaceuticals, Whippany, NJ, USA, [8]Medical Oncology, Bayer Consumer Care AG, Basel, Switzerland, [9]Urology, University Hospital Cologne, Cologne, Germany, [10]Urology, University of Montreal Hospital Center, Montreal, QC, Canada

Background: Ra-223 phase 3 study (ALSYMPCA) was conducted before Abi became available. The Ra-223 iEAP study included Abi-treated pts. Here, we assessed SSEs, OS and bone health agent (BHA) use in Ra-223-treated pts who received Abi as a prior treatment.

Methods: This open-label, single-arm trial enrolled pts with bone-predominant mCRPC (≥2 bone metastases [BM]). Pts who received prior anti-cancer therapies were included; use of BHAs (bisphosphonates and denosumab) was permitted before/during the study. Median follow-up was 7.5 mo. Baseline characteristics, SSEs, (EBRT, symptomatic pathological fractures, spinal cord compression or surgical intervention) and OS were analysed descriptively for pts who completed prior Abi therapy and Abi-naïve pts.

Results: Of 708 mCRPC pts, 85% of prior Abi and 36% of Abi-naïve pts had previously received docetaxel (Table). During Ra-223 therapy, 14% and 17% of pts received concomitant bisphosphonates and 20% and 17% concomitant denosumab in the prior Abi and Abi-naïve groups, respectively. Median time since BM diagnosis and start of Ra-223 was 37 and 21 mo in the prior Abi and Abi-naïve pts, respectively. Median OS was 15.9 mo overall (11.2 mo for prior Abi and 17.1 mo for Abi-naïve pts). More pts had SSEs in the prior Abi (26%) than the Abi-naïve group (14%); proportions of treatment-emergent fractures were similar in both groups (4% and 3%, respectively), as was incidence of pathological bone fractures (5% for both).

Conclusions: Pts in the prior Abi group had a longer time from diagnosis of BM to Ra-223 initiation. These pts seem more advanced, as reflected by higher median baseline PSA and more pts with prior docetaxel therapy. BHAs appear to be under-utilised in clinical practice in this pt population. A similar rate of pathological and non-pathological fractures was reported in Ra-223-treated pts regardless of prior use of Abi.

Clinical trial identification: NCT01618370.

825P Randomized phase II trial of radium-223 (RA) plus enzalutamide (EZ) vs. EZ alone in metastatic castration refractory prostate cancer (mCRPC)

B.L. Maughan[1], A. Hahn[2], J. Hoffman[3], K. Morton[3], S. Gupta[4], J. Batten[3], J. Thorley[3], J. Hawks[3], G. Nachaegari[3], R. Nussenzveig[3], K. Boucher[3], N. Agarwal[5]

[1]Medical Oncology, Huntsman Cancer Institute, Salt Lake City, UT, USA, [2]Internal Medicine, University of Utah, Salt Lake City, UT, USA, [3]Medical Oncology, Huntsman Cancer Institute, Salt Lake City, UT, USA, [4]Oncology, Huntsman Cancer Institute, Salt Lake City, UT, USA, [5]Oncology/ Internal Medicine, Huntsman Cancer Institute, Salt Lake City, UT, USA

Background: RA, a bone targeting alpha radiopharmaceutical, and EZ, are approved for mCRPC. Per phase 3 SWOG0421 trial, subset of men with mCRPC with the high serum bone metabolism markers (BMM) had improved survival with concomitant decrease in these markers on treatment (Rx) with atrasentan, a bone targeting agent (Lara P et al, JNCI, 2014). Our hypothesize was that Rx with RA+ EZ will be safe, and decrease bone metabolism markers compared to EZ alone.

Methods: In this phase 2 trial (NCT02199197), men with progressive mCRPC were treated with EZ (160 mg daily) ± RA (standard dose of 55 kBq/kg IV Q4 weeks x 6), until disease progression or unacceptable toxicities. Primary objectives: 1) changes in N-telopeptide compared from baseline to end of treatment or disease progression (whichever occurred first) between the two arms, and 2) safety of combining RA+EZ. Secondary objectives: changes in 4 other markers of bone resorption or formation, and clinical outcomes. The bone markers were compared between treatment arms on the log scale using Analysis of Covariance (ANCOVA) with baseline bone marker values as a covariate.

Results: Combining RA+EZ was safe (2018 ASCO annual meeting abstract: 5057). Efficacy data are presented here. After a safety lead in phase (n = 8), 39 men were randomized (2:1) to RA+EZ vs EZ. The study met the primary endpoint with a significant decline in the N-telopeptide levels in RA+EZ vs EZ. There was a significant decline in all but one BMMs in RA+ EZ vs EZ alone. (Table). The clinical outcomes favored RA+EZ (data will be presented in the meeting).

Table: 825P

Marker	Ratio of RA+EZ to EZ	95% CI	P-value

Treatment-emergent fracture, n (%)	8 (4)	11 (3)	31 (4)
Experienced pathological bone fracture, n (%)	12 (5)	15 (5)	39 (6)

Conclusions: Per SWOG0421 trial, high BMMs in men with mCRPC portends poor prognosis and have improved outcomes with bone targeting agent atrasentan with concomitant decline in BMMs. In the current study, BMMs significantly declined with RA+EZ vs EZ, thus providing the rationale for combining RA with EZ.

Clinical trial identification: NCT02199197.

Background: When the Ra-223 phase 3 clinical trial (ALSYMPCA) was conducted, Abi was not available; REASSURE is a prospective, observational clinical study of Ra-223 in pts with mCRPC with a 7-year follow-up (NCT02141438). Pts could have had antihormonal agents, such as Abi, prior to receiving Ra-223. The objective of this interim review was to evaluate the fractures and skeletal-related events (SREs) based on prior Abi and the use of BHAs, denosumab and bisphosphonates.

Methods: Descriptive statistics were generated for baseline characteristics, fractures, SREs and overall survival (OS) by BHA use in pts who had completed Abi treatment prior to receiving Ra-223 (prior Abi) or who had no prior Abi (Abi-naïve). An SRE was defined as any skeletal-related adverse event or any radiotherapy to bone.

Results: As of Nov 2017, 1439 pts were enrolled, with a median follow-up time of 9.1 months. 708 (49%) pts had received BHAs at baseline, and BHAs were given concomitantly with Ra-223 in 553 (38%) pts. 430 (30%) pts received prior Abi, and Ra-223 was given as second line in 37% (157/430) of those pts; 705 (49%) pts were considered Abi-naïve. For the prior Abi group, median time of exposure to Abi was 11 months. In the prior Abi group SREs occurred in 17% and 22% of pts, with and without BHAs, respectively. In the Abi-naïve group, 16% of pts had SREs regardless of BHA use. Fractures were reported in 7/430 pts (1.6%) in the prior Abi group. In the Abi-naïve group fractures were reported in 2/311 (1%) and 8/394 (2%) pts with and without BHAs, respectively (Table).

Conclusions: BHAs were under-utilised in this study despite several guidelines and recommendations. The rate of fracture was the same in those who were Abi-naïve compared with those who received Abi prior to Ra-223. Pts with prior Abi had a shorter OS; these pts received Ra-223 at a later time during their disease course, as reflected by a longer time from CRPC to Ra-223 initiation.

Median time from castration resistance to death (months)	29	26	26
OS, median (95% CI) (months)	10.5 (8.6, 12.3)	9.8 (7.8, 13.2)	15.2 (13.2, 16.3)

Methods: This was a retrospective study of data from the Flatiron prostate cancer registry, providing electronic health records from >245 US cancer clinics. Data were collected from 01/01/2013–30/06/2017. Ra-223-treated mCRPC pts were included; prior to receiving Ra-223, pts completed Abi/Enza/both. Prior Abi and prior Enza groups excluded pts with concomitant/concurrent Abi or Enza. Baseline was defined as the index date at start of Ra-223 therapy. Pts were followed until death or study end. Descriptive analysis was performed for baseline characteristics, prior Abi or Enza therapy, skeletal-related events (SREs) and OS (Kaplan–Meier method).

Results: Among 625 Ra-223-treated pts, 29.9% (n = 187) and 26.2% (n = 164) completed prior Abi or Enza treatment, respectively (Table). At baseline, SREs were documented in 50% (314/625) of pts (48% [89/187] in prior Abi and 53% [87/164] in prior Enza pts). During/following Ra-223 therapy, SREs were reported at a similar rate in prior Abi (21% [39/185]) and prior Enza pts (20% [33/163]). Pathological fractures were reported in 10% (61/623) of pts (7% [13/185] and 6% [10/163] in prior Abi and prior Enza pts, respectively). Median (95% CI) OS was 15.2 (13.2–16.3) months in all pts (10.5 [8.6–12.3] for prior Abi and 9.8 [7.8–13.2] for prior Enza pts).

Conclusions: In this retrospective RW study of 4 yr clinical practice, a high proportion of pts had SREs prior to start of Ra-223. Sequential use of Ra-223 after Abi or Enza does not negatively affect bone-related safety outcomes when compared with the overall cohort. Ra-223 is a feasible treatment option after Abi or Enza.

828P Symptomatic skeletal event (SSE) dynamics in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC) treated with radium-223 (Ra-223): An interim review of a prospective, non-interventional study (PARABO)

T. Poeppel[1], S. Eschmann[2], A. Werner[3], I. Selkinski[4], M-O. Möllers[5], T. Neußer[6], A. Benson[7], J. Kalinovsky[8], H. Palmedo[9]

[1]Nuclear Medicine, University Hospital Essen, Essen, Germany, [2]Nuclear Medicine, Marienhospital, Stuttgart, Germany, [3]Nuclear Medicine, Radiology Schwetzingen, Schwetzingen, Germany, [4]Nuclear Medicine, Helios Dr. Horst Schmidt Kliniken Wiesbaden, Wiesbaden, Germany, [5]Nuclear Medicine, Prof. Dr. Uhlenbrock & Partner, Dortmund, Germany, [6]Non-Interventional Studies, Bayer Vital GmbH, Leverkusen, Germany, [7]Medical Affairs Statistics and Integrated Analysis, Bayer HealthCare, Whippany, NJ, USA, [8]Medical Oncology, Bayer Consumer Care AG, Basel, Switzerland, [9]Nuclear Medicine, Nuclear Medicine Center for Radiology, Bonn, Germany

Background: Phase III Ra-223 study (ALSYMPCA) was conducted before the availability of abiraterone (Abi). The ongoing PARABO study will investigate the outcome of Ra-223-treated mCRPC pts in real-life clinical practice in Germany (NCT02398526). This analysis aimed to describe the SSE profile in Ra-223-treated pts based on extent of disease (EOD) or prior Abi use.

Methods: PARABO is a prospective, single-arm observational study of 348 pts with mCRPC and bone metastases who initiated Ra-223 treatment. A descriptive analysis was carried out for overall survival (OS) and SSEs (EBRT, symptomatic pathologic fractures, spinal cord compression or surgical intervention) in Ra-223-treated pts who received Abi as part of previous treatment. SSEs were summarised by EOD (0–2: ≤20 metastases; 3–4: >20 metastases/Superscan).

Results: Of 333 Ra-223-treated pts, 165 (50%) had EOD 3–4; 67 (20%) had completed prior Abi (median duration of Abi: 10.8 mo). Median time from castration resistance to Ra-223 treatment: 9.5 mo for all pts, 18.9 mo for prior Abi pts. At baseline, 45/66 (68%) prior Abi pts had EOD 3–4 and 45/67 (67%) had received prior chemotherapy. Bone health agent use at baseline was reported in 22 (33%) prior Abi pts. Median follow-up was 6.4 mo for the overall cohort. Median OS (95% CI): 16.9 (12.6–18.9) mo for all pts, 11.2 (8.1–15.2) mo for prior Abi pts. SSEs occurred in 10% of the overall cohort and 20% of prior Abi pts. Pts with more advanced disease (EOD 3–4) received more EBRT, while pathological fracture rate was ∼3% in all groups.

Table: 828P

SSE, n (%)[a]	All patients N = 333	Prior Abi n = 67	EOD 0–2 (≤20 metastatic lesions) n = 149	EOD 3–4 (>20 metastatic lesions) n = 165
During Ra-223 treatment	8/312 (2.6)	3/57 (5.3)	0/144 (0)	8/151 (5.3)
Follow-up after end of Ra-223 treatment	6/162 (3.7)	2/28 (7.1)	1/84 (1.2)	5/74 (6.8)
During long-term follow-up[b]	21/144 (14.6)	7/30 (23.3)	9/71 (12.7)	12/70 (17.1)
Over the course of the study EBRT Pathological fractures Spinal cord compression Surgical intervention	33/315 (10.5) 24/315 (7.6) 10/315 (3.2) 8/315 (2.5) 6/315 (1.9)	12/59 (20.3) 9/59 (15.3) 2/59 (3.4) 2/59 (3.4) 1/59 (1.7)	10/145 (6.9) 5/145 (3.4) 5/145 (3.4) 3/145 (2.1) 4/145 (2.8)	23/153 (15.0) 19/153 (12.4) 5/153 (3.3) 5/153 (3.3) 2/153 (1.3)

[a]Percentages calculated based on number of pts for whom documentation was available within the specified time period.
[b]>30 days after treatment completion.

Conclusions: Pts previously treated with Abi received Ra-223 18.9 mo after CRPC diagnosis, had generally received prior chemotherapy and had higher tumour burden, resulting in 11.2 mo median OS. Pts with higher tumour burden or prior Abi had more SSEs, mainly related to EBRT use; frequency of fractures was low and similar across groups.

Clinical trial identification: NCT02398526.

Background: In the ALSYMPCA study a survival benefit of Radium-223 (Ra-223) treated metastasized Castration Resistant Prostate Cancer (mCRPC) patients with bone disease was established. However, the effect of Ra-223 treatment on pain and Quality of Life (QoL) was not explored. 200 mCRPC patients treated with Ra-223 in 20 Dutch hospitals were included in the prospective ROTOR registry.

Methods: QoL (FACT-P) and pain (BPI-S) were recorded at Base-Line (BL) and at every Ra-223 cycle. Patients with complete questionnaires at BL and at least one on treatment were included in the analysis. Patients with a BPI-S Pain At Its Worst (PAIW) of ≥ 4 were considered symptomatic. A decrease of FACT-P and BPI-S PAIW of ≥ 6 points and ≥2 points, respectively, were considered clinically meaningfull.

Results: Currently, data is collected from 244 patients. In 101 (41%) patients QoL and pain could be evaluated. Mean age was 72.9 (range 47.8-89.8) years, 85 (83%) had ≥6 bone metastases, an average of 4.8 (CI 4.6-5.1) cycles were administered and 51 (50%) were treated with 6 cycles. The mean total FACT-P in was 70.6 (CI 68.4-72.8). The lowest FACT-P score was at cycle 3 (67.6; CI65.0-70.1) and was 67.0 (CI 66.3-73.6) at cycle 6, which were 3.0 and 3.6 points lower than BL, respectively. The mean total BPI-S score was 43.5 (CI 38.9-48.0) at baseline. Asymptomatic patients (57; 56%) had a PAIW score of 2.1 (CI 1.8-2.5) and a mean total score of 31.0 (CI 25.9-36.0) at base line. The lowest PAIW score was at cycle 5 (1.7; CI 1.1-2.2) and mean total score of 23.4 (CI 16.2-30.6). Symptomatic patients (54; 53%) had a PAIW of 6.9 (CI 6.5-7.2) and a mean total score of 56.0 (CI 51.0-60.9). The lowest PAIW score was at cycle 2 (6.1; CI 5.6-6.6) and mean total score of 53.2 (CI 44.9-59.4) which were 0.8 and 2.8 points lower than base line, respectively. Patients treated with 6 cycles of Ra-223 had a PAIW of 7.1 (CI 6.1-8.2) and a mean score of 56.1 (CI 35.5-67.7).

Conclusions: QoL and pain remained stable during Ra-223 treatment. The lack of pain response might be related to opiate use, which will be analyzed.

Clinical trial identification: NCT03223727.

830P Synthetic DNA immunotherapy in biochemically relapsed prostate cancer

N. Shore[1], E.I. Heath[2], L.T. Nordquist[3], H. Cheng[4], K. Bhatt[5], M. Morrow[6], T. McMullan[7], K. Kraynyak[6], J. Lee[8], B. Sacchetta[8], L. Liu[6], S. Rosencranz[8], S.T. Tagawa[9], L.J. Appleman[10], R. Tutrone[11], J. Garcia[12], Y. Whang[13], W. Kelly[14], I. Csiki[8], M.L. Bagarazzi[8]

[1]Urology, Carolina Urologic Research Center, Myrtle Beach, SC, USA, [2]Oncology, Karmanos Cancer Center, Detroit, MI, USA, [3]Medical Oncology, Urology Cancer Center and GU Research Network, Omaha, NE, USA, [4]Medical Oncology, University of Washington School of Medicine, Seattle, WA, USA, [5]Clinical, Inovio Pharmaceuticals Inc, Plymouth Meeting, PA, USA, [6]Immunology, Inovio Pharmaceuticals, Inc., Plymouth Meeting, PA, USA, [7]Biostatistics, Inovio Pharmaceuticals, Inc., Plymouth Meeting, PA, USA, [8]Clinical, Inovio Pharmaceuticals, Inc., Plymouth Meeting, PA, USA, [9]Medical Oncology, Weill Cornell Medical College, New York, NY, USA, [10]Medical Oncology, University of Pittsburgh Cancer Institute, Pittsburgh, PA, USA, [11]Medical Oncology, Chesapeake Urology Associates, Towson, MD, USA, [12]Medical Oncology, Cleveland Clinic, Cleveland, OH, USA, [13]Medical Oncology, Lineberger Comprehensive Cancer Center, Chapel Hill, NC, USA, [14]Medicine, Thomas Jefferson University, Philadelphia, PA, USA

Background: INO-5150 (PSA and PSMA) +/- INO-9012 (IL-12), a synthetic DNA immunotherapy, was assessed for safety, immunogenicity and efficacy in biochemically recurrent prostate cancer patients (pts).

Methods: Phase I, open-label, multi-center study in the US included pts with rising PSA after surgery and/or RT, PSA doubling time (PSADT) >3 months (mos), testosterone >150 ng/dL and no concurrent ADT. Safety, immunogenicity and efficacy (PSA kinetics, PFS) were evaluated in 4 treatment arms of 15 pts each. Arms A: 2mg INO-5150, B: 8.5 mg INO-5150, C: 2mg INO-5150 + 1mg INO-9012 and D: 8.5mg INO-5150 + 1mg INO-9012. Pts received 4 IM doses of vaccine followed by electroporation on day 0, wks 3, 12 and 24 and were followed for 72 wks.

Results: 50/61 (82%) pts completed all visits and treatments were well tolerated with no safety concerns. Median PFS for overall population [N = 61, baseline (D0) PSADT range (mos) 1.5-217.1, median 9.8] and for a subset of pts with D0 PSADT ≤12mos (N = 36) has not yet been reached (FU 3-19 mos). 86% of pts with D0 PSADT ≤12 mos were progression free through 19mos FU. 27 out of 36 (75%) pts with D0 PSADT≤ 12 mos had disease stabilization at wks 27 evidenced by significant improvement in log_2PSA change over time (slope) and PSADT from D0 (Slope=0.19 declined to 0.1, PSADT=5.3 improved to 10.1 mos, p = <0.0001). This effect was maintained at wk 72 (Slope=0.09, PSADT=10.6, p = <0.0001). Immunogenicity was observed in 77% (47/61) of pts by multiple immunologic assessments. Patient immunogenicity to INO-5150 as determined by CD38 and Perforin + CD8 T cell immune reactivity correlated with attenuated % PSA rise compared to pts without reactivity (p = 0.05, n = 50).

Conclusions: INO-5150 +/- INO-9012 was safe, well tolerated and immunogenic. Clinical efficacy was observed in the patients with D0 PSADT≤ 12 mos as evidenced by a significant dampening of log_2PSA change over time and increased PSADT up to 72 weeks FU. Additional genomic analyses are ongoing to further elucidate the correlation of immunologic efficacy and clinical benefit. (NCT02514213).

831P Clinical experience with 100 consecutive patients treated with Lu-177-labeled PSMA-I&T radioligand therapy for metastatic castration-resistant prostate cancer: Final analysis

R.L. Tauber[1], K. Knorr[2], S. Schwaiger[1], M. Retz[1], T. Maurer[1], C. D'Alessandria[2], H-J. Wester[3], J. Gschwend[1], W. Weber[2], M. Schwaiger[2], M.M. Heck[1], M. Eiber[2]

[1]Urology, Klinikum rechts der Isar TUM, Muenchen, Germany, [2]Nuclear Medicine, Klinikum rechts der Isar TUM, Muenchen, Germany, [3]Institute of Pharmaceutical Radiochemistry, Technical University Munich, Munich, Germany

Background: Final analysis of our experience with ^{177}Lutetium-labeled prostate-specific membrane antigen-ligand (^{177}Lu-PSMA-I&T) for systemic radioligand therapy in 100 consecutive patients with metastatic castration-resistant prostate cancer (mCRPC).

Methods: Patients were treated under a review board-approved compassionate use protocol. Eligibility criteria for ^{177}Lu-PSMA-I&T therapy included previous treatment with abiraterone or enzalutamide, taxane-based chemotherapy or unsuitability for taxanes as well as positive ^{68}Ga-PSMA tracer uptake of metastases in a prior PET-scan. Intravenous treatment with ^{177}Lu-PSMA-I&T was given 6- to 8-weekly with an activity of 7.4GBq up to 6 cycles in patients without clinical or radiographic progression. We report prostate-specific antigen (PSA) decline, clinical progression-free survival (cPFS), overall survival (OS), subgroupanalysis and toxicity.

Results: Median age was 72 years (range 46-85) and median PSA level was 165 ng/ml (range 0-6178). Bone, lymph node and visceral metastases were present in 96%, 87% and 35% of patients. The median number of previous treatment regimens for mCRPC was 3 (range 1-6) and 82% of patients were pretreated with chemotherapy. At the time of evaluation, 319 cycles with ^{177}Lu-PSMA-I&T were applied (median 2 cycles per patient, range 1-6). No treatment was ongoing. 4 and 6 cycles were applied in 44 and 20 patients. PSA decline $\geq$30%, $\geq$50% and $\geq$90% was achieved in 47%, 38% and 11% of patients. Median cPFS was 4.1 months (95%CI 2.5-5.7) and median OS was 12.9 months (95%CI 9.9-15.9). In the subgroupanalysis visceral metastases were associated with a worse prognosis concerning PSA decline >50% (26 vs. 44%, p = 0.06), median cPFS (3.1 vs. 5.9 months, p < 0.01) and median OS (8.0 vs. 14.0%, p = <0,05). Treatment-emergent hematologic grade 3/4 toxicities were anemia (9%), thrombocytopenia (4%) and neutropenia (6%). Grade 3/4-non-hematologic toxicities were not observed. The main non-hematologic grade 1/2 toxicities were dry mouth (24%), fatigue (20%) and loss of appetite (10%).

Conclusions: Radioligand therapy with ^{177}Lu-PSMA I&T appears to be safe and active in late-stage mCRPC.

832P Association between patient reported quality of life (QOL) and survival: Analysis of E3805 chemohormonal androgen ablation randomized trial in prostate cancer

A.K. Morgans[1], Y-H. Chen[2], D. Jerrard[3], M.A. Carducci[4], R. Dipaola[5], L. Wagner[6], D. Cella[7], C. Sweeney[8]

[1]Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL, USA, [2]Biostatistics, ECOG, Boston, MA, USA, [3]Urology, University of Wisconsin, Madison, WI, USA, [4]Oncology, Johns Hopkins University, Baltimore, MD, USA, [5]Medicine, University of Kentucky, Lexington, KY, USA, [6]Social Sciences & Health Policy, Wake Forest University School of Medicine, Winston-Salem, NC, USA, [7]Medical Social Sciences, Northwestern University, Chicago, IL, USA, [8]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, USA

Background: Chemohormonal therapy (docetaxel and androgen deprivation (ADT+D)) for metastatic hormone sensitive prostate cancer (mHSPC) prolongs overall survival (OS) versus ADT alone. We assessed the association between QOL and OS in men with mHSPC treated with ADT+D vs ADT.

Methods: Men were randomized to ADT+D (6 cycles) or ADT. QOL was assessed using the Functional Assessment of Cancer Therapy-Prostate (FACT-P), FACIT-Fatigue, and Brief Pain Inventory (BPI). Logrank test and Cox proportional hazards models were used to evaluate the association between QOL and OS.

Results: 790 men were randomized (ADT+D, N = 397, and ADT, N = 393). OS was significantly poorer for ADT patients with baseline FACT-P $\leq$ median than > median (p = 0.03), but not for ADT+D patients (p = 0.34). FACT-P at 3 months was associated with OS for ADT patients (median OS lowest vs highest quartile 26.5 vs 44.1 mo, p = 0.003), but not ADT+D (median OS lowest vs highest quartile 46.1 vs 48.4 mo, p = 0.98 and Table). Change in QOL from baseline to 12 months in the patients with most improvement and most decline was associated with OS (median OS in best vs worst 25% in ADT 36.1 vs 23.7 mo, p = 0.048; median OS in best vs worst 25% in ADT+D NR vs 37.1 mo, p = 0.006). Baseline fatigue, but not baseline pain, was associated with OS after adjusting for multiple prognostic factors (BPI (p = 0.86); FACIT-Fatigue 3-unit increase HR = 0.95, p = 0.006).

Table: 832P Association between 3-month FACT-P and OS (worst 25% and best 25% of patients)

Treatment	HR (worst 25% vs best 25%)[1]	95% CI
ADT+D	0.70	0.37-1.34
ADT	2.51	1.37-4.58

1. Adjusted for treatment arm, disease volume, ECOG PS, Gleason, prior local therapy and BMI, and stratification factors at randomization.

Conclusions: In men with mHSPC, baseline and 3 month poor QOL are associated with OS in ADT patients but not ADT+D. The latter may be due to positive treatment effect from docetaxel in pts with poor baseline QOL. There was no association between chemotherapy induced poor QOL and OS.

Clinical trial identification: NCT00309985.

Background: The PI3K pathway plays an important role in cell growth and survival of *PTEN*-null tumours. An ongoing phase 1/2 study (NCT01884285) previously reported that AZD8186, a potent and selective inhibitor of PI3Kβ (minimal PI3Kδ activity), can be well tolerated in pts with solid tumours; here we present preliminary data in heavily pretreated mCRPC.

Methods: Pts with mCRPC received escalating doses of AZD8186 (5 days on, 2 days off; 2 days on, 5 days off; or continuous schedules) as monotherapy (study Part A) or in combination with AAP (1000 mg qd + prednisone 10 mg qd, study Part C1) until progressive disease (PD) or dose-limiting toxicities. Analyses included tolerability, RECIST tumour response, prostate-specific antigen response, circulating tumour cell counts and cell-free DNA.

Results: Fifty-two pts with mCRPC were treated with AZD8186 as monotherapy (n = 39) or in combination with AAP (n = 13). Prior treatment status: AAP (n = 14), enzalutamide (enza, n = 10), both (n = 21) or AAP/enza-naive (n = 7). Diarrhoea (39%) and nausea (27%) were the most frequently reported adverse events (AEs, all grades) related to AZD8186. Grade 3 AEs of interest included diarrhoea/colitis (10%), which was fully reversible with dose interruption/SoC treatment, and rash (7%). Two (4%) pts had grade 4 AEs (thrombocytopenia, hypokalaemia); no grade 5 AEs. AZD8186 did not appear to alter tolerability of AAP. Among pts with RECIST measurable disease, one had a confirmed partial response (Part C1), 10 had stable disease, nine had PD. Nine (17%) pts had reduction in PSA >30%. Twelve pts completed >16 weeks of treatment, five pts >24 weeks (PTEN-proficient [n = 0], PTEN-deficient [n = 3], PTEN-unknown [n = 2]). Recruitment of pts with PTEN-deficient mCRPC into an expansion phase in combination with AAP is ongoing.

Conclusions: Data from this phase 1/2 study indicates that the tolerability of AZD8186 supports combination treatment with AAP in pts with metastatic prostate cancer. Preliminary evidence of antitumour activity has been observed. Updated results will be presented.

Background: Niraparib is a potent inhibitor of poly (ADP-ribose) polymerase (PARP)-1 and PARP-2, enzymes involved in DNA repair. PARP-1 is involved in modulating androgen receptor (AR) signaling and function. A phase 1b study (Bedivere) of niraparib + AR-targeted therapy (ART), which combines 1000 mg abiraterone acetate and 10 mg prednisone (AA-P), in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC) who failed $\geq$1 line of chemotherapy and ART is ongoing.

Methods: The objectives of this multicenter, open-label study were to establish the recommended phase 2 dose (RP2D) of niraparib and to evaluate the safety and pharmacokinetics (PK) of niraparib + ART. A standard 3 + 3 design was used in part 1, followed by niraparib dose expansion in part 2 with the RP2D of niraparib + AA-P. Pts received niraparib 200 or 300 mg once daily + AA-P. Dose-limiting toxicities (DLTs) were evaluated during the first cycle (28 days).

Results: At data cutoff, 16 pts were treated; 12 at 200 mg and 4 at 300 mg niraparib + AA-P. Median age was 62 years (49–81), median PSA was 70.0 ng/mL (2.7–766.9) and median treatment duration was 3.0 months (0.4–6.6). Most pts (11/16) are still on treatment. No DLT was observed with niraparib 200 mg + AA-P. Two pts had grade 4 neutropenia with niraparib 300 mg + AA-P. Niraparib 200 mg + AA-P is selected as the RP2D to be evaluated in part 2. Preliminary PK data (n = 6) suggest the absence of significant interaction between niraparib and AA-P; systemic exposure of the 2 drugs was comparable to that observed with respective monotherapies. At the RP2D (200 mg + AA-P), most common adverse events (AEs) were nausea (5/12, 41.7%), constipation, vomiting, fatigue and back pain (4/12, 33.3% each); serious AEs (SAEs) included nausea and vomiting (1/12, 8.3% each). In the 200 mg cohort, 10 pts (83.3%) had AEs; 1 pt (8.3%) had an SAE. AEs leading to dose interruption/reduction occurred in 3 pts (25%); 2 pts (16.7%) discontinued treatment due to AEs.

Conclusions: Data to date from the Bedivere study support safety and tolerability of a combination of niraparib 200 mg + AA-P in pts with mCRPC. A future phase 3 clinical study will be needed to assess the clinical benefit of the combination in mCRPC pts with DNA repair gene defects.

835P CYP11A1 inhibition as a therapeutic approach for the treatment of castration resistant prostate cancer

R. Oksala, K. Räsänen, M. Karimaa, R. Riikonen, M. Ramela, P. Vehmaan-Kreula, O. Simola, P. Rummakko, G. Wohlfahrt, M. Mustonen

Orion Corporation, Orion Pharma, Espoo, Finland

Background: Prostate cancer is a major global challenge due to the increasing number of aging population and frequency of diagnosis. During the past decade new treatments have been targeted to the androgen signaling axis either by inhibiting the binding of androgens to androgen receptor (AR) and AR nuclear translocation, or by inhibiting androgen production via CYP17A1 enzyme. Despite the significant progress on the research and new therapies, CRPC is still incurable and there is urgent need for better, more effective treatments. ODM-208 is an oral, non-steroidal and selective inhibitor of CYP11A1 enzyme, suppressing the synthesis of all steroid hormones that could be potential AR ligands.

Methods: The inhibition of CYP11A1 was measured in vitro by the formation of radiolabelled isocapronic acid in a human adrenal cortex cell line (H295R). The tumor growth inhibition of ODM-208 was studied in VCaP CRPC xenograft model. Full length AR (AR-FL) and AR-V7 were analysed from the tumors by western blot and also key enzymes of androgen biosynthesis, CYP17A1, AKR1C3, SRD5A1 were quantified by qPCR. At the end of the xenograft study, plasma ACTH and LH, and key steroid hormone concentrations were analysed from plasma and target tissues.

Results: ODM-208 potently inhibits CYP11A1 enzyme in vitro. In addition, in vivo in the VCaP CRPC xenograft model ODM-208 significantly inhibited tumor growth. Importantly, the amount of AR-FL and AR-V7 levels remained unchanged in the tumors after ODM-208 treatment. Slight increase of CYP17A1 and SRD5A1 enzyme levels was observed, indicating the activation of steroidogenesis in VCaP tumors in vivo. Treatment had no effect on plasma LH, whereas ACTH was significantly increased demonstrating reduction in glucocorticoid levels by negative feedback. In line with ACTH, all measured steroid hormones were significantly reduced both in plasma and target tissues.

Conclusions: ODM-208 shows promising antitumor activity in preclinical CRPC models and has favorable toxicological profile. Thus, ODM-208 might have potential for treating patients with CRPC. Based on the nonclinical results, a phase 1/2 clinical trial (NTC03436485) has been initiated.

836P Use of nuclear-localized androgen receptor splice variant 7 protein in CTCs after 1st androgen receptor signaling inhibitor (ARSi) as a predictive biomarker for overall survival on a second ARSi or taxane chemotherapy in metastatic castration-resistant prostate cancer (mCRPC)

H.I. Scher[1], R.P. Graf[2], M. Hulling[1], E. Carbone[1], R. Dittamore[2]

[1]Genitourinary Oncology Service, Memorial Sloan-Kettering Cancer Center, New York, NY, USA, [2]Translational Research, Epic Sciences, Inc., San Diego, CA, USA

Background: In the U.S., most mCRPC patients will receive an ARSi (abiraterone, enzalutamide) in 1st line. More than 60% will receive a second, sequential ARSi (A-A) as opposed to ARSi then Taxane (A-T). No randomized studies exist comparing A-A and A-T. Recent real-world cohort risk-adjusted analyses were not able to discern differences in overall survival (OS) between A-A and A-T, despite a wide range of observed outcomes within groups. Using a cross-sectional cohort of standard of care in a tertiary center, we sought to determine if observations were consistent with community, and evaluate if nuclear AR-V7 could have additive effect on OS, specifically post-ARSi failure.

Methods: We previously reported utility of nuclear AR-V7 in two cross-sectional cohorts (Scher et al 2016 and Scher et al 2018). Blood was drawn from mCRPC patients prior to new line of therapy, AR-V7 testing by Epic Sciences, and therapy choice by physician without knowledge of AR-V7 status. OS data was updated, and a subset of

these combined cohorts were analyzed (n = 148): those who had failed an ARSi, and were about to go onto a second ARSi (n = 73) or taxane (n = 75). A risk score was used to adjust for underlying patient imbalances and therapy choice propensity.

Results: 75 of 148 (51%) received A-T and 73 of 148 (49%) received A-A. Adjusting for patient risk, a discernable difference in OS was not detected (HR: 1.16, CI: 0.73 – 1.85, p = 0.52). Incorporating AR-V7, there was a significant interaction between positivity for AR-V7 and OS on taxanes (HR: 0.16, CI: 0.052 – 0.52, p = 0.0020). In risk-matched analysis, there was a significant difference in OS between AR-V7(+) patients on taxanes vs. ARSi (11.6mo vs. 5.5mo, p = 0.0029).

Conclusions: Sequential ARSi use in the U.S. is common. Adjusting for patient risk and physician therapy choice, AR-V7 use after ARSi failure identifies patients who would live longer on taxanes vs. ARSi. Physician intuition alone was not sufficient to achieve predictive effect of AR-V7.

837P Prediction of prostate cancer gleason score upgrading from biopsy to radical prostatectomy (RP) using a validated 17-gene panel assay

J. Cullen[1], H.J. Lawrence[2], Y. Chen[1], R. Lu[2], S. Srivastava[1], I. Rosner[1], T. Brand[1], I. Sesterhenn[1]

[1]Surgery, Center for Prostate Disease Research, USUHS, Rockville, NY, USA, [2]Urology, Genomic Health, Redwood City, CA, USA

Background: We have previously shown that a 17-gene, biopsy-based RT-PCR assay (Oncotype Dx® Genomic Prostate Score™, GPS™) is a strong independent predictor of 1) adverse pathology (defined as surgical GS > 4 + 3 and/or non-organ confined disease) at radical prostatectomy (RP), and 2) biochemical recurrence after RP in men with biopsy GS 6 and 7 prostate cancer. We performed a more refined analysis of the association between GPS and upgrading from biopsy to surgery.

Methods: Patients in a prior clinical validation study of the GPS assay were assigned a biopsy Gleason sum (BxG) and pathologic ISUP 2014 surgical Gleason grade (pGS) by a single uropathologist (IS) in a blinded fashion. We performed logistic regression analyses to model the association of GPS with Gleason upgrading (GU) defined as (i) Any downgrade, (ii) Any increase in GS, (iii) BxG 6 to pGS 3 + 4, (iv) BxG 6 to pGS 4 + 3, and (v) BxG 7 to pGS 8-10, all versus no change in GS. GPS values, as determined from diagnostic biopsy tissue, are reported on a scale of 0-100, and predictions of GU were modeled in 20-unit GPS increments.

Results: Among 395 patients, median patient age at RP and GPS score was 62 years and 30.3, respectively. There were 249 patients (63%) who had no change in GS from biopsy to surgery, 45 patients (11%) were down-graded (BxG 7 to pGS 6) and 101 patients (31%) were upgraded (85 BxG 6 to pGS3 + 4, 10 BxG 6 to pGS 4 + 3, and 6 BxG 7 to pGS 8-9). GPS was a significant predictor of any GS upgrade, BxG 6 to pGS 3 + 4, and BxG 7 to pGS 8-9 (see Table).

Table: 837P

BxG vs pGS	OR/ per 20 units in GPS	95% CI of OR		P value
Any GS Downgrade	1.00	0.58	1.74	0.978
Any GS upgrade	1.77	1.20	2.60	0.004
bGS6 to pGS3 + 4	1.61	1.06	2.41	0.027
bGS6 to pGS 4 + 3	2.46	0.90	6.73	0.079
bGS 7 to pGS 8-9	4.49	1.32	15.533	0.017

Referent in all models is no change in GS.

Conclusions: GPS is a significant predictor of the likelihood of Gleason score upgrading from biopsy to RP. Incorporation of GPS results into treatment decision making can improve risk assessment for newly diagnosed patients with clinically low-risk prostate cancer.

838P PI3K/AKT pathway deleterious mutations in lethal prostate cancer

P. Rescigno[1], M. Rediti[1], D. Dolling[2], D.N. Rodrigues[1], D. Bianchini[1], R. Riisnaes[2], C. Messina[1], M. Barrero[1], A. Petremolo[1], A. Sharp[1], S. Sumanasuriya[1], G. Seed[2], I. Figueiredo[2], S. Miranda[2], J. Goodall[2], J. Mateo[2], R. Chandler[1], W. Yuan[2], S. Carreira[2], J.S. de Bono[1]

[1]Prostate Cancer Targeted Therapy Group, The Royal Marsden Hospital and Institute of Cancer Research, London, UK, [2]Prostate Cancer Targeted Therapy Group, The Institute of Cancer Research, London, UK

Background: PI3K/AKT signaling is commonly hijacked in prostate cancer (PC), associating with poorer prognosis and worse response to next generation hormonal treatment (NGHT) including abiraterone and enzalutamide. We studied deleterious pathway mutations in metastatic castration resistant PC (mCRPC) patients correlating these to prognosis and response to NGHT in a case-control study.

Methods: Patients with mCRPC and available treatment-naïve and/or CRPC tumor samples were evaluated. Mutation analyses involved MiSeq™ based targeted next generation sequencing (NGS); PTEN was assessed by immunohistochemistry (IHC) with the control cohort having no PTEN IHC loss. Correlations between pathway mutations and outcomes and response to NGHT utilized Cox and Kaplan-Meier analyses.

Results: Overall 418 samples (from Feb/15 to Dec/17) were sequenced by targeted NGS; 46 (11%) had mutated pathway genes of which 26 (6%) (PIK3CA, n = 18; AKT1, n = 6; PIK3R1, n = 2) were pathogenic pathway activating mutations. Among these 25 were previously described, while an undescribed PIK3R1 mutation (R543*), located in the iSH2 domain, was also identified. We then randomly selected 56 tumour samples with normal PTEN expression by IHC as a control group without detected pathway aberrations. Overall, 43% (10/23) of patients with mutated cancers had NGHT in pre-, and 57% (13/23) in post-chemotherapy settings, while 3 were NGHT naïve. In the control group, 14 patients (25%) were pre-chemotherapy while 42 (75%) post-chemotherapy. Deleterious pathway mutations were associated with a shorter median overall survival (2.8 vs 4.3 years; HR: 2.73; p < 0.001) and median duration of NGHT (5.9 vs 10.0 mo; p < 0.001), despite a higher proportion of post-chemotherapy patients in the control group.

Conclusions: PI3K/AKT pathway deleterious mutations impart a poor prognosis from mCRPC and are associated with shorter responses to NGHT. We envision that these data can impact treatment selection in a targeted treatment approach for mCRPC.

839P Clinico-genomic profiling and outcome prediction of neuroendocrine prostate cancer (NEPC)

V. Conteduca[1], C. Oromendia[2], M. Sigouros[1], A. Sborner[3], D.M. Nanus[1], S.T. Tagawa[1], K. Ballman[2], H. Beltran[1]

[1]Division of Hematology and Medical Oncology, Weill Cornell Medical College, New York, NY, USA, [2]Department of Healthcare Policy & Research, Weill Cornell Medical College, New York, NY, USA, [3]Institute of Precision Medicine, Weill Cornell Medical College, New York, NY, USA

Background: NEPC is a variant of prostate cancer that may present "de novo" or after androgen receptor (AR)-targeted therapies ("treatment related") with a spectrum spanning both small cell prostate cancer (SCPC) and adenocarcinoma with neuroendocrine differentiation (adeno-NE). The comprehensive clinical and molecular landscape of different NEPC subtypes and its potential impact on outcome is poorly understood.

Methods: 274 prostate cancer patients (pts) with metastatic biopsy tumor morphology confirming NEPC (n = 97; 36 with SCPC and 51 with adeno-NE) or castration resistant adenocarcinoma (CRPC) (n = 187) between 2004 and 2017 in a single academic center were evaluated. Baseline, treatment and outcomes data along with tumor whole-exome and RNA-seq data were retrospectively reviewed. Statistical comparisons utilized Cox regression analysis and Kaplan-Meier method for association with NEPC, CRPC and overall/progression-free survival (OS/PFS).

Results: In NEPC, PSA at time of biopsy was lower compared with CRPC (median 1.18 vs 38.0, p = 0.001) and liver metastases were more common (32.2% vs 52.1%, p = 0.027). OS from time of prostate cancer diagnosis differed by subtype, with SCPC having shortest survival (median 2.98 years), followed by adeno-NE (median 5.98 years) then CRPC (median 12.14 years) (log rank p < 0.0001), with similar results seen with time from metastases (log rank p < 0.0001). AR alterations were more frequent in CRPC (p < 0.001), while RB1 (p = 0.001) and TP53 (p = 0.048) alterations and high NEPC mRNA score (p = 0.007) were more common in NEPC. For CRPC pts treated with abiraterone or enzalutamide, shorter PFS was observed when somatic alterations in RB1 (p = 0.067) or TP53 (p < 0.0001) were present. Elevated NEPC score (p = 0.006), serum CGA above upper limit of normal (p = 0.033), and presence of liver metastases (p < 0.001) were prognostic for time to death from diagnosis among pts with CRPC.

Conclusions: NEPC is associated with lower PSA, higher frequency of liver metastases, and worse prognosis compared with CRPC, with SCPC having the shortest OS. The presence of NEPC clinical or molecular features in CRPC is also prognostic. Further studies of this aggressive form of prostate cancer are warranted.

840P Prognostic value of free testosterone (FT) levels during salvage chemotherapy with carboplatin plus weekly docetaxel in metastatic castration- and docetaxel-resistant prostate cancer (mDRPC)

C.W.M. Reuter[1], S. Brunotte[1], P. Ivanyi[1], M.A. Morgan[2], V. Grünwald[3]
[1]Hematology, Hemostaseology, Oncology and Stell Cell Transplantation, Hannover Medical School, Hannover, Germany, [2]Exp. Hematology, Hannover Medical School, Hannover, Germany, [3]Hematology, Hemostaseology, Oncology and Stem Cell Transplantation, Medical School Hannover, Hannover, Germany

Background: Recent data suggest that carboplatin plus weekly docetaxel (DC) may be effective in mDRPC. Platinum(II)-complexes have been shown to interfere with steroid biosynthesis lowering testosterone levels by inhibiting the cholesterol side chain cleavage enzyme (CYP11A1), 3β-hydroxysteroid dehydrogenase (HSD3B1,2) and 17α hydroxylase/C17,20-lyase (CYP17A1).

Methods: Docetaxel failure/resistance was defined according to the Prostate Cancer Working Group (PCWG2 2007) criteria. Treatment consisted of at least two cycles of carboplatin AUC5 iv for 30 min on day 1 every 4 weeks (q4w), docetaxel at a dose of 35 mg/m2 iv for one hour on days 1, 8, (15) plus prednisone 2x5mg/day orally after receiving informed consent until disease progression or occurrence of intolerable adverse effects. Efficacy measures were done following PCWG2 recommendations. Free testosterone levels were measured before (n = 82) and during carboplatin/docetaxel chemotherapy (n = 76).

Results: Of the 106 pts. treated since February 2005, 96.2% had bone and 63.2 % soft tissue metastases (45% lymph node, 27% liver and 21% lung involvement). At the time of the current analysis, the median follow-up time was 13.5 months, 101 pts. had died and 102 had progressive disease. The objective response rate was 43.2% and the disease control rate 64.2% in the 67 pts. with measureable disease. Response of prostate-specific antigen (≥50%) was observed in 50 patients (47.1%). Median progression-free survival (PFS) for all patients was 6.9 months (CI 95% 5.7, 8.0) and median OS was 14.1 months (CI 95% 10.9, 17.3). The most common reversible grade 3/4 toxicity was leukopenia/ neutropenia (40.5/32.1%). Median free and total testosterone levels were reduced below the detection limit during DC treatment (from 0.55 pg/ml to < 0.18 pg/ml and 0.08 to < 0.05 ng/ml, respectively). Testosterone nadir values <0.18 pg/ml during DC treatment were associated with longer PFS, OS and post-hoc OS ($p < 0.05$).

Conclusions: These data suggest that carboplatin plus weekly docetaxel may be an important second-line treatment option for DRPC patients by inhibition the testosterone biosynthesis.

841P Prevalence of clinically actionable germline pathogenic variants (PVs) in advanced prostate cancer (aPC)

A.W. Hahn[1], A.L. Kapron[2], J. Boyle[2], W. Kohlmann[3], A. Poole[1], D.M. Gill[1], S. Greenberg[3], P. Hale[1], C. Teerlink[2], B.L. Maughan[1], L. Cannon-Albright[2], N. Agarwal[4], K.A. Cooney[1]
[1]Medical Oncology, Huntsman Cancer Institute/University of Utah, Salt Lake City, UT, USA, [2]Internal Medicine, University of Utah, Salt Lake City, UT, USA, [3]Clinical Genetics, Huntsman Cancer Institute/University of Utah, Salt Lake City, UT, USA, [4]Oncology/ Internal Medicine, Huntsman Cancer Institute, Salt Lake City, UT, USA

Background: Recently, germline PVs in 20 cancer predisposition genes were found in 11.8% of patients with aPC in a multi-center study (Pritchard et al, NEJM 2017).These PVs appeared to be predictive of response to PARP inhibitors (PARPi). We sought to evaluate the prevalence of clinically actionable PVs in a comparable aPC cohort and investigate possible associations of PVs with baseline patient and disease characteristics.

Methods: Clinical data and germline DNA samples from 352 consecutive aPC patients were retrospectively collected. A custom target panel (Qiagen QiaSeq V3) composed of 35 genes deemed clinically actionable and/or included in the Pritchard publication were sequenced on an Illumina HiSeq2500. GATK best practices were followed for alignment and variant calling. Variants were filtered based on ClinVar pathogenicity and reviewed by genetic counselors to confirm clinical significance. Baseline patient characteristics were compared using the Chi-squared, Fisher's, and Mann-Whitney U tests.

Results: Clinically actionable, germline PVs were found in 26/352 (7.4%) of this aPC cohort. 11 of the 26 mutation carriers had a PV in BRCA1, BRCA2, or ATM (overall prevalence 3.1%). 96.6% of men were Caucasian of North European descent. Baseline characteristics were similar in those with or without PVs in clinically actionable genes, including age at diagnosis ($p = 0.77$), Gleason score ($p = 0.22$), or presence of metastatic disease at diagnosis ($p = 0.08$).

Conclusions: Our aPC cohort appears to have a lower prevalence of clinically actionable, germline PVs than previously reported studies. These findings may help inform recommendations for clinical genetic testing in this population, and help estimate the pace of enrollment on multiple ongoing clinical trials with PARPi in this population.

842P CTC-based biomarkers & PSMA-targeted imaging in patients with metastatic castrate-resistant prostate cancer (mCRPC)

M.J. Morris[1], N.J. Vogelzang[2], O. Sartor[3], A. Armour[4], R. Messmann[5], M. Groaning[5], A. Robarts[6], A.W. Tolcher[7], M. Gordon[8], H.M. Babiker[9], P. Kuo[9], M. Kearney[10], A. Jendrisak[10], Y. Wang[11], M. Landers[11], D.P. Petrylak[12]
[1]Memorial Sloan-Kettering Cancer Center, Memorial Sloan-Kettering Cancer Center, New York, NY, USA, [2]US Oncology Research c/o Comprehensive Cancer Crts of NV, US Oncology Research c/o Comprehensive Cancer Crts of NV, Las Vegas, NV, USA, [3]Tulane Cancer Center, Tulane Medical School, New Orleans, LA, USA, [4]Endocyte, Indianapolis, IN, USA, [5]Medical Affairs, Endocyte, West Lafayette, IN, USA, [6]GU, Memorial Sloan Kettering Cancer Center, New York, NY, USA, [7]Clinical Research, NEXT OncologyTM, San Antonio, TX, USA, [8]Medical Oncology, HonorHealth Virginia G Piper Cancer Care Network, Scottsdale, AZ, USA, [9]Cancer Center, University of Arizona Cancer Center, Tucson, AZ, USA, [10]Clinical Operations, Epic Sciences, San Diego, CA, USA, [11]Translational Research, Epic Sciences, San Diego, CA, USA, [12]Medical Oncology, Yale University School of Medicine Medical Oncology, New Haven, CT, USA

Background: Prostate-specific membrane antigen (PSMA) is highly expressed in prostate cancers, making it an imaging & therapeutic target of interest. The utility of the PSMA-targeted imaging agent ^{99m}Tc-EC0652 is being evaluated, along with biomarker analysis of circulating tumor cells (CTCs), in pts with mCRPC in a completed PSMA-targeted chemotherapeutic study. We now report the PSMA heterogeneity via CTC vs. imaging in the pt population treated to date.

Methods: A total of 51 pts evaluated at the time of the data cut had baseline CT & bone scans performed in addition to a ^{99m}Tc-EC0652 SPECT/CT as a measure of imaging-based PSMA expression. 41 of 51 pts provided pre-treatment blood samples evaluable for CTC biomarker analysis, which included PSMA expression & predicted genomic instability status (pGI). Images collected from pts were analyzed for both their PSMA$^+$ status as well as sensitivity relative to conventional imaging.

Results: 41 of 51 pts (80.4%) had detectable CTCs in their samples prior to therapy while 32 of 38 (84.2%) of the analyzed paired on-therapy samples had CTCs after treatment. At baseline PSMA$^+$ CTCs were found in 19 of 51 (37.2%) pts and overall was expressed on 33% (IQR 11.3% - 40.1%) of CTCs within each pt sample. 15 of 17 (88%) PSMA$^+$ pt samples were also pGI$^+$. 31 of the 51 pts (60.7%) of the pts had bone scan (BS) data available to analyze. 27 of the 51 pts had CT scan data available to analyze for nodal lesions. Concordance between Conventional Imaging & ^{99m}Tc-EC0652.

Table: 842P

	^{99m}Tc-EC0652$^+$	^{99m}Tc-EC0652$^-$	BS$^+$	BS$^-$	CT$^+$	CT$^-$
Bone Lesion (770)	770 (100%)	0	587 (76.2%)	183 (23.8%)	N/A	N/A
Nodes >1.5cm (54)	48 (88.9%)	6 (11.1%)	N/A	N/A	54	N/A
Nodes <1.5cm (69)	69	N/A	N/A	N/A	N/A	N/A

Conclusions: In this cohort, most pts had CTCs for assessment. The majority of pts with CTCs had PSMA$^-$CTCs. The pts CTCs expressing PSMA accounted for a small percentage of the total CTCs observed. These PSMA$^+$ CTCs had high pGI. Pts with CTCs had PSMA imagable disease, especially in bone. The discordance between CTCs & imaging illustrate the disease heterogeneity in regards to PSMA expression. These data should be considered in designing future PSMA-directed regimens.

843P The neutrophil-to-lymphocyte ratio (NLR) as a predictive marker of response to abiraterone acetate: A retrospective analysis of the COU302 study

T. Loubersac[1], S. Chakak[2], M. Nguile-Makao[2], V. Fradet[2], P. Toren[2]
[1]Urology, CHU de Nantes, Nantes, France, [2]Uro-oncology, CHU Hotel dieu quebec, Quebec City, QC, Canada

Background: The neutrophil–lymphocyte ratio (NLR) is recognized as a prognostic marker in many cancers, including metastatic castration-resistant prostate cancer (mCRPC). In this study, we perform a retrospective analysis of the pivotal COU302 study of abiraterone acetate (AA) as first line therapy for men mCRPC.

Methods: The COU302 study randomized men with minimally symptomatic mCRPC to 1000mg AA once daily plus 5mg prednisone (AA + P) twice daily or placebo plus 5mg prednisone (P) twice daily. We utilized Kaplan–Meier survival and cox proportional hazard analyses to assess the effect of baseline NLR on response to AA + P versus P. Adjustment co-variates were selected from a recently reported analysis of the PREVAIL study of enzalutamide in men with mCRPC. Based on this analysis, we selected a NLR cut-off value of 2.5. Outcomes assessed included the co-primary endpoints from the COU302 study overall survival (OS) , radiographic progression free-survival (RPFS) and PSA progression-free survival (PFS).

Results: Among the 1088 patients in the COU302 study, baseline NLR values showed significant differences according to baseline albumin below median (3.16 vs 2.92, $p = 0.011$), but no other baseline covariates. Mean NLR significantly increased following treatment initiation and at the end of study compared to baseline. Among patients with a baseline NLR $\geq$2.5, there was similar OS in AA + P and P treatment arms ($p = 0.26$), which was confirmed on adjusted cox proportional hazards (AA +P HR 0.95, $p = 0.65$). AA + P showed a significant OS benefit versus P ($p = 0.0011$) in men with baseline NLR <2.5, with an adjusted HR of 0.723($p = 0.012$). For RPFS, benefits for AA + P were seen in men with NLR <2.5 or $\geq$ 2.5, with the magnitude of benefit greater in men with NLR <2.5. In the AA + P arm, men with baseline NLR <2.5 had significantly better PSA PFS compared to baseline NLR $\geq$2.5 ($p = 0.03$); no significant differences were seen in men in the placebo arm.

Conclusions: In the COU302 study, we observed that patients with a screening NLR<2.5 had a significant benefit to AA + P compared to P, whereas for patients with a screening NLR $\geq$2.5, this benefit was less evident. Increases in the NLR value from baseline could not be used to predict response to AA.

844P The clinical impact of targeted next generation sequencing (tNGS) in the treatment of metastatic prostate cancer

P.M.C. Coelho Barata, P. Mendiratta, M. Sadaps, S. Klek, M. Ornstein, T. Gilligan, P. Grivas, B.I. Rini, D. Sohal, J.A. Garcia

Medical Oncology, Taussig Cancer Institute Cleveland Clinic, Cleveland, OH, USA

Background: Tumor profiling by tNGS is increasingly common in patients (pts) with metastatic solid tumors. It is unclear if this strategy leads to changes in treatment decision for mPCa pts.

Methods: A retrospective analysis of mPCa pts treated at Cleveland Clinic with available comprehensive genomic profiling using tumor tissue (FoundationOne, F1) or cell-free circulating tumor DNA (FoundationAct, Guardant360) was conducted. Targetable genomic alterations (tGA) were defined as a change in the copy number (amplification/duplication) or a mutation (deletion/rearrangement/truncation/fusion) in AR, DNA repair genes, mismatch repair (MMR) genes, cyclin-dependent kinases (CDK), ERBB2, BRAF, TSC and PIK3-mTOR pathway.

Results: Within 2013-2017, 66 pts, median age 68y (49-85), median ECOG PS1 (0-2), with mPCa, Gleason 9 (6-10), 86% castration-resistant (CRPC), received a median of 3 (0-7) systemic treatments for CRPC before tNGS panel. The most common tNGS platform used was F1 (91%) based on archival tumor tissue (45% primary, 55% metastatic). Overall, frequent alterations included TP53 (42%), PTEN (35%), AR (30%), DNA repair (30%), PIK3CA signaling pathway (21%), CDK (15%) and MSI-H/MMR (9%). Median tumor mutational burden was 7 (0.8-32) mutations/Mb. Among 45 with tGA+ pts, tNGS influenced treatment in 13 pts: PARP inhibitor (n = 7; olaparib 6, niraparib 1), mTOR inhibitor (n = 4; everolimus 3, temsirolimus 1), pembrolizumab 2, trastuzumab 1. PSA decline was observed in 54% and median (m) PFS was 4.1 months (95%CI, 2.8-5.4) with 9 pts (69%) progressing on therapy to date. Among tGA+ pts not treated with tGA-based therapy, first subsequent treatment (n = 17) included chemotherapy (71%), abiraterone (18%), cabozantinb (6%) and other (6%). PSA decline was observed in 24% and mPFS was 4.3 months (95%CI, 2.6-6.0); 12 pts (71%) progressed on therapy. There was no difference in mPFS between tGA+/tGA- pts ($p = 0.652$). The median OS was 60.4 months (95%CI, 51.9-68.9) compared with 17 months (95%CI, 10.5-23.5) after tNGS was ordered.

Conclusions: tNGS was ordered somewhat late in the course of the disease. tGA results only impacted therapy selection in 20% of pts but with modest clinic benefit.

845P Phase III double-blind study evaluating lens opacifications (LO) in patients with nonmetastatic prostate cancer (PCa) receiving denosumab (Dmab) for bone loss due to androgen deprivation therapy (ADT)

S.T. Tagawa[1], T. Dai[2], D. Jandial[3]

[1]Urology, Weill Cornell Medical College, New York, NY, USA, [2]Biostatistics, Amgen Inc., Thousand Oaks, CA, USA, [3]Oncology, Amgen Inc., Thousand Oaks, CA, USA

Background: Men with PCa undergoing ADT experience bone loss that may be associated with fracture risk and reduced survival. Therapy with Dmab (Prolia®, Amgen, Inc) significantly increased bone mass and reduced vertebral fracture risk in men with nonmetastatic PCa receiving ADT. However, in that study (unlike other Dmab randomized trials), cataracts were reported more often in the Dmab group (4.7% vs 1.2% for placebo [PBO]). This trial (NCT00925600) assessed the effect of Dmab on LO (cataract) development or progression in men with nonmetastatic PCa receiving ADT.

Methods: Men aged $\geq$30 years with nonmetastatic PCa with bilateral orchiectomy or initiated ADT were randomized 1:1 to receive Dmab 60 mg or PBO subcutaneously every 6 months, stratified by Lens Opacities Classification System III (LOCS III) score (<3.0 at all sites, $\geq$3.0 at any site), age (<75, $\geq$75 years), and prior cataract history. The primary endpoint was LO development or progression by month 12 based on a change of $\geq$ 1.0 in posterior subcapsular cataract, $\geq$1.0 in cortical cataract, or $\geq$ 0.7 in nuclear opalescence per LOCS III score. Noninferiority was demonstrated if the upper bound of the 95% 2-sided CI was <10%.

Results: 769 men with median age 71 were randomized to receive Dmab (n = 383) or PBO (n = 386). Baseline demographics were balanced. Development or progression of LO by month 12 was similar in the Dmab and PBO groups (33.5% vs 33.2%); the absolute risk difference was 0.4% (95% CI, –6.3 to 7.2; noninferiority P = 0.0026), indicating that Dmab was noninferior to PBO for the primary endpoint. Results for other LO endpoints also showed no increased risk of cataracts with Dmab (Table). Rates of AEs, serious AEs, AEs leading to treatment discontinuation, AEs of interest, and death were similar in the 2 groups.

Table: 845P

Endpoint (Parameters)	Dmab, n/N* (%)	PBO, n/N* (%)	Risk Difference (95% CI)
Development or progression of LO by month 12	127/379 (33.5)	124/374 (33.2)	0.4 (–6.3 to 7.2) Noninferiority P = 0.0026
Incidence of LO development or progression by month 12	32/379 (8.4)	40/374 (10.7)	–2.2 (–6.4 to 2.0)
Incidence of LO development or progression by month 6	72/379 (19.0)	72/374 (19.3)	–0.3 (–5.9 to 5.3)
Incidence of confirmed LO development or progression by month 12†	59/367 (16.1)	66/361 (18.3)	–2.2 (–7.6 to 3.3)

*N is the number of patients with at least one post-baseline LOCS III measurement by month 12. †A confirmed LO development or progression was defined as two directly subsequent events per protocol assessments at the same location; for this endpoint, N is the number of patients with at least two post-baseline LOCS III measurements by month 12.

Conclusions: Dmab did not increase the short-term risk of cataracts in men with PCa.

Clinical trial identification: NCT00925600.

846P Patterns of therapy in pelvic lymph node positive prostate cancer in Europe and Asia: A real-world data analysis

M. Prentice[1], S. Mpima[2], P. Nasuti[2], A. Martinez-Pinillos[2], I. Wong[3], K. Durno[1], R. Davda[1], H. Payne[1]

[1]Oncology, University College London Hospital UCLH NHS Foundation Trust, London, UK, [2]Real World and Analytics Solutions, IQVIA, London, UK, [3]Department of Policy and Practice, UCL School of Pharmacy, London, UK

Background: Treatment for node positive prostate cancer can vary from palliation to radical therapy. Guidance for N1 prostate cancer is unclear but evidence supports a multimodal approach including radical radiotherapy, hormonal manipulation and possible surgery while a survival benefit for neoadjuvant docetaxel has been demonstrated. Recent improvements in diagnostic techniques and technical advances in radiation therapy including intensity modulated radiotherapy (IMRT) which is capable of delivering a radical dose of radiation to pelvic nodes within acceptable toxicity profiles are anticipated to result in an increased use of radiation in this patient population. This study assesses changes in treatment modality for N1 prostate cancer over time to reflect real world practice.

Methods: Patient data from 17,695 prostate cancer cases taken from a cross-sectional survey of physicians in France, Germany, Italy, Spain, UK, China, Japan and S. Korea between Jan 1997 – Dec 2016 was reviewed. Patients with non-metastatic, node positive cancer were included for analysis. Any exposure to any of three therapy types (systemic, radiation, surgery) prior to recurrence.

Results: 2542 patients were included in the analysis. Over the time studied, the use of surgery has decreased (from 36% in pre 2009 to 16% in 2016) and initially, this decline was matched by a rise in the use of systemic therapy alone (37% to 51%). Since 2011 systemic therapy alone has reduced to 40%. In the same time period, there has been an increase in the use of radiation (with or without systemic therapy) to treat node positive prostate cancer (15% to 29%). The average increase in radiotherapy use across European countries was 11% (range Italy 2% - Spain 19%). A group of patients receiving combined surgery, radiation and systemic therapy comprise 11% of all cases, a figure that does not vary over time.

Conclusions: These data have demonstrated an international change in the management of node positive prostate cancer with decreasing use of surgery and increasing use of radiation. Although initially rising, the recent decline in the use of lone systemic therapy is likely to represent an increasing view that N1 prostate cancer is no longer a definitively palliative diagnosis.

847P The prognostic significance of the 2014 International Society of Urological Pathology (ISUP) grading system in patients with high-risk prostate cancer

J. Liu, J. Zhao

Department of Urology, Institute of Urology, West China Hospital, SiChuan Univer, West China Hospital, Sichuan University, Chengdu, China

Background: Since the new 2014 grading system was recommended by international society of urological pathology (ISUP), it has been validated in patients with localized prostate cancer(PCa) with excellent prognostic value. However, its predictive power in high-risk PCa has not been verified.

Methods: A total of 420 patients with high-risk PCa underwent radical prostatectomy(RP) were included. The predictive accuracy of the 2005 and 2014 grading systems were validated and compared. Biochemical-recurrence free survival (BRFS) was set as the endpoint.

Results: Compared to the 2005 system, the 2014 system could fairly well distinguish BRFS of patients into five groups with higher predictive accuracy(C-index: 0.599 vs 0.646). In multivariate analyses, together with baseline prostate specific antigen, extraprostatic extension and perineural invasion status, the new system was independent predictor for BRFS in these population. The relatively higher proportion of tertiary Gleason pattern 5 (TGP5) among patients with Gleason grade group 3(GGG3) could be considered as an important interfering factor leading to the overlap of survival between GGG4 and GGG3.

Conclusions: This is the first study to validate the new 2014 ISUP grading system in patients with high-risk PCa underwent RP. The new system could better separate patients into five groups with higher predictive accuracy over the old one. It should be paid attention that, the existence of TGP5 need to be routinely reported in clinical practice, which could help retaining the predictive ability of the new grading system. Due to miscellaneous factors among these patients, the prognostic prediction need to be comprehensively evaluated.

848P Overall survival (OS) implications for patients with mCRPC through coverage and adoption of nuclear AR-V7 testing by healthcare systems

J. Hornberger[1], R.P. Graf[2], M. Hulling[3], G. Attard[4], A. Allan[5], R. Dittamore[2], H.I. Scher[3]

[1]Clinical Economics and Outcomes Research, Genomic Health, Redwood City, CA, USA, [2]Translational Research, Epic Sciences, Inc., San Diego, CA, USA, [3]Genitourinary Oncology Service, Memorial Sloan-Kettering Cancer Center, New York, NY, USA, [4]Medical Oncology, The Institute of Cancer Research and The Royal Marsden, London, UK, [5]Oncology and Anatomy and Cell Biology, Western University, London, ON, Canada

Background: Nuclear-localized AR-V7 testing of circulating tumor cells (CTCs) has been validated as a predictive biomarker of chemotherapy response and ARSI non-response in 2nd+ line therapy for metastatic castration-resistant prostate cancer (mCRPC). A validation study showed that AR-V7(+) pts have improved OS with taxane chemotherapy, and AR-V7(-) pts have improved OS with ARSi. We assessed the effect of AR-V7 testing on OS when generalized to non-trial clinical settings, as found in third-party US healthcare systems.

Methods: The causal effect of treatment and nuclear AR-V7 status on OS was estimated from risk-adjusted hazard rates of the MSK, ICR, LHS validation study. Therapeutic strategies assessed were (1) taxanes only, (2) ARSi only, (3) current US utilization rate of ARSis, and (4) nuclear AR-V7-guided treatment. Quality of life adjustments were extracted from meta-analysis of large cohort studies. We applied US utilization rate of consecutive ARSi administration (abiraterone after enzalutamide, or enzalutamide after abiraterone) and compared to switching with taxane-based chemotherapy (docetaxel after abiraterone, or docetaxel after enzalutamide).

Results: The following table shows OS, adjusted and unadjusted for quality of life, and treatment by strategy. The net effects on OS were robust to variation on the clinical effects, and on systems covariates, e.g., demographic, patient, and payer case-mix.

Table: 848P

2nd line mCRPC therapy strategy	% ARSi	OS (months) QALY (Unadj / Adj.)	Net OS gain (months) QALY (Unadj / Adj)
Only use taxanes	0%	19.2 / 12.2	-3.7 /-2.0
Only use ARSi's	100%	25.4 / 15.6	2.5 / 1.4
Current use of ARSi (US)	60%	22.9 / 14.2	- REF -
AR-V7 guided treatment	77%	27.3 / 16.7	4.4 / 2.5

Conclusions: Health outcome modeling of the validation data support that current use and access to 2nd ARSi therapy can improve OS of patients over strict use of taxane chemotherapy (+3.7mo OS). 2nd+ line nuclear-localized AR-V7 guided treatment for men with progressive mCRPC provides higher OS than non-guided, almost doubling the gain (+4.4 mo OS) observed with current US utilization rate of ARSi versus taxanes only. Cost effectiveness analyses of the adoption/coverage of nuclear AR-V7 testing in healthcare systems is ongoing.

849P Quality of docetaxel toxicity reporting for castration resistant prostate cancer (CRPC): A systematic review

S. Cheng, M. Qureshi, V. Arciero, K.K-W. Chan, U. Emmenegger
Medical Oncology, Sunnybrook Odette Cancer Center, Toronto, ON, Canada

Background: Prostate cancer trial design is structured following the Prostate Cancer Clinical Trials Working Group (PCWG) guidelines which focus on harmonization of inclusion criteria and outcome data. The PCWG, however, does not provide clear outlines for reporting of safety data. In fact, there is a perceived lack of widely accepted guidelines for safety reporting.

Methods: A PubMed search of phase II and III clinical trials published until 2015 (included) was conducted using keywords "prostate cancer" and "docetaxel." Docetaxel-naïve CRPC patients who received 75 mg/m^2 docetaxel monotherapy every three weeks were included. To assess quality of toxicity reporting, the Consolidated Standards of Reporting Trials (CONSORT) harms checklist was adapted and each trial scored by two independent reviewers. CONSORT scores as well as PSA and radiological response rates over time were examined with Spearman correlation coefficients. Univariable and multivariable linear regression examined associations between scores and phase II versus III trials, publication year, midpoint of accrual, number of patients, sponsor type, journal impact factor, presence of supplementary data, and geographical region.

Results: From 21 clinical trials including 5,460 patients in docetaxel monotherapy arms, the median CONSORT score was 15.3 (IQR 13.7–16.5) out of 22. Correlation coefficients were not significant for all comparisons of CONSORT scores and response rates versus years of accrual or year of publication. In univariable linear regression, phase III clinical trials were associated with a significantly higher CONSORT score ($p = 0.01$) as was a journal impact factor greater than 15 ($p = 0.02$). In exploratory analyses, none of the examined factors were significant in multivariable linear regression.

Conclusions: CONSORT scores and thus toxicity reporting quality in CRPC trials studying docetaxel show need for improvement and should be subject to further discussion. There has been no significant improvement in toxicity reporting quality over time. It remains to be studied if our findings also apply to other agents used for the treatment of CRPC. Legal entity responsible for the study: Sunnybrook Research Institute.

850P Intermittent short course enzalutamide in biochemically recurrent prostate cancer: Analysis of PSA recovery, testosterone levels and tolerability

M. Al Harthy[1], H. Singh[2], F. Karzai[3], P. Arlen[4], M. Theoret[5], J. Marte[3], M. Bilusic[6], A. Couvillon[3], H. Owens[3], A. Hankin[3], L. Cordes[6], I. Rosner[7], J. Strauss[6], W.D. Figg[8], J. Schlom[9], W. Dahut[6], J. Gulley[6], R. Madan[3]
[1]Genitourinary Malignancies Branch, National Cancer Institute, Bethesda, MD, USA, [2]Hematology and Oncology, Food and Drug Administration, Silver Spring, MD, USA, [3]Genitourinary Malignancies Branch, National Cancer Institute, Bethesda, MD, USA, [4]Medical Oncology, Precision Biologics, Rockville, NY, USA, [5]Office of Oncology Drug Products, Food and Drug Administration, Silver Spring, MD, USA, [6]Medical Oncology, National Cancer Institute, Bethesda, MD, USA, [7]Medical Oncology, Walter Reed Medical Center, Washington, DC, USA, [8]Genitourinary Malignancies Branch, NCI /NIH, Bethesda, MD, USA, [9]Laboratory of Tumor Immunology and Biology, National Cancer Institute, Bethesda, MD, USA

Background: Androgen deprivation therapy (ADT) and surveillance are standard options for patients (pts) with biochemically recurrent (non-metastatic, castration sensitive) prostate cancer (BCRpc) after localized therapy. Enzalutamide (enz) extends survival in advanced prostate cancer and is being tested in earlier stages of disease.

Methods: Eligible pts had a PSA between 2.0-20.0 ng/ml, no metastatic disease, normal testosterone (T), and a PSA doubling time of less than 12 months. Treatment for all pts included enz 160 mg daily for 84 days (D) with/without PROSTVAC (recombinant poxvirus PSA vaccine), but no ADT. After an amendment, pts were eligible for a 2nd course of enz after PSA returned to baseline and confirmation of non-metastatic disease. This analysis evaluated all pts for the impact of enz on PSA and T regardless of randomization as findings were similar in each group.

Results: Median age for all pts ($n = 36$) was 64 years (range: 54-85) with a median baseline PSA of 5.02 (range: 2.02–19.43). The median PSA decline during the first course of enz was >99% (range: 84 - >99). After enz was discontinued, the median time to first PSA rise was 28 D (range:13–182) and median recovery to baseline PSA was 224 D (range:84–924+). 22 of the 36 evaluable pts received a 2ndcourse of enz. Similarly, these patients had a median PSA decline of 99% (range 87->99). After the 2ndcourse of enz, the median time to first PSA rise was 29 D (range:0–83) with a median time to 2nd PSA recovery of 189 D (range:78–400). Enz was well tolerated with no grade 4 or 5 adverse events (AEs). Grade 3 AEs included increased ALT (5%) and decreased ANC (3%). The most common grade 2 AEs included fatigue (18%), dizziness (8%), decreased WBC (8%), and a decreased ALC (8%). T increased above normal limits in 20/36 pts (median Tmax = 834 ng/dl).

Conclusions: Intermittent, short course (84 d) enz without ADT leads to deep and prolonged PSA suppression below baseline in pts with BCRpc, a median of more than 7.5 months beyond treatment period. Pts who received a 2nd 84 D course of enz had similar depth and duration of PSA suppression below baseline (more than 6.5 months after enz treatment). Intermittent enz was well tolerated and warrants further study in BCRpc.

Clinical trial identification: NCT01875250.

851P Pharmacokinetic/pharmacodynamic relationship of enzalutamide and its active metabolite N-desmethyl enzalutamide in metastatic castration-resistant prostate cancer patients

M-L. Joulia[1], E. Carton Vienet Legue[1], M. Allard[2], O. Huillard[3], M. Peyromaure[4], M. Zerbib[4], M. Vidal[2], F. Goldwasser[1], J. Alexandre[1], B. Blanchet[2]
[1]Medical Oncology, Hôpital Cochin, Paris, France, [2]Clinical Pharmacology, Hôpital Cochin, Paris, France, [3]Medical Oncology, Hôpital Cochin, Paris, France, [4]Urology, Hôpital Cochin, Paris, France

Background: Enzalutamide (ENZA) is an oral androgen receptor inhibitor approved for the treatment of metastatic Castration-Resistant Prostate Cancer (mCRPC). ENZA is extensively metabolized by CYP 3A4 into N-desmethyl enzalutamide (NDE). Based on in vitro assays, NDE has been identified as pharmacologically active metabolite. We aimed to explore the relationship between ENZA, NDE plasma concentration and progression-free survival (PFS) in mCRPC.

Methods: Trough plasma concentrations of ENZA and NDE were measured at steady-state one month after treatment start, using liquid chromatography. Trough ENZA and NDE plasma concentrations were dichotomized into 2 groups (high and low) according to their median value. Progression was defined as clinical progression, PSA increase or imaging progression according to the prostate working group criteria 3 or death. A survival analysis was used to explore relationship between PFS and plasma drug exposure.

Results: From January 2015 to May 2017, 18 mCRPC patients treated with ENZA (median age 77.5 years, Interquartile range (IQR) 67.2-82.7) were prospectively included. Median follow-up was 10.6 months (ms) (IQR 5.1-21.3 ms). Median trough plasma concentration of ENZA and NDE were 10.5 ± 3.7 µg/mL (Coefficient of variation (CV) = 33.8%; IQR 8.2-13.2) and 8.1 ± 4.2 µg/mL (CV = 52.7%; IQR 5,4-10,1), respectively. Pearson correlation coefficient value was 0,3 ($p = 0.21$). Eleven patients (61%) achieved a PSA response. Median PFS in the whole cohort was 11.2 ms (IQR 3.4-12.4). High trough plasma concentration of ENZA was associated with a shorter PFS (9 ms vs 22.6 ms respectively in the high and the low group) (Hazard Ratio (HR) 0.2; 95% CI 0.04-0.57; $p = 0.005$). Conversely, a high trough plasma concentration of NDE was associated with a longer PFS: 12,8 ms vs 7.2 ms respectively in the high and low group (HR 3.04; 95% CI 1.19-48.45; $p = 0.03$).

Conclusions: Overall, these results suggest that NDE could be more pharmacologically active than ENZA in vivo. Plasma monitoring of ENZA and NDE could lead to early identification of patients who will not benefit from ENZA as well as to optimize their treatment choice.

852P Pharmacokinetic (PK) analysis of concurrent administration of enzalutamide (enza) and crizotinib (crizo) in patients with metastatic castration resistant prostate cancer (CRPC)

A. tripathi[1], J.G. Supko[2], K.P. Gray[3], Z. Melnick[1], M-E. Taplin[1], A.D. Choudhury[1], M. Pomerantz[1], J. Bellmunt[1], C. Yu[1], Z. Sun[4], S. Srinivas[5], P.W. Kantoff[6], C. Sweeney[7], L.C. Harshman[1]

[1]Lank Center for Genitourinary Oncology, Dana-Farber Cancer Institute, Boston, MA, USA, [2]Clinical Pharmacology Laboratory, Massachusetts general Hospital, Boston, MA, USA, [3]Biostatistics and Computational Biology, Dana-Farber Cancer Institute, Boston, MA, USA, [4]Department of Urology, Stanford University, Stanford, CA, USA, [5]Department: Medicine - Med/Oncology, Stanford University, Stanford, CA, USA, [6]Department of Medical Oncology, Memorial Sloan Kettering Cancer Center, New York, NY, USA, [7]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, USA

Background: Androgen receptor (AR) inhibition can upregulate c-MET expression which can drive CRPC progression. We have previously described the safety and toxicity profile of concurrent treatment with enza and crizo, a potent c-MET inhibitor in a phase 1 study. Since crizo is a substrate for CYP3A4, which is strongly induced by enza, we performed a PK analysis to evaluate its impact on steady state crizo levels.

Methods: A 3 + 3 dose escalation design was employed to test increasing doses of crizo at 250mg daily (dose level 1; n = 3), 200 mg BID (dose level 2; n = 6) and 250mg BID (dose level 3; n = 15) in combination with a fixed dose of enza 160 mg daily in 28 day cycles. PK samples drawn during cycle 2 were used to estimate steady state PK parameters including peak (Cmaxss) and trough (Cminss) plasma concentration and area under the curve over a dosing interval (AUCτss), reported as the geometric mean ± SD.

Results: The crizo Cminss increased progressively across dose levels from 20.7 ± 1.8 ng/mL (250 mg QD) to 70.2 ± 36.4 ng/mL (250 mg BID). Among the 12 patients enrolled on dose level 3 with available PK data, the crizo Cmaxss and AUCτss were 104 ± 45 ng/mL and 1,000 ± 476 ng-h/mL respectively. This represents a 73.8% decrease in crizo steady state exposure compared to a historical data for NSCLC patients with normal renal function treated with crizo monotherapy at 250 mg BID (Cminss: 285.0 ng/mL; Cmaxss: 315 ng/mL and AUCτss: 3,817 ng-h/mL; Tan et al Inv. New Drugs 2016). Enza Cminss was similar across the crizo dose levels (250mg QD: 10.6 ± 4.6 μg/mL; 250mg BID: 12.5 ± 3.2 μg/mL) and was in excellent agreement with previously reported steady state levels in the phase 3 AFFIRM trial (11.7 ± 2.9μg/mL; Gibbons et al Clin Pharmacokinetics 2015).

Conclusions: Concurrent administration of enza resulted in a clinically significant ~74% increase in the apparent oral clearance of crizo suggestive of a clinically significant PK drug interaction. Further investigation into the optimal combination of c-MET inhibitors with novel AR inhibitors is required. Our results highlight the importance of considering PK interactions when evaluating novel combination strategies in CRPC.

853P Long-term adverse effects (AEs) after dose-escalation with high-dose rate brachytherapy in combination with external beam radiation therapy (BT/RT). Comparison to external beam radiation therapy alone (RT)

T.B. Wedde, S.D. Fosså, A. Dahl, M-B. Schulz, W. Lilleby

Oncology, Oslo University Hospital, Oslo, Norway

Background: Few studies have compared long-term patient reported AEs of men with Prostate Cancer (PCa) treated with dose-escalation by means of BT/RT to RT (70-78 Gy) alone. In this study, we compare AEs and quality of life (QoL) between these two treatment modalities.

Methods: 259 eligible men from the BT/RT cohort (2004-2011) and 123 patients (2009-2010) from a RT cohort assessed their AEs and QoL by questionnaires a minimum of 5 years after treatment. Hormonal therapy was given for 1-2 years. EPIC-26 covered urinary, sexual and bowel function and bother. The hormone domain was excluded. The SF-12 questionnaire covered QoL. The scores ranged from 0 (worst) to 100 (best). Clinical significance was set to a score difference > 10 points. Statistical significance was evaluated by Student t-test with significance level $p < 0.05$. Chronic fatigue was reported as percentage.

Results: Median age at survey was 74 years for both cohorts. The EPIC-26 and SF12 scores for the above domains were similar in the two cohorts with no clinical or statistical significance (Table). Chronic fatigue was higher after treatment with RT compared BT/RT, although not significantly.

Table: 853P

Measure	BT/RT Mean (SD)	RT Mean (SD)	P value
Sexual function	27.9 (29.5) n = 255	20.8 (24.3) n = 120	0.06
Sexual bother	48.2 (37.5) n = 254	45.9 (34.7) n = 121	0.56
Urinary function	83.6 (18.0) n = 258	80.1 (20.5) n = 123	0.10
Urinary irritation/obstruction	81.3 (19.6) n = 249	81.8 (16.8) n = 113	0.80
Urinary incontinence	88.7 (18.1) n = 258	85.0 (22.5) n = 123	0.11
Urinary bother	79.9 (26.5) n = 257	77.6 (30.0) n = 123	0.47
Bowel function	86.7 (20.6) n = 254	83.1 (21.7) n = 121	0.12
Bowel bother	83.0 (25.1) n = 258	80.4 (26.7) n = 121	0.34
PCS12 (SF12)	46.4 (10.5) n = 224	45.1 (10.1) n = 101	0.30
MCS12 (SF12)	53.6 (8.0) n = 224	52.7 (9.2) n = 101	0.38
Chronic fatigue	22.0% n = 199	27.1% n = 86	0.28

Conclusions: Dose-escalation by means of BT/RT does not increase the AEs reported for the urinary, bowel and sexual domains of EPIC-26 or health-related QoL. Hence, BT/RT is a good treatment option for eligible patients.

854P Clinical characteristics, treatment outcomes and potential novel therapeutic options for patients with neuroendocrine carcinoma of the prostate (NEPC)

L. Apostolidis[1], C. Nientiedt[1], E.C. Winkler[1], A.K. Berger[1], C. Kratochwil[2], A. Kaiser[3], D. Jäger[1], M. Hohenfellner[4], C. Hüttenbrink[5], S. Pahernik[5], F. Distler[5], C. Grüllich[1]

[1]Department of Medical Oncology, National Center for Tumor Diseases, University Hospital Heidelberg, Heidelberg, Germany, [2]Department of Nuclear Medicine, University Hospital Heidelberg, Heidelberg, Germany, [3]Institute of Pathology, Klinikum Nürnberg, Paracelsus Medical University, Nürnberg, Germany, [4]Department of Urology, University Hospital Heidelberg, Heidelberg, Germany, [5]Department of Urology, Klinikum Nürnberg, Paracelsus Medical University, Nürnberg, Germany

Background: Neuroendocrine Carcinomas of the prostate (NEPCs) are rare tumors with poor prognosis. While platinum and etoposide based chemotherapy regimens (PE) are commonly applied in first-line for advanced disease, clinical-grade evidence for treatment options in second-line and beyond is very limited. The aim of this study was to analyze the treatment outcomes of NEPC patients.

Methods: Retrospective analysis of all patients NEPCs including mixed differentiation with adenocarcinoma component and well differentiated neuroendocrine tumors (NETs, carcinoids) at two high volume oncological centers between 12/2000 and 11/2017.

Results: Of 43 identified patients 18 (41.9 %) had a prior diagnosis of prostatic adenocarcinoma only, 19 (44.2 %) had a mixed differentiation at NEPC diagnosis, 29 (67.4 %) developed visceral metastases, 5 (15.4 %) showed paraneoplastic syndromes. Overall survival from diagnosis of any prostatic malignancy was 69.2 months, from NEPC diagnosis 15.5 months. 31 patients received palliative first line chemotherapy, mostly PE. Overall response rate (ORR) for PE was 50 %, median progression-free survival (PFS) was 6.6 months. 15 patients received second line therapy, mostly with poor response rates. Regimens with notable activity were topotecan (1 PR, 3 PD), enzalutamide (1 SD), abiraterone (1 SD), FOLFIRI (2 SD), and ipilimumab+nivolumab (1 PR). A single patient with prostatic carcinoid was sequentially treated with octreotide, peptide receptor radionuclide therapy (PRRT) and everolimus and survived for more than 9 years.

Conclusions: Visceral metastases and paraneoplastic syndromes are frequent in NEPC. EP in first-line shows notable ORR, however limited PFS. For patients with progression after first line therapy, topotecan, FOLFIRI, enzalutamide, abiraterone and immune checkpoint blockade are possible treatment options. Prostatic carcinoids can be treated in analogy to well differentiated NETs of the gastrointestinal tract.

Clinical trial identification: The trial was approved by the institutional research ethics committee (approval S-428/2014).

Legal entity responsible for the study: National Center for Tumor Diseases, University Hospital Heidelberg.

Funding: Has not received any funding.

855P Effect of prednisone on docetaxel pharmacokinetics in metastatic prostate cancer: A randomized drug-drug interaction study

B.P.S.I. Belderbos[1], K.G.A.M. Hussaarts[1], L. van Harten[1], E. Oomen-De Hoop[1], P. de Bruijn[1], P. Hamberg[2], R.J. van Alphen[3], B.C.M. Haberkorn[4], R.J. van Soest[1], R. de Wit[1], R.H.J. Mathijssen[1]

[1]Department of Medical Oncology, Erasmus MC Cancer Institute, Rotterdam, Netherlands, [2]Department of Medical Oncology, St Franciscus Gasthuis, Rotterdam, Netherlands, [3]Department of Medical Oncology, Twee Steden Ziekenhuis, Tilburg, Netherlands, [4]Department of Medical Oncology, Maasstad, Rotterdam, Netherlands

Background: In metastatic hormone-naïve prostate cancer it is currently unclear whether docetaxel chemotherapy should be administered with or without prednisone. Furthermore, the role of corticosteroids in metastatic castration-resistant prostate cancer is controversial, concerning its limited effect on chemotherapy-induced toxicities, small biological anti-tumor effect on PSA-response, and potential toxicity of long-term use. Prednisone is known to induce CYP3A4, which metabolizes taxanes, resulting in a possible drug-drug interaction (DDI). Therefore, we investigated the pharmacological aspects of the addition of prednisone to docetaxel chemotherapy in men with metastatic prostate cancer.

Methods: We conducted a prospective randomized pharmacokinetic (PK) cross-over study in metastatic prostate cancer patients, who received 6 cycles of docetaxel (Q3W, 75mg/m^2), in which prednisone was added to 3 consecutive chemotherapy cycles. These were followed or preceded (determined by randomization) by 3 consecutive cycles of docetaxel monotherapy. Blood sampling for PK purposes occurred during cycle 3 and cycle 6. Primary endpoint was the difference in docetaxel exposure ($AUC_{0\text{-}inf}$) with concomitant prednisone, compared to exposure of docetaxel monotherapy by means of a linear mixed model analysis on log-transformed data.

Results: Eighteen patients were evaluable for the primary endpoint. Docetaxel exposure with concomitant prednisone (geomean $AUC_{0\text{-}inf}$ 2784 ng*h/mL, CV 27%) was slightly higher (1.8%; 95% CI -9.9% till 15.2%, $p = 0.75$) as compared to docetaxel monotherapy (geomean $AUC_{0\text{-}inf}$ 2647 ng*h/mL, CV 22%). Toxicity rates were similar for docetaxel cycles with and without prednisone.

Conclusions: No difference in docetaxel pharmacokinetics in cycles with or without prednisone was observed. Moreover, we found similar toxicity profiles in the docetaxel cycles with concomitant prednisone as in the docetaxel monotherapy cycles. This suggests that docetaxel for metastatic prostate cancer can be administrated safely without prednisone from a pharmacological perspective.

856P Differences in treatment recommendations for advanced prostate cancer according to region and medical specialization: Analysis of the APCCC 2017 voting results

S. Fischer[1], S. Gillessen[2], M.R. Sydes[3], A.G. Omlin[1]

[1]Medical Oncology and Haematology, Kantonsspital St. Gallen, St. Gallen, Switzerland, [2]Division of Cancer Sciences, University of Manchester and the Christie, Manchester, UK and Division of Medical Oncology and Haematology, Kantonsspital St. Gallen, St. Gallen, University of Bern, Switzerland, [3]MRC Clinical Trials Unit at UCL, Institute of Clinical Trials and Methodology-UCL, London, UK

Background: Development of new agents & therapy combinations in prostate cancer has led to uncertainty in best management approaches. The widely-attended Advanced Prostate Cancer Consensus Conference (APCCC) 2017 convened in Mar-2017 to provide expert opinions on open questions.

Methods: The 52 invited APCCC 2017 panelists were 15 urologists, 26 medical oncologists (onc), 11 radiation onc (incl. 4 clinical onc), from the following regions: 19 Europe, 24 N America, 9 other incl. Australia. We assessed the relationship of panelists' specialization & regions with the responses to the consensus questions.

Results: Voting results of 3 APCCC 2017 consensus questions (Table) cover adding docetaxel to androgen deprivation (ADT) in low-volume (LV) castration-naïve metastatic PCa (mCNPC), adding radium-223 in men with progression on treatment with abiraterone/enzalutamide and first-line treatment for castration-resistant prostate cancer (CRPC) after chemo-hormonal therapy. There was a confirmed difference in preference for docetaxel in LV pts by region; there may be differences on other matters by region of practice and specialization. Results of further questions will be presented.

Conclusions: This dataset allows exploration of expert recommendations by region and medical specialization. Our data suggests that there are substantial differences highlighting the importance of international and multidisciplinary representation in consensus conferences.

Background: The way in which prostate cancer (PC) is diagnosed and treated is fragmented across some Asian countries. We have established a PC registry (UFO) with the aim of providing a comprehensive picture of PC diagnosis, prognosis, treatment and outcome. The registry will collect patient-reported treatment outcomes and underlying reasons for clinical decision-making.

Methods: This is a large multi-national, prospective, observational registry of PC patients presenting to tertiary care hospitals in China, India, Japan, Malaysia, Singapore, South Korea, Taiwan and Thailand. Patients with existing or newly diagnosed high-risk localized PC (HRL), non-metastatic biochemically recurrent PC (M0), or metastatic PC (M1), are being consecutively enrolled and followed for up to 5 years. Patient history, demographic and disease characteristics were collected at first PC diagnosis and enrollment. The first interim analysis of baseline characteristics includes all patients enrolled from study start (15 Sept 2015) until 17 May 2017.

Results: 2,063 eligible patients were enrolled in the interim analysis: 357 (17%), 378 (19%), and 1328 (64%) had HRL, M0 or M1 PC. Among M1 patients, 1038 had hormone-sensitive PC (mHSPC) and 290 had castration-resistant PC (mCRPC). Mean age at first diagnosis was similar in each group (Table). At enrollment, 62% of patients had at least one co-morbidity; mainly cardiovascular disease or diabetes and 14.3% of M0 patients were castration-resistant. A total of 84.5% of patients with mHSPC and 75.9% with mCRPC had de novo metastases. Decisions to start therapy were mainly driven by PSA or clinical progression. Decision to discontinue therapy was most often due to disease progression (hormonal therapy) or completion of therapy (chemotherapy).

Conclusions: The UFO registry will provide descriptive data on current disease characteristics and treatment landscape among patients with PC in Asia.

858P Deployment of advanced real-world data (RWD) analytics for the accelerated recruitment of patients into an ongoing metastatic castrate-resistant prostate cancer (mCRPC) trial, together with the development of a sophisticated patient referral network

M.G. Cushion

Analytics Centre of Excellence, IQVIA, London, UK

Background: Proprietary advanced analytics were applied within US RWD, e.g. medical/prescription claims and physician reference data, to identify high potential sites and physicians treating eligible mCRPC patients, with the aim of accelerating recruitment into an ongoing mCRPC clinical trial. Furthermore, a bespoke methodology to identify physician-to-investigator relationships was used to implement an advanced data driven patient referral network.

Methods: Relevant standard diagnosis, drug, and procedure codes were applied to medical and prescription claims datasets and cross-linked with physician reference data, to identify medical oncologists treating the target patient population. Physicians were also referenced to their affiliated sites. Shared patient counts between investigators and local physicians were also quantified, providing valuable insights into physician-to-investigator relationships to prioritise and leverage into a patient referral network.

Results: Selected results summarised below: ~20k eligible patients were identified - 270 sites each with ≥20 eligible patients were identified ~2k oncologists treating eligible patients and with trial experience in the past year were identified ~4k shared patients between targeted physicians and trial investigators were identified.

Conclusions: To facilitate faster patient access to effective medicines, novel methods such as those outlined above are required to optimise clinical trial operations and increase efficiency. Together with the innovative use of RWD to find eligible mCRPC patients and the physicians and sites treating these, we implemented sophisticated techniques to quantify shared patient counts between identified physicians and investigators. This created a foundation for a referral network that has been successfully implemented, as an alternative to the lengthy and costly initiation of a new site(s). This approach would be invaluable in future trials with ever smaller patient populations, for example within rare diseases and precision medicine.

859TiP TALAPRO-1: An open-label, response rate phase II study of talazoparib (TALA) in men with DNA damage repair defects (DDR) and metastatic castration-resistant prostate cancer (mCRPC) who previously received taxane-based chemotherapy (CT) and progressed on ≥ 1 novel hormonal therapy (NHT)

J.S. de Bono[1], C. Higano[2], F. Saad[3], K. Miller[4], M. Casey[5], A. Czibere[6], C. Healy[5], K. Fizazi[7]

[1]Drug Development Unit, The Royal Marsden NHS Foundation Trust, London, UK, [2]Medical Oncology, Fred Hutchinson Cancer Research Center, Seattle, WA, USA, [3]Urology, Centre Hospitalier de l'Universite de Montréal (CHUM), Montreal, QC, Canada, [4]Medical Oncology, Charité–Universitätsmedizin Berlin, Berlin, Germany, [5]Medical Oncology, Pfizer, Inc., Collegeville, PA, USA, [6]Medical Oncology, Pfizer, Inc., Cambridge, MA, USA, [7]Cancer Medicine, Institut Gustave Roussy, Villejuif, France

Background: No therapies are currently approved for men with mCRPC who have progressed on taxane and NHT. Preclinical evidence has shown that DDR+ prostate tumours may be sensitized to PARP inhibition. TALA inhibits PARP activity and traps PARP on DNA, preventing DNA damage repair and causing cell death in BRCA1/2-mutated cells.

Trial design: Approximately 100 patients (pts) will be enrolled. Eligible pts are ≥18 yrs with measurable soft tissue disease per RECIST v1.1 and have progressive mCRPC, DDR likely to sensitize to PARP inhibition, ECOG PS ≤ 2, no brain metastases, and received 1-2 CT regimens (including ≥1 taxane-based regimen) and progressed on ≥ 1 NHT (enzalutamide or abiraterone acetate). Pts who received a prior PARP inhibitor, cyclophosphamide, mitoxantrone, or a platinum-based CT within 6 mos of study entry or progressed on a platinum-based CT at any time are excluded. Pts will receive TALA 1 mg/d orally (or 0.75 mg/d for those with moderate renal impairment) until radiographic progression, unacceptable toxicity, or withdrawal of consent. Study drug should not be discontinued based on increased PSA or circulating tumour cell (CTC) count alone. Primary endpoint is best objective response (OR) rate (exact 2-sided 95% CI), defined as a complete or partial soft tissue response per RECIST v1.1. Responses must be confirmed ≥4 wks later by CT/MRI with no evidence of confirmed bone progression per PCWG3 criteria on repeat bone scan ≥6 wks later. Secondary endpoints include time to OR, duration of response, PSA decrease ≥50%, CTC count conversion (to CTC=0 and CTC <5 per 7.5 mL of blood), time to PSA progression, radiographic progression-free survival, overall survival, safety, patient-reported outcomes, and pharmacokinetics of TALA. Efficacy will be assessed every 8 wks during the first 24 wks, then every 12 wks thereafter. An initial safety and efficacy analysis will be performed on 20 pts after receiving study drug ≥8 wks. An interim efficacy analysis is planned when 60 pts have completed ≥6 mos of treatment.

Clinical trial identification: NCT03148795.

860TiP Phase II trial evaluating olaparib maintenance in patients with MCRPC after docetaxel treatment reaching partial or stable response

M.J. Juan Fita[1], L. Heras Lopez[2], B. Mellado[3], M.J. Mendez Vidal[4], U. Anido[5], D. Lorente[6], J.M. Sepulveda[7], C. Alvarez[8]

[1]Medical Oncologist, Fundación Instituto Valenciano de Oncología, Valencia, Spain, [2]Medical Oncologist, ICO, Barcelona, Spain, [3]Medical Oncologist, Hospital Clinic y Provincial de Barcelona, Barcelona, Spain, [4]Medical Oncologist, University Hospital Reina Sofia, Cordoba, Spain, [5]Medical Oncologist, CHU Santiago, Santiago, Spain, [6]Medical Oncologist, HULa Fe, Valencia, Spain, [7]Medical Oncologist, Juan Manuel Sepúlveda, Valencia, Spain, [8]Medical Oncologist, HCU Asturias, Asturias, Spain

Background: Durable and complete responses following docetaxel chemotherapy in patients with advanced prostate cancer (PC) are uncommon. Most patients will ultimately experience disease progression within 6-months after initial response. Optimal second line therapy in metastatic castration resistant PC (MCRPC) is not well established and several options are possible. Maintenance treatment in tumpurs as non-small cell lung cancer or ovarian cancer has become a standard improving overall survival (OS), and a phase II study in bladder cancer has demonstrated longer progression-free-survival (PFS) after first-line platinum with vinflunine maintenance.Recently PARP-inhibitors have demonstrated improvement in response and PFS in MCRPC with somatic or germline DNA-repair defects (1-4).

Trial design: IMANOL (NCT03434158) is a phase II trial of olaparib (300 mg tablet bid) maintenance in patients with MCRPC and a complete or partial response to docetaxel treatment and germline or somatic mutation studied by a next-generation sequencing panel of homologous recombination repair genes. Primary endopint is to assess the effect of olaparib maintenance on radiologic PFS in these patients (RECIST v1.1). Secondary endpoints are: effect of maintenance treatment on PSA-PFS and clinical PFS, PSA response rate, safety and tolerability. Exploratory objectives are: to determine the frequency of BRCA and other genes mutations and to stablish a correlation between tumour and germline mutation presence. Previous studies showed that one year rPFS was about 10%. To accept treatment efficacy we will assume that the 12 months rPFS with olaparib maintenance will be at least 30%. An overall simple size of 27 patients achieves 80% power at a 0,05 significance level (alpha) to accept the efficacy of this treatment after completion 6-8 cycles of docetaxel. An accrual time of 12 months in 8 SOGUG centres in Spain is planned.

Clinical trial identification: NCT03434158.

Legal entity responsible for the study: SOGUG.

Funding: AstraZeneca.

861TiP Multimodality treatment for pN1 prostate cancer: Adding elective para-aortic radiation in the PART trial

C. Berghen[1], S. Joniau[2], C. Draulans[1], G. De Meerleer[1]

[1]Radiation Oncology, University Hospitals Leuven, Leuven, Belgium, [2]Urology, University Hospitals Leuven, Leuven, Belgium

Background: Multimodality treatment offers promising results in patients with histopathological proven pelvic lymph node metastatic (pN1) prostate cancer. Improved cause-specific survival rates are reported when treating the primary tumor combined with whole pelvic radiotherapy and androgen deprivation therapy (ADT) compared to ADT alone. However, in case of tumoral invasion of > 1 pelvic lymph node, approximately 40% of the patients relapse biochemically and clinically. This clinical relapse is located in the para-aortic lymph nodes (M1a disease) in up to 77% of relapsed cases. We hypothesize that adding elective para-aortic radiation will reduce the development of both retroperitoneal nodal (M1a) and distant metastasis (M1b/M1c), postpone the need for palliative ADT and prolong the time to castration-refractory disease.

Trial design: This is a multicenter, non-randomized phase 2 trial (NCT03079323) conducted in 5 sites in Belgium. Men are eligible for the study when (1) age >18 years, (2) histological proven adenocarcinoma of the prostate at biopsy (cT1-4) and referred for primary high-dose radiotherapy or after radical prostatectomy (pT2-4), and (3) presence of pN1 disease after extended pelvic lymph node dissection. If pN1 disease is present, patients are eligible if one of the following criteria is fulfilled: $\geq$ 2 positive lymph nodes, a ratio positive / removed lymph nodes > 7% or presence of extracapsular metastatic extension at the level of any lymph node. Patients will receive radiotherapy on the prostate (bed), pelvic lymph nodes and the para-aortic lymph nodes combined with 24 months of ADT. We aim to include 137 patients to detect an improvement in clinical relapse free survival (cRFS) by 15% at 5 years (power of 80%).

The primary endpoint is 5 year-clinical relapse-free survival (cRFS) defined as the absence of any clinical relapse that would be visible at top of the line imaging. Secondary endpoints are Quality of life (QoL), treatment-related acute and late toxicity, time to palliative ADT, time to castration refractory prostate cancer (CRPC), cause-specific survival (CSS) and in field pelvic and para-aortic disease control. Recruitment is ongoing, with the first patient included in the trial on 06/02/2017.

Clinical trial identification: NCT03079323.

Legal entity responsible for the study: University Hospitals Leuven, Belgium.

Funding: "Kom op tegen kanker (Stand up to Cancer), the Flemish Cancer Society". (ref. 0010048).

Disclosure: All authors have declared no conflicts of interest.

862TiP ReCab II: A phase II trial of Cabazitaxel +/- Rhenium -188-HEDP in patients with metastatic castration resistant prostate cancer who progressed on or after a docetaxel containing treatment

E. Bouman-Wammes[1], J.M. van Dodewaard-De Jong[2], H. Bloemendal[2], H.M. Verheul[1], J.M.H. de Klerk[3], A.J.M. van den Eertwegh[1]

[1]Medical Oncology, Vrije University Medical Centre (VUMC), Amsterdam, Netherlands, [2]Medical Oncology, Meander Medical Center, Amersfoort, Netherlands, [3]Nuclear medicine, Meander Medical Center, Amersfoort, Netherlands

Background: Bone is the most common site of metastases in patients with castration resistant prostate cancer (CRPC) leading to serious morbidity and mortality. Nowadays, cabazitaxel is the standard second line of chemotherapy. Besides, a survival benefit has been proven for the alfa-emitting radiopharmaceutical Radium-223-chloride and has been suggested for other, beta-emitting, radiopharmaceuticals such as rhenium-188-HEDP as well. Rhenium-188-HEDP has a proven and favorable effect on pain caused by bone metastases. In this trial, we will investigate the effect of the addition of rhenium-188-HEDP to standard treatment with cabazitaxel on the progression free survival, overall survival and quality of life.

Trial design: In total, 86 patients with CRPC metastatic to bone and progressive disease during or after treatment with docetaxel will be included. Patients will be randomized between two arms. Patients in arm A will be treated with the standard schedule of cabazitaxel; cabazitaxel 25mg/m^2 every three weeks. Patients in the intervention arm will receive an injection of rhenium-188-HEDP 40 MBq/kg three weeks after the second and three weeks after the fourth administration of cabazitaxel 25mg/m^2. The interval between the injection of the rhenium-188-HEDP and the next cycle of cabazitaxel will be 4 weeks because of nadir of the expected thrombopenia after 4 weeks. The primary endpoint is progression free survival, with overall survival, clinical benefit, quality of life, PSA and pain response and toxicity as secondary endpoints. PSA, pain and quality of life will be measured every treatment cycle (i.e. every 3 weeks), imaging will be performed pre-cycle 4 and pre-cycle 7, or when progression is suspected based on clinical findings or a rise in PSA. The statistical analysis will be performed by using a stratified logrank test comparing both groups with respect to the time to progression. Time-to-event will be analyzed by the Kaplan-Meier method.

Blokhin Russian Cancer Research Center, Moscow, Russian Federation, [9]Urology, Russian Scientific Center of Roentgenoradiology, Moscow, Russian Federation, [10]Medical Oncology, Clinical Hospital No. 1 of the Poznan University of Medical Sciences, Poznan, Poland, [11]Department of Medicine, University of Washington and Fred Hutchinson Cancer Research Center, Seattle, WA, USA, [12]Medical Oncology, Herlev Hospital, University of Copenhagen, Herlev, Denmark, [13]Medical Oncology, Maria Sklodowska-Curie Memorial Cancer Center, Warsaw, Poland, [14]Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea, [15]Surgery, Université Laval, Quebec, QC, Canada, [16]Medical Oncology, Hospital Universitario Ramon y Cajal, Madrid, Spain, [17]Medical Oncology, Merck & Co., Inc., Kenilworth, NJ, USA, [18]Medical Oncology, Georgetown Lombardi Comprehensive Cancer Center, Washington, DC, USA

Background: KEYNOTE-427 (NCT02853344) is a single-arm, open-label, 2-cohort, phase 2 study to evaluate efficacy and safety of the PD-1 inhibitor pembrolizumab (pembro) as first-line monotherapy in advanced ccRCC and non-ccRCC. Results from the ccRCC cohort (cohort A) are presented.

Methods: Pembro 200 mg was administered intravenously Q3W for 2 y or until confirmed progressive disease, unacceptable toxicity, or patient (pt) decision to withdraw. Pts with histologically confirmed advanced ccRCC who had received no prior systemic therapy were eligible. Additional key eligibility criteria: measurable disease (RECIST v1.1, independent central review [ICR]) and Karnofsky performance status $\geq$70%. Primary end point: ORR per RECIST v1.1, by ICR. Additional end points: DOR, PFS, OS, safety, and biomarkers associated with response.

Results: At data cutoff (Oct 6, 2017), median (range) follow-up was 7.2 (0.9-11.7) mo. 110 pts enrolled; 107 were included in efficacy analysis (opportunity for $\geq$1 postbaseline assessment). Treatment was ongoing for 64 (58.2%) pts. Median age (range) was 64 (29-87) years; 78% were male. 37.3%, 47.3%, and 15.5% had IMDC risk categories of favorable, intermediate, and poor, respectively. Confirmed ORR by ICR was 33.6% (n = 36; 95% CI 24.8-43.4) with 1 complete response (0.9%) and 35 (32.7%) partial responses. 39 (36.4%) had stable disease. ORR for pts with favorable or intermediate/poor risk IMDC was 27.5% and 37.3%, respectively. Median DOR was not reached (range 1.4+ to 8.2+ mo); 86.1% of responders had response $\geq$3 months. Median PFS was 6.9 (95% CI 5.1-NR) mo; PFS rate at 6 mo was 53.6%. OS rates at 3 and 6 mo were 97.2% and 92.4%, respectively. 73.6% of pts had a treatment-related adverse event (AE); most common ($\geq$10%) were fatigue (23.6%), pruritus (21.8%), diarrhea (16.4%), rash (12.7%), and arthralgia (11.8%). 18.2% experienced a grade 3-5 treatment-related AE; 1 pt had grade 5 pneumonitis.

Conclusions: Pembro monotherapy showed encouraging efficacy and acceptable tolerability in pts with advanced ccRCC. Updated analyses will be presented using additional follow-up data and outcomes by PDL-1 status and other relevant subgroups.

Clinical trial identification: NCT02853344. Trial initiated August 2, 2016.

872P Phase Ib study (COSMIC-021) of cabozantinib in combination with atezolizumab: Results of the dose escalation stage in patients (pts) with treatment-naïve advanced renal cell carcinoma (RCC)

N. Agarwal[1], U. Vaishampayan[2], M. Green[3], F. di Nucci[3], P-Y. Chang[4], C. Scheffold[4], S. Pal[5]

[1]Internal Medicine, Huntsman Cancer Institute, Salt Lake City, UT, USA, [2]Oncology, Karmanos Cancer Center, Detroit, MI, USA, [3]Genentech, South San Francisco, CA, USA, [4]Clinical Science, Exelixis Inc., South San Francisco, CA, USA, [5]Medical Oncology & Therapeutics Research, City of Hope, Duarte, CA, USA

Background: Cabozantinib (C) is an inhibitor of multiple receptor tyrosine kinases involved in tumor cell proliferation, neovascularization, and immune cell regulation, including MET, VEGFRs, and TAM family of kinases (TYRO3, MER, and AXL). Preclinical/clinical studies suggest that C promotes an immune-permissive environment that may facilitate synergistic effects with checkpoint inhibitors. This Phase 1b study evaluates C in combination with the programmed death ligand (PD-L1) targeting antibody atezolizumab (A) in pts with solid tumors (NCT03170960).

Methods: Safety and clinical activity of C (2 dose levels: 40 mg, 60 mg QD) + A (1200 mg Q3W) administered in 3-week cycles were evaluated in a 3 + 3 dose escalation design. Safety data of all pts and criteria for dose limiting toxicity (DLT) determined the recommended dose (RD) for a subsequent expansion stage. Tumor response was assessed by CT/MRI and bone scan (RECIST v 1.1).

Results: 12 pts with treatment-naïve advanced RCC (mostly clear-cell subtype) were treated in the dose escalation stage (6 at each dose level). At data cutoff, all pts were actively receiving study treatment (range, 3–12 cycles). There were no DLTs or serious adverse events (AEs) in either C+A dose cohort. Most AEs were Grade 1/2 including immune-related AEs. Grade 3 AEs included 3 events of hypertension, 2 events each of diarrhea and hypophosphatemia, and 1 pulmonary embolism. There were no Grade 4/5 AEs. Among 10 pts investigator-assessed confirmed ORR was 50% (1 CR, 4 PRs); 2 additional pts had unconfirmed PRs with only 1 tumor assessment at data cut-off.

Conclusions: C+A is well tolerated and shows encouraging anti-tumor activity in advanced RCC. C 40 mg QD + A 1200 mg Q3W was selected as the RD for expansion in multiple solid tumor cohorts including RCC.

Clinical trial identification: NCT03170960.

Hoffmann-La Roche, Ltd, Basel, Switzerland, [14]US Medical Affairs, Genentech, Inc., South San Francisco, CA, USA, [15]Department of Oncology, Aarhus University Hospital, Aarhus, Denmark

Background: Atezo (anti–PD-L1) + bev (anti-VEGF) demonstrated improved PFS and favourable safety vs sun in Ph II and III trials in patients (pts) with untreated mRCC (McDermott 2018; Motzer ASCO GU 2018). To further explore the improved tolerability with this regimen, we performed additional safety analyses using pooled data from the atezo + bev and sun arms of these studies.

Methods: Safety data were assessed from the primary analyses of the Ph II IMmotion150 and Ph III IMmotion151 trials, which enrolled treatment-naive pts with mRCC with clear-cell and/or sarcomatoid histology. Pts were randomised 1:1 to receive atezo 1200 mg IV q3w + bev 15 mg/kg IV q3w or sun 50 mg PO QD 4 wk on/2 wk off until progression (RECIST v1.1) or loss of clinical benefit.

Results: Pooled cohorts included 552 atezo + bev–treated pts and 546 sun-treated pts. Mean duration of treatment for atezo + bev was 11.4 mo for atezo and 10.8 mo for bev vs 10.0 mo for sun. Treatment-related AEs (TRAEs) occurred in 91% of pts with atezo + bev and 96% with sun. Grade 3-4 TRAEs were reported in 40% and 54% of pts with atezo + bev and sun, respectively, with hypertension (14%, 16%), proteinuria (4%, 1%) and fatigue (1%, 6%) as the most common reported events. Grade 5 TRAEs occurred in 1% of pts in each cohort. TRAEs leading to treatment regimen (atezo + bev or sun) discontinuation occurred in 5% of pts with atezo + bev and 8% with sun. AEs of special interest (AESIs), commonly reported with atezo treatment regardless of investigator attribution, were Grade 1-2 in 79% of pts receiving atezo + bev and 78% receiving sun. Corticosteroid use for AESIs (mostly Grade 1-2) occurred in 16% of pts with atezo + bev and 5% with sun. The safety profile in pts with components of sarcomatoid histology or with PD-L1+ tumours was similar to that in pts with clear-cell mRCC. Additional safety data will be reported.

Conclusions: Atezo + bev had a tolerable safety profile in mRCC, with fewer high-grade TRAEs and TRAEs leading to regimen discontinuation than with sun. Corticosteroid use for atezo AESIs was low. Toxicities were consistent with each agent alone, and no new toxicities were identified.

Clinical trial identification: NCT01984242, NCT02420821.

Background: Pts with metastatic melanoma who discontinue N+I may experience sustained clinical benefit and a delayed need for subsequent therapy. In this analysis, TFI was retrospectively analyzed using data from the phase 3 CheckMate 214 trial, in which N+I demonstrated superior efficacy vs S in pts with IMDC intermediate/poor (int/poor)-risk aRCC.

Methods: In CheckMate 214, pts with previously untreated clear cell aRCC were randomized 1:1 to N 3 mg/kg + I 1 mg/kg every 3 weeks for 4 doses followed by N 3 mg/kg every 2 weeks, or S 50 mg daily orally for 4 weeks (6-week cycles). TFI was defined as the time from last dose of N+I or S to the start of subsequent systemic therapy or death. All randomized pts with IMDC int/poor-risk aRCC (N+I, 425; S, 422) were analyzed. Kaplan–Meier curves and log-rank tests were used to compare TFI between N+I and S.

Results: With median overall survival follow-up of 25.2 months, pts in the N+I arm had significantly longer time from randomization to subsequent systemic therapy or death than pts in the S arm (median, 15.4 vs 8.5 months; $P < 0.0001$); 2 years after randomization, 42% vs 19% of pts were alive and not requiring subsequent therapy. Overall, 320 (75%) N+I pts and 359 (85%) S pts discontinued treatment, most commonly due to disease progression (N+I, 42%; S, 58%) or study drug–related adverse events (N+I, 23%; S, 11%). In pts who discontinued, TFI was significantly longer with N+I than with S ($P < 0.0001$); 18 months after discontinuation, 19% of N+I pts vs 4% of S pts remained treatment-free. TFI was also significantly longer with N+I than with S, irrespective of best overall response on study ($P < 0.0001$). 18 months after discontinuation, 48% of N+I pts vs 6% of S pts with complete/partial response were still free of subsequent treatment; at the same time point, 13% of N+I pts vs 4% of S pts with stable disease remained treatment-free.

Conclusions: The use of N+I was associated with a significant longer TFI beyond treatment discontinuation in pts with IMDC int/poor-risk aRCC and irrespective of whether pts achieved response or disease control. TFI should be considered along with traditional efficacy measures when evaluating treatment options for aRCC.

Background: N+I demonstrated superior objective response rate (ORR) and overall survival (OS) vs sunitinib in pts with IMDC intermediate/poor (int/poor)-risk aRCC in the phase 3 CheckMate 214 trial. Further characterization of response may inform clinical practice.

Table: 875P

Outcome	N+I int/poor-risk pts			S int/poor-risk pts		
	Total n = 425	CR n = 40	PR n = 137	Total n = 422	CR n = 5	PR n = 107
BOR (95% CI), %	42 (37–47)	9	32	27 (22–31)	1	25
Median (range) time to response, months	2.8 (0.9–11.3)	2.8 (0.9–11.0)	2.8 (1.4–11.3)	3.0 (0.6–15.0)	2.9 (2.8–4.2)	3.1 (0.6–15.0)
Median (95% CI) duration of response, months	NR (21.8–NE)	NR	NR (18.8–NE)	18.2 (14.8–NE)	NR	18.2 (13.9–NE)
Pts with ongoing response in responders, n/N (%)	128/177 (72)	34/40 (85)	94/137 (69)	71/112 (63)	5/5 (100)	66/107 (62)
12-month PFS rate (95% CI), %	50 (44–55)	97 (83–100)	81 (73–86)	43 (37–48)	100 (100–100)	79 (69–86)
18-month OS rate (95% CI), %	78 (74–81)	100 (100–100)	94 (89–97)	68 (63–72)	100 (100–100)	92 (85–96)

BOR, best overall response; NE, not estimable; NR, not reached; PR, partial response

Methods: In CheckMate 214, pts with previously untreated aRCC were randomly assigned 1:1 to N 3 mg/kg + I 1 mg/kg Q3W for 4 doses then N 3 mg/kg Q2W or S 50 mg QD for 4 weeks on, 2 weeks off. Efficacy, safety, and quality of life (QoL) were explored in int/poor-risk pts with complete response (CR) or partial response to N+I or S.

Results: At 25.2 months median follow-up, confirmed ORR per independent radiology review committee in int/poor-risk pts was 42% for N+I vs 27% for S ($P < 0.001$; Table) with 36% vs 18% of pts achieving best tumor reduction ≥50% with N+I vs S. Of N+I vs S responders, 72% vs 63% have ongoing response, 47% and 34% remain on treatment, and 53% and 66% discontinued, most often for disease progression (N+I, 22%; S, 40%) or toxicity (N+I, 23%; S, 13%). N+I responders received a median of 21.0 months of treatment (vs 3.8 months for N+I nonresponders). Response lasting ≥18 months was seen in 13% of N+I and 4% of S pts. Grade 3–4 treatment-related adverse events (TRAEs) occurred in 52% of N+I and 68% of S responders. Mean change from baseline at 24 weeks in Functional Assessment of Cancer Therapy–Kidney Symptom Index 19 score was 3.0 in N+I responders (better) vs − 0.7 in S responders (worse). Updated 3-year data on responders, including use of subsequent therapies, will be presented.

Conclusions: ORR and OS were significantly improved with N+I compared with S in pts with int/poor-risk aRCC in CheckMate 214. Responses to N+I were more likely to be CRs and were more durable than responses to S. High-grade TRAEs were less frequent and QoL was better in N+I responders compared with S responders.

876P A new prognostic model for overall survival (OS) in second line (2L) for metastatic renal cell carcinoma (mRCC): Development and external validation

L. Derosa[1], M.A. Bayar[2], L. Albiges[1], G. Le Teuff[2], B. Escudier[1]

[1]Department of Medical Oncology, Gustave Roussy, Villejuif, France, [2]Biostatistics, Institut Gustave Roussy, Villejuif, France

Background: The IMDC classification scheme for OS has been validated in 2L mRCC. Recently, we showed that two new prognostic factors, Time from first to second line (<, ≥ 1 year) and tumor burden (<, ≥100 mm), are independently associated with OS in the same setting. Here, we present a new classification scheme.

Methods: mRCC patients treated in 2L between January 2005 and December 2014 after initial first line clinical trials at Gustave Roussy Cancer Campus (GRCC) formed the discovery set. Patients from 2 phase III clinical trials from Pfizer database (PFIZERDB), AXIS (NCT00678392) and INTORSECT (NCT00474786), formed the external validation set. In addition to the IMDC predictors, the 2 new prognostic factors were tested using a multivariable Cox model with a backward selection procedure. The performance of the new GRCC model and the classification scheme derived from it, measuring by R^2, c-index and calibration, was evaluated on the validation set and compared to MSKCC and IMDC.

Results: Two-hundred and twenty-one patients were included in GRCC cohort and 855 patients in PFIZERDB. Median OS was similar in the two datasets (16.8 [95%CI=12.9-21.7] and 15.3 [13.6-17.2] months, respectively). Time from first to second line and tumor burden confirmed their significant effect on OS with HR = 1.68 [1.23-2.31] and 1.43 [1.03-1.99]. The new classification, derived by counting the number of factors, allows categorizing patients into 4 risk groups: median OS from the start of 2L in the validation cohort was not reached (NE) (95% CI 24.9-NE) in the favorable risk group (n = 20, 4 deaths, 0 risk factor), 21.8 months (11.6–15.8) in the intermediate risk group (n = 367, 135 deaths, 1-2 risk factors), 12.7 months (11.0–15.8) in the low-poor risk group (n = 347, 211 deaths, 3-4 risk factors), and 5.5 months (4.7–6.4) in the high-poor risk group (n = 121, 105 deaths, ≥5 risk factors). Not surprisingly, the incorporation of factors that characterize post first line features and the new stratification allowed a better performance compared to previous models.

Conclusions: The GRCC classification derived from the model is a new reliable prognostic tool that can be applied to better predict OS in previously treated mRCC patients.

877P First-line (1L) or second-line (2L) avelumab monotherapy in patients (pts) with advanced renal cell carcinoma (aRCC) enrolled in the phase Ib JAVELIN solid tumor trial

U.N. Vaishampayan[1], P. Schöffski[2], A. Ravaud[3], C. Borel[4], T. Song[5], S. Guenther[6], J. Grewal[7], J. Gulley[8]

[1]Oncology, Karmanos Cancer Institute, Detroit, MI, USA, [2]Department of General Medical Oncology, University Hospitals Leuven, Leuven, Belgium, [3]Oncologie, Groupe Hospitalier Saint André - Hôpital St. André, Bordeaux, France, [4]Oncologie Médicale, Centre Paul Strauss, Strasbourg, France, [5]Biostatistics, EMD Serono, Billerica, MA, USA, [6]Medical Affairs, Merck KGaA, Darmstadt, Germany, [7]Immuno-Oncology, EMD Serono, Billerica, MA, USA, [8]Genitournary Malignancies Branch, National Cancer Institute, Bethesda, MD, USA

Background: Avelumab is a human anti–PD-L1 IgG1 monoclonal antibody approved for the treatment of metastatic Merkel cell carcinoma and, in the US/Canada, advanced urothelial carcinoma progressed on platinum therapy. Here, we report phase 1b data from the multicohort JAVELIN Solid Tumor trial (NCT01772004) in pts with aRCC treated with avelumab monotherapy in either the 1L or 2L setting.

Methods: Eligible pts in the 1L subgroup had measurable aRCC with a clear cell component and ECOG ≤1; in the 2L subgroup, pts must have progressed after 1 prior line of therapy. All pts received avelumab 10 mg/kg IV Q2W until disease progression, unacceptable toxicity, or withdrawal. Assessments included objective response rate (ORR; according to RECIST v1.1 per investigator), progression-free survival (PFS), overall survival (OS), and safety.

Results: As of 27 April 2017, 82 pts received avelumab: 62 pts as 1L (median follow-up, 14.2 mo [range, 6-17 mo]; 24 pts remained on treatment) and 20 pts as 2L (median follow-up, 22.1 mo [range, 16-23 mo]; 2 pts remained on treatment). Efficacy data are summarized below. The rates of treatment-related adverse events (TRAEs) were 75.8% (grade ≥3, 12.9%) and 70.0% (grade ≥3, 5.0%) in the 1L and 2L subgroups, respectively. The only grade ≥3 TRAE that occurred in > 1 pt was elevated lipase (n = 4); no TR deaths or unexpected immune-related TRAEs occurred. Updated data will be presented.

Table: 877P

	1L (n = 62)	2L (n = 20)
Response ORR (95% CI), %	16.1 (8.0-27.7)	10.0 (1.2-31.7)
Duration of response, median (95% CI), mo	10.4 (2.8-10.4)	NE (6.9-NE)
PFS Median (95% CI), mo 6-mo rate (95% CI), %	8.3 (5.5-9.7) 55.7 (41.9-67.4)	5.6 (2.3-8.2) 44.9 (21.9-65.6)
OS Median (95% CI), mo 12-mo rate (95% CI), %	NE 85.9 (73.4-92.8)	16.9 (8.3-NE) 65.0 (40.3-81.5)

NE, not estimable.

Conclusions: Avelumab, administered either as 1L or 2L monotherapy, showed durable responses, promising survival outcomes, and an acceptable safety profile in pts with aRCC. These data, as well as those recently reported from a phase 1b trial investigating the 1L combination of avelumab + axitinib (VEGF pathway inhibitor; NCT02493751), provide a rationale for the randomized, phase 3 JAVELIN Renal 101 trial (NCT02684006) comparing avelumab + axitinib with sunitinib as 1L treatment for pts with aRCC.

Clinical trial identification: NCT01772004.

878P TiNivo - tivozanib combined with nivolumab: Safety and efficacy in patients with metastatic renal cell carcinoma (mRCC)

P. Barthelemy[1], B. Escudier[2], A. Ravaud[3], S. Negrier[4], M.N. Needle[5], L. Albiges[6]

[1]Medical Oncology, C.H.U. Strasbourg-Nouvel Hopital Civil, Strasbourg, France, [2]GU Oncology, Gustave Roussy Institut de Cancérologie, Villejuif, France, [3]Medical Oncology, CHU Bordeaux Hopital St. André, Bordeaux, France, [4]Medical Oncology, Centre Léon Bérard, Lyon, France, [5]Aveo Pharmaceuticals Inc, Cambridge, MA, USA, [6]Medical Oncology, Institut Gustave Roussy, Villejuif, France

Background: Recently approved in the EU, tivozanib is a VEGFR-TKI with high specificity and lower incidence of class effect adverse events. We reported earlier that tivozanib can be combined with nivolumab at full dose of each drug. We report herein safety and efficacy data from a phase Ib/II combination of tivozanib and nivolumab.

Methods: In the phase Ib portion of the study, tivozanib was administered orally at 1.0 mg and 1.5 mg, once daily for 21 days every 28 day cycle using a standard 3 + 3 dose escalation design in combination with nivolumab 240 mg every 14 days intravenously. As there were no DLTs in phase I, in the phase II portion of the study tivozanib was administered orally at 1.5 mg in combination with nivolumab.

Results: 28 patients have been enrolled, 6 in phase Ib and 22 in phase II. 25 were treated with full dose tivozanib, 1.5 mg daily for 21 days with nivolumab. The median age was 63; 8 patients were IMDC favorable; 19 IMDC intermediate; 1 IMDC poor. 18 patients were ECOG 0 and 9 ECOG 1; and there were 20 males. 24 had clear cell histology. All patients experienced at least one AE and 52% experienced a grade 3/4 AE. 44% experienced a grade 3/4 AE related to study drug. The most common grade 3/4 adverse events were hypertension, hand foot syndrome, and elevated lipase seen in 4, 2 and 2 patients respectively. The most common AEs (all grades) were hypertension, asthenia, arthralgia, dysphonia, mucocitis, diarrhea, and anorexia. 9 of the first 14 patients (64%) enrolled and treated with full dose tivozanib had a partial response. Final efficacy and safety data on all 28 patients will be available at the meeting.

Conclusions: The combination of tivozanib with nivolumab is safe and manageable at full dose of both drugs. The safety profile and the activity is favorable for a combination of a TKI with a checkpoint inhibitor as would be expected for a highly selective and well tolerated TKI.

879P Activity of cabozantinib (cabo) after PD-1/PD-L1 immune checkpoint blockade (ICB) in metastatic clear cell renal cell carcinoma (mccRCC)

B.A. McGregor[1], A-K. Lalani[2], W. Xie[3], J.A. Steinharter[1], D.J. Martini[4], P.V. Nuzzo[1], N. Martinez Chanza[1], L.C. Harshman[5], M.A. Bilen[6], T.K. Choueiri[7]

[1]Medical Oncology, Dana Farber Cancer Institute, Boston, MA, USA, [2]Medical Oncology, McMaster University, Hamilton, ON, Canada, [3]Biostatistics and Computational Biology, Dana Farber Cancer Institute, Boston, MA, USA, [4]Hematology and Medical Oncology, Emory University School of Medicine, Atlanta, GA, USA, [5]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, USA, [6]Oncology, Emory University Winship Cancer Institute, Atlanta, GA, USA, [7]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, USA

Background: Cabo is approved for mccRCC based on trials in which the vast majority of patients were ICB-naive. We analyzed the activity of cabo in mccRCC patients who had progressed on ICB.

Methods: We included 69 patients with mccRCC who received cabo after progression on ICB alone or in combination with VEGF or other therapies. Baseline characteristics, best response (BR, investigator-assessed), time to treatment failure (TTF) and overall survival (OS) were analyzed.

Results: Median age was 62 years (range 37-78). Median number of prior therapies was 2 (range 1-10). Median time on prior ICB was 3.9 months (range 0.5-38). Type of prior therapy was ICB single agent (54%) or in combination with a VEGF inhibitor (35%) or other therapies (12%). At time of cabo initiation, IMDC risk groups were 6% good, 67% intermediate and 27% poor. BR was 33% PR, 46% SD, 17% PD, 3% unevaluable. Median follow up after cabo initiation was 12 months. At time of analysis, 35% (n = 24) remained on cabo and median TTF was 6.6 (95%CI: 5.3-8.5) months. Of those discontinuing cabo, 58% (n = 26) received additional therapy. At time of analysis, 62% (n = 43) were alive with 1-year OS rate of 53% (95%CI: 37%-66%).

Table: 879P

		Best Response to Cabo			
	N	PR	SD	PD	Unevaluable
All patients	69	23(33%)	32(46%)	12(17%)	2(3%)
By prior ICB type					
ICB alone	37	16(43%)	15(41%)	5(14%)	1(3%)
ICB+VEGF	24	6(25%)	12(50%)	5(21%)	1(4%)
ICB+Other	8	1(13%)	5(63%)	2(25%)	
By prior ICB duration					
<6mos	42	12(29%)	22(52%)	8(19%)	
>6mos	27	11(41%)	10(37%)	4(15%)	2(7%)

Conclusions: Cabo is active in patients treated after PD-1/PD-L1 based ICB independent of prior combination therapy with VEGF inhibitors, with 79% achieving disease control at minimum. These results support the continued use of cabo irrespective of ICB timing. Equal contribution: BAM, AAL.

Background: RESORT trial (NCT01444807) was the largest prospective study whose aim was to assess the role of VEGF inhibition in mRCC pts after radical metastasectomy. It showed that sorafenib (SO) was safe and feasible but did not affect Relapse-Free Survival (RFS) compared to observation (OBS) in this population. Early identification of dynamic predictors of outcome, such as Circulating Tumor cells (CTCs) may be helpful to move up clinical tumor relapse.

Methods: Pts were randomized (1:1) within 12 weeks from surgery to receive SO or OBS for a maximum of 52 weeks or until disease recurrence, with stratification according to time from nephrectomy to metastases (more or less than 12 months), site of disease (lung vs others) and number of lesions (single vs multiple). Blood samples for CTCs were performed at baseline, month 6, end of treatment and at disease relapse. Peripheral blood samples (5 mL) were processed with the AdnaTest Prostate Cancer Select kit for CTC enrichment. CTCs identification was based on expression levels of EPCAM, MUC1 and ERBB2 measured by RT-multiplex PCR (Breast Cancer Detect Adna Test kit) using cutoffs defined on purpose based on expression in healthy donors.

Results: From November 2012 to November 2017, 76 pts were enrolled (32 in SO and 36 in Obs arm); 6 were screening failure and 2 pts never started treatment. A total of 55 pts had single metastasis resected, 26 in SO arm and 29 in OBS arm; the remaining 13 pts had multiple lesions, 6 in SO arm and 7 in OBS arm. Pts with single mets showed a longer median RFS in comparison to pts with multiple resected mets (39 vs 29 months), irrespective of the arm. Pts with single mets had an improved RFS when received SO compared to pts in the OBS arm (39 vs 20 months). A positive CTCs status was observed at baseline in 31% of pts in both arms and was not associated with RFS. Similarly, no associations were observed between CTCs status switches during SO or Obs and RFS.

Conclusions: Patients with single metastasectomy had better prognosis compared to pts with multiple lesions; SO improved RFS in this group of pts. CTC status and its changes during treatment were not associated with RFS.

Clinical trial identification: NCT01444807; EudraCT: 2012-000708-14.

881P Correlations between disease-free survival (DFS) and overall survival (OS) in patients (pts) with renal cell carcinoma (RCC) at high risk for recurrence: Results from S-TRAC trial

D.J. George[1], A.J. Pantuck[2], R. Figlin[3], B. Escudier[4], S. Halabi[5], M. Casey[6], X. Lin[7], L. Serfass[8], M.J. Lechuga Frean[9], A. Ravaud[10]

[1]Division of Oncology, Duke University Medical Center, Durham, NC, USA, [2]Department of Urology, Ronald Reagan UCLA Medical Center, Los Angeles, CA, USA, [3]Medicine - Hematology Oncology, Cedars-Sinai Medical Center, Los Angeles, CA, USA, [4]Department of Medical Oncology, Gustave Roussy Institut de Cancérologie, Villejuif, France, [5]Biostatistics and Bioinformatics, Duke University, Durham, NC, USA, [6]Department of Oncology, Pfizer Inc, Collegeville, PA, USA, [7]Oncology, Pfizer Inc, La Jolla, CA, USA, [8]Medical, Pfizer, Paris, France, [9]Oncology, Pfizer, Milan, Italy, [10]Department of Medical Oncology, CHU Bordeaux Hopital St. André, Bordeaux, France

Background: S-TRAC, a prospective phase 3 randomized trial in pts with resected RCC at high risk for recurrence, demonstrated a statistically significant improvement in DFS with sunitinib (SU) vs placebo; HR 0.76; 95% CI: 0.59, 0.98; P = 0.03. We hypothesized that DFS is a surrogate for OS and evaluated the association of DFS events with OS.

Methods: DFS (by blinded independent review) was defined from randomization to first evidence of recurrence, second primary malignancy, or death, whichever occurred first. Pts were categorized as having DFS or censored $\leq$2 years vs DFS >2 years, and as having OS or censored $\leq$5 years vs OS > 5 years. The odds ratio (OR), positive predictive values (PPV) and negative PV (NPV) were reported. To determine if DFS can be a surrogate for OS, 2 conditions need to be tested: 1) DFS and OS are strongly correlated, and 2) the treatment effect on DFS is sufficiently correlated with the effect on OS. The validity of the surrogate is reflected by the strength of these correlations. The correlation between DFS and OS is tested at the pt level through copula models to estimate the correlation coefficient (Kendall τ). Trial level correlations have been explored considering region as the trial unit.

Results: Median follow-up for OS was approximately 6.5 years with 141 (23%) observed deaths. There were 257 (42%) DFS events. Of 261 pts with DFS or censored $\leq$2 years of enrollment, 97 were alive and in follow-up >5 years (37%). In 354 pts with DFS >2 years, 318 pts were alive >5 years (90%). The OR, PPV and NPV were 14.9, 0.9 and 0.63, respectively. Kendall's τ ranged from 0.51 to 0.88 using the Hougaard, Clayton, and Plackett copula, suggesting a moderate correlation at the individual pt level. Similar results were observed with investigator assessed DFS. Analyses of trial level correlations also suggest a moderate correlation. Further analyses are being explored.

Conclusions: A moderate correlation between DFS and OS was observed in S-TRAC despite immature OS data. Additional analyses across completed trials are warranted to further assess the relationship between DFS and OS.

Clinical trial identification: NCT00375674.

882P Potent natural killer (NK) and myeloid blood cell remodeling by cabozantinib (Cabo) in pre-treated metastatic renal cell carcinoma (mRCC) patients (pts)

E. Verzoni[1], S. Ferro[2], G. Procopio[1], A. Cova[2], R. Ratta[1], A. Raimondi[1], P. Sepe[1], P. Squarcina[2], L. Lalli[3], V. Huber[2], D. Rinchai[4], D. Bedognetti[4], L. Rivoltini[2]

Background: Cabo is an emerging tyrosine kinase inhibitor in mRCC but its impact on systemic tumor immunity is unknown. We investigated the activity of Cabo in modulating blood innate and adaptive immunity in mRCC pts.

Methods: 15 mRCC pts receiving Cabo (60 mg per os/daily) as per clinical practice were prospectively analyzed at baseline and 3 months for blood immune profiling by 13-color cytofluorimetry on peripheral blood mononuclear cell (PBMC). Pts had clear (n = 12) or non-clear cells (n = 4) histology, with intermediate (n = 7), poor (n = 8) and good (n = 1) risk according to Heng prognostic score, and received at least 2 (n = 9), 1 (n = 2) or none (n = 5) previous therapies, including Nivolumab (n = 4).

Results: A significant reduction of myeloid immunosuppressive cell subsets in favor of protective antitumor adaptive and innate immunity was detected in most post vs pre PBMC. Specifically, granulocytic myeloid-derived suppressor cells (MDSC) ($CD11b^+CD15^+HLA\text{-}DR^{neg}$), monocytic MDSC ($CD11b^+CD14^+HLA\text{-}DR^{neg}$) and TIM3+ myeloid cells ($CD15^+TIM3^+$ and $CD14^+TIM3^+$) were remarkably reduced. Total $CD11b^+CD14^+$ cells were also decreased, while classical protective ($CD14^+CD16^-HLA\text{-}DR^{high}$) and patrolling ($CD14^+CD16^{dim}CX3CR1^+$) monocytes showed a clear boost. Concomitantly, higher frequency of cytolytic and activated NK cells ($CD3^-CD16^+CD56^{dim}$ vs $CD3^-CD56^+CD16^+PD\text{-}1^+$, respectively), paralleled by a decrease of anergic NK cells ($CD3^+CD16^+CD56^+TIM3^+$), was detected in post-Cabo samples. Activated $CD8^+$ and $CD4^+$ T cells ($CD3^+CD8/CD4^+$ $CD69^+$ cells) were also raised by treatment along with a specific increase of ADCC-prone $CD3^+CD16^{dim}CD56^-$ T cells. These latter data indicate that Cabo could intensify direct and Ab-mediated enhancing tumor killing potential in NK and T cells, either as direct effect or through the reduced immunosuppressive pressure exerted by myeloid populations.

Conclusions: Cabo mediates a rapid remodeling of myeloid cells from an immunosuppressive to an antitumor phenotype, with a priming of circulating cytotoxic NK and T cells. Even in advanced disease, Cabo can still contribute to reset systemic immune conditions by creating more favorable conditions for immunotherapy.

883P Metastatic clear cell renal cell carcinoma patients with ECOG performance status 2 treated with pazopanib: The Pazo2 trial of efficacy and safety

E. Porfiri[1], S. Pirrie[2], A-M. Hodgkins[2], D. Farrugia[3], K. Fife[4], C. McDonald-Smith[5], N.S. Vasudev[6], G. Nixon[2], N.D. James[7], C. Stubbs[2]

[1]Cancer Centre, Queen Elizabeth-University Hospital Birmingham NHS Foundation Trust, Birmingham, UK, [2]Cancer Research UK Clinical Trials Unit (CRCTU), School of Cancer and Genomics, Th University of Birmingham - College of Dental and Medical Sciences, Birmingham, UK, [3]Oncology Centre, Cheltenham General Hospital Gloucestershire Oncology Centre, Cheltenham, UK, [4]Oncology Centre, Cambridge University Hospitals NHS Foundation Trust - Addenbrooke's Hospital, Cambridge, UK, [5]Oncology, Ysbyty Gwynedd, Bangor, UK, [6]St James's Institute of Oncology, St. James's University Hospital Leeds, Leeds, UK, [7]Clinical Trials Unit, Queen Elizabeth-University Hospital Birmingham NHS Foundation Trust, Birmingham, UK

Background: Patients with metastatic clear cell renal cell carcinoma (mRCC) and Performance Status 2 have historically been excluded from clinical trials, resulting in a lack of evidence on which to base treatment decisions. Pazo2 was a phase II, multicentre, single arm trial that aimed to determine tolerability and efficacy of pazopanib in

mRCC patients with ECOG PS2. The Bryant and Day design allows for joint evaluation of two primary outcomes. Tolerability was defined as the proportion of patients at 6 months who were free from drug-related grade 3-4 toxicities resulting in SAE reporting or drug discontinuation > =3 weeks. Efficacy was defined as the proportion of patients progression free (RECIST 1.1) and alive at 6 months. Secondary endpoints included response, drug safety, progression free survival (PFS) and overall survival (OS).

Methods: Patients with mRCC and ECOG PS 2 without prior systemic treatment were registered. Undesirable tolerability was set at 40%, with 60% being desirable. Undesirable efficacy was set at 25%, with 44% being desirable (power 85% α 5%). Treatment comprised pazopanib 800mg PO once daily (OD). Dose modifications using 600mg PO, OD and 400mg PO, OD were permitted. Treatment continued until progression or unacceptable toxicity.

Results: A total of 75 patients were registered into the trial from 26 UK sites between 2013-2016. All patients were ECOG PS 2; median age 68 years (IQR 64, 76), 72% were male, HENG poor prognosis 59% and intermediate prognosis 41%. 47 patients met the tolerability criteria (vs 34 required). Further analysis showed that 18 (24%) patients stopped treatment due to toxicity within the same period. 23 patients were required to be progression free and alive at 6 months with 38 being observed. Kaplan Meier 6 month PFS was 66% (95% CI, 54, 76), with a median PFS of 9 months (95% CI 7.6, 13.5). Overall survival data is not yet mature.

Conclusions: Our results suggest that treatment with pazopanib is tolerable and shows similar efficacy in ECOG PS 2 patients as compared to previously reported data with ECOG PS 0/1. This suggests that excluding patients from trials based solely on their performance status may not appropriate.

884P Real-world effectiveness of pazopanib in patients with intermediate prognostic risk advanced renal cell carcinoma (PRINCIPAL study)

G. Procopio[1], A. Bamias[2], M. Schmidinger[3], R. Hawkins[4], A. Rodriguez Sanchez[5], S. Vazquez[6], N. Srihari[7], H. Kalofonos[8], P. Bono[9], C. Pisal[10], Y. Hirschberg[11], L. Dezzani[11], Q. Ahmad[11], C. Suarez Rodriguez[12], E. Jonasch[13]

[1]Medical Oncology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [2]Oncology Unit, Department of Clinical Therapeutics, Alexandra Hospital, Athens, Greece, [3]Oncology, Medical University of Vienna, Vienna, Austria, [4]Medical Oncology, The Christie NHS Foundation Trust, Manchester, UK, [5]Oncology, University Hospital of Leon, Leon, Spain, [6]Medical Oncology, Hospital Lucus Augusti, Lugo, Spain, [7]Medical Oncology, Shrewsbury & Telford Hospitals NHS Trust, Shrewsbury, UK, [8]Medical Oncology, University of Patras, Patras, Greece, [9]Comprehensive Cancer Center, Helsinki University Hospital, Helsinki, Finland, [10]Clinical Research, Novartis Healthcare Private Limited, Hyderabad, India, [11]Clinical Research, Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA, [12]Medical Oncology, Vall d'Hebron University Hospital and Institute of Oncology, Universitat Autònoma de Barcelona, Barcelona, Spain, [13]GU Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA

Background: Stratification by prognostic risk informs efficacy for various treatments in patients (pts) with advanced renal cell carcinoma (RCC). Whether further stratification beyond prognostic risk aids in predicting treatment outcomes is unknown. We conducted a post-hoc analysis of the real-world PRINCIPAL study (NCT01649778) to assess the effectiveness of pazopanib (PAZ) in pts with intermediate risk advanced RCC.

Methods: In this prospective, observational study, pts with advanced and/or metastatic clear cell RCC were enrolled within 30 days of initiating PAZ. Data on progression, survival, and safety were collected approximately every 3 months (mos) until death, consent withdrawal, or loss to follow-up, for up to 30 mos. Primary efficacy end points included overall survival (OS), progression-free survival (PFS), and overall response rate (ORR). A post-hoc analysis of pts with intermediate risk per Memorial Sloan Kettering Cancer Center (MSKCC) and International Metastatic Renal Cell Carcinoma Database Consortium (IMDC) criteria was conducted to evaluate effectiveness by number or risk factors (1 vs 2), age (<65 vs ≥ 65 years), and Eastern Cooperative Oncology Group performance status (ECOG PS).

Results: Of the 657 enrolled pts who received ≥1 dose of PAZ, 363 (55.3%) and 343 (52.2%) had intermediate risk per MSKCC and IMDC criteria, respectively. Within the subgroup of pts with intermediate risk MSKCC and IMDC, median PFS (but not OS) was numerically longer in pts with 1 (vs 2) risk factors, and outcomes were poorer in pts with ECOG PS ≥ 2 (vs < 2) (Table). Median OS within each MSKCC and IMDC risk group was longer than anticipated based on previous clinical trial and real-world data.

Table: 884P Median progression-free survival

	MSKCC intermediate risk (n = 363)		IMDC intermediate risk (n = 343)	
	Disease progression or death/N (%)	Median (95% CI) months	Disease progression or death/N (%)	Median (95% CI) months
Number of risk factors*				
1	85/147 (57.8)	13.8 (10.7-18.1)	88/171 (51.5)	13.1 (10.7-18.1)
2	85/141 (60.3)	7.4 (6.2-10.3)	88/133 (66.2)	8.1 (6.4-10.7)
Age				
<65 years	79/142 (55.6)	12.3 (9.0-16.4)	73/136 (53.7)	13.1 (10.3-18.4)
≥65 years	131/219 (59.8)	10.7 (9.0-13.8)	123/205 (60.0)	10.7 (9.0-13.1)
ECOG PS				
<2	189/333 (56.8)	11.2 (9.5-14.1)	177/316 (56.0)	11.8 (9.9-15.4)
≥2	8/8 (100.0)	5.6 (1.3-12.8)	8/8 (100.0)	2.3 (1.2-10.7)

*Patients with 1 missing risk factor were excluded.
CI; confidence interval; ECOG PS, Eastern Cooperative Oncology Group performance status; IMDC, International Metastatic Renal Cell Carcinoma Database Consortium; MSKCC, Memorial Sloan Kettering Cancer Center.

Conclusions: The results of the PRINCIPAL study suggest pts with advanced RCC of intermediate prognostic risk can be further stratified to predict treatment outcomes.

Clinical trial identification: NCT01649778.

Background: The Italian Renal Cell Cancer Early Access Program was an expanded access program that allowed access to nivolumab, for patients (pts) with mRCC prior to regulatory approval.

Methods: Pts with mRCC previously treated with agents targeting the vascular endothelial growth factor pathway were eligible to receive nivolumab 3 mg/kg once every 2 weeks. Pts included in the analysis had received $\geq$ 1 dose of nivolumab and were monitored for adverse events (AEs) using CTCAE v.4.0. Association between sex, age, BMI, metastatic sites, number and kind of previous therapies, ECOG PS and related toxicity were evaluated with a logistic regression model that identified only age $\geq$ 65 years (Odds Ratio= 1.54 (1.00-2.38; P = 0.05).

Results: A total of 389 pts were enrolled between July 2015 and April 2016, 79% after 2 or more lines of therapy. The most common any-grade treatment-related AEs were fatigue (13%) and rash (9%). Twenty-two (5.7%) pts discontinued treatment due to AEs. There were no treatment-related deaths. Treatment-related AEs (grade 1-4) were reported in 32% of pts. Median time to appearance of AEs was 1.4 months (range 0-11.4). Grade 3–4 AEs occurred in 27 (7%) pts. Of the 22 serious AEs who induced treatment discontinuation, 11 (50%) were considered irAEs including: grade 4 hyperglicemia (n = 1), grade 3 diarrhea (n = 1), grade 3 pulmonitis (n = 1), grade 3 bronchiolitis obliterans organising pneumonia (BOOP) (n = 1), grade 3 asthenia (n = 1), grade 3 hypertension (n = 1), grade 3 skin toxicity (n = 1), grade 3 tremor (n = 1), grade 2 eyelid ptosis (n = 1), grade 2 liver toxicity (n = 1), grade 2 hypothyroidism (n = 1). AEs were generally manageable with treatment as per protocol-specific guidelines. At a median follow-up of 12 months, the median progression-free survival was 4.5 months (95% CI 3.7 - 6.2), the 12-months overall survival rate was 63%. Pts with toxicity (124 pts) had a significant (P = 0.01) longer survival (1 year OS 69%) in comparison to pts who did not experience AEs (1 year OS 59%).

Conclusions: The appearance of AEs strongly correlates with survival benefit in a real-life population of mRCC pts treated with Nivolumab.

886P Adiponectin-AdipoR1 axis in renal cell carcinoma plays a pivotal role in tumor progression and drug resistance

G. Sun, X. Zhang, J. Zhao, J. Chen, P. Shen, Z. Liu, H. Zeng

Urology, West China Hospital, Sichuan University, Chengdu, China

Background: It is well established that renal cell carcinoma (RCC) is an obesity-associated cancer. Adiponectin, a major adipocyte-secreted adipokine, plays anti-tumor properties in many malignancies, but exerted paradoxical actions on RCC. Herein, we investigated the effects of adiponectin on RCC progression and resistance to sunitinib, and to exploit this molecular mechanism.

Methods: Tissues were collected from 126 patients with metastatic renal cell carcinoma (mRCC) treated with tyrosine kinase inhibitor (TKI) therapy. Tumor Adiponectine receptor 1 (AdipoR1) and Adiponectine receptor 2 (AdipoR2) were detected by immunohistochemistry. Assays with RCC cell lines were used to examine the signal transduction pathways of adiponectin in RCC.

Results: AdipoR2 was generally lower expressed than AdipoR1 in mRCC tumor (15.6% vs 89.1%, $p < 0.001$). AdipoR1 expression, but not AdipoR2, was a significant independent predictor of favorable responding to TKI and good survival outcomes. In cultured RCC cells adiponectin inhibited migration and invasion of RCC cells and sensitized cells to killing by sunitinib. Mechanistic investigations of ligand–receptor interactions revealed that AdipoR1 could hinder migration and invasion of RCC cells by blocking GSK3β and β-Catenin pathway and increase cells sensitivity to sunitinib through inhibiting AKT and NF-κB pathway. However, AdipoR2 was not associated with the tumor-limiting properties of adiponectin.

Conclusions: These results show that AdipoR1 is a potential prognostic marker for favorable outcomes of mRCC patients. Adiponectin-AdipoR1 axis could be a plausible target to impede tumor progression and sensitize tumors to TKI therapy.

887P Identification of IMDC intermediate-risk subgroups in patients with metastatic clear-cell renal cell carcinoma (ccRCC)

A. Guida[1], G. Le Teuff[2], E. Colomba[3], G. Baciarello[3], L. Derosa[4], Y. Loriot[3], K. Fizazi[3], C. Massard[5], B. Escudier[3], L. Albiges[3]

[1]Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy, [2]Statistics, Gustave Roussy, Villejuif, France, [3]Department of Medical Oncology, Gustave Roussy, Villejuif, France, [4]INSERM, Gustave Roussy, Villejuif, France, [5]DITEP, Gustave Roussy Institut de Cancérologie, Villejuif, France

Background: Majority of patients (pts) with ccRCC at first line (1L) treatment are classified in the IR subgroup according to International Metastatic Renal Cell Carcinoma Database Consortium (IMDC) model. IR represents a heterogeneous class of pts while frontline strategies will be chosen on prognostic selection. The aim of this study is to better characterize IR pts.

Methods: Retrospective analysis was performed from IGReCC (Institut Gustave Roussy Renal Cell Carcinoma) database. Overall survival (OS) was defined from start of 1L therapy to death or last follow-up. A multivariable Cox model with backward selection procedure (alpha level = 0.01) and a Classification and Regression Tree (CART) analysis were performed to identify which prognostic factors of IMDC score (time from diagnosis to treatment [DDT] < 1 year, Karnofsky Performance Status [KPS] < 80%, Hemoglobin < lower limit of normal [LNL], neutrophils > upper normal level [UNL], platelet > UNL, calcium > UNL) were associated to OS in IR pts.

Results: From 2005 to 2016, 777 pts with ccRCC were treated with an anti-VEGF first line therapy. Among 571 evaluable pts for IMDC score, 199 (35%) pts were classified as good risk, 82 (14%) as poor risk and 290 (51%) as IR. Median OS for IR pts was 24 months (mo). Within the IR population, only platelet (PLT) count was significantly associated to OS with a hazard ratio 1.88 (95%CI 1.27-2.88) p = 0.0017. Median OS for pts with PLT > UNL was 18 months (mo) [95%CI 12-23] versus 29 mo [95%CI 21.4-35.7] for pts with normal PLT count. Therefore, the selection of PLT count was confirmed on bootstrap samples and was also selected for the first split of the CART-tree analysis.

Conclusions: Pts in the IR group have a heterogeneous prognosis. Elevated PLT count seems identifies a subgroup of pts with poor outcome in the IMDC intermediate-risk population with ccRCC.

Van der Veldt[4], E.G.E. de Vries[2], O. Boerman[6], W.T.A. van der Graaf[8], W.J.G. Oyen[1], C.M.L. van Herpen[1]

[1]Medical Oncology, Radboud University Medical Centre Nijmegen, Nijmegen, Netherlands, [2]Medical Oncology, University Hospital Groningen (UMCG), Groningen, Netherlands, [3]Medical Oncology, Vrije University Medical Centre (VUMC), Amsterdam, Netherlands, [4]Medical Oncology, Erasmus University Medical Center, Rotterdam, Netherlands, [5]Epidemiolgy, Julius Center of Health Academy, Utrecht, Netherlands, [6]Radiology and Nuclear Medicine, Radboud University Medical Centre Nijmegen, Nijmegen, Netherlands, [7]Radiology & Nuclear Medicine, Vrije University Medical Centre (VUMC), Amsterdam, Netherlands, [8]Division of Clinical Studies, Royal Marsden Hospital Institute of Cancer Research, Sutton, Surrey, UK

Background: As slow disease progression is observed in a subset of mccRCC patients, watchful waiting can be considered, thereby postponing toxicity of systemic treatment. To identify those patients, the IMPACT trial evaluated the role of anti-Carbonic

Anhydrase IX antibody ^{89}Zr-girentuximab and ^{18}F-fluorodeoxyglucose (FDG) PET/CT (PET). Here, we report preliminary analyses of a secondary endpoint: comparison of baseline contrast-enhanced(ce)CT, ^{89}Zr-girentuximab and FDG PET to detect metastases.

Methods: mccRCC pts with good or intermediate prognosis (according to IMDC) and eligible for watchful waiting were included. Patients underwent 3 scans, i.e. ceCT, ^{89}Zr-girentuximab and ^{18}F-FDG PET. So far, baseline scans of 29 of the 40 pts to be accrued were independently reviewed by 3 experienced readers. Lesions by ceCT were defined positive according to RECIST1.1. For lesions with prominent uptake of ^{89}Zr-girentuximab or ^{18}F-FDG, maximum Standardized Uptake Values (SUVmax) were calculated. Analyses were performed on a lesion level, taking clustering of data within patients and lesions into account.

Results: In total 325 lesions were detected by at least one modality (mean 11(2-33) per pt); ceCT detected 52% (95%CI:45;58), ^{18}F-FDG PET 61% (95%CI:55;67) and ^{89}Zr-girentuximab PET 69% (95%CI:63;74). Differences in lesion detection varied across organ sites($p < 0.001$). Lesions were visualized by ceCT and ^{18}F-FDG PET in all pts,whereas ^{89}Zr-girentuximab PET detected lesions in 27 of 29 pts. Compared to ceCT, ^{89}Zr-girentuximab PET visualized additional lesions in all organ sites. Location was strongly related with ^{89}Zr-girentuximab uptake; highest uptake in kidney and adrenal gland tumor (mean SUVmax 63.2 and 70.3, resp) and lowest uptake in lung and lymph nodes (mean SUVmax 10.9 and 15.0, resp). After correction for location, no relation was observed between ^{89}Zr-girentuximab SUVmax and tumor size, as measured by ceCT, and ^{18}F-FDG SUVmax.

Conclusions: ^{89}Zr-girentuximab and ^{18}F-FDG PET visualize additional lesions compared to ceCT, however correlation was poor. The addition of ^{89}Zr-girentuximab or ^{18}F-FDG PET might aid in deciding to either delay or start systemic treatment.

Background: In an era of increasing treatment options for mRCC, optimal treatment sequence after IO therapy has not been well established. This study compares the effect of targeted therapy (TT) (VEGFR TKI [axitinib, sunitinib, cabozantinib, pazopanib, bevacizumab, and sorafenib] vs mTORI [everolimus and temsirolimus]) after progression on IO therapy.

Methods: Data from 7 International mRCC Database Consortium (IMDC) centers were used to examine time to treatment discontinuation (TTD: time from TT initiation to discontinuation for any reason) and objective response rate (ORR: complete or partial tumor response) among mRCC patients (pts) treated with TT after IO between 2010-2018. Kaplan Meier analysis and Cox proportional hazards model adjusting for age, sex, IMDC risk score, and line of therapy were conducted. Overall survival will be reported when data is more mature.

Results: Pts treated with VEGFR TKI (N = 156 [85%]) and mTORI (N = 28 [15%]) post IO had similar age and IMDC risk scores (mean age: 61 vs 63 years; IMDC favorable: 5% vs 8%; IMDC intermediate: 62% vs 48%). Most common TT post IO were axitinib (35%), cabozantinib (18%), and sunitinib (15%). Unadjusted median TTD was significantly longer for VEGFR TKI vs mTORI (5.3 vs 2.5 months, p = 0.002). VEGFR TKI vs mTORI post IO was significantly associated with a longer TTD (adjusted hazard ratio [aHR]: 0.44, p = 0.002). A trend toward better TTD with axitinib post IO vs other TT was observed (aHR: 0.66, p = 0.08). ORR was numerically higher in VEGFR TKI vs mTORI. Reported results are across all lines of therapy. The table has descriptive statistics.

Table: 889P Descriptive statistics of clinical outcomes among patients treated with targeted therapy (i.e., VEGFR TKI, mTORI) subsequent to IO treatment

	Total N	Number of treatment discontinuation for any reason (%)	Median TTD, (95% CI) months	Objective response rate[1] N (%)
All	184	118 (64)	4.9 (4.0, 5.6)	20 (17)
By class VEGFR TKI[2]				
All lines	156	93 (60)	5.3 (4.3, 6.9)	19 (20)
2nd line	44	28 (64)	3.8 (3.2, 5.4)	7 (23)
3rd line	72	43 (60)	5.7 (4.3, 9.8)	10 (22)
≥ 4th line	40	22 (55)	6.1 (4.2, 10.9)	2 (10)
mTORI[3]				
All lines	28	25 (89)	2.5 (1.4, 3.4)	1 (5)
2nd line	0	-	-	-
3rd line	20	19 (95)	2.3 (1.0, 4.9)	1 (6)
≥ 4th line	8	6 (75)	3.2 (1.3, 4.9)	0 (0)

IO: immuno-oncology; VEGFR TKI: vascular endothelial growth factor receptor tyrosine kinase inhibitor; mTORI: mammalian target of rapamycin inhibitor; CI: confidence interval; ORR: objective response rate; TTD: time to treatment discontinuation Notes: [1] Objective response rate, defined as the sum of partial responses and complete responses, was assessed during the line of targeted therapy subsequent to IO treatment. The total number of patients assessed was 116. [2] VEGFR TKI included axitinib, sunitinib, cabozantinib, pazopanib, bevacizumab, and sorafenib. [3] mTORI included everolimus and temsirolimus.

Conclusions: Subsequent to IO therapy, VEGFR TKI pts had significantly longer adjusted TTD than mTORI pts. When larger sample sizes are available for TT, further examination of sequences is warranted.

Background: Novel therapies are needed as an initial or salvage treatment for patients with metastatic or locally advanced RCC. This study aimed to assess the safety and efficacy of everolimus in patients with metastatic recurrent and/or unresectable clear cell RCC.

Methods: EVERMORE is an open-label, multicenter, single-arm, phase 2 study (NCT01206764) that enrolled patients aged ≥ 18 yrs with advanced and histologically confirmed clear or non-clear cell RCC. Everolimus 10 mg/d was administered orally, as a first line or after cytokine therapy, until disease progression (PD), unacceptable toxicity, or study discontinuation for any other reason. The primary endpoint was progression-free survival (PFS) rate over time. The secondary endpoints were disease control rate (DCR; stable disease + partial response [PR] + complete response [CR]), objective response rate (ORR), duration of response (DOR), overall survival (OS), and safety.

Results: From 2009 to 2017, 142 patients with a mean age of 55.5 years from 10 countries were enrolled. Most of the patients (58.2%) have a clear cell adenocarcinoma as histology/cytology and 53.1% had stage IV disease at initial diagnosis. Of 142 patients, everolimus was received in 117 as first-line and in 25 as second-line treatment. The most common reason for early discontinuation of treatment was PD (n = 88, 62.0%). The median PFS for all assessed patients was 7.0 months (95% CI: 22.00, 37.29). The ORR was 12.0% (n = 17; 95% CI: 7.1, 18.5). The median DOR in patients who had either CR or PR was 39.0 months (n = 17). The DCR was 74.6% (n = 106; 95% CI: 66.7, 81.6). The median OS was not evaluable. The most commonly reported adverse events (AEs) of all grades were anemia (45.1%), stomatitis (29.6%), hyperglycemia (26.1%), and decreased appetite (22.5%). The most commonly reported serious AEs were pneumonia (n = 6), dyspnea (n = 4), urinary tract infection, decreased appetite, dehydration and diarrhea (n = 3 each). In the study, 33 deaths were reported, of which, 19 deaths were due to study indication.

Conclusions: The PFS and safety results of everolimus when administered in patients as first-line or after cytokine therapy are consistent with the previously published data (RECORD-3).

Clinical trial identification: NCT01206764.

Pascale", Naples, Italy, [6]Oncology, Azienda Ospedaliera Sta Maria, Terni, Italy, [7]Medical Oncology Unit, Azienda Ospedaliera Universitaria Integrata (AOUI), University of Verona, Verona, Italy, [8]Oncologia Medica, Azienda Ospedaliera Arcispedale Santa Maria Nuova - IRCCS, Reggio Emilia, Italy, [9]Medical Oncology Unit, S. Salvatore Hospital, University of L'Aquila, L'Aquila, Italy, [10]Oncologia Medica, AUSL di Imola, Imola, Italy, [11]Oncologia, Azienda Ospedaliera di Parma, Parma, Italy, [12]Oncologia, Ospedale degli Infermi, Faenza, Italy, [13]Oncologia, AOU Ospedali Riuniti Ancona Università Politecnica delle Marche, Ancona, Italy, [14]Oncologia, Ospedale San Matteo, Pavia, Italy, [15]U.O.C. of Medical Oncology, Ospedale San Donato, Arezzo, Italy

Background: Immunotherapy (IO) has brought dramatic clinical benefits to patients with mRCC. Most patients tolerate IO, but serious irAE have been reported. Some studies indicate the correlation of irAEs and clinical response in other cancer types such as lung cancer and melanoma. For mRCC, the impact of irAE on clinical outcome is unknown.

Methods: A retrospective review of patients with mRCC treated with nivolumab as standard of care between March 2017-January 2018 from 13 Italian centers of the IGO group (Innovators in Genitourinary Oncology) was performed. Patients enrolled in clinical trial or expanded access program were excluded. IrAEs were assessed based on the treating physician diagnosis.

Results: A total of 111 patients (pts) met criteria. Median age was 67 yr, 83 pts (75%) were male. Histology was clear cell in 102 pts (92%) and non clear cell in 9 pts (8%). IrAE was noted in 48 pts (43%) with steroid required in 21 pts (44%). The time from the beginning of nivolumab treatment to the irAE occurrence ranged 1-81 weeks (mean 10 weeks). Most patients received nivolumab as a second or third line of treatment (61% and 37% respectively). The most common irAEs were cutaneous (21%), endocrinologic (17%), gastrointestinal and pulmonary (both 15%). In patients who developed irAE, 2% of complete response (CR), 22% of partial response (PR), 41% of stable disease (SD) and 35% of progression disease (PD) (according to RECIST criteria) were observed versus 0% CR, 7% PR, 37% SD and 57% PD in patients who did not develop irAE. Development of irAE had a statistically significant impact on response rates (p = 0.007). There was also no significant association of steroid use with response rates (p = 0.643). Because of the short follow up, survival data were not mature at the time of the analysis.

Conclusions: The development of irAE may be correlated with better response to nivolumab. This data may be limited by sample size and retrospective nature. A long-term follow-up is required to determine the impact of irAE on survival in mRCC patients treated with nivolumab.

892P Treatment sequences in metastatic renal cell carcinoma: Efficacy results from the Czech registry (RENIS)

J. Finek[1], R. Demlova[2], K. Kopeckova[3], T. Buchler[4], B. Melichar[5], J. Prausova[3], A. Poprach[6], T. Hrnciarova[7], T. Mlcoch[7], T. Dolezal[7]

[1]Oncology and Radiotherapy, Teaching Hospital Pilsen and Faculty of Medicine in Pilsen, Charles University, Plzen, Czech Republic, [2]Pharmacology Department,, Faculty of Medicine, Masaryk University and Masaryk Memorial Cancer Institute, Brno, Czech Republic, [3]Oncology, Second Faculty of Medicine, Charles University and Motol University Hospital, Prague, Czech Republic, [4]Oncology, First Faculty of Medicine, Charles University and Thomayer Hospital, Prague, Czech Republic, [5]Oncology, University Hospital Olomouc, Olomouc, Czech Republic, [6]Department of Comprehensive Cancer Care, Masaryk Memorial Cancer Institute, Brno, Czech Republic, [7]IHETA, Institute of Health Economics and Technology Assessment, Prague, Czech Republic

Background: Efficacy data of treatment sequences in mRCC are rare. In the Czech Republic, data on efficacy and safety of all targeted therapies for mRCC are collected in the RENIS patient registry. Thus, RENIS provides data from the real-world clinical practice. The aim of this study was to compare outcomes of selected treatment

sequences in mRCC while adjusting for differences in patient characteristics using inverse propensity score weighting method (IPWS).

Methods: Data of mRCC patients treated using most common treatment sequences were collected in RENIS between 06/2007 and 02/2018. Overall survival (OS) and progression free survival (PFS) were evaluated. Baseline characteristics were balanced using IPWS. The propensity score was evaluated with nominal logistic model to balance Eastern Cooperative Oncology Group (ECOG) performance status, time from diagnosis to first treatment, nephrectomy, Memorial Sloan-Kettering Cancer Center (MSKCC) score, and age. Median and confidence intervals (CI) were derived from IPWS weighted Kaplan-Meier curves that were compared using log-rank test.

Results: Overall, 745 patients in five treatment sequences were included and analysed. Differences in OS were significant ($p < 0.001$) with sunitinib→axitinib→everolimus and sunitinib→axitinib sequences associated with improved survival over other sequences. These differences could be also linked to time when these drugs were introduced. PFS did not differ between sunitinib and pazopanib used as first line treatments ($p = 0.44$) but the PFS in the second line differed significantly ($p = 0.035$) (Table).

Table: Results of OS and PFS for examined sequences computed using inverse propensity score weighting. Sunitinib → Axitinib → Everolimus sequence should be assessed with caution due to immortal time bias.

Table: 892P

Parameter	Treatment sequence	n	Median	95% CI for median		p
				Lower limit	Upper limit	
OS (months)	Sunitinib → Everolimus	312	26.3	23.8	29.0	<0.001
	Sunitinib → Axitinib	154	47.6	31.3	50.5	
	Sunitinib → Axitinib → Everolimus†	114	46.0	44.7	50.9	
	Pazopanib → Everolimus	74	32.9	30.9	33.8	
	Pazopanib → Sunitinib	91	27.2	26.7	28.8	
PFS 1st line (months)	Sunitinib	580	10.2	9.8	10.8	0.440
	Pazopanib	165	9.2	8.5	10.0	
PFS 2nd line (months)	Sunitinib → Everolimus	312	5.8	5.1	6.3	0.035
	Sunitinib → Axitinib	268	6.4	6.0	7.1	
	Pazopanib → Everolimus	74	5.1	4.1	5.5	
	Pazopanib → Sunitinib	91	5.3	5.1	7.1	

Conclusions: Improved outcomes were associated with sequences using second-line axitinib over those using second-line sunitinib or everolimus in a cohort of patients from a national registry.

893P Cabozantinib in metastatic renal cell carcinoma (mRCC): Data from UK expanded access program (EAP)

A. Gomez de Liano Lista[1], B. Venugopal[2], K. Fife[3], S. Symeonides[4], N.S. Vasudev[5], S.M. Rudman[6], S. Vohra[2], L. Khasati[7], C. Pettinger[4], B. Szabados[1], L. Morrison[8], T. Powles[9], E. Boleti[8]

[1]Medical Oncology, Barts Cancer Institute, London, UK, [2]Medical Oncology, Beatson West of Scotland Cancer Centre, Glasgow, UK, [3]Medical Oncology, Cambridge University Hospitals NHS Foundation Trust - Addenbrooke's Hospital, Cambridge, Cambridgeshire, UK, [4]Medical Oncology, Cancer Research UK Edinburgh Centre, Edinburgh, UK, [5]Oncology, St. James's University Hospital Leeds, Leeds, Yorkshire, UK, [6]Medical Oncology, Guy's and St. Thomas' Hospital NHS Trust, London, UK, [7]Medical Oncology, Cambridge University Hospitals NHS Foundation Trust - Addenbrooke's Hospital, Cambridge, UK, [8]Academic Oncology, Royal Free Hospital School of Medicine, London, UK, [9]Barts Cancer Institute, London, UK

Background: Cabozantinib demonstrated increased efficacy over everolimus in patients with mRCC progressing on VEGF targeted therapy in the randomised phase III METEOR trial. We report real world experience with Cabozantinib in 7 centres across the UK.

Methods: In this retrospective study, patients who started Cabozantinib from September 2016 to September 2017 within the UK EAP were included. Patients had mRCC progressing after at least 1 prior systemic treatment, PS 0-2 and adequate organ function. The goal was to analyse toxicities, efficacy and access to other drugs after progression. Adverse events (AEs) were graded using the NCI CTCAE v.4.0.3. Survival times were calculated from the start of Cabozantinib using a Kaplan-Meier model. Radiological response was assessed locally by RECIST 1.1.

Results: 128 patients were included. Median follow-up was 10.5 months. Median age was 62 years, 84% had clear cell histology, and 49% were classified as intermediate risk by IMDC score. 87% had visceral M1 and 52% bone M1. Patients received a median of 2 previous lines (1-6) of therapy. Cabozantinib was used as 2nd line, 3rd line and 4th line or beyond in 56 (44%), 38 (30%) and 34 (26%) patients respectively. Baseline characteristics are summarized in the table. 48 (37%) of the patients developed G3/4 AEs, mainly fatigue (N = 14, 11%), diarrhoea (N = 12, 9%), mucositis (N = 7, 5%) and hand-foot syndrome (N = 6, 5%). No treatment-related deaths were seen. 71 patients (55%) required dose reductions. 12 (15%) discontinued Cabozantinib due to toxicity. Median OS was 9.1 months (95% CI 6.6-11.6), being 14.3 vs 9.3 vs 6.0 months for good, intermediate and poor prognostic patients, respectively (p 0.01). Median PFS was 7.7 months (95% CI 5.3-10.1). Partial response to Cabozantinib was 26%, stable disease 24%, Progressive disease 30% and was not evaluated in 20%. Only 21/81 patients (26%) stopping Cabozantinib started on subsequent treatment.

Conclusions: Cabozantinib was safe and active in pretreated patients with mRCC.

894P Comparative effect of body-mass index on outcome with targeted therapy and immunotherapy in patients with metastatic renal cell carcinoma (mRCC)

N. Dizman[1], P. Bergerot[1], C.D. Bergerot[1], E.J. Philip[2], M.M. Salgia[1], J. Hsu[1], J. Adashek[1], S.K. Pal[1]

[1]Medical Oncology, City of Hope, Duarte, CA, USA, [2]The Notre Dame Laboratory for Psycho-Oncology Research, University of Notre Dame, Notre Dame, IN, USA

Background: A previous study identified an association between high body mass index (BMI) and better overall survival (OS) in mRCC patients treated with vascular endothelial growth factor-tyrosine kinase inhibitors (VEGF-TKIs) (Albiges et al JCO 2016). We assessed whether the effect of BMI on OS extended beyond VEGF-TKI to immunotherapy (IO) or VEGF/IO combination regimens.

Methods: A retrospective study was done among patients diagnosed with mRCC treated at a single institution from 2009 to 2017. Demographic and clinical variables were collected. BMI was characterized as high ($\geq$25 kg/m^2) versus low ($<$25 kg/m^2). The Kaplan-Meier method was used to estimate the difference in OS, segregated by BMI and further by treatment type (e.g., VEGF-TKI, IO or VEGF/IO).

Results: Among 235 patients, median age was 65 years (33-90), 73% were male, and 65% were overweight or obese (BMI $\geq$ 25 kg/m^2). The majority of patients had undergone nephrectomy (86%). The most systemic therapy was VEGF-TKI (58%), followed by IO (17%) and VEGF/IO (25%). In patients treated with VEGF-TKI with low BMI, median OS was 25.0 months (95% CI: 18.7-31.2) versus 36.0 months (95% CI: 25.2-46.7) in patients with high BMI (P = 0.01). A similar result was found for patients treated with VEGF/IO, where median OS was 18.0 months (95% CI:10.0-25.9) for patients with low BMI versus 24.0 months (95% CI: 14.8-33.2) in patients with high BMI (P = 0.01). However, patients treated with IO with low BMI, median OS was 55.0 months (95% CI: 33.7-76.7) versus 22.9 months (95% CI: 17.7-28.1) in patients with high BMI (P = 0.33).

Conclusions: High BMI was associated with improved OS in patients with mRCC treated with VEGF-TKI or VEGF/IO, but the inverse trend was observed among patients receiving IO. In addition to validating previous findings associating VEGF-TKI, BMI and clinical outcome, our data highlight the need to reassess this phenomenon in the context of IO-based regimens.

895P Advanced treatment line (ATL) with lenvatinib and everolimus (Len+Eve) for metastatic renal cell carcinoma (mRCC): Analysis of a national early access program (EAP)

A. Peer[1], M. Kolin[1], K. Rouvinov[2], D. Keizman[3], D. Sarid[4], R. Leibowitz-Amit[5], R. Berger[5], A. Sella[6], A. Rasco[6], E. Rosenbaum[7], C. Maurice-Dror[1], A. Neumann[1], V. Neiman[7]

[1]Oncology, Rambam Health Care Center, Haifa, Israel, [2]Oncology, Soroka University Medical Center, Beer Sheva, Israel, [3]Oncology, Meir Medical Center, Kfar Saba, Israel, [4]Oncology, Tel Aviv Sourasky Medical Center-(Ichilov), Tel Aviv, Israel, [5]Oncology, Chaim Sheba Medical Center, Ramat Gan, Israel, [6]Oncology, Asaf Harofeh Medical Center, Zerifin, Israel, [7]Oncology, Rabin Medical Center Davidoff Cancer Centre, Beilinson Campus, Petah Tikva, Israel

Background: VEGFR inhibition is a mainstay in the treatment of mRCC. In recent years third generation TKIs offer advantages in treatment efficacy while combinations further improve clinical activity. Treatment with Len+Eve is approved based on a randomized phase 2 study in the second line setting. Data on activity and efficacy of this combination as ATL beyond second line is limited. We aimed to report the activity of Len+Eve in mRCC patients (pts) treated per a national EAP.

Methods: Records from consecutive mRCC (pts) treated with Len+Eve in ATL per a national EAP in 7 centers, were retrospectively reviewed. We report the clinical benefit, progression free survival (PFS), overall survival (OS), and toxicity.

Results: Between 11/2016 – 12/2017, 39 mRCC pts were treated with Len+Eve. Median age 60 (39-82), male 72%. Majority of the pts (82%) underwent nephrectomy. Heng risk was good/intermediate/poor in 13% (n = 5)/41% (n = 16)/46% (n = 18). According to the treating physician, 69% (n = 27) of pts had high burden disease at treatment initiation. 13% (n = 5) were treated as second line, 51% (n = 20) as third and 36% (n = 14) as fourth line. All patients in the third and fourth line received prior immunotherapy. Clinical benefit (stable disease+ partial response) was 74% (54% partial response and 20% stable disease). Median PFS was 6 months (mos). After a median follow up time of 9 mos, 62% of the pts with a clinical benefit are still with a benefit and on treatment (range 5-16m). Most pts (72%, n = 28) are alive, with median OS not reached. Dose reduction was required in 49% of the patients due to mainly grade 3 toxicity. There were no treatment discontinuations due to toxicity.

Conclusions: Len+Eve as ATL in mRCC may benefit patients beyond second line treatment, and is associated with responses similar to those seen in a clinical trial setting in the ATL setting, with manageable toxicity.

896P Predictive radiomics signature for treatment response to nivolumab in patients (pts) with advanced renal cell carcinoma (RCC)

H-W. Sim, A. Stundzia, S. Pierre, U. Metser, M. O'Malley, E. Elimova, S.S. Sridhar, A. Hansen

Department of Medical Oncology, Princess Margaret Cancer Center, Toronto, ON, Canada

Background: Although nivolumab has been widely adopted as a treatment for advanced RCC, only a minority of pts benefit. We aimed to use radiomics as a predictive biomarker. By extracting quantitative information from serial imaging, this non-invasive method captures the spatial and temporal heterogeneity of tumors, more than tissue biopsy. We hypothesized to find an imaging correlate of host immune recognition, characterized by infiltration of the invasive tumor margin by immune effector cells, that would identify pts to benefit from nivolumab.

Methods: We retrospectively identified all advanced RCC pts treated with nivolumab at our institution from 2013-2017. Pts were labelled as responders (CR / PR / durable SD) or non-responders based on clinical data. For each pt, lesions were contoured from pre-treatment and first on-treatment CT scans. All lesions were manually contoured in tandem by two trained investigators. This information was used to train a radial basis function support vector machine classifier to learn a prediction rule to distinguish responders versus non-responders. The classifier was internally validated by 10-fold nested cross-validation.

Results: 37 pts were identified. Excluded: imaging unavailable = 3, incompatible CT protocols = 7. 104 lesions were contoured from 27 pts. Median age 56 years, 78% male, 89% clear cell histology, 89% prior nephrectomy, 89% prior systemic therapy. 19 responders vs 8 non-responders. Lesions: 60% lymph nodes, 23% lung metastases, 17% renal/adrenal metastases. For the classifier trained on the baseline CT scans, 69% accuracy was achieved. For the classifier trained on the first on-treatment CT scans, 66% accuracy was achieved.

Conclusions: Based on preliminary computations, the radiomics signature could discriminate nivolumab responders from non-responders. Additional texture feature analysis with over 72 billion calculations is underway to improve the classifier performance to discriminate tumor responses to immunotherapy. External validation against the comprehensive patient dataset from the International Metastatic Renal Cell Cancer Database Consortium is planned.

897P A phase Ib study of safety and preliminary efficacy of extracranial stereotactic body radiation therapy (SBRT) in patients with metastatic renal cell carcinoma (mRCC) treated with systemic therapy

N. Dengina[1], T. Mitin[2], S. Gamayunov[3], S. Safina[4], Y. Kreinina[5], I. Tsimafeyeu[6]

[1]Radiotherapy Department, Ulyanovsk Regional Clinical Cancer Center, Ulyanovsk, Russian Federation, [2]Radiation Medicine, Oregon Health & Science University, Portland, OR, USA, [3]Thoracic and Abdominal Surgery Department, Republical Clinical Cancer Center, Cheboksary, Russian Federation, [4]Medical Oncology, Republical Clinical Cancer Center, Kazan, Russian Federation, [5]Brachytherapy Department, Russian Scientific Center of Roentgen Radiology, Moscow, Russian Federation, [6]Russian Society of Clinical Oncology, Moscow, Russian Federation

Background: Tyrosine kinase inhibitors (TKI) and checkpoint inhibitors (CI) have been established as effective treatment for mRCC, but only a minority of patients achieves complete response and additional strategies are necessary to improve the efficacy of these agents. We have designed a prospective phase 1b "Volga" study to determine the safety and efficacy of extracranial SBRT in patients with clear-cell mRCC.

Methods: Patients were included if they had stable disease for at least 4 months on TKI or CI. SBRT was delivered to an organ with multiple comparable lesions, where one lesion was in the treatment target (target lesion) and the other one was intentionally left untreated (control lesion). Dose of radiation and number of fractions were determined based on target lesion localization and the proximity of organs at risk. Response in both target and control lesions was scored using RECIST 1.1 criteria at least 2 months after completion of SBRT.

Results: 17 patients were enrolled, 12 of them received TKI and 5 patients received nivolumab. SBRT was delivered to lungs (n = 5), bones (n = 4), lymph nodes (n = 4), liver (n = 1), primary RCC (n = 1), and locally recurrent RCC (n = 2). Equivalent Dose (EQD) with alpha/beta ratio of 2.6 was 114 Gy (range, 40-276 Gy). With a median follow-up of 8 months (range, 3-18), cumulative rate of SBRT-related toxicity (grade 1) was 12% (n = 2), consisting of esophagitis (n = 1) and skin erythema (n = 1). No grade 2 or higher toxicity was detected. Radiographic response in the target lesion was seen in 13 patients (76%), with complete response in 5 (29%) patients and partial response in 8 (47%) including abscopal effect in 1 patient. Control lesions were stable in 16 patients. The difference between response in target and control lesions as judged by mean sizes of these lesions before and at 2 months after SBRT was statistically significant (P < 0.01). Fraction size of equal to or greater than 10 Gy was associated with complete response in the target lesion.

Conclusions: Extracranial SBRT in patients with mRCC treated with TKI or CI is well tolerated and could be effective. This approach will be studied in an expanded cohort of patients.

Clinical trial identification: NCT02864615.

898P VOTRAGE study pazopanib in a population of "frail" elderly patients after geriatric assessment: A phase I study with geriatric criteria

L. Mourey[1], A. Ravaud[2], L. Digue[2], B. Cabarrou[3], C.A. Gomez-Roca[4], T. Valentin[1], P. Olivier[5], A. Fabre[6], M. Mounier[6], L. Balardy[7], T. Filleron[3]

[1]Medical Oncology, Institut Universitaire du Cancer de Toulouse - Oncopole, Toulouse, France, [2]Medical Oncology, CHU Bordeaux Hopital St. André, Bordeaux, France, [3]Biostatistic Unit, Institut Universitaire du Cancer de Toulouse - Oncopole, Toulouse, France, [4]Medical Oncology, Institut Universitaire du Cancer de Toulouse - Oncopole, Toulouse, Haute-Garonne, France, [5]Pharmacology Department, CHU Toulouse, Toulouse, France, [6]Clinical Research Unit, Institut Universitaire du Cancer de Toulouse - Oncopole, Toulouse, France, [7]Geriatric Medicine, CHU Toulouse Hôpital Purpan, Toulouse, France

Background: Efficacy and toxicity of targeted therapies don't seem to vary with age, but the impact of side effects in frail elderly patients ($\geq$ 75 years-old) (EP) is a major concern for clinicians. Our study aims to explore an original method to find the maximum tolerated dose of Pazopanib (P), in a population of EP, classified as "frail" after comprehensive geriatric assessment (CGA), using a phase I methodology, integrating a geriatric criterion for DLT (2 points drop in Activity of Daily Living Score (ADL)). Pharmacokinetic and pharmacogenomic studies were planned.

Methods: Open-label, multicenter (2), non-randomized, phase 1 dose escalation clinical trial (standard 3 + 3 design) to determine MTD and DLT of P in a population of frail EP, selected after CGA. Tested dose levels of P were 400, 600 and 800 mg /day. Toxicity was assessed during the first cycle (28days). Patients received P until progression. The MTD was defined as the highest dose level for which 6 patients are treated with a maximum of one patient (~20%) presenting a DLT. Main inclusion criteria • Age $\geq$ 75 • Metastatic solid cancers (kidney, lung, pancreatic-neuroendocrine, sarcoma, ovary, thyroid, bladder or breast) • "Frail" by CGA.

Results: From 11/2012 to 09/2017, 18 pts were included. Median age was of 82.5 (range 75-91). No DLT was reported at 400mg/day. There was 1 DLT (asthenia Grade 3) at 600 mg/day. At 800 mg/day, 3/6 patients experienced a DLT. Two patients had treatment interruption longer than two weeks due to side effects and one experienced a grade 3 hypertension. Diarrhea, fatigue and hypertension were the most frequently treatment related toxicity.

Conclusions: Our study used an original way to assess feasibility of an approved treatment in population of frail EP ($\geq$ 75 years-old). The results demonstrate that it is probably deleterious to initiate a treatment with P in this vulnerable population at the approved dose level of 800mg/day. The treatment should be initiated at a lower dose (600mg/day). Our results reinforce the need to proceed to geriatric assessment in EP before initiation of cancer treatment to individualize their management.

Clinical trial identification: EudraCT: 2011-005012-29.

Background: Atezolizumab is a PD-L1 inhibitor, which is licenced in metastatic urothelial cancer. This study investigates the efficacy and safety of neoadjuvant atezolizumab given prior to cystectomy in operable muscle invasive transitional cell carcinoma of the bladder.

Methods: This single arm phase 2 study investigated 2 cycles of atezolizumab (1200mg Q3) prior to cystectomy in muscle invasive transitional cell cancer (T2-4N0M0). Pathological complete response (pCR) occurring in $\geq$ 20% of patients was the primary endpoint. Biomarker analysis on sequential tissue was a co-primary endpoint. Cross sectional imaging was performed at baseline and prior to cystectomy which occurred 4 - 8 weeks after starting atezolizumab. Radiological response was assessed. Adverse events (AEs) and surgical complications were assessed using CTCAE v4.03 and the Clavien-Dindo classification. Updated analysis with 75 patients will be presented. IMCORE provided biomarker analysis.

Results: At baseline pT2, T3, T4 disease occurred in 73%, 20% and 7% of patients respectively. 16 (21%) patients had only 1 cycle (9 due to AEs). 7 patients did not have cystectomy (1 disease progression, 2 treatment related AE). There was 1 potential treatment related death during treatment/perioperative period (cardiovascular disease). Treatment related grade 3/4 toxicity occurred in 12% of patients. Grade 3 or 4 surgical complications occurred in 31% of pt. The pCR rate was 20/68 (29%) [95%CI: 19% to 42%] (pT0 24%, Tis 6%, T1 9% T2 24% T3 22% T4 15% stage at surgery). 39% of patients were down staged to non-muscle invasive disease. 3/20 (15%) of the pCR patients had pT3/4 disease at baseline. 47% patients were positive for PD-L1 ($\geq$5% IC SP142); pCR rates were 38% and 27% in PD-L1 positive and negative tumours respectively (n = 62). 47 patients had sequential imaging and radiologically measurable disease at baseline. 28% [95%CI, 16% to 43%] and 17% [95%CI, 8% to 31%] of these patients radiologically responded and progressed respectively.

Conclusions: Neoadjuvant atezolizumab is safe and associated with a meaningful pathological CR rate at this interim stage. Further exploration is justified.

Background: FGFR3 GA are implicated in the pathogenesis of UC; ≈ 15% of pts with advanced UC have mutations and 6% have translocations. INCB054828, a selective, potent, oral inhibitor of FGFR1, 2, and 3, has shown efficacy in pts with FGF/FGFR GA tumors.

Methods: This study (NCT02872714) is enrolling pts with metastatic or unresectable UC who failed $\geq$ 1 therapy or are platinum ineligible and have FGFR3 mutations/fusions (cohort A, n = 100) or other FGF/FGFR GAs (cohort B, n = 40). Pts receive oral INCB054828 13.5 mg once daily on a 21-day cycle (2 wk on, 1 wk off) until disease

progression or unacceptable toxicity. The primary endpoint is overall response rate (ORR) in cohort A, assessed by independent review per RECIST v1.1. Secondary endpoints include ORR in cohort B, duration of response, progression-free survival, overall survival, and safety/tolerability. The primary objective of this interim analysis is to evaluate the efficacy and safety of INCB054828 in pts in cohort A who had ≥ 1 postbaseline tumor assessment or discontinued the study.

Results: As of data cutoff (7 Feb 2018), 64 and 36 pts were enrolled in cohorts A and B, respectively. In cohort A, 84% (54/64) had ECOG PS ≤ 1, 39% (25/64) received ≥ 3 prior therapies, and 36% (23/64) had a prior PD-1/L1 inhibitor. Of 64 pts, 51 had ≥ 1 postbaseline scan or discontinued. Best overall responses in cohort A were 7 confirmed partial responses (PRs), 6 unconfirmed PRs (ongoing), and 17 stable disease (10 ongoing). ORR, including unconfirmed PRs, was 25% (95% CI, 14%–40%). In cohort B, 1 pt with FGF10 amplification had an unconfirmed PR. Common treatment-emergent adverse events (TEAEs) in all pts were diarrhea (40%), alopecia (32%), fatigue (29%), constipation (28%), and dry mouth (28%). Grade ≥ 3 TEAEs in > 5% of pts were urinary tract infections (7%) and fatigue (6%). Hyperphosphatemia (any postbaseline serum phosphate > 5.5 mg/dL) was 68% in cohort A and 64% in all pts.

Conclusions: INCB054828 was generally well tolerated and showed preliminary efficacy in previously treated pts with UC and FGFR3 GA. Updated data will be presented.

Clinical trial identification: NCT02872714.

Background: Well-defined prognostic factors (PF) and risk groups have been shown to impact OS in first- and second-line chemotherapy (chemo) for UC. Post hoc analysis of survival outcome per level of risk was conducted using data from the phase 3 KEYNOTE-045 trial (NCT02256436).

Methods: Data from the Oct 26, 2017 data cut were included. The presence or absence of 4 predefined criteria applied at study randomization was noted for each patient: ECOG PS (0 vs 1 or 2), hemoglobin level (<10 g/dL vs ≥ 10 g/dL), liver metastases (yes vs no), and time from prior chemotherapy (<3 months vs ≥ 3 months). Patients were grouped per the number of PFs they had (0, 1, 2, or 3/4), and OS was estimated for each risk group receiving pembrolizumab (pembro) or chemo, using Kaplan-Meier (K-M) statistics.

Results: Data from 529/542 patients were included. Stratified randomization ensured that the distribution of risk levels was similar between the 2 treatment arms. Overall, OS decreased with increasing numbers of PFs for pembro (from 19 to 5 months) and chemo (from 18 to 3 months) (Table). Within the chemo arm, the results of the K-M survival profiles were consistent with previously published data, in which each risk group had different outcomes. Within the pembro arm, outcomes of pts with 0 and 1 PF were distinct from those with 2 and 3/4 PF groups. OS was longer with pembro than with chemo across all PF subgroups.

Conclusions: OS within the pembro and chemo arms decreased with increasing numbers of PFs. OS of patients treated with pembro was longer than those receiving chemo across the risk groups. Patients treated with pembro who had 2 or 3/4 PFs had overall similar outcomes. Additional analyses are needed to characterize novel risk models for patients treated with immunotherapies.

Clinical trial identification: NCT02256436, trial initiation date: October 3, 2014.

902P Biological features and clinical outcomes in atezolizumab (atezo)-treated patients (pts) with metastatic urothelial cancer (mUC) of the upper vs lower urinary tract (UTUC vs LTUC)

M.D. Galsky[1], R. Banchereau[2], E.E. Kadel, III[2], T. Ramirez-Montagut[2], S. Mariathasan[3], A. Thåström[2], J. Rosenberg[4], T. Powles[5], M.S. van der Heijden[6], A. Necchi[7]

[1]Hematology-Oncology, Mount Sinai Hospital, New York, NY, USA, [2]Genentech, Inc., South San Francisco, CA, USA, [3]Oncology Biomarker Department, Genentech, Inc., San Francisco, CA, USA, [4]Genitourinary Oncology Service, Memorial Sloan Kettering Cancer Center, New York, NY, USA, [5]Experimental Cancer Medicine, Barts Cancer Institute, Experimental Cancer Medicine Centre, Queen Mary University of London, London, UK, [6]Molecular Carcinogenesis, Netherlands Cancer Institute, Amsterdam, Netherlands, [7]Medical Oncology, Medical Oncology, Fondazione IRCCS, Istituto Nazionale dei Tumori, Milan, Italy

Background: mUC arising from UTUC vs LTUC may involve distinct biology resulting in different treatment responses & outcomes. However, this hypothesis has not been comprehensively explored. Here, data from 2 prospective trials of atezo (anti–PD-L1) in platinum-treated mUC (IMvigor210 Cohort 2; IMvigor211) were used to explore relationships between UTUC/LTUC primary tumor site, objective response rate (ORR)/overall survival (OS) & biomarker status.

Methods: PD-L1 (VENTANA SP142 IHC assay), targeted DNA sequencing (FoundationOne) and RNA sequencing (Expression Analysis) were evaluated in archival samples. Microsatellite status (MSI) was determined at 114 loci, & tumor mutational burden (TMB) on 1.1 Mb sequenced DNA. Biomarker-evaluable pts had tumors with known baseline PD-L1 status & RNAseq profiles.

Results: 220 IMvigor210 & 339 IMvigor211 pts were efficacy evaluable (Table), of whom 24% & 28%, respectively, had UTUC. Numerically higher ORR was seen in LTUC vs UTUC (IMvigor210, 23% vs 14%; IMvigor211, 18% vs 10%); these differences were not statistically significant. In both cohorts LTUC pts had significantly higher TMB (IMvigor210 P = 0.05; IMvigor211 P = 0.02) & a trend toward higher PD-L1 expression. Lund molecular subtype distribution also differed between UTUC vs LTUC (IMvigor210 P = 0.005; IMvigor211 P = 0.098) with increased frequency of genomically unstable tumors in LTUC pts. FGFR3 alterations did not associate with UTUC vs LTUC or with response in these groups. In the combined IMvigor210 and IMvigor211 cohorts, MSI-high tumors occurred in 1/146 (< 1%) of UTUC and 5/413 (1%) of LTUC subgroups.

Conclusions: Our data suggest pts with LTUC may have improved outcomes with atezo vs pts with UTUC, although benefit was observed in both groups. Numerically higher ORR/OS in pts with platinum-treated LTUC may be partly related to non-overlapping underlying biology & warrants further study in different settings.

Table: 902P

	UTUC	LTUC
IMvigor210 (n = 220)[a]		
n	52	168
ORR (%)	13	23
Median OS (mo)	10.3	11.7
IMvigor211 (n = 339)[a]		
n	94	245
ORR (%)	11	18
Median OS (mo)	9.7	10.9

[a]Biomarker-evaluable pts from overall cohorts of 310 pts (IMvigor210 cohort 2) & 467 pts (IMvigor211). P values in the abstract are shown for descriptive purposes only based on this post hoc analysis.

Background: Neuroendocrine carcinoma of the urinary bladder (NCUB) is a rare malignancy, accounting for <1% of bladder cancers. Despite high sensitivity to platinum-based chemotherapy (CT), prognosis remains poor.

Methods: We retrospectively reviewed patients treated for NCUB in 18 French institutions to determine clinical/biologic characteristics, treatment efficacy and outcomes. Patient characteristics, treatment, follow-up and histological data were obtained from medical records. Tissue samples were pooled for further biological analyses.

Results: From 1992 to 2017, we reviewed 234 NCUB cases (84% male, age 31–93 [median 67] years, ECOG PS 0–3 [median 1]). Small cell carcinoma was found in 47% of patients and large cell carcinoma in 9%; urothelial carcinoma was present in 51% of patients. Hematuria (71%) and pain (19%) were the main symptoms. Main metastatic sites at diagnosis of metastatic disease were lymph node (76%), liver (42%), bone (42%), pelvic recurrence (33%), lung (19%) or brain (12%). Of 230 patients evaluable for staging at diagnosis, 168 had stage I–III disease: stage I (3%), II (20%), III (34%), not evaluable (16%). They were treated with neoadjuvant CT (49%; mainly based on a

platinum-based agent + etoposide [85%]), surgery (74%), radiotherapy (24%), and/or adjuvant CT (24%). Ninety-nine patients (59%) had metastatic recurrence. Median time to relapse was 4 months, disease-free survival was 14 months (95% confidence interval [CI] 12–18]), and median overall survival (mOS) was 28 months (95% CI 20–32). Of 62 patients (27%) with metastases at diagnosis, first-line CT was based on platinum + etoposide (81%), platinum + other drug (15%), or taxanes (4%). For these patients, median progression-free survival (mPFS) was 7 months (95% CI 4–9). Only 28 patients had second-line CT with mPFS of 5.2 months and mOS of 11 months (95% CI 8–15).

Conclusions: This is, to our knowledge, the largest cohort of NCUB patients studied to date. Data emphasize the heterogeneity and aggressiveness of this disease. Future studies should investigate disease biology and the activity of targeted therapies in NCUB. Molecular characteristics based on tumor tissue analysis are underway.

904P Impact of different programmed cell death ligand-1 (PD-L1) expression algorithms on patient selection and durvalumab efficacy in urothelial carcinoma (UC)

J. Walker[1], M. Zajac[1], J. Ye[2], M. Scott[3], M. Ratcliffe[1], P. Scorer[3], C. Barker[3], H. Al-Masri[4], M.C. Rebelatto[5], A. Gupta[2], P. Mukhopadhay[2], S. Ferro[2], T. Powles[6], J.A. Williams[1]

[1]Oncology Companion Diagnostics Unit, AstraZeneca, Cambridge, UK, [2]Biometrics and Information Sciences, GMD Unit, AstraZeneca, Gaithersburg, MD, USA, [3]Precision Medicine and Genomics, IMED Biotech Unit, AstraZeneca, Cambridge, UK, [4]Anatomic Pathology & Clinical Pathology, Hematogenix, Tinley Park, IL, USA, [5]Experimental Pathology, Translational Sciences-Research, MedImmune, Gaithersburg, MD, USA, [6]Barts & The London School of Medicine & Dentistry, Barts Cancer Center, London, UK

Background: Antibodies targeting programmed cell death-1/PD-L1 (PD-1/PD-L1) have shown clinical activity in advanced UC. The ability of PD-L1 to predict response has been investigated using different antibody clones and scoring algorithms. It is important to understand if these assays/algorithms identify the same patients and how they compare in predicting response.

Methods: Archival UC tumour samples from 335 patients from a commercial source were stained with VENTANA SP263, VENTANA SP142, PD-L1 IHC pharmDx 28-8 and PD-L1 IHC pharmDx 22C3 Assays; classified according to their respective algorithms: tumour cell (TC) or immune cell (IC) staining ≥25% (TC/IC≥25%), PD-L1 staining IC area ≥5% of tumour (IC ≥ 5%), TC staining ≥1% or combined positive score (CPS ≥10). Overlap between populations was assessed by overall percent agreement (OPA), negative percent agreement (NPA) and positive percent agreement (PPA). UC samples from study 1108 (NCT01693562) were stained using VENTANA SP263 and TC/IC≥25%, IC ≥ 5% and CPS≥10 algorithms were applied. Objective response rates (ORR; data cutoff Oct 2017) in patients classified as PD-L1 high or low by these algorithms were investigated.

Results: There was moderate overlap between populations identified by VENTANA SP263 (TC/IC≥25%) and PD-L1 IHC pharmDx 28-8 (TC ≥ 1%) or PD-L1 IHC pharmDx 22C3 (CPS≥10) and minimal overlap between VENTANA SP263 (TC/IC≥25%) and VENTANA SP142 (IC ≥ 5%) (Table). Applying different algorithms to data from study 1108 also gave differences in patient classification. ORR in patients determined as PD-L1 high vs low/negative were as follows: TC/IC≥25%: 28% vs 6%, IC ≥ 5%: 48% vs 14%, CPS≥10 25% vs 13%.

Conclusions: The TC/IC≥25% algorithm identifies a different population to IC ≥ 5% or CPS10. In CD-ON MEDI4736-1108, highest response rates were seen in PD-L1 high patients determined by IC ≥ 5%, whereas TC/IC≥25% was optimal in predicting non-responders to durvalumab.

Table: 904P Overall (OPA), negative (NPA) and positive percent agreement (PPA) between PD-L1 assays

Clinical Algorithm (assay)	VENTANA SP263 (TC/IC 25%) Assay used as reference, % agreement (95% CI[a])		
	OPA	PPA	NPA
CPS ≥1 (PD-L1 IHC pharmDx22C3	77.0% (72.9%)	90.7% (85.0%)	69.6% (64.0%)
CPS ≥10 (PD-L1 IHC pharmDx 22C3)	81.5% (77.6%)	62.7% (54.8%)	91.7% (87.9%)
TC ≥ 1% (PD-L1 IHC pharmDx 28-8)	75.5% (71.3%)	66.9% (59.1%)	80.2% (75.2%)
$IC_{TumorArea}$ ≥5% (VENTANA SP142)	69.9% (65.5%)	15.3% (10.1%)	99.5% (97.8%)

[a]For each metric, lower boundary of 95% confidence interval (CI) was calculated with no upper bound using the Clopper-Pearson method

905P CD103+ tissue-resident CD8+ T Cells correlate with protective anti-tumoral immune responses in muscle-invasive bladder cancer patients

Z. Liu, J. Zhang, B. Dai

Department of Urology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: CD103+ Tissue-resident CD8+ T cells are previously reported as memory CD8+ T cells and thus could promote adaptive immune response. While immunotherapy shows a great potential in muscle-invasive bladder cancer (MIBC) treatment, it is urgent to discover which subgroup MIBC patients could benefit most from immunotherapy. We here tried to explore the prognostic and predictive value of CD103+ tissue-resident CD8+ T cells, and provide possible molecular explanations.

Methods: We selected 259 MIBC patients who underwent radical cystectomy between 2002 and 2014. CD103+ tissue-resident CD8+ T Cells were evaluated via immunofluorescence of CD103 and CD8 performed in our constructed tissue microarrays. Prognostic value of CD103+ CD8+ T cells in MIBC was assessed, and was further validated in TCGA-BLCA cohort using tissue-resident CD8+ T cell core signatures. 10 fresh MIBC specimens were analyzed by flow cytometry to explore the anti-tumoral immune response and immune check-point expression of tissue-resident CD8+ T cell.

Results: Patients with higher CD103+ tissue-resident CD8+ T cells infiltration had a significant better overall survival in both our study population and TCGA-BLCA cohort (HR = 0.504, 95%CI: 0.312-0.816; P = 0.005 and HR = 0.637, 95%CI: 0.444-0.913; P = 0.014). Further Cox regression indicated that CD103+ tissue-resident CD8+ T cells was an independent prognosticator in MIBC patients. Flow cytometry results revealed that CD103+ CD8+ T cells tended to express more IFN-γ and granzyme B than CD103- CD8+ T cells (P < 0.001 and P = 0.007, respectively) (n = 10). However, expression of perforin did not show significant differences between CD103+ CD8+ T cells and CD103- CD8+ T cells. We then analyzed PD-L1 and TIM3 expression in CD103+ tissue-resident CD8+ T cells. Surprisingly, there was no significant differences of PD-L1 expression between CD103+ CD8+ T cells and CD103- CD8+ T cells. Nonetheless, CD103+ CD8+ T cells had more TIM3+ phenotypes than CD103- CD8+ T cells (P = 0.034).

Conclusions: High CD103+ tissue-resident CD8+ T cells could predict better prognosis in MIBC patients. Patients with high infiltration of CD103+ tissue-resident CD8+ T cells might benefit most from anti-TIM3 immunotherapy.

906P Immune-checkpoint inhibitors in previously treated patients with urothelial carcinoma: A systematic review and meta-analysis

E. De Luca[1], V. Di Nunno[2], C. Buttigliero[3], M. Tucci[3], F. Vignani[1], C. Zichi[1], A. Ardizzoni[2], F. Massari[2], M. Di Maio[1]

[1]Division of Medical Oncology, "Ordine Mauriziano" Hospital, Turin, Italy, [2]Division of Oncology, S.Orsola-Malpighi Hospital, Bologna, Italy, [3]Division of Medical Oncology, "San Luigi Gonzaga" Hospital, Orbassano, Turin, Italy

Background: Very few therapeutic options are available in patients with advanced or metastatic urothelial carcinoma progressed or unfit to platinum based therapy. After decades of failures, a new classes of agents: the immune-checkpoint inhibitors seem to be a new promising hope for these patients. However, to date of the two randomized studies comparing these compounds to standard chemotherapy only one trial showed a clear survival advantage in this setting.

Methods: We performed a systematic review and meta-analysis to assess the efficacy, in terms of overall survival, of single agent immune-checkpoint inhibitors vs. single agent chemotherapy as second-line treatment. Moreover, we evaluated the assessed ORR of single-agent immune-checkpoint inhibitors in patients with advanced urothelial cancer exploring the predictive value of patients' selection according to PD-L1 expression. To do this, we reviewed clinical trials published on Pubmed/Medline, Cochrane library and clinical abstracts presented on main International meeting between 2014 and 2018.

Results: Systematic review included randomized (n = 2) and non-randomized (n = 9) clinical trials. We restricted meta-analysis to trials exploring immune-checkpoint inhibitors in previously platinum treated patients.In randomized trials, immune checkpoint inhibitors were associated with a significant improvement of overall survival compared to chemotherapy in unselected patients, with pooled Hazard Ratio 0.80 (95% confidence interval 0.69 – 0.93, p = 0.003), while the difference was not statistically significant in the subgroup of patients selected for the highest PD-L1 expression (Hazard Ratio 0.72, 95% confidence interval 0.48 – 1.09, p = 0.12). Polled probability of objective response was 0.18 (95% confidence interval 0.16 – 0.20) in unselected patients and 0.27% (95% confidence interval 0.25 – 0.32) in patients selected for the highest expression of PD-L1.

Conclusions: Immunotherapy showed a significant survival advantage in patients not selected for PD-L1 expression while both OS and ORR analysis suggested that the predictive value of PD-L1 expression is far from being optimal.

907P Match-adjusted indirect comparison of durvalumab and chemotherapy for locally advanced or metastatic urothelial carcinoma (UC) following failure of platinum-based therapy

C.K. Hoyle[1], A.B. Klein[1], K.A. Patel[1], N. Shire[1], H. Wang[1], B.C. Chu[2], M. Ouwens[1], B.L. Nordstrom[2], L. Horne[3], H-T. Arkenau[4]

[1]Health Economics & Payer Analytics, AstraZeneca, Cambridge, UK, [2]Real-World Evidence, Evidera, Waltham, MA, USA, [3]Oncology Business Unit, AstraZeneca, Gaithersburg, MD, USA, [4]Sarah Cannon Research Institute SCRI UK, London, UK

Background: Durvalumab gained FDA approval for locally advanced or metastatic UC following failure of platinum-based chemotherapy (CTx) based on the open-label, single arm study 1108. Real-world evidence can be used to enable comparative analyses by matching patients' baseline characteristics from independent datasets. Overall survival (OS) of patients on durvalumab vs CTx was evaluated by comparing patients in the phase 1/2 study 1108 (NCT01693562) with a real-world dataset.

Methods: Data from patients on durvalumab were compared with data from patients in the Flatiron oncology electronic medical record database treated with physician's choice of 2nd line CTx. All patients had progressed following platinum-based CTx. Patients were matched on propensity score to adjust for differences in baseline demographics and disease characteristics. Treatment effect for OS was estimated using Cox proportional hazards models. Prognostic impact of expression of programmed cell death ligand-1 (PD-L1) (≥25% of tumour cells [TC]/immune cells [IC] [high] or < 25% TC/IC [low/negative]) on OS was also evaluated. As PD-L1 expression was only available for patients in study 1108, PD-L1 subgroups were compared to otherwise-matched CTx patients.

Results: After adjustment for baseline differences between the 2 groups, durvalumab demonstrated a statistically significant improvement in OS vs CTx (n = 158/arm; HR = 0.634, 95% CI 0.479-0.839; median OS 11.2 vs 8.19 months). Treatment effect of durvalumab was greater in the PD-L1 high subgroup (n = 91 /arm; HR = 0.434, 95% CI 0.292-0.645; median OS 19.9 vs 7.84 months) vs matched CTx patients. There was no significant difference in OS for the PD-L1 low/negative subgroup for durvalumab vs CTx (n = 74/arm; HR = 0.989, 95% CI 0.679-1.440; median OS 4.86 vs 7.20 months).

Conclusions: This indirect, match-adjusted comparison of durvalumab vs CTx suggests that durvalumab provides a statistically significant improvement in OS vs CTx for patients with locally advanced or metastatic UC who progressed after platinum-based CTx; treatment effect was more pronounced in the PD-L1 high subgroup vs the PD-L1 low/negative subgroup.

Hospotal, Cheonan, Republic of Korea, [12]Division of Hematology-Oncology, Department of Medicine, Gyeongsang National University Hospital, Jinju, Republic of Korea, [13]Medical Oncology, International St. Mary's Hospital, Incheon, Republic of Korea, [14]Division of Hematology-Oncology, Department of Medicine, Samsung Changwon Hospital, Changwon, Republic of Korea

Background: In the AJCC 7th edition, bladder cancer with lymph node metastasis is classified into stage IV regardless of the extent or number of lymph node metastasis. T1A-T4a, N1, and M0 were changed to stage IIIA, and T1a-T4a, N2-N3, and M0 were changed to stage IIIB in the AJCC 8th edition revised in 2018. Therefore, it is necessary to think about treatment strategy for clinically node positive bladder cancer. The aim of this study was to compare the treatment outcomes of chemotherapy, surgery, and combination therapy in patients with lymph node-positive bladder cancer.

Methods: From January 01, 2010 to December 31, 2015, patients with bladder cancer with clinically local lymph node metastasis at the time of diagnosis and were treated with neoadjuvant chemotherapy followed by cystectomy or cystectomy followed by adjuvant chemotherapy or palliative chemotherapy or cystectomy were retrospectively analyzed based on the clinical indices and survival time based on the medical record review.

Results: Of 230 patients with bladder cancer, 44(19.1%) were treated with palliative chemotherapy, 30(13.0%) with neoadjuvant chemotherapy followed by cystectomy, 129(56.1%) with cystectomy followed by adjuvant chemotherapy, and 27(11.7%) with cystectomy alone. Median survival was 30.4 months retrospectively. In palliative chemotherapy group, median OS was 19.3 months. Median OS for neoadjuvant chemotherapy followed by cystectomy was 49.1 months and for cystectomy followed by adjuvant chemotherapy was 42.6 months. Cystectomy show 11.2 months of median OS. The prognosis was different according to stage of lymph node in each groups (42.6 months for N1 vs 21.3 months for N2-3), especially survival rate of cystectomy followed by adjuvant chemotherapy was good in N1 stage.

Conclusions: This study is meaningful in understanding the actual clinical treatment patterns of lymph node - positive bladder cancer and comparing the results according to each treatment group.

909P Plasma miR-371a-3p for detection of non-teratomatous viable germ cell tumor in testicular cancer

L. Nappi[1], M. Thi[2], B.J. Eigl[1], A. Lum[3], D. Huntsman[4], C. Martin[5], B. O Neil[5], D.J. Khalaf[1], K.N. Chi[1], M.E. Gleave[6], A. So[2], P. Black[2], S. Daneshmand[7], C.R. Nichols[8], C.K. Kollmannsberger[1]

[1]Medical Oncology, British Columbia Cancer Agency, Vancouver, BC, Canada, [2]Urologic Science, Vancouver Prostate Centre, Vancouver, BC, Canada, [3]Department of Molecular Oncology, British Columbia Cancer Research Centre, Vancouver, BC, Canada, [4]Department Pathology and Laboratory Medicine, British Columbia Cancer Agency, Vancouver, BC, Canada, [5]Surgery, Huntsman Cancer Institute, Salt Lake City, UT, USA, [6]Urologic Science, University of British Columbia Faculty of Medicine, Vancouver, BC, Canada, [7]Urology, University of South California, Los Angeles, CA, USA, [8]Testicular Cancer Commons, Salt Lake City, UT, USA

Background: Active surveillance for CSI testicular cancer is currently based on serial radiological imaging and classic tumor markers (β-HCG, AFP, LDH). The management of borderline suspicious tumor markers negative enlarging nodes and of the post-chemotherapy residual disease is challenging, and currently relies on clinical follow-up with imaging to establish patterns of growth or pathological confirmation with biopsy or retroperitoneal lymphadenectomy (RPLND). A blood-based approach to reliably identify patients with non teratoma viable GCT (NTVGCT) would be valuable.

Methods: Plasma miR-371a-3p (miR371) of pts with GCT was analyzed by RT-PCR. Spike-in cel-miR-39-3p and miR-30b-5p as internal controls. miR-451a and miR-23a-

3p were used as quality control for the hemolysis. The miR371 expression was used to calculate its area under the ROC curve, sensitivity and specificity in detecting viable NTGCT.

Results: One hundred samples from 79 patients (44 CSI and 35 metastatic) were analyzed. Nineteen CSI pts presented suspicious enlarging nodes ($\geq$ IIA) during surveillance and 8/19 had confirmed relapse. miR371 predicted the clinical relapse in 6/8 of pts while the 11 CSI pts with unconfirmed enlarging nodes were all negative for miR-371. miR371 was expressed in all the pre-chemotherapy metastatic pts and negative after chemotherapy (n = 25). miR371 was negative in all the pts with post-chemotherapy residual radiographic findings (n = 24). No residual NTVGCT was detected in any of these 24 pts by either pathology at resection (n = 16) or clinical follow-up (n = 8). The area under the ROC curve was 0.94, the sensitivity and specificity were 89% and 98%, respectively. The results showed a high concordance comparing 2 independent experiments conducted in house and in an outside lab (r = 0.98 and 0.87, respectively).

Conclusions: Detectable circulating miR371 expression predicts the presence of NTVGCT. If validated in larger real world settings, this may result in significant change in the practice for all patients with germ cell tumors by moving it to a biological rather than radiological decision base. These encouraging findings inform upcoming North American trials for further definition of miR371 operating characteristics in GCTs.

910P Increased risk of non-germ cell second cancer (SC) after cisplatin-based chemotherapy (CBCT) in 1-year testicular cancer (TC) survivors (TCS)

R. Hellesnes[1], Ø. Kvammen[2], R.M. Bremnes[3], A. Karlsdottir[4], T.Å. Myklebust[5], H. Negaard[6], T. Tandstad[7], T. Wilsgaard[8], S.D. Fosså[9], H.S. Haugnes[1]

[1]Department of Oncology, University Hospital of North Norway, Tromso, Norway, [2]Department of Oncology, Ålesund Hospital, Ålesund, Norway, [3]Department of Clinical Medicine, UiT The Arctic University of Norway, Tromsø, Norway, [4]Department of Oncology, Haukeland University Hospital, Bergen, Norway, [5]Department of Registration, Cancer Registry of Norway, Oslo, Norway, [6]Department of Oncology, Oslo University Hospital, Oslo, Norway, [7]The Cancer Clinic, St. Olavs Hospital, Trondheim, Norway, [8]Institute of Community Medicine, UiT The Arctic University of Norway, Tromsø, Norway, [9]National Advisory Unit on Late Effects after Cancer Treatment, Oslo University Hospital, Radiumhospitalet, Oslo, Norway

Background: Previous studies have documented that TCS have a 1.7 to 3.5-fold increased risk of developing SC compared with an age-matched general population after chemotherapy (CT) and/or radiotherapy (RT), but no increased risk after surgery only. Previous studies lack treatment details, and/or include patients treated before the introduction of cisplatin.

Methods: All Norwegian 1-year TCS diagnosed with their first TC 1980-2009 and with no prior history of cancer (n = 5625), were identified through the Cancer Registry of Norway (CRN). Clinical parameters, including detailed information on all cancer treatment given initially and in case of a relapse, were extracted from medical records and linked with data from CRN. The TCS were categorized into treatment groups: Surgery only (24.8%), CT (43.9%), RT (27.4%) and CT and RT combined ((CT + RT) 3.9%). Age-adjusted Cox regression models were performed to evaluate the impact of cancer treatment on the risk of SC, stratified according to decade of diagnosis.

Results: Median observation time was 16.6 years (IQR 10.9-23.8), during which 572 TCS (10.2%) were diagnosed with a non-germ cell SC. Median time to SC was 18.1 years (IQR 11.1-24.2). Overall, compared with surgery only, there was an elevated risk of SC after RT (Hazard Ratio (HR) 1.36, 95% CI 1.07-1.73) and RT + CT (HR 1.64 95% CI 1.10-2.46). When excluding TCS with <10 years observation time, all treatment groups had increased risks for SC (CT: HR 1.57, 95% CI 1.14-2.16; RT: HR 1.77, 95% CI 1.31-2.39; RT + CT: HR 1.83, 95% CI 1.14-2.96). There was an increased risk for SC with increasing number of cisplatin-based CT (CBCT), significant for 4 cycles (HR 1.35, 95% CI 1.01-1.81) and $\geq$5 cycles (HR 1.69, 95% CI 1.06-2.70). The risk for bladder cancer increased after CBCT (HR 3.81, 95% CI 1.29-11.21) and RT (HR 2.93, 95% CI 1.00-8.60). RT + CT was associated with elevated risks for leukemia (HR 13.82, 95% CI 1.20-159.67) and cancers of the stomach (HR 6.79, 95% CI 1.60-28.70) and thyroid (HR 8.71, 95% CI 1.56-52.08).

Conclusions: Cytotoxic treatment increases the risk of SC in TCS. After CBCT, the risk significantly increases after $\geq$4 cycles. Long-term follow-up of TCS focusing on prevention and early detection of SC seem to be important.

911P Vascular damage and pulmonary function in very long-term survivors of testicular cancer (TC) treated with cisplatin-based chemotherapy (CT)

J. Stelwagen[1], S. Lubberts[1], L.C. Steggink[1], G. Steursma[1], L.M. Kruyt[1], J.W. Donkerbroek[1], A.M. van Roon[2], A.I. van Gessel[2], S.C. van de Zande[2], C. Meijer[1], J.B. Wempe[3], C.H. Gräfin zu Eulenburg[4], J. Nuver[1], A.M.E. Walenkamp[1], J.D. Lefrandt[2], J.A. Gietema[1]

[1]Medical Oncology, University Hospital Groningen (UMCG), Groningen, Netherlands, [2]Internal Medicine, University Hospital Groningen (UMCG), Groningen, Netherlands, [3]Pulmonology, University Hospital Groningen (UMCG), Groningen, Netherlands, [4]Epidemiology, University Hospital Groningen (UMCG), Groningen, Netherlands

Background: Late effects are a source of long term cardiovascular and pulmonary morbidity in testicular cancer (TC) survivors. The objective was to assess vascular damage and pulmonary function in TC survivors more than 20 years after cisplatin-bleomycin combination CT and compare this to age-matched patients treated for TC with surgery only (SU) as well as healthy male controls (CO).

Methods: Aortic stiffness was measured by the gold standard of aortic pulse-wave velocity (aPWV) from the carotid to femoral artery. aPWV is considered an accurate predictor of cardiovascular risk. Additional blood markers for vascular damage were assessed, including factor VIII, v-WF and fibrinogen. Pulmonary function including Diffusion Capacity Carbon Monoxide (DLCO) was assessed according to international guidelines using spirometry, body-plethysmography and the single breath-holding method parameters.

Results: After a mean follow-up duration of 28 years (range: 20-42), aPWV and DLCO was assessed in 118 TC survivors (63 CT patients and 55 SU patients) and 56 controls. aPWV (m/s) was higher in the CT group as compared to the SU and CO group (geometric mean 8.49 vs 7.69 and 7.64 respectively, P = 0.005). DLCO (% predicted) was significantly reduced in CT patients compared to SU patients (87% vs 94%, P = 0.02).A significant reduction in DLCO (defined as < 80% of predicted) occurred in 27% and 13% for CT and SU patients, respectively (X^2; P = 0.055). In the CT patient group, aPWV and DLCO were associated (r = 0.3, P = 0.03). Furthermore, in the CT patient group, DLCO and endothelial activation markers were associated (vWF r=-0.30, P = 0.02; F-VIII r=-0.31, P = 0.01; fibrinogen r=-0.27, P = 0.03).

Conclusions: TC survivors treated with cisplatin-bleomycin combination chemotherapy have an increased aortic stiffness and reduced DLCO more than 20 years after treatment. This implicates an increased risk of cardiovascular morbidity and impaired pulmonary function. Association between markers for vascular damage and reduced DLCO suggests a role of vascular damage in the etiology of pulmonary dysfunction for TC survivors.

Clinical trial identification: NCT02572934.

912P Sexual function and quality of life in a national cohort of bilateral testicular cancer survivors

M. Bandak[1], J. Lauritsen[1], C. Johansen[1], M.B. Kreiberg[1], J.W. Skøtt[1], M. Agerbaek[2], N.W. Holm[3], K.G. Daugaard[1]

[1]Department of Oncology, Copenhagen University Hospital - Rigshospitalet, Copenhagen, Denmark, [2]Department of Oncology, Aarhus University hospital, Aarhus, Denmark, [3]Department of Oncology, Odense University Hospital, Odense, Denmark

Background: Sexual function and quality of life remain unexplored in long-term survivors of bilateral testicular cancer (TC). The aim was to investigate sexual function, fatigue, anxiety and depression in long-term survivors of bilateral TC (unilateral TC with contralateral germ cell neoplasia in situ (TC+GCNIS) or bilateral TC (BTC)).

Methods: Cross-sectional study of 2479 long-term TC survivors of whom 126 were treated with contralateral radiotherapy due to GCNIS, 93 were treated with bilateral orchiectomy due to BTC and 2260 had unilateral TC (reference group). Outcomes were assessed with validated questionnaires with a median time since diagnosis of 17 years (interquartile range (IQR) 12-23 years). Results in TC+ GCNIS and BTC were compared with the reference group. Adjustment was made for age and treatment for disseminated disease.

Results: The age-adjusted risk of anxiety was significantly increased in BTC survivors (odds ratio 1.7 (1.1-2.8) p = 0.002). Apart from increased risk of reduced motivation in survivors with TC+GCNIS there were no other significant differences between the groups. Limitations include the few cases with symptoms of depression.

Conclusions: Survivors of BTC had increased risk of anxiety but did not experience impairment of other aspects of quality of life. These results are of importance for evidence-based information on late effects for bilateral TC patients.

913P The prognostic value of DNA damage level in peripheral blood lymphocytes in germ cell cancer patients

M. Mego[1], Z. Sestakova[2], K. Kalavska[1], L. Hurbanova[2], D. Jurkovicova[2], J. Gursky[2], M. Chovanec[1], D. Svetlovska[1], V. Miskovska[3], J. Obertova[1], P. Palacka[4], K. Rejlekova[1], Z. Sycova-Mila[1], J. Mardiak[1], M. Chovanec[2]

[1]Department of Oncology, National Cancer Institute(Národn Onkologick Ustav), Bratislava, Slovak Republic, [2]Department of Genetics, Cancer Research Institute, Biomedical Research Center, Slovak Academy of Sciences, Bratislava, Slovak Republic, [3]Oncology, St. Elisabeth Cancer Institute, Bratislava, Slovak Republic, [4]Department of Outpatient Chemotherapy, National Cancer Institute(Národn Onkologick Ustav), Bratislava, Slovak Republic

Background: Germ cell tumors (GCTs) are extraordinarily sensitive to cisplatin (CDDP)-based chemotherapy. DNA damage represents one of the most important factors contributing to the toxic effects of CDDP-based chemotherapy. Previously, in a pilot study, we observed prognostic value of the DNA damage level in peripheral blood lymphocytes (PBLs) from chemo-naïve GCT patients. This study was aimed to validate the prognostic value of the DNA damage level in PBL in chemo-naïve, as well as chemotherapy pre-treated GCT patients.

Methods: PBLs isolated from 123 GCT patients (101 chemotherapy-naïve and 22 chemotherapy pre-treated) baseline and before 2nd cycle of chemotherapy were included into this prospective study. The DNA damage levels in PBLs were evaluated by the Comet assay and scored as percentage of DNA in tail by the Metafer-MetaCyte analyzing software. The DNA damage level in PBL was categorized as 'low' or 'high' according to the cut-off level of the mean.

Results: The mean ± SEM (standard error of the mean) of the endogenous DNA damage level was 5.25 ± 0.64. Chemotherapy-naïve patients with "low" DNA damage levels at baseline had significantly better progression-free survival (PFS) (hazard ratio [HR] = 0.05 95%CI (0.02 – 0.17), P = 0.0001) and overall survival (OS) (HR = 0.00, P = 0.0002, no death occurred in patients with "low" DNA damage level) compared to patients with "high" DNA damage levels. In multivariate analysis, prognostic value of the DNA damage level in PBL was significantly associated with PFS and OS independently of IGCCCG risk group. Moreover, there was significant correlation between the DNA damage level and response to treatment, non-pulmonary visceral metastases, number of metastatic sites, presence of mediastinal lymph nodes metastases and serum tumor markers level. There was no prognostic value of DNA damage level in PBL before 2nd cycle of chemotherapy and/or in pre-treated GCTs.

Conclusions: These data suggest that the DNA damage levels in PBLs of GCT patients are a novel prognostic marker timely identifying patients with poor outcome. We hypothesize that altered DNA damage level in PBLs could be induced by GCTs similarly to cancer-related immunosuppression and is abolished by administration of chemotherapy.

Background: Germ cell tumor patients with intermediate prognosis (IPGCT) according to the IGCCCG classification represent a heterogeneous group exhibiting a variety of clinical features. We established a registry to identify prognostic markers to further characterize IPGCT.

Methods: A retrospective observational study was performed. Eligibility criteria were intermediate prognosis according to IGCCCG criteria, male sex, age ≥16 years. Patients were diagnosed from 1979 to 2014. Clinical characteristics were evaluated with uni- and multivariate analyses to detect new prognosticators. AFP and HCG were available in 85% and LDH levels in 72% of the cases, respectively. Overall survival (OS) was the primary endpoint.

Results: The database included n = 707 IPGCT with a median follow-up of 8.6 years (IQR: 14.4). First line cisplatin-based chemotherapy was administered to 701 patients (99%) and the 5-year OS rate was 87%. First diagnosis in the 1980s (n = 115), the 1990s (n = 158), and after 2000 (n = 434) were associated with 5-year OS rates of 81%, 85%, and 89%, respectively. Statistical analyses revealed AFP and LDH, but not HCG levels prior chemotherapy as prognosticators. A patient stratification according to AFP levels <1000 IU/ml (n = 360), 1000 to 2000 IU/ml (n = 77), >2000 to 5000 IU/ml (n = 93) and >5000 (n = 74) IU/ml prior first course of chemotherapy, revealed a significant correlation between AFP levels and OS, associated with 5-year OS rates of 89%, 87%, 86% and 82%, respectively (p = 0.037). LDH levels prior chemotherapy also correlated with outcome, associated with five-year OS rates of 92% for <2 ULN (n = 289), 88% for ≥2 to 3 ULN (n = 91), 80% for >3 to 4 ULN (n = 37), and 78% for >4 ULN (n = 89), respectively (p = 0.011). In multivariate analysis cut-off values of AFP levels >6000 IU/ml (p = 0.036; HR 2.096) and LHD levels >2 ULN (p = 0.02; HR 2.121) or > 3 ULN (p = <0.001; HR 2.305) were independent prognosticators for OS.

Conclusions: Prognostication according to LDH and AFP levels prior chemotherapy could offer a new approach to stratify IPGCT. The largest fraction of patients had AFP levels <2000 IU/ml and LDH <2 ULN associated with an outcome similar to the good prognosis category. These results need to be confirmed in the upcoming IGCCCG reclassification.

915P Long term follow-up of the MRC TE23 randomized phase II trial of intensive induction chemotherapy (CBOP/BEP) in poor prognosis germ cell tumours (GCT) (CRUK/05/014; ISRCTN53643604)

R.A. Huddart[1], F. Cafferty[2], J. White[3], J. Shamash[4], I.M. Hennig[5], M. Cullen[6], S. Stenning[2]

[1]Radiotherapy and Imaging, Royal Marsden Hospital Institute of Cancer Research, Sutton, UK, [2]MRC Clinical Trials Unit at UCL, UCL, London, UK, [3]Medical Oncology, Beatson West of Scotland Cancer Centre, Glasgow, UK, [4]Dept of Medical Oncology, St Bartholomew's Hospital, London, UK, [5]Department of Clinical Oncology, Nottingham University Hospitals NHS Trust-City Hospital Campus, Nottingham, Nottinghamshire, UK, [6]Dept of Medical Oncology, Queen Elizabeth-University Hospital Birmingham NHS Foundation Trust, Birmingham, UK

Background: Up to 50% of men with poor prognosis non-seminoma GCT die with standard BEP chemotherapy. An intensive regimen, CBOP/BEP (carboplatin, bleomycin, vincristine, cisplatin/BEP), met response targets in a phase II, multicentre, open-label, randomized trial (74% with complete response or partial response marker negative, 90% CI 61% to 85%; primary outcome). Here, we report long term outcomes and prognostic factors.

Methods: Patients with extracranial GCT and IGCCCG poor prognosis features were randomised to 4xBEP or CBOP/BEP (2xCBOP, 2xBO, 3xBEP with bleomycin dose 15,000iu). Low-dose, stabilising chemotherapy prior to entry was permitted. This analysis focuses on progression-free survival (PFS), overall survival (OS) and toxicity (all secondary outcomes), and exploratory analysis of prognostic factors and the impact of marker decline (as defined in GETUG13).

Results: 89 patients (43 CBOP/BEP) were randomised. After median 63 months follow-up, 3-year PFS is 55.7% (95% CI 39.7%, 69.0%) for CBOP/BEP arm, 38.7% (24.7%, 52.4%) for BEP (HR 0.59 (0.33, 1.06), p = 0.079). 3-year OS is 65.0% (48.8%, 77.2%) and 58.5% (43.0%, 71.2%) respectively (HR 0.79 (0.41, 1.52), p = 0.49). 12-month toxicity was affected by subsequent treatments, with no clear differences between arms. There was no grade ≥3 toxicity in the CBOP/BEP arm. In multivariate models, use of pre-protocol chemotherapy was the only factor associated with poorer PFS (HR2.09 (1.14, 3.81), p = 0.017). Mediastinal primary (HR 2.13 (1.02, 4.46), p = 0.045) and use of pre-protocol chemotherapy (HR 3.40 (1.74, 6.63), p < 0.001) were associated with poorer OS. Unfavourable marker decline, in 60 (70%) patients, was not associated with other prognostic factors, nor with long term outcomes (HR 0.82 (0.44, 1.53), p = 0.54 for PFS).

Conclusions: The trial was not powered to compare PFS and OS, but PFS results for CBOP/BEP are promising, and similar to the intensive arm of GETUG13. Impact on OS was less clear (and will be affected by subsequent therapy). Use of pre-protocol chemotherapy was associated with poorer outcomes. Further study in an international phase III trial is warranted.

916P Sunitinib tolerance following an initial exposure period: Results of longitudinal PRO data from S-TRAC study

D.J. George[1], R. Figlin[2], R.J. Motzer[3], J. Paty[4], M.J. Lechuga Frean[5], G. Zanotti[6], H. Bhattacharyya[7], K. Ramaswamy[7], L. Deannuntis[8], A. Ravaud[9]

[1]Medical Oncology, Duke University Medical Center, Durham, NC, USA, [2]Medicine - Hematology Oncology, Cedars-Sinai Medical Center, Los Angeles, CA, USA, [3]Oncology, Memorial Sloan-Kettering Cancer Center, New York, NY, USA, [4]Real World & Analytic Solutions, IQVIA, New York, NY, Pittsburgh, USA, [5]Oncology, Pfizer Italy, Milan, Italy, [6]Global HEOR, Oncology, Pfizer, Inc., New York, NY, USA, [7]Oncology, Pfizer Inc., New York, NY, USA, [8]Worldwide Safety and Regulatory, Pfizer Inc., Collegeville, PA, USA, [9]Medical Oncology, CHU Bordeaux University Hospital St. André, Bordeaux, France

Background: Sunitinib (SU) was FDA-approved for adjuvant treatment of patients (pts) with renal cell carcinoma (RCC) at high risk of recurrence post nephrectomy, based upon a 24% reduction in disease-free survival with up to 1 year of SU treatment vs placebo (PBO) (S-TRAC trial). The analysis of patient-reported outcomes (PRO) data showed a statistically significant difference favoring PBO in most EORTC QLQ-C30 scales, and in the symptoms appetite loss and diarrhea, a clinically meaningful difference ($\geq$ 10 points) favoring PBO was observed. Recognizing that some pts did not tolerate SU early on, with higher discontinuation and dose reduction rates for SU than PBO, we describe a baseline reset analysis to assess the longitudinal PRO profile of pts who were able to tolerate and stay on treatment beyond the first 2 cycles (C).

Methods: After censoring the data from C1 and 2, and resetting a new baseline at C 3, the baseline reset analysis described here used the same statistical analysis done for PRO data in S-TRAC. For each scale, comparison of the two treatment arms was carried out using longitudinal repeated measures mixed effect.

Results: Of the 615 pts enrolled in S-TRAC, 580 were included in the PRO analyses. Of these, 506 pts had PRO data at C 3 and were included in this analysis. The longitudinal between treatment comparison resulted in statistically significant differences favoring PBO in 6 of the 15 scales with no clinically meaningful differences ($\geq$10 points) (see Table). The discontinuation rates of the 2 treatment groups were comparable from C 3 onward.

Table: 916P Summary results: EORTC QLQ-C30: Scores between treatment comparison intent-to-treat population (cycles 3-9)

	Sunitinib (n = 241) Model Estimated Mean	Placebo (n = 265) Model Estimated Mean	Difference (Sunitinib – Placebo)
EORTC QLQ-C30			
Global Health status/QoL (large values better)	69.87	72.20	-2.32*
Functional scales (large values better)			
Physical functioning	85.12	86.18	-1.06
Role functioning	80.84	83.49	-2.65*
Emotional functioning	81.52	82.49	-0.97
Cognitive functioning	85.59	86.35	-0.76
Social functioning	83.10	85.31	-2.22*
Symptom items/scales (large values worse)			
Fatigue	27.40	24.55	2.85*
Nausea and vomiting	6.50	5.30	1.21
Pain	20.78	18.68	2.10
Dyspnea	14.36	14.04	0.32
Insomnia	20.71	20.89	-0.18
Appetite loss	12.21	7.74	4.47 *
Constipation	10.46	10.63	-0.17
Diarrhea	18.67	10.67	8.00 *
Financial difficulties	14.10	13.53	0.58

A repeated measures longitudinal analysis with an intercept term, and treatment, time, treatment by time, and baseline as covariate over all cycles.

*P < 0.05

P-values not adjusted for multiplicity.

Conclusions: These analyses suggest that for pts who are able to tolerate SU for > 2 cycles (3 months), PRO profiles for SU are similar to PBO pts with similar discontinuation rates. Some pts do not tolerate SU early on in the adjuvant setting, but for the majority who do, long term tolerance may be more acceptable than originally thought.

917TiP Phase II study of paclitaxel and TAK-228 in metastatic urothelial carcinoma and the impact of PI3K-mTOR pathway genomic alterations

A. Rodríguez-Vida[1], J.L. Pérez-Gracia[2], A. Taus[1], T. Bonfill[3], F.J. Vázquez-Mazón[4], S. Galtes[1], B. Pons[1], L. Cano[1], S. Macia[5], P. Maroto[6], J. Bellmunt[1]

[1]Medical Oncology, Hospital del Mar, Barcelona, Spain, [2]Medical Oncology, Clínica Universitaria de Navarra, Pamplona, Spain, [3]Medical Oncology, Hospital Parc Taulí, Barcelona, Spain, [4]Medical Oncology, Hospital General de Elche, Elche, Spain, [5]Medical Department, Pivotal, La Florida, Madrid, Spain, [6]Medical Oncology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background: Metastatic urothelial carcinoma (mUC) is an aggressive disease associated with poor outcomes. Despite the recent incorporation of several immunotherapy agents targeting the PD-1 pathway, most patients will ultimately experience progressive disease. Moreover, there are no available predictive biomarkers to these novel agents. Clinical studies testing new anticancer drugs embedded with biomarkers analysis are still urgently needed for mUC. Mammalian target of rapamycin (mTOR) is a key intracellular target involved in several cellular signaling pathways, promoting cell proliferation and tumor angiogenesis. TAK-228 is a new investigational mTOR inhibitor of both TORC1 and TORC2. TAK-228 is currently being investigated in several phase II studies as treatment for advanced cancers. Paclitaxel, a taxane chemotherapy that stabilizes microtubules interfering with normal cell division, is a valid treatment option in mUC progressing to platinum-based chemotherapy. The combination of TAK-228 and paclitaxel has shown synergistic activity in bladder cancer cell lines, xenograft models and a phase I trial in advanced solid tumors.

Trial design: This is a single-arm open-label phase II study evaluating the efficacy and safety of TAK-228 (given orally on days 2 – 4, 9 – 11, 16 – 18 and 23 – 25 of 28-day cycles) in combination with paclitaxel (given on days 1, 8 and 15). Eligibility criteria include patients with mUC, performance status 0 – 1, prior platinum-based chemotherapy with no limit in number of lines, adequate organ function and measurable disease. The primary endpoint of the study is objective response rate (ORR). Secondary endpoints include safety, tolerability, progression-free survival and overall survival. As an exploratory endpoint, PI3K/AKT/mTOR pathway mutations will be characterized and correlated with clinical outcomes. A maximum of 52 patients will be enrolled in order to obtain 40 evaluable patients. The combination will be considered for further testing should the ORR increase from a historical 10% to $\geq$ 26%. A sample size of 40 patients will have a 90% power to detect this change with a 10% alpha risk. The trial is open, and enrollment is ongoing.

Clinical trial identification: EudraCT: 2017-004486-27.

918TiP EV-201: A single-arm, open-label, multicenter study of enfortumab vedotin for treatment of patients with locally advanced or metastatic urothelial cancer who previously received immune checkpoint inhibitor therapy

J.E. Rosenberg[1], A. Balar[2], P.H. O'Donnell[3], E.I. Heath[4], N.M. Hahn[5], N.M. Cavazos[6], A. Melhem-Bertrandt[7], D.P. Petrylak[8]

[1]Medicine, Memorial Sloan-Kettering Cancer Center, New York, NY, USA, [2]Departments of Medical Oncology and Urology, NYU Langone Medical Center, New York, NY, USA, [3]Department of Medicine, University of Chicago, Chicago, IL, USA, [4]Oncology, Karmanos Cancer Center, Detroit, MI, USA, [5]Johns Hopkins Sidney Kimmel Cancer Center, Baltimore, MD, USA, [6]Clinical Research, Seattle Genetics, Bothell, WA, USA, [7]Astellas Pharma USA, Northbrook, IL, USA, [8]Medical Oncology, Yale University School of Medicine Medical Oncology, New Haven, CT, USA

Background: Most patients (pts) with locally advanced or metastatic urothelial cancer (la/mUC) will not respond to immune checkpoint inhibitors (CPIs) in the post-platinum or first-line cisplatin ineligible setting. Enfortumab vedotin (EV), an antibody-drug conjugate, delivers the microtubule-disrupting agent monomethyl auristatin E to tumors expressing Nectin-4, which is highly expressed in 97% of mUC pt samples

(Petrylak ASCO 2017). In a phase 1 study (NCT02091999), EV monotherapy was generally well tolerated at the recommended dose of 1.25 mg/kg. In this study, 29% of mUC pts had liver metastasis, and most had prior treatment with a CPI (79%), platinum (94%), and/or taxanes (29%). Interim results in mUC pts treated at 1.25 mg/kg showed a confirmed objective response rate (ORR) of 41% (46 of 112) and an ORR of 40% in pts previously treated with a CPI (36 of 89). The most common treatmentrelated adverse events (AEs) among pts with mUC were fatigue (54%), alopecia (45%), and decreased appetite (40%). There were no treatment-related Grade $\geq$3 AE in $\geq$ 5% of mUC pts. Four possibly treatmentrelated fatal AEs were reported: respiratory failure, urinary tract obstruction, diabetic ketoacidosis, and multiorgan failure. These encouraging results along with a favorable safety and tolerability profile warrant further investigation of EV as a monotherapy.

Trial design: This single-arm, open-label, multicenter phase 2 study (NCT03219333) evaluates the antitumor activity and safety of EV monotherapy in la/mUC pts with prior CPI treatment. The study will enroll ~100 platinum-treated pts (Cohort 1) and ~100 platinum-naive and cisplatin-ineligible pts (Cohort 2). The primary objective is to determine antitumor activity of EV as measured by ORR assessed per RECIST v1.1. Secondary objectives include assessment of duration of response, disease control rate, PFS, OS, safety, and tolerability. Pts must have tumor tissue available for exploratory analyses. Study enrollment began in Sep 2017.

Clinical trial identification: NCT03219333.

919TiP The potential of patient reported outcomes in urothelial cancer patients receiving immuno- or chemotherapy: A feasibility study of electronic reporting in an aging and comorbid population

G.A. Taarnhøj[1], H. Lindberg[2], H. Pappot[1], L.H. Dohn[2], C. Johansen[1]

[1]Oncology, Copenhagen University Hospital - Rigshospitalet, Copenhagen, Denmark, [2]Oncology, Copenhagen University Hospital Herlev, Herlev, Denmark

Background: Worldwide urothelial cancer (UC) is one of the most common malignant diseases and causes of death. Patients with UC often have comorbidities, troubling completion of treatment, thus enhancing the need for better supportive instruments during treatment. Patient-reported outcomes (PROs) have been suggested as such, although the use of these has not yet been demonstrated feasible in this aging and comorbid population. Furthermore the literature is sparse on toxicities and quality of life (QoL) during treatment for UC patients outside of clinical trials. This study shall demonstrate the feasibility of electronic reporting of PROs and describe toxicities and QoL in the UC population.

Trial design: From February 2018, inclusion of patients with UC stage T2-T4NxMx was initiated. All patients initiating chemo- or immunotherapy outside a clinical trial at Rigshospitalet and Herlev Hospital, Denmark, are approached. Recruitment continues until 40 patients are enrolled. All patients will at baseline and weekly during treatment complete four e-questionnaires: EORTC QLQ-C30 & QLQ-BLM30, HADS, selected PRO-CTCAE^{TM} questions and finally three general health questions. Reminders to complete the questionnaires are sent to patients electronically. Clinicians will in turn have an overview of the patients' answers categorized into groups of severity. The overview is automatically incorporated into the electronic medical charts. The study will evaluate the feasibility of electronic reporting and describe toxicities, QoL, rate of completion and hospital admissions. The results of this study will contribute to the content of a randomized patient-reported outcomes study in the UC population initiated this autumn (2018).

920TiP Erdafitinib compared with vinflunine or docetaxel or pembrolizumab in patients (pts) with metastatic or surgically unresectable (M/UR) urothelial carcinoma (UC) and selected fgfr gene alterations (FGFRalt): The phase III THOR study

Y. Loriot[1], A. Necchi[2], S.H. Park[3], R.A. Huddart[4], E. Burgess[5], B. Zhong[6], A. Santiago-Walker[7], S. Little[8], T. Roccia[9], P. De Porre[10], A.O. Siefker-Radtke[11]

[1]Department of Cancer Medicine, Institut Gustave Roussy, Villejuif, France, [2]Medical Oncology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [3]Hematology-Oncology, Samsung Medical Center, Seoul, Republic of Korea, [4]Radiotherapy, Institute of Cancer Research, Sutton, UK, [5]Medical Oncology, Levine Cancer Institute, Carolinas HealthCare System, Charlotte, NC, USA, [6]Biostatistics, Janssen Research & Development, Spring House, PA, USA, [7]Oncology Translational Research, Janssen Research & Development, Spring House, PA, USA, [8]Clinical Oncology, Janssen Research & Development, Spring House, PA, USA, [9]Clinical Oncology, Janssen Research & Development, Buckinghamshire, UK, [10]Clinical Oncology, Janssen Research & Development, Beerse, Belgium, [11]Genitourinary Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA

Background: Pts with M/UR UC have poor prognoses. Programmed death (ligand)-1 (PD-[L]1) inhibitors have improved outcomes in some pts, but responses vary based on genotypic subtype. FGFRalt are present in 20% of pts with UC, and may reflect an immunologically "cold" tumor that does not respond well to immunotherapy (Siefker-Radtke ASCO GU 2018). In early phase 2 data, the pan-FGFR (1-4) inhibitor erdafitinib (ERDA, 8 mg/d continuous) demonstrated tolerability and a favorable 42% objective response rate (ORR) in pts with M/UR UC and FGFRalt; uptitration to 9 mg/d was feasible. Activity of single-agent ERDA will be compared with chemo or pembrolizumab in pts with M/UR UC in this randomized phase 3 study.

Trial design: Adult pts (ECOG performance status $\leq$ 2 and adequate bone marrow, liver, and renal function; no uncontrolled cardiovascular disease, known HIV, hepatitis B or C, or baseline phosphate persistently above the upper limit of normal allowed) with stage 4 M/UR UC and specific pathogenic FGFRalt (FGFR3 mutations or FGFR2/3 fusions) who have received 1 line of prior systemic therapy are eligible. Pts will be screened for FGFRalt and randomized 1:1 to cohort 1 or 2. In cohort 1 (n ~280), pts with prior chemo and PD-(L)1 inhibitor (prior PD-[L]1 inhibitor alone allowed for cisplatin-ineligible pts) in combination or in maintenance setting will receive 8 mg/d continuous ERDA vs chemo (1:1) with docetaxel or vinflunine. In cohort 2, pts (n ~350) with prior chemo but no prior PD-(L)1 inhibitor will receive 8 mg/d ERDA vs pembrolizumab (1:1). Uptitration of ERDA to 9 mg/d is recommended in pts with serum phosphate $\leq$ 9 mg/dL. Primary end point: overall survival. Secondary end points: progression-free survival, ORR, duration of response, pt-reported outcomes, safety, and pharmacokinetics. PD-L1 expression level per immunohistochemistry and UC subtype per RNA sequencing or other methods are exploratory end points. Pts are being enrolled at sites in 25 countries. For additional information on specific sites/countries: https://clinicaltrials.gov/ct2/show/NCT03390504.

Clinical trial identification: NCT03390504.

921TiP An open-label phase II study to evaluate PT2977 for the treatment of von hippel-lindau disease associated renal cell carcinoma

E. Jonasch[1], E. Park[2], S. Thamake[2], M. Hirmand[2], R. Srinivasan[3]

[1]GU Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [2]Clinical Development, Peloton Inc., San Francisco, CA, USA, [3]Center for Cancer Research, National Cancer Institute, Bethesda, MD, USA

Background: In VHL disease, renal cell carcinomas (RCC) are known to be of clear cell histology (ccRCC). HIF-2α has been established as an oncogenic driver in ccRCC, where VHL deficiency is the underlying genomic alteration. In this setting of VHL gene inactivation, HIF-2α accumulates under normoxic conditions, driving the expression of genes associated with progression of ccRCC, including vascular endothelial growth factor A (VEGFA), cyclin D1 and other factors that contribute to tumor growth and proliferation. Clinical management of VHL disease-associated renal tumors involves active surveillance until surgery is required for tumors larger than 3 cm to prevent metastasis. Repeated surgical procedures can carry significant morbidity. Systemic therapy options that can delay or obviate the need for surgery by reducing tumor size are needed.

Trial design: This open-label Phase 2 study will evaluate the efficacy and safety of PT2977, a highly selective small molecule inhibitor of HIF-2α, in patients with VHL disease who have at least 1 measurable ccRCC (as defined by RECIST 1.1). PT2977 will be administered orally at a dosage of 120 mg once daily. Key inclusion criteria include a germline VHL alteration and at least 1 measurable solid ccRCC but no tumor >3.0 cm that requires immediate surgical intervention. Patients may have VHL disease-associated tumors in other organ systems. Key exclusion criteria include prior systemic therapy for VHL disease, an immediate need for surgical intervention, evidence of metastatic disease, and history of a non-VHL disease-associated invasive malignancy in the past 2 years. The primary efficacy endpoint is objective response rate (ORR) of ccRCC tumors per RECIST 1.1. Secondary efficacy endpoints include duration of response (DOR), time to response (TTR), progression-free survival (PFS), and time to surgery (TTS) for ccRCC tumors as well as efficacy evaluations for non-ccRCC VHL disease-associated tumors. Safety/tolerability and pharmacokinetics of PT2977 in this trial will also be evaluated. Patient recruitment is ongoing.

Clinical trial identification: NCT03401788; EudraCT: 2018-000125-30.

922TiP EV-301: An open-label, randomized phase III study to evaluate enfortumab vedotin versus chemotherapy in patients with previously treated locally advanced or metastatic urothelial cancer (la/mUC)

D.P. Petrylak[1], J. Rosenberg[2], I. Duran[3], Y. Loriot[4], G. Sonpavde[5], C. Wu[6], E. Gartner[7], A. Melhem-Bertrandt[8], T. Powles[9]

[1]Medical Oncology and Urology, Yale University School of Medicine, New Haven, CT, USA, [2]Genitourinary Oncology Service, Memorial Sloan Kettering Cancer Center, New York, NY, USA, [3]Medical Oncology, Hospital Universitario "Marqués de Valdecilla", Santander, Spain, [4]Medical Oncology, Institut Gustave Roussy, Paris, France, [5]Medical Oncology, Dana Farber Cancer Institute, Boston, MA, USA, [6]Biostatistics, Astellas Pharma US, Inc., Northbrook, IL, USA, [7]Experimental Medicine, Seattle Genetics, Inc., Bothell, WA, USA, [8]Development Medical Sciences - Oncology, Astellas Pharma US, Inc., Northbrook, IL, USA, [9]Barts Cancer Institute, Queen Mary University of London, London, UK

Background: Standard first-line treatment for patients (pts) with la/mUC is cisplatin-based chemotherapy or carboplatin-based chemotherapy for pts unfit for cisplatin. Recently, immune checkpoint inhibitors (CPIs) have become standard treatment options for pts who progressed during/after platinum-based chemotherapy or are ineligible for cisplatin. While some pts with la/mUC achieve durable responses with CPIs, only a minority respond. Following failure with CPI, no therapies are approved. Enfortumab vedotin (EV) is a fully humanized monoclonal antibody that delivers the microtubule-disrupting agent monomethyl auristatin E to tumors expressing Nectin-4, which is highly expressed in 97% of mUC patient samples (Petrylak ASCO 2017). In a phase 1 study (EV-101; NCT02091999), single-agent EV at the established recommended phase 2 dose of 1.25 mg/kg was generally well tolerated and demonstrated a confirmed objective response rate of 41% (n = 46/112) across the overall population of pts with mUC; in pts with prior CPI therapy, a confirmed ORR of 40% (n = 36/89) was observed.

Trial design: EV-301 is a global, multicenter, open-label phase 3 trial (NCT03474107) enrolling adult pts with la/mUC and an ECOG score ≤1, who have received one prior platinum-containing chemotherapy, and have experienced disease progression during or following treatment with a CPI. Approximately 550 pts will be randomized 1:1 to receive EV 1.25 mg/kg (Arm A) or chemotherapy (Arm B); randomization will be stratified by ECOG score, regions of the world, and liver metastases at baseline. Patients in Arm A will receive EV on Days 1, 8, and 15 of each 28-day cycle; pts in Arm B will receive either docetaxel, paclitaxel, or vinflunine (determined by investigator) on Day 1 of every 21-day cycle. Patients will continue to receive study treatment until disease progression, intolerance, or other discontinuation criterion is met. The primary endpoint is overall survival; secondary endpoints include progression-free survival, duration of response, and overall response rate, as well as assessment of safety/tolerability, and quality-of-life parameters.

Clinical trial identification: NCT03474107.

923TiP A phase III study of INCB054828 as adjuvant therapy in patients (pts) with high-risk urothelial carcinoma (UC) harboring fibroblast growth factor receptor 3 (FGFR3) genomic alterations

A. Necchi[1], J.L. Pérez-Gracia[2], Y. Loriot[3], W. Witjes[4], F. Montorsi[5], A. Bjartell[6], S.F. Shariat[7]

[1]Medical Oncology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [2]Medical Oncology, Clínica Universitaria de Navarra, Pamplona, Spain, [3]Department of Cancer Medicine, Institut Gustave Roussy, Villejuif, France, [4]Research Foundation, European Association of Urology, Arnhem, Netherlands, [5]Urological Research Institute (URI), IRCCS San Raffaele, Milan, Italy, [6]Urology, Skåne University Hospital Malmö, Malmö, Sweden, [7]Urology, Medical University of Vienna, Vienna, Austria

Background: After neoadjuvant chemotherapy (NAC), about 20% of pts with muscle-invasive UC are found to have advanced pT-stage or lymph node involvement and 5-year overall survival (OS) of them is < 30%. Tumor samples from these pts may provide information about chemotherapy resistance, and may predict for the activity of new drugs given postoperatively. Alterations of FGFR3 gene represent a therapeutic target in UC and FGFR3 mutations/fusions are enriched in UC Luminal-1 subtype. The pan-FGFR inhibitor INCB054828 has shown promising results in chemotherapy-treated patients with genomic alterations of FGFR3 in tumor tissue and is currently being evaluated in an international phase 2 study (fight-201, NCT02872714). Our study aims to assess the safety and efficacy of adjuvant INCB054828 in pts with FGFR3 mutations/fusions.

Trial design: This is an open-label, single-arm, phase 2 study. Subjects will receive INCB054828 at a once-daily (QD) dose of 13.5 mg on a 2-weeks-on and 1-week-off schedule. Treatment should start within 60 days of surgery and will continue until 12 months, or until the evidence of disease recurrence or unacceptable toxicity onset. Key inclusion criteria are predominant UC histology, FGFR3 mutations/fusions (FoundationOne), bladder or upper tract UC, previous radical cystectomy or nephroureterectomy, previous administration ≥3 cycles of CDDP-based NAC, pT3-4 and/or pN1-3 stage. Relapse-free survival (RFS) is the primary endpoint, assessed every 9 weeks until disease recurrence or death. No interim analyses are planned. It is expected that about 30% of the total screened pts will harbor FGFR3 aberrations. In a single-stage design, with 90% power and one-sided alpha at 0.10, the total enrolled pts will be 56 (H0: 2-y RFS: 30%; H1: 2-y RFS: 45%). Translational research on tissue samples will include associations of immune-inflamed phenotype with next-generation sequencing results and outcome of treatment, and response to any subsequent immunotherapy. The study is sponsored by the EAU-Research Foundation and will involve 15 centers in Europe (EudraCT number 2017-004426-15).

924TiP A phase I study of HERV-E TCR transduced autologous T Cells (HERV-E TCR T Cells) in patients (pts) with metastatic clear cell renal cell carcinoma (mccRCC)

R. Nadal[1], E. Cherkasova[1], S. Barisic[1], D. Granadier[1], G. Aue[1], B. Wells[1], G. Hawks[1], T. Hughes[1], R. Shalabi[1], D. Stroncek[2], S. Highfill[2], G. Scurti[3], L. Chen[1], R. Reger[1], M. Nishimura[1], R. Childs[1]

[1]Laboratory of Transplantation Immunotherapy, National Heart, Lung, and Blood Institute. NIH, Bethesda, MD, USA, [2]Transfusion Medicine Department, National Institutes of Health, Bethesda, MD, USA, [3]Tumor Immunology and Immunotherapy, Loyola University, Chicago, IL, USA

Background: Our team isolated cytotoxic T lymphocyte (CTL) lines from a patient who had sustained mccRCC regression after an allogeneic transplant that showed specific killing of ccRCC. Utilizing these CTL and cDNA expression cloning, we discovered: transcripts encoding antigens targeted by these CTL were derived from a novel human endogenous retrovirus (HERV-E); selective HERV-E expression was present in most ccRCC tumors but not in normal tissues and VHL inactivation lead to transcription of HERV-E in ccRCC. Using HERV-E reactive CTL, we cloned a TCR that recognizes a HERV-E HLA-A11 restricted peptide (CT-RCC-1) into a retroviral vector containing a truncated CD34 cassette for enrichment of transduced cells. Transduced T cells acquired selective killing of HLA-A11+ ccRCC cells. A GMP method to manufacture enriched HERV-E TCR T cells was developed that incorporated cytokine stimulation of PBMCs followed by CD4+ depletion, T cell transduction, CD34 enrichment & ex vivo expansion. A scale up of this manufacturing process in 3 healthy donors showed transduced T cells: > 90% CD34+ and had > 90% CT-RCC-1 tetramer specificity. When co-cultured with HERV-E+ ccRCC cells, T cells secreted high levels of IFN-γ and killed ccRCC cells (Table).

Trial design: Phase 1 (3 + 3 design) cell dose-escalation study (1×10^6, 5×10^6, 1×10^7 and 5×10^7 cells/kg) to determine the MTD of HERV-E TCR T cells in mccRCC. Pts first receive cyclophosphamide and fludarabine conditioning, followed by single infusion of HERV-E TCR T cells & moderate-dose IL-2. Eligibility criteria: histologically-confirmed ccRCC, progressive disease and 2 prior lines of therapy. Primary endpoint: safety by day 21. Adverse events assessed using CTCAEv5. Biomarker objectives: persistence of HERV-E TCR T cells in blood, T cell lineage/functionality of these cells over time; cytokine profiles & HERV-E expression and presence of HERV-E TCR T cells in tumor tissue.

Table: 924TiP

	HERV-E TCR T cells (n = 3 donors)	Method
Cell number after ex vivo expansion (range)	7.55×10^8 (1.34×10^8-6.34×10^9)	Cellometer-based
CD34+, % (range)	96.4 (96.1-96.8)	Flow
CT-RCC-1 tetramer+, % (range)	93.2 (91.3-94.5)	Flow
Tumor Specific lysis, % (SD)	46 ± 8.5	LDH assay
IFN-γ secretion, pg/ml (range)	1635 (1555-1750)	ELISA

Clinical trial identification: NCT03354390.

925TiP Phase Ib/II study to evaluate the safety, tolerability and pharmacokinetics of rogaratinib in combination with atezolizumab in cisplatin-ineligible patients with locally advanced or metastatic urothelial cancer and FGFR mRNA overexpression

J. Rosenberg[1], A. Necchi[2], R.F. Sweis[3], K. Nakajima[4], C. Lu[5], H. Nogai[6]

[1]Genitourinary Oncology Service, Memorial Sloan Kettering Cancer Center, New York, NY, USA, [2]Medical Oncology, Istituto Nazionale dei Tumori di Milano - Fondazione IRCCS, Milan, Italy, [3]Section of Hematology/Oncology - Department of Medicine, University of Chicago, Chicago, IL, USA, [4]Clinical Development, Bayer HealthCare Pharmaceuticals, Whippany, NJ, USA, [5]Clinical Statistics, Bayer HealthCare Pharmaceuticals, Whippany, NJ, USA, [6]Oncology, Bayer AG, Berlin, Germany

Background: PD-(L)1 inhibitors have been shown to be effective in patients with metastatic urothelial cancer (UC) who are ineligible to receive cisplatin-based chemotherapy, with the PD-L1 inhibitor atezolizumab being FDA-approved. Dysregulation of fibroblast growth factor receptors (FGFR) has been shown to play a role in UC development and progression, and FGFR3 overexpression/molecular alterations are associated with a non-T-cell inflamed tumor microenvironment. Rogaratinib, an oral pan-FGFR 1-4 inhibitor, has shown promising efficacy in a phase I study in UC patients selected based on FGFR1-3 overexpression, including patients who rapidly progressed on immunotherapy. The aim of this study is to explore the clinical safety and benefit of combining rogaratinib with atezolizumab.

Trial design: This is a multicenter, phase 1b/2 study of rogaratinib in combination with atezolizumab in patients with FGFR-positive locally advanced or metastatic UC. The primary objectives of the single-arm phase 1b portion are to determine the safety, tolerability, recommended phase-2 dose (RP2D) and pharmacokinetics of rogaratinib in combination with atezolizumab. The primary objective of the randomized phase 2 portion is to compare progression-free survival (PFS) of rogaratinib plus atezolizumab versus placebo plus atezolizumab in chemotherapy-untreated patients with FGFR-positive locally advanced or metastatic UC. Patients will be tested for FGFR1/3 mRNA expression levels in archival tumor samples (RNAscope®) and patients with FGFR-positive UC will enter into screening, regardless of the presence of FGFR mutations or translocations. Eligible patients will be treated with a starting dose of daily rogaratinib 800 mg po bid together with a fixed dose of 1200 mg atezolizumab iv on day 1 of a 21-day cycle. Following determination of the RP2D, patients will be randomized 1:1 to rogaratinib plus atezolizumab versus placebo plus atezolizumab. The primary efficacy variable is PFS based on assessment of blinded independent central review. Approximately 160 patients will be enrolled.

Clinical trial identification: NCT03473756.

926TiP Neo-adjuvant ipilimumab and nivolumab in high risk resectable bladder urothelial cancer (NABUCCO)

N. van Dijk[1], C.U. Blank[1], P. Kvistborg[2], T.N. Schumacher[2], E. Hooijberg[3], K. Sikorska[4], B.V. Rhijn[5], M.S. van der Heijden[6]

[1]Medical Oncology, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, [2]Molecular Oncology and Immunology, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, [3]Pathology, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, [4]Biometrics, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, [5]Surgical oncology, Het Nederlands Kanker Instituut Antoni van Leeuwenhoek (NKI-AVL), Amsterdam, Netherlands, [6]Medical Oncology, Het Nederlands Kanker Instituut Antoni van Leeuwenhoek (NKI-AVL), Amsterdam, Netherlands

Background: Although muscle-invasive urothelial cancer (UC) can be cured by surgery, recurrence rates are high. Despite impressive response rates to neo-adjuvant cisplatin-based chemotherapy, the absolute overall survival benefit is only 5%. Immunotherapy targeting the PD-1/PD-L1-axis has shown promising activity in UC, particularly when combined with anti-CTLA-4, and patients with lymph node only disease treated with frontline immunotherapy appear to benefit most. Since responses to immunotherapy often appear to be durable, neo-adjuvant immunotherapy may improve prognosis, particularly for high risk N+ disease. Preliminary data on neo-adjuvant pembrolizumab showed remarkable pCR rates (38.9%) and a manageable toxicity profile after 3 cycles of pembrolizumab in resectable T2-3N0 UC, underpinning the potential of neo-adjuvant combination trials for high risk UC.

Trial design: This is a single-arm phase 1B trial to establish whether sequenced pre-operative ipilimumab and nivolumab is safe and effective in high risk UC, defined as upper/lower tract cT3-4aN0 OR ≥T1, cN+ OR ≥T1, any N, resectable retroperitoneal lymph node metastasis. Patients are eligible if they are ≥ 18 years with WHO performance 0-1. Patients must be cisplatin ineligible or refuse cisplatin-based chemo with no previous treatment with PD-(L)1 and CTLA-4 immunotherapy. To mitigate the risk of immune-related toxicity, patients are treated with a mitigated schedule (based on Meerveld-Eggink et al., Ann Oncol 2017): ipi 3 mg/kg (day 1), ipi 3 mg/kg + nivo 1 mg/kg (day 22) and nivo 3 mg/kg (day 43) followed by radical cystectomy or nefro/ureterectomy (day 57-71) with appropriate LN dissection. Six patients will undergo a re-TUR for in-depth analysis of T cell infiltrates. The primary endpoint of this trial is the percentage of patients having surgery <12 weeks after study enrollment. Secondary endpoints are efficacy (pCR) and translational. In total 24 patients will be included. At the time of abstract submission, 5 patients were included.

Clinical trial identification: NCT03387761.

Legal entity responsible for the study: The Netherlands Cancer Institute.

Funding: BMS.

Disclosure: All authors have declared no conflicts of interest.

927TiP A phase III, randomized, placebo-controlled trial of adjuvant nivolumab plus ipilimumab in patients (pts) with localized renal cell carcinoma (RCC) who are at high risk of relapse after radical or partial nephrectomy (CheckMate 914)

A. Bex[1], V. Grünwald[2], P. Russo[3], Y. Tomita[4], E. Berghorn[5], M.B. McHenry[6], R.J. Motzer[7]

[1]Department of Urology, Netherlands Cancer Institute, Amsterdam, Netherlands, [2]Department of Hematology, Hemostasis, Oncology, and Stem Cell Transplantation, Hannover Medical School, Hannover, Germany, [3]Department of Surgery, Memorial Sloan Kettering Cancer Center, New York, NY, USA, [4]Department of Molecular Oncology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan, [5]Global Clinical Research, Bristol-Myers Squibb, Princeton, NJ, USA, [6]Global Biometeric Sciences, Bristol-Myers Squibb Company, Princeton, NJ, USA, [7]Department of Medicine, Memorial Sloan-Kettering Cancer Center, New York, NY, USA

Background: Surgery is the standard treatment for non-metastatic RCC. Unfortunately, pts with stage II or III RCC have high risk of relapse with 5-year survival rates of 20% to 53%; prevention of recurrence is an unmet need. In CheckMate 214, the nivolumab + ipilimumab treatment combination demonstrated significant improvement in overall survival (OS) in first-line treatment of pts with advanced or metastatic RCC, with a manageable safety profile. This phase III multinational study will evaluate adjuvant nivolumab + ipilimumab vs placebo in pts with high risk of relapse after nephrectomy (NCT03138512).

Trial design: Key inclusion criteria: Radical or partial nephrectomy with negative surgical margins >4 weeks and ≤12 weeks before randomization; predominantly clear primary tumor cell histology; pathologic TNM staging T2a (grade [G] 3 or 4), T2b (any G), T3 (any G), or T4 (any G) N0M0, or any T (any G) N1M0; Eastern Cooperative Oncology Group performance status ≤1, no clinical/radiological evidence of macroscopic residual disease or distant metastases post-nephrectomy, and tumor tissue obtained ≤3 months pre-enrollment. Key exclusion criteria: Pts with conditions requiring corticosteroid or immunosuppressive systemic treatment, autoimmune disease, prior treatment with drugs specifically targeting T-cell co-stimulation or checkpoint pathways, and prior systemic treatment for RCC. Pts are randomized 1:1 to receive nivolumab and ipilimumab at the specified dose on specified days for 24 weeks, or placebo infusions on the same schedule for 24 weeks or until recurrence, unacceptable toxicity, or withdrawal of consent. Stratification factors: TNM staging and type of nephrectomy procedure. Primary endpoint: Disease-free survival per blinded independent central review. Secondary endpoints: OS, safety, and tolerability. Tertiary/exploratory endpoints include disease-related symptoms based on the Functional Assessment of Cancer Therapy-Kidney Symptom Index, and changes in global health status based on EuroQoL's EQ-5D-3L. Enrollment began July 2017 with a target of 800 pts.

Clinical trial identification: NCT03138512.

928TiP ATLAS: A phase II, open-label study of rucaparib in patients (pts) with locally advanced (unresectable) or metastatic urothelial carcinoma

S. Chowdhury[1], S. Feyerabend[2], Y. Loriot[3], A. Necchi[4], S. Gupta[5], D.H. Josephs[6], A. Rodríguez-Vida[7], S. Srinivas[8], Y. Zakharia[9], D. Nepert[10], K. Wride[11], D. Thomas[12], A. Loehr[13], A.D. Simmons[13], P. Grivas[14]

[1]Medical Oncology, Guy's Hospital and Sarah Cannon Research Institute, London, UK, [2]Urologic Oncology, Studienpraxis Urologie, Nürtingen, Germany, [3]Department of Cancer Medicine, Gustave Roussy Cancer Campus, Villejuif, France, [4]Department of Medical Oncology, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy, [5]Genitourinary Oncology Program, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT, USA, [6]Department of Medical Oncology, Guy's and St. Thomas' Hospital, London, UK, [7]Genitourinary Cancer Unit, Hospital del Mar, Barcelona, Spain, [8]Urologic Oncology Clinic, Stanford University School of Medicine, Stanford, CA, USA, [9]Division of Hematology, University of Iowa and Holden Comprehensive Cancer Center, Iowa City, IA, USA, [10]Clinical Science, Clovis Oncology, Inc., Boulder, CO, USA, [11]Biostatistics, Clovis Oncology, Inc., Boulder, CO, USA, [12]Clinical Operations, Clovis Oncology, Inc., Boulder, CO, USA, [13]Translational Medicine, Clovis Oncology, Inc., Boulder, CO, USA, [14]Dept. of Medicine, Division of Oncology, University of Washington, Seattle, WA, USA

Background: There are currently no standard treatment options for pts with metastatic urothelial carcinoma (mUC) who have progressed on or after platinum (cisplatin/carboplatin)–based chemotherapy (PBC) and/or immune checkpoint inhibitors (ICIs). Analysis of The Cancer Genome Atlas bladder cancer dataset suggests that approximately 60% of bladder tumours have homologous recombination deficiency (HRD), as identified by a deleterious mutation in a homologous recombination pathway gene or high genomic loss of heterozygosity (LOH). Poly(ADP-ribose) polymerase (PARP) inhibitors have demonstrated clinical activity and are approved in other indications for tumours with HRD. We hypothesise that PARP inhibition has antitumour activity in mUC. The ATLAS (NCT03397394) trial is evaluating the efficacy and safety of the PARP inhibitor rucaparib as monotherapy treatment for pts with locally advanced (unresectable) or metastatic UC previously treated with PBC and/or ICI.

Trial design: Eligible pts must have received 1–2 prior standard-of-care treatments (eg, PBC and/or ICI) and have radiographic progression, measurable disease (RECIST v1.1) and adequate organ function. Confirmation of HRD status before enrolment is not required; however, fresh tumour or recently obtained archival tissue is mandatory for central HRD profiling. Prior PARP inhibitor treatment is exclusionary. All pts will receive rucaparib monotherapy (600 mg BID) until disease progression or other reason for discontinuation. The coprimary endpoints are confirmed objective response rate (investigator-assessed per RECIST v1.1) in the HRD-positive (signature based on tumour genomic LOH) and intent-to-treat populations. Secondary endpoints include response duration, progression-free survival, overall survival, safety and pharmacokinetics. Exploratory endpoints include evaluation of molecular biomarkers associated with response and resistance to rucaparib, including changes in plasma and tumour samples. Pts are being enrolled in 6 countries (target, N = 200). The study has >90% power to reject the null hypothesis (P = 0.10) at a 5% significance level if the true response rate for rucaparib is 20%.

Clinical trial identification: NCT03397394.

929TiP BAYOU: Phase II study of efficacy and safety of durvalumab plus olaparib as first-line therapy in cisplatin-ineligible patients (pts) with stage iv urothelial cancer (UC)

J.E. Rosenberg[1], D.F. Bajorin[1], A. Smith[2], C. D'Cruz[3], M. Lanasa[3]

[1]Genitourinary Oncology, Memorial Sloan-Kettering Cancer Center, New York, NY, USA, [2]Biometrics & Information Sciences, AstraZeneca, Cambridge, UK, [3]GMed Cancer Immunotherapy, AstraZeneca, Gaithersburg, MD, USA

Background: UC is platinum-responsive and hypothesized to be sensitive to targeted DNA-damaging agents such as PARP inhibitors (PARPi). Cisplatin (cis)-ineligible pts with metastatic/unresectable primary UC have limited effective treatment options. Immune checkpoint blockade may increase the proportion of pts that respond to PARPi. Durvalumab is a selective, high-affinity, engineered, human IgG1 monoclonal Ab that blocks PD-L1 binding to PD-1 and CD80. In UC, the combination of olaparib (a PARPi) + durvalumab may broaden the therapeutic effect of monotherapy given their different mechanisms of action, with potentially enhanced benefit for pts with metastatic/unresectable UC and DNA repair deficiencies (mutations in homologous recombination repair genes [HRRm]).

Trial design: BAYOU is a double-blind, randomized, placebo-controlled, multicenter phase 2 study designed to assess the efficacy and safety of durvalumab + olaparib vs durvalumab + placebo in cis-ineligible pts with stage IV UC. Adult pts ($\geq$18 years) who are cis-ineligible with histologically/cytologically confirmed unresectable stage IV UC, WHO performance status 0-2, and with known HRRm status will be enrolled. Pts with active/prior autoimmune disorders, brain metastases, prior PARPi/immune therapy, current/prior immunosuppressive agents, non-UC invasive malignancies, and concomitant use of strong CYP3A inhibitors/inducers are excluded. All pts will be randomized (1:1) to durvalumab (1500 mg intravenous, every 4 weeks) + placebo or durvalumab + olaparib (tablet) until disease progression. Olaparib dose will be 300 mg twice daily in pts with CrCl >50 mL/min and 200 mg twice daily in pts with CrCl $\geq$31 to $\leq$ 50 mL/min. The primary endpoint is progression-free survival in HRRm patients (investigator assessed, RECIST v1.1). Secondary endpoints are overall survival (OS), duration of response, objective response rate, proportion of pts alive and progression free at 6 months, and OS at 18 months. Safety, pharmacokinetics, and immunogenicity will also be assessed. The trial is currently enrolling pts.

Editorial acknowledgement: Editorial assistance, which was in accordance with Good Publication Practice (GPP3) guidelines, was provided by Ingrid Monteiro of Cactus Communications (Mumbai, India).

930TiP Phase II/III study of rogaratinib versus chemotherapy in patients with locally advanced or metastatic urothelial carcinoma selected based on FGFR1/3 mRNA expression

C.N. Sternberg[1], J. Bellmunt[2], H. Nishiyama[3], D.P. Petrylak[4], D.I. Quinn[5], K. Nakajima[6], C. Lu[7], A. Holynskyj[6]

[1]Medical Oncology, San Camillo Forlanini Hospital, Rome, Italy, [2]Medical Oncology, IMIM-Hospital del Mar Medical Research Institute, Barcelona, Spain, [3]Urology, University of Tsukuba, Tsukuba, Japan, [4]Medical Oncology, Yale University School of Medicine Medical Oncology, New Haven, CT, USA, [5]Translation and Clinical Science Program / Oncology, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA, USA, [6]Clinical Development, Bayer HealthCare Pharmaceuticals, Whippany, NJ, USA, [7]Clinical Statistics, Bayer HealthCare Pharmaceuticals, Whippany, NJ, USA

Background: Long-term survival is poor for patients with locally advanced or metastatic urothelial carcinoma (UC) receiving chemotherapy and/or immunotherapy following progression with platinum-containing chemotherapy. Genetic alterations of fibroblast growth factor receptors (FGFR) have been shown to play a role in UC development and progression. Non-genetic and epigenetic activation of FGFR gene expression have also been described. Rogaratinib, an oral pan-FGFR 1-3 inhibitor, has shown promising activity and a manageable safety profile in a phase I study in patients with UC who were selected based on FGFR1-3 mRNA overexpression and/or activating mutations in the FGFR3 gene.

Trial design: This is a randomized, open-label, phase 2/3 study to evaluate the efficacy and safety of rogaratinib compared to chemotherapy in patients with FGFR-positive locally advanced or metastatic UC who have received prior platinum-containing chemotherapy. The primary objective is to show superiority of rogaratinib over chemotherapy in prolonging overall survival (OS) of UC patients with FGFR-positive tumors. Secondary objectives include: objective response rate (ORR), progression-free survival, disease control rate, duration of response, and safety. Testing for FGFR1 and 3 mRNA over expression will be conducted centrally using an RNA in situ hybridization (RNA-ISH) in archival samples. Eligible patients will be randomized 1:1 to rogaratinib (800 mg po bid) or iv chemotherapy Q3W (docetaxel 75 mg/m^2; paclitaxel 175 mg/m^2; or 320 mg/m^2 vinflunine). Randomization will be stratified according to PIK3CA and/or RAS activating mutations, prior immunotherapy, and modified 4-factor Bellmunt risk score. The objective for the phase 2 part of the study is ORR. A total of 116 patients in PIK3CA and RAS WT patients will be enrolled to the phase 2 part of the study to rule out a low difference in ORR between rogaratinib and chemotherapy as futility. The phase 3 portion of the study is powered to detect an increase in median OS in PIK3CA and RAS WT patients. Total patient enrollment expected to be approximately 400 patients.

Clinical trial identification: NCT03410693.

931TiP PRISM: A randomised phase II trial of nivolumab in combination with alternatively scheduled ipilimumab in first-line treatment of patients with advanced or metastatic renal cell carcinoma

F. Collinson[1], S. Brown[1], H. Buckley[1], G. Ainsworth[1], H. Howard[1], H. Poad[1], G. Carr[1], R.E. Banks[2], J. Brown[2], G. Velikova[3], J. Larkin[4], P. Nathan[5], T.B. Powles[6], N.S. Vasudev[3]

[1]Leeds Clinical Trials Research Unit, University of Leeds, Leeds, UK, [2]Leeds Institute of Cancer and Pathology, University of Leeds, Leeds, UK, [3]St James's Institute of Oncology, St. James's University Hospital Leeds, Leeds, UK, [4]Department of Medical Oncology, Royal Marsden NHS Foundation Trust, London, UK, [5]Department of Medical Oncology, Mount Vernon Cancer Centre, Northwood, Middlesex, UK, [6]Department of Oncology, St. Bartholomew's Hospital, London, UK

Background: Initial results from the CheckMate 214 randomised phase III study demonstrate an overall survival advantage for combination ipilimumab plus nivolumab over sunitinib in front-line treatment of patients with intermediate/poor risk metastatic renal cell carcinoma (mRCC). However, the safety profile of nivolumab-plus-ipilimumab could be further optimised: 46% (250/547) of patients experienced a Grade 3-4 adverse reaction (AR), 22% (118/547) discontinued therapy due to ARs and (35%) (152/436) patients needed high dose steroids to resolve immune-mediated ARs. The aim of the PRISM trial is to explore safer and more tolerable scheduling of these agents. We hypothesise that 12-weekly rather than standard 3-weekly dosing of ipilimumab, in combination with nivolumab, will result in lower rates of grade 3-4 ARs whilst maintaining treatment efficacy.

Trial design: PRISM is a multi-centre phase II trial randomising patients (1:2) to nivolumab 3mg/kg combined with ipilimumab 1mg/kg every 3 weeks for 4 doses, followed by nivolumab 240mg flat-dose every 2 weeks (standard arm) versus nivolumab 3mg/kg combined with ipilimumab 1mg/kg at weeks 1, 13, 25 & 37 (4 doses) with single-agent 2-weekly nivolumab 240mg given in intervening weeks (experimental arm). Patients with untreated metastatic clear cell RCC will form the study population and patients with good, intermediate and poor prognosis disease, as per IMDC criteria, are eligible. The primary endpoint of the study is the rate of grade 3 or 4 ARs within the initial 12 months of treatment. Progression-free survival (PFS) at 12 months forms a key secondary endpoint, to exclude the PFS rate of no interest and support further investigation in a subsequent definitive phase III trial. Other secondary endpoints include treatment discontinuation rates, quality of life, overall response rate and duration of response. An exploratory objective is to examine circulating and tissue-based biomarkers of response. The study aims to recruit 189 patients across 15 UK centres over a 2-year period and opened in March 2018. To date, 4 patients have been recruited.

Clinical trial identification: EudraCT: 2017-001476-33.

Background: Therapeutic options in late line ROC offer limited efficacy, especially for pts who are considered platinum (plat) resistant (res) or refractory (ref). Pts whose cancers harbor *BRCA* mutations (*BRCA*mut) have been included in poly (ADP-ribose) polymerase inhibitor (PARPi) trials and derived modest benefit from treatment (ORR ≈25% for plat-res and 0-14% for plat-ref pts). QUADRA evaluated niraparib monotherapy in ROC pts regardless of their plat and biomarker status.

Methods: Eligible pts received treatment with single agent niraparib in 4th or later line of therapy. Pts were evaluated for *BRCA*mut and HRD status (MyChoice HRD Test). Pts received niraparib 300 mg once daily until progression; treatment emergent adverse events (AEs) were managed with dose reduction to 200 or 100 mg. The primary endpoint was ORR per RECIST v1.1.

Results: 463 pts were treated. Median age was 65 years (range: 29-91). 162 pts were plat ref (defined as progression within 28 days of the last dose of plat); 152 plat res (defined as less than 6 months between last dose of plat and subsequent progression); 118 plat sensitive; 31 unknown. Results in HRD+ pts have been presented at a prior congress. We focus here on the t*BRCA*mut (both germline and somatic) PARPi-naïve subgroup. ORR for 4th line or later, PARPi-naïve t*BRCA*mut pts (n = 55) was 31% (95% CI: 19-45), including 18 plat-sensitive pts (ORR 39%), 21 plat-res pts (ORR 33%), and 16 plat-ref pts (ORR 19%). The combined ORR in the plat-res and -ref pts (n = 37) was 27%. The median DOR among all t*BRCA*mut pts was 9.2 months, with an estimated 43% of responding pts maintaining their response at 24 months. In the entire study cohort, 197 pts (42.5%) experienced a serious AE (SAE) and 91 pts (19.7%) a treatment-related SAE. The most frequent treatment-emergent SAEs were gastrointestinal disorders (19.9%), thrombocytopenia (8.4%), small intestinal obstruction (6.6%), and vomiting (5.1%).

Conclusions: Niraparib demonstrated meaningful and durable responses among the difficult-to-treat patient population, including platinum resistant and refractory t*BRCA*mut patients.

Clinical trial identification: NCT02354586.

Background: Programmed cell death ligand 1 (PD-L1) expression and preliminary evidence of antitumor activity with anti-PD-1 therapy have been reported in ovarian cancer. PLD, a pegylated, liposomal form of doxorubicin, is a standard option for this population; durva is an anti-PD-L1 antibody. The primary objectives of this study are to determine the safety of the combination and to evaluate clinical efficacy by progression-free survival rate at 6 months (PFS6) using RECIST 1.1.

Methods: This is a phase 1/2, multicenter, open-label study (NCT02431559) of durva in patients (pts) with PROC, scheduled to receive PLD. The study includes a dose escalation (phase 1: 3 + 3 design; DLT evaluation over one 28-day cycle; n = 6-18) and a dose expansion (phase 2: n = 41). PLD has been reported to have a 25% PFS6. A sample size of 41 evaluable pts yields 80% power to test the null hypothesis of a PFS6 rate of ≤ 25% against the alternative hypothesis of a PFS rate of ≥ 45% at an alpha level of 0.05 (one-sided). Blood and tumor samples were also collected for assessment of correlative immunologic responses.

Results: First pt dosed: 09Aug2016. As of 05Mar2018, 40 female pts (median age: 65 [32-83] years) were enrolled in phase 2 of the study; each received at least 1 dose of study therapy (PLD 40 mg/m^2 + durva 1500 mg Q4W) and are included in the safety analyses. Most frequent (in ≥ 25% pts) treatment-emergent adverse events (AEs, all causality) were palmar-plantar erythrodysesthesia syndrome (PPES)/rash, stomatitis, fatigue, abdominal pain, nausea, pyrexia, and vomiting. Grade 3 treatment-related AEs in ≥ 2 pts included PPES/rash, stomatitis, lymphocyte count decreased, lipase increased, and anemia. As of the cutoff date, 33 pts reached the timepoint for PFS6 assessment. Twelve pts were progression-free at 6 months; PFS6 = 30% (12/40 pts). The remaining data will mature by July 2018, and further improvement in PFS6 may occur. Updated PFS6 and preliminary correlative results will be presented at the meeting.

Conclusions: The combination of durva and PLD in women with PROC appears to have a tolerable safety profile and promising efficacy. PFS6 and translational endpoints are pending additional data.

Clinical trial identification: NCT02431559. May 1st 2015.

946P Brain metastases in primary ovarian cancer: Real-world data

E. Ratner[1], M. Bala[2], M. Louie-Gao[2], S. Hazard[3], P. Brastianos[4]

[1]Obstetrics, Gynecology and Reproductive Sciences, Yale University, New Haven, CT, USA, [2]Health Economics and Outcomes Research, Tesaro, Inc., Waltham, MA, USA, [3]Clinical Science, Tesaro, Inc., Waltham, MA, USA, [4]Hematology/Oncology, Dana-Farber Harvard Cancer Center, Harvard Medical School, Hematology/Oncology, Massachusetts General Hospital, Boston, MA, USA

Background: Brain metastasis (BM) is infrequently reported in patients (pts) with ovarian cancer (OC), with past studies reporting a rate of approximately 1%.[1] This study estimated real-world incidence of BM in OC and assessed whether *BRCA* mutation (*BRCA*mut) increased risk of BM in OC pts.

Methods: This retrospective study included 4515 pts diagnosed with OC between Jan 1, 2011 and Jan 31, 2018 from the Flatiron Health database. This is a longitudinal, demographically and geographically diverse database derived from electronic health record data from over 265 cancer clinics and over 2 million active US cancer pts. A time-to-event analysis was conducted to assess whether pts with a known *BRCA*mut were more likely to develop BM compared with *BRCA* wild type (*BRCA*wt) pts.

Results: Of 4515 OC pts, 473 were *BRCA*mut, 1679 were *BRCA*wt, and 2363 had unknown *BRCA* status. A total of 46 pts (1%) had a diagnosis of BM subsequent to OC diagnosis. Of those with *BRCA*mut, 3% (14/473) developed BM; the BM rate was 0.6% (10/1679) for *BRCA*wt. The K-M estimate for the proportion of pts with BM within 5 years of diagnosis was 5.7% in the *BRCA*mut population compared with 1.4% in *BRCA*wt. *BRCA*mut pts had a significantly higher risk of developing BM compared with *BRCA*wt (HR 4.44 [95% CI 1.97, 10.00], $P < 0.0001$). A total of 281 OC pts also had a breast cancer (BC) diagnosis (186 developed BC prior to OC, 95 developed BC after OC diagnosis). After excluding these pts from the analysis, the HR for developing BM among *BRCA*mut pts vs. *BRCA*wt pts was 3.84 (95% CI 1.60, 9.22), $P = 0.001$. Multivariate models adjusting for other pt characteristics yielded similar HRs. Among pts who developed BM, median time from OC diagnosis to BM diagnosis was 27 months in *BRCA*mut pts and 35 months in *BRCA*wt. Median survival after diagnosis of BM was 7.16 months (95% CI 3.48, 16.49). Overall survival after BM did not differ significantly by *BRCA* status.

Conclusions: OC pts with *BRCA*mut seem to have a higher risk of developing BM. Further research is needed to confirm these findings and better understand potential mechanisms and implications for management, given the poor prognosis in pts who develop BM. [1]Pectasides et al. The Oncologist 2006;11:252–260.

Gemelli IRCCS Università Cattolica del Sacro Cuore Roma, Rome, Italy, [11]Gynecological Unit, Gustave Roussy Cancer Center, INSERM U981, and Groupe d'Investigateurs Nationaux pour l'Etude des Cancers Ovariens (GINECO), Villejuif, France, [12]Department of Gynecologic Oncology, Florida Hospital Cancer Institute, Orlando, FL, USA, [13]Medical Oncology Department, Oncology Center of Galicia, La Coruña, Spain, [14]Medical Oncology Department, Auckland City Hospital, Auckland, New Zealand, [15]Department of Oncology, Cancer Care Services, Royal Brisbane and Women's Hospital and University of Queensland, Herston, Australia, [16]Clinical Research Gynecologic Oncology, The Ohio State University, James Cancer Center, Columbus, OH, USA, [17]Gynaecology Unit, The Royal Marsden NHS Foundation Trust, London, UK, [18]Biostatistics, Clovis Oncology, Inc., Boulder, CO, USA, [19]Clinical Science, Clovis Oncology, Inc., Boulder, CO, USA, [20]Department of Oncology, UCL Cancer Institute and UCL Hospitals, London, UK

Background: In the randomised, placebo-controlled, phase 3 study ARIEL3, patients were randomised 2:1 to oral rucaparib (600 mg BID) or placebo as maintenance treatment following response to platinum-based chemotherapy. Rucaparib significantly improved progression-free survival (PFS) vs placebo in all patient populations regardless of biomarker status (Coleman et al. *Lancet.* 2017;390:1949-61). This post hoc exploratory analysis investigated the effect of the number of prior chemotherapy regimens on the primary and secondary endpoints of investigator-assessed and blinded independent central review (BICR)-assessed PFS in ARIEL3.

Methods: In ARIEL3, all patients received ≥2 prior platinum-based regimens in accordance with the protocol. PFS was explored in subgroups of patients who received 2 or ≥ 3 prior chemotherapy regimens. These subgroup analyses were presented for the following predefined cohorts: *BRCA* mutant; *BRCA* mutant or *BRCA* wild type/high loss of heterozygosity (LOH); and intent-to-treat (ITT) population (ie, all randomised patients).

Results: The visit cutoff dates for efficacy and safety were 15 April 2017 and 15 August 2017, respectively. In each predefined cohort, rucaparib significantly improved PFS compared to placebo irrespective of the number of prior chemotherapy regimens (ie, 2 or ≥ 3) (Table). Rucaparib's safety profile was consistent between patients who received 2 or ≥ 3 prior chemotherapy regimens as assessed by the rate of all grade (100% and 100%) and grade ≥3 (59% and 59%) treatment-emergent adverse events (TEAEs) and dose modifications (ie, treatment interruptions and/or dose reductions due to a TEAE) (70% and 74%) in each respective subgroup.

Table: 947P

Cohort	Rucaparib, n	Placebo, n	PFS (investigator review)		PFS (BICR)	
			HR* (95% CI) Rucaparib vs placebo	Median PFS, mo; *P* value† Rucaparib vs placebo	HR* (95% CI) Rucaparib vs placebo	Median PFS, mo; *P* value† Rucaparib vs placebo
Patients with 2 prior chemotherapy regimens						
BRCA mutant	73	40	0.24 (0.14–0.40)	21.9 vs 5.4; *P*<0.0001	0.24 (0.13–0.45)	26.8 vs 5.5; *P*<0.0001
BRCA mutant or *BRCA* wild type/ high LOH	136	75	0.34 (0.23–0.49)	14.1 vs 5.5; *P*<0.0001	0.33 (0.21–0.52)	26.8 vs 5.5; P < 0.0001
ITT	231	124	0.42 (0.32–0.55)	10.4 vs 5.4; *P*<0.0001	0.37 (0.27–0.50)	17.1 vs 5.4; *P*<0.0001
Patients with ≥3 prior chemotherapy regimens						
BRCA mutant	57	26	0.21 (0.11–0.40)	13.7 vs 5.4; *P*<0.0001	0.17 (0.08–0.35)	18.0 vs 5.4; *P*<0.0001
BRCA mutant or *BRCA* wild type/high LOH	100	43	0.27 (0.16–0.44)	11.1 vs 5.4; *P*<0.0001	0.30 (0.18–0.52)	13.6 vs 5.4; *P*<0.0001
ITT	144	65	0.28 (0.19–0.41)	11.1 vs 5.3; *P*<0.0001	0.36 (0.24–0.53)	13.3 vs 5.3; *P*<0.0001

*Cox proportional hazards model; *P* values for treatment-by-prior chemotherapy regimen subgroup interaction were nonsignificant for all analyses. †Stratified log-rank *P* value. CI, confidence interval; HR, hazard ratio.

Conclusions: Maintenance treatment with rucaparib improved PFS vs placebo in all 3 predefined cohorts regardless of the number of prior chemotherapy regimens received.

Clinical trial identification: NCT01968213.

948P Intraperitoneal chemotherapy (IP CT) after cytoreductive surgery benefits survival in epithelial ovarian cancer (EOC): Results of a pooled meta-analysis including 9 randomized clinical trials (RCT)

M. Jimenez-Heredia[1], J.A. Perez Fidalgo[2], M. Morales Suarez-Varela[3], J. Sanchis[4], M. Aranda[4], A. Cervantes[2]

[1]Pharmacology, Hospital Clínico Universitario de Valencia. INCLIVA, Valencia, Spain, [2]Medical Oncology, Hospital Clinico Universitario de Valencia. INCLIVA. CIBERONC Spain, Valencia, Spain, [3]Public Health, University of Valencia. CIBERESP, Valencia, Spain, [4]Gynaecology, Hospital Clinico Universitario de Valencia. INCLIVA, Valencia, Spain

Background: IP CT after upfront cytoreductive surgery has been the standard of care in EOC. Nevertheless, results from the recent GOG252 trial showed no impact of this strategy vesus IV CT in the concurrence of bevacizumab therapy. The aim of this study was to perform a meta-analysis of the survival benefit of IP vs IV CT after cytoreductive surgery including recent evidence.

Methods: A literature search in order to identify most relevant RCT comparing IV vs IP CT after cytoreductive surgery in EOC was performed. Non comparative studies or trials with no hazard or risk ratios were excluded. Statistical analyses were done using SPSS STATISTICS V.21. Fixed-effect meta-analysis for combining data was made. Degree of heterogeneity using the I^2statistic was calculated. Endpoints meta-analysed were disease-free survival (DFS) and overall survival (OS).

Results: Initially 92 papers were identified. After exclusion criteria only nine RCT including pooled data from 3668 pts (2068 treated with IP CT and 1620 treated with IV CT) were included. In 8 RCTs IPCT was given after upfront surgery and in 1 (OV21/PETROC) after neoadjuvant CT. In all RCTs 6 CT cycles were foreseen in the IP arms. Seven RCTs including 3006 pts had DFS as endpoint. Among these, GOG252 cohorts A and B were analysed separately. IP CT showed a survival benefit over IV CT with HR = 0.86; (95% confidence interval (CI): 0.80 to 0.93). Heterogeneity was moderate (I^2=37.3) Eight RCTs including 2289 pts had OS as endpoint. IP CT showed a significant impact on OS with HR = 0.81; 95% CI: 0.73 to 0.90). Heterogeneity was low (I^2<0.01). Benefit of IP CT remained unchanged in the sensitivity analysis performed for both DFS and OS by eliminating the latest RCT of the meta-analysis.

Conclusions: IP CT benefits DFS and OS in this meta-analysis of pooled data from 9 RCTs and 3668 pts including latest negative results.

949P Mirvetuximab soravtansine, a folate receptor alpha (FRα)-targeting antibody-drug conjugate (ADC), with pembrolizumab in platinum-resistant ovarian cancer (PROC): Initial results of an expansion cohort from FORWARD II, a phase Ib study

U.A. Matulonis[1], K.N. Moore[2], L.P. Martin[3], I.B. Vergote[4], C. Castro[5], L. Gilbert[6], K. Malek[7], M.J. Birrer[8], D.M. O'Malley[9]

[1]Medical Oncology, Dana Farber Cancer Institute, Boston, MA, USA, [2]Gynecologic Oncology, Stephenson Cancer Center/University of Oklahoma, Oklahoma City, OK, USA, [3]Department of Hematology/Oncology, Fox Chase Cancer Center, Philadelphia, PA, USA, [4]Gynaecology, University Hospitals Leuven, Leuven, Belgium, [5]Medical Oncology, Massachusetts General Hospital, Boston, MA, USA, [6]Obstetrics and Gynecology, McGill University Health Center, Montreal, QC, Canada, [7]Clinical Development, Immuno Gen Inc., Waltham, MA, USA, [8]Division of Hematology-Oncology, University of Alabama at Birmingham, Birmingham, MA, USA, [9]Clinical Research Gynecologic Oncology, The Ohio State University, James Cancer Center, Columbus, OH, USA

Background: Mirvetuximab soravtansine is an ADC comprised of a FRα-binding antibody linked to the tubulin-disrupting maytansinoid DM4. This agent activates monocytes and upregulates immunogenic cell death markers on ovarian tumor cells, providing a rationale for combining with immune checkpoint blockade. Mirvetuximab soravtansine is being evaluated in combination with pembrolizumab in patients with PROC.

Methods: Eligibility criteria include FRα positivity by IHC ($\geq$ 25% of cells with $\geq$ 2+ staining intensity), 2-4 prior systemic treatments, and no prior immunotherapy. Mirvetuximab soravtansine (6 mg/kg; adjusted ideal body weight) and pembrolizumab (200 mg) were administered intravenously on day 1 of a 21-day cycle. Responses were assessed with RECIST 1.1 and adverse events (AEs) by CTCAE v4.03.

Results: During dose-escalation (n = 14 patients), the mirvetuximab soravtansine-pembrolizumab combination demonstrated favorable tolerability, with primarily $\leq$ grade 2 AEs observed. Overall, the AE profile was manageable and consistent with the known profiles of each agent. In addition, promising evidence of durable antitumor activity was observed, including a confirmed objective response rate of 43%, median duration of response of 6.9 months, and median progression-free survival of 5.2 months. These findings supported enrollment of an expansion cohort to further evaluate this combination in the setting of PROC. At time of analysis, 37/46 patients were enrolled, who received a median of 3 prior regimens. Median age was 62y (range 40-77), and 92% had tumors with high grade serous histology. Initial safety, antitumor activity, and exploratory biomarker data will be presented, including for the subset of patients with medium/high FRα expression, which showed the highest degree of clinical activity during escalation.

Conclusions: Preliminary data have demonstrated a manageable safety profile and encouraging signals of clinical activity for the mirvetuximab soravtansine-pembrolizumab combination in recurrent PROC. The results of this expansion cohort will guide further development of this novel combination.

Clinical trial identification: NCT02606305.

Background: The PARP inhibitor olaparib (Lynparza®) is approved as maintenance therapy in pts with PSR OC who are in complete or partial response to platinum-based chemotherapy. Currently, pts with SD are observed until disease progression; the efficacy of maintenance olaparib in these pts is unknown. In a Phase II study (NCT01081951), progression-free survival (PFS) was significantly prolonged in pts with PSR OC receiving olaparib plus platinum-based chemotherapy followed by maintenance olaparib vs those receiving platinum-based chemotherapy alone (Oza et al. Lancet Oncol 2015). This post hoc analysis evaluated outcomes in pts with SD on scans at the end of chemotherapy and the efficacy of maintenance olaparib vs observation.

Methods: In this open-label, multicentre trial, pts with PSR serous OC, primary peritoneal cancer or fallopian tube cancer were randomized to olaparib capsules 200 mg twice daily (bid) on days 1–10 of each 21-day cycle plus paclitaxel and carboplatin AUC 4 on day 1 (n = 81) followed by maintenance olaparib 400 mg bid (continuously), or paclitaxel and carboplatin AUC 6 on day 1 (n = 81) without maintenance olaparib. The latest scan from randomization up to 2 weeks after the final dose of carboplatin was used to assess the best objective RECIST v1.1 response at the end of chemotherapy (blinded independent central review).

Results: At the end of chemotherapy, 24 (29.6%) pts who had also received low-dose olaparib and 21 (25.9%) pts without olaparib had SD as their best response (timing of the scan ranged from 2.10 months before to 0.49 months after the last dose of carboplatin). Median PFS, calculated from the end of chemotherapy, was 8.74 months with maintenance olaparib at standard dose vs 5.40 months without maintenance olaparib (hazard ratio 0.50; 95% CI 0.25, 1.00). Delayed responses following the end of chemotherapy occurred in four pts receiving maintenance olaparib (16.7%; two complete and two partial responses) and three pts without maintenance olaparib (14.3%; all partial responses). The number of lines of prior chemotherapy did not appear predictive of PFS benefit.

Conclusions: Maintenance olaparib may prolong PFS in OC pts with SD following platinum-based therapy.

951P A phase Ib study of navicixizumab & weekly paclitaxel in heavily pre-treated platinum resistant ovarian, primary peritoneal or fallopian tube cancer

S. Fu[1], B. Corr[2], E. Hamilton[3], R.A. Burger[4], R. Wenham[5], R.W. Naumann[6], R. Stagg[7], K.N. Moore[8]

[1]Department of Investigational Cancer Therapeutics, MD Anderson Cancer Center, Houston, TX, USA, [2]Gynecologic Oncology, University of Colorado Denver, Aurora, CO, USA, [3]Gynecologic Oncology, Sarah Cannon at Tennessee Oncology, Nashville, TN, USA, [4]Gynecologic Oncology, University of Pennsylvania Medical Center, Philadelphia, PA, USA, [5]Gynecologic Oncology, Moffitt Cancer Center, Tampa, FL, USA, [6]Gynecologic Oncology, Levine Cancer Institute, Charolette, NC, USA, [7]Clinical Research, Oncomed Pharmaceuticals, Redwood City, CA, USA, [8]Gynecologic Oncology, Stephenson Cancer Center/University of Oklahoma, Oklahoma City, OK, USA

Background: Anti-VEGF & anti-DLL4 have both demonstrated single agent activity in ovarian cancer. Navicixizumab is an anti-DLL4/VEGF IgG2 bispecific monoclonal antibody that had a response rate of 25% (3/12) in heavily pretreated ovarian cancer pts who were treated in an earlier single agent phase Ia trial.

Methods: This is an ongoing Phase 1b study of paclitaxel & navicixizumab in platinum resistant ovarian cancer pts who have failed > 2 prior therapies &/or bevacizumab. Paclitaxel 80 mg/m2 is given on Days 1, 8 and 15 & navicixizumab is given on Days 1 & 15 of every 28 day cycle. This study was designed as a dose escalation trial testing navicixizumab doses of 3 or 4 mg/kg followed by an expansion cohort to enroll a total of 30 patients. The expansion cohort was undertaken with 3 mg/kg of navicixizumab as higher doses did not show increased activity, but did result in more pronounced chronic toxicity in the Phase 1a study. A standardized treatment algorithm for hypertension is being employed.

Results: Eighteen pts were treated; 5 are still ongoing. The median number of prior therapies was 4 (range 2-8), all 18 pts had received prior paclitaxel & 13 had received bevacizumab. Eight pts (44%) had a PR, 6 (33%) had SD, 2 (11%) had PD & 2 (11%) were NE. The clinical benefit rate was 78%. Ten of 14 (71%) pts with an elevated CA-125 had a GCIG-defined response. The related AEs (all grades) that occurred in > 15% of the pts were: hypertension (67%), fatigue (44%), diarrhea (44%), headache (22%), neutropenia (17%), GERD (17%) & decrease appetite (17%). Other related AEs of significance were an infusion reaction (6%), Gr2 pulmonary hypertension (6%), Gr 4 thrombocytopenia (6%) & Gr4 GI perforation (6%). Anti-drug antibody occurred in 3 of 16 pts who have been evaluated; drug exposure was impacted in 1 pt.

Conclusions: The efficacy data in these heavily pre-treated platinum resistant ovarian cancer pts are encouraging & enrollment is ongoing. The safety profile appears to be manageable with hypertension being the most common adverse event related to navicixizumab.

Clinical trial identification: NCT03030287 January 25, 2017.

[1]Gynecologic Oncology, Chaim Sheba Medical Center, Tel Aviv University, Tel Aviv, Israel, [2]Medical Oncology, Lyon University Hospital Cancer Institute, Lyon, France, [3]Gynaecology Unit, The Royal Marsden NHS Foundation Trust, London, UK, [4]NHMRC Clinical Trials Centre, University of Sydney, Camperdown, Australia, [5]Gynecologic Oncology, Hartford Healthcare Cancer Institute, New Britain, CT, USA, [6]Medical Oncology and Hematology, Princess Margaret Cancer Center, Toronto, ON, Canada, [7]Medical Oncology, Fundación Instituto Valenciano de Oncología, Valencia, Spain, [8]IRCCS Fondazione Pascale, Istituto Nazionale Tumori, Naples, Italy, [9]Walter and Eliza Hall Institute of Medical Research, Peter MacCallum Cancer Centre, Melbourne, Australia, [10]Division of Gynaecology, Istituto Europeo di Oncologia, Milan, Italy, [11]Gynaecological Oncology, Kliniken Essen-Mitte, Essen, Germany, [12]Gynecologic Oncology, National Hospital Organization Shikoku Cancer Center, Matsuyama, Japan, [13]Department of Medical Oncology, The Netherlands Cancer Institute, Amsterdam, Netherlands, [14]Department of Clinical Pharmacology and Chemotherapy, NN Blokhin Russian Cancer Research Center, Moscow, Russian Federation, [15]Gynecologic Oncology, Seoul National University College of Medicine, Seoul, Republic of Korea, [16]Oncology Research Center, Pérola Byington Hospital, São Paulo, Brazil, [17]Gynecology, University of Leuven, Leuven Cancer Institute, Leuven, Belgium, [18]Global Medicines Development, AstraZeneca, Cambridge, UK, [19]Medical Oncology, Université Paris Descartes, AP-HP, Paris, France

Background: The PARP inhibitor olaparib (Lynparza®) has shown significant efficacy as maintenance therapy for patients (pts) with PSR OC, especially pts with BRCA mutations, as capsules (Ledermann et al Lancet Oncol 2014) and tablets (Pujade-Lauraine et al Lancet Oncol 2017). Olaparib capsules have shown long-term benefit, with pts staying on treatment for ≥5 years (yrs; Gourley et al ASCO 2017). We analysed the long-

term tolerability of olaparib tablets in the SOLO2 trial (ENGOT-Ov21; NCT01874353).

Methods: In SOLO2, pts with BRCA-mutated PSR OC in response to platinum received maintenance olaparib tablets (300 mg bid) or placebo until disease progression. Adverse events (AEs) were graded by CTCAE v4.0.

Results: At the primary data cut-off (DCO; 19 Sep 2016), of 195 pts treated with olaparib, 62 (32%) had received olaparib for ≥1–<2 yrs (Group 1) and 59 (30%) for ≥2 yrs (Group 2), vs 12/99 (12%) and 9/99 (9%), respectively, who received placebo. Most AEs that began after ≥1 yr (Group 1) or ≥ 2 yrs (Group 2) were grade 1–2, with few serious AEs (Table). The most common AEs with onset during the second yr of olaparib treatment were anaemia (19%), nausea (18%), and vomiting (15%). The most common AEs with onset after ≥2 yrs were diarrhoea (8%), abdominal pain (5%), and upper abdominal pain (5%). Four pts in Group 1 discontinued olaparib because of AEs (acute myeloid leukaemia, decreased neutrophil count, muscular weakness, disturbance in attention and depression; all n = 1) vs no pts in Group 2.

Table: 952P Long-term AE data for olaparib tablets as maintenance therapy

	Group 1 (n = 62) AEs with onset reported during the second yr (≥1–<2 yrs) of olaparib treatment	Group 2 (n = 59) AEs with onset reported after ≥2 yrs of olaparib treatment
AE (any grade), n (%)	54 (87)	23 (39)
AE (grade ≥3), n (%)	11 (18)	1 (2)
Serious AE, n (%)	7 (11)	1 (2)
Dose interruption caused by AE, n (%)	14 (23)	4 (7)
Dose reduction caused by AE, n (%)	4 (6)	0
Treatment discontinuation caused by AE, n (%)	4 (6)	0

Conclusions: AEs reported during long-term olaparib maintenance therapy were mostly low grade, non-serious and associated with a low rate of treatment discontinuation. Common AEs were consistent with the known safety profile. Olaparib tablets are suitable for long-term maintenance therapy for PSR OC pts, without cumulative toxicity and with few late-onset AEs.

953P The impact of lymph node dissection on high risk versus low risk endometrial cancer

C. Zhang, A. Soochit, J.H. Liu

Gynecologic Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: The aim of this study is to determine the benefits of lymph node dissection (LND) and the pattern of recurrence in low and high risk endometrial cancer (EC) patients.

Methods: EC patients who underwent surgery as primary treatment between April 2003 to March 2012 was identified and stratified into low-risk and high-risk groups for lymph node metastasis (LNM) according to these criteria: poor differentiation, non-endometrioid histology, deep myometrial invasion, cervical stromal involvement, adnexal involvement, tumor diameter ≥ 3cm, suspicious node in imaging. Univariate survival analysis followed by Cox-regression model for multivariate analysis was used to find prognostic factors for survival. The χ^2 and Fisher's exact test were used to compare categorical valuables.

Results: A total of 847 patients were included, among whom 524 received LND. After stratification 579 patients were assigned to high-risk group while 268 patients were assigned to low-risk group. LND was performed in 451 high-risk patients and in 73 low-risk patients with a rate of positive nodes of 14.1% (n = 64) and 2.7% (n = 2), respectively. Poor differentiation, non-endometrioid histology, deep myometrial invasion and adnexal involvement were independent prognostic factors. Whereas LNM was an independent prognostic factor for overall survival (OS, p = 0.03) but not for progression-free survival (PFS, p = 0.07). LND did not improve PFS (p = 0.56) or OS (p = 0.47) in the low-risk group and was not associated with OS (p = 0.17) in high-risk group. In 89 patients who had recurrence, 73 (13.9%) occurred in those with LND and 16 (5.0%) in those without LND. In high-risk group no significant difference was noted in recurrence rate (LND 16.0% vs without LND 8.6%, p = 0.06). Distant organs (lung, liver, bone, spleen and brain) and distant lymph nodes were the most common site of recurrence in both patients who underwent (5.9%, n = 31) LND and those who did not undergo (3.4%, n = 11) LND (p = 0.14).

Conclusions: According to our findings LND seemed not to have survival benefit for both high-risk and low-risk patients based on the above criteria, and it could not decrease risk of distance recurrence. A more reliable stratification model should be considered to determine the benefit of LND in EC.

954P HOXA9 methylation in circulating tumor DNA as a prognostic biomarker in BRCA-mutated ovarian cancer patients treated with PARP inhibitor

M. Rusan[1], R. Fredslund Andersen[2], A. Jakobsen[1], K.D. Steffensen[3]

[1]Dept. of Oncology, Vejle Hospital Sygehus Lillebaelt, Vejle Sygehus, Vejle, Denmark, [2]Dept. of Biochemistry, Vejle Hospital, Vejle, Denmark, [3]Department of Clinical Oncology, Vejle Hospital Sygehus Lillebaelt, Vejle Sygehus, Vejle, Denmark

Background: Quantification of circulating tumour DNA methylation is a promising novel approach for predicting and monitoring treatment efficacy in cancer. The currently frequently employed biomarker CA-125, has been recently shown to not be prognostic for overall survival in platinum-resistant patients, making it further relevant for identifying novel biomarkers. HOXA9 promoter methylation has been observed in a large proportion of patients with high grade serous ovarian carcinoma (OC), and hypermethylation of HOXA9 is associated with worse progression-free survival and overall survival. The aim of the current study was to investigate whether HOXA9 methylation at baseline and during treatment, could predict treatment efficacy in BRCA-mutated ovarian cancer patients treated with the PARP inhibitor, Veliparib.

Methods: Plasma from OC patients was retrieved at baseline before initiation of daily oral single agent Veliparib, as well as following each treatment cycle, as part of a phase II investigator initiated trial (NCT01472783). DNA was purified from 4 ml of plasma, bisulfite converted and analysed by droplet digital PCR with a HOXA9 methylation-specific assay. Beta-2-microglobulin alleles/mL were used for normalization, and the fractional abundance of methylated HOXA9 was calculated.

Results: 32 patients were enrolled in a phase II trial, of which 24 had methylated HOXA9 at baseline. There was no significant different in overall survival based on HOXA9 methylation at baseline (p = 0.4), however patients with HOXA9 methylation following three treatment cycles had a significantly worse overall survival compared to patients with non-methylated HOXA9 (median overall survival was 8 months vs. 19 months for patients with methylated vs. non-methylated HOXA9, respectively, p = 0.0001). A similar trend was noted for progression free survival.

Conclusions: Methylation of HOXA9 detected in circulating tumor DNA may serve as a prognostic and treatment efficacy biomarker in BRCA-mutated ovarian cancer patients undergoing treatment with PARP inhibitors.

Clinical trial identification: NCT01472783.

955P Prevalence and clinical implications of mismatch repair (MMR) deficiency in unselected endometrial cancer (EC) patients

C.M.A. Orbegoso Aguilar[1], K. Vroobel[2], S. Lalondrelle[1], A. Taylor[3], M. Nobbenhuis[3], A. Attygalle[2], S. Banerjee[3], A. George[1]

[1]Gynae-Oncology Unit, Royal Marsden Hospital NHS Foundation Trust, London, UK, [2]Histopathology, Royal Marsden Hospital NHS Foundation Trust, London, UK, [3]Gynaecology, Royal Marsden Hospital NHS Foundation Trust, London, UK

Background: Endometrial cancer (EC) is the most common gynaecological malignancy worldwide. The TCGA data suggested up to 30% of EC pts have a MMR deficient (MMRd) tumours, however the exact concordance of this with the presence of a germline mutation (Lynch syndrome) in an unselected population is unclear. Lynch-associated tumours appear to have a better prognosis, however the implications for prognosis and survival in all MMRd tumours are less known.

Methods: 396 pts with primary endometrial cancer, treated at RMH were evaluated for MMR proteins by immunohistochemistry (IHC). Tumours with loss of at least one protein were considered MMRd, those with intact expression were MMR proficient (MMRp). Clinico-pathological characteristics and survival data was collected from electronic records. Progression free survival (PFS) and overall survival (OS) were assessed using Kaplan Meier and log-rank tests.

Results: Of 396 samples tested to date, 29% (114 pts) were MMRd. Frequencies of IHC MMR loss of expression were: MLH1/PMS2 loss: 80, MSH2/MSH6 loss: 10, MSH6 loss: 12, PMS2 loss: 9, other patterns: 3. Germline testing has been completed in 37% (42 pts) thus far; 14pts had a concordant germline mutation: MLH1 (2/25), MSH2 (3/7), MSH6 (7/8), PMS2 (2/2) respectively. Mean age varied significantly, at 66 yrs (MMRd), 65yrs (MMRp) and 58 yrs (Lynch mutation carriers, LS) $p = 0.022$: as did mean BMI: 33 (MMRd), 26 (LS) and 36 (MMRp), $p = 0.023$. Stage at diagnosis did not differ significantly between the groups but MMRd and LS patients were significantly more likely to have LVSI than MMRp ($p = 0.01$), and to be high EORTC risk ($p = 0.006$). OS for the entire cohort was 160mths (75-244.9) and PFS was 51.6mths (32.4-70.7). MMRd pts had a shorter OS (96.4mths, 95%CI 65.7 – 127) than MMRp (160mo, 54.9 – 265) and a shorter PFS median PFS 41.4mo (IC 95% 18.9– 64) vs 51.6mo (IC 95% 30- 72), p.021].

Conclusions: Almost one in three EC tumours are MMRd, with concordance between IHC loss and presence of a germline mutation varying by gene. Those with somatically derived MLH1/PMS2 loss may have a poorer prognosis, and as a group may potentially benefit from checkpoint inhibitors. Further exploration of the clinical correlations and outcome with MMR status is warranted.

956P A phase Ib and randomised phase II trial of pazopanib with or without fosbretabulin in advanced recurrent ovarian cancer

R.D. Morgan[1], G.C. Jayson[1], S. Banerjee[2], A.R. Clamp[1], A.R. Lyon[3], W.D. Ryder[4], R. Hutson[5], N. Mescallado[1], C. Orbegoso Aguilar[6], S. Taylor[7], J. Tugwood[7], M. Hall[8], C. Dive[9], G.J.S. Rustin[8]

[1]Medical Oncology, The Christie NHS Foundation Trust, Manchester, UK, [2]Gynaecology, The Royal Marsden NHS Foundation Trust in Chelsea, London, UK, [3]Cardiology, Royal Brompton Hospital and Imperial College, London, London, UK, [4]MAHSC-CTU, The Christie NHS Foundation Trust, Manchester, UK, [5]CTU, The Christie NHS Foundation Trust, Manchester, UK, [6]Medical Oncology, Royal Marsden Hospital NHS Foundation Trust, London, UK, [7]Clinical & Experimental Pharmacology Group, Cancer Research UK Manchester Institute, Macclesfield, UK, [8]Medical Oncology, Mount Vernon Cancer Centre, Northwood, Middlesex, UK, [9]Clinical & Experimental Pharmacology, Cancer Research UK Manchester Institute, Manchester, UK

Background: Prospective trials have validated angiogenesis as a treatment target in ovarian cancer although improvements in PFS have been modest. One potential strategy to improve efficacy is to combine anti-vascular agents. Fosbretabulin (F) is an intravenous vascular disrupting agent and pazopanib (P) is an oral VEGFR tyrosine kinase inhibitor.

Methods: A multi-centre Phase 1b(P1b)/randomised phase 2 (RP2) trial that recruited women with recurrent epithelial ovarian cancer and a platinum-free interval of 3-12 months. Any Bevacizumab had been received $\geq$6 months prior to recruitment. Phase 1b dose levels ranged from $F = 54mg/m^2$ d1,8,15q28d + $P = 600mg/day$ (F54+P600) up to $F = 60mg/m^2$ d1,8,15q28d + $P = 800mg/day$. In RP2 participants received either RP2D or $P = 800mg/day$ (P800). Primary outcome in P1b was safety plus RP2D and in RP2 was RECIST PFS.

Results: 12 and 21 patients were recruited to P1b & RP2 respectively. The RP2D was F54+P600. In the RP2 median PFS was 7.6 months (95%CI 4.1-not estimated) in F54+P600 group vs. 3.7 months (95%CI 1.0-8.1) in P800 group (HR 0.30, 95%CI 0.08-1.03, $P = 0.06$). Four patients who received F+P (2 in P1b and 2 in RP2) developed acute hypertension plus reversible secondary cardiac toxicity. The occurrence of cardiac toxicity resulted in premature discontinuation of the trial. Data on circulating biomarkers of angiogenesis collected in in P1b & RP2 will also be presented.

Conclusions: F54+P600 appeared effective but was associated with reversible secondary cardiac toxicity that with better hypertension control might have been avoided.

Clinical trial identification: EudraCT: 2013-005471-40.

Legal entity responsible for the study: The Christie NHS Foundation Trust.

Funding: Novartis & Mateon Therapeutics.

Disclosure: G.J.S. Rustin: Advisory board: Mateon, Roche, AstraZeneca in past 3 years, only Roche in past year. All other authors have declared no conflicts of interest.

957P Genomic profiling of the residual disease of advanced high-grade serous ovarian cancer after neoadjuvant chemotherapy

J-Y. Lee[1], S. Paik[2]

[1]Gynecologic Cancer Center, Yonsei Cancer Center Yonsei University, Seoul, Republic of Korea, [2]Genomics, Yonsei University, Seoul, Republic of Korea

Background: Tumor response to NAC predicts survival and can be considered a surrogate prognostic marker. Three tiered chemotherapy response score (CRS) of omental tissue sections showed a significant association with survival. In patients with CRS 1 or 2, NAC selects a subpopulation of chemotherapy resistant tumor cells. Residual tumors remaining after neoadjuvant chemotherapy contain cell population intrinsically resistant to chemotherapy. However, the standard of care for patients who have residual disease after NAC is the same regimen, as therapies that would be effective in reducing recurrences are unknown. We hypothesize that comprehensive molecular analyses of residual disease after NAC measured by targeted sequencing and Immunohistochemistry would be helpful to find out innovate new therapeutic targets.

Methods: During the study period between 2006 and 2018, Pre- and post NAC tumor tissue samples were collected from patients with advanced HGSC. Combined NGS and IHC was performed to identify actionable target and pathway activation in chemo-resistant tumor cells. We examined whether profiling residual HGSC after NAC identifies targetable molecular lesions in the chemotherapy-resistant component of tumor.

Results: Alteration in TP53 were identified in 76 of 104 post-NAC samples (72.1%). HRR gene alteration were found in 30 of 104 post-NAC samples (28.8%). Patients with DNA repair alterations (BRCA1, BRCA2, ATM mutations) were found in 30% of HGSC and they had better chemotherapy sensitivity and survival outcomes than those with intact DNA repair system. Otherwise, rare individual actionable targets (less than 5%) were found in most of patients.

Conclusions: We showed the genomic landscape of drug-resistant tumor cells remaining in advanced HGSC after NAC.

Clinical trial identification: NCT03491033.

Legal entity responsible for the study: Jung-Yun Lee.

Funding: NRF.

Disclosure: All authors have declared no conflicts of interest.

958P Cemiplimab, a human PD-1 monoclonal antibody, in patients (pts) with recurrent or metastatic cervical cancer: Interim data from phase I cohorts

D. Rischin[1], M. Gil-Martin[2], A. González-Martín[3], I. Brana[4], J.Y. Hou[5], D. Cho[6], G.S. Falchook[7], S. Formenti[8], S. Jabbour[9], K. Moore[10], A. Naing[11], K.P. Papadopoulos[12], J. Baranda[13], A. Weise[14], M.G. Fury[15], M. Feng[16], J. Li[17], I. Lowy[15], M. Mathias[15]

Background: For pts who progress after first–line platinum based therapy for recurrent/metastatic cervical cancer, there are no therapies available that have been demonstrated to improve survival or quality of life. Cemiplimab (REGN2810), a human monoclonal antibody to PD-1, exhibited encouraging efficacy and acceptable tolerability in a phase 1 dose escalation study. The present report focuses on interim data from the phase 1 cervical cancer expansion cohorts (ECs) of cemiplimab as a monotherapy

(EC 23) or in combination with hypofractionated radiotherapy (hfRT) (EC 24) (NCT02383212).

Methods: Pts with recurrent or metastatic cervical cancer resistant to or intolerant of platinum and taxane doublet therapy received cemiplimab 3 mg/kg Q2W for up to 48 weeks, in ECs 23 and 24, and hfRT (9 Gy x 3 times/week given 1 week after first dose of cemiplimab) in EC 24. The co-primary objectives were to evaluate the safety, tolerability, and efficacy of cemiplimab monotherapy or in combination with hfRT. Tumour response assessments (in non-irradiated target lesions) were performed by RECIST 1.1 Q8W.

Results: As of 1 Sept, 2017, these ECs were fully enrolled with 20 pts (EC 23, n = 10, EC 24, n = 10). Median (range) age was 55.0 (31–76) years (EC 23) and 51.5 (29–65) years (EC 24). ECOG performance status 1 vs. 0 was 60% vs. 40% and 80% vs. 20%, respectively, for EC 23 and EC 24. Investigator-assessed overall response rate (ORR; complete response [CR] + partial response [PR]) was 10.0% (0 CR and 1 PR) in each of EC 23 and EC 24. At the time of data cut-off, both responses were ongoing with durations of 3.7+ months. The most common treatment-emergent adverse events (TEAEs) of any grade were diarrhoea (40.0%), fatigue, hypokalaemia and pain in extremity (each 30.0%) in EC 23, and diarrhoea and urinary tract infection (each 30.0%) in EC 24. There was no grade ≥3 TEAE reported in > 1 patient in either cohort.

Conclusions: Cemiplimab as monotherapy and in combination with hfRT demonstrated antitumour activity with an acceptable safety profile in pts with metastatic or recurrent cervical cancer. Cemiplimab monotherapy vs. chemotherapy in ≥ 2nd line cervical cancer is currently being evaluated in a global randomised phase 3 study (NCT03257267).

Clinical trial identification: NCT02383212.

959P Molecular profiles as a function of treatment response/progression free survival in a prospective cervical cancer study (RAIDs)

S. Scholl[1], L. De Koning[2], M. Popovic[3], D.L.R. Anne[4], A. Floquet[5], E. Berns[6], G. Kenter[7], A. Kereszt[8], E. Girard[9], H. von der Leyen[10], S. Dureau[11], V. Fourchotte[12], R. Rouzier[12], M. Kamal[1], R. Consortium[1]

[1]Department of Drug Development and Innovation, Institut Curie, Paris, France, [2]Translational Department, Institut Curie, Paris, France, [3]Surgery, Institut of Oncology of Vojvodina, Novisad, Serbia, [4]Radiotherapy, Institut Curie, Paris, France, [5]Oncologie Médicale, Institute Bergonié, Bordeaux, France, [6]Biology, Erasmus, Rotterdam, Netherlands, [7]Gynaecology, NKI, Amsterdam, Netherlands, [8]SeqOmics, Moraholem, Hungary, [9]Bioinformatics, Institut Curie, Paris, France, [10]HCTC, Hanover, Germany, [11]Biometry, Institut Curie, Paris, France, [12]Surgery, Institut Curie, Paris, France

Background: BioRAIDs is a supervised longitudinal collection of tumor and blood together with clinical outcome data in 419 primary cervical cancer patients from 7 European countries (NCT02428842).

Methods: Molecular analysis [Next Generation Sequencing (NGS) at SeqOmics (Hungary) & Reverse Phase Protein array (RPPA) at Institut Curie] was performed on quality-controlled primary tumor samples in 295 patients (70%) who subsequently had received primary radio chemotherapy (RCT). Integrative bioinformatics analyses were performed to identify pathway activations suggesting the need for additional/different therapies.

Results: NGS demonstrated driver Tyrosine Kinase Receptor/ PI3 kinase (TKR/PI3K) pathway mutations in 27%; TKR/PI3K + epigenetic pathway alterations (MLL2, MLL3) in 32 % and epigenetic alterations alone in 13% of patients. At a median follow up of 19 months [2-38], tumors for which no mutations in relevant genes from the TKR/PI3K pathways nor alterations in genes involved in epigenetic signaling appeared to be associated with a significantly better prognostic profile: HR = 2.4 [95% CI: 1.1 – 5.2]. RPPA analysis was carried out separating patients in 3 subgroups according to signaling pathway activation [EMT (epithelial mesenchymal transition), DNA damage and MAPK/PI3K], none of which was associated with bad prognosis.

Conclusions: The high frequency of epigenetic alterations with or without TKR/PI3K pathway mutations, suggests that epigenetically acting drugs (Vorinostat[R]) may be relevant for patients whose tumors have genetic mutations of significance in epigenetically acting enzymes. Relevance of copy number alterations and of other frequently mutated genes (CSMD3, SYNE1), needs to be integrated and cross validated in a larger complementary dataset.

Clinical trial identification: NCT02428842.

960P Phase I study of BVAC-C in HPV type 16 or 18 positive recurrent cervical carcinoma: Safety, clinical activity and immunologic correlates

C.H. Choi[1], H.J. Choi[2], J-W. Lee[2], E-S. Kang[2], D. Cho[2], Y-M. Kim[3], D. Kim[3], H. Seo[4], M. Park[4], W. Kim[5], T. Oh[5], C-Y. Kang[4], B-G. Kim[2]

[1]Obstetrics and Gynecology, Samsung Medical Center Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [2]Obstetrics and Gynecology, Samsung Medical Center, Seoul, Republic of Korea, [3]Obstetrics and Gynecology, Asan Medical Center, Seoul, Republic of Korea, [4]Molecular Medicine and Biopharmaceutical Sciences, Seoul National University, Seoul, Republic of Korea, [5]Cellid Inc., Seoul, Republic of Korea

Background: BVAC-C is a B cell- and monocyte-based immunotherapeutic vaccine transfected with recombinant HPV E6/E7 gene and loaded with alpha-galactosyl ceramide, a natural killer T cell ligand. It may have activity against HPV positive cancer. This phase I study was performed to determine the safety and tolerability of BVAC-C in patients with HPV type 16 or 18 positive recurrent cervical carcinoma and to preliminarily assess antitumor activity and immunologic correlates.

Methods: Ten patients who had experienced recurrence after at least one prior platinum-based combination chemotherapy, received three intravenous infusion of BVAC-C every 4 weeks in dose-escalating three-patient cohorts at $1x10^7$, $4x10^7$, or $1x10^8$ cells/dose.

Results: BVAC-C was well tolerated: grade 1 fever or myalgia were the most frequently observed without any grade 3 or 4 toxicity. One patient expired 3 weeks following 3rd dose for clinical disease progression. Of the 8 evaluable cases, one partial responses (12.5 %), and four stable diseases (50%) were seen. Three patients are surviving more than a year. Adenocarcinoma and bulky tumor burden were associated with poor response to the therapy. Immunologic response analysis showed that BVAC-C induced activation of natural killer T cells, natural killer cells, and HPV E6/E7 specific CD4 and CD8 T cells upon vaccinations in all patients evaluated. More follow-up results will be presented.

Conclusions: BVAC-C is well tolerated and associated with evidence of antitumor activity in HPV 16 or 18 positive cervical carcinoma. We are now planning further phase 2 efficacy trial.

Clinical trial identification: NCT02866006.

961P Risk of secondary hematological malignancies and hematological toxicities in recurrent ovarian cancer patients treated with poly adenosine diphosphate ribose polymerase (PARP) inhibitors maintenance

K.Z. Thein[1], A. Sultan[1], M.H. Zaw[2], M.M. Han[3], R. Yendala[1], M.M. Zin[4], S. Awasthi[1], N. D'Cunha[1], F. Hardwicke[1], C. Jones[1]

[1]Hematology Oncology, Texas Tech University Health Sciences Center, Lubbock, TX, USA, [2]Internal Medicine, The Brooklyn Hospital Center, Brooklyn, NY, USA, [3]Oncologic Emergency, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [4]Internal Medicine, Kingsbrook Jewish Medical Center, Brooklyn, NY, USA

Background: Most patients with advanced ovarian cancer, the eighth most common cause of cancer death in women worldwide, recur after they receive initial platinum-based chemotherapy. PARP inhibitors showed a synthetic lethality in cancer cells via specific DNA repair defects. Yet, the risk of secondary hematological malignancies (SHM) and hematological toxicities, remains substantial. We undertook a systematic review and meta-analysis of randomized controlled trials (RCT) to determine the risk of SHM and hematological toxicities.

Methods: MEDLINE, EMBASE databases and meeting abstracts from inception through March 2018 were queried. Phase III RCTs that mention any hematological malignancies and toxicities as adverse effects were incorporated in the analysis. Mantel-Haenszel (MH) method was used to calculate the estimated pooled risk ratio (RR) and absolute risk difference (RD) with 95% confidence interval (CI). Fixed effects model was applied.

Results: Three phase III RCTs with 1401 patients were eligible. The study arms used olaparib or niraparib or rucaparib while the control arms utilized placebo. The I^2 statistic for heterogeneity was 16.86, and the heterogeneity X^2 (Cochran's Q) was 2 ($P = 0.30$), suggesting homogeneity. The SHM incidence was 12 (1.28%) in PARP inhibitors group vs 5 (1.07%) in control group. The RR for SHM was 1.14 (95% CI: 0.42 – 3.08, $P = 0.79$) and RD was 0.002 (95% CI: - 0.01 – 0.014, $P = 0.72$). The RR of all-grade side effects were as follows: anemia, 6.57 (95% CI: 4.64 – 9.30, $p < 0.001$); thrombocytopenia, 9.80 (95% CI: 6.19 – 15.50, $p < 0.001$); and neutropenia, 4.13 (95% CI: 2.79 – 6.12, $p < 0.001$). The RR of high-grade adverse effects were as follows: anemia, 28.85 (95% CI: 10.06 – 82.72, $p < 0.001$); thrombocytopenia, 28.74 (95% CI: 8.24 – 100.24, $p < 0.001$); and neutropenia, 5.90 (95% CI: 3.01 – 11.57, $p < 0.001$).

Conclusions: Patients on PARP inhibitors experienced a notable increase in the risk of all grades of hematological toxicities. However, there was no significant increase in the risk of secondary hematological malignancies in PARP inhibitors group. Long-term follow-up of these patients is required to determine the actual relation.

Background: Treatment options for recurrent or metastatic cervical cancer are limited, with no standard of care beyond 1L treatment and 2L response rates of ~13%. Tisotumab vedotin (TV) is an antibody-drug conjugate comprised of a fully human monoclonal antibody specific for tissue factor (TF) conjugated to the microtubule disrupting-agent monomethyl auristatin E (MMAE) via a protease cleavable linker. TV is being evaluated in GEN701 (innovaTV 201), a Phase I/IIa dose-escalation and expansion study in patients (pts) with previously treated recurrent locally advanced or metastatic solid tumours. A previous report of the preliminary expansion cohort for cervical cancer (n = 34) showed an investigator (INV)-assessed response rate of 32% (26% confirmed) (Vergote et al., ESMO 2017 abstract #931O). INV response for the full cervical expansion cohort (N = 55) and response by independent imaging review (IIR) (n = 34) are presented here.

Methods: Key eligibility criteria included recurrent or metastatic cervical cancer that progressed on standard therapy, adequate organ function and ECOG 0-1. TV 2 mg/kg Q3W was given until progression, toxicity or withdrawal. Activity and safety were assessed by RECIST 1.1 and CTCAE 4.03, respectively. Enrollment started in November 2015 and continued through May 2018.

Results: The full cohort has 55 pts (median age was 47 y [21-74]). Updated efficacy by INV review, safety data, and response by TF expression will be presented. Median age in the first 34 pts was 44 y (21-74) and pts received a median of 2 prior lines for recurrent or metastatic disease. ORR by IIR of 41% (95% CI: 25%-59%), including 1 CR and 13 PR. 8 (1 CR, 7 PRs) were confirmed (24%; 95% CI: 11%-41%). Confirmed response rate was concordant between INV and IIR (26% and 24%). Median duration of response was 4.9 months and median PFS was 4.2 months by IIR.

Conclusions: These data demonstrate that TV has encouraging activity in previously treated recurrent or metastatic cervical cancer, an underserved population with a high unmet need, and that responses observed with TV are numerically higher than those achieved by historical controls. These data support the continued investigation of TV in this population.

Clinical trial identification: NCT02001623.

Background: Aim of this study was to evaluate the predictive role for C-reactive protein (CRP) and thrombocyte count as surrogate markers for the interleukin-6 pathway for longterm survival with ovarian cancer.

Methods: Patients and methods: Within the tumorbank ovarian cancer (TOC) preoperative CRP values and thrombocyte counts were collected for longterm survivors (survival of $\geq$ 8 years after initial diagnosis) from seven gynecologic-oncology centers as well as classical ovarian cancer patients diagnosed in the same timeframe (survival < 5 years after initial diagnosis). Receiver operating characteristics (ROC) curves and logistic regression analyses were conducted to evaluate differences between cohorts.

Results: In this study 336 longterm survivors (LTS) and 172 control patients could be included. There was no difference in preoperative thrombocyte count with a median of 326/nl in LTS (n = 136) vs. 325/nl in control patients (n = 151), $p = 0.59$. Regarding preoperative CRP values at initial diagnosis there was a significant difference in both univariate and multivariate analyses: Median CRP was 9.2 mg/l in LTS (n = 56) compared to 18.4 mg/l in control patients (n = 85), $p = 0.002$. ROC-curves showed an area under the curve of 0.66 (95% CI 0.56-0.75), $p = 0.002$. After adjusting for age, FIGO stage, grading and histology there was still a significant difference between the two cohorts ($p = 0.002$). Patients with CRP <1.3 mg/l had a 15-fold higher chance to survive longer than eight years compared to patients with a CRP >40 mg/l at initial diagnosis ($p = 0.001$, 95% CI 3.3-70.5).

Conclusions: Preoperative C-reactive protein was significantly lower in longterm survivors compared to classical ovarian cancer patients indicating the potential role of CRP as prognostic marker for longterm survival. Further studies are highly warranted in order to gain more insight in this unique and sparcely known patient cohort.

Background: Uterine leiomyosarcomas (uLMSs) are rare and aggressive tumours. Despite complete tumour resection, uLMSs are destined to relapse, and its prognosis is poor. The prognostic factors are not sufficiently known.

Methods: We performed a multi-institutional, retrospective study of women with stage I–IV uLMS, who were diagnosed between 2000 and 2012. For all cases, the histopathological slides of primary lesions were submitted to the central pathological review. Data obtained from medical records included clinicopathological factors, treatment and outcome information.

Results: In total of 259 patients (median age 54 years) were confirmed to have uLMS of which 159 (61%) were stage I, 19 (7%) were stage II, 21 (8%) were stage III, 58 (22%) were stage IV and 2 (1%) were unknown. The median disease-free survival (DFS) period was 18.2 months [95% confidence interval (CI) 13.6–24.1], and the median overall survival (OS) period was 44.2 months [95% CI 32.7–66.2]. Overall, 161 (62%) patients received adjuvant treatment; 155 (60%) received chemotherapy and 8 received radiotherapy. With regard to chemotherapy regimens, 65 (42%) were given docetaxel and gemcitabine; 32 (21%) were given Ifosfamide, doxorubicin and cisplatin; 10 (6%) were administered taxane and carboplatin; 39 (25%) were given other regimens and 9 (6%) were unknown. In a multivariate analysis, stage III–IV disease, high serum lactate dehydrogenase (LDH) level and no adjuvant treatment were significantly associated with shorter median DFS and OS periods. Even in stage I of the disease, high LDH level and no adjuvant treatment were significantly associated with shorter median DFS and OS.

Conclusions: Advanced stage, high LDH level and no adjuvant treatment were associated with poor prognoses. In stage I of the disease, when the tumour was confined to the corpus uteri, postoperative adjuvant chemotherapy was associated with improved survival.

966P Screening for inherited cancer syndromes in Chinese patients with endometrial cancer

H. Wang[1], W. Tian[1], R. Bi[2], Y. Ren[1], H. He[3], S. Shi[4], B. Shan[1], Q. Wang[5]

[1]Department of Gynecologic Oncology, Fudan University Shanghai Cancer Center, Shanghai, China, [2]Department of Pathology, Fudan University Shanghai Cancer Center, Shanghai, China, [3]Medical Affairs, Shanghai Topgen Bio-Pharm Co, Ltd., Shanghai, China, [4]Research and Development, Shanghai Topgen Bio-Pharm Co, Ltd., Shanghai, China, [5]Plateforme de Génomique des Cancers, Centre Léon Bérard, Lyon, France

Background: Endometrial cancer (EC) is a component of several cancer syndromes especially the Lynch syndrome, caused by the germline mutations in corresponding cancer predisposition genes. This study aims to outline the mutation prevalence, clinical and biological characteristics of the cancer susceptibility genes in Chinese EC patients, and to establish a screening criterion for identifying affected individuals.

Methods: The pathologic diagnosed EC patients meeting at least one of the following criteria were involved: (1) diagnosed before 50 years, (2) personal or (3) family history of Lynch related cancers, (4) loss of any MMR protein expression by immunohistochemistry (IHC). Next generation sequencing (NGS) was used for the germline mutation screening in 29 genes (APC, ATM, AXIN2, BLM, BMPR1A, BRCA1, BRCA2, BUB1B, CDH1, CDKN2A, CHEK2, EPCAM, GALNT12, GREM1, MLH1, MLH3, MSH2, MSH3, MSH6, MUTYH, PALB2, PMS1, PMS2, POLD1, POLE, PTEN, SMAD4, STK11 and TP53). Multiplex ligation-dependent probe amplification (MLPA) method were used for quantitative detection of genomic deletions and duplications.

Results: Of the 199 patients recruited, 71 (35.7%) were diagnosed before 50 years, 26 (13.1%) had a second LS related cancer, 50 (25.1%) had a family history and 157 (78.9%) performed dMMR by IHC. We identified 43 (21.6%) deleterious mutations, of which, 41 located in LS associated genes (10 MLH1, 17 MSH2, 11 MSH6 and 3 PMS2) and 2 located in non-LS genes (1 BRCA1 and 1 PALB2). 58 uncertain significance variations were also identified in 53 patients (26.6%) while 20 (34.5%) of them were located in LS genes. Two suspected genomic deletion in MSH2 were detected and were still under further verification. 18 (72%) deleterious mutations were detected in the 25 patients meeting 3 or 4 inclusion criteria and 12 (25%) were detected in 48 patients meeting 2 criteria.

Conclusions: To our knowledge, this is the first NGS based study focus on inherited EC in Asian population. The high frequency of positive results indicated that multi-gene panel testing could be recommended to the patients with high risk of hereditary EC. The selection criterion used in current study is feasible and at a high sensitivity for screening the suspected inherited individuals.

967P Clinical relevance of circulating MACC1 and S100A4 transcripts in serum of ovarian cancer patients

P. Wimberger[1], T. Link[1], P. Herrmann[2], D. Kobelt[2], Y. Vassileva[1], F. Kerstin[3], J.D. Kuhlmann[1], U. Stein[2]

[1]Department of Gynecology and Obstetrics, Technische Universität Dresden, Dresden, Germany, [2]Dept. Translational Oncology of Solid Tumors, Charité - Universitätsmedizin Berlin, Berlin, Germany, [3]DRK-Blood Donor Service, ITM Plauen, Dresden, Germany

Background: Metastasis-associated in colon cancer 1 (MACC1) and S100 calcium binding protein A4 (S100A4) promote metastasis. Their overexpression in the tumor was proposed as a prognostic and/or predictive biomarker for a variety of solid malignancies, including ovarian cancer. However, clinical relevance of circulating MACC1 and S100A4 transcripts as blood-based biomarkers for ovarian cancer is unknown. Therefore, the objective of our study was to systematically track serum levels of both transcripts in the course of surgery and adjuvant therapy and to analyze their clinical relevance for ovarian cancer.

Methods: The levels of MACC1 and S100A4 transcripts were analyzed in a total of 318 serum samples from 79 ovarian cancer patients (thereof 80% FIGO III or IV), including samples at primary diagnosis and at 4 follow-up time points in the course of treatment. MACC1 was relatively quantified by RT-qPCR and S100A4 was absolutely quantified by digital droplet PCR.

Results: MACC1 and S100A4 transcripts were significantly elevated in serum of ovarian cancer patients, compared to healthy controls ($p = 0.024$;$p<0.001$) and showed a highly concordant (CA125 independent) dynamic in the course of treatment. Higher levels of MACC1 and S100A4 at primary diagnosis paralleled advanced disease ($p = 0.023$;$p=0.004$) and predicted ineffective primary debulking surgery with no achievement of a macroscopically complete tumor resection ($p = 0.011$;$p=0.006$). Moreover, higher levels of MACC1 and S100A4 at primary diagnosis indicated poor DFS ($p = 0.0035$; $p = 0.0019$) and OS ($p < 0.001$;$p=0.001$).

Conclusions: This is the first liquid biopsy approach, systematically analyzing MACC1 and S100A4 transcripts in ovarian cancer and proposing their prognostic capacity at primary diagnosis.

968P Outcomes of ovarian clear cell carcinoma (OCCC) of the Vall d'Hebron Hospital/Vall d'Hebron Institute of Oncology (VHIO)

F. Amair Pinedo[1], L. Fariñas-Madrid[1], V. Rodriguez Freixinos[1], F.J. Ros Montañá[1], G. Villacampa[2], R. Dienstmann[2], A. Oaknin[1]

[1]Medical Oncology, Vall d'Hebron University Hospital, Barcelona, Spain, [2]Oncology Data Science, Vall d'Hebron University Hospital, Barcelona, Spain

Background: OCCC is a rare entity linked to good prognosis at early stages but chemoresistance and poor survival in advanced setting. Molecular heterogeneity is common in OCCC, with PI3K/mTOR pathway alterations as most common drivers.

Methods: Consecutive series of 75 patients (pts) with OCCC treated in VHH/VHIO from 2000 to 2016. Objective: to study outcomes with standard therapy (progression-free survival [PFS], overall survival [OS]) and treatment selection in a chemotherapy (ChT) resistant setting based on molecular profiling performed in house (targeted NGS panel).

Results: Median age was 55 years (y), FIGO (2014) stage I 51%, II 11%, III 33%, IV 5%. Primary surgery was performed in 92% achieving optimal cytoreduction in 86%. All pts received first-line of platinum (Pt)-based ChT. With a median follow-up of 9.5 y,

50.6% pts relapsed (I 34.2%, II 62.5%, III 68%, IV 50%), median OS was 11.2 y (CI95%: 6-NR). Factors significantly associated with relapse and death in univariate Cox models were ECOG performance status and stage at diagnosis ($p < 0.001$). At 1st and 2nd relapse, 58 and 50% remained Pt-sensitive, respectively. Median PFS with therapies after 1st relapse in a Pt-sensitive setting (91% Pt combos) was 12.6 months (m) (CI95% 9.5-25.4) and in Pt-resistant setting (69% non-platinum ChT) 3 m (2.5-NA). In total, 18 pts (24%) had genomic profiling (7 PIK3CA mut, 1 BRCA1 mut, 1 MSH6 mut), and 16 pts (21%) received experimental agents after 1st relapse (8 antiangiogenic, 4 targeted or immunotherapy unmatched, 4 targeted matched [3 PI3K inh and 1 PARP inh]). Median PFS was 4.8, 5.6 and 9.6 m respectively. When compared to non-Pt ChT in a Pt-resistant setting increased PFS was found with matched targeted agents (HR = 0.26, CI95% 0.1-1).

Conclusions: As reported in the literature, in our cohort, OCCC are more frequent diagnosed at early stages having a better prognosis. In the relapse setting Pt sensibility and Pt-based ChT imply better outcomes. However, in the Pt-resistant setting targeted therapies result in better PFS compared to ChT. Molecular profiling allows to select matched agents which may improve outcomes in this poor prognosis population. Further research in molecular characterization and matched targeted therapy is an unmet need.

969P A systematic review and meta- analysis of randomized controlled trials to evaluate the risk of gastrointestinal and hepatic toxicities in patients with recurrent ovarian cancer treated with poly adenosine diphosphate ribose polymerase inhibitors maintenance

K.Z. Thein[1], A. Sultan[1], M.H. Zaw[2], M.M. Han[3], A.M. Hein[4], H.H. Aung[5], S. Awasthi[1], C. Jones[1], F. Hardwicke[1], N. D'Cunha[1]

[1]Hematology Oncology, Texas Tech University Health Sciences Center, Lubbock, TX, USA, [2]Internal Medicine, The Brooklyn Hospital Center, Brooklyn, NY, USA, [3]Oncologic Emergency, The University of Texas MD Anderson Cancer Center, Houston, TX, USA, [4]Internal Medicine, Nassau University Medical Center, New York, NY, USA, [5]Internal Medicine, Kingsbrook Jewish Medical Center, New York, NY, USA

Background: Inhibition of poly adenosine diphosphate ribose polymerase (PARP) enzymes resulted in synthetic lethality in ovarian cancer cells by terminating an alternative DNA repair pathway in homologous recombination deficient tumors. Many PARP inhibitors have shown to improve survival with noteworthy safety concerns. We undertook a systematic review and meta-analysis of randomized controlled trials (RCT) to determine the risk of gastrointestinal (GI) and hepatic toxicities.

Methods: We conducted a comprehensive literature search using MEDLINE, EMBASE databases and meeting abstracts from inception through March 2018. Phase III RCTs that mention GI toxicities and elevation of liver function tests (LFT) either aspartate or alanine aminotransferase as adverse effects were incorporated in the analysis. Mantel-Haenszel (MH) method was used to calculate the estimated pooled risk ratio (RR) with 95% confidence interval (CI). Fixed effects model was applied.

Results: Three phase III RCTs with 1401 patients were eligible. The study arms used olaparib or niraparib or rucaparib while the control arms utilized placebo. The randomization ratio was 2:1 in all studies. The RR of all-grade side effects were as follows: diarrhea, 1.29 (95% CI: 1.05 – 1.58, P = 0.015); dyspepsia, 1.73 (95% CI: 1.20 – 2.49, P = 0.003); nausea, 2.11 (95% CI: 1.86 – 2.40, P < 0.001); vomiting, 2.20 (95% CI: 1.76 – 2.75, P < 0.001); dysgeusia, 4.38 (95% CI: 3.00 – 6.41, P < 0.001); and elevated LFT, 4.74 (95% CI: 2.82 – 7.95, P < 0.001). The RR of high-grade side effects were as follows: diarrhea, 1.225 (95% CI: 0.992 – 1.512, P = 0.060); nausea, 4.35 (95% CI: 1.45 – 13.06, P = 0.009); vomiting, 3.39 (95% CI: 1.19 – 9.63, P = 0.02); and elevated LFT, 10.19 (95% CI: 2.47 – 42.06, P = 0.001).

Conclusions: Our meta-analysis demonstrated that PARP inhibitors increased the risk of all grades of GI and hepatic toxicities with a relative risk of 10.19 for grade 3 and 4 elevated LFT. These toxicities have significant impact on patients' quality of life and may ultimately affect patients' compliance. Timely intervention with proper supportive care is necessary.

970P Evaluation of chemotherapy response score and lymphocytic infiltration as prognostic markers in ovarian cancer patients treated with neoadjuvant chemotherapy

M. Liontos[1], M. Sotiropoulou[2], M. Kaparelou[1], K. Tzannis[1], G. Tsironis[1], A. Kyriazoglou[1], A. Tsiara[1], R. Zakopoulou[1], K. Koutsoukos[1], F. Zagouri[1], D. Vlachos[3], N. Thomakos[3], D. Haidopoulos[3], A. Rodolakis[3], M.A.C. Dimopoulos[1], A. Bamias[1]

[1]Oncology Unit, Department of Clinical Therapeutics, Alexandra Hospital, Athens, Greece, [2]Pathology Department, Alexandra Hospital, Athens, Greece, [3]Obstetrics and Gynecology Department, Alexandra Hospital, Athens, Greece

Background: Neoadjuvant Chemotherapy (NACT) followed by Interval Debulking Surgery (IDS) is an alternative frontline treatment in patients with advanced Epithelial Ovarian Cancer (EOC). Histopathologic assessment of tumor post NACT is an ideal mean of response to treatment. The present study aims to characterize the pathological response and to examine its prognostic significance in these patients.

Methods: Medical records of women with EOC treated at Alexandra Hospital from 2011 to 2016 were retrospectively identified. Clinicopathological data, treatment and survival data were analyzed. IDS specimens were reviewed by study pathologist and Chemotherapy Response Score (CRS), lymphocytic infiltration, necrosis and mitosis were assessed. Survival differences were estimated using the long-rank test.

Results: 55 patients with EOC treated with NACT were identified, 48 had complete clinical and pathological data. Median age was 63 years. All patients had high grade disease and 45 of them had serous carcinoma. At baseline 38 patients had stage IIIc disease and 10 stage IV. All patients received Paclitaxel-Carboplatin combination for 3 cycles. 20 patients had complete debulking (no macroscopic residual disease), 18 had optimal (macroscopic disease <1cm) and 7 suboptimal. 22 patients received also bevacizumab as part of their treatment post IDS. CRS assessed at omentum predicted PFS when adjusted for age, stage, debulking status (complete, optimal, suboptimal) and post IDS bevacizumab administration (mPFS CRS 1vs2vs3: 11.9-14-19.5 months 95% CI [7.4-18.3], [12.2-20.7], [13.5-31.3]). Lymphocytic invasion was associated with improved OS (log-rank test p = 0.022). Presence of necrosis and mitosis per HPF did not predict either PFS or OS. BRCA status was known for 19 patients and presence of BRCA1/2 mutations was strongly correlated with lymphocytic infiltration (P = 0.011) but not CRS (p = 0.801).

Conclusions: Our study confirms the predictive value of CRS in EOC patients treated with NACT and IDS, but also demonstrates the prognostic significance of lymphocytic infiltration in IDS specimens. The later was associated with presence of BRCA mutations with obvious therapeutic implications.

971P Embryonic protein nodal as a novel marker of progression and drug resistance in ovarian cancer

O. Bilyk[1], L. Lee[1], N. Le[2], L. Cook[3], M. Koebel[4], L. Postovit[1]

[1]Oncology, University of Alberta, Edmonton, AB, Canada, [2]Cancer Control Research, British Columbia Cancer Research Center, Vancouver, BC, Canada, [3]Internal Medicine, University of New Mexico, New Mexico, NM, USA, [4]Arnie Charbonneau Cancer Institute, University of Calgary, Calgary, AB, Canada

Background: Cancer cells can exploit normally dormant embryonic stem cell pathways to promote cancer progression. Studying embryonic signaling pathways in aggressive cancers has led to the discovery of the re-expression of the embryonic protein Nodal. It maintains pluripotency and cell plasticity of human embryonic stem cells. In many cancers Nodal signalling promotes tumor growth and metastasis. The objective of this study is to investigate the role of Nodal as a potential biomarker of ovarian cancer (OC) progression and resistance to chemotherapy.

Methods: We applied bioinformatics approach and RNA sequencing to investigate the impact of Nodal on biological processes in OC cells and disease outcome in OC patients (TCGA data). In vitro assays designed to assess cancer stem cell phenotypes and chemoresistance in OC cells wherein Nodal was overexpressed, or knocked out with CRISP/Cas9 genome editing were conducted. We performed IHC staining of Nodal in tissue microarrays of high-grade serous OCs (HGSOC) to evaluate prognostic significance of Nodal. HGSOC samples were obtained from Ovarian Cancer in Alberta and British Columbia study (OVAL-BC) cohort of OC patients (563 HGSOC samples).

Results: RNA seq data showed that Nodal induces transcriptional reprogramming in OC cells via altering immune response, metabolism and drug resistance gene expression. In vitro, we showed that Nodal is a stress response gene which expression and protein increased in OC cells after treatment with cisplatin/carboplatin and retained for 96h after drug withdrawal. OC cells overexpressing Nodal characterized by increased resistance to cytostatic drugs, tumorigenicity and cell plasticity (partial EMT and stem cell-like phenotype). Analysis of TCGA microarray data and IHC staining of tissue microarrays of HGSOCs determined that Nodal predicts poor overall and progression-free survival in HGSOC patients.

Conclusions: Nodal predicts poor survival in HGSOC patients and likely drives tumorigenic potential and resistance to platinum in OC cells by promoting cancer stem cell plasticity and upregulating target genes involved in immune response, drug

resistance and metabolism, and may hold promise as a therapeutic target to prevent disease recurrence following chemotherapy.

Background: Here is no convincing active treatment for patients with PROC. Anti-apoptotic bcl-2 proteins have been implicated in chemotherapy (CT) resistance. In pre-clinical studies, we demonstrated promising activity of Navitoclax, an anti-apoptotic inhibitor of Bcl-2 family, in ROC tumors, suggesting a potential action in platinum resistant pts. We conducted a multicentric phase II trial of Navitoclax monotherapy and reported modest efficacy (ESMO 2017, abstract #2269). Here we aimed to describe the relationship between Bcl-2 protein expression and response to Navitoclax; we also reported response to subsequent line of CT.

Methods: Pts (N = 46) with high grade serous PROC received oral Navitoclax (150 mg daily for 7 days followed by 250 mg daily) until disease progression or toxicity. All pts had a biopsy of relapsed disease before navitoclax initiation to assess the expression level of Bcl-2 proteins by histoimmunochemistry (IHC), as low, medium or high. We first evaluated the efficacy of Navitoclax for pts with high BIM level, then with high BIM expression combined with low Mcl-1 and/or phospho-ERK. Response to subsequent CT was also described.

Results: 44 pts (with median of 4 prior lines) were assessable for efficacy: PFS was 50 days [6-234] with 1 partial response (PR), 15 stable diseases (SD). IHC data were available for 35 pts. BIM was highly expressed in 9 pts, 4 of them with PR/SD ($p = 0.68$). Among them, 7 had a low expression of Mcl-1 and/or phospho-ERK, of whom 4 with PR/SD, showing no evidence of relation with clinical response. After Navitoclax, 32 pts were retreated with CT: 4PR and 9SD were noted, including 11 pts with long response (6-13 months). Median delay from previous platinum-based treatment to subsequent CT was 9 months [2-23] for PR/SD pts. Especially, 12 pts received platinum after Navitoclax with high response rate (3PR/4SD, 58%), median delay from previous platinum-CT was 18 months.

Conclusions: BIM expression, alone or combined with Mcl-1 and/or pERK, is not predictive of Navitoclax benefit. High proportion of PROC pts response to platinum rechallenge; the potential implication of Navitoclax needs further explorations. Other Bcl-2 family proteins (activator BH3-only BID and PUMA) expression may be more relevant. This trial is granted by the French Cancer Research Hospital Program in 2011 and the Mariapia Bressan award in GINEGEPS 2014.

973P Expression of CD4, CD8 and Foxp3 and its clinical significance in neoadjuvant chemotherapy for locally advanced cervical cancer

X. Yin

Obstetrics and Gynecolgoy, Renji Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: Cervical cancer ranks first among gynecologic malignancies. Neoadjuvant chemotherapy combined with surgery is currently a recommended treatment for locally advanced cervical cancer, however the patient's prognosis is still poor and easy to recur even if the chemotherapy works significantly. We need more effective assessment method for local advanced cervical cancer. Therefore, we evaluated relationship between chemotherapeutic effect and prognosis on the expression of immunological biomarkers including CD4+, CD8+ and Foxp3 pre- and post-neoadjuvant chemotherapy for locally advanced cervical cancer.

Methods: CD4+, CD8+ and Foxp3 expression by IHC in 45 cases of locally advanced (IB2-IIB) cervical cancer pre- and post-neoadjuvant chemotherapy, computer software was used to quantitatively analyzed. The relationship between IHC results and clinicopathological characteristics, chemotherapy efficacy, PFS and OS was analyzed by SPSS software.

Results: The expression of CD4, CD8 and Foxp3 in locally advanced cervical cancer before and after neoadjuvant chemotherapy was not related to patients' age and size of tumor ($P > 0.05$), which was related to FIGO staging and histological grade. The expression of CD4 and CD8 increased significantly after chemotherapy ($P = 0.016$, $P = 0.009$), while the expression of FoxP3 decreased significantly ($P = 0.002$). There was a significant correlation between the expression of CD8 ($P = 0.005$), Foxp3 ($P = 0.041$) and PFS in locally advanced cervical cancer, while CD4 had no significant correlation ($P = 0.581$). However, there is no significant correlation between OS and CD4 ($P = 0.686$), CD8 ($P = 0.858$) and Foxp3 ($P = 0.689$).

Conclusions: CD4, CD8 and Foxp3 are associated with tumor staging and pathological grading in neoadjuvant chemotherapy for locally advanced cervical cancer, and the expression change of CD8 and Foxp3 before and after chemotherapy can be used as an independent prognostic indicator.

974P Clinical study on the efficacy of apatinib treatment for advanced ovarian cancer after second-line chemotherapy failure

S. Sun, D. Zhai, C. Yu

Gynecologic Department of Traditional Chinese Medicine, Changhai Hospital of Shanghai, Shanghai, China

Background: Ovarian carcinoma has the highest mortality rate among gynecologic malignancies. Primary drug resistance and multi-drug resistance are major clinical obstacles to treatment and is the main reason for the dismal 5-year survival rate of patients. Apatinib is independently developed in China as an effective small-molecule tyrosine kinase inhibitor. It mainly functions by competitively blocking the binding of VEGF with VEGFR-2 and auto-phosphorylation of VEGFR-2, thereby inhibiting the function of VEGF in stimulating endothelial cell proliferation and migration and reducing microvascular density to elicit its anti-tumor effects.

Methods: This study is a prospective, open label, single-arm clinical trial aimed to evaluate the efficacy and safety of apatinib mesylate as treatment after failure of second-line chemotherapy in patients with advanced epithelial ovarian cancer. The study enrolled 20 patients, and 17 were evaluated. Patients received an oral dosage of apatinib (500 mg or 250 mg) once daily for 28 days as an observation cycle. The efficacy of the treatment was evaluated after three treatment cycles. The objective response rate (ORR), disease control rate (DCR), progression-free survival (PFS), overall survival (OS) and adverse events (AEs) were assessed.

Results: After 3 cycles of treatment, 6 (35.3%) and 2 (11.8%) patients achieved partial response (PR) and stable disease (SD), respectively. The ORR and DCR were 35.3% and 47.1%, respectively. The efficacy of apatinib was not significantly different between patients with initial dosages of 500 mg (ORR, 30%; DCR, 30%) and 250 mg (ORR, 42.8%; DCR, 71.4%). The median PFS was 2.2 months (95% confidence interval (CI), 1.0m-8.9m) and the median OS was 6.3months (95% CI, 1.5m-12.8m). The most common AEs were hypertension (70.6%), hand-foot syndrome (52.9%), and oral mucosa damage (35.3%).

Conclusions: In conclusion, oral apatinib treatment was efficacious, safe, and had no serious adverse effects in patients with advanced EOC who failed second-line chemotherapy.

Clinical trial identification: ChiCTR-OOC-16008034. Registration time: 2016-03-01.

975P Clear cell ovarian cancer (CCOC): Predicting risk of relapse (ROR)

M-J. Devlin[1], J.A. Ledermann[2], M. Lockley[1], N. Wilkinson[3], J. McDermott[4], R.S. Kristeleit[5], R. Miller[1]

[1]Medical Oncology, University College London Hospital UCLH NHS Foundation Trust, London, UK, [2]Cancer Trials Centre, University College London Cancer Institute, London, London, UK, [3]Pathology, University College London Hospital UCLH NHS Foundation Trust, London, UK, [4]Academic Pathology, University College London Hospital UCLH NHS Foundation Trust, London, UK, [5]Academic Department of Oncology, UCL Cancer Institute, London, UK

Background: Patients (pts) with advanced CCOC have a significantly poorer prognosis than other Epithelial ovarian cancer (EOC) subtypes. Being able to predict which pts are more likely to relapse could assist with treatment and monitoring decisions. The system inflammatory score (SIS) aims to predict postsurgical prognosis for CCOC by stratifying pts into 3 groups (gps). The Risk of OVarian cAncer Relpase (ROVAR) score aims to predict ROR for EOC following first line treatment and stratifies pts into low/intermediate (int)/high gps. We attempted to validate both scores in a non-trial population.

Methods: We reviewed the medical records for pts with CCOC treated at two UK gynaecological cancer centres between 2002 and 2017. Data comprising pt and tumor characteristics, treatment and outcome. Analysis was performed using Mantel Cox and Fisher Exact Tests.

Results: 119 pts; stage I (65), II (19), III (22), IV (10) and unknown (3). ROVAR was calculated for 90 (75%) pts; 24 (20%) had incomplete data, 6 (5%) excluded for other. Pts classified into low (20%), int (44%) and high (36%) gps. ROR for low or int gps vs high $p = 0.0001$; ROR for low vs int gps $p = 1$. Compared to low/int, pts in high-risk gp were younger 53.87yrs (34-72) vs 57.81yrs (35-74), had smaller tumours 106mm (45-240) vs 136mm (50-230), with increase in both hypercalcaemia (21% vs 5%; $p = 0.306$) and thromboembolic events (37.5% vs 10%; $p = 0.0047$). SIS was calculated for 67 pts (56%); 39 (33%) had insufficient data, 13 (11%) excluded for other. Pts classified into gp 0 (34.3%), 1 (37.3%) and 2 (28.3%) with no statistical difference in PFS ($p = 0.9118$) or OS ($p = 0.849$) between gps.

Conclusions: ROVAR significantly predicts ROR in CCOC in pts with high vs low/int risk disease. Our data suggests that the features that promote treatment-resistance are linked to paraneoplastic phenomenon and emerge early in tumour development, resulting in diagnosis at a smaller size in younger women. Another possibility is that these are two pathologically similar, but ultimately distinct, disease entities from the outset. Patients with high risk disease may benefit from more intensive follow-up and, given the chemo-resistant phenotype of the disease, early enrolment in clinical trials.

976P Comparison of PARPi with angiogenesis inhibitors and chemotherapy for maintenance in ovarian cancer: A network meta-analysis

Y.L. Feng, J.H. Liu, H. Huang, C. Zhang, T. Wan, C.J. Tong, T. Deng, H. Tu, Y.W. Huang, G. Liu, Q.D. Huang, Z.M. Liu

Gynecologic Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Recent targeted therapies such as poly-ADP ribose polymerase inhibitors (PARPi) and angiogenesis inhibitors (AI) are known to ease burden and recurrence of ovarian cancer. This network meta-analysis conducted an indirect treatment comparison between PARPi, AI and chemotherapeutic agents (CTA) in terms of clinical efficacy and safety as maintenance therapy in ovarian cancer patients irrespective of BRCA status.

Methods: We searched relevant sources (PubMed, EMBASE) to identify randomized controlled trials in ovarian cancer patients undergoing maintenance therapy. Studies assessing efficacy and safety of PARPi ($n = 4$), AIs ($n = 12$), CTA ($n = 8$) with placebo were analyzed. Primary outcome included progression free survival (PFS), safety and tolerability were secondary outcomes. A network meta-analysis to compare 3 drug classes was performed using statistical software R.

Results: PARPi [Hazard Ratio (HR) =0.64; 95% Credible Intervals (CrI) =0.55-0.73] and AI (HR = 0.87; 95% CrI=0.81-0.93) showed significant improvement in PFS compared to placebo but not CTA (HR = 1.00; 95% CrI=0.86-1.15, Table). PARPi showed significant improvement in PFS compared to AI (HR = 0.73; 95% CrI=0.63-0.86) and CTA (HR = 0.64; 95% CrI=0.52-0.78). Adverse events (AEs) leading to treatment discontinuation and dose reduction were lower in PARPi [Incidence Rate Ratio (IRR) =1.64; CrI=0.84-3.19, IRR=0.73, 95% CrI=0.50-1.06 respectively] compared to AI, but not significant.

Table: 976P Comparison of PFS data across different therapies

Treatment	AI	CTA	PARPi	Placebo
AI	-	1.14 (0.98, 1.35)	0.73 (0.63, 0.86)	1.15 (1.07, 1.24)
CTA	0.87 (0.74, 1.02)	-	0.64 (0.52, 0.78)	1.00 (0.87, 1.16)
PARPi	1.37 (1.16, 1.6)	1.57 (1.28, 1.92)	-	1.57 (1.36, 1.81)
Placebo	0.87 (0.81, 0.93)	1.00 (0.86, 1.15)	0.64 (0.55, 0.73)	-

AI angiogenesis inhibitors; CTA chemotherapeutic agents; PARPi poly ADP ribose polymerase inhibitors.

Conclusions: PARPi as maintenance treatment improved PFS in ovarian cancer and was relatively safer in terms of AEs caused implications when compared to other therapies. This network meta-analysis provides valuable evidence and significant insights in treatment of ovarian cancer.

977P The role of bevacizumab plus front-line chemotherapy in patients with malignant ascites of ovarian cancer

M. Nikolaou[1], N. Ziras[2], I. Athanasiadis[3], A. Ardavanis[4], M. Vaslamatzis[5], N. Kentepozidis[6], P. Makrantonakis[7], A.N. Christopoulou[8], V. Michalaki[9], A. Polizos[10], C. Emmanouilidis[11], V. Georgoulias[12]

[1]Oncology Unit, General and Maternity Hospital Helena Venizelou, Athens, Greece, [2]Oncology Department, Metaxa, Athens, Greece, [3]Oncology Department, Hygeia Hospital, Athens, Greece, [4]Oncology Department, Agios Savvas Regional Cancer Hospital, Athens, Greece, [5]Oncology Department, Evangelismos General Hospital of Athens, Athens, Greece, [6]Oncology Unit, 251 Hellenic Airforce General Hospital, Athens, Greece, [7]Oncology Department, Theagenion Cancer Hospital, Thessaloniki, Greece, [8]Oncology Unit, Hospital AG. Andreas, Patras, Greece, [9]Oncology Department, Areteion Hospital, University of Athens, Athens, Greece, [10]Oncology Unit, Laiko, Athens, Greece, [11]Oncology Department, Balkan Medical Centre, Thessaloniki, Greece, [12]Oncology Department, University Hospital of Heraklion, Heraklion, Greece

Background: Epithelial Ovarian Cancer (EOC) is a group of different types of cancer and is the most common cause of death among women. The time at diagnosis 75% of them have stage III - IV disease. The standard of care is the combination of a taxane plus a platinum (TC) compound whereas, the addition of bevacizumab (bev) as a part of first-line treatment (TC-bev) was evaluated in many trials and has been shown to improve the PFS but OS only in retrospective subgroup analysis. Patients with ascites appear to have more aggressive disease and less overall survival. We aimed to evaluate the role of TC-bev in EOC patients suffering from ascites. Ferris et al. proved that, ascites may predict the population of women more likely to derive long-term benefit from bevacizumab.

Methods: A multi-center observational, Phase IV study, which enrolled patients with stage III/IV EOC was conducted (11.2011-06.2014) in Greece. 314 patients were treated with front-line TC-bev ($n = 205$ pts) or TC ($n = 109$ pts) according to the physician's choice. There were two independent cohorts of patients with similar characteristics. 83 (40.5%) and 40 (36.7%) in the TC-bev and TC groups presented with ascites. The data were collected from the patients' records; the study has been approved by the institutional review board (IRB) of the participating centers.

Results: Patients treated with TC-bev experienced a better overall response rate (ORR) (68.7% Vs 55%) and less progression disease (PD) compared to patients received TC (13.2% Vs 30.8%). It is worth mentioning that the Complete Response (CR) was 20.5% and 10% in the TC-bev and TC respectively and Partial Response (PR) was 48.2% and 45% respectively. Both of arms showed the expected toxicity and Bev-TC was well tolerated. The median PFS was 18.1mo and 10.3mo in the TC-bev and TC group respectively ($p < 0.001$). OS is not mature (mOS has not reached in the TC-bev group and it is 22.5m in the TC group) ($p = 0.023$). The 3 year survival rate was 55.3% and 30% in the TC-bev and TC respectively.

Conclusions: Patients with advanced or metastatic ovarian cancer and ascites are in high risk group and have worse OS and PFS. The addition of Bevacizumab to TC offer survival benefit in patients with stage III/IV EOC and ascites. We need largest studies to confirm these observations.

Clinical trial identification: NCT01982500.

Background: Cervical cancer (CC) is the fourth most common malignancy worldwide and 85% of new cases are diagnosed in low and middle-income countries. CC impact women health quality of life (HQoL) although the association between socioeconomic factors and HQoL is not well described in the literature. We aim to evaluate HQoL in patients newly diagnosed with CC in Brazil.

Methods: This is a prospective, observational cohort study (EVITA) that included patients from 16 institutions in Brazil. Main eligibility criteria were age $\geq$18 years-old, newly diagnosed stage I to IV invasive CC. Data were collected during a medical visit and from medical charts. HQoL was assessed at baseline using EORTC QLQ-C30 and CX24 questionnaires. Educational level and household income were assessed as a continuous variable and categorized for this analysis as $<$ 8y or $>=$9y and $<$1 or $>=$1 minimum wage, respectively. Student t test was used for comparisons between early (stages I and II) and advanced (stages III and IV) disease.

Results: A total of 631 patients were included from January 2016 to November 2017. Mean age at diagnosis was 49.3y ($\pm$13.9). Most patients had $<$8 years of formal education (69.5%), household income £ one minimum wage (20.9%) and were treated in the public health system (95.7%). Regarding stage at diagnosis, patients with early stage disease (I and II) displayed better physical functioning (88 vs 80; $P < 0.001$) and role functioning (72 vs 61; $P = 0.0115$) scores, while patients with advanced disease had worse fatigue (27 vs 39; $P = 0.0114$), pain (26 vs 43; $P < 0.001$), constipation (23 vs 35; $P = 0.0072$), sexual activity (90 vs 95; $P = 0.008$), symptom experience (18 vs 24; $P = 0.0083$) and sexual worry (24 vs 33; $P = 0.0489$) scores. Sexual worry was worse in patients with $>=$9 years of education (21 vs 32; $P = 0.0022$). Other quality of life measures were not different among educational level and household income subgroups.

Conclusions: This is the most comprehensive evaluation of HQoL in cervical cancer in Brazil. Our study found that patients with advanced stage at diagnosis had worse quality of life. In patients newly diagnosed CC socioeconomic factors were of limited association with HQoL.

979P Oregovomab (orego) and nivolumab (nivo) as a combinatorial immunotherapy strategy for recurrent epithelial ovarian cancer (rEOC): ORION-01 phase Ib cohort

J.J. Chan[1], S.H. Tan[2], T.W. Lim[2], T.J.Y. Tan[1], W.Y. Chay[1], E.H. Lim[1], L.T. Soh[1], S.L. Lim[3], J.W.K. Chia[4]

[1]Division of Medical Oncology, National Cancer Centre Singapore, Singapore, [2]Division of Clinical Trials & Epidemiological Sciences, National Cancer Centre Singapore, Singapore, [3]Department of Gynaecological Oncology, KK Women and Children's Hospital, Singapore, [4]OncoCare Cancer Centre, Singapore

Background: Orego is an anti-CA 125 cancer vaccine whereas nivo is a programmed death-1 inhibitor. Both agents are clinically active in advanced EOC. We hypothesize that their combination will elicit a systemic CA 125-specific T cell response which is synergistic, safe and clinically efficacious in rEOC patients (pts).

Methods: Pts with rEOC, fallopian tube or primary peritoneal carcinoma who have received $\geq$2 prior chemotherapy lines were recruited in this phase Ib/IIa study. Study objectives were to characterize the safety and tolerability of orego + nivo, and determine the recommended dose for expansion (RDE)/recommended phase II dose (RP2D) of this combination. Using a modified 3 + 3 design, pts were treated starting at orego 2mg Q4W (dose level 1) + nivo 240mg Q2W. 2 lower doses of orego were specified in case of dose-limiting toxicities (DLT). A minimum of 6 and maximum of 18 pts would be accrued for dose finding. Additional 14 pts will be treated at RP2D in the dose expansion cohort.

Results: 6 pts with median age 61 years (range 52.0 – 63.0) and ECOG performance status 1 were treated at dose level 1. All had EOC (4 high grade serous, 2 clear cell) and a median of 4 (range 3 – 9) treatment lines before study entry. No DLT were observed. Treatment-related adverse events (AE) included grade 1 events of arthralgia, rash, transaminitis, fatigue, and anorexia. 2/6 (33.3%) pts experienced grade 1-2 thyroid-related immune-related AE. 5 serious adverse events (SAE) were observed but they were deemed unlikely/not related to study treatment, including 2 episodes of grade 4 sepsis in 1 pt who eventually died of progressive disease (PD). Dose delay of orego and nivo occurred in 1 pt because of hospitalization for fever (SAE) followed by scheduling reasons. Dose omissions of nivo occurred in 2 pts due to grade 4 sepsis in 1 pt, and grade 1 thyroiditis in another. Analysis of exploratory immune correlate(s) is underway and will be reported at the meeting.

Conclusions: Orego 2mg Q4W with nivo 240mg Q2W was selected as the RDE/RP2D to treat rEOC. Further evaluation of safety and efficacy of this novel combination is ongoing in our dose expansion cohort.

Clinical trial identification: NCT03100006.

980P Genomic characterization of vulvar squamous cell carcinoma

K. Prieske[1], M. Alawi[2], S.A. Joosse[3], K. Eylmann[1], E. Burandt[4], B. Schmalfeldt[5], L. Oliveira-Ferrer[1], L. Woelber[1]

[1]Department of Gynecology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [2]Bioinformatics Core, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [3]Tumorbiology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [4]Institute of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [5]Gynaecology, AGO Study Group & Technical University of Munich - Klinikum rechts der Isar; University of Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: Despite an increasing incidence, vulvar squamous cell cancer (VSCC) is still a rare disease. So far two etiological pathways have been described: A high-risk human papillomavirus (HPV)-dependent route and an HPV–independent pathway often associated with lichen sclerosus. To date, therapeutic strategies in VSCC are not influenced by molecularpathological information and therapeutic options for advanced or recurrent disease are limited.

Methods: Whole exome sequencing of DNA isolated from 34 VSCC samples and matched normal tissue for each individual was performed on an Illumina HiSeq4000. Short variant discovery was carried out using BWA and MuTect2. Variants were annotated using ANNOVAR. For the detection structural variants and copy number aberrations, Pindel, ADTEx and FREEC were employed. Presence of HPV integration sites was assessed using Bowtie2.

Results: All pts (median age 60) received surgery with (partial) vulvectomy as primary treatment. In 82% a surgical staging of the groins was performed. FIGO stages were: n = 5 IB, n = 13 II, n = 5 stage III and n = 2 IVA (n = 7 unknown). 10/34 (29.4%) samples were HPV positive (all HPV16). 17.6% pts suffered from recurrence (4 local, 2 groin, 1 pelvic) after a median of 10 months. TP53 mutations were most commonly detected, with 41% (14/34). Additionally, we observed mutations in the following genes, which were affected in at least three samples: MUC3A (7/34), FSIP2 (4/34), AKAP9 (4/34), TDRD15, PKD1L1, FCHO1, RANBP2, FBXW7, VPS13C, MDGA2, SCN9A, VEPH1, ABCA5, KIAA0368, NCAM2, GCC2, MYCBP2, PRPF39, WDR49, ZNF729, UTRN, ANKRD36, GRAMD1c, ADGRV1 in 3/34 samples. Significantly less mutations were detected in pts with a OS $>$ 48 months ($p = 0.032$). However, there was no significant difference in PFS or OS between HPV positive and negative tumors ($p = 0.78$ and 0.92). In an univariate analysis there was a significant correlation between HPV negative tumors and TP53 mutations ($p < 0.0001$). No correlation between pT status, pN status, tumor size or number of mutations and HPV status was detected.

Conclusions: The key mutation in vulvar cancer affects TP53. This first work and progress analysis of whole exome sequencing of VSCC with corresponding normal tissue has the potential to identify further key mutations and therewith new targets for the treatment of VSCC.

981P Economic and humanistic burden of cervical cancer in the United States

C. Nwankwo[1], R. Shah[2], Y. Kwon[2], S. Corman[2]

[1]MRL, Merck & Co., Inc., Kenilworth, NJ, USA, [2]HEOR, Pharmerit International, Inc, Bethesda, MD, USA

Background: An estimated 12,820 women in the United States (US) will be diagnosed with cervical cancer this year, with 4,210 deaths from the disease. The economic and humanistic burden of cervical cancer has not been adequately studied.

Methods: This was a retrospective, cross-sectional analysis of Medical Expenditure Panel Survey (MEPS) data from 2006-2015. Cervical cancer cases were identified using ICD-9 CM code 180 or clinical classification software code 26. The control group consisted of women without a diagnosis of cancer. Study outcomes included healthcare resource use (institutional inpatient and outpatient, ER, and physician office visits), healthcare costs, activities of daily living (physical, cognitive, social, and activity limitations), quality of life measures (general health, SF-12v2 physical component score [PCS], mental component score [MCS], EQ-5D and SF-6D health utility, and PHQ-2 depression severity). Multivariate generalized linear models (GLMs) which controlled for key socio-demographic and clinical covariates were conducted to compare study outcomes in cervical cancer cases to non-cancer controls.

Results: The analytic cohort consisted of 275,246 cervical cancer cases and 146,061,609 non-cancer controls. Cervical cancer cases were significantly older (mean age: 42.03 vs 36.98 years), and had a higher comorbidity burden (mean Charlson comorbidity index: 1.06 vs 0.46) as compared to non-cancer controls (all $p < 0.05$). Results from the GLMs suggested that cervical cancer cases had significantly higher institutional outpatient costs ($1,610 vs $502), physician visit costs ($2,422 vs $1,321), and total healthcare costs ($10,031 vs $4,913) (all $P < 0.05$) compared to controls. Cervical cancer patients were 1.99 (odds ratio [OR]: 1.991; 95% CI: 1.23 to 3.22) and 2.56 (OR: 2.562; 95% CI: 1.78 to 3.68) times as likely to report activity limitations and poor general health as compared to non-cancer controls. Cervical cancer patients had a significantly lower PCS, MCS, EQ-5D health utility, and higher PHQ-2 depression severity (all $P < 0.01$).

Conclusions: Cervical cancer is associated with significant economic burden, activity limitations, and quality of life impairment among ambulatory women in the US.

982P Risk of fatigue and neuropathy in patients with advanced cancer treated with olaparib: A meta-analysis of randomized controlled trials

V.C. Ruiz-Schutz[1], L.M. Gomes[2], C.Z. Oliveira[2], R.C. Mariano[3], D.V.P. Almeida[3], J.M. Pimenta[2], G.Z. Dal Molin[4], F.R. Kater[3], R. Yamamura[3], F.C. Maluf[3], F.A. Schutz[3]

[1]Internal Medicine, Universidade de São Paulo, São Paulo, Brazil, [2]Oncology, Hospital Beneficência Portuguesa de São Paulo, São Paulo, Brazil, [3]Medical Oncology, BP - A Beneficência Portuguesa de São Paulo, São Paulo, Brazil, [4]Oncology, MD Anderson Cancer Center, Houston, TX, USA

Background: Poly ADP ribose polymerase (PARP) inhibitors are a new class of drugs that are currently being studied in several malignancies. Olaparib is FDA-approved for patients with advanced breast cancer and advanced ovarian cancer. Fatigue is the most common symptom associated with advanced cancer and treatment. Neuropathy is also a treatment related adverse event associated commonly with platinum and taxanes. We did a systematic and up to date review of the literature and a meta-analysis of randomized controlled trials (RCT) to characterize the risk of fatigue and neuropathy associated with olaparib use.

Methods: PubMed databases were searched for articles published till February 2018. The search was restricted to randomized controlled trials (RCTs) with olaparib and were selected according PRISMA. Safety profile from each selected study was evaluated for all-grade and high-grade fatigue and neuropathy events in control/placebo and olaparib arms. Summary incidences and the relative risk (RR), with 95% confidence intervals, of all-grade and high-grade events were calculated using random-effects or fixed-effects model based on the heterogeneity of selected studies.

Results: A total of 7 trials were selected, and included a total of 1750 patients with advanced ovarian, gastric or breast cancer. 746 patients received placebo/control treatments and 1004 received olaparib alone or in association with control. All-grade fatigue was increased by 21% (HR 1.21; 95% CI 1.07-1.37) while all-grade neuropathy was increased by 55% (HR 1.55; 95% CI 1.14-2.09). High-grade fatigue analysis showed a HR of 1.64 (95% CI 0.98-2.77) and high-grade neuropathy a HR of 3.61 (95% CI 0.60-21.85).

Conclusions: Our findings suggest that the olaparib treatment is associated with an increased risk of fatigue and neuropathy adverse events. Since fatigue and neuropathy are very common treatment related adverse events, and both can impair the quality of life of patients, it is important to identify it early and manage it accordingly in order to optimize the overall treatment.

983P Risk of cancer associated death in younger vs older patients with FIGO stage I endometrial cancer

J. Ko[1], B. Lester[2], G. Bowering[1], C. Rugayan[2], I. Ghement[3], K. Aalok[4]

[1]Medical Oncology, BC Cancer - Abbotsford, Abbotsford, BC, Canada, [2]Radiation Oncology, BC Cancer - Abbotsford, Abbotsford, BC, Canada, [3]Biostatistics, Ghement Statistics, Vancouver, BC, Canada, [4]Medical Oncology, BC Cancer - Surrey, Surrey, BC, Canada

Background: Although age is considered a traditional risk factor for relapse in stage I endometrial cancer, whether it impacts endometrial cancer-related death is unclear. We aimed to assess disease risk factors, overall survival (OS), disease-free survival (DFS), and cancer-specific survival, in patients $>=70$ (OP) vs. <70 (YP) years of age with or without adjuvant therapy.

Methods: We reviewed medical records of all patients who underwent surgery for stage I endometrial cancer between 2000 and 2013 in British Columbia, Canada. Descriptive, logistic regression, multivariate Cox regression and competing risks analyses were used to evaluate patient outcomes.

Results: 365 OP and 1063 YP were included ($n = 1428$). No significant differences were found between OP and YP with regards to disease risk factors such as stage IB disease and lymphovascular invasion (LVI). However, OP had higher odds of non-endometrioid histology (OR 1.88, $p < 0.001$). 22 (6%) OP and 78 (7.3%) YP received adjuvant chemotherapy (CT); 120 (32.9%) OP and 290 (27.3%) YP received adjuvant radiotherapy (RT). When adjusted for histology, LVI and grade, YP were more likely to receive CT (OR 2.10, $p = 0.009$); no significant difference in odds of receiving RT was found between YP and OP (OR 0.86, $p = 0.33$). OP experienced higher odds of relapse (OR 1.95, $p = 0.001$) and worse OS (HR 4.12, $p < 0.001$) and DFS (HR 2.18, $p < 0.001$) than YP after adjusting for risk factors. 10-year OS (endometrioid: 61.9 vs 89.2%; non-endometrioid: 46.1 vs 85.8%, $p < 0.001$) and DFS (endometrioid: 86.7 vs 91.9%; non-endometrioid: 69.6 vs 84.5%, $p < 0.001$) were worse for OP. Controlling for risk factors, OP experienced a higher incidence of endometrial cancer-related death than YP ($HR = 2.09$, $p < 0.001$).

Conclusions: In patients with stage I endometrial cancer, patients $>=70$ years had higher odds of having non-endometrioid histology as well as relapse and death due to endometrial cancer, yet were less likely to receive adjuvant CT. Appropriate adjuvant therapy should be considered regardless of age, as recurrent disease is still a significant cause of mortality in older patients with stage I endometrial cancer.

984P Clinical outcomes according to age and comorbidities in the OSCAR UK observational study of front-line bevacizumab (BEV)-containing therapy for advanced ovarian cancer (aOC)

M. Hall[1], G. Bertelli[2], L. Li[3], C. Green[4], S. Chan[5], C.C. Yeoh[6], J. Hasan[7], A. Ograbek[8], T.J. Perren[9]

[1]Department of Medical Oncology, Mount Vernon Cancer Centre, Northwood, Middlesex, UK, [2]Sussex Cancer Centre, Brighton & Sussex University Hospitals NHS Trust, Brighton, UK, [3]Department of Oncology and Radiotherapy, James Cook University Hospital, Middlesbrough, UK, [4]Oncology Department, Southampton University NHS Trust, Southampton, UK, [5]Department of Oncology and Radiotherapy, Nottingham University Hospital NHS Trust (City Hospital Campus), Nottingham, UK, [6]Oncology Department, Queen Alexandra Hospital Portsmouth, Portsmouth, UK, [7]Department of Medical Oncology, The Christie Hospital, Manchester, UK, [8]Medical Affairs, Roche Products Ltd, Welwyn Garden City, UK, [9]Leeds Institute of Cancer and Pathology, St James's University Hospital, Leeds, UK

Background: The efficacy and safety of front-line BEV with carboplatin and paclitaxel (CP) for aOC were demonstrated in two randomised phase III trials (GOG-0218 and ICON7). OSCAR (NCT01863693; funded by Roche Products Ltd) evaluated front-line BEV-containing therapy in routine oncology practice in 29 UK centres.

Methods: Eligible patients received BEV (7.5 or 15 mg/kg q3w, typically for up to 12 months, per UK clinical practice) during and after front-line chemotherapy (physician's choice) for high-risk stage IIIB–IV ovarian cancer. Co-primary endpoints were progression-free survival (PFS) and safety (NCI CTCAE v4.0). Patients were evaluated according to standard practice/physician's discretion during BEV treatment, with an end-of-study assessment 12 months after the last BEV dose. We report post hoc subgroup analyses in populations defined by age and comorbidities.

Results: Of 299 patients starting treatment between May 2013 and Mar 2015, 80 were aged $\geq$70 years, of whom 9 were $\geq$80 years. Almost all patients (91%) had comorbidities (pre-existing medical condition at BEV initiation), most commonly hypertension/essential hypertension (27%), constipation (22%) or fatigue (22%). Most (93%) received BEV 7.5 mg/kg with CP; 22% had primary debulking surgery, 40% interval debulking surgery and 38% no surgery. Patient characteristics, treatment exposure,

PFS and safety are summarised below. In multivariable Cox regression analysis, neither age nor number of comorbidities was prognostic for PFS.

Conclusions: Older patients were more likely to receive single-agent chemotherapy, have ongoing comorbidities and have worse surgical outcome than their younger counterparts. However, median BEV exposure, incidence of grade 3/4 AEs and median PFS were similar in younger and older patients. Grade ≥3 AEs were more common in patients with ≥3 than <3 comorbidities but PFS was similar.

Clinical trial identification: NCT01863693.

985P Prolonged survival (SV) associated with pulmonary metastasectomy (PM) for carcinomas of the cervix (CC)

J.F. Corona-Cruz[1], A. Castillo-Castañon[1], C.Z. Deneken[2], L.A. Ramirez-Tirado[1], A. Gonzalez-Enciso[3], D. Gallardo-Rincon[3], E. Jimenez-Fuentes[1], O. Arrieta[4]

[1]Thoracic Oncology Clinic, Instituto Nacional de Cancerologia - Mexico, Mexico City, Mexico, [2]Centro de Cancer ABC, Centro Medico ABC, Mexico City, Mexico, [3]Gynecology Oncology Clinic, Instituto Nacional de Cancerologia - Mexico, Mexico City, Mexico, [4]Thoracic Oncology Clinic, Instituto Nacional de Cancerologia, Mexico City, Mexico

Background: CC is a public health problem in developing countries. Dissemination is typically lymphogenous but can develop hematogenous metastases. Chemotherapy alone is associated with a median SV of 13 months on metastatic disease. In selected cases with Isolated lung metastases (LM), PM is associated with prolonged SV.

Methods: Observational, retrospective cohort. Patients (ptes) with CC who underwent PM at the National Cancer Institute (INCan) Mexico from January 2005 to December 2017. Primary end-points were Overall Survival (OS) and Disease-Free Survival (DFS) Secondary end-points were morbidity and mortality of PM.

Results: A total of 29 ptes were identified. Squamous carcinoma was primary histology in 21 (72.4%). Most presented with advanced tumors at initial diagnosis, 11 (37.9%) stage II, 5 (17.2%) stage III and 7 (24.1%) stage IV. Unilateral nodules were seen in 27 (93.1%) and a single nodule was present in 24 (82.4%). Nodules were diagnosed as metachronous (after 6 months of diagnosis) in 21 (72.4%). Surgery was the initial treatment in 25 (86.2%) and only 4 (13.8%) received pre-operative chemotherapy. A wedge resection was performed in 16 (55.2%), interestingly, a lobectomy was needed in 12 cases (41.4%) and 1 case required a pneumonectomy. One case developed hemothorax requiring exploration for a 90-day morbity of 3.4% and 90-day mortality was 0%. An R0 resection was achieved in 26 (89.7%) On pathological analysis, only in 20 ptes (69%) LM were confirmed, in the other ptes a benign condition was diagnosed. Postoperative chemotherapy was indicated in 12 cases. Median follow up was 101.5 months (6 – 260). For SV analysis only ptes with proved LM were included. Median OS has not been reached, 5-year OS 35%. Median DFS 100 months (6.4 -193.5) Only R2 resection (p 0.05), no postoperative chemotherapy (p 0.025) and disease relapse (p 0.007) were statistically significantly associated with a worst SV.

Conclusions: In our cohort, PM is associated with better OS than chemotherapy alone. Although some ptes required a lobectomy, a very low morbidity and zero mortality in our cases is very encouraging. PM should be considered as fundamental part of multidisciplinary treatment in cases of CC with isolated LM.

986P Real world occurrence of top three clinical-trial reported adverse events of PARP inhibitor niraparib maintenance therapy in platinum-sensitive, recurrent ovarian cancer, a national retrospective observational study of a 200 mg/day starting-dose cohort

J.R. Gallagher[1], K.J. Heap[2], S. Carroll[3]

[1]Department of Analytics, Clarity Pharma Research, LLC, Spartanburg, SC, USA, [2]Research Management, Clarity Pharma Research, LLC, Spartanburg, SC, USA, [3]Clarity Pharma Research, LLC, Spartanburg, SC, USA

Background: Niraparib (Zejula®) is an oral poly (adenosine diphosphate [ADP]–ribose) polymerase (PARP) 1/2 inhibitor that has demonstrated efficacy in patients with platinum-sensitive, recurrent ovarian cancer. Nausea, thrombocytopenia, and fatigue were commonly occurring adverse events (AEs) in the phase 3 clinical trial in which patients were started at 300 mg daily dose of niraparib. After dose adjustments in this trial, a daily dose of 200 mg was the most commonly administered dose. This analysis provides a description of AEs among patients receiving an initial dose of 200 mg niraparib.

Methods: In a retrospective observational patient study, 53 randomly selected study-qualified physicians from a national database (61% of qualified physicians screened) extracted requested anonymous information from the medical charts of 153 qualified patients. Qualified patients had received a starting dose of 200 mg/day niraparib for recurrent epithelial ovarian, fallopian tube, or primary peritoneal cancer and were in complete or partial response to platinum-based chemotherapy.

Table: 984P

Characteristic, n (%)		Age, years		No. of comorbidities	
		<70 (n = 219)	≥70 (n = 80)	<3 (n = 109)	≥3 (n = 190)
Age, years	<65 ≥65	160 (73) 59 (27)	0 80 (100)	68 (62) 41 (38)	92 (48) 98 (52)

AE leading to BEV discontinuation		21 (10)	12 (15)	11 (10)	22 (12)
Median BEV duration, months (range)		10.6 (<1–29.7)	10.4 (≤1–41.4)	10.9 (<1–29.7)	10.3 (<1–41.4)
Grade 3/4 AEs, n (%)		118 (54)	42 (53)	50 (46)	110 (58)
Grade 5 AEs, n (%)		5 (2)[d]	2 (3)[e]	1 (1)	6 (3)
Median PFS, months (95% CI)		16.1 (14.5–18.5)	14.8 (12.2–16.1)	16.5 (14.7–18.0)	14.9 (13.4–16.1)

[a]Stage III with ≥1 cm residuum, any stage IV, or no surgery.
[b]Includes essential hypertension.
[c]Includes high protein level in urine.
[d]Gastrointestinal perforation, febrile neutropenia, cardiac arrest, pneumonia, metastases to meninges.
[e]Abdominal pain, pneumonia aspiration. AE=adverse event.

Results: Of the 153 patients, 56 (37%) experienced at least one of the three AEs evaluated within the first three months after niraparib initiation, and 49 (32%) experienced only grades 1/2 AEs. Among the 153 patients, fatigue was reported for 24% (36/153) (CI 17.4% - 31.0%); nausea for 16% (25/153) (CI 10.5% - 22.2%) and thrombocytopenia for 14% (21/153) (CI 8.3% - 19.2%). Of the 21 patients with thrombocytopenia, 3 were grade 3/4 severity (2% of overall). Among the patients, 4% (6/153) had a dose interruption, 11% reduced their dose (17/153), and 2% discontinued niraparib altogether (3/153) due to AEs.

Conclusions: While over 60% of patients in the phase 3 clinical trial reported experiencing the three AEs observed in the study, only 37% reported such in real-world usage. This difference may be due to the higher dosing in the trial study (initial dose of 300 mg/day vs. 200 in the observational study). Additional real-world research is needed to understand the effects of niraparib dosing on AEs.

987P Trabectedin plus pegylated liposomal doxorubicin (PLD) in patients with platinum-sensitive recurrent ovarian cancer (PSROC) regardless of prior use of antiangiogenics: First results of an observational, prospective study

S. Pignata[1], G. Scambia[2], T. Mazzei[3], M. Arruti Barbia[4], E. Naglieri[5], L.M. de Sande[6]

[1]Urology and Gynecology, Istituto Nazionale Tumori – I.R.C.C.S - Fondazione Pascale, Naples, Italy, [2]Medical Oncology, Policlinico Universitario A. Gemelli, Rome, Italy, [3]Medical Oncology, Azienda Ospedaliero-Universitaria Careggi, Florence, Italy, [4]Medical Oncology, Hospital de Galdakao, Galdakao, Spain, [5]Medical Oncology, Istituto Oncologico Giovanni Paolo II, Bari, Italy, [6]Medical Oncology, Hospital de León, Leon, Spain

Background: The non-interventional NIMES-ROC phase IV trial (NCT02825420) aimed to evaluate trabectedin (1.1 mg/m^2)+PLD (30 mg/m^2) in real-life clinical practice and given in accordance with the marketing authorization to women with PSROC regardless of previous anti-angiogenic treatment.

Methods: Eligible patients were adults with PSROC who have received ≥1 cycle of trabectedin+PLD before inclusion. The primary endpoint was to assess the PFS according to investigator criteria.

Results:

Table: 987P

NIMES-ROC*	PRIOR USE OF ANTIANGIOGENICS		
	Yes (n = 96)	No (n = 62)	Total (n = 158)

Not evaluable / Missing	15 (15.6)	6 (9.7)	21 (13.3)

∗Patients may be represented in multiple categories. CI, confidence interval; nr, not reached; PFI, platinum-free interval; PLD, pegylated liposomal doxorubicin; PS, performance status; ROC, recurrent ovarian cancer; T, trabectedin.

158 patients from 50 sites across Europe were evaluated. Median number of trabectedin+PLD cycles received per patient was 6, with 95 patients (50.6%) receiving ≥6 cycles and up 34 cycles. Median treatment duration was 22.2 weeks (range: 3-124), with no statistical difference concerning prior use of antiangiogenics, and mostly on an outpatient basis (≥63% of patients). Bevacizumab was the most used antiangiogenic in 84% of patients. With 73 PFS events and 32 deaths recorded, median PFS (11.4 months; 95% CI: 10-14) and OS (see Table) was significantly larger in patients not pretreated with antiangiogenics (PFS: $p < 0.009$; OS: $p < 0.018$). Non-antiangiogenic pretreated patients also obtained better overall response rate (ORR, 47% vs 32%) and disease control rate (ORR + SD: 79% vs 58%). A total of 108 trabectedin-emergent adverse reactions (TEAR) occurred. Most common grade 3/4 TEARs were neutropenia (25%) and asthenia (4%). The toxicity profile between subgroups was not different from that of the overall population.

Conclusions: Our results confirm that trabectedin+PLD is active in patients with PSROC with an acceptable and manageable safety profile. Overall our data favorably compare with those of the pivotal OVA-301 trial (NCT00113607) and suggest major benefits in patients non-pretreated with antiangiogenics who obtained significantly longer PFS.

Clinical trial identification: NCT02825420; ET-D-031-14.

988P Benefit from subsequent conventional cytotoxic chemotherapy (CTx) to immunotherapy (IT) in patients (pts) with gynaecological malignancies (GM)

F.J. Ros Montañá[1], V. Rodriguez Freixinos[1], L. Fariñas Madrid[2], F. Amair Pinedo[1], F. Ruiz-Pace[3], E. Garralda[4], R. Dienstmann[5], A. Oaknin[1]

[1]Medical Oncology, Vall d'Hebron University Hospital, Barcelona, Spain, [2]Oncology, Vall d'Hebron University Hospital, Barcelona, Spain, [3]Oncology Data Science Group (ODysSey), Vall dHebron Institute of Oncology (VHIO)-Cellex Center, Barcelona, Spain, [4]Early Drug Development Unit, Vall d'Hebron Institute of Oncology (VHIO)-Cellex Center, Barcelona, Spain, [5]Oncology Data Science, Vall d'Hebron University Hospital, Barcelona, Spain

Background: IT has been a breakthrough for the treatment of many tumour types, nevertheless it's use in GM remains an area of ongoing clinical research. Early evidence suggests that IT treatment may sensitize to subsequent CTx. Our aim was to investigate the efficacy of pre-and post-IT CTx in a cohort of GM.

Methods: From 2014 to 2017, 60 GM pts were treated with IT in phase I/II trials at Vall dHebron Hospital. Data was retrospectively collected from those pts who received Ctx pre- and post-IT. Endpoints: Progression free survival (PFS), clinical benefit rate (CBR) at 6 months (m) and overall response rate (ORR).

Results: A total of 28 (47%) pts (18 ovarian cancer [OC], 8 cervical cancer [CC] and 2 endometrial cancer [EC]) with median age of 53 (31-77), ECOG 0-1 (95%) and 2 median (1-5) pre-IT CTx lines were identified. IT was single agent PD1/L1 inhibitor in 46% of cases, the remaining receiving a combination of IT drugs. Median PFS on IT was 3.0m (2.0-5.3), CBR was 36% and ORR 10%. Platinum-based CTx was given to 83% of the patients pre-IT and 50% post-IT. The table summarizes clinical endpoints stratified by tumor type. Of note, 2 OC pts had longer PFS with platinum-based Ctx post-IT compared to pre-IT (15.9 vs 5.4 m and 21.4 vs 16.5 m). Such pattern was not observed in any pt with CC or EC. There was no association between benefit on IT and pattern of response to post-IT CTx.

Conclusions: A significant proportion of heavily pretreated GM pts are still treated with CTx after failure of IT. Although limited by sample size, our study did not show signals of improved sensitivity to CTx post-IT. GM pts retained the potential to respond to subsequent CTx. Further studies are needed to define the optimal timing of IT and to define potential predictors of improved CTx benefit.

989P Identification research and application for protein phosphorylation modification sites in human ovarian carcinoma

X. Zhan[1], N. Li[2]

[1]Key Laboratory of Cancer Proteomics of Chinese Ministry of Health, Xiangya Hospital, Central South University, Changsha, China, [2]Key Laboratory of Cancer Proteomics of Chinese Ministry of Health, Xiangya Hospital, Changsha, China

Background: Phosphorylation modification, as one kind of protein post-translational modification (PTM), increases the diverse protein functions, such as cell signaling, protein folding, enzymatic activity, protein degradation, and their subcellular location. However, the subcellular phophoproteomic of ovarian carcinoma mitochondrial proteins has not been elucidated.

Methods: Here, an 8-plex isobaric tag for relative and absolute quantification (iTRAQ) proteomics was used to identify mitochondrial expressed proteins (mtEPs) and phosphorylation modification sites of ovarian carcinomas relative to controls, followed by bioinformatics analysis.

Results: The iTRAQ-based proteomics identified 5115 proteins and 99 phosphorylated proteins with quantitative information from purified mitochondrial samples, and 262 proteins were significantly related to overall survival in ovarian cancer patients. Interestingly, the results demonstrated that cancer cells exhibit an increased dependence on lipid metabolism, such as biosynthesis of unsaturated fatty acids, butanoate metabolism, fatty acid degradation, fatty acid metabolism, which might play an important role in ovarian carcinoma invasion and metastasis. Moreover 33 proteins related to lipid metabolism as potential markers for the development of ovarian carcinoma were identified.Additionally, 3 drug-associated phosphorylation proteins and 3 phosphorylation proteins as tumor markers in the plasma were obtained. The 99 phosphorylated proteins and TCGA data were integarated, thus obtained 9 important proteins. Among those, HSP60 were highly related with lipid metabolism. In cells with increased Hsp60 levels both the amounts of total mitochondrial short-chain acyl-CoA dehydrogenase (ACADS) proteins and folded ACADS were increased, which may influence mitochondrial protein folding and lipid metabolism.

Conclusions: The current study provides a large-scale mitochondrial proteomic profiling and mitochondrion phosphoproteome with quantitative information, a certain number of proteins with the potential biomarkers, drug targets and a novel vision in the lipid metabolism bio-mechanism of human ovarian carcinoma.

990P Enhancing prognosis prediction using nodal SUVmax and HPV status in cervical squamous cell carcinoma

S.Y. Jeong[1], G.O. Chong[2], C.M. Hong[1]

[1]Nuclear Medicine, Kyungpook National University School of Medicine, Daegu, Republic of Korea, [2]Obstetrics and Gynecology, Kyungpook National University School of Medicine, Daegu, Republic of Korea

Background: A risk stratification model using metabolic variables on PET/CT combined with other known prognostic factors has not been proposed. To evaluate the prognostic classification model for predicting tumor recurrence using metabolic parameters on F-18-FDG PET/CT, status of human papillomavirus (HPV) infection and known prognostic variables in patients with locally advanced cervical cancer treated with concurrent chemoradiotherapy (CCRT).

Methods: A total of 129 patients with cervical squamous cell carcinoma who underwent initial CCRT were eligible for this study. The clinical, pathological parameters, HPV status and metabolic parameters of pre-operative F-18 FDG PET/CT were used for analysis. Univariate and multivariate analysis for disease-free survival (DFS) were performed using traditional prognostic factors, metabolic parameters and HPV infection. Classification and regression decision tree (CART) was used to establish new classification.

Results: Among 129 patients, 29 patients (22.5%) had recurrence after a median follow-up of 60 months (range, 3–125 months). In univariate analysis, FIGO stage, tumor size, status of para-aortic lymph node metastasis, Nodal SUVmax, HPV positive were statistically significant in DFS. Multivariate analysis revealed that tumor size, paraaortic lymph node metastasis, nodal SUVmax and HPV infection status were independent prognostic factors. CART analysis classified the patients into three groups. First node was nodal SUVmax and HPV status was second node for patients with nodal SUVmax$\leq$7.49 ($p < 0.001$); Group A (nodal SUVmax$\leq$7.49 and HPV positive), group B (nodal SUVmax$\leq$7.49 and HPV negative) and group C (nodal SUVmax>7.49). There was significant difference of DFS among 3 groups ($p = 0.0012$).

Conclusions: The present study revealed that the nodal SUVmax on F-18 FDG PET/CT and HPV infection status before CCRT are powerful an independent prognostic factor for the prediction of disease free survival in patients with cervical squamous cell carcinoma who underwent initial CCRT. Furthermore, simple prognostic classification model using nodal SUVmax and HPV infection status can provide classification of recurrence.

991P Clinical characteristics of ovarian cancer relapse in BRCA1/2 germ-line mutation carriers and non-carriers

A.P. Sokolenko, T.V. Gorodnova, A.O. Ivantsov, I.V. Berlev, E.N. Imyanitov

Department of Tumor Growth Biology, N.N. Petrov Institute of Oncology, St. Petersburg, Russian Federation

Background: Approximately 15% of ovarian cancer (OC) incidence is attributed to germ-line mutations in BRCA1 or BRCA2 genes. Being a distinct biological subset of OC disease, BRCA1/2-driven cancers are usually characterized by good response to chemotherapy. However, even if OC patient undergoes complete surgical cytoreduction and potentially effective systemic therapy, the probability of the tumor relapse is high. This study aimed to compare some essential clinical features of OC relapses in hereditary vs. sporadic OC.

Methods: We identified 212 women with relapsed high-grade serous OC, who were treated in the N.N. Petrov Institute of Oncology within years 2000-2014, underwent complete primary (n = 113) or interval (n = 99) surgical debulking, and had available clinical data for analysis. 66 women were BRCA1/2 germ-line mutation carriers and 146 were mutation negative. Recurrences were classified according to anatomical location (local, regional, distant, marker), type (systemic or discrete) and pattern of spread.

Results: As expected, median PFI (platinum-free interval) in BRCA1/2 carriers was longer as compared to sporadic cases (13.2 months vs. 8.0 months) [$p < 0.001$]. The proportion of OC cases with PFI > 12 months was significantly higher among BRCA1/2 carriers [38/66 (58%) vs. 51/146 (35%), $p = 0.003$]. There was no statistical difference in the frequency of distant relapses between these groups [10/66 (15%) vs. 31/146 (21%), $p = 0.4$]. Systemic recurrences (i.e., multiple lesions) occurred significantly more frequently in sporadic cases as compared to patients with BRCA1/2 mutation [98/144 (68%) vs. 30/60 (50%), $p = 0.02$] and were associated with shorter duration of PFI [$p = 0.003$]. The proportion of patients who could be subjected to the local treatment (locoregional discrete recurrence with lymphatic/transcoelomic spread) was higher among BRCA1/2 mutation carriers than non-carriers [29/66 (44%) vs. 45/146 (31%), $p = 0.045$].

Conclusions: BRCA1/2-driven OC are characterized by more favorable mode of relapse than sporadic high-grade serous ovarian cancers.

992P Phase Ib study of metformin in combination with carboplatin/paclitaxel chemotherapy in patients with advanced epithelial ovarian cancer

K.E. Broekman[1], A.K.L. Reyners[1], D.J. Touw[2], M.A.J. Hof[2], M. Jalving[1]

[1]Medical Oncology, University Hospital Groningen (UMCG), Groningen, Netherlands, [2]Clinical Pharmacy and Pharmacology, University Medical Centre Groningen (UMCG), Groningen, Netherlands

Background: Metformin is associated with reduced cancer risk in epidemiological studies and has preclinical anti-cancer activity in ovarian cancer models, likely through inhibition of the mTOR pathway. The primary study objective was to determine the recommended phase II dose (RP2D) of metformin in combination with carboplatin/paclitaxel in ovarian cancer patients. Secondary objectives were to describe safety and pharmacokinetics.

Methods: In this phase Ib single-centre trial the RP2D of metformin in combination with carboplatin/paclitaxel chemotherapy in patients with advanced epithelial ovarian cancer was determined using a 3 + 3 escalation rule at 3 fixed dose levels: 500 mg tds, 850 mg tds and 1000 mg tds. Chemotherapy consisted of carboplatin AUC6 and paclitaxel 175 mg/m^2 q3w. Metformin was started on day 3 of the first cycle and continued until three weeks after the last chemotherapy administration. The RP2D was defined as the dose level at which 0 of 3 or $\leq$ 1 of 6 evaluable subjects experienced a metformin-related dose-limiting toxicity (DLT) during chemotherapy cycle 1 or 2. Safety was assessed according to CTCAE v4.0. Pharmacokinetic samples were collected during treatment cycles 1 and 2.

Results: Fifteen patients undergoing neo-adjuvant (n = 5) or palliative (n = 10) treatment were included. No DLTs were observed. Three patients discontinued study treatment during cycle 1 for other reasons than DLT. Six patients were treated at the RP2D of metformin 1000 mg tds. Preliminary safety data showed that most common low-grade toxicities were anemia and hypomagnesaemia. Grade 3 AE's occurred in ten patients, most commonly leukopenia (n = 4), thrombocytopenia (n = 3) and increased GGT (n = 3). There were no grade 4 AE's. Pharmacokinetic analysis showed a metformin induced increase in AUC of carboplatin (Δ24%, $p = 0.028$). All metformin trough levels were <4 mg/L.

Conclusions: The RP2D of metformin in combination with carboplatin and paclitaxel in advanced ovarian cancer is 1000mg tds. This is higher than the metformin RP2D in combination with targeted agents. The clinical relevance of the metformin-induced increase in carboplatin AUC remains to be elucidated.

Clinical trial identification: NCT02312661.

993P Individual and familial phenotype in hereditary ovarian cancer

M.B.D.O. Mira[1], I. Miguel[2], S. Fragoso[3], A. Opinião[2], A.C. Luís[2], A. Clara[2], S. Bento[2], P. Machado[3], S. Santos[3], P. Rodrigues[2], J. Parreira[2], F. Vaz[2]

[1]Medical Oncology, Instituto Português de Oncologia de Lisboa Francisco Gentil, E.P.E. (IPOLFG EPE), Lisbon, Portugal, [2]Family Risk Clinic, Instituto Português de Oncologia de Lisboa Francisco Gentil, E.P.E. (IPOLFG EPE), Lisbon, Portugal, [3]Molecular Pathology Investigational Center, Instituto Português de Oncologia de Lisboa Francisco Gentil, E.P.E. (IPOLFG EPE), Lisbon, Portugal

Background: Germline mutations impacting homologous recombination repair (HCR) have been associated with predisposition to breast (BC) and ovarian cancer (OC), and more than 1/5 of OC have hereditary susceptibility (HOC). Other genes than BRCA have been associated with HOC.

Methods: All index, consecutive, non-mucinous OC patients (pts) counselled between September 2016-December 2017 were tested upfront for a panel testing (PT) including BRCA1, BRCA2, RAD50, RAD51C, RAD51D and BRIP1 (BRCA Hereditary Cancer MASTER Plus methodology). We analyze the molecular results, their clinical characteristics and family history (FH).

Results: One hundred and one female pts with OC diagnosis consented to PT. Pathogenic variants (PV) were found in 19 pts (18.8%): BRCA2 – 8 (42%), BRCA1 – 5 (26%), RAD51C – 3 (16%), RAD51D – 2 (11%), RAD50 – 1 (5%). The majority of these OC had been previously classified as high-grade serous (HGS) (n = 13 - 68%).We identified 2 pts with low-grade serous carcinoma (LGSC) with pathogenic variants (1 BRCA2; 1 RAD51C). Although median age of diagnosis (MAD) was lower for BRCA2 (55 years) and BRCA1 (58 years) than "non-hereditary" and RAD50/RAD51C/RAD51D pts (both groups with MAD of 63 years), difference was non significant ($p = 0.21$). As for FH (defined as: other OC and/or BC < 50 years and/or male BC), only 54% of BRCA1/2 pts and none of RAD50/RAD51C/RAD51D had a positive FH. Eighteen percent of "non-hereditary" OC pts had positive FH. With a median follow up of 5 yrs, 63% of pts harboring PV and 50% of those with no PV relapsed, with 2 pts having central nervous system relapses (1 - RAD51D and 1 - RAD50). All but 7 pts were alive at analysis time, only one with a germline mutation impacting HCR (RAD50 mutation).

Conclusions: Family history was not associated with the detection of germline pathogenic variants and should not be a criteria for selection of OC for genetic testing. While the inclusion of other genes in our panel may increase our detection rate, excluding LGSC (not included in some guidelines as candidates for testing) would not detect an undetermined number of pts, since the association between LGSC and HOC is not clarified. Longer follow up may help clarify if there is a genotype/phenotype correlation regarding patterns of relapse in hereditary ovarian cancer.

994P Role of FGFR2 amplification in prognosis of patients with ovarian cancer

A. Tyulyandina[1], I. Demidova[2], M. Gikalo[2], S. Tjulandin[1], I. Tsimafeyeu[3]

[1]Department of Clinical Pharmacology and Chemotherapy, N. N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation, [2]Laboratory of Molecular Genetics, Moscow City Oncology Hospital No. 62, Moscow, Russian Federation, [3]Head Office, Russian Society of Clinical Oncology, Moscow, Russian Federation

Background: Fibroblast growth factor receptor (FGFR) signaling has been implicated to play a role in tumorigenesis. Aim of this study was to evaluate rate of FGFR2 amplification and preliminary role in patients (pts) with ovarian cancer (OC).

Methods: Material from each patient with advanced OC included 3 paraffin-embedded samples: primary ovarian tumor, primary metastatic lesion, and relapse lesion. Samples were analyzed by fluorescence in situ hybridization (FISH) to identify FGFR2 amplification and level of polysomy. Scoring for amplification and polysomy level was adopted from previous studies for gastric cancer [Su et al. BJC 2014]. The analysis was performed in all three samples regardless of the presence of FGFR2 amplification or heterogeneity in primary tumor.

Results: 166 samples from 67 pts with advanced ovarian cancer (OC) stage Ic-IV were analysed. Amplification was detected in 11 of 67 pts (16.4%) and high-level polysomy in 31 of 67 (46.3%). All three tumour samples were analyzed in 43 pts. FGFR2 amplification, high-level polysomy were detected in 9 (20.9%) and 19 (44.2%), respectively. Analysis of survival differences revealed no statistically significant difference between

the pts with polysomy and non-amplified pts (HR 2.12; 95% CI 0.17-0.21, p = 0.32). Median progressive free survival (PFS) after first line platinum based chemotherapy was 12.6 months in pts with amplification in comparison with 23.1 months in non-amplified (p = 0,012). Pts with amplification in primary tumour (ovary) had statistically poor prognosis than non-amplified pts: median PFS was 12.0 and 22.6 months respectively (p = 0.003). Pts with FGFR2 amplification in primary metastatic lesions and relapsed tumour had tendency to poor prognosis: PFS was 10.3 and 19.6 months in primary metastasis lesions (p = 0.09), and 10.3 vs 22.6 months in relapsed lesions (p = 0.07).

Conclusions: We described FGFR2 amplification in 16.4% of pts with advanced OC. Preliminary data demonstrate a negative impact of the FGFR2 amplification in primary tumour (ovary) on long-term outcomes.

995P MONITOR VII: Treatment strategies of low grade ovarian carcinomas – A German survey of the Charité – Berlin and Kliniken Essen Mitte with support of the study groups NOGGO and AGO

S. Alavi[1], P. Harter[2], R. Richter[3], M. Keller[4], G. Oskay-Özcelik[1], A. Mustea[5], B. Schmalfeldt[6], P. Wimberger[7], F. Trillsch[8], S. Mahner[8], M. Klar[9], U. Wagner[10], R. Chekerov[1], A. du Bois[2], J. Sehouli[1]

[1]Department of Gynecology and Center for Oncological Surgery and European Competence Center for Ovarian Cancer, Charité Medical University, Berlin, Germany, [2]Gynecology & Gynecologic Oncology, Kliniken Essen Mitte Evang. Huyssens-Stiftung, Essen, Germany, [3]Department of Gynecology, European Competence Center for Ovarian Cancer, Charité - Universitätsmedizin Berlin, Berlin, Germany, [4]NOGGO, North-Eastern German Society of Gynecological Oncology, Berlin, Germany, [5]Department of Gynecology and Obstetrics, University Medicine Greifswald, Greifswald, Germany, [6]Gynaecology, University of Medical Center Hamburg-Eppendorf, Hamburg, Germany, [7]Department of Gynecology and Obstetrics, Universitätsklinikum Dresden, Dresden, Germany, [8]Gynaecology, AGO Study Group & University of Munich, Munich, Germany, [9]Department of Obstetrics and Gynecology, University Clinics of Freiburg, Freiburg, Germany, [10]Klinik für Gynäkologie, Gyn. Endokrinologie und Onkologie, University of Gießen and Marburg GmbH Site Marburg, Marburg, Germany

Background: Low grade serous carcinomas (LGSC), accounting for approximately 10% of the ovarian tumors, are associated with a better prognosis compared to high-grade serous carcinomas (HGSC). Nevertheless, we are confronted with a challenging treatment, since the median age at diagnosis is younger (55.5 years versus 62.6 years), standard platinum-based chemotherapy is less effective and most importantly, it has still not been as well studied as HGSC. The aim of this survey was to identify the current treatment strategies in Germany.

Methods: An anonymous, digital multiple-choice questionnaire, including 38 questions, was developed and provided to gynaecologists, gynaecologic oncologists and oncologists via Internet.

Results: From December 2017 to January 2018, a total of 180 participants took part in the survey (28% head physicians; 46% senior physicians). The median age was 49 years. 53% stated to have more than 15 years of experience in the treatment of cancer patients. No significant difference was seen in the extent of surgery between HGSC and LGSC (answered by 45%). While 88% stated to perform lymphonodectomy (LNE) for diagnostic and prognostic reasons, 69% used LNE as a decision-making tool for adjuvant therapy (answered by 47%). The most important factors for the indication of chemotherapy (answered by 47%) were comorbidities (92%), residual tumor (79%) and tumor histology (77%). While 43% did not consider antihormonal therapy as a treatment option, 39% stated to indicate a therapy with PARP-inhibitors (answered by 47%).

Conclusions: The results of this study underline the uncertainty in the treatment of LGSC. The implementation of own treatment standards and a prospective register for patients with LGSC is necessary and planed.

996P The ability of whole body SUVmax on F-FDG PET/CT in predicting suboptimal cytoreduction at primary debulking surgery in advanced ovarian cancer

G.O. Chong[1], S.Y. Jeong[2], S-W. Lee[2]

[1]Obstetrics and Gynecology, Kyungpook National University School of Medicine, Daegu, Republic of Korea, [2]Nuclear Medicine, Kyungpook National University School of Medicine, Daegu, Republic of Korea

Background: The role of F-18 FDG PET/CT to predict primary optimal cytoreductive surgery for advanced ovarian cancer has not been reported. The aim of this study was to evaluate the predictive value of SUVmax on FDG PET/CT to predict suboptimal cytoreduction and to make risk model for predicting suboptimal cytoreduction using metabolic parameters in advanced ovarian cancer.

Methods: From 2011-2015, 51 patient underwent primary cytoreductive surgery for advanced ovarian cancer (FIGO stage III-IV). Residual disease measuring > 1 cm in maximal diameter was considered a suboptimal surgical result. Whole body 1 SUVmax (WB1SUVmax) was defined as sum of SUVmax in nine abdominal regions (central, right upper, epigastrium, left upper, left flank, left lower, pelvis, right lower, right flank). Whole body 2 SUVmax (WB2SUVmax) was added SUVmax of 3 regional lymph nodes (pelvis, paraaortic and extra-abdominal) to WB1SUVmax. We used the multiple logistic regression analysis to determine predictive value of WBSUVmax. Furthermore, disease-free survival (DFS) and overall survival (OS) were performed using risk model.

Results: Seventeen of 51 patients (33.3%) underwent suboptimal cytoreduction. According to the univariate analysis only ECOG status was associated with suboptimal cytoreduction with marginal significance among the clinical parameters (OR, 4.091; 95% CI, 0.97-17.29; p = 0.0520). Among the PET metabolic parameters, PET central (OR, 5.250; 95% CI, 1.41-19.59; p = 0.0136), PET right upper (OR, 4.148; 95% CI, 1.13-15.19; p = 0.0317), and PET left upper (OR, 5.921; 95% CI, 1.17-30.02; p = 0.0318) were significantly associated with prediction of suboptimal cytoreduction. Moreover, WB2SUVmax was significantly associated with suboptimal cytoreduction (OR, 4.148; 95% CI, 1.13-15.19; p = 0.0317). Kaplan-Meier survival plots showed DFS and OS of high risk group were significantly worse compared to those of low risk group (p = 0.0379 for DFS; p = 0.0211 for OS).

Conclusions: WBSUVmax was significantly associated with suboptimal cytoreduction. Furthermore, hypermetabolic lesions at central and both upper had predictive value for suboptimal cytoreduction.

997P Brain metastasis in ovarian cancer patients

A.A.B.A. da Costa[1], E.S. Dos Santos[1], L. de Brot[1], A.R.G. Ribeiro[2], D.P. Cotrim[2], N. Carvalho Pandolfi[3], M.G. Cesca[3], M.J. Chen[4], G. Baiocchi[5]

[1]Medical Oncology, A.C. Camargo Cancer Center, São Paulo, Brazil, [2]Medical Oncology, A. C. Camargo Cancer Center, São Paulo, Brazil, [3]Clinical Oncology, A. C. Camargo Cancer Center, São Paulo, Brazil, [4]Radiation Therapy, A. C. Camargo Cancer Center, São Paulo, Brazil, [5]Gynaecology Oncology, A. C. Camargo Cancer Center, São Paulo, Brazil

Background: Central nervous system (CNS) metastasis is a rare event in ovarian cancer patients and current prognostic index used for other tumors do not fit for ovarian cancer patients with brain metastasis (BM). We sought to evaluate prognostic factors for overall survival (OS) in ovarian cancer patients with BM.

Methods: We retrospectively evaluated patients with diagnosis of ovarian carcinoma and BM treated at A.C. Camargo Cancer Center from January 2007 to December 2017. Clinical data from diagnosis and at the moment of diagnosis of BM were collected. OS was defined as the time from diagnosis of BM to the moment of death by any cause. OS was calculated using Kaplan Meier curves and log rank test was used to compare OS curves. Univariate cox regression was used to evaluate prognostic factors for OS.

Results: From 560 patients 26 presented BM. Median age at diagnosis of BM was 62.9 years old, 23 patients had high grade serous carcinoma, 2 had high grade endometrial carcinoma and 1 carcinosarcoma. Recurrences in the brain were classified as platinum sensitive in 14 patients (53.8%) and platinum resistant in 11 patients (42.3%), ECOG performance status was 0 or 1 in sixteen patients. Fourteen patients (53.8%) had disease progression exclusively in the CNS. The median number of BM was 4, and medium size of the largest lesion was 3.2cm. Median time from initial diagnosis to BM was 31.7

months. Eight patients were treated with surgery, 15 with whole brain radiotherapy (RT), 5 with stereotaxic RT and 4 patients received systemic treatment at the moment of BM diagnosis. Median follow up was 18.7 months and median OS was 10.8 months. Factors associated to OS were as following: platinum sensitive recurrence (HR 0.34, CI95% 0.12-0.99; p = 0.049), higher number of previous treatment lines (HR 1.57, CI95% 1.12-2.19; p = 0.008), ECOG performance status (HR 2.52, CI95% 1.24-5.09; p = 0.010), and longer interval from initial diagnosis to BM (p = 0.025). Notably, number of brain metastasis, largest tumor size and progression outside CNS were not related to survival.

Conclusions: Factors related to sensitivity to platinum therapy and BM as early event during the course of disease seem to be more related to survival than factors usually related to survival in BM from other cancers.

Ltd., Beijing, China

Background: Poly (ADP-ribose) polymerase inhibitors (PARPis) represent a class of antitumor agents that exert their cytotoxic effects by inhibiting PARP activity. PARPis are also capable of trapping PARP proteins complexes on damaged DNA, further augmenting cell death. Pamiparib is a selective PARP1/2 inhibitor with potent PARP trapping ability that can cross the blood-brain barrier and has demonstrated antitumor activity in both in vitro and in vivo nonclinical tumor models harboring BRCA gene mutations ($BRCA^{mut}$) and other homologous recombination deficiencies. In Phase 1 studies (NCT02361723; NCT03333915), single-agent pamiparib was generally well tolerated and showed antitumor activity, notably in patients with high-grade non-mucinous ovarian cancer (HGOC). Antitumor activity was observed in patients with BRCA mutant and BRCA wild type ovarian cancers, whose tumors were either sensitive or had platinum-resistant disease. Data from these Phase 1 studies support the recommended Phase 2 pamiparib monotherapy dose of 60 mg PO BID.

Trial design: In this ongoing study of pamiparib in China (NCT03333915), patients with HGOC harboring germline $BRCA^{mut}$ who have received ≥2 prior lines of therapy are being enrolled in the Phase 2 part of the study. Patients with either platinum-sensitive (progression occurring ≥6 months after last dose of platinum) or platinum-resistant (progression occurring <6 months after last dose of platinum) HGOC are eligible. Germline $BRCA^{mut}$ status is identified or confirmed by central testing before enrollment. Approximately 100 patients with HGOC (platinum-sensitive, n = 80; platinum-resistant, n = 20) will receive pamiparib 60 mg PO BID until disease progression. The primary objective is to assess overall response rate according to RECIST v1.1; secondary objectives include assessment of pamiparib's safety, tolerability, and pharmacokinetic profile. Evaluation of antitumor activity will include an estimation of overall and progression-free survival, as well as duration of clinical response.

Clinical trial identification: NCT03333915.

999TiP OVARIO: A single-arm, open-label phase II study of maintenance therapy with niraparib + bevacizumab (bev) in patients (pts) with advanced ovarian cancer (OC) after response to frontline platinum-based chemotherapy (chemo)

M. Hardesty[1], J.M. Hope[1], T. Krivak[2], J. Chen[3], M. Wainszelbaum[3], D. Gupta[4], D. Richardson[5]

[1]Obstetrics & Gynecology, Alaska Women's Cancer Care, Anchorage, AK, USA, [2]Obstetrics & Gynecology, The Western Pennsylvania Hospital, Pittsburgh, PA, USA, [3]Biostatistics, Tesaro, Inc., Waltham, MA, USA, [4]Clinical Science, Tesaro, Inc., Waltham, MA, USA, [5]Gynecologic Oncology, Oklahoma University, Health Sciences Center, Oklahoma City, OK, USA

Background: Most pts with advanced OC will experience recurrence within 2 years of initial platinum-based treatment. An unmet need exists for therapies that delay disease recurrence. Niraparib (Zejula®) is a selective poly(ADP-ribose) polymerase (PARP) 1/2 inhibitor approved for maintenance in pts with recurrent OC regardless of BRCA or homologous recombination deficiency (HRD) status. Bev is a VEGF inhibitor approved in OC for treatment and maintenance therapy. Targeted therapies + VEGF inhibition showed synergy in preclinical models. Induction of intratumoural hypoxia downregulating *BRCA* and *RAD51* may sensitize tumours to PARP inhibition and lead to apoptosis via contextual synthetic lethality. Niraparib + bev is being explored in the treatment setting in the ongoing phase 1/2 AVANOVA trial, which has shown that niraparib can be safely combined with bev. In OVARIO, niraparib + bev will be evaluated in the maintenance setting in pts with advanced OC who have recovered from primary debulking surgery and responded to frontline platinum-based chemo with bev.

Trial design: Target enrolment is 90 pts, regardless of *BRCA* or HRD status, with stage 3b and 4 epithelial ovarian, fallopian tube, or peritoneal cancer. Pts must achieve complete or partial response or no evidence of disease after frontline platinum-based chemo with bev. The starting dose of niraparib will be based on baseline body weight and/or platelet count. Pts weighing ≥77 kg with a platelet count of ≥ 150,000/μL will receive 300 mg qd. Pts weighing <77 kg or with a platelet count of < 150,000/μL will receive 200 mg qd. The bev dosage will be 15 mg/kg q3w up to 15 months. Pts will be treated continuously until disease progression or unacceptable toxicity. The primary objective for OVARIO is progression-free survival at 18 months. Secondary objectives include overall survival, time to first subsequent therapy, and safety and tolerability.

Clinical trial identification: NCT03326193.

1000TiP OPINION: A single-arm, open-label, phase IIIb study of olaparib maintenance monotherapy in patients (pts) with platinum-sensitive relapsed ovarian cancer (PSROC) and without germline BRCA mutations (non-gBRCAm)

A.M. Poveda[1], R. Davidson[2], C. Blakeley[2], A. Milner[3]

[1]Department of Gynecologic Oncology, Fundación Instituto Valenciano de Oncología, Valencia, Spain, [2]GMA Oncology TA, AstraZeneca, Cambridge, UK, [3]Biometrics and Information Sciences, AstraZeneca, Cambridge, UK

Background: Olaparib (tablet formulation) is approved in the US for maintenance treatment of PSROC based on 2 pivotal studies (Study 19 [NCT00753545], SOLO2 [NCT01874353]), which showed a significant progression free survival (PFS) benefit. In Study 19, clinical benefit was observed in pts with or without BRCA mutations, supporting the hypothesis that platinum sensitivity is a surrogate marker for homologous recombination deficiency (HRD). This study was designed to further prospectively explore olaparib activity in non-gBRCAm pts.

Trial design: This single-arm, open-label, multicenter, phase 3b study (OPINION; NCT03402841) was designed to assess the efficacy and safety of olaparib maintenance therapy in women with non-gBRCAm, high-grade serous or endometrioid PSROC. Eligible pts (≥18 y, ECOG PS 0-1, ≥2 lines of prior platinum therapy [PT], and in response [CR/PR] to last PT) will be treated with olaparib 300 mg tablets twice daily until disease progression or unacceptable toxicity. Primary endpoint is investigator-assessed PFS (RECIST v1.1). Secondary endpoints are time to first subsequent therapy or death, time to treatment discontinuation or death, chemotherapy-free interval, PFS by tumor HRD status, and health-related quality of life (FACT-O). Safety and tolerability also will be assessed. Exploratory endpoints are overall survival, evaluating treatment impact and disease state on health state utility (EQ-5D-5L), and PFS in pts stratified by molecular subgroups (including mutations in HR repair genes, microsatellite instability status, TP53 mutation disruption status, and tumor mutation load score). Correlation between HRD status from tumor and circulating tumor DNA in matched pts also will be explored. A sample size of 250 pts was opted for adequate level of precision for PFS estimation, with mean 95% CI width at 30 mo after first pt is

estimated at 3.27 mo from 500 simulations of a piecewise exponential model with median PFS of 8.5 mo at 12 mo enrollment. Efficacy analyses will be based on all enrolled pts and safety analyses on enrolled pts receiving ≥1 olaparib dose. Enrollment is ongoing.

Clinical trial identification: NCT03402841.

Editorial acknowledgement: Editorial assistance, which was in accordance with Good Publication Practice (GPP3) guidelines, was provided by Kaveri Sidhu, PhD, of Cactus Communications (Mumbai, India).

1001TiP A phase II clinical trial of veliparib and topotecan in patients with platinum resistant ovarian cancer

A.E. Wahner Hendrickson[1], B. Costello[1], A. Jewell[2], V. Kennedy[3], G. Fleming[4], B. Corr[5], S.E. Taylor[6], J. Lea[7], J. Reid[8], E. Swisher[9], D. Satele[10], J. Allred[10], J. Lensing[1], S.P. Ivy[11], C. Erlichman[1], A.A. Adjei[1], S. Kaufmann[8]

[1]Department of Oncology, Mayo Clinic, Rochester, MN, USA, [2]Department of Obstetrics and Gynecology, University of Kansas, Kansas City, KS, USA, [3]Department of Obstetrics and Gynecology, UC Davis Medical Center, Davis, CA, USA, [4]Department of Medicine (Section of Hematology/Oncology), University of Chicago, Chicago, IL, USA, [5]Department of Gynecologic Oncology, University of Colorado Denver, Aurora, CO, USA, [6]Department of Obstetrics, Gynecology and Reproductive Services, University of Pittsburgh Cancer Institute, Pittsburgh, PA, USA, [7]Department of Obstetrics and Gynecology, University of Texas Southwestern Medical Center, Dallas, TX, USA, [8]Department of Oncology Research, Mayo Clinic, Rochester, NY, USA, [9]Department of Gynecologic Oncology, University of Washington, Seattle, WA, USA, [10]Department of Biostatstics, Mayo Clinic, Rochester, NY, USA, [11]Cancer Therapy Evaluation Program, National Cancer Institute, Bethesda, MD, USA

Background: Preclinical observations indicate that addition of PARP inhibitors to topoisomerase I-directed agents such as topotecan results in increased antitumor efficacy in vitro and in vivo. However, when veliparib or olaparib were combined with conventional 5 day topotecan in patients, the regimens were quite myelosuppressive. In contrast, a phase I trial of veliparib in combination with weekly topotecan, a less myelosuppressive but routinely used regimen, demonstrated a manageable safety profile and early signs of activity. This was manifested by responses or disease stability for ≥ 4 months in 52% of patients, particularly in ovarian cancer patients with deleterious germline repair pathway mutations. Therefore, a phase 2 clinical trial is now underway.

Trial design: This single arm, multi-center clinical trial is open and available at Experimental Therapeutics Clinical Trials Network (ETCTN) sites in the US. The primary endpoint is response rate and the secondary endpoint is progression free survival. Correlative goals include assessing differences in toxicity and efficacy based on BRCA1/2 mutation status as well as evaluating the association between pretreatment tumor cell levels of topoisomerase 1, PARP, XRCC1 or P-glycoprotein and response. Eligible patients must have platinum resistant ovarian, primary peritoneal or fallopian tube cancer and have received 2 or fewer prior chemotherapy regimens. ECOG performance status of 0, 1, or 2 and adequate bone marrow, renal and hepatic function are also required. No prior PARP inhibitor therapy is allowed.

Clinical trial identification: NCT01012817.

Legal entity responsible for the study: NCI CTEP.

1002TiP BAROCCO: A randomized phase II study of weekly paclitaxel vs cediranib-olaparib with continuous schedule vs cediranib-olaparib with intermittent schedule in advanced platinum resistant ovarian cancer

N. Colombo[1], O. Nicoletto[2], P. Benedetti Panici[3], G. Tognon[4], A.A. Lissoni[5], A. Bologna[6], F. Tomao[3], R. Fossati[7], F. Tettamanzi[7], E. Rulli[7], F. Galli[7], M.F. Alvisi[7], V. Torri[7], E. Biagioli[7]

[1]Gynecologic Oncology, European Institute of Oncology and University of Milan-Bicocca, Milan, Italy, [2]Oncology, IRCCS Istituo Oncologico Veneto - IOV, Padua, Italy, [3]Gynecological and Obstetrics Sciences and Urological Sciences, Azienda Ospedaliera Universitaria Policlinico Umberto I, Rome, Italy, [4]Gynecology and Obstetrics, Università degli Studi di Brescia, Brescia, Italy, [5]Gynecologic Oncology, Ospedale S. Gerardo, Monza, Italy, [6]Oncology, IRCCS Azienda Ospedaliera Arcispedale Santa Maria Nuova, Reggio Emilia, Italy, [7]Oncology, IRCCS Istituto di Ricerche Farmacologiche Mario Negri, Milan, Italy

Background: Cediranib and olaparib have shown efficacy in ovarian cancer (OC) throughout several clinical settings. A phase II study demonstrated that the combination of the two drugs increased progression free survival (PFS) in women with recurrent platinum sensitive OC with respect to olaparib (Liu et al, 2014). The greatest benefit from the combination was observed in wild-type/unknown BRCA patients, therefore suggesting a possible effect of the combination in platinum resistant OC which are mainly BRCA proficient tumors. The most frequent grade ≥ 3 AEs with the combination were hypertension, diarrhea and fatigue, suggesting an amplificatory effect caused by cediranib. The purpose of this study is to test the efficacy of olaparib/cediranib combination in platinum resistant disease, comparing this regimen with weekly paclitaxel, and to identify a more tolerable schedule for this combination treatment.

Trial design: This is a randomized multicenter phase II open label study. Patients with platinum resistant OC will be randomized in a 1:1:1 ratio in a control and two experimental arms. Control treatment consists of administration of 80 mg/m^2 weekly paclitaxel, up to a maximum of 24 weeks or to progression. Combination therapy is administered up to progression with two different schedules: i. Continuous with 600 mg olaparib (tablets) and 20 mg cediranib given every day; ii. Intermittent with 600 mg olaparib (tablets) given every day and 20 mg cediranib given 5 days/week. The study has two primary endpoints: 1) PFS, to compare the efficacy between control and experimental arms with a 80% power to detect a benefit ≥ 3.3 months and, 2) the number of evacuations/day in the first 28 days of the combination therapy as tolerability indicator. If both experimental arms show superiority - in terms of PFS - to control treatment, these will be compared for tolerability. The study is registered at clinicaltrials.gov (NCT03314740) and is currently recruiting. Eighty-seven patients out of 100 planned have already been enrolled from 6 experimental sites in Italy in 11 months.

Clinical trial identification: EudraCT: 2016-003964-38; NCT03314740.

[1]Medical Oncology Division, Hospital das Clínicas da Faculdade de Medicina de Ribeirão Preto, Ribeirao Preto, Brazil, [2]Division of Gynecologic Oncology, Hospital das Clínicas da Faculdade de Medicina de Ribeirão Preto, Ribeirão Preto, Brazil, [3]Radiology and Oncology Department, Insituto do Cancer do Estado de São Paulo/Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [4]Division of Radiology and Radiotherapy, Hospital das Clínicas da Faculdade de Medicina de Ribeirão Preto, Ribeirão Preto, Brazil, [5]Gynecology, Insituto do Cancer do Estado de São Paulo/Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [6]Oncogynecologic Department, Hospital Quironsalud, Valencia, Spain, [7]Gynecology and Obstetrics, Ribeirão Preto Medical School, Ribeirao Preto, Brazil

Background: Chemoradiation is the current standard of care for advanced cervical cancer, however radiation is associated with long term side effects that may impair the quality of life of survivors. Recent findings from observational and case series suggest that women with stage IB2, IIA, and IIB who respond to neoadjuvant chemotherapy might be a candidate for radical surgery as the definitive treatment. This approach can

reduce long-term complications associated with chemoradiation and improve patient quality of life.

Trial design: Eligible patients are women aged ≥ 18y diagnosed with invasive cervical cancer stages IB2, IIA or IIB. The stage will be assessed by clinical examination and confirmed by pelvic MRI, CT of upper abdomen and CT of thorax. ECOG PS 0-1 and adequate organ function are required. Two hundred and forty-four patients will be randomly assigned to one of two arms. In arm 1, patients will receive standard chemoradiation (cisplatin 40mg/m2 IV: D1, D8, D15, D29 and D36 in concomitancy with external radiation 50.4Gy fractionated in 28 sessions of 1,8Gy followed by brachytherapy in four insertions of 7 Gy). In arm 2, patients will receive intravenous neoadjuvant chemotherapy (cisplatin 75mg/m2 D1 plus paclitaxel 80mg/m2) D1, D8 e D15, each 21 days, 3 cycles. After each cycle, the patient will be evaluated to verify toxicity and tumor response. After the third cycle, the patients with a complete clinical response or substantial tumor reduction (tumor restricted to cervix ≤4 cm), confirmed by pelvic MRI will undergo Piver-Rutledge class III abdominal hysterectomy and pelvic lymphadenectomy 3-6 weeks after the last cycle. Patients with tumor progression or severe toxicity after any cycle of neoadjuvant chemotherapy, or with inoperable tumor after the third cycle of neoadjuvant chemotherapy will be treated with definitive standard chemoradiation. The primary end point will be 5-years overall survival. Secondary endpoints will include survival free of disease, the rate of operability and complete pathological response in the neoadjuvant arm. The study is ongoing; one patient has been included, and three more are under preliminary evaluation for eligibility.

1017P **Estimating the incidence of cryptogenic organising pneumonia in chronic lymphocytic leukaemia patients: A real-world cohort study**

I. Faghmous[1], H. Ramroth[1], C. Aguilar[2], A. Van Troostenburg[2], P. Badyal[1]

[1]Epidemiology, Gilead Sciences, Uxbridge, UK, [2]PVE, Gilead Sciences, Uxbridge, UK

Background: Cryptogenic Organising Pneumonia (COP) is an understudied lung disease characterised by presence of granulation tissue within the alveolar ducts and alveoli. While prognosis of patients with COP is generally positive there remains a paucity of information on the condition in the academic literature. This abstract presents the largest real-world study of COP in Chronic lymphocytic Leukaemia (CLL) patients to date.

Methods: A retrospective cohort study utilising the IMS Pharmetrics Plus database. A CLL patient cohort was identified using ICD9/10 codes; patients with previous history of COP prior to CLL diagnosis were excluded from the analysis. As a comparator, a random 5% sample of all patients with no history of CLL was taken. Crude Incidence rates (CR) of COP were estimated in both groups. A Poisson regression model (PRM) was

fitted to estimate the age and sex adjusted incidence rate ratio (IRR) of experiencing COP in CLL patients versus those with no history of CLL. Tests for trend were conducted for age and sex.

Results: A total of 64,773 CLL and 3,201,48 non-CLL patients were included in the study. The CLL cohort comprised of 59% males with a total of 436 patients experiencing COP. The non-CLL cohort comprised of 47% males with 1,971 patients experiencing COP. The CR of COP in the CLL cohort was 2.4 (95% CI 2.2- 2.61) per 1,000 person years (py) and 0.20 (95% CI 0.19- 0.21) per 1,000 py in the non CLL cohort. An age and sex adjusted PRM estimated an IRR of 7.7 (95% CI 6.9- 8.68, p-value <0.001). A significant trend of increasing COP incidence was observed for age (p-value <0.001). However, no differences found for gender.

Conclusions: This study indicated that CLL patients had a higher rate of experiencing an episode of COP as opposed to non-CLL patients, adjusted for age and sex. As COP is difficult to distinguish from the infectious and non-infectious inflammatory pulmonary process in CLL patients, awareness of this increased risk may lead to earlier diagnosis and institution of treatment of COP. The role of co-morbidities and co-medications will be investigated in further analyses.

1018P Progression of disease within 2 years (POD24) is a clinically significant endpoint to identify follicular lymphoma patients with high risk of death

C. Sortais[1], A. Lok[1], T. Gastinne[1], B. Mahé[1], V. Dubruille[1], N. Blin[1], S. Howlett[2], A. Tabah[2], P. Arnaud[2], A. Moreau[3], P. Moreau[1], C. Leux[4], S. Le Gouill[1]

[1]*Service d'Hématologie Clinique, CHU de Nantes, Nantes, France,* [2]*Lymphoma Department, Celgene Medical, Summit, NJ, USA,* [3]*Service d'Anatomopathologie, CHU de Nantes, Nantes, France,* [4]*Service d'Information Médicale, CHU de Nantes, Nantes, France*

Background: Follicular lymphoma (FL) is an indolent non-Hodgkin's lymphoma with heterogeneous outcomes among patients. Casulo et al (JCO 2015) showed that progression of disease within 2 years (POD24) after diagnosis for FL patients treated by R-CHOP was associated with poor outcomes, needing further validations before using it as a standard endpoint to evaluate treatment efficacy. We investigated the POD24 predictive value for all patients treated or not with R-CHOP in our institution (Nantes Medical University, France).

Methods: Patients with grade 1, 2 or 3a FL treated from 2007 were registered in our local database (approved by French authorities, CNIL) and included in the present retrospective monocentric study, with up-dating of patient's outcomes. FL diagnosis was performed by local pathologist experts (members of the national LYSA-pathologist group, France).

Results: Between 2007 and 2016, 317 patients with confirmed FL were included. At diagnosis: 24 did not received any treatment (Wait and watch), 259 were treated with Rituximab (R) (including R alone in 98 cases), 143 received an anthracycline-containing regimen (mainly R-CHOP like), 5 received bendamustine-containing regimen, radiotherapy alone in 11 cases and another chemotherapy regimen in 36 cases (mainly R-COP). Second line treatment (N = 151) consisted of chemotherapy in 91 cases, R alone in 37 cases. After first line therapy, 61 patients relapsed or died within 2y (POD24+), 99 patients after 2y, including 21 transformations, and 154 patients did not progress or die (missing = 3). At the time of the present analysis, the median follow-up is 5y. Median PFS is 58.2 months. OS at 1y, 3y, and 5y are 98.4% [97.0-99.8], 95.1% [92.6-97.6] and 92.5% [89.3-95.9] respectively. The 5y OS was statistically worst for POD24+ patients (82 % [71.9-93.5]) than for POD24- patients (93.3% [88.98-97.8]) (p = 0.00001). Age at diagnosis (≥60), performance status (PS ≥ 1), FLIPI, FLIPI2 scores (high) and transformation are predictive of OS in univariate analysis. PS (≥1) at diagnostic is predictive of POD24+.

Conclusions: POD24 is predictive of a worse OS regardless of first line treatment nature and can be recommended as a relevant endpoint for clinical trials.

1019P Impact of genetic polymorphisms on prognosis and survival of diffuse large B-cell lymphoma

O. Novosad[1], I. Pastushenko[1], T. Skrypets[1], I. Tytorenko[1], T. Kadnikova[1], O. Skachkova[2], O. Gorbach[2], N. Svergun[2], N. Khranovska[2], I. Kriachok[1]

[1]*Onco-Hematology, National Cancer Institute of the MPH Ukraine, Kiev, Ukraine,* [2]*Experimental Oncology, National Cancer Institute of the MPH Ukraine, Kiev, Ukraine*

Background: DLBCL is the most common subtype of NHL in adults. The efficacy of chemotherapy in DLBCL patients has significantly increased in the last 10 years. Growing evidence has shown genetic and environmental factors are involved in the etiology and prognosis of DLBCL. Genetic polymorphisms can influence the individual susceptibility and clinical outcome for different types of Lymphomas. The aim of this study was to investigate the genetic polymorphism of glutathione S-transferase P1 (GSTP1), as a prognostic factor for patients with DLBCL.

Methods: 136 patients with DLBCL, 56 men and 80 women, median age - 47 y.o were included in the study. The patients received R-CHOP-like regimens. Genomic DNA was extracted from blood samples. GSTP1 polymorphism (c. 313 A > G, p. Ile105Val) were analyzed by Allelic Discrimination Real-Time PCR.

Results: A homozygous for the A313A GSTP1 genotype was detected in 65/136 (47.8%) patients, heterozygous A313G – in 57/136 (42%) and 14/136 (10.2%) were homozygous for the G313G genotype of DLBCL ($p < 0.05$). The GSTP1 genotype distribution was conformed to Hardy-Weinberg equilibrium ($\chi 2=0.05$;$p=1.01$). The frequency of the homozygous wild genotype of the GSTP1 was significantly higher in patients with advanced disease vs patients with early stages of DLBCL (57% vs 43%, $p < 0.05$). The ORR was 76% (104/136) during the follow-up (median – 16 months; range 25–96 months), 41% of patients (56/136) had relapse or progression and 42 (31%) of them died during the follow-up period. We found an association of GSTP1 homozygous wild genotype with an unfavorable prognosis of DLBCL. The A313A genotype was strongly associated with increased risk of the DLBCL r/r disease as compared with A313G or G313G genotypes (23% vs 14% vs 4%, respectively, $p < 0.05$). 5-years EFS for patients with A313A GSTP1 genotype was lower compared to patients with A313G or G313G genotypes (42 % vs 52%, $p < 0.05$). Thus, the A313A genotype impacts survival of DLBCL.

Conclusions: Results suggest the genotype of the GSTP1 (A313A) is associated with unfavorable prognosis of DLBCL, reduce EFS rate. Results can be promising, but further investigations might provide a possible application of this marker as a prognostic factor of DLBCL.

1021P Long term treatment outcome of patients with refractory or relapsed Hodgkin's lymphoma in the anthracycline era: A single-center intention-to-treat analysis

T.I. Bogatyreva, A.Y. Terekhova, S.S. Shklyaev, V.V. Pavlov, N.A. Falaleeva

Department of Radiotherapy and Chemotherapy for Hematological Malignancies, A.F. Tsyb Medical Radiological Research Center - Branch of the National Medical Research Center of Radiology of the Ministry of Health of the Russian Federation, Obninsk, Russian Federation

Background: High dose chemotherapy (HDT) with autologous stem cell transplantation (ASCT) is currently the treatment of choice for refractory or relapsed Hodgkin's lymphoma (HL) and cures up to 50% of patients. However, its applicability is restricted to selected eligible patients and/or responding to salvage chemotherapy. The aim was to compare outcomes after salvage regimens with and without HDT and ASCT in HL patients who failed or relapsed after ABVD or BEACOPP regimens.

Methods: From 856 patients with newly diagnosed HL registered in the MRRC database between 1998 and 2017 there were identified 131 patients with refractory disease (gr.1, n = 89), early (gr. 2, n = 31) or late (gr.3, n = 11) relapse. At first relapse, patients had median age 30 years (range, 17 to 69); male, 46%; stage III/IV, 70%; B symptoms, 28%. Of 131 patients, 76 (58%) received standard CT regimens (ST) when HDT was not available (n = 64) or contraindicated (12). HDT was initiated in 55 (42%) patients, but withdrawn in 38 of them (adverse effects, 9; progression, 24; low cytopheresis, 5). ASCT was performed in 17 (31%) patients.

Results: Median follow-up time after first failure for survived patients (79 of 131, 60%) was 60 months (8-186). Durable second remissions were achieved in 10 (59%) of 17 patients after ASCT and in 30 (40%) of 76 patients after ST. In an intention-to-treat (ITT) analysis median freedom from second failure (FF2F) after HDT and ST was, respectively, 4 vs. 15 months in Gr.1 (p = 0.018) but did not differ (15 and 16 months) in Gr.2; Gr.3 was too small for ITT. Median overall survival (OS2) after HDT and ST was, respectively, 22 vs. 158 months in Gr.1 (p = 0.036) and 42 vs. 52 months in Gr.2 (n.s).

Conclusions: This single center analysis demonstrates the effectiveness of standard CT regimens as first-line salvage in patients not eligible for HDT/ASCT. It also demonstrates the high failure rate due to inadequate chemo-responsiveness at salvage in patients referred to HDT: An effect not accounted for in studies analyzing only outcome following HDT/ASCT.

1022P Population-based use of intravenous bisphosphonates in patients newly diagnosed with symptomatic multiple myeloma in Denmark in 2005-2015: Impact of patient characteristics

V. Ehrenstein[1], A.G. Ording[1], S.P. Ulrichsen[1], I.T. Andersen[1], A. Seesaghur[2], C. Helleberg[3], T. Silkjær[4], R. Hernandez[5], D. Niepel[6], N. Abildgaard[7]

[1]Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark, [2]Amgen Limited, Cambridge, UK, [3]Department of Hematology, Herlev Hospital, Herlev, Denmark, [4]Department of Hematology, THG, University Hospital, Aarhus, Denmark, [5]Center for Observational Research, Amgen Inc., Thousand Oaks, CA, USA, [6]Amgen GmbH, Zug, Switzerland, [7]Department of Hematology, Odense University Hospital, Odense, Denmark

Background: Bone and kidneys are among the main affected organ systems in symptomatic multiple myeloma (MM) and may be associated with debilitating complications. Thus, bone health and renal protection are at the core of MM management. Bisphosphonates (BP) are recommended for prevention of bone complications in all newly diagnosed symptomatic MM patients, but BPs are also potentially nephrotoxic and are cleared by the kidneys. This study describes the routine clinical use of BP among MM patients in Denmark.

Methods: Adult patients newly diagnosed with MM between 01.01.2005 and 30.06.2015 were identified in the Danish National Multiple Myeloma Registry, and information on BP treatment in first-line (1L) anti-MM therapy was analyzed.

Results: Among 2,633 MM patients with information on BP treatment in 1L, 1,838 (69.8%) received BP. Median time from MM diagnosis to BP treatment was 19 days (IQR: 9, 35). Receipt of BP among 1L-treated patients by therapy was: 79.4% (635/799) in autologous stem cell transplant recipients, 75.0% (793/1,058) in patients treated with conventional chemotherapy, and 70.2% (903/1,286) in those treated with bortezomib-, lenalidomide-, or thalidomide-containing regimens. Among the BP-treated patients, 67.2% (543/1,838) had no recorded hypercalcemia at MM diagnosis, 81.0% (1,489/1,838) had a record of skeletal-related events (SRE) in the 12 months before MM diagnosis, and 80.0% (1,470/1,838) had a record of osteolytic foci at 1L. An additional 431 patients had a record of osteolytic foci but no record of BP treatment. Patients without a record of BP treatment had higher prevalence of overall hospital-registered comorbidity, anemia, or higher ISS stage at MM diagnosis than patients with a record of BP treatment. Severe renal impairment (stages 4 - 5) was recorded at MM diagnosis in 31.8% of patients with no BP record and in 12.6% of patients with BP record at 1L start.

Conclusions: In newly diagnosed MM patients receiving 1L, co-administration of BP and anti-MM therapy is widespread, though less prevalent in patients with renal impairment or comorbidity burden.

1023P Role of liposomal doxorubicin as a first line agent with VTd regimen in newly diagnosed multiple myeloma

M. Khanderia[1], G. Badarkhe[2], S. Bj[3], R. Naik[3]

[1]Medical Oncology, HCG Bangalore Institute of Oncology Speciality Centre, Bangalore, India, [2]Hematology and Bone Marrow Transplant, HCG Hospital, Bangalore, India, [3]Medical Oncology, HCG Hospital, Bangalore, India

Background: Triple drug regimens are standard of care in newly diagnosed Multiple Myeloma (MM). Studies show 4 drug regimens to be highly active. In an economically backward country like India, newer drugs and Autologous transplant may not always be feasible because of financial constraints. We studied the effect of adding Pegylated Liposomal Doxorubicin (PLD) to standard regimen on the Response Rates (RR).

Methods: 60 newly diagnosed cases of MM were included in this double armed prospective, observational, comparative study. Patients were randomly assigned into 2 arms (30 Patients in each arm). Arm A consisted of VTd regimen (Inj. Bortezomib Day (D)1, D8, D15, D22 1.3mg/ / m^2, Tab. Thalidomide Daily 100mg, Inj. Dexamethasone D1, D8, D15, D22 40 mg / once in 28 days). Arm B consisted of VTdD regimen (PLD D1 i.v 30mg / m^2 + VTd). Hematological and biochemical parameters were noted at baseline and after completion of 4 cycles. Response assessment was done as per the criteria defined by International Myeloma Working Group (IMWG). The outcomes between the two treatment arms in terms of RR were compared.

Results:

Table: 1023P

RR	VTd	VTdD
Overall Response Rates	86.6%	93.3%
>very good partial response	73.3%	86.6%
Stringent Complete Response	33.3%	53.3%

The differences in sCR rates were clinically very significant. However, on application of Pearson chi-square test significance p of 0.118 was seen, which maybe attributed to the lower power of the study. Poorest responses noted were highest in the 71-80 age group. Both the regimens were equally effective in ISS B patients. Neutropenia, thrombocytopenia, infections, mucositis, edema, dizziniess/somnolence and DVT were not significantly different between the two arms ($P > 0.05$). Palmar–plantar erythrodysesthesia (PPE) was the only new complication seen in (10%) VTdD group. Grade 3–4 toxicities were similar in both arms.

Conclusions: The role of liposomal doxorubicin in first line setting as a 4th agent along with triple drug regimen in treatment of MM looks promising, especially in countries with financial constraints for the newer drugs. Larger studies are needed to validate this.

1024P The β2-microgloulin is associated with the prognosis in patients with peripheral t-cell lymphoma, not otherwise specified

B.S. Sohn[1], S-N. Lim[2], J. Kim[3], D.H. Yoon[3], S. Kim[3], J. Huh[3], S-E. Park[1], Y.J. Yuh[1], C. Suh[3]

[1]Internal Medicine, Inje University Sanggye Paik Hospital, Seoul, Republic of Korea, [2]Internal Medicine, Inje University Haeundae Paik Hospital, Busan, Republic of Korea, [3]Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea

Background: Peripheral T-cell lymphomas (PTCLs) are a heterogeneous group of tumors and subdivided into specified and not otherwise specified (NOS) types. Clinically, the International Prognostic Index (IPI), Prognostic Index for T-cell lymphoma, and Bologna score have been the prognostic model to discriminate the prognosis of patients with PTCL-NOS. However, no simple prognostic marker has been satisfactory in predicting treatment outcomes in patients with PTCL-NOS.

Methods: From Sep 2005 to Aug 2016, we identified 94 patients diagnosed with PTCL-NOS initially treated with CHOP or CHOP-like regimens. Event-free survival (EFS) was calculated from the date of diagnosis to the date of disease progression, treatment failure, relapse, or death from any cause. Overall survival (OS) was calculated from the date of diagnosis to the date of death from any cause. The cut-off of serum β_2-microgloulin (B_2MG) was defined as > 3.2 mg/L.

Results: Among 94 patients, 41 (43.6%) patients showed $B_2MG > 3.2$ mg/L, 37 (39.4%) patients showed B symptoms. According to IPI scores, 19 (20.2%) patients belonged to the low risk group (L), 25 (26.6%) to the low-intermediate (LI), 29 (30.9%) to the high-intermediate (HI), and 21 (22.3%) to the high (H). Complete response (CR), EFS, and OS were associated with B_2MG, B symptoms, performance status, lactate dehydrogenase, extranodal involvement, Ann Arbor stage, and IPI risk group in univariate analysis. After multivariate analysis, B_2MG was associated with CR (> 3.2 mg/L vs. ≤3.2 mg/L, odd ratio [OR]: 4.053, 95% confidence interval [CI]: 1.314–12.503, $P = 0.015$), EFS (hazard ratio [HR]: 1.721, 95% CI: 1.026–2.887, $P = 0.040$), but OS (HR: 1.449, 95% CI: 0.803–2.615, $P = 0.218$). IPI risk group was associated with CR (L/LI vs. HI/H, $P = 0.022$), EFS ($P < 0.001$), and OS ($P < 0.001$). In 50 patients of HI/H risk group, B_2MG showed association with CR (OR: 5.464, 95% CI: 1.256–23.774, $P = 0.024$), EFS (HR: 2.160, 95% CI: 1.095–4.260, $P = 0.026$), and OS (HR: 2.158, 95% CI: 0.979–4.759, $P = 0.057$).

Conclusions: B_2MG could be a simple prognostic factor for the patients with PTCL-NOS. $B_2MG > 3.2$ mg/L was associated with worse prognosis of patients with PTCL-NOS, especially in HI/H risk group. The larger scaled study is warranted to confirm our result.

1026P Impact of prior bortezomib therapy on the incidence of lenalidomide-induced skin rash in multiple myeloma: A propensity score-matched multi-institutional cohort study

S. Dote[1], K. Ito[2], S. Itakura[3], T. Yasu[4], D. Hira[5], S. Noda[6], S. Yamada[2], Y. Kobayashi[1], T. Terada[6]

[1]Department of Pharmacy, Kyoto-Katsura Hospital, Kyoto, Japan, [2]Department of Pharmacy, Fujita Health University Hospital, Aichi, Japan, [3]Department of Pharmacy, Japanese Red Cross Kyoto Daiichi Hospital, Kyoto, Japan, [4]Department of Pharmacy, The Institute of Medical Science, The University of Tokyo, Tokyo, Japan, [5]College of Pharmaceutical Sciences, Ritsumeikan University, Shiga, Japan, [6]Department of Pharmacy, Shiga University of Medical Science Hospital, Shiga, Japan

Background: Rash is a well-known toxicity induced by lenalidomide (LEN) therapy in multiple myeloma (MM). LEN has immunomodulatory effects activating function of effector immune cell such as T-cells, which may result in rash onset. Conversely,

bortezomib (BOR), another key drug of MM therapy, has strong Immunosuppressive effects decreasing CD4 T-cell count. Although the two drugs have different immunological aspects, the association between prior BOR therapy and LEN-induced rash has not been reported.

Methods: We conducted a four-institutional cohort study. Eligible MM patients treated with initial LEN therapy were divided into two propensity score-matched cohorts according to presence or absence of prior BOR therapy. The primary endpoint was the incidence of rash. The secondary endpoint was the incidence of eosinophilia defined more than 10% of the leukocyte after LEN therapy.

Results: One-hundred forty-four patients were evaluated. The incidence of rash was 35 (50/144) %, of which 34 (17/50) % were discontinued LEN therapy due to rash. The median time to rash onset was 8.5 days after LEN initiation. Each cohort contained 43 patients after performing propensity-score matching. As compared to in the absence of prior BOR therapy, the incidence of rash was significantly lower in the presence of prior BOR therapy (30% vs 53%, $p = 0.04$). Median period of BOR therapy was significantly shorter in patients with rash, as compared with those without rash (109 days vs 164 days, $p = 0.046$). Also, the patients with rash showed significantly higher incidence of eosinophilia than those without rash, within one month after LEN initiation (26% vs 8%, $p < 0.01$).

Conclusions: Prior BOR therapy could reduce the incidence of LEN-induced rash. LEN-induced rash may be characterized by eosinophilia, suggesting that LEN enhance Th2 immune responses. Regarding the patients failed to continue LEN therapy due to rash, they may have a chance of LEN re-treatment after adequate BOR therapy.

1027P The significance of FMS-like tyrosine kinase 3 surface receptor expression in acute myeloblastic leukemia and precursor B-acute lymphoblastic leukemia patients

S.A. Al Hassanin[1], I.A. Ahmedy[2]

[1]Clinical Oncology Department, Faculty of Medicine - Menoufia University, Shebin El Kom, Egypt, [2]Clinical Pathology Department, Faculty of Medicine - Menoufia University, Shebin El Kom, Egypt

Background: FMS-Like Tyrosine Kinase III (FLT3 / CD135), also known as stem cell tyrosine kinase 1 (STK1) or fetal liver kinase 2 (FLK2), belong to the group of class3 receptor of tyrosine kinase activity. The expression of FLT3 receptor is confined to early hematopoietic progenitor's cells in normal BM. Even though new FLT3 mutations in Acute Myeloid Leukemia (AML) are increasing, the role of FLT3 receptor surface expression in AML and precursor B acute lymphoblastic leukemia (pre-B-ALL) had infrequently been addressed.

Methods: To further evaluate the significance of FLT3 (CD135) expression in AML and pre B-ALL we investigated FLT3 level of expression in newly diagnosed 76 AML patients, 80 pre B-ALL patients and 72 healthy control donors by flowcytometry. The cut-off value for FLT3 positivity was 20%. FLT3 expression was correlated with standards prognostic parameters.

Results: We demonstrated FLT3 protein expression >20% in 68.4% of AML patients, its level was different in FAB subtypes with increasing levels in the following order: M1<M2<M3<M5. Positive FLT3 expression correlated with older age, hepatosplenomegaly, high percentages of bone marrow blasts, high leukocyte counts. Furthermore, it correlated with, CD14, CD64, HLADR, CD $135^+/34^+$, $CD117^+$ and high LDH. Finally, $FLT3^+$ correlated with poor clinical outcome, shorter disease-free survival and overall survival than $FLT3^-$, Regarding pre B-ALL, $FLT3^+$ protein expression >20% was 65%. It correlated with age ≤10 years, with absence of lymphadenopathy and absence of CNS infiltration, high percentages of bone marrow blasts, leukocyte counts $\leq 50 \times 10^3$. Furthermore, it correlated with CD 10^+, $CD34^+$. Finally, $FLT3^+$ correlated with good clinical outcome, longer free disease survival and overall survival than $FLT3^-$.

Conclusions: High FLT3 expression can predict outcome and is associated with poor prognostic factors in AML while it is associated with good prognostic factors in ALL.

1028P Prognostic factors of clinical use in acute myeloid leukemia

P.A. Chorão[1], N.T. Tavares[2], E. Aguiar[1], M.L. Amorim[1], P. Gomes[1], F. Príncipe[1], J.E. Guimarães[1]

[1]Clinical Hematology Department, Centro Hospitalar São João, EPE, Porto, Portugal, [2]Medical Oncology Department, Centro Hospitalar São João, EPE, Porto, Portugal

Background: The heterogeneity in acute myeloid leukemia (AML) is influenced by disease and host-specific factors. In recent years, independent molecular factors and host characteristics that affect prognosis have been described. Nevertheless, data is needed to warrant their clinical use.

Methods: We retrospectively reviewed data on 356 AML patients from October 2008 to June 2017, including age, Charlson Comorbity Index (CCI), ECOG performance status (PS), laboratory parameters (complete blood count, bone marrow blasts, lactic dehydrogenase) and disease factors (de novo or secondary AML (sAML), genetic alterations). The 2017 European Leukemia Net genetics risk stratification (GRS) was used. Univariate and multivariate Cox regression analysis was performed.

Results: The intensive chemotherapy (IC) group comprised of 241 patients, median age 58 years (y), 95% having PS ≤ 1, 67% CCI ≤2 and 22% were sAML. GRS was 23% favorable, 44% intermediate, 27% adverse and 6% unknown. Median overall survival (OS) was 15 months (mo), with 28% 3y-OS. In multivariate analysis (Table), age older than 60y (median 6 versus (vs) 22mo), PS ≥ 2 (median 7 vs 15mo) and higher risk GRS (median 35mo favorable vs 13mo intermediate and 11mo adverse) impacted on survival. The non-IC group included 112 patients, median age 67y, 76% having PS ≤ 1, 6% CCI ≤2 and 37% were sAML. GRS was 12% favorable, 49% intermediate, 24% adverse and 15% unknown. Median OS was 3mo, with 10% 3y-OS. In multivariate analysis (Table), age older than 60y (median 2 vs 17mo), PS ≥ 2 (median 1 vs 5mo) and higher risk GRS (median not reached in favorable vs 4mo intermediate and 1mo adverse) impacted on prognosis.

Table: 1028P

		Intensive chemotherapy HR [95% CI]	Non-intensive therapy HR [95% CI]
Age	≤60 years	Ref	Ref
	>60 years	2.41 [1.76-3.31]	3.09 [1.70-5.65]
ECOG PS	≤ 1	Ref	Ref
	> 1	2.36 [1.23-4.53]	2.25 [1.27-3.98]
ELN2017 genetics	Favorable	Ref	Ref
	Intermediate	2.04 [1.33-3.14]	3.26 [1.30-8.15]
	Adverse	2.26 [1.42-3.59]	5.55 [2.13-14.44]

Conclusions: In spite of the high number of recognized risk factors, in real-life only GRS, age and PS were of clinical use to predict survival in both IC and non-IC sets. In our sample, there was no significant impact of sAML, CCI and laboratory parameters. Efforts are needed to identify more factors that aid clinical decision in the treatment of AML.

1029P Frequency and clinical impact of compound mutation in chronic myeloid leukemia patients resistant to tyrosine kinase inhibitor

S. Bonecker[1], M. Carneiro[2], M. Bonamino[2], I. Zalcberg[1]

[1]Centro de Transplante de Medula Ossea, INCA - Instituto Nacional de Cancer, Rio de Janeiro, Brazil, [2]Programa de Carcinogêse, INCA - Instituto Nacional de Cancer, Rio de Janeiro, Brazil

Background: Chronic myeloid leukemia is characterized by onco-protein BCR-ABL1 which is constitutively activated. This particularity allowed the development of the first specific tyrosine kinase inhibitor (TKI) which changed the course of this disease. However, resistance to TKI is still a growing clinical problem. The canonical mechanism of resistance is point mutation in ABL1 kinase domain (KD). After the introduction of second and third TKI, the presence of multiple mutations was grown and the clinical importance is still controversial.

Methods: We included 21 resistant patients with two BCR-ABL1 KD mutations detected by direct sequencing. 43% failed to two therapies, 8 to three and 4 failed only to imatinib. For two patients we had sequential samples. We cloned ABL1 region and sequenced minimum of 10 clones. In order to evaluate the frequency of false compound mutation we cloned sample with only T315I mutation, other with F317L and 1:1 dilution of both samples.

Results: We observed that 66.7% of double mutations detected by direct sequencing were compound mutations. Our ratio of false positive compound mutation was 9%. T315I plus other mutation was the most frequently compound mutation in our cohort. Patients who failed to more than one TKI had higher frequency of compound mutation. Analyzing sequential samples we observed mutated clones in samples up to 5 months earlier than direct sequencing. The frequency of clones harboring compound mutations with more than two missense mutations was low (6%), comparing with silent mutations, suggesting a limited tolerance for BCR-ABL1 KD missense mutations. The number of transition was higher than transversion. Among patients with compound mutations: 5/7 progressed to advanced phases presented compound mutation, 1/2 died, 5/8 achieved molecular response (MR) during second or third line therapy and 3/4 did not achieve MR (median follow up 26 months).

Conclusions: We did not find correlation between presence of compound mutation and probability to respond therapy or progression. Analyze higher number of sample is needed. Indeed, the importance to detect clones harboring high resistance mutation such T315I earlier could help the clinician to choose the therapy to avoid clone progression.

1030P Poor outcome of double-protein expressor diffuse large B-cell lymphoma

E.V. Kharchenko[1], T. Semiglazova[1], A. Artemeva[2], V. Kushnarev[2], P.S. Shilo[1]

[1]Department of Innovative Methods of Therapeutic Oncology and Rehabilitation, N.N. Petrov National Medical Research Center of Oncology, St. Petersburg, Russian Federation, [2]Department of Pathology, N.N. Petrov National Medical Research Center of Oncology, St. Petersburg, Russian Federation

Background: In previous several studies it was confirmed that double expression of both c-myc and bcl-2 in Diffuse Large B-cell lymphoma patients (DLBCL) predict aggressive course. We suggest that it can be independent risk factor and early treatment intensification can provide potential benefit for this poor risk group.

Methods: To analyze data we used chi-square test for independence, odds ratio (OR), full analisys test. Progression free survival (PFS) were estimated by Kaplan-Meier method, comparison of PFS in experimental groups (long-rank test), multifactor analysis of PFS (multinomial logistic regression). Statistically significant difference if $p < 0,05$.

Results: We analyzed 240 pts with DLBCL, from 18 to 85 y.o. (median age 56 y.o), who underwent treatment in National Medical Research center from 2008 to 2018. Seventy six (32%)-with early stage of disease (I,II) and 164 pts (68%)-advance stage (III,IV). Extranodal involvements were observed in 61 pts (25%) and B-symptoms in 109 (45%), GCB-subtype in 47% and non-GCB in 53% (Hans algorithm). DA-EPOCH-R, Hyper-CVAD-R as first line received 26 pts (11%) and up-front high-dose chemotherapy with AutoSCT received 17 pts (7%). 2-years PFS was 86% for all pts [95% CI 78-94]. PFS was significantly lower in pts with B-symptoms (38% vs 84%; RR 3,3 [95% CI 0,85 – 1,4], $p < 0,05$); advance stage (42% vs 89%; RR 3,0 [95% CI 1,7 – 2,1], $p < 0,05$); c-myc expression (45% vs 84%); RR 1,9 [95% CI 0,3 - 0,9], $p < 0,05$); bcl-2-expression (60% vs 83%) RR 1,6 [95% CI 1,2 – 1,9], $p < 0,05$); Ki-67 higher than 70% (59% vs 89%; RR 2,5 [95% CI 0,9 – 1,2], $p < 0,05$). Double-expressor lymphoma (DEL) (both c-myc and bcl-2) were observed in 33% (80 patients). Among patients with DEL, PFS were lower but not significantly different comparing with non-DEL ($p = 0,03$). These data were related to early treatment intensification in this subgroup (DA-EPOCH-R, Hyper-CVAD-R, up-front high-dose chemotherapy with AutoSCT). DEL subgroup was also associated with advance stage of the disease (III-IV 68% vs I-II 39%, $p < 0,05$), B-symptoms (69% vs 47%, $p = 0,03$) and Ki-67 higher than 70% (81% vs 71%, $p > 0,05$).

Conclusions: These data confirm more aggressive course of the disease in patients with DEL comparing with standard group and may suggest benefit for patients to undergo early-treatment intensification.

1031P Combination of chemotherapy and radiation improve the prognosis of primary diffuse large B-cell lymphoma of the tonsil

S-N. Lim[1], B.S. Sohn[2], H-J. Shin[3], C. Suh[4], W.S. Kim[5], W.S. Lee[6], J.S. Kim[7]

[1]Internal Medicine, Inje University Haeundae Paik Hospital, Busan, Republic of Korea, [2]Internal Medicine, Inje University - Sanggye Paik Hospital, Seoul, Republic of Korea, [3]Internal Medicine, Pusan National University School of Medicine, Pusan National University Hospital, Busan, Republic of Korea, [4]Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, [5]Internal Medicine, Sungkyunkwan University School of Medicine, Samsung Medical Center, Seoul, Republic of Korea, [6]Internal Medicine, Inje University College of Medicine, Busan Paik Hospital, Busan, Republic of Korea, [7]Internal Medicine, Yonsei University College of Medicine, Severance Hospital, Seoul, Republic of Korea

Background: The most common histological type of tonsil lymphoma is diffuse large B-cell lymphoma (DLBCL). Treatment approaches that have used include surgery, chemotherapy (CTx) alone, radiation (RT) alone, and combination of both. We reviewed our data and evaluate treatment outcome of patient with DLBCL of the tonsil.

Methods: Retrospective review of 114 stage I-II DLBCL patients between 1995 and 2010. Forty-five (39.5%) patients had stage I disease and B-symptoms were present in only 7 patients. Seventy-two (65.5%) patients were treated with CTx alone, whereas the remaining 38 received treatment with a combination of CTx and RT. Chemotherapy was CHOP-based, with R-CHOP in 80 patients (70%). Median involved-field RT dose was 3,960 cGy, with 96% receiving more than 3,000 cGy.

Results: The median age was 59 years and 61% of patients were males. Low to low intermediate by International prognostic index (IPI) was 97.3%. LDH level. Overall CR rate was 73.5% and seven (13.5%) of the patients who had achieved CR had recurred. The median follow-up was 28 months. Five-year disease-free survival (DFS) and overall survival (OS) were 86.3% and 82.5%, respectively. Significant prognostic factors included: age $\geq$ 60 years old (OS, $P = 0.011$), LDH >upper normal limit (OS, $P = 0.003$; DFS, $P < 0.001$), IPI>0 (OS, $P = 0.007$; DFS, $P = 0.034$) and combination of CTx and RT (OS, $P = 0.025$; DFS, $P = 0.038$). Germinal center (GC) and non-GC phenotype were not predictors of outcome in localized DLBCL of the tonsil. Chemoimmunotherapy-treated patients with rituximab did not show a significantly better OS and DFS than those without rituximab. On multivariate analysis; LDH >upper normal limit (DFS: hazard ratio [HR], 14.958; 95% CI, 2.474-90.432, $P = 0.003$; OS: HR, 9.341; 95% CI, 1.635-53.361, $P = 0.012$), and combination of CTx and RT (DFS: HR, 0.088: 95% CI, 0.009-0.834, $P = 0.034$; OS: HR, 0.112; 95% CI, 0.014-0.918, $P = 0.041$), retained statistical significance.

Conclusions: The DFS and OS rates were significantly better for patients receiving combination of CTx and RT. A combined treatment, consisting of CTx and RT (with RT dose of $\geq$ 45 Gy), results in a satisfactory outcome in patients with localized primary DLBCL of tonsil.

1032P The impact of serum microRNA-21 on outcome of diffuse large B-cell lymphoma patients

S.F. Gohar[1], S. Kamal Eldin[2], F. El-Bassal[2], A. Shehata[3], A. Azzam[4], E. Tawfik[1], S.A. Al Hassanin[1]

[1]Clinical Oncology, Faculty of Medicine - Menoufia University, Shebin El Kom, Egypt, [2]Clinical Pathology, Faculty of Medicine - Menoufia University, Shebin El Kom, Egypt, [3]Clinical and Chemical Pathology, Menoufia University, Menoufia, Egypt, [4]Clinical Biochemistry and Molecular Diagnostics, National Liver Institute, Menoufia, Shebin El Kom, Egypt,

Background: The utilization of circulating microRNAs (miRNAs) as non-invasive diagnostic and predictive tools have become substantial and promising scope of cancer research. The link between the aberrant expressions of various miRNAs and the pathogenesis of diffuse large B-cell lymphoma (DLBCL) has been revealed by multiple studies. This study planned to investigate the relative expression levels of serum miRNA-21 and to demonstrate its potential prognostic impact in DLBCL patients who were treated by cyclophosphamide, doxorubicin, vincristine, prednisone plus rituximab (R-CHOP) protocol.

Methods: Polymerase chain reaction (PCR) based technique was used to analyze serum miRNA-21 relative expression levels in 65 DLBCL patients prior to immunochemotherapy in comparison with 35 healthy individuals. Receiver operating characteristic curve analysis was used to gauge the optimal miRNA-21 cutoff and Kaplan-Meier method was performed to estimate overall patients' survival.

Results: Serum miRNA-21 overexpression was significantly observed in DLBCL patients compared to the control group ($P < 0.001$). MiRNA-21 expression levels were closely associated with stage, C-reactive protein (CRP), lactate dehydrogenase (LDH) and β2 microglobulin ($P < 0.001$; $P = 0.02$; $P = 0.003$; $P < 0.001$ respectively). However, there was no relationship with other characteristics, such as gender, age, B symptoms, extranodal site involvement, international prognostic index (IPI) and initial response to therapy (all $Ps > 0.05$). Overall survival was significantly worse in patients with high miRNA-21 expression levels compared to those with low expression levels ($P = 0.01$).

Conclusions: Serum miRNA-21 may be employed as valuable non-invasive diagnostic and prognostic marker in DLBCL patients treated with R-CHOP regimen.

1033P Efficacy and safety of bosutinib vs imatinib in Indian and non-Indian patients with newly diagnosed chronic phase chronic myeloid leukemia: Subgroup analysis from the BELA trial

H. Malhotra[1], A. Maru[2], N. Khattry[3], M.V. Ramanan[4], E. Leip[5], R.J. Crescenzo[6], C. Gambacorti-Passerini[7], J.E. Cortes[8]

[1]Division of Medical Oncology, Birla Cancer Center, Jaipur, India, [2]Department of Medical Oncology, Sarvodaya Multispeciality & Cancer Hospital, Hisar, India, [3]Department of Medical Oncology, Tata Memorial Hospital, Mumbai, India, [4]Department of Medical Oncology, Jehangir Hospital, Pune, India, [5]Clinical Statistics, Pfizer Inc, Cambridge, MA, USA, [6]Clinical Development, Pfizer Inc, Collegeville, PA, USA, [7]Department of Medicine and Surgery, University of Milano-Bicocca, Monza, Italy, [8]Department of Leukemia, University of Texas MD Anderson Cancer Center, Houston, TX, USA

Background: The international, phase 3 BELA trial (NCT00574873) evaluated first-line bosutinib vs imatinib in Philadelphia chromosome–positive patients (pts) with chronic phase chronic myeloid leukemia.

Methods: Pts were randomized to receive bosutinib 500 mg once daily (QD) or imatinib 400 mg QD; the primary endpoint was complete cytogenetic response (CCyR) rate at 12 mo. We compared efficacy and safety of bosutinib and imatinib in Indian and non-Indian pts after 48 mo of follow-up. Efficacy was assessed in the intent-to-treat population; safety was assessed in all pts who received ≥1 dose of study drug.

Results: In all, 54 Indian pts (median age 34.5 y; 61% male) and 448 non-Indian pts (median age 48.5 y; 56% male) were randomized to receive bosutinib (n = 25 and n = 225 [2 untreated], respectively) or imatinib (n = 29 and n = 223 [1 untreated]). At 12 mo, major molecular response (MMR) and CCyR rates, respectively, for bosutinib vs imatinib were 44% vs 24% and 72% vs 86% in Indian pts, and 37% vs 26% and 70% vs 66% in non-Indian pts (Table). After 48 mo of follow-up, cumulative MMR and CCyR rates, respectively, for bosutinib vs imatinib were 64% vs 69% and 84% vs 97% in Indian pts, and 68% vs 67% and 78% vs 79% in non-Indian pts. The most frequently reported treatment-emergent adverse events (TEAEs; any grade) with bosutinib were diarrhea (44%) and thrombocytopenia (36%) in Indian pts, and diarrhea (73%) and nausea (39%) in non-Indian pts. 8 pts in the entire study were lost to follow-up while on-treatment; 7 (6 bosutinib; 1 imatinib) were from Indian sites.

Table: 1033P

	Indian pts		Non-Indian pts	
	Bosutinib n = 25	Imatinib n = 29	Bosutinib n = 225	Imatinib n = 223
Sokal Risk Group, n (%)				
Low	11 (44)	13 (45)	77 (34)	76 (34)
Medium	11 (44)	13 (45)	106 (47)	105 (47)
High	3 (12)	3 (10)	42 (19)	42 (19)
Cumulative response, any time on–treatment, % (95% CI)				
MMR	64 (45–83)	69 (52–86)	68 (61–74)	67 (61–73)
CCyR	84 (70–98)	97 (90–100)	78 (73–84)	79 (74–84)
Response at 12 mo, % (95% CI)				
MMR	44 (25–64)	24 (9–40)	37 (31–44)	26 (20–31)
CCyR	72 (54–90)	86 (74–99)	70 (64–76)	66 (60–72)
Probability of retaining response at 48 mo (95% CI)*				
MMR	80 (49–93)	100 (100–100)	93 (86–96)	98 (93–99)
CCyR	89 (62–97)	78 (58–90)	93 (88–96)	91 (85–95)
Transformation to AP/BP CML, n (%)	1 (4)	2 (7)	4 (2)	10 (5)
Overall survival				
Deaths, n (%)	1 (4)	1 (3)	14 (6)	14 (6)
At 48 mo (95% CI)*	96 (72–99)	96 (77–100)	95 (91–97)	94 (89–96)

*Kaplan-Meier estimate

AP=accelerated phase; BP=blast phase; CCyR=complete cytogenetic response; CI=confidence interval; CML=chronic myeloid leukemia; MMR=major molecular response

Conclusions: Response rates for bosutinib were comparable between Indian and non-Indian pts. MMR rates were higher for bosutinib vs imatinib at 12 mo, but not 48 mo, in Indian pts; comparison of bosutinib vs imatinib was limited by the small number of Indian pts. TEAEs were consistent with the known bosutinib safety profile, although Indian pts had a lower rate of diarrhea than non-Indian pts.

1034P A prospective multicenter study of primary breast lymphoma in the rituximab era: Prognostic implication of beta 2 microglobulin and interlukin-6 & interlukin-10

L. Ezz Elarab[1], E. Hamada[2], A. Mostafa[1], A. Saber[2], M. Abdel-Gawad[3], R.M. Haggag[4], H.D. Darwish[5], S.A. Elhassanin[6], M. Swellam[7]

[1]Clinical Oncology, Ain Shams University Faculty of Medicine, Cairo, Egypt, [2]Clinical Oncology, Minya University Medical School, Minya, Egypt, [3]Clinical Oncology, Faculty of Medicine, Assuit University, Cairo, Egypt, [4]Medical Oncology, Zagazig University Faculty of Medicine, Zagazig, Egypt, [5]Medical Oncology, Damietta Cancer Institute (DCI), Damietta, Egypt, [6]Clinical Oncology, Faculty of Medicine, Menoufiia University, Cairo, Egypt, [7]Biochemestry, Genetic Engineering and Biotechnology, National Research Center, Cairo, Egypt

Background: Primary breast diffuse large B-cell lymphoma (DLBCL) is a rare entity representing ≤ 2% of extra-nodal non-Hodgkin lymphoma. We aimed to define clinical profile, prognostic factors and the incidence of the central nervous system (CNS) relapse in the era of rituximab and clarify the prognostic value of beta$_2$ microglobulin(B_2M), interlukins-6 (IL-6) and interlukin -10(IL-10).

Methods: Between Jan 2012 to Dec 2016, a prospective analysis of 28 patients presenting to 7 academic Egyptian centers. All patients were females. Only patients with newly diagnosed stage I and II disease DLBCL were included. Patients with evidence of baseline CNS disease and patients with hepatitis B and HIV were excluded. All patients were scheduled to receive R-CHOP protocol plus involved- field radiotherapy. The prognostic significance of B_2M, and IL-6 and 10 were assessed.

Results: About 75% presented with breast mass, 4 cases with inflammatory symptoms, 3 cases were discovered by mammography. Right breast was more involved (64%), 86% had ≤ 1 ECOG performance status, and LDH elevated was in 39% and 18% had B symptoms. HCV was positive in 32% (9 patients). Stage I was detected in 57%. The stage–modified International prognostic index was ≤1 in 54%. Ten cases underwent breast surgery (2 modified radical mastectomy, 8 conservative breast surgery). Complete response was achieved in 23/28 (82%) with median follow-up of 28 months, 39% of patients had relapsed, contralateral breast was the site of initial relapse in two cases, 11% developed CNS relapse and 21% in other nodal and extranodal sites. Three years disease free survival and overall survival were 68% and 79%. Favorable prognostic factors according to univariate analysis were stage I, IPI≤1, tumor size < 5cm, B_2M. IL6 and IL-10, while for multivariate analysis they were IPI≤1 and B_2 M and IL-6.

Conclusions: Primary breast DLBCL has high rate of CNS relapse in spite of era of rituximab so CT or MRI of CNS is necessary during follow-up. Prophylaxis to CNS should be considered in the initial treatment to improve outcome. In addition, assessment of pretreatment serum levels of B_2M, and IL-6 in newly diagnosed DLBCL may indicate a possible prognostic role.

1035P Experience in treatment of newly diagnosed multiple myeloma patients with renal failure required dialysis

S. Semochkin[1], E. Zhelnova[2], E. Misyurina[2], T. Tolstykh[2], N. Arkhipova[2], E. Baryakh[2], E. Grishina[2], E. Karimova[2], O. Kochneva[2], E. Mavrina[2], Y. Polyakov[2], E. Yaskova[2]

[1]Oncology, Hematology and Radiotherapy, Pirogov Russian National Research Medical University, Moscow, Russian Federation, [2]Hemalology, Moscow City Hospital #52, Moscow, Russian Federation

Background: About 2-4% of patients with newly diagnosed multiple myeloma (MM) present with severe dialysis required renal failure (RF), which is associated with significant morbidity and early death. The aim of this article was to analyze own experience in treating this category.

Methods: During 10.2014-12.2017 the sixty-two patients with severe RF with a glomerular filtration rate (eGFR) <30 ml/min/1.73m^2 were enrolled in this retrospective study. All patients received bortezomib-based regimens: 41 (66.1%) VDC; 2 (3.2%) PAD; 12 (19.4%) VD and 7 (11.3%) VMP. Seven (11.3%) patients underwent high-dose therapy with ASCT. IMWG (2010) renal response criteria were used. Myeloma response was evaluated using the standard IMWG (2006) criteria.

Results: At the time of presentation 48 (77%) patients required dialysis. The mean eGFR was 6.0 (95% CI 4.4-7.6) for patients requiring dialysis (Group A) and 22.2 (16.4-29.2) ml/min/1.73 m^2 for those (Group B) are a dialysis independent (P < 0.001). Mean level of involved free light chain (iFLC) was 7400 (3440-10840) mg/l vs 2900 (780-5020) mg/l respectively (P < 0.001). The median time from RF to start of MM chemotherapy comprise 39 and 21 days for two groups respectively. Six (9.7%) patients died within the first 60 days of therapy (induction mortality). At least minimal renal response (> =MRrenal) documented in 23.5% and 57.1% patients respectively. If the duration RF before initiation of MM treatment was >1 month no one patient required dialysis restored a renal function. Among all patients, overall myeloma response (> =PR) documented in 81% cases, including 39.6% very good partial response (VGPR) and 14.6% complete response (CR/sCR). Two-years overall survival (OS) was 67.8 ± 6.4% without any different between groups.

Conclusions: In conclusion, our data indicate that bortezomib-based triplets are associated with a significant probability of renal response. In at least a 23.5% of patients

with MM presenting with dialysis-requiring severe RF may improve their renal function and discontinue dialysis. Unfortunately, our results are inferior to the literature data according to which up to 50% of patients become independent of dialysis.

1036P Inmunohistochemical (IHQ) classification of DLBCL into CGB and non-CGB subtypes to predict survival after chemoimmunotherapy at the Virgen de la Victoria University Hospital

L. Galvez Carvajal, C. Quero Blanco, M. Robles Lasarte, I. Moreno Perez, L. Vicioso, I. Ramos Garcia, C. Bandera Lopez, J. Baena Espinar, C. Ithurbisquy, E. Alba

Oncología Médica, Hospital Universitario Virgen de la Victoria, Málaga, Spain

Background: It is known that diffuse large-B-cell lymphoma (DLBCL) is a clinically heterogeneous entity. The most important clinical predictor of survival is the International Prognostic Index, which does not provide information regarding the heterogeneous biology of tumors. Two major subtypes of DLBCL have been identified by gene expression profiling (GEP) and classified by cell of origin into germinal center B-cell–like (GCB) and activated B-cell–like (ABC). GEP has become a reliable method for predicting the outcome of patients with DLBCL treated with R-CHOP chemotherapy. However, that it́s not easily applicable in clinical practise. Several IHC algorithms have been developed to assign patients into GCB and non-GCB/ABC subtypes.

Methods: We retrospectively analyzed 142 patients diagnosed of de novo DLBCL from 1999 to 2017 at our Hospital treated with chemoimmunotherapy. DLBCL was classified using the Hans algorithm into GCB and non-GCB subtypes. The primary end point was progression-free survival (PFS) according to the Hans algorithm, that it was estimated by the Kaplan–Meier method.

Results: The percentage of GCB and non-GCB subtypes was 54% and 46%, respectively. After a median follow-up of 37 months, the median progression-free survival was 100 months in the global population. No significant differences were found in PFS, although there was a trend to favor CGB subtype (PFS at 24 months 70% in CGB group and 59% in non-CGB group, with a median of 60 months in non-CGG and not reached in CGB group, $p = 0.177$). Despite of being a retrospective study and the low median follow-up of patients, in CGB subtype there was a trend towards better overall survival (OS) (2-year OS: 72% vs. 68%), not statistically significant ($p = 0.661$).

Conclusions: In our study there is a lack of evidence supporting the use of the Hans algorithm for stratifying patients into distinct prognostic groups, probably due to the low median follow-up. Rather, GEP remains the preferred method for predicting prognosis. IHQ for subclassification of DLBCL is feasible and reproducible, but the harmonization of techniques and centralized consensus review is necessary.

1037P Quality of life evaluation in acute leukemia patients receiving induction chemotherapy

T. Lymanets[1], I. Skrypnyk[1], G. Maslova[1], I. Gusachenko[2]

[1]Ukrainian Medical Stomatological Academy, Poltava, Ukraine, [2]Hematology, Poltava Regional Clinical Hospital M.V. Sklifosovsky, Poltava, Ukraine

Background: Over the past decades, special attention has been paid to study of quality of life (QoL) indicators in hematological patients receiving chemotherapy (CT). Nowadays QoL is conceptually viewed as an important complement to traditional objective evaluation measures. Aim. To assess QoL in patients with acute leukemia (AL) depending on the presence of concomitant ischemic heart disease (IHD) during the induction CT.

Methods: Our study involved 83 patients with newly diagnosed AL, of which 19 were lymphoblastic, 64 – myeloid leukemia, aged 16-72, 43 (51.8%) men, 40 (48.2%) women, according to ECOG I-II. Patients received standard induction CT. According to concomitant IHD patients were divided into groups: I ($n = 47$) - AL without cardiological diseases; II ($n = 36$) - AL with concomitant IHD. Patients were evaluated using SF-36 questionnaire to calculate physical and mental health components before treatment and after 2 induction courses of CT reaching remission.

Results: The indicators of physical and mental QoL components in patients of both groups before CT were significantly lower compared with healthy respondents. After reaching the remission in patients of group I, all QoL parameters improved, with the exception of bodily pain and social functioning. The average physical status indicators in patients of groups I and II did not significantly change. At the same time, the psychological status of patients improved: in group I in 1.5 times (40.9 ± 2.25 vs 27.1 ± 2.77 before CT, $p < 0.05$), in group II - in 1.3 times (37.3 ± 2.82 vs 28.3 ± 2.37 before CT; $p < 0.05$). Minimum values of all scales after CT were characteristic for patients with concomitant IHD in group II. Differences between groups were not statistically significant in all scales, except for the index of physical activity (41.7 ± 1.36 vs 46.6 ± 2.02; $p < 0.05$). However, in comparison with the data of practically healthy respondents, QoL of patients with AL after CT remained significantly lower.

Conclusions: The QoL evaluation in patients with AL with comorbid IHD during induction CT is an important component of the management of oncological patients, which allows individualizing the approach to each patient in the presence of this type of syntropy.

[1]Onco-Hematology, National Cancer Institute of the MPH Ukraine, Kiev, Ukraine, [2]Experimental Oncology, National Cancer Institute of the MPH Ukraine, Kiev, Ukraine, [3]Radiology, Clinical Hospital "Feofaniya", Kiev, Ukraine, [4]Hematology, Clinical Hospital "Feofaniya", Kiev, Ukraine, [5]Hematology, Cherkassy Regional Oncology Center, Cherkassy, Ukraine, [6]Hematology, Odessa Regional Hospital, Odessa, Ukraine, [7]Radiology, Oncology Hospital "LISOD", Kiev, Ukraine, [8]Radiology, Center of Nuclear Medicine KMCOC, Kiev, Ukraine, [9]Hematology, Kiev Centre of Bone Marrow Transplantation, Kiev, Ukraine, [10]Hematology, Oncology Clinic "Innovation", Kiev, Ukraine, [11]Hematology, Regional Clinical Hospital, Kherson, Ukraine

Background: Nowadays, there are different guidelines in diagnostics and PET-guided treatment of lymphomas. But questions about benefits and predictive role of PET-CT in pts with early-stage Hodgkin lymphoma (HL) still remain debatable. Here we report results of Ukrainian multicenter retrospective study about the role of PET-CT in early-stage HL pts.

Methods: 56 patients, with stages I-II, were registered in the study between August 2012 and Feb 2018 in 9 Ukrainian hematological centers. Metabolic PET-CT imaging was performed according to standard protocols. The threshold of positivity was set for a residual uptake higher than the liver background (Deauville score (DS) 4and 5). Patients were treated with ABVD or BEACOPPesc regimens based on risk group. The primary endpoint was event-free survival (EFS), defined as disease progression or death from HL.

Results: Median age of patients at diagnosis was 29 years (range 18-50), 16 (28,5%) male and 40 (71,5%) pts were female. Bulky disease (>10 cm in any dimension) were presented in 6/56 (10,7%) of pts, B symptoms - in 16/56 (28,5%) and extranodal disease had 4/56 (7%). Median follow-up was 24 months from diagnosis. Interim PET (PET2) was performed in 50 pts at 15.5 ±3 days (range, 5-26) after 2xABVD or 2xBEACOPP esc cycles. Interim PET-CT was assessed as DS 1-2 in 34 patients (60,7%), DS 3 in 11 (19,6%), DS 4-5 in 5 pts (8,8%). In total, disease progression was documented in 5/56 (9%). Among them, 2/5 (40%) patient were PET2-positive (PET2+) and 3/5 (60%) PET2-negative (PET2-), ($p > 0.05$). There were no registered deaths from the refractory disease. We did not find any significant difference between EFS rate in pts with PET2+ vs PET2- (log-rank test, $p = 0.4$). 47 pts have proceeded for end-of-treatment PET-CT (PET3). Results showed 3/47 pts (6,3%) were PET3+ and PET3- were 44/47 (93,7%), ($p < 0,05$). EFS was compared and assessed depending on DS. Achieved rate of 3-year EFS in pts with PET3 DS 1-2, DS 3 and DS 4-5 were 94,4%, 50% and 0%, respectively ($p < 0.006$).

Conclusions: End of treatment PET-CT plays an important role in patients with early-stage HL and could be a beneficial prognostic factor. However, there is still need for prospective confirmation of interim PET-CT as a prognostic factor.

1039P Assessment to predict survival and risk of progression in patients with newly multiple myeloma in different age groups

I. Kriachok, O. Novosad, K. Ulianchenko, T. Skrypets, T. Kadnikova

Onco-Hematology, National Cancer Institute of the MPH Ukraine, Kiev, Ukraine

Background: Treatment options and outcomes for multiple myeloma (MM) pts were greatly changed over the last 10 years. Treatment according to different age groups requires careful consideration of the balance between maximizing efficacy and acceptable tolerability.

Methods: 100 pts (median age: 63, range 34-80; m: 63, f: 37) were registered in NCI from Jan 2006 to Jan 2018. 19% (19/100) of patients received M2, MP, DAV therapy (group1), 46% (46/100) - thalidomide-based (group2) and 35% (35/100) -PI-based regimens (group3). In 28% patients t(4:14), del13, and del17p13] were assessed. The primary endpoint was EFS and OS.

Results: For 100 pts the ORR was 70 %. We recorded 39% relapses in the follow-up after the 1st line therapy (median – 10.9 months; range 2–129). 61.1% vs 47.8% vs 17.1% relapses were diagnosed in group1 vs group2 vs group3, respectively ($p < 0.05$). 3-year EFS for group1 was 18% vs 30% in group3 and 20% vs 30% for group2 vs group3, respectively ($p = 0.002$). ROC analysis confirmed bortezomib-based regimens improved EFS in MM patients without age correlation (Se = 81%; Sp = 54%; AUC=0.7, $p = 0.0001$). EFS was higher in the group 2 pts <65 y.o. vs > 65 y.o (40% vs 18%, $p < 0.05$). 3-year OS was 65% vs 45% in younger pts vs elderly pts, respectively ($p = 0.009$). Thrombosis complications in group 2 were compared in pts >65 y.o (20%) vs < 65 y.o (7.7%), ($p < 0.05$). 3-year EFS and OS were similar in the group 3 ($p = 0.4$). Also, neurotoxicity was the same in different age groups (58.6% vs 60%). 50% vs 33.8% cases of disease progression had patients who received doublet and triplet regimens, respectively ($p < 0.05$). ROC analysis confirmed doublet regimen association with lower EFS pts >65 y.o (Se = 50%; Sp = 100%; AUC=0.7, $p = 0.04$). Median EFS in pts with del17p13 was lower without any correlation with age (10.9 vs 29.7 months). We did not find any significant association between patients with del13 or t(4:14) and clinical outcome of MM.

Conclusions: Bortezomib-based regimens are still in a priority for the 1st-line treatment in different age groups. Thalidomide might be an option for younger pts, because thrombosis events are more frequent in elderly pts. To achieve better response in the 1st-line therapy, it is preferable to use triplet regimens in pts <65 and >65 years old.

1040P Impact of bisphosphonate and anti-myeloma therapy on bone turnover markers in multiple myeloma

A. Jandial[1], S. HJ[1], K. Mishra[1], S. Bhadada[2], A. Sood[1], M. Prakash[3], A. Meshram[1], R. Sandal[1], D. Lad[1], R. Aggarwal[4], G. Prakash[1], S. Vikas[1], A.R. Khadwal[1], S. Kumari[1], N. Varma[1], S.C. Varma[1], P. Malhotra[1]

[1]Internal Medicine, PGIMER, Chandigarh, India, [2]Endocrinology, PGIMER, Chandigarh, India, [3]Radiodiagnosis, PGIMER, Chandigarh, India, [4]Immunopathology, PGIMER, Chandigarh, India

Background: Bone involvement is a defining feature of symptomatic multiple myeloma (MM). There is little information on changes in bone mineral metabolism that occur with bisphosphonates and anti-myeloma medication.

Methods: Newly-diagnosed MM patients were prospectively enrolled from January to December 2017. Serum bone turnover markers estimation [CTX, P1NP, and Osteocalcin (OC)], DEXA scan, and Tc99 bone scintigraphy were assessed at baseline. Antimyeloma drugs and monthly bisphosphonates were given as per institutional protocol. Bone turnover markers were re-assessed at 3 months.

Results: 24 patients were enrolled. Median age was 55 years (35 – 76 years); 79.16% males. Bone pains and anemia were most common [renal failure 45.8% and hypercalcemia 45.8%]. IgG subtype was most common (52%) [IgA 21%, light chain 16%]. 83.3% had ISS stage III disease; mean β-2 microglobulin was 17.81 (± 25.16) mg/mL. 70.83% patients had multiple lytic lesions and 29.16% had baseline fracture. On DEXA scan, 41.67% had osteopenia and 12.5% had osteoporosis. All bone markers showed a graded but statistically insignificant correlation with the extent of bone involvement, $P > 0.05$. Baseline CTX levels in patients with pathological fractures were significantly higher. Baseline β-2 microglobulin significantly correlated with CTX ($r = 0.44$) and P1NP ($r = 0.43$) levels; OC showed no such correlation. At 3 months, a significant decline was seen in CTX levels [0.46 (±0.84) v 1.16 (±1.19), $P = 0.001$]; minimal rise was seen in P1NP and OC levels, $P > 0.05$. Fall in CTX levels in patients receiving VTD regimen was significantly greater than VCD regimen, $P = 0.012$. The decline in CTX among patients exclusively treated with zoledronate was significantly larger than those who received initial ibandronate followed by zoledronate, $P = 0.017$. At 3 months, overall response rate was 75% [CR 16.7%, VGPR 50%, PR 33.3%].

Conclusions: The bone turnover markers significantly correlated with β-2 microglobulin. Bisphosphonates and anti-myeloma medications considerably reduced CTX (bone resorption marker) but had a trivial effect on P1NP and OC. Larger prospective studies with longer follow up are required to interpret dynamics of bone turnover markers in myeloma.

1041P Assessment of bleeding risk by sonoclot in acute lymphoblastic leukemia

K. Mishra[1], A. Jandial[1], A. Meshram[1], R. Sandal[1], D. Lad[1], G. Prakash[1], A.R. Khadwal[1], R. Dhiman[2], N. Varma[1], S.C. Varma[1], P. Malhotra[1]

[1]Internal Medicine, PGIMER, Chandigarh, India, [2]Hepatology, PGIMER, Chandigarh, India

Background: At the same level of thrombocytopenia, patients with acute lymphoblastic leukemia (ALL), receive more prophylactic platelet transfusion in comparison to immune thrombocytopenia (ITP). Routine investigation cann't differentiate the risk of bleeding between ALL and ITP. Sonoclot is a global test of coagulation, a bed side tool, also assesses platelet function. It is widely used in cardiac surgery and hepatology to assess need for blood plasma and platelet transfusion. Aim of the study was to evaluate role of sonoclot in assessing the risk of bleeding in ALL with severe thrombocytopenia.

Methods: In this prospective observational study, twenty-five cases of ALL and fifty cases of ITP (control) were included. All patients included had platelet counts lower than 20000/μL and there was no evidence of any active bleeding. Blood samples were evaluated by conventional coagulation tests as well as by Sonoclot. Sonoclot measures activated clotting time (ACT), clot rate (R1) and platelet function (PF).

Results:

Table: 1041P Comparison of ALL and Control (ITP)

	ITP (n = 50)	ALL (n = 25)		
Parameters	(mean ± SD)	(mean ± SD)	p	Normal Value
Platelet (/μL)	9536.73 ± 5048.05	12240 ± 4576.02	NS	150000-450000
Prothombin time (seonds)	14.1 ± 1.43	14.72 ± 2.13	NS	11-14
Activated partial thromboplastin time (seconds)	29.66 ± 1.99	29.77 ± 2.13	NS	25-35
ACT (seconds)	251.1 ± 37.97	260.16 ± 51.2	NS	100-155
CR (unit)	22.17 ± 6.43	19.56 ± 4.55	0.371	9-35
PF (unit)	1.54 ± 0.72	0.94 ± .83	0.007	>1.6

Both the groups were matched for platelet count. There was no statistically significant difference between two groups when prothrombin time and activated partial thromboplastin time were compared. On sonoclot analysis, the ACT did not show any difference in the two groups, and though clot rate (CR) was different in two groups, it was not statistically significant. However, platelet function (PF) was significantly lower in the ALL than the ITP group (Table).

Conclusions: This is the first study to the best of our knowledge demonstrating the use of sonoclot in ALL with severe thrombocytopenia. We conclude that sonoclot, a point of care device, can assess the risk of bleeding amongst patients with ALL.

1042P Clinically actionable mutations identified in Korean patients with high-risk acute lymphoblastic leukemia

K-J. Park, I-S. Kim

Department of Laboratory Medicine, Pusan National University Yangsan Hospital, Yangsan, Republic of Korea

Background: Identification of clinically actionable mutations in cancer is essential for catalyzing precision oncology based on risk stratification. Currently, little is known about the mutation profile of high-risk acute lymphoblastic leukemia (ALL) in Korean patients. We aimed to develop a multigene panel for ALL and to investigate clinically actionable mutations in the Korean patients with high-risk ALL.

Methods: We developed a multigene panel targeting 102 genes with diagnostic, prognostic, or therapeutic significance in ALL and validated it using reference materials and clinical samples. The mutation analyses were done in a total of 18 patients with high-risk ALL {T lymphoblastic leukemia (T-ALL, n = 7), B lymphoblastic leukemia in relapse (relapsed B-ALL, n = 5), and Philadelphia chromosome-positive ALL (Ph+ ALL, n = 6)}. High-risk ALL was categorized based on clinical findings and laboratory tests including immunophenotyping, chromosome analyses, fluorescence in situ hybridization, and RT-PCR. Clinically actionable mutations were selected based on a four-tiered system recommended by Association for Molecular Pathology in 2017.

Results: A total of 28 clinically actionable mutations including 6 novel mutations were identified in 83% of the patients. The most frequent alterations in Korean patients were loss of function mutations of KMT2C (78%), followed by mutations of NOTCH1 (17%) and SUZ12 (11%). There is no difference in the frequency of KMT2C mutation among T-ALL, relapsed B-ALL, and Ph+ ALL, while mutations in NOTCH1 and

SUZ12 were observed only in T-ALL. Additional 8 genes including NT5C2 and KRAS were mutated. Furthermore, potential germline pathogenic variants were discovered in 3 patients including one previously diagnosed as neurofibromatosis type 1.

Conclusions: This study showed that KMT2C mutations were recurrently observed in Korean patients with high-risk ALL. The KMT2C mutation status could be an effective risk stratification strategy for Korean patients with ALL. This study provides clinically actionable mutational portrait of high-risk ALL, albeit in a limited number of patients and gives novel insight into genetic heterogeneity of the disease.

1043TiP A phase IIA dose optimization study of ASLAN003 in acute myeloid leukemia (AML)

C.H. Ng[1], S.B. Ting[2], W.Y.K. Hwang[3], A. Bajel[4], R. Eek[5], M. McHale[6], H-J. Shih[7], N. McIntyre[8], J. Kwek[9], B. Lindmark[6]

[1]Haematology-Oncology, National University Hospital, Singapore, [2]Haematology Department, Eastern Health, Box Hill Hospital, Box Hill, Australia, [3]Haematology, Singapore General Hospital and National Cancer Centre, Singapore, [4]Department of Clinical Haematology, Royal Melbourne Hospital, Parkville, Australia, [5]Medical Oncology, Border Medical Oncology Research Unit, Albury, Australia, [6]Medical, ASLAN Pharmaceuticals, Singapore, [7]Medical, ASLAN Pharmaceuticals, Taipei, Taiwan, [8]Statistical, ASLAN Pharmaceuticals, Singapore, [9]Clinical Operations, ASLAN Pharmaceuticals, Singapore

Background: AML is a heterogeneous hematologic malignancy. For patients who are ineligible for standard treatment, relapsed from prior remission, or failed prior treatment, only few options are available for further treatment and the responses are limited. A recent study has identified dihydroorate dehydrogenase (DHODH) as a critical enzyme in the myeloid differentiation of human AML blast. At present there is no specific molecular marker to identify likely responders to DHODH inhibition. ASLAN003, a potent small molecular DHODH inhibitor, which has completed phase 1, has demonstrated the ability to induce differentiation in AML cell lines, xenograft models, and the primary AML blast obtained from patients. ASLAN003 has shown a safe and tolerable profile in prior phase I studies.

Trial design: A multicenter, single arm phase IIA study to evaluate ASLAN003 as monotherapy in patients with AML who are ineligible for standard therapy. The primary objective is to determine the optimum dose of ASLAN003 based on the efficacy, safety and tolerability profile, of doses already studied in healthy volunteers. Safety will be assessed based on Adverse Events and other safety measures including vital signs, laboratory tests, electrocardiography. Efficacy will be assessed using the Overall Complete Remission Rate (OCRR, % of complete remission (CR) + complete remission with incomplete hematologic recovery (CRi)). Secondary objective is to assess the pharmacokinetics (PKs) of ASLAN003 and its metabolite and to further assess the efficacy based on relapse-free survival and clinical benefit rate (CBR, % of partial remission +CR+ CRi). Exploratory objectives is to exam the myeloid differentiation effects of ASLAN003 ex vivo and explore the possible relationships between the clinical response and AML molecular profile. The study contains 3 cohorts (ASLAN003 100 mg, 200 mg, and 300 mg once daily). Accrual has started on December 2017, with planned enrollment for 6 patients for each cohort. Safety data will be listed and summarized. Overall AML response data will be listed and summarized showing frequency and proportion of the best response, OCRR and CBR by dose levels. Concentrations and PK parameters will be listed and summarized using descriptive statistics.

Clinical trial identification: Clinical trial information: NCT03451084.

Background: The EXTREME regimen (cetuximab + PBT ≤ 6 cycles followed by cetuximab-alone maintenance until progressive disease [PD]) was the first treatment in 30 years to significantly improve disease control and overall survival (OS) vs PBT in patients (pts) with first-line (1L) R/M SCCHN (median progression-free survival [PFS], 5.6 vs 3.3 months; median OS, 10.1 vs 7.4 months). ENCORE is a multinational, observational, prospective, open-label study investigating the real-world treatment practices, efficacy, and safety of the EXTREME regimen in 1L R/M SCCHN. The primary objective was to characterize the ways the 1L R/M treatment regimen is administered in SCCHN.

Methods: This study (EMR 062202-566) enrolled 225 pts with previously untreated R/M SCCHN from Italy, France, Portugal, Russia, Algeria, and South Africa, who were planned to receive 1L treatment with cetuximab + PBT.

Results: 221 pts were evaluable. Median age was 64 years, 76% were male, and 85% had an ECOG performance status of 0 or 1. 51% of patients had recurrent disease, 9% had recurrent and metastatic disease, and 40% had metastasis at first presentation. 40% of patients received cisplatin, and 59% received carboplatin. Only 54% of patients received 5-fluorouracil (5-FU). 14% had previously received cetuximab as part of their concomitant treatment, and 12% had PD < 6 months since the last platinum dose in the locally advanced setting. 206 pts (93%) were planned to receive cetuximab maintenance until PD, and 97 of the 202 pts with known stop date (48%) received cetuximab maintenance. Median PFS was 6.5 months (95% CI, 5.4–7.6), and median OS was 10.2 months (95% CI, 8.5–12.6). Serious adverse events occurred in 36% of pts, with 5% related to cetuximab.

Conclusions: The ENCORE trial showed, in an international real-world setting, OS and PFS with 1L cetuximab + PBT that were comparable to what was observed in the randomized, phase 3 EXTREME study. Notably, the EXTREME regimen was feasible in an unselected population and was adapted in a substantial proportion of patients, with almost half of them not receiving 5-FU. Final data will be presented at the congress.

1058P Elderly patients with locally advanced head and neck squamous cell carcinoma treated with NBTXR3 nanoparticles activated by radiotherapy: A phase I trial

C. Le Tourneau[1], V. Calugaru[1], V. Moreno[2], X. Mirabel[3], B. Dodger[2], E. Calvo[2], T. Jouffroy[1], J. Rodriguez[1], A. Chilles[1], M. Yemi[1], C. Hoffmann[1]

[1]Medical Oncology, Institut Curie, Paris, France, [2]Medical Oncology-Start Madrid-FJD, University Hospital "Fundacion Jimenez Diaz", Madrid, Spain, [3]Medical Oncology, Oscar Lambret Center, Lille, France

Background: Elderly patients (pts) with head and neck squamous cell carcinoma (HNSCC) represent 25% of the affected population. They are not always eligible to the same treatment of younger pts, thus require new therapies. NBTXR3, injectable hafnium oxide nanoparticles activated by radiotherapy (RT), was developed to increase the local deposit of energy within the tumor. It is currently evaluated in a phase I trial for locally advanced HNSCC in elderly and frail pts.

Methods: So far, 16 pts ≥65 years ineligible for surgery and cisplatin, the non-surgical standard of care, or intolerant to cetuximab, but eligible for RT with stage III or IV HNSCC of the oral cavity/oropharynx were treated with a single NBTXR3 intratumoral (IT) injection. A 3 + 3 dose escalation design was applied with dose levels at 5%, 10%, 15%, 22% of baseline tumor volume followed by intensity-modulated RT (IMRT; 70 Gy / 35 fractions / 7 weeks). Primary endpoints were determining the Recommended Dose and of Dose Limiting Toxicities (DLTs). NBTXR3 leakage in

nearby healthy tissues and efficacy per RECIST 1.1 response via MRI were evaluated. Pts are followed until disease progression/study cut-off date.

Results: Enrollment is at the fourth level at 22% (5 pts) and complete for the first three at 5% (3 pts), 10% (3 pts), 15% (5 pts) with no early DLTs. Two adverse events (AE; asthenia, grade 1; oral pain, grade 2) related to NBTXR3 and four AEs (two tumor hemorrhage, grade 1; asthenia, grade 1; oral pain, grade 2) related to the IT injection were reported. NBTXR3 persistence in the tumor with no leakage was assessed per CT scan between 24h and 7 weeks post injection. In 13 evaluable pts, the best response per RECIST 1.1 on investigator assessment were 6 CR, 4 PR, 3 NC.

Table: 1058P

	5% (n = 3)	10% (n = 3)	15% (n = 5)	22% (n = 2)	Total (n = 13)
Complete response (CR)	0	1 (33%)	4 (80%)	1 (50%)	6 (46%)
Partial response (PR)	2 (67%)	1 (33%)	1 (20%)	0	4 (31%)
No change (NC)	1 (33%)	1 (33%)	0	1(50%)	3 (23%)

Conclusions: Current results indicate a safe and well tolerated profile for NBTXR3 even at the highest doses highlighting an encouraging perspective in the elderly. This population stress a medical need of which few HNSCC trials answer.

Clinical trial identification: NCT01946867.

1059P Long lasting responses to adoptive T-cell therapy in relapsed EBV-related nasopharyngeal carcinoma

S. Secondino[1], P. Bossi[2], A. Gurrado[3], S. Basso[3], I. Imarisio[1], A. Pagani[1], M. Zecca[4], I. Pisani[3], J. Bagnarino[3], M. Casanova[5], C. Bergamini[2], C. Perotti[6], L.F. Licitra[2], P. Comoli[3], P. Pedrazzoli[1]

[1]Oncology Departement, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy, [2]Head and Neck Medical Oncology Unit, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [3]Cell Factory, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy, [4]Pediatric Hematology Oncology Department, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy, [5]Pediatric Oncology Unit, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [6]Immunohaematology and Transfusion Service, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

Background: Epstein-Barr virus (EBV)-related Nasopharyngeal carcinoma (NPC) is a highly chemo-radiosensitive cancer. However, when relapsing without surgical or reirradiation options, NPC carries a dismal prognosis; survival >2 years being reported in 7-14% metastatic pts (1,2). We have previously achieved disease control using autologous EBV-specific cytotoxic T lymphocytes (CTL) in refractory/relapsed pts following conventional treatments (3). The aim of the present study was to evaluate outcomes in pts receiving T-cell therapy after first line chemotherapy (CT) for recurrent disease.

Methods: Sixteen patients (13 males, median age 41 yrs) with metastatic (n = 12; 7/12 with visceral metastasis, and 5/12 with bone and nodes lesions) or locally recurrent (n = 4) NPC received 2 administrations of EBV-specific CTL at a total cell dose/infusion of 1.5-3 x 10^8, following completion of first line CT. The best response after first-line CT had been progressive disease (PD) in 4 pts, stable disease (SD) in 3, partial response (PR) in 5 and complete response (CR) in 4.

Results: No severe adverse events were recorded, following CTL therapy. Among patients in CR after first-line CT, 3 remain in CR at 58, 76 and 77+ months, while one patient relapsed, but attained a long-lasting CR after treatment with 2nd-line CT. In the 12 patients treated with persistent disease (PR, SD, PD), the best response observed after CTL therapy, in some cases (3/12) associated with 1subsequent line of CT or radiotherapy, was PD in 8 patients, and CR (range 39-78+ months) in 4. At a median follow-up of 64 months, 8/16 patients are alive with no evidence of disease. Among the factors associated with positive outcome are response to first-line CT, and metastatic disease with limited tumor burden.

Conclusions: EBV-specific CTL therapy administered following first line CT for recurrent NPC, is safe and associated with remarkable clinical benefit in some patients, including long-lasting CR.

1060P Radiotherapy alone for human papillomavirus-related locally advanced oropharyngeal squamous cell carcinoma: A single-arm, phase II study

N. Takemoto[1], M. Suzuki[1], Y. Seo[2], K. Ogawa[2], H. Inohara[1]

[1]Otorhinolaryngology-Head and Neck Surgery, Osaka University Graduate School of Medicine, Osaka, Japan, [2]Radiation Oncology, Osaka University Graduate School of Medicine, Osaka, Japan

Background: Oropharyngeal squamous cell carcinoma (OPSCC) is divided into two entities: human papillomavirus-related (HPV-related) and HPV-unrelated. Although it is established that patients with HPV-related locally advanced OPSCC (LA-OPSCC) survive significantly better than those with HPV-unrelated LA-OPSCC when treated with chemoradiotherapy (CRT), CRT remains the standard treatment for HPV-related LA-OPSCC. Given the young generation being more prone to be affected by HPV-related OPSCC, patients suffer from severe late toxicity associated with CRT for a long time. The hypothesis has emerged that patients with HPV-related LA-OPCC could be well managed by de-intensified treatment, resulting in long-term less morbidity without compromising survival. A series of clinical trials are in progress to certify this hypothesis.

Methods: We did a single-arm, phase 2 trial, enrolling patients with newly diagnosed, biopsy-proven, stage III or IV (excluding T4 and/or N3) OPSCC, positive for both p16 and HPV DNA. Patients received intensity-modulated radiotherapy alone for 70 Gy in 35 fractions. The primary endpoint was response at 11th week after treatment, assessed on RECIST and PERCIST.

Results: Between August 2013 and November 2016, 39 patients were enrolled with a median age of 64 years (range, 49-83). The majority of patients (24, 62%) had ≥10 pack-years smoking history. 35 (90%) patients showed complete response on RECISIT and/or complete metabolic response on PERCIST. One patient had regional recurrence, and two had distant metastasis. The 2-year overall survival rate and progression-free survival rate was 96% and 91% (95% CI, 76-99 and 75-97), respectively. During treatment 10 patients had grade 3 adverse events, but no grade 4 events were reported. 7 patients had gastrostomy tube placed during treatment, but no patient was dependent on gastrostomy tube at 4 weeks after treatment.

Conclusions: Radiotherapy alone was associated with high disease control and an improved toxicity profile. Radiotherapy alone has the potential to replace CRT as the standard treatment for HPV-related LA-OPSCC.

Clinical trial identification: UMIN000008953; Release date: 09/20/2012.

Background: Advanced and metastatic head and neck (HN) cancers are a heterogeneous tumour with poor outcome as few therapeutic options are available. Until now, no accepted genomic profiles can lead to an oriented treatment. We performed a retrospective analysis of the MOSCATO-01 trial for patients with advanced and metastatic HN cancer.

Methods: Patients included in MOSCATO-01 trial underwent biopsies for molecular screening analyses by Comparative Genomic Hybridisation Array, Next Generation Sequencing or RNA Seq. Patients were treated by targeted treatment on the molecular alteration screening. Progression-free survival (PFS) ratio was the primary endpoint corresponding to PFS2/PFS1 (PFS2: PFS in patients treated according to molecular alteration; PFS1: PFS in patients treated with usual treatment).

Results: 129 patients (12.4%) with advanced or metastatic HN cancers were included in MOSCATO-01 trial among 1035 patients. The most frequent histologic type was squamous cell carcinoma (62.7%), followed by adenocarcinoma and kystic adenoid carcinoma (6.5% each) and muco epidermoid carcinoma (3.7%). Patients were in most of the cases heavily pre-treated, as 65% of them received 3 lines of prior systemic treatment. More than 60% of the patients had a RMH score at 0. Of 107 patients (82.9%) who underwent a biopsy, 45 (42%) presented potential targetable molecular alterations: PI3KCA, ERBB2, NOTCH and MET where the most frequent targeted

molecular alterations. Moreover, 33.3% of them (n = 15) had a targeted treatment: 9 patients in phase 1 trial and 6 with off label use therapeutic. The median progression free survival of the 15 patients treated according to molecular alteration was 1.7 months [0.26-6.93]. The PFS ratio was above 1.3 for 46% of the patients.

Conclusions: MOSCATO-01 for HN cancers showed that a large proportion of patients have cancer with actionable molecular alteration, with benefit on PFS ratio of oriented treatment guided by molecular screening. Precision medicine in advanced HN cancers could bring new therapeutic options in these hard to treat cancers.

1062P Pembrolizumab and afatinib for recurrent or metastatic head and neck squamous cell carcinoma

H-F. Kao, R-L. Hong

Department of Oncology, National Taiwan University Hospital, Taipei, Taiwan

Background: Head and neck squamous cell carcinoma (HNSCC) is an important malignancy in Taiwan. Anti-PD-1, including nivolumab or pembrolizumab (pembro), had shown the efficacies against recurrent or metastatic (R/M) HNSCC. Afatinib, an irreversible EGFR tyrosine kinase inhibitor (TKI), had showed its activity against head and neck squamous cell carcinoma. In vitro and animal study showed that afatinib can inhibit macrophage function, increase antigen presentation, and augment the T cell response. The role of afatinib for cancer immunotherapy have not been explored in human. We hypothesized that adding afatinib with pembro may improve the treatment efficacy for patients with R/M HNSCC.

Methods: For HNSCC patients who decided to take pembro, the combination with afatinib would be discussed between the physician and the patient. Pembro was planned for 4 cycles. Afatinib was prescribed concurrently with pembro, and will be kept after discontinuation of pembro, until disease progression. For patients taking pembrolizumab and afatinib (P+A), the medical records were reviewed. Patients who have monotherapy with pembrolizumab or afatinib before the P+A were excluded. RECIST 1.1 were used for evaluating tumor response.

Results: From Nov. 1, 2016 to Sep. 30, 2017, 41 R/M HNSCC patients (pts) took P+A. The median age was 59 years, and 38 pts were men. The cancer types were: oral cavity: 29 pts, oropharynx: 5 pts, and hypopharynx: 7 pts. The initial treatments were: pembrolizumab 200mg: 27pts; 2mg/kg: 14pts. Eighteen pts are platinum naïve, and 23 pts are platinum refractory. Until Mar. 30, 2018, the median follow-up was 7.6 months. The clinical response was: CR+PR 24/41 (58.5%, 95% CI: 42.8% -74.3%), SD: 9/41, PD: 8/41. The median PFS was 7.2 (5.0-9.3) months. The median of OS was not reached. The most common toxicities were: diarrhea 56%, skin rash 44%, mucositis 32%, and hand-foot-skin reaction 24%. The incidence of grade 3 or 4 toxicities was 3/41. No pneumonitis were noted in the cohort.

Conclusions: The addition of afatinib with pembrolizumab showed good efficacies and tolerable toxicities. Biomarker studies are ongoing. Further confirmatory prospective trial is indicated.

1063P A multicenter phase II trial of paclitaxel, carboplatin and cetuximab (PCE) followed by chemoradiotherapy in patients with unresectable locally advanced squamous cell carcinoma of the head and neck (SCCHN)

T. Enokida[1], T. Ogawa[2], A. Homma[3], K. Okami[4], S. Minami[5], S. Iwae[6], A. Nakanome[2], Y. Shimizu[7], A. Motegi[8], D. Maki[4], Y. Ueda[1], T. Fujisawa[1], S. Nomura[9], S. Okano[1], M. Tahara[1]

[1]Head and Neck Medical Oncology, National Cancer Center Hospital East, Kashiwa, Japan, [2]Otolaryngology and Head and Neck Surgery, Tohoku University School of Medicine, Sendai, Japan, [3]Department of Otolaryngology, Head & Neck Surgery, Hokkaido University Graduate School of Medicine, Sapporo, Japan, [4]Department of Otolaryngology-Head Neck Surgery, Tokai University, Isehara, Japan, [5]Department of Otorhinolaryngology, National Hospital Organization Tokyo Medical Center, Tokyo, Japan, [6]Head and Neck Surgery, Hyogo Cancer Center, Akashi, Japan, [7]Department of Medical Oncology, Hokkaido University Hospital, Sapporo, Japan, [8]Division of Radiation Oncology and Particle Therapy, National Cancer Center Hospital East, Kashiwa, Japan, [9]Clinical Biostatistics Division, Center for Research Administration and Support, National Cancer Center, Kashiwa, Japan

Background: Induction chemotherapy (IC) often compromises the compliance of following chemoradiotherapy (CRT) in LA-SCCHN. In particular, impaired compliance of cisplatin (CDDP) during CRT negatively affects outcomes. Here, we aimed to assess the feasibility and efficacy of paclitaxel (PTX), carboplatin (CBDCA), and cetuximab (Cmab) as IC for unresectable LA-SCCHN.

Methods: Patients with biopsy-proven, unresectable LA-SCCHN were enrolled. IC consisted of CBDCA AUC = 1.5, PTX 80mg/m^2 and Cmab with an initial dose of 400mg/m^2 followed by 250mg/m^2 administered weekly for 8 weeks. Following IC, CDDP (20mg/m^2, 4 days x 3 cycles) and concurrent radiotherapy (70Gy/35fr) were started. Primary endpoint was the rate of CRT completion, defined by (1) completion of planned CDDP relative dose intensity (RDI) $\geq$ 80%, and (2) completion of radiotherapy within 2 weeks after planned completion date. PCE was planned to be deemed effective if the Bayesian posterior probability (PP) that the rate of CRT completion was $>$ 65% exceeded 84%.

Results: 35 patients were eligible and received study treatment. Cases were hypopharynx/oropharynx/larynx in 17/17/1 patients, all Stage IV (stage IVA: 24, stage IVB: 11). Of 35 patients, 34 (97%) completed IC and 32 received CRT (FAS). Of 32 FAS cases, the rate of CRT completion was 96.9%, and the study's primary endpoint was therefore met (PP = 99.9% $>$ 84%). Mean cumulative dose and RDI of CDDP in CRT was 232.5mg (160-240mg) and 100% (66.7-100%), respectively. Response rate was 88.6% in the IC phase and 93.8% in the CRT phase. 2-year rates of local progression, distant metastasis, event-free survival and overall survival were 34.9%, 16.7%, 55.1% and 83.5%, respectively. Main grade 3 toxicities included neutropenia (11%), skin rash (6%), and anemia (6%) in the IC phase; and oral mucositis (31%), neutropenia (13%), and radiation dermatitis (13%) in the CRT phase. No grade 4 toxicity or treatment-related death was seen.

Conclusions: PCE as IC was feasible, with promising efficacy and no effect on compliance of following CRT in unresectable LA-SCCHN. A Phase III comparison with CRT alone is warranted.

Clinical trial identification: UMIN000014430.

Legal entity responsible for the study: IC-PCE Study Executive Committee.

Background: Cetuximab in combination with platinum-based chemotherapy followed by cetuximab maintenance until progression significantly prolonged overall survival (OS) in patients with first line recurrent and/or metastatic squamous-cell carcinoma of the head and neck (SCCHN) (EXTREME trial).

Methods: SOCCER is an ongoing German prospective, non-interventional study to evaluate symptom control in patients with recurrent and/or metastatic SCCHN treated with cetuximab in combination with platinum-based chemotherapy or radiotherapy in clinical routine. Desciptive statistics were used for the current interim analysis (data cut-off 6 DEC 2017) focusing on efficacy outcomes.

Results: This interim analysis involves 399 patients (median age: 62.0 years (range 29-89 years), 82.2% male, ECOG 0-1: 74.2%, 61.9% metastatic disease) who received at least one dose of cetuximab. In 289 of 399 patients cetuximab was applied in combination with platinum-based chemotherapy (CT) only (165 cis- (41.3%), 124 carboplatin (31.1%)), in 80 patients (20.1%) in combination with radiotherapy (RT) only; and other regimens in 30 patients (7.5%). Current median duration of cetuximab therapy was 6.1 weeks in combination with RT and 12.9 weeks in combination with CT. Median observation time was 11.7 months (reverse Kaplan-Meier estimate). In the 251 patients with available response data (CR, PR, SD, PD) the objective response and disease control rate were 45.0% and 80.5%, respectively. Median progression-free survival and OS after start of cetuximab therapy was 5.5 and 9.3 months (5.2/9.3 months for the cetuximab + CT and 8.7/9.3 months for the cetuximab + RT).

Conclusions: Interim results of the non-interventional SOCCER study indicate that efficacy outcomes of cetuximab in combination with platinum-based CT under routine conditions are in line with the results of the EXTREME trial.

Background: In the randomized phase III Study CA209141, Nivolumab (N) demonstrated significant overall survival benefit as treatment for platinum refractory R/M SCCHN and is now approved for these patients. N has demonstrated a manageable safety profile compared to chemotherapies commonly used in patients with platinum-refractory R/M SCCHN. The main objective of the study is to provide additional insight into the frequency of high-grade AEs related to N and their outcome.

Methods: Between August 2017 and October 2017, 75 patients were included in the multicenter, open-label, non-controlled phase II safety study TOPNIVO. The main inclusion criteria were patients with platinum refractory R/M SCCHN with progressive disease, ECOG 0-2. Patients received N 3mg/kg every 2 weeks intravenously over 30 minutes. We report here the safety results of the three first months of treatment.

Results: Of 73 patients treated with N, median age was 64.0 yr, 75% were male, 23% were ECOG 0, 62% 1, 15% 2, 81% were current or former smoker. The primary site of cancer was oral cavity 27%, oropharynx 34%, larynx 19%, hypopharynx 19%. 36% had loco regional relapse, 34% had metastatic disease and 30% had both. 48% had received one prior line of chemotherapy and 32% two prior lines. 37 pts (51%) received at least 6 administrations of N during the first three months of treatment. 5% of administrations were delayed, mainly for intercurrent disease. 38 pts (52%) ended N within the first three months, 28 pts for progressive disease, 8 due to death (thrombus 1pt, progressive disease or related to cancer 7 pts), 1 for pneumonitis, 1 for pain. 35 pts experienced at least 1 AE grade 3/4/5. On the 52 AEs grade 3-4, 7 (mainly asthenia and lipase increase) were related to N. On the 7 AEs grade 5, 1 (pneumonitis) was related to N. 28 pts (38%) experienced at least 1 SAE. On the 38 SAEs, 3 were related to N. 6 patients experienced tumor bleeding (grade 1 2 pts, grade 2 1 pt, grade 3 1 pt, grade 4 1 pt, grade 5 1 pt), none were related to N.

Conclusions: The first results of the TOPNIVO study show an acceptable toxicity profile without additional toxicities compared to what has been described previously.

Clinical trial identification: NCT03226756; EudraCT: 2017-000424-10.

1066P A phase II trial of docetaxel plus cisplatin in recurrent and/or metastatic non-squamous cell carcinoma of head and neck

Y. Imamura[1], N. Kiyota[1], K. Tanaka[2], H. Hayashi[2], I. Ota[3], K. Nario[3], S. Hirano[4], A. Arai[4], S. Iwae[5], T. Onoe[6], S. Minami[7], T. Shimada[7], K. Yane[8], T. Yamazaki[9], Y. Nagatani[1], M. Toyoda[1], N. Otsuki[10], K-I. Nibu[10], H. Minami[1]

[1]Medical Oncology/Hematology, Kobe University Hospital, Kobe, Japan, [2]Medical Oncology, Kindai University Faculty of Medicine, Osaka, Japan, [3]Otolaryngology Head and Neck Surgery, Nara Medical University, Kashihara, Japan, [4]Otorhinolaryngology, Kyoto Prefectural University of Medicine, Kyoto, Japan, [5]Head and Neck Surgery, Hyogo Cancer Center, Akashi, Japan, [6]Medical Oncology, Hyogo Cancer Center, Akashi, Japan, [7]Otolaryngology, National Hospital Organization Tokyo Medical Center, Tokyo, Japan, [8]Otolaryngology, Nara Hospital, Faculty of Medicine, Kindai University, Nara, Japan, [9]Head and Neck Cancer Oncology, Miyagi Cancer Center, Natori, Japan, [10]Otolaryngology-Head and Neck Surgery, Kobe University Hospital, Kobe, Japan

Background: Due to the rarity and heterogeneity of recurrent and/or metastatic head and neck non-squamous cell carcinoma (R/M HN non-SCC), no standard chemotherapy for this condition has yet been established. This multicenter phase II trial evaluated the efficacy and safety of docetaxel and cisplatin combination (DC) in R/M HN non-SCC.

Methods: Eligibility criteria were R/M HN non-SCC; progressive disease within the last 6 months; no prior systemic therapy, or interval of at least 24 weeks since the last induction chemotherapy or chemoradiotherapy with curative intent; measurable disease; and ECOG performance status of 0 or 1. Patients (pts) received docetaxel (75 mg/m^2 on day 1) and cisplatin (75 mg/m^2 on day 1), repeated every 21 days for 6 cycles. The primary endpoint was objective response rate (ORR).

Results: From Nov 2012 to Oct 2016, a total of 23 pts were enrolled, characterized as 15 females, median age 57 years (range, 32-76), and 96% metastatic. Among 22 evaluable pts, ORR was 45.5% (95% confidential interval [CI], 24.4-67.8%), and the lower bound of the 95% CI of 24.4% exceeded the predefined hypothesis of 10%. ORRs according to primary tumor site and histology are shown in the table below. With a median follow-up period of 18.8 months, median progression-free survival and overall survival were 6.7 and 20.1 months, respectively. Grade 3/4 adverse events included neutropenia (91%), febrile neutropenia (FN) (39%), anemia (22%), appetite loss (17%), and fatigue (13%). The FN rate was significantly lower in the pts with prophylactic antibiotics (57 vs 11%, P = 0.04). No treatment-related deaths were observed.

Table: 1066P Objective response rates according to primary tumor site and histology

	Adenoid cystic carcinoma	Aadenocarcinoma, not otherwise specified	Salivary duct carcinoma	Sebaceous carcinoma	Mucoepidermoid carcinoma	NUT midline carcinoma	Acinic cell carcinoma	Total
Salivary gland	2/4	2/3	2/3			0/1		6/11
Nasal cavity/paranasal sinus	1/3							1/3
Ocular	0/1			2/2*				2/3
Oral cavity/lip					1/1		0/1	1/2
Oropharynx	0/1	0/1						0/2
Ear	0/1							0/1
Total	3/10	2/4	2/3	2/2	1/1	0/1	0/1	10/22

*complete response

Conclusions: This phase II study of DC met its primary endpoint. This DC regimen is effective and represents a new treatment option in the treatment of progressive R/M HN non-SCC, although prophylactic antibiotics for FN should be considered.

Clinical trial identification: UMIN000008333.

1067P Multicenter phase II trial of nab-paclitaxel and cisplatin (AP) followed by chemoradiation therapy (CRT) for locally advanced head and neck squamous cell carcinoma (HNSCC)

D. Adkins[1], J. Ley[1], H.A. Gay[2], M. Daly[2], R. Jackson[3], J. Rich[3], P. Pipkorn[3], R.C. Paniello[3], K. Trinkaus[4], P. Neupane[5], J. Zevallos[3], W. Thorstad[2], P. Oppelt[1]

[1]Internal Medicine/Medical Oncology, Washington University School of Medicine, St. Louis, USA, [2]Radiation Oncology, Washington University School of Medicine, St. Louis, MO, USA, [3]Otolaryngology, Washington University School of Medicine, St. Louis, MO, USA, [4]Biostatistics, Washington University School of Medicine, St. Louis, MO, USA, [5]Medical Oncology, University of Kansas Cancer Center, Fairway, KS, USA

Background: The results of two consecutive phase II trials of patients with locally advanced HNSCC showed relapse rates of 13% after nab-paclitaxel, cisplatin, 5-FU and cetuximab (APFC) followed by CRT (Cancer 2013) and 3% after APF (no cetuximab) and CRT (Oral Oncology 2016). The complete response (CR) rates at the primary tumor site after 2 cycles of APFC was 53% and APF 77%. A comparison of APFC and CRT to APF and CRT showed no benefit of cetuximab (Oral Oncology 2017). In this phase II trial, we hypothesized similar efficacy with AP (no 5-FU) and CRT.

Methods: Eligibility criteria were similar to prior trials: stage III-IV oropharynx (OP), larynx, or hypopharynx SCC and adequate organ function and performance status (ECOG 0-1). T_1 tumors were excluded. Treatment: 3 cycles of AP followed by CRT. AP: nab-paclitaxel 100 mg/m^2 days 1,8 and 15 + cisplatin 75 mg/m^2 day 1 in 3 week/cycles. CRT: Cisplatin 100 mg/m^2 days 1, 22 and 43 or cetuximab weekly (if cisplatin-ineligible) and intensity modulated RT 70 Gy (200 cGy/day). The primary endpoint was clinical CR rate at the primary tumor site after 2 cycles of AP, determined by visual exam. With a non-inferiority margin of 19% (lower boundary: 58%), a 40 patient sample provided power = 0.80 at p = 0.05 to conclude the CR rate at the primary tumor site with AP was non-inferior to APF (77%).

Results: Characteristics of the 40 enrolled patients: mean age 57 years (range 42-77), smoker 68%, male 90%, and ECOG 0 (78%). Tumor characteristics: $T_{3\text{-}4}$ (68%), > N_{2c} (58%), and human papillomavirus (HPV)-related OPSCC (73%) or HPV-unrelated HNSCC (28%). CRT included cisplatin (36) or cetuximab (4). Clinical CR rate at the primary tumor site after 2 cycles AP was 70% (28 patients). Primary tumor site biopsies obtained following 2 cycles AP in 29 patients showed no cancer in 24 (83%). Post-cycle 2 biopsies showed no cancer in 19 of 20 evaluable patients with clinical CR. Median follow-up was 12.0 months (range: 0.1-19.6). Relapse rate was 8% (3 patients).

Conclusions: The CR rate at the primary tumor site after 2 cycles of AP was not inferior to that with APF. Deletion of 5-FU from APF did not reduce tumor response.

Clinical trial identification: NCT02573493.

1068P Cetuximab in combination with methotrexate (MTX) as first-line treatment in recurrent or metastatic (R/M) squamous cell carcinoma of the head and neck (SCCHN): A phase Ib randomized phase II study versus single agent MTX

J. Ham[1], E. Meerten[2], E. Fiets[3], F. Jeurissen Mc Haaglanden[4], M. Slingerland[5], W.T.A. van der Graaf[6], C.M.L. van Herpen[1], L.V. Beerepoot[7]

[1]Medical Oncology, Radboud University Medical Centre Nijmegen, Nijmegen, Netherlands, [2]Medical Oncology, Erasmus Cancer Institute, Rotterdam, Netherlands, [3]Medical Oncology, Medical Center Leeuwarden, Leeuwarden, Netherlands, [4]Internal Medicine, Medisch Centrum Haaglanden, Westeinde, Den Haag, Netherlands, [5]Medical Oncology, Leiden University Medical Center (LUMC), Leiden, Netherlands, [6]Division of Clinical Studies, Royal Marsden Hospital Institute of Cancer Research, Sutton, UK, [7]Internal Medicine, St. Elisabeth Tweesteden Hospital, Tilburg, Netherlands

Background: First-line palliative treatment in R/M SCCHN consists of the combination of cetuximab with cisplatin and 5-FU with a median progression free survival (PFS) and overall survival (OS) of 5.5 and 10.1 months, respectively, at the expense of substantial toxicity. Single agent MTX has minimal side effects, but response rate, gain in PFS and OS are limited. We hypothesized that adding cetuximab to MTX could improve PFS without adding major toxicities. Because this combination had not been tested before, we first performed a phase Ib study followed by a randomized phase II study.

Methods: In the phase Ib study, patients (pts) with previously untreated R/M SCCHN were treated with weekly MTX 40 mg/m^2 and cetuximab 250 mg/m^2, after a loading dose of cetuximab 400 mg/m^2. The primary objectives of the phase Ib study were feasibility and safety of the combination of cetuximab and MTX. In the phase II study pts were randomized to either MTX or the combination (1:2). The primary objective of the phase II study was to detect an increase in median PFS from 3 to 5 months with combination vs single agent MTX. Secondary endpoints were toxicity and OS.

Results: Six pts were included in the phase Ib study. No dose limiting toxicities were observed, median PFS was 24.4 weeks (range 7.1-55.0). In the phase II study 45 pts were included; 15 pts received MTX (73% male, median age 64 years (range 50-77)) and 30 pts cetuximab and MTX (77% male, median age 69 years (range 46-80)). In the phase II study median PFS was significantly different: 8.0 weeks (range 3.0-39.0) in the MTX arm and 17.0 weeks (range 3.9-76.6+) in the combination arm (p=.009). Nine pts in the combination arm experienced a serious adverse event (SAE), 3 were possible treatment-related (pneumonia, pneumonitis and hypersensitivity reaction) compared with 5 pts with an SAE in the MTX group, all unrelated. OS and detailed toxicity results will be presented later.

Conclusions: The combination of cetuximab and MTX in pts with R/M SCCHN is feasible. This randomised phase II study met its primary endpoint: a significantly longer PFS in the cetuximab and MTX combination arm, while toxicity was acceptable.

Clinical trial identification: NCT02054442.

1069P Phase II study of biweekly TPFL induction chemotherapy for locally advanced squamous cell carcinoma of head and neck

C.Y. Hsieh[1], M.Y. Lein[1], C-H. Hua[2]

[1]Division of Hematology and Oncology, Department of Internal Medicine, China Medical University Hospital, Taichung City, Taiwan, [2]Department of Otolaryngology, China Medical University Hospital, Taichung City, Taiwan

Background: The induction chemotherapy (ICT) with triweekly TPF had been considered as an effective treatment in locally advance squamous cell carcinoma of head and neck (SCCHN). However, the treatment needs inpatient care and may have more toxicities for Asian patients. We conducted a phase 2 study of alternative biweekly TPFL as induction chemotherapy and evaluated the outcome and toxicities.

Methods: Patients with locally advanced SCCHN were enrolled in the study. Induction chemotherapy with Docetaxel 50mg/m2, cisplatin 50mg/m2, 5-fluorouracil 2500 mg/m^2 and leucovorin 250 mg/m^2 was administered biweekly for six cycles, followed by local treatment including concurrent chemoradiotherapy, bio-radiotherapy or surgery plus adjuvant RT. Our primary endpoint is response rate after ICT.

Results: Total 58 patients were enrolled in the study from June 2014 to September 2015. The median age is 53 years (from 28 to 69 y/o). The patients' characteristics was mentioned as: primary site of oral cavity/oropharynx/hypopharynx: 18/25/15; stage IVa/IVb: 35/23; male /female: 54/4; performance status ECOG 0-1/2:57/1. In the oropharyngeal cancer patients neither p16 nor HPV16 status was not studied. Of those 58 patients, 56 patients received at least 4 cycles of chemotherapy. The overall response rate after ICT was 89.6 % (CR: 31% PR: 58.6%). Two patients escaped during induction chemotherapy. Grade 3/4 neutropenia was 25/9%; grade 3/4 mucositis was 1.7%; grade 3/4 diarrhea was 1.7%. Infection rate was 19%. The response rate after following treatment was 75 % (CR: 66.0%, PR: 9.0 %) The median follow-up time was 31.8 months. The overall 3 years PFS/OS was 34.3 %/56.1%. Local recurrence rate was 29.3% and distant metastasis rate was 10.3%. Six patients had second primary tumor. (10.3%) The 3 years PFS of patients with CR/PR were 59.3%/25.5%. The 3 years OS of patients with CR/PR were 81.7%/49.1%.

Conclusions: Biweekly TPFL induction chemotherapy has excellent response rate in locally advanced SCCHN. In addition, the grade 3/4 adverse event was acceptable. The patients achieved CR after induction chemotherapy had very good outcomes.

1070P Evaluate the role of induction chemotherapy in the treatment of stage II nasopharyngeal carcinoma in intensity modulated radiotherapy era

T. Jin, P-J. Li

Radiation Department, Zhejiang Cancer Hospital, Hangzhou, China

Background: While the combined modality treatment of concurrent chemoradiotherapy (CCRT) with or without adjuvant chemotherapy has now been accepted as the standard treatment for advanced Nasopharyngeal carcinoma (NPC), induction chemotherapy +concurrent chemoradiotherapy (ICRT) is commonly used as well. The prognosis of II NPC patients is favorable. We should be more mindful to living quality during/after treatment, length of hospital stay, treatment cost and so forth. Therefore, the purpose of this study is to contrast prognosis of stage II NPC patients underwent the following two treatment modalities: ICRT vs CCRT.

Methods: 173 patients with American Joint Committee on Cancer 7th stage II NPC are included and divided into two groups: ICRT and CCRT. Induction chemotherapy consisted of 1 to 3 cycles of cisplatin plus fluorouracil or paclitaxel plus cisplatin. Concurrent chemotherapy includes cisplatin only. We retrospectively assess overall survival (OS), progression-free survival (PFS), locoregional free survival (LRFS) and distant metastasis free survival (DMFS).

Results: With a median follow up of 64.7 months, no significant differences are found in grade 3–4 hematologic toxicity, liver dysfunction and renal impairment between ICRT and CCRT groups. Univariable analyses show adding induction chemotherapy to CCRT significantly decreases 5-year OS (87.9% vs 95.5%, P = 0.033), PFS (74.0% vs 86.1%, P = 0 .035), LRFS (80.0% vs 91.2%, P = 0.016), but there is no statistically significant difference in DMFS (87.1% vs 94.7%, P = 0.095). In multivariable analyses, we find the consistent results that induction chemotherapy is a negative factor associated with OS (HR of death =3.768, 95% CI = 1.117 to 12.709; P = 0.032), PFS (HR of progression = 2.156, 95% CI = 1.060 to 4.386; P = 0.034), LRFS (HR of locoregional relapse = 2.435, 95% CI = 1.009 to 5.874; P = 0.048) and also DMFS (HR of metastasis = 2.873, 95% CI = 1.005 to 8.211; P = 0.049), in stage II NPC patients.

Conclusions: In present study, we find that induction chemotherapy causes deleterious effect on stage II NPC patients. However, this is a retrospective study and the adverse effects of induction chemotherapy has not been previously reported. It warrants further investigation.

Legal entity responsible for the study: Zhejiang Cancer Hospital.

Funding: Has not received any funding.

1071P Phase II study of CC-486 in previously treated patients (pts) with locally advanced/metastatic nasopharyngeal cancer (NPC): Final results

R. Mesia Nin[1], P. Bossi[2], A. Hansen[3], C. Hsieh[4], L.F. Licitra[5], E.H. Tan[6], P. Chen[7], J. Miller[8], L.L. Siu[9], R. Haddad[10]

[1]Medical Oncology, Catalan Institute of Oncology (ICO Badalona), Hospital Germans Trias i Pujol, Badalona, Barcelona, Spain, [2]Medical Oncology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [3]Medical Oncology, Princess Margaret Hospital, Toronto, ON, Canada, [4]Medical Oncology, China Medical University Hospital, Taichung, Taiwan, [5]Head and Neck Medical Oncology Unit, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [6]Medical Oncology, National Cancer Center, Singapore, [7]Biostatistics, Celgene Corporation, Summit, NJ, USA, [8]Oncology Clinical Research and Development, Solid Tumor, Celgene USA, Basking Ridge, NJ, USA, [9]Medical Oncology, Princess Margaret Hospital, Toronto, ON, Canada, [10]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, USA

Background: Second/third-line treatment (Tx) options are limited for pts with NPC. The efficacy and safety of CC-486 were assessed using Simon's optimal 2-stage design in a phase 2 study. The predefined criterion for advancement to stage 2 (> 4 complete/partial responses) was not met. Here, we present final results from stage 1.

Methods: The single-arm, open-label study (NCT02269943) included pts with locally advanced/metastatic NPC who had ≥ 1 prior Tx, including ≥ 1 platinum-containing regimen. Pts received CC-486 300 mg orally on d 1-14 of a 21-d cycle until disease progression/unacceptable toxicity. The first 6 Asian-Pacific (AP) pts received CC-486 200 mg; if well tolerated, subsequent AP pts received 300 mg. Primary endpoints (per independent reviewer assessment): overall response rate, progression-free survival. Key secondary endpoints: overall survival, disease control rate, safety, pharmacokinetics (PK).

Results: Median age of 36 enrolled pts was 54.0 y. Most were male (81%), had ECOG PS of ≤ 1 (97%), and had ≥ 2 prior systemic anticancer Tx (58%); 36% were AP. Pts received a median of 7.0 Tx cycles; 44% had ≥ 1 dose interruption and 39% had ≥ 1 dose reduction. 22 pts died: 1 on- and 21 post-Tx (> 28 d after last dose); 18 died due to disease complications. The table shows efficacy outcomes. PK analysis showed rapid absorption; exposure was comparable between doses. However, large inter-pt variability and small pt numbers did not allow definitive conclusions. All 36 safety-evaluable pts had ≥ 1 Tx-emergent adverse event (TEAE). Common TEAEs included vomiting (72%) and nausea (67%). Common grade 3/4 TEAEs included neutropenia (33%) and febrile neutropenia (11%).

Conclusions: The safety profile of CC-486 in pts with NPC was consistent with that in other solid tumors and of azacitidine. CC-486 monotherapy did not show sufficient clinical activity in the selected pt population to support further development in these pts.

Table: 1071P

Primary Endpoints	Efficacy-Evaluable Population (n = 25)
Overall response rate, n (%)	3 (12)
Partial response	3 (12)
Median progression-free survival (90% CI), mo	4.7 (3.1 - 7.3)
Secondary Endpoints	
Disease control rate, n (%)	13 (52)
Median overall survival (90% CI), mo	18 (14.8 - not reached)

Clinical trial identification: NCT02269943.

Background: Head and neck squamous cell carcinoma (HNSCC) is the sixth most common cancer worldwide. A special entity among HNSCCs is HPV-associated oropharyngeal cancer (OPC) with p16 positivity as a surrogate marker of cancer's viral etiology. A standard of definitive treatment for these tumors is cisplatin (CDDP) given concurrently with radiotherapy (RT). Another possible option being investigated is replacement of CDDP with cetuximab (C225). However, the optimal treatment for HPV-positive OPC remains unclear, until ongoing studies provide more evidence on this matter. The aim of this meta-analysis is to provide guidance regarding treatment decision-making in this subgroup of patients.

Methods: We performed a systematic literature search using the MEDLINE, PubMed, EMBASE, Web of Science, ScienceDirect, and Scopus databases. Meta-analysis included studies which directly compared the efficacy of CDDP vs. C225 given concurrently with RT as definitive treatment of p16-positive and locally advanced/unresectable OPC. Primary endpoints included 2-year overall survival (OS) (death from any cause) and 2-year locoregional recurrence (LRR) (recurrence at primary site and/or regional lymph nodes), analysed separately. Six studies were included in the final analysis, including a total of 526 patients (range 18-205).

Results: 2-year OS. There were 313 patients in the CDDP + RT group and 113 patients in the C225 + RT group. The pooled odds ratio (OR), calculated for CDDP + RT vs. C225 + RT, was 0.35 (95% CI, 0.17-0.71; P = 0.003). 2-year LRR. There were 382 patients in the CDDP + RT group and 144 patients in the C225 + RT group. The pooled OR, calculated for CDDP + RT vs. C225 + RT, was 0.25 (95% CI, 0.15-0.45; P < 0.0001).

Conclusions: According to our results, patients receiving CDDP with irradiation had 2.9 and 4-fold decreased risk for death from any cause and locoregional recurrence, respectively. Further investigations are needed in order to determine the optimal treatment modalities in both p16-positive and negative OPC. Until then, CDDP-based chemoradiotherapy should be considered as first line therapy option and standard of care in p16-positive and locally advanced/unresectable OPC.

1073P Survival benefit of adjuvant chemotherapy vs active surveillance in locally advanced nasopharyngeal carcinoma: A multicenter retrospective study

P. Danchaivijitr[1], A. Dechaphunkul[2], C. Paoin[1], J. Setakornnukul[3], T. Dechaphunkul[4], R. Jiratrachu[5], S. Niyomnaitham[6], B. Suktitipat[7], C. Sookthon[8], P. Pattaranutaporn[9], C. Jiarpinitnun[9], N. Ngamphaiboon[8]

[1]Medicine, Siriraj Hospital, Mahidol University, Bangkok, Thailand, [2]Medicine, Prince of Songkla University, Songkhla, Thailand, [3]Radiology, Siriraj Hospital, Mahidol University, Bangkok, Thailand, [4]Otorhinolaryngology Head and Neck Surgery, Songkhlanagarind Hospital, Songkla, Thailand, [5]Radiology, Songklanagarind Hospital, Hat Yai, Thailand, [6]Pharmacology, Siriraj Hospital, Mahidol University, Bangkok, Thailand, [7]Biochemistry, Siriraj Hospital, Mahidol University, Bangkok, Thailand, [8]Medicine, Ramathibodi Hospital, Bangkok, Thailand, [9]Radiology, Ramathibodi Hospital, Bangkok, Thailand

Background: Adjuvant chemotherapy (AC) is not a standard of care, but commonly utilized, in locally advanced nasopharyngeal carcinoma (LA-NPC) after definitive concurrent chemoradiotherapy (CCRT). Prospective randomized studies showed unclear overall survival benefit of AC compared with active surveillance (AS).

Methods: We conducted retrospective medical record review from 2005 to 2017 from the 3 university hospitals. LA-NPC patients who underwent definitive CCRT were included. Patients who received adjuvant platinum doublet chemotherapy (AC) were compared with AS patients. The primary objectives were overall survival (OS) and disease-free survival (DFS). Toxicities were also analyzed.

Results: Patients' demographic data as shown in the table. Median follow up was 54.4months. Median OS in AC arm was 120 months vs 49.3 months in AS arm (HR = 0.51, P < 0.001, 95% CI 0.37 - 0.70). Median DFS in AC arm was 107.1 months vs 35.4 months in AS arm (HR = 0.49, P < 0.001, 95% CI 0.36 - 0.66). Weight loss and decline of renal function were observed but not statistically significant between two groups.

Conclusions: AC should be considered for patients with LA-NPC who completed definitive CCRT. AC in LA-NPC should be further validated in a randomized clinical study.

1074P Paclitaxel in combination with anti-EGFR therapy as induction chemotherapy for patients unfit for cisplatin with locally advanced head and neck squamous cell carcinoma (LA-HNSCC)

J.A. Marín[1], M. Oliva Bernal[1], M. Plana Serrahima[1], M. Ferrer[1], N. Vilariño Quintela[1], S. Vazquez[1], E. Vilajosana[1], A. Lozano[2], J. Nogués[3], A. Marí[4], O. Bermejo[5], R. Mesia Nin[6], M. Taberna Sanz[1]

[1]Medical Oncology, Institut Catala de Oncologia, Barcelona, Spain, [2]Radiation Oncology, Institut Catala de Oncologia, Barcelona, Spain, [3]Otorhinolaryngology, Hospital Universitari de Bellvitge, Barcelona, Spain, [4]Maxillofacial Surgery, Hospital Universitari de Bellvitge, Barcelona, Spain, [5]Plastic Surgery, Hospital Universitari de Bellvitge, Barcelona, Spain, [6]Medical Oncology, Catalan Institute of Oncology (ICO Badalona), Hospital Germans Trias i Pujol, Badalona, Spain

Background: Induction chemotherapy (ICT) followed by bioradiotherapy (BRT) is a validated conservative approach for fit LA-HNSCC patients (pts). However, in pts unfit for cisplatin-based chemotherapy, this treatment strategy remains a challenge. Paclitaxel in combination with anti-EGFR therapy is active and well-tolerated in the recurrent/metastatic setting. This study aims to evaluate this regimen as ICT followed by BRT.

Methods: A retrospective single institution analysis (2010-2016) of LA-HNSCC pts unfit for cisplatin-based chemotherapy (≥70 years-old and/or significant comorbidity) was performed. Pts were treated with paclitaxel plus anti-EGFR monoclonal antibody up to 9 weeks followed by radical BRT (IMRT with concurrent anti-EGFR therapy). Overall survival (OS) and progression free survival (PFS) were estimated by Kaplan-Meier method.

Results: A total of 44 pts were evaluated: median age 72 years-old (50-83), male 42; tumor location, pts (%): larynx 14 (32), oropharynx 10 (23) (HPV+ 0), hypopharynx 9 (21), oral cavity 7 (16), cervical unknown primary 4 (9); 7thed TNM stage, pts (%): EIII 11 (25), EIVa 19 (43) and EIVb 14 (32). ECOG status 0/1/2: 1/38/5 pts. Response rate to ICT: 32 pts (73%); 5 complete responses (CR) and 27 partial responses (PR). During ICT 5 pts (11%) presented grade 3/4 adverse events, and 1 patient (2%) died due to febrile neutropenia. 37 pts (84%) continued with radical BRT: 20 pts (45%) achieved CR, and 6 of them recurred. Median follow-up: 13.5 (1-52) months. For the whole cohort, median OS and PFS were 15.6 (95% CI 4.7-26.6) and 10.4 (95% CI 7.0-13.7) months, respectively. For the 35 pts who completed ≥6 weeks of ICT, median OS and PFS were 22.2 (95% IC 7.2-37.2) and 15.6 (95% IC 8.4-22.9) months, respectively. Larynx pts showed better outcome in comparison with other locations: median OS not reached (NR) vs 10.7 (p = 0.003) and median PFS NR vs 0 (p = 0.001); 9 pts (64%) preserved a functioning larynx and were alive by the time of the analysis.

Conclusions: Paclitaxel plus anti-EGFR therapy was well-tolerated and might be an effective ICT regimen for LA-HNSCC pts unfit for cisplatin. In our cohort, larynx pts obtained the greatest benefit from this regimen.

1075P Safety and efficacy of nivolumab (nivo) in platinum-refractory recurrent/metastastic head and neck squamous cell (PR R/M HNSCC) patients (pts): Real-life experience

G. Bruixola[1], J. Caballero Daroqui[2], A.J. Cunquero Tomas[3], S. Sandiego[4], J. García Sánchez[5], S. Blasco[6], S. Ochenduszko[7], A. Iranzo[1], J. Lavernia[4], A. Berrocal Jaime[3], M. Pastor Borgoñón[2]

[1]Medical Oncology, Hospital Clinico Universitario de Valencia - INCLIVA, Valencia, Spain, [2]Medical Oncology, Hospital Universitari i Politècnic La Fe, Valencia, Spain, [3]Medical Oncology, Hospital General Universitario Valencia, Valencia, Spain, [4]Medical Oncology, Instituto Valenciano de Oncología, València, Spain, [5]Oncology, Hospital Arnau de Vilanova, Valencia, Spain, [6]Medical Oncologiy, Hospital de Sagunto, Valencia, Spain, [7]Medical Oncology, Hospital Dr. Peset Aleixandre, Valencia, Spain

Background: PR R/M HNSCC pts present a poor prognosis. In the randomized phase 3 trial CheckMate141, nivo showed benefit in OS with manageable toxicity. In our region, nivo is available for clinical practice since April 2017. Aim: to evaluate the safety and activity of nivo in a real-world setting.

Methods: This multicenter, retrospective analysis included PR R/M HNSCC pts treated with nivo 3mg/kg every 2 weeks at 7 centers from Valencia region. We assessed demographics, safety (CTCAE v4.0 criteria), response evaluation (RECIST 1.1) progression-free survival (PFS) and OS. Pts included in the analysis should have received >1 dose of nivo.

Results: A total of 50 pts were treated between May 2017 and April 2018. At the time of this analysis 38 patients were evaluable (updated data of the complete cohort and follow-up will be presented in ESMO congress). Nivo was administered as first-line palliative treatment in 8 pts (21,1%), as second-line in 18 pts (47,4%) and in third or subsequent lines in 12 pts (31,6%). The median number of doses administered was 5 (range 1-26) with 6 one-week treatment delays due to respiratory infections. Analysis of concurrent antibiotic therapy is pending. The objective response rate was (ORR) 23,7% with 9 partial responses, whereas 9 pts (23,7%) had stable disease. No confirmed hyperprogression was observed. Median time since last dose of platinum was 2,9 months (range 0-24) with 10 pts with a period time longer than 6 months. With a median follow-up of 6 months (range 1-16), median PFS was 3,4 months

Table: 1073P

Characteristics	All (n = 675)	Adjuvant chemotherapy (n = 595)	Active surveillance (n = 80)	p-value
Age (mean±SD)	49.52269 ± 11.91209	48.96639 ± 11.63714	53.425 ±13.4473	0.002
Male (%)	465 (69)	416 (69.92)	49 (61.25)	0.116
BMI kg/m^2 (mean±SD)	23.26 ±4.08	23.25 ±4.10	23.35 ± 4.00	0.824
Smoking Status Non-smoking Previous Current Missing	419 135 100 29	367 120 84 26	49 13 15 3	0.454
T stage T1-T2 T3-T4	359 316	309 286	50 30	0.075
N stage N0 N1-N2 N3, N3a, N3b	75 516 73	62 463 60	13 53 13	0.054
Stage at diagnosis Stage 1 Stage 2 Stage 3 Stage 4 Stage 4a Stage 4b	4 117 306 33 137 78	3 100 275 32 120 65	1 17 31 1 17 13	0.255

(CI95% 1,3-5,6) and median OS was 8,8 months (CI95% 3,8-13,9). 6-month and 9-month overall survival rates were 55% and 45% respectively. No immunorelated adverse events (irAE) grade 3-4 were reported. Most frequent grade 1-2 irAE observed were: asthenia (31,6% 12 pts) arthralgias (15,6%, 6 pts), thyroid disorders (10,5%, 4 pts) and skin rash (1pt).

Conclusions: To date, there are few data on the use of nivo in routine clinical practice in PR R/M HNSCC pts. In our population, more heavilyy pretreated than in ChekcMate141, RR and OS were maintained. These promising results encourage the use of nivo in this population, but further follow-up is still needed.

1076P Comparison of 3-weekly cisplatin versus 3-weekly carboplatin in patients with locally advanced nasopharyngeal carcinoma (LA-NPC) receiving concurrent chemoradiotherapy (CCRT): A multicenter retrospective study

A. Dechaphunkul[1], P. Danchaivijitr[2], R. Jiratrachu[3], T. Dechaphunkul[4], C. Sookthon[5], C. Jiarpinitnun[6], C. Paoin[2], J. Setakornnukul[7], S. Niyomnaitham[8], B. Suktitipat[9], P. Pattaranutaporn[6], N. Ngamphaiboon[10]

[1]Medicine, Division of Medical Oncology, Prince of Songkla University, Hat Yai, Thailand, [2]Medicine, Siriraj Hospital, Mahidol University, Bangkok, Thailand, [3]Radiology, Prince of Songkla University, Hat Yai, Thailand, [4]Otorhinolaryngology Head and Neck Surgery, Songkhlanagarind Hospital, Songkla, Thailand, [5]Medicine, Ramathibodi Hospital, Bangkok, Thailand, [6]Radiology, Ramathibodi Hospital, Bangkok, Thailand, [7]Radiology, Siriraj Hospital, Mahidol University, Bangkok, Thailand, [8]Pharmacology, Siriraj Hospital, Mahidol University, Bangkok, Thailand, [9]Biochemistry, Siriraj Hospital, Mahidol University, Bangkok, Thailand, [10]Medicine, Division of Medical Oncology, Ramathibodi Hospital, Bangkok, Thailand

Background: Although CCRT with high-dose cisplatin remains the standard protocol for patients with LA-NPC, carboplatin has been alternatively used especially for cisplatin-ineligible patients. However, the comparable efficacy of these 2 regimens is still unclear. This study aimed to compare the efficacy and tolerability of 3-weekly carboplatin with 3-weekly cisplatin.

Methods: From May 2005 to November 2014, we retrospectively reviewed medical information for 787 LA-NPC patients treated with CCRT from 3 university hospitals in Thailand. Chemotherapy regimen would be either cisplatin (75-100 mg/m^2) or carboplatin (AUC-5 or 6), followed by adjuvant chemotherapy (platinum plus 5-fluorouracil). Tolerability and survival were analyzed and compared.

Results: Patient demographics, baseline characteristics, and treatment for the patients was shown in the table. During CCRT, 52% of patients in the cisplatin arm completed the 3 planned cycles of treatment, compared to 88% in the carboplatin arm ($P < 0.0001$). Fifty-six percent of patients in the cisplatin, whereas only 5% in the carboplatin arm required dose reduction of chemotherapy due to toxicities ($P < 0.0001$). At the time of analysis, the 5-year disease-free survival was 60% (95% confidence interval [CI], 56 to 63) and 62% (95% CI, 50 to 72) ($P = 0.21$), and 5-year overall survival was 74% (95% CI, 70 to 77) and 67% (95% CI, 56 to 77) ($P = 0.19$), in the cisplatin and carboplatin groups, respectively.

Table: 1076P

Variables	Treatment group		P-value
	Cisplatin (n = 710)	Carboplatin (n = 77)	
Median age (years)	50	48	0.915
Sex [n (%)] Male	500 (70)	56 (73)	0.391
Smoking Yes [n (%)]	225 (32)	47 (61)	<0.0001
Comorbidity Yes [n (%)]	96 (14)	18 (23)	0.019
Stage I [n (%)] II [n (%)]	2 (0.3) 110 (15.6)	1 (1) 11 (15)	0.454
III [n (%)] IVa-IVb [n (%)]	289 (41)	28 (36) 37 (48)	
	308 (43)		
WHO classification I [n (%)]	5 (0.7) 206 (29)	0 (0) 39 (51)	0.401
II [n (%)] III [n (%)]	161 (22.7)	38 (49) 0 (0)	
Missing [n (%)]	338 (47.6)		
Median baseline Cr (mg%)	0.87	0.94	<0.0001

Conclusions: Carboplatin showed similar efficacy to that of cisplatin with better tolerability and could be used as an alternative regimen.

1077P Comparison of concurrent chemoradiation therapy plus induction chemotherapy with cisplatin, fluorouracil and docetaxel versus gemcitabine and cisplatin in advanced nasopharyngeal carcinoma

Z. Zeng[1], R. Yan[2], L. Tu[1], Y. Wang[2], P. Chen[3], F. Luo[4], L. Liu[5]

[1]Department of Medical Oncology, Cancer Center and State Key Laboratory of Biotherapy, and Lung Cancer Center, West China Hospital, Sichuan University, Chengdu, China, [2]Department of Medical Oncology, Cancer Center, West China Hospital, Sichuan University, Chengdu, China, [3]School of Public Health, Sichuan University, Chengdu, China, [4]Department of Medical Oncology, Cancer Center and Lung Cancer Center, West China Hospital, Sichuan University, Chengdu, China, [5]Department of Medical Oncology, Cancer Center, State Key Laboratory of Biotherapy, West China Hospital, Sichuan University, Chengdu, China

Background: Induction chemotherapy treatment for nasopharyngeal carcinoma (NPC) is controversial. The aim of this study was to evaluate the treatment outcomes and toxicities between two induction chemotherapy regimens, with both followed by concurrent chemoradiotherapy.

Methods: A retrospective study of 113 patients with eligible NPC (stage III–IV NPC with non-distant metastases) treated at the West China Hospital Cancer Center between May 2009 and Dec 2014 was conducted. Among them, 58 patients received cisplatin, fluorouracil, and docetaxel (TPF) and 55 received gemcitabine and cisplatin (GP) induction chemotherapy. Both groups received CCRT incorporating IMRT and cisplatin-based chemotherapy.

Results: The average follow-up time was 51.4 (16.8–98.3) months. Ninety-four patients (83.2%) were alive after 36-months follow-up. The median overall survival (OS) and progression-free survival (PFS) time were 48.3 and 39.7 months, respectively. The 3-year OS for the TPF regimen was 87.9% and 87.4% with GP chemotherapy($P = 0.928$). The 3-year PFS of the TPF treatment was 84.5%, while it was 83.5% for the GP group($P = 0.551$). OS (Log-Rank $P = 0.928$) and PFS (Log-Rank $P = 0.551$) did not differ significantly between the two groups. Patients in the TPF induction chemotherapy plus CCRT group, did not show better LRFS outcomes in comparison to those in the GP induction group (Log-Rank $P = 0.073$). Furthermore, DMFS rates were not different between the treatment groups (Log-Rank $P = 0.892$).

Conclusions: There were no significant differences in adverse toxicities or treatment efficacy between the chemotherapy regimens in the treatment of locoregionally advanced NPC. Furthermore, the adverse toxicities were similar and could be tolerated. However, the TPF group had a high proportion of grade 3 or 4 adverse reactions.

1078P Genomic profiling and matched therapy for recurrent or metastatic malignant salivary gland tumors

E.R. Malone[1], R. Jang[1], A. Spreafico[1], I. Weinreb[2], S. Jennings[1], L.L. Siu[1], A. Hansen[1]

[1]Medical Oncology, Princess Margaret Cancer Center, Toronto, ON, Canada, [2]Laboratory Medicine Program, University of Toronto, Toronto, ON, Canada

Background: MSGT are rare with limited systemic treatments. This ongoing trial is a single-institution, prospective study in advanced MSGT involving 2 phases: genomic profiling followed by treatment with either genomically-matched or unmatched therapy. The aim is to determine response rates as per RESIST v1.1 in patients (pts) with MSGT treated with matched or unmatched therapy.

Methods: Pts with recurrent/metastatic MSGT with archived paraffin-embedded tumor samples were enrolled in the profiling phase. Following pathology review and DNA extraction, targeted next generation sequencing was performed in a CLIA certified laboratory. Immunohistochemistry for androgen receptor (AR) and fluorescence in-situ hybridization for HER2 and ALK was done. Successfully profiled pts then proceeded to treatment phase when their disease was progressing to receive a matched therapy via early phase clinical trials or approved agents. If no actionable mutations were identified or no matched agents were available, pts could receive selinexor, an oral selective inhibitor of nuclear export (SINE) that inhibits XPO1 at a dose of 60mg twice weekly. Non-progressing pts remained on active surveillance.

Results: Since July 2014, 38 pts (19M/19F, median age 62 yrs [range 37-85]) have been enrolled in the profiling phase. Disease subtypes include adenoid cystic (n = 19), salivary duct (n = 8) and other (n = 11). Four pts failed screening due to lack of tissue, 4 tumor samples are currently being analysed. Of the 30 evaluable pts, 13 (43%) had at least one actionable mutation. Aberrations identified include PIK3CA (6), TP53 (5), AR (4), BRAF (2), HRAS (2), HER2 amplification (1), HER2 mutation (1), KIT (1), EGFR (1) and PTEN (1). Eight pts were treated with genomically matched therapy and 7 received selinexor. See table for outcomes.

Table: 1078P

	Matched Treatment	Selinexor
Median Duration of treatment	9 months (mo)	4mo
Median overall survival	19.2mo	21.3mo
Stable disease rate	88% (7/8)	86% (6/7)
Progressive disease rate	12% (1/8)	14% (1/7)

Conclusions: Genomic profiling may be integrated into clinical care for pts with MSGT permitting pts to receive targeted therapy. This is an ongoing study, we will present updated data at the conference.

Clinical trial identification: NCT02069730.

1079P Analysis of functional androgen receptor-pathway activity to predict response to androgen deprivation therapy in salivary duct carcinoma

W. van Boxtel[1], I. van Engen-van Grunsven[2], D. van Strijp[3], J.B.A. van Zon[3], M.J.L. Ligtenberg[4], G. Verhaegh[5], J. Schalken[5], S. Neerken[6], A. van de Stolpe[3], C.M.L. van Herpen[1]

[1]Medical Oncology, Radboud University Medical Center, Nijmegen, Netherlands, [2]Pathology, Radboud University Medical Center, Nijmegen, Netherlands, [3]Philips Research, Philips, Eindhoven, Netherlands, [4]Oncogenetics, Radboud University Medical Center, Nijmegen, Netherlands, [5]Urology, Radboud University Medical Center, Nijmegen, Netherlands, [6]Molecular Pathway Dx, Philips Healthcare, Eindhoven, Netherlands

Background: Treatment response to androgen deprivation therapy (ADT) in androgen receptor (AR)-positive salivary duct carcinoma (SDC) is 18-50%. The cause of ADT-resistance is unknown. We aim to predict treatment response through analysis of functional AR-pathway activity.

Methods: Patients who received palliative ADT (n = 28) for locally recurrent or metastatic SDC were selected. ADT consisted of bicalutamide or combined androgen blockade. AR-pathway analysis was performed in all patients. For this, RNA was extracted from annotated, formalin-fixed paraffin embedded sections from tumor tissue prior to treatment. For quantitative measurement of functional AR pathway activity, mRNA expression of the AR pathway target genes was measured using one-step RT-qPCR, and a pathway activity score between 0 and 100 was provided (Verhaegh et al, Cancer Res. 2014). Patients were analyzed for treatment response, progression free survival (PFS) and overall survival (OS).

Results: AR pathway activity score was divided in tertiles. Patients with highest AR activity had the longest progression free survival (PFS) and overall survival (OS) upon ADT treatment. Partial responders (PR) were only observed in the group with the highest AR activity (n = 3, p = 0.0267, two-sided Fisher exact), while highest incidence of progressive disease (PD) was found in the lowest AR activity group.

Table: 1079P

	AR-pathway activity (range)	Response (number of patients)			Median PFS (months)	Median OS (months)
Tertile 1	33.10-43.55	0 PR	1 SD	9 PD	2	12
Tertile 2	43.71-50.35	0 PR	2 SD	7 PD	2	13
Tertile 3	51.91-65.58	3 PR	4 SD	2 PD	5	33

Conclusions: Functional AR pathway activity measured by this new method was predictive for clinical response to ADT in this small retrospective SDC cohort. Extended validation of clinical utility in a larger patient cohort is in preparation.

1080P Prognostics factors in adenoid cystic carcinoma of the head and neck (ACCHN): Retrospective study of 15 years

P. Neji[1], R.S. Conde[1], S. Esteves[2], M.T.A. Alexandre[1], M. Ferreira[1], E. Netto[3], J. Santos[4], M. Magalhães[5], A. Moreira[1]

[1]Medical Oncology, Instituto Português de Oncologia de Lisboa Francisco Gentil, E.P.E, Lisbon, Portugal, [2]Biostatistics, Instituto Português de Oncologia de Lisboa Francisco Gentil, E.P.E, Lisbon, Portugal, [3]Radiotherapy, Instituto Português de Oncologia de Lisboa Francisco Gentil, E.P.E, Lisbon, Portugal, [4]Head and Neck Surgery, Instituto Português de Oncologia de Lisboa Francisco Gentil, E.P.E, Lisbon, Portugal, [5]Otorhinolaryngology, Instituto Português de Oncologia de Lisboa Francisco Gentil, E.P.E, Lisbon, Portugal

Background: ACCHN is a rare entity mainly found in the major and minor salivary glands. Localized disease is frequent and very late recurrences are common. The treatment of choice is surgery, when feasible, followed by radiotherapy (RT). RT alone is used in unresectable [RC1] patients (pts).

Methods: Retrospective analyses of consecutive pts with ACCHN from Jan 2000 to Dec 2015 at Instituto Português de Oncologia de Lisboa was done [RC1]. Aims: to characterize clinical, demographic and treatment data, the related prognostic factors and evaluate the 5-years overall survival (OS) and the disease-free survival (DFS) for non-metastatic pts, and the 5-years OS for the entire cohort.

Results: Of the 112 pts with ACCHN, 100 had localized and 12 metastatic disease. The median age at diagnosis was 62 years (range 18-91). Of the 100 pts with localized disease, the most frequent location was in major salivary glands (40%) followed by minor salivary glands in oral cavity (28%). At presentation, T3/T4 tumors was found in 35% of pts and positive lymph nodes in 5%. Curative surgery was performed in 91% of pts and adjuvant RT in 86%. Positive surgical margins were R1 in 52% of pts and R2 in 15%. Perineural invasion was present in 68%. Of the 100 pts, 32 recurred, 16 locally and 13 of these had a second [RC1] surgery. Palliative cisplatin-based chemotherapy was used 12%. With a median follow-up of 6 years, the disease-free survival at 5 years was 63% (CI 95%, 53-75). The median time to recurrence in relapse pts was 24 months. Positive surgical margin (R1/R2) (p = 0.0045) and T3/T4 tumors (p = 0.000165) significantly reduced DFS and OS. Perineural invasion, positive lymph nodes and radiotherapy treatment did not impact on local control. The 5-years OS for the localized ACCHN was 71% (CI 95%, 62-82) and 68% (CI 95%, 59-78) for the global cohort.

Conclusions: Tumor size and surgical margins were found to be prognostic factors for local control and for survival. The low percentage of positive lymph nodes probably prevents its prognostic value. Our survival data was similar to those found in the literature.

1081P Molecular analysis of NRAS, BRAF, C-KIT, ROS1, ALK and RET alterations in serial biopsies in sinonasal mucosal melanoma

G. Anguera Palacios[1], L.P. del Carpio[1], M-A. Molina[2], C. Aguado[2], J.R. Gras-Cabrerizo[3], X. Leon[3], M. Gonzalez-Cao[4], N. Karachaliou[5], A. Mozos[6], A. Gonzalez[6], A. Barnadas[1], R. Rosell[4], M. Majem[1]

[1]Oncology Department, Hospital de la Santa Creu i Sant Pau and Universitat Autònoma de Barcelona, Barcelona, Spain, [2]Quirón Dexeus University Hospital, Pangaea Biotech S.L, Barcelona, Spain, [3]Otolaryngology/Head and Neck Surgery, Hospital de la Santa Creu i Sant Pau and Universitat Autònoma de Barcelona, Barcelona, Spain, [4]Instituto Oncológico Dr. Rosell, Hospital Universitario Quirón Dexeus, Barcelona, Spain, [5]University Hospital Sagrat Cor, Institute of Oncology Rosell, Barcelona, Spain, [6]Department of Pathology, Hospital de la Santa Creu i Sant Pau and Universitat Autònoma de Barcelona, Barcelona, Spain

Background: Sinonasal mucosal melanoma (SNMM) is a rare entity with no specific treatment. Little is known about SNMM molecular profile, a low rate of genetic alterations has been describe compared to cutaneous melanoma. We aimed to screen for several genetic alterations in SNMM.

Methods: From 1988 to 2017, we collected 20 formalin-fixed paraffin primary tumors blocks from SNMM patients and 12 local recurrences and/or distant metastasis from the same patients. We analyzed the spectrum of mutations in KIT gene (exon 9, 11 13 and 17) by standard PCR followed by Sanger sequencing, NRAS gene (exon 2, 3 and 4) by pyrosequencing and BRAF gene (exon 15) by Taqman PCR. Finally, RET, ALK and ROS1 fusions and gene expression levels were determined by nCounter.

Results: We identified gene mutations in 6/20 cases (30%). We found 2 cases (10%) with mutations in NRAS gene (both in exon 2: G12V), 3 cases (15%) with mutations in KIT (all in the exon 11: R586K, G565R, M552I) and 1 case (5%) with KRAS mutation (G12A). No BRAF mutations were detected. Interestingly, we found discrepancies in the NRAS mutational status of tumor samples obtained from 2 patients. In the first case, at diagnosis, we identified the NRAS mutation in 1 of 2 samples, and in 2 of 3 samples at the time of local recurrence. In the second case, the NRAS mutation was present at diagnosis but only in 2 of 4 samples of distant recurrence. Finally, nCounter did not reveal RET, ALK no ROS1 gene fusions or mRNA overexpression in any sample.

Conclusions: In our series of SNMM, we have found mutations in 6/20 tumors (30%) in KIT, NRAS and KRAS genes. No fusions or overexpression were found for ALK, ROS1 or RET genes. To our knowledge, this is the first reported study on these genes. We plan to further characterize this orphan population by analyzing immune-related genes.

1082P Programmed death-ligand 1 (PD-L1) expression and HPV-associated p16 in oropharyngeal squamous cell carcinoma (OSCC) treated with primary curative radiotherapy (RT)

T. Steiniche[1], J.G. Eriksen[2], J.K. Lilja-Fischer[2], J. Georgsen[1], P-T. Vo[3], M. Busch-Sørensen[4], D.R. Chirovsky[5], J. Cheng[6], D. Aurora-Garg[7], R. Swaby[8], J. Overgaard[2]

[1]Pathology, Aarhus University Hospital, Aarhus, Denmark, [2]Department of Experimental Clinical Oncology, Aarhus University Hospital, Aarhus, Denmark, [3]Pharmacoepidemiology, MSD - Merck & Co USA, Kenilworth, NJ, USA, [4]Busch-Sørensen Consulting ApS, Virum, Denmark, [5]Outcomes Research, MSD - Merck & Co USA, Kenilworth, NJ, USA, [6]Medical Oncology, Merck & Co Inc, North Wales, PA, USA, [7]Translational Biomarkers, Merck & Co, Inc, Kenilworth, NJ, USA, [8]Medical Oncology, Merck & Co, Inc, Kenilworth, NJ, USA

Background: PD-L1 expression in malignancies contributes to an immunosuppressive microenvironment and disruption of anti-tumoral immune responses. Data are limited on the association between PD-L1 expression and survival in OSCC, overall and by HPV p16 status. We explored the prognostic effect of PD-L1 and p16 in localized or locally advanced OSCC treated with primary RT.

Methods: Patients (pts) diagnosed with OSCC from 2000-12 were identified from the Danish Head and Neck Cancer database (DAHANCA). PD-L1 expression was measured in tumor tissue using Agilent's investigational PD-L1 imunohistochemistry (IHC) PharmDx Assay (clone 22C3). PDL1+ expression was defined as a score >1 using Tumor Proportion Score (TPS) as % of neoplastic cells expressing PDL1 at any intensity, Mononuclear Inflammatory Density Score (MIDS) as the estimate of PDL1 expressing mononuclear inflammatory cells associated with neoplastic cells, and Combined Positive Score (CPS) calculated using both TPS and MIDS. HPV oncogene expression was assessed using a > 70% cut-point for p16 IHC (clone E6H4). Data were analyzed using Cox proportional hazard model.

Results: 303 OSCC pts with full clinical data, and PD-L1 and p16 staining were evaluated. Median follow up was 55 months (2-184). Median age (range) was 59 years (34-85), 72% were male, 91% had WHO 0-1 performance status, 55% were current smokers. All had primary RT, 66-68Gy, 2Gy/fx, 6 fx/wk, and 3% had concomitant cisplatin. 81% were UICC 7 stage 3-4 tumors. 55% were p16+. 76% were PD-L1+ by CPS, 35% by TPS, and 31% by MIDS. TPS was significantly associated with MIDS (Chi square p = 0.003). p16 was a strong prognostic factor for loco-regional control [crude hazard ratio (HR) of 0.31 (95% CI: 0.21-0.49)], disease-specific survival [0.39 (0.26-0.57)] and overall survival [0.34 (0.25-0.46)]. PD-L1 expressed as CPS, TPS or MIDS, was not prognostic of the clinical endpoints, overall or by p16 status. Adjustment for other covariates did not change the results.

Conclusions: PD-L1 expression is not prognostic in localized or locally advanced OSCC, including p16 positive disease. p16 is affirmed the strongest biological prognostic factor in OSCC.

1083P Dynamics of immune checkpoint molecule (ICM) expression in immune cell subsets during curative conventional therapy of head and neck squamous cell carcinoma (HNSCC)

A. Grages[1], S.S. Jeske[1], L.K. Puntigam[1], C. Brunner[1], J. Kraus[2], H. Kestler[2], J. Döscher[1], T.K. Hoffmann[1], P.J. Schuler[1], S. Laban[1]

[1]Department of Otorhinolaryngology and Head & Neck Surgery, University Medical Center Ulm, Ulm, Germany, [2]Institute for Medical Systems Biology, Ulm University, Ulm, Germany

Background: Immune checkpoint modulation is a promising treatment strategy in HNSCC. PD-1 inhibition is currently studied in combination with conventional oncologic treatments. However, the impact of curative conventional treatment (surgery, (chemo-)radiotherapy (CRT)) on the expression of targetable ICM has not been studied previously.

Methods: In a prospective non-interventional immune monitoring trial (Immune Response Evaluation to curative Conventional Therapy; IRECT; NCT03053661) peripheral blood mononuclear cells (PBMC) from 22 patients with HNSCC were collected at 8 pre-specified time points during curative conventional treatment (baseline, post-surgery, mid-CRT, end of CRT, 3-, 6-, 9-, 12-months post end of treatment (EOT)). PBMC were analyzed by flow cytometry. Nine ICM (PD1, CTLA4, BTLA, CD137, CD27, GITR, OX40, LAG3, TIM3) were determined in different immune cell subsets (CD8, CD4, CD19, CD39 Treg) over the course of treatment.

Results: Paired samples tests revealed significant changes compared to pre-treatment samples. Compared to baseline, surgery had no significant impact on ICM expression. Median CD8/PD1 were significantly lower at 3 and 6 months post EOT, CD4/PD1, CD19/PD1 and Treg/PD1 were significantly higher at the end of CRT, whereas Treg/PD1 were significantly lower at 3 and 6 months post EOT. CD8/BTLA were significantly decreased from mid-CRT until 12 months post EOT, whereas CD4/BTLA and Treg/ BTLA were significantly decreased from 3 to12 months post EOT. CD4/CD27 were significantly lower from mid-CRT until 12 months post EOT, whereas CD19/CD27 and Treg/CD27 were significantly decreased from 3 to 12 months post EOT. CD4/OX40 and Treg/OX40 increased mid-CRT until 3 months post EOT, but significance was not confirmed after correcting for multiple testing.

Conclusions: Whereas surgery alone seems not to alter ICM expression, CRT has a significant impact on the expression of PD1, BTLA and CD27. OX40 seems to increase during CRT. These results reveal a rational for the combination of PD1 inhibitors with CRT. Combining such a treatment with OX40 inhibitors may be a promising strategy.

Clinical trial identification: NCT03053661.

1084P Multiobjective optimization reveals distinct cancer-testis antigen patterns by primary site and human papilloma virus status in head and neck squamous cell carcinoma

S. Laban[1], G. Völkel[2], J. Ezic[1], T.K. Hoffmann[1], H-G. Rammensee[3], J. Döscher[1], P.J. Schuler[1], C. Brunner[1], J. Kraus[2], H. Kestler[2]

[1]Department of Otorhinolaryngology and Head & Neck Surgery, University Medical Center Ulm, Ulm, Germany, [2]Institute for Medical Systems Biology, Ulm University, Ulm, Germany, [3]Department of Immunology, University of Tübingen, Tübingen, Germany

Background: Most previous vaccination attempts in cancer immunotherapy have been focused on a single antigen. Consequently, the expression of the selected antigen needs to be determined before trial inclusion resulting in a high screening failure rate. The establishment of a multi-antigen vaccine may improve the coverage of potential patients, especially if the selected antigens are semipersonalized for clinical patient subgroups.

Methods: Analysis and Visualization of Alteration Data (AVATAR), a novel bioinformatic software tool for multi-objective optimization of large datasets, was used to analyze publicly available datasets of transcriptome data from The Cancer Genome Atlas (TCGA) and a dataset from Gene Expression Omnibus (GSE 40774). Cancer-testis antigens (CTA) were selected as model antigens for multi-objective optimization based on the primary tumor site and HPV-status. Dichotomized data were pooled and edited resulting in a cohort of 865 patients, of which 125 were HPV-positive (HPV+). Primary tumor sites included were oral cavity (n = 208), oropharynx (n = 150) and larynx (n = 208).

Results: Selecting 10 CTA genes for the whole cohort results in a coverage of 89.3%. When optimizing gene selections for each primary tumor site, distinct 10-gene-selections are revealed improving the coverage in the respective group markedly. Antigen selections overlap only to a minor degree with the solutions for all patients or other patient groups. Even in predominantly HPV- primary sites such as OC and L, antigen selections are remarkably different from each other. When optimizing for HPV-status, distinct selections were found for optimal coverage in the respective patient group overlapping only in one gene.

Conclusions: AVATAR can be used to identify antigen selections with optimal coverage within a specified patient group. A semi-personalized antigen selection based on multi-objective optimization may be a useful strategy to plan trials for antigen-specific vaccination.

Background: HPV-related oropharyngeal cancer (OPC) patients have favorable prognosis, but around 20% fail to treatment. The HPV16-E5 oncoprotein increases recycling of activated epidermal growth factor receptor (EGFR) to the cell surface, enhancing factor signal transduction. Our aim was to evaluate viral HPV16-E5 oncogene expression as well as EGFR and its activated form, phosphorylated EGFR (pEGFR), protein levels as biomarkers for clinical outcome in a retrospective cohort of OPC patients.

Methods: Formalin-fixed-paraffin-embedded OPC were collected from pathology archives. Samples containing HPV-DNA were further subject to HPV E6*I mRNA detection and $p16^{INK4a}$ immunohistochemistry (IHC). HPV16-positive cases were evaluated for HPV16-E5 (RT-PCR) and EGFR/pEGFR (IHC). A stratified random sample of HPV-negative samples was evaluated for EGFR/pEGFR. Overall survival (OS) and disease-free survival (DFS) estimates were assessed.

Results: Among the 788 OPC patient samples from a retrospective cohort, 54 where double positive for HPV16-DNA and $p16^{INK4a}$. HPV16-E5 expression was found in 41 samples (77.4%). Expression of EGFR was observed in 37.7% vs 70.8% HPV16-positive and HPV-negative samples, respectively; (adjusted Odds Ratio (OR) 0.15[95%Confident Interval (CI):0.04-0.56]). Expression of pEGFR followed an inverse pattern with 39.6% and 24.9% detection in HPV16-positive and HPV-negative samples, respectively; (adjusted OR 1.58[0.48-5.17]). Within HPV16-positive cases, no association between HPV16-E5 and EGFR or pEGFR was observed. The combination of HPV status and EGFR or pEGFR expression were predictors of OS and DFS.

Conclusions: HPV16-E5 is highly expressed on HPV16-positive OPCs. Interestingly, HPV16-positive cases expressed more pEGFR while HPV-negative cases expressed significantly more EGFR. The combinations of HPV status and EGFR or pEGFR expression are useful biomarkers for prognosis outcome in OPC patients.

1086P Combined analysis of gene expression profiles in 2 preoperative trials with afatinib and cetuximab in head and neck squamous cell carcinoma

P. Bossi[1], S. Schmitz[2], J-P. Machiels[3], L.F. Licitra[1], C. Fortpied Lefevre[4], C. Caballero[5], S. Canevari[6], L. De Cecco[6]

[1]Head and Neck Medical Oncology Unit, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [2]Department of Head and Neck Surgery, Cliniques Universitaires St. Luc, Brussels, Belgium, [3]Oncology, Cliniques Universitaires St. Luc, Brussels, Belgium, [4]Statistical, EORTC, Brussels, Belgium, [5]Head and Neck Group, EORTC, Brussels, Belgium, [6]Functional Genomics and Bioinformatics, Department of Applied Research and Technology Development, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy

Background: Only a minority of head and neck squamous cell carcinoma (HNSCC) patients (pts) respond to targeted agents acting on epidermal growth factor pathway. We investigated the changes of gene expression profiles in 2 preoperative window of opportunity trials, to allow a further investigation in mechanisms of response.

Methods: Thirty and 20 pts with similar characteristics were treated for 2 weeks before surgery with afatinib (EORTC 90111-24111 NOCI HNCG trial, Ann Oncology 2017) and cetuximab (Schmitz S, Ann Oncology 2013), respectively. The gene expression profile obtained by microarray platform was compared by a paired analysis pre and post treatment. Gene sets were defined according to GSEA and only sets with q-value FDR < 0.05 differences were considered. Clinical response was analysed according to primary endpoint of the trials (FDG-PET response).

Results: Pre- and post-targeted treatment paired histological samples from 20 and 15 pts were evaluable for gene expression, from afatinib and cetuximab series, respectively. The following gene sets were commonly downregulated by the treatment: G2M checkpoint, MYC and E2F targets and MTORC. On the opposite, the gene sets which resulted upregulated were: angiogenesis, epithelial-mesenchymal transition, inflammatory response and NOTCH signalling. A substantial overlapping of molecular alteration between the 2 series has been observed, thus allowing a further meta-analysis combining the 2 datasets to analyse profiles associated to response. Preliminary data in afatinib series showed a strong downregulation of hypoxia gene signature only in responding pts.

Conclusions: In 2 independent studies with afatinib and cetuximab in window of opportunity setting, we observed similar molecular alterations induced by the drugs. Further insights in the pathways involved in response to both drugs are ongoing.

1087P Association of LIPI score with immune checkpoint inhibitors (ICI) outcomes in recurrent or metastatic squamous cell carcinoma of the head and neck (R/M SCCHN) patients (pts)

R.G. Herrera Gomez[1], L. Mezquita[2], E. Auclin[3], K. Saleh[2], N. Baste Rotllan[1], M. Iacobs[1], S.C. Bursuc[1], L. Mayache Badis[1], F.R. Ferrand[4], O. Casiraghi[5], S. Temam[1], I. Breuskin[1], Y. Tao[6], B. Besse[7], C. Even[1]

[1]Department of Head and Neck Surgical & Medical Oncology, Gustave Roussy Institute, Villejuif, France, [2]Department of Medical Oncology, Gustave Roussy Institute, Villejuif, France, [3]Medical Oncology, European Hospital Georges Pompidou, Paris, France, [4]Medical Oncology, Bégin Military Teaching Hospital, Saint-Mandé, France, [5]Department of Biopathology, Gustave Roussy Institute, Villejuif, France, [6]Department of Radiation-Oncology, Gustave Roussy Institute, Villejuif, France, [7]Department of Medical Oncology, Gustave Roussy Institute, Villejuif, France

Background: Lung Immune Prognosis Index (LIPI), based on pretreatment dNLR (neutrophils/(leucocytes-neutrophils)) and LDH, correlated with outcome after immune checkpoint inhibitors (ICI) in advanced NSCLC pts. We tested if LIPI, could have the same role in R/M SCCHN pts.

Methods: We conducted a retrospective study of 86 R/M HNSCC pts treated with ICI in our institution between Sep 2014 and Dec 2017. Complete blood cell counts and LDH were collected before ICI treatment. LIPI characterized 3 groups: good risk if dNLR < 3 and normal LDH, intermediate if dNLR > 3 or LDH $>$ upper limit of normal (ULN), and poor if dNLR >3 and LDH $>$ULN. ICI benefit was analyzed according to overall survival (OS) and progression free survival (PFS).

Results: In our cohort, 65 pts (76%) were males, 61 (71%) current/former smokers, 81 (94%) had PS ≤ 1, with median age 59 years. According to the location: 19 (22%) had oral cavity carcinoma, 43 (50%) oropharynx, 11 (13%) hypopharynx and 13 (15%) larynx. HPV by immunohistochemistry was positive in 11/52 pts (10 oropharynx, 1 oral cavity). Twenty-eight (33%) pts received PD1, PDL1, or CTLA-4 inhibitors in monotherapy, and 58 (67%) in combination. The median of prior lines was 1 (0-6). The median follow-up was 8 months (m) [95% CI:7-12], median PFS 3 m [95% CI:2-4] and median OS 12 m [95% CI 8-NA]. The dNLR >3 (36%) and LDH $>$ULN (10%) were associated with poor OS ($P = 0.005$). Based on them, LIPI considered: 44 pts (51%) as good, 38 (44%) intermediate and 4 (5%) poor prognosis group. LIPI was an independent factor for OS (hazard ratio [HR 2.49, 95% CI 1.2-5.2] for intermediate LIPI and [HR 7.97, 95%CI 1.9-32.6] for poor LIPI, $P = 0.005$) and PFS ($P = 0.004$). Median OS for poor, intermediate, and good LIPI was 3.5 m [95% CI, 2- not reached (NR)], 7 m (95% CI, 5-NR), and 12 m (95% CI, 8-NR), respectively ($P = 0.003$).

Conclusions: High LIPI was correlated with worse ICI outcomes in R/M SCCHN pts. Further studies are warranted to confirm the prognostic impact of this score and the potential predictive role for ICI.

1088P Analysis of immune and genomic landscapes of patients with recurrent/metastatic head and neck squamous cell carcinoma (R/M HNSCC) treated with pembrolizumab in the INSPIRE study

M. Oliva Bernal[1], S. Lien[2], B.X. Wang[2], S.C. Yang[3], A. Spreafico[1], R. Jang[1], S. Elston[1], S. Jennings[1], H. Jiang[4], B. Haibe-Kains[5], T. Pugh[3], P. Ohashi[2], L.L. Siu[1], A. Hansen[1]

[1]Medical Oncology, Princess Margaret Hospital, Toronto, ON, Canada, [2]Department of Immunology, Princess Margaret Cancer Centre, University of Toronto, Toronto, ON, Canada, [3]Medical Biophysics, Princess Margaret Cancer Centre, University of Toronto, Toronto, ON, Canada, [4]Biostatistics, Princess Margaret Cancer Centre, University of Toronto, Toronto, ON, Canada, [5]Department of Computer Sciences, Princess Margaret Cancer Centre, University of Toronto, Toronto, ON, Canada

Background: Despite the survival gain observed with antiPD-1 agents in R/M HNSCC, responses are modest and no predictive biomarkers have been validated. We investigated immune and genomic biomarkers of response in a prospective cohort of R/M HNSCC patients (pts) treated with pembrolizumab 200 mg IV Q3W in the INSPIRE study.

Methods: Pts had blood samples (BS) collected at baseline (BL) and on treatment (OT) at cycle 3 (week 9); fresh tumor biopsies (FTB) collected at BL and OT (week 6-9). Analyses included tumor whole exome sequencing and immunophenotyping by flow cytometry of FTB and BS; tumor PD-L1 staining (clone 22C3) using modified proportion score. Response rate (RR) using RECIST 1.1. Median progression-free survival (PFS) and overall survival (OS) estimated by Kaplan-Meier method. Time to progression (TTP) was estimated using cumulative incidence function. Univariable analyses of genomic and immune parameters were conducted to identify response predictors.

Results: Seventeen pts were enrolled: median age 62 years (48-71); smoking history > =10 pack-year (PY)= 11; oral cavity=7, oropharynx=6 (5 HPV+), larynx/hypopharynx=4. Platinum-refractory= 15; > = 2 prior lines of therapy= 4; PD-L1 > = 1%= 9. RR = 3 partial responses (PR), 10 stable disease (SD), 4 progressive disease (PD). Median follow-up was 4.9 months (m)(0.6-19.3); TTP 9.7m (3.5-not-reached (NR)), PFS 4m (2.3-9.5); OS 7.9m (3.4-NR). Pts with PR had >10 PY, PD-L1 >50% and no local recurrence. Pts with PR+SD had less proliferating ki67+, FoxP3+ T-regulatory cells (Tregs) in blood compared to PD pts (p0.05). Seven pts had FTB for analysis (1 PR, 3 SD, 3 PD): patient with PR (HPV+ oropharynx) had less immunosuppressive Tregs via lower expression of CTLA-4 and CD39 in BL tumor and increased proliferating Tregs at paired OT FTB. Tumor somatic coding mutation burden and percent genome copy alteration in FTB at BL (N = 9) did not predict response (PR+SD) but a trend was observed with percent loss of heterozygosity (p0.15).

Conclusions: This preliminary data suggest peripheral and tumor T-regs might play a critical role in R/M HNSCC pts treated with anti-PD1 agents. Dynamic immune-cell changes were more informative than BL genomic markers.

Clinical trial identification: NCT02644369.

1089P C1GALT1 predicts poor prognosis and is a potential therapeutic target in head and neck cancer

M-C. Lin[1], P-H. Chien[1], H-Y. Wu[2], S-T. Chen[3], H-F. Juan[4], N-Y. Lin[3], P-J. Lou[1], M-C. Huang[3]

[1]Otolaryngology, National Taiwan University Hospital, Taipei, Taiwan, [2]Instrumentation Center, National Taiwan University, Taipei, Taiwan, [3]Graduate Institute of Anatomy and Cell Biology, National Taiwan University, Taipei, Taiwan, [4]Department of Life Science, Graduate Institute of Biomedical Electronics and Bioinformatics, National Taiwan University, Taipei, Taiwan

Background: Head and neck squamous carcinoma (HNSCC) accounts for more than 600,000 cases annually worldwide. Glycosylation is the most common post-translational modification of proteins, and aberrant glycosylation is a hallmark of cancers. Core 1 β1,3-galactosyltransferase (C1GALT1) controls the crucial step in O-glycosylation and promotes malignant behavior in various cancers. However, its role in HNSCC remains unclear.

Methods: Immunohistochemistry was performed to analyze expression of C1GALT1 in 153 HNSCC tumors. Student t-test, Kaplan-Meier analysis, and Cox-regression analyses were used to analyze correlation of C1GALT1 expression with clinicopathological factors and survivals. CRISPR/Cas9 system was used to knock out C1GALT1. MTT assay, transwell migration, and Matrigel invasion assays were carried out to evaluate HNSCC cell viability, migration, and invasion, respectively. Human phospho-RTK array and Western blot analyses were performed to evaluate signaling pathways. ELISA was used to evaluate EGF-EGFR binding affinity. Mass spectrometry was used to identify O-glycopeptides on EGFR. Molecular docking simulation was used for searching C1GALT1 inhibitors. In vivo effects of C1GALT1 and its inhibitor were evaluated in NOD/SCID mice.

Results: C1GALT1 was overexpressed in HNSCC tumors and predicts poor survivals. C1GALT1 overexpression enhanced whereas C1GALT1 knockdown/knockout suppressed cell viability, migration, and invasion in HNSCC cells. Mechanistically, C1GALT1 modulated O-glycosylation of EGFR and enhanced EGF-EGFR binding affinity, leading to increased EGFR signaling and malignant phenotypes. Using mass spectrometry, we identified five O-glycopeptides on EGFR, among which four are within the ligand binding domain. Itraconazole, a C1GALT1 inhibitor, directly bound to C1GALT1 and changed O-glycans on cell surfaces and EGFR. Targeting C1GALT1 with CRISPR/Cas9, shRNA, or itraconazole was able to significantly suppress tumor growth in NOD/SCID mice.

Conclusions: Our findings indicate C1GALT1 as an attractive therapeutic target for HNSCC.

1090P Frequency of PIK3CA mutations in head and neck squamous cell carcinoma (HNSCC) in southern Thailand

P. Thongwatchara[1], P. Thongsuksai[2], T. Dechaphunkul[3], A. Dechaphunkul[1]

[1]Unit of Medical Oncology, Department of Internal Medicine, Faculty of Medicine, Prince of Songkla University, Songkhla, Thailand, [2]Department of Pathology, Faculty of Medicine, Prince of Songkla University, Songkhla, Thailand, [3]Otorhinolaryngology Head and Neck Surgery, Songklanagarind Hospital, Songkhla, Thailand

Background: Phosphatidylinositol-4, 5-bisphosphate 3-kinase catalytic subunit alpha (PIK3CA) mutations have been reported in many cancers including HNSCC. The presence of mutations have shown to associate with prognosis and might predict response to phosphoinositide 3-kinase (PI3K) inhibitors. However, the frequency of mutations is various among primary tumor locations, so this might be relevant to distinguish the possibility of treatments and outcomes among HNSCC. In this study, we examined the frequency of PIK3CA mutations in patients with oral cavity and hypopharyngeal carcinoma.

Methods: Ninety-six fresh biopsies consisted of 73 oral cavity and 23 pyriform sinus carcinoma were collected for DNA extraction. DNA samples were first investigated to ascertain a reference mutational points in PIK3CA exons 4, 9 and 20. We subsequently designed two probes labelled with two different fluorescent dyes for the wild-type and mutated alleles. Mutational analysis was further carried out by using allele-specific real time PCR.

Results: We identified mutations in 10% of patients (10 out of 96 HNSCC specimens). Among 10 mutant specimens, there were 5 missense mutations (2 samples in exon 9 (E545K) and 3 samples in exon 20 (H1047R)), and 5 silence mutation in exon 20 (T1025T). None of mutation was found in exon 4. Exon 9 mutation was detected in 2 out of 96 cases and was merely from hypopharyngeal carcinoma. In exon 20, 8 mutations were found (2 hypopharyngeal carcinoma and 6 oral cavity carcinoma). Overall frequency of mutations in three exons were 8% and 17% in oral cavity and hypopharyngeal carcinoma, respectively.

Table: 1090P Frequency of PIK3CA mutations in HNSCC

Location of HNSCC	% PIK3CA mutation			Overall % PIK3CA mutation
	Exon 4	Exon 9	Exon 20	in three exons
Oral cavity carcinoma	0 (0/61)	0 (0/73)	8 (6/73)	8 (6/73)
Hypopharyngeal carcinoma	0 (0/21)	8 (2/23)	8 (2/23)	17 (4/23)
Frequency of mutation				10 (10/96)

Conclusions: Our study showed more frequency of PIK3CA mutations in hypopharyngeal carcinoma than oral cavity carcinoma. These results suggest that its mutation may be more involved in the carcinogenesis, and hypopharynx should be primary site of interest for further studies.

1091P Comparison between the 7th and the proposed 8th editions of the UICC staging system for nasopharyngeal carcinoma patients without cervical lymph node metastasis: A retrospective analysis

C. Hu

Department of Radiation Oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: To evaluate the prognostic value of the proposed 8th Edition of the American Joint Committee on Cancer (AJCC)/Union for International Cancer Control (UICC) staging system for nasopharyngeal carcinoma (NPC) patients without cervical lymph node metastasis in comparison with the AJCC/ UICC 7th edition.

Methods: This is a retrospective study of 382 newly diagnosed non-metastatic NPC patients without cervical Lymph node metastasis who were treated with intensity-modulated radiotherapy (IMRT). All received elective neck irradiation to levels II, III, VA. Univariate and multivariate analyses were applied to evaluate the prognostic values between adjacent stage categories of the AJCC/ UICC 7th edition and the proposed 8th edition, including overall survival (OS), local relapse-free survival (LRFS), regional relapse-free survival (RRFS), distant metastasis-free survival (DMFS), and disease–free survival (DFS). The Akaike information criterion (AIC) and Harrell's concordance index (c-index) were applied to compare the two prognostic systems with different numbers of stages.

Results: The median follow-up time was 61.1 months, with a range from 1 months to 91 months. The 5-year OS, LRFS, RFFS, DMFS and DFS were 86.9%, 96.7%, 99.1%, 93.3% and 82.6%, respectively. For LRFS and DMFS, the proposed eighth editions had superior prognostic value to the AJCC/ UICC 7th edition ($P = 0.032$ vs. $P = 0.086$ and $P = 0.013$ vs. $P = 0.112$). The 5-year OS and DFS were found to be significant both by the seventh and the proposed 8th editions. The difference between T1 and T3, T1 and T4, T2 and T3 and T2 and T4 by the proposed eighth edition were found to be significant ($P = 0.042$, $P = 0.041$, $P = 0.000$, and $P = 0.000$), however, there was no significant difference between T1 and T3, T2 and T3 by the seventh edition ($P = 0.204$, and $P = 0.215$). In addition, the difference between T1, T2, T3 with T4 were found to be significant in DFS ($P = 0.000$, $P = 0.000$, $P = 0.037$) and there was no significant difference between T1 and T3 ($P = 0.162$) by the seventh edition and there was significantly different between T2 and T4 ($P = 0.026$) by the proposed 8th editions. Multivariate analysis demonstrated that age, T stage of the proposed 8th editions and chemotherapy were independent prognostic factors for OS, LRFS, DMFS and DFS. The AIC value was smaller for the 8th edition compared to the 7th edition staging system. The C-index value was larger for the 8th edition compared to the 7th edition staging system.

Conclusions: IMRT with elective neck irradiation provides excellent local-regional control for NPC patients without cervical lymph node metastasis. The proposed eighth editions had superior prognostic value to the AJCC/ UICC 7th edition for LRFS and DMFS and lead a better distinction between adjacent T stages of nasopharyngeal carcinoma patients for OS and DFS. Overall, the proposed 8th UICC T classification seems to be superior to the 7th UICC T classification for nasopharyngeal carcinoma patients without cervical lymph node metastasis.

1092P Validation of the clinical AJCC/UICC TNM 8th edition for human papillomvirus related oropharyngeal squamous cell carcinoma

S. Deschuymer[1], R. Dok[2], A. Laenen[3], E. Hauben[4], S. Nuyts[1]

[1]Department of Radiation Oncology, University Hospitals Leuven, Leuven, Belgium, [2]Laboratory of Experimental Radiotherapy - Department of Oncology, University of Leuven, Leuven, Belgium, [3]Leuven Biostatistics and Statistical Bioinformatics Centre (L-Biostat), KU Leuven University, Leuven, Belgium, [4]Department of Imaging and Pathology, University Hospitals Leuven, Leuven, Belgium

Background: With the growing interest in treatment de-intensification trials for human papillomavirus positive (HPV+) oropharyngeal squamous cell carcinoma (OPC), accurate patient stratification has become essential for patient selection. The aim of this study was to validate the prognostic ability of the AJCC/UICC TNM 8th edition (8th Ed) for HPV+ OPC.

Methods: Patients with HPV+ OPC treated with curative (chemo)radiotherapy ((C)RT) between 2004 and 2017 were classified according to the TNM 7th edition (7th Ed) and the new clinical TNM 8th Ed. HPV status was determined by p16 immunohistochemistry staining. The 5-year overall survival (5YOS) was estimated using the Kaplan-Meier method and groups were compared using the log-rank test. Harrell's C-index was used as measure of model performance.

Results: A total of 333 OPC were identified of whom 100 were HPV+. The median follow-up was 63.7 months (IQR 30.0;99.9). The 5Y-OS with the 7th Ed were stage I/II 88.9% (CI95% 43.3;98.4), stage III 70.0% (CI95% 22.5;91.8), stage IVa 71.4% (CI95% 57.3;81.6) and stage IVb 29.8% (1.4;71.1) ($p = 0.38$). With the TNM 8th Ed, the 5Y-OS of stage I, II and III were 91.6% (CI95% 76.1;97.2), 55.2% (CI95% 29.2;75.1) and 38.0% (CI95% 8.7;68.2) ($p = 0.006$). On Cox regression analysis, when compared to stage I, OS was significantly lower for stage II ($p = 0.018$, Hazard ratio (HR)= 4.24 (CI95% 1.27;14.13)) and for stage III ($p = 0.004$, HR = 5.40 (CI95% 1.69;17.26)). Nevertheless, there was no significant difference between stage II and III ($p = 0.60$, HR = 1.27 (CI95% 0.51;3.17)). The Harrell's C-index for TNM 8th Ed stage was 0.67.

Conclusions: Although the TNM 8th Ed provides better OS stratification than the 7th Ed for HPV+ OPC following (C)RT, better prognostic models are needed due to the lack of differentiation between stage II and stage III. This study emphasizes the importance of further research in patient selection and personalized treatment for HPV+ OPC.

1093P Development of overall survival (OS) and progression free survival (PFS) nomograms for Australian patients with locoregionally advanced oropharyngeal squamous cell carcinoma (LA OPSCC)

K. Xu[1], A. Lo[2], V. Chin[1], C. Gzell[3], C. O'Connor[3], D. Forstner[3], R. Gallagher[1], R. Bova[1], J. Crawford[1], R. Harvey[1], A. Lochhead[4], P. Earls[4], M.R. Qiu[4], E. Hsu[5], G. Bigg-Wither[5], L. Chan[6], H. Bao[6], P. Foltyn[7], H-W. Sim[1], A. Prawira[1]

[1]Medical Oncology, The Kinghorn Cancer Centre, Darlinghurst, Australia, [2]School of Medicine, The University of New South Wales, Sydney, Australia, [3]Radiation Oncology, Genesis Cancer Care, Darlinghurst, Australia, [4]Anatomical Pathology, St Vincent's Pathology, Darlinghurst, Australia, [5]Medical Imaging, St Vincent's Hospital, Darlinghurst, Australia, [6]Nuclear Medicine, St Vincent's Hospital, Darlinghurst, Australia, [7]Oral Health and Dentistry, St Vincent's Hospital, Darlinghurst, Australia

Background: The majority of patients with squamous cell carcinoma of the head and neck present with locally advanced disease. Despite treatment with curative intent, approximately 40% of patients eventually relapse. It is currently difficult to predict those who will relapse at treatment outset. Nomograms can improve prognostic discussions for individual patients and potentially guide future research to individualise treatment. We aim to develop OS and PFS nomograms using retrospective data from patients with LA OPSCC treated in our institution.

Methods: We performed a retrospective analysis of baseline characteristics and outcomes of LA OPSCC patients who underwent curative-intent treatment in our institution from January 2008 to December 2017. Nomograms were constructed to estimate OS and PFS incorporating age, gender, performance status, smoking history, stage, grade, and p16 status. Multivariable Cox models were selected by backward elimination using the Akaike information criterion, and validated internally using bootstrap with 1000 resamples. Nomogram points were assigned proportional to variable effect size.

Results: A total of 417 patients have been identified so far. An initial cohort of 74 patients with complete clinical annotations were analysed. Median follow-up was 24 months, with 9 deaths and 25 events during follow-up. ECOG 0, N stage 0-1, histological grade 1-2 and p16 positive status were favourable predictors in the OS nomogram. Age ≤ 50, male gender, smoking history ≤ 10 pack-years and p16 positive status were favourable predictors in the PFS nomogram. The concordance index for OS was 0.86 (95% CI 0.76 to 0.99) and for PFS was 0.72 (95% CI 0.65 to 0.83). Bias-corrected indices were 0.82 and 0.69, respectively.

Conclusions: We present the first OS and PFS nomograms for Australian patients with LA OPSCC. The nomograms demonstrated clinically useful prediction of OS and PFS in patients with LA OPSCC, relying on four routinely collected variables, with superior concordance to previously reported models. Expansion of the retrospective cohort is ongoing and validation in an external patient cohort is planned.

1094P Clinical prognostic factors in patients (pts) with recurrent and/or metastatic (RM) head and neck carcinoma (HNC) treated with cetuximab plus chemotherapy

P. Bossi[1], R. Depenni[2], M. cossu rocca[3], D. Ferrari[4], G. Azzarello[5], M. Alù[6], F. Nolè[3], C. Codecà[4], G. Boscolo[5], M. Piccininni[7], S. Cavalieri[1], G. Pugliese[8], L.F. Licitra[1]

[1]Head and Neck Medical Oncology Unit, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [2]Department of Oncology/Hematology, Modena Cancer Center, Modena, Italy, [3]Medical Oncology, Istituto Europeo di Oncologia, Milan, Italy, [4]Oncology, Azienda Ospedaliera San Paolo, Milan, Italy, [5]Oncology Unit, Department of Internal Medical Sciences, Unità Locale Socio Sanitaria 13, Mirano, Italy, [6]Medical Oncology, Arnas Civico, Palermo, Italy, [7]Basic Medical Sciences, Neuroscience and Sense Organs, University of Bari "Aldo Moro", Bari, Italy, [8]Oncologia, Azienda Ospedaliero-Universitaria Policlinico di Modena, Modena, Italy

Background: There is limited information about prognostic factors in RM HNC pts receiving first-line platinum-based chemotherapy and cetuximab. Moreover, we lack survival data in a real-world population, without the selection bias affecting pts enrolled in clinical trials.

Methods: We evaluated all consecutive pts treated from 1/2007 to 12/2016 in 6 Italian Centres. The following baseline prognostic factors were investigated: sex, age, site of disease, tumor grading, HPV status for oropharyngeal cancer, performance status (PS), weight loss in the previous 3 months (less/more than 5%), comorbidities (according to ACE-27), residual tumor at primary site, previous chemotherapy or cetuximab in curative setting, previous radiotherapy, platinum type (cisplatin/carboplatin, CBDCA), chemotherapy schedule (weekly/3-weekly), platinum and cetuximab doublet or with a third drug (i.e. 5FU or paclitaxel).

For each potential predictor variable, Kaplan-Meier curves for OS and PFS were estimated, and a Log-rank test was used to compare survivorship in different levels of the variable. A Cox proportional hazard model was run including only predictors characterized by a significant ($p < 0.05$) Log-rank test.

Results: We analyzed 340 pts, with a median PFS/OS of 5.0/10.6 months. The 1-year and 3-year OS rate for all pts was 44.2% (CI: 39.1-50.0) and 7.8% (CI: 5.1-12.0). Only one out of two pts received a second-line therapy. In univariate analysis lower OS was associated with PS > 0 ($p < 0.001$), residual tumor at primary site ($p < 0.001$) and CBDCA use ($p = 0.012$) while lower PFS was associated with paranasal sinus site ($p = 0.008$), PS > 0 ($p = 0.001$), CBDCA use ($p = 0.035$) and residual tumor at primary site ($p < 0.001$). All these predictors except for platinum type remained significant at multivariate analysis. Pts with clinical response to treatment carried a more favorable prognosis, while progressive disease as best response had a dismal median OS of 5.8 months.

Conclusions: In non-selected RM HNC pts, we obtained a median PFS and OS of 5.0 and 10.6 months, very similar to 5.6 and 10.1 months reported in Extreme trial (Vermorken et al. 2008). At baseline, PS and residual tumor at primary site could be used to define pt prognosis.

1095P Prognostic value of MRI-derived residual retropharyngeal lymph node after intensity-modulated radiotherapy in nasopharyngeal carcinoma and a nomogram for the prediction of it

W-Z. Li[1], H. Liang[1], X. Lv[1], L-R. Ke[2], Y-F. Ye[3], Y-H. Yu[1], W-Z. Qiu[1], G-Y. Liu[1], X-J. Huang[1], K-Y. Liu[1], S-H. Lv[1], X. Guo[1], Y-Q. Xiang[1], W-X. Xia[1]

[1]Department of Nasopharyngeal Carcinoma, Sun Yat-sen University Cancer Center, Guangzhou, China, [2]Department of Radiology, Sun Yat-sen University Cancer Center, Guangzhou, China, [3]Clinical Trial Design Division, Sun Yat-sen Memorial Hospital, Guangzhou, China

Background: In nasopharyngeal carcinoma (NPC) patients with retropharyngeal lymph node (RLN) metastasis who receive intensity-modulated radiotherapy (IMRT), the incidence of magnetic resonance imaging (MRI)-derived residual retropharyngeal lymph node (RRLN) is not rare and its prognostic value is uncertain. In present study, we aim to investigate the prognostic value of MRI-derived RRLN and sought to develop a nomogram for the prediction of it.

Methods: A total of 922 patients with RLN metastasis without distant metastasis NPC treated with IMRT were enrolled in present study. The Kaplan-Meir survival curves and cox proportional regression model were used to assess the prognostic value of RRLN. The patients were then randomly assigned into the training cohort (n = 645) and the validation cohort (n = 277). Factors significantly associated with RRLN were identified and used to construct nomogram with multivariate logistic regression model. The discrimination and performance of nomogram were evaluated in training cohort and confirmed in validation cohort.

Results: The incidence of RRLN was 28.2%. The 5-year OS, DFS, DMFS, LRRFS of the RRLN group and non-RRLN group were 84.1% vs. 93.2%, 65.1% vs. 87.3%, 71.2% vs. 94.2% and 87.8% vs. 95.6%, respectively (for all rates, $P < 0.05$). Necrosis, extra-nodal neoplastic spread (ENS), minimum axial dimeter (MAD) and the percentage volume of the GTVnx receiving 95% of the prescribed dose (GTVnx V95%) were identified as independent factors associated with RRLN and used to construct the nomogram. The nomogram showed favorable calibration and discrimination in training cohort (AUC, 0.746) and validation cohorts (AUC, 0.738). Patients with high-risk scores had a higher probability of developing RRLN than patients with low-risk scores in training cohort (OR, 5.183, 95% CI 2.845-8.525) and validation cohort (OR, 6.977, 95% CI 3.990-12.200).

Conclusions: MRI-derived RRLN was a negative independent prognostic factor for OS, PFS, DMFS and LRRFS in NPC patients with RLN metastasis who received IMRT. We constructed a nomogram based on clinical and radiological characteristics that predicted an individual's risk of RRLN.

1096P Proteomic comparison based on 18FDG-PET/CT defined metabolic tumor volume in non-metastatic nasopharyngeal carcinoma

C. Chen[1], L. Li[2], Z. Fei[1], J. Wang[2], T. Chen[2]

[1]Radiation Oncology, Fujian Cancer Hospital, Fuzhou, China, [2]Radiation Oncology, Fujian Cancer Hospital, Fujian Medical University, Fuzhou, China

Background: Various PET/CT based metabolic tumor volume (MTV) was found to influence the prognosis of non-metastatic nasopharyngeal carcinoma. The proteomic analysis of primary tumor was compared for ^{18}FDG-PET/CT based MTV in non-metastatic nasopharyngeal carcinoma. We tried to find the potential biomarker related to MTV.

Methods: We respectively analyzed 110 patients with PET/CT confirmed non-metastatic nasopharyngeal carcinoma at our institution. MTV of primary tumors was defined with $SUV_{2.5}$.The ROC curve was portrayed with treatment failure events of patients.With the optimal cut-off point of MTV,another 25 nasopharyngeal carcinoma patients were divided into two groups to compare the primary tumor proteomics.Proteomic analysis was conducted with the combination of iTRAQ and nano-RPLC-MS/MS.We analyzed the previous tumor specimens(97/110) to verify the potential biomarker found by proteomics.

Results: The area under the ROC curve (AUC) was 0.726. And the best cut-off point for MTV was 9.88 ml (≈10 ml). MTV ≤10 ml appeared a favorable disease-free survival (DFS, 93.5% vs 81.3%, P = 0.035). A total of 7913 proteins were identified with proteomics, of which 360 had significant differences. In MTV>10ml group, the expression of 244 proteins was up-regulated and the other 116 was down-regulated. According to GO analysis and clustering, these proteins were mainly localized in organelles (34%), cytoplasm (20%), extracellular matrix (13%), and plasma membrane (10%). They were involved in many biological processes and molecules features. KEGG suggested that these differential proteins participated in metabolism, migration and inflammation-related pathways. The PPI interaction network showed that the core proteins were mainly implicated in protein phosphorylation, signal transduction and cell adhesion. Higher TRIM29 protein expression was found in the MTV>10ml group by immunohistochemistry (x^2=19.041, $P < 0.001$).

Conclusions: With proteomic comparison based on MTV, the differential proteins were closely related to tumor cell growth, migration, metabolism and immunity. Also, patients with MTV ≤10 ml had a favorable DFS. Lower expression of TRIM29 found in this group might be considered as a promising prognostic biomarker.

1097P Prognostic value of metabolic tumor volume in recurrent and/or metastatic head and neck squamous cell carcinoma treated with platinum-based chemotherapy

M. Suzuki[1], N. Takemoto[1], T. Fukuzumi[1], M. Yamamoto[1], S. Otozai[2], T. Yoshii[2], T. Fujii[2], H. Inohara[1]

[1]Otorhinolaryngology/Head and Neck Surgery, Osaka University Graduate School of Medicine, Osaka, Japan, [2]Head and Neck Surgery, Osaka International Cancer Institute, Osaka, Japan

Background: The standard first-line treatment for recurrent and/or metastatic head and neck squamous cell carcinoma (R/M HNSCC) is platinum-based chemotherapy, while the predictor of survival has yet to be established, except for tumor human papillomavirus (HPV) status. The present study aimed to evaluate the usefulness of metabolic tumor volume (MTV) measured on FDG-PET/CT in predicting survival of patients with R/M HNSCC after platinum-based chemotherapy.

Methods: Patients with R/M HNSCC treated with platinum-based chemotherapy as first-line treatment following FDG-PET/CT between 2006 and 2017 at Osaka University Medical School Hospital and Osaka International Cancer Institute were eligible. Exclusion criteria were nasopharyngeal carcinoma, >60 days duration between FDG-PET/CT and chemotherapy initiation. FDG-PET/CT data were transferred into the workstation in the DICOM format. A total amount of MTV in the whole body was measured using a SUV-based automated contouring program (PETSTAT Viewer Ver. 2.2), with the SUV threshold being 2.5. Tumor HPV status was determined by p16 immunohistochemistry. The risk of death was assessed by Cox proportional hazard model.

Results: One hundred and four patients met the criteria. The median follow-up duration of surviving patients was 13.1 months (range, 3.2-79.6). The median MTV was 21.9ml (range, 0.0-1118.7). The risk of death increased by 1.03 fold (95% confidence interval, 1.02-1.04; $P < 0.0001$) for every 10-ml increment of MTV, independently of tumor HPV status. The median overall survival was 15.3 months in patients with MTV larger than the median and 9.2 months in patients with MTV equal to or smaller than the median.

Conclusions: MTV is a useful predictor of survival in patients with R/M HNSCC after platinum-based chemotherapy. MTV needs to be considered in allocation for randomized clinical trials.

1098P The prognostic value of early tumor response in metastatic nasopharyngeal carcinoma patients treated with first-line chemotherapy

W-X. Xia, L. Guoying, X. Lv, S-H. Lv, X-J. Huang, W-Z. Qiu, H. Liang, W-Z. Li, K-Y. Liu, Y-H. Yu, Y-Q. Xiang, X. Guo
Department of Nasopharyngeal Carcinoma, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: The prognostic value of the early tumor response to first-line chemotherapy remains unknown in metastatic nasopharyngeal carcinoma (mNPC). The aim of this study was to explore the association between early tumor response (response at 6 weeks) and survival outcomes and to assess the relationship between best (response at 18 weeks) and early tumor response.

Methods: A total of 433 mNPC patients with measurable lesions, who received first line chemotherapy between 2005 and 2016 were enrolled in this study. Response was assessed at completion of 6 weeks and 18 weeks of chemotherapy using RECIST 1.1. To estimate in an unbiased way, the landmark method was used in this study. Log-rank test and Cox regression were used to analyze survival data. The correlation between early tumor response and best tumor response was measured by Kappa agreement, Pearson correlation and receiver operating curves.

Results: The median follow-up time was 54.3 months (IQR: 38.6-79 months). Two hundred and sixty-five patients achieved tumor response at 6 weeks. From the 6-week landmark, patients with tumor response were significantly associated with better OS (hazard ratio, HR = 0.566, $P < 0.001$, median OS: 30.3 versus 21.7 months) and PFS (HR = 0.426, $P < 0.001$, median PFS: 9.2 versus 7.3 months) than the patients without. After adjusting for potential confounders, the early tumor response was an independent prognostic factor associated with OS (HR = 0.539, 95% CI, 0.428 to 0.679, $P < 0.001$) and PFS (HR = 0.467, 95% CI, 0.378 to 0.576, $P < 0.001$), respectively. There was a good correlation between the early and best tumor response (Kappa: 0.82; Pearson: 0.83). The sensitivity, specificity, positive and negative predictive values of early tumor response in predicting best response were 100%, 79%, 88% and 100%.

Conclusions: Early tumor response is an independent prognostic factor in determining survival. The early and best tumor response correlated very well. The data could provide a basis for trial design that addresses alteration of first line chemotherapy intensity. Validation studies are awaited.

1099P Potential clinical management changes in patients harboring locally advanced squamous-cell carcinoma of head and neck by incorporating pre and post chemoradiotherapy 18.FDG PET/CT: A prospective trial

U.R. Nicolau[1], A.C.M.D. Queiroz[1], T. Felismino[1], E.P.N. Lima[2], V.H.F. Jesus[1], L. Cezana[1], M.S. Alves[1], A.C.A. Pellizzon[1], P.N. Pinto[3], G.M. Porto[3], G.B. Carvalho[4], C.A.L. Pinto[5], V.S.E. Silva[1], A.P. Guimarães[1], T.B. Oliveira[1], M.K. Ikeda[4], T.F. Paiva Jr[1], P.C. Bes[1], L.P. Kowalski[4]
[1]Medical Oncology, A.C. Camargo Cancer Center, São Paulo, Brazil, [2]Nuclear Medicine, A.C. Camargo Cancer Center, São Paulo, Brazil, [3]Medical Radiology, A.C. Camargo Cancer Center, São Paulo, Brazil, [4]Head and Neck Surgery, A.C. Camargo Cancer Center, São Paulo, Brazil, [5]Pathology, A.C. Camargo Cancer Center, São Paulo, Brazil

Background: The utility of performing 18.FDG PET/CT in the tumor staging and as a clinical management tool in the post-12Th-week chemoradiotherapy (CRT) in patients (pts) harboring locally advanced squamous-cell carcinoima of head and neck (LASCCHN) has been established. The aim of this report is to evaluate the impact of incorporating a staging 18.FDG-PET/CT and post CRT, for pts harboring 7Thedition AJCC staged III-IVA/B treated in a single medical centre.

Methods: Patients harboring LASCCHN who underwent induction chemotherapy (IC) with triplet taxane-containing regimen followed by concurrent CRT were prospectively evaluated as part of the A.C. Camargo Cancer Center PET/CT trial. Our pts underwent three 18.FDG-PET/CT. First as a baseline, second after cycle-1 IC and third at 10 to 12 weeks after completion of CRT. Our primary objective was early 18.FDG-PET/CT tumor response assessment after cycle-1 IC, which has been reported elsewhere. Herein we report changes in clinical staging, radiotherapy and surgical management generated by baseline and post-therapy PET-CTs. All pts provided signed consent for trial participation.

Results: Between February 2010 and July 2013, 49 pts (41 oropharynx, 4 hypopharynx and 4 larynx) were recruited. Upstaging in neck lymph nodes were registered in 6 cases (12.2%): N0 to N1 in 2, N1 to N2b in 1, N1 to N2c in 1, N2a to N2c in 1, N2b to N2c in one. One patient harboring unilateral N3 had demonstrated bilateral lymph node disease. Downstaging N1 to N0 was registered in 2 pts. Suspected distant metastatic disease was registered in 2 cases (lung 1, bone 1). Primary occult tumor was identified in 3, and secondary synchronic colorectal tumor was diagnosed in one case. Radiotherapy planning changes were generated by detection of new regional metastatic lymph nodes or identification of primary tumor in 10 patients (20.4%). Post-radiotherapy 18.FDG PET/CT was able to detect residual lymph node disease and residual primary disease in 3 and 1 pts respectively.

Conclusions: These findings confirm the clinical utility of performing pre and post CRT 18.FDG PET/CT in pts harboring LASCCHN.

1100P Patterns of local failures and suggestions for reduction of clinical target volume for nasopharyngeal carcinoma patients without cervical lymph node metastasis

C. Hu, Y. Li
Department of Radiation Oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: To investigate the initial irradiated dose of the recurrent site and local failures patterns after Intensity-modulated radiation therapy (IMRT) for nasopharyngeal carcinoma (NPC) patients with retropharyngeal lymph nodes (RLNs) metastasis only, with the aim to demonstrate the adequacy and overall quality of the target volume definitions for further improvement of outcome and therapeutic ratio.

Methods: 382 newly diagnosed non-metastatic NPC patients were retrospectively enrolled, receiving elective neck irradiation to to levels II, III, VA. For patients with local failure, the location and extent of local failures were transferred to the pretreatment planning CT for dosimetric analysis. The dose of radiation received by GTVr (gross tumor volume of recurrence) was calculated and analyzed with dose-volume histogram (DVH). Failures were classified as: "in field" if 95% of GTVr was within the 95% isodose, "marginal" if 20% to 95% of GTVr was within the 95% isodose, or "outside" if less than 20% of GTVr was inside the 95% isodose.

Results: With a median follow-up time of 61.3 months, 12 patients have developed local recurrence (10 cases available). The 5-year OS, LRFS, RRFS, DMFS and DFS were 87.8%, 95.2%, 99.1%, 93.3% and 82.5%, respectively. Dose conformity with IMRT was excellent and the recurrence was mainly within 3 years after the first treatment. The dosimetric analysis showed that 7 failures were classified as "in-field", 2 failures as "marginal" and only 1 failures as "out-field". Most local relapse site located just the same site of primary tumor and most anatomic sites were at low risk of concurrent bilateral tumor invasion.

Conclusions: IMRT with elective neck irradiation provides excellent local control for NPC patients without cervical lymph node metastasis. In-field failures are the main patterns for local recurrence and the radioresistant subvolumes within the GTV are needed to be identified. We proposed suggestions for reduction of target volume during IMRT treatment for NPC patients.

1101P Target delineation and dose prescription for adaptive replanned intensity-modulated radiotherapy in nasopharyngeal carcinoma

X.D. Huan
Radiation Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: To investigate the feasibility and benefits of target re-delineation and dose prescription for adaptive replanned radiotherapy in nasopharyngeal carcinoma (NPC) patients who underwent intensity-modulated radiotherapy (IMRT).

Methods: Fifty-four consecutive NPC patients who underwent IMRT were enrolled in this study. The replanning CT (CT-II) for each patient was generated at the 22nd fraction of the IMRT. In Plan-I, GTVnx-I was defined as all detected gross disease. The high-risk clinical target volume (CTV1-I), as subclinical disease consisting of a 1-cm margin surrounding the GTVnx-I. The low-risk clinical target volume (CTV2), as a 0.5- to 1.0-cm margin surrounding the CTV1-I. In Plan-II, the GTVnx-II, as all detected gross disease detected after 22 fractions. CTV1-II maintained the extent of the originally irradiated CTV1-I, including the area in which the tumor disappeared/dissolved after 22 fractions. The CTV2 was not delineated. The doses prescribed were as follows: Plan-I: PGTVnx/rpn/nd 53-54 Gy/25 F; PCTV1/nd 47.5-48 Gy/25 F; PCTV2 45 Gy/25 F; and Plan-II: PGTVnx/rpn/nd: 15-15.5 Gy/7 F; PCTV1/nd 13.5 Gy/7 F. The parameters were compared. Clinical outcomes and toxicities were evaluated.

Results: The median reductions in the GTVnx, GTVnd-R, bilateral parotids and bilateral submandibular glands were 25.07%, 38.17%, 23.43% (left), 21.12% (right), 23.37% (left) and 23.00% (right) ($P < 0.05$), respectively; bilateral RPLN and GTVnd-L

exhibited median reductions of 22.50% (left), 25.00% (right), and 32.80% ($P > 0.05$), respectively. The average V95% of PGTVnx reached nearly 100% in the two plans. Plan-II significantly reduced the Dmean% in the optic chiasma, thyroid gland, hypopharynx, spinal cord, brain stem, pituitary, oropharynx and oral cavity compared with Plan-A ($P < 0.05$). Recurrence did not occur in the regression area, and the acute reactions were mild. The 3-year OS/LRFFS/DMFS rates were 93.3%/90.5%/91.4%, respectively.

Conclusions: Adaptive replanned IMRT in NPC provided a new perspective for target re-delineation and dose prescription. The results of this study showed significant dosimetric and clinical benefits without recurrence and reducing survival.

1102P Significance of pre-treatment F-18 FDG PET/CT parameters in nasopharyngeal carcinoma treated with intensity-modulated radiation therapy

Y. Huang[1], C. Chen[2], Y. Li[1], X. Qiu[1], T. Chen[1]

[1]Radiation Oncology, Fujian Cancer Hospital, Fujian Medical Univercity, Fuzhou, China, [2]Radiation Oncology, Fujian Cancer Hospital, Fuzhou, China

Background: The aim of this study was to assess the prognostic significance of parameters derived from pretreatmentF-18 fluorodeoxyglucose positron emission tomography/computed tomography (F-18 FDG PET/CT) for patients with nasopharyngeal carcinoma (NPC) received intensity-modulated radiation therapy (IMRT). Furthermore, the functional information provided by PET/CT may offer the feasibility of biological conformality in tumor target delineation and dose planning.

Methods: We retrospectively reviewed 82 NPC patients who underwent pretreatment F-18 FDG PET/CT and received IMRT between 2010 and 2013. Maximum standardized uptake value (SUV_{max}) and metabolic tumor volume (MTV) of the primary tumor were measured by F-18 FDG PET/CT. MTV might be viewed as a collection of absolute SUV values equal to or greater than a certain threshold on each axial image of PET/CT. The ROC curve was used to determine the appropriate cut-off point of SUV_{max} and MTV. The prognostic significance of MTV, SUV_{max} was assessed in the study. Meanwhile, the paper studies the relation between SUV_{max}, MTV, and primary tumor volume (PTV). Receiver operating characteristic (ROC) analysis was used to determine the optimal MTV cut-off value.

Results: Positive correlations between PTV and MTV, SUV_{max} and MTV were found. PTV, SUV_{max}, and MTV were significant predictors of survival. The 3-year progression-free survival (PFS) for $SUV_{max} \leq 8.20$ and $SUV_{max} > 8.20$ were 91.1% and 73.0% ($p = 0.027$). With furthermore analysis, patients having tumor with lower MTV had higher 3-year PFS than patients having tumor with higher MTV. The percentage of the $MTV_{5.0}$ in PTV was 14.66±15.75% (95%CI,11.20-18.13).

Conclusions: Our study indicated that PET/CT-derived parameters, SUV_{max} and MTV, are very important in assessing prognosis and making radiotherapy planning. Patients having tumor with lower MTV had higher 3-year PFS than patients having tumor with higher MTV. It is necessary to give a more aggressive treatment for patients with higher MTV. The $MTV_{5.0}$ might be an appropriate quantitative definition of hypoxic sub-volumes for radiotherapy boost to improve the therapeutic effect.

1103P Sentinel lymph node biopsy for clinically N0 oral squamous cell carcinoma

H. Goda, K-I. Nakashiro

Oral and Maxillofacial Surgery, Ehime University Graduate School of Medicine, Ehime, Japan

Background: Despite advances in early detection, diagnosis, and treatment of oral squamous cell carcinoma (OSCC), the survival for patients with early stage OSCC remains at 80% for the past 30 years. Nodal status is still the most significant prognostic factor of OSCC. Therefore, early detection of the cervical lymph nodes metastasis is expected to further improve survival. Sentinel lymph node biopsy (SLNB) is a widely accepted procedure in various human malignancies. In clinically N0 (cN0) OSCC cases, SLNB has received considerable attention for its role in deciding whether to perform neck dissection. In this study, we assessed the efficiency of SLNB for cN0 OSCC in a single-institution experience.

Methods: A total of 135 patients with cN0 OSCC underwent SLNB between 2001 and 2016, of which 128 were clinically T1 and T2. The primary site was tongue, gingiva, oral floor, buccal mucosa, and lip in 49%, 36%, 7%, 6%, and 1%, respectively. The location of sentinel lymph node (SLN) was determined by radioisotope (RI) method with preoperative lymphoscintigraphy and intraoperative use of a handheld gamma probe and/or dye method and evaluated by histopathological examination and genetic analysis.

Results: SLNB was performed with RI method (90%) or dye method (10%). SLNs were successfully identified with RI method (100%) and dye method (70%). The average number of SLN/case was 1.9 with RI method and 2.3 with dye method. The rate of SLN identified side was 85% in ipsilateral, 9% in bilateral, and 6% in contralateral. Twenty two of 135 patients (16%) had metastasis-positive SLN. Thirteen patients with negative SLN developed the latent neck lymph node metastasis. The sensitivity, specificity, and accuracy was 62.9% (22/35), 100% (100/100), and 90.4% (122/135), respectively. Three-year overall survival rate for SLNB-negative patients was 95.6% (108/113).

Conclusions: SLNB is a minimally invasive and highly reliable method staging the cN0 for patients with OSCC. Patients with negative SLNB showed more excellent neck control rate and the SLNB provides more accurate staging than elective neck dissection or wait and see.

1104P An insight on head and neck cancer management in China

Y. Xiaoshi[1], D. Weiyi[2]

[1]Department of Epidemiology, China Medical University, Shenyang, China, [2]Head and Neck Cancer Center, Stomatology Hospital of China Medical University, Shenyang, China

Background: As no Chinese data has evaluated the oncologists' strategy for treatment and management of the head and neck cancer (HNC), this survey investigated Chinese oncologists' treatment strategy in HNC.

Methods: This survey was conducted during October 2017 to January 2018 in 100 randomly selected tertiary Chinese hospitals from 21 cities. The plan was to include 300 non-randomly selected Chinese oncologists to know their responses on HNC. The investigating stages included: development of a questionnaire after consulting 9 experts in HNC; execution of a pre-test by 40 oncologists from 5 cities; reliability and validity evaluation followed by finalisation of the questionnaire; and conduct of formal investigation with oncologists. Results for all evaluations were presented as percentages.

Results: Of the 296 questionnaires received, 272 were considered valid. Among valid respondents, 65.1% oncologists reported nasopharyngeal carcinoma as the most common HNC, followed by laryngeal/hypopharyngeal (22.1%) carcinoma. 71.3% oncologists acknowledged having a multidisciplinary team for HNC treatment in their hospitals. Prescribed regimens for recurrent/metastatic HNC included taxane + platinum (TP), taxane-cisplatin-5fluorouracil (TFP), PF, TF and others (45.2%, 27.9%, 21%, 2.2% and 3.7%). Oncologists (77.6%) add target therapy to chemotherapy as the first line therapy in recurrent/metastatic cancer. For locally advanced HNC, anti-EGFR would be preferred by 84.2% oncologists. 39.0% oncologists reported considering inclusion of targeted therapy at combined radical radiotherapy and chemotherapy stage. HPV was believed to be associated with HNC prognosis by 72.0% oncologists; 1.9% oncologists disagreed and 26.1% were unsure. HPV testing rate was 67.3%. The reasons for not testing HPV were immature technical conditions (41.2%), no impact on treatment (40.8%), no consent by patients (25.0%) and low HPV incidence in Chinese HNC patients (18.01%).

Conclusions: In conclusion, oncologists in China have not fully followed international guidelines of HNC which might be due to practical considerations. These findings will provide future education for HNC management.

1105P Real-world outcomes and costs in patients with recurrent or metastatic squamous cell carcinoma of the head and neck

A. Lafuma[1], F-E. Cotté[2], C. Le Tourneau[3], C. Emery[1], A-F. Gaudin[2], E. Torreton[1], J. Gourmelen[4], J. Bonastre[5]

[1]Health Economy, Cemka-Eval, Bourg-la-Reine, France, [2]Health Economics and Outcome Research, Bristol-Myers Squibb, Rueil-Malmaison, France, [3]Medical Oncology, Institut Curie, Paris, France, [4]UMS 011, UVSQ, INSERM, Villejuif, France, [5]CESP, Gustave Roussy, Villejuif, France

Background: Overall survival (OS) of patients with recurrent or metastatic (R/M) squamous cell carcinoma of the head and neck (SCCHN) is extremely poor. New therapeutic options emerge but need to establish their economic value. The objective was to describe OS and costs in French R/M SCCHN patients.

Methods: The EGB, a random representative sample (1/97th) of the French national healthcare system claims database was used. All adult patients with a diagnosis of SCCHN with a first R/M between Jan 2009 and Dec 2014 were selected. Data were analyzed from the index date (first chemotherapy) until patients' death or Dec 2015 (minimum follow-up of 12 months). Two periods were distinguished: 'chemotherapy treatment' (CT) and 'end-of-life' (EoL) (from last CT to death). OS was estimated using the Kaplan-Meier method. Costs included all hospitalizations for SCCHN, consultations, medical devices, biology and imaging procedures, supportive and palliative

care, transportation, patients' out of pocket expenses and indirect cost (daily allowances for sick leaves and disability pensions).

Results: Among 267 patients identified, 85% were men, 44% had metastases at the index date and mean age was 62.0 years (±9.9). Most common tumor locations were oropharynx (29%), oral cavity (12%), larynx (10%) and hypopharynx (10%) but 39% of the patient had multiple locations. Median OS was 9.3 months in overall population with no significant difference between recurrent or metastatic patients (10.5 vs. 8.3 months, p = 0.092). The median OS ranged from 8.3 months for tumors located in the oro/hypopharynx to 10.9 months for those in the oral cavity. The average cost per patient was €48,069 breakdown into €31,136 [95CI: 27,935–34,336] for hospitalizations and €16,933 [14,866–19,000] for outpatient care. During CT period (209 days on average), main cost drivers were CT acquisition and administration (€13,755), home care (€2454), transportation (€1954) and physician fees (€1214). During EoL period (125 days), palliative care (€3548), home care (€977), nursing care (€711) and physician fees (€618) were the main cost drivers.

Conclusions: This analysis of real-world data confirms the poor prognosis in patients with R/M SCCHN and provides cost data for future economic evaluations.

1106P Treatment patterns in elderly patients with locally advanced head and neck squamous cell carcinoma (LA-HNSCC): Results from an EORTC led survey

S. Oosting[1], I. Desideri[2], D. Staelens[3], C. Caballero[3], S. Tribius[4], C. Simon[5], S. Singer[6], V. Gregoire[7], C. Fortpied[3], A. Luciani[8]

[1]Medical Oncology, University Hospital Groningen (UMCG), Groningen, Netherlands, [2]Radiation Oncology, Università di Firenze, Dipartimento di Patologia e Oncologia Sperimentali, Florence, Italy, [3]EORTC - European Organisation for Research and Treatment of Cancer, Brussels, Belgium, [4]Radiation Oncology, Asklepios Klinik St. Georg, Hamburg, Germany, [5]Otolaryngology/Head and Neck Surgery, Centre Hospitalier Universitaire Vaudois - CHUV, Lausanne, Switzerland, [6]Institute of Medical Biostatistics, Division of Epidemiology and Health Services Research, University Medical Center Mainz, Mainz, Germany, [7]Radiation Oncology, Leon Berard Cancer Center, Lyon, France, [8]Medical Oncology, Azienda Ospedaliera S. Paolo, Milan, Italy

Background: An increase in the number of elderly patients diagnosed with head and neck cancer is expected, but there is no consensus on what is the optimal treatment for patients >70 years with locally advanced disease. Geriatric assessment (GA) is recommended but not validated for guiding treatment decisions. We hypothesized that significant heterogeneity will exist across institutions in patterns of care delivered to elderly patients with LA-HNSCC and in the use of GA and assessment of quality of life (QoL).

Methods: Members of the EORTC, the European Head and Neck Society and national groups in Europe were asked to complete a questionnaire about treatment delivered and use of GA and QoL assessment in elderly patients with LA-HNSCC.

Results: Investigators from 111 centers replied, including 90 (81.1%) academic centers, 16 (14.4%) community hospitals and 5 (4.5%) private clinics. Large differences in treatment patterns were found. For instance, for oropharyngeal carcinoma, one third of the centers indicate that they treat <5% of elderly patients with chemoradiation, while 18 centers (16.2%) treat >40% of elderly patients with chemoradiation. More than half of the centers hardly or never use cetuximab in elderly patients with hypopharyngeal carcinoma, while one in five centers treat >20% of the elderly patients with cetuximab. Furthermore, 3 centers (2.7%) treat <5% of elderly patients with oral cavity cancer with surgery and postoperative radiotherapy, while 73 centers (65.7%) offer this to at least 40% of their elderly patients. Fourteen centers (12.6%) routinely perform GA while 43 centers (38.7%) never do, and 39 centers (35.1%) sometimes do. QoL is assessed on a routine basis in one fifth of the centers.

Conclusions: Large differences exist across institutions in the patterns of care delivered to elderly patients with LA-HNSCC. Prospective studies are required in this population to learn how to use GA, how to improve QoL and ultimately improve treatment outcome. For that, consensus on standard of care is essential.

1107P The importance of comorbidity assessment in patients with oral squamous cell carcinoma (OSCC): Could the adult comorbidity evaluation – 27 (ACE-27) provide an additional information?

U.M. Jariod Ferrer[1], S. Blanco Sanfrutos[2], M.A. Gavin Clavero[1], T. Uson Bouthelier[1], B. Nadal Cristobal[1], I. Moral Saez[1], I. Pajares Bernad[3], A.I. Cisneros Gimeno[4], J. Martinez Trufero[3]

[1]Oral and Maxillofacial Surgery, Hospital Miguel Servet, Zaragoza, Spain, [2]Oral and Maxillofacial Surgery, Hospital Can Misses Ibiza, Ibiza, Spain, [3]Medical Oncology Department, Hospital Miguel Servet, Zaragoza, Spain, [4]Anatomy Department, University of Zaragoza, Zaragoza, Spain

Background: Disease stage is the most powerful prognostic factor in OSCC but is not accurate enough to identify highest risk patients. Other patient-related conditions as comorbidity add relevant prognostic value. We show the importance of the comorbidity assessment in contrast to other historic prognosis factors.

Methods: Retrospective review of patients with resectable OSCC from 2011 to 2014. Baseline pretreatment comorbidity data were collected according to ACE–27. Clinical, pathological, presurgical blood samples and treatment data were collected. Kaplan-Meier and Cox proportional hazards modeling were used to determine associations with OS (Overall Survival), DSS (Disease-Specific Survival) and DFS (Disease-Free Survival).

Results: Among 215 patients, median age was 67 years (range 32-96). Median follow-up was 31 months (1– 78). 74% suffered at least one previous comorbid condition. 3-year OS, DSS and DFS were 68%, 77% and 65%, respectively. The multivariable model is showed in the table. Suffering a severe comorbidity had the highest prognostic value, greater than present a locally advanced OSCC [HR = 6.24; 95%CI=2.08-18.67p< 0.001].

Table: 1107P Multivariable model

Variable	HR	95%CI	p
Low comorbidity	2.61	[0.95-7.21]	0.006
Moderate comorbidity	3.17	[1.24-8.11]	0.02
Severe comorbidity	6.24	[2.08-18.67]	<0.001
Haemoglobin < 13.6 g/dL	1.92	[1.04-3.55]	0.04
Stage II	2.57	[0.87-7.58]	0.009
Stage III-IV	4.10	[1.15-14.67]	0.03
N0. Watchful waiting	2.82	[0.98 – 8.12]	0.05
Therapeutic neck disection	2.57	[1- 6.60]	0.05
PLR (platelets to lymphocytes ratio) >66	3.98	[0.88-17.93]	0.07
Age > 80	2.88	[1.28-6.46]	0.01

Conclusions: We described the account of comorbidity assessment as a prognosis factor of resectable OSCC. We provide the importance of additional clinical and easily accessible information to tumor stage, capable of discriminating prognostic risk factors in resectable OSCC.

1108P Can concomitant diseases predict the compliance with cisplatin plus RT in patients with LA SCCHN? An exploratory endpoint analysis of the COMPLY trial

J. Dunst[1], G. Hildebrandt[2], M. Becker-Schiebe[3], T. Kuhnt[4], F. Weykamp[5], F. Martucci[6], D. Vordermark[7], M. Pless[8], D. Hofmann[9], V. Bühler[10], S.I. Rothschild[11]

[1]Klinik für Strahlentherapie, Universitätsklinikum Schleswig-Holstein, Kiel, Germany, [2]Radiooncology, Universitätsklinikum Rostock, Rostock, Germany, [3]Radiooncology, Klinikum Braunschweig, Braunschweig, Germany, [4]Radiooncology, Universitätsklinikum Leipzig, Leipzig, Germany, [5]Strahlentherapie, Universitätsklinikum Heidelberg, Heidelberg, Germany, [6]Radiooncology, IOSI - Ospedale Regionale Bellinzona e Valli, Bellinzona, Switzerland, [7]Radiooncology, Universitätsklinikum Halle/Saale, Halle/Saale, Germany, [8]Radiooncology, Kantonsspital Winterthur, Winterthur, Switzerland, [9]Medical Affairs Oncology, Merck Serono GmbH, Darmstadt, Germany, [10]Medical Affairs Oncology, Merck (Schweiz) AG, Zug, Switzerland, [11]Radiooncology, Universitätsspital Basel, Basel, Switzerland

Background: International guidelines recommend the use of high-dose platinum chemoradiotherapy (CRT) (3 x 100 mg/m^2, q3w) for the treatment of LA SCCHN. The clinical benefit of CRT decreases with lower cumulative dosage. Dose reductions to ≤ 200 mg/m^2 lead to a significantly lowered OS. Predictive factors would help to select patients who are suitable for an optimal cumulative dose of cisplatin.

Methods: The COMPLY trial included patients with LA SCCHN from Germany and Switzerland. Eligible patients were treated in 2013/2014. The planned target dose of cisplatin had to be > 200 mg/m^2. Compliance was defined as an administration of > 200 mg/m^2 cisplatin. R/M SCCHN, nasopharyngeal carcinomas, adjuvant treatment or participation in other clinical trials were excluded. The exploratory objective was to identify a predictive score for therapy compliance with platinum-based CRT. A multiple logistic regression analysis was performed to identify independent explanatory variables associated with compliance with cisplatin. Only independent variables with a p-value <0.15 in the univariate analysis were considered for multiple logistic regression analysis.

Results: 184 patients in 9 sites were included. Median age was 61.0 years, 82.6% were male, 167 patients (90.8%) were ECOG 0-1. A significant difference in treatment compliance with cisplatin was shown for patients with concomitant musculoskeletal/connective tissue disorders (odds ratio for absence of disease vs. presence: 9.43; 95% CI: 1.20, 74.02; p = 0.03) and respiratory, thoracic and mediastinal disorders (odds ratio for absence of disease vs. presence: 6.59; 95% CI: 1.47, 29.48; p = 0.01) by system organ class. The probability of treatment compliance with cisplatin, being an estimate from a scoring system developed for the study, was 43.4% in subjects with absence of both disorders while the treatment compliance was 8.9% in subjects who presented with either one of the disorders and 1.2% in subjects with both disorders.

Conclusions: These exploratory results indicate that subjects without musculoskeletal/connective tissue and respiratory, thoracic and mediastinal disorders as concomitant diseases were more likely to have received cisplatin >200 mg/m^2.

1109P Comparison of acute hematologic and renal toxicities in two chemotherapy schedules of cisplatin for epithelial cell carcinoma of head and neck

A. Ameri[1], S. Norouzi[1], A. Sourati[1], K. Novin[2], S. Azghandi[3]

[1]Jorjani Cancer Center, Imam Hossein Hospital, Teheran, Iran, [2]Radiation Oncology Department, Shohada Haftetir Hospital, Teheran, Iran, [3]Radiation Oncology Department, Shohada Tajrish Hospital, Teheran, Iran

Background: Standard approach for treatment of locally advanced head and neck carcinoma is concurrent chemoradiation with cisplatin 100mg/m^2 every three week. However, prescribing cisplatin at this dose is associated with increased toxicity that can interrupt and compromise treatment results. Many centers use alternative schedules of weekly cisplatin at doses of 30-40 mg/m^2 per week.

Methods: In this study, 77 patients with head and neck cancer were randomized in a phase II clinical trial to compare toxicity for two cisplatin schedules, 100mg/m^2 three weekly and 40mg/m^2 weekly.

Results: The incidence of grade 3-4 hematologic events was not significantly different between the two groups, but the mean level of glomerular filtration rate in the three weekly group was significantly higher than the weekly group. There was no significant difference between the two groups in terms of mean overall treatment time and mean dose of cisplatin. Cisplatin cumulative dose $\geq$ 200mg/m^2 was higher in the weekly group, but no significant difference was observed. The main reason for treatment interruption was neutropenia for the three-weekly group, but in the weekly group, it was renal dysfunction for chemotherapy delay, and thrombocytopenia for radiotherapy break.

Conclusions: Weekly prescribing cisplatin can lead to higher cumulative doses, which may improve treatment outcomes. The incidence of grade 3-4 hematologic events was not significantly different between the two groups; However, the weekly schedule was associated with a higher drop in GFR, requiring further investigation.

Clinical trial identification: IRCT20180223038829N.

1110P Patient reports of mouth symptoms after radiotherapy treatment for head and neck cancer: An international survey

C. Curtis[1], A. Nicotera[2], C. Griseri[2], H. Roddam[3]

[1]The Swallows Head and Neck Cancer Support Group, Blackpool, UK, [2]Allied Health Research Unit, University of Central Lancashire, Preston, UK, [3]Health Sciences, University of Central Lancashire, Preston, UK

Background: People with head and neck cancer frequently have symptoms that are caused by their disease or by their treatments, which may significantly impact on their quality of life living with and beyond cancer. This international research survey captured a self-rating report by people who have had radiotherapy (RT) treatment for head and neck cancer about their experience of oral symptoms, including Dry Mouth (Xerostomia).

Methods: This survey was designed by patients, and then submitted for ethical approvals in collaboration with a healthcare researcher. The international survey was open to anyone over 18 who has had treatment for head and neck cancer, whether or not they currently have symptoms of Dry Mouth. The electronic survey was only in English and the ethical permissions granted that patients who wished to take part could request assistance if needed; due to illness, fatigue, confidence in accessing the internet, or English literacy. Participant recruitment was supported through a wide range of networks including healthcare practitioners, charities and patient support groups. The average time to complete the 18-item survey was under 10 minutes; including both multiple choice and open questions. The statistical analysis reflected correlations between the participant demographics and self-report of symptoms. An interpretive analysis of free text responses highlighted patient values and priorities.

Results: Over 100 individuals responded, from across UK, US, Canada, Australia, India and mainland Europe. The analysis demonstrates patterns between the patient demographics, types of radiotherapy treatments, time since treatment, and current symptoms. This is the first time that this original dataset will be presented. The findings also generated insights into the self-reported impact of these symptoms on patients' quality of life.

Conclusions: This study comprises important evidence of patients' experiences and symptoms following RT treatment. The cross-sectional dataset also indicates the global view of recent and current RT treatment approaches. Future collaborative research by healthcare researchers, patient groups and relevant pharma is imperative. This research will be presented by a Patient Advocate.

1111P Risk factors for aspiration pneumonia during concurrent chemoradiotherapy or bio-radiotherapy for head and neck cancer

H. Shirasu[1], T. Yokota[1], K. Fushiki[1], H. Inoue[1], M. Shibata[1], M. Furuta[1], T. Kawakami[1], S. Kawai[2], S. Hamauchi[1], A. Todaka[1], T. Tsushima[1], N. Machida[1], K. Yamazaki[1], A. Fukutomi[1], Y. Onozawa[1], H. Yasui[1]

[1]Division of Gastrointestinal Oncology, Shizuoka Cancer Center, Shizuoka, Japan, [2]Division of Medical Oncology, Shizuoka Cancer Center, Shizuoka, Japan

Background: Aspiration pneumonia (AP) is one of the most important side effects in chemoradiotherapy (CRT) and bio-radiotherapy (BRT) for patients (pts) with head and neck cancer (HNC). AP is involved in on-cancer related mortality in HNC pts. However, the relation between AP during CRT or BRT and treatment outcomes in HNC pts has not been identified. The aims of this study were to assess the influence of AP on treatment outcomes, and to identify clinical risk factors for AP during definitive CRT or BRT for HNC pts.

Methods: We retrospectively assessed the data of pts with locally advanced HNC who received definitive CRT or BRT at Shizuoka Cancer Center (August 2006 to December 2016). AP was defined as a clinical condition that met all the following criteria: (i) pts with both subjective and objective symptoms of pneumonia; (ii) the presence of aspiration was suspected clinically (choking or delayed swallowing) or by endoscopy or video-fluorography exams; (iii) no evidence of micro-organisms that cause atypical pneumonia.

Results: Of 374 HNC pts who received CRT or BRT, 95 (25.4%) developed AP during treatment. The study cohort of 374 pts had the following features: median age 65 years (range: 19-83); male/female, 322/52; performance status 0/1/2/3, 196/109/14/3; number of metastatic sites 1/2/3/4, 98/60/27/4; primary site larynx/nasopharynx/nasal-sinus/oropharynx/oral-cavity/ear-canal, 57/48/132/21/101/14/1; T-classification 1/2/3/4a/4b, 32/136/86/92/28; N-classification (UICC 7th) 0/1/2a/2b/2c/3, 76/54/19/134/75/16; induction chemotherapy -/+, 273/101; chemotherapy regimen cisplatin/carboplatin/cetuximab, 278/64/32. AP was significantly associated with treatment response of CRT or BRT (multivariate-adjusted odds ratio for complete response 0.55, p < 0.029). Multivariate analyses identified four independent factors for AP, including poor oral hygiene, high N-classification, hypoalbuminemia before treatment, and inpatient treatment.

Conclusions: AP during CRT or BRT has a detrimental effect on treatment response in HNC pts. Careful attention should be paid to AP in HNC pts with these risk factors receiving CRT or BRT.

1112P Nutritional support dependence after curative chemoradiotherapy in head and neck cancer: A supplementary analysis of a phase II trial (JCOG0706S1)

Y. Imamura[1], N. Kiyota[1], T. Akimoto[2], G. Ogawa[3], J. Eba[3], S. Minami[4], Y. Hasegawa[5], S. Iwae[6], N. Monden[7], K. Matsuura[8], H. Fujii[9], Y. Onozawa[10], A. Homma[11], R. Hayashi[12], M. Tahara[13]

[1]Medical Oncology/Hematology, Kobe University Hospital, Kobe, Japan, [2]Radiation Oncology, National Cancer Center Hospital East, Kashiwa, Japan, [3]Japan Clinical Oncology Group Data Center/Operations Office, National Cancer Center Hospital East, Tokyo, Japan, [4]Otolaryngology, National Hospital Organization Tokyo Medical Center, Tokyo, Japan, [5]Head and Neck Surgery, Aichi Cancer Center Hospital, Nagoya, Japan, [6]Head and Neck Surgery, Hyogo Cancer Center, Akashi, Japan, [7]Head and Neck Surgery, National Hospital Organization Shikoku Cancer Center, Matsuyama, Japan, [8]Head and Neck Surgery, Miyagi Cancer Center, Natori, Japan, [9]Clinical Oncology, Jichi Medical University, Shimotsuke, Japan, [10]Clinical Oncology, Shizuoka Cancer Center, Shizuoka, Japan, [11]Otolaryngology-Head and Neck Surgery, Hokkaido University, Sapporo, Japan, [12]Head and Neck Surgery, National Cancer Center Hospital East, Kashiwa, Japan, [13]Head and Neck Medical Oncology, National Cancer Center Hospital East, Kashiwa, Chiba, Japan

Background: Curative chemoradiotherapy (CRT) for locally advanced head and neck cancer (LA-HNC) causes severe acute and late adverse reactions, including nutritional support dependence. The aim of this supplementary analysis of a previous single-arm phase II study of CRT with S-1 plus cisplatin for unresectable LA-HNC (JCOG0706) which demonstrated promising efficacy (Cancer Sci.2015;106:726) was to explore risk factors of laryngo-esophageal dysfunction-free survival (LEDFS) and nutritional support dependence over 12 months (NSD12M).

Methods: The study population comprised 45 patients (pts) in the JCOG0706. Risk factors of LEDFS and NSD12M were analyzed using Cox regression models and logistic regression models, respectively, with consideration to the pts' laboratory data just before CRT. Radiation fields were reviewed to analyze the relationship between the extent of irradiated fields and functional outcomes.

Results: Proportions of alive without nutritional support at registration and 2, 6, 12, and 24 months after registration were 82.2%, 35.6%, 68.9%, 77.8%, and 64.4%. All six pts who required nutritional support at 12 months remained tube feeding-dependent thereafter. With a median follow-up period of 3.5 years of all pts, 3-year LEDFS was 48.9%. For LEDFS, the hazard ratio was 0.42 in pts with nutritional support at registration (vs. without nutritional support; 95% confidence interval [CI] 0.17-1.04). For NSD12M, odds ratio was 6.78 in pts with hemoglobin less than the median value of 13.4 g/dL (vs. higher than or equal to the median; 95% CI 1.24-36.85); and was 6.00 in pts with albumin less than the median value of 3.9 g/dL (vs. higher than or equal to the median; 95% CI 1.11-32.54). Primary sites in disease-free pts with NSD12M were the oropharynx (N = 2) or hypopharynx (N = 1), and all their pharyngeal constriction muscles were irradiated with a curative dose of 70 Gy/35 fr.

Conclusions: Functional outcomes were affected by severe dysphasia requiring nutritional support before CRT, and lower pretreatment values of hemoglobin and albumin. These risk factors should therefore be taken into consideration in planning treatment strategy for pts with LA-HNC.

Clinical trial identification: UMIN000001272.

Legal entity responsible for the study: JCOG.

1113P The retrospective analysis of nephrotoxicity for cisplatin dose of CRT compared 100 mg/m2 to 80 mg/m2 for head and neck cancer (HNC) patients

T. Oguri[1], K. Nakano[1], N. Fukuda[1], K. Kawaguchi[1], T. Urasaki[1], M. Nishizawa[1], M. Yunokawa[1], M. Ono[1], S. Taira[1], J. Tomomatsu[1], T. Toshiyasu[2], H. Mitani[3], S. Takahashi[4]

[1]Department of Medical Oncology, The Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, Japan, [2]Department of Radiation Oncology, The Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, Japan, [3]Head and Neck Surgery, The Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, Japan, [4]Department of Medical Oncology, Cancer Institute Hospital of JFCR, Tokyo, Japan

Background: Concurrent chemoradiotherapy (CRT) with single agent cisplatin for patients with head and neck cancers (HNC) have been used as the standard treatment for a long time. Although recommended dose of cisplatin is 100mg/m2, we sometimes reduced cisplatin dose to 80mg/m2 depends on general condition in real world setting. It remains unclear whether the efficacy and the safety, especially in nephrotoxicity, for CRT of HNC patients with cisplatin dose 100mg/m2 or 80mg/m2 are different.

Methods: We reviewed medical records of NHC patients who received CRT in our institute retrospectively. The primary objectives of this study were to evaluate the nephrotoxicity and the rate of patients treated with cumulative dose of cisplatin 200mg/m2 or more.

Results: During January 2014 to October 2017, 261 HNC patients who received CRT were treated. The starting dose of cisplatin were 80mg/m2 in 118 patients vs 100mg/m2 in 143 patients, respectively. There were more patients over 70 years who received cisplatin in 80mg/m2 than 100mg/m2 (27.1% vs 4.2%, $p < 0.001$). The mean Creatinine Clearance (Ccr) obtained using the Cockcroft-Gaut at baseline was significantly lower in 80mg/m2 than 100mg/m2 (87.82 vs 97.28, $p = 0.0022$). There were no significantly differences in patient's other characteristics as follows gender, performance states, pathology. The incidence of Grade 2 or higher elevation in creatinine was 2 (1.7%) in 80mg/m2 group and 4 (2.8%) in 100mg/m2 group, respectively ($p = 0.554$). The rate of change in CCR showed no difference between both groups (-5.73% in 80mg/m2 vs -7.63% in 100mg/m2, $p = 0.2927$), either. The rate of cumulative dose of cisplatin ≧200mg/m2 was significantly higher in 100mg/m2 than 80mg/m2 (97.2% vs 72.0%, $p < 0.001$). 2-year PFS rate was not significantly different between 80 mg/m2and 100 mg/m2 in oropharynx (89.3% vs 88.2%, $p = 0.7760$) and in hypopharynx/ larynx (70.28% vs 80.92%, $p = 0.4740$), respectively.

Conclusions: Cisplatin dose of CRT for HNC patients in 100mg/m2was feasible without increasing the nephrotoxicity and the rate of cumulative dose of cisplatin ≧ 200mg/m2was higher compared to 80mg/m2.

1114P Comparison of treatment outcomes and tolerability of patients with recurrent (R) nasopharyngeal carcinoma (NPC) and metastatic disease at diagnosis (M1): A retrospective analysis

C. Sookthon[1], P. Pattaranutaporn[2], C. Jiarpinitnun[2], N. Ngamphaiboon[3]

[1]Medicine, Ramathibodi Hospital, Bangkok, Thailand, [2]Radiology, Ramathibodi Hospital, Bangkok, Thailand, [3]Medicine, Division of Medical Oncology, Ramathibodi Hospital, Bangkok, Thailand

Background: In current clinical trials and practice, patients with R and M1 NPC are considered the same entity and typically received similar systemic treatments. However, natural history, treatment outcomes and tolerability of systemic chemotherapy between both groups remains unknown.

Methods: R and M1 NPC patients were identified. Patient characteristics, treatment modalities, tolerability, and survival outcome were retrospectively abstracted. Tolerability of chemotherapy was defined by dose reduction, hospitalization, delayed, and/or termination of chemotherapy.

Results: A total of 144 NPC patients (R = 98, M1=46) were analyzed. In R patients, locoregional recurrence and distant metastasis were observed in 30% and 66%, respectively. In R group, median time to recurrence was 16.6 months. Median OS of M1 patients was not difference from R group (12.3 vs 11.8 months; $p = 0.09$). However, patients with M1 had shorter OS when compared with locoregional group (12.3 vs 26.7 months; $p = 0.01$). Patients who received doublet had longer OS than single agent chemotherapy in both groups. There was no different in OS between 1st line cisplatin- and carboplatin-based chemotherapy in R group (34.2 vs 19.3 months; $p = 0.15$), but significant difference in M1 patients (14.7 vs 12.3 months; $p = 0.05$). Tolerability to systemic chemotherapy were comparable among R and M1 NPC patients.

Table: 1114P

Characteristic	Metastasis at diagnosis N = 46 (%)	Recurrence N = 98(%)	P-value
Baseline Patient Characteristics			
-Median age (range)	56(29-75)	50(19-79)	0.17
-male	34 (73.9)	75 (76.5)	0.73
-smoker	21(45.7)	42(42.9)	0.84
ECOG 0-1 >2	41 (89.1) 3 (6.5)	95 (96.9) 2 (2.0)	0.18
chemotherapy			
1st line	33 (71.7)	66(67.3)	0.60
2nd line	15 (32.6)	28 (28.6)	0.62
>=3rd line	7 (15.2)	11 (11.2)	0.50
doublet single	32(69.6) 0	53(54.1) 11 (11.2)	0.01
cisplatin carboplatin	22(47.8) 10(21.7)	12(12.2) 41(41.8)	<0.01

Conclusions: There was no different in tolerability and survival of R and M1 NPC patients. Physicians should expect similar outcomes of R and M1 NPC patients who received systemic chemotherapy.

1115P Impact of the multidisciplinary approach on the survival of squamous head and neck cancer in our institution

M.J. Martínez-Ortiz[1], Á. Martínez-Ortiz[2], G. Marín-Zafra[1], P. Cerezuela-Fuentes[1], J. Balsalobre[1], J.A. Díaz-Manzano[3], J. Trujillo-Santos[4], M.T. García-García[1]

[1]Medical Oncology, Hospital Universitario Santa Lucia, Cartagena, Spain, [2]Radiotherapy and Radiology, Hospital Universitario Santa Lucia, Cartagena, Spain, [3]ORL, HCUV Arrixaca, Murcia, Spain, [4]Internal Medicine, Hospital Universitario Santa Lucia, Cartagena, Spain

Background: Our hospital has about 650 beds. Since 2008, the multidisciplinary tumours team (MDT) evaluates once a week, all new cases of head and neck cancer, approximately 75/year. The main objective is to ascertain the 2-year survival of patients with squamous cell cancer of the head and neck (HNSCC) treated by a MDT and without an MDT, determining whether there are statistically significant differences.

Methods: Observational retrospective study of two cohorts, which aims to analyse the survival in the cohort by an MDT (C1, those from 01/01/2005 to 12/31/2008) with respect to the cohort without an MDT (C2, 01/01/2009 to 12/31/2012). We included all patients with an initial diagnosis of HNSCC at our centre. With access to the Pathological Anatomy database, the records of the MDT, the medical history, we collected the primary endpoint (survival at 2 years) and characteristics related to the patient, tumour, treatment and tracking (date and cause of death). Definitive sample consists of 408 patients, 200 in pre-MDT cohort and 208 in post-MDT cohort. A descriptive analysis is given of the demographic, clinical and epidemiological characteristics of the sample and a survival analysis with rates calculated using the Kaplan Meier method. The log-rank test was used to assess the differences in survival between cohorts, and a Cox proportional-hazards regression model was used to perform the univariate and multivariate survival analysis.

Results: Our population presents age (mean) 64.2y (SD 12.4), male 82.6%, ECOG<2 89%, 32.1% laryngeal location, tumour stage IVA 31.6%. Treatment with surgery (S) 43.4%. From our comparative analysis we want to highlight (C1 vs C2) 2-years OS was 59.5% and 70.2% ($p = 0.042$). After univariate and multivariate survival analysis, MDT is an independent variable of better prognosis in terms of overall survival in our study (HR 0.696).

Conclusions: The population served in our area presents demographic and clinical and epidemiological characteristics similar to those of other series published in our country. There is a statistically significant improvement in the survival of patients treated by MDT, this approach being an independent variable of better prognosis in terms of overall survival in our study.

1125P Prophylactic versus reactive nutritional supplement in local advanced nasopharyngeal carcinoma patients receiving radical chemo-radiotherapy

Y-Y. Chen, S. Huang, X. Chen, Q. Hu

Radiation Oncology, Zhejiang Cancer Hospital, Hangzhou, China

Background: The aim of this study was to investigate the effect of prophylactic versus reactive nutritional supplement on nutritional status and treatment tolerance in local advanced nasopharyngeal carcinoma (NPC) patients receiving neoadjuvant chemotherapy (NACT) and concurrent chemoradiotherapy (CCRT).

Methods: NPC patients were randomly assigned to prophylactic nutritional intervention group (A) or the control group (B). Patients in group A were supported with enteral nutrition supplement except daily diet from the beginning of radiotherapy (RT). Nutritional intervention aimed to reach 30 kcal/kg/d. Group B was treated with conventional diet guidance at first, appropriate nutritional intervention will be given when serious malnutrition (PG-SGA≥4) appeared. Weight and nutritional questionnaires (NRS 2002, PG-SGA) were collected at the baseline, before, during and after CCRT.

Results: From October 2016 to May 2018, 114 patients from our cancer center were randomly assigned to the group A and B (58 vs 56). The completion rates of NACT and RT were 88.6% and 100%. 80.7% of patients completed CCRT (A vs B = 90% vs 71%, P = 0.013, 95%IC=0.038-0.326). Grade 3/4 mucositis and grade 2/3 skin reaction were observed in 26.3% and 23.7% of patients. Though more serious radiation reactions were observed in group B, no statistical difference between group A and B (22.4% vs 30.4% and 21% vs 27%, $P > 0.05$). All patients experienced weight loss during the NACT and CCRT. Comparing to baseline, the rate of weight loss ≥5% and≥10% before, during, after RT and 1 month after RT were 3.5%, 28.9%, 29.8%, 64.7% and 0, 4.4%, 18.4%, 31%. The overall incidence of PG-SGA≥4 and ≥9 were32.6%, 39%, 95.9%, 100%, 78.7% and 2.3%, 10.5%, 50%, 72.3%, 14.8%, respectively. But the repeated measures showed that the difference of weight loss and PG-SGA scores between two groups were not significant ($P > 0.05$).

Conclusions: Malnutrition risk was gradually increased during the treatment of NPC.Prophylactic nutritional intervention can improve the tolerance of concurrent chemotherapy, but it has no advantage in weight loss and scores of short-term nutritional assessments.

Clinical trial identification: NCT02948699.

1116TiP A randomized phase III study to evaluate the value of the omission of prophylactic neck dissection for stage I/II tongue cancer (RESPOND: JCOG1601)

N. Hanai[1], T. Asakage[2], N. Kiyota[3], A. Homma[4], N. Monden[5], H. Fukushima[6], T. Fujii[7], T. Ogawa[8], K. Tanaka[9], J. Mizusawa[10], J. Eba[11], R. Hayashi[12]

[1]Head and Neck Surgery, Aichi Cancer Center Hospital, Nagoya, Japan, [2]Department of Head and Neck Surgery, Graduate School of Medicine, Tokyo Medical and Dental University, Tokyo, Japan, [3]Medical Oncology/Hematology, Kobe University Hospital, Kobe, Japan, [4]Otolaryngology-Head and Neck Surgery, Hokkaido University, Sapporo, Japan, [5]Head and Neck Surgery, National Hospital Organization Shikoku Cancer Center, Matsuyama, Japan, [6]Department of Otolaryngology-Head and Neck Surgery, Cancer Institute Hospital, Tokyo, Japan, [7]Department of Otolaryngology, Osaka International Cancer Institute, Osaka, Japan, [8]Department of Otorhinolaryngology, Head and Neck Surgery, Tohoku University Graduate School of Medicine, Sendai, Japan, [9]1 JCOG Data Center/Operations Office, National Cancer Center Hospital, Tokyo, Japan, [10]JCOG Data Center/ Operations Office, National Cancer Center, Tokyo, Japan, [11]JCOG Data Center, National Cancer Center, Tokyo, Japan, [12]Head and Neck Surgery, National Cancer Center Hospital East, Kashiwa, Japan

Background: The standard local treatment for early-stage tongue cancer with no clinical lymph node metastases is partial glossectomy. However, whether or not prophylactic neck dissection (ND) should be performed has been controversial. In 2015, D'Cruz et al. reported that prophylactic ND contributes to the improvement of overall survival (OS) for clinical T1-2N0 tongue cancer regardless of the depth of invasion (DOI). However, considering the occult lymph node metastasis of 30% and disadvantages associated with prophylactic ND such as cosmetic issues and complications including accessory and facial nerve paralysis, partial glossectomy alone can still be regarded as a treatment option for patients (pts) carefully selected by DOI, provided there is appropriate follow-up with full use of computed tomography (CT) and other diagnostic imaging modalities to detect recurrence early enough to conduct salvage surgery.

Trial design: We have commenced a phase III randomized controlled trial to confirm the non-inferiority of glossectomy alone compared to glossectomy with prophylactic ND (standard arm) in terms of OS. Histologically proven stage I/II tongue cancer with DOI 3-10 mm by enhanced magnetic resonance imaging is eligible. The selection based on the DOI is a novel aspect of this study. We set the key inclusion criterion of DOI as 3-10 mm since prophylactic ND is unnecessary for pts with DOI < 3 mm according to the data from D'Cruz et al, and pts with DOI > 10 mm are classified as T3 according to the 8th TNM classification. The primary endpoint is OS. The secondary endpoints include relapse-free survival (RFS), local-RFS, proportion of non-resectable recurrence, proportion of neck lymph node recurrence, and adverse events. We assumed a 5-year OS of 85% in the standard arm and set the non-inferiority margin at 7.5%. The sample size was set at 440 pts, with a one-sided α of 5%, power of 70%, an accrual period of 5 years, and a follow-up period of 5 years. For follow-up observation, CT is essential at 3, 6, 12, 18, and 24 months postoperatively and then annually thereafter. Enrollment launched November, 2017 and five pts were enrolled as of April 2018.

Clinical trial identification: UMIN000030098.

Legal entity responsible for the study: National Cancer Center.

1117TiP IMvoke010: Randomized phase III study of atezolizumab (atezo) as adjuvant monotherapy after definitive therapy of squamous cell carcinoma of the head and neck (SCCHN)

R. Haddad[1], D.J. Wong[2], Y. Guo[3], J. Fayette[4], E.E.W. Cohen[5], M. Kowgier[6], A. Sandler[7], C. Matheny[8], F. Kabbinavar[9], D. Raben[10]

[1]Department of Adult Oncology, Dana-Farber Cancer Institute, Boston, MA, USA, [2]Medicine, Hematology/Oncology, University of California Los Angeles, Los Angeles, CA, USA, [3]Department of Clinical Chinese Medicine, Tongji University East Hospital, Shanghai, China, [4]ENT, Lung, Sarcomas and GIST, Centre Léon Bérard, Lyon, France, [5]Moores Cancer Center, University of California San Diego, La Jolla, CA, USA, [6]Biostatistics, F. Hoffmann-La Roche, Ltd, Mississauga, ON, Canada, [7]Product Development - Oncology, Genentech Inc. - Roche - USA, South San Francisco, CA, USA, [8]Product Development - Oncology, Genentech, Inc, South San Francisco, CA, USA, [9]PDO, Genentech, Inc, San Francisco, CA, USA, [10]Radiation Oncology, University of Colorado, Denver, CO, USA

Background: Locally advanced SCCHN is associated with a high risk for local recurrence and distant metastases. Treatment includes a combination of surgery, radiation therapy and chemotherapy to optimize the chances for long-term disease control and improved survival. After definitive local therapy, patients (pts) are monitored for local recurrence and/or distant metastases as standard of care. No effective systemic adjuvant treatment has been identified. Atezo is an anti–programmed death-ligand 1 (PD-L1) monoclonal antibody that prevents PD-L1 from binding to its receptors PD-1 and B7.1, thereby restoring anti-tumor immunity. Efficacy results from a cohort of pts with recurrent/metastatic SCCHN in the Phase I PCD4989g study suggest that atezo offers a potential clinical benefit. The objective of IMvoke010 (NCT03452137) is to evaluate the efficacy and safety of adjuvant atezo in pts with locally advanced SCCHN who are at high risk for disease recurrence or progression following definitive curative therapy.

Trial design: IMvoke010 is a global, double-blind, placebo-controlled, randomized Phase III trial enrolling pts who have completed definitive local/regional therapy for Stage III human papillomavirus (HPV)-positive oropharyngeal carcinoma or Stage IVA or IVB HPV-negative SCCHN involving the oral cavity, oropharynx, larynx or hypopharynx and are at high risk for disease recurrence or progression. Approximately 400 pts will be randomized 1:1 to receive placebo or atezo 1200 mg Q3W for up to a year ($\leq$16 cycles) or until unacceptable toxicity, disease recurrence or progression. Pts with nasopharyngeal carcinoma, metastatic disease, or progressive disease during or at completion of definitive local therapy will be excluded. Stratification factors include HPV status, response to definitive local therapy and whether primary surgery was performed as part of definitive therapy. Primary endpoints are independent review facility-assessed event-free survival (EFS) and overall survival. Key secondary endpoints include investigator-assessed EFS, safety, and patient reported outcomes. Exploratory biomarkers will also be assessed.

Clinical trial identification: NCT03452137.

1118TiP A phase I/II dose escalation study of the CDK4/6 inhibitor, palbociclib in combination with cetuximab and intensity modulated radiation therapy (IMRT) for locally advanced squamous cell carcinoma of the head and neck (SCCHN)

N. Ngamphaiboon[1], S. Lukerak[1], C. Jiarpinitnun[2], A. Jinawath[3], N. Jinawath[4], J. Juengsamarn[1], L. Arsa[3], J. Konmun[5], N. Kongsuphon[5], N. Sankaseam[1], E. Sirachainan[1], P. Witoonpanich[2], A. Kositwattanarerk[2], P. Pattaranutaporn[2]

[1]Medicine, Ramathibodi Hospital, Bangkok, Thailand, [2]Radiology, Ramathibodi Hospital, Bangkok, Thailand, [3]Pathology, Ramathibodi Hospital, Bangkok, Thailand, [4]Traslational Medicine, Ramathibodi Hospital, Bangkok, Thailand, [5]Pharmacy, Ramathibodi Hospital, Bangkok, Thailand

Background: Alterations in CDK4-cyclin D-retinoblastoma (Rb) pathway may lead to carcinogenesis in many cancers. Human Papilloma Virus (HPV) plays a major role in SCCHN carcinogenesis. It induces many alterations in the CDK4-Cyclin D-Rb and apoptotic pathways such as up-regulation of p16, loss of Rb and p53 functions. Loss of p16 expression is known as a poor prognostic marker in SCCHN for survival. A novel therapy for p16/HPV-negative SCCHN is clearly an unmet medical need. Palbococlib is an orally active, highly selective inhibitor of the CDK4/6 with ability to block Rb phosphorylation. In a phase I study of palbociclib and cetuximab in refractory recurrent/metastatic SCCHN, the maximum tolerated dose (MTD) was not reached. In addition, palbociclib showed a radiosensitization property in a preclinical study. Thus, addition of palbociclib to cetuximab and IMRT provides a strong rationale to improve an efficacy for treatment of locally advanced SCCHN, especially in p16/HPV-negative tumor.

Trial design: This is a dose escalation phase I/II study designed to determine the MTD and toxicity of palbociclib, cetuximab, and IMRT for locally advanced SCCHN, using a classical 3 + 3 design. The study included locally advanced SCCHN of oral cavity, oropharynx, larynx, and hypopharynx. Nasopharyngeal carcinoma and other SCCHNs were excluded. Palbociclib has been escalated in 3 dose levels (DLs), starting from 75 mg, and escalated to 100 and 125 mg PO daily for 21 days on and 7 days off for 2 cycles. In all DLs, cetuximab was given at 400 mg/m^2 IV on day -7 and then 250 mg/m^2 IV weekly for 7 weeks. IMRT was delivered 5 days on and 2 days off with a total dose of 70 Gy for 33 fractions. At the MTD or RP2D, we will accrue up to 15 locally advanced p16-negative SCCHN patients to allow for definitive evaluation of tolerability, correlative endpoints and preliminary efficacy. Potential biomarkers involving the CDK4-cyclin D-Rb pathway alterations and HPV status will be explored. To date, a total of 8 patients were accrued in the study. The latest patient was accrued to the DL3 cohort, which is the last dose level.

Clinical trial identification: NCT03024489.

1119TiP Randomized phase II multicenter study comparing modified PFE regimen with modified TPEx regimen in recurrent or metastatic squamous cell carcinoma of the head and neck: TEMPER study

M. Shimokawa[1], M. Suzuki[2], M. Sugasawa[3], K. Shiga[4], T. Satoh[5], H. Inohara[6]

[1]Clinical Research Institute, National Kyushu Cancer Center, Fukuoka, Japan, [2]Department of Otorhinolaryngology for Head and Neck Surgery, Osaka University Graduate School of Medicine, Suita, Japan, [3]Department of Head and Neck Surgery, Saitama Medical University International Medical Center, Hidaka, Japan, [4]Department of Head and Neck Surgery, Iwate Medical University School of Medicine, Morioka, Japan, [5]Department of Frontier Science for Cancer and Chemotherapy, Osaka University Graduate School of Medicine, Suita, Japan, [6]Department of Otorhinolaryngology for Head and Neck Surgery, Osaka University, Osaka, Japan

Background: Recurrent or metastatic squamous cell carcinoma of the head and neck have a poor prognosis. The PFE (Platinum, 5-FU and Cetuximab) regimen is established as the first-line standard therapy in the world, as per a Phase III study conducted in Europe. A phase II study conducted in China suggested that lower dose of cisplatin and 5-FU achieve similar outcome than PFE in an Asian population with an acceptable toxicity profile. In a phase II study, TPEx (Docetaxel, Platinum and Cetuximab) regimen showed favorable overall survival and response rate when indirectly compared to the PFE regimen. Administration of the TPEx regimen in Asian population is likely to be more toxic than in Caucasian patients. Therefore, we considered to compare the modified TPEx regimen and the modified PFE regimen to assess the efficacy and safety of this regimen.

Trial design: TEMPER is open-label, randomized, a multicenter phase II study comparing modified TPEx regimen vs. modified PFE regimen as the first-line treatment with recurrent or metastatic squamous cell carcinoma of the head and neck. Patients will be allocated randomly (1:1) to the two treatment groups with dynamic allocation method. Treatment will be stratified by ECOG PS, p16-positive oropharynx carcinoma and history of chemotherapy. The primary endpoint is progression-free survival. Secondary endpoints are response rate, adverse events and overall survival. A median progression-free survival of 6.0 months is assumed for the modified PFE, and 148 events are deemed necessary to detect a hazard ratio of 0.71 in modified TPEx, with 80% power and a two-sided significance level of 20%. The target sample size is set at 180 patients (90 patients in both groups), allowing for dropouts. Clinical trial information: UMIN000025436. This study is supported by Merck KGaA.

1120TiP Randomized phase III study in EBV positive locally advanced nasopharyngeal carcinoma treated with concurrent chemo-radiotherapy with or without anti-viral drug

K. Alsaleh[1], A. Elbasmi[2], A. Hussein[1], F. Alshaflan[3], M. El-Sherify[1]

[1]Radiation Oncology Department, Kuwait Cancer Control Centre Al Sabah Hospital, Shuwaikh, Kuwait, [2]Cancer Registry Department, Kuwait Cancer Control Centre Al Sabah Hospital, Shuwaikh, Kuwait, [3]Virology Department, Kuwait Cancer Control Centre Al Sabah Hospital, Shuwaikh, Kuwait

Background: Nasopharyngeal is relatively prevalent in South East Asia and mainland China, northern Africa and Alaska. For advanced disease, there is a greater than 50% risk of recurrence after radiotherapy (RT) alone, and approx. half of all recurrences are distant failures. A meta-analysis of 6 randomized trials showed that addition of chemotherapy (CT) to RT significantly improved disease-free/ progression-free survival rates by 34% to 40% respectively. Epstein-Barr virus (EBV) has yielded significant insight into pathogenesis of NPC. It is undifferentiated form of NPC that shows most consistent worldwide association with EBV suggesting that targeted approaches should be considered for preventive and therapeutic intervention. The prognostic value of pre-treatment EBV DNA viral load for non-endemic areas proved in retrospective study conducted in Italy, disease free survival (DFS) and over all survival (OS) were significantly longer in patients with pre-treatment negative EBV DNA than in positive patients. Antiviral drugs have been used to inhibit EBV replication and target viral DNA polymerase Aim of this study is to define the efficacy of adding anti-viral treatment to eliminate PCR-DNA EBV in patients with NPC. It will also be correlated with the response rate (RR), local control, DFS, and OS.

Trial design: Patients and Methods: All patients with diagnosis of nasopharyngeal squamous cell carcinoma, . Patients should have positive PCR-DNA EBV. Patients will receive concurrent chemoradiotherapy which consisted of Cisplatin 40 mg/m2 weekly or 100mg/m2 every 3 weeks with IMRT 70Gy/35 fractions. Randomization to antiviral therapy acyclovir tablets 800 mg/day during the whole course of treatment Or Placebo. We aim to enroll 100 patients for study with 2:1 randomization. Follow up with PCR-DNA EBV will be done mid-treatment and immediately after treatment then with usual follow up of the NPC cases.

Legal entity responsible for the study: Radiation Oncology Department, Kuwait Cancer Control Center.

Funding: Has not received any funding.

Disclosure: All authors have declared no conflicts of interest.

1121TiP KEYNOTE-412: Phase III study of pembrolizumab plus chemoradiation vs chemoradiation alone for locally advanced head and neck squamous cell carcinoma (HNSCC)

J-P. Machiels[1], L. Licitra[2], Y.G. Tao[3], C-J. Yen[4], D. Rischin[5], J.N. Waldron[6], B.A. Burtness[7], V. Gregoire[1], S.S. Agarwala[8], J. Yorio[9], J-P. Delord[10], S. Aksoy[11], S. Ikeda[12], R-L. Hong[13], J.Y. Ge[14], H. Brown[14], B. Bidadi[14], L.L. Siu[6]

Background: Preclinical data suggest improved tumor growth control and survival when radiation therapy (RT) is combined with a PD-1 inhibitor. Pembrolizumab is effective for treatment of recurrent/metastatic HNSCC, and initial results from a phase 1b study suggest that pembrolizumab plus chemoradiation therapy (CRT) is tolerable in patients with locally advanced (LA) HNSCC. KEYNOTE-412 (NCT03040999) is a phase 3, randomized, placebo-controlled, double-blind trial to determine efficacy and safety of pembrolizumab plus CRT and as maintenance therapy vs placebo plus CRT in LA-HNSCC.

Trial design: Eligibility criteria are age ≥18 years; newly diagnosed, treatment-naive, oropharyngeal p16–positive (any T4 or N3), oropharyngeal p16–negative (any T3-T4 or N2a-N3), or larynx/hypopharynx/oral cavity (any T3-T4 or N2a-N3) SCC; evaluable tumor burden (RECIST v1.1); and ECOG performance status 0/1. Patients will be randomly assigned (1:1) to receive pembrolizumab 200 mg every 3 weeks plus cisplatin-based CRT or placebo plus cisplatin-based CRT. Treatment will be stratified by RT regimen (accelerated RT [56-70 Gy, 6 fractions/week for 6 weeks] or standard RT [56-70 Gy, 5 fractions/week for 7 weeks]), tumor site/p16 status (oropharynx p16 positive vs p16 negative or larynx/hypopharynx/oral cavity), and disease stage (III vs IV). Priming dose of pembrolizumab or placebo will be given 1 week before CRT, followed by 2 doses during CRT, and an additional 14 doses after CRT, for a total of 17 pembrolizumab or placebo infusions. Response will be assessed by MRI and CT 12 weeks after CRT, every 3 months for 3 years, then every 6 months for years 4 and 5. Treatment will be discontinued at time of centrally confirmed disease progression, unacceptable toxicity, or patient/physician decision to withdraw. Patients will be evaluated to determine necessity of neck dissection 12 weeks after completion of CRT. Primary end point is event-free survival and secondary end points are overall survival, safety, and patient-reported outcomes. Biomarkers will be an exploratory end point. Recruitment is ongoing in 21 countries and will continue until ∼780 patients are enrolled.

Clinical trial identification: NCT03040999, trial initiation date: 2/2/17.

1122TiP Pembrolizumab in patients with recurrent or metastatic cutaneous squamous cell carcinoma (cSCC): The phase II KEYNOTE-629 study

L.F. Licitra[1], L.L. Siu[2], E.E.W. Cohen[3], P. Zhang[4], B. Gumuscu[4], R. Swaby[4], K. Harrington[5]

[1]Head and Neck Medical Oncology Unit, Fondazione IRCCS Istituto Nazionale dei Tumori, University of Milan, Milan, Italy, [2]Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada, [3]Department of Translational Science, University of California San Diego Health, Moores Cancer Center, La Jolla, CA, USA, [4]Medical Oncology, Merck & Co, Inc, Kenilworth, NJ, USA, [5]Head and Neck/Skin Units, The Institute of Cancer Research, London, UK

Background: There are no approved treatments or standard of care for recurrent or metastatic cSCC. Effectiveness of common therapies for cSCC is limited. Regimens effective for SCC of the head and neck (HNSCC) may also be effective for cSCC. Pembrolizumab is a programmed death 1 (PD-1) inhibitor that directly blocks the interaction between PD-1 and its ligands, PD-L1 and PD-L2. Evidence of pembrolizumab efficacy and safety has been shown in patients with recurrent or metastatic HNSCC in the phase 1b KEYNOTE-012 study. The single-arm, open-label phase 2 KEYNOTE-629 trial will be conducted to evaluate the efficacy and tolerability of pembrolizumab in patients with previously treated recurrent or metastatic cSCC (NCT03284424).

Trial design: Patients will be given pembrolizumab 200 mg every 3 weeks by intravenous infusion, continued for 35 doses (∼2 years) or until disease progression, unacceptable toxicity, intercurrent illness, nonadherence, or investigator or patient decision to withdraw. Radiographic imaging will be performed every 6 weeks for year 1 and every 9 weeks thereafter. Adverse events will be monitored and graded per National Cancer Institute Common Terminology Criteria for Adverse Events, version 4.0. Key inclusion criteria are age ≥18 years; histologically confirmed cSCC as the primary site of malignancy; metastatic disease or locally recurrent disease not curable by surgery or radiation; measurable disease per RECIST v1.1; and Eastern Cooperative Oncology Group performance status 0/1. There is no requirement for prior chemotherapy or biological systemic treatment for incurably recurrent/metastatic disease. Primary end point is objective response rate per RECIST v1.1 assessed by blinded independent central review. Secondary end points are duration of response, disease control rate (complete or partial response or stable disease for ≥12 weeks), progression-free survival per RECIST v1.1, overall survival, safety, and tolerability. Pharmacokinetics, biomarkers, and health-related quality of life will be evaluated as exploratory end points. Recruitment is ongoing in 10 countries and will continue until 100 patients are enrolled.

Clinical trial identification: NCT03284424. Trial initiated September 15, 2017.

1123TiP A randomized phase II study of cisplatin plus radiotherapy versus durvalumab plus radiotherapy followed by adjuvant durvalumab versus durvalumab plus radiotherapy followed by adjuvant tremelimumab and durvalumab in intermediate risk, HPV-positive, locoregionally advanced oropharyngeal squamous cell cancer (LA-OSCC) (Canadian Cancer Trials Group HN.9)

A. Spreafico[1], K. Sultanem[2], B. Chen[3], S.V. Bratman[4], J. Ringash[4], A.V. Louie[5], A. McNiven[4], K. Whelan[3], J. Hilton[6], J. Yoo[7], J-P. Machiels[8], L.F. Licitra[9], S. Oosting[10], J.N. Waldron[11], L.L. Siu[11], W.R. Parulekar[12]

[1]Medical Oncology and Hematology, Princess Margaret Cancer Center, Toronto, ON, Canada, [2]Radiation Oncology, The Jewish General Hospital, Montreal, Montreal, QC, Canada, [3]HN, Canadian Cancer Trial Group, Kingston, ON Canada, Kingston, ON, Canada, [4]Radiation Oncology, Princess Margaret Cancer Center, Toronto, ON, Canada, [5]Radiation Oncology, London Health Science Centre, London, ON, Canada, [6]Medical Oncology, The Ottawa Hospital Regional Cancer Centre, Ottawa, ON, Canada, [7]Surgical Oncology, London Health Science Centre, London, ON, Canada, [8]Oncology, Cliniques Universitaires St. Luc, Brussels, Belgium, [9]Head and Neck Medical Oncology Unit, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [10]Medical Oncology, University Hospital Groningen (UMCG), Groningen, Netherlands, [11]Medical Oncology, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada, [12]Oncology and Medicine, Canadian Cancer Trial Group, Kingston, ON Canada, Kingston, ON, Canada

Background: Definitive cisplatin-based chemoradiotherapy (CRT) in patients (pts) with locoregionally advanced head and neck SCC is associated with acute and long-term toxicities. Immune checkpoint inhibitors, such as anti-PD1/L1 and anti-CTLA4 antibodies, are actively being investigated in this disease setting. HN.9 evaluates a chemosparing approach in pts with HPV+ intermediate risk LA-OSCC (defined by AJCC 8th edition as: T1-2N1 smokers; T3N0-N1 smokers and T1-3N2 any smoking history).

Trial design: CCTG HN.9 is a non-comparative, randomized phase II study in intermediate risk HPV+ LA-OSCC. Pts will be randomized at a 1:1:1 ratio to: CRT (arm A); immunoradiotherapy (IRT) with durvalumab (durva) followed by durva maintenance (Arm B); IRT followed by durva and tremelimumab (treme) maintenance (Arm C). Treatment schedule: 70 Gy/35 over 7 weeks (RT) + cisplatin 100mg/m2 d1, 22, 43 (Arm A); RT + durva 1500 mg d-7, 22 (IRT) followed by Q4W for 6 doses (Arm B); IRT followed by durva Q4W for 6 doses + treme Q4W for 4 doses (Arm C). Key eligibility criteria: intermediate risk HPV+ LA-OSCC; adequate organ function; no autoimmune disorders; no immunosuppressive therapy. Pts will be stratified by smoking status, age, ECOG PS and TNM classification. The primary objective is to estimate the efficacy of the 3 treatment arms in terms of event-free survival (EFS). Secondary objectives: overall survival; locoregional control; distant metastasis-free survival; quality of life and swallowing assessments; economic evaluation. Correlative studies include: immunophenotyping, radiomic, ctDNA, microbiome analyses. The planned sample size is 240 pts over 2.5 years with 3 years follow-up. Assuming the new treatment will improve 3-years EFS from 83 to 91%, with one-sided type I error of 0.1, 80 pts/arm, the study will have 80% of power to reject the null hypothesis (3-year EFS rate is 83% or lower). Study activation: April 2018.

Clinical trial identification: NCT03410615.

Editorial acknowledgement: Supported by AstraZeneca.

1124TiP Randomized, phase II study of ficlatuzumab with or without cetuximab in patients (pts) with cetuximab-resistant, recurrent/metastatic (R/M) head and neck squamous cell carcinoma (HNSCC)

J.E. Bauman

Medicine, University of Arizona Cancer Center, Tucson, AZ, USA

Background: Cetuximab, an anti-EGFR monoclonal antibody (mAb), is approved for R/M HNSCC but only a minority benefits. c-Met and EGFR signaling converge at the PI3K/Akt and MAPK nodes. Preclinical evidence shows that c-Met can drive tumor-intrinsic resistance to EGFR inhibition. Ficlatuzumab is an IgG1 mAb against HGF, the sole ligand for cMet. We recently completed a phase Ib study evaluating ficlatuzumab and cetuximab in pts with cetuximab-resistant, R/M HNSCC (Bauman JE et al, ASCO 2017). Twelve pts were treated; 11 were platinum-refractory. Grade 3 adverse events included edema, hypoalbuminemia, infection, and thromboembolism. No DLTs were seen. Median progression-free survival (PFS) at the recommended phase II dose (RP2D) was 6.0 mos (90% CI = 2 mos – not reached). Confirmed overall response rate (ORR) was 17% (90% CI = 0-28%). Clinical benefit rate was 67%. Serum Veristrat, a proteomic classifier predictive of differential treatment benefit from anti-EGFR therapy, did not correlate with PFS. We designed a randomized phase II trial evaluating ficlatuzumab with or without cetuximab in patients with cetuximab-resistant, R/M HNSCC. The combination arm follows the hypothesis that continued anti-EGFR blockade may overcome reciprocal compensation between the EGFR and cMet pathways.

Trial design: This is a multicenter phase II trial with a randomized, non-comparative, 2-arm design (Arm A: ficlatuzumab and Arm B: ficlatuzumab + cetuximab) in pts with R/M HNSCC after failure of cetuximab. Key eligibility criteria include: R/M HNSCC; cetuximab resistance (recurrence during or within 6 mos of cetuximab-radiation or palliative cetuximab); ECOG 0-1; mandatory baseline research biopsy. The primary objective is to assess the efficacy of ficlatuzumab, with or without cetuximab, as measured by PFS. To test the hypothesis that either regimen improves historical PFS from 2 months to 3.33 months requires 66 eligible patients. Key secondary endpoints are ORR and survival. Biomarkers to be correlated with efficacy include tumor HGF/cMet dimers, phosphoproteins, and immunoscores and serum Veristrat. Two of 66 patients have enrolled.

1126TiP Nivolumab and ipilimumab in combination with radiotherapy in patients with locally advanced head and neck cancer

J.M. Johnson[1], V. Bar Ad[2], E. Lorber[1], A. Luginbuhl[3], J.M. Curry[3], D. Cognetti[3], S. Keith[4], R. Axelrod[1], R. Zinner[1], U. Rodeck[5], L.A. Harshyne[6], A. Argiris[7]

[1]Department of Medical Oncology, Thomas Jefferson University, Philadelphia, PA, USA, [2]Department of Radiation Oncology, Thomas Jefferson University, Philadelphia, PA, USA, [3]Department of Otolaryngology, Thomas Jefferson University, Philadelphia, PA, USA, [4]Department of Pharmacology & Experimental Therapeutics, Thomas Jefferson University, Philadelphia, PA, USA, [5]Department of Dermatology and Cutaneous Biology, Thomas Jefferson University, Philadelphia, PA, USA, [6]Department of Neurosurgery, Thomas Jefferson University, Philadelphia, PA, USA, [7]Medical Oncology, Hygeia Hospital, Athens, Greece

Background: Definitive treatment of locally advanced squamous cell carcinoma of the head and neck (LA SCCHN) often incorporates concurrent chemoradiotherapy. Platinum agents have been the backbone of systemic therapy in combined modality approaches. However, the addition of cisplatin to radiotherapy (RT) results in a modest survival benefit and is associated with multiple acute and late toxicities. The study of alternative approaches is warranted. Nivolumab (nivo), a fully human anti-programmed cell death-1 (PD-1) monoclonal antibody (mAb), has demonstrated a survival advantage when compared with standard treatment in patients with platinum-refractory recurrent or metastatic SCCHN. Combination of nivo with the CTLA-4 directed mAb ipilimumab (ipi) has yielded improvements in antitumor activity in melanoma and is under investigation in multiple other solid tumor types including SCCHN. Similarly, the combination of RT and immunotherapy leads to synergistic effects in the laboratory and has promise in early phase clinical trials. This clinical trial combines immunotherapy and RT to build upon these observations.

Trial design: This is a single arm pilot trial that enrolls previously untreated patients with LA SCCHN who are candidates for curative intent, including stage IVA-B tumors of the oral cavity, oropharynx, hypopharynx, and larynx. HPV+ oropharyngeal tumors must be staged as T4, or N2c or N3 by AJCC 7th edition. Nivo and ipi are initiated 2 weeks prior to the beginning of RT. Nivo 3 mg/kg is administered every 2 weeks IV for a total of 17 doses and ipi 1 mg/kg is administered every 6 weeks for a total of 6 doses. RT (using IMRT) is prescribed as 2 Gy/fraction/day to a total dose of 70 Gy. The primary objective is the safety of the combination of nivo and ipi with RT with a focus on in-field toxicities (mucositis, dermatitis, edema, bleeding) with secondary endpoints of 1-year PFS, ORR, and OS. Exploratory correlative studies include tumor PD-L1 expression, tumor immune bias via the Th1/Th2 ratio, and exosome quantity and composition. The sample size is 24 patients following a two-stage design with 12 patients enrolled in the first stage and 12 more in the expansion cohort. Enrollment began in May 2017 and is ongoing.

Clinical trial identification: NCT03162731.

Legal entity responsible for the study: Thomas Jefferson University - Sidney Kimmel Cancer Center.

Background: Therapeutic options for second line metastatic pancreatic ductal adenocarcinoma (PDAC) are limited with FOLFOX or FOLFIRI having mOS of 5-6 months. PDAC has low tumor mutational burden and tumor infiltrating CD8+ T cells are rare, which may explain why immune-oncology approaches to date have been less than promising. Pegilodecakin (AM0010) is a pegylated recombinant human interleukin-10 that stimulates activation, survival and clonal expansion of intra-tumoral, tumor antigen specific CD8+ T cells. Pegilodecakin also up-regulates IFNγ and the expression of MHC, which enables tumor antigen presentation in neoplasias of low mutational burden and promotes immunosurveillance by expanding effector memory T cells (Mumm et al. 2010, 2011). Finally, pegilodecakin reduces tumor inflammatory processes such as angiogenesis and and metastatic dissemination (Oft 2017), the off-target auto-immune side effects of immunotherapy and the inflammatory-related side effects of some chemotherapies, including FOLFOX-induced peripheral neuropathy (Krukowski JNeurosci 2016).

Methods: In a 353 patient phase 1/1b dose escalation and expansion study conducted in the US from 2013 to 2017, 21 heavily pretreated metastatic PDAC subjects received pegilodecakin in combination with FOLFOX. Responses were assessed by irRC. CD8 T cell activity was determined by IHC and TCR clonality in the blood.

Results:

Table: 1143P

Pegilodecakin Regimen	N E (ITT)[2]	Prior Therapies Median (Range)	ORR (%)	CR (%)	DCR (%)	mPFS (mos)	mOS (mos)[3]	One-Year OS (%)	Two-Year OS (%)
Plus FOLFOX[1]	19 (21)	2 (1-5)	15.8	10.5	73.7	2.6	10.2	42.9	28.6

[1]Pegilodecakin 5.0 μg/kg + FOLFOX;

[2]E (evaluable - baseline tumor assessment + >1 post-baseline assessments, and no major protocol deviations); ITT (intent to treat); All treated/safety population: n = 25; 25 pts were treated with pegilodecakin (5 ug/kg) in combination with FOLFOX. 21 out of 25 pts progressed on prior gemcitabine containing regimen and did not receive prior platinum containing therapy.

[3]Subjects with OS > 8 mos had 75-250 CD8+ T cells/mm^2 in the retreatment tumor and had a clonal expansion of new T cell clones in the blood. Data cut on 05.01.18; Median follow-up 26.4 months (22.0-32.0 months).

Grade 3/4 TrAEs included thromobocytopenia (56%), anemia (44%), neutropenia (36%), leukopenia (12%) and fatigue (12%). Grade 1/2 neuropathy was observed in 16% of patients but no grade 3/4 neuropathy.

Conclusions: Pegilodecakin in combination with FOLFOX is well-tolerated in patients with metastatic PDAC, and has a reduced incidence of FOLFOX related neuropathy. Immune activation and overall survival are encouraging in this advanced PDAC population.

Clinical trial identification: NCT02009449.

Background: Responses in NSCLC to agents targeting the PD-1/PD-L1 axis are correlated with PD-L1 expression by immunohistochemistry (IHC), tumor mutational burden (TMB), interferon associated mRNA Expression Profile (GEP) and the absence of liver metastases. Pegilodecakin (AM0010) is a pegylated recombinant human interleukin-10 that stimulates activation, survival and clonal expansion of intra-tumoral, tumor antigen specific CD8+ T cells. Pegilodecakin also up-regulates IFNγ and the expression of MHC, which enables tumor antigen presentation in neoplasias of low mutational burden and promotes immunosurveillance by expanding effector memory T cells (Mumm et al. 2010, 2011). Finally, pegilodecakin reduces tumor inflammatory processes such as angiogenesis and and metastatic dissemination (Oft 2017), the off-target auto-immune side effects of immunotherapy and the inflammatory-related side effects of some chemotherapies.

Methods: In a 353 patient phase 1/1b dose escalation and expansion study, 34 pre-treated NSCLC subjects received pegilodecakin with pembrolizumab or nivolumab. Responses were assessed by irRC. PD-L1 was tested with the 22C3 IHC assay, TMB by whole exome sequencing and pre-treatment GEP by Nanostring.

Results:

Conclusions: Pegilodecakin when added to anti-PD-1 therapy in advanced NSCLC patients was associated with response rates and durability of benefit greater than has been seen with anti-PD-1 alone. Responses were seen in settings in which anti-PD-1 therapy has demonstrated limited benefit, such as absent PD-L1 expression, low TMB and/or the presence of liver metastasis. These preliminary findings support further studies of pegilodecakin with anti-PD-1 therapies.

Clinical trial identification: NCT02009449.

1145P Responses and durability of clinical benefit in triple negative breast cancer patients treated with pegilodecakin monotherapy or in combination with platinum plus taxane-based chemotherapy

A. Naing[1], K.A. Autio[2], G.S. Falchook[3], F. Meric-Bernstam[1], J.K. Litton[4], N.K. Ibrahim[4], A. Hung[5], M. Oft[6], J. Leveque[7], M.R. Patel[8]

[1]Investigational Cancer Therapeutics, Division of Cancer Medicine, MD Anderson Cancer Center, Houston, TX, USA, [2]Medical Oncology, Memorial Sloan Kettering Cancer Center, New York, NY, USA, [3]Drug Development, Sarah Cannon Research Institute, Denver, CO, USA, [4]Breast Medical Oncology, Division of Cancer Medicine, MD Anderson Cancer Center, Houston, TX, USA, [5]Biostatistics, ARMO BioSciences, Redwood City, CA, USA, [6]Pre-Clinical and Clinical Development, ARMO BioSciences, Redwood City, CA, USA, [7]Scientific Affairs, ARMO BioSciences, Redwood City, CA, USA, [8]Oncology, Sarah Cannon Research Institute/Florida Cancer Specialists, Sarasota, FL, USA

Background: Late line, triple negative breast cancer (TNBC) is an unmet need. Pegilodecakin (AM0010) is a pegylated recombinant human interleukin-10 that stimulates activation, survival and clonal expansion of intra-tumoral, tumor antigen specific CD8+ T cells. Pegilodecakin also up-regulates IFNγ and the expression of MHC, which enables tumor antigen presentation in neoplasias of low mutational burden and promotes immunosurveillance by expanding effector memory T cells (Mumm et al. 2010, 2011). Finally, pegilodecakin reduces tumor inflammatory processes such as angiogenesis and and metastatic dissemination (Oft 2017), the off-target auto-immune side effects of immunotherapy and the inflammatory-related side effects of some chemotherapies.

Table: 1144P

Pegilodecakin[1]	N	Prior Therapies	ORR	DCR	mPFS	mOS	irAE[11]	irAE[11]

[7]PD-L1 <1%;
[8]TMB High (tumor mutational burden high) >243 mut/exome;
[9]TMB Low (tumor mutational burden low) <243 mut/exome;
[10]E (evaluable - baseline tumor assessment + >1 post-baseline assessments, and no major protocol deviations); ITT (intent to treat);
[11]irAE - Immune-Related Adverse Events (e.g. pneumonitis, adrenal insufficiency, thyroiditis, hypothyroiditis, hypophysitis, mucositis/stomatis, colitis, hepatitis, cholangitis, polyarthritis, myasthenia gravis, optic neuritis); Data cut on 05.01.18; Median follow-up for pembrolizumab cohort 37.3 months (35.9-39.1 months); Median follow-up for nivolumab cohort 23.2 months (9.1-32.0 months)

Methods: In a 353 patient phase 1/1b dose escalation and expansion study conducted in the US from 2013 to 2017, 18 heavily pretreated TNBC subjects received pegilodecakin alone (N = 8) or in combination with platinum and taxane-based chemotherapy (N = 8) or platinum and gemcitabine chemotherapy (N = 10). Responses were assessed by irRC.

Results: G3/4 TrAEs in monotherapy are anemia (38%), thrombocytopenia (38%) and fatigue (25%); and in the platinum/taxane combo: anemia (75%), neutropenia (75%), thrombocytopenia (75%), leukopenia (50%), and febrile neutropenia (25%); in carbo/gem combo: thrombocytopenia (60%), fatigue (30%) and anemia (20%).

Table: 1145P

Pegilodecakin	N	Prior Therapies	ORR	DCR	mPFS	mOS
Regimen	E (ITT)[5]	Median (Range)	%	%	mos	mos
Monotherapy[1]	4 (8)	5 (3-8)	-	25.0	2.0	5.3
Plus Chemotherapy 1[2]	7 (8)	4 (2-5)	28.6	71.4	3.9	11.2

Pooled Plus Chemotherapy[4]	16 (18)	4 (1-5)	12.5	62.5	3.7	8.0

[1]20μg/kg QD SC;
[2]Pegilodecakin 10 μg/kg + Carboplatin + Paclitaxel or Pegilodecakin 2.5 or 10 μg/kg + Carboplatin + Docetaxel or Pegilodecakin 10 μg/kg + Cisplatin + Paclitaxel or Cisplatin + Docetaxel;
[3]Pegilodecakin 5.0 or 10 μg/kg + Carboplatin + Gemcitabine;
[4]Chemotherapy cohorts 1 & 2 combined;
[5]E (evaluable - baseline tumor assessment + >1 post-baseline assessments, and no major protocol deviations); ITT (intent to treat); Data cut on 05.01.18.

Conclusions: Pegilodecakin in combination with platinum and taxane-based chemotherapy in advanced TNBC was associated with objective responses and durable clinical benefit as measured by disease control and overall survival. These preliminary findings support further studies of pegilodecakin in combination with standard of care chemotherapy in both later and earlier stages patients with TNBC.

Clinical trial identification: NCT02009449.

1146P Durability of clinical benefit in metastatic epithelial ovarian cancer patients treated with pegilodecakin monotherapy or in combination with platinum plus taxane-based chemotherapy

K.A. Autio[1], A. Naing[2], A. Hung[3], M. Oft[4], J. Leveque[5], G.S. Falchook[6]

[1]Medical Oncology, Memorial Sloan Kettering Cancer Center, New York, NY, USA, [2]Investigational Cancer Therapeutics, MD Anderson Cancer Center, Houston, TX, USA, [3]Biostatistics, ARMO BioSciences, Redwood City, CA, USA, [4]Pre-Clinical and Clinical Development, ARMO BioSciences, Redwood City, CA, USA, [5]Scientific Affairs, ARMO BioSciences, Redwood City, CA, USA, [6]Drug Development, Sarah Cannon Research Institute at HealthONE, Denver, CO, USA

Background: Checkpoint inhibition as monotherapy has limited success in advanced metastatic epithelial ovarian cancer (epOC) and strategies to increase immunogenicity are needed. Pegilodecakin (AM0010) is a pegylated recombinant human interleukin-10 that stimulates activation, survival and clonal expansion of intra-tumoral, tumor antigen specific CD8+ T cells. Pegilodecakin also up-regulates IFNγ and expression of MHC, which enables tumor antigen presentation in neoplasias of low mutational burden (eg, epOC) and promotes immunosurveillance by expanding effector memory T cells (Mumm et al 2010, 2011). Pegilodecakin reduces tumor inflammatory processes such as angiogenesis and metastatic dissemination (Oft 2017), the off-target autoimmune side effects of immunotherapy and the inflammatory-related side effects of some chemotherapies. Preclinical data suggest synergy of pegilodecakin in reducing tumor volume when combined with platinum/taxane based chemotherapy.

Methods: In a 353 pt phase 1/1b dose escalation and expansion study conducted in the US (2013-2017), 12 platinum-refractory, heavily pretreated epOC pts received daily pegilodecakin alone (N = 9) or in combination with platinum/taxane-based chemotherapy (N = 3). Responses were assessed by irRC.

Results: In monotherapy 4 (44%) had a PFS of more than 3.5 months and a survival of more than 14.7 months. No IRAEs were seen. G3/4 TrAEs in monotherapy: anemia (33%), fatigue (33%), thrombocytopenia (22%); in platinum/taxane combo: anemia (33%), diarrhea (33%), neutropenia (33%), thrombocytopenia (33%).

Table: 1146P

Pegilodecakin	N	Prior Therapies	ORR	DCR	mPFS	mOS
Regimen	E (ITT)[3]	Median (Range)	%	%	mos	mos
Monotherapy[1]	9 (9)	5 (4-11)	-	66.7	2.4	13.8
Plus Chemotherapy[2]	3 (3)	2 (1-7)	-	66.7	5.2	10.7

[1]1.0 or 20 μg/kg;
[2]Pegilodecakin 10 μg/kg + Carboplatin + Paclitaxel or Pegilodecakin 10 μg/kg + Cisplatin + Paclitaxel or Pegilodecakin 2.5 μg/kg + Carboplatin + Docetaxel;
[3]E (evaluable - baseline tumor assessment + >1 post-baseline assessments, and no major protocol deviations); ITT (intent to treat); Data cut on 05.01.18.

Conclusions: Pegilodecakin alone demonstrated durable disease control with manageable toxicity in a proportion of treatment refractory epOC pts. Preliminary findings in a small subset of epOC pts who received pegilodecakin in combination with platinum plus taxane-based chemotherapy yielded promising results.

1147P Preliminary results from a phase I study of GBR 1302, a bispecific antibody T-cell engager, in HER2 positive cancers

M. Wermke[1], J. Alt[2], J. Kauh[3], J. Back[4], Y. Salhi[5], V. Reddy[6], M. Barve[7], S. Ochsenreither[8]

[1]University Hospital Carl-Gustav-Carus, Dresden, Germany, [2]University Medical Center, Johannes Gutenberg University Mainz, Mainz, Germany, [3]Clinical Sciences, Glenmark Pharmaceuticals, Inc, Mahwah, NJ, USA, [4]Drug Discovery, Glenmark Pharmaceuticals SA, La Chaux-de-Fonds, Switzerland, [5]Biometrics, Glenmark Pharmaceuticals, Inc, Mahwah, NJ, USA, [6]Biologics Research, Glenmark Pharmaceuticals, Inc, Mahwah, NJ, USA, [7]Oncology, Mary Crowley Cancer Research, Dallas, TX, USA, [8]Charité Comprehensive Cancer Center, Charité University of Medicine, Berlin, Germany

Background: GBR 1302 is a HER2xCD3 bispecific antibody engineered to direct T-cells to HER2expressing tumor cells. This ongoing firstinhuman study (NCT02829372) in subjects with HER2positive cancers aims to evaluate the safety, tolerability, and preliminary efficacy of GBR 1302.

Methods: Adults with HER2-positive (immunohistochemistry 2+ or 3+) solid tumors with no available standard treatment receive GBR 1302 on Day 1 and Day 15 in 28-day treatment cycles at escalating dose levels, starting at 1 ng/kg. The primary endpoint includes determination of the maximum tolerable dose and safety profile of GBR 1302. Secondary and exploratory endpoints include pharmacodynamic (PD) testing for modulation of cellular and cytokine biomarkers.

Results: To date, 19 evaluable subjects for dose limiting toxicity (DLT) have been treated up to a dose of 750 ng/kg; dose escalation is ongoing. Grade (G) 1 to 2 infusion related reaction (IRR)/cytokine release syndrome (CRS) is the most comment treatment emergent adverse event that has been observed in subjects treated at doses ≥100 ng/kg. The majority of subjects were managed with conservative treatment. 2 subjects experienced DLT events: one asymptomatic subject (100 ng/kg) was noted to have reduced left ventricular ejection fraction on routine echocardiogram at 4 weeks, which resolved spontaneously after treatment discontinuation; the second subject (500 ng/kg) experienced G4 IRR/CRS which required ICU care but resolved within 36 hours. Beginning at 30 ng/kg, CD3, CD4, and CD8 positive T-cell populations decreased within 6 hours of administration and recovered to levels at or above baseline by 48 hours. Dose-proportional, transient increases in cytokines (IL-2, IL-6, IL-10, IFN-γ, TNF-α), which peaked at 6 hours and began to normalize within 48 hours, were observed. No subjects have documented radiological response, but 2 subjects (HER2 3+ gastroesophageal adenocarcinoma and HER2 2+ breast adenocarcinoma) have prolonged disease stabilization lasting ≥4 months.

Conclusions: The combination of clinical findings and PD changes suggests T-cell activation with higher dosages of GBR 1302. Dose escalation is continuing and updated results will be presented.

Clinical trial identification: NCT02829372.

1148P A phase Ia study of a personalized TSA-CTL (tumor specific antigen-induced cytotoxic T lymphocytes) therapy in metastatic melanoma

B. Li, S. Qiu

GenoImmune Therapeutics, BGI-Shenzhen, Shenzhen, China

Background: Neoantigens are derived from tumor specific mutations and presented by MHC on cancer cells. The set of neoantigens likely bypass immune tolerance and less likely induce autoimmunity because they are absent from normal cells. Targeting multiple neoantigens may significantly enhance the clinical efficacy of anti-tumor treatment with less toxicity. We present the proof-of-concept clinical application of personalized neoantigens induced T cell therapy.

Methods: This open-label phase Ia clinical trial is designed to test the safety and objective response of the tumor specific antigen-induced cytotoxic T lymphocytes (TSA-CTL). This study will enroll 9 advanced melanoma patients. Participants should have measurable metastases with at least one lesion that is resectable or tumor biopsies for DNA and RNA extraction. For each patient, we generate autologous TSA-CTLs based on neoantigens which identified through machine learning approaches with exome sequencing. Patients will receive 6 doses of TSA-CTL infusion. Toxicity (endpoint 1) will be defined by Common Terminology Criteria for Adverse Events v5.0, and objective response (endpoint 2) will be determined by the Response Evaluation Criteria in Solid Tumors.

Results: Seven patients have been enrolled so far and three of them have completed 3 cycles of TSA-CTL infusion. The fifth patient display pruritus grade 1. No other related adverse events just after the treatment were observed. We detected neoantigen-specific CD8+ T cells in peripheral blood through pMHC tetramer and found that neoantigen-specific CD8+ T cell increased after the TSA-CTL infusions for the third patient and the fifth patient. After three cycles of TSA-CTL infusion, the third and the fourth patient was assessed as SD with three metastasis' regression and PR, respectively. Further treatment and analyses are ongoing.

Conclusions: No major direct side effects are observed. Although with very limited trial subjects, a few patients did show favorable responses. Our study highlights the promise of personalized cell therapy for tumor-specific T cells and provide guidance for the future development. Clinical trial information: NCT02959905.

Clinical trial identification: NCT02959905; Release date: November 9, 2016.

1149P Safety, tolerability, and pharmacokinetics of the OX40 agonist ABBV-368 in patients with advanced solid tumors

A. Spira[1], K. Chung[2], A. Patnaik[3], A.W. Tolcher[4], M.E. Blaney[5], A. Parikh[5], A. Reddy[5], W. Henner[5], M. McDevitt[5], D. Afar[5], J. Powderly[6]

[1]Research Institute, Virginia Cancer Specialists, Fairfax, VA, USA, [2]Hematology/Oncology, Greenville Health System, Greenville, SC, USA, [3]Clinical Research, South Texas Accelerated Research Therapeutics (START), San Antonio, TX, USA, [4]Clinical Research, South Texas Accelerated Research Therapeutics (START); NEXT OncologyTM, San Antonio, TX, USA, [5]Oncology, AbbVie Inc., Redwood City, CA, USA, [6]Medical Oncology, Carolina BioOncology Institute, Huntersville, NC, USA

Background: ABBV-368 is a novel humanized IgG1 agonist monoclonal antibody specific for human OX40, a TNF receptor superfamily member expressed on activated and memory T-cell subsets, as well as T regulatory cells. The proposed ABBV-368 therapeutic mechanism of action includes activation of T effector cells and inhibition of the suppressive capacity of T regulatory cells. This ongoing first-in-human, phase 1, two-part study (NCT03071757) is investigating the safety, pharmacokinetics (PK), pharmacodynamics (PD), immunogenicity, and preliminary antitumor activity of ABBV-368 in patients (pts) with advanced solid tumors.

Methods: Eligible pts include adults (≥18 years) with advanced or metastatic solid tumors. ABBV-368 was administered intravenously in a 3 + 3 dose-escalation design at doses ranging from 0.01 to 3.0 mg/kg every 2 weeks (4 cohorts). PK was assessed in cycle 1 and cycle 3. OX40 receptor saturation, Ki67 proliferation marker expression in peripheral blood immune cell subsets, and additional PD biomarkers were evaluated.

Results: As of Feb 12, 2018, 38 pts with advanced or metastatic tumors were enrolled in dose-escalation cohorts. Median age was 65 years (range, 38–78). No dose-limiting toxicities were reported during dose escalation. Overall, 15 (39.5%) pts reported grade (Gr) ≥3 treatment-emergent adverse events (TEAEs). Three (7.9%) pts reported Gr ≥ 3 TEAEs related to ABBV-368. Two investigator-reported immune-related AEs were documented, including hypothyroidism; neither were serious. ABBV-368 PK was approximately dose-proportional from 0.1- to 3-mg/kg doses during cycle 1, with dose-dependent target saturation. Initial antitumor activity has been observed. Updated safety, PK, PD, and efficacy data will be reported.

Conclusions: ABBV-368 was well tolerated; a maximum tolerated dose was not reached. Antitumor activity was observed at doses predicted to be biologically active. Further evaluation of ABBV-368 is ongoing in pts with advanced solid tumors.

Clinical trial identification: NCT03071757.

Background: Patients with metastatic nasopharyngeal cancer (NPC) who experienced disease progression after standard therapy have limited treatment options. NPC is closely associated with Epstein–Barr Virus (EBV) infection and has been reported to have high levels of PD-L1 expression and tumor infiltrating lymphocytes, favoring immune-therapy potential in treating NPC. JS001, a humanized recombinant IgG4 antibody against PD-1, selectively blocks the interactions of PD-1 with its ligands PD-L1 and PD-L2, and promotes antigen specific T cell activation. Phase I studies of JS001 in subjects with heavily pretreated solid tumors had demonstrated an acceptable safety profile in doses up to 10 mg/kg Q2W.

Methods: Refractory/metastatic NPC Patients received JS001 3 mg/kg Q2W until disease progression or unacceptable toxicity. All patients with measurable disease were assessed for clinical response every 8 weeks. Tumor PD-L1 expression (SP142) and plasma EBV DNA levelwere monitored for correlation with clinical response.

Results: Between Dec 22th 2016 and May 4th 2018, 139 NPC pts were enrolled into the study. The median age was 46 years, 84% male (n = 117), with average 3.4 lines of prior systemic therapies. By Nov 15th 2017, treatment related AEs occurred in 84% patients, which were mostly grade 1 or 2, including fever (18.2%), hypothyroidism (18.2%), proteinuria (10.9%), fatigue (9.1%), TBIL increase (9.1%), leukopenia (9.1%) and anemia (7.3%). Grade ≥ 3 treatment related AEs occurred in 14.5% patients. Out of 52 evaluable pts by Jan 2018, 16 partial responses (30.8% ORR) and 16 stable diseases (61.5% DCR) were observed. PD-L1+ pts had slightly higher ORR 38.5% and 65.4% DCR. Interestingly, an average drop of 47-fold plasma EBV DNA copy number was observed in responding pts, which typically proceeded the radiographic identification of clinical benefits.

Conclusions: PD-1 mAb JS001 has demonstrated encouraging clinical activity in heavily pretreated NPC pts and a manageable safety profile. A change in plasma EBV DNA copy number might serve as a prognosis marker for NPC upon immunotherapy.

Clinical trial identification: NCT02915432.

Chiles Research Institute, Robert W. Franz Cancer Center, Providence Portland Medical Center and The Oregon Clinic, Portland, OR, USA,* [10]*Department of Radiation Oncology, Weill Cornell Medicine, New York, NY, USA,* [11]*Department of Internal Medicine, Division of Hematology/Oncology, University of Kansas Cancer Center, Kansas City, KS, USA,* [12]*Clinical Research, START, San Antonio, TX, USA,* [13]*Clinical Sciences, Regeneron Pharmaceuticals, Inc., Basking Ridge, NJ, USA,* [14]*Biostatistics & Data Management, Regeneron Pharmaceuticals, Inc., Basking Ridge, NJ, USA,* [15]*Clinical Sciences, Regeneron Pharmaceuticals, Inc., Tarrytown, NY, USA*

Background: For pts with unresectable HCC, systemic therapy options are limited. Sorafenib is approved in the US and Europe for HCC treatment. For pts who progress on sorafenib, regorafenib and nivolumab are approved as second-line therapy. Cemiplimab (REGN2810) has demonstrated encouraging efficacy and safety profile in a Phase 1 dose escalation study in pts with advanced malignancies (NCT02383212). We present results of the Phase 1 HCC expansion cohort.

Methods: HCC pts who were not candidates for surgery and had progressed on, could not tolerate, or refused first-line systemic therapy received cemiplimab 3 mg/kg Q2W for up to 48 weeks. The main objectives were to evaluate the safety, tolerability, and antitumour activity of cemiplimab.

Results: As of 1 Sept, 2017, 26 pts were enrolled (25 M/1 F), median (range) age was 65 (40–78) years; 24 pts (92.3%) had $\geq$1 prior systemic therapy; ECOG performance status was 1 in 19 pts (73.1%), 0 in 6 (23.1%) and missing in 1. Median duration of follow-up was 7.2 (range: 1.8–15.5) months. By investigator assessment, 5 pts (19.2%) had partial response, 14 (53.8%) had stable disease, 6 (23.1%) had progressive disease and 1 was not evaluable. Median progression-free survival was 3.7 months (95% CI: 2.3–9.1). Five pts (19.2%) completed the planned 48-week treatment, and 21 (80.8%) discontinued prematurely, mainly due to disease progression (65.4%). Three of the 5 pts who completed planned treatment remained without disease progression at the last response assessment. The most common treatment-emergent adverse events (TEAEs) of any grade were fatigue (26.9%), decreased appetite, increased aspartate aminotransferase (AST), abdominal pain, pruritus, and dyspnoea (each 23.1%). Grade $\geq$3 TEAEs occurring in $\geq$ 2 pts were hyponatraemia (3 pts), autoimmune hepatitis (2 pts) and increased AST (2 pts). Two pts (7.7%) had a TEAE resulting in death: 1 with pulmonary embolism that was considered unrelated to treatment and another with hepatic failure considered possibly related to treatment.

Conclusions: Cemiplimab demonstrated evidence of antitumour activity in pts with advanced or metastatic HCC. The safety profile is comparable with that of other anti-PD-1 inhibitors.

Clinical trial identification: NCT02383212.

Background: MEDI0562, a humanized IgG4 OX40 monoclonal antibody, demonstrated a manageable safety profile and pharmacologic activity in preliminary analyses of the Phase 1 study (NCT02318394) in pts with advanced solid tumors.[1] Here we present updated safety data and clinical activity for pts treated during the dose-escalation phase.

Methods: Pts were treated with one of 6 escalating doses of MEDI0562 (0.03, 0.1, 0.3, 1.0, 3.0, and 10 mg/kg) every 2 weeks (Q2W) until confirmed disease progression or unacceptable toxicity. Tumor assessments were performed every 8 weeks with immune-related Response Evaluation Criteria in Solid Tumors (irRECIST).

Results: A total of 55 pts received MEDI0562 across 6 dose cohorts (3 + 3 design), with a maximum administered dose of 10 mg/kg Q2W and no DLTs observed. Median duration of exposure was 10 (2 to 48) weeks. Adverse events (AEs) and treatment-related AEs (trAEs) were reported in 96% and 67% of pts, respectively; the most common trAEs were fatigue (31%) and infusion-related reaction (15%). Gr 3 trAEs occurred in 16% of pts with the most common being pyrexia (4%); 53% of pts had trAEs of Gr1 or 2, with no apparent dose relation. There were no trAEs leading to discontinuation or Gr 4 or 5 trAEs. Of 50 response evaluable pts, 2 pts (sq cell carcinoma of the larynx – 0.03 mg/kg Q2W and bladder cancer – 3 mg/kg Q2W) had irPR at the first tumor assessment, with an overall survival of 13.8 and 10.2+ mos, respectively. Stable disease was seen in 22 (44%) pts with SD in 20 pts lasting >3 mos. Serum exposure of MEDI0562 increased approximately dose proportionally. Posttreatment antidrug antibody (ADA) was detected in 26 (51%) of 55 pts. ADA exhibited variable impact on PK exposure at all doses below 3 mg/kg. A 1.5 to 3.0-fold increase in mean peaks of the percentage of peripheral Ki67+ CD4+ and Ki67+ CD8 +memory T cells was observed across ascending dose levels.

Conclusions: MEDI0562 was generally well tolerated in adult pts with advanced solid tumors and exhibited clinical and pharmacological activity. Based on the ADA data, a suggested MEDI0562 Phase 2 dose of $\geq$ 3 mg/kg Q2W was selected. 1. Glisson et al Ann Oncol ESMO 2016.

1153P Autologous dendritic-cell vaccine based on cancer-testis antigens "CaTeVac" in the treatment of soft tissue sarcoma

N. Pipia[1], I.A. Baldueva[1], T.L. Nekhaeva[1], A.V. Novik[1], A.B. Danilova[1], N.A. Avdonkina[1], S.A. Protsenko[2], Y.I. Komarov[2], D.V. Girdyuk[1], A.P. Oganesyan[2], A.M. Belyaev[3]

[1]*Oncoimmunology, N.N. Petrov Research Institute of Oncology, St. Petersburg, Russian Federation,* [2]*Chemotherapy and Innovative Technology, N.N. Petrov Research Institute of Oncology, St. Petersburg, Russian Federation,* [3]*N.N. Petrov Research Institute of Oncology, St. Petersburg, Russian Federation*

Background: Recent advances in the cancer immunotherapy provide an opportunity to develop the therapeutic autologous dendritic cell vaccine for metastatic forms of soft tissues sarcomas (STS). Previous studies showed the possibility of developing delayed

effects from this treatment. The aim of this study is to compare efficacy of the 2nd line therapy of STS patients with or without CaTeVac therapy during the whole systemic treatment.

Methods: Seventy-four patients (pts.) were included since 2008 to 2017. All patients had stage III inoperable or stage IV STS and received 2nd line of systemic therapy. Group 1 received CaTeVac as adjuvant therapy or maintenance therapy after the 1st or 2nd line of systemic therapy or as monotherapy after at least 1 line of chemotherapy. Group 2 never received CaTeVac during treatment course. Patients in the groups were comparable by histologic types and previous treatment. Overall survival (OS) from the start of the 2nd line of therapy to death was assessed as efficacy measure.

Results: Median OS of patients in group 1 was 24,4 mo (741 days, 95% CI, 509-973), versus 14.2 mo (431 days, 95% CI, 56-806) in group 2 (Log-Rank $p = 0.019$, Breslow $p = 0.03$). Relative risk of death (exp(B)) in group 1 was 0,358 (95% CI 0.171-0.751) in the Cox regression and was independent from and comparable to the treatment effect (exp(B) 0.254 (95% CI 0.133-0.484), $p = 0.000011$. Sex and age showed no impact on survival ($p > 0.05$).

Conclusions: CaTeVac shows impact on overall survival and should be assessed in randomized clinical trials with OS endpoints.

1154P A phase I study of MEDI1873, a novel GITR agonist, in advanced solid tumors

C.S. Denlinger[1], J.R. Infante[2], R. Aljumaily[3], A. Naing[4], A. Chintakuntlawar[5], N.A. Rizvi[6], H. Ross[7], M. Gordon[8], R. Kumar[9], M. Ma[9], L. Yan[10], P. Vicini[11], N. Standifer[10], J. Cann[9], A. Perera[11], N. Durham[9], S. Krishnan[9], A. Balmanoukian[12]

[1]Medical Oncology, Fox Chase Cancer Center, Philadelphia, PA, USA, [2]Cancer Center, Sarah Cannon Research Institute, Nashville, TN, USA, [3]Oncology, Oklahoma University Medical Center, Oklahoma City, OK, USA, [4]Oncology, MD Anderson Cancer Center, Houston, TX, USA, [5]Internal Medicine, Mayo Clinic, Rochester, MN, USA, [6]College of Physicians and Surgeons, Columbia University Medical Center, New York, NY, USA, [7]Oncology, Mayo Clinic, Scottsdale, AZ, USA, [8]Medical Oncology, HonorHealth Research Institute, Scottsdale, AZ, USA, [9]Medical Oncology, MedImmune, Gaithersburg, MD, USA, [10]Medical Oncology, MedImmune, South San Francisco, CA, USA, [11]Medical Oncology, MedImmune, Cambridge, UK, [12]Medical Oncology, The Angeles Clinic and Research Institute, Los Angeles, CA, USA

Background: MEDI1873 is a novel GITR-ligand/IgG1 agonist fusion protein that binds the co-stimulatory glucocorticoid-induced TNF receptor family-related protein (GITR) on $CD4^+$ and $CD8^+$ effector T cells and regulatory T cells. This Phase 1 study evaluated safety, maximum tolerated dose (MTD), pharmacokinetics (PK), immunogenicity, immunomodulatory effects and preliminary antitumor activity in pts with advanced solid tumors.

Methods: MEDI1873 was administered IV Q2W. During dose escalation (DE), it was evaluated in 2 single pt cohorts (1.5 and 3 mg), followed by 3 + 3 DE in 6 cohorts (7.5, 25, 75, 250, 500 and 750 mg). Pts with NSCLC, HNSCC or CRC receiving 75 or 250 mg were evaluated in pharmacodynamic (PD) cohorts using biopsies pretreatment and at day 29. All pts had flow cytometric assessment of lymphocytes pre- and on-treatment up to day 43. Antitumor response was assessed using RECIST v 1.1.

Results: As of 1 March 2018, 40 pts were dosed in the DE (28) and PD (12) cohorts. An MTD was not reached (maximum administered dose was 750 mg). Three DLTs occurred: Grade 3 worsening tumor pain at 250 mg, Grade 3 nausea and vomiting at 500 mg and Grade 3 non-STEMI at 750 mg. Any-grade drug-related AEs occurred in 82.5% of pts, most commonly headache (25%) and infusion related reaction (IRR, 20%). Grade 3 drug-related AEs occurred in 22.5% of pts; amylase increase was the only one reported in > 1 pt (n = 2). There were no drug-related Grade 4 or 5 AEs. PK was dose-proportional over a range of 1.5 to 500 mg; elimination half-life was approximately 2 days. Anti-drug antibody incidence was low with minimal PK impact. MEDI1873 engaged GITR on $CD4^+$ T cells and increased $CD4^+Ki67^+$ T cells at doses ≥25 mg. Intratumorally, MEDI1873 induced a ≥ 25% decrease in $GITR^+/FOXP3^+$ T cells in 5 of 5 pts with evaluable cells. Immune PD changes were observed in 8 pts who underwent paired biopsies. Best overall response was stable disease (SD) in 42.5% of pts; 17.5% had SD ≥ 24 weeks. Three pts (pancreatic neuroendocrine tumor, lung cancer and mesothelioma) stayed on MEDI1873 for ≥52 weeks without progression.

Conclusions: MEDI1873 has an acceptable safety profile in heavily pretreated pts with solid tumors. PD changes in blood and tumor coupled with prolonged SD in several pts support further clinical exploration of doses ≥250 mg.

Clinical trial identification: NCT02583165, October 22, 2015.

1155P Phase I adoptive cellular therapy trial with ex-vivo stimulated autologous CD8+ T-cells against multiple targets (ACTolog® IMA101) in patients with relapsed and/or refractory solid cancers

A-M. Tsimberidou[1], H. Ma[2], C. Stewart[2], O. Schoor[3], D. Maurer[3], R. Mendrzyk[3], A. Satelli[2], J. Fritsche[3], G. Stephens[2], A. Mohamed[2], P. Hwu[4], C. Yee[4], C. Reinhardt[3], T. Weinschenk[2], K. Gharpure[1], A. Stungis[1], D.J. Vining[4], H. Singh[2], S. Walter[2], B.S. Andersson[4]

[1]Investigatonal Cancer Therapeutics, MD Anderson Cancer Center, Houston, TX, USA, [2]Oncology, Immatics US., Inc., Houston, TX, USA, [3]Immunology, Immatics Biotechnologies GmbH, Martinsried, Germany, [4]Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA

Background: Adoptive cellular therapy in patients (pts) with solid tumors is limited due to lack of cancer targets with high specificity or relapse often associated with loss of single antigen (Ag) expression. To address multiple novel tumor Ags, we utilized Ag-specific T cells (IMA101) against cancer targets. Target positive tumors were identified by qPCR. Expression levels predictive for Ag presentation were determined by mass spectrometry. Autologous T cells against ACTolog targets are in vitro primed in the presence of IL-21 followed by HLA tetramer-guided cell sorting and expansion prior to infusion.

Methods: HLA-A*02:01 positive pts with relapsed/refractory solid tumors are eligible for treatment if their tumors express ≥1 of 8 possible Ag targets from a predefined antigen warehouse. These pts undergo leukapheresis, followed by IMA101 cell manufacturing. Treatment consists of lymphodepletion (Fludarabine/Cyclophosphamide) followed by IMA101 infusion of up to 4 Ag-specific T cell products and IL-2.

Results: From 8/2017 to 5/2018, 86 pts were prescreened, 38 were HLA-A*02:01 positive, 18 had tumor biopsy, 11 had leukapheresis and 3 were treated so far: hormone receptor pos, HER2 neg. breast cancer (56 yr, fem.); synovial sarcoma (28 yr, fem.); and liposarcoma (36 yr, male); No. of prior therapies, 12, 6, 8, respectively. Respective time to recovery was: ANC >1.0: day 41, 8, and 61; Platelets > 50: day 47, no decrease <50, and 61. Pts developed Grade 1-2 cytokine release syndrome, without evidence of infection. The third patient developed bradycardia on day 9, which was reversible with discontinuation of IL-2. Peripheral blood analysis at 2 wks demonstrated that CD8+ T cells specific for cancer targets were 0.4%, 12%, and 46% of total circulating CD8+ T cells, respectively. Pts had disease stabilization at 6 wks.

Conclusions: In the 3 pts treated, treatment was tolerable. To our knowledge, this is the first time that pts received multiple defined Ag-specific products. Initial T-cell persistence data demostrated high prevalence and the expected T-cell phenotype, which are important prerequisites for clinical activity. The trial is ongoing.

Clinical trial identification: NCT02876510.

1156P Initial safety assessment of MAGE-A4 SPEAR T-cells

D.S. Hong[1], M.O. Butler[2], M. Johnson[3], A.J. Olszanski[4], E. Norry[5], E. Van Winkle[5], K.D. Chagin[6], R.G. Amado[7]

[1]Medical Oncology, The University of Texas M. D. Anderson Cancer Center, Houston, TX, USA, [2]Medical Oncology, Princess Margaret Cancer Centre, Toronto, ON, Canada, [3]Sarah Cannon Research Institute, Tennessee Oncology, Nashville, TN, USA, [4]Department of Hematology/Oncology, Fox Chase Cancer Center, Philadelphia, PA, USA, [5]Clinical, Adaptimmune, Philadelphia, PA, USA, [6]Clinical, Adaptimmune LLC, Philadelphia, PA, USA, [7]Clinical, Adaptimmune LLC, Philadelphia, PA, USA

Background: This ongoing study (NCT03132922) evaluates the safety and tolerability of genetically engineered autologous specific peptide enhanced affinity receptor (SPEAR) T-cells (MAGE-A4^{c1032}T cells) directed towards a MAGE-A4 peptide expressed on tumors in the context of HLA-A*02.

Methods: This first-in-human T-cell dose-escalation study utilizes a modified 3 + 3 design to evaluate safety, including dose-limiting toxicities (DLT). Patients who are HLA-A*02 positive (excluding *02:05 and *02:07) and have inoperable or metastatic (advanced) NSCLC, urothelial cancer, melanoma, synovial sarcoma, MRCLS, squamous cell head and neck, ovarian, gastric or esophageal tumors with MAGE-A4 expression and meet all other entry criteria are eligible for treatment. Following apheresis, T-cells are isolated, transduced with a lentiviral vector containing the MAGE-A4^{c1032}TCR, and expanded. Prior to transduced cell infusion, patients are given lymphodepleting chemotherapy (Flu 30 mg/m^2/d and Cy 600 mg/m^2/d, on days -7, -6 and -5 in dose groups 1 and 2, and additional Flu 30 mg/m^2/d on day -4 in dose group 3). Groups 1, 2 and 3 will consist of 3-6 patients, and transduced cell doses will be as follows: 0.1×10^9 (±20%), 1×10^9 (range: $0.5 – 1.2 \times 10^9$), and 5×10^9 (range: $1.2 – 6 \times 10^9$), respectively. The DLT observation period is the first 30 days following the infusion of SPEAR T-cells for each patient in all groups. Following dose escalation, up to 30 patients will be enrolled at 5×10^9 (range: 1.2×10^9 -10×10^9).

Results: 3 patients were treated with 0.1×10^9 MAGE-A4 SPEAR T-cells, and transduced cells are detectable in peripheral blood. AEs for the first 2 patients reported at grade (G) ≥3 include anemia, hypoglycemia, hyponatremia, lymphopenia, neutropenia, and thrombocytopenia. Serious AEs included G4 hyponatremia, G3 atrial fibrillation, G3 syncope (unrelated to T-cell therapy), G1 CRS and G2 encephalopathy syndrome (both related), and G2 generalized muscle weakness (possibly related). None of the events were considered DLTs by the Safety Review Committee.

Conclusions: MAGE-A4 SPEAR T-cells at the 0.1×10^9 transduced cell dose appear to show no evidence of on-target or off-target toxicity. Preliminary data support continued investigation of the TCR, and this trial is ongoing. Updated safety data will be presented.

Clinical trial identification: NCT03132922.

1157P Phase I trial of a novel hTERT vaccination strategy addressing T effector cells and immune-suppressor mechanisms

J. Spicer[1], V. Kwatra[1], C. Verma[2], K. Ioannou[3], R. Goldstein[1], T. Brier[1], J. Eremin[1], N. Zareian[1], L. Walker[4], D. Lobo[2], F. Farzaneh[3], O. Eremin[2]

[1]School of Cancer and Pharmaceutical Sciences, King's College London Guy's Hospital, London, UK, [2]Nottingham Digestive Diseases Centre, University of Nottingham, Nottingham, UK, [3]School of Cancer and Pharmaceutical Sciences, King's College London, London, UK, [4]Department of Cancer Rehabilitation, University of Hull, Hull, UK

Background: Inability to generate activated T effector cells and the presence of strong suppressor mechanisms have limited cancer vaccine efficacy. Human telomerase reverse transcriptase (hTERT) is expressed in > 90% of tumours but is HLA dependent, which has restricted its use to patients with a particular HLA haplotype. We sought to address these problems with a novel vaccination strategy.

Methods: Each vaccination was preceded by 10 days of metronomic low dose oral cyclophosphamide, designed to reduce Tregs. A vaccine consisting of 7 hTERT peptides, predicted to bind MHC Class I and II proteins, not HLA restricted, was given 3-weekly ID. Adjuvants (Montanide ID and topical imiquimod), were used to optimise hTERT presentation. The primary objective was safety, with secondary objectives of immunological and clinical efficacy. Blood lymphocyte phenotypic profiles were analysed ex vivo and post culture to identify activated T effector cells, checkpoint-regulatory T cells and Tregs. T cell receptor (TCR) sequencing was performed prior to and post vaccination.

Results: 17 patients (pts) have completed treatment. Vaccination was well tolerated, 1 withdrew following an injection site reaction. 4 pts (24%) had stable disease for >6 months (colorectal, lung, pancreas, prostate). Baseline activated T cells in pts (CD8+CTLA-4+, n = 9) were similar to healthy donors (HDs), but increased up to 3-fold post-vaccination (p = 0.017). T cells from 5 pts were cultured in vitro post-vaccination; peptide-specific activation of CD4+ and CD8+ T cells was seen in 4/5 and 3/5, respectively. Baseline checkpoint regulatory (PD-1+) CD4+/CD8+ T cells were 8-10 fold higher in pts (CD4+, p = 0.011; CD8+, p = 0.004) than HDs; post-vaccination levels fell but remained >HDs. Post-treatment Tregs fell significantly (FOXP3+PD-1+, p = 0.016). TCR sequencing demonstrated the emergence of clonally expanded T cells, including hTERT-specific clones.

Conclusions: This pan-tumour generic vaccine was safe, with sustained disease stabilisation in a subset of patients with a range of tumour types. Immune-suppressor T cell numbers fell, and hTERT-specific T effector cells were generated.

Clinical trial identification: EudraCT: 2014-003025-18.

Background: AGEN2034 is a fully-human immunoglobulin (IgG)-4 monoclonal antibody antagonist targeting programmed death protein 1 (PD-1). The objective was to assess safety, maximum tolerated dose, preliminary efficacy, and pharmacokinetic (PK) and pharmacodynamic (PD) characteristics of AGEN2034 in patients (pts) with advanced malignancies.

Methods: 30 pts were enrolled at dose cohorts of 1, 3, and 10 mg/kg. AGEN2034 is given intravenously Q2w for ≤2 years with cohorts at Q3w dosing at 6 and 10 mg/kg. A phase 2 expansion of AGEN2034 3 mg/kg Q2w in pts with relapsed/refractory cervical cancer is under way.

Results: 10 pts were enrolled at each dose level. Median age was 58 y, with ECOG scores 0–1. No dose-limiting toxicities were observed. Immune-related adverse events (AEs) consistent with this drug class were observed, including pneumonitis, colitis, diarrhea, rash, and pruritus. 21 of 30 pts had treatment-related AEs (TRAEs). 13 (43%) subjects discontinued (d/c) due to disease progression and 1 patient each d/c due to TRAEs of hepatitis and pneumonitis. At the time of data cutoff, in 25 evaluable heavily pretreated pts, 3 partial responses (2 confirmed) were noted in pts with cervical, ovarian, and breast cancers in the 1 and 3 mg/kg cohorts. 13 patients had stable disease, including 5 of 5 patients with ovarian cancer. AGEN2034 demonstrates a dose-proportional C_{max} of 19.6 μg/mL at 1 mg/kg and 73.6 μg/mL at 3 mg/kg in 12 pt samples analyzed in the first 2 cohorts. Average PD-1 receptor occupancy (RO) on circulating CD8$^+$ and CD4$^+$ effector memory T lymphocytes (n = 18) demonstrated >59% saturation at all dose levels at day 15 post infusion.

Conclusions: AGEN2034 is pharmacologically active, well-tolerated PD-1 antagonist antibody, demonstrating early signals of clinical activity in cervical and ovarian cancers. PK and RO results are comparable to commercial PD-1 antagonists. Updated safety and efficacy results for the dose escalation and the relapsed cervical cancer cohorts will be presented. (NCT03104699). A phase 2 combination study of AGEN2034 and AGEN1884 (CTLA-4) is under way.

Clinical trial identification: NCT03104699.

Editorial acknowledgement: Editorial support was provided by The Medicine Group, LLC (New Hope, PA, USA) and funded by Agenus Inc. (Lexington, MA, USA).

Legal entity responsible for the study: The licensed antibody AGEN2034 was originally developed under a Collaborative Research and Development Agreement between Ludwig Cancer Research, 4-Antibody AG (now Agenus Switzerland Inc.) and Recepta Biopharma S.A. This antibody is partnered with Recepta Biopharma S.A. for certain South American rights.

Funding: Agenus Inc. (Lexington, MA, USA).

Background: Spartalizumab is a humanized IgG4 anti-PD1 mAb, which has previously shown favorable PK and safety, and preliminary clinical activity.

Methods: This Phase I/II, open-label, dose escalation/expansion study (NCT02404441) characterized the safety and efficacy of spartalizumab in patients (pts) with advanced solid tumors. In dose escalation, the recommended Phase II dose was declared as 400 mg Q4W (alternative: 300 mg Q3W). Here, we present expansion data for anti-PD(L)1-naïve cohorts with advanced melanoma and NSCLC. PD-L1 expression was assessed centrally (Dako PD-L1 IHC 22C3 pharmaDx).

Results: As of Nov 13, 2017, 61 pts with melanoma received 400 mg spartalizumab Q4W; 36% of pts were treatment-naïve, 20% had ≥2 prior therapies, and all were anti-PD(L)1-naïve. Suspected-related AEs (all grades, ≥5%) were fatigue (15%), decreased appetite (11%), hypothyroidism (8%), rash (8%), asthenia (7%), vitiligo (7%). ORR (confirmed responses) was 26% (16/61), including 1 CR. 41 pts (67%) had baseline PD-L1 data: 63% were PD-L1– (TPS <1%). ORR was 40% (6/15) for PD-L1 + (TPS ≥1%) and 19% (5/26) for PD-L1– pts. 118 pts with NSCLC received 400 mg Q4W (n = 59) or 300 mg Q3W (n = 59); all pts had received prior treatment, 27% had ≥2 therapies. Suspected-related AEs (≥5%) were diarrhea, nausea, decreased appetite, hypothyroidism (5% each). ORR (confirmed responses) was 9% (11/118). 77 pts (65%) had baseline PD-L1 data: 61% were PD-L1–. More Q3W than Q4W treated pts were PD-L1– (70% vs 52%). ORR was 6% (3/47) in PD-L1–, 11% (1/9) in PD-L1 1–49%, and 19% (4/21) in PD-L1 ≥50%. ORR was lower in Q3W (5%; 3/59) than Q4W treated pts (14%; 8/59) but was higher in PD-L1+ pts in both groups (Q3W: 18.2% vs 3.8%, Q4W: 15.8% vs 9.5%). PK analyses confirmed flat dosing (Q3W or Q4W) achieved drug exposure comparable with weight-based dosing.

Conclusions: Spartalizumab was well tolerated with a manageable safety profile. Efficacy was observed in pts with NSCLC (Q3W and Q4W) and melanoma (Q4W), and was as expected given the high proportion of pts with PD-L1– disease. ORRs were higher in PD-L1+ pts, corroborating previous findings that PD-L1 expression enriches for response to anti-PD1 agents in certain tumor types.

Clinical trial identification: NCT02404441, CPDR001X2101.

1160P Phase I/II evaluation of intratumoral INT230-6 for the treatment of solid tumors

A. El-Khoeuiry[1], L.L. Siu[2], N. Azad[3], I.B. Walters[4], L. Bender[5], L. Kamen[5], A.J. Olszanski[6]

[1]Phase 1 Program, USC Norris Comprehensive Cancer Center, Los Angeles, CA, USA, [2]Phase 1 Program, Princess Margaret Hospital, Toronto, ON, Canada, [3]Phase 1 Clinical Trials Group, Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD, USA, [4]Clinical Research, Intensity Therapeutics, Westport, CT, USA, [5]Clinical Research, Intensity Therapeutics, Westport, CT, USA, [6]Phase 1 Developmental Therapeutics Program, Fox Chase Cancer Center, Philadelphia, PA, USA

Background: INT230-6 is a formulation of cisplatin and vinblastine with an amphiphillic penetration enhancer to improve dispersion and diffusion into cancer cells. This is the first product designed for selective delivery into tumors with the potential to deliver high payload levels directly into cancer cells while sparing healthy cells. In colon 26 animal models, injection into a sentinel lesion led to tumor necrosis, recruitment of dendritic cells into the tumor and activation of CD4 and CD8 T-cells. Injected tumors experienced high rates of complete response (up to 80%). Importantly, untreated lesions distal to the injection site also responded. Efficacy was synergistic when combined with checkpoint inhibitors.

Methods: Initial cohort enrolled subjects with advanced solid tumors with superficial lesions amenable to local injection. INT230-6 was administered intratumorally at a ratio of 1ml for each 4 cubic cm of tumor volume, once each month for a total of 5 cycles. Both the maximal dose into one tumor and the total dose (over multiple lesions) could be escalated on repeat cycles if no DLTs. Patients were monitored for safety weekly. Pharmacokinetic(Pk) samples and peripheral blood were collected for flow cytometry and circulating cytokines. Subsequent cohorts of twice monthly injections into superficial tumors and monthly injection into deep tumors commenced after comprehensive review of safety data in superficial tumors.

Results: Thirteen subjects were treated with either melanoma, SCC, ovarian, chordoma, cholangiocarcinoma or H&N into single or multiple lesions. Pk analysis revealed negligible amounts of reduced platinum and vinblastine in blood, suggesting retention in the tumor compartments. No DLTs or drug related SAEs were reported. The most frequent adverse event was grade 1 or 2 injection site pain, or other local symptom (infection or blister). Subjectively, some injected lesions were noted to change as soon as 1 week with flattening and areas of necrosis.

Conclusions: INT230-6 was safe when administered locally to tumors at doses given. Updated results will be presented including biomarker and response data. Additional cohorts including higher drug concentrations and combination with an anti-PD1 antibody.

Clinical trial identification: NCT:03058289.

1161P OMTX705, a powerful stroma-targeting ADC to treat invasive tumors with low response to immunotherapeutic anti-PD-1 treatments

M. Fabre[1], C. Ferrer[1], S. Dominguez-Hormaetxe[1], R. Kontermann[2], K. Pfizenmaier[2], O. Seifert[2], P.P. López-Casas[3], M. Abbas[4], W. Richter[4], L. Simon[1], M. Hidalgo[5]

[1]R&D Department, Oncomatryx Biopharma S.L, Derio, Spain, [2]Institute of Cell Biology and Immunology, Stuttgart University, Stuttgart, Germany, [3]Gastrointestinal Cancer Clinical Research Unit, CNIO, Madrid, Spain, [4]R&D Department, Tube Pharmaceuticals, GmBH, Vienna, Austria, [5]Department of Medicine, Harvard Medical School, Boston, MA, USA

Background: Tumor microenvironment represents 20-60% of solid tumor mass and is increasingly recognized to play a key role in promotion, invasiveness and metastasis. Mounting evidence suggests that FAP-expressing CAFs, the predominant stroma cell type, is involved in the tumor immune response. A novel antibody-drug conjugate, OMTX705, was generated through CYS-based conjugation of a new anti-FAP humanized antibody, with high specificity and affinity, to a novel cytolysin, using an optimized vcPABA linker.

Methods: In vivo studies were performed in patient-derived xenograft models for pancreatic and NSCL cancer in immunodeficient and humanized mice. Tumor volume and animal weight were monitorized 3 times a week over 4 weeks of treatment with OMTX705, administered intravenously at different doses, either as single agent or in combination with chemotherapy such as Gemcitabine or Paclitaxel, or immunotherapy such as Pembrolizumab. FACS and IHC analysis of CD45, CD25, CD3, CD4, CD8 and Fox3P markers were performed on blood and tumor samples to study the effect of OMTX705 on immune system in these models.

Results: OMTX705 showed 100% tumor growth inhibition and regression in the PDX murine models for pancreatic and NSCL cancer, both as single agent and in combination with Gemcitabine and Nab-Paclitaxel, Paclitaxel, or Pembrolizumab, without weight loss. When treated with OMTX705 in combination with chemotherapy, the response was maintained for a longer period without further treatment: re-growth of tumors was delayed and tumors kept responding upon re-treatment, showing lack of resistance to OMTX705 treatment. In combination with Pembrolizumab immunotherapy in a humanized PDX model for lung cancer, OMTX705 efficacy was even higher at lower dose, inducing full regression and significant delay in tumor recurrence, through CD8(+) T cell dependent immunomodulation.

Conclusions: FAP-targeted OMTX705 represents a potent novel strategy for cancer treatment at invasive stages. Due to the broad expression of FAP in the tumor microenvironment of a wide array of carcinomas, OMTX705 is a highly promising candidate to treat different solid tumors with low response to anti-PD1 immunotherapies.

Franz Cancer Center, Providence Portland Medical Center and The Oregon Clinic, Earle A. Chiles Research Institute, Portland, OR, USA, [8]Department of Radiation Oncology, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ, USA, [9]Division of Hematology-Oncology, UCLA, Los Angeles, CA, USA, [10]Medical Oncology Department, Hospital Universitario Ramon y Cajal, Madrid, Spain, [11]Department of Radiology, Hospital Universitario Ramón y Cajal, Madrid, Spain, [12]Clinical Sciences, Regeneron Pharmaceuticals, Inc., Tarrytown, NY, USA, [13]Biostatistics & Data Management, Regeneron Pharmaceuticals, Inc., Basking Ridge, NJ, USA, [14]Clinical Sciences, Regeneron Pharmaceuticals, Inc., Basking Ridge, NJ, USA

Background: Cemiplimab (REGN2810), a human monoclonal antibody to PD-1, has exhibited substantial antitumour activities in patients (pts) with advanced malignancies in a Phase 1 study. Most patients with advanced NSCLC do not respond to PD-1 inhibitor monotherapy. Here we report results of the Phase 1 EC 2, a combination regimen of cemiplimab plus RT in advanced NSCLC (NCT02383212).

Methods: Pts with advanced NSCLC who had relapsed after or were refractory to at least first-line therapy and for whom palliative RT was clinically indicated, received cemiplimab 3 mg/kg every 2 weeks for up to 48 weeks plus RT (9 Gy × 3 times/week given 1 week after first dose of cemiplimab) to a single lesion. The co-primary objectives were to evaluate the safety, tolerability, and efficacy of cemiplimab plus RT. Tumour measurements (of non-irradiated target lesions) were performed by RECIST 1.1 every 8 weeks.

Results: As of 1 Sept, 2017, 33 pts (22 M/ 11 F; median age 67.0 years [range, 47–82]) were enrolled; 66.7% and 30.3% had an ECOG performance status of 1 and 0, respectively; the status of one pt was unknown. Overall response rate (ORR; complete response [CR] + partial response [PR]) was 18.2% (0 CR and 6 PRs) with a median duration of response of 14.9 months (95% CI: 5.5–14.9). Disease control rate (ORR + stable disease [SD]) was 72.7% (6 PRs + 18 SDs). The most common treatment-emergent adverse events (TEAEs) of any grade were decreased appetite (30.3%), fatigue (27.3%), and cough (24.2%). Grade $\geq$3 TEAEs occurring in $\geq$ 2 patients include anaemia (12.1%), hypophosphataemia, and urinary tract infection (each 6.1%). One patient had a TEAE of pneumonitis, considered related to study drug, with an outcome of death.

Conclusions: Cemiplimab plus RT demonstrated antitumour activity in pretreated pts with NSCLC. The safety profile is comparable with other anti-PD-1 agents and RT. The combination therapy regimen did not produce greater efficacy above that which can be achieved with PD-1 inhibitor monotherapy for advanced NSCLC.

Clinical trial identification: NCT02383212.

1163P Study on treatment of stage IV solid tumors with mutant neoantigen specific T cells

Q. Song[1], J. Song[2], H. Sun[2], W. Du[3], L. Wu[1], L. Wang[1], Z. Wei[4], Y. Wang[2], Y. Guan[2], X. Xia[2], X. Yi[2], S. Jiao[1]

[1]Oncology Department, The General Hospital of People's Liberation Army, Beijing, China, [2]Research and Development Center, Geneplus-Beijing Institute, Beijing, China, [3]Medical Administration Division, The General Hospital of People's Liberation Army, Beijing, China, [4]Department of Health Care, Chinese PLA Joint Staff Headquarters Guard Bureau, Beijing, China

Background: As an important tumor immunotherapy, the specificity and efficiency of PD1 inhibitor is not yet satisfactory. The treatment of solid tumor with mutant neoantigen specific T (MNaS-T) cells developed in this study is an adoptive cell therapy which is specific for each patient. The aim is to explore the difference in safety and efficacy between MNaS-T cells and PD1 inhibitors, and to evaluate the charateristic of immune repertoire (IR) as predictive biomarker.

Methods: A total number of 11 patients with advanced solid tumors who failed after multiline treatments were recruited. They were treated with MNaS-T cells, PD1 inhibitors and BSC; other 11 patients were treated with PD1 inhibitors and BSC as control. Peripheral blood was collected at baseline and per cycle (21-28d) respectively. Multiple PCR and NGS on TCR beta chain was used to detect IR.

Results: PFS of two groups had a statistical significance ($P < 0.05$), suggesting MNaS-T cells prolong patients' PFS. The safety was analyzed from routine blood urine stool test, coagulation function, liver and kidney function. There was no significant difference at baseline ($P > 0.05$). Compared with C group, total protein and albumin in T group had a transient decrease in 3rd, 4th and 5th follow-up respectively ($P < 0.05$), however, It can be recovered autonomously before 6th cycle. Evenness index and Clonality indexe were examined to illuminate the diversity and clonality of IR seperately. Compared to baseline, T cell repertoir of disease-progression patients and no-disease-progression patients after 1st cycle showed significantly different changes: Evenness 3.29 vs 0.85, $P = 0.013$; Clonality 0.76 vs 1.20, $P = 0.015$. Elevated Clonality may indicate amplification of tumor specific T cells which could recognize mutant neoantigen specifically.

Table: 1163P Demographic and clinical characteristics of 22 patients

Characteristic		MNaS-T cells plus PD1 inhibitors plus BSC (N = 11)			PD1 inhibitors plus BSC (N = 11)
		Disease Progression (N=4)	No Disease Progression (N=7)	Total (N = 11)	
Age–no.(%)					
	<60	4 (100)	5 (71.4)	9 (81.8)	6 (54.5)
	> =60	0	2 (28.6)	2 (18.2)	5 (45.5)
Sex–no.(%)					
	Male	3 (75)	3 (42.9)	6 (54.5)	8 (72.7)
	Female	1 (25)	4 (57.1)	5 (45.5)	3 (27.3)
Previous treatments–no.					
	Chemotherapy	4	7	11	11
	Targeted therapy	4	7	11	11
ECOG–no.(%)					
	0	0	0	0	0
	1	1	6	7	6
	≥2	3	1	4	5
Stage–no.	IV	4	7	11	11
Peripheral IR Diversity–mean (SD)					
Evenness					
	Baseline	0.01 (0.01)	0.07 (0.08)	0.05 (0.07)	
	1st cycle	0.05 (0.05)	0.06 (0.07)	0.05 (0.06)	
	1st cycle / Baseline	3.29 (2.09)	0.85 (0.44)	1.74 (1.71)	
Clonality					
	Baseline	0.32 (0.09)	0.25 (0.18)	0.27 (0.15)	
	1st cycle	0.25 (0.12)	0.27 (0.16)	0.26 (0.14)	
	1st cycle / Baseline	0.76 (0.18)	1.2 (0.27)	1.04 (0.32)	

Conclusions: The combined immunotherapy of MNaS-T cells and PD1 inhibitors is more effective than PD1 inhibitor alone in prolonging the PFS, and has a good safety. IR Clonality change shows its potential as a predictive biomarker.

Background: Racotumomab-alum is an anti-idiotypic vaccine that induces immunological response against N-glycolilated gangliosides in NSCLC patients. Nimotuzumab is a humanized anti-EGFR monoclonal antibody that has shown activity in NSCLC patients. The aim of this study is to evaluate safety and efficacy of racotumomab-alum or nimotuzumab versus docetaxel as second line or switch maintenance therapy for advanced NSCLC.

Methods: This phase III, multicenter, open label, randomized trial is designed to enroll 743 stage IIIB-IV NSCLC patients, after first line therapy, with PS 0-2, with written informed consent. The primary endpoint is Overall Survival (OS). Patients are been randomized (2:2:1) to 3 arms: racotumomab-alum, nimotuzumab or docetaxel, and stratified according to response to first line (progressor or non-progressor patients). Racotumomab-alum treatment consists in 5 bi-weekly intradermal doses and re-immunizations every 4 weeks. Nimotuzumab arm receives 6 weekly infusions followed by bi-weekly doses. Docetaxel is used at 75 mg/m2 for 6 cycles, if there is no evidence of progressive disease after 3 cycles. As second-line therapy, both experimental drugs will be classified as non-inferior (NI) to docetaxel, if 1- year OS rate is 23.1 % and HR C/T=0.76, [d0 (0,28), d0= - ln HR(C/T)] using a 10% NI margin. Here we report the interim analysis in 255 progressor patients.

Results: 106 patients in racotumomab, 97 in nimotuzumab and 54 in docetaxel arm with at least 1 year follow up were analyzed (ITT). The median OS and 1-year survival rate were 4.67 months (CI: 4.0-5.3) and 14.5 % with nimotuzumab, 4.83 months (CI: 3.7-5.9) and 23.5 % with racotumomab-alum and 5.85 months (CI: 3.9-7.7) and 20.2 % with docetaxel, respectively. Most frequent treatment-related adverse events were induration (10.7%), local erythema in injection site (8.8%) and arthralgia (8.2%) with racotumomab-alum; myalgia (12.1%), fever (7.9%) and nausea (7.0%) with nimotuzumab, and nausea (16.5%), asthenia (13.2%) and vomiting (12.1%) after docetaxel.

Conclusions: These data do not confirm the non-inferiority of racotumomab-alum or nimotuzumab versus docetaxel as second-line therapy. Both experimental treatments were safely administered at primary level of health assistance.

Clinical trial identification: RPCEC0000017.

1165P Preliminary safety, pharmacokinetics (PK) and efficacy results from a phase I study of CS1001, an anti-programmed death ligand-1 (PD-L1) monoclonal antibody (mAb) in patients (pts) with advanced tumors

L. Shen[1], J. Cao[2], J. Gong[1], D. Ji[2], Z. Qin[3], H. Dai[3], K. Wu[3], J. Xu[3], J. Yang[3]

[1]Gastrointestinal Oncology, Peking University Cancer Hospital & Institute, Beijing, China, [2]Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China, [3]Clinical Development, CStone Pharmaceuticals (Su Zhou) Co., Ltd., Shanghai, China

Background: Anti-PD-L1 mAbs have demonstrated anti-tumor activities in multiple indications. CS1001 is the first full-length, fully human anti-PD-L1 mAb developed by OMT transgenic animal platform, which mirrors natural IgG4 human antibody with expected PK profiles, and may potentially reduce the risk of immunogenicity and toxicity in pts.

Methods: A phase I, multi-center study was conducted to evaluate the safety, tolerability, PK and anti-tumor activity of CS1001 in pts with advanced tumors. A 3 + 3 dose-escalation design was undertaken. Pts received CS1001 intravenously once every three week (Q3W). Safety and tolerability were assessed by monitoring adverse events (AEs). Tumor assessments were performed per RECIST v1.1 (solid tumors) or Lugano 2014 (lymphomas).

Results: As of 8 Apr 2018, a total of 19 Asian pts [median age 50 (31–74) yrs] with advanced tumors were treated by CS1001 Q3W across 5 dose-escalating cohorts (3 mg/kg, N = 3; 10 mg/kg, N = 4; 20 mg/kg, N = 3; 40 mg/kg, N = 3; and 1200 mg, N = 6). All pts had received at least 1 prior line of anti-cancer treatment (median 2 [1–7]). Median duration of study treatment was 63 (6–172) days. 14 pts remain on study. No dose-limiting toxicity was observed, and maximum tolerated dose was not reached. The most frequent treatment-emergent AEs were grade (G) 1/2 anemia (n = 7), nausea (n = 6), decreased appetite (n = 5), blood bilirubin increased (n = 4), protein urine present (n = 4), white blood cell count decreased (n = 4) and proteinuria (n = 4). Immune-related AEs (G1-3) occurred in 5 pts. No treatment-related serious AE was reported. PK analysis was conducted using observed CS1001 serum concentrations from 16 pts across all 5 cohorts. The PK of CS1001 was linear and the terminal elimination half-life was about 12 days. Among 12 efficacy evaluable pts, four achieved unconfirmed partial response and all remain on treatment. Three additional pts achieved a best overall response of stable disease.

Conclusions: CS1001 appears to be generally well tolerated in pts with advanced tumors, with a linear PK profile. The preliminary safety profile and anti-tumor activity support continued exploration and development of CS1001.

Clinical trial identification: NCT03312842, October 18, 2017.

1166P An oral dual inhibitor of IDO and TDO enhances anti-cancer immunity and synergizes with immune checkpoint blockade

C. Kim[1], N.K. Lee[1], J.S. Kim[2], W.R. Kim[3], D.H. Kim[4], D.J. Kim[5], J.S. Oh[4], S.K. Chang[6], J.W. Kim[3], H.J. Chon[1]

[1]Medical Oncology, Bundang Cha Medical Center, Seongnam, Republic of Korea, [2]Research Department, CMG Pharmaceutical, Seongnam, Republic of Korea, [3]Surgery, CHA Bundang Medical Center, Seongnam, Republic of Korea, [4]Internal Medicine, CHA Bundang Medical Center, Seongnam, Republic of Korea, [5]Radiology, CHA Bundang Medical Center, Seongnam, Republic of Korea, [6]Radiation Oncology, Bundang Cha Medical Center, Seongnam, Republic of Korea

Background: Indolamine 2,3-dioxygenase (IDO) blockade is a new therapeutic strategy to enhance cancer immunity. However, IDO blockade alone cannot completely block the immunosuppressive tryptophan-kynurenine (Trp-Kyn) pathway in the tumor microenvironment. Recent studies have demonstrated that Trp 2,3-dioxygenase (TDO) is an alternative enzyme employed by various tumors that can be used as a target for the Trp-Kyn pathway; therefore, here we developed an orally available dual inhibitor that targets IDO and TDO.

Methods: Small-molecule inhibitors for IDO and TDO were synthesized and screened by in vitro IDO/TDO enzyme and cell-based assays. CT26 colon or 4T1 breast tumor-bearing mice were treated with CB548 either alone or in combination with an anti-PD1 antibody. We monitored tumor growth and analyzed the tumor microenvironment using flow cytometry, qPCR, and confocal microscopy.

Results: A lead compound, CB548, showed potent inhibition of IDO and TDO in the enzyme and cell-based assays with various human and murine cancer cell lines. Oral administration of CB548 revealed a good pharmacokinetic profile, and the conversion of Trp to Kyn in tumors was effectively suppressed. Moreover, the CB548 monotherapy revealed a dose-dependent inhibition of CT26 colon or 4T1 breast cancer growth as well as markedly increased CD8+ T cell infiltration in the tumor microenvironment. Additionally, the combination immunotherapy of CB548 and anti-PD1 antibody suppressed tumor growth to a greater extent than did the monotherapy, and led to durable tumor regression. There was no significant systemic toxicity with the CB548 treatment.

Conclusions: Overall, our study demonstrates that CB548, a novel IDO/TDO dual inhibitor, can elicit a robust anti-cancer immunity and synergistically inhibit cancer progression in combination with an immune checkpoint inhibitor.

Background: AGEN1884 is a novel anti–cytotoxic T-lymphocyte-associated antigen (CTLA)-4 fully human immunoglobulin (IgG)-1 monoclonal antibody. Objective: Assess safety, maximum tolerated dose, and pharmacokinetics (PK)/pharmacodynamics of AGEN1884 in patients (pts) with advanced/refractory malignancies and in pts refractory to recent anti–programmed death 1 (PD-1)/PD-L1 therapy.

Methods: Adult pts with relapsed/refractory lymphoma or solid tumors received AGEN1884 at 0.1, 0.3, 1, 3, or 6 mg/kg (3 + 3 design). 10 more pts each were enrolled in 1 and 3 mg/kg expansion cohorts. 10 pts with disease progression after prior treatment with approved or investigational PD-1/PD-L1 inhibitor as most recent therapy (2–5 weeks [wks] before first study drug) will be enrolled at 1 mg/kg. AGEN1884 was administered intravenously Q3 wks for 4 doses, then Q3, 6, or 12 wks at investigator's discretion.

Results: 33 pts enrolled as of 03Jan2018: 0.1 mg/kg (n = 5; 2 not evaluable [NE] for dose-limiting toxicity [DLT]); 0.3 mg/kg (n = 3); 1 mg/kg (n = 10); 3 mg/kg (n = 12; 2 NE for DLT); 6 mg/kg (n = 3). Median age: 61 y (range 26–88); baseline ECOG scores: 0 (n = 4), 1 (n = 25), unknown (n = 4); median 10 (range 3–26) prior therapies. No DLTs reported as of 31Jan2018. Immune-related adverse events (AEs) reported in 10 (30.3%) pts: 0.1 mg/kg (1, 20.0%), 0.3 mg/kg (1, 33.3%), 1 mg/kg (1, 10%), 3 mg/kg (6, 50%); included hypophysitis, colitis, diarrhea, rash, pruritus. Most were mild-moderate, consistent with other CTLA-4 inhibitors. 6 (18.2%) pts came off study due to disease progression or AEs, none treatment-related. Of 11 pts evaluable for response, 1 had complete response (angiosarcoma, 0.1 mg/kg). Stable disease (SD) in 3 pts: 1 with adenoid cystic carcinoma (0.3 mg/kg, 53 wks of SD) and 2 with breast cancer (3 mg/kg, SD at wks 6 and 12, respectively).

Conclusions: AGEN1884 was well tolerated at 0.1, 0.3, 1, and 3-mg/kg dose levels. Enrollment is ongoing at 6 mg/kg. Updated safety, PK, and results for the anti–PD-1/PD-L1 refractory expansion cohort will be presented. A starting dose of 1 mg/kg is being evaluated in ongoing trials in combination with PD-1 blockade.

Clinical trial identification: NCT02694822.

Background: Cytotoxic T-lymphocyte-associated antigen (CTLA)-4 and programmed death 1 (PD-1) pathways have important, distinct roles in T-cell modulation; blockade of both has been synergistic in vitro and in the clinic. This study will assess safety and tolerability of AGEN1884 (anti–CTLA-4 human immunoglobulin [IgG]-1 monoclonal antibody [mAb]) in combination with AGEN2034 (anti–PD-1 human IgG4 mAb) in patients (pts) with advanced/refractory solid tumors, with expansion into select solid tumors.

Methods: A dose-escalation phase and expansion focusing on adult female pts with recurrent/metastatic cervical cancer that has relapsed after platinum-containing doublet treatment. Phase 1 (Ph1) pts (n = 20) will be enrolled to 2 dose regimens of AGEN1884 + AGEN2034 (starting: 1 mg/kg AGEN1884 Q6w + 1 mg/kg AGEN2034 Q2w; escalating: 1 mg/kg AGEN1884 Q6w + 3 mg/kg AGEN2034 Q2w). Escalation phase primary endpoints: safety, determination of recommended Ph2 dose (RP2D); Ph2 (n = 40) also includes best overall response assessment by Independent Endpoint Review Committee per RECIST 1.1. Secondary endpoints: AGEN1884 and AGEN2034 pharmacokinetic (PK)/pharmacodynamic (PD) profiles, objective response rate, duration of response, progression-free and overall survival.

Results: 0 pts were enrolled 01Dec2017–10Apr2018 in 3 Australia centers: 7 pts at starting dose, 3 pts at escalating dose. No dose-limiting toxicity has been observed; most common toxicities observed were expected for therapeutic class. 8 pts experienced toxicity, mostly grade 1 or 2. Most common toxicities: diarrhea/nausea/vomiting, n = 6; rash/pruritus, n = 2; transaminases elevated, n = 1; fever/flu-like, n = 3; fatigue, n = 2. There was 1 serious adverse event and grade 3 toxicity unrelated to study drug. No discontinuation due to study drug, no deaths observed. Median dose administered was 1 for AGEN1884, 3 for AGEN2034. Dose level 2 was determined for RP2D. Updated safety, efficacy, and PK/PD of AGEN1884 + AGEN2034 will be presented.

Conclusions: AGEN1884 (1 mg/kg Q6w) + AGEN2034 (3 mg/kg Q2w) is well tolerated and being evaluated in Ph2 combination in 2L cervical cancer and other solid tumors.

1169P RORγ agonist LYC-55716 in combination with pembrolizumab to treat metastatic non-small cell lung cancer: An open-label, multicenter phase Ib trial

D.R. Camidge[1], S.M. Gadgeel[2], H.J. Wilkins[3], G. Weems[3], R. Santana-Davila[4], M. Johnson[5]

[1]Division of Medical Oncology, University of Colorado Cancer Center, Aurora, CO, USA, [2]Department of Internal Medicine, University of Michigan, Ann Arbor, MI, USA, [3]Clinical Development, Lycera Corp., Plymouth Meeting, PA, USA, [4]Medical Oncology, Seattle Cancer Care Alliance, Seattle, WA, USA, [5]Lung Cancer Program, Sarah Cannon Research Institute, Nashville, TN, USA

Background: The first-in-class, oral, small-molecule agonist of retinoic acid receptor–related orphan receptor γ (RORγ), LYC-55716, is an investigational agent under development as an immunotherapy for solid tumors. A Phase 1/2a trial demonstrated the safety of LYC-55716 as monotherapy and provided evidence of clinical activity, including a confirmed partial response in a patient with non–small cell lung cancer (NSCLC). Based on pre-clinical testing, the combination of RORγ agonist and a PD-1 inhibitor may enhance immune activation and the favorable effects of PD-1 inhibition on the tumor microenvironment. This ongoing open-label, multicenter Phase 1b trial is assessing the safety as well as clinical and biologic activity of LYC-55716 in combination with pembrolizumab (L+P) in patients with NSCLC.

Methods: A run-in cohort of patients (n = 3) is receiving L+P to monitor for safety signals. After determining a dose for further study, 1 main cohort (n = 15) will receive L+P until disease progression or unacceptable toxicity. Pre- and post-treatment biopsies will be obtained for patients in the main study cohort. Primary endpoints are safety (monitoring of adverse events, physical examination, lab results) and incidence of dose-limiting toxicities during the run-in period and ongoing treatment. Secondary endpoints include cellular and molecular immune response and biomarkers, objective response rate, duration of response determined via response evaluation criteria in solid tumors (RECIST) v1.1 and immune-related RECIST, and pharmacokinetics. Immune biomarkers are being assessed by immunohistochemistry (IHC) and a comprehensive gene profiling panel using a NanoString platform.

Results: Enrollment of patients in the run-in cohort is pending. IHC assay validation for RORγ and other immune markers is complete. Results of safety, preliminary efficacy, and biomarker evaluation will be available for patients initially enrolled at the time of presentation.

Conclusions: The LYC-55716 safety profile and clinical activity as a monotherapy agent support investigation of L+P to treat patients with metastatic NSCLC.

Clinical trial identification: NCT03396497.

1170P ABP-100: A tetravalent bispecific T-cell engaging antibody for HER2+ solid tumors

A. Boudot[1], X. Huang[1], S. Murphy[1], V. Appleman[1], H. Xu[2], N-K. Cheung[2], G. Macbeath[1]

[1]Therapeutics, Abpro, Woburn, MA, USA, [2]Nai-Kong Cheung Lab, Memorial Sloan Kettering, New York, NY, USA

Background: Clinical success with CAR-T therapy highlights the value of engaging cytotoxic T cells (CTLs) to treat cancer. Bispecific antibodies that link CTLs to tumor cells in an MHC-independent manner offer an off-the-shelf solution to T cell therapy that is accessible and scalable. Most bispecific antibodies are built as heterodimers, with monovalent binding to a highly expressed antigen on the tumor cell and to CD3 on the T cell. Here, we describe ABP-100, a HER2-specific T-cell engaging antibody built using a tetravalent bispecific (TetraBi) format that provides several significant advantages over the traditional format of bi-specific antibodies

Methods: ABP-100 was constructed by fusing a CD3-binding scFv to the light chain of an aglycosylated anti-HER2 IgG1, resulting in two binding sites each for HER2 and CD3. This TetraBi format was compared with a clinical-stage heterodimeric antibody that is monovalent for HER2 and CD3. The biophysical features of the two formats were compared, along with functional characteristics associated with both efficacy and safety.

Results: We observed that bivalent binding to HER2 provides a stronger association with HER2+ tumor cells than monovalent binding, but that locating the CD3-binding domains in the hinge regions of ABP-100 results in functionally monovalent binding to CD3. ABP-100 showed a similar safety profile (cytokine release) to the heterodimer molecule both in vitro and in vivo. In models of HER2+ cancer, however, ABP-100 showed highly potent antitumor activity, resulting in complete responses in mice at doses as low as 0.1 mg/kg with no evidence of tumor regrowth after treatments were stopped. Overall, the efficacy of ABP-100 was strongly dependent on HER2 levels and synergistic effects were observed when ABP-100 was combined with a PD-L1 inhibitor.

Conclusions: The TetraBi format of ABP-100 provides a potentially larger therapeutic index than more traditional bispecific formats that feature monovalent recognition of HER2. Moreover, because ABP-100 is designed to engage CTLs, it provides a novel mechanism for treating HER2+ disease relative to current therapies. These data support the clinical development of ABP-100 in HER2+ solid tumors.

Background: Most pts with R/M HNSCC do not respond to PD-1 inhibitor monotherapy. Cemiplimab is a human monoclonal anti-PD-1. An expansion cohort in the phase 1 study (NCT02383212) combined cemiplimab with other potential immune-supportive treatments for pts with R/M HNSCC.

Methods: Pts with R/M HNSCC who were refractory to at least first-line therapy and for whom palliative RT is clinically indicated received cemiplimab 3 mg/kg Q2W for up to 48 weeks plus RT (9 Gy × 3 times/week beginning 6–8 days after first dose of cemiplimab), cyclophosphamide (200 mg/m^2 every 14 days for 4 doses), and GM-CSF (200 µg daily for 7-days after each of the first 4 doses of cemiplimab). The co-primary objectives were to characterise the safety, tolerability, and efficacy of cemiplimab in combination with RT, cyclophosphamide and GM-CSF in 15 pts with R/M HNSCC. Tumour assessments were performed by RECIST 1.1 Q8W.

Results: As of 1 Sept, 2017, 15 pts (9 M/ 6 F) had been enrolled. Median (range) age was 62.0 (45–78) years; ECOG performance status was 1 in 12 pts (80%), and 0 in 3 (20%); and 14 (93.3%) had received prior RT. The primary site of cancer was upper aerodigestive tract of head and neck. With a median (range) duration of follow-up of 3.3 (0.5–10.2) months, treatment is ongoing in 3 pts (20.0%) and 12 (80%) had discontinued, mainly due to disease progression/recurrence (53.3%). The most common treatment-emergent adverse events (TEAEs) of any grade were fatigue (40.0%), constipation (26.7%), asthenia, dyspnoea, maculo-papular rash and pneumonia (each 20%). The only grade ≥3 TEAE that occurred in > 1 pts was pneumonia (13.3%). By investigator-assessment, there was 1 partial response (6.7%); disease control rate was 40.0% (95% CI: 16.3–67.7; 5 stable disease), 7 pts had progressive disease and 2 were not evaluable. Median progression-free survival by investigatorassessment was 1.8 months (95% CI: 1.7–4.7).

Conclusions: The combination therapy regimen did not demonstrate efficacy above that which can be achieved with PD-1 inhibitor monotherapy for R/M HNSCC.

Clinical trial identification: NCT02383212.

1172P A first-in-class, first-in-human phase I/IIa trial of CAN04, targeting interleukin-1 receptor accessory protein (IL1RAP), in patients with solid tumors

A. Awada[1], F.A.L.M. Eskens[2], D.G. Robbrecht[2], U.N. Lassen[3], M. Sorensen[3], J.H.M. Schellens[4], J.S. de Groot[4], C. Jungels[1], P.G. Aftimos[1], S.O. Fretland[5], L. Thorsson[6], T.K. Guren[5]

[1]Medical Oncology Clinic, Institut Jules Bordet, Université Libre de Bruxelles, Brussels, Belgium, [2]Department of Medical Oncology, Erasmus MC Cancer Institute, Rotterdam, Netherlands, [3]Onkologisk Klinik/Dept. of Oncology, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark, [4]Division of Clinical Pharmacology, Department of Medical Oncology, The Netherlands Cancer Institute, Amsterdam, Netherlands, [5]Radiumhospitalet, Oslo University Hospital, Oslo, Norway, [6]Clinical Development, Cantargia AB, Lund, Sweden

Background: CAN04 is a first-in-class fully humanized monoclonal antibody targeting IL1RAP, a co-receptor for the IL-1 receptor which is expressed on human cancer cells. CAN04 binds to IL1RAP with high affinity in a manner that blocks signal transduction from IL-1 and IL-33 into the cells. Binding of CAN04 to IL1RAP also allows NK-cells to recognize tumor cells and subsequent killing by antibody dependent cellular cytotoxicity (ADCC).

Methods: The primary objective was to assess safety and tolerability of weekly CAN04 in order to define the Maximum Tolerated Dose/Recommended Phase 2 Dose. Patients with relapsed or refractory non-small cell lung cancer (NSCLC), pancreatic ductal adenocarcinoma (PDAC), breast or colorectal cancer were included in the initial part of the trial using a 3 + 3 dose escalation design. Key eligibility criteria were ECOG ≤1, normal organ function and no bleeding disorder or coagulopathy. Tumor responses were evaluated according to irRC every 8 weeks. Plasma samples were obtained for pharmacokinetic evaluation and for assessment of circulatory biomarkers of immunological activity (e g IL-1α, IL-1β, IL-1RA, IL-6, IL-8, IL-33 and TNF-α).

Results: Nine subjects were enrolled across 3 initial cohorts (1-3 mg/kg). Demography: mean age 66 yrs (48-77); gender 5 M and 4 F; median number of prior lines of therapy 5 (range 2-11). No dose limiting toxicities (DLTs) were observed and MTD has not been reached yet. AEs occurred mainly following the first dose and the most common AEs were: fatigue (67%), nausea (44%), pyrexia (44%), infusion related reaction (IRR) (44%) and pruritus (44%). AE grade 3 or 4: one grade 3 IRR following an initial dose of 1.0 mg/kg in cohort 3. Stable disease was achieved in 2/6 and progressive disease in 4/6 patients after 8 weeks of treatment.

Conclusions: CAN04 demonstrated a manageable safety profile in the initial 3 cohorts with no DLTs observed and the dose escalation will be continued as planned. The dose expansion phase of the trial will then evaluate CAN04 as monotherapy as well as in combination with standard of care therapy for NSCLC and PDAC in separate arms.

Clinical trial identification: NCT03267316.

1173P Immunostimulatory AdCD40L gene therapy in patients with advanced solid tumours

S. Irenaeus[1], J. Wenthe[2], E. Eriksson[2], J. Krause[3], A. Sundin[3], H. Ahlström[3], T. Tötterman[2], A. Loskog[2], G. Ullenhag[1]

[1]Department of Immunology, Genetics and Pathology and Department of Oncology, Uppsala University Hospital, Uppsala, Sweden, [2]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden, [3]Department of Surgical Sciences, Section of Radiology and Department of Radiology, Uppsala University Hospital, Uppsala, Sweden

Background: CD40-CD40L is a key activator of adaptive immunity. AdCD40L is a replication-deficient adenovirus carrying the CD40 ligand gene. We have conducted a phase I/II study (NCT01455259) for patients with advanced cancer receiving intratumoral injections of AdCD40L. Patients with metastatic malignant melanoma were treated in the first three cohorts in which we demonstrated that low dose cyclophosphamide before the first and fourth intratumoral injection given in the second and the third cohort was of clinical value with four patients surviving >1 year, while radiotherapy combination was not. In these patients, AdCD40L increased the Teffector to Tregulatory cell ratio showing its action via T cell activation. We now report the results of the fourth and final cohort treating patients with other solid malignancies.

Methods: Six patients with metastatic solid cancer underwent treatment with four weekly percutaneous intratumoral injections of $2.5x10^{11}$ VP AdCD40L and low dose cyclophosphamide conditioning (300 mg/m^2) before the first and fourth injection. All patients had good performance status at inclusion. The primary tumor was kidney cancer (n = 2) or cholangiocarcinoma (n = 1), rectal- (n = 1), ovarian- (n = 1), and breast cancer (n = 1). Correlation analysis between immunological data and survival was performed.

Results: The treatment was generally well tolerated. Patients received the injection in metastases located in the liver (n = 4), lymph node (n = 1), or muscle (n = 1). The performance status for one patient improved during the treatment and this patient was therefore accepted for re-treatment. The median survival was 54 weeks ranging from 5 to 101 weeks compared to the melanoma patients that had a median survival of 27 weeks (5 to 220 weeks). Immunological data from five of the patients showed a significant negative correlation between IL10 concentrations at week 3 and survival ($p = 0.0283$). In addition, TNFα and IL12 was higher post-treatment in the two patients with the longest survival.

Conclusions: Intratumoral injections of AdCD40L in combination with cyclophosphamide is feasible in patients with solid cancer. Desirable immune effects were noted and the potential of the treatment was also demonstrated in one patient who improved clinically.

Clinical trial identification: NCT01455259 Realease date: September 2011.

1174P Patterns of progression to immune checkpoint targeted monoclonal antibodies in phase I trials

A. Bernard-Tessier[1], C. Baldini[1], E. Castanon Alvarez[1], S. Ammari[2], P. Martin Romano[1], S. Champiat[3], A. Hollebecque[1], S. Postel-Vinay[1], A. Varga[1], R. Bahleda[1], A. Gazzah[1], J-M. Michot[1], V. Ribrag[1], J-P. Armand[1], A. Marabelle[1], J-C. Soria[1], C. Massard[1]

[1]Drug Development Department (DITEP), Gustave Roussy, Villejuif, France, [2]Imaging, Gustave Roussy, Villejuif, France, [3]Drug Development Department (DITEP), Gustave Roussy, Villejuif, France

Background: New patterns of progression under immune checkpoint targeted (ICT) monoclonal antibodies (mAb) have been described such as pseudoprogression (PsPD). Except for melanoma, variations between studies reveal difficulties to establish their real incidence. This study aims to assess different patterns of progression in ICT mAb phase I trials.

Methods: All patients participating in ICT mAb phase I trials at the Drug Development Department at Gustave Roussy for solid tumors excluding melanoma, were enrolled. Radiological evaluations according to iRECIST 1.1 were correlated with prospectively registered patient characteristics and outcomes.

Results: Among 360 patients included between August 2015 and November 2017, 70.6% received ICT mAb combination: 58.3% with another ICT mAb, 27.9% with targeted therapy and 13.8% with radiotherapy. Patients received a median of 2 previous lines of therapy (range 0-10). The objective response rate was 17.2%. PsPD were observed in 10 (2.8%) of patients (1 NSCLC, 1 microsatellite-high colon cancer, 1 hepatocarcinoma, 2 renal, 2 bladder, 1 cervix, 1 thyroid and 1 thymic cancer). PsPD patients had a median PFS (until confirmed PD according to iRECIST) of 17.3 months (95%CI[4.8-N.R]) that was comparable to other responders patients PFS (median unreached 95%CI[13.8-N.R]; HR, 2.0; 95%CI[0.7-6.1]; p = 0.2). Dissociated responses (defined as a concomitant progressing and responding lesions) were reported for 4.2% of patients with a median PFS of 4.8 months (95%CI[3.0-15.6]) comparable to stable disease patients (median PFS 5.0 months 95%CI[4.3-6.4]; HR, 0.9; p = 0.6). Among the 203 patients who progressed at first evaluation, 139 (68%) were withdrawn from the phase I study at first assessment, whereas 64 (32%) continued ICT mAb and underwent another CT scan evaluation one-month later.

Conclusions: We showed a low rate of PsPD and dissociated response in a large cohort of patients excluding melanoma. Using iRECIST, 32% of progressing patients underwent another CT scan at one month confirming PD, which may delay the initiation of a new regimen. This work suggests that prognosis or on-treatment biomarkers are needed to identify early patients who should (or not) continue ICI treatment once a first progression is evidenced.

Background: Vaccine therapy INVAC-1 (a DNA vaccine encoding human telomerase reverse transcriptase (hTERT)), is a new class of anti-cancer agents and was evaluated in a Phase 1 trial (INVAC1-CT-101 study) in patients with advanced cancer. We propose to study tumour patterns of response on imaging evaluations of patients under vaccine in a retrospective CT study.

Methods: The tumour growth rate (TGR) of the tumor burden (sum of lesions) was calculated before and during therapy. Patients with decrease of the TGR after initiation of therapy were considered responders whereas patients with stability or increase of the TGR were considered non responders. Overall survival (OS) and response according to anatomical location were also analysed.

Results: 10/19 patients were responders according to the tumour growth rate. The median [IQR] of OS was 9.6 month [6.8, 13.3] versus 5.3 month [5.1, 15.0] for non-responders (p = 1.3.10-5). Regarding organ sensitivity to vaccine therapy, we observed that none of the liver metastases responded to treatment, whereas the majority of lymph node lesions responded.

Conclusions: The decrease of the tumor growth rate in patients treated by vaccine therapy INVAC-1 could predict a benefit in terms of overall survival. The efficiency could vary depending on the location of the metastases.

1176P Oncolytic virotherapy for multiple myeloma targeting CD40, 41BB and/or IL6R

J. Wenthe, S. Naseri, A-C. Hellström, E. Eriksson, A. Loskog

Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden

Background: Despite current treatment options in multiple myeloma (MM), most patients acquire resistance to therapy and relapse. As MM remains incurable, novel therapies are needed. A potentially promising approach is immunostimulatory therapy via an armed oncolytic adenovirus. The herein investigated LOAd viruses are serotype Ad5/35 chimera and therefore infect cells via CD46, which is often upregulated in MM. Viral replication is restricted to tumor cells due to a deletion in E1A. LOAd viruses express transgenes under the control of a CMV promoter. LOAd703 encodes for trimerized membrane-bound (TMZ) CD40L and 4-1BBL, whereas LOAd713 carries a gene encoding a single chain fragment against the IL-6 receptor in combination with TMZ-CD40L. IL-6 is identified as an essential growth and survival factor in MM. Hence, LOAd713 therapy may be of special interest as it not only induces immune cell activation via TMZ-CD40L but also blocks IL-6R signaling.

Methods: A panel of MM cell lines (ANBL-6, L363, LP-1, OPM-2, RPMI-8226, U266-84) were infected with LOAd viruses. Viral replication was evaluated with qPCR detecting viral DNA and viability was analyzed by MTS assay. Surface expression of TMZ-CD40L, 4-1BBL and markers for an immunogenic phenotype were analyzed by flow cytometry. Cell culture supernatants were investigated by multiplex analysis.

Results: All MM cell lines were sensitive to LOAd infection, leading to viral replication and decreased cell viability. TMZ-CD40L and 4-1BBL were expressed in all cells infected with the respective viruses carrying the transgenes. LOAd infection induced an immunogenic phenotype with the upregulation of molecules that facilitate recognition and killing by the immune system. These included CD40, 4-1BB, Fas, HLA-DR, CD80 and CD86. In the supernatants of infected cells, the pro-inflammatory cytokine MIP-1α was increased in 4/6 cell lines. The suggested MM growth factor MCP-1 as well as sIL2R were decreased in 3/6 cell lines.

Conclusions: LOAd viruses infected and replicated in MM cells. The encoding transgenes induced transgene expression and subsequently an immunogenic phenotype in infected cells. Immunostimulatory oncolytic LOAd viruses may be an attractive approach for MM therapy.

1177P Humanized knock-in mouse models for evaluating in vivo efficacy of immune-oncology drugs targeting stimulatory immune checkpoint molecules

T. Gan[1], J. Xiang[2], C. Guo[1], Y. Guo[1]

[1]Pharmacology Study Platform, Beijing Biocytogen Co., Ltd., Beijing, China, [2]Pharmacology Study Platform, Biocytogen LLC, Worcester, MA, USA

Background: Cancer immunotherapy is one of the most promising research areas in the field of cancer therapy. Many pharmaceutical and biotech companies in the world are devoting great effort to develop cancer immunity-related treatment antibodies. However, along the IO drug development process, in vivo efficacy models have always been a rate-limiting step.

Methods: In most cases, a human monoclonal antibody does not have mouse cross-reactivity. Mouse surrogate antibodies were often used in immune-competent syngeneic mouse models to evaluate in vivo efficacy of IO drugs. However, the efficacy of a surrogate antibody cannot fully represent the human drug in the clinical scenario. Therefore, we generated humanized knock-in mice to evaluate the in vivo efficacy of human IO antibodies.

Results: For example, human 4-1BB knock-in (B-h4-1BB) mice were generated with a chimeric 4-1BB receptor, which is recognizable by stimulatory human 4-1BB antibodies. Additionally, more knock-in mice targeting stimulatory immune checkpoint molecules were developed and validated, such as B-hCD3e, B-hCD40, B-hOX40, B-hGITR, B-hCD27, B-hCD28 et al.

Conclusions: All these mouse models response well to the corresponding human IO antibodies, proving that they are powerful tools for in vivo efficacy evaluation of human stimulatory immune checkpoint antibodies.

1178P Tackling fratricide to manufacture clinical grade NKG2D-CAR T cells for cancer therapy

B. Demoulin, B. Eytan, D. Gilham

R&D, Celyad SA, Mont Saint Guibert, Belgium

Background: T cells bearing a chimeric antigen receptor (CAR) T-cell consisting of the fusion of the NKG2D NK receptor with the intracellular domain of CD3zeta (CYAD-01) can recognize eight stress ligands expressed in a large variety of cancers. However, activated T cells undergo stress and transiently express NKG2D ligands (NKG2DL). Consequently, CYAD-01 T cells kill sister cells preventing the large-scale manufacturing of CYAD-01 for clinical application.

Methods: Inclusion of the PI-3K inhibitor LY294002 into the manufacturing process was the first strategy used as an initial effort focused upon blunting the activity of the CAR T cells. We subsequently developed a process that included a NKG2D blocking antibody during the expansion phase of cell culture.

Results: LY294002 was shown to reversibly reduce NKG2D expression at the cell surface. Consequently, this inhibitor partially controlled fratricide during manufacturing and enhanced viability post-thawing which enabled the initiation of the THINK (NCT03018405) clinical trial. As the trial moved through the dose-escalation phase towards the upper dose level (production of more than 10^{10} cells), there was an increase in the level of manufacturing failures. This was largely linked to the effect of LY294002 upon T cell proliferation and the challenge faced manufacturing CAR T cells from patients with advanced cancer. Therefore, we subsequently developed a process that included a NKG2D blocking antibody during the expansion phase of cell culture. This strategy enabled the expansion of CYAD-01 T cells to the levels required for the THINK clinical trial. After fine tuning the process, the CYAD-01 CAR T cells generated showed high comparability to the CYAD-01 CAR T cells produced in the first part of the trial. This process has been in place for the THINK trial since January 2018.

Conclusions: Together, these results indicate that when fratricide is an issue preventing clinical development, CAR T cells can be efficiently manufactured through PI-3K inhibition and antibody mediated receptor blockade.

1179P The high expression of NKG2D ligands on tumor and the lack of surface expression on healthy tissues provides a strong rationale to support NKG2D-based therapeutic approaches for cancer

S. Agaugue[1], A. Hargreaves[2], P. De Sousa[3], P. De Waele[4], D. Gilham[1]

[1]R&D, Celyad SA, Mont Saint Guibert, Belgium, [2]R&D, Pathcelerate, Cheshire, UK, [3]R&D, PDC Line Pharma, Liège, Belgium, [4]R&D, Advanced Therapies Consulting Ltd, Ghent, Belgium

Background: The NKG2D receptor is a type II transmembrane glycoprotein playing an important role in anti-tumor responses. In humans, NKG2D binds to eight ligands, MHC class I–related chain MICA and B and unique long 16 (UL16)-binding proteins ULBP 1-6. The surface expression of NKG2D ligands (NKG2DL) is highly regulated to avoid inappropriate immune responses in physiological conditions but is induced by various stress situations such as malignant transformation or inflammation. NKG2DL expression on tumors has been reported in the literature. However, a systematic study on all NKG2DL in a large array of normal tissues and tumor samples is lacking. Celyad is pursuing the clinical development of NKG2D based chimeric antigen receptor (CAR) T cell therapy and robust data are thus required to adequately support this work.

Methods: We performed an extensive immunohistochemistry study on primary tumors and normal adjacent tissues from patients suffering from pancreatic, breast, ovarian, bladder, colorectal and lung carcinomas and on a series of normal tissues from non-cancer patients.

Results: MICA/B were the most frequently and highly expressed. Interestingly the subset of triple negative breast cancers (TNBC) showed strong membranous staining for all NKG2DL on tumor cells making this patient subpopulation a very attractive therapeutic target for NKG2D-based therapies. There was no clear correlation between the expression of NKG2DL and the clinical stage of the tumors indicating that every stage of the diseases could be targeted. In bladder, TNBC, CRC and pancreatic tumors, tumor cells were frequently stained for multiple NKG2DL implying that these tumors would not be susceptible to immune escape. Tumor-associated fibrovascular structures displayed generally membranous staining within the endothelial compartment suggesting that NKG2D-based CAR T therapy can target simultaneously both the tumor and the tumor microenvironment.

Conclusions: In conclusion, this extensive immunohistochemistry study supports the concept of targeting NKG2DL for cancer therapy.

Legal entity responsible for the study: Celyad SA.

1180P Combination of pegilodecakin and docetaxel shows synergy in tumor rejection in immune resistant TNBC model

N. Ratti[1], N. Shifrin[1], S. McCauley[1], R. Verma[1], P. Van Vlasselaer[1], M. Oft[1], J. Leveque[2]
[1]Pre-Clinical and Clinical Development, ARMO BioSciences, Redwood City, CA, USA, [2]Scientific Affiars, ARMO BioSciences, Redwood City, CA, USA

Background: Immune checkpoint inhibitors (ICI) induce durable tumor responses and increased overall survival (OS) of cancer patients. Patients with low PD-L1, low tumor mutational burden (TMB) or without intra-tumoral CD8+ T cells, have a poor response rate to ICIs. Pegilodecakin (AM0010) is a pegylated recombinant human interleukin-10, which overcomes tumor immune escape by stimulating the activation, survival and clonal expansion of intra-tumoral, tumor antigen specific CD8+ T cells. Pegilodecakin up-regulates IFNγ in CD8+ T cells and MHC expression, which facilitates antigen presentation even in tumors with low CD8+ T cells and low TMB. Here we explore the combination of Pegilodecakin with SOC docetaxel in an ICI resistant mouse triple negative breast cancer model.

Methods: 4T1 cells were established SC for two weeks prior to treatment. Pegilodecakin was administered at suboptimal doses, docetaxel was dosed at the MTD. Quantitation of T cell infiltration and tumor cell death was quantified by IHC. Intra-tumoral and systemic cytokine and T cell activity were evaluated.

Results: Docetaxel did not induce regressions but inhibited tumor growth by 65%. Pegilodecakin alone induced tumor growth inhibition and delayed tumor regression in 75% of mice with an 80% reduction of tumor size after 4 weeks of treatment. Pegilodecakin + docetaxel lead to a synergistic tumor control and complete responses in 75% of mice. While pegilodecakin induced T cell infiltration and tumor cell apoptosis with 95% of the measurable tumor being reduced to scar tissue, the tumor size initially continued to increase, indicative of pseudo-progression. In contrast, Pegilodecakin / docetaxel therapy led to a complete eradication of the tumor without pseudoprogression.

Conclusions: The determination of clinical efficacy of immune therapy can be difficult due to delayed immune responses and pseudoprogression related to immune effector cell infiltration. Here we show that largely necrotic tumors on pegilodecakin may have a delayed clearance despite overwhelming anti-tumor efficacy. The combination of immunotherapy with chemotherapy may facilitate clearance of the necrotic tumor mass leading to complete responses of measurable tumor burden.

1181P Mutations in interferon gamma and antigen presentation pathways are frequent in hiper/ultra-mutated (HiMut) tumors and could be result of immune-editing processes in HiMut tumors

J.M. Piulats Rodriguez[1], S. Garcia-Mulero[1], L. Valle[2], V. Moreno[3], X. Matias-Guiu[4], R. Sanz-Pamplona[3]
[1]Medical Oncology, Institut Catala d'Oncologia (ICO), Barcelona, Spain, [2]Translational Research Laboratory, Institut Catala d'Oncologia (ICO), Barcelona, Spain, [3]Prevención del Cancer, Institut Catala d'Oncologia (ICO), Barcelona, Spain, [4]Pathology, Hospital de Bellvitge, Barcelona, Spain

Background: Tumors with a phenotype associated with a high mutational load such as POLE-mutated or those showing microsatellite instability (MSI) are more likely to have clinical responses to immune-checkpoints blockade therapy. Indeed, several clinical trials are currently on-going targeting PD-1 in a variety of cancer types. However, some of these patients do not respond to immunotherapy. Recently, mutations in JAK1 and JAK2 has been reported to be responsible for this resistance.

Methods: Here we explore the effect of functional mutations in genes in the interferon gamma (IFG) signaling and antigen presentation (AP) pathway in endometrial, colorectal, and gastric POLE-mutated and MSI tumors extracted from TCGA.

Results: As a result, we have found that POLE-MSI tumors accumulated more mutations in IFG and AP pathways than randomly expected. Using gene expression data, we corroborate that IFN pathway is under-expressed in IGF/AP mutant tumors. MSI IGF/AP mutant tumors over-express T cell receptor pathway probably as a compensatory mechanism. Moreover, when cell infiltration was assessed, these tumors have a tendency to present higher levels of cytotoxic lymphocytes than non-mutated tumors. However, they showed over-expression of pathways related to anti-PD1 resistance such as epithelial to mesenchymal transition or angiogenesis. These results suggest that despite being infiltrated, IGF/AP mutant tumors are able to evade immune surveillance. Regarding survival, although overall these tumors have a very good prognosis, we observed that IGF/AP mutated endometrial tumors showed higher clinical grade than the non-mutated ones.

Conclusions: Based on these results, we show that regardless of cancer type, HiMut tumors with functional mutations in IFG and AP pathways shows a more aggressive phenotype, and present activation of cellular processes that have been related to immune-resistance, probably to evade destruction by a very active T-cell stroma due to the high amount of neoantigens. This phenotype is even more evident in ultra-mutated POLE tumors. Therefore, HiMut tumors could be exploited as a surrogate to understand mechanisms of immune-resistance.

1182P Anti-CTLA4 toxicity associates with genetic variation correlating with serum antibody diversity

D. Simpson[1], R. Ferguson[1], M. Gowen[2], K.M. Giles[2], J. Tchack[2], H. Zhou[3], U. Moran[1], Z. Dawood[2], A. Pavlick[4], S. Hu[5], M.A. Wilson[4], H. Zhong[6], M. Krogsgaard[7], J.S. Weber[8], I. Osman[2], T. Kirchhoff[9]
[1]Perlmutter Cancer Center, New York University Medical Center, New York, NY, USA, [2]Dermatology, New York University Medical Center, New York, NY, USA, [3]Bioinformatics Core, New York University Medical Center, New York, NY, USA, [4]Department of Medicine, New York University - Perlmutter Cancer Center - Langone Medical Center, New York, NY, USA, [5]CDI Laboratories, CDI, Baltimore, MD, USA, [6]Biostatistics, New York University Medical Center, New York, NY, USA, [7]Department of Pathology, New York University Medical Center, New York, NY, USA, [8]Perlmutter Cancer Center, NYU Langone Medical Center, New York, NY, USA, [9]Perlmutter Cancer Center, New York University, New York, NY, USA

Background: While anti-CTLA4 immunotherapy (IT) improves survival in metastatic melanoma patients, it manifests with severe toxicity. Recently, we identified serum antibody signatures associated with toxicity outcomes following anti-CTLA4 IT. In this study, capitalizing on our recent data showing that the expression of autoimmunity risk genes is controlled by germline genetic variation in melanoma survival, we tested whether antibody profiles linked with IT-related toxicity are impacted by underlying genetic variation.

Methods: We have integrated serum data from 37 anti-CTLA4 IT-treated patients, profiled by HuProt human proteome array with germline whole-exome sequencing (WXS), comparing 28 patients with none/mild toxicity (CTCAE score 0-2) and 9 patients with severe toxicity (CTCAE score 3-5). The associations between toxicity and germline genetic variation were assessed by gene-burden analysis (SKAT). SKAT was integrated with differential proteome analysis of toxicity to identify individual proteins coded by genes and/or pathway enrichment putatively controlled by genetic variation associated with anti-CTLA4 related toxicity.

Results: The proteomic analysis identified 915 proteins that were differentially expressed ($p < 0.05$) in non/mild versus sever toxicity outcomes in anti-CTLA4 IT. SKAT analysis of genetic variation identified 1947 significant genes ($p < 0.05$) associated with toxicity, of which 78 were also significant ($p < 0.05$) in the proteomic analysis. The functional pathway analysis of 78 proteins showed enrichment for the regulation of interferon production, and a significant enrichment was observed for molecular pathways involved in autoimmunity.

Conclusions: We present a novel framework integrating germline genetic information and serum protein expression levels to identify associations with toxicity in anti-CTLA4 IT. We found enrichment for interferon production and pathways involved in autoimmunity controlled by genetic variation. The data strongly support the importance of genetic variation in immune system regulation and its effect on IT-related toxicity. The effect of genetic variants on protein expression is currently further tested in the context of toxicity response to IT treatment.

1183P PD-L1 expression is strongly associated with TIGIT, FOXP3 and LAG3 across advanced cancers, but not OX40, TIM3 and IDO

S.K. Pal[1], A.M. Vanderwalde[2], C. Szeto[3], S. Reddy[3], O. Hamid[4]
[1]Medical Oncology and Therapeutics Research, City of Hope, Duarte, CA, USA, [2]Hematology/Oncology, University of Tennessee, Memphis, TN, USA, [3]Bioinformatics, NantOmics, Culver City, CA, USA, [4]Research/Immuno-Oncology, The Angeles Clinic and Research Institute, Los Angeles, CA, USA

Background: Multiple trials are ongoing to evaluate combinations of immune checkpoint inhibitors (ICIs) across a variety of tumor types. Most of these studies utilize programmed death-1(PD-1) or programmed death-ligand 1 (PD-L1) inhibitors as a backbone. We interrogate the relationship of PD-L1 with other immune checkpoints to inform rational combination strategies.

Methods: We performed whole transcriptomic sequencing (RNA-Seq; ~200x10^6 reads/tumor) across 1,467 unselected clinical cases (NantHealth; Culver City, CA). Cases reflected 38 distinct histologies; the most common histologies were breast (17.8%), colon (9.5%) and lung (7.9%). High and low PD-L1 was delineated as the top

and bottom 15th percentile of expression values. Co-expression of checkpoint markers (TIGIT, FOXP3, LAG3, OX40, TIM3 and IDO) was analyzed within PD-L1-defined categories, along with putative markers of ICI resistance (e.g, VEGF-A/B/C). Tumor mutational burden (TMB; defined as exonic nonsynonymous mutations) was characterized across checkpoints.

Results: High PD-L1 expression was strongly associated with high expression of TIGIT, FOXP3 and LAG3 ($P < 0.001$ for each). In contrast, there was no significant difference in expression of OX40, TIM3 and IDO in groups subdivided by high and low PD-L1 expression. High expression of PD-L1 was associated with elevated levels of VEGF-C, but there was no relationship with VEGF-A or VEGF-B expression. Very limited concordance was seen between elevated TMB (> 200 nonsynonymous mutations) and checkpoint expression.

Conclusions: Recent results of combination trials assessing IDO and PD-1 inhibitors may be attributable to a lack of concomitant expression of these markers, thereby limiting synergy. Combinations of PD-1/-L1-directed therapies with TIGIT and LAG3 inhibitors may therefore be of greater interest. Enrichment strategies using TMB for these combinations may be challenging, given the lack of association with checkpoint expression.

Lee Moffitt Cancer Center University of South Florida, Tampa, FL, USA, [14]Pfizer, Inc., New York, NY, USA, [15]Gastrointestinal Oncology, National Cancer Center Hospital East, Kashiwa, Chiba, Japan

Background: PF-04518600 (PF-8600) and utomilumab (uto) are human IgG2 agonistic mAbs against the tumor necrosis factor superfamily receptors OX40 and 4-1BB, respectively. Both receptors play key roles in T cell survival, proliferation, and activation. PF-8600 has been shown to increase proliferation and activation of peripheral CD4 memory T cells and uto has a similar effect on CD8 memory T cells. Previously, in patients treated with PF-8600, PD changes have been observed in tumor biopsy samples, including enrichment of gene sets associated with immune activation as well as CD4/8 T cell clonal expansion in peripheral blood. PD changes in tumors and peripheral TCR repertoire for PF-8600 + uto are reported here.

Methods: Paired biopsy samples at baseline and week 6 were collected from 5 dose cohorts (0.1/20, 0.3/20, 0.3/100, 1.0/100, 3.0/100; dose of PF-8600 in mg/kg / flat dose of uto in mg) during dose escalation. Biopsy tissues were analyzed by IHC and RNAseq to evaluate the PD effects of PF-8600 + uto. CD4, CD8, OX40, and FoxP3 expression was measured by IHC. Changes in transcriptional profile were measured by RNAseq analysis and gene ranking-based gene set enrichment analysis. CD4/8 cells were isolated from blood samples at the same time points. DNA was extracted and submitted for high-throughput sequencing of TCRβ.

Results: In an analysis of paired biopsy samples from dose cohorts including ≥ 0.3 mg/kg PF-8600, OX40 was among the genes that showed increased expression. The top gene sets exhibiting significant enrichment by RNAseq were associated with immune activation. TCR sequencing revealed clonal expansion of CD4/8 T cells at all dose levels.

Conclusions: Increases in immune-related markers including OX40 and enrichment of gene sets associated with immune activation were observed in tumor tissue, providing evidence of an active, immunomodulatory mechanism for PF-8600 + uto. Peripheral CD4/8 T cell populations exhibited clonal expansion at all dose levels, further suggesting an immune-activating PD effect. Further evaluation of PF-8600 + uto safety, efficacy, and PD continues in NSCLC and melanoma cohorts.

Clinical trial identification: NCT02315066.

1185P Using MultiOmyx™ to analyze correlations between immunosuppressive cells and tumor-infiltrating lymphocytes in the pancreatic tumor microenvironment

A. Juncker-Jensen, J. Fang, J. Kuo, M.L. Nagy, R.K. Padmanabhan, E. Leones, F. Sahafi, S. Zhu, Q. Au, N. Hoe, J. William

MultiOmyx, NeoGenomics, Aliso Viejo, CA, USA

Background: Pancreatic ductal adenocarcinoma (PDAC) is one of the most aggressive forms of cancer with a five-year survival rate that has remained below 10% for the past two decades. While immunotherapy-based treatment in recent years has demonstrated great success in stimulating anti-tumor T cell immunity in a wide variety of cancers, immunotherapy has had very limited success in pancreatic cancer patients. PDAC is characterized by a highly immunosuppressive tumor microenvironment (TME), dominated by Myeloid Derived Suppressor Cells (MDSCs), Type 2 Tumor-Associated Macrophages (M2 TAMs), and T regulatory cells (Tregs). While the presence of these cell types in the PDAC TME is well characterized, much still remains to be understood about how they function within the TME and how they co-operate with each other and tumor-resident lymphocytes to regulate antitumor immunity.

Methods: MultiOmyx™, a novel hyperplexed multi "omic" technology, enables visualization and characterization of multiple biomarkers on a single 4 µm tissue section. MultiOmyx protein immunofluorescence (IF) assays utilize a pair of directly conjugated Cyanine dye-labeled (Cy3, Cy5) antibodies per round of staining. Each round of staining is imaged and followed by novel dye inactivation chemistry, enabling repeated rounds of staining and deactivation for up to 60 protein biomarkers. In this study, MultiOmyx hyperplexed IF assay was utilized to measure CD11b, CD14, CD15, CD16, CD33, CD45RO, CD68, CD163, FoxP3, HLA-DR, Arginase1, PD-1, PD-L1, granzymeB, Ki67, and PanCK protein expression from a single 4 µm FFPE section.

Results: Using the MultiOmyx™ multiplexing assay in combination with proprietary algorithms for specific biomarker classification, we will report on the correlation between the presence of monocytic MDSCs (CD11b+CD33+CD14+CD15-HLA-DR-), granulocytic MDSCs (CD11b+CD33+CD15+CD14-HLA-DR-), M2-TAMs (CD68+CD163+), Tregs (CD3+CD4+FoxP3+) and the activation state of TILs, as well as their spatial relationship in tumor tissue from patients with PDAC.

Conclusions: Using the MultiOmyx™ multiplexing assay will allow us to analyze correlations between immunosuppressive cells and TILs in the pancreatic TME.

1186P Interim results from exploratory study to determine S-588410-induced tumor infiltrating lymphocytes and changes in the tumor microenvironment in esophageal cancer patients

T. Kojima[1], T. Marafioti[2], T. Fujiwara[3], Y. Shirakawa[3], T. Nakatsura[4], K. Kato[5], I. Puccio[2], M. Nagira[6], N. Ide[7], K. Stoeber[8], A. Arimura[7], H. Daiko[9]

[1]Department of Gastroenterology and Gastrointestinal Oncology, National Cancer Center Hospital East, Kashiwa, Chiba, Japan, [2]Department of Cellular Pathology, University College London Hospital, London, UK, [3]Gastroenterological Surgery, Okayama University Hospital, Okayama, Japan, [4]Cancer Immunotherapy, Exploratory Oncology Research & Clinical Trial Center, National Cancer Center, Kashiwa, Japan, [5]Gastrointestinal Medical Oncology Division, National Cancer Center Hospital, Tokyo, Japan, [6]Drug Discovery & Disease Research Laboratory, Shionogi & Co., Ltd., Osaka, Japan, [7]Project Management Department, Shionogi & Co., Ltd., Osaka, Japan, [8]Business Development, Shionogi & Co., Ltd., Osaka, Japan, [9]Esophageal Surgery Division, National Cancer Center Hospital, Tokyo, Japan

Background: S-588410 is a cancer peptide vaccine composed of 5 HLA-A*24:02-restricted peptides derived from 5 cancer-testis antigens, DEPDC1, MPHOSPH1, URLC10, CDCA1 and KOC1, all of which have been found to be upregulated in esophageal cancer. The aim of this study is to evaluate the effects of S-588410 on the number of tumor-infiltrating CD8-positive lymphocytes (TIL) and PD-L1 expression in the tumor tissue before and after the short-term treatment with S-588410 in the pre-surgical treatment.

Methods: HLA-A*24:02-positive patients (pts) with esophageal cancer who can start the treatment more than 30 days prior to the surgery were eligible. S-588410 was injected subcutaneously once weekly, 5 times or more in total. Tumor tissues of pre- and post-treatment were collected for immunohistochemistry (IHC) analysis for target antigens, CD8, PD-L1 and HLA class I. Peptide-specific CTLs in PBMC were evaluated using ELISpot assay.

Results: As Apr 13, 2018, total 15 pts were enrolled and tumor tissues of the first half of the pts, 8 pts were analyzed. 8 pts received 3 to 6 injections of S-588410. All 5 antigens and HLA class I on tumor tissues were detected in all pts except for one whose tumor expressed 4 target antigens. CTL activity circulating in blood markedly increased in all 8 pts at least for 1 of 5 peptides. IHC analysis demonstrated that TIL density and PD-L1 expression on post-treatment tissues clearly increased compared to the baseline; $CD8^+$ TIL density at baseline was $\leq$ 1% in 5 pts and 1%-10% in 3 pts and that for post-treatment 1%-10% in 2 pts, 10%-50% in 6 pts, and PD-L1 expression at base line was $\leq$ 1% in 7 pts and 1%-5% in one patient and that for post-treatment was $\leq$ 1% in one patient, 1%-5% in 4 pts and 5%-50% in 3 pts.

Conclusions: The short-term treatment with S-588410 generated peptide-specific CTL and markedly increased $CD8^+$ TIL density and PD-L1 expression on tumor tissue of esophageal cancer pts. These interim results suggest that the combination of S-588410 with anti-PD-1/PD-L1 antibody is expected to be more effective than monotherapy, particularly in pts with low TIL/PD-L1 status.

1187P Clinical implication of PDL1 expression and TILs in male breast cancer: More hype or new hope? Results from the UMBREAC trial (NCT03240510)

S. Abdeljaoued[1], I. Bettaieb[1], A. Goucha[1], O. Adouni[1], H. El Mokh[1], H. Bouzaiene[2], J. Ben Hassouna[2], H. Boussen[3], K. Rahal[2], A. Gamoudi[1]

[1]Immuno-Histo-Cytology, Institut Salah Azaïz, Tunis, Tunisia, [2]Surgical Oncology, Institut Salah Azaïz, Tunis, Tunisia, [3]Department of Medical Oncology, Hopital Abderrahman Mami, Ariana, Tunisia

Background: Whether PDL1 or TILs have any indication for prognosis in male breast cancer (MBC) patients remains unknown. In this study, we investigated the relationship between the expression and degree of PDL1 and TILs and evaluated the prognostic value of these factors in MBC.

Methods: We retrospectively identified 150 MBC patients diagnosed between 2003 and 2013 at Salah Azaïz Cancer Institute. PDL1, Stromal (str) CD8+ and CD4+ TILs were evaluated immunohistochemically. TILs levels were evaluated following 2014 International TILs Working Group guidelines.

Results: Fifty three percent of MBC patients had low str-TILs and 47% had moderate str-TILs. No lymphocyte predominant breast cancer was identified. Only 12% of MBC patients had high str-CD8+TILs and 11% had high str-CD4+TILs. TNBC subtype and HER2 enriched tumors had higher median levels of str-CD8+TILs, str-CD4+ TILs and str-TILs at diagnosis. On univariate analysis, higher levels of str-CD8+TILs, str-CD4+ TILs and str-TILs were associated with better OS ($p = 0.035$, $p = 0.043$ and $p = 0.040$ respectively). Multivariate analysis identified str-CD8+ TILs and str-TILs as independent prognostic factors for OS ([HR = 0.851 (0.706-0.997), $p = 0.000$] and [HR = 0.69 (0.43-0.96), $p = 0.045$] respectively). High expression of PD-L1 was observed in 64.5% of MBC samples. Patients with high PD-L1 expression had significantly shorter overall survival (OS) than patients with low expression ($p = 0.002$, hazard ratio HR = 5 [2.624 –10.642]). Multivariate analysis identified PD-L1 as independent prognostic factor for OS ($p < 0.001$, HR = 0.775 [0.680–0.870]).

Conclusions: PD-L1 expression, Str-CD8+ T cells and str-TILs represents promising novel biomarkers with prognostic significance in MBC. Thus, successful inclusion of these markers in prognostic clinical models is becoming a realistic hope in MBC.

1188P Identification of prognostic and predictive factors for durvalumab efficacy by modeling of tumor response and overall survival (OS) in patients with non-small cell lung cancer (NSCLC)

Y. Zheng[1], R. Narwal[2], C. Jin[1], P. Baverel[3], A. Gupta[4], P. Mukhopadhyay[5], B.W. Higgs[6], L. Roskos[2]

[1]Clinical Pharmacology & DMPK, MedImmune, South San Francisco, CA, USA, [2]Clinical Pharmacology & DMPK, MedImmune, Gaithersburg, MD, USA, [3]Clinical Pharmacology & DMPK, MedImmune, Cambridge, UK, [4]Immuno-Oncology Global Medicines Development, AstraZeneca, Gaithersburg, MD, USA, [5]Biometrics & Information Sciences, AstraZeneca, Gaithersburg, MD, USA, [6]Translational Medicine, MedImmune, Gaithersburg, MD, USA

Background: Durvalumab, a human anti–PD-L1 mAb, is currently approved for treatment of patients with Stage III unresectable NSCLC. The objectives of this analysis were to identify prognostic and predictive factors for tumor growth and shrinkage, as well as for OS in NSCLC patients treated with durvalumab.

Methods: Longitudinal tumor size (TS) and OS data obtained from NSCLC patients in Study 1108 (all comers) and ATLANTIC (Stage III and above) who received durvalumab were analyzed using a nonlinear mixed effect model that describes the growth and regression of sensitive and insensitive tumor cells, as well as delay in immune response leading to tumor killing. A linked OS-dropout model was developed by relating model-predicted tumor changes to OS and dropout probability over time. Potential prognostic and predictive factors were evaluated in a multivariate covariate analysis using the models.

Results: The longitudinal TS and OS data from NSCLC patients in both studies are generally well described by the models. Liver metastasis, neutrophil-to-lymphocyte ratio (NLR), EGFR mutation, and durvalumab clearance (CL) are identified as prognostic factors for tumor growth, and tumor cell PD-L1 expression (TC) and baseline tumor size as predictive factors for tumor killing ($p < 0.01$). The significant factors for OS after accounting for the tumor size changes included TC and immune cell PD-L1 expression (IC), NLR, lactate dehydrogenase, as well as CL ($p < 0.01$). Among all factors tested, NLR is the most influential factor on the predicted 1-year survival rates (~60% vs. 30% with NLR below and above the median [4.56]). Positive PD-L1 expression (TC or IC $\geq$ 25%) is predicted to result in ~10-20% increase in one-year survival rates. Increasing the cutoff value is not predicted to result in substantially greater improvement in the survival rate.

Conclusions: The modeling results provided quantitative assessments of the impact of various prognostic and predictive factors, as well as biomarker cutoff values on the efficacy of durvalumab in NSCLC patients, and can be used to inform patient selection criteria in future monotherapy or combination studies.

Clinical trial identification: NCT01693562.

1189P Intrinsic and extrinsic regulation of PD-L2 expression by transcription factor STAT3 or c-FOS in oncogene-driven non-small cell lung cancer

D. Shibahara[1], K. Tanaka[2], E. Iwama[2], N. Kubo[2], K. Ota[3], K. Azuma[4], T. Harada[2], J. Fujita[1], Y. Nakanishi[5], I. Okamoto[2]

[1]Infectious Disease, Respiratory and Digestive Medicine, Ryukyu University Hospital, Okinawa, Japan, [2]Respiratory Medicine, Kyushu University Hospital, Fukuoka, Japan, [3]Respiratory, Kyushu University Hospital, Fukuoka, Japan, [4]Respirology, Neurology, and Rheumatology, Kurume University School of Medicine, Fukuoka, Japan, [5]Research Institute for Diseases of the Chest, Kyushu University Hospital, Fukuoka, Japan

Background: Treatment with antibodies that target programmed cell death 1 (PD-1) or its ligand programmed death ligand 1 (PD-L1) has demonstrated durable efficacy for various malignant tumors. Programmed death ligand 2 (PD-L2), which is another ligand of PD-1, has recently been shown to be implicated in tumor immune escape. The regulation of PD-L2 expression in tumor cells has remained unclear, however. We here examined intrinsic and extrinsic regulation of PDL2 expression in NSCLC.

Methods: PD-L2 expression was evaluated by reverse transcription and real-time polymerase chain reaction analysis and by flow cytometry.

Results: BEAS-2B cells stably expressing an activated mutant form of the epidermal growth factor receptor (EGFR) or the EML4-ALK fusion oncoprotein manifested increased expression of PD-L2 at both mRNA and protein levels. Furthermore, treatment of NSCLC cell lines that harbor such driver oncogenes with corresponding EGFR or ALK tyrosine kinase inhibitors or depletion of EGFR or ALK by siRNA transfection suppressed expression of PD-L2, demonstrating that activating EGFR mutations or EML4-ALK fusion intrinsically induce PD-L2 expression. We also found that interferon-γ extrinsically induced expression of PD-L2 via STAT1 signalingin NSCLC cells. Oncogene-driven expression of PD-L2 in NSCLC cells was inhibited by knockdown of the transcription factors STAT3 or c-FOS. Interferon-γ also activated STAT3 and c-FOS. Knockdown of STAT3 or c-FOS decreased Interferon-γ-induced expression of PD-L2, suggesting that these proteins may also contribute to the extrinsic induction of PD-L2 expression.

Conclusions: Expression of PD-L2 is induced intrinsically by activating EGFR mutations or EML4-ALK fusion as well as extrinsically by interferon-γ, with STAT3 and c-FOS possibly contributing to both intrinsic and extrinsic pathways. Our results thus provide insight into the complexity of tumor immune escape in NSCLC.

1190P Microsatellite instability detection by targeted sequencing of cell-free DNA

A. Artyomenko[1], M. Sikora[1], M. Lefterova[2], V.M. Raymond[2], D. Gavino[2], C. Barbacioru[1], C. Artieri[2], E. Helman[1], D. Chudova[1], R.B. Lanman[2], J. Odegaard[3], J.A. Willis[4], M. Fakih[5], S. Kopetz[6], A. Talasaz[3]

[1]Bioinformatics, Guardant Health, Redwood City, CA, USA, [2]Medical Affairs, Guardant Health, Redwood City, CA, USA, [3]Guardant Health, Redwood City, CA, USA, [4]Oncology, The University of Texas MD Anderson Cancer Center, Huston, TX, USA, [5]Medical Oncology Department, City of Hope, Duarte, CA, USA, [6]Department of Gastrointestinal Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA

Background: Microsatellite instability (MSI) is a guideline-recommended biomarker used in assessment of prognosis and treatment choices, including checkpoint inhibitors recently approved for cancers with MSI-high (MSI-H) status. Plasma-based next generation DNA sequencing (NGS) tests are increasingly used for comprehensive genomic profiling of cancer; however, sensitive methods to detect MSI status from cell-free DNA (cfDNA) are not available for clinical patient care. Additionally, the impact of variable tumor shedding on MSI detection has not been evaluated.

Methods: We developed an accurate method to assess MSI status using targeted sequencing of cfDNA using the Guardant360® clinical platform across a many cancer types, which allows broad coverage of simple repeats. For each microsatellite locus, the number of differently-sized repeats in experimental samples is quantified using a probabilistic log likelihood-based score designed to accurately discriminate biological signal derived from cfDNA fragments of somatic origin from noise arising from technical artifacts. Loci are considered unstable if the likelihood score is greater than a threshold computed from a cohort of normal samples. MSI status of a sample is determined by the presence of a minimum 5 unstable microsatellite loci among the 91 scored.

Results: We simulated MSI high (MSI-H) samples across a range of tumor fractions by combining data from 82 healthy donor samples with in silico spike-ins of differentially sized repeats. Simulated data demonstrates a sensitivity of 94% at 0.2% (limit of detection) tumor content for an expected specificity of 99.9% estimated from healthy donor samples. When applied to a prospective test set of 134 advanced cancer samples, this method demonstrated 98.5% (125/127) specificity and 86% sensitivity (6/7) relative to standard tissue PCR-based MSI assessment across a ctDNA range of 0.1%-15%.

Conclusions: Targeted sequencing of cfDNA data can enable highly accurate detection of MSI in cancer samples, even for samples with low tumor shedding. This novel approach enables non-invasive assessment of MSI status concurrent with comprehensive genomic profiling and allows potential access to immunotherapies for patients whose tumor types are not routinely tested for MSI.

1191P Immune checkpoints and T-lymphocytes as immunotherapeutic target in the treatment of sebaceous gland carcinoma

L. Singh[1], M.K. Singh[2], N. Pushker[3], S. Bakhshi[4], M.A. Rizvi[1], S. Sen[2], S. Kashyap[2]

[1]Biosciences, Jamia Millia Islamia, New Delhi, India, [2]Ocular Pathology, All India Institute of Medical Sciences, New Delhi, India, [3]Ophthalmology, All India Institute of Medical Sciences, New Delhi, India, [4]Medical Oncology, All India Institute of Medical Sciences, New Delhi, India

Background: Immune checkpoint blockade strategies have gained attention in the treatment/prognosis of cancers via targeting the PD-1/PD-L1 pathway or in combination with the CTLA-4 blockade and are currently in clinical trials. The present study investigated the expression of PD-1, PD-L1, CTLA-4, CD4 and CD8 proteins and their prognostic value in the tumor microenvironment of sebaceous gland carcinoma patients (SGC).

Methods: Stromal and tumor cells expressing PD-1, PD-L1, CTLA-4, CD4 and CD8 protein were assessed in 52 cases of sebaceous gland carcinoma by Immunohistochemistry and their mRNA expression was measured by quantitative Reverse-Transcriptase PCR (qRT-PCR). Kaplan–Meier curves and Cox proportional hazard models, analyzed the correlation of proteins with clinicopathological parameters and disease-free survival.

Results: Pagetoid spread was the frequent histopathological high-risk factor in our study. Expression of PD-L1 was found to be more common in tumor cells than stromal cells. In univariate analysis, patients expressing PD-1 and PD-L1 in tumor cells were associated with reduced disease-free survival, whereas stromal-PD-L1 showed an increased survival of the patients ($p < 0.05$). However, in multivariate analysis, expression of PD-1 in tumor cells was found to be an independent prognostic factor for poor survival.

Conclusions: This is the first report describing the association of clinicopathological features and outcomes of immune checkpoint expression along with T-Lymphocytes in sebaceous gland carcinoma. These results support the consideration that PD-1/PD-L1 pathway might play an important role in tumor microenvironment for mediating immune response in the pathogenesis of sebaceous gland carcinoma patients.

1192P Evaluation of OX40 receptor density, influence of IgG Isotype and dosing paradigm in anti-OX40-mediated efficacy and biomarker responses with PD-1 blockade

H. Jackson[1], S. Bhattacharya[1], P. Bojczuk[1], D. Kilian[1], L. Seestaller Wehr[1], A. Hahn[1], H. Shi[1], M. Bi[1], M. Adam[1], J. Jing[1], P. Morley[2], C. Hopson[1], E. Paul[1], A. Hoos[1], J. Smothers[1], R. Srinivasan[1], N. Yanamandra[1]

[1]Immuno-Oncology Combinations DPU, GlaxoSmithKline USA, Collegeville, PA, USA, [2]Biopharm Molecular Discovery, GlaxoSmithKline USA, Stevenage, UK

Background: GSK3174998 is an agonistic IgG1-anti-OX40 (aOX40) monoclonal antibody (mAB) that binds to OX40 receptors expressed on activated T cells. GSK3174998 engages the immune system via several T cell-mediated pathways. The following studies examine 1) OX40 receptor expression and enumeration in T cell populations in patient tumors 2) influence of IgG isotype on GSK3174998-mediated FcγRIIIa engagement 3) dosing regimen effects on efficacy and pharmacodynamic response with the anti-OX40 /anti-PD-1 (aPD-1) combination in preclinical models.

Methods: In vitro, an FcγRIIIa reporter assay was used to compare GSK3174998 with other IgG isotype variants and its combination with pembrolizumab. In vivo studies were performed to evaluate tumor growth and survival following concurrent and sequential dosing regimens of aOX40 ± aPD-1 mAbs. Biomarkers of response were monitored by flow cytometry, NanoString, TCRb sequencing and multiplex cytokine analysis.

Results: OX40 receptor density was observed as highest on intra-tumoral Tregs (compared to CD4 effectors and CD8+ T cells) in several primary tumor samples. FcγRIIIa engagement correlated strongly with receptor density and was dependent on an IgG1 wild type Fc isotype. GSK3174998 in combination with pembrolizumab increased inflammatory and Th1 cytokine production in human PBMCs. In vivo studies suggest that concurrent dosing of aOX40 with aPD-1 offers superior anti-tumor efficacy and survival compared to sequential regimens. Furthermore, combination with aPD-1 led to enhanced expression of inflammatory and Th1 cytokines, increased T cell activation, proliferation and cytotoxicity compared to either monotherapy. Concurrent treatment also significantly increased T cell clonal expansion in the periphery, increased clonality both in blood and tumor and induced migration of the expanded clones into the tumors over monotherapy.

Conclusions: Overall, the combination of aOX40 and aPD-1 elicited stronger qualitative and quantitative changes in immune markers both in vitro and in vivo. The potential synergy of concurrent dosing formed the basis for combining GSK3174998 with pembrolizumab in phase I/II clinical studies.

1193P Impact of tissue processing and interferents on the reproducibility and robustness of a multi-plex gene expression assay measuring tumor inflammation

B. Wallden[1], S. Church[1], I. Pekker[1], S. Zimmerman[1], S. Popa[1], A. Sullivan[1], C. Ngouenet[1], E. Harris[1], N. Dowidar[1], A. Bergdahl[1], C. Schaper[1], P. Danaher[2], S. Ferree[1]

[1]Dx Development, NanoString Technologies, Seattle, WA, USA, [2]Bioinformatics, NanoString Technologies, Seattle, WA, USA

Background: The Tumor Inflammation Signature (TIS) is an investigational use RNA expression assay on the NanoString nCounter Dx Analysis System, which provides a measure of tumor inflammation across multiple solid tumor types. TIS measures immune genes in tumors from multiple origins, and it is possible that inclusion of tissue-specific interferents, such as non-tumor lymphoid aggregates (NTLA) could influence TIS performance. Here we describe the validation of the reproducibility of the TIS assay starting from FFPE tissues and robustness of the TIS across 8 potential tissue interferents.

Methods: TIS includes both review of an H&E tumor slide by a Pathologist and sample processing of unstained slides by an assay user. Analytical validation of the reproducibility of the TIS assay from 3 different Pathologists and 3 different assay users was performed using at least 10 patient specimens for 11 different tumor types (>110 independent tumors tested) from excisional and core biopsies. The robustness of the TIS assay to potential tissue interferents (genomic DNA, adjacent non-tumor tissue, NTLA, mucin, hemorrhagic, necrotic, and fibrotic tissue) was also assessed.

Results: The assay was validated to be reproducible with $\geq$ 95% concordance in assay results between independent pathologists. The total standard deviation of the TIS score was less than 2% of the score range from tissue including different pathology review and users. The interference studies demonstrated that the presence of mucin, necrotic, hemorrhagic and fibrotic tissue did not influence TIS results. However, if not properly removed, contamination with large concentrations of genomic DNA, non-tumor tissue, and NTLA can reduce biomarker concordance by increasing the TIS score.

Conclusions: The analytical performance of the NanoString TIS assay has been validated to be reproducible between users and pathologists when potential interferents are removed as instructed in the assay procedures. TIS is well suited for decentralized clinical testing and use as a potential biomarker to enrich for patients based on their inflamed phenotype across multiple tumors.

[1]Oncology, University of Colorado Denver, Denver, CO, USA, [2]Oncology, MedImmune, Mountain View, CA, USA, [3]Oncology, MedImmune, Gaithersburg, MD, USA, [4]Oncology, MedImmune, Cambridge, UK, [5]Oncology, Johns Hopkins University, Baltimore, MD, USA, [6]Oncology, Istituto Europeo di Oncologia, Milan, Italy, [7]Oncology, University of California San Diego, San Diego, CA, USA, [8]Oncology, Hospital Universitario Virgen del Rocío, Seville, Spain, [9]Oncology, University Hospital Ramón y Cajal, Madrid, Spain, [10]Oncology, Henry Ford Hospital, Detroit, MI, USA, [11]MedImmune, Gaithersburg, MD, USA, [12]Memorial Sloan Kettering Cancer Center, New York, NJ, USA

Background: PD-1/L1 blocking agents have transformed the treatment of multiple cancers, but some tumor types including MSS-CRC appear to be refractory. Monalizumab (anti-NKG2A) and Durvalumab (anti-PD-L1) may promote antitumor immunity via non-redundant mechanisms targeting innate and adaptive immunity. The safety and preliminary efficacy of this combination (NCT02671435) was previously reported (ASCO 2018). Here, we present the results of baseline and longitudinal pharmacodynamic biomarker assessments in peripheral blood and tumor in patients with MSS-CRC treated with Monalizumab plus Durvalumab.

Methods: Peripheral biomarkers evaluated included NKG2A receptor occupancy (RO), and frequency and functional status of immune cells (N = 23). In tumors, changes in NK and CD8 cells in pre/post-tumor biopsies were evaluated by immunohistochemistry (IHC, N = 7). Gene expression profiling of tumors was determined by RNAseq in N = 15 pretreated and N = 4 paired biopsies.

Results: In peripheral blood, full and sustained NKG2A RO was observed. Expansion of activated or proliferating NK cells was detected in 14/23 and 10/20 patients respectively, while increases in T cell proliferation ($KI67^+$) were observed at levels expected for Durvalumab monotherapy (1.5-2-fold). In an in vitro assay system, similar changes on T/NK cell phenotyping were observed upon exposure to Monalizumab and Durvalumab. No consistent pharmacodynamics changes in tumoral NK and CD8 cells by gene expression or IHC were observed. However, modulation of pathways associated with metabolism, DNA repair and cell cycle were detected in tumors on treatment.

Conclusions: In peripheral blood, pharmacodynamic effects consistent with the proposed mechanism of action of Monalizumab and Durvalumab were observed in patients with MSS-CRC.

Clinical trial identification: NCT02671435; February 22, 2016.

1195P Alterations in peripheral T cell subsets, T cell activation markers and immune checkpoint molecules in advanced pancreatic cancer patients receiving FOLFIRINOX or gemcitabine + nab-paclitaxel

L.E. Sams[1], S. Kruger[1], V. Heinemann[1], D. Bararia[2], S. Haebe[1], S. Alig[1], B. Westphalen[1], M. Haas[1], T. Kirchner[3], S. Ormanns[3], S. Endres[4], O. Weigert[2], M. von Bergwelt-Baildon[1], S. Kobold[4], F. Rataj[4], S. Boeck[1]

[1]Medizinische Klink und Poliklinik III Großhadern, LMU Klinikum der Universität München, Munich, Germany, [2]Experimentelle Leukämie - und Lymphom-Forschung (ELLF), Medizinische Klinik und Poliklinik III Ludwigs Maximilians Universität, Munich, Germany, [3]Pathologisches Institut, Ludwig Maximilians Universität - Campus Innenstadt, Munich, Germany, [4]Abteilung für Klinische Pharmakologie, Medizinische Klinik IV, Ludwig Maximilians Universität - Campus Innenstadt, Munich, Germany

Background: Efforts to develop successful immunotherapeutic treatments in pancreatic cancer have failed so far. One possible strategy might be the combination of established chemotherapeutic regimens (FOLFIRINOX or gemcitabine plus nab-paclitaxel [gem/nab-pac]) with checkpoint inhibitors. The goal of the present pilot study is to provide a better understanding of alterations in the expression of T cell activation markers and immune checkpoint molecules in patients with advanced pancreatic cancer receiving FOLFIRINOX or gem/nab-pac.

Methods: We conducted a prospective single-center study with selected advanced pancreatic cancer patients who received FOLFIRINOX or gem/nab-pac between 2015 and 2017. Blood samples (15 ml heparinized blood, 10 ml serum) were taken at day 1 and 30 of first-line chemotherapy. Ficoll density gradient separation was used to isolate peripheral blood mononuclear cells (PBMCs). After short-term storage at -80 °C, flow cytometry was performed using a LSR Fortessa flow cytometer (BD Biosciences). CD3+ CD4+ and CD3+ CD8+ T cell count as well as the expression of FoxP3, PD-1, CTLA4, CCR7, CD62L, CD69, Tim3 and LAG 3 on CD3+ T cells was analyzed.

Results: 25 eligible patients were included in the study. Two consecutive blood samples were available for 21 of these patients (FOLFIRINOX: n = 18, gem/nab-pac: n = 3). We found a broad variability within T cell subsets and change of expression in T cell activation/immune checkpoint molecules during therapy. While the majority of patients (n = 13/21, 62%) is still in follow-up, first results indicate a correlation of an increase of FOXP3+ T cells in peripheral blood during chemotherapy and worse outcome. No correlation between increase of PD-1 on peripheral T cells and prognosis was observed.

Conclusions: A comprehensive RNA based (nanostring nCounter®) analysis of intratumoral immune cell infiltration of all included patients is currently ongoing. It will provide further insights on the interplay between tumoral and peripheral (T cell) immunity during chemotherapy in advanced pancreatic cancer.

1196P Resistance to anti-PD-1 therapy is associated with the retention of CXCR3+ CD4+ CD8- T cells in blood

X. Han[1], T. Tan[2], J. Sun[1], X. Chen[1], X. Cai[1], P. Lin[1], Y. Tan[2], B. Wang[1], Y. Wang[1], J. Wang[1], Z. Yu[1], X. Wu[2], Q. Xu[2], Y. Gu[1]

[1]Department of Oncology, The First Affiliated Hospital of Nanjing Medical University (Jiangsu Province Hospital), Nanjing, China, [2]State Key Laboratory of Pharmaceutical Biotechnology and Collaborative Innovation Center of Chemistry for Life Sciences, Nanjing University, Nanjing, China

Background: Immune checkpoint blockades have received significant clinical efficacy in the past decade in many malignancies. However, both primary and acquired resistance becomes one of the major obstacles that cannot be ignored, which seriously limits its clinical efficacy. To predict immunotherapy efficacy remains challenging. Dynamic

changes in the systemic immune signature in response to multiple infusions of anti-PD-1antibody are poorly understood.

Methods: We collected whole blood samples from cancer patients before and after every cycle anti-PD-1 infusion and isolated PBMCs using Ficoll gradient centrifugation. PBMCs were stained for mass cytometry analyses, and the data were acquired on a CyTOF 2 Helios (Fluidigm). We evaluated tumour responses using Response Evaluation Criteria in Solid Tumours, version 1.1 (RECIST v1.1) by computed tomography (CT). In addition, we conducted animal experiments to verify our experimental results.

Results: We revealed a marked increase in the percentage of $CXCR3^+$ $CD4^+$ $CD8^-$ T cells in blood from cancer patients after the first pembrolizumab infusion. Intriguingly, the percentage went down after the second infusion in responding patients. Interestingly, a continuous high percentage of $CXCR3^+$ $CD4^+$ $CD8^-$ T cells was observed from patients with progressing disease, while a low percentage with stable disease or partial response confirmed by conventional flow cytometry. Furthermore, depletion of $CXCR3^+$ cells abolished the improvement of melanoma by anti-PD-1 treatment in mice.

Conclusions: The dynamic changes in $CXCR3^+$ $CD4^+$ $CD8^-$ T cells in blood could be a prognostic factor and a continuous high percentage of $CXCR3^+$ $CD4^+$ $CD8^-$ T cells may reflect resistance to anti-PD-1 therapy.

1197P Cerebrospinal fluid lymphocytosis: A hallmark of neurological immune related adverse events (irAEs) during checkpoint inhibitor treatment

K.P. Suijkerbuijk[1], F.Y.F.L. De Vos[1], J.J. Koldenhof[1], T.J. Snijders[2]

[1]Medical Oncology, University Medical Center Utrecht Cancer Center, Utrecht, Netherlands, [2]Brain Center Rudolf Magnus, Department of Neurology & Neurosurgery, University Medical Center Utrecht, Utrecht, Netherlands

Background: Checkpoint inhibitors have reshaped the oncology landscape, but their success comes at the price of immune related adverse events (irAEs). Although rare, neurological irAEs are often disabling and in some cases fatal.

Methods: We analyzed the clinical data of all patients who were treated with checkpoint inhibitors and were subsequently diagnosed with neurological irAEs in our institute since January 2015. Alternative diagnoses such as progressive disease and infectious causes were ruled out by MRI and cerebrospinal fluid (CSF) cytology and PCR.

Results: Neurological irAEs were diagnosed in six patients. All patients received anti-PD1, in two cases combined with ipilimumab. Three patients were diagnosed with aseptic meningitis, two with encephalitis and one patient with radiculitis. In all cases, there was a remarkable cerebrospinal fluid (CSF) lymphocytosis (70-99%). All six patients were treated with high-dose steroids. Subsequent intravenous immunoglobulins were administered in three patients. All patients experienced improvement of neurological symptoms after immunosuppressive treatment, with complete resolution of symptoms in three patients.

Conclusions: These data illustrate that CSF lymphocytosis is a hallmark of neurological checkpoint inhibitor toxicity and can be used as a diagnostic aid. Since lymphocytic pleiocytosis is not pathognomonic for neurological irAEs, alternative explanations for lymphocytic pleiocytosis such as viral infections should be ruled out. We encourage clinicians to assess leukocyte differentiation in patients with neurological symptoms that are treated with immune checkpoint inhibitors.

1198P Serum markers as predictors of immune checkpoint inhibitors (ICI) related adverse events in a real-world scenario

D. Iacono[1], M.G. Vitale[2], F. Cortiula[2], M. Cinausero[2], A. Tullio[3], F. Valent[3], M. Macerelli[1], A. Follador[1], A. Vogrig[4], A.M. Minisini[1], F. Puglisi[2], G. Fasola[1]

[1]Department of Oncology, ASUIUD Santa Maria della Misericordia, Udine, Italy, [2]Department of Medicine (DAME), University of Udine, Udine, Italy, [3]Hygiene and Clinical Epidemiology Unit, ASUIUD Santa Maria della Misericordia, Udine, Italy, [4]Department of Neurosciences, ASUIUD Santa Maria della Misericordia, Udine, Italy

Background: Immune checkpoint inhibitors (ICI), both anti CTLA-4 and anti PD-1/PD-L1 agents, have drastically changed the cancer therapies landscape. However, by unleashing the host immune system, a new class of immune related adverse events (irAEs) have emerged. It is still unknown if any biomarker may predict irAEs onset.

Methods: A retrospective series of 130 consecutive patients (pts) treated with anti PD-1/PD-L1 or anti CTLA-4 agents from Jan 2012 to Dec 2017 was analyzed. IrAEs were graded according to CTCAE v.4.0. The aim of the study was to evaluate changes in serum markers in pts with irAEs onset. Wilcoxon's signed rank test was used to assess the statistical significance of changes in biomarkers. Gray's test was used to assess differences in the cumulative incidence function of irAEs among groups of pts.

Results: Pts with a diagnosis of NSCLC n = 64 (49%), melanoma n = 55 (42%), kidney n = 9 (7%) and others n = 2 (2%) were investigated. Median age was 69 years. Baseline ECOG PS was ≤ 1 in 96% of the pts. ICI represented first line treatment for 27% pts, second line for 57% and third or further line for the remaining 16%. In detail, 18% were treated with ipilimumab and 82% with anti PD-1/PD-L1 agents (nivolumab 60%, pembrolizumab 21%, atezolizumab 1%). Overall, 41 (36% of pts) irAEs occurred, 39% of those were grade 1, 39% grade 2, 15% grade 3 and 7% grade 4. Among pts who developed irAEs, 50% (21 pts) required immunosuppressive treatment, 25% (11 pts) needed hospitalization and 25% (11 pts) required ICI discontinuation. In patients with irAEs, eosinophilic count increased significantly from the therapy start ($p = 0.03$). Higher NLR (neutrophil to lymphocytes ratio) was associated with lower risk to develop colitis or diarrhea ($p = 0.04$). Additionally, absolute lymphocytic count decreased in patients with irAEs ($p = 0.07$) and monocyte count increased in patients with irAEs ($p = 0.07$) and endocrine irAE ($p = 0.06$). No statistically significant differences in irAEs incidence were seen according to age ($>$ or ≤ 65 years) or sex. Ipilimumab had higher rates of irAEs ($p = 0.03$).

Conclusions: These results suggest changes in the white cell subpopulation count in pts who experience irAEs. Further studies are needed to confirm our findings.

1199P Clinical and molecular characteristics associated with efficacy of PD-1/PD-L1 inhibitors for solid tumors: A meta-analysis

M. Peng[1], Y. Weng[2], Y. Yao[1], Q. Song[2]

[1]Oncology, Renmin Hospital of Wuhan University, Wuhan, China, [2]Cancer Center, Enmin Hospital of Wuhan University, Wuhan, China

Background: In the new era of precision medicine, identifying clinical or molecular factors that predict benefit of immune checkpoint inhibitors is crucial to prevent patients from autoimmune adverse effects and high cost of such agents.

Methods: We conducted this meta-analysis on the basis of the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analyses) statement. Two reviews independently completed a search of PubMed and Web of science to identify relevant clinical trials. The search was conducted using keywords "nivolumab", "pembrolizumab", "atezolizumab" and "immune checkpoint". The search was limited to randomized controlled trails (RCTs) published in English.

Results: Eleven eligible studies, including 5,663 patients, were included in this meta-analysis. In our analysis, PD-1/PD-L1 inhibitor was associated with a 31% reduction in the risk of death (HR = 0.69; 95%CI, 0.64-0.74; $P < 0.00001$). In subgroup analysis, patients got overall survival (OS) benefit from PD-1/PD-L1 inhibitors regardless of PD-L1 expression, and a dose effect relationship between expression of PD-L1 and OS benefit from PD-1/PD-L1 inhibitors was observed (Interaction, $P < 0.00001$). Patients with smoking history achieved greater OS benefits (HR = 0.69, 95% CI 0.61-0.77; $P < 0.00001$) than never smoker (HR = 0.88, 95% CI 0.70-1.11; $P = 0.28$). Compared with second or later line treatment, there was better OS benefits in first line treatment subgroup (Interaction, $P = 0.02$). The OS benefits were similar according to age (Interaction, $P = 0.74$), sex (Interaction, $P = 0.43$), performance status (Interaction, $P = 0.68$), central nervous system (CNS) metastasis (Interaction, $P = 0.59$), tumor histology (Interaction, $P = 0.64$) and treatment type (Interaction, $P = 0.36$).

Conclusions: In conclusion, PD-L1 expression, smoking status and line of treatment were potential biomarkers for PD-1/PD-L1 inhibitors. Besides, patients $>$ 75 years of age might not get OS benefits from this treatment. These results may improve treatment strategies and patient selection for PD-1/PD-L1 inhibitors.

1200P Serum biomarkers during the first cycle of anti-PD-1 antibody therapies in non-small cell lung cancer

T. Ota[1], T. Takeda[2], T. Fukui[3], Y. Nakahara[3], K. Kudo[4], T. Okabe[5], H. Hayashi[6], S. Otani[3], Y. Hiyoshi[3], K. Yonesaka[6], T. Sugiura[1], T. Suzumura[7], M. Terashima[1], Y. Nakano[1], Y. Hasegawa[1], H. Tsukuda[1], K. Matsui[1], N. Masuda[1], M. Fukuoka[1]

[1]Medical Oncology, Izumi City General Hospital, Izumi, Japan, [2]Respiratory Medicine, Uji-Tokushukai Medical Center, Uji, Japan, [3]Respiratory Medicine, Kitasato University School of Medicine, Sagamihara, Japan, [4]Medical Oncology and Respiratory Medicine, National Hospital Organization Osaka Minami Medical Center, Kawachinagano, Japan, [5]Medical Oncology, Nara Hospital Kindai University Faculty of Medicine, Ikoma, Japan, [6]Medical Oncology, Kindai University Faculty of Medicine, Osaka-Sayama, Japan, [7]Clinical Oncology, Osaka City University Graduate School of Medicine, Osaka, Japan

Background: PD-1 blockade by anti-PD-1 antibodies restore the function of exhausted T cells and release perforin, granzyme B and cytokines which induce cytotoxic activity against tumor cells. We examined serum perforin, granzyme B and immune modulators as biomarkers of response to PD-1 blockade in non-small cell lung cancer (NSCLC) patients.

Methods: Advanced NSCLC patients treated with nivolumab or pembrolizumab were studied. Serum were collected on days 1, 2, 8 and 15 for nivolumab and on days 1, 2, 8, 15 and 22 for pembrolizumab. Concentration of perforin was determined by enzyme-linked immunosorbent assay (ELISA) and ten immune modulators, including granzyme B, were measured by a multiplex immunoassay. Best objective response was evaluated by Response Evaluation Criteria in Solid Tumors (RECIST) 1.1. Patients were followed more than 3 months.

Results: Plasma samples were obtained from 29 patients with nivolumab and 18 patients with pembrolizumab. With nivolumab, in 57% of responding patients, there were two aspects; (i) baseline levels of perforin concentration were higher in responders than in non-responders, or (ii) a ratio of perforin concentration on day 2 to the baseline was elevated (≧1.2). With pembrolizumab, there were no significant differences in baseline concentration between responders and non-responders. If patients who passed away within 3 months were excluded, in responding patients, a ratio of perforin concentration on day 22 to the baseline were significantly higher than in non-responders (partial response vs. progressive disease, $p = 0.0330$). The multiplex assay was performed on a part of samples (nivolumab, $n = 10$ and pembrolizumab, $n = 6$). By the multiplex assay, two out of 10 immune modulators were detected in more than 30% of samples; CD137 and FAS ligand. The correlation between these two analytes and the response to anti-PD-1 antibodies were hard to determine.

Conclusions: From serum, most immune modulators were difficult to measure. Sequential changes in perforin levels and the efficacy by two different anti-PD-1 antibodies were dissimilar. Concentration of serum perforin during the first cycle could be used to predict response to anti-PD1 antibody therapies in advanced NSCLC patients.

1201P Association of immune-related adverse (irAEs) with immune-checkpoint inhibitors (ICIs) efficacy in solid tumors

M. Riudavets Melia[1], L.P. del Carpio[1], I. Gabriela Sullivan[1], A. Barba Joaquín[1], P. Maroto Rey[1], G. Anguera Palacios[1], D. Páez López-Bravo[1], A. Callejo Pérez[1], C. González Blanco[2], D. Castillo Villegas[3], C. Facundo Molas[4], E. Garcia Planella[5], I. Genua Trullos[1], A. López Pousa[1], A. Sebio García[1], C. Martín Lorente[1], A.C. Virgili Manrique[1], O. Gallego Rubio[1], A. Barnadas Molins[1], M. Majem Tarruella[1]

[1]Medical Oncology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [2]Endocrinology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [3]Pneumology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [4]Nephrology, Puigvert Foundation, Barcelona, Spain, [5]Gastroenterology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background: ICIs can induce irAEs that may compromise treatment continuation. We report the incidence of irAEs in patients (pts) with solid tumors receiving ICIs and its correlation with efficacy.

Methods: We retrospectively analyzed 178 pts with solid tumors receiving ICIs in our institution from 3/2014 to 1/2018. IrAEs were graded following CTCAE v4.0. Kaplan Meier and log-rank tests were used to evaluate progression-free and overall survival (PFS, OS).

Results: Median age was 64.1 [33-88] years, 72% male. Most common tumors were lung (63.5%), bladder (14.6%) and melanoma (11.8%). 96% had advanced disease. Most frequent ICIs were nivolumab (38.2%), pembrolizumab (28.7%) and atezolizumab (17.4%), used as monotherapy (74.7%) or in combination with ICIs (3.4%), chemotherapy (17.4%) or targeted therapies (4.5%). Median duration of treatment was 2.1 [0.5-26.5] months. 95 (53.4%) pts developed 158 irAEs, mean 1.2 [0-4] irAEs/pts. Most frequent irAEs were rash (24.7%), diarrhea (17.7%), pruritus (17.7%), thyroid dysfunction (13.3%), arthritis (6.9%), hepatitis (3.8%), pneumonitis (3.2%). 12 (6.7%) pts presented grade (G) 3-4 irAEs: 4 diarrhea, 2 liver dysfunction, 1 pneumonitis, 1 hypopituitarism, 1 mucositis, 1 arthritis, 1 nephritis and 1 haemolytic anemia. 2 treatment-related deaths due to pneumonitis were reported. 15 (8.4%) pts discontinued treatment due to irAEs. At the time of data analysis, 89.2% of irAEs had improved. With a median follow-up of 7.0 [0.5-46.3] months, median OS was superior in pts with advanced disease experiencing irAEs: 37.3 [95%CI, 19.2-51.4] vs 7.8 [95%CI, 4.9-10.8] months ($p < 0.0001$). Similarly, PFS was higher: 7.9 [95%CI, 4.4-11.4] vs 2.6 [95%CI, 2.0-3.2] months ($p < 0.0001$). 82 (46%) pts required systemic corticosteroids during therapy, 31.7% for irAEs management. OS was longer in pts who did not receive steroids: 35.3 [95%CI, 13.5-57.1] vs 10.2 [95%CI, 4.7-15.7] months (p 0.007). No association was found between efficacy and use of antibiotics in the 3 months before first ICIs injection or during treatment.

Conclusions: Development of irAEs in pts with advanced solid tumors treated with ICIs was associated with efficacy. A negative correlation between use of systemic corticosteroids and outcomes was found.

1202P Use of immune checkpoint inhibitors (CPI) in patients with cancer and concomitant myasthenia gravis (MG)

H. Safa[1], N. Abdel-Wahab[2], V.A. Trinh[1], D.H. Johnson[3], T.E. Rodgers[1], M. Suarez-Almazor[2], A. Diab[1]

[1]Department of Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA, [2]Department of Internal Medicine, Section of Rheumatology & Clinical Immunology, MD Anderson Cancer Center, Houston, TX, USA, [3]Melanoma, MD Anderson Cancer Center, Houston, TX, USA

Background: The safety of CPI in patients (pts) with autoimmune diseases was never fully assessed since they were always excluded from clinical trials for fear of unleashing the underlying autoimmunity, and susceptibility to severe immune-related adverse events (irAEs). Pts with MG require special consideration as they are known to have severe morbidities and might be susceptible to life-threatening complications.

Methods: We identified from pharmacy records pts who had received CPI between January 2004 and June 2017 at our institution ($n = 4,406$). Claims data were obtained for all pts from 6 months prior to first infusion to last follow-up or death. ICD 9 & 10 diagnostic codes were used to identify pts with MG. We systematically reviewed the literature databases through March 2018 to identify similar pts.

Results: A total of 39 pts were retrieved; 5 from institutional databases and 34 from literature. Median age was 73 (57-86) years; 56% male, 49% had metastatic melanoma and other cancer types. Most received anti-PD1/PD-L1 agents (79%). A prior diagnosis of MG was reported in 23%; most were maintained on corticosteroids, anticholinesterase, azathioprine, or mycophenolate mofetil, and only one had active disease symptoms at initiation of CPI. In the remaining 77%, MG manifested clinically only after initiation of CPI therapy. Overall, 38% developed respiratory failure requiring mechanical ventilation, including 8 pts who needed urgent intubation. MG symptoms occurred with other irAEs (myositis, myocarditis, polyneuropathy, and Guillain Barre Syndrome) in 15%. Most pts required treatment with high dose corticosteroids (90%), intravenous immunoglobulin (45%), and plasmapheresis (42%). Other treatments included azathioprine, mycophenolate mofetil, rituximab, or infliximab. Discontinuation of CPI was recommended in 87%. Most pts (81%) improved with treatment. In melanoma pts, 54% (7/13) achieved partial or complete response to CPI. In all pts, death was reported in 40%, primarily because of respiratory failure in 11%.

Conclusions: CPI seems to be associated with serious consequences and high rate of death in pts with MG. Further studies are needed to establish the risk-benefit profile in this population.

1203P Safety assessment of anti-PD(L)1 rechallenge after immune-related adverse events

Simonaggio[1], J.-M. Michot[2], S. Champiat[2], A. Vozy[3], A. Lapera[1], A. Marabelle[2], J. Le Pavec[4], A.-L. Voisin[5], A. Lallart[6], G. Cengizalp[6], O. Lambotte[7]

[1]Ile de France, Gustave Roussy DITEP, Villejuif, France, [2]Drug Development Department (DITEP), Institut Gustave Roussy, Villejuif, France, [3]Oncology, Institut Gustave Roussy, Villejuif, France, [4]Ile de France, Hôpital Marie Lannelongue, Le Plessi Robinson, France, [5]Pharmacovigilance Unit, Gustave Roussy Institute, Villejuif, France, [6]Ile de France, Gustave Roussy Pharmacovigilance, Villejuif, France, [7]Department of Internal Medicine and Clinical Immunology, Hôpital Bicêtre, Le Kremlin-Bicêtre, France

Background: Immune checkpoint inhibitors (ICI) have demonstrated efficacy in many cancers. Patients can experience immune-related adverse events (irAE) and their management become crucial. Evidence-based guidance regarding the safety of rechallenge remains scarce. This study aims to prospectively investigate the safety of patients rechallenged after irAE.

Methods: Patients rechallenged after irAE grade ≥2 induced by anti-PD(L)1 and referred at the multidisciplinary board committee of immune toxicity (iTOX) of Gustave Roussy between August 2015 and December 2017 were included in this study.

Results: One hundred eighteen patients had a confirmed irAE. Median age was 62. Tumour types were melanoma (25.4%, n = 30), lung carcinoma (22.9%, n = 27), colorectal cancer (8.5%, n = 10), lymphoma (7.6%, n = 9), renal cell carcinoma (7.6%, n = 9), urothelial (6.8%, n = 8) and others (21.2%, n = 25). IrAE distribution was grade 2 (n = 56, 47.5%), grade 3 (n = 44, 37.3%) and grade 4 (n = 18, 15.2%). IrAE toxicities were hepatitis (15.2%, n = 18), skin toxicities (14.4%, n = 17), pneumonitis (13.6%, n = 16), colitis (10.2%, n = 12), arthralgia (8.4%, n = 10), hematologic (7.6%, n = 9) muscular (6.8%, n = 8), neurologic (5.9%, n = 7), ocular (5.1%, n = 6) toxicities, lipase increases (4.2%, n = 5), endocrine (4.2%, n = 5), nephrologic (2.5%, n = 3), cardiac toxicities (0.8%, n = 1) and infused related reaction (0.8%, n = 1). Forty patiens (33.8%) were hold and then rechallenged. Rechallenged and non-rechallenged patients didn't differ in term of age, distributions and grades of toxicity and steroids use. Patients were rechallenged after an irAE grade 2 (n = 18, 45%), grade 3 (n = 17, 42.5%) grade 4 (n = 5, 12.5%). 40% (16/40) had no recurrence, 35% (14/40) had recurrence of the same irAE, 15% (6/40) experienced a new irAE, and 10% (4/43) had multiple irAE. No patient had died after rechallenge. IrAE recurrence rates rates were 3/5 for colitis, 3/6 for arthralgia, 3/5 for hepatitis, 1/5 for pneumonitis, 0/3 for pancreatitis, 2/3 for neutropenia, 3/7 for skin toxicities. Recurrence rates were not different in grade 2 compared to grades 3-4.

Conclusions: The rechallenge of ICI after mild or severe irAE was associated with 60% of irAE grade ≥2 recurrence or new irAE. Toxicity profile was acceptable but required a close monitoring.

1204P Long term disease control and abscopal effects by stereotactic radiotherapy for growing metastases during anti-PD1

K.P. Suijkerbuijk[1], S.Y. El Sharouni[2], P.P. Damen[2], A.V. Lindert[3], G. Groenewegen[1], J.J.C. Verhoeff[2]

[1]Medical Oncology, University Medical Center Utrecht Cancer Center, Utrecht, Netherlands, [2]Radiation Oncology, University Medical Center Utrecht Cancer Center, Utrecht, Netherlands, [3]Pulmonary Oncology, University Hospital Utrecht, Utrecht, Netherlands

Background: Recent reports have described the safety and clinical utility of combining anti-PD1 checkpoint inhibition with radiotherapy. Abscopal effects - radiotherapy inducing clinically meaningful distant responses in unirradiated sites - have been hypothesized, though clinical proof is scarce.

Methods: We analyzed efficacy and toxicity of combined stereotactic ablative radiotherapy (SABR) and anti-PD1 in consecutive melanoma and non-squamous cell lung cancer (NSCLC) patients that underwent stereotactic radiotherapy for a limited number of growing metastases during anti-PD-1 in our institute since January 2017.

Results: Ten patients, 8 with metastatic melanoma and 2 patients with metastatic NSCLC, were included in this series. SABR was given at a median of 11,5 months (range 3-21 months) after the start of anti-PD1 treatment (nivolumab or pembrolizumab). A single metastasis was irradiated in 8 patients, 2 simultaneously in 1 patient and 3 in the last patient. Disease control of the irradiated lesion was established in all 10 patients. With a median follow-up of 5,5 months (range 1-16 months) all patients were still alive without the need to start a subsequent systemic therapy. Additionally, abscopal effects, defined as a significant decrease of unirradiated metastases that were previously stable under immunotherapy, were seen in 4/10 patients after SABR. One patient developed a pneumonitis (outside high dose radiation field) shortly after SABR that was considered to be related to nivolumab. No other severe toxicities of the combined treatments were observed.

Conclusions: These data show that combining SABR and checkpoint inhibition for patients with oligo-progressive disease during PD1-inhibition is a strategy that can induce long-term disease control and additionally can lead to abscopal effects in unirradiated tumor sites. In order to explore feasibility for all patients with oligo-progressive disease during PD1-inhibition, prospective clinical studies are needed.

1205P Clinical impact of hypothyroidism and PD-L1 SNPs in patients with non-small cell lung cancer treated with nivolumab

T. Yamamoto, T. Nomizo, H. Ozasa, T. Tsuji, Y. Yasuda, H. Yoshida, Y. Sakamori, T. Hirai, Y.H. Kim

Respiratory Medicine, Kyoto University-Graduate School of Medicine, Kyoto, Japan

Background: Nivolumab improves the prognosis of lung cancer, but its use can cause immune-related adverse events (irAEs). However, patients with irAEs are reported to have a longer progression free survival (PFS). We previously reported an association between Programmed death ligand 1 (PD-L1) single nucleotide polymorphisms (SNPs) and PFS following nivolumab treatment. We hypothesized that the irAEs were associated with PFS and the SNPs of Programmed death l (PD-1) and PD-L1.

Methods: Between January 2016 and June 2017, a total of 79 consecutive patients who were diagnosed with non-small lung cancer (NSCLC) and who had not undergone definitive operation were treated with nivolumab at Kyoto University Hospital. Of these 79 patients, 68 participated in this study. We retrospectively analyzed patients to evaluate the relationship between adverse events and PFS, and to assess the relationship between these adverse events and the PD-1/PD-L1 SNPs.

Results: The response rate was 13% and the median PFS was 61 days. A significantly longer PFS was observed in patients with the adverse event of hypothyroidism than without hypothyroidism (56 days vs. N.R.; P = 0.016). Occurence of hypothyroidism, which is defined as the low free T4 level, was associated with the SNPs of PD-L1; rs1411262 and rs822339. Hypothyroidism developed in patients with the T/T and C/T genotypes of rs1411262 (P = 0.0269) and with the A/A and A/G genotypes of rs822339 (P = 0.0216). A significantly longer PFS was also associated with the T/T genotype than with the C/T and C/C genotypes of rs1411262 (P = 0.031) and the A/A genotype than the A/G and G/G genotypes of rs822339 (P = 0.017).

Conclusions: Patients with advanced NSCLC who developed hypothyroidism after nivolumab treatment had a significantly longer PFS when compared with those without hypothyroidism, and patients with the T allele of rs1411262 and the A allele of rs822339 tended to develop hypothyroidism. The T/T genotype of rs1411262 and the A/A genotype of rs822339 were significantly associated with longer PFS. The SNPs of PD-L1 might be associated with maintained functioning of the PD-1 and PD-L1 pathway following nivolumab treatment.

1206P Incidence of immune related adverse events in patients 70 years old treated with anti-PD-(L)1 therapy

C. Baldini[1], P. Martin-Romano[1], A-L. Voisin[2], F.X. Danlos[1], S. Champiat[1], S. Laghouati[3], M. Kfouri[1], H. Vincent[4], C. Nagera[5], S. Postel-Vinay[1], A. Varga[6], V. Ribrag[1], B. Besse[7], A. Hollebecque[1], O. Lambotte[7], J-M. Michot[1], J-C. Soria[8], C. Massard[9], A. Marabelle[1]

[1]Drug Development Department (DITEP), Gustave Roussy, Villejuif, France, [2]Drug Development, Institut Gustave Roussy, Villejuif, France, [2]Pharmacovigilance Unit, Gustave Roussy Institute, Villejuif, France, [3]Pharmacovigilance Unit, Institut Gustave Roussy, Villejuif, France, [4]Medical Oncology, Gustave Roussy, Villejuif, France, [5]DITEP, Gustave Roussy, Villejuif, France, [6]Dept of Cancer Medicine, Gustave Roussy Institut de Cancérologie, Villejuif, France, [7]Ile de France, Hospital Kremlin Bicetre, Kremlin Bicetre, France, [8]DITEP, Medimmune, Gaithersburg, USA, [9]DITEP, Gustave Roussy Institut de Cancérologie, Villejuif, France

Background: Advanced age is an important risk factor of cancer and is associated with poor prognosis. Changes in the immune system called immunosenescence may occur with older age. However, the impact of aging on efficacy and safety of immune checkpoint inhibitors (ICI), such as anti-PD(L)1, remains undetermined.

Methods: Patients with advanced solid tumours treated with an anti-PD(L)1 agent monotherapy between June 2014 and October 2017 and prospectively included within the Gustave Roussy ICI-dedicated pharmacovigilance registry REISAMIC (Registre des Effets Indésirables Sévères des Anticorps Monoclonaux Immunomodulateurs en Cancérologie) were retrospectively reviewed. Incidence of immune-related adverse events (irAEs) of grade ≥2 was compared between patients aged ≥ 70 and < 70 years old using Chi-squared test.

Results: Among the 615 patients included in the analysis, 191 were ≥ 70 years old (OP) and 424 < 70 years old (YP). The median age of OP and YP were respectively 77 (70 - 93) and 59 (17 - 69). A total of 165 irAEs were included in the analysis (103 Grade 2 and 58 Grade 3-4). The overall occurrence of irAEs grade ≥ 2 was higher in OP compared to YP (33% versus 25%, p = 0.03). Statistical significance was lost when stratifying irAEs according to their severity grade, suggesting that this effect was constant whatever the grade (p = 0.08 for Grade 2 and p = 0.13 for Grade 3-4). Anti-PD(L)1-related deaths were registered in 1 OP and 3 YP (0.5% and 0.7% respectively; NS). The most frequent organs toxicities in OP were skin rash (49%), endocrine (14%), hepatic (10%); it was skin rash (28%), endocrine (25%), digestive (15%) in YP. Median time to

toxicity was similar between the two groups (7 weeks in YP and 6 weeks in OP, $p = 0.31$).

Conclusions: Anti-PD(L)1 immunotherapies are an acceptable treatment option for OPs, by being aware that immune related adverse events are more frequent in this population. Further dedicated studies are warranted to explore prospectively immune-related safety in OPs. Impact: Older patients should be monitored closely as they may be at risk of increased significant immune-related toxicity compared to their younger counterparts.

1207P PD-1 inhibitor-related pneumonitis in patients with minimal interstitial lung shadows before treatment

K. Takahashi, C. Kondo, A. Inukai, G. Asai, M. Okuno, H. Saito

Respiratory Medicine, Aichi Cancer Center Aichi Hospital, Okazaki, Japan

Background: Programmed cell death 1 (PD-1) inhibitors have exhibited significant efficacy in various types of cancer including non-small-cell lung cancer (NSCLC). PD-1 inhibitors are expected to be used increasingly as monotherapy or in combination. Pneumonitis is relatively uncommon but potentially fatal toxicity induced by anti PD-1 therapy. Although patients with apparent interstitial pneumonia are excluded from clinical trials of anti PD-1 therapy, patients with minimal interstitial lung opacity on chest CT scans can be treated with PD-1 inhibitors in the clinical practice. Little is known about the incidence of pneumonitis in such cases.

Methods: Among patients with NSCLC treated with PD-1 inhibitors in our institution, we identified those who developed pneumonitis. We reviewed medical records and chest imaging studies. We investigated association between background factors including lung opacities on chest CT scan before anti PD-1 therapy and development of pneumonitis.

Results: We analyzed a total of 79 patients treated with PD-1 inhibitors. At the baseline CT scan, ground glass opacities and reticular opacities were observed in 20 patients (25%) and 18 patients (23%), respectively. All of these interstitial opacities were very mild, and the case of obvious interstitial pneumonia was not observed. During the anti PD-1 therapy, pneumonitis developed in 16 patients (20%). Of the 20 patients with ground glass opacities, ten patients (50%) developed pneumonitis, and of the 18 patients with reticular opacities, nine patients (50%) developed pneumonitis. Ground glass opacities and reticular opacities at baseline were significantly associated with the incidence of pneumonitis ($p < 0.001$ and $p = 0.001$, respectively). Among the 49 patients who did not have either of these opacities, three patients (6%) developed pneumonitis. There were no association between pneumonitis and other background factors such as presence of radiation pneumonitis or pulmonary emphysema.

Conclusions: Ground glass opacities and reticular opacities on chest CT scan before treatment can be risk factors of pneumonitis, even if they are mild. For the patients without these opacities, anti PD-1 therapy appears relatively safe.

1208P PD-1 blockade in renal transplant patients with poor prognosis cancer and minimizing risk of organ rejection using comprehensive immune monitoring and screening techniques: A safety study

R. Carroll[1], J.R. Zalcberg[2], H. Tang[3]

[1]Central Northern Adelaide Renal and Transplant Service, Royal Adelaide Hospital RAH Cancer Centre, Adelaide, Australia, [2]Department of Medical Oncology, Alfred Hospital, Melbourne, Australia, [3]Oncology, Royal Adelaide Hospital, Adelaide, Australia

Background: Renal transplant patients have been excluded from studies involving immune checkpoint inhibitors, notwithstanding the fact that these patients develop many of the tumour types that are known to respond to such therapy, for fear of such approaches inducing organ rejection. At the time of initiation of this safety trial there had been 9 case reports of checkpoint inhibitors in organ transplant patients. 4 patients suffered fulminant transplant organ failure. In all of these cases there was prior major reduction in standard immunosuppressive medications.

Methods: Renal transplant and incurable locally advanced or metastatic cancer that has progressed despite first-line standard anti-tumour treatment or defined metastatic solid tumours, will be enrolled onto a Phase 1 trial. Patients will receive Nivolumab as per approved label. Patients are closely monitored for signs of early rejection and for evidence of safety/toxicity and any anti-tumour effect. Standard inclusion/exclusion criteria for oncological trials were used with the addition of the following: serum creatinine <180 umol/l; absence of Human Leukocyte Antigen (HLA) donor specific antibodies; patients willing to accept potential development of renal transplant failure. All patients were counselled by both a transplant physician and oncologist before signing an ethically approved patient information sheet. Patients were allowed to have minimization of immunosuppression but no medication was completely stopped.

Results: Four patients with metastatic cancer (renal cell, melanoma, SCC head and neck, bladder) were treated with 1, 2, 3 and 9 infusions of nivolumab. One patient has a sustained partial response (after 9 infusions) of their tumour but suffered likely interstitial nephritis which resolved with oral steroid. 3 patients died of progressive cancer after 1,2 and 3 cycles but did not suffer any rejection episodes.

Conclusions: Selected renal transplant patients on low dose immunosuppressive regimens, without significant donor specific allo antibodies, can be treated with nivolumab without rejection episodes and some can have sustained anti tumour responses.

1209P Immunotherapy in the immunodeficient: A treatment paradox?

N.J. Campbell[1], J. Longley[1], A. Pascalis[2], J. Bennett[3], M. Remer[1], R. Stone[1], D. Muller[1], I. Karydis[1], O. Donnelly[4], M. Wheater[1], C. Ottensmeier[1]

[1]Medical Oncology, Southampton General Hospital Southampton University Hospitals NHS Trust, Southampton, UK, [2]Medical Oncology, Institute of Cancer Research, London, UK, [3]Southampton Experimental Cancer Medicine Centre, University of Southampton, Southampton, UK, [4]Clinical Oncology Department, Southampton General Hospital Southampton University Hospitals NHS Trust, Southampton, UK

Background: Patients with immunodeficiency are typically excluded from trials involving Immunotherapy, however they are at increased risk of developing malignancy. There is currently a lack of evidence to guide clinicians making difficult decisions in this cohort who have a theoretical risk of being unable to mount an adequate immune response.

Methods: Patients diagnosed with Metastatic Melanoma treated with either single or dual immunotherapy regimes at University Hospital Southampton NHS Foundation Trust were identified through our electronic chemotherapy prescribing system. Those with a background of immunosuppressive states were analysed including high intensity chemotherapy or stem cell transplant for prior malignancy and HIV.

Results: A total of 124 patients received Pembrolizumab monotherapy and 47 patients received Iplimumab with Nivolumab. Six patients were considered immunodeficient, including three patients treated with curative intent with intensive chemotherapy for prior lymphoma, one patient with HIV with undetectable viral load, one patient continuing on Ibrutinib treatment for Small Lymphocytic Lymphoma and one patient under a watch and wait approach for Chronic Lymphocytic Leukaemia. All patients in this group had any grade treatment related toxicity, with five experiencing severe grade 3-4 toxicity requiring hospitalisation. With a median follow up of 16.5 months no patients had reactivation of previous malignancy. Four out of six patients have had a complete radiological response and two patients had disease progression.

Conclusions: In our cohort the majority of patients had a significant response to immunotherapy with toxicity managed without any long-term comorbidity. These patients were able to mount an anti-tumour immune response despite concurrent immunodeficiency and experienced an increased incidence of toxicity when compared with other patients treated at our centre. Despite the limitations of a small retrospective series our data would support offering immunotherapy even in the context of apparent immunodeficient states.

1211P Hyperprogression during immuno-checkpoint inhibitors (ICIs): A clinically significant problem?

E. Farè[1], S. Sdao[2], S. Damian[1], S. Cresta[1], M. Del Vecchio[1], M. Di Bartolomeo[1], L.A. Di Guardo[1], M. Duca[1], A. Indini[1], A. Necchi[1], M. Niger[1], M. Prisciandaro[1], G. Procopio[1], D. Raggi[1], E. Verzoni[1], G. Pruneri[3], M. Di Nicola[1], F.G.M. de Braud[1]

[1]Medical Oncology, Istituto Nazionale dei Tumori di Milano - Fondazione IRCCS, Milan, Italy, [2]Radiology and Imaging Diagnostics, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy, [3]Department of Pathology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy

Background: ICIs can overcome immune-suppression and activate effective immune responses against cancer cells. Therapy with ICIs have led to a clinically-meaningful extension in overall survival across several solid tumors, being endowed with long term disease control-rate in a part of responding patients (pts). However, an acceleration of the tumor growth rate (TGR) during ICI, defined as hyperprogressive disease (HPD), has been reported in 9-29% of pts. Mechanisms underlying HPD are unknown, yet murine double minute 2 (MDM2) family amplification was found in some of these pts.

Methods: We retrospectively identified a series of 334 pts with miscellaneous advanced solid tumors treated with anti-PD1/PD-L1-containing ICI (mono or combo therapy) at our Institution. Inclusion criteria included imaging assessment at 3 timepoints: during reference period (from 3 months to 2 weeks before ICI baseline scan), before ICI therapy start (baseline scan, performed within 28 days) and during ICI treatment. Patients were considered HPD if they showed progressive disease (PD) by RECIST 1.1 at first radiological evaluation and a $\geq$ 2-fold increase of the TGR during ICI therapy compared to reference period. FISH analysis to evaluate MDM2 family genes amplification was performed in HPD cases whose paraffin embedded tumor material was available.

Results: 73 cases were initially excluded from our analysis due to lack of tumor assessment during ICI. Of the remaining pts, 109 reported PD at first evaluation. Of them, only 45 were suitable for the analyses, having all requested radiological examinations available. Seven cases met HPD criteria: 3,5% of evaluable pts (7/197) and 6.4% of all the PD. No correlation with histology, age, serum biomarkers and type of ICI was found. FISH test for MDM2 family has been performed on 3 cases: one case showed amplification MDM4 gene (mean of signals $>$ 8); other cases showed only increased MDM4 ratio score of unknown significance.

Conclusions: Despite the limits of a retrospective analysis and small numbers, in our series HPD is a rare but clinically relevant event. The role of MDM2 family alteration as predictive biomarker is promising and deserves more investigations. Prospective studies including genomic and biological analysis are warranted.

1212P Pathogenesis, clinical evolution and outcomes of patients with immune checkpoint inhibitor induced acute liver injury: A multicentre study

L. Au[1], R. Nathwani[2], L. Possamai[2], C. Barlow[3], T. Tillett[4], R. Bowen[5], L. Spain[6], J. Thomas[1], M. Backhouse[4], A. Gurung[3], R. Morrison[7], T. Cross[8], C. Herbert[9], R. Goldin[2], M.E. Gore[10], J. Larkin[11], C. Antoniades[2], S. Turajlic[1]

[1]Skin and Renal Unit, Royal Marsden Hospital NHS Foundation Trust, London, UK, [2]Gastroenterology, Imperial College London, London, UK, [3]Medical Oncology, Musgrove Park Hospital, Somerset, UK, [4]Medical Oncology, Royal United Hospitals Bath NHS, Avon, UK, [5]Medical Oncology, Royal United Hospitals Bath NHS Foundation Trust, Bath, UK, [6]Skin, Renal & Gynaecological Cancers Unit, Royal Marsden Hospital NHS Foundation Trust, London, UK, [7]Histopathology, Imperial College London, London, UK, [8]Gastroenterology, Royal Liverpool University Hospital, Liverpool, UK, [9]Medical Oncology, University Hospitals Bristol NHS Trust Bristol Haematology and Oncology Centre, Bristol, UK, [10]Medicine, Royal Marsden Hospital NHS Foundation Trust, London, UK, [11]Department of Medical Oncology, Royal Marsden NHS Foundation Trust, London, UK

Background: Immune checkpoint inhibitor (CPI) induced acute liver injury (ALI) is a frequently encountered toxicity occurring in up to 30% patients (pts). There is a lack of systemic evaluation of CPI induced ALI pathogenesis, clinical evolution and outcome of patients (pts).

Methods: Retrospective analysis was performed on pts with CPI induced ALI presenting to 6 UK oncology centres between 2013-17. Indices of ALI, therapy complications and outcome were recorded. ALI grading was based on Common Terminology Criteria for Adverse Events.

Results: 65% (36/57) pts received ipilimumab+nivolumab (N) or pembrolizumab (P) (combo group) and 35% (21/57) P or N alone (mono group). Median therapy duration to ALI onset was 96 days in the mono and 22 days in the combo group. At presentation, all pts had acute elevations in transaminases (ALT, median 325U/L [range 155-543], ALP 111U/L [72-250]). Immunogolulins and autoantibodies were normal. One pt developed acute synthetic dysfunction without encephalopathy (Bilirubin 64umol/L, INR 1.5). 79% received steriods (mean dose 1.3mg/kg); 34% MMF. Steroid refractory ALI was treated with anti-thymocyte globulin (ATG) in 4 pts. Pathological findings (n = 6 liver biopsies) revealed lobular hepatitis and myelo-lymphoid cell infiltrate/aggregates (CD3+,CD8+,CD68+). Pts with severe, refractory (G4) ALI had significant reductions in circulating lymphocytes/monocytes. 63% (n = 35) had a temporal association between recent infection and ALI. 15% (n = 8) also received anti-TNF-a therapy for colitis. This was not associated with more severe ALI, and ALI resolved in all cases. 21% (n = 11) developed bacterial infections. Fungal sepsis (aspergillus) occurred in all ATG (n = 4) treated patients. Overall no deaths were due to liver failure. 14 pts died with 13 due to disease progression and 1 due to immunotherapy related neuropathy. All deaths due to progressive disease were in pts whose ALI peaked at G3-4. Acturial median survival was significantly lower in G3-4 (14.5 months) vs G1-2 (25 months) liver injury.

Conclusions: Our data report on the largest cohort of CPI induced ALI identifying disease evolution, markers of disease severity and strong correlation with increased morbidity and mortality.

1214P Establishing the need for immuno-oncology (IO) therapy (tx) in second-line (2L) small cell lung cancer (SCLC)

L. Schwartzberg[1], J.R. Penrod[2], Y. Yuan[2], T. Gu[2], T.K. Le[3], P. Abraham[2], B. Korytowsky[2], G. Selvaggi[2]

[1]Oncology, West Cancer Center, Germantown, TN, USA, [2]Worldwide Health Economics & Outcomes Research, Bristol-Myers Squibb, Princeton, NJ, USA, [3]Center for Observational Research & Data Sciences, Bristol-Myers Squibb, Princeton, NJ, USA

Background: 2L tx for SCLC is heavily dependent on 1L platinum (PT) response. NCCN guidelines recommend PT retreatment if recurrence is $>$ 3-6 months post 1L PT; while alternative options should be considered for rapid relapse (topotecan [TOP] in 2L PT-resistant). In 2016, nivolumab (NIVO) +/- ipilimumab (IPI), were added to 2L NCCN guidelines. This study evaluates 2L SCLC patterns of care and outcomes and attempts to contextualize CheckMate 032 data by creating a matched real-world comparator.

Methods: Adult SCLC pts receiving systemic tx from the Flatiron Health database were selected (01Jan2011-30Sep2017). Index date was SCLC diagnosis (dx). Pts were included if: not on clinical trial; no secondary malignancy within 3 years (y); no IO use; and $\geq$2 months (mo) of medical data on/after dx. PT sensitivity was based on a 90 day gap. Median, 1-y and 2-y overall survival (OS) by Kaplan-Meier was calculated from 2L initiation to death. Median duration of therapy (mDoT) was assessed. A matched 2L cohort was constructed using CheckMate 032 Inclusion/Exclusion criteria (I/E).

Results: 2,056 pts initiated 1L tx (full cohort), of which 628 pts went on to 2L; 42% received TOP and 58% other txs. Within 2L, mean age was 65y; 69% were white, 51% were female, 98% had a smoking history and 95% were treated in the community. Of 2L pts, 68% had extensive and 27% had limited disease at dx. 372 were PT-sensitive and 231 pts were PT-resistant. Upon matching for CheckMate 032 I/E, 903 pts were identified of whom 254 initiated 2L. For the full and matched cohorts respectively, 2L mDoT for TOP was 2.0 mo (SD = 2.5) and 2.2 mo (SD = 2.7) and for other tx was 2.6 mo (SD = 2.2) and 2.8 mo (2.4). Median, 1-y and 2-y OS results for the full/ matched cohorts and CheckMate 032 are shown (Table).

Table: 1214P Overall survival from diagnosis and 2L initiation in Flatiron Health and CheckMate 032

	median OS, months [95%CI]	1-year / 2-year survival (%)
FULL COHORT		
From Diagnosis		
All (N = 2056)	11.6 [11.1,12.3]	48.6/ 22.0
Limited disease (n = 680)	19.6 [18.0,21.5]	71.9/ 42.3
Extensive disease (n = 1,263)	9.4 [8.9,9.9]	35.2/ 10.5
From Initiation of 2L		
All (n = 628)	4.2 [3.7,4.7]	13.3/ 3.3
PT-sensitive (n = 372)	5.4 [4.4,6.2]	15.9/ 4.2
PT-refractory (n = 231)	3.0 [2.6,3.6]	9.1/ 2.9
MATCHED COHORT		
From Diagnosis		
All (N = 903)	12.5 [11.5,14.3]	47.0/ 26.4
Limited disease (n = 348)	23.8 [20.0,29.5]	72.0/ 49.5
Extensive disease (n = 507)	9.8 [8.9,10.6]	37.9/ 12.1

Continued

Table: 1214P *Continued*

	median OS, months [95%CI]	1-year / 2-year survival (%)
From Initiation of 2L		
All (n = 254)	4.9 [4.0,6.2]	14.6/ 3.8
PT-sensitive (n = 158)	6.3 [5.6,7.5]	18.4/ 6.0
PT-refractory (n = 90)	2.7 [2.1,3.3]	5.6/ 1.9
CHECKMATE 032		
NIVO 3 mg/kg cohort (n = 98)	4.4 [3.0–9.3]	33/ NR
NIVO 1 mg/kg + IPI 3 mg/kg (n = 61)	7.7 [3.6–18.0]	43/ NR
NIVO 3 mg/kg + IPI 1 mg/kg (n = 54)	6.0 [3.6–11.0]	35/ NR

*NR=not reported; PT=platinum; NIVO=nivolumab; IPI=ipilimumab

Conclusions: This large retrospective data set highlighting 2L SCLC outcomes demonstrates poor survival in this setting underscoring the need for novel tx. Results from CheckMate 032 present IO as a potential option for SCLC pts.

1215P Sequential blockade of PD-1 and PD-L1 causes fulminant cardiotoxicity: From case report to mice model validation

Y-J. Chen[1], W-C. Huang[2], S-Y. Liu[3], C-C. Ko[3]

[1]Department of Radiation Oncology, Mackay Memorial Hospital, Taipei City, Taiwan, [2]Department of Surgery, Mackay Memorial Hospital, Taipei City, Taiwan, [3]Department of Medical Research, Mackay Memorial Hospital, Taipei City, Taiwan

Background: In clinical practice, the sequential use of shifting from a programmed cell death 1 (PD-1) inhibitor to its ligand 1 (PD-L1) inhibitors in consideration of ineffectiveness or toxicity is becoming more common due to prolonged survival. We report a patient in whom fatal myocarditis developed after sequential use of PD-1 and PD-L1 inhibitors. To validate this finding, a syngeneic tumor-bearing mice model was used.

Methods: A 61-year-old woman with metastatic lung adenocarcinoma, who had received 5 doses of nivolumab (3 mg/kg) and then 1 dose of atezolimumab (1200 mg), complained of chest tightness and dyspnea 4 weeks later. The workup revealed sinus tachycardia, a normal Troponin I level (< 0.01 ng/mL), an elevated creatine kinase-myocardial band (CK-MB) level (10 ng/mL), and an elevated N-terminal pro-brain natriuretic peptide (NT-proBNP) level (2960 ng/mL). Serial echocardiograms revealed left ventricular ejection fractions declining from 66.3 to 59.2 %. Under a diagnosis of myocarditis, she was treated with intravenous methylprednisolone at 5 mg/kg/day and oral mycophenolate mofetil at 1000 mg/day. The progressive clinical deterioration was noted with serial elevation of Troponin I, CK-MB and NT-proBNP levels up to 1.3, 24 and 15738 ng/mL, respectively. Cardiac arrest was noted later. The Balb/c mice bearing lung metastasis of CT26 colon cancer cells were treated with PD-1 and PD-L1 inhibitors for pathological and immuohistochemical studies.

Results: The pathology shows that the combination of anti-PD-1 and anti-PD-L1, either sequentially or simultaneously administered, caused myocarditis lesions with myocyte injury and patchy mononuclear infiltrates in the myocardium in all combination group mice (n = 3 for each). The myocarditis lesions were not seen in mice treated with anti-PD-1 or anti-PD-L1 alone. Marked expression of PD-L1 in infiltrating lymphocytes and expression of PD-1 in myocytes was noted only in mice with combination blockade, implying a possible role for pathogenesis of myocarditis.

Conclusions: The combinatory use of PD-1 and PD-L1 blockade, either sequentially or concurrently, may cause fulminant cardiotoxicity, and such usage should be cautious.

1216P Impact of anti-infectious and corticosteroids on immunotherapy: Nivolumab and pembrolizumab follow-up in a French study

J-P. Metges[1], E. Michaud[2], D. Deniel Lagadec[3], F. Marhuenda[4], A. Chaslerie[2], F. Grude[4]

[1]Oncology and Hematology Institute, C.H.U. Brest - Hôpital Morvan, Brest, France, [2]Medical Department, Regional Health Insurance, Nantes, France, [3]Cancer Observatory, CHRU Brest, Brest, France, [4]Cancer Observatory, ICO Paul Papin, Angers, France

Background: Immunotherapy is a new paradigm with EMA approval in melanoma and lung cancer. However, B Routy and al has recently published a decrease of efficacy of immunotherapy via gut microbiome antiobiotics influence and potential drug interactions between antiobiotics/corticoids and immunotherapy associated with decrease of overall survival have been underlined too. The Observatory of Drugs, Medical Device and Therapeutic Innovations (OMEDIT) Bretagne/ Pays de la Loire (B-PL), in collaboration with French Regional Health Insurance System (FRHIS), wanted to carry out a study about the impact of these treatments on the efficacy of immunotherapy.

Methods: FRHIS (PL) has made an extract in its database for patients who initiated treatment with Nivolumab/Opdivo® and Pembrolizumab/Keytruda® between January 2016 and end of June 2017. Dispensing of antibiotics, corticoids and antifungals 60 days before initiation of immunotherapy and after the beginning of treatment (within 30 or 150 days after). The patient's clinical data (age, sex; diagnosis, indication, grade III/IV side-effects, response rate, survival) would be crossed with the use or not of anti-infectious drug treatment in order to define the impact of taking these drugs on the treatment of immunotherapy.

Results: 798 patients were identified including 377 in 2016 and 421 in the first half of 2017: 148 with malignant melanoma and 650 with lung cancer. 763 were treated with nivolumab and 35 with pembrolizumab. Before the beginning of immunotherapy, 14% of these patients received an antibiotic, 17% a corticoid and 2% an antifungal. After the beginning of immunotherapy (within 30 days after), 8% received a corticoid, 6% an antibiotic and 2% an antifungal. Response to treatment, Progression Free Survival and Overall Survival (PFS and OS) in correlation with the use or not of these drugs for Bretagne and PL areas would be presented at the meeting.

Conclusions: The good use of immunotherapy was crucial to optimize the response rate and to increase OS. Use of anti-infectious and corticosteroids was usual in routine. Antibiotics were found to be prescribed in 20% of the patients receiving immunotherapy. Results about their impact in term of response, PFS and OS would be shown at the meeting.

1217P Real-world safety of nivolumab in patients with non-small cell lung cancer (NSCLC) in Japan: Interim summary of post-marketing all-case surveillance

Y. Ohe[1], A. Gemma[2], K. Nakagawa[3], N. Yamamoto[4], T. Saito[5], A. Akamatsu[5], K. Kuwano[6], Y. Nakanishi[7]

[1]Pulmonary Medicine, National Cancer Center Hospital, Tokyo, Japan, [2]Department of Pulmonary Medicine and Oncology, Nippon Medical School, Tokyo, Japan, [3]Department of Internal Medicine, Kindai University Faculty of Medicine, Osaka, Japan, [4]Pulmonary Medicine, Wakayama Medical University, Wakayama, Japan, [5]Pharmacovigilance Division, Ono Pharmaceutical Co., Ltd., Osaka, Japan, [6]Pulmonary Medicine, The Jikei University School of Medicine, Tokyo, Japan, [7]Research Institute for Diseases of the Chest, Kyushu University Hospital, Fukuoka, Fukuoka, Japan

Background: Nivolumab, a fully humanized anti-PD-1 antibody, was approved in December 2015 in Japan for the treatment of previously-treated, unresectable, advanced or recurrent NSCLC. A post-marketing all-case surveillance was imposed as a condition for approval, to accumulate real-world safety data for nivolumab, because clinical trial data were limited.

Methods: This all-case surveillance is an ongoing mandatory observational register, searching for new treatment-related safety issues. All NSCLC patients treated with nivolumab between 17 December 2015 and 31 March 2016 were registered and monitored for one year. Safety data were accumulated using case report forms (CRFs) in accordance with Good Post-Marketing Study Practice Ministerial Ordinance in Japan. This interim summary is based on data collected and summarized from patients whose CRFs were available by 3 January 2018.

Results: Overall, 3681 patients were enrolled from 17 December 2015 to 31 March 2016, with 3303 CRFs collected by 3 January 2018. The safety analysis set included 3297 of 3303 patients. Background characteristics of patients: median age was 67 years; 74% of patients were current or former smokers; 77% of patients had an ECOG performance status score of 0 (24%) or 1 (53%); 66% and 28% of patients had adenocarcinoma or squamous cell carcinoma, respectively. The frequency of adverse drug reactions of any grade was 45%. The most frequent (5% or higher) adverse events of special interest were interstitial lung disease (ILD, 9.1%; grade ≥ 3, 3.9%), thyroid dysfunction (8.7%; grade ≥ 3, 0.3%), hepatic function disorder (7.8%; grade ≥ 3, 2.0%), infusion reaction (5.4%; grade ≥ 3, 0.3%) and colitis/severe diarrhea (5.3%; grade ≥ 3, 1.3%). The overall survival rate at 1 year was 37% (95% CI, 35.2 to 38.6). We will report updated data along with estimated risk factors for ILD.

Conclusions: Among Japanese patients with previously-treated, unresectable, advanced or recurrent NSCLC, nivolumab showed an almost consistent safety profile with clinical trial data except for frequency of ILD. The benefit-risk profiles should continuously be monitored.

1218P Immune-related adverse events: Comparison of melanoma and non-small cell lung cancer patients treated with anti-PD1 therapy

N. Duma[1], A-G. Azzouqa[2], S. Yadav[1], K. Hoversten[3], C. Reed[3], A.N. Sitek[3], Y. Lou[2], J. Molina[1], T. Halfdanarson[1], K. Leventakos[1], R.W. Joseph[2], R. Manochakian[2], R. Dronca[2]

[1]Medical Oncology, Mayo Clinic, Rochester, NY, USA, [2]Medical Oncology, Mayo Clinic, Jacksonville, FL, USA, [3]Internal Medicine, Mayo Clinic, Rochester, NY, USA

Background: Immune-related adverse events (IRAEs) represent a clinical challenge, potentially limiting the clinical benefits of immunotherapy. Data suggests nivolumab and pembrolizumab IRAEs rates are similar but no comparisons across tumor types exist. Therefore, we studied IRAEs in patients (pts) with metastatic melanoma and non-small cell lung cancer (NSCLC) treated with anti-PD1 therapy.

Methods: All pts with metastatic melanoma and NSCLC seen at the Mayo Clinic Rochester and Florida from 2015 to 2018 were reviewed. Patients that received prior immunotherapies or thoracic radiation were excluded. Chi-square test was used to estimate differences in categorical data.

Results: Out of 510 pts, 266 (52%) had melanoma and 244 (48%) NSCLC. Baseline characteristics were similar across groups, except for sex (NSCLC: 51% women; melanoma: 40% women). 80% of the pts with NSCLC received chemotherapy prior to immunotherapy compared to 14% of the pts with melanoma. 75% (200) of melanoma pts received pembrolizumab and 66% (161) of NSCLC pts received nivolumab. Higher rates of IRAEs were observed in the melanoma pts (55% vs. 41%, <0.001) (Table). No difference in grade ≥3 IRAEs was observed. Melanoma pts were more likely to develop diarrhea/colitis and endocrinopathies compared to the NSCLC pts (19% vs. 7%, $p < 0.008$; 33% vs. 18%, $p < 0.01$, respectively). Contrarily, pts with NSCLC had higher rates of pneumonitis (14% vs. 6%, $p < 0.007$). Most pts resumed the anti-PD1 agent after developing IRAEs (60% and 57%, respectively). In 31% of the pts experiencing IRAEs the anti-PD1 agent was permanently discontinue due to toxicity.

Table: 1218P

	Melanoma % (n)	NSCLC % (n)	p value
IRAEs	55 (146)	41 (99)	<0.001
Grade ≥2 IRAEs	76 (110)	75 (76)	0.98
Grade ≥3 IRAEs	34 (49)	36 (36)	0.68
Prescribed systemic steroids	66 (97)	60 (59)	0.26
Required intravenous steroids	25 (37)	27 (27)	0.75
IRAEs: Subtype (all grades)			
Diarrhea/Colitis	19 (28)	7 (7)	0.008
Dermatologic Toxicities	19 (28)	22 (22)	0.62
Endocrinopathies	33 (48)	18 (18)	0.01
Pneumonitis	6 (8)	14 (14)	0.007
Transaminitis	14 (21)	9 (9)	0.24
Immunotherapy was restarted	60 (88)	57 (56)	0.60
Immunotherapy DC due to toxicity	31 (45)	31 (31)	0.99

Conclusions: Patients with metastatic melanoma were more likely to develop IRAEs with anti-PD1 therapy. We observed differences in the IRAEs developed across groups. These associations could be attributed to intrinsic tumor characteristics or differences between anti-PD1 agents. Larger studies are needed to enhance our understanding of these differences.

Background: IO has become one of the major pillars of anti-cancer therapy. A range of immune-related adverse events (IRAE) are recognized within various organs. Acute vascular events (AVE) are generally not considered IRAE. Considering the role of inflammation in acute ischemic cardiovascular events, we assumed such events can be triggered by IO. We aimed to evaluate the frequency and nature of AVEs occurring shortly after the initiation of IO.

Methods: Computerized search of Sheba medical center (SMC) electronic medical records was done for patients (pts) that received IO (any of: pembrolizumab, nivolumab, atezolizumab, ipilimumab). Out of those, we searched for cases with a diagnosis of AVE within 1 month after initiation of IO. Search was for the diagnoses: cerebrovascular accident (CVA), transient ischemic attack (TIA), myocardial infarct (MI), non-ST-elevation MI, ST-elevation MI, embolic event, pulmonary emboli (PE) and deep vein thrombosis (DVT). We excluded cases with AVE within a year prior to the initiation of therapy, concomitant chemotherapy, and cases of a single-site DVT.

Results: Between 1st January 2015 and 14th March 2018, 1396 pts received IO in SMC. 14 pts were identified in the computerized search. Excluded: 4 with a single site DVT, 1 with a prior cardiovascular event within a year prior to initiation of IO, 1 with concomitant chemotherapy, 3 excluded due to AVE not definitely diagnosed, leaving 5 pts not excluded. 8 additional pts were identified by reports of physicians aware of this project, of these 2 were also identified by the computerized search, thus a total of 11 pts fit our study criteria. Events were: multiple CVA (3), PE (2), sudden cardiac death (2), bilateral DVT (1), CVA (1), TIA (1), MI (1). In one pt marantic endocarditis was suspected. 7 pts had diabetes, 7 pts had hypertension, 2 pts had a body mass index > 30, 3 were smoking within < 10 years ago, none had a family history of cardiovascular disease. 9 of the pts were treated in SMC, constituting a frequency of 0.6%.

Conclusions: AVEs occur at a low frequency shortly after initiation of IO. Initiation of IO may be the trigerring event of those events. Further retrospective studies and analyses of clinical trials data are required to evaluate whether this is a random association or a true IRAE.

1220P Real-world experience of pembrolizumab in patients with advanced melanoma: A large retrospective observational study

F.X. Liu[1], W. Ou[2], S.J. Diede[3], E.D. Whitman[4]

[1]CORE, Merck & Co Inc, Kenilworth, NJ, USA, [2]CORE, Merck & Co., Inc., Kenilworth, NJ, USA, [3]Clinical Oncology, Merck & Co., Inc., Kenilworth, NJ, USA, [4]Atlantic Melanoma Center, Carol G. Simon Cancer Center, Morristown, NJ, USA

Background: Pembrolizumab (PEM), a humanized antibody targeting programmed death-1 receptor, has been approved by FDA for the treatment of patients (pts) with advanced melanoma (AM) in the US for over 3 years. The study examined the real-world (RW) use of PEM and associated patient (pt) outcomes in the US Oncology Clinical Practices.

Methods: Flatiron Health longitudinal database was used to identify adult pts with AM who received ≥1 dose of PEM between September 4, 2014 and December 31, 2016. These pts were followed up to December 31, 2017. Pts in clinical trials were excluded. Pt demographic, treatment, and clinical characteristics were described. Time on treatment (ToT) and overall survival (OS) were analyzed using the Kaplan Meier (KM) method, with the first dose of any PEM as the starting point.

Results: Five hundred and thirty-two patients were included in the analysis. Of the 532 patients, 315 in first line (1L), 152 second line (2L), and 65 third line or beyond (3L+). Overall, median age at PEM initiation was 68 years (range, 18-84); most were male (66.4%) and Caucasian (93.5%). 32.9% of pts are confirmed BRAF mutant, 53.6% BRAF wildtype, and 13.5% unknown. When data were available, 21.2% had an elevated lactate dehydrogenase (>ULN), 18.0% had brain metastases, and 23.3% had an ECOG performance status of > 1. At the time of analysis, pts were followed for a median of 12.9 months (mo, range, 0.03 – 39.7). The overall median ToT was 4.4 mo (95% CI, 3.5-5.2), with 4.2, 4.7, 4.2 mo in 1L, 2L, and 3L+, respectively. The overall median OS was 21.9 mo (95% CI, 15.5-29.1), not reached for 1L, and 13.3 and 12.5 mo for 2L and 3L+ respectively. The 1-year and 2-year survival, using the KM method, was 60.9% (95% CI, 56.5-65.0; 1L, 64.9%; 2L, 55.3%; 3L+, 54.6%) and 48.1% (95% CI, 43.2-52.8; 1L, 53.4%; 2L, 41.5%; 3L+, 39.0%) respectively.

Conclusions: The study reports RW use of PEM in a large cohort of pts with AM in US Oncology Clinical Practices. The study pt population is more heterogeneous than that of clinical trials (KEYNOTE-002 and KEYNOTE-006). The findings of ToT and 2-year OS based on RW clinical decision making were consistent with those reported in PEM clinical trials, supporting the RW effectiveness of PEM in pts with AM.

Background: Selecting the appropriate pts to receive IO remains a challenge due to the lack of optimal biomarkers. We investigated the association between sites of metastatic disease and CO in pts enrolled on IO-based phase 1 clinical trials.

Methods: We conducted a retrospective review of 90 pts treated on IO-based phase 1 clinical trials at Winship Cancer Institute of Emory University between 2009-2017, including sites of metastasis. Overall survival (OS) and progression-free survival (PFS) were measured from the first dose of IO to date of death or clinical or radiographic progression, respectively. Clinical benefit (CB) was defined as a complete response (CR), partial response (PR), or stable disease (SD). Univariate analysis (UVA) and multivariate analysis (MVA) was carried out using Cox proportional hazard model or logistic regression model.

Results: The median age was 63 years and 53% of pts were men. The most common histologies were melanoma (33%) and gastrointestinal cancers (22%). Sites of metastasis were lymph node (N = 58), liver (N = 40), lung (N = 37), bone (N = 24), and brain (N = 8). Most pts (81%) were Royal Marsden Hospital (RMH) good risk. Liver metastases were associated with significantly shorter OS, PFS, and lower rate of CB (Table).

Conclusions: Liver metastases are a poor prognostic factor in pts treated on IO-based phase 1 clinical trials. These findings should be validated in a larger study. Equal Contribution: MAB, JMS, DJM.

1222P Clinical outcome of immune related hepatitis (IrHep) in patients with advanced melanoma (AM) treated with single agent or combination immune checkpoint inhibitors (ICIs)

N. Shah[1], J. Puthiamadathil[1], M.T. Serzan[1], A. Belouali[1], W.J. Kelly[1], B. MA[1], M. blackburn[1], A. Knoedler[1], S. OchoaGonzaelz[1], M. Janni[1], S. Madhavan[1], G.T. Gibney[2], M.B. Atkins[2]

[1]Medicine, Lombardi Cancer Center Georgetown University, Washington DC, USA, [2]Oncology & Medicine, Georgetown-Lombardi Comprehensive Cancer Center, Washington DC, USA

Background: Immune related adverse events with single agent or combination ICIs are well described in patients (pts) with AM, but comprehensive clinical characterization of IrHep is still lacking. Here we report retrospectively collected clinical outcomes of IrHep in pts with AM treated with ICIs at Medstar Health Network hospitals.

Methods: Pts with AM treated with ICIs (n = 189): ipilimumab (ipi) (n = 73), nivolumab (n = 17) or pembrolizumab (n = 48) (anti-PD1), or combination nivolumab plus ipilimumab (combo) (n = 51) were identified by pharmacy records. IrHep was defined as any elevation of aspartate aminotransferase (AST) and/or alanine aminotransferase (ALT) and graded in accordance with CTCAE v4.03. Pts with grade >2 ALT/AST elevation at baseline or rise attributed to causes other than IrHep were excluded. Highest grade ALT/AST was reported for each pt. Median time to resolution (MTR) to baseline

Table: 1221P UVA and MVA† of liver metastases with CO

	OS				PFS				CB			
	UVA		MVA		UVA		MVA		UVA		MVA	
	HR (CI)	p-value	HR (CI)	p-value	HR (CI)	p-value	HR (CI)	p-value	OR (CI)	p-value	OR (CI)	p-value
No liver metastases (n = 50)	0.42 (0.23-0.78)	0.006*	0.38 (0.17-0.84)	0.017*	0.60 (0.39-0.93)	0.024*	0.73 (0.42-1.26)	0.255	2.64 (1.11-6.28)	0.028*	1.09 (0.27-4.44)	0.903
	Median: 21.9 months 12 month survival: 60%				Median: 3.6 months 12 month survival: 13%				Rate: 56% (6 PR, 22 SD, 17 PD, 5 NE)			
Liver metastases (n = 40)	Median: 8.1 months 12 month survival: 19%				Median: 1.8 mos 12 month survival: 5%				Rate: 33% (1 CR, 1 PR, 11 SD, 24 PD, 3 NE)			

†Covariates included in MVA were age, whether IO is indicated for the pts histology, ECOG PS, RMH risk group, number of metastatic sites and histology
*statistically significant PD: Progressive disease, NE: Not evaluable

was analyzed by KM analysis. Steroid use was captured from its initiation to for IrHep, till their discontinuation.

Results: IrHep any grade was identified in 80 (42%) pts (19 (26%) ipi; 24 (37%) anti-PD-1; 37 (73%) combo). Median time to highest grade IrHep for ipi, anti-PD1, and combo groups was 8.78, 9.65 and 6.15 weeks respectively. IrHep grade $\geq$3 occurred in 3 (4%), 2 (3%) and 14 (27%) combo pts respectively. For IrHep grade $\geq$3 (n = 18), MTR was 5 weeks, median starting systemic steroid dose was 1mg/kg and median duration of steroid treatment was 5 weeks. For irHep grade 2 (n = 22), 32% (n = 7) pts were treated with systemic steroid (2 progressed to grade 3 and 5 resolved), 22.7% (n = 5) pts progress to grade 3-4 with treatment interruption, 22.7% resolved with treatment interruption and 22.7% resolved without treatment interruption. TTF failure for pts with/without IrHep was 5.1/12.4, 12.9/12.5 and NR/24.7 months with ipi, PD1 and combo pts respectively.

Conclusions: In our real-world experience, IrHep was identified more frequently than in past AM studies, particularly in pts treated with combo. Pts with grade 3 $\geq$irHep resolved within 5 weeks with systemic steroids at starting dose of 1mg/kg. Pts with grade 2 irHep, one should not proceed with treatment unless they resolved to grade $\leq$1.

1223P Potential drug cost impact of dual agent immunotherapy (DAIO) with nivolumab (N) plus ipilimumab (I) in patients with DNA mismatch repair deficient (dMMR) metastatic colorectal cancer (mCRC) in Canada

K. Virik[1], R.B. Wilson[2]

[1]Oncology, Queen's University, CCSEO, Kingston, ON, Canada, [2]Surgery, University of NSW, Liverpool, Australia

Background: The overall 5-year survival for mCRC remains poor (14%) despite the use of current chemotherapeutic and biologic agents. Immunotherapy (IO) is a promising treatment option in tumors with a high mutational burden. This includes mCRC DNA dMMR tumors which have upregulation of immune checkpoints and a poorer prognosis. The CheckMate 142 phase II trial in pretreated dMMR mCRC patients using DAIO with N and I showed improved responses and disease control compared to N alone. The use of this DAIO has an anticipated budgetary impact on health care systems within the context of this potentially funded utilization of IO.

Methods: An estimation of the drug acquisition cost for N and I for new cases diagnosed in 2017 and treated upon relapse in Canada was undertaken. A cost estimate for N and I treatment in the first line of dMMR mCRC in relapses and de novo was undertaken should this be a future option. N and I drug costs per patient were calculated based on treatment indication, median number of cycles, standard dose/schedule as per the CheckMate 142 trial. The analysis was performed in Canadian dollars ($) and assumed complete drug delivery and uncomplicated cycles. The cost of N and I was obtained from the pan Canadian Oncology Drug Review (pCODR) costings for N in lung cancer and I in melanoma respectively. The number of target patients and N and I utilization was derived from constructed schema to give a budget impact estimate.

Results: Estimated DAIO drug costs per treated patient are $131,040. Assuming 65% patients received first line chemotherapy, the cost of DAIO second line and third line in mCRC respectively ranges from $32.9 Million (M) – $50.7M and $17.8M – $24.7M. For 1st line DAIO in 65% of patients: the cost of treating early stage dMMR CRC which subsequently recurs would be $45.7M and the cost for treatment of dMMR de novo mCRC would be $22.8M. A sensitivity analysis was performed.

Conclusions: DAIO drug costs in dMMR mCRC potentially add a substantial cost burden to the publically funded Canadian healthcare system. As data evolves, longer duration of therapy and potential first line use will add further to the estimated budgetary impact.

1224P Q-TWiST analysis to assess benefit-risk of pembrolizumab in patients with PD-L1-positive advanced or metastatic NSCLC

M. Huang[1], M.C. Pietanza[2], A. Samkari[3], J. Pellissier[1], T. Burke[4], S. Chandwani[4], F. Kong[5], A.S. Pickard[6]

[1]Economic and Data Sciences, Merck & Co Inc, North Wales, PA, USA, [2]Clinical Research, Merck & Co, Kenilworth, NJ, USA, [3]Clinical Research, Merck & Co Inc, North Wales, PA, USA, [4]Center for Observational and Real World Evidence, Merck & Co, Rahway, NJ, USA, [5]Stat Programming, Merck & Co Inc, North Wales, PA, USA, [6]Outcomes Research, Second City Outcomes Research, LLC, Oak Park, IL, USA

Background: Pembrolizumab monotherapy showed significantly longer progression-free survival and overall survival (OS), and fewer treatment-related adverse events (AEs) compared to chemotherapy in patients with metastatic non-small cell lung cancer (mNSCLC) with PD-L1 positive tumors in the first-line setting (KEYNOTE-024 (KN024)) and in those previously treated (KEYNOTE-010 (KN010)). The objective of this analysis is to assess the benefit-risk of pembrolizumab in terms of quality-adjusted survival amongst patients in these trials.

Methods: The Quality-adjusted Time without Symptoms of disease progression or Toxicity of treatment (Q-TWiST) analysis was used to compare the trial arms. Survival time of each patient was partitioned into three health states: with toxicity before disease progression, without toxicity before disease progression, and disease progression until death. Toxicities considered were grade 3+ AEs. Mean utility scores for the three health states were estimated using EQ-5D-3L data collected in the trials. Q-TWiST was calculated as the utility-weighted sum of the mean health state durations. KN024 and KN010 have undergone several interim analyses. Data from each of these analyses were examined. The published criterion [Revicki 2006] for a 'clearly clinically important' improvement in Q-TWiST is 15% of mean OS in a study.

Results: Based on the most recent analysis of KN024 from July 10, 2017 and KN010 from March 24, 2017, patients randomized to pembrolizumab had 3.25 months (about 20% of mean OS) greater Q-TWiST ($P < 0.001$) compared to those randomized to platinum-based chemotherapy in KN024, and 3.11 months (about 25% of mean OS) greater Q-TWiST ($P < 0.001$) compared to docetaxel in KN010. Results across KN024 and KN010 trial analyses showed an increase in trend for the Q-TWiST improvement of pembrolizumab over time.

Conclusions: Pembrolizumab showed statistically significant and clinically meaningful improvement in quality-adjusted survival using the Q-TWiST analysis compared to chemotherapy in mNSCLC in both previously untreated and treated patients. The benefits continued to accrue over the trial follow-up period with extended survival.

1225P Impact of immune-checkpoint inhibitors (ICPIs) as treatment of patients (pts) with metastatic primary uveal melanoma (UM): Results of a single-institution database

C.L. Lee[1], G. Gullo[1], N. Horgan[2], D. Smith[1], M. Moran[1], J.P. Crown[1]

[1]Medical Oncology, St Vincents University Hospital, Dublin, Ireland, [2]Surgery, Royal Victoria Eye & Ear Hospital, Dublin, Ireland

Background: Metastatic primary UM (MUM) is a rare cancer with a poor prognosis and a median overall survival (OS) of about 6 months in historical datasets. Despite the significant improvements produced by ICPIs in metastatic cutaneous melanoma, pts with MUM have been excluded from most trials of ICPIs thus causing an almost complete lack of prospective clinical data.

Methods: An analysis of all pts with MUM included in our institutional prospectively accrued database of all primary UM pts. OS was calculated from date of first diagnosis of metastatic disease to date of death or last follow up.

Results: Out of 169 pts registered between April 2008 and April 2018, 39 pts had MUM. Pts characteristics: males 20 (51%), median age 63 years (range 34-85), median tumour thickness at diagnosis 9mm (range 2-22), tumour location: choroidal 19 (49%) ciliochoroidal 8 (20%), undefined/unknown 12 (31%). Primary therapy (PTx): enucleation 22 (56%), brachytherapy 15 (38%), both 2 (5%). Sites of metastases: liver only 29 (74%), liver + other sites 7 (18%), extra-hepatic only 3 (8%). Median follow-up is 37.9mos. 11 pts had resectable disease at diagnosis and underwent primary metastatectomies, 28 patients underwent: immunotherapy (15), other systemic therapies (5), locoregional Tx (3), best supportive care (5). Median OS is 14.25 mos. At the database lock-out (April 30th 2018), 27 pts (70%) have died of MUM. Pts without hepatic involvement tend to have longer median OS (25.9mos) vs those with liver only disease (16.6mos) or liver + other sites (OS 8.9 mos). Overall, 32/39 pts (82%) received ICPIs during the course of their disease: ipilimumab 13 (40%), single agent anti-PD1 5 (16%), sequential/concomitant ipilimumab and anti-PD1 14 (44%). Median OS is 23.7 mos (sequential Ipilimumab and anti-PD1) vs and single-agent ipilimumab (13.8mos) vs single-agent PD-1 (14.7mos).

Conclusions: In our single-institution experience of nonresectable MUM pts, sequential/concomitant ICPIs produced a longer median OS than single-agent ipilimumab or anti-PD1 and should be considered the preferred treatment option. A more indolent disease could have contributed to more prolonged OS in a subgroup of pts without hepatic involvement.

1226P Anti-PD1 inhibitors: Assessment of proper use, efficacy and economic impact in daily practice

M. Valery
Hôpital de la Salpêtrière, Paris, France

Background: Nivolumab and pembrolizumab have been approved in France in treatment of several metastatic cancers, with an approximate monthly processing cost of €5,550 per patient. The objective of our study was to evaluate efficacy and correct use of these anti-PD1 antibodies in daily practice since its approvals.

Methods: We retrospectively collected data from patients treated with nivolumab or pembrolizumab for solid tumor since July 2015. Data included the correct use of anti-PD1 according to the Summary of Product Characteristics, requiring compliance with indications, a WHO status < 2 and a limit of 20 mg per day of corticosteroids. Progression-free survival (PFS) and overall survival (OS) were analyzed for the global population and according to the correct use of anti-PD1 (C+ group) or not (C- group).

Results: 129 patients were treated with nivolumab or pembrolizumab: 108 (83%) patients for lung cancer, 11 (9%) for clear cell renal cancer and 10 (8%) for melanoma. At the cut-off analysis, with a median follow-up of 9,6 months (0,03 – 31,9), 89 patients (69%) had a progressive disease, 64 patients (50 %) were still alive with 18 patients (14%) still receiving anti-PD1, 44 patients (34 %) were deceased and 21 patients (16%) were lost to follow-up. The correct use of anti-PD1 was observed in 85 patients (65%), 29 (21%) patients had a WHO status of 2, 7 (5%) patients had a WHO status of 3, and 12 patients received corticosteroids. The poor utilization of treatment for these 44 patients (34%) totaled 338 injections, costing about €470,000 for a total of €3,000,000 of expenditures using this treatment. Median PFS were respectively 6,7 m (CI 95% 3,9 - 11,7) in the C+ group and 2,5 m (CI 95% 1,6- 5,1) in the C- group (p = 0,03). Median OS were respectively 22,3m (CI 95% 13,6- NR) in the C+ group and 8,4 m (CI 95% 3,9-11,8) in the C- group (p < 0,001). Response rate were respectively 34 % in the C+ group and 25% in the C- group.

Conclusions: In our retrospective study, 34% patients were not meeting the SPC criteria with a WHO status, costing for 25% of the total expenditures. These results reflect the willingness of oncologists to give patients access to innovative and promising treatments but should be balanced with the high cost and the poor outcomes in the C- group.

1227P Immune-related adverse events (irAEs) predict therapeutic efficacy of an anti-PD-1 antibody in cancer patients

J. Rogado[1], N. Romero Laorden[1], J.M. Sanchez Torres[1], A.I. Ballesteros Garcia[1], V.E. Pacheco-Barcia[1], R. Arranz[2], R. Mondéjar Solís[1], P. Gullón[3], A. Lorenzo[4], R. Colomer Bosch[1]

[1]Medical Oncology, Hospital Universitario de La Princesa, Madrid, Spain, [2]Hematology, Hospital Universitario de La Princesa, Madrid, Spain, [3]Social and Cardiovascular Epidemiology Research Group, Universidad de Alcalá, Madrid, Spain, [4]Hematology, Hospital Universitario de Mostoles, Mostoles, Spain

Background: In addition to inducing clinical responses, cancer immunetherapy may awaken autoimmune disorders. We have attempted to establish if the incidence of any irAE after Nivolumab used in advanced malignant diseases is associated with anti-PD-1 treatment efficacy.

Methods: We studied all advanced cancer patients treated with Nivolumab between January 2016 and September 2017 at our institution. IrAEs were identified according to CTCAE-4.0. Efficacy was evaluated with objective response rate (ORR, immune RECIST criteria) and progression free survival (PFS). Odds Ratio tests were performed to determine the association between irAEs and ORR.

Results: Finally, 64 patients were included. Primary tumor diagnosis were: lung cancer (n = 47), squamous cell carcinoma of head and neck (n = 5), melanoma (n = 4), clear cell renal carcinoma (n = 4), Hodgkińs lymphoma (n = 2), and urothelial bladder carcinoma and gallbladder adenocarcinoma (n = 1, each one). IrAEs were observed in 27 patients (42.2%), and included hypothyroidism (n = 15), nephritis (n = 5) and hyperthyroidism (n = 4) as more frequent. ORR was observed in 28 patients (43.7%). Median PFS was 6 months (1-25). 21 of the 27 patients with irAEs had objective response (77.7%) vs 7 of the 37 cases without irAEs (18.9%) (OR 15.0, p < 0.000001). PFS in patients with irAEs vs non-irAEs was 7 vs 5 months (HR 2.2, p = 0.016). These results were independent of cancer type, age, sex, histology, ECOG performance status, smoking habit or prior lines of therapy.

Conclusions: In advanced cancer patients treated with an anti-PD-1 antibody, the incidence of irAEs after Nivolumab is associated with a dramatically improved ORR and PFS. Future studies of anti-PD-1 cancer immunotherapy will need to address this association of toxicity and efficacy in order to reveal the underlying biological mechanisms.

1228P Previous immunotherapy treatments may improve tumor responses with subsequent chemotherapy regimens

I. Baraibar Argota[1], P. Martin-Romano[2], M.F. Sanmamed[1], M. Rodriguez-Ruiz[1], J.L. Pérez-Gracia[1], I. Gil-Bazo[1], I. Melero[3], L. Resano[1], A. Chopitea Ortega[1], J. Rodriguez[1], J.M. Aramendia[1], I. Gardeazabal[1], L. Ceniceros[1], P. Sala Elarre[1], M. Ponz-Sarvisé[1], E. Castanon Alvarez[1]

[1]Department of Oncology, Clinica Universidad de Navarra, Pamplona, Spain, [2]Drug Development, Institut Gustave Roussy, Villejuif, France, [3]Laboratory of Immunology, Clinica Universitaria de Navarra, Pamplona, Spain

Background: First line therapies usually induce the longest progression free survival (PFS) in advanced/metastatic cancer as compared to subsequent lines of treatment. However, immunotherapy (IT) due to its mechanisms of action could influence sensitivity to conventional cancer therapy (CCT) after progression to IT and thereby, influence both tumor growth rate (TGR) and progression free survival (PFS). We have studied TGR and PFS before and after participation in phase I IT trials.

Methods: We retrospectively studied 173 patients who were enrolled in Phase I IT trials at our institution between January 2012 and September 2017. Patients should have received at least one line of CCT before and after IT. Baseline characteristics (sex, age, tumor type, presence of liver disease, number of CCT lines prior to IT, type of CCT and IT) were recorded. PFS before and after IT was calculated. A ratio of PFS after/before IT (PFS_{aftIT} /PFS_{beffT}) over 1.2 was considered clinically significant. TGR was calculated based on the formulas: TGR = 100 (exp(TG)−1), TG = 3 Log(Dt/D0)/t.

Results: 37 patients met inclusion criteria. Baseline characteristics are shown in the table. Nine of 37 patients (6 CRC, 3 renal cancer) presented a PFS_{aftIT}/PFS_{beffT} rate over 1.2. Regarding TGR, of 16 patients in whom TGRpre and TGRpost were available, 3

patients (2 CRC, 1 NSCLC) presented a decrease in TGR greater than 15% when given treatment after IT therapy.

Table: 1228P

Characteristics	N = 37
Female	17
Median (M) age at diagnosis (range)	55 (31-79)
M lines prior to IT (range)	2 (1-5)
Primary tumor Gastrointestinal	19 7 5 4 1 1
Genitourinary Gynecological NSCLC	
Head and neck Breast cancer	
Presence of liver disease (pre/IT/pro)	15/18/31
CCT class (pre/post IT) Platinum derivatives	14/18 0/3 14/21 3/0 13/7
Other alkylating agents (a)	5/4 17/19 1/3 4/1 4/3
Antimetabolites a Anthracyclines	
Topoisomerase inhibitors (i)	
Antimicrotubules a Antiangiogenic a	
Signal transduction i Immunotherapy	
Others	
Combined/monotherapy during IT	22/15

Conclusions: Our data suggest a better outcome on ensuing systemic therapies after IT. Further prospective investigations are needed to select the subset of patients who are more prone to a re-sensitization to CCT and to understand the mechanisms underlying.

1229P Real world incidence, severity and timing of adverse events (AEs) among patients with metastatic non-small cell lung cancer (NSCLC) receiving second-line (2L) immuno-oncology (IO) therapy vs chemotherapy (C)

M.E. Gutierrez[1], A.D. Norden[2], D.C. Lane[3], B.F. Canavan[4], E.D. Nwokeji[3], Y. Xu[5], S. Kaur[2], S.L. Goldberg[2], L. Noh[2], L. Siegartel[3], J. Whittington[6], K. Tuell[7], B. Korytowsky[3]

[1]Medical Oncology, The John Theurer Cancer Center, Hackensack, NJ, USA, [2]Cota, Inc, New York, NY, USA, [3]US HOER Oncology, Bristol-Myers Squibb, Lawrenceville, NJ, USA, [4]Medical Oncology, Regional Cancer Care Associates, Edison, NJ, USA, [5]US HOER Strategy, Bristol-Myers Squibb, Lawrenceville, NJ, USA, [6]US Pharmaceuticals, Medical Oncology, Bristol-Myers Squibb, Lawrenceville, NJ, USA, [7]US HOER Emerging Health Sectors, Bristol-Myers Squibb, Lawrenceville, NJ, USA

Background: Randomized clinical trials (RCTs) in metastatic NSCLC have demonstrated superior responses and lower rates of AEs with 2L IO compared with 2L C. Real-world data (RWD) are lacking to confirm tolerability of IO reported in the controlled environment of RCTs. This study examines RWD on AEs among patients (pts) with metastatic NSCLC receiving either 2L IO or C.

Methods: Cota database electronic health records (EHR) of 55 oncologists at 13 US centers (2 academic; 11 community) were reviewed to identify pts with stage IV NSCLC who received 2L therapy following prior first-line C (March 2015 - December 2017). EHR documented AEs were graded per CTCAE v4 criteria by trained oncology nurses.

Results: Of 206 pts identified, 152 received 2L IO and 54 2L C. No differences were noted between cohorts in age (median [years]; IO: 70; C: 65; $p = 0.21$), sex (IO: 55% male, C: 41%; $p = 0.08$), or age-adjusted Charlson comorbidity index (IO: 4; C: 4; $p = 0.92$); more IO pts had squamous cell histology (IO: 23%; C: 9%; $p = 0.03$). Median duration of 2L therapy [mo (range)] was 2.3 (0-19.1) with IO and 1.7 (0-21.6) with C. AEs of grade 3-4 or any grade resulting in treatment change or discontinuation occurred in 39 (19%) pts; less frequently with IO (13%) vs C (35%; $p < 0.01$); with 87% of AEs occurring by 3 mo. Cumulative % of pts experiencing AEs by 1, 2, 3, and 4 mo of treatment was significantly lower ($p < 0.05$) at all time-points with IO vs. C (5.3, 8.6, 10.5, 10.5 vs. 25.9, 25.9, 33.3, 35.2, respectively). Unadjusted survival data were similar.

Conclusions: This retrospective study of RWD shows 2L therapy with IO, compared with C, is associated with a lower frequency of AEs of grade 3-4 or any grade leading to treatment discontinuation, over 1 to 4 months of therapy. A limitation is that spontaneous reporting of AEs in RWD likely captures fewer AEs compared with RCTs.

Legal entity responsible for the study: Cota.

Table: 1229P Frequency of adverse events during initial 3 months of treatment

Adverse Events	IO Cohort (n = 152) Grade 2 with treatment discontinued	IO Cohort (n = 152) Grade 3-4	C Cohort (n = 54) Grade 2 with treatment discontinued	C Cohort (n = 54) Grade 3-4	p-value Grades 3-4

1230P Anti-PD-1 therapy combined with chemotherapy or target therapy in patients with advanced biliary tract cancer in real-world clinical setting

D. Sun[1], J. Ma[1], C. Han[1], J. Wang[1], Y. Qian[1], G. Chen[1], X. Li[1], J. Zhang[1], J. Song[2], X. Zhao[2], S. Cai[2], Y. Hu[1]

[1]Department of Medical Oncology, Chinese PLA General Hospital, Beijing, China, [2]The Medicine Department, 3D Medicines Inc., Shanghai, China

Background: Biliary tract cancer (BTC) is associated with poor prognosis and lack of effective treatment. As the deregulation of the immune system playing a key role in the pathogenesis of BTC, immunotherapy has emerged as a promising treatment. However, the objective response rate (ORR) of pembrolizumab monotherapy is only 17.4% in programmed death ligand-1 (PD-L1) positive advanced BTSs. Immune checkpoint inhibitors combined with other treatment may be a potential way to improve efficacy, but related evidence is limited. We aimed to evaluate the efficacy and safety of nivolumab/pembrolizumab with chemotherapy or target therapy compared with monotherapy in advanced BTCs.

Methods: Advanced BTCs patients treated with PD-1 inhibitors alone or plus chemotherapy or target therapy from Dec 2015 to Oct 2017 were retrospectively screened for eligibility. Patients previously treated with any agent targeting T-cell co-stimulation or checkpoint pathways were excluded. The primary outcome was overall survival (OS). Secondary outcome were progression-free survival (PFS), ORR and safety.

Results: In total, 37 patients were included (monotherapy, n = 15; combination, n = 22). Combination group represented significantly longer OS (median, 8.2 vs 3.6 months, HR 0.47 [0.20-1.10], p = 0.011) and longer PFS (median, 3.9 vs 2.0 months, HR 0.58 [0.28-1.19], p = 0.034) than monotherapy group. The ORR was 22.7% (5/22) in combination group and 6.7% (1/15) in monotherapy group (p = 0.368) though no significant difference was observed. No significant difference in the incidence of grade 3-4 treatment-related adverse events (TRAEs) were detected between groups (p > 0.05). Most common grade 3-4 adverse events were thrombocytopenia (13.6%) and leukopenia (9.1%) in combination group, and thrombocytopenia (6.7%) in monotherapy group.

Conclusions: Combination of anti-PD-1 plus chemotherapy or target therapy is effective and tolerable as first-line or beyond for advanced BTCs. Prospective study with larger sample size is needed in the future to further confirm our results.

1231P The efficacy and safety of solid tumors combination therapy with immune checkpoint inhibitor: A systematic review and meta-analysis

M. Peng[1], Y. Weng[2], Y. Yao[1], Q. Song[2]

[1]Oncology, Renmin Hospital of Wuhan University, Wuhan, China, [2]Cancer Center, Renmin Hospital of Wuhan University, Wuhan, China

Background: The value of combination therapy with immune checkpoint inhibitor (ICI) for patients with solid tumors remains unclear. Following the completion of several large phase III clinical trials, the role of combination ICI therapy in solid tumors should be redefined.

Methods: Pub-med, EMBASE, Cochrane Library and ClinicalTrials.gov website were searched for eligible randomized controlled trials (RCTs). The selection criteria were defined according to the PICO question: In patients with solid tumors (population), is there any difference of efficacy and safety (outcome) between combination ICI therapy (intervention) and traditional monotherapy (comparison)?

Results: 17 RCTs with 6,616 patients were included in this meta-analysis. The combination therapy of ICI was signifcantly associated with improvement of overall response rate (ORR) (RR = 1.56 [95% CI 1.24, 1.96], P = 0.0001), progression free survival (PFS) (HR = 0.69 [95% CI 0.59, 0.81], P < 0.00001) and overall survival (OS) (HR = 0.76 [95% CI 0.67, 0.87], P < 0.0001) in solid tumor. In subgroup analyses, combination ICI therapy obviously prolonged OS in melanoma patients (HR = 0.64 [95% CI 0.57, 0.72], P < 0.00001), but not in SCLC (HR = 0.94 [95% CI 0.82, 1.08], P = 0.40) and NSCLC (HR = 0.92 [95% CI 0.79, 1.07], P = 0.26) patients. As for toxicity, there was an increased risk of fatigue, rash, diarrhoea and increased transaminases with combination ICI therapy.

Conclusions: In conclusion, our meta-analysis found that combination ICI therapy showed significant benefits in ORR, PFS and OS for patients with solid tumors. Both of combination of ICI with chemoradiotherapy and dual ICI were effective and relatively safe. Melanoma patients got definite survival benefit from combinaiton ICI therapy. Combination ICI therapy should be taken into account in clinical practice and future study designs for melanoma patients. There was also a tendency of improvement of survival for SCLC and NSCLC patients. However, the current data of our analyses didn't support the large-scale clinical application of combination ICI therapy in NSCLC and SCLC patients. Furthermore, numerous RCTs assessing the efficacy and safety of combination therapy with ICI are ongoing.

1232P Model-based assessment of benefit-risk profile of nivolumab (NIVO) flat dosing schedules (Q2W and Q4W) across multiple tumor types

X. Zhao[1], J. Shen[1], M. Gopalakrishnan[2], Y. Feng[1], B.J. Schmidt[1], P. Statkevich[1], T. Kelleher[3], M. Rashford[4], V. Ivaturi[2], J.V.S. Gobburu[2], S. Agrawal[1], A. Bello[1], A. Roy[1]

[1]Clinical Pharmacology and Pharmacometrics, Bristol-Myers Squibb, Princeton, NJ, USA, [2]Center for Translational Medicine, School of Pharmacy, University of Maryland, Baltimore, MD, USA, [3]Global Biometric Sciences, Bristol-Myers Squibb, Wallingford, CT, USA, [4]Oncology Clinical Development, Bristol-Myers Squibb, Princeton, NJ, USA

Background: Flat dosing regimens of NIVO 240 mg every 2 weeks (Q2W) and 480 mg every 4 weeks (Q4W) were approved in the US across indications (not including 480 Q4W in MSI-H or dMMR CRC) and the EU across indications (240 mg Q2W) and in melanoma and renal cell carcinoma (480 mg Q4W) to provide flexible and convenient treatment options than the initially approved 3 mg/kg Q2W weight-based regimen. These changes were supported by model-based bridging of available efficacy and safety data.

Methods: NIVO exposures with flat dosing regimens were predicted and compared with 3 mg/kg Q2W dosing for 3817 patients with melanoma, non-small cell lung cancer, renal cell carcinoma, squamous cell carcinoma of the head and neck, urothelial carcinoma, classical Hodgkin's lymphoma, small cell lung cancer, hepatocellular carcinoma, colorectal carcinoma, and gastric carcinoma. The impact on differences in time-varying exposure on safety were assessed by time-to-event models of Grade (Gr)2+ immune-mediated adverse events (IMAEs) and treatment-related AEs (TRAEs). The impact of differences in early (month 1) exposure on efficacy was assessed by models of tumor growth dynamics and overall survival (OS). Additionally, the potential impact of time-varying exposure on efficacy was assessed by predicting intratumoral programmed cell death 1 (PD-1) receptor occupancy (RO).

Results: The predicted time-averaged concentration at steady-state for 240 mg Q2W and 480 mg Q4W was similar to 3 mg/kg Q2W (<6% difference), whereas the peak and time-averaged concentration after the first dose were higher with 480 mg Q4W. The predicted cumulative probability of experiencing Gr2+ IMAEs or TRAEs with NIVO 240 mg Q2W and 480 mg Q4W were similar to 3 mg/kg Q2W (<1% difference at 2 years). The exposure–response relationship of tumor shrinkage and growth rates were flat. Hazard ratios of OS with NIVO 240 mg Q2W and 480 mg Q4W relative to standard-of-care were predicted to be similar to 3 mg/kg Q2W. The median trough intratumoral RO at steady state was predicted to be maintained above 90% for all 3 dosing regimens.

Conclusions: The benefit-risk of NIVO 240 mg Q2W and 480 mg Q4W regimens are expected to be similar to 3 mg/kg Q2W, with the added convenience and flexibility for patients and providers.

1233P Imunotherapy in clinical practice: Real world multicentric Brazilian experience

J. Cé Coelho[1], A.C. Zimmer Gelatti[1], E. Mascarenhas[2], C. Dutra[3], T. Rebelato[4], R. D'Avila[5], F. Zaffaroni Caorsí[6], B.M. Rocha Garcia[3], A.C. de Mirandae Figueiredo[3], M. Souto[2], A. Baldasso Zanon[1], N. Balzan[1], G. Werutsky[5], S. Jobim de Azevedo[1]

[1]UPCO - Unidade de Pesquisa Clinica em Oncologia, Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil, [2]Oncology, Nucleo de Oncologia da Bahia, Salvador, Brazil, [3]Oncology, CEPON - Centro de Pesquisas Oncológicas, Florianópolis, Brazil, [4]Oncology, Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil, [5]Oncology, Hospital São Lucas da PUCRS, Porto Alegre, Brazil, [6]Oncology, Latin American Oncology Group, Porto Alegre, Brazil

Background: Immunotherapy is a new standard of care for metastatic NSCLC patients. Approval of this therapy was based on randomized phase 3 trials. Clinical trials employees' strict patient selection criteria, and this may not represent the 'real-world' population.

Methods: From January 2011 to December 2017, all patients with metastatic NSCLC referred for first oncological evaluation at 4 Hospitals in Brazil were identified by electronic database and included in the analysis. Main eligibility criteria used in first-line phase 3 immunotherapy trials were selected to be evaluated. OS was estimated by Kaplan-Meier curves. Cox proportional hazards model was performed to identify factors associated with survival. All statistical analyses were performed using SAS 9.4.

Results: 537 patients were included in this analysis. Mean age was 62.73 ± 10.47 years, 57.3% male and 67.0% had adenocarcinoma. 332 (61.8%) patients didn't meet one or more eligible criteria. Patients with ECOG PS ≥ 2 and/or active brain metastasis accounted alone for 78.3% of non-eligibility cases. The median OS after the diagnosis of metastatic disease was 7.56 (95% CI: 6.37 to 9.59) months in the non-eligible group and 14.55 (95% CI: 12.16 to 18.23) in the eligible group. Logrank test detected a statistically significant difference between the survival curves in both groups ($p = 0.0001$). The hazard ratio (HR) of 1.778 (95% CI: 1.425 - 2.217) to mortality reflects worse prognostic features in non-eligible group. Also, Logrank test detected a statistically significant difference between the survival curves of ECOG 0-1 and ECOG 2-4 (HR 2.313 95% CI: 1.839 – 2.909 $p < 0.0001$) and histology, with a HR of 1.479 (95% CI: 1.135 – 1.927 $p = 0.0036$) in favor of adenocarcinoma. Median OS in ECOG 0-1 group was 13.17 months (95% CI: 11.89 – 15.05) and in ECOG 2-4 was 6.05 months (95% CI: 4.67 – 6.77). Median OS in Adenocarcinoma group was 12.48 months (95% CI: 9.63 – 13.83) and in Squamous cell was 6.51 months (95% CI: 5.29 – 11.17).

Conclusions: A significant part of real life Brazilian NSCLC population doesn't fit the strict selection criteria specified by clinical trials. As soon as the experience and safety with this treatment improves, is desirable that future trials admits patiets more representative of real world NSCLC population.

1234P Correlation, in a real-world setting, between clinical-disease characteristics and compliance with immunotherapy in solid metastatic tumors: First results of an Italian CORE-IMMUNO study

C. Masini[1], A. Berselli[1], M. Banzi[1], C. Bonelli[1], A. Romagnani[1], M. Pagano[1], A. Damato[1], G. Prati[2], E. Gasparini[3], G. Moretti[1], I.T. Lorenzetti[1], F. Zanelli[1], F. Iachetta[1], C. Pinto[1]

[1]Oncology Unit, AUSL di Reggio Emilia-IRCCS, Reggio Emilia, Italy, [2]Oncology, Day Hospital Oncology, Ospedale Civile di Guastalla, Guastalla, Italy, [3]Medical Oncology, Day Hospital Oncology, Ospedale Magati di Scandiano, AUSL Reggio Emilia, Reggio Emilia, Italy

Background: Nivolumab, Pembrolizumab and Ipilimumab monotherapy has shown survival benefits in patients (pts) with melanoma, kidney, lung and head-neck cancer. The aim of this study is to evaluate safety and treatment compliance in terms of delays in the administration or withdrawal of drugs due to toxicity, according to disease and clinical characteristics of pts in clinical practice.

Methods: In this retrospective study, data were evaluated on pts in the Reggio Emilia Provincial Oncology Network who were treated for solid metastatic tumors with Nivolumab, Pembrolizumab and Ipilimumab monotherapy in clinical practice. The pts included in the study had received at least 1 dose of therapy by December 2017 and were monitored for adverse events (AE) using Common Terminology Criteria for Adverse Events (v. 4.1).

Results: A total of 92 pts were analyzed, of which 42 with lung cancer, 35 with melanoma, 12 with kidney cancer and 3 with head-neck cancer. Sixty-five pts (71%) were treated with Nivolumab, 17% with Pembrolizumab and 12% with Ipilimumab. Overall, 36 pts (39%) experienced an immunorelated adverse event (iAE) of any grade; 33/92 pts (36%) presented a G1-2 iAEs, while only 7% had a G3-4. Out of the 92 pts, the immunotherapy of 17% was delayed due to toxicity, but only 5% of pts discontinued treatment due to iAEs. No statistically significant differences in PFS (9.5 vs. 5.9 months, $p = 0.12$) and OS (21.9 vs. 12.2 months, $p = 0.15$) were found between pts who experienced iAEs and those who did not. Cox regression was performed for PFS and OS using sex, performance status (PS), comorbidities, presence of brain metastases, number of previous lines of therapy, number of metastatic sites and age as covariates. For both, only PS (1-2) significantly correlates with poor PFS and OS with respect to PS 0 ($p < 0.001$).

Conclusions: The data supports the use of immune checkpoint-inhibitors in pts treated in clinical practice with different solid tumors. These treatments are suitable for elderly pts with multiple comorbidities, pts with brain metastases and heavily pretreated pts. However, the use of these drugs should be evaluated with caution in pts with poor PS.

1235P Safety of immunotherapy in elderly patients: A retrospective analysis of a phase I unit

E. Ferraro, G. Viale, B. Achutti Duso, C. Belli, C. Criscitiello, L. Mazzarella, A. Esposito, S. Morganti, D. Trapani, P. Tarantino, P. D'Amico, C. Busacca, M.A. Massaro, G. Curigliano

Division of Early Drug Development for Innovative Therapies and Department of Oncology and Hemato-Oncology, European Institute of Oncology and University of Milan, Milan, Italy

Background: Cancer immunotherapy has been used in patients over 70 years old with controversial results. Several age-associated changes including the dysregulation of the immune system could be involved. The main goal of our study is to retrospectively investigate the safety of immunotherapy in elderly patients enrolled in early phase studies regardless tumor type.

Methods: We retrospectively reviewed all cases of patients ≥70 years old enrolled in early phase trials with different immunotherapeutics between January 2016 and March 2018. Eligible patients have received at least one cycle of single agent or a combination of first and/or second generation immune-modulating drugs. The primary aim of the study was to evaluate the safety of such an approach in the elderly population. Toxicity has been graded using the NCI CTCAE v 4.0. Secondary objective was disease control rate (DCR). Fisher test was used to perform the comparison analysis.

Results: We identified 29 patients, of those 21 were eligible and 8 were screening failures. Patients included in the analysis had an ECOG performance status 0-1. Twelve patients were treated with combo regimens (including a backbone of an anti-PD1 in combination with a new generation immune-checkpoint inhibitor) and 9 with monotherapy. Only 2 patients, one treated with combo and one with monotherapy, experienced a grade 3 immuno-related toxicity leading to treatment discontinuation: an autoimmune thyroiditis in one case and an autoimmune hepatitis, histologically proved, in the other one. The most common adverse event (AE) was G1-G2 fatigue that occurred in 33% of patients. Immuno-related AEs of any grade were observed in 22% of patients treated with monotherapy compared to 33% in the combo group. Three out of 9 patients treated with monotherapy had a partial response or a stable disease with a DCR of 33%, whereas in the combo group the observed DCR was 66%. Differences were not statistically significant between the two groups for neither toxicity nor efficacy (p value 0.65 and 0.19, respectively). No complete response was observed.

Conclusions: Our results suggest that immunotherapy is an effective and well tolerated treatment for older patients with solid tumors.

1236TiP The safety and efficacy of durvalumab in combination with paclitaxel for the treatment of metastatic triple negative breast cancer

H. Ghebeh[1], A.N. Alsayed[2], K. Suleman[2], T. Al-Tweigeri[2]

[1]Stem Cell & Tissue Re-engineering Program, King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia, [2]Oncology Centre, King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia

Background: Metastatic triple negative breast cancer has poor prognosis and limited treatment options. Immunotherapy with anti-PD-L1 monoclonal antibodies has shown promising results in several types of cancer including triple negative breast cancer. We have initiated a clinical trial to test the safety and efficacy of a combination of the investigational anti-PD-L1 monoclonal antibody durvalumab and paclitaxel for the treatment of metastatic breast cancer. The rationale behind this trial is that treatment with paclitaxel correlates with development of tumor infiltrating lymphocytes (Demaria et al. 2001; Sardella et al. 2006), and the upregulation of PD-L1 on tumor cells. On the other hand, response to targeted anti-PD-L1 therapy correlates with the level of expression of PD-L1 on tumor cells and the pre-existing tumor immunity like CD8+ infiltrating cells and type I helper CD4+ activated lymphocytes (Herbst, Soria et al. 2014). In addition, PD-L1 has anti-apoptotic function that its blockade will synergize with the apoptotic effect of chemotherapeutic agents like paclitaxel. Therefore, the combination of these two agents is likely to be synergistic.

Trial design: The treatment is designed to start with one cycle of paclitaxel alone to enhance the immunogenicity and immune cell infiltration followed by the combination of the two agents. Paclitaxel will be delivered weekly on days 1, 8 and 15 of each 28 days cycle while Durvalumab will be given every two weeks (Days 1 and 15 of each cycle). Paclitaxel is given for 6 cycles only while Durvalumab is given until disease progression, or unacceptable toxicity. The primary endpoint of the study is to measure safety and tolerability of the combination while the secondary endpoints include efficacy monitoring.

Legal entity responsible for the study: T. Al-Tweigeri, M.D.

Funding: This clinical trial is an investigator-initiated trial sponsored partially by AstraZeneca as an externally sponsored research (ESR 14 10649).

1237TiP VSV-IFNβ-NIS intratumoral (IT) injection: A first-in-human (FIH), phase I study of an innovative oncolytic virotherapy, alone and with an anti-PD-L1 antibody, in patients with refractory solid tumors

S.F. Powell[1], M.R. Patel[2], J. Merchan[3], J. Strauss[4], T.P. Cripe[5], M.O. Old[6], R.M. Diaz[7], M. Reckner[8], B. Brunton[9], N. Packiriswamy[9], D. Upreti[9], L. Suksanpaisan[10], R. Vandergaast[10], R. Khan[9], S.J. Russell[11], K.W. Peng[12], A.S. Bexon[13]

[1]Sanford Cancer Center, Sanford Health, Sioux Falls, SD, USA, [2]Minnesota Medical School, Minneapolis, MN, USA, [3]Miami School of Medicine, Miami, FL, USA, [4]Medical Oncology, Mary Crowley Medical Research Center, Dallas, TX, USA, [5]Hematology/Oncology/BMT, Nationwide Children's Hospital, Columbus, OH, USA, [6]Arthur James Cancer Hospital, The Ohio State University, Columbus, OH, USA, [7]Regulatory and Clinical Affairs, Vyriad, Rochester, MN, USA, [8]Clinical Development, Bexon Clinical Consulting, Montclair, NJ, USA, [9]Molecular Medicine, Mayo Clinic, Rochester, NY, USA, [10]Diagnostics, Imanis Life Sciences, Rochester, NY, USA, [11]Vyriad, Rochester, NY, USA, [12]CTO, Vyriad, Rochester, NY, USA, [13]CMO, Vyriad, Rochester, NY, USA

Background: VSV-IFNβ-NIS (Voyager V1; VV1) is derived from VSV, a bullet-shaped, negative-sense RNA virus with low human seroprevalence; it is engineered to replicate selectively in and kill human cancer cells. VV1 encodes hIFNβ to increase antitumoral immune response and tumor specificity, plus the thyroidal sodium iodide symporter NIS to allow imaging of virus. VV1 is synergistic with different anti-PD-(L)1 antibodies in several tumor models. Three phase 1 clinical studies of VV1 are ongoing (IV and IT). The IT trial described here includes a monotherapy and a combination arm with an anti-PD-L1.

Trial design: The study uses two 2-part, open-label, phase 1, parallel, staggered escalations to determine safety, PK and tumor/biomarker response, after a single VV1 IT dose into 1 target lesion. VV1 is given alone in the 1st arm and in combination with IV anti-PD-L1 in the 2nd arm. Each arm has 2 parts: a single ascending VV1 dose escalation all comers (alone or in combination with anti-PD-L1 until PD) followed by a dose expansion at the RP2D in patients with metastatic colorectal cancer. Virus is injected under radiological guidance. The VV1 dose is escalated from 3×10^6 to 3×10^9 $TCID_{50}$ (dose infecting 50% of cells in culture). The primary objective is to identify MTD/RP2D alone and in combination. Endpoints include PK by RT- PCR for viral genomes, serum IFNβ levels, Tc-99m SPECT/CT imaging of virus infection in injected lesions, peripheral blood immunophenotyping with 11-color flow cytometry for activation markers on T cells, T- regs, NK cells, and MDSCs, and serial biopsies to assess the tumor microenvironment. IHC is performed on tumor biopsies for CD3, CD8, CD4, FoxP3, CD68, CD45, PD-1 and PD-L1 pre- and post-treatment (~day 29) in non-injected and injected lesions. All patients must have $\geq$1 measurable lesion per RECIST 1.1 amenable for a single IT injection and at least one patient per cohort is required to have $\geq$2 measurable lesions, one for injection and one to assess abscopal effects. The study started in 2017 and monotherapy escalation should be near completion, with combination underway, by October 2018.

Clinical trial identification: NCT02923466.

Background: Local therapeutic vaccination with tumor antigen-encoding mRNAs is being investigated in various clinical trials. We have developed a novel class of RNA-lipoplex ($RNA_{(LIP)}$) immunotherapeutics for intravenous application allowing systemic targeting of antigen-presenting cells (APCs). $RNA_{(LIP)}$ is a novel nanoparticulate formulation of lipid-complexed mRNA which selectively delivers the functional mRNA to APCs in lymphoid compartments body-wide for efficient mRNA uptake and expression of the encoded antigen by APCs. Moreover, this formulation has intrinsically strong adjuvant activity, mimics a systemic viral infection, and induces synchronized activation of potent adaptive as well as type-I-IFN-mediated innate immune responses (Kranz et al., Nature 2016).

Trial design: The first-in-human phase I/II dose escalation Lipo-MERIT trial (NCT02410733) is the first clinical trial to investigate the intravenous administration of a RNA-based cancer vaccine. The trial assesses the safety and tolerability of systemic $RNA_{(LIP)}$ immunotherapy in patients with stage IIIB/C and IV melanoma in four German study centers. Patients are treated with repeated dosing of the tetravalent Lipo-MERIT vaccine composed of $RNA_{(LIP)}$ products encoding the shared melanoma-associated antigens NY-ESO-1, tyrosinase, MAGE-A3, and TPTE based on the expression of at least one of these antigens in routinely collected patients tumor samples. Patients in dose escalation cohorts (classical 3 + 3 design) follow a step-up dosing towards different target doses. Pharmacodynamic activity and immunogenicity of the vaccine is investigated by concerted immune monitoring and correlative biomarker studies. Clinical activity is assessed following imaging according to irRECIST1.1.

Clinical trial identification: EudraCT: 2013-001646-33.

Hoffmann-La Roche, Ltd, Basel, Switzerland, [12]Medicine, UCLA Medical Center, Los Angeles, CA, USA

Background: Significant survival benefit has been achieved with CIT across multiple tumour types, but only subsets of patients (pts) experience durable response with CIT monotherapy. Efficacious CIT combinations targeting multiple cancer immune escape mechanisms need to be identified to extend clinical benefit to more pts. The MORPHEUS platform includes multiple Phase Ib/II trials designed to identify early signals of safety and activity of CIT combinations. Using a randomised trial design, multiple CIT combination arms are compared with a single standard-of-care control arm. We present 7 tumour type–specific MORPHEUS trials, each evaluating various CIT combinations that simultaneously enhance immune-cell priming and activation, tumour infiltration and/or recognition of tumour cells for elimination.

Trial design: The MORPHEUS trials described here are global, open-label, randomised, Phase Ib/II trials enrolling pts with 1 of the following cancers: pancreatic ductal adenocarcinoma (PDAC), gastric or gastro-oesophageal junction cancers (GC/GEJ), hormone receptor-positive or triple-negative breast cancers (HR+/TNBC), non-small cell lung cancer (NSCLC), or colorectal cancer (CRC) (Table). These trials have the flexibility to open new treatment arms with novel CIT combinations as they become available and to close arms that show minimal activity or unacceptable toxicity. Pts experiencing loss of clinical benefit or unacceptable toxicity may be eligible to switch to a different CIT combination arm. Eligibility requires measurable disease per RECIST v1.1. Further eligibility criteria will be provided. Primary endpoints are safety and investigator-assessed ORR per RECIST v1.1. Secondary endpoints include PFS, OS, DCR and DOR. Exploratory biomarkers will also be examined.

Clinical trial identification: NCT03193190, NCT03281369, NCT03280563, NCT03424005, NCT03337698.

1240TiP Phase II study of cemiplimab, a human monoclonal anti-PD-1, in patients with advanced basal cell carcinoma (BCC) who experienced progression of disease on, or were intolerant of prior hedgehog pathway inhibitor (HHI) therapy

K.D. Lewis[1], M.G. Fury[2], E. Stankevich[3], M. Mathias[2], K.K. Mohan[2], S. Li[4], K. Nunnink[2], C. Perry[2], A. Narwal[3]

[1]School of Medicine, University of Colorado Hospital, Denver, CO, USA, [2]Clinical Sciences, Regeneron Pharmaceuticals, Inc., Tarrytown, NY, USA, [3]Clinical Sciences, Regeneron Pharmaceuticals, Inc., Basking Ridge, NJ, USA, [4]Biostatistics & Data Management, Regeneron Pharmaceuticals, Inc., Basking Ridge, NJ, USA

Background: BCC is the most common cancer worldwide. There is no approved agent to treat advanced BCC in patients who experience disease progression on, or who are intolerant of HHIs. Cemiplimab (REGN2810), an anti-PD-1 has demonstrated encouraging efficacy and favourable tolerability in a phase 1 study of patients with advanced malignancies (NCT02383212).

Trial design: We are conducting a phase 2, non-randomised, 2-group, multi-centre study of cemiplimab in patients with advanced BCC who experienced disease progression or are intolerant to HHI therapy (NCT03132636). Group 1 will enrol patients with both nodal and distant metastatic BCC. Group 2 will enrol patients with locally advanced BCC who are not candidates for surgery. Cemiplimab will be administered intravenously every 3 weeks in all patients. The primary objective of the study is to evaluate overall response rate (ORR) as determined by central review. The ORR will be assessed separately for patients in Group 1 or Group 2 (by RECIST 1.1 for radiology, and modified WHO for photography). Up to 137 patients will be enrolled. For Group 1, 50 patients are required to provide at least 85% power to reject a null hypothesis of an ORR of 15% at a 2-sided significance level of 5% if the true ORR is 34%. For Group 2, 80 patients are required to provide at least 85% power to reject a null hypothesis of an ORR of 20% at a 2-sided significance level of 5% if the true ORR is 35%. An additional 5% in sample size will account for patient withdrawals. This study is ongoing.

Clinical trial identification: NCT03132636.

Table: 1239TiP

Summary of Cancer-Type Specific MORPHEUS Trials

Cancer Type	Cohort	No. of Experimental Arms[a]	Countries Currently Targeted for Enrolment
PDAC	2L	3	Germany, South Korea, Spain, United States
GC and GEJ	1L	2	Germany, South Korea, Spain, Taiwan, United Kingdom, United States
	2L	4	
HR+ BC	2L	4	France, South Korea, Spain, United Kingdom, United States
TNBC	2L	5	Australia, France, Germany, South Korea, Spain, United Kingdom, United States
NSCLC	1L	2	Australia, France, South Korea, Spain, United Kingdom, United States
	2L+[b]	5	
CRC	3L	2	Australia, France, South Korea, Spain, United Kingdom, United States

[a]Not all experimental arms may be open at the same time.

[b]Patients who have progressed on prior platinum chemotherapy and anti–PD-L1/PD-1 treatment given concurrently or sequentially. CIT, cancer immunotherapy; CRC, colorectal cancer; GC, gastric cancer; GEJ, gastro-oesophageal junction cancer; HR+ BC, hormone receptor–positive breast cancer; NSCLC, non-small cell lung cancer; PD-1, programmed death-1; PDAC, pancreatic ductal adenocarcinoma; PD-L1, programmed death-ligand 1; TNBC, triple-negative breast cancer.

1241TiP JAVELIN PARP medley: A phase Ib/II study of avelumab (anti–PD-L1) plus talazoparib in locally advanced or metastatic solid tumors

T.A. Yap[1], J.T. Beck[2], R.A. Stewart[3], S.C. Dahm[3], C. Chappey[4], R. Cesari[5], A. Scheuber[6], M.D. Galsky[7], D. Wise[8]

[1]Investigational Cancer Therapeutics, University of Texas MD Anderson Cancer Center, Houston, Surrey, TX, USA, [2]Medical Oncology and Hematology, Highlands Oncology Group, Fayetteville, AZ, USA, [3]Oncology, Pfizer, San Diego, CA, USA, [4]Oncology, Pfizer, San Francisco, CA, USA, [5]Oncology, Pfizer, Milan, Italy, [6]Oncology, Pfizer, Philadelphia, PA, USA, [7]Medicine, Hematology, and Medical Oncology, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY, USA, [8]Medicine, NYU Laura and Isaac Perlmutter Cancer Center, New York, NY, USA

Background: Avelumab, a human anti–PD-L1 IgG1 monoclonal antibody, is approved for the treatment of metastatic Merkel cell carcinoma in various countries and advanced urothelial carcinoma after progression on platinum therapy in the United States and Canada. Talazoparib is a potent, orally bioavailable PARP inhibitor with a dual mechanism (PARP enzyme inhibition and PARP trapping). Preclinical studies suggest that the combination of an immune checkpoint inhibitor and PARP inhibitor may have additive antitumor activity, and initial clinical studies support evaluation of this combination.

Trial design: JAVELIN PARP Medley (NCT03330405) is an open-label, multicohort, phase 1b/2 trial investigating avelumab plus talazoparib in ≈316 patients with selected solid tumors. Eligible adult patients have locally advanced (primary/recurrent) or metastatic solid tumors that are not amenable for treatment with curative intent, including non-small cell lung cancer with no EGFR mutations, triple-negative breast cancer, hormone receptor–positive and HER2-negative breast cancer, recurrent platinum-sensitive ovarian cancer, urothelial carcinoma, castration-resistant prostate cancer (CRPC), or advanced solid tumors with BRCA/ATM defects. Requirements for prior anticancer therapy and platinum exposure vary between phases 1b and 2 and between tumor types. Prior treatment with a PARP inhibitor or immunotherapy is not permitted. Different daily oral doses of talazoparib plus avelumab 800 mg IV Q2W will be administered in phase 1b to define the recommended phase 2 dose for the combination before enrolling patients in phase 2. The primary endpoint in phase 1b is first-cycle dose-limiting toxicity, and in phase 2, it is objective response according to RECIST 1.1 (also according to Prostate Cancer Working Group 3 [PCWG3] for patients with CRPC). Other endpoints include duration of response and progression-free survival according to RECIST 1.1 (plus PCWG3 for CRPC), overall survival, adverse events, laboratory abnormalities, pharmacokinetic parameters, and tumor tissue biomarkers. Enrollment in phase 2 of the study is expected to begin in Q3 2018.

Clinical trial identification: B9991025 (NCT03330405).

1242TiP Study of TBI-1301 (NY-ESO-1 specific TCR gene transduced autologous T lymphocytes) in patients with solid tumors

M.O. Butler[1], H. Majeed[1], M. Nelles[2], S. Saibil[1], L. Bonilla[1], S. Boross-Harmer[1], V. Sotov[2], S. Elston[2], K. Ross[2], B. van As[2], M. Le[2], M. Fyrsta[2], C. Lo[2], J. Yam[2], J. Nie[2], L. Scheid[2], P. Ohashi[3], L. Nguyen[2], S. Tanaka[4], N. Hirano[1]

[1]Medical Oncology, Princess Margaret Cancer Centre, Toronto, ON, Canada, [2]Tumor Immunotherapy Program, Princess Margaret Cancer Centre, Toronto, ON, Canada, [3]Immunology, Campbell Family Institute for Cancer Research, University Health Network, Toronto, ON, Canada, [4]Immunotherapy, Takara Bio Inc, Kusatsu, Japan

Background: The use of cell based immune therapies involving infusion of autologous T-lymphocytes with anti-tumor activity targeting tumor-associated antigens is a rapidly evolving area of research. One approach involves the use of peripheral blood as a source of lymphocytes that are then used in the generation of cytotoxic tumor-specific T cells via introducing a tumor-specific TCR gene into T lymphocytes. NY-ESO-1 is a cancer testis antigen expressed in numerous cancers yet absent in most adult normal tissues apart from high expression in adult testes – thereby making it an ideal target for immunotherapy.

Trial design: TB1-1301 is a gene-modified T cell product that contains a NY-ESO-1 specific TCR introduced with the MS3II-NY-ESO1-SiTCR retroviral vector. This vector encodes for TCR α and β chains that recognize an NY-ESO-1 derived epitope (amino acids 157-165: SLLMWITQC) that is presented in the context of HLA-A*02:01 and HLA-A*02:06 molecules. The vector also encodes for siRNA (small interfering RNA) that are homologous to the constant region sequence of the endogenous, but not transduced TCR α and β chain mRNAs – these siRNAs in turn increase expression of the transduced TCR. Pre-clinical murine studies demonstrated safety, persistence, and efficacy of transduced T cells. This study represents a Phase 1b study of TBI-1301 in patients with advanced solid tumors, which express NY-ESO-1 (synovial sarcoma, ovarian cancer, and melanoma). A pre-conditioning lymphodepletion regimen of cyclophosphamide 750 mg/m^2 will be used on Day -3 and Day -2 prior to infusion of cell product. The objectives of this study include assessing the safety profile of TBI-1301, determining the RP2D dose, and evaluating the efficacy of TBI-1301 via RECIST v1.1.

Clinical trial identification: NCT02869217.

KG, Rhein, Germany, [10]Pharmacovigilance, Sarah Cannon Development Innovations, Nashville, TN, USA, [11]Oncology, Sarah Cannon, Nashville, TN, USA

Background: Lymphocyte-activation gene 3 (LAG-3) is a negative regulator of immune response implicated in T cell exhaustion and tumor immune escape. Available data demonstrate that tumor-derived T cells frequently co-express the PD-1 and LAG-3 co-inhibitory receptors and that dual blockade of the LAG-3 and PD-1 pathways results in more potent reactivation of T-cell function and anti-tumor immune response than blockade of the individual pathway. BI 754091 and BI 754111 are monoclonal IgG4Pro antibodies (mAbs) against PD-1 and LAG-3, respectively. In this Phase I study, we investigate the safety, tolerability, PK, and preliminary efficacy of the combination of these 2 mAbs.

Trial design: This 2-part, open-labeled, non-randomized ongoing study consists of dose escalation in pts with advanced solid tumors followed by expansion cohorts in pts with NSCLC, microsatellite stable (MSS) mCRC, or any PD-1/PD-L1 pretreated solid tumor with high tumor mutational burden (TMB-H) and/or high microsatellite instability and/or DNA mismatch repair deficiency (MSI-H/MMRd). Dose escalation in pts with solid tumors started at 4mg q3w BI 754111 and was guided by Bayesian Logistic Regression Method. All dose levels of BI 754111 were co-administered with 240 mg q3w BI 754091 (the BI 754091 RPIID selected from 1381.1 phase I [Johnson, et al. ASCO-SITC 2017 abstract 212]). Enrollment in the solid tumor dose escalation portion is nearly complete. The expansion phase will use a combination dose selected from the solid tumor dose escalation. Primary endpoints in the dose escalation are the number of pts with dose-limiting toxicities and the combination MTD. The primary endpoint of the dose expansion portion is the objective response rate.

Clinical trial identification: NCT03156114.

Background: Adjuvant therapy with dabrafenib plus trametinib (D + T) for 12 months significantly reduced the risk of relapse or death vs placebo (Pbo; HR, 0.47; P < .001) in patients (pts) in the COMBI-AD trial with resected BRAF V600–mutant stage III melanoma (NCT01682083), leading to the recent US FDA approval in this indication. We used a cure-rate model to estimate long-term RFS benefit and explore the association of baseline factors with RFS to better characterize pts likely to benefit from adjuvant treatment.

Methods: COMBI-AD randomized pts with completely resected BRAF V600E/K–mutant stage III melanoma to receive adjuvant D (150 mg twice daily) + T (2 mg once daily) or Pbo for 12 months. Long-term RFS (proportion of pts who did not experience an event) was estimated using a Weibull cure-rate model. Baseline covariates were analyzed using a stratified Cox regression model for RFS, with P values calculated using a Wald χ^2 test. AJCC 7th edition criteria were used for pt staging at baseline.

Results: Eight hundred seventy pts were enrolled (D + T, n = 438; Pbo, n = 432). The median follow-up was 2.8 years. Estimation of long-term RFS using a cure-rate model showed a 55% (95% CI, 49%-61%) long-term RFS rate in the D + T arm vs 38% (95% CI, 33%-43%) in the Pbo arm. Evaluation of the association between baseline disease characteristics and RFS demonstrated that lower T stage, lesser nodal involvement, and a superficial spreading melanoma subtype were independently associated with better RFS (Table). Conversely, tumor ulceration and the presence of in-transit metastases were not associated with RFS. With respect to baseline patient demographics, an association was observed between female sex and RFS benefit (P = .030).

Conclusions: The results of the long-term RFS analysis suggest potential long-term RFS in > 50% of pts treated with D + T. Lower T stage and less nodal involvement at baseline were associated with better RFS.

Clinical trial identification: NCT01682083.

Background: In COMBI-AD (NCT01682083), adjuvant D + T led to a significant improvement in relapse-free survival vs Pbo in pts with resected BRAF V600–mutant stage III melanoma supporting recent US FDA approval in this indication. There were no new safety signals; however, a higher rate of permanent discontinuation due to AEs was observed compared with metastatic disease (26% [10% due to grade 3/4 AEs]); pyrexia (9%) and chills (4%) were most common. Here we further characterize AEs in COMBI-AD.

Methods: COMBI-AD was a randomized, double-blind, Pbo-controlled phase III trial comparing 12 mo of adjuvant D (150 mg twice daily) + T (2 mg once daily) vs Pbo in pts with resected BRAF V600E/K–mutant stage III melanoma. AEs were graded according to CTCAE v4.0. To assess AEs over time, exposure-adjusted AE rates (no. of occurrences/pt/3-mo exposure) were calculated over 3-mo intervals.

Results: Although most pts in both arms experienced ≥ 1 AE, the majority of AEs reported were low grade (eg, pyrexia [% of pts in D + T arm]: grade 1 [29%], grade 2 [29%], grade 3 [5%], grade 4 [< 1%]). In the first 3 mo of treatment, the exposure-adjusted AE rate of any event in pts treated with D + T was 6.14 occurrences/pt/3-mo exposure. However, the AE rates declined substantially with increased time on treatment (3 to < 6 mo [2.58]; 6 to < 9 mo [1.80]; 9 to < 12 mo [1.65]). Similar results were observed in pts in the Pbo arm, albeit at lower rates. Adjusted AE rates for the 10 most common AEs observed in COMBI-AD in the D + T arm also declined after the initial 3 mo (Table). Results were similar in pts who completed 12 mo of treatment.

Table: 1251P AE occurrences per patient per 3-month exposure

Preferred Term	Dabrafenib + Trametinib (n = 435)				Placebo (n = 432)			
	0 to < 3 mo	3 to < 6 mo	6 to < 9 mo	9 to < 12 mo	0 to < 3 mo	3 to < 6 mo	6 to < 9 mo	9 to < 12 mo
Pyrexia	1.26	0.65	0.50	0.45	0.08	0.05	0.05	0.02
Fatigue	0.53	0.17	0.10	0.13	0.27	0.09	0.05	0.04
Nausea	0.49	0.14	0.08	0.09	0.20	0.07	0.06	0.05
Headache	0.50	0.17	0.13	0.12	0.27	0.10	0.09	0.07
Chills	0.55	0.29	0.21	0.14	0	0	0	0
Diarrhea	0.32	0.11	0.09	0.10	0.14	0.08	0.06	0.05
Vomiting	0.32	0.13	0.09	0.08	0	0	0	0
Arthralgia	0.30	0.12	0.07	0.07	0.09	0.05	0.06	0.05
Rash	0.26	0.07	0.10	0.08	0.08	0.04	0.03	0.02
Cough	0.14	0.04	0.03	0.01	0	0	0	0

Conclusions: These results show that most AEs with adjuvant D + T occurred during the first 3 mo of treatment and declined thereafter, highlighting the importance of AE management early during treatment to prevent premature discontinuations and allow patients to complete 1 year of adjuvant treatment.

1252P Management of melanoma recurrence following adjuvant anti-PD1 therapy

C. Owen[1], D. Palmieri[2], A. Guminski[3], M.S. Carlino[4], A.M. Menzies[5], G.V. Long[6]

[1]Melanoma Medical Oncology, Melanoma Institute Australia, Sydney, Australia, [2]Medical Oncology, Westmead Hospital, Westmead, Australia, [3]Department of Medical Oncology, Melanoma Institute Australia, The University of Sydney, Royal North Shore and Mater Hospitals, North Sydney, Australia, [4]Medical Oncology, The Crown Princess Mary Cancer Centre, Melanoma Institute Australia, Sydney University, Westmead, Australia, [5]Medical Oncology, Melanoma Institute Australia, University of Sydney, North Sydney, Australia, [6]Medical Oncology, Melanoma Institute Australia, University of Sydney, North Sydney, Australia

Background: Anti-PD1 immunotherapy prolongs recurrence-free survival when used as adjuvant therapy in high-risk resected melanoma. To date, detailed data on nature and management of recurrences following adjuvant anti-PD1 therapy are lacking.

Methods: All patients with resected stage III or IV melanoma who received adjuvant anti-PD1-based therapy (pembrolizumab or nivolumab) at two sites since 2015 and had a melanoma recurrence were included. Disease characteristics prior to adjuvant therapy, adjuvant treatments received, timing and nature of recurrences, and subsequent local and systemic management and their outcomes were examined.

Results: 28 patients (pts) had a melanoma recurrence during or following adjuvant anti-PD1 therapy (including 5 on nivolumab/ipilimumab combination). Prior to adjuvant therapy, 26 patients had stage III (13 IIIB, 12 IIIC, 1 IIID), 2 had resected stage IV melanoma, 16 were male, median age 59 years, and 12 were BRAF V600 mutation positive (11 wildtype, 5 unknown). 22 (79%) recurred during adjuvant therapy, 6 recurred following cessation of therapy (1 after completing 12 months, 4 after ceasing early for toxicity, 1 withdrew consent). Median time to recurrence from surgery was 6.8mo (range 2.8-28.2). 15 recurrences were detected clinically and 13 on 3-monthly imaging. 13 (46%) recurrences were loco-regional only, and 15 distant (2 brain). 12 (43%) patients were treated with surgery at recurrence (10 local, 1 brain and 1 lung metastasis) to no evidence of disease, and 6 have subsequently recurred. Data on systemic therapy after recurrence (either 1st relapse or 2nd after salvage surgery) are in the Table. 3 of 17

(18%) treated with systemic therapy after recurrence have progressed. 1 (4%) patient has died, 9 months after recurrence.

Table: 1252P

Systemic treatment	N	Best RECIST response				
		CR	PR	SD	PD	Not reached first scan
BRAF/MEKi	7	1	3	0	1	2
Anti-PD1	3	0	0	0	2	1
Combination anti-PD1/-CTLA-4	4	1	1	0	0	2
Combination anti-PD1/-LAG-3	2	0	0	0	1	1
MEK+CDK4/6i	1	0	0	0	1	0
Total	17	2	4	0	5	6

Conclusions: These data are the first to demonstrate the utility of salvage therapy for pts who progress early despite adjuvant anti-PD1. Early data suggest that this is a challenging group, likely to require multimodal treatment. Updated analyses will be presented.

1253P High response rate with T-VEC in early metastatic melanoma (stage IIIB/C-IVM1a)

V. Franke[1], D.M.S. Berger[2], W.M.C. Klop[2], B. van der Hiel[3], B.A. van de Wiel[4], S. Ter Meulen[1], M. Wouters[1], W. van Houdt[5], A.C.J. van Akkooi[6]

Background: Talimogene laherparepvec (T-VEC) is a modified herpes simplex virus, type 1 (HSV-1), which can be administered intralesionally in patients with stage IIIB/C-IVM1a unresectable melanoma (EMA label). The phase 3 OPTiM registration study showed an overall response rate (ORR) of 26%.

Methods: Since approval of T-VEC in the Netherlands in December 2016, 35 eligible patients started treatment with T-VEC monotherapy at the Netherlands Cancer Institute. We included 23 patients with a follow up time $\geq$6 months. Analysis of overall response rate (ORR), adverse events (AE), prior treatment for melanoma and baseline characteristics, documented in a prospectively maintained database. Besides clinical evaluation, in this study we used PET-CT and histological biopsies for response evaluation.

Results: The median follow-up was 11.3 months. Of 23 patients, 12 (52.2%) had a complete response (CR) as their best response, all except for one ongoing after stopping treatment. As their best response, 7 (30.4%) patients had a partial response (PR), 2 (8.7%) patients had a mixed response and 2 (8.7%) patients showed progressive disease (PD). ORR for the analyzed cohort was 82.6%. Disease Control Rate (DCR) was 91.3%. At baseline, the mean number of lesions was between 5 and 50 lesions. Grade 1-2 AE's occurred in all patients. Mostly, these consisted of fatigue, influenza-like symptoms and injection site pain. 1 patient had to pause treatment due to $\geq$grade 3 AE (colitis). Prior treatment was documented: all 23 patients underwent surgical resection, 13 isolated limb perfusion (56.5%), 1 targeted therapy (4.3%), 2 immunotherapy (8.7%), 2 radiotherapy (8.7%). Prior treatment did not influence response or toxicity of T-VEC. PET-CT and biopsies proved to be a clinically useful tool to evaluate treatment response for T-VEC monotherapy, confirming pCR or PD to stage IV disease requiring systemic treatment.

Conclusions: ORR for T-VEC monotherapy at our institute was 82.6% with 52.2% achieving a CR. This prospective study for T-VEC in early metastatic (stage IIIB/C-IVM1a) melanoma demonstrated superior results to the phase 3 OPTiM study and confirms the role of oncolytic immunotherapy for melanoma.

1254P Neoadjuvant cytoreductive treatment with BRAF/MEK inhibition of prior unresectable regionally advanced melanoma to allow complete surgical resection, REDUCTOR trial

S. Blankenstein[1], M.W. Rohaan[2], W.M.C. Klop[3], B. van der Hiel[4], B. van de Wiel[5], D. Peeper[6], A.C.J. van Akkooi[1], J.B.A.G. Haanen[7]

[1]Surgical oncology, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, [2]Medical Oncology, Het Nederlands Kanker Instituut Antoni van Leeuwenhoek (NKI-AVL), Amsterdam, Netherlands, [3]Head and Neck Surgery and Oncology, Netherlands Cancer Institute/Antoni van Leeuwenhoek hospital (NKI-AVL), Amsterdam, Netherlands, [4]Nuclear medicine, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, [5]Pathology, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, [6]Molecular Oncology and Immunology, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, [7]Medical Oncology, The Netherlands Cancer Institute Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands

Background: The aim of this trial is to evaluate the potency of short-term neoadjuvant cytoreductive therapy with dabrafenib and trametinib (BRAF and MEK inhibitor respectively) to allow radical surgical resection in patients with unresectable BRAF-mutated, locally advanced stage III or oligometastatic stage IV melanoma.

Methods: A total of 25 patients with BRAF-mutated, unresectable locally advanced stage III or oligometastatic stage IV ($\leq$3 metastases) melanoma will be treated with dabrafenib and trametinib for 8 weeks. Response evaluation by positron emission tomography/computed tomography (PET/CT) will occur at 2 and 8 weeks. If sufficient downsizing occurs, surgical resection will be performed. Biopsies for translational research will be taken at baseline and 2 weeks. The dissection specimen will be stored at 8 weeks.
